14.7 Server Status Variables

Server status variables provide information about the global status of the server and the status of the current session in TiDB. Most of these variables are designed to be compatible with MySQL.

You can retrieve the global status using the SHOW GLOBAL STATUS command, and the status of the current session using the SHOW SESSION STATUS command.

Additionally, the FLUSH STATUS command is supported for MySQL compatibility.

14.7.1 Variable reference

14.7.1.1 Compression

- Scope: SESSION
- Type: Boolean
- Indicates if the MySQL Protocol uses compression or not.

14.7.1.2 Compression_algorithm

- Scope: SESSION
- Type: String
- Indicates the compression algorithm that is used for the MySQL Protocol.

14.7.1.3 Compression_level

- Scope: SESSION
- Type: Integer
- The compression level that is used for the MySQL Protocol.

14.7.1.4 Ssl_cipher

- Scope: SESSION | GLOBAL
- Type: String
- TLS Cipher that is in use.

14.7.1.5 Ssl_cipher_list

- Scope: SESSION | GLOBAL
- Type: String
- The list of TLS Ciphers that the server supports.

14.7.1.6 Ssl_server_not_after

- Scope: SESSION | GLOBAL
- Type: Date
- The expiration date of the X.509 certificate of the server that is used for TLS connections.

14.7.1.7 Ssl_server_not_before

- Scope: SESSION | GLOBAL
- Type: String
- The start date of the X.509 certificate of the server that is used for TLS connections.

14.7.1.8 Ssl_verify_mode

- Scope: SESSION | GLOBAL
- Type: Integer
- The TLS verification mode bitmask.

14.7.1.9 Ssl_version

- Scope: SESSION | GLOBAL
- Type: String
- The version of the TLS protocol that is used

14.7.1.10 Uptime

- Scope: SESSION | GLOBAL
- Type: Integer
- Uptime of the server in seconds.

14.7.1.11 ddl_schema_version

- Scope: SESSION | GLOBAL
- Type: Integer
- The version of the DDL schema that is used.

14.7.1.12 last_plan_binding_update_time New in v5.2.0

- Scope: SESSION
- Type: Timestamp
- The time and date of the last plan binding update.

14.7.1.13 server_id

- Scope: SESSION | GLOBAL
- Type: String
- The UUID of the server.

14.7.1.14 tidb_gc_last_run_time

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the last run of GC.

14.7.1.15 tidb_gc_leader_desc

- Scope: SESSION | GLOBAL
- Type: String
- Information about GC leader, including the hostname and process id (pid).

14.7.1.16 tidb_gc_leader_lease

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the GC lease.

14.7.1.17 tidb_gc_leader_uuid

- Scope: SESSION | GLOBAL
- Type: String
- The UUID of the GC leader.

14.7.1.18 tidb_gc_safe_point

- Scope: SESSION | GLOBAL
- Type: String
- The timestamp of the GC safe point.

14.8 Configuration File Parameters

14.8.1 TiDB Configuration File

The TiDB configuration file supports more options than command-line parameters. You can download the default configuration file `config.toml.example` and rename it to `config.toml`. This document describes only the options that are not involved in command line options.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.8.1.0.1 `split-table`

- Determines whether to create a separate Region for each table.
- Default value: `true`
- It is recommended to set it to `false` if you need to create a large number of tables (for example, more than 100 thousand tables).

14.8.1.0.2 `tidb-max-reuse-chunk` New in v6.4.0

- Controls the maximum cached chunk objects of chunk allocation. Setting this configuration item to too large a value might increase the risk of OOM.
- Default value: `64`
- Minimum value: `0`
- Maximum value: `2147483647`

14.8.1.0.3 `tidb-max-reuse-column` New in v6.4.0

- Controls the maximum cached column objects of chunk allocation. Setting this configuration item to too large a value might increase the risk of OOM.
- Default value: `256`
- Minimum value: `0`
- Maximum value: `2147483647`

14.8.1.0.4 `token-limit`

- The number of sessions that can execute requests concurrently.
- Type: Integer
- Default value: `1000`
- Minimum value: `1`
- Maximum value: `1048576`

14.8.1.0.5 `temp-dir` New in v6.3.0

- File system location used by TiDB to store temporary data. If a feature requires local storage in TiDB nodes, TiDB stores the corresponding temporary data in this location.
- When creating an index, if `tidb_ddl_enable_fast_reorg` is enabled, data that needs to be backfilled for a newly created index will be at first stored in the TiDB local temporary directory, and then imported into TiKV in batches, thus accelerating the index creation.
- When `IMPORT INTO` is used to import data, the sorted data is first stored in the TiDB local temporary directory, and then imported into TiKV in batches.
- Default value: `"/tmp/tidb"`

> **Note:**
>
> If the directory does not exist, TiDB will automatically create it upon startup. If the directory creation fails or TiDB does not have the read and write permissions on that directory, `Fast Online DDL` might experience unpredictable issues.

14.8.1.0.6 `oom-use-tmp-storage`

> **Warning:**
>
> Since v6.3.0, this configuration item is deprecated and superseded by the system variable `tidb_enable_tmp_storage_on_oom`. When the TiDB cluster is upgraded to v6.3.0 or a later version, it will automatically initialize the variable with the value of `oom-use-tmp-storage`. After that, changing the value of `oom-use-tmp-storage` **does not** take effect anymore.

- Controls whether to enable the temporary storage for some operators when a single SQL statement exceeds the memory quota specified by the system variable tidb_mem_quota_query.
- Default value: true

14.8.1.0.7 tmp-storage-path

- Specifies the temporary storage path for some operators when a single SQL statement exceeds the memory quota specified by the system variable tidb_mem_quota_query.
- Default value: <temporary directory of OS>/<OS user ID>_tidb/MC4wLjAuMDo0MDAwLzAuMC4wL=/tmp-storage. MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA= is the Base64 encoding result of <host>:<port>/<statusHost>:<statusPort>.
- This configuration takes effect only when the system variable tidb_enable_tmp_storage_on_oom is ON.

14.8.1.0.8 tmp-storage-quota

- Specifies the quota for the storage in tmp-storage-path. The unit is byte.
- When a single SQL statement uses a temporary disk and the total volume of the temporary disk of the TiDB server exceeds this configuration value, the current SQL operation is cancelled and the Out of Global Storage Quota! error is returned.
- When the value of this configuration is smaller than 0, the above check and limit do not apply.
- Default value: -1
- When the remaining available storage in tmp-storage-path is lower than the value defined by tmp-storage-quota, the TiDB server reports an error when it is started, and exits.

14.8.1.0.9 lease

- The timeout of the DDL lease.
- Default value: 45s
- Unit: second

14.8.1.0.10 compatible-kill-query

- Determines whether to set the KILL statement to be MySQL compatible.
- Default value: false
- compatible-kill-query takes effect only when enable-global-kill is set to false.
- When enable-global-kill is false, compatible-kill-query controls whether you need to append the TIDB keyword when killing a query.

  - When `compatible-kill-query` is `false`, the behavior of `KILL xxx` in TiDB is different from that in MySQL. To kill a query in TiDB, you need to append the `TIDB` keyword, such as `KILL TIDB xxx`.
  - When `compatible-kill-query` is `true`, to kill a query in TiDB, there is no need to append the `TIDB` keyword. It is **STRONGLY NOT RECOMMENDED** to set `compatible-kill-query` to `true` in your configuration file UNLESS you are certain that clients will be always connected to the same TiDB instance. This is because pressing Control+C in the default MySQL client opens a new connection in which `KILL` is executed. If there is a proxy between the client and the TiDB cluster, the new connection might be routed to a different TiDB instance, which possibly kills a different session by mistake.

- When `enable-global-kill` is `true`, `KILL xxx` and `KILL TIDB xxx` have the same effect.
- For more information about the `KILL` statement, see KILL [TIDB].

14.8.1.0.11 `check-mb4-value-in-utf8`

- Determines whether to enable the `utf8mb4` character check. When this feature is enabled, if the character set is `utf8` and the `mb4` characters are inserted in `utf8`, an error is returned.
- Default value: `false`
- Since v6.1.0, whether to enable the `utf8mb4` character check is determined by the TiDB configuration item `instance.tidb_check_mb4_value_in_utf8` or the system variable `tidb_check_mb4_value_in_utf8`. `check-mb4-value-in-utf8` still takes effect. But if both `check-mb4-value-in-utf8` and `instance.tidb_check_mb4_value_in_utf8` are set, the latter takes effect.

14.8.1.0.12 `treat-old-version-utf8-as-utf8mb4`

- Determines whether to treat the `utf8` character set in old tables as `utf8mb4`.
- Default value: `true`

14.8.1.0.13 `alter-primary-key` (Deprecated)

- Determines whether to add or remove the primary key constraint to or from a column.
- Default value: `false`
- With this default setting, adding or removing the primary key constraint is not supported. You can enable this feature by setting `alter-primary-key` to `true`. However, if a table already exists before the switch is on, and the data type of its primary key column is an integer, dropping the primary key from the column is not possible even if you set this configuration item to `true`.

Note:

This configuration item has been deprecated, and currently takes effect only when the value of `@tidb_enable_clustered_index` is `INT_ONLY`. If you need to add or remove the primary key, use the `NONCLUSTERED` keyword instead when creating the table. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

14.8.1.0.14 `server-version`

- Modifies the version string returned by TiDB in the following situations:
  - When the built-in `VERSION()` function is used.
  - When TiDB establishes the initial connection to the client and returns the initial handshake packet with version string of the server. For details, see MySQL Initial Handshake Packet.
- Default value: ""
- By default, the format of the TiDB version string is `8.0.11-TiDB-${tidb_version}`.

Note:

TiDB nodes use the value of `server-version` to verify the current TiDB version. Therefore, to avoid unexpected behaviors, before upgrading the TiDB cluster, you need to set the value of `server-version` to empty or the real version of the current TiDB cluster.

14.8.1.0.15 `repair-mode`

- Determines whether to enable the untrusted repair mode. When the `repair-mode` is set to `true`, bad tables in the `repair-table-list` cannot be loaded.
- Default value: `false`
- The `repair` syntax is not supported by default. This means that all tables are loaded when TiDB is started.

14.8.1.0.16 `repair-table-list`

- `repair-table-list` is only valid when `repair-mode` is set to `true`. `repair-table-list` is a list of bad tables that need to be repaired in an instance. An example of the list is: ["db.table1","db.table2"...].
- Default value: []
- The list is empty by default. This means that there are no bad tables that need to be repaired.

14.8.1.0.17 `new_collations_enabled_on_first_bootstrap`

- Enables or disables the new collation support.
- Default value: `true`
- Note: This configuration takes effect only for the TiDB cluster that is first initialized. After the initialization, you cannot use this configuration item to enable or disable the new collation support.

14.8.1.0.18 `max-server-connections`

- The maximum number of concurrent client connections allowed in TiDB. It is used to control resources.
- Default value: `0`
- By default, TiDB does not set limit on the number of concurrent client connections. When the value of this configuration item is greater than `0` and the number of actual client connections reaches this value, the TiDB server rejects new client connections.
- Since v6.2.0, the TiDB configuration item `instance.max_connections` or the system variable `max_connections` is used to set the maximum number of concurrent client connections allowed in TiDB. `max-server-connections` still takes effect. But if `max-server-connections` and `instance.max_connections` are set at the same time, the latter takes effect.

14.8.1.0.19 `max-index-length`

- Sets the maximum allowable length of the newly created index.
- Default value: `3072`
- Unit: byte
- Currently, the valid value range is `[3072, 3072*4]`. MySQL and TiDB (version < v3.0.11) do not have this configuration item, but both limit the length of the newly created index. This limit in MySQL is `3072`. In TiDB (version =< 3.0.7), this limit is `3072*4`. In TiDB (3.0.7 < version < 3.0.11), this limit is `3072`. This configuration is added to be compatible with MySQL and earlier versions of TiDB.

14.8.1.0.20 `table-column-count-limit` New in v5.0

- Sets the limit on the number of columns in a single table.
- Default value: `1017`
- Currently, the valid value range is `[1017, 4096]`.

14.8.1.0.21 `index-limit` New in v5.0

- Sets the limit on the number of indexes in a single table.
- Default value: `64`
- Currently, the valid value range is `[64, 512]`.

14.8.1.0.22 `enable-telemetry` New in v4.0.2 and deprecated in v8.1.0

> **Warning:**
>
> Starting from v8.1.0, the telemetry feature in TiDB is removed, and this configuration item is no longer functional. It is retained solely for compatibility with earlier versions.

- Before v8.1.0, this configuration item controls whether to enable telemetry collection in a TiDB instance.
- Default value: `false`

14.8.1.0.23 `deprecate-integer-display-length`

- Deprecates the display width for integer types when this configuration item is set to `true`.
- Default value: `true`. Before v8.5.0, the default value is `false`.

14.8.1.0.24 `enable-tcp4-only` New in v5.0

- Enables or disables listening on TCP4 only.
- Default value: `false`
- Enabling this option is useful when TiDB is used with LVS for load balancing because the real client IP from the TCP header can be correctly parsed by the "tcp4" protocol.

14.8.1.0.25 `enable-enum-length-limit` New in v5.0

- Determines whether to limit the maximum length of a single `ENUM` element and a single `SET` element.
- Default value: `true`
- When this configuration value is `true`, the maximum length of a single `ENUM` element and a single `SET` element is 255 characters, which is compatible with MySQL 8.0. When this configuration value is `false`, there is no limit on the length of a single element, which is compatible with TiDB (earlier than v5.0).

14.8.1.0.26 `graceful-wait-before-shutdown` New in v5.0

- Specifies the number of seconds that TiDB waits when you shut down the server, which allows the clients to disconnect.
- Default value: `0`
- When TiDB is waiting for shutdown (in the grace period), the HTTP status will indicate a failure, which allows the load balancers to reroute traffic.

> **Note:**
>
> The duration that TiDB waits before shutting down the server is also affected by the following parameters:
>
> - When you use a platform that employs SystemD, the default stop timeout is 90 seconds. If you need a longer timeout, you can set `TimeoutStopSec=`.
> - When you use the TiUP Cluster component, the default `--wait-timeout` is 120 seconds.
> - When you use Kubernetes, the default `terminationGracePeriodSeconds` is 30 seconds.

14.8.1.0.27 `enable-global-kill` New in v6.1.0

- Controls whether to enable the Global Kill (terminating queries or connections across instances) feature.
- Default value: `true`
- When the value is `true`, both `KILL` and `KILL TIDB` statements can terminate queries or connections across instances so you do not need to worry about erroneously terminating queries or connections. When you use a client to connect to any TiDB instance and execute the `KILL` or `KILL TIDB` statement, the statement will be forwarded to the target TiDB instance. If there is a proxy between the client and the TiDB cluster, the `KILL` and `KILL TIDB` statements will also be forwarded to the target TiDB instance for execution.
- Starting from v7.3.0, you can terminate a query or connection using the MySQL command line Control+C when both `enable-global-kill` and `enable-32bits-connection-id` are set to `true`. For more information, see `KILL`.

14.8.1.0.28 `enable-32bits-connection-id` New in v7.3.0

- Controls whether to enable the 32-bit connection ID feature.

- Default value: `true`
- When both this configuration item and `enable-global-kill` are set to `true`, TiDB generates 32-bit connection IDs. This enables you to terminate queries or connections by the MySQL command-line Control+C.

> **Warning:**
>
> When the number of TiDB instances in the cluster exceeds 2048 or the concurrent connection count of a single TiDB instance exceeds 1048576, the 32-bit connection ID space becomes insufficient and is automatically upgraded to 64-bit connection IDs. During the upgrade process, existing business and established connections are unaffected. However, subsequent new connections cannot be terminated using Control+C in the MySQL command-line.

14.8.1.0.29 `initialize-sql-file` New in v6.6.0

- Specifies the SQL script to be executed when the TiDB cluster is started for the first time.
- Default value: `""`
- All SQL statements in this script are executed with the highest privilege without any privilege check. If the specified SQL script fails to execute, the TiDB cluster might fail to start.
- This configuration item is used to perform such operations as modifying the value of a system variable, creating a user, or granting privileges.

14.8.1.0.30 `enable-forwarding` New in v5.0.0

- Controls whether the PD client and TiKV client in TiDB forward requests to the leader via the followers in the case of possible network isolation.
- Default value: `false`
- If the environment might have isolated network, enabling this parameter can reduce the window of service unavailability.
- If you cannot accurately determine whether isolation, network interruption, or downtime has occurred, using this mechanism has the risk of misjudgment and causes reduced availability and performance. If network failure has never occurred, it is not recommended to enable this parameter.

14.8.1.0.31 `enable-table-lock` New in v4.0.0

Warning:

The table lock is an experimental feature. It is not recommended that you use it in the production environment.

- Controls whether to enable the table lock feature.
- Default value: `false`
- The table lock is used to coordinate concurrent access to the same table among multiple sessions. Currently, the `READ`, `WRITE`, and `WRITE LOCAL` lock types are supported. When the configuration item is set to `false`, executing the `LOCK TABLES` or `UNLOCK TABLES` statement does not take effect and returns the "LOCK/UNLOCK TABLES is not supported" warning. For more information, see `LOCK TABLES` and `UNLOCK TABLES`.

14.8.1.0.32 `labels`

- Specify server labels. For example, `{ zone = "us-west-1", dc = "dc1", rack = "rack1", host = "tidb1" }`.
- Default value: `{}`

Note:

- In TiDB, the `zone` label is specially used to specify the zone where a server is located. If `zone` is set to a non-null value, the corresponding value is automatically used by features such as `txn-score` and `Follower read`.
- The `group` label has a special use in TiDB Operator. For clusters deployed using TiDB Operator, it is **NOT** recommended that you specify the `group` label manually.

14.8.1.1 log

Configuration items related to log.

14.8.1.1.1 `level`

- Specifies the log output level.
- Value options: `debug`, `info`, `warn`, `error`, and `fatal`.
- Default value: `info`

14.8.1.1.2 `format`

- Specifies the log output format.
- Value options: `json` and `text`.
- Default value: `text`

14.8.1.1.3 `enable-timestamp`

- Determines whether to enable timestamp output in the log.
- Default value: `null`
- If you set the value to `false`, the log does not output timestamp.

> **Note:**
>
> - To be backward compatible, the initial `disable-timestamp` configuration item remains valid. But if the value of `disable-timestamp` semantically conflicts with the value of `enable-timestamp` (for example, if both `enable-timestamp` and `disable-timestamp` are set to `true`), TiDB ignores the value for `disable-timestamp`.
> - Currently, TiDB use `disable-timestamp` to determine whether to output timestamps in the log. In this situation, the value of `enable-timestamp` is `null`.
> - In later versions, the `disable-timestamp` configuration will be removed. Discard `disable-timestamp` and use `enable-timestamp` which is semantically easier to understand.

14.8.1.1.4 `enable-slow-log`

- Determines whether to enable the slow query log.
- Default value: `true`
- To enable the slow query log, set `enable-slow-log` to `true`. Otherwise, set it to `false`.
- Since v6.1.0, whether to enable slow query log is determined by the TiDB configuration item `instance.tidb_enable_slow_log` or the system variable `tidb_enable_slow_log`. `enable-slow-log` still takes effect. But if `enable-slow-log` and `instance.tidb_enable_slow_log` are set at the same time, the latter takes effect.

14.8.1.1.5 slow-query-file

- The file name of the slow query log.
- Default value: `tidb-slow.log`
- The format of the slow log is updated in TiDB v2.1.8, so the slow log is output to the slow log file separately. In versions before v2.1.8, this variable is set to "" by default.
- After you set it, the slow query log is output to this file separately.

14.8.1.1.6 slow-threshold

- Outputs the threshold value of consumed time in the slow log.
- Default value: `300`
- Unit: Milliseconds
- When the time consumed by a query is larger than this value, this query is considered as a slow query and its log is output to the slow query log. Note that when the output level of `log.level` is `"debug"`, all queries are recorded in the slow query log, regardless of the setting of this parameter.
- Since v6.1.0, the threshold value of consumed time in the slow log is specified by the TiDB configuration item `instance.tidb_slow_log_threshold` or the system variable `tidb_slow_log_threshold`. `slow-threshold` still takes effect. But if `slow-threshold` and `instance.tidb_slow_log_threshold` are set at the same time, the latter takes effect.

14.8.1.1.7 record-plan-in-slow-log

- Determines whether to record execution plans in the slow log.
- Default value: `1`
- Since v6.1.0, whether to record execution plans in the slow log is determined by the TiDB configuration item `instance.tidb_record_plan_in_slow_log` or the system variable `tidb_record_plan_in_slow_log`. `record-plan-in-slow-log` still takes effect. But if `record-plan-in-slow-log` and `instance.tidb_record_plan_in_slow_log` are set at the same time, the latter takes effect.

14.8.1.1.8 expensive-threshold

> **Warning:**
>
> Starting from v5.4.0, the `expensive-threshold` configuration item is deprecated and replaced by the system variable `tidb_expensive_query_time_threshold`.

- Outputs the threshold value of the number of rows for the `expensive` operation.
- Default value: `10000`
- When the number of query rows (including the intermediate results based on statistics) is larger than this value, it is an `expensive` operation and outputs log with the `[ ↪ EXPENSIVE_QUERY]` prefix.

14.8.1.1.9 `general-log-file` New in v8.0.0

- The filename of the general log.
- Default value: `""`
- If you specify a filename, the general log is written to this specified file. If the value is blank, the general log is written to the server log of the TiDB instance. You can specify the name of the server log using `filename`.

14.8.1.1.10 `timeout` New in v7.1.0

- Sets the timeout for log-writing operations in TiDB. In case of a disk failure that prevents logs from being written, this configuration item can trigger the TiDB process to panic instead of hang.
- Default value: `0`, indicating no timeout is set.
- Unit: second
- In some user scenarios, TiDB logs might be stored on hot-pluggable or network-attached disks, which might become permanently unavailable. In these cases, TiDB cannot recover automatically from such disaster and the log-writing operations will be permanently blocked. Although the TiDB process might seem to be running, it does not respond to any requests. This configuration item is designed to handle such situations.

14.8.1.2 log.file

Configuration items related to log files.

`filename`

- The file name of the general log file.
- Default value: “”
- If you set it, the log is output to this file.

`max-size`

- The size limit of the log file.
- Default value: 300
- Unit: MB
- The maximum value is 4096.

`max-days`

- The maximum number of days that the log is retained.
- Default value: `0`
- The log is retained by default. If you set the value, the expired log is cleaned up after `max-days`.

`max-backups`

- The maximum number of retained logs.
- Default value: `0`
- All the log files are retained by default. If you set it to `7`, seven log files are retained at maximum.

`compression` New in v8.0.0

- The compression method for the log.
- Default value: `""`
- Value options: `""`, `"gzip"`
- The default value is `""`, which means no compression. To enable the gzip compression, set this value to `"gzip"`. After compression is enabled, all log files are affected, such as `slow-query-file` and `general-log-file`.

14.8.1.3 security

Configuration items related to security.

14.8.1.3.1 enable-sem

- Enables the Security Enhanced Mode (SEM).
- Default value: `false`
- The status of SEM is available via the system variable `tidb_enable_enhanced_security`.

14.8.1.3.2 ssl-ca

- The file path of the trusted CA certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-cert`, `--ssl-key` at the same time, TiDB authenticates the client certificate based on the list of trusted CAs specified by this option when the client presents the certificate. If the authentication fails, the connection is terminated.
- If you set this option but the client does not present the certificate, the secure connection continues without client certificate authentication.

14.8.1.3.3 `ssl-cert`

- The file path of the SSL certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-key` at the same time, TiDB allows (but not forces) the client to securely connect to TiDB using TLS.
- If the specified certificate or private key is invalid, TiDB starts as usual but cannot receive secure connection.

14.8.1.3.4 `ssl-key`

- The file path of the SSL certificate key in the PEM format, that is, the private key of the certificate specified by `--ssl-cert`.
- Default value: “”
- Currently, TiDB does not support loading the private keys protected by passwords.

14.8.1.3.5 `cluster-ssl-ca`

- The CA root certificate used to connect TiKV or PD with TLS.
- Default value: “”

14.8.1.3.6 `cluster-ssl-cert`

- The path of the SSL certificate file used to connect TiKV or PD with TLS.
- Default value: “”

14.8.1.3.7 `cluster-ssl-key`

- The path of the SSL private key file used to connect TiKV or PD with TLS.
- Default value: “”

14.8.1.3.8 `cluster-verify-cn`

- A list of acceptable X.509 Common Names in certificates presented by clients. Requests are permitted only when the presented Common Name is an exact match with one of the entries in the list.
- Default value: [], which means that the client certificate CN check is disabled.

14.8.1.3.9 `spilled-file-encryption-method`

- Determines the encryption method used for saving the spilled files to disk.
- Default value: `"plaintext"`, which disables encryption.
- Optional values: `"plaintext"` and `"aes128-ctr"`

14.8.1.3.10 `auto-tls`

- Determines whether to automatically generate the TLS certificates on startup.
- Default value: `false`

14.8.1.3.11 `tls-version`

> **Warning:**
>
> `"TLSv1.0"` and `"TLSv1.1"` protocols are deprecated in TiDB v7.6.0, and will be removed in v8.0.0.

- Set the minimum TLS version for MySQL Protocol connections.
- Default value: "", which allows TLSv1.2 or later versions. Before TiDB v7.6.0, the default value allows TLSv1.1 or later versions.
- Optional values: `"TLSv1.2"` and `"TLSv1.3"`. Before TiDB v8.0.0, `"TLSv1.0"` and `"TLSv1.1"` are also allowed.

14.8.1.3.12 `auth-token-jwks` New in v6.4.0

- Set the local file path of the JSON Web Key Sets (JWKS) for the `tidb_auth_token` authentication method.
- Default value: `""`

14.8.1.3.13 `auth-token-refresh-interval` New in v6.4.0

- Set the JWKS refresh interval for the `tidb_auth_token` authentication method.
- Default value: `1h`

14.8.1.3.14 `disconnect-on-expired-password` New in v6.5.0

- Determines whether TiDB disconnects the client connection when the password is expired.
- Default value: `true`
- Optional values: `true`, `false`
- If you set it to `true`, the client connection is disconnected when the password is expired. If you set it to `false`, the client connection is restricted to the "sandbox mode" and the user can only execute the password reset operation.

14.8.1.3.15 `session-token-signing-cert` New in v6.4.0

- The certificate file path, which is used by TiProxy for session migration.
- Default value: ""
- Empty value will cause TiProxy session migration to fail. To enable session migration, all TiDB nodes must set this to the same certificate and key. This means that you should store the same certificate and key on every TiDB node.

14.8.1.3.16 `session-token-signing-key` New in v6.4.0

- The key file path used by TiProxy for session migration.
- Default value: ""
- Refer to the descriptions of `session-token-signing-cert`.

14.8.1.4 performance

Configuration items related to performance.

14.8.1.4.1 `max-procs`

- The number of CPUs used by TiDB.
- Default value: `0`
- The default `0` indicates using all the CPUs on the machine. You can also set it to n, and then TiDB uses n CPUs.

14.8.1.4.2 `server-memory-quota` New in v4.0.9

> **Warning:**
>
> Since v6.5.0, the `server-memory-quota` configuration item is deprecated and replaced by the system variable `tidb_server_memory_limit`.

- The memory usage limit of tidb-server instances.
- Default value: `0` (in bytes), which means no memory limit.

14.8.1.4.3 `max-txn-ttl`

- The longest time that a single transaction can hold locks. If this time is exceeded, the locks of a transaction might be cleared by other transactions so that this transaction cannot be successfully committed.

- Default value: `3600000`
- Unit: Millisecond
- The transaction that holds locks longer than this time can only be committed or rolled back. The commit might not be successful.
- For transactions executed using the `"bulk"` DML mode, the maximum TTL can exceed the limit of this configuration item. The maximum value is the greater value between this configuration item and 24 hours.

14.8.1.4.4 `stmt-count-limit`

- The maximum number of statements allowed in a single TiDB transaction.
- Default value: `5000`
- If a transaction does not roll back or commit after the number of statements exceeds `stmt-count-limit`, TiDB returns the `statement count 5001 exceeds the transaction limitation, autocommit = false` error. This configuration takes effect **only** in the retryable optimistic transaction. If you use the pessimistic transaction or have disabled the transaction retry, the number of statements in a transaction is not limited by this configuration.

14.8.1.4.5 `txn-entry-size-limit` New in v4.0.10 and v5.0.0

- The size limit of a single row of data in TiDB.
- Default value: `6291456` (in bytes)
- The size limit of a single key-value record in a transaction. If the size limit is exceeded, TiDB returns the `entry too large` error. The maximum value of this configuration item does not exceed `125829120` (120 MB).
- Starting from v7.6.0, you can use the system variable `tidb_txn_entry_size_limit` to dynamically modify the value of this configuration item.
- Note that TiKV has a similar limit. If the data size of a single write request exceeds `raft-entry-max-size`, which is 8 MB by default, TiKV refuses to process this request. When a table has a row of large size, you need to modify both configurations at the same time.
- The default value of `max_allowed_packet` (the maximum size of a packet for the MySQL protocol) is 67108864 (64 MiB). If a row is larger than `max_allowed_packet`, the row gets truncated.
- The default value of `txn-total-size-limit` (the size limit of a single transaction in TiDB) is 100 MiB. If you increase the `txn-entry-size-limit` value to be over 100 MiB, you need to increase the `txn-total-size-limit` value accordingly.

14.8.1.4.6 `txn-total-size-limit`

- The size limit of a single transaction in TiDB.
- Default value: `104857600` (in bytes)

- In a single transaction, the total size of key-value records cannot exceed this value. The maximum value of this parameter is `1099511627776` (1 TB).
- In TiDB v6.5.0 and later versions, this configuration is no longer recommended. The memory size of a transaction will be accumulated into the memory usage of the session, and the `tidb_mem_quota_query` variable will take effect when the session memory threshold is exceeded. To be compatible with previous versions, this configuration works as follows when you upgrade from an earlier version to TiDB v6.5.0 or later:
    - If this configuration is not set or is set to the default value (`104857600`), after an upgrade, the memory size of a transaction will be accumulated into the memory usage of the session, and the `tidb_mem_quota_query` variable will take effect.
    - If this configuration is not defaulted (`104857600`), it still takes effect and its behavior on controlling the size of a single transaction remains unchanged before and after the upgrade. This means that the memory size of the transaction is not controlled by the `tidb_mem_quota_query` variable.
- When TiDB executes transactions in the `tidb_dml_type` `"bulk"` mode, transaction size is not limited by the TiDB configuration item `txn-total-size-limit`.

14.8.1.4.7 `tcp-keep-alive`

- Determines whether to enable `keepalive` in the TCP layer.
- Default value: `true`

14.8.1.4.8 `tcp-no-delay`

- Determines whether to enable TCP_NODELAY at the TCP layer. After it is enabled, TiDB disables the Nagle algorithm in the TCP/IP protocol and allows sending small data packets to reduce network latency. This is suitable for latency-sensitive applications with a small transmission volume of data.
- Default value: `true`

14.8.1.4.9 `cross-join`

- Default value: `true`
- TiDB supports executing the `JOIN` statement without any condition (the `WHERE` field) of both sides tables by default; if you set the value to `false`, the server refuses to execute when such a `JOIN` statement appears.

> **Note:**
>
> When creating a cluster, **DO NOT** set `cross-join` to false. Otherwise, the cluster will fail to start up.

14.8.1.4.10 `stats-lease`

- The time interval of reloading statistics, updating the number of table rows, checking whether it is needed to perform the automatic analysis, using feedback to update statistics and loading statistics of columns.
- Default value: `3s`
    - At intervals of `stats-lease` time, TiDB checks the statistics for updates and updates them to the memory if updates exist.
    - At intervals of `20 * stats-lease` time, TiDB updates the total number of rows generated by DML and the number of modified rows to the system table.
    - At intervals of `stats-lease`, TiDB checks for tables and indexes that need to be automatically analyzed.
    - At intervals of `stats-lease`, TiDB checks for column statistics that need to be loaded to the memory.
    - At intervals of `200 * stats-lease`, TiDB writes the feedback cached in the memory to the system table.
    - At intervals of `5 * stats-lease`, TiDB reads the feedback in the system table, and updates the statistics cached in the memory.
- When `stats-lease` is set to 0s, TiDB periodically reads the feedback in the system table, and updates the statistics cached in the memory every three seconds. But TiDB no longer automatically modifies the following statistics-related system tables:
    - `mysql.stats_meta`: TiDB no longer automatically records the number of table rows that are modified by the transaction and updates it to this system table.
    - `mysql.stats_histograms`/`mysql.stats_buckets` and `mysql.stats_top_n`: TiDB no longer automatically analyzes and proactively updates statistics.
    - `mysql.stats_feedback`: TiDB no longer updates the statistics of the tables and indexes according to a part of statistics returned by the queried data.

14.8.1.4.11 `pseudo-estimate-ratio`

- The ratio of (number of modified rows)/(total number of rows) in a table. If the value is exceeded, the system assumes that the statistics have expired and the pseudo statistics will be used.
- Default value: `0.8`
- The minimum value is `0` and the maximum value is `1`.

14.8.1.4.12 `force-priority`

- Sets the priority for all statements.
- Default value: `NO_PRIORITY`
- Value options: The default value `NO_PRIORITY` means that the priority for statements is not forced to change. Other options are `LOW_PRIORITY`, `DELAYED`, and `HIGH_PRIORITY` in ascending order.

- Since v6.1.0, the priority for all statements is determined by the TiDB configuration item instance.tidb_force_priority or the system variable tidb_force_priority. force-priority still takes effect. But if force-priority and instance.tidb_force_priority are set at the same time, the latter takes effect.

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.8.1.4.13 distinct-agg-push-down

- Determines whether the optimizer executes the operation that pushes down the aggregation function with Distinct (such as select count(distinct a)from t) to Coprocessors.
- Default: false
- This variable is the initial value of the system variable tidb_opt_distinct_agg_push_down.

14.8.1.4.14 enforce-mpp

- Determines whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution.
- Default value: false
- This configuration item controls the initial value of tidb_enforce_mpp. For example, when this configuration item is set to true, the default value of tidb_enforce_mpp is ON.

14.8.1.4.15 enable-stats-cache-mem-quota New in v6.1.0

- Controls whether to enable the memory quota for the statistics cache.
- Default value: true

14.8.1.4.16 `stats-load-concurrency` New in v5.4.0

- The maximum number of columns that the TiDB synchronously loading statistics feature can process concurrently.
- Default value: `0`. Before v8.2.0, the default value is `5`.
- Currently, the valid value range is `[0, 128]`. The value `0` means the automatic mode, which automatically adjusts concurrency based on the configuration of the server. Before v8.2.0, the minimum value is `1`.

14.8.1.4.17 `stats-load-queue-size` New in v5.4.0

- The maximum number of column requests that the TiDB synchronously loading statistics feature can cache.
- Default value: `1000`
- Currently, the valid value range is `[1, 100000]`.

14.8.1.4.18 `concurrently-init-stats` New in v8.1.0 and v7.5.2

- Controls whether to initialize statistics concurrently during TiDB startup. This configuration item takes effect only when `lite-init-stats` is set to `false`.
- Default value: `false` for versions earlier than v8.2.0, `true` for v8.2.0 and later versions.

14.8.1.4.19 `lite-init-stats` New in v7.1.0

- Controls whether to use lightweight statistics initialization during TiDB startup.
- Default value: `false` for versions earlier than v7.2.0, `true` for v7.2.0 and later versions.
- When the value of `lite-init-stats` is `true`, statistics initialization does not load any histogram, TopN, or Count-Min Sketch of indexes and columns into memory. When the value of `lite-init-stats` is `false`, statistics initialization loads histograms, TopN, and Count-Min Sketch of indexes into memory but does not load any histogram, TopN, or Count-Min Sketch of primary keys and columns into memory. When the optimizer needs the histogram, TopN, and Count-Min Sketch of a specific primary key or column, the necessary statistics are loaded into memory synchronously or asynchronously (controlled by `tidb_stats_load_sync_wait`).
- Setting `lite-init-stats` to `true` speeds up statistics initialization and reduces TiDB memory usage by avoiding unnecessary statistics loading. For details, see Load statistics.

14.8.1.4.20 `force-init-stats` New in v6.5.7 and v7.1.0

- Controls whether to wait for statistics initialization to finish before providing services during TiDB startup.

- Default value: `false` for versions earlier than v7.2.0, `true` for v7.2.0 and later versions.
- When the value of `force-init-stats` is `true`, TiDB needs to wait until statistics initialization is finished before providing services upon startup. Note that if there are a large number of tables and partitions and the value of `lite-init-stats` is `false`, setting `force-init-stats` to `true` might prolong the time it takes for TiDB to start providing services.
- When the value of `force-init-stats` is `false`, TiDB can still provide services before statistics initialization is finished, but the optimizer uses pseudo statistics to make decisions, which might result in suboptimal execution plans.

14.8.1.5 opentracing

Configuration items related to opentracing.

14.8.1.5.1 `enable`

- Enables opentracing to trace the call overhead of some TiDB components. Note that enabling opentracing causes some performance loss.
- Default value: `false`

14.8.1.5.2 `rpc-metrics`

- Enables RPC metrics.
- Default value: `false`

14.8.1.6 opentracing.sampler

Configuration items related to opentracing.sampler.

14.8.1.6.1 `type`

- Specifies the type of the opentracing sampler. The string value is case-insensitive.
- Default value: `"const"`
- Value options: `"const"`, `"probabilistic"`, `"ratelimiting"`, `"remote"`

14.8.1.6.2 `param`

- The parameter of the opentracing sampler.
  - For the `const` type, the value can be `0` or `1`, which indicates whether to enable the `const` sampler.
  - For the `probabilistic` type, the parameter specifies the sampling probability, which can be a float number between `0` and `1`.

- For the `ratelimiting` type, the parameter specifies the number of spans sampled per second.
- For the `remote` type, the parameter specifies the sampling probability, which can be a float number between `0` and `1`.

- Default value: `1.0`

14.8.1.6.3 `sampling-server-url`

- The HTTP URL of the jaeger-agent sampling server.
- Default value: `""`

14.8.1.6.4 `max-operations`

- The maximum number of operations that the sampler can trace. If an operation is not traced, the default probabilistic sampler is used.
- Default value: `0`

14.8.1.6.5 `sampling-refresh-interval`

- Controls the frequency of polling the jaeger-agent sampling policy.
- Default value: `0`

14.8.1.7 opentracing.reporter

Configuration items related to opentracing.reporter.

14.8.1.7.1 `queue-size`

- The queue size with which the reporter records spans in memory.
- Default value: `0`

14.8.1.7.2 `buffer-flush-interval`

- The interval at which the reporter flushes the spans in memory to the storage.
- Default value: `0`

14.8.1.7.3 `log-spans`

- Determines whether to print the log for all submitted spans.
- Default value: `false`

14.8.1.7.4 local-agent-host-port

- The address at which the reporter sends spans to the jaeger-agent.
- Default value: ""

14.8.1.8 tikv-client

14.8.1.8.1 grpc-connection-count

- The maximum number of connections established with each TiKV.
- Default value: 4

14.8.1.8.2 grpc-keepalive-time

- The keepalive time interval of the RPC connection between TiDB and TiKV nodes. If there is no network packet within the specified time interval, the gRPC client executes ping command to TiKV to see if it is alive.
- Default: 10
- Minimum value: 1
- Unit: second

14.8.1.8.3 grpc-keepalive-timeout

- The timeout of the RPC keepalive check between TiDB and TiKV nodes.
- Default value: 3
- Minimum value: 0.05
- Unit: second

14.8.1.8.4 grpc-compression-type

- Specifies the compression type used for data transfer from TiDB nodes to TiKV nodes. The default value is "none", which means no compression. To enable the gzip compression, set this value to "gzip".
- Default value: "none"
- Value options: "none", "gzip"

> **Note:**
>
> The compression algorithm for response messages returned from TiKV nodes to TiDB nodes is controlled by the TiKV configuration item grpc-↪ compression-type.

14.8.1.8.5 `commit-timeout`

- The maximum timeout when executing a transaction commit.
- Default value: `41s`
- It is required to set this value larger than twice of the Raft election timeout.

14.8.1.8.6 `batch-policy` New in v8.3.0

- Controls the batching strategy for requests from TiDB to TiKV. When sending requests to TiKV, TiDB always encapsulates the requests in the current waiting queue into a `BatchCommandsRequest` and sends it to TiKV as a packet. This is the basic batching strategy. When the TiKV load throughput is high, TiDB decides whether to wait for an additional period after the basic batching based on the value of `batch-policy` ↪ . This additional batching allows more requests to be encapsulated in a single `BatchCommandsRequest`.
- Default value: `"standard"`
- Value options:
  - `"basic"`: the behavior is consistent with versions before v8.3.0, where TiDB performs additional batching only if `tikv-client.max-batch-wait-time` is greater than 0 and the load of TiKV exceeds the value of `tikv-client.overload-` ↪ `threshold`.
  - `"standard"`: TiDB dynamically batches requests based on the arrival time intervals of recent requests, suitable for high-throughput scenarios.
  - `"positive"`: TiDB always performs additional batching, suitable for high-throughput testing scenarios to achieve optimal performance. However, in low-load scenarios, this strategy might introduce unnecessary batching wait time, potentially reducing performance.
  - `"custom{...}"`: allows customization of batching strategy parameters. This option is intended for the internal testing of TiDB and is **NOT recommended** for general use.

14.8.1.8.7 `max-batch-size`

- The maximum number of RPC packets sent in batch. If the value is not `0`, the `BatchCommands` API is used to send requests to TiKV, and the RPC latency can be reduced in the case of high concurrency. It is recommended that you do not modify this value.
- Default value: `128`

14.8.1.8.8 `max-batch-wait-time`

- Waits for `max-batch-wait-time` to encapsulate the data packets into a large packet in batch and send it to the TiKV node. It is valid only when the value of `tikv-client.max-batch-size` is greater than `0`. It is recommended not to modify this value.
- Default value: `0`
- Unit: nanoseconds

14.8.1.8.9 `batch-wait-size`

- The maximum number of packets sent to TiKV in batch. It is recommended not to modify this value.
- Default value: `8`
- If the value is `0`, this feature is disabled.

14.8.1.8.10 `overload-threshold`

- The threshold of the TiKV load. If the TiKV load exceeds this threshold, more `batch` packets are collected to relieve the pressure of TiKV. It is valid only when the value of `tikv-client.max-batch-size` is greater than `0`. It is recommended not to modify this value.
- Default value: `200`

14.8.1.8.11 `copr-req-timeout` New in v7.5.0

> **Warning:**
>
> This configuration parameter might be deprecated in future versions. **DO NOT** change the value of it.

- The timeout of a single Coprocessor request.
- Default value: `60`
- Unit: second

14.8.1.8.12 `enable-replica-selector-v2` New in v8.0.0

> **Warning:**
>
> Starting from v8.2.0, this configuration item is deprecated. The new version of the Region replica selector is used by default when sending RPC requests to TiKV.

- Whether to use the new version of the Region replica selector when sending RPC requests to TiKV.
- Default value: `true`

14.8.1.9 tikv-client.copr-cache New in v4.0.0

This section introduces configuration items related to the Coprocessor Cache feature.

14.8.1.9.1 `capacity-mb`

- The total size of the cached data. When the cache space is full, old cache entries are evicted. When the value is `0.0`, the Coprocessor Cache feature is disabled.
- Default value: `1000.0`
- Unit: MB
- Type: Float

14.8.1.10 txn-local-latches

Configuration items related to the transaction latch. These configuration items might be deprecated in the future. It is not recommended to use them.

14.8.1.10.1 `enabled`

- Determines whether to enable the memory lock of transactions.
- Default value: `false`

14.8.1.10.2 `capacity`

- The number of slots corresponding to Hash, which automatically adjusts upward to an exponential multiple of 2. Each slot occupies 32 Bytes of memory. If set too small, it might result in slower running speed and poor performance in the scenario where data writing covers a relatively large range (such as importing data).
- Default value: `2048000`

14.8.1.11 status

Configuration related to the status of TiDB service.

14.8.1.11.1 `report-status`

- Enables or disables the HTTP API service.
- Default value: `true`

14.8.1.11.2 `record-db-qps`

- Determines whether to transmit the database-related QPS metrics to Prometheus.
- Default value: `false`

14.8.1.11.3 `record-db-label`

- Determines whether to transmit the database-related QPS metrics to Prometheus.
- Supports more metrics types than `record-db-qps`, for example, duration and statements.
- Default value: `false`

14.8.1.12 pessimistic-txn

For pessimistic transaction usage, refer to TiDB Pessimistic Transaction Mode.

14.8.1.12.1 max-retry-count

- The maximum number of retries of each statement in pessimistic transactions. If the number of retries exceeds this limit, an error occurs.
- Default value: `256`

14.8.1.12.2 deadlock-history-capacity

- The maximum number of deadlock events that can be recorded in the `INFORMATION_SCHEMA.DEADLOCKS` table of a single TiDB server. If this table is in full volume and an additional deadlock event occurs, the earliest record in the table will be removed to make place for the newest error.
- Default value: `10`
- Minimum value: `0`
- Maximum value: `10000`

14.8.1.12.3 deadlock-history-collect-retryable

- Controls whether the `INFORMATION_SCHEMA.DEADLOCKS` table collects the information of retryable deadlock errors. For the description of retryable deadlock errors, see Retryable deadlock errors.
- Default value: `false`

14.8.1.12.4 pessimistic-auto-commit New in v6.0.0

- Determines the transaction mode that the auto-commit transaction uses when the pessimistic transaction mode is globally enabled (`tidb_txn_mode='pessimistic'`). By default, even if the pessimistic transaction mode is globally enabled, the auto-commit transaction still uses the optimistic transaction mode. After enabling `pessimistic-auto-commit` (set to `true`), the auto-commit transaction also uses pessimistic mode, which is consistent with the other explicitly committed pessimistic transactions.
- For scenarios with conflicts, after enabling this configuration, TiDB includes auto-commit transactions into the global lock-waiting management, which avoids deadlocks and mitigates the latency spike brought by deadlock-causing conflicts.
- For scenarios with no conflicts, if there are many auto-commit transactions (the specific number is determined by the real scenarios. For example, the number of auto-commit transactions accounts for more than half of the total number of applications), and a single transaction operates a large data volume, enabling this configuration causes performance regression. For example, the auto-commit `INSERT INTO SELECT` statement.
- When the session-level system variable `tidb_dml_type` is set to `"bulk"`, the effect of this configuration in the session is equivalent to setting it to `false`.
- Default value: `false`

14.8.1.12.5 constraint-check-in-place-pessimistic New in v6.4.0

- Controls the default value of the system variable `tidb_constraint_check_in_place_pessimistic`.
- Default value: `true`

14.8.1.13 isolation-read

Configuration items related to read isolation.

14.8.1.13.1 engines

- Controls from which engine TiDB allows to read data.
- Default value: ["tikv", "tiflash", "tidb"], indicating that the engine is automatically selected by the optimizer.
- Value options: Any combinations of "tikv", "tiflash", and "tidb", for example, ["tikv", "tidb"] or ["tiflash", "tidb"]

14.8.1.14 instance

14.8.1.14.1 `tidb_enable_collect_execution_info`

- This configuration controls whether to record the execution information of each operator in the slow query log and whether to record the usage statistics of indexes.
- Default value: `true`
- Before v6.1.0, this configuration is set by `enable-collect-execution-info`.

14.8.1.14.2 `tidb_enable_slow_log`

- This configuration is used to control whether to enable the slow log feature.
- Default value: `true`
- Value options: `true` or `false`
- Before v6.1.0, this configuration is set by `enable-slow-log`.

14.8.1.14.3 `tidb_slow_log_threshold`

- Outputs the threshold value of the time consumed by the slow log.
- Default value: `300`
- Range: `[-1, 9223372036854775807]`
- Unit: Milliseconds
- When the time consumed by a query is larger than this value, this query is considered as a slow query and its log is output to the slow query log. Note that when the output level of `log.level` is `"debug"`, all queries are recorded in the slow query log, regardless of the setting of this parameter.
- Before v6.1.0, this configuration is set by `slow-threshold`.

14.8.1.14.4 `in-mem-slow-query-topn-num` New in v7.3.0

- The configuration controls the number of slowest queries that are cached in memory.
- Default value: 30

14.8.1.14.5 `in-mem-slow-query-recent-num` New in v7.3.0

- The configuration controls the number of recently used slow queries that are cached in memory.
- Default value: 500

14.8.1.14.6 `tidb_expensive_query_time_threshold`

- This configuration is used to set the threshold value that determines whether to print expensive query logs. The difference between expensive query logs and slow query logs is:
  - Slow logs are printed after the statement is executed.
  - Expensive query logs print the statements that are being executed, with execution time exceeding the threshold value, and their related information.
- Default value: `60`
- Range: `[10, 2147483647]`
- Unit: Seconds
- Before v5.4.0, this configuration is set by `expensive-threshold`.

14.8.1.14.7 `tidb_record_plan_in_slow_log`

- This configuration is used to control whether to include the execution plan of slow queries in the slow log.
- Default value: `1`
- Value options: `1` (enabled, default) or `0` (disabled).
- The value of this configuration will initialize the value of system variable `tidb_record_plan_in_slow_log`
- Before v6.1.0, this configuration is set by `record-plan-in-slow-log`.

14.8.1.14.8 `tidb_force_priority`

- This configuration is used to change the default priority for statements executed on a TiDB server.
- Default value: `NO_PRIORITY`
- The default value `NO_PRIORITY` means that the priority for statements is not forced to change. Other options are `LOW_PRIORITY`, `DELAYED`, and `HIGH_PRIORITY` in ascending order.
- Before v6.1.0, this configuration is set by `force-priority`.

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.8.1.14.9 `max_connections`

- The maximum number of connections permitted for a single TiDB instance. It can be used for resources control.
- Default value: `0`
- Range: `[0, 100000]`
- The default value `0` means no limit. When the value of this variable is larger than `0`, and the number of connections reaches the value, the TiDB server will reject new connections from clients.
- The value of this configuration will initialize the value of system variable `max_connections`
- Before v6.2.0, this configuration is set by `max-server-connections`.

14.8.1.14.10 `tidb_enable_ddl`

- This configuration controls whether the corresponding TiDB instance can become a DDL owner or not.
- Default value: `true`
- Possible values: `OFF`, `ON`
- The value of this configuration will initialize the value of the system variable `tidb_enable_ddl`
- Before v6.3.0, this configuration is set by `run-ddl`.

14.8.1.14.11 `tidb_enable_stats_owner` New in v8.4.0

- This configuration controls whether the corresponding TiDB instance can run automatic statistics update tasks.
- Default value: `true`
- Possible values: `true`, `false`
- The value of this configuration will initialize the value of the system variable `tidb_enable_stats_owner`.

14.8.1.14.12 `tidb_stmt_summary_enable_persistent` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Controls whether to enable statements summary persistence.
- Default value: `false`
- For more details, see Persist statements summary.

14.8.1.14.13 `tidb_stmt_summary_filename` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the file to which persistent data is written.
- Default value: `tidb-statements.log`

14.8.1.14.14 `tidb_stmt_summary_file_max_days` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum number of days to keep persistent data files.
- Default value: `3`
- Unit: day
- You can adjust the value based on the data retention requirements and disk space usage.

14.8.1.14.15 `tidb_stmt_summary_file_max_size` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum size of a persistent data file.
- Default value: `64`
- Unit: MiB
- You can adjust the value based on the data retention requirements and disk space usage.

14.8.1.14.16 `tidb_stmt_summary_file_max_backups` New in v6.6.0

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- When statements summary persistence is enabled, this configuration specifies the maximum number of data files that can be persisted. `0` means no limit on the number of files.
- Default value: `0`
- You can adjust the value based on the data retention requirements and disk space usage.

14.8.1.15 proxy-protocol

Configuration items related to the PROXY protocol.

14.8.1.15.1 `networks`

- The list of proxy server's IP addresses allowed to connect to TiDB using the PROXY protocol
- Default value: ""

- In general cases, when you access TiDB behind a reverse proxy, TiDB takes the IP address of the reverse proxy server as the IP address of the client. By enabling the PROXY protocol, reverse proxies that support this protocol, such as HAProxy, can pass the real client IP address to TiDB.
- After configuring this parameter, TiDB allows the configured source IP address to connect to TiDB using the PROXY protocol; if a protocol other than PROXY is used, this connection will be denied. If this parameter is left empty, no IP address can connect to TiDB using the PROXY protocol. The value can be an IP address (192.168.1.50) or CIDR (192.168.1.0/24) with `,` as the separator. `*` means any IP addresses.

> **Warning:**
>
> Use `*` with caution because it might introduce security risks by allowing a client of any IP address to report its IP address. In addition, using `*` might also cause the internal component that directly connects to TiDB (such as TiDB Dashboard) to be unavailable.

14.8.1.15.2 `fallbackable` New in v6.5.1

- Controls whether to enable the PROXY protocol fallback mode. If this configuration item is set to `true`, TiDB can accept clients that belong to `proxy-protocol.networks` ↪ to connect to TiDB without using the PROXY protocol specification or without sending the PROXY protocol header. By default, TiDB only accepts client connections that belong to `proxy-protocol.networks` and send a PROXY protocol header.
- Default value: `false`

14.8.1.16 experimental

The `experimental` section, introduced in v3.1.0, describes the configurations related to the experimental features of TiDB.

14.8.1.16.1 `allow-expression-index` New in v4.0.0

- Controls whether an expression index can be created. Since TiDB v5.2.0, if the function in an expression is safe, you can create an expression index directly based on this function without enabling this configuration. If you want to create an expression index based on other functions, you can enable this configuration, but correctness issues might exist. By querying the `tidb_allow_function_for_expression_index` variable, you can get the functions that are safe to be directly used for creating an expression.
- Default value: `false`

14.8.2 TiKV Configuration File

The TiKV configuration file supports more options than command-line parameters. You can find the default configuration file in etc/config-template.toml and rename it to `config.toml`.

This document only describes the parameters that are not included in command-line parameters. For more details, see command-line parameter.

> **Tip:**
>
> If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.8.2.1 Global configuration

14.8.2.1.1 `abort-on-panic`

- Sets whether to call `abort()` to exit the process when TiKV panics. This option affects whether TiKV allows the system to generate core dump files.
  - If the value of this configuration item is `false`, when TiKV panics, it calls `exit()` to exit the process.
  - If the value of this configuration item is `true`, when TiKV panics, TiKV calls `abort()` to exit the process. At this time, TiKV allows the system to generate core dump files when exiting. To generate the core dump file, you also need to perform the system configuration related to core dump (for example, setting the size limit of the core dump file via `ulimit -c` command, and configure the core dump path. Different operating systems have different related configurations). To avoid the core dump files occupying too much disk space and causing insufficient TiKV disk space, it is recommended to set the core dump generation path to a disk partition different to that of TiKV data.
- Default value: `false`

14.8.2.1.2 `slow-log-file`

- The file that stores slow logs
- If this configuration item is not set, but `log.file.filename` is set, slow logs are output to the log file specified by `log.file.filename`.
- If neither `slow-log-file` nor `log.file.filename` are set, all logs are output to "stderr" by default.

- If both configuration items are set, ordinary logs are output to the log file specified by `log.file.filename`, and slow logs are output to the log file set by `slow-log-file`.
- Default value: `""`

14.8.2.1.3 `slow-log-threshold`

- The threshold for outputting slow logs. If the processing time is longer than this threshold, slow logs are output.
- Default value: `"1s"`

14.8.2.1.4 `memory-usage-limit`

- The limit on memory usage of the TiKV instance. When the memory usage of TiKV almost reaches this threshold, internal cache will be evicted to release memory.
- In most cases, the TiKV instance is set to use 75% of the total available system memory, so you do not need to explicitly specify this configuration item. The rest 25% of the memory is reserved for the OS page cache. See `storage.block-cache.capacity` for details.
- When deploying multiple TiKV nodes on a single physical machine, you still do not need to set this configuration item. In this case, the TiKV instance uses `5/3 * block -cache.capacity` of memory.
- The default value for different system memory capacity is as follows:
  - system=8G block-cache=3.6G memory-usage-limit=6G page-cache=2G
  - system=16G block-cache=7.2G memory-usage-limit=12G page-cache=4G
  - system=32G block-cache=14.4G memory-usage-limit=24G page-cache=8G

14.8.2.2 log New in v5.4.0

- Configuration items related to the log.
- From v5.4.0, to make the log configuration items of TiKV and TiDB consistent, TiKV deprecates the former configuration item `log-rotation-timespan` and changes `log-level`, `log-format`, `log-file`, `log-rotation-size` to the following ones. If you only set the old configuration items, and their values are set to non-default values, the old items remain compatible with the new items. If both old and new configuration items are set, the new items take effect.

14.8.2.2.1 `level` New in v5.4.0

- The log level
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`
- Default value: `"info"`

14.8.2.2.2 `format` New in v5.4.0

- The log format
- Optional values: `"json"`, `"text"`
- Default value: `"text"`

14.8.2.2.3 `enable-timestamp` New in v5.4.0

- Determines whether to enable or disable the timestamp in the log
- Optional values: `true`, `false`
- Default value: `true`

14.8.2.3 log.file New in v5.4.0

- Configuration items related to the log file.

14.8.2.3.1 `filename` New in v5.4.0

- The log file. If this configuration item is not set, logs are output to "stderr" by default. If this configuration item is set, logs are output to the corresponding file.
- Default value: `""`

14.8.2.3.2 `max-size` New in v5.4.0

- The maximum size of a single log file. When the file size is larger than the value set by this configuration item, the system automatically splits the single file into multiple files.
- Default value: `300`
- Maximum value: `4096`
- Unit: MiB

14.8.2.3.3 `max-days` New in v5.4.0

- The maximum number of days that TiKV keeps log files.
    - If the configuration item is not set, or the value of it is set to the default value `0`, TiKV does not clean log files.
    - If the parameter is set to a value other than `0`, TiKV cleans up the expired log files after `max-days`.
- Default value: `0`

14.8.2.3.4 `max-backups` New in v5.4.0

- The maximum number of log files that TiKV keeps.
  - If the configuration item is not set, or the value of it is set to the default value `0`, TiKV keeps all log files.
  - If the configuration item is set to a value other than `0`, TiKV keeps at most the number of old log files specified by `max-backups`. For example, if the value is set to `7`, TiKV keeps up to 7 old log files.
- Default value: `0`

14.8.2.4 server

- Configuration items related to the server.

14.8.2.4.1 `addr`

- The listening IP address and the listening port
- Default value: `"127.0.0.1:20160"`

14.8.2.4.2 `advertise-addr`

- Advertise the listening address for client communication
- If this configuration item is not set, the value of `addr` is used.
- Default value: `""`

14.8.2.4.3 `status-addr`

- The configuration item reports TiKV status directly through the `HTTP` address

> **Warning:**
> If this value is exposed to the public, the status information of the TiKV server might be leaked.

- To disable the status address, set the value to `""`.
- Default value: `"127.0.0.1:20180"`

14.8.2.4.4 status-thread-pool-size

- The number of worker threads for the HTTP API service
- Default value: 1
- Minimum value: 1

14.8.2.4.5 grpc-compression-type

- The compression algorithm for gRPC messages. It affects gRPC messages between TiKV nodes. Starting from v6.5.11, v7.1.6, v7.5.3, v8.1.1, and v8.2.0, it also affects gRPC response messages sent from TiKV to TiDB.
- Optional values: "none", "deflate", "gzip"

> **Note:**
> TiDB does not support "deflate". Therefore, if you want to compress gRPC response messages sent from TiKV to TiDB, set this configuration item to "gzip".

- Default value: "none"

14.8.2.4.6 grpc-concurrency

- The number of gRPC worker threads. When you modify the size of the gRPC thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: 5
- Minimum value: 1

14.8.2.4.7 grpc-concurrent-stream

- The maximum number of concurrent requests allowed in a gRPC stream
- Default value: 1024
- Minimum value: 1

14.8.2.4.8 grpc-memory-pool-quota

- Limits the memory size that can be used by gRPC
- Default value: No limit
- Limit the memory in case OOM is observed. Note that limit the usage can lead to potential stall

14.8.2.4.9 `grpc-raft-conn-num`

- The maximum number of connections between TiKV nodes for Raft communication
- Default value: `1`
- Minimum value: `1`

14.8.2.4.10 `max-grpc-send-msg-len`

- Sets the maximum length of a gRPC message that can be sent
- Default value: `10485760`
- Unit: Bytes
- Maximum value: `2147483647`

14.8.2.4.11 `grpc-stream-initial-window-size`

- The window size of the gRPC stream
- Default value: `2MiB`
- Unit: KiB|MiB|GiB
- Minimum value: `"1KiB"`

14.8.2.4.12 `grpc-keepalive-time`

- The time interval at which that gRPC sends `keepalive` Ping messages
- Default value: `"10s"`
- Minimum value: `"1s"`

14.8.2.4.13 `grpc-keepalive-timeout`

- Disables the timeout for gRPC streams
- Default value: `"3s"`
- Minimum value: `"1s"`

14.8.2.4.14 `concurrent-send-snap-limit`

- The maximum number of snapshots sent at the same time
- Default value: `32`
- Minimum value: `1`

14.8.2.4.15 `concurrent-recv-snap-limit`

- The maximum number of snapshots received at the same time
- Default value: `32`
- Minimum value: `1`

14.8.2.4.16 `end-point-recursion-limit`

- The maximum number of recursive levels allowed when TiKV decodes the Coprocessor DAG expression
- Default value: `1000`
- Minimum value: `1`

14.8.2.4.17 `end-point-request-max-handle-duration`

- The longest duration allowed for a TiDB's push down request to TiKV for processing tasks
- Default value: `"60s"`
- Minimum value: `"1s"`

14.8.2.4.18 `end-point-memory-quota` New in v8.2.0

- The maximum amount of memory that TiKV Coprocessor requests can use. If this limit is exceeded, subsequent Coprocessor requests are rejected with the error "server is busy."
- Default value: 45% of the total system memory. If 45% of the total system memory exceeds 500 MiB, the default value is 500 MiB.

14.8.2.4.19 `snap-io-max-bytes-per-sec`

- The maximum allowable disk bandwidth when processing snapshots
- Default value: `"100MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"1KiB"`

14.8.2.4.20 `snap-min-ingest-size` New in v8.1.2

- Specifies the minimum threshold for whether TiKV adopts the ingest method when processing snapshots.
    - When the snapshot size exceeds this threshold, TiKV adopts the ingest method, which imports SST files from the snapshot into RocksDB. This method is faster for large files.
    - When the snapshot size does not exceed this threshold, TiKV adopts the direct write method, which writes each piece of data into RocksDB individually. This method is more efficient for small files.
- Default value: `"2MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `0`

14.8.2.4.21 `enable-request-batch`

- Determines whether to process requests in batches
- Default value: `true`

14.8.2.4.22 `labels`

- Specifies server attributes, such as `{ zone = "us-west-1", disk = "ssd" }`.
- Default value: `{}`

14.8.2.4.23 `background-thread-count`

- The working thread count of the background pool, including endpoint threads, BR threads, split-check threads, Region threads, and other threads of delay-insensitive tasks.
- Default value: when the number of CPU cores is less than 16, the default value is `2`; otherwise, the default value is `3`.

14.8.2.4.24 `end-point-slow-log-threshold`

- The time threshold for a TiDB's push-down request to output slow log. If the processing time is longer than this threshold, the slow logs are output.
- Default value: `"1s"`
- Minimum value: `0`

14.8.2.4.25 `raft-client-queue-size`

- Specifies the queue size of the Raft messages in TiKV. If too many messages not sent in time result in a full buffer, or messages discarded, you can specify a greater value to improve system stability.
- Default value: `16384`

14.8.2.4.26 `simplify-metrics` New in v6.2.0

- Specifies whether to simplify the returned monitoring metrics. After you set the value to `true`, TiKV reduces the amount of data returned for each request by filtering out some metrics.
- Default value: `false`

14.8.2.4.27 `forward-max-connections-per-address` New in v5.0.0

- Sets the size of the connection pool for service and forwarding requests to the server. Setting it to too small a value affects the request latency and load balancing.
- Default value: `4`

14.8.2.5 readpool.unified

Configuration items related to the single thread pool serving read requests. This thread pool supersedes the original storage thread pool and coprocessor thread pool since the 4.0 version.

14.8.2.5.1 `min-thread-count`

- The minimal working thread count of the unified read pool
- Default value: `1`

14.8.2.5.2 `max-thread-count`

- The maximum working thread count of the unified read pool or the UnifyReadPool thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Value range: `[min-thread-count, MAX(4, CPU quota * 10)]`. `MAX(4, CPU quota * 10)` takes the greater value out of `4` and the `CPU quota * 10`.
- Default value: MAX(4, CPU * 0.8)

> **Note:**
>
> Increasing the thread count will lead to more context switches, which might cause a performance decrease. It is not recommended to modify the value of this configuration item.

14.8.2.5.3 `stack-size`

- The stack size of the threads in the unified thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.8.2.5.4 max-tasks-per-worker

- The maximum number of tasks allowed for a single thread in the unified read pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.8.2.5.5 auto-adjust-pool-size New in v6.3.0

- Controls whether to automatically adjust the thread pool size. When it is enabled, the read performance of TiKV is optimized by automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. The possible range of the thread pool is `[max-thread-count, MAX(4, CPU)]`. The maximum value is the same as the one of `max-thread-count`.
- Default value: `false`

14.8.2.6 readpool.storage

Configuration items related to storage thread pool.

14.8.2.6.1 use-unified-pool

- Determines whether to use the unified thread pool (configured in `readpool.unified`) for storage requests. If the value of this parameter is `false`, a separate thread pool is used, which is configured through the rest parameters in this section (`readpool.storage`).
- Default value: If this section (`readpool.storage`) has no other configurations, the default value is `true`. Otherwise, for the backward compatibility, the default value is `false`. Change the configuration in `readpool.unified` as needed before enabling this option.

14.8.2.6.2 high-concurrency

- The allowable number of concurrent threads that handle high-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.8.2.6.3 normal-concurrency

- The allowable number of concurrent threads that handle normal-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.8.2.6.4 low-concurrency

- The allowable number of concurrent threads that handle low-priority `read` requests
- When `8 cpu num 16`, the default value is `cpu_num * 0.5`; when `cpu num` is smaller than `8`, the default value is `4`; when `cpu num` is greater than `16`, the default value is `8`.
- Minimum value: `1`

14.8.2.6.5 max-tasks-per-worker-high

- The maximum number of tasks allowed for a single thread in a high-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.8.2.6.6 max-tasks-per-worker-normal

- The maximum number of tasks allowed for a single thread in a normal-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.8.2.6.7 max-tasks-per-worker-low

- The maximum number of tasks allowed for a single thread in a low-priority thread pool. `Server Is Busy` is returned when the value is exceeded.
- Default value: `2000`
- Minimum value: `2`

14.8.2.6.8 stack-size

- The stack size of threads in the Storage read thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.8.2.7 readpool.coprocessor

Configuration items related to the Coprocessor thread pool.

14.8.2.7.1 use-unified-pool

- Determines whether to use the unified thread pool (configured in readpool.unified ↪) for coprocessor requests. If the value of this parameter is false, a separate thread pool is used, which is configured through the rest parameters in this section (readpool.coprocessor).
- Default value: If none of the parameters in this section (readpool.coprocessor) are set, the default value is true. Otherwise, the default value is false for the backward compatibility. Adjust the configuration items in readpool.unified before enabling this parameter.

14.8.2.7.2 high-concurrency

- The allowable number of concurrent threads that handle high-priority Coprocessor requests, such as checkpoints
- Default value: CPU * 0.8
- Minimum value: 1

14.8.2.7.3 normal-concurrency

- The allowable number of concurrent threads that handle normal-priority Coprocessor requests
- Default value: CPU * 0.8
- Minimum value: 1

14.8.2.7.4 low-concurrency

- The allowable number of concurrent threads that handle low-priority Coprocessor requests, such as table scan
- Default value: CPU * 0.8
- Minimum value: 1

14.8.2.7.5 max-tasks-per-worker-high

- The number of tasks allowed for a single thread in a high-priority thread pool. When this number is exceeded, Server Is Busy is returned.
- Default value: 2000
- Minimum value: 2

14.8.2.7.6 max-tasks-per-worker-normal

- The number of tasks allowed for a single thread in a normal-priority thread pool. When this number is exceeded, Server Is Busy is returned.
- Default value: 2000
- Minimum value: 2

14.8.2.7.7 `max-tasks-per-worker-low`

- The number of tasks allowed for a single thread in a low-priority thread pool. When this number is exceeded, `Server Is Busy` is returned.
- Default value: `2000`
- Minimum value: `2`

14.8.2.7.8 `stack-size`

- The stack size of the thread in the Coprocessor thread pool
- Type: Integer + Unit
- Default value: `"10MiB"`
- Unit: KiB|MiB|GiB
- Minimum value: `"2MiB"`
- Maximum value: The number of Kbytes output in the result of the `ulimit -sH` command executed in the system.

14.8.2.8 storage

Configuration items related to storage.

14.8.2.8.1 `data-dir`

- The storage path of the RocksDB directory
- Default value: `"./"`

14.8.2.8.2 `engine` New in v6.6.0

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the engine type. This configuration can only be specified when creating a new cluster and cannot be modified once being specified.
- Default value: `"raft-kv"`
- Value options:
  - `"raft-kv"`: The default engine type in versions earlier than TiDB v6.6.0.
  - `"partitioned-raft-kv"`: The new storage engine type introduced in TiDB v6.6.0.

14.8.2.8.3 `scheduler-concurrency`

- A built-in memory lock mechanism to prevent simultaneous operations on a key. Each key has a hash in a different slot.
- Default value: `524288`
- Minimum value: `1`

14.8.2.8.4 `scheduler-worker-pool-size`

- The number of threads in the Scheduler thread pool. Scheduler threads are mainly used for checking transaction consistency before data writing. If the number of CPU cores is greater than or equal to `16`, the default value is `8`; otherwise, the default value is `4`. When you modify the size of the Scheduler thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `4`
- Value range: `[1, MAX(4, CPU)]`. In `MAX(4, CPU)`, `CPU` means the number of your CPU cores. `MAX(4, CPU)` takes the greater value out of `4` and the `CPU`.

14.8.2.8.5 `scheduler-pending-write-threshold`

- The maximum size of the write queue. A `Server Is Busy` error is returned for a new write to TiKV when this value is exceeded.
- Default value: `"100MiB"`
- Unit: MiB|GiB

14.8.2.8.6 `enable-async-apply-prewrite`

- Determines whether Async Commit transactions respond to the TiKV client before applying prewrite requests. After enabling this configuration item, latency can be easily reduced when the apply duration is high, or the delay jitter can be reduced when the apply duration is not stable.
- Default value: `false`

14.8.2.8.7 `reserve-space`

- When TiKV is started, some space is reserved on the disk as disk protection. When the remaining disk space is less than the reserved space, TiKV restricts some write operations. The reserved space is divided into two parts: 80% of the reserved space is used as the extra disk space required for operations when the disk space is insufficient, and the other 20% is used to store the temporary file. In the process of reclaiming space, if the storage is exhausted by using too much extra disk space, this temporary file serves as the last protection for restoring services.

- The name of the temporary file is `space_placeholder_file`, located in the `storage.data-dir` directory. When TiKV goes offline because its disk space ran out, if you restart TiKV, the temporary file is automatically deleted and TiKV tries to reclaim the space.
- When the remaining space is insufficient, TiKV does not create the temporary file. The effectiveness of the protection is related to the size of the reserved space. The size of the reserved space is the larger value between 5% of the disk capacity and this configuration value. When the value of this configuration item is `"0MiB"`, TiKV disables this disk protection feature.
- Default value: `"5GiB"`
- Unit: MiB|GiB

14.8.2.8.8 `enable-ttl`

Warning:

- Set `enable-ttl` to `true` or `false` **ONLY WHEN** deploying a new TiKV cluster. **DO NOT** modify the value of this configuration item in an existing TiKV cluster. TiKV clusters with different `enable-ttl` values use different data formats. Therefore, if you modify the value of this item in an existing TiKV cluster, the cluster will store data in different formats, which causes the "can't enable TTL on a non-ttl" error when you restart the TiKV cluster.
- Use `enable-ttl` **ONLY IN** a TiKV cluster. **DO NOT** use this configuration item in a cluster that has TiDB nodes (which means setting `enable-ttl` to `true` in such clusters) unless `storage.api-version = 2` is configured. Otherwise, critical issues such as data corruption and the upgrade failure of TiDB clusters will occur.

- TTL is short for "Time to live". If this item is enabled, TiKV automatically deletes data that reaches its TTL. To set the value of TTL, you need to specify it in the requests when writing data via the client. If the TTL is not specified, it means that TiKV does not automatically delete the corresponding data.
- Default value: `false`

14.8.2.8.9 `ttl-check-poll-interval`

- The interval of checking data to reclaim physical spaces. If data reaches its TTL, TiKV forcibly reclaims its physical space during the check.
- Default value: `"12h"`
- Minimum value: `"0s"`

14.8.2.8.10 `background-error-recovery-window` New in v6.1.0

- The maximum allowable time for TiKV to recover after RocksDB detects a recoverable background error. If some background SST files are damaged, RocksDB will report to PD via heartbeat after locating the Peer to which the damaged SST files belong. PD then performs scheduling operations to remove this Peer. Finally, the damaged SST files are deleted directly, and the TiKV background will work as normal again.
- The damaged SST files still exist before the recovery finishes. During such a period, RocksDB can continue writing data, but an error will be reported when the damaged part of the data is read.
- If the recovery fails to finish within this time window, TiKV will panic.
- Default value: 1h

14.8.2.8.11 `api-version` New in v6.1.0

- The storage format and interface version used by TiKV when TiKV serves as the RawKV store.
- Value options:
  - `1`: Uses API V1, does not encode the data passed from the client, and stores data as it is. In versions earlier than v6.1.0, TiKV uses API V1 by default.
  - `2`: Uses API V2:
    - The data is stored in the Multi-Version Concurrency Control (MVCC) format, where the timestamp is obtained from PD (which is TSO) by tikv-server.
    - Data is scoped according to different usage and API V2 supports co-existence of TiDB, Transactional KV, and RawKV applications in a single cluster.
    - When API V2 is used, you are expected to set `storage.enable-ttl = true` at the same time. Because API V2 supports the TTL feature, you must turn on `enable-ttl` explicitly. Otherwise, it will be in conflict because `storage.enable-ttl` defaults to `false`.
    - When API V2 is enabled, you need to deploy at least one tidb-server instance to reclaim obsolete data. This tidb-server instance can provide read and write services at the same time. To ensure high availability, you can deploy multiple tidb-server instances.
    - Client support is required for API V2. For details, see the corresponding instruction of the client for the API V2.
    - Since v6.2.0, Change Data Capture (CDC) for RawKV is supported. Refer to RawKV CDC.
- Default value: `1`

Warning:

- API V1 and API V2 are different from each other in the storage format. You can enable or disable API V2 directly **only** when TiKV contains only TiDB data. In other scenarios, you need to deploy a new cluster, and migrate data using RawKV Backup & Restore.
- After API V2 is enabled, you **cannot** downgrade the TiKV cluster to a version earlier than v6.1.0. Otherwise, data corruption might occur.

14.8.2.9 `txn-status-cache-capacity` New in v7.6.0

- Sets the capacity of the transaction status cache in TiKV. Do not modify this parameter.
- Default value: `5120000`

14.8.2.10 storage.block-cache

Configuration items related to the sharing of block cache among multiple RocksDB Column Families (CF).

14.8.2.10.1 `capacity`

- The size of the shared block cache.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is 45% of the size of total system memory.
  - When `storage.engine="partitioned-raft-kv"`, the default value is 30% of the size of total system memory.
- Unit: KiB|MiB|GiB

14.8.2.10.2 `low-pri-pool-ratio` New in v8.0.0

- Controls the proportion of the entire block cache that the Titan component can use.
- Default value: `0.2`

14.8.2.11 storage.flow-control

Configuration items related to the flow control mechanism in TiKV. This mechanism replaces the write stall mechanism in RocksDB and controls flow at the scheduler layer, which avoids secondary disasters caused by the stuck Raftstore or Apply threads.

14.8.2.11.1 `enable`

- Determines whether to enable the flow control mechanism. After it is enabled, TiKV automatically disables the write stall mechanism of KvDB and the write stall mechanism of RaftDB (excluding memtable).
- Default value: `true`

14.8.2.11.2 `memtables-threshold`

- When the number of kvDB memtables reaches this threshold, the flow control mechanism starts to work. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf|lockcf).max-write-buffer-number`.
- Default value: `5`

14.8.2.11.3 `l0-files-threshold`

- When the number of kvDB L0 files reaches this threshold, the flow control mechanism starts to work. When `enable` is set to `true`, this configuration item overrides `rocksdb` ↪ `.(defaultcf|writecf|lockcf).level0-slowdown-writes-trigger`.
- Default value: `20`

14.8.2.11.4 `soft-pending-compaction-bytes-limit`

- When the pending compaction bytes in KvDB reach this threshold, the flow control mechanism starts to reject some write requests and reports the `ServerIsBusy` error. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|` ↪ `writecf|lockcf).soft-pending-compaction-bytes-limit`.
- Default value: `"192GiB"`

14.8.2.11.5 `hard-pending-compaction-bytes-limit`

- When the pending compaction bytes in KvDB reach this threshold, the flow control mechanism rejects all write requests and reports the `ServerIsBusy` error. When `enable` is set to `true`, this configuration item overrides `rocksdb.(defaultcf|writecf` ↪ `|lockcf).hard-pending-compaction-bytes-limit`.
- Default value: `"1024GiB"`

14.8.2.12 storage.io-rate-limit

Configuration items related to the I/O rate limiter.

14.8.2.12.1 `max-bytes-per-sec`

- Limits the maximum I/O bytes that a server can write to or read from the disk (determined by the `mode` configuration item below) in one second. When this limit is reached, TiKV prefers throttling background operations over foreground ones. The value of this configuration item should be set to the disk's optimal I/O bandwidth, for example, the maximum I/O bandwidth specified by your cloud disk vendor. When this configuration value is set to zero, disk I/O operations are not limited.
- Default value: `"0MiB"`

14.8.2.12.2 `mode`

- Determines which types of I/O operations are counted and restrained below the `max-bytes-per-sec` threshold. Currently, only the write-only mode is supported.
- Value options: `"read-only"`, `"write-only"`, and `"all-io"`
- Default value: `"write-only"`

14.8.2.13 pd

14.8.2.13.1 `enable-forwarding` New in v5.0.0

- Controls whether the PD client in TiKV forwards requests to the leader via the followers in the case of possible network isolation.
- Default value: `false`
- If the environment might have isolated network, enabling this parameter can reduce the window of service unavailability.
- If you cannot accurately determine whether isolation, network interruption, or downtime has occurred, using this mechanism has the risk of misjudgment and causes reduced availability and performance. If network failure has never occurred, it is not recommended to enable this parameter.

14.8.2.13.2 `endpoints`

- The endpoints of PD. When multiple endpoints are specified, you need to separate them using commas.
- Default value: `["127.0.0.1:2379"]`

14.8.2.13.3 `retry-interval`

- The interval for retrying the PD connection.
- Default value: `"300ms"`

14.8.2.13.4 `retry-log-every`

- Specified the frequency at which the PD client skips reporting errors when the client observes errors. For example, when the value is `5`, after the PD client observes errors, the client skips reporting errors every 4 times and reports errors every 5th time.
- To disable this feature, set the value to `1`.
- Default value: `10`

14.8.2.13.5 `retry-max-count`

- The maximum number of times to retry to initialize PD connection
- To disable the retry, set its value to `0`. To release the limit on the number of retries, set the value to `-1`.
- Default value: `-1`

14.8.2.14 raftstore

Configuration items related to Raftstore.

14.8.2.14.1 `prevote`

- Enables or disables `prevote`. Enabling this feature helps reduce jitter on the system after recovery from network partition.
- Default value: `true`

14.8.2.14.2 `capacity`

- The storage capacity, which is the maximum size allowed to store data. If `capacity` is left unspecified, the capacity of the current disk prevails. To deploy multiple TiKV instances on the same physical disk, add this parameter to the TiKV configuration. For details, see Key parameters of the hybrid deployment.
- Default value: `0`
- Unit: KiB|MiB|GiB

14.8.2.14.3 `raftdb-path`

- The path to the Raft library, which is `storage.data-dir/raft` by default
- Default value: `""`

14.8.2.14.4 `raft-base-tick-interval`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The time interval at which the Raft state machine ticks
- Default value: `"1s"`
- Minimum value: greater than `0`

14.8.2.14.5 `raft-heartbeat-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The number of passed ticks when the heartbeat is sent. This means that a heartbeat is sent at the time interval of `raft-base-tick-interval` * `raft-heartbeat-ticks`.
- Default value: `2`
- Minimum value: greater than `0`

14.8.2.14.6 `raft-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The number of passed ticks when Raft election is initiated. This means that if Raft group is missing the leader, a leader election is initiated approximately after the time interval of `raft-base-tick-interval` * `raft-election-timeout-ticks`.
- Default value: `10`
- Minimum value: `raft-heartbeat-ticks`

14.8.2.14.7 `raft-min-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The minimum number of ticks during which the Raft election is initiated. If the number is `0`, the value of `raft-election-timeout-ticks` is used. The value of this parameter must be greater than or equal to `raft-election-timeout-ticks`.
- Default value: `0`
- Minimum value: `0`

14.8.2.14.8 `raft-max-election-timeout-ticks`

> **Note:**
>
> This configuration item cannot be queried via SQL statements but can be configured in the configuration file.

- The maximum number of ticks during which the Raft election is initiated. If the number is `0`, the value of `raft-election-timeout-ticks` * `2` is used.
- Default value: `0`
- Minimum value: `0`

14.8.2.14.9 `raft-max-size-per-msg`

- The soft limit on the size of a single message packet
- Default value: `"1MiB"`
- Minimum value: greater than `0`
- Maximum value: `3GiB`
- Unit: KiB|MiB|GiB

14.8.2.14.10 `raft-max-inflight-msgs`

- The number of Raft logs to be confirmed. If this number is exceeded, the Raft state machine slows down log sending.
- Default value: `256`
- Minimum value: greater than `0`
- Maximum value: `16384`

14.8.2.14.11 `raft-entry-max-size`

- The hard limit on the maximum size of a single log
- Default value: `"8MiB"`
- Minimum value: `0`
- Unit: MiB|GiB

14.8.2.14.12 `raft-log-compact-sync-interval` New in v5.3

- The time interval to compact unnecessary Raft logs
- Default value: `"2s"`
- Minimum value: `"0s"`

14.8.2.14.13 `raft-log-gc-tick-interval`

- The time interval at which the polling task of deleting Raft logs is scheduled. `0` means that this feature is disabled.
- Default value: `"3s"`
- Minimum value: `"0s"`

14.8.2.14.14 `raft-log-gc-threshold`

- The soft limit on the maximum allowable count of residual Raft logs
- Default value: `50`
- Minimum value: `1`

14.8.2.14.15 `raft-log-gc-count-limit`

- The hard limit on the allowable number of residual Raft logs
- Default value: the log number that can be accommodated in the 3/4 Region size (calculated as 1MiB for each log)
- Minimum value: `0`

14.8.2.14.16 `raft-log-gc-size-limit`

- The hard limit on the allowable size of residual Raft logs
- Default value: 3/4 of the Region size
- Minimum value: greater than `0`

14.8.2.14.17 `raft-log-reserve-max-ticks` New in v5.3

- After the number of ticks set by this configuration item passes, even if the number of residual Raft logs does not reach the value set by `raft-log-gc-threshold`, TiKV still performs garbage collection (GC) to these logs.
- Default value: `6`
- Minimum value: greater than `0`

14.8.2.14.18 `raft-engine-purge-interval`

- The interval for purging old TiKV log files to recycle disk space as soon as possible. Raft engine is a replaceable component, so the purging process is needed for some implementations.
- Default value: `"10s"`

14.8.2.14.19 `raft-entry-cache-life-time`

- The maximum remaining time allowed for the log cache in memory
- Default value: `"30s"`
- Minimum value: `0`

14.8.2.14.20 `max-apply-unpersisted-log-limit` New in v8.1.0

- The maximum number of committed but not persisted Raft logs that can be applied.
    - Setting this configuration item to a value greater than `0` enables the TiKV node to apply committed but not persisted Raft logs in advance, effectively reducing long-tail latency caused by IO jitter on that node. However, it might also increase the memory usage of TiKV and the disk space occupied by Raft logs.
    - Setting this configuration item to `0` disables this feature, meaning that TiKV must wait until Raft logs are both committed and persisted before applying them. This behavior is consistent with the behavior before v8.2.0.
- Default value: `1024`
- Minimum value: `0`

14.8.2.14.21 `hibernate-regions`

- Enables or disables Hibernate Region. When this option is enabled, a Region idle for a long time is automatically set as hibernated. This reduces the extra overhead caused by heartbeat messages between the Raft leader and the followers for idle Regions. You can use `peer-stale-state-check-interval` to modify the heartbeat interval between the leader and the followers of hibernated Regions.
- Default value: `true` in v5.0.2 and later versions; `false` in versions before v5.0.2

14.8.2.14.22 `split-region-check-tick-interval`

- Specifies the interval at which to check whether the Region split is needed. `0` means that this feature is disabled.
- Default value: `"10s"`
- Minimum value: `0`

14.8.2.14.23 `region-split-check-diff`

- The maximum value by which the Region data is allowed to exceed before Region split
- Default value: 1/16 of the Region size.
- Minimum value: `0`

14.8.2.14.24 `region-compact-check-interval`

- The time interval at which to check whether it is necessary to manually trigger RocksDB compaction. `0` means that this feature is disabled.
- Default value: `"5m"`
- Minimum value: `0`

14.8.2.14.25 `region-compact-check-step`

- The number of Regions checked at one time for each round of manual compaction
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `100`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.
- Minimum value: `0`

14.8.2.14.26 `region-compact-min-tombstones`

- The number of tombstones required to trigger RocksDB compaction
- Default value: `10000`
- Minimum value: `0`

14.8.2.14.27 `region-compact-tombstones-percent`

- The proportion of tombstone required to trigger RocksDB compaction
- Default value: `30`
- Minimum value: `1`
- Maximum value: `100`

14.8.2.14.28 `region-compact-min-redundant-rows` New in v7.1.0

- The number of redundant MVCC rows required to trigger RocksDB compaction.
- Default value: `50000`
- Minimum value: `0`

14.8.2.14.29 `region-compact-redundant-rows-percent` New in v7.1.0

- The percentage of redundant MVCC rows required to trigger RocksDB compaction.
- Default value: `20`
- Minimum value: `1`
- Maximum value: `100`

14.8.2.14.30 `report-region-buckets-tick-interval` New in v6.1.0

> **Warning:**
>
> `report-region-buckets-tick-interval` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

- The interval at which TiKV reports bucket information to PD when `enable-region-bucket` is true.
- Default value: `10s`

14.8.2.14.31 `pd-heartbeat-tick-interval`

- The time interval at which a Region's heartbeat to PD is triggered. `0` means that this feature is disabled.
- Default value: `"1m"`
- Minimum value: `0`

14.8.2.14.32 `pd-store-heartbeat-tick-interval`

- The time interval at which a store's heartbeat to PD is triggered. `0` means that this feature is disabled.
- Default value: `"10s"`
- Minimum value: `0`

14.8.2.14.33 `pd-report-min-resolved-ts-interval` New in v7.6.0

> **Note:**
>
> This configuration item is renamed from `report-min-resolved-ts-interval`. Starting from v7.6.0, `report-min-resolved-ts-interval` is no longer effective.

- Specifies the minimum interval for TiKV to report Resolved TS to the PD leader. Setting it to `0` disables the reporting.
- Default value: `"1s"`, which is the minimum positive value. Before v6.3.0, the default value is `"0s"`.
- Minimum value: `0`
- Unit: second

14.8.2.14.34 `snap-mgr-gc-tick-interval`

- The time interval at which the recycle of expired snapshot files is triggered. `0` means that this feature is disabled.
- Default value: `"1m"`
- Minimum value: `0`

14.8.2.14.35 `snap-gc-timeout`

- The longest time for which a snapshot file is saved
- Default value: `"4h"`
- Minimum value: `0`

14.8.2.14.36 `snap-generator-pool-size` New in v5.4.0

- Configures the size of the `snap-generator` thread pool.
- To make Regions generate snapshot faster in TiKV in recovery scenarios, you need to increase the count of the `snap-generator` threads of the corresponding worker. You can use this configuration item to increase the size of the `snap-generator` thread pool.
- Default value: `2`
- Minimum value: `1`

14.8.2.14.37 `lock-cf-compact-interval`

- The time interval at which TiKV triggers a manual compaction for the Lock Column Family
- Default value: `"10m"`
- Minimum value: `0`

14.8.2.14.38 `lock-cf-compact-bytes-threshold`

- The size out of which TiKV triggers a manual compaction for the Lock Column Family
- Default value: `"256MiB"`
- Minimum value: `0`
- Unit: MiB

14.8.2.14.39 `notify-capacity`

- The longest length of the Region message queue.
- Default value: `40960`
- Minimum value: `0`

14.8.2.14.40 `messages-per-tick`

- The maximum number of messages processed per batch
- Default value: `4096`
- Minimum value: `0`

14.8.2.14.41 `max-peer-down-duration`

- The longest inactive duration allowed for a peer. A peer with timeout is marked as `down`, and PD tries to delete it later.
- Default value: `"10m"`
- Minimum value: When Hibernate Region is enabled, the minimum value is `peer-stale-state-check-interval * 2`; when Hibernate Region is disabled, the minimum value is `0`.

14.8.2.14.42 `max-leader-missing-duration`

- The longest duration allowed for a peer to be in the state where a Raft group is missing the leader. If this value is exceeded, the peer verifies with PD whether the peer has been deleted.
- Default value: `"2h"`
- Minimum value: greater than `abnormal-leader-missing-duration`

14.8.2.14.43 `abnormal-leader-missing-duration`

- The longest duration allowed for a peer to be in the state where a Raft group is missing the leader. If this value is exceeded, the peer is seen as abnormal and marked in metrics and logs.
- Default value: `"10m"`
- Minimum value: greater than `peer-stale-state-check-interval`

14.8.2.14.44 `peer-stale-state-check-interval`

- The time interval to trigger the check for whether a peer is in the state where a Raft group is missing the leader.
- Default value: `"5m"`
- Minimum value: greater than `2 * election-timeout`

14.8.2.14.45 `leader-transfer-max-log-lag`

- The maximum number of missing logs allowed for the transferee during a Raft leader transfer
- Default value: `128`
- Minimum value: `10`

14.8.2.14.46 `max-snapshot-file-raw-size` New in v6.1.0

- When the size of a snapshot file exceeds this configuration value, this file will be split into multiple files.
- Default value: `100MiB`
- Minimum value: `100MiB`

14.8.2.14.47 `snap-apply-batch-size`

- The memory cache size required when the imported snapshot file is written into the disk
- Default value: `"10MiB"`
- Minimum value: `0`
- Unit: MiB

14.8.2.14.48 `consistency-check-interval`

> **Warning:**
>
> It is **NOT** recommended to enable the consistency check in production environments, because it affects cluster performance and is incompatible with the garbage collection in TiDB.

- The time interval at which the consistency check is triggered. `0` means that this feature is disabled.
- Default value: `"0s"`
- Minimum value: `0`

14.8.2.14.49 raft-store-max-leader-lease

- The longest trusted period of a Raft leader
- Default value: "9s"
- Minimum value: 0

14.8.2.14.50 right-derive-when-split

- Specifies the start key of the new Region when a Region is split. When this configuration item is set to true, the start key is the maximum split key. When this configuration item is set to false, the start key is the original Region's start key.
- Default value: true

14.8.2.14.51 merge-max-log-gap

- The maximum number of missing logs allowed when merge is performed
- Default value: 10
- Minimum value: greater than raft-log-gc-count-limit

14.8.2.14.52 merge-check-tick-interval

- The time interval at which TiKV checks whether a Region needs merge
- Default value: "2s"
- Minimum value: greater than 0

14.8.2.14.53 use-delete-range

- Determines whether to delete data from the rocksdb delete_range interface
- Default value: false

14.8.2.14.54 cleanup-import-sst-interval

- The time interval at which the expired SST file is checked. 0 means that this feature is disabled.
- Default value: "10m"
- Minimum value: 0

14.8.2.14.55 local-read-batch-size

- The maximum number of read requests processed in one batch
- Default value: 1024
- Minimum value: greater than 0

14.8.2.14.56 `apply-yield-write-size` New in v6.4.0

- The maximum number of bytes that the Apply thread can write for one FSM (Finite-state Machine) in one round of poll. This is a soft limit.
- Default value: `"32KiB"`
- Minimum value: greater than `0`
- Unit: KiB|MiB|GiB

14.8.2.14.57 `apply-max-batch-size`

- Raft state machines process data write requests in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests in one batch.
- Default value: `256`
- Minimum value: greater than `0`
- Maximum value: `10240`

14.8.2.14.58 `apply-pool-size`

- The allowable number of threads in the pool that flushes data to the disk, which is the size of the Apply thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `2`
- Value ranges: `[1, CPU * 10]`. `CPU` means the number of your CPU cores.

14.8.2.14.59 `store-max-batch-size`

- Raft state machines process requests for flushing logs into the disk in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests in one batch.
- If `hibernate-regions` is enabled, the default value is `256`. If `hibernate-regions` is disabled, the default value is `1024`.
- Minimum value: greater than `0`
- Maximum value: `10240`

14.8.2.14.60 `store-pool-size`

- The allowable number of threads in the pool that processes Raft, which is the size of the Raftstore thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `2`
- Value ranges: `[1, CPU * 10]`. `CPU` means the number of your CPU cores.

14.8.2.14.61 `store-io-pool-size` New in v5.3.0

- The allowable number of threads that process Raft I/O tasks, which is the size of the StoreWriter thread pool. When you modify the size of this thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `1` (Before v8.0.0, the default value is `0`)
- Minimum value: `0`

14.8.2.14.62 `future-poll-size`

- The allowable number of threads that drive `future`
- Default value: `1`
- Minimum value: greater than `0`

14.8.2.14.63 `cmd-batch`

- Controls whether to enable batch processing of the requests. When it is enabled, the write performance is significantly improved.
- Default value: `true`

14.8.2.14.64 `inspect-interval`

- At a certain interval, TiKV inspects the latency of the Raftstore component. This parameter specifies the interval of the inspection. If the latency exceeds this value, this inspection is marked as timeout.
- Judges whether the TiKV node is slow based on the ratio of timeout inspection.
- Default value: `"100ms"`
- Minimum value: `"1ms"`

14.8.2.14.65 `raft-write-size-limit` New in v5.3.0

- Determines the threshold at which Raft data is written into the disk. If the data size is larger than the value of this configuration item, the data is written to the disk. When the value of `store-io-pool-size` is `0`, this configuration item does not take effect.
- Default value: `1MiB`
- Minimum value: `0`

14.8.2.14.66 `evict-cache-on-memory-ratio` New in v7.5.0

- When the memory usage of TiKV exceeds 90% of the system available memory, and the memory occupied by Raft entry cache exceeds the used memory * `evict-cache-on-memory-ratio`, TiKV evicts the Raft entry cache.
- If this value is set to `0`, it means that this feature is disabled.
- Default value: `0.1`
- Minimum value: `0`

14.8.2.14.67 `periodic-full-compact-start-times` New in v7.6.0

> **Warning:**
>
> Periodic full compaction is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Set the specific times that TiKV initiates periodic full compaction. You can specify multiple time schedules in an array. For example:
  - `periodic-full-compact-start-times = ["03:00", "23:00"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM, based on the local time zone of the TiKV node.
  - `periodic-full-compact-start-times = ["03:00 +0000", "23:00 +0000"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM in UTC timezone.
  - `periodic-full-compact-start-times = ["03:00 +0800", "23:00 +0800"]` indicates that TiKV performs full compaction daily at 03:00 AM and 11:00 PM in UTC+08:00 timezone.
- Default value: `[]`, which means periodic full compaction is disabled by default.

14.8.2.14.68 `periodic-full-compact-start-max-cpu` New in v7.6.0

- Limits the maximum CPU usage rate for TiKV periodic full compaction.
- Default value: `0.1`, which means that the maximum CPU usage for periodic compaction processes is 10%.

14.8.2.14.69 `follower-read-max-log-gap` New in v7.4.0

- The maximum number of logs a follower is allowed to lag behind when processing read requests. If this limit is exceeded, the read request is rejected.
- Default value: `100`

14.8.2.14.70 `inspect-cpu-util-thd` New in v7.6.0

- The CPU utilization threshold for determining whether a TiKV node is busy during slow node detection.
- Value range: `[0, 1]`
- Default value: `0.4`, which means `40%`.

14.8.2.14.71 `inspect-kvdb-interval` New in v8.1.2

- The interval and timeout for checking the KV disk during slow node detection in TiKV. If KVDB and RaftDB share the same mount path, this value is overridden by `0` (no detection).
- Default value: `2s`

14.8.2.14.72 `min-pending-apply-region-count` New in v8.0.0

- The maximum number of Regions in the busy state of applying Raft logs when TiKV starts. Raftstore accepts leader transfers only when the number of such Regions is below this value, reducing availability degradation during rolling restarts.
- Default value: `10`

14.8.2.14.73 `request-voter-replicated-index-interval` New in v6.6.0

- Controls the interval at which the Witness node periodically retrieves the replicated Raft log position from voter nodes.
- Default value: `5m`, which means 5 minutes.

14.8.2.14.74 `slow-trend-unsensitive-cause` New in v6.6.0

- When TiKV uses the SlowTrend detection algorithm, this configuration item controls the sensitivity of latency detection. A higher value indicates lower sensitivity.
- Default value: `10`

14.8.2.14.75 `slow-trend-unsensitive-result` New in v6.6.0

- When TiKV uses the SlowTrend detection algorithm, this configuration item controls the sensitivity of QPS detection. A higher value indicates lower sensitivity.
- Default value: `0.5`

14.8.2.15 coprocessor

Configuration items related to Coprocessor.

14.8.2.15.1 `split-region-on-table`

- Determines whether to split Region by table. It is recommended for you to use the feature only in TiDB mode.
- Default value: `false`

14.8.2.15.2 batch-split-limit

- The threshold of Region split in batches. Increasing this value speeds up Region split.
- Default value: 10
- Minimum value: 1

14.8.2.15.3 region-max-size

- The maximum size of a Region. When the value is exceeded, the Region splits into many.
- Default value: region-split-size / 2 * 3
- Unit: KiB|MiB|GiB

14.8.2.15.4 region-split-size

- The size of the newly split Region. This value is an estimate.
- Default value: "256MiB". Before v8.4.0, the default value is "96MiB".
- Unit: KiB|MiB|GiB

14.8.2.15.5 region-max-keys

- The maximum allowable number of keys in a Region. When this value is exceeded, the Region splits into many.
- Default value: region-split-keys / 2 * 3

14.8.2.15.6 region-split-keys

- The number of keys in the newly split Region. This value is an estimate.
- Default value: 2560000. Before v8.4.0, the default value is 960000.

14.8.2.15.7 consistency-check-method

- Specifies the method of data consistency check
- For the consistency check of MVCC data, set the value to "mvcc". For the consistency check of raw data, set the value to "raw".
- Default value: "mvcc"

14.8.2.16 coprocessor-v2

14.8.2.16.1 `coprocessor-plugin-directory`

- The path of the directory where compiled coprocessor plugins are located. Plugins in this directory are automatically loaded by TiKV.
- If this configuration item is not set, the coprocessor plugin is disabled.
- Default value: None

14.8.2.16.2 `enable-region-bucket` New in v6.1.0

- Determines whether to divide a Region into smaller ranges called buckets. The bucket is used as the unit of the concurrent query to improve the scan concurrency. For more about the design of the bucket, refer to Dynamic size Region.
- Default value: None, which means disabled by default.

> **Warning:**
>
> - `enable-region-bucket` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.
> - This configuration makes sense only when `region-split-size` is twice of `region-bucket-size` or above; otherwise, no bucket is actually generated.
> - Adjusting `region-split-size` to a larger value might have the risk of performance regression and slow scheduling.

14.8.2.16.3 `region-bucket-size` New in v6.1.0

- The size of a bucket when `enable-region-bucket` is true.
- Default value: Starting from v7.3.0, the default value is changed from `96MiB` to `50MiB`.

> **Warning:**
>
> `region-bucket-size` is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

14.8.2.17 rocksdb

Configuration items related to RocksDB

14.8.2.17.1 `max-background-jobs`

- The number of background threads in RocksDB. When you modify the size of the RocksDB thread pool, refer to Performance tuning for TiKV thread pools.
- Default value:
  - When the number of CPU cores is 10, the default value is `9`.
  - When the number of CPU cores is 8, the default value is `7`.
  - When the number of CPU cores is `N`, the default value is `max(2, min(N - 1, 9))`.
- Minimum value: `2`

14.8.2.17.2 `max-background-flushes`

- The maximum number of concurrent background memtable flush jobs
- Default value:
  - When the number of CPU cores is 10, the default value is `3`.
  - When the number of CPU cores is 8, the default value is `2`.
  - When the number of CPU cores is `N`, the default value is `[(max-background-jobs + 3)/ 4]`.
- Minimum value: `1`

14.8.2.17.3 `max-sub-compactions`

- The number of sub-compaction operations performed concurrently in RocksDB
- Default value: `3`
- Minimum value: `1`

14.8.2.17.4 `max-open-files`

- The total number of files that RocksDB can open
- Default value: `40960`
- Minimum value: `-1`

14.8.2.17.5 `max-manifest-file-size`

- The maximum size of a RocksDB Manifest file
- Default value: `"128MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.6 `create-if-missing`

- Determines whether to automatically create a DB switch
- Default value: `true`

14.8.2.17.7 `wal-recovery-mode`

- WAL recovery mode
- Optional values:
  - `"tolerate-corrupted-tail-records"`: tolerates and discards the records that have incomplete trailing data on all logs
  - `"absolute-consistency"`: abandons recovery when corrupted logs are found
  - `"point-in-time"`: recovers logs sequentially until the first corrupted log is encountered
  - `"skip-any-corrupted-records"`: post-disaster recovery. The data is recovered as much as possible, and corrupted records are skipped.
- Default value: `"point-in-time"`

14.8.2.17.8 `wal-dir`

- The directory in which WAL files are stored. If not specified, the WAL files will be stored in the same directory as the data.
- Default value: `""`

14.8.2.17.9 `wal-ttl-seconds`

- The living time of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- unit: second

14.8.2.17.10 `wal-size-limit`

- The size limit of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.11 `max-total-wal-size`

- The maximum RocksDB WAL size in total, which is the size of `*.log` files in the `data-dir`.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `"4GiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `1`.

14.8.2.17.12 `stats-dump-period`

- The interval at which statistics are output to the log.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `"10m"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `"0"`.

14.8.2.17.13 `compaction-readahead-size`

- Enables the readahead feature during RocksDB compaction and specifies the size of readahead data. If you are using mechanical disks, it is recommended to set the value to 2MiB at least.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.14 `writable-file-max-buffer-size`

- The maximum buffer size used in WritableFileWrite
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.15 `use-direct-io-for-flush-and-compaction`

- Determines whether to use `O_DIRECT` for both reads and writes in the background flush and compactions. The performance impact of this option: enabling `O_DIRECT` bypasses and prevents contamination of the OS buffer cache, but the subsequent file reads require re-reading the contents to the buffer cache.
- Default value: `false`

14.8.2.17.16 `rate-bytes-per-sec`

- When Titan is disabled, this configuration item limits the I/O rate of RocksDB compaction to reduce the impact of RocksDB compaction on the foreground read and write performance during traffic peaks. When Titan is enabled, this configuration item limits the summed I/O rates of RocksDB compaction and Titan GC. If you find that the I/O or CPU consumption of RocksDB compaction and Titan GC is too large, set this configuration item to an appropriate value according the disk I/O bandwidth and the actual write traffic.
- Default value: `10GiB`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.17 `rate-limiter-refill-period`

- Controls how often I/O tokens are refilled. A smaller value reduces I/O bursts but causes more CPU overhead.
- Default value: `"100ms"`

14.8.2.17.18 `rate-limiter-mode`

- RocksDB's compaction rate limiter mode
- Optional values: `"read-only"`, `"write-only"`, `"all-io"`
- Default value: `"write-only"`

14.8.2.17.19 `rate-limiter-auto-tuned` New in v5.0

- Determines whether to automatically optimize the configuration of the RocksDB's compaction rate limiter based on recent workload. When this configuration is enabled, compaction pending bytes will be slightly higher than usual.
- Default value: `true`

14.8.2.17.20 `enable-pipelined-write`

- Controls whether to enable Pipelined Write. When this configuration is enabled, the previous Pipelined Write is used. When this configuration is disabled, the new Pipelined Commit mechanism is used.
- Default value: `false`

14.8.2.17.21 `bytes-per-sync`

- The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.22 `wal-bytes-per-sync`

- The rate at which OS incrementally synchronizes WAL files to disk while the WAL files are being written
- Default value: `"512KiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.23 `info-log-max-size`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-size`.

- The maximum size of Info log
- Default value: `"1GiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.17.24 `info-log-roll-time`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated. TiKV no longer supports automatic log splitting based on time. Instead, you can use the configuration item `log.file.max-size` to set the threshold for automatic log splitting based on file size.

- The time interval at which Info logs are truncated. If the value is `0s`, logs are not truncated.
- Default value: `"0s"`

14.8.2.17.25 `info-log-keep-log-file-num`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-backups`.

- The maximum number of kept log files
- Default value: `10`
- Minimum value: `0`

14.8.2.17.26 `info-log-dir`

- The directory in which logs are stored
- Default value: `""`

14.8.2.17.27 `info-log-level`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.level`.

- Log levels of RocksDB
- Default value: `"info"`

14.8.2.17.28 `write-buffer-flush-oldest-first` New in v6.6.0

Warning:

This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the flush strategy used when the memory usage of `memtable` of the current RocksDB reaches the threshold.
- Default value: `false`
- Value options:
    - `false`: `memtable` with the largest data volume is flushed to SST files.
    - `true`: The earliest `memtable` is flushed to SST files. This strategy can clear the `memtable` of cold data, which is suitable for scenarios with obvious cold and hot data.

14.8.2.17.29 `write-buffer-limit` New in v6.6.0

Warning:

This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Specifies the total memory limit of `memtable` for all RocksDB instances in a single TiKV. `0` means no limit.
- Default value:
    - When `storage.engine="raft-kv"`, the default value is none, which means no limit.
    - When `storage.engine="partitioned-raft-kv"`, the default value is 20% of the size of total system memory.
- Unit: KiB|MiB|GiB

14.8.2.17.30 `track-and-verify-wals-in-manifest` New in v6.5.9, v7.1.5, v7.5.2, and v8.0.0

- Controls whether to record information about Write Ahead Log (WAL) files in the RocksDB MANIFEST file and whether to verify the integrity of WAL files during startup. For more information, see RocksDB Track WAL in MANIFEST.
- Default value: `true`
- Value options:
    - `true`: records information about WAL files in the MANIFEST file and verifies the integrity of WAL files during startup.
    - `false`: does not record information about WAL files in the MANIFEST file and does not verify the integrity of WAL files during startup.

14.8.2.17.31 `enable-multi-batch-write` New in v6.2.0

- Controls whether to enable RocksDB write optimization, allowing the contents of WriteBatch to be written concurrently to the memtable, reducing write latency.
- Default value: None. However, it is enabled by default unless explicitly set to `false` ↪ or if `rocksdb.enable-pipelined-write` or `rocksdb.enable-unordered-write` is enabled.

14.8.2.18 rocksdb.titan

Configuration items related to Titan.

14.8.2.18.1 `enabled`

Note:

- To enhance the performance of wide table and JSON data writing and point query, starting from TiDB v7.6.0, the default value changes from `false` to `true`, which means that Titan is enabled by default.
- Existing clusters upgraded to v7.6.0 or later versions retain the original configuration, which means that if Titan is not explicitly enabled, it still uses RocksDB.
- If the cluster has enabled Titan before upgrading to TiDB v7.6.0 or later versions, Titan will be retained after the upgrade, and the `min-blob-` ↪ `size` configuration before the upgrade will be retained. If you do not explicitly configure the value before the upgrade, the default value of the previous version `1KiB` will be retained to ensure the stability of the cluster configuration after the upgrade.

- Enables or disables Titan.
- Default value: `true`

14.8.2.18.2 `dirname`

- The directory in which the Titan Blob file is stored
- Default value: `"titandb"`

14.8.2.18.3 `disable-gc`

- Determines whether to disable Garbage Collection (GC) that Titan performs to Blob files
- Default value: `false`

14.8.2.18.4 `max-background-gc`

- The maximum number of GC threads in Titan. From the **TiKV Details** > **Thread CPU** > **RocksDB CPU** panel, if you observe that the Titan GC threads are at full capacity for a long time, consider increasing the size of the Titan GC thread pool.
- Default value: `1`. Before v8.0.0, the default value is `4`.
- Minimum value: `1`

14.8.2.19 rocksdb.defaultcf | rocksdb.writecf | rocksdb.lockcf | rocksdb.raftcf

Configuration items related to `rocksdb.defaultcf`, `rocksdb.writecf`, and `rocksdb.lockcf`.

14.8.2.19.1 `block-size`

- The default size of a RocksDB block
- Default value for `defaultcf` and `writecf`: `"32KiB"`
- Default value for `lockcf`: `"16KiB"`
- Minimum value: `"1KiB"`
- Unit: KiB|MiB|GiB

14.8.2.19.2 `block-cache-size`

> **Warning:**
>
> Starting from v6.6.0, this configuration is deprecated.

- The cache size of a RocksDB block.
- Default value for `defaultcf`: `Total machine memory * 25%`
- Default value for `writecf`: `Total machine memory * 15%`
- Default value for `lockcf`: `Total machine memory * 2%`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.19.3 `disable-block-cache`

- Enables or disables block cache
- Default value: `false`

14.8.2.19.4 `cache-index-and-filter-blocks`

- Enables or disables caching index and filter
- Default value: `true`

14.8.2.19.5 `pin-l0-filter-and-index-blocks`

- Determines whether to pin the index and filter blocks of the level 0 SST files in memory.
- Default value: `true`

14.8.2.19.6 `use-bloom-filter`

- Enables or disables bloom filter
- Default value: `true`

14.8.2.19.7 `optimize-filters-for-hits`

- Determines whether to optimize the hit ratio of filters
- Default value for `defaultcf`: `true`
- Default value for `writecf` and `lockcf`: `false`

14.8.2.19.8 `optimize-filters-for-memory` New in v7.2.0

- Determines whether to generate Bloom/Ribbon filters that minimize memory internal fragmentation.
- Note that this configuration item takes effect only when `format-version` >= 5.
- Default value: `false`

14.8.2.19.9 `whole-key-filtering`

- Determines whether to put the entire key to bloom filter
- Default value for `defaultcf` and `lockcf`: `true`
- Default value for `writecf`: `false`

14.8.2.19.10 `bloom-filter-bits-per-key`

- The length that bloom filter reserves for each key
- Default value: `10`
- Unit: byte

14.8.2.19.11 `block-based-bloom-filter`

- Determines whether each block creates a bloom filter
- Default value: `false`

14.8.2.19.12 `ribbon-filter-above-level` New in v7.2.0

- Determines whether to use Ribbon filters for levels greater than or equal to this value and use non-block-based bloom filters for levels less than this value. When this configuration item is set, `block-based-bloom-filter` will be ignored.
- Note that this configuration item takes effect only when `format-version` >= 5.
- Default value: None, which means disabled by default.

14.8.2.19.13 `read-amp-bytes-per-bit`

- Enables or disables statistics of read amplification.
- Optional values: `0` (disabled), > `0` (enabled).
- Default value: `0`
- Minimum value: `0`

14.8.2.19.14 `compression-per-level`

- The default compression algorithm for each level
- Default value for `defaultcf`: [“no”, “no”, “lz4”, “lz4”, “lz4”, “zstd”, “zstd”]
- Default value for `writecf`: [“no”, “no”, “lz4”, “lz4”, “lz4”, “zstd”, “zstd”]
- Default value for `lockcf`: [“no”, “no”, “no”, “no”, “no”, “no”, “no”]

14.8.2.19.15 `bottommost-level-compression`

- Sets the compression algorithm of the bottommost layer. This configuration item overrides the `compression-per-level` setting.
- Ever since data is written to LSM-tree, RocksDB does not directly adopt the last compression algorithm specified in the `compression-per-level` array for the bottommost layer. `bottommost-level-compression` enables the bottommost layer to use the compression algorithm of the best compression effect from the beginning.
- If you do not want to set the compression algorithm for the bottommost layer, set the value of this configuration item to `disable`.
- Default value: `"zstd"`

14.8.2.19.16 `write-buffer-size`

- Memtable size
- Default value for `defaultcf` and `writecf`: `"128MiB"`
- Default value for `lockcf`:
  - When `storage.engine="raft-kv"`, the default value is `"32MiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `"4MiB"`.
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.19.17 `max-write-buffer-number`

- The maximum number of memtables. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.memtables-threshold` overrides this configuration item.
- Default value: `5`
- Minimum value: `0`

14.8.2.19.18 `min-write-buffer-number-to-merge`

- The minimum number of memtables required to trigger flush
- Default value: `1`
- Minimum value: `0`

14.8.2.19.19 `max-bytes-for-level-base`

- The maximum number of bytes at base level (level-1). Generally, it is set to 4 times the size of a memtable. When the level-1 data size reaches the limit value of `max-bytes-for-level-base`, the SST files of level-1 and their overlapping SST files of level-2 will be compacted.

- Default value for `defaultcf` and `writecf`: `"512MiB"`
- Default value for `lockcf`: `"128MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB
- It is recommended that the value of `max-bytes-for-level-base` is set approximately equal to the data volume in L0 to reduce unnecessary compaction. For example, if the compression method is "no:no:lz4:lz4:lz4:lz4:lz4", the value of `max-bytes-for-level-base` should be `write-buffer-size * 4`, because there is no compression of L0 and L1 and the trigger condition of compaction for L0 is that the number of the SST files reaches 4 (the default value). When L0 and L1 both adopt compaction, you need to analyze RocksDB logs to understand the size of an SST file compressed from a memtable. For example, if the file size is 32 MiB, it is recommended to set the value of `max-bytes-for-level-base` to 128 MiB (`32 MiB * 4`).

14.8.2.19.20 `target-file-size-base`

- The size of the target file at base level. This value is overridden by `compaction-guard-max-output-file-size` when the `enable-compaction-guard` value is `true`.
- Default value: None, which means `"8MiB"` by default.
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.19.21 `level0-file-num-compaction-trigger`

- The maximum number of files at L0 that trigger compaction
- Default value for `defaultcf` and `writecf`: `4`
- Default value for `lockcf`: `1`
- Minimum value: `0`

14.8.2.19.22 `level0-slowdown-writes-trigger`

- The maximum number of files at L0 that trigger write stall. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.l0-files-threshold` overrides this configuration item.
- Default value: `20`
- Minimum value: `0`

14.8.2.19.23 `level0-stop-writes-trigger`

- The maximum number of files at L0 required to completely block write
- Default value: `36`
- Minimum value: `0`

14.8.2.19.24 `max-compaction-bytes`

- The maximum number of bytes written into disk per compaction
- Default value: `"2GiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.19.25 `compaction-pri`

- The priority type of compaction
- Optional values:
    - `"by-compensated-size"`: compact files in order of file size and large files are compacted with higher priority.
    - `"oldest-largest-seq-first"`: prioritize compaction on files with the oldest update time. Use this value **only** when updating hot keys in small ranges.
    - `"oldest-smallest-seq-first"`: prioritize compaction on files with ranges that are not compacted to the next level for a long time. If you randomly update hot keys across the key space, this value can slightly reduce write amplification.
    - `"min-overlapping-ratio"`: prioritize compaction on files with a high overlap ratio. When a file is small in different levels (the result of `the file size in the next level ÷ the file size in this level` is small), TiKV compacts this file first. In many cases, this value can effectively reduce write amplification.
- Default value for `defaultcf` and `writecf`: `"min-overlapping-ratio"`
- Default value for `lockcf`: `"by-compensated-size"`

14.8.2.19.26 `dynamic-level-bytes`

- Determines whether to optimize dynamic level bytes
- Default value: `true`

14.8.2.19.27 `num-levels`

- The maximum number of levels in a RocksDB file
- Default value: `7`

14.8.2.19.28 `max-bytes-for-level-multiplier`

- The default amplification multiple for each layer
- Default value: `10`

14.8.2.19.29 `compaction-style`

- Compaction method
- Optional values: `"level"`, `"universal"`, `"fifo"`
- Default value: `"level"`

14.8.2.19.30 `disable-auto-compactions`

- Determines whether to disable auto compaction.
- Default value: `false`

14.8.2.19.31 `soft-pending-compaction-bytes-limit`

- The soft limit on the pending compaction bytes. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.soft-pending-compaction-bytes-limit` overrides this configuration item.
- Default value: `"192GiB"`
- Unit: KiB|MiB|GiB

14.8.2.19.32 `hard-pending-compaction-bytes-limit`

- The hard limit on the pending compaction bytes. When `storage.flow-control.enable` is set to `true`, `storage.flow-control.hard-pending-compaction-bytes-limit` overrides this configuration item.
- Default value: `"256GiB"`
- Unit: KiB|MiB|GiB

14.8.2.19.33 `enable-compaction-guard`

- Enables or disables the compaction guard, which is an optimization to split SST files at TiKV Region boundaries. This optimization can help reduce compaction I/O and allows TiKV to use larger SST file size (thus less SST files overall) and at the time efficiently clean up stale data when migrating Regions.
- Default value for `defaultcf` and `writecf`: `true`
- Default value for `lockcf`: None, which means disabled by default.

14.8.2.19.34 `compaction-guard-min-output-file-size`

- The minimum SST file size when the compaction guard is enabled. This configuration prevents SST files from being too small when the compaction guard is enabled.
- Default value: `"8MiB"`
- Unit: KiB|MiB|GiB

14.8.2.19.35 `compaction-guard-max-output-file-size`

- The maximum SST file size when the compaction guard is enabled. The configuration prevents SST files from being too large when the compaction guard is enabled. This configuration overrides `target-file-size-base` for the same column family.
- Default value: `"128MiB"`
- Unit: KiB|MiB|GiB

14.8.2.19.36 `format-version` New in v6.2.0

- The format version of SST files. This configuration item only affects newly written tables. For existing tables, the version information is read from the footer.
- Optional values:
    - `0`: Can be read by all TiKV versions. The default checksum type is CRC32 and this version does not support changing the checksum type.
    - `1`: Can be read by all TiKV versions. Supports non-default checksum types like xxHash. RocksDB only writes data when the checksum type is not CRC32. (version `0` is automatically upgraded)
    - `2`: Can be read by all TiKV versions. Changes the encoding of compressed blocks using LZ4, BZip2 and Zlib compression.
    - `3`: Can be read by TiKV v2.1 and later versions. Changes the encoding of the keys in index blocks.
    - `4`: Can be read by TiKV v3.0 and later versions. Changes the encoding of the values in index blocks.
    - `5`: Can be read by TiKV v6.1 and later versions. Full and partitioned filters use a faster and more accurate Bloom filter implementation with a different schema.
- Default value:
    - When `storage.engine="raft-kv"`, the default value is `2`.
    - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.

14.8.2.19.37 `ttl` New in v7.2.0

- SST files with updates older than the TTL will be automatically selected for compaction. These SST files will go through the compaction in a cascading way so that they can be compacted to the bottommost level or file.
- Default value: None, meaning that no SST file is selected by default.
- Unit: s(second)|h(hour)|d(day)

14.8.2.19.38 `periodic-compaction-seconds` New in v7.2.0

- The time interval for periodic compaction. SST files with updates older than this value will be selected for compaction and rewritten to the same level where these SST files originally reside.
- Default value: None, meaning that periodic compaction is disabled by default.
- Unit: s(second)|h(hour)|d(day)

14.8.2.19.39 `max-compactions` New in v6.6.0

- The maximum number of concurrent compaction tasks. The value `0` means no limit.
- Default value: `0`

14.8.2.20 rocksdb.defaultcf.titan

> **Note:**
>
> Titan can only be enabled in `rocksdb.defaultcf`. It is not supported to enable Titan in `rocksdb.writecf`.

Configuration items related to `rocksdb.defaultcf.titan`.

14.8.2.20.1 `min-blob-size`

> **Note:**
>
> - Starting from TiDB v7.6.0, Titan is enabled by default to enhance the performance of wide table and JSON data writing and point query. The default value of `min-blob-size` changes from `1KiB` to `32KiB`. This means that values exceeding `32KiB` is stored in Titan, while other data continues to be stored in RocksDB.
> - To ensure configuration consistency, for existing clusters upgrading to TiDB v7.6.0 or later versions, if you do not explicitly set `min-blob-size` before the upgrade, TiDB retains the previous default value of `1KiB`.
> - A value smaller than `32KiB` might affect the performance of range scans. However, if the workload primarily involves heavy writes and point queries, you can consider decreasing the value of `min-blob-size` for better performance.

- The smallest value stored in a Blob file. Values smaller than the specified size are stored in the LSM-Tree.
- Default value: None, which means `"32KiB"` by default.
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.20.2 `blob-file-compression`

Note:

- Snappy compressed files must be in the official Snappy format. Other variants of Snappy compression are not supported.
- Starting from TiDB v7.6.0, the default value of `blob-file-compression` changes from `"lz4"` to `"zstd"`.

- The compression algorithm used in a Blob file
- Optional values: `"no"`, `"snappy"`, `"zlib"`, `"bzip2"`, `"lz4"`, `"lz4hc"`, `"zstd"`
- Default value: `"zstd"`

14.8.2.20.3 `zstd-dict-size`

- The zstd dictionary compression size. The default value is `"0KiB"`, which means to disable the zstd dictionary compression. In this case, Titan compresses data based on single values, whereas RocksDB compresses data based on blocks (`32KiB` by default). When the average size of Titan values is less than `32KiB`, Titan's compression ratio is lower than that of RocksDB. Taking JSON as an example, the store size in Titan can be 30% to 50% larger than that of RocksDB. The actual compression ratio depends on whether the value content is suitable for compression and the similarity among different values. You can enable the zstd dictionary compression to increase the compression ratio by configuring `zstd-dict-size` (for example, set it to `16KiB`). The actual store size can be lower than that of RocksDB. But the zstd dictionary compression might lead to about 10% performance regression in specific workloads.
- Default value: `"0KiB"`
- Unit: KiB|MiB|GiB

14.8.2.20.4 `blob-cache-size`

- The cache size of a Blob file
- Default value: `"0GiB"`
- Minimum value: `0`

- Recommended value: `0`. Starting from v8.0.0, TiKV introduces the `shared-blob-cache` configuration item and enables it by default, so there is no need to set `blob-cache-size` separately. The configuration of `blob-cache-size` only takes effect when `shared-blob-cache` is set to `false`.
- Unit: KiB|MiB|GiB

14.8.2.20.5 `shared-blob-cache` New in v8.0.0

- Controls whether to enable the shared cache for Titan blob files and RocksDB block files.
- Default value: `true`. When the shared cache is enabled, block files have higher priority. This means that TiKV prioritizes meeting the cache needs of block files and then uses the remaining cache for blob files.

14.8.2.20.6 `min-gc-batch-size`

- The minimum total size of Blob files required to perform GC for one time
- Default value: `"16MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.20.7 `max-gc-batch-size`

- The maximum total size of Blob files allowed to perform GC for one time
- Default value: `"64MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.20.8 `discardable-ratio`

- When the ratio of obsolete data (the corresponding key has been updated or deleted) in a Blob file exceeds the following threshold, Titan GC is triggered. When Titan writes the valid data of this Blob file to another file, you can use the `discardable-ratio` value to estimate the upper limits of write amplification and space amplification (assuming the compression is disabled).

  Upper limit of write amplification = 1 / `discardable-ratio`

  Upper limit of space amplification = 1 / (1 - `discardable-ratio`)

  From these two equations, you can see that decreasing the value of `discardable_ratio` can reduce space amplification but results in more frequent GC in Titan. Increasing the value reduces the frequency of Titan GC, thereby lowering the corresponding I/O bandwidth and CPU usage, but increases disk usage.

- Default value: `0.5`
- Minimum value: `0`
- Maximum value: `1`

14.8.2.20.9 `sample-ratio`

- The ratio of (data read from a Blob file/the entire Blob file) when sampling the file during GC
- Default value: `0.1`
- Minimum value: `0`
- Maximum value: `1`

14.8.2.20.10 `merge-small-file-threshold`

- When the size of a Blob file is smaller than this value, the Blob file might still be selected for GC. In this situation, `discardable-ratio` is ignored.
- Default value: `"8MiB"`
- Minimum value: `0`
- Unit: KiB|MiB|GiB

14.8.2.20.11 `blob-run-mode`

- Specifies the running mode of Titan.
- Optional values:
  - `normal`: Writes data to the blob file when the value size exceeds `min-blob-size`.
  - `read-only`: Refuses to write new data to the blob file, but still reads the original data from the blob file.
  - `fallback`: Writes data in the blob file back to LSM.
- Default value: `normal`

14.8.2.20.12 `level-merge`

- Determines whether to optimize the read performance. When `level-merge` is enabled, there is more write amplification.
- Default value: `false`

14.8.2.21 raftdb

Configuration items related to `raftdb`

14.8.2.21.1 `max-background-jobs`

- The number of background threads in RocksDB. When you modify the size of the RocksDB thread pool, refer to Performance tuning for TiKV thread pools.
- Default value: `4`
- Minimum value: `2`

14.8.2.21.2 `max-sub-compactions`

- The number of concurrent sub-compaction operations performed in RocksDB
- Default value: `2`
- Minimum value: `1`

14.8.2.21.3 `max-open-files`

- The total number of files that RocksDB can open
- Default value: `40960`
- Minimum value: `-1`

14.8.2.21.4 `max-manifest-file-size`

- The maximum size of a RocksDB Manifest file
- Default value: `"20MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.5 `create-if-missing`

- If the value is `true`, the database will be created if it is missing
- Default value: `true`

14.8.2.21.6 `stats-dump-period`

- The interval at which statistics are output to the log
- Default value: `10m`

14.8.2.21.7 `wal-dir`

- The directory in which Raft RocksDB WAL files are stored, which is the absolute directory path for WAL. **Do not** set this configuration item to the same value as `rocksdb.wal-dir`.
- If this configuration item is not set, the log files are stored in the same directory as data.
- If there are two disks on the machine, storing RocksDB data and WAL logs on different disks can improve performance.
- Default value: `""`

14.8.2.21.8 `wal-ttl-seconds`

- Specifies how long the archived WAL files are retained. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: second

14.8.2.21.9 `wal-size-limit`

- The size limit of the archived WAL files. When the value is exceeded, the system deletes these files.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.10 `max-total-wal-size`

- The maximum RocksDB WAL size in total
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `"4GiB"`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `1`.

14.8.2.21.11 `compaction-readahead-size`

- Controls whether to enable the readahead feature during RocksDB compaction and specify the size of readahead data.
- If you use mechanical disks, it is recommended to set the value to `2MiB` at least.
- Default value: `0`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.12 `writable-file-max-buffer-size`

- The maximum buffer size used in WritableFileWrite
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.13 `use-direct-io-for-flush-and-compaction`

- Determines whether to use `O_DIRECT` for both reads and writes in the background flush and compactions. The performance impact of this option: enabling `O_DIRECT` bypasses and prevents contamination of the OS buffer cache, but the subsequent file reads require re-reading the contents to the buffer cache.
- Default value: `false`

14.8.2.21.14 `enable-pipelined-write`

- Controls whether to enable Pipelined Write. When this configuration is enabled, the previous Pipelined Write is used. When this configuration is disabled, the new Pipelined Commit mechanism is used.
- Default value: `true`

14.8.2.21.15 `allow-concurrent-memtable-write`

- Controls whether to enable concurrent memtable write.
- Default value: `true`

14.8.2.21.16 `bytes-per-sync`

- The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously
- Default value: `"1MiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.17 `wal-bytes-per-sync`

- The rate at which OS incrementally synchronizes WAL files to disk when the WAL files are being written
- Default value: `"512KiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.18 `info-log-max-size`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-size`.

- The maximum size of Info logs
- Default value: `"1GiB"`
- Minimum value: `0`
- Unit: B|KiB|MiB|GiB

14.8.2.21.19 `info-log-roll-time`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated. TiKV no longer supports automatic log splitting based on time. Instead, you can use the configuration item `log.file.max-size` to set the threshold for automatic log splitting based on file size.

- The interval at which Info logs are truncated. If the value is `0s`, logs are not truncated.
- Default value: `"0s"` (which means logs are not truncated)

14.8.2.21.20 `info-log-keep-log-file-num`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.file.max-backups`.

- The maximum number of Info log files kept in RaftDB
- Default value: `10`
- Minimum value: `0`

14.8.2.21.21 `info-log-dir`

- The directory in which Info logs are stored
- Default value: `""`

14.8.2.21.22 `info-log-level`

> **Warning:**
>
> Starting from v5.4.0, RocksDB logs are managed by the logging module of TiKV. Therefore, this configuration item is deprecated, and its function is replaced by the configuration item `log.level`.

- Log levels of RaftDB
- Default value: `"info"`

14.8.2.22 raft-engine

Configuration items related to Raft Engine.

> **Note:**
>
> - When you enable Raft Engine for the first time, TiKV transfers its data from RocksDB to Raft Engine. Therefore, you need to wait extra tens of seconds for TiKV to start.
> - The data format of Raft Engine in TiDB v5.4.0 is not compatible with earlier TiDB versions. Therefore, if you need to downgrade a TiDB cluster from v5.4.0 to an earlier version, **before** downgrading, disable Raft Engine by setting `enable` to `false` and restart TiKV for the configuration to take effect.

14.8.2.22.1 `enable`

- Determines whether to use Raft Engine to store Raft logs. When it is enabled, configurations of `raftdb` are ignored.
- Default value: `true`

14.8.2.22.2 `dir`

- The directory at which raft log files are stored. If the directory does not exist, it will be created when TiKV is started.
- If this configuration item is not set, `{data-dir}/raft-engine` is used.
- If there are multiple disks on your machine, it is recommended to store the data of Raft Engine on a different disk to improve TiKV performance.
- Default value: `""`

14.8.2.22.3 `spill-dir` New in v8.4.0

- The auxiliary directory for storing Raft log files. When the disk for the `dir` directory is full, new Raft logs will be stored under this directory. If this auxiliary directory does not exist after configuration, it will be automatically created when TiKV is started.
- If this configuration is not set, the auxiliary directory is not enabled.

Note:

- This configuration takes effect only when the `dir` and `spill-dir` of the Raft Engine are set to different disk drives.
- After enabling this feature, if you want to disable it, you need to perform the following operations before restarting TiKV. Otherwise, TiKV will fail to start.
  1. Stop TiKV.
  2. Copy all the Raft Logs from the `spill-dir` directory to the `dir` directory.
  3. Remove this configuration from the TiKV configuration file.
  4. Restart TiKV.

14.8.2.22.4 `batch-compression-threshold`

- Specifies the threshold size of a log batch. A log batch larger than this configuration is compressed. If you set this configuration item to `0`, compression is disabled.
- Default value: `"8KiB"`

14.8.2.22.5 `bytes-per-sync`

Warning:

Starting from v6.5.0, Raft Engine writes logs to disk directly without buffering. Therefore, this configuration item is deprecated and no longer functional.

- Specifies the maximum accumulative size of buffered writes. When this configuration value is exceeded, buffered writes are flushed to the disk.
- If you set this configuration item to `0`, incremental sync is disabled.
- Before v6.5.0, the default value is `"4MiB"`.

14.8.2.22.6 `target-file-size`

- Specifies the maximum size of log files. When a log file is larger than this value, it is rotated.
- Default value: `"128MiB"`

14.8.2.22.7 `purge-threshold`

- Specifies the threshold size of the main log queue. When this configuration value is exceeded, the main log queue is purged.
- This configuration can be used to adjust the disk space usage of Raft Engine.
- Default value: `"10GiB"`

14.8.2.22.8 `recovery-mode`

- Determines how to deal with file corruption during recovery.
- Value options: `"absolute-consistency"`, `"tolerate-tail-corruption"`, `"tolerate-any-corruption"`
- Default value: `"tolerate-tail-corruption"`

14.8.2.22.9 `recovery-read-block-size`

- The minimum I/O size for reading log files during recovery.
- Default value: `"16KiB"`
- Minimum value: `"512B"`

14.8.2.22.10 `recovery-threads`

- The number of threads used to scan and recover log files.
- Default value: `4`
- Minimum value: `1`

14.8.2.22.11 `memory-limit`

- Specifies the limit on the memory usage of Raft Engine.
- When this configuration value is not set, 15% of the available system memory is used.
- Default value: `Total machine memory * 15%`

14.8.2.22.12 `format-version` New in v6.3.0

> **Note:**
>
> After `format-version` is set to `2`, if you need to downgrade a TiKV cluster from v6.3.0 to an earlier version, take the following steps **before** the downgrade:
>
> 1. Disable Raft Engine by setting `enable` to `false` and restart TiKV to make the configuration take effect.
> 2. Set `format-version` to `1`.
> 3. Enable Raft Engine by setting `enable` to `true` and restart TiKV to make the configuration take effect.

- Specifies the version of log files in Raft Engine.
- Value options:
  - `1`: Default log file version for TiKV earlier than v6.3.0. Can be read by TiKV >= v6.1.0.
  - `2`: Supports log recycling. Can be read by TiKV >= v6.3.0.
- Default value:
  - When `storage.engine="raft-kv"`, the default value is `2`.
  - When `storage.engine="partitioned-raft-kv"`, the default value is `5`.

14.8.2.22.13 `enable-log-recycle` New in v6.3.0

> **Note:**
>
> This configuration item is only available when `format-version` >= 2.

- Determines whether to recycle stale log files in Raft Engine. When it is enabled, logically purged log files will be reserved for recycling. This reduces the long tail latency on write workloads.
- Default value: `true`

14.8.2.22.14 `prefill-for-recycle` New in v7.0.0

> **Note:**
>
> This configuration item only takes effect when `enable-log-recycle` is set to `true`.

- Determines whether to generate empty log files for log recycling in Raft Engine. When it is enabled, Raft Engine will automatically fill a batch of empty log files for log recycling during initialization, making log recycling effective immediately after initialization.
- Default value: `false`

14.8.2.22.15 `compression-level` New in v7.4.0

- Sets the compression efficiency of the LZ4 algorithm used by Raft Engine when writing Raft log files. A lower value indicates faster compression speed but lower compression ratio.
- Range: `[1, 16]`
- Default value: `1`

14.8.2.23 security

Configuration items related to security.

14.8.2.23.1 `ca-path`

- The path of the CA file
- Default value: `""`

14.8.2.23.2 `cert-path`

- The path of the Privacy Enhanced Mail (PEM) file that contains the X.509 certificate
- Default value: `""`

14.8.2.23.3 `key-path`

- The path of the PEM file that contains the X.509 key
- Default value: `""`

14.8.2.23.4 `cert-allowed-cn`

- A list of acceptable X.509 Common Names in certificates presented by clients. Requests are permitted only when the presented Common Name is an exact match with one of the entries in the list.
- Default value: `[]`. This means that the client certificate CN check is disabled by default.

14.8.2.23.5 `redact-info-log` New in v4.0.8

- This configuration item enables or disables log redaction. Value options: `true`, `false`, `"on"`, `"off"`, and `"marker"`. The `"on"`, `"off"`, and `"marker"` options are introduced in v8.3.0.
- If the configuration item is set to `false` or `"off"`, log redaction is disabled.
- If the configuration item is set to `true` or `"on"`, all user data in the log is replaced by `?`.
- If the configuration item is set to `"marker"`, all user data in the log is wrapped in `‹ ›`. If user data contains `‹` or `›`, `‹` is escaped as `‹‹`, and `›` is escaped as `››`. Based on the marked logs, you can decide whether to desensitize the marked information when the logs are displayed.
- Default value: `false`
- For details on how to use it, see Log redaction in TiKV side.

14.8.2.24 security.encryption

Configuration items related to encryption at rest (TDE).

14.8.2.24.1 `data-encryption-method`

- The encryption method for data files
- Value options: “plaintext”, “aes128-ctr”, “aes192-ctr”, “aes256-ctr”, and “sm4-ctr” (supported since v6.3.0)
- A value other than “plaintext” means that encryption is enabled, in which case the master key must be specified.
- Default value: `"plaintext"`

14.8.2.24.2 `data-key-rotation-period`

- Specifies how often TiKV rotates the data encryption key.
- Default value: `7d`

14.8.2.24.3 `enable-file-dictionary-log`

- Enables the optimization to reduce I/O and mutex contention when TiKV manages the encryption metadata.
- To avoid possible compatibility issues when this configuration parameter is enabled (by default), see Encryption at Rest - Compatibility between TiKV versions for details.
- Default value: `true`

14.8.2.24.4 `master-key`

- Specifies the master key if encryption is enabled. To learn how to configure a master key, see Encryption at Rest - Configure encryption.

14.8.2.24.5 `previous-master-key`

- Specifies the old master key when rotating the new master key. The configuration format is the same as that of `master-key`. To learn how to configure a master key, see Encryption at Rest - Configure encryption.

14.8.2.25 import

Configuration items related to TiDB Lightning import and BR restore.

14.8.2.25.1 `num-threads`

- The number of threads to process RPC requests
- Default value: `8`
- Minimum value: `1`

14.8.2.25.2 `stream-channel-window`

- The window size of Stream channel. When the channel is full, the stream is blocked.
- Default value: `128`

14.8.2.25.3 `memory-use-ratio` New in v6.5.0

- Starting from v6.5.0, PITR supports directly accessing backup log files in memory and restoring data. This configuration item specifies the ratio of memory available for PITR to the total memory of TiKV.
- Value range: [0.0, 0.5]

- Default value: `0.3`, which means that 30% of the system memory is available for PITR. When the value is `0.0`, PITR is performed through downloading log files to a local directory.

> **Note:**
>
> In versions earlier than v6.5.0, point-in-time recovery (PITR) only supports restoring data by downloading backup files to a local directory.

14.8.2.26 gc

14.8.2.26.1 `batch-keys`

- The number of keys to be garbage-collected in one batch
- Default value: `512`

14.8.2.26.2 `max-write-bytes-per-sec`

- The maximum bytes that GC worker can write to RocksDB in one second.
- If the value is set to `0`, there is no limit.
- Default value: `"0"`

14.8.2.26.3 `enable-compaction-filter` New in v5.0

- Controls whether to enable the GC in Compaction Filter feature
- Default value: `true`

14.8.2.26.4 `ratio-threshold`

- The garbage ratio threshold to trigger GC.
- Default value: `1.1`

14.8.2.26.5 `num-threads` New in v6.5.8, v7.1.4, v7.5.1, and v7.6.0

- The number of GC threads when `enable-compaction-filter` is `false`.
- Default value: `1`

14.8.2.27 backup

Configuration items related to BR backup.

14.8.2.27.1 num-threads

- The number of worker threads to process backup
- Default value: `MIN(CPU * 0.5, 8)`
- Value range: `[1, CPU]`
- Minimum value: `1`

14.8.2.27.2 batch-size

- The number of data ranges to back up in one batch
- Default value: `8`

14.8.2.27.3 sst-max-size

- The threshold of the backup SST file size. If the size of a backup file in a TiKV Region exceeds this threshold, the file is backed up to several files with the TiKV Region split into multiple Region ranges. Each of the files in the split Regions is the same size as `sst-max-size` (or slightly larger).
- For example, when the size of a backup file in the Region of `[a,e)` is larger than `sst-max-size`, the file is backed up to several files with regions `[a,b)`, `[b,c)`, `[c,d)` and `[d,e)`, and the size of `[a,b)`, `[b,c)`, `[c,d)` is the same as that of `sst-max-size` (or slightly larger).
- Default value: `"384MiB"`. Before v8.4.0, the default value is `"144MiB"`.

14.8.2.27.4 enable-auto-tune New in v5.4.0

- Controls whether to limit the resources used by backup tasks to reduce the impact on the cluster when the cluster resource utilization is high. For more information, refer to BR Auto-Tune.
- Default value: `true`

14.8.2.27.5 s3-multi-part-size New in v5.3.2

> **Note:**
>
> This configuration is introduced to address backup failures caused by S3 rate limiting. This problem has been fixed by refining the backup data storage structure. Therefore, this configuration is deprecated from v6.1.1 and is no longer recommended.

- The part size used when you perform multipart upload to S3 during backup. You can adjust the value of this configuration to control the number of requests sent to S3.
- If data is backed up to S3 and the backup file is larger than the value of this configuration item, multipart upload is automatically enabled. Based on the compression ratio, the backup file generated by a 96-MiB Region is approximately 10 MiB to 30 MiB.
- Default value: 5MiB

14.8.2.28 backup.hadoop

14.8.2.28.1 `home`

- Specifies the location of the HDFS shell command and allows TiKV to find the shell command. This configuration item has the same effect as the environment variable `$HADOOP_HOME`.
- Default value: `""`

14.8.2.28.2 `linux-user`

- Specifies the Linux user with which TiKV runs HDFS shell commands.
- If this configuration item is not set, TiKV uses the current linux user.
- Default value: `""`

14.8.2.29 log-backup

Configuration items related to log backup.

14.8.2.29.1 `enable` New in v6.2.0

- Determines whether to enable log backup.
- Default value: `true`

14.8.2.29.2 `file-size-limit` New in v6.2.0

- The size limit on backup log data to be stored.
- Default value: 256MiB
- Note: Generally, the value of `file-size-limit` is greater than the backup file size displayed in external storage. This is because the backup files are compressed before being uploaded to external storage.

14.8.2.29.3 `initial-scan-pending-memory-quota` New in v6.2.0

- The quota of cache used for storing incremental scan data during log backup.
- Default value: `min(Total machine memory * 10%, 512 MiB)`

14.8.2.29.4 `initial-scan-rate-limit` New in v6.2.0

- The rate limit on throughput in an incremental data scan during log backup, which means the maximum amount of data that can be read from the disk per second. Note that if you only specify a number (for example, `60`), the unit is Byte instead of KiB.
- Default value: 60MiB
- Minimum value: 1MiB

14.8.2.29.5 `max-flush-interval` New in v6.2.0

- The maximum interval for writing backup data to external storage in log backup.
- Default value: 3min

14.8.2.29.6 `num-threads` New in v6.2.0

- The number of threads used in log backup.
- Default value: CPU * 0.5
- Value range: [2, 12]

14.8.2.29.7 `temp-path` New in v6.2.0

- The temporary path to which log files are written before being flushed to external storage.
- Default value: `${deploy-dir}/data/log-backup-temp`

14.8.2.30 cdc

Configuration items related to TiCDC.

14.8.2.30.1 `min-ts-interval`

- The interval at which Resolved TS is calculated and forwarded.
- Default value: `"1s"`.

> **Note:**
>
> In v6.5.0, the default value of `min-ts-interval` is changed from `"1s"` to `"200ms"` to reduce CDC latency. Starting from v6.5.1, this default value is changed back to `"1s"` to reduce network traffic.

14.8.2.30.2 `old-value-cache-memory-quota`

- The upper limit of memory usage by TiCDC old values.
- Default value: `512MiB`

14.8.2.30.3 `sink-memory-quota`

- The upper limit of memory usage by TiCDC data change events.
- Default value: `512MiB`

14.8.2.30.4 `incremental-scan-speed-limit`

- The maximum speed at which historical data is incrementally scanned.
- Default value: `"128MiB"`, which means 128 MiB per second.

14.8.2.30.5 `incremental-scan-threads`

- The number of threads for the task of incrementally scanning historical data.
- Default value: `4`, which means 4 threads.

14.8.2.30.6 `incremental-scan-concurrency`

- The maximum number of concurrent executions for the tasks of incrementally scanning historical data.
- Default value: `6`, which means 6 tasks can be concurrent executed at most.
- Note: The value of `incremental-scan-concurrency` must be greater than or equal to that of `incremental-scan-threads`; otherwise, TiKV will report an error at startup.

14.8.2.30.7 `incremental-scan-concurrency-limit` New in v7.6.0

- The maximum queue length for the tasks of incrementally scanning historical data waiting to be executed. When the number of tasks waiting to be executed exceeds this limit, new tasks will be rejected.
- Default value: `10000`, which means that at most 10000 tasks can be queued for execution.
- Note: `incremental-scan-concurrency-limit` must be greater than or equal to `incremental-scan-concurrency`; otherwise, TiKV uses `incremental-scan-concurrency` to override this configuration.

14.8.2.31 resolved-ts

Configuration items related to maintaining the Resolved TS to serve Stale Read requests.

14.8.2.31.1 `enable`

- Determines whether to maintain the Resolved TS for all Regions.
- Default value: `true`

14.8.2.31.2 `advance-ts-interval`

- The interval at which Resolved TS is calculated and forwarded.
- Default value: `"20s"`

14.8.2.31.3 `scan-lock-pool-size`

- The number of threads that TiKV uses to scan the MVCC (multi-version concurrency control) lock data when initializing the Resolved TS.
- Default value: `2`, which means 2 threads.

14.8.2.32 pessimistic-txn

For pessimistic transaction usage, refer to TiDB Pessimistic Transaction Mode.

14.8.2.32.1 `wait-for-lock-timeout`

- The longest time that a pessimistic transaction in TiKV waits for other transactions to release the lock. If the time is out, an error is returned to TiDB, and TiDB retries to add a lock. The lock wait timeout is set by `innodb_lock_wait_timeout`.
- Default value: `"1s"`
- Minimum value: `"1ms"`

14.8.2.32.2 `wake-up-delay-duration`

- When pessimistic transactions release the lock, among all the transactions waiting for lock, only the transaction with the smallest `start_ts` is woken up. Other transactions will be woken up after `wake-up-delay-duration`.
- Default value: `"20ms"`

14.8.2.32.3 `pipelined`

- This configuration item enables the pipelined process of adding the pessimistic lock. With this feature enabled, after detecting that data can be locked, TiKV immediately notifies TiDB to execute the subsequent requests and write the pessimistic lock asynchronously, which reduces most of the latency and significantly improves the performance of pessimistic transactions. But there is a still low probability that the asynchronous write of the pessimistic lock fails, which might cause the failure of pessimistic transaction commits.
- Default value: `true`

14.8.2.32.4 `in-memory` New in v6.0.0

- Enables the in-memory pessimistic lock feature. With this feature enabled, pessimistic transactions try to store their locks in memory, instead of writing the locks to disk or replicating the locks to other replicas. This improves the performance of pessimistic transactions. However, there is a still low probability that the pessimistic lock gets lost and causes the pessimistic transaction commits to fail.
- Default value: `true`
- Note that `in-memory` takes effect only when the value of `pipelined` is `true`.

14.8.2.32.5 `in-memory-peer-size-limit` New in v8.4.0

- Controls the memory usage limit for in-memory pessimistic locks in a Region. When this limit is exceeded, TiKV writes pessimistic locks persistently.
- Default value: `512KiB`
- Unit: KiB|MiB|GiB

14.8.2.32.6 `in-memory-instance-size-limit` New in v8.4.0

- Controls the memory usage limit for in-memory pessimistic locks in a TiKV instance. When this limit is exceeded, TiKV writes pessimistic locks persistently.
- Default value: `100MiB`
- Unit: KiB|MiB|GiB

14.8.2.33 quota

Configuration items related to Quota Limiter.

14.8.2.33.1 `max-delay-duration` New in v6.0.0

- The maximum time that a single read or write request is forced to wait before it is processed in the foreground.
- Default value: `500ms`
- Recommended setting: It is recommended to use the default value in most cases. If out of memory (OOM) or violent performance jitter occurs in the instance, you can set the value to 1S to make the request waiting time shorter than 1 second.

14.8.2.33.2 Foreground Quota Limiter

Configuration items related to foreground Quota Limiter.

Suppose that your machine on which TiKV is deployed has limited resources, for example, with only 4v CPU and 16 G memory. In this situation, the foreground of TiKV might process too many read and write requests so that the CPU resources used by the background are

occupied to help process such requests, which affects the performance stability of TiKV. To avoid this situation, you can use the foreground quota-related configuration items to limit the CPU resources to be used by the foreground. When a request triggers Quota Limiter, the request is forced to wait for a while for TiKV to free up CPU resources. The exact waiting time depends on the number of requests, and the maximum waiting time is no longer than the value of `max-delay-duration`.

`foreground-cpu-time` New in v6.0.0

- The soft limit on the CPU resources used by TiKV foreground to process read and write requests.
- Default value: `0` (which means no limit)
- Unit: millicpu (for example, `1500` means that the foreground requests consume 1.5v CPU)
- Recommended setting: For the instance with more than 4 cores, use the default value `0`. For the instance with 4 cores, setting the value to the range of `1000` and `1500` can make a balance. For the instance with 2 cores, keep the value smaller than `1200`.

`foreground-write-bandwidth` New in v6.0.0

- The soft limit on the bandwidth with which transactions write data.
- Default value: `0KiB` (which means no limit)
- Recommended setting: Use the default value `0` in most cases unless the `foreground-cpu-time` setting is not enough to limit the write bandwidth. For such an exception, it is recommended to set the value smaller than `50MiB` in the instance with 4 or less cores.

`foreground-read-bandwidth` New in v6.0.0

- The soft limit on the bandwidth with which transactions and the Coprocessor read data.
- Default value: `0KiB` (which means no limit)
- Recommended setting: Use the default value `0` in most cases unless the `foreground-cpu-time` setting is not enough to limit the read bandwidth. For such an exception, it is recommended to set the value smaller than `20MiB` in the instance with 4 or less cores.

14.8.2.33.3 Background Quota Limiter

Configuration items related to background Quota Limiter.

Suppose that your machine on which TiKV is deployed has limited resources, for example, with only 4v CPU and 16 G memory. In this situation, the background of TiKV might process too many calculations and read and write requests, so that the CPU resources used by the foreground are occupied to help process such requests, which affects the performance stability

of TiKV. To avoid this situation, you can use the background quota-related configuration items to limit the CPU resources to be used by the background. When a request triggers Quota Limiter, the request is forced to wait for a while for TiKV to free up CPU resources. The exact waiting time depends on the number of requests, and the maximum waiting time is no longer than the value of `max-delay-duration`.

> **Warning:**
>
> - Background Quota Limiter is an experimental feature introduced in TiDB v6.2.0, and it is **NOT** recommended to use it in the production environment.
> - This feature is only suitable for environments with limited resources to ensure that TiKV can run stably in those environments. If you enable this feature in an environment with rich resources, performance degradation might occur when the amount of requests reaches a peak.

`background-cpu-time` New in v6.2.0

- The soft limit on the CPU resources used by TiKV background to process read and write requests.
- Default value: `0` (which means no limit)
- Unit: millicpu (for example, `1500` means that the background requests consume 1.5v CPU)

`background-write-bandwidth` New in v6.2.0

- The soft limit on the bandwidth with which background transactions write data.
- Default value: `0KiB` (which means no limit)

`background-read-bandwidth` New in v6.2.0

- The soft limit on the bandwidth with which background transactions and the Coprocessor read data.
- Default value: `0KiB` (which means no limit)

`enable-auto-tune` New in v6.2.0

- Determines whether to enable the auto-tuning of quota. If this configuration item is enabled, TiKV dynamically adjusts the quota for the background requests based on the load of TiKV instances.
- Default value: `false` (which means that the auto-tuning is disabled)

14.8.2.34 causal-ts New in v6.1.0

Configuration items related to getting the timestamp when TiKV API V2 is enabled (`storage.api-version = 2`).

To reduce write latency, TiKV periodically fetches and caches a batch of timestamps locally. Cached timestamps help avoid frequent access to PD and allow short-term TSO service failure.

14.8.2.34.1 `alloc-ahead-buffer` New in v6.4.0

- The pre-allocated TSO cache size (in duration).
- Indicates that TiKV pre-allocates the TSO cache based on the duration specified by this configuration item. TiKV estimates the TSO usage based on the previous period, and requests and caches TSOs satisfying `alloc-ahead-buffer` locally.
- This configuration item is often used to increase the tolerance of PD failures when TiKV API V2 is enabled (`storage.api-version = 2`).
- Increasing the value of this configuration item might result in more TSO consumption and memory overhead of TiKV. To obtain enough TSOs, it is recommended to decrease the `tso-update-physical-interval` configuration item of PD.
- According to the test, when `alloc-ahead-buffer` is in its default value, and the PD leader fails and switches to another node, the write request will experience a short-term increase in latency and a decrease in QPS (about 15%).
- To avoid the impact on the business, you can configure `tso-update-physical-interval = "1ms"` in PD and the following configuration items in TiKV:
  - `causal-ts.alloc-ahead-buffer = "6s"`
  - `causal-ts.renew-batch-max-size = 65536`
  - `causal-ts.renew-batch-min-size = 2048`
- Default value: `3s`

14.8.2.34.2 `renew-interval`

- The interval at which the locally cached timestamps are updated.
- At an interval of `renew-interval`, TiKV starts a batch of timestamp refresh and adjusts the number of cached timestamps according to the timestamp consumption in the previous period and the setting of `alloc-ahead-buffer`. If you set this parameter to too large a value, the latest TiKV workload changes are not reflected in time. If you set this parameter to too small a value, the load of PD increases. If the write traffic is strongly fluctuating, if timestamps are frequently exhausted, and if write latency increases, you can set this parameter to a smaller value. At the same time, you should also consider the load of PD.
- Default value: `"100ms"`

14.8.2.34.3 `renew-batch-min-size`

- The minimum number of TSOs in a timestamp request.
- TiKV adjusts the number of cached timestamps according to the timestamp consumption in the previous period. If only a few TSOs are required, TiKV reduces the TSOs requested until the number reaches `renew-batch-min-size`. If large bursty write traffic often occurs in your application, you can set this parameter to a larger value as appropriate. Note that this parameter is the cache size for a single tikv-server. If you set the parameter to too large a value and the cluster contains many tikv-servers, the TSO consumption will be too fast.
- In the **TiKV-RAW** > **Causal timestamp** panel in Grafana, **TSO batch size** is the number of locally cached timestamps that has been dynamically adjusted according to the application workload. You can refer to this metric to adjust `renew-batch-min-size`.
- Default value: `100`

14.8.2.34.4 `renew-batch-max-size` New in v6.4.0

- The maximum number of TSOs in a timestamp request.
- In a default TSO physical time update interval (`50ms`), PD provides at most 262144 TSOs. When requested TSOs exceed this number, PD provides no more TSOs. This configuration item is used to avoid exhausting TSOs and the reverse impact of TSO exhaustion on other businesses. If you increase the value of this configuration item to improve high availability, you need to decrease the value of `tso-update-physical-interval` at the same time to get enough TSOs.
- Default value: `8192`

14.8.2.35 resource-control

Configuration items related to resource control of the TiKV storage layer.

14.8.2.35.1 `enabled` New in v6.6.0

- Controls whether to enable scheduling for user foreground read/write requests according to Request Unit (RU) of the corresponding resource groups. For information about TiDB resource groups and resource control, see Use Resource Control to Achieve Resource Group Limitation and Flow Control.
- Enabling this configuration item only works when 'tidb_enable_resource_control is enabled on TiDB. When this configuration item is enabled, TiKV will use the priority queue to schedule the queued read/write requests from foreground users. The scheduling priority of a request is inversely related to the amount of resources already consumed by the resource group that receives this request, and positively related to the quota of the corresponding resource group.
- Default value: `true`, which means scheduling based on the RU of the resource group is enabled.

14.8.2.35.2 `priority-ctl-strategy` New in v8.4.0

Specifies the flow control strategy for low-priority tasks. TiKV ensures that higher priority tasks are prioritized for execution by applying flow control to low-priority tasks.

- Value options:
  - `aggressive`: this policy prioritizes the performance of high-priority tasks, ensuring that the throughput and latency of high-priority tasks are largely unaffected, but low-priority tasks will run slower.
  - `moderate`: this policy imposes a balanced flow control on low-priority tasks and has a lower impact on high-priority tasks.
  - `conservative`: this policy prioritizes ensuring that system resources are fully utilized, allowing low-priority tasks to fully utilize system available resources as needed, and therefore has a greater performance impact on high-priority tasks.
- Default value: `moderate`.

14.8.2.36 split

Configuration items related to Load Base Split.

14.8.2.36.1 `byte-threshold` New in v5.0

- Controls the traffic threshold at which a Region is identified as a hotspot.
- Default value:
  - `30MiB` per second when `region-split-size` is less than 4 GiB.
  - `100MiB` per second when `region-split-size` is greater than or equal to 4 GiB.

14.8.2.36.2 `qps-threshold`

- Controls the QPS threshold at which a Region is identified as a hotspot.
- Default value:
  - `3000` when `region-split-size` is less than 4 GiB.
  - `7000` when `region-split-size` is greater than or equal to 4 GiB.

14.8.2.36.3 `region-cpu-overload-threshold-ratio` New in v6.2.0

- Controls the CPU usage threshold at which a Region is identified as a hotspot.
- Default value:
  - `0.25` when `region-split-size` is less than 4 GiB.
  - `0.75` when `region-split-size` is greater than or equal to 4 GiB.

14.8.2.37 memory New in v7.5.0

14.8.2.37.1 `enable-heap-profiling` New in v7.5.0

- Controls whether to enable Heap Profiling to track the memory usage of TiKV.
- Default value: `true`

14.8.2.37.2 `profiling-sample-per-bytes` New in v7.5.0

- Specifies the amount of data sampled by Heap Profiling each time, rounding up to the nearest power of 2.
- Default value: `512KiB`

14.8.2.37.3 `enable-thread-exclusive-arena` New in v8.1.0

- Controls whether to display the memory allocation status at the TiKV thread level to track the memory usage of each TiKV thread.
- Default value: `true`

14.8.2.38 in-memory-engine New in v8.5.0

TiKV MVCC in-memory engine (IME) configuration items related to the storage layer.

14.8.2.38.1 `enable` New in v8.5.0

> **Note:**
>
> You can configure this configuration item in the configuration file, but cannot query it via SQL statements.

- Whether to enable the in-memory engine to accelerate multi-version queries. For more information about the in-memory engine, see TiKV MVCC In-Memory Engine
- Default value: `false` (in-memory engine is disabled)
- It is recommended to configure at least 8 GiB of memory for the TiKV node, with 32 GiB or more for optimal performance.
- If the available memory for the TiKV node is insufficient, the in-memory engine will not be enabled even if this configuration item is set to `true`. In such cases, check the TiKV log file for messages containing `"in-memory engine is disabled because"` to learn why the in-memory engine is not enabled.

14.8.2.38.2 `capacity` New in v8.5.0

> **Note:**
>
> - After the in-memory engine is enabled, `block-cache.capacity` automatically decreases by 10%.
> - If you manually configure `capacity`, `block-cache.capacity` does not automatically decrease. In this case, you need to manually adjust its value to avoid OOM.

- Controls the maximum memory size that the in-memory engine can use. The maximum value is 5 GiB. You can manually configure it to use more memory.
- Default value: 10% of the system memory.

14.8.2.38.3 `gc-run-interval` New in v8.5.0

- Controls the time interval that the in-memory engine GC caches MVCC versions. Reducing this parameter can increase the GC frequency, and decrease the number of MVCC versions, but will increase CPU consumption for GC and increase the probability of in-memory engine cache miss.
- Default value: `"3m"`

14.8.2.38.4 `mvcc-amplification-threshold` New in v8.5.0

- Controls the threshold for MVCC read amplification when the in-memory engine selects and loads Regions. The default value is `10`, indicating that if reading a single row in a Region requires processing more than 10 MVCC versions, this Region might be loaded into the in-memory engine.
- Default value: `10`

14.8.3 Configure TiFlash

This document introduces the configuration parameters related to the deployment and use of TiFlash.

14.8.3.1 PD scheduling parameters

You can adjust the PD scheduling parameters using pd-ctl. Note that you can use `tiup ctl:v<CLUSTER_VERSION> pd` to replace `pd-ctl -u <pd_ip:pd_port>` when using tiup to deploy and manage your cluster.

- `replica-schedule-limit`: determines the rate at which the replica-related operator is generated. The parameter affects operations such as making nodes offline and add replicas.

> **Note:**
>
> The value of this parameter should be less than that of `region-schedule-limit`. Otherwise, the normal Region scheduling among TiKV nodes is affected.

- `store-balance-rate`: limits the rate at which Regions of each TiKV/TiFlash store are scheduled. Note that this parameter takes effect only when the stores have newly joined the cluster. If you want to change the setting for existing stores, use the following command.

> **Note:**
>
> Since v4.0.2, the `store-balance-rate` parameter has been deprecated and changes have been made to the `store limit` command. See store-limit for details.

```
- Execute the `pd-ctl -u <pd_ip:pd_port> store limit <store_id> <value>`
    ↪ command to set the scheduling rate of a specified store. To get `
    ↪ store_id`, you can execute the `pd-ctl -u <pd_ip:pd_port> store`
    ↪ command.
- If you do not set the scheduling rate for Regions of a specified store,
    ↪ this store inherits the setting of `store-balance-rate`.
- You can execute the `pd-ctl -u <pd_ip:pd_port> store limit` command to
    ↪ view the current setting value of `store-balance-rate`.
```

- `replication.location-labels`: indicates the topological relationship of TiKV instances. The order of the keys indicates the layering relationship of different labels. If TiFlash is enabled, you need to use `pd-ctl config placement-rules` to set the default value. For details, see geo-distributed-deployment-topology.

14.8.3.2 TiFlash configuration parameters

This section introduces the configuration parameters of TiFlash.

Tip:

If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.8.3.2.1 Configure the `tiflash.toml` file

`listen_host`

- The listening host for supporting services such as TPC/HTTP.
- It is recommended to configure it as `"0.0.0.0"`, which means listening on all IP addresses of this machine.

`tcp_port`

- The TiFlash TCP service port. This port is used for internal testing and is set to 9000 by default.
- Before TiFlash v7.1.0, this port is enabled by default with a security risk. To enhance security, it is recommended to apply access control on this port to only allow access from whitelisted IP addresses. Starting from TiFlash v7.1.0, you can avoid the security risk by commenting out the configuration of this port. When the TiFlash configuration file does not specify this port, it will be disabled.
- It is **NOT** recommended to configure this port in any TiFlash deployment. (Note: Starting from TiFlash v7.1.0, TiFlash deployed by TiUP >= v1.12.5 or TiDB Operator >= v1.5.0 disables the port by default and is more secure.)
- Default value: `9000`

`mark_cache_size`

- The cache size limit of the metadata of a data block. Generally, you do not need to change this value.
- Default value: `1073741824`

`minmax_index_cache_size`

- The cache size limit of the min-max index of a data block. Generally, you do not need to change this value.
- Default value: `1073741824`

`delta_index_cache_size`

- The cache size limit of the DeltaIndex.
- Default value: `0`, which means no limit.

`path`

- The storage path of TiFlash data. If there are multiple directories, separate each directory with a comma.
- Starting from TiDB v4.0.9, `path` and `path_realtime_mode` are deprecated. Use the configurations in the `storage` section to get better performance in the multi-disk deployment scenarios.
- Starting from TiDB v5.2.0, if you need to use the `storage.io_rate_limit` configuration, you need to set the storage path of TiFlash data to `storage.main.dir` at the same time.
- When the `storage` configurations exist, both `path` and `path_realtime_mode` configurations are ignored.

`path_realtime_mode`

- If you set it to `true` and multiple directories are set in the `path`, the latest data is stored in the first directory and older data is stored in the rest directories.
- Starting from TiDB v4.0.9, `path` and `path_realtime_mode` are deprecated. Use the configurations in the `storage` section to get better performance in the multi-disk deployment scenarios.
- When the `storage` configurations exist, both `path` and `path_realtime_mode` configurations are ignored.
- Default value: `false`

`tmp_path`

- The path in which the TiFlash temporary files are stored.
- By default, it is the first directory in `path` or in `storage.latest.dir` appended with `"/tmp"`.

storage New in v4.0.9

Configure storage path related settings.

`format_version`

- The DTFile format.
- Default value: `7`
- Value options: `2`, `3`, `4`, `5`, `6`, `7`
    - `format_version = 2`: the default format for versions < v6.0.0.

- `format_version = 3`: the default format for v6.0.0 and v6.1.x, which provides more data validation features.
- `format_version = 4`: the default format for versions from v6.2.0 to v7.3.0, which reduces write amplification and background task resource consumption.
- `format_version = 5`: introduced in v7.3.0, the default format for versions from v7.4.0 to v8.3.0, which reduces the number of physical files by merging smaller files.
- `format_version = 6`: introduced in v8.4.0, which partially supports the building and storage of vector indexes.
- `format_version = 7`: introduced in v8.4.0, the default format for v8.4.0 and later versions, which supports the build and storage of vector indexes.

storage.main

`dir`

- The list of directories to store the main data. For example: `[ "/tidb-data/tiflash-9000" ]` or `[ "/ssd0/tidb-data/tiflash", "/ssd1/tidb-data/tiflash" ]`.
- More than 90% of the total data is stored in the directory list.

`capacity`

- The maximum storage capacity of each directory in `storage.main.dir`. For example `[10737418240, 10737418240]`.
- If it is not set, or is set to multiple `0`, the actual disk (the disk where the directory is located) capacity is used.
- Unit: Byte. Note that human-readable numbers such as `"10GB"` are not supported yet.
- The size of the `capacity` list should be the same with the `storage.main.dir` size.

storage.latest

`dir`

- The list of directories to store the latest data. About 10% of the total data is stored in the directory list. The directories (or directory) listed here require higher IOPS metrics than those `storage.main.dir`.
- If it is not set (by default), the values of `storage.main.dir` are used.

`capacity`

- The maximum storage capacity of each directory in `storage.latest.dir`. If it is not set, or is set to multiple `0`, the actual disk (the disk where the directory is located) capacity is used.

storage.io_rate_limit New in v5.2.0

Configure the I/O traffic limit settings.

`max_bytes_per_sec`

- The total I/O bandwidth for disk reads and writes. This configuration item determines whether to limit the I/O traffic, which is disabled by default. This traffic limit in TiFlash is suitable for cloud storage that has the disk bandwidth of a small and specific size.
- Default value: `0`, which means the I/O traffic is not limited by default.
- Unit: Byte

`max_read_bytes_per_sec`

- The total I/O bandwidth for disk reads.
- `max_read_bytes_per_sec` and `max_write_bytes_per_sec` configuration items limit I/O bandwidth for disk reads and writes separately. You can use them for cloud storage that calculates the limit of I/O bandwidth for disk reads and writes separately, such as the Persistent Disk provided by Google Cloud.
- When the value of `max_bytes_per_sec` is not `0`, `max_bytes_per_sec` is prioritized.
- Default value: `0`

`max_write_bytes_per_sec`

- The total I/O bandwidth for disk writes.
- `max_read_bytes_per_sec` and `max_write_bytes_per_sec` configuration items limit I/O bandwidth for disk reads and writes separately. You can use them for cloud storage that calculates the limit of I/O bandwidth for disk reads and writes separately, such as the Persistent Disk provided by Google Cloud.
- When the value of `max_bytes_per_sec` is not `0`, `max_bytes_per_sec` is prioritized.
- Default value: `0`

`foreground_write_weight`

- TiFlash internally divides I/O requests into four types: foreground writes, background writes, foreground reads, background reads. `foreground_write_weight` controls the bandwidth weights assigned to foreground write I/O traffic type. Generally, you do not need to adjust these parameters.
- When the I/O traffic limit is initialized, TiFlash allocates bandwidth for these four types of requests according to the ratio of `foreground_write_weight`, `background_write_weight`, `foreground_read_weight`, and `background_read_weight`.
- If the weight is configured to `0`, the corresponding I/O traffic is not limited.
- Default value: `25`, representing an allocation of 25% of the bandwidth.

`background_write_weight`

- TiFlash internally divides I/O requests into four types: foreground writes, background writes, foreground reads, background reads. `background_write_weight` controls the bandwidth weights assigned to background write I/O traffic type. Generally, you do not need to adjust these parameters.
- When the I/O traffic limit is initialized, TiFlash allocates bandwidth for these four types of requests according to the ratio of `foreground_write_weight`, `background_write_weight`, `foreground_read_weight`, and `background_read_weight`.
- If the weight is configured to `0`, the corresponding I/O traffic is not limited.
- Default value: `25`, representing an allocation of 25% of the bandwidth.

`foreground_read_weight`

- TiFlash internally divides I/O requests into four types: foreground writes, background writes, foreground reads, background reads. `foreground_read_weight` controls the bandwidth weights assigned to foreground read I/O traffic type. Generally, you do not need to adjust these parameters.
- When the I/O traffic limit is initialized, TiFlash allocates bandwidth for these four types of requests according to the ratio of `foreground_write_weight`, `background_write_weight`, `foreground_read_weight`, and `background_read_weight`.
- If the weight is configured to `0`, the corresponding I/O traffic is not limited.
- Default value: `25`, representing an allocation of 25% of the bandwidth.

`background_read_weight`

- TiFlash internally divides I/O requests into four types: foreground writes, background writes, foreground reads, background reads. `background_read_weight` controls the bandwidth weights assigned to background read I/O traffic type. Generally, you do not need to adjust these parameters.
- When the I/O traffic limit is initialized, TiFlash allocates bandwidth for these four types of requests according to the ratio of `foreground_write_weight`, `background_write_weight`, `foreground_read_weight`, and `background_read_weight`.
- If the weight is configured to `0`, the corresponding I/O traffic is not limited.
- Default value: `25`, representing an allocation of 25% of the bandwidth.

`auto_tune_sec`

- TiFlash supports automatically tuning the traffic limit for different I/O types according to the current I/O load. Sometimes, the tuned bandwidth might exceed the weight ratio set above.
- `auto_tune_sec` indicates the interval of automatic tuning. If the value of auto_tune_sec is `0`, the automatic tuning is disabled.

- Default value: `5`
- Unit: Seconds

storage.s3

The following configuration items only take effect for the TiFlash disaggregated storage and compute architecture mode. For details, see TiFlash Disaggregated Storage and Compute Architecture and S3 Support.

`endpoint`

- The S3 endpoint address. For example: `http://s3.{region}.amazonaws.com`.

`bucket`

- TiFlash stores all data in this bucket.

`root`

- The root directory where data is stored in the S3 bucket. For example: `/cluster1_data`.

`access_key_id`

- The ACCESS_KEY_ID used to access S3.

`secret_access_key`

- The SECRET_ACCESS_KEY used to access S3.

storage.remote.cache

`dir`

- The local data cache directory of the Compute Node in the disaggregated storage and compute architecture.

`capacity`

- Example: `858993459200` (800 GiB)

flash

`service_addr`

- The listening address of TiFlash coprocessor services.

`compact_log_min_gap` New in v7.4.0

- When the gap between the `applied_index` advanced by the current Raft state machine and the `applied_index` at the last disk spilling exceeds `compact_log_min_gap`, TiFlash executes the `CompactLog` command from TiKV and spills data to disk.
- Increasing this gap might reduce the disk spilling frequency of TiFlash, thus reducing read latency in random write scenarios, but it might also increase memory overhead. Decreasing this gap might increase the disk spilling frequency of TiFlash, thus alleviating memory pressure in TiFlash. However, at this stage, the disk spilling frequency of TiFlash will not be higher than that of TiKV, even if this gap is set to `0`.
- It is recommended to keep the default value.
- Default value: `200`

`compact_log_min_rows` New in v5.0

- When the number or the size of rows in the Regions cached by TiFlash exceeds either `compact_log_min_rows` or `compact_log_min_bytes`, TiFlash executes the `CompactLog` command from TiKV and spills data to disk.
- It is recommended to keep the default value.
- Default value: `40960`

`compact_log_min_bytes` New in v5.0

- When the number or the size of rows in the Regions cached by TiFlash exceeds either `compact_log_min_rows` or `compact_log_min_bytes`, TiFlash executes the `CompactLog` command from TiKV and spills data to disk.
- It is recommended to keep the default value.
- Default value: `33554432`

`disaggregated_mode`

- This configuration item only takes effect for the TiFlash disaggregated storage and compute architecture mode. For details, see TiFlash Disaggregated Storage and Compute Architecture and S3 Support.
- Value options: `"tiflash_write"`, `"tiflash_compute"`

flash.proxy

`addr`

- The listening address of proxy.

- Default value: `"127.0.0.1:20170"`

`advertise-addr`

- The external access address of `addr`. If it is left empty, `addr` is used by default.
- You should guarantee that other nodes can access through `advertise-addr` when you deploy the cluster on multiple nodes.

`status-addr`

- The listening address from which the proxy pulls metrics or status information.
- Default value: `"127.0.0.1:20292"`

`advertise-status-addr`

- The external access address of status-addr. If it is left empty, the value of `status-addr` is used by default.
- You should guarantee that other nodes can access it through `advertise-status-addr` when you deploy the cluster on multiple nodes.

`engine-addr`

- The external access address of the TiFlash coprocessor service.

`data-dir`

- The data storage path of proxy.

`config`

- The configuration file path of proxy.

`log-file`

- The log path of proxy.

logger

Note that the following parameters only take effect in TiFlash logs and TiFlash error logs. If you need to configure log parameters of TiFlash Proxy, specify them in `tiflash-learner.toml`.

`level`

- The log level.
- Default value: `"info"`
- Value options: `"trace"`, `"debug"`, `"info"`, `"warn"`, `"error"`

`log`

- The log of TiFlash.

`errorlog`

- The error log of TiFlash. The `"warn"` and `"error"` level logs are also output to this log file.

`size`

- The size of a single log file.
- Default value: `"100M"`

`count`

- The maximum number of log files to save. For TiFlash logs and TiFlash error logs, the maximum number of log files to save is `count` respectively.
- Default value: `10`

raft

`pd_addr`

- The PD service address.
- Multiple addresses are separated with commas. For example, `"10.0.1.11:2379,10.0.1.12:2379,10`
  ↪ .

status

`metrics_port`

- The port through which Prometheus pulls metrics information.
- Default value: `8234`

profiles.default

`dt_enable_logical_split`

- Determines whether the segment of DeltaTree Storage Engine uses logical split. Using the logical split can reduce the write amplification. However, these are at the cost of disk space waste.
- It is strongly recommended to keep the default value `false` and not to change it to `true` in v6.2.0 and later versions. For details, see known issue #5576.
- Default value: `false`

`max_threads`

- `max_threads` indicates the internal thread concurrency when TiFlash executes an MPP task. When it is set to `0`, TiFlash uses the number of logical CPU cores as the execution concurrency.
- This parameter only takes effect when the system variable `tidb_max_tiflash_threads` is set to `-1`.
- Default value: `0`

`max_memory_usage`

- The memory usage limit for the generated intermediate data in a single query.
- When the value is an integer, the unit is byte. For example, `34359738368` means 32 GiB of memory limit.
- When the value is a floating-point number in the range of `[0.0, 1.0)`, it means the ratio of the allowed memory usage to the total memory of the node. For example, `0.8` means 80% of the total memory, and `0.0` means no limit.
- When a query attempts to consume memory that exceeds this limit, the query is terminated and an error is reported.
- Default value: `0`, which means no limit.

`max_memory_usage_for_all_queries`

- The memory usage limit for the generated intermediate data in all queries.
- When the value is an integer, the unit is byte. For example, `34359738368` means 32 GiB of memory limit, and `0` means no limit.
- Starting from v6.6.0, you can set the value to a floating-point number in the range of `[0.0, 1.0)`. This number represents the ratio of the allowed memory usage to the total node memory. For example, `0.8` means 80% of the total memory, and `0.0` means no limit.
- When the queries attempt to consume memory that exceeds this limit, the queries are terminated and an error is reported.
- Default value: `0.8`, which means 80% of the total memory. Before v6.6.0, the default value is `0`, which means no limit.

`cop_pool_size` New in v5.0

- Specifies the maximum number of cop requests that TiFlash Coprocessor executes at the same time. If the number of requests exceeds the specified value, the exceeded requests will queue. If the configuration value is set to `0` or not set, the default value is used, which is twice the number of physical cores.
- Default value: twice the number of physical cores

`cop_pool_handle_limit` New in v5.0

- Specifies the maximum number of cop requests that TiFlash Coprocessor handles at the same time, including the requests being executed and the requests waiting in the queue. If the number of requests exceeds the specified value, the error `TiFlash Server is Busy` is returned.
- `-1` indicates no limit; `0` indicates using the default value, which is `10 * cop_pool_size`.

`cop_pool_max_queued_seconds` New in v5.0

- Specifies the maximum time that a cop request can queue in TiFlash. If a cop request waits in the queue for a time longer than the value specified by this configuration, the error `TiFlash Server is Busy` is returned.
- A value less than or equal to `0` indicates no limit.
- Default value: `15`

`batch_cop_pool_size` New in v5.0

- Specifies the maximum number of batch requests that TiFlash Coprocessor executes at the same time. If the number of requests exceeds the specified value, the exceeded requests will queue. If the configuration value is set to `0` or not set, the default value is used, which is twice the number of physical cores.
- Default value: twice the number of physical cores

`manual_compact_pool_size` New in v6.1

- Specifies the number of requests that TiFlash can concurrently process when it receives `ALTER TABLE ... COMPACT` from TiDB.
- If the value is set to `0`, the default value `1` prevails.
- Default value: `1`

`enable_elastic_threadpool` New in v5.4.0

- Controls whether to enable the elastic thread pool feature, which significantly improves CPU utilization in high concurrency scenarios of TiFlash.

- Default value: `true`

`dt_compression_method`

- Compression algorithm of the TiFlash storage engine.
- Default value: `LZ4`
- Value options: `LZ4`, `zstd`, `LZ4HC`. The value is case-insensitive.

`dt_compression_level`

- Compression level of the TiFlash storage engine.
- It is recommended that you set this value to `1` if `dt_compression_method` is `LZ4`.
- It is recommended that you set this value to `-1` (smaller compression rate, but better read performance) or `1` if `dt_compression_method` is `zstd`.
- It is recommended that you set this value to `9` if `dt_compression_method` is `LZ4HC`.
- Default value: `1`

`dt_page_gc_threshold` New in v6.2.0

- Specifies the minimum ratio of valid data in a PageStorage data file. When the ratio of valid data in a PageStorage data file is less than the value of this configuration, GC is triggered to compact data in the file.
- Default value: `0.5`

`max_bytes_before_external_group_by` New in v7.0.0

- Specifies the maximum memory available for the Hash Aggregation operator with the `GROUP BY` key before a disk spill is triggered. When the memory usage exceeds the threshold, Hash Aggregation reduces memory usage by spilling to disk.
- Default value: `0`, which means that the memory usage is unlimited and spill to disk is never used for Hash Aggregation.

`max_bytes_before_external_sort` New in v7.0.0

- Specifies the maximum memory available for the sort or topN operator before a disk spill is triggered. When the memory usage exceeds the threshold, the sort or topN operator reduces memory usage by spilling to disk.
- Default value: `0`, which means that the memory usage is unlimited and spill to disk is never used for sort or topN.

`max_bytes_before_external_join` New in v7.0.0

- Specifies the maximum memory available for the Hash Join operator with equi-join conditions before a disk spill is triggered. When the memory usage exceeds the threshold, HashJoin reduces memory usage by spilling to disk.
- Default value: `0`, which means that the memory usage is unlimited and spill to disk is never used for Hash Join with equi-join conditions.

`enable_resource_control` New in v7.4.0

- Controls whether to enable the TiFlash resource control feature. When it is set to `true`, TiFlash uses the pipeline execution model.

`task_scheduler_thread_soft_limit` New in v6.0.0

- This item is used for the MinTSO scheduler. It specifies the maximum number of threads that one resource group can use. For more information, see TiFlash MinTSO Scheduler.
- Default value: `5000`

`task_scheduler_thread_hard_limit` New in v6.0.0

- This item is used for the MinTSO scheduler. It specifies the maximum number of threads in the global scope. For more information, see TiFlash MinTSO Scheduler.
- Default value: `10000`

`task_scheduler_active_set_soft_limit` New in v6.4.0

- This item is used for the MinTSO scheduler. It specifies the maximum number of queries that can run simultaneously in a TiFlash instance. For more information, see TiFlash MinTSO Scheduler.
- Default value: Before v7.4.0, the default value is `vcpu * 0.25`, which means a quarter of the number of vCPUs. Starting from v7.4.0, the default value is `vcpu * 2`, which means twice the number of vCPUs.

security New in v4.0.5

Configure security related settings.

`redact_info_log` New in v5.0

- Controls whether to enable log redaction.
- Default value: `false`
- Value options: `true`, `false`, `"on"`, `"off"`, and `"marker"`. The `"on"`, `"off"`, and `"marker"` options are introduced in v8.2.0.
- If the configuration item is set to `false` or `"off"`, log redaction is disabled.

- If the configuration item is set to `true` or `"on"`, all user data in the log is replaced by `?`.
- If the configuration item is set to `"marker"`, all user data in the log is wrapped in `‹ ›`. If user data contains `‹` or `›`, `‹` is escaped as `‹‹`, and `›` is escaped as `››`. Based on the marked logs, you can decide whether to desensitize the marked information when the logs are displayed.
- Note that you also need to set `security.redact-info-log` for tiflash-learner's logging in `tiflash-learner.toml`.

`ca_path`

- Path of the file that contains a list of trusted SSL CAs. If set, `cert_path` and `key_path` are also needed.

`cert_path`

- Path of the file that contains X509 certificate in PEM format.

`key_path`

- Path of the file that contains X509 key in PEM format.

14.8.3.2.2 Configure the `tiflash-learner.toml` file

The parameters in `tiflash-learner.toml` are basically the same as those in TiKV. You can refer to TiKV configuration for TiFlash Proxy configuration. The following are only commonly used parameters. Note that:

- Compared with TiKV, TiFlash Proxy has an extra `raftstore.snap-handle-pool-size` parameter.
- The `label` whose key is `engine` is reserved and cannot be configured manually.

log

`level` New in v5.4.0

- The log level of TiFlash Proxy.
- Default value: `"info"`
- Value options: `"trace"`, `"debug"`, `"info"`, `"warn"`, `"error"`

log.file

`max-backups` New in v5.4.0

- The maximum number of log files to save.
- If this parameter is not set or set to the default value `0`, TiFlash Proxy saves all log files.
- If this parameter is set to a non-zero value, TiFlash Proxy retains at most the number of old log files specified by `max-backups`. For example, if you set it to `7`, TiFlash Proxy retains at most 7 old log files.
- Default value: `0`

`max-days` New in v5.4.0

- The maximum number of days that the log files are retained.
- If this parameter is not set or set to the default value `0`, TiFlash Proxy retains all log files.
- If this parameter is set to a non-zero value, TiFlash Proxy cleans up outdated log files after the number of days specified by `max-days`.
- Default value: `0`

raftstore

`apply-pool-size`

- The allowable number of threads in the pool that flushes Raft data to storage.

`store-pool-size`

- The allowable number of threads that process Raft, which is the size of the Raftstore thread pool.

`snap-handle-pool-size` New in v4.0.0

- The number of threads that handle snapshots. If you set it to `0`, the multi-thread optimization is disabled.
- Default value: `2`

security

`redact-info-log` New in v5.0

- Controls whether to enable log redaction.
- Default value: `false`
- Value options: `true`, `false`, `"on"`, `"off"`, and `"marker"`. The `"on"`, `"off"`, and `"marker"` options are introduced in v8.3.0.
- If the configuration item is set to `false` or `"off"`, log redaction is disabled.

- If the configuration item is set to `true` or `"on"`, all user data in the log is replaced by `?`.
- If the configuration item is set to `"marker"`, all user data in the log is wrapped in `‹ ›`. If user data contains `‹` or `›`, `‹` is escaped as `‹‹`, and `›` is escaped as `››`. Based on the marked logs, you can decide whether to desensitize the marked information when the logs are displayed.

security.encryption

`data-encryption-method`

- The encryption method for data files. A value other than `"plaintext"` means that encryption is enabled, in which case the master key must be specified.
- Default value: `"plaintext"`, which means encryption is disabled by default.
- Value options: `"aes128-ctr"`, `"aes192-ctr"`, `"aes256-ctr"`, `"sm4-ctr"`, `"plaintext"`. `"sm4-ctr"` is introduced in v6.4.0.

`data-key-rotation-period`

- Specifies how often the data encryption key is rotated.
- Default value: `7d`

security.encryption.master-key

- Specifies the master key if encryption is enabled. To learn how to configure a master key, see Configure encryption.

security.encryption.previous-master-key

- Specifies the old master key when rotating the new master key. The configuration format is the same as that of `master-key`. To learn how to configure a master key, see Configure encryption.

14.8.3.2.3 Schedule replicas by topology labels

See Set available zones.

14.8.3.2.4 Multi-disk deployment

TiFlash supports multi-disk deployment. If there are multiple disks in your TiFlash node, you can make full use of those disks by configuring the parameters described in the following sections. For TiFlash's configuration template to be used for TiUP, see The complex template for the TiFlash topology.

Multi-disk deployment with TiDB version earlier than v4.0.9

For TiDB clusters earlier than v4.0.9, TiFlash only supports storing the main data of the storage engine on multiple disks. You can set up a TiFlash node on multiple disks by specifying the `path` (`data_dir` in TiUP) and `path_realtime_mode` configuration.

If there are multiple data storage directories in `path`, separate each with a comma. For example, `/nvme_ssd_a/data/tiflash,/sata_ssd_b/data/tiflash,/sata_ssd_c/data/tiflash`. If there are multiple disks in your environment, it is recommended that each directory corresponds to one disk and you put disks with the best performance at the front to maximize the performance of all disks.

If there are multiple disks with similar I/O metrics on your TiFlash node, you can leave the `path_realtime_mode` parameter to the default value (or you can explicitly set it to `false`). It means that data will be evenly distributed among all storage directories. However, the latest data is written only to the first directory, so the corresponding disk is busier than other disks.

If there are multiple disks with different I/O metrics on your TiFlash node, it is recommended to set `path_realtime_mode` to `true` and put disks with the best I/O metrics at the front of `path`. It means that the first directory only stores the latest data, and the older data are evenly distributed among the other directories. Note that in this case, the capacity of the first directory should be planned as 10% of the total capacity of all directories.

Multi-disk deployment with TiDB v4.0.9 or later

For TiDB clusters with v4.0.9 or later versions, TiFlash supports storing the main data and the latest data of the storage engine on multiple disks. If you want to deploy a TiFlash node on multiple disks, it is recommended to specify your storage directories in the `[storage]` section to make full use of your node. Note that the configurations earlier than v4.0.9 (`path` and `path_realtime_mode`) are still supported.

If there are multiple disks with similar I/O metrics on your TiFlash node, it is recommended to specify corresponding directories in the `storage.main.dir` list and leave `storage.latest.dir` empty. TiFlash will distribute I/O pressure and data among all directories.

If there are multiple disks with different I/O metrics on your TiFlash node, it is recommended to specify directories with higher metrics in the `storage.latest.dir` list, and specify directories with lower metrics in the `storage.main.dir` list. For example, for one NVMe-SSD and two SATA-SSDs, you can set `storage.latest.dir` to `["/nvme_ssd_a/data/tiflash"]` and `storage.main.dir` to `["/sata_ssd_b/data/tiflash", "/sata_ssd_c/data/tiflash"]`. TiFlash will distribute I/O pressure and data among these two directories list respectively. Note that in this case, the capacity of `storage.latest.dir` should be planned as 10% of the total planned capacity.

Warning:

The `[storage]` configuration is supported in TiUP since v1.2.5. If your TiDB cluster version is v4.0.9 or later, make sure that your TiUP version is v1.2.5 or later. Otherwise, the data directories defined in `[storage]` will not be managed by TiUP.

14.8.4 PD Configuration File

The PD configuration file supports more options than command-line parameters. You can find the default configuration file here.

This document only describes parameters that are not included in command-line parameters. Check here for the command line parameters.

Tip:

If you need to adjust the value of a configuration item, refer to Modify the configuration.

14.8.4.0.1 `name`

- The unique name of a PD node
- Default value: `"pd"`
- To start multiply PD nodes, use a unique name for each node.

14.8.4.0.2 `data-dir`

- The directory in which PD stores data
- Default value: `default.${name}"`

14.8.4.0.3 `client-urls`

- The list of client URLs to be listened to by PD
- Default value: `"http://127.0.0.1:2379"`
- When you deploy a cluster, you must specify the IP address of the current host as `client-urls` (for example, `"http://192.168.100.113:2379"`). If the cluster runs on Docker, specify the IP address of Docker as `"http://0.0.0.0:2379"`.

14.8.4.0.4 `advertise-client-urls`

- The list of advertise URLs for the client to access PD
- Default value: `"${client-urls}"`
- In some situations such as in the Docker or NAT network environment, if a client cannot access PD through the default client URLs listened to by PD, you must manually set the advertise client URLs.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 2380:2380`. In this case, you can set `advertise-client-urls` to `"http://192.168.100.113:2380"`. The client can find this service through `"http://192.168.100.113:2380"`.

14.8.4.0.5 `peer-urls`

- The list of peer URLs to be listened to by a PD node
- Default value: `"http://127.0.0.1:2380"`
- When you deploy a cluster, you must specify `peer-urls` as the IP address of the current host, such as `"http://192.168.100.113:2380"`. If the cluster runs on Docker, specify the IP address of Docker as `"http://0.0.0.0:2380"`.

14.8.4.0.6 `advertise-peer-urls`

- The list of advertise URLs for other PD nodes (peers) to access a PD node
- Default: `"${peer-urls}"`
- In some situations such as in the Docker or NAT network environment, if the other nodes (peers) cannot access the PD node through the default peer URLs listened to by this PD node, you must manually set the advertise peer URLs.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 2380:2380`. In this case, you can set `advertise-peer-urls` to `"http://192.168.100.113:2380"`. The other PD nodes can find this service through `"http://192.168.100.113:2380"`.

14.8.4.0.7 `initial-cluster`

- The initial cluster configuration for bootstrapping
- Default value: `"{name}=http://{advertise-peer-url}"`
- For example, if `name` is "pd", and `advertise-peer-urls` is `"http://192.168.100.113:2380"` ↪ , the `initial-cluster` is `"pd=http://192.168.100.113:2380"`.
- If you need to start three PD servers, the `initial-cluster` might be:

```
pd1=http://192.168.100.113:2380, pd2=http://192.168.100.114:2380, pd3
    ↪ =192.168.100.115:2380
```

14.8.4.0.8 `initial-cluster-state`

- The initial state of the cluster
- Default value: `"new"`

14.8.4.0.9 `initial-cluster-token`

- Identifies different clusters during the bootstrap phase
- Default value: `"pd-cluster"`
- If multiple clusters that have nodes with same configurations are deployed successively, you must specify different tokens to isolate different cluster nodes.

14.8.4.0.10 `lease`

- The timeout of the PD Leader Key lease. After the timeout, the system re-elects a Leader.
- Default value: Starting from v8.5.2, the default value is `5`. Before v8.5.2, the default value is `3`.
- Unit: second

14.8.4.0.11 `quota-backend-bytes`

- The storage size of the meta-information database, which is 8GiB by default
- Default value: `8589934592`

14.8.4.0.12 `auto-compaction-mod`

- The automatic compaction modes of the meta-information database
- Available options: `periodic` (by cycle) and `revision` (by version number).
- Default value: `periodic`

14.8.4.0.13 `auto-compaction-retention`

- The time interval for automatic compaction of the meta-information database when `auto-compaction-retention` is `periodic`. When the compaction mode is set to `revision`, this parameter indicates the version number for the automatic compaction.
- Default value: 1h

14.8.4.0.14 `tick-interval`

- Equivalent to the `heartbeat-interval` configuration item of etcd. It controls the Raft heartbeat interval between embedded etcd instances in different PD nodes. A smaller value accelerates failure detection but increases network load.
- Default value: `500ms`

14.8.4.0.15 `election-interval`

- Equivalent to the `election-timeout` configuration item of etcd. It controls the election timeout for embedded etcd instances in PD nodes. If an etcd instance does not receive a valid heartbeat from other etcd instances within this period, it initiates a Raft election.
- Default value: `3000ms`
- This value must be at least five times the `tick-interval`. For example, if `tick-interval` is `500ms`, `election-interval` must be greater than or equal to `2500ms`.

14.8.4.0.16 `enable-prevote`

- Equivalent to the `pre-vote` configuration item of etcd. It controls whether the embedded etcd in the PD node enables Raft pre-vote. When enabled, etcd performs an additional election phase to check whether enough votes can be obtained to win the election, minimizing service disruption.
- Default value: `true`

14.8.4.0.17 `force-new-cluster`

- Determines whether to force PD to start as a new cluster and modify the number of Raft members to `1`
- Default value: `false`

14.8.4.0.18 `tso-update-physical-interval`

- The interval at which PD updates the physical time of TSO.
- In a default update interval of TSO physical time, PD provides at most 262144 TSOs. To get more TSOs, you can reduce the value of this configuration item. The minimum value is `1ms`.
- Decreasing this configuration item might increase the CPU usage of PD. According to the test, compared with the interval of `50ms`, the CPU usage of PD will increase by about 10% when the interval is `1ms`.
- Default value: `50ms`
- Minimum value: `1ms`

14.8.4.1 pd-server

Configuration items related to pd-server

14.8.4.1.1 `server-memory-limit` New in v6.6.0

Warning:

This configuration is an experimental feature. It is not recommended to use it in production environments.

- The memory limit ratio for a PD instance. The value `0` means no memory limit.
- Default value: `0`
- Minimum value: `0`
- Maximum value: `0.99`

14.8.4.1.2 `server-memory-limit-gc-trigger` New in v6.6.0

Warning:

This configuration is an experimental feature. It is not recommended to use it in production environments.

- The threshold ratio at which PD tries to trigger GC. When the memory usage of PD reaches the value of `server-memory-limit` * the value of `server-memory-limit-gc-trigger`, PD triggers a Golang GC. Only one GC is triggered in one minute.
- Default value: `0.7`
- Minimum value: `0.5`
- Maximum value: `0.99`

14.8.4.1.3 `enable-gogc-tuner` New in v6.6.0

Warning:

This configuration is an experimental feature. It is not recommended to use it in production environments.

- Controls whether to enable the GOGC Tuner.
- Default value: `false`

14.8.4.1.4 `gc-tuner-threshold` New in v6.6.0

> **Warning:**
>
> This configuration is an experimental feature. It is not recommended to use it in production environments.

- The maximum memory threshold ratio for tuning GOGC. When the memory exceeds this threshold, i.e. the value of `server-memory-limit` * the value of `gc-tuner-threshold`, GOGC Tuner stops working.
- Default value: `0.6`
- Minimum value: `0`
- Maximum value: `0.9`

14.8.4.1.5 `flow-round-by-digit` New in TiDB 5.1

- Default value: 3
- PD rounds the lowest digits of the flow number, which reduces the update of statistics caused by the changes of the Region flow information. This configuration item is used to specify the number of lowest digits to round for the Region flow information. For example, the flow `100512` will be rounded to `101000` because the default value is `3`. This configuration replaces `trace-region-flow`.

> **Note:**
>
> If you have upgraded your cluster from a TiDB 4.0 version to the current version, the behavior of `flow-round-by-digit` after the upgrading and the behavior of `trace-region-flow` before the upgrading are consistent by default. This means that if the value of `trace-region-flow` is false before the upgrading, the value of `flow-round-by-digit` after the upgrading is 127; if the value of `trace-region-flow` is `true` before the upgrading, the value of `flow-round-by-digit` after the upgrading is `3`.

14.8.4.1.6 `min-resolved-ts-persistence-interval` New in v6.0.0

- Determines the interval at which the minimum resolved timestamp is persistent to the PD. If this value is set to `0`, it means that the persistence is disabled.

- Default value: Before v6.3.0, the default value is `"0s"`. Starting from v6.3.0, the default value is `"1s"`, which is the smallest positive value.
- Minimum value: `0`
- Unit: second

> **Note:**
>
> For clusters upgraded from v6.0.0~v6.2.0, the default value of `min-resolved-ts-persistence-interval` does not change after the upgrade, which means that it will remain `"0s"`. To enable this feature, you need to manually change the value of this configuration item.

14.8.4.2 security

Configuration items related to security

14.8.4.2.1 cacert-path

- The path of the CA file
- Default value: ""

14.8.4.2.2 cert-path

- The path of the Privacy Enhanced Mail (PEM) file that contains the X509 certificate
- Default value: ""

14.8.4.2.3 key-path

- The path of the PEM file that contains the X509 key
- Default value: ""

14.8.4.2.4 redact-info-log New in v5.0

- Controls whether to enable log redaction in the PD log
- Optional value: `false`, `true`, `"marker"`
- Default value: `false`
- For details on how to use it, see Log redaction in PD side.

14.8.4.3 log

Configuration items related to log

14.8.4.3.1 `level`

- Specifies the level of the output log
- Optional value: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`
- Default value: `"info"`

14.8.4.3.2 `format`

- The log format
- Optional value: `"text"`, `"json"`
- Default value: `"text"`

14.8.4.3.3 `disable-timestamp`

- Whether to disable the automatically generated timestamp in the log
- Default value: `false`

14.8.4.4 `log.file`

Configuration items related to the log file

14.8.4.4.1 `max-size`

- The maximum size of a single log file. When this value is exceeded, the system automatically splits the log into several files.
- Default value: `300`
- Unit: MiB
- Minimum value: `1`

14.8.4.4.2 `max-days`

- The maximum number of days in which a log is kept
- If the configuration item is not set, or the value of it is set to the default value 0, PD does not clean log files.
- Default value: `0`

14.8.4.4.3 `max-backups`

- The maximum number of log files to keep
- If the configuration item is not set, or the value of it is set to the default value 0, PD keeps all log files.
- Default value: `0`

14.8.4.5 `metric`

Configuration items related to monitoring

14.8.4.5.1 `interval`

- The interval at which monitoring metric data is pushed to Prometheus
- Default value: `15s`

14.8.4.6 `schedule`

Configuration items related to scheduling

> **Note:**
>
> To modify these PD configuration items related to `schedule`, choose one of the following methods based on your cluster status:
>
> - For clusters to be newly deployed, you can modify the PD configuration file directly.
> - For existing clusters, use the command-line tool PD Control to make changes instead. Direct modifications to these PD configuration items related to `schedule` in the configuration file do not take effect on existing clusters.

14.8.4.6.1 `max-merge-region-size`

- Controls the size limit of `Region Merge`. When the Region size is greater than the specified value, PD does not merge the Region with the adjacent Regions.
- Default value: `54`. Before v8.4.0, the default value is `20`. Starting from v8.4.0, the default value is `54`.
- Unit: MiB

14.8.4.6.2 `max-merge-region-keys`

- Specifies the upper limit of the `Region Merge` key. When the Region key is greater than the specified value, the PD does not merge the Region with its adjacent Regions.
- Default value: `540000`. Before v8.4.0, the default value is `200000`. Starting from v8.4.0, the default value is `540000`.

14.8.4.6.3 `patrol-region-interval`

- Controls the running frequency at which the checker inspects the health state of a Region. The smaller this value is, the faster the checker runs. Normally, you do not need to adjust this configuration.
- Default value: `10ms`

14.8.4.6.4 `patrol-region-worker-count` New in v8.5.0

> **Warning:**
>
> Setting this configuration item to a value greater than 1 enables concurrent checks. This is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

- Controls the number of concurrent operators created by the checker when inspecting the health state of a Region. Normally, you do not need to adjust this configuration.
- Default value: `1`

14.8.4.6.5 `split-merge-interval`

- Controls the time interval between the `split` and `merge` operations on the same Region. That means a newly split Region will not be merged for a while.
- Default value: `1h`

14.8.4.6.6 `max-movable-hot-peer-size` New in v6.1.0

- Controls the maximum Region size that can be scheduled for hot Region scheduling.
- Default value: `512`
- Unit: MiB

14.8.4.6.7 `max-snapshot-count`

- Controls the maximum number of snapshots that a single store receives or sends at the same time. PD schedulers depend on this configuration to prevent the resources used for normal traffic from being preempted.
- Default value value: `64`

14.8.4.6.8 `max-pending-peer-count`

- Controls the maximum number of pending peers in a single store. PD schedulers depend on this configuration to prevent too many Regions with outdated logs from being generated on some nodes.
- Default value: `64`

14.8.4.6.9 `max-store-down-time`

- The downtime after which PD judges that the disconnected store cannot be recovered. When PD fails to receive the heartbeat from a store after the specified period of time, it adds replicas at other nodes.
- Default value: `30m`

14.8.4.6.10 `max-store-preparing-time` New in v6.1.0

- Controls the maximum waiting time for the store to go online. During the online stage of a store, PD can query the online progress of the store. When the specified time is exceeded, PD assumes that the store has been online and cannot query the online progress of the store again. But this does not prevent Regions from transferring to the new online store. In most scenarios, you do not need to adjust this parameter.
- Default value: `48h`

14.8.4.6.11 `leader-schedule-limit`

- The number of Leader scheduling tasks performed at the same time
- Default value: `4`

14.8.4.6.12 `region-schedule-limit`

- The number of Region scheduling tasks performed at the same time
- Default value: `2048`

14.8.4.6.13 `enable-diagnostic` New in v6.3.0

- Controls whether to enable the diagnostic feature. When it is enabled, PD records the state during scheduling to help diagnose. If enabled, it might slightly affect the scheduling speed and consume more memory when there are many stores.
- Default value: Starting from v7.1.0, the default value is changed from `false` to `true`. If your cluster is upgraded from a version earlier than v7.1.0 to v7.1.0 or later, the default value does not change.

14.8.4.6.14 `hot-region-schedule-limit`

- Controls the hot Region scheduling tasks that are running at the same time. It is independent of the Region scheduling.
- Default value: `4`

14.8.4.6.15 `hot-region-cache-hits-threshold`

- The threshold used to set the number of minutes required to identify a hot Region. PD can participate in the hotspot scheduling only after the Region is in the hotspot state for more than this number of minutes.
- Default value: `3`

14.8.4.6.16 `replica-schedule-limit`

- The number of Replica scheduling tasks performed at the same time
- Default value: `64`

14.8.4.6.17 `merge-schedule-limit`

- The number of the `Region Merge` scheduling tasks performed at the same time. Set this parameter to `0` to disable `Region Merge`.
- Default value: `8`

14.8.4.6.18 `high-space-ratio`

- The threshold ratio below which the capacity of the store is sufficient. If the space occupancy ratio of the store is smaller than this threshold value, PD ignores the remaining space of the store when performing scheduling, and balances load mainly based on the Region size. This configuration takes effect only when `region-score-formula-version` is set to `v1`.
- Default value: `0.7`
- Minimum value: greater than `0`
- Maximum value: less than `1`

14.8.4.6.19 `low-space-ratio`

- The threshold ratio above which the capacity of the store is insufficient. If the space occupancy ratio of a store exceeds this threshold value, PD avoids migrating data to this store as much as possible. Meanwhile, to avoid the disk space of the corresponding store being exhausted, PD performs scheduling mainly based on the remaining space of the store.
- Default value: `0.8`
- Minimum value: greater than `0`
- Maximum value: less than `1`

14.8.4.6.20 `tolerant-size-ratio`

- Controls the `balance` buffer size
- Default value: `0` (automatically adjusts the buffer size)
- Minimum value: `0`

14.8.4.6.21 `enable-cross-table-merge`

- Determines whether to enable the merging of cross-table Regions
- Default value: `true`

14.8.4.6.22 `region-score-formula-version` New in v5.0

- Controls the version of the Region score formula
- Default value: `v2`
- Optional values: `v1` and `v2`. Compared to v1, the changes in v2 are smoother, and the scheduling jitter caused by space reclaim is improved.

> **Note:**
>
> If you have upgraded your cluster from a TiDB 4.0 version to the current version, the new formula version is automatically disabled by default to ensure consistent PD behavior before and after the upgrading. If you want to change the formula version, you need to manually switch through the `pd-ctl` setting. For details, refer to PD Control.

14.8.4.6.23 `store-limit-version` New in v7.1.0

- Controls the version of the store limit formula
- Default value: `v1`
- Value options:
  - `v1`: In v1 mode, you can manually modify the `store limit` to limit the scheduling speed of a single TiKV.
  - `v2`: In v2 mode, you do not need to manually set the `store limit` value, as PD dynamically adjusts it based on the capability of TiKV snapshots. For more details, refer to Principles of store limit v2.

14.8.4.6.24 `enable-joint-consensus` New in v5.0

- Controls whether to use Joint Consensus for replica scheduling. If this configuration is disabled, PD schedules one replica at a time.
- Default value: `true`

14.8.4.6.25 `hot-regions-write-interval` New in v5.4.0

- The time interval at which PD stores hot Region information.
- Default value: `10m`

> **Note:**
>
> The information about hot Regions is updated every three minutes. If the interval is set to less than three minutes, updates during the interval might be meaningless.

14.8.4.6.26 `hot-regions-reserved-days` New in v5.4.0

- Specifies how many days the hot Region information is retained.
- Default value: `7`

14.8.4.6.27 `enable-heartbeat-breakdown-metrics` New in v8.0.0

- Controls whether to enable breakdown metrics for Region heartbeats. These metrics measure the time consumed in each stage of Region heartbeat processing, facilitating analysis through monitoring.
- Default value: `true`

14.8.4.6.28 `enable-heartbeat-concurrent-runner` New in v8.0.0

- Controls whether to enable asynchronous concurrent processing for Region heartbeats. When enabled, an independent executor handles Region heartbeat requests asynchronously and concurrently, which can improve heartbeat processing throughput and reduce latency.
- Default value: `true`

14.8.4.7 `replication`

Configuration items related to replicas

14.8.4.7.1 `max-replicas`

- The number of replicas, that is, the sum of the number of leaders and followers. The default value `3` means 1 leader and 2 followers. When this configuration is modified dynamically, PD will schedule Regions in the background so that the number of replicas matches this configuration.
- Default value: `3`

14.8.4.7.2 `location-labels`

- The topology information of a TiKV cluster
- Default value: `[]`
- Cluster topology configuration

14.8.4.7.3 `isolation-level`

- The minimum topological isolation level of a TiKV cluster
- Default value: `""`
- Cluster topology configuration

14.8.4.7.4 `strictly-match-label`

- Enables the strict check for whether the TiKV label matches PD's `location-labels`.
- Default value: `false`

14.8.4.7.5 `enable-placement-rules`

- Enables `placement-rules`.
- Default value: `true`
- See Placement Rules.

14.8.4.8 `label-property` (deprecated)

Configuration items related to labels, which only support the `reject-leader` type.

> **Note:**
>
> Starting from v5.2, the configuration items related to labels are deprecated. It is recommended to use Placement Rules to configure the replica policy.

14.8.4.8.1 `key` (deprecated)

- The label key for the store that rejected the Leader
- Default value: `""`

14.8.4.8.2 `value` (deprecated)

- The label value for the store that rejected the Leader
- Default value: `""`

14.8.4.9 `dashboard`

Configuration items related to the TiDB Dashboard built in PD.

14.8.4.9.1 `disable-custom-prom-addr`

- Whether to disable configuring a custom Prometheus data source address in TiDB Dashboard.
- Default value: `false`
- When it is set to `true`, if you configure a custom Prometheus data source address in TiDB Dashboard, TiDB Dashboard reports an error.

14.8.4.9.2 `tidb-cacert-path`

- The path of the root CA certificate file. You can configure this path when you connect to TiDB's SQL services using TLS.
- Default value: `""`

14.8.4.9.3 `tidb-cert-path`

- The path of the SSL certificate file. You can configure this path when you connect to TiDB's SQL services using TLS.
- Default value: `""`

14.8.4.9.4 `tidb-key-path`

- The path of the SSL private key file. You can configure this path when you connect to TiDB's SQL services using TLS.
- Default value: `""`

14.8.4.9.5 `public-path-prefix`

- When TiDB Dashboard is accessed behind a reverse proxy, this item sets the public URL path prefix for all web resources.
- Default value: `/dashboard`
- Do **not** modify this configuration item when TiDB Dashboard is accessed not behind a reverse proxy; otherwise, access issues might occur. See Use TiDB Dashboard behind a Reverse Proxy for details.

14.8.4.9.6 `enable-telemetry`

> **Warning:**
>
> Starting from v8.1.0, the telemetry feature in TiDB Dashboard is removed, and this configuration item is no longer functional. It is retained solely for compatibility with earlier versions.

- Before v8.1.0, this configuration item controls whether to enable telemetry collection in TiDB Dashboard.
- Default value: `false`

14.8.4.10 `replication-mode`

Configuration items related to the replication mode of all Regions. See Enable the DR Auto-Sync mode for details.

14.8.4.11 controller

This section describes the configuration items that are built into PD for Resource Control.

14.8.4.11.1 `degraded-mode-wait-duration`

- Time to wait to trigger the degradation mode. Degradation mode means that when the Local Token Bucket (LTB) and Global Token Bucket (GTB) are lost, the LTB falls back to the default resource group configuration and no longer has a GTB authorization token, thus ensuring that the service is not affected in the event of network isolation or anomalies.
- Default value: 0s
- The degradation mode is disabled by default.

14.8.4.11.2 `request-unit`

The following are the configuration items about the Request Unit (RU).

`read-base-cost`

- Basis factor for conversion from a read request to RU
- Default value: 0.125

`write-base-cost`

- Basis factor for conversion from a write request to RU
- Default value: 1

`read-cost-per-byte`

- Basis factor for conversion from read flow to RU
- Default value: 1/(64 * 1024)
- 1 RU = 64 KiB read bytes

`write-cost-per-byte`

- Basis factor for conversion from write flow to RU
- Default value: 1/1024
- 1 RU = 1 KiB write bytes

`read-cpu-ms-cost`

- Basis factor for conversion from CPU to RU
- Default value: 1/3
- 1 RU = 3 millisecond CPU time

14.9 CLI

14.9.1 TiKV Control User Guide

TiKV Control (`tikv-ctl`) is a command line tool of TiKV, used to manage the cluster. Its installation directory is as follows:

- If the cluster is deployed using TiUP, `tikv-ctl` directory is in the in `~/.tiup/components/ctl/{VERSION}/` directory.

14.9.1.1 Use TiKV Control in TiUP

Note:

It is recommended that the version of the Control tool you use is consistent with the version of the cluster.

`tikv-ctl` is also integrated in the `tiup` command. Execute the following command to call the `tikv-ctl` tool:

```
tiup ctl:v<CLUSTER_VERSION> tikv
```

```
Starting component `ctl`: /home/tidb/.tiup/components/ctl/v4.0.8/ctl tikv
TiKV Control (tikv-ctl)
Release Version: 4.0.8
Edition:         Community
Git Commit Hash: 83091173e960e5a0f5f417e921a0801d2f6635ae
Git Commit Branch: heads/refs/tags/v4.0.8
UTC Build Time:  2020-10-30 08:40:33
Rust Version:    rustc 1.42.0-nightly (0de96d37f 2019-12-19)
Enable Features: jemalloc mem-profiling portable sse protobuf-codec
Profile:         dist_release

A tool for interacting with TiKV deployments.
USAGE:
    TiKV Control (tikv-ctl) [FLAGS] [OPTIONS] [SUBCOMMAND]
FLAGS:
    -h, --help                Prints help information
        --skip-paranoid-checks Skip paranoid checks when open rocksdb
    -V, --version             Prints version information
OPTIONS:
        --ca-path <ca-path>          Set the CA certificate path
        --cert-path <cert-path>      Set the certificate path
        --config <config>            TiKV config path, by default it's <
            ↪ deploy-dir>/conf/tikv.toml
        --data-dir <data-dir>        TiKV data directory path, check <deploy-
            ↪ dir>/scripts/run.sh to get it
        --decode <decode>            Decode a key in escaped format
        --encode <encode>            Encode a key in escaped format
        --to-hex <escaped-to-hex>    Convert an escaped key to hex key
        --to-escaped <hex-to-escaped> Convert a hex key to escaped key
        --host <host>                Set the remote host
        --key-path <key-path>        Set the private key path
        --log-level <log-level>      Set the log level [default: warn]
```

```
        --pd <pd>                    Set the address of pd
SUBCOMMANDS:
    bad-regions         Get all regions with corrupt raft
    cluster             Print the cluster id
    compact             Compact a column family in a specified range
    compact-cluster     Compact the whole cluster in a specified range in one
        ↪  or more column families
    consistency-check   Force a consistency-check for a specified region
    decrypt-file        Decrypt an encrypted file
    diff                Calculate difference of region keys from different
        ↪ dbs
    dump-snap-meta      Dump snapshot meta file
    encryption-meta     Dump encryption metadata
    fail                Inject failures to TiKV and recovery
    help                Prints this message or the help of the given
        ↪ subcommand(s)
    metrics             Print the metrics
    modify-tikv-config Modify tikv config, eg. tikv-ctl --host ip:port
        ↪ modify-tikv-config -n
                        rocksdb.defaultcf.disable-auto-compactions -v true
    mvcc                Print the mvcc value
    print               Print the raw value
    raft                Print a raft log entry
    raw-scan            Print all raw keys in the range
    recover-mvcc        Recover mvcc data on one node by deleting corrupted
        ↪ keys
    recreate-region     Recreate a region with given metadata, but alloc new
        ↪ id for it
    region-properties   Show region properties
    scan                Print the range db range
    size                Print region size
    split-region        Split the region
    store               Print the store id
    tombstone           Set some regions on the node to tombstone by manual
    unsafe-recover      Unsafely recover the cluster when the majority
        ↪ replicas are failed
```

You can add corresponding parameters and subcommands after `tiup ctl:v<CLUSTER_VERSION> tikv`.

14.9.1.2 General options

`tikv-ctl` provides two operation modes:

- Remote mode: use the `--host` option to accept the service address of TiKV as the

argument

For this mode, if SSL is enabled in TiKV, `tikv-ctl` also needs to specify the related certificate file. For example:

```
tikv-ctl --ca-path ca.pem --cert-path client.pem --key-path client-key.
    ↪ pem --host 127.0.0.1:20160 <subcommands>
```

However, sometimes `tikv-ctl` communicates with PD instead of TiKV. In this case, you need to use the `--pd` option instead of `--host`. Here is an example:

```
tikv-ctl --pd 127.0.0.1:2379 compact-cluster
```

```
store:"127.0.0.1:20160" compact db:KV cf:default range:([], []) success
    ↪ !
```

- Local mode:
    - Use the `--data-dir` option to specify the local TiKV data directory path.
    - Use the `--config` option to specify the local TiKV configuration file path.

In this mode, you need to stop the running TiKV instance.

Unless otherwise noted, all commands support both the remote mode and the local mode.

Additionally, `tikv-ctl` has two simple commands `--to-hex` and `--to-escaped`, which are used to make simple changes to the form of the key.

Generally, use the `escaped` form of the key. For example:

```
tikv-ctl --to-escaped 0xaaff
\252\377
tikv-ctl --to-hex "\252\377"
AAFF
```

> **Note:**
>
> When you specify the `escaped` form of the key in a command line, it is required to enclose it in double quotes. Otherwise, bash eats the backslash and a wrong result is returned.

14.9.1.3 Subcommands, some options and flags

This section describes the subcommands that `tikv-ctl` supports in detail. Some subcommands support a lot of options. For all details, run `tikv-ctl --help <subcommand>`.

14.9.1.3.1 View information of the Raft state machine

Use the `raft` subcommand to view the status of the Raft state machine at a specific moment. The status information includes two parts: three structs (**RegionLocalState**, **RaftLocalState**, and **RegionApplyState**) and the corresponding Entries of a certain piece of log.

Use the `region` and `log` subcommands to obtain the above information respectively. The two subcommands both support the remote mode and the local mode at the same time.

For the `region` subcommand:

- To specify the Regions to be viewed, use the `-r` option. Multiple Regions are separated by `,`. You can also use the `--all-regions` option to view all Regions. Note that `-r` and `--all-regions` cannot be used at the same time.
- To limit the number of Regions to be printed, use the `--limit` option (default: `16`).
- To query which Regions are included in a certain key range, use the `--start` and `--end` options (default: no range limit, in Hex format).

For example, to print the Region with the ID `1239`, use the following command:

```
tikv-ctl --host 127.0.0.1:20160 raft region -r 1239
```

The output is as follows:

```
"region id": 1239
"region state": {
    id: 1239,
    start_key: 7480000000000000FF4E5F728000000000FF1443770000000000FA,
    end_key: 7480000000000000FF4E5F728000000000FF21C4420000000000FA,
    region_epoch: {conf_ver: 1 version: 43},
    peers: [ {id: 1240 store_id: 1 role: Voter} ]
}
"raft state": {
    hard_state {term: 8 vote: 5 commit: 7}
    last_index: 8)
}
"apply state": {
    applied_index: 8 commit_index: 8 commit_term: 8
    truncated_state {index: 5 term: 5}
}
```

To query which Regions are included in a certain key range, use the following command:

- If the key range is in a Region range, the Region information is output.

- If the key range is the same as a Region range, for example, when the given key range is the same as the Region `1239`, because the Region range is a left-closed and right-open interval, and Region `1009` takes the `end_key` of Region `1239` as the `start_key`, the Region `1009` information is also output.

```
tikv-ctl --host 127.0.0.1:20160 raft region --start 7480000000000000
    ↪ FF4E5F728000000000FF1443770000000000FA --end 7480000000000000
    ↪ FF4E5F728000000000FF21C4420000000000FA
```

The output is as follows:

```
"region state": {
    id: 1009
    start_key: 7480000000000000FF4E5F728000000000FF21C4420000000000FA,
    end_key: 7480000000000000FF5000000000000000F8,
    ...
}
"region state": {
    id: 1239
    start_key: 7480000000000000FF4E5F728000000000FF06C6D60000000000FA,
    end_key: 7480000000000000FF4E5F728000000000FF1443770000000000FA,
    ...
}
```

14.9.1.3.2 View the Region size

Use the `size` command to view the Region size:

```
tikv-ctl --data-dir /path/to/tikv size -r 2
```

The output is as follows:

```
region id: 2
cf default region size: 799.703 MB
cf write region size: 41.250 MB
cf lock region size: 27616
```

14.9.1.3.3 Scan to view MVCC of a specific range

The `--from` and `--to` options of the `scan` command accept two escaped forms of raw key, and use the `--show-cf` flag to specify the column families that you need to view.

```
tikv-ctl --data-dir /path/to/tikv scan --from 'zm' --limit 2 --show-cf lock,
    ↪ default,write
```

```
key: zmBootstr\377a\377pKey
    ↪ \000\000\377\000\000\373\000\000\000\000\000\377\000\000s
    ↪ \000\000\000\000\000\372
        write cf value: start_ts: 399650102814441473 commit_ts:
            ↪ 399650102814441475 short_value: "20"
key: zmDB:29\000\000\377\000\374\000\000\000\000\000\000\377\000H
    ↪ \000\000\000\000\000\000\371
        write cf value: start_ts: 399650105239273474 commit_ts:
            ↪ 399650105239273475 short_value:
            ↪ "\000\000\000\000\000\000\000\002"
        write cf value: start_ts: 399650105199951882 commit_ts:
            ↪ 399650105213059076 short_value:
            ↪ "\000\000\000\000\000\000\000\001"
```

14.9.1.3.4 View MVCC of a given key

Similar to the `scan` command, the `mvcc` command can be used to view MVCC of a given key.

```
tikv-ctl --data-dir /path/to/tikv mvcc -k "zmDB
    ↪ :29\000\000\377\000\374\000\000\000\000\000\000\377\000H
    ↪ \000\000\000\000\000\000\371" --show-cf=lock,write,default
```

```
key: zmDB:29\000\000\377\000\374\000\000\000\000\000\000\377\000H
    ↪ \000\000\000\000\000\000\371
        write cf value: start_ts: 399650105239273474 commit_ts:
            ↪ 399650105239273475 short_value:
            ↪ "\000\000\000\000\000\000\000\002"
        write cf value: start_ts: 399650105199951882 commit_ts:
            ↪ 399650105213059076 short_value:
            ↪ "\000\000\000\000\000\000\000\001"
```

In this command, the key is also the escaped form of raw key.

14.9.1.3.5 Scan raw keys

The `raw-scan` command scans directly from the RocksDB. Note that to scan data keys you need to add a `'z'` prefix to keys.

Use `--from` and `--to` options to specify the range to scan (unbounded by default). Use `--limit` to limit at most how many keys to print out (30 by default). Use `--cf` to specify which cf to scan (can be `default`, `write` or `lock`).

```
tikv-ctl --data-dir /var/lib/tikv raw-scan --from 'zt' --limit 2 --cf
    ↪ default
```

```
key: "zt\200\000\000\000\000\000\000\377\005_r
    ↪ \200\000\000\000\000\377\000\000\001\000\000\000\000\000\372\372b2
    ↪ ,^\033\377\364", value: "\010\002\002\002%\010\004\002\010root
    ↪ \010\006\002\000\010\010\t\002\010\n\t\002\010\014\t\002\010\016\t
    ↪ \002\010\020\t\002\010\022\t\002\010\024\t\002\010\026\t\002\010\030\
    ↪ t\002\010\032\t\002\010\034\t\002\010\036\t\002\010 \t\002\010\"\t

    ↪ \002\0100\t\002\0102\t\002\0104\t\002"
key: "zt\200\000\000\000\000\000\000\377\025_r
    ↪ \200\000\000\000\000\377\000\000\023\000\000\000\000\000\372\372b2
    ↪ ,^\033\377\364", value: "\010\002\002&slow_query_log_file\010\004\002
    ↪ P/usr/local/mysql/data/localhost-slow.log"

Total scanned keys: 2
```

14.9.1.3.6 Print a specific key value

To print the value of a key, use the `print` command.

14.9.1.3.7 Print some properties about Region

In order to record Region state details, TiKV writes some statistics into the SST files of Regions. To view these properties, run `tikv-ctl` with the `region-properties` sub-command:

```
tikv-ctl --host localhost:20160 region-properties -r 2
```

```
num_files: 0
num_entries: 0
num_deletes: 0
mvcc.min_ts: 18446744073709551615
mvcc.max_ts: 0
mvcc.num_rows: 0
mvcc.num_puts: 0
mvcc.num_versions: 0
mvcc.max_row_versions: 0
middle_key_by_approximate_size:
```

The properties can be used to check whether the Region is healthy or not. If not, you can use them to fix the Region. For example, splitting the Region manually by `middle_key_approximate_size`.

14.9.1.3.8 Compact data of each TiKV manually

Use the `compact` command to manually compact data of each TiKV.

- Use the `--from` and `--to` options to specify the compaction range in the form of escaped raw key. If not set, the whole range will be compacted.
- Use the `--region` option to compact the range of a specific region. If set, `--from` and `--to` will be ignored.
- Use the `-c` option to specify the column family name. The default value is `default`. The optional values are `default`, `lock`, and `write`.
- Use the `-d` option to specify the RocksDB that performs compaction. The default value is `kv`. The optional values are `kv` and `raft`.
- Use the `--threads` option allows you to specify the concurrency for the TiKV compaction and its default value is `8`. Generally, a higher concurrency comes with a faster compaction speed, which might yet affect the service. You need to choose an appropriate concurrency count based on your scenario.
- Use the `--bottommost` option to include or exclude the bottommost files when TiKV performs compaction. The value options are `default`, `skip`, and `force`. The default value is `default`.
    - `default` means that the bottommost files are included only when the Compaction Filter feature is enabled.
    - `skip` means that the bottommost files are excluded when TiKV performs compaction.
    - `force` means that the bottommost files are always included when TiKV performs compaction.
- To compact data in the local mode, use the following command:

```
tikv-ctl --data-dir /path/to/tikv compact -d kv
```

- To compact data in the remote mode, use the following command:

```
tikv-ctl --host ip:port compact -d kv
```

14.9.1.3.9 Compact data of the whole TiKV cluster manually

Use the `compact-cluster` command to manually compact data of the whole TiKV cluster. The flags of this command have the same meanings and usage as those of the `compact` command. The only difference is as follows:

- For the `compact-cluster` command, use `--pd` to specify the address of the PD, so that `tikv-ctl` can locate all TiKV nodes in the cluster as the compact target.
- For the `compact` command, use `--data-dir` or `--host` to specify a single TiKV as the compact target.

14.9.1.3.10 Set a Region to tombstone

The `tombstone` command is usually used in circumstances where some data written in the Raft state machine is lost caused by power down.

In a TiKV instance, you can use this command to set the status of some Regions to tombstone. Then when you restart the instance, those Regions are skipped to avoid the restart failure caused by damaged Raft state machines of those Regions. Those Regions need to have enough healthy replicas in other TiKV instances to be able to continue the reads and writes through the Raft mechanism.

In general cases, you can remove the corresponding Peer of this Region using the `remove -peer` command:

```
pd-ctl operator add remove-peer <region_id> <store_id>
```

Then use the `tikv-ctl` tool to set a Region to tombstone on the corresponding TiKV instance to skip the health check for this Region at startup:

```
tikv-ctl --data-dir /path/to/tikv tombstone -p 127.0.0.1:2379 -r <region_id>
```

```
success!
```

However, in some cases, you cannot easily remove this Peer of this Region from PD, so you can specify the `--force` option in `tikv-ctl` to forcibly set the Peer to tombstone:

```
tikv-ctl --data-dir /path/to/tikv tombstone -p 127.0.0.1:2379 -r <region_id
    ↪ >,<region_id> --force
```

```
success!
```

Note:

- The `tombstone` command only supports the local mode.
- The argument of the `-p` option specifies the PD endpoints without the `http` prefix. Specifying the PD endpoints is to query whether PD can safely switch to Tombstone.

14.9.1.3.11 Send a `consistency-check` request to TiKV

Use the `consistency-check` command to execute a consistency check among replicas in the corresponding Raft of a specific Region. If the check fails, TiKV itself panics. If the TiKV instance specified by `--host` is not the Region leader, an error is reported.

```
tikv-ctl --host 127.0.0.1:20160 consistency-check -r 2
success!
tikv-ctl --host 127.0.0.1:20161 consistency-check -r 2
DebugClient::check_region_consistency: RpcFailure(RpcStatus { status:
    ↪ Unknown, details: Some("StringError(\"Leader is on store 1\")") })
```

Note:

- It is **NOT** recommended to use the `consistency-check` command, because it is incompatible with the garbage collection in TiDB and might mistakenly report an error.
- This command only supports the remote mode.
- Even if this command returns `success!`, you need to check whether TiKV panics. This is because this command is only a proposal that requests a consistency check for the leader, and you cannot know from the client whether the whole check process is successful or not.

14.9.1.3.12 Dump snapshot meta

This sub-command is used to parse a snapshot meta file at given path and print the result.

14.9.1.3.13 Print the Regions where the Raft state machine corrupts

To avoid checking the Regions while TiKV is started, you can use the `tombstone` command to set the Regions where the Raft state machine reports an error to Tombstone. Before running this command, use the `bad-regions` command to find out the Regions with errors, so as to combine multiple tools for automated processing.

```
tikv-ctl --data-dir /path/to/tikv bad-regions
```

```
all regions are healthy
```

If the command is successfully executed, it prints the above information. If the command fails, it prints the list of bad Regions. Currently, the errors that can be detected include the mismatches between `last index`, `commit index` and `apply index`, and the loss of Raft log. Other conditions like the damage of snapshot files still need further support.

14.9.1.3.14 View Region properties

- To view in local the properties of Region 2 on the TiKV instance that is deployed in `/path/to/tikv`:

```
tikv-ctl --data-dir /path/to/tikv/data region-properties -r 2
```

- To view online the properties of Region 2 on the TiKV instance that is running on `127.0.0.1:20160`:

```
tikv-ctl --host 127.0.0.1:20160 region-properties -r 2
```

14.9.1.3.15 Modify the TiKV configuration dynamically

You can use the `modify-tikv-config` command to dynamically modify the configuration arguments. Currently, the TiKV configuration items that can be dynamically modified and the detailed modification are consistent with modifying configuration using SQL statements. For details, see Modify TiKV configuration dynamically.

- `-n` is used to specify the full name of the configuration item. For the list of configuration items that can be modified dynamically, see Modify TiKV configuration dynamically.
- `-v` is used to specify the configuration value.

Set the size of `shared block cache`:

```
tikv-ctl --host ip:port modify-tikv-config -n storage.block-cache.capacity -
    ↪ v 10GB
```

```
success
```

When `shared block cache` is disabled, set `block cache size` for the `write` CF:

```
tikv-ctl --host ip:port modify-tikv-config -n rocksdb.writecf.block-cache-
    ↪ size -v 256MB
```

```
success
```

```
tikv-ctl --host ip:port modify-tikv-config -n raftdb.defaultcf.disable-auto-
    ↪ compactions -v true
```

```
success
```

When the compaction rate limit causes accumulated compaction pending bytes, disable the `rate-limiter-auto-tuned` mode or set a higher limit for the compaction flow:

```
tikv-ctl --host ip:port modify-tikv-config -n rocksdb.rate-limiter-auto-
    ↪ tuned -v false
```

```
success
```

```
tikv-ctl --host ip:port modify-tikv-config -n rocksdb.rate-bytes-per-sec -v
    ↪ "1GB"
```

```
success
```

14.9.1.3.16 Force Regions to recover services from failure of multiple replicas (deprecated)

> **Warning:**
>
> It is not recommended to use this feature. Instead, you can use Online Unsafe Recovery in `pd-ctl` which provides one-stop automatic recovery capabilities. Extra operations such as stopping services are not needed. For detailed introduction, see Online Unsafe Recovery.

You can use the `unsafe-recover remove-fail-stores` command to remove the failed machines from the peer list of Regions. Before running this command, you need to stop the service of the target TiKV store to release file locks.

The `-s` option accepts multiple `store_id` separated by comma and uses the `-r` flag to specify involved Regions. If you need to perform this operation on all Regions in a specific store, you can simply specify `--all-regions`.

> **Warning:**
>
> - If any misoperation is performed, it might be hard to recover the cluster. Be aware of the potential risks and avoid using this feature in a production environment.
> - If the `--all-regions` option is used, you are expected to run this command on all the remaining stores connected to the cluster. You need to ensure that these healthy stores stop providing services before recovering the damaged stores. Otherwise, the inconsistent peer lists in Region replicas will cause errors when you run `split-region` or `remove-peer`. This further causes inconsistency between other metadata, and finally, the Regions will become unavailable.
> - Once you have run `remove-fail-stores`, you cannot restart the removed nodes or add these nodes to the cluster. Otherwise, the metadata will be inconsistent, and finally, the Regions will be unavailable.

```
tikv-ctl --data-dir /path/to/tikv unsafe-recover remove-fail-stores -s 3 -r
    ↪ 1001,1002
```

```
success!
```

```
tikv-ctl --data-dir /path/to/tikv unsafe-recover remove-fail-stores -s 4,5
    ↪ --all-regions
```

Then, after you restart TiKV, the Regions can continue providing services with the remaining healthy replicas. This command is commonly used when multiple TiKV stores are damaged or deleted.

Note:

- You are expected to run this command for all stores where the specified Regions' peers are located.
- This command only supports the local mode. It prints `success!` when successfully run.

14.9.1.3.17 Recover from MVCC data corruption

Use the `recover-mvcc` command in circumstances where TiKV cannot run normally caused by MVCC data corruption. It cross-checks 3 CFs ("default", "write", "lock") to recover from various kinds of inconsistency.

- Use the `-r` option to specify involved Regions by `region_id`.
- Use the `-p` option to specify PD endpoints.

```
tikv-ctl --data-dir /path/to/tikv recover-mvcc -r 1001,1002 -p
    ↪ 127.0.0.1:2379
success!
```

Note:

- This command only supports the local mode. It prints `success!` when successfully run.

- The argument of the `-p` option specifies the PD endpoints without the `http` prefix. Specifying the PD endpoints is to query whether the specified `region_id` is validated or not.
- You need to run this command for all stores where specified Regions' peers are located.

14.9.1.3.18 Ldb Command

The `ldb` command line tool offers multiple data access and database administration commands. Some examples are listed below. For more information, refer to the help message displayed when running `tikv-ctl ldb` or check the documents from RocksDB.

Examples of data access sequence:

To dump an existing RocksDB in HEX:

```
tikv-ctl ldb --hex --db=/tmp/db dump
```

To dump the manifest of an existing RocksDB:

```
tikv-ctl ldb --hex manifest_dump --path=/tmp/db/MANIFEST-000001
```

You can specify the column family that your query is against using the `--column_family =<string>` command line.

`--try_load_options` loads the database options file to open the database. It is recommended to always keep this option on when the database is running. If you open the database with default options, the LSM-tree might be messed up, which cannot be recovered automatically.

14.9.1.3.19 Dump encryption metadata

Use the `encryption-meta` subcommand to dump encryption metadata. The subcommand can dump two types of metadata: encryption info for data files, and the list of data encryption keys used.

To dump encryption info for data files, use the `encryption-meta dump-file` subcommand. You need to create a TiKV config file to specify `data-dir` for the TiKV deployment:

```
### conf.toml
[storage]
data-dir = "/path/to/tikv/data"
```

The `--path` option can be used to specify an absolute or relative path to the data file of interest. The command might give empty output if the data file is not encrypted. If `--path` is not provided, encryption info for all data files will be printed.

```
tikv-ctl --config=./conf.toml encryption-meta dump-file --path=/path/to/tikv
    ↪ /data/db/CURRENT
```

```
/path/to/tikv/data/db/CURRENT: key_id: 9291156302549018620 iv:
    ↪ E3C2FDBF63FC03BFC28F265D7E78283F method: Aes128Ctr
```

To dump data encryption keys, use the `encryption-meta dump-key` subcommand. In additional to `data-dir`, you also need to specify the current master key used in the config file. For how to config master key, refer to Encryption-At-Rest. Also with this command, the `security.encryption.previous-master-key` config will be ignored, and the master key rotation will not be triggered.

```
### conf.toml
[storage]
data-dir = "/path/to/tikv/data"

[security.encryption.master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
```

Note if the master key is a AWS KMS key, `tikv-ctl` needs to have access to the KMS key. Access to a AWS KMS key can be granted to `tikv-ctl` via environment variable, AWS default config file, or IAM role, whichever is suitable. Refer to AWS document for usage.

The `--ids` option can be used to specified a list of comma-separated data encryption key ids to print. If `--ids` is not provided, all data encryption keys will be printed, along with current key id, which is the id of the latest active data encryption key.

When using the command, you will see a prompt warning that the action will expose sensitive information. Type "I consent" to continue.

```
tikv-ctl --config=./conf.toml encryption-meta dump-key
```

```
This action will expose encryption key(s) as plaintext. Do not output the
    ↪ result in file on disk.
Type "I consent" to continue, anything else to exit: I consent
current key id: 9291156302549018620
9291156302549018620: key: 8B6B6B8F83D36BE2467ED55D72AE808B method: Aes128Ctr
    ↪  creation_time: 1592938357
```

```
tikv-ctl --config=./conf.toml encryption-meta dump-key --ids
    ↪ =9291156302549018620
```

```
This action will expose encryption key(s) as plaintext. Do not output the
    ↪ result in file on disk.
```

```
Type "I consent" to continue, anything else to exit: I consent
9291156302549018620: key: 8B6B6B8F83D36BE2467ED55D72AE808B method: Aes128Ctr
    ↪  creation_time: 1592938357
```

> **Note:**
>
> The command will expose data encryption keys as plaintext. In production, DO NOT redirect the output to a file. Even deleting the output file afterward may not cleanly wipe out the content from disk.

14.9.1.3.20 Print information related to damaged SST files

Damaged SST files in TiKV might cause TiKV processes to panic. Before TiDB v6.1.0, these files cause TiKV to panic immediately. Since TiDB v6.1.0, TiKV processes panic 1 hour after SST files are damaged.

To clean up the damaged SST files, you can run the `bad-ssts` command in TiKV Control to show the needed information. The following is an example command and output.

> **Note:**
>
> Before running this command, stop the running TiKV instance.

```
tikv-ctl --data-dir </path/to/tikv> bad-ssts --pd <endpoint>
```

```
--------------------------------------------------------
corruption info:
data/tikv-21107/db/000014.sst: Corruption: Bad table magic number: expected
    ↪ 9863518390377041911, found 759105309091689679 in data/tikv-21107/db
    ↪ /000014.sst

sst meta:
14:552997[1 .. 5520]['0101' seq:1, type:1 .. '7
    ↪ A7480000000000000FF0F5F728000000000FF0002160000000000FAFA13AB33020BFFFA
    ↪ ' seq:2032, type:1] at level 0 for Column family "default" (ID 0)
it isn't easy to handle local data, start key:0101

overlap region:
```

```
RegionInfo { region: id: 4 end_key: 7480000000000000FF0500000000000000F8
    ↪ region_epoch { conf_ver: 1 version: 2 } peers { id: 5 store_id: 1 },
    ↪ leader: Some(id: 5 store_id: 1) }

refer operations:
tikv-ctl ldb --db=/path/to/tikv/db unsafe_remove_sst_file 000014
tikv-ctl --data-dir=/path/to/tikv tombstone -r 4 --pd <endpoint>
------------------------------------------------------------
corruption analysis has completed
```

From the output above, you can see that the information of the damaged SST file is printed first and then the meta-information is printed.

- In the `sst meta` part, `14` means the SST file number; `552997` means the file size, followed by the smallest and largest sequence numbers and other meta-information.
- The `overlap region` part shows the information of the Region involved. This information is obtained through the PD server.
- The `suggested operations` part provides you suggestion to clean up the damaged SST file. You can take the suggestion to clean up files and restart the TiKV instance.

14.9.1.3.21 Get the state of a Region's `RegionReadProgress`

Starting from v6.5.4 and v7.3.0, TiKV introduces the `get-region-read-progress` subcommand to get up-to-date details of the resolver and `RegionReadProgress`. You need to specify a Region ID and a TiKV, which can be obtained from Grafana (`Min Resolved TS Region` and `Min Safe TS Region`) or `DataIsNotReady` logs.

- `--log` (optional): If specified, TiKV logs the smallest `start_ts` of locks in the Region's resolver in this TiKV at `INFO` level. This option helps you identify locks that might block resolved-ts in advance.
- `--min-start-ts` (optional): If specified, TiKV filters out locks with smaller `start_ts` than this value in logs. You can use this to specify a transaction of interest for logging. It defaults to `0`, which means no filter.

The following is an example:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 14 --log --min
    ↪ -start-ts 0
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 0,
    applied_index: 92,
```

```
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
    pending back item (latest) applied index: 0,
    paused: false,
Resolver:
    exist: true,
    resolved_ts: 0,
    tracked index: 92,
    number of locks: 0,
    number of transactions: 0,
    stopped: false,
```

The subcommand is useful in diagnosing issues related to Stale Read and safe-ts. For details, see Understanding Stale Read and safe-ts in TiKV.

14.9.2 PD Control User Guide

As a command line tool of PD, PD Control obtains the state information of the cluster and tunes the cluster.

14.9.2.1 Install PD Control

> **Note:**
>
> It is recommended that the version of the Control tool you use is consistent with the version of the cluster.

14.9.2.1.1 Use TiUP command

To use PD Control, execute the `tiup ctl:v<CLUSTER_VERSION> pd -u http://<pd_ip>:<pd_port> [-i]` command.

14.9.2.1.2 Download the installation package

To obtain `pd-ctl` of the latest version, download the TiDB server installation package. `pd-ctl` is included in the `ctl-{version}-linux-{arch}.tar.gz` package.

Installation package	OS	Architecture	SHA256 checksum
https://download.pingcap.org/tidb-community-server-{version}-linux-amd64.tar.gz (pd-ctl)	Linux	amd64	https://download.pingcap.org/tidb-community-server-{version}-linux-amd64.tar.gz.sha256
https://download.pingcap.org/tidb-community-server-{version}-linux-arm64.tar.gz (pd-ctl)	Linux	arm64	https://download.pingcap.org/tidb-community-server-{version}-linux-arm64.tar.gz.sha256

Note:

`{version}` in the link indicates the version number of TiDB. For example, the download link for `v8.5.1` in the `amd64` architecture is `https://download.pingcap.org/tidb-community-server-v8.5.1-linux-amd64.tar.gz`.

14.9.2.1.3 Compile from source code

1. Go 1.23 or later is required because the Go modules are used.
2. In the root directory of the PD project, use the `make` or `make pd-ctl` command to compile and generate `bin/pd-ctl`.

14.9.2.2 Usage

Single-command mode:

```
tiup ctl:v<CLUSTER_VERSION> pd store -u http://127.0.0.1:2379
```

Interactive mode:

```
tiup ctl:v<CLUSTER_VERSION> pd -i -u http://127.0.0.1:2379
```

Use environment variables:

```
export PD_ADDR=http://127.0.0.1:2379
tiup ctl:v<CLUSTER_VERSION> pd
```

Use TLS to encrypt:

```
tiup ctl:v<CLUSTER_VERSION> pd -u https://127.0.0.1:2379 --cacert="path/to/ca" --cert="path/to/cert" --key="path/to/key"
```

14.9.2.3 Command line flags

14.9.2.3.1 `--cacert`

- Specifies the path to the certificate file of the trusted CA in PEM format
- Default: “”

14.9.2.3.2 `--cert`

- Specifies the path to the certificate of SSL in PEM format
- Default: “”

14.9.2.3.3 `--detach` / `-d`

- Uses the single command line mode (not entering readline)
- Default: true

14.9.2.3.4 `--help` / `-h`

- Outputs the help information
- Default: false

14.9.2.3.5 `--interact` / `-i`

- Uses the interactive mode (entering readline)
- Default: false

14.9.2.3.6 `--key`

- Specifies the path to the certificate key file of SSL in PEM format, which is the private key of the certificate specified by `--cert`
- Default: “”

14.9.2.3.7 `--pd` / `-u`

- Specifies the PD address
- Default address: `http://127.0.0.1:2379`
- Environment variable: `PD_ADDR`

14.9.2.3.8 `--version` / `-V`

- Prints the version information and exit
- Default: false

14.9.2.4 Command

14.9.2.4.1 `cluster`

Use this command to view the basic information of the cluster.

Usage:

```
>> cluster                                  // To show the cluster information
{
  "id": 6493707687106161130,
  "max_peer_count": 3
}
```

14.9.2.4.2 `config [show | set <option> <value> | placement-rules]`

Use this command to view or modify the configuration information.

Usage:

```
>> config show                              // Display the config information
   ↪ of the scheduling
{
  "replication": {
    "enable-placement-rules": "true",
    "isolation-level": "",
    "location-labels": "",
    "max-replicas": 3,
    "strictly-match-label": "false"
  },
  "schedule": {
    "enable-cross-table-merge": "true",
    "high-space-ratio": 0.7,
    "hot-region-cache-hits-threshold": 3,
    "hot-region-schedule-limit": 4,
    "leader-schedule-limit": 4,
    "leader-schedule-policy": "count",
    "low-space-ratio": 0.8,
    "max-merge-region-keys": 540000,
    "max-merge-region-size": 54,
    "max-pending-peer-count": 64,
```

```
    "max-snapshot-count": 64,
    "max-store-down-time": "30m0s",
    "merge-schedule-limit": 8,
    "patrol-region-interval": "10ms",
    "region-schedule-limit": 2048,
    "region-score-formula-version": "v2",
    "replica-schedule-limit": 64,
    "scheduler-max-waiting-operator": 5,
    "split-merge-interval": "1h0m0s",
    "tolerant-size-ratio": 0
  }
}
>> config show all                          // Display all config information
>> config show replication                  // Display the config information
   ↪ of replication
{
  "max-replicas": 3,
  "location-labels": "",
  "isolation-level": "",
  "strictly-match-label": "false",
  "enable-placement-rules": "true"
}

>> config show cluster-version              // Display the current version of
   ↪ the cluster, which is the current minimum version of TiKV nodes in
   ↪ the cluster and does not correspond to the binary version.
"8.5.1"
```

- `max-snapshot-count` controls the maximum number of snapshots that a single store receives or sends out at the same time. The scheduler is restricted by this configuration to avoid taking up normal application resources. When you need to improve the speed of adding replicas or balancing, increase this value.

```
config set max-snapshot-count 64 // Set the maximum number of snapshots
   ↪  to 64
```

- `max-pending-peer-count` controls the maximum number of pending peers in a single store. The scheduler is restricted by this configuration to avoid producing a large number of Regions without the latest log in some nodes. When you need to improve the speed of adding replicas or balancing, increase this value. Setting it to 0 indicates no limit.

```
config set max-pending-peer-count 64 // Set the maximum number of
   ↪ pending peers to 64
```

- `max-merge-region-size` controls the upper limit on the size of Region Merge (the unit is MiB). When `regionSize` exceeds the specified value, PD does not merge it with the adjacent Region. Setting it to 0 indicates disabling Region Merge.

```
config set max-merge-region-size 16 // Set the upper limit on the size
    ↪ of Region Merge to 16 MiB
```

- `max-merge-region-keys` controls the upper limit on the key count of Region Merge. When `regionKeyCount` exceeds the specified value, PD does not merge it with the adjacent Region.

```
config set max-merge-region-keys 50000 // Set the upper limit on
    ↪ keyCount to 50000
```

- `split-merge-interval` controls the interval between the `split` and `merge` operations on a same Region. This means the newly split Region won't be merged within a period of time.

```
config set split-merge-interval 24h // Set the interval between `split`
    ↪  and `merge` to one day
```

- `enable-one-way-merge` controls whether PD only allows a Region to merge with the next Region. When you set it to `false`, PD allows a Region to merge with the adjacent two Regions.

```
config set enable-one-way-merge true // Enables one-way merging.
```

- `enable-cross-table-merge` is used to enable the merging of cross-table Regions. When you set it to `false`, PD does not merge the Regions from different tables. This option only works when key type is "table".

```
config set enable-cross-table-merge true // Enable cross table merge.
```

- `key-type` specifies the key encoding type used for the cluster. The supported options are ["table", "raw", "txn"], and the default value is "table".

    - If no TiDB instance exists in the cluster, `key-type` will be "raw" or "txn", and PD is allowed to merge Regions across tables regardless of the `enable-cross-table-merge` setting.
    - If any TiDB instance exists in the cluster, `key-type` should be "table". Whether PD can merge Regions across tables is determined by `enable-cross-table-merge`. If `key-type` is "raw", placement rules do not work.

```
config set key-type raw // Enable cross table merge.
```

- `region-score-formula-version` controls the version of the Region score formula. The value options are `v1` and `v2`. The version 2 of the formula helps to reduce redundant balance Region scheduling in some scenarios, such as taking TiKV nodes online or offline.

```
config set region-score-formula-version v2
```

- `patrol-region-interval` controls the execution frequency that the checker inspects the health status of Regions. A shorter interval indicates a higher execution frequency. Generally, you do not need to adjust it.

```
config set patrol-region-interval 10ms // Set the execution frequency
    ↪ of the checker to 10ms
```

- `patrol-region-worker-count` controls the number of concurrent operators created by the checker when inspecting the health state of a Region. Normally, you do not need to adjust this configuration. Setting this configuration item to a value greater than 1 enables concurrent checks. Currently, this feature is experimental, and it is not recommended that you use it in the production environment.

```
config set patrol-region-worker-count 2 // Set the checker concurrency
    ↪ to 2
```

- `max-store-down-time` controls the time that PD decides the disconnected store cannot be restored if exceeded. If PD does not receive heartbeats from a store within the specified period of time, PD adds replicas in other nodes.

```
config set max-store-down-time 30m // Set the time within which PD
    ↪ receives no heartbeats and after which PD starts to add replicas
    ↪ to 30 minutes
```

- `max-store-preparing-time` controls the maximum waiting time for the store to go online. During the online stage of a store, PD can query the online progress of the store. When the specified time is exceeded, PD assumes that the store has been online and cannot query the online progress of the store again. But this does not prevent Regions from transferring to the new online store. In most scenarios, you do not need to adjust this parameter.

  The following command specifies that the maximum waiting time for the store to go online is 4 hours.

```
config set max-store-preparing-time 4h
```

- `leader-schedule-limit` controls the number of tasks scheduling the leader at the same time. This value affects the speed of leader balance. A larger value means a higher speed and setting the value to 0 closes the scheduling. Usually the leader scheduling has a small load, and you can increase the value in need.

```
config set leader-schedule-limit 4    // 4 tasks of leader scheduling
    ↪ at the same time at most
```

- `region-schedule-limit` controls the number of tasks of scheduling Regions at the same time. This value avoids too many Region balance operators being created. The default value is `2048` which is enough for all sizes of clusters, and setting the value to `0` closes the scheduling. Usually, the Region scheduling speed is limited by `store-limit`, but it is recommended that you do not customize this value unless you know exactly what you are doing.

```
config set region-schedule-limit 2    // 2 tasks of Region scheduling
    ↪ at the same time at most
```

- `replica-schedule-limit` controls the number of tasks scheduling the replica at the same time. This value affects the scheduling speed when the node is down or removed. A larger value means a higher speed and setting the value to 0 closes the scheduling. Usually the replica scheduling has a large load, so do not set a too large value. Note that this configuration item is usually kept at the default value. If you want to change the value, you need to try a few values to see which one works best according to the real situation.

```
config set replica-schedule-limit 4   // 4 tasks of replica scheduling
    ↪ at the same time at most
```

- `merge-schedule-limit` controls the number of Region Merge scheduling tasks. Setting the value to 0 closes Region Merge. Usually the Merge scheduling has a large load, so do not set a too large value. Note that this configuration item is usually kept at the default value. If you want to change the value, you need to try a few values to see which one works best according to the real situation.

```
config set merge-schedule-limit 16  // 16 tasks of Merge scheduling at
    ↪ the same time at most
```

- `hot-region-schedule-limit` controls the hot Region scheduling tasks that are running at the same time. Setting its value to `0` means disabling the scheduling. It is not recommended to set a too large value. Otherwise, it might affect the system performance. Note that this configuration item is usually kept at the default value. If you want to change the value, you need to try a few values to see which one works best according to the real situation.

```
config set hot-region-schedule-limit 4 // 4 tasks of hot Region
    ↪ scheduling at the same time at most
```

- `hot-region-cache-hits-threshold` is used to set the number of minutes required to identify a hot Region. PD can participate in the hotspot scheduling only after the Region is in the hotspot state for more than this number of minutes.

- `tolerant-size-ratio` controls the size of the balance buffer area. When the score difference between the leader or Region of the two stores is less than specified multiple times of the Region size, it is considered in balance by PD.

```
config set tolerant-size-ratio 20   // Set the size of the buffer area
    ↪ to about 20 times of the average Region Size
```

- `low-space-ratio` controls the threshold value that is considered as insufficient store space. When the ratio of the space occupied by the node exceeds the specified value, PD tries to avoid migrating data to the corresponding node as much as possible. At the same time, PD mainly schedules the remaining space to avoid using up the disk space of the corresponding node.

```
config set low-space-ratio 0.9         // Set the threshold value of
    ↪ insufficient space to 0.9
```

- `high-space-ratio` controls the threshold value that is considered as sufficient store space. This configuration takes effect only when `region-score-formula-version` is set to `v1`. When the ratio of the space occupied by the node is less than the specified value, PD ignores the remaining space and mainly schedules the actual data volume.

```
config set high-space-ratio 0.5        // Set the threshold value of
    ↪ sufficient space to 0.5
```

- `cluster-version` is the version of the cluster, which is used to enable or disable some features and to deal with the compatibility issues. By default, it is the minimum version of all normally running TiKV nodes in the cluster. You can set it manually only when you need to roll it back to an earlier version.

```
config set cluster-version 8.5.1         // Set the version of the
    ↪ cluster to 8.5.1
```

- `replication-mode` controls the replication mode of Regions in the dual data center scenario. See Enable the DR Auto-Sync mode for details.

- `leader-schedule-policy` is used to select the scheduling strategy for the leader. You can schedule the leader according to `size` or `count`.

- `scheduler-max-waiting-operator` is used to control the number of waiting operators in each scheduler.

- `enable-remove-down-replica` is used to enable the feature of automatically deleting DownReplica. When you set it to `false`, PD does not automatically clean up the downtime replicas.

- `enable-replace-offline-replica` is used to enable the feature of migrating OfflineReplica. When you set it to `false`, PD does not migrate the offline replicas.

- `enable-make-up-replica` is used to enable the feature of making up replicas. When you set it to `false`, PD does not add replicas for Regions without sufficient replicas.
- `enable-remove-extra-replica` is used to enable the feature of removing extra replicas. When you set it to `false`, PD does not remove extra replicas for Regions with redundant replicas.
- `enable-location-replacement` is used to enable the isolation level checking. When you set it to `false`, PD does not increase the isolation level of a Region replica through scheduling.
- `enable-debug-metrics` is used to enable the metrics for debugging. When you set it to `true`, PD enables some metrics such as `balance-tolerant-size`.
- `enable-placement-rules` is used to enable placement rules, which is enabled by default in v5.0 and later versions.
- `store-limit-mode` is used to control the mode of limiting the store speed. The optional modes are `auto` and `manual`. In `auto` mode, the stores are automatically balanced according to the load (deprecated).
- `store-limit-version` controls the version of the store limit formula. In v1 mode, you can manually modify the `store limit` to limit the scheduling speed of a single TiKV. In v2 mode, you do not need to manually set the `store limit` value, as PD dynamically adjusts it based on the capability of TiKV snapshots. For more details, refer to Principles of store limit v2.

```
config set store-limit-version v2  // using store limit v2
```

- PD rounds the lowest digits of the flow number, which reduces the update of statistics caused by the changes of the Region flow information. This configuration item is used to specify the number of lowest digits to round for the Region flow information. For example, the flow `100512` will be rounded to `101000` because the default value is `3`. This configuration replaces `trace-region-flow`.
- For example, set the value of `flow-round-by-digit` to `4`:

```
config set flow-round-by-digit 4
```

14.9.2.4.3 config [show | set service-middleware <option> [<key> <value> | <label> <qps|concurrency> <value>]]

`service-middleware` is a configuration module in PD, mainly used to manage and control middleware functions of PD services, such as audit logging, request rate limiting, and concurrency limiting. Starting from v8.5.0, you can modify the following configurations of `service-middleware` using `pd-ctl`:

- `audit`: controls whether to enable audit logging for HTTP requests processed by PD (enabled by default). When enabled, `service-middleware` logs information about HTTP requests in PD logs.
- `rate-limit`: limits the maximum rate and concurrency of HTTP API requests processed by PD.
- `grpc-rate-limit`: limits the maximum rate and concurrency of gRPC API requests processed by PD.

> **Note:**
>
> To avoid the impact of request rate limiting and concurrency limiting on PD performance, it is not recommended to modify configurations in `service-middleware`.

Display the configuration information of `service-middleware`:

```
config show service-middleware
```

```
{
  "audit": {
    "enable-audit": "true"
  },
  "rate-limit": {
    "enable-rate-limit": "true",
    "limiter-config": {}
  },
  "grpc-rate-limit": {
    "enable-grpc-rate-limit": "true",
    "grpc-limiter-config": {}
  }
}
```

`service-middleware audit` enables or disables the audit logging function for HTTP requests. For example, to disable this function, run the following command:

```
config set service-middleware audit enable-audit false
```

`service-middleware grpc-rate-limit` controls the maximum rate and concurrency of the following gRPC API requests:

- `GetRegion`: get information about a specified Region
- `GetStore`: get information about a specified store

- `GetMembers`: get information about PD cluster members

To control the maximum rate of gRPC API requests, such as `GetRegion` API requests, run the following command:

```
config set service-middleware grpc-rate-limit GetRegion qps 100
```

To control the maximum concurrency of gRPC API requests, such as `GetRegion` API requests, run the following command:

```
config set service-middleware grpc-rate-limit GetRegion concurrency 10
```

View the modified configuration:

```
config show service-middleware
```

```
{
  "audit": {
    "enable-audit": "true"
  },
  "rate-limit": {
    "enable-rate-limit": "true",
    "limiter-config": {}
  },
  "grpc-rate-limit": {
    "enable-grpc-rate-limit": "true",
    "grpc-limiter-config": {
      "GetRegion": {
        "QPS": 100,
        "QPSBurst": 100, // Automatically adjusted based on QPS, for display
            ↪ only
        "ConcurrencyLimit": 10
      }
    }
  }
}
```

Reset the preceding settings:

```
config set service-middleware grpc-rate-limit GetRegion qps 0
config set service-middleware grpc-rate-limit GetRegion concurrency 0
```

`service-middleware rate-limit` controls the maximum rate and concurrency of the following HTTP API requests:

- `GetRegion`: get information about a specified Region

- `GetStore`: get information about a specified store

To control the maximum rate of HTTP API requests, such as `GetRegion` API requests, run the following command:

```
config set service-middleware rate-limit GetRegion qps 100
```

To control the maximum concurrency of HTTP API requests, such as `GetRegion` API requests, run the following command:

```
config set service-middleware rate-limit GetRegion concurrency 10
```

Reset the preceding settings:

```
config set service-middleware rate-limit GetRegion qps 0
config set service-middleware rate-limit GetRegion concurrency 0
```

14.9.2.4.4 config placement-rules [disable | enable | load | save | show | rule-group]

For the usage of `config placement-rules [disable | enable | load | save | show | rule-group]`, see Configure placement rules.

14.9.2.4.5 health

Use this command to view the health information of the cluster.

Usage:

```
>> health                              // Display the health information
[
  {
    "name": "pd",
    "member_id": 13195394291058371180,
    "client_urls": [
      "http://127.0.0.1:2379"
      ......
    ],
    "health": true
  }
  ......
]
```

14.9.2.4.6 hot [read | write | store| history <start_time> <end_time> [<key> <value>]]

Use this command to view the hot spot information of the cluster.

Usage:

```
>> hot read                              // Display hot spot for the read
   ↪ operation
>> hot write                             // Display hot spot for the write
   ↪ operation
>> hot store                             // Display hot spot for all the read
   ↪ and write operations
>> hot history 1629294000000 1631980800000 // Display history hot spot for
   ↪ the specified period (milliseconds). 1629294000000 is the start time
   ↪ and 1631980800000 is the end time.
{
  "history_hot_region": [
    {
      "update_time": 1630864801948,
      "region_id": 103,
      "peer_id": 1369002,
      "store_id": 3,
      "is_leader": true,
      "is_learner": false,
      "hot_region_type": "read",
      "hot_degree": 152,
      "flow_bytes": 0,
      "key_rate": 0,
      "query_rate": 305,
      "start_key": "7480000000000000FF5300000000000000F8",
      "end_key": "7480000000000000FF5600000000000000F8"
    },
    ...
  ]
}
>> hot history 1629294000000 1631980800000 hot_region_type read region_id
   ↪ 1,2,3 store_id 1,2,3 peer_id 1,2,3 is_leader true is_learner true //
   ↪ Display history hotspot for the specified period with more conditions
{
  "history_hot_region": [
    {
      "update_time": 1630864801948,
      "region_id": 103,
      "peer_id": 1369002,
      "store_id": 3,
      "is_leader": true,
```

```
      "is_learner": false,
      "hot_region_type": "read",
      "hot_degree": 152,
      "flow_bytes": 0,
      "key_rate": 0,
      "query_rate": 305,
      "start_key": "7480000000000000FF5300000000000000F8",
      "end_key": "7480000000000000FF5600000000000000F8"
    },
    ...
  ]
}
```

14.9.2.4.7 label [store <name> <value>]

Use this command to view the label information of the cluster.

Usage:

```
>> label                              // Display all labels
>> label store zone cn                // Display all stores including the "zone
   ↪ ":"cn" label
```

14.9.2.4.8 member [delete | leader_priority | leader [show | resign | transfer <member_name>]]

Use this command to view the PD members, remove a specified member, or configure the priority of leader.

Usage:

```
>> member                             // Display the information of all members
{
  "header": {......},
  "members": [......],
  "leader": {......},
  "etcd_leader": {......},
}
>> member delete name pd2             // Delete "pd2"
Success!
>> member delete id 1319539429105371180 // Delete a node using ID
Success!
>> member leader show                 // Display the leader information
{
  "name": "pd",
  "member_id": 13155432540099656863,
```

```
  "peer_urls": [......],
  "client_urls": [......]
}
>> member leader resign // Move leader away from the current member
......
>> member leader transfer pd3 // Migrate leader to a specified member
......
```

Specify the priority of PD leader:

```
member leader_priority pd-1 4
member leader_priority pd-2 3
member leader_priority pd-3 2
member leader_priority pd-4 1
member leader_priority pd-5 0
```

Note:

In all available PD nodes, the node with the highest priority number becomes the leader.

14.9.2.4.9 `operator [check | show | add | remove]`

Use this command to view and control the scheduling operation.

Usage:

```
>> operator show                                  // Display all operators
>> operator show admin                            // Display all admin
   ↪ operators
>> operator show leader                           // Display all leader
   ↪ operators
>> operator show region                           // Display all Region
   ↪ operators
>> operator add add-peer 1 2                      // Add a replica of Region
   ↪ 1 on store 2
>> operator add add-learner 1 2                   // Add a learner replica of
   ↪  Region 1 on store 2
>> operator add remove-peer 1 2                   // Remove a replica of
   ↪ Region 1 on store 2
>> operator add transfer-leader 1 2               // Schedule the leader of
   ↪ Region 1 to store 2
>> operator add transfer-region 1 2 3 4           // Schedule Region 1 to
   ↪ stores 2,3,4
```

```
>> operator add transfer-peer 1 2 3              // Schedule the replica of
   ↪ Region 1 on store 2 to store 3
>> operator add merge-region 1 2                 // Merge Region 1 with
   ↪ Region 2
>> operator add split-region 1 --policy=approximate // Split Region 1 into
   ↪ two Regions in halves, based on approximately estimated value
>> operator add split-region 1 --policy=scan     // Split Region 1 into two
   ↪ Regions in halves, based on accurate scan value
>> operator remove 1                             // Remove the scheduling
   ↪ operation of Region 1
>> operator check 1                              // Check the status of the
   ↪ operators related to Region 1
```

The splitting of Regions starts from the position as close as possible to the middle. You can locate this position using two strategies, namely "scan" and "approximate". The difference between them is that the former determines the middle key by scanning the Region, and the latter obtains the approximate position by checking the statistics recorded in the SST file. Generally, the former is more accurate, while the latter consumes less I/O and can be completed faster.

14.9.2.4.10 `ping`

Use this command to view the time that `ping` PD takes.

Usage:

```
>> ping
time: 43.12698ms
```

14.9.2.4.11 `region <region_id> [--jq="<query string>"]`

Use this command to view the Region information. For a jq formatted output, see jq-formatted-json-output-usage.

Usage:

```
>> region                           //  Display the information of all
   ↪ Regions
{
  "count": 1,
  "regions": [......]
}

>> region 2                         // Display the information of the Region
   ↪ with the ID of 2
{
  "id": 2,
```

```
  "start_key": "7480000000000000FF1D00000000000000F8",
  "end_key": "7480000000000000FF1F00000000000000F8",
  "epoch": {
    "conf_ver": 1,
    "version": 15
  },
  "peers": [
    {
      "id": 40,
      "store_id": 3
    }
  ],
  "leader": {
    "id": 40,
    "store_id": 3
  },
  "written_bytes": 0,
  "read_bytes": 0,
  "written_keys": 0,
  "read_keys": 0,
  "approximate_size": 1,
  "approximate_keys": 0
}
```

14.9.2.4.12 region key [--format=raw|encode|hex] <key>

Use this command to query the Region that a specific key resides in. It supports the raw, encoding, and hex formats. And you need to use single quotes around the key when it is in the encoding format.

Hex format usage (default):

```
>> region key 7480000000000000FF1300000000000000F8
{
  "region": {
    "id": 2,
    ......
  }
}
```

Raw format usage:

```
>> region key --format=raw abc
{
  "region": {
    "id": 2,
```

```
    ......
  }
}
```

Encoding format usage:

```
>> region key --format=encode 't\200\000\000\000\000\000\000\377\035_r
   ↪ \200\000\000\000\000\377\017U\320\000\000\000\000\000\000\372'
{
  "region": {
    "id": 2,
    ......
  }
}
```

14.9.2.4.13 `region scan`

Use this command to get all Regions.

Usage:

```
>> region scan
{
  "count": 20,
  "regions": [......],
}
```

14.9.2.4.14 `region sibling <region_id>`

Use this command to check the adjacent Regions of a specific Region.

Usage:

```
>> region sibling 2
{
  "count": 2,
  "regions": [......],
}
```

14.9.2.4.15 `region keys [--format=raw|encode|hex] <start_key> <end_key> <limit>`

Use this command to query all Regions in a given range `[startkey, endkey)`. Ranges without `endKeys` are supported.

The `limit` parameter limits the number of keys. The default value of `limit` is `16`, and the value of `-1` means unlimited keys.

Usage:

```
>> region keys --format=raw a    // Display all Regions that start from the
   ↪  key a with a default limit count of 16
{
  "count": 16,
  "regions": [......],
}

>> region keys --format=raw a z // Display all Regions in the range [a, z)
   ↪ with a default limit count of 16
{
  "count": 16,
  "regions": [......],
}

>> region keys --format=raw a z -1 // Display all Regions in the range [a,
   ↪ z) without a limit count
{
  "count": ...,
  "regions": [......],
}

>> region keys --format=raw a "" 20 // Display all Regions that start from
   ↪ the key a with a limit count of 20
{
  "count": 20,
  "regions": [......],
}
```

14.9.2.4.16 region store <store_id>

Use this command to list all Regions of a specific store.

Usage:

```
>> region store 2
{
  "count": 10,
  "regions": [......],
}
```

14.9.2.4.17 region topread [limit]

Use this command to list Regions with top read flow. The default value of the limit is 16.

Usage:

```
>> region topread
{
  "count": 16,
  "regions": [......],
}
```

14.9.2.4.18 region topwrite [limit]

Use this command to list Regions with top write flow. The default value of the limit is 16.

Usage:

```
>> region topwrite
{
  "count": 16,
  "regions": [......],
}
```

14.9.2.4.19 region topconfver [limit]

Use this command to list Regions with top conf version. The default value of the limit is 16.

Usage:

```
>> region topconfver
{
  "count": 16,
  "regions": [......],
}
```

14.9.2.4.20 region topversion [limit]

Use this command to list Regions with top version. The default value of the limit is 16.

Usage:

```
>> region topversion
{
  "count": 16,
  "regions": [......],
}
```

14.9.2.4.21 region topsize [limit]

Use this command to list Regions with top approximate size. The default value of the limit is 16.

Usage:

```
>> region topsize
{
  "count": 16,
  "regions": [......],
}
```

14.9.2.4.22 region check [miss-peer | extra-peer | down-peer | pending-peer | offline-peer | empty-region | hist-size | hist-keys] [--jq="<query string>"]

Use this command to check the Regions in abnormal conditions. For a jq formatted output, see jq formatted JSON output usage.

Description of various types:

- miss-peer: the Region without enough replicas
- extra-peer: the Region with extra replicas
- down-peer: the Region in which some replicas are Down
- pending-peer: the Region in which some replicas are Pending

Usage:

```
>> region check miss-peer
{
  "count": 2,
  "regions": [......],
}
```

14.9.2.4.23 resource-manager [command]

View the controller configuration of Resource Control

```
resource-manager config controller show
```

```
{
    "degraded-mode-wait-duration": "0s",
    "ltb-max-wait-duration": "30s",
    "request-unit": {               # Configurations of RU. Do not modify.
        "read-base-cost": 0.125,
        "read-per-batch-base-cost": 0.5,
```

```
        "read-cost-per-byte": 0.0000152587890625,
        "write-base-cost": 1,
        "write-per-batch-base-cost": 1,
        "write-cost-per-byte": 0.0009765625,
        "read-cpu-ms-cost": 0.3333333333333333
    },
    "enable-controller-trace-log": "false"
}
```

- `ltb-max-wait-duration`: the maximum waiting time of Local Token Bucket (LTB). The default value is `30s`, and the value range is `[0, 24h]`. If the estimated Request Unit (RU) consumption of the SQL request exceeds the current accumulated RU of LTB, the request needs to wait for a certain period of time. If the estimated waiting time exceeds this maximum value, an error message `ERROR 8252 (HY000): Exceeded resource group quota limitation` is returned to the application in advance. Increasing this value can reduce the occurrence of encountering `ERROR 8252` in cases of sudden concurrency increase, large transactions, and large queries.
- `enable-controller-trace-log`: control whether to enable the controller diagnostic log.

Modify the controller configuration of Resource Control

To modify the `ltb-max-wait-duration` configuration, use the following command:

```
pd-ctl resource-manager config controller set ltb-max-wait-duration 30m
```

14.9.2.4.24 scheduler [show | add | remove | pause | resume | config | describe]

Use this command to view and control the scheduling policy.

Usage:

```
>> scheduler show                                    // Display all created schedulers
>> scheduler add grant-leader-scheduler 1           // Schedule all the leaders of the Regions on store 1 to store 1
>> scheduler add evict-leader-scheduler 1           // Move all the Region leaders on store 1 out
>> scheduler config evict-leader-scheduler          // Display the stores in which the scheduler is located since v4.0.0
>> scheduler config evict-leader-scheduler add-store 2 // Add leader eviction scheduling for store 2
>> scheduler config evict-leader-scheduler delete-store 2 // Remove leader eviction scheduling for store 2
```

```
>> scheduler add evict-slow-store-scheduler        // When there is one and
   ↪  only one slow store, evict all Region leaders of that store
>> scheduler remove grant-leader-scheduler-1       // Remove the
   ↪ corresponding scheduler, and `-1` corresponds to the store ID
>> scheduler pause balance-region-scheduler 10     // Pause the balance-
   ↪ region scheduler for 10 seconds
>> scheduler pause all 10                          // Pause all schedulers
   ↪ for 10 seconds
>> scheduler resume balance-region-scheduler       // Continue to run the
   ↪ balance-region scheduler
>> scheduler resume all                            // Continue to run all
   ↪ schedulers
>> scheduler config balance-hot-region-scheduler   // Display the
   ↪ configuration of the balance-hot-region scheduler
>> scheduler describe balance-region-scheduler     // Display the running
   ↪ state and related diagnostic information of the balance-region
   ↪ scheduler
```

14.9.2.4.25 `scheduler describe balance-region-scheduler`

Use this command to view the running state and related diagnostic information of the `balance-region-scheduler`.

Since TiDB v6.3.0, PD provides the running state and brief diagnostic information for `balance-region-scheduler` and `balance-leader-scheduler`. Other schedulers and checkers are not supported yet. To enable this feature, you can modify the `enable-diagnostic` configuration item using `pd-ctl`.

The state of the scheduler can be one of the following:

- `disabled`: the scheduler is unavailable or removed.
- `paused`: the scheduler is paused.
- `scheduling`: the scheduler is generating scheduling operators.
- `pending`: the scheduler cannot generate scheduling operators. For a scheduler in the `pending` state, brief diagnostic information is returned. The brief information describes the state of stores and explains why these stores cannot be selected for scheduling.
- `normal`: there is no need to generate scheduling operators.

14.9.2.4.26 `scheduler config balance-leader-scheduler`

Use this command to view and control the `balance-leader-scheduler` policy.

Since TiDB v6.0.0, PD introduces the `Batch` parameter for `balance-leader-scheduler` to control the speed at which the balance-leader processes tasks. To use this parameter, you can modify the `balance-leader batch` configuration item using pd-ctl.

Before v6.0.0, PD does not have this configuration item, which means `balance-leader batch=1`. In v6.0.0 or later versions, the default value of `balance-leader batch` is `4`. To set this configuration item to a value greater than `4`, you need to set a greater value for `scheduler-max-waiting-operator` (whose default value is `5`) at the same time. You can get the expected acceleration effect only after modifying both configuration items.

```
scheduler config balance-leader-scheduler set batch 3 // Set the size of
    ↪ the operator that the balance-leader scheduler can execute in a batch
    ↪  to 3
```

`scheduler config balance-hot-region-scheduler`

Use this command to view and control the `balance-hot-region-scheduler` policy.

Usage:

```
>> scheduler config balance-hot-region-scheduler // Display all
    ↪ configuration of the balance-hot-region scheduler
{
  "min-hot-byte-rate": 100,
  "min-hot-key-rate": 10,
  "min-hot-query-rate": 10,
  "max-zombie-rounds": 3,
  "max-peer-number": 1000,
  "byte-rate-rank-step-ratio": 0.05,
  "key-rate-rank-step-ratio": 0.05,
  "query-rate-rank-step-ratio": 0.05,
  "count-rank-step-ratio": 0.01,
  "great-dec-ratio": 0.95,
  "minor-dec-ratio": 0.99,
  "src-tolerance-ratio": 1.05,
  "dst-tolerance-ratio": 1.05,
  "read-priorities": [
    "query",
    "byte"
  ],
  "write-leader-priorities": [
    "key",
    "byte"
  ],
  "write-peer-priorities": [
    "byte",
    "key"
  ],
  "strict-picking-store": "true",
  "enable-for-tiflash": "true",
  "rank-formula-version": "v2"
```

```
}
```

- `min-hot-byte-rate` means the smallest number of bytes to be counted, which is usually 100.

```
scheduler config balance-hot-region-scheduler set min-hot-byte-rate 100
```

- `min-hot-key-rate` means the smallest number of keys to be counted, which is usually 10.

```
scheduler config balance-hot-region-scheduler set min-hot-key-rate 10
```

- `min-hot-query-rate` means the smallest number of queries to be counted, which is usually 10.

```
scheduler config balance-hot-region-scheduler set min-hot-query-rate 10
```

- `max-zombie-rounds` means the maximum number of heartbeats with which an operator can be considered as the pending influence. If you set it to a larger value, more operators might be included in the pending influence. Usually, you do not need to adjust its value. Pending influence refers to the operator influence that is generated during scheduling but still has an effect.

```
scheduler config balance-hot-region-scheduler set max-zombie-rounds 3
```

- `max-peer-number` means the maximum number of peers to be solved, which prevents the scheduler from being too slow.

```
scheduler config balance-hot-region-scheduler set max-peer-number 1000
```

- `byte-rate-rank-step-ratio`, `key-rate-rank-step-ratio`, `query-rate-rank-step-ratio`, and `count-rank-step-ratio` respectively mean the step ranks of byte, key, query, and count. The rank-step-ratio decides the step when the rank is calculated. `great-dec-ratio` and `minor-dec-ratio` are used to determine the `dec` rank. Usually, you do not need to modify these items.

```
scheduler config balance-hot-region-scheduler set byte-rate-rank-step-
    ↪ ratio 0.05
```

- `src-tolerance-ratio` and `dst-tolerance-ratio` are configuration items for the expectation scheduler. The smaller the `tolerance-ratio`, the easier it is for scheduling. When redundant scheduling occurs, you can appropriately increase this value.

```
scheduler config balance-hot-region-scheduler set src-tolerance-ratio
    ↪ 1.1
```

- `read-priorities`, `write-leader-priorities`, and `write-peer-priorities` control which dimension the scheduler prioritizes for hot Region scheduling. Two dimensions are supported for configuration.

    - `read-priorities` and `write-leader-priorities` control which dimensions the scheduler prioritizes for scheduling hot Regions of the read and write-leader types. The dimension options are `query`, `byte`, and `key`.
    - `write-peer-priorities` controls which dimensions the scheduler prioritizes for scheduling hot Regions of the write-peer type. The dimension options are `byte` and `key`.

> **Note:**
>
> If a cluster component is earlier than v5.2, the configuration of `query` dimension does not take effect. If some components are upgraded to v5.2 or later, the `byte` and `key` dimensions still by default have the priority for hot Region scheduling. After all components of the cluster are upgraded to v5.2 or later, such a configuration still takes effect for compatibility. You can view the real-time configuration using the `pd-ctl` command. Usually, you do not need to modify these configurations.

```
scheduler config balance-hot-region-scheduler set read-priorities query
    ↪ ,byte
```

- `strict-picking-store` controls the search space of hot Region scheduling. Usually, it is enabled. This configuration item only affects the behavior when `rank-formula-version` is `v1`. When it is enabled, hot Region scheduling ensures hot Region balance on the two configured dimensions. When it is disabled, hot Region scheduling only ensures the balance on the dimension with the first priority, which might reduce balance on other dimensions. Usually, you do not need to modify this configuration.

```
scheduler config balance-hot-region-scheduler set strict-picking-store
    ↪ true
```

- `rank-formula-version` controls which scheduler algorithm version is used in hot Region scheduling. Value options are `v1` and `v2`. The default value is `v2`.

    - The `v1` algorithm is the scheduler strategy used in TiDB v6.3.0 and earlier versions. This algorithm mainly focuses on reducing load difference between stores and avoids introducing side effects in the other dimension.
    - The `v2` algorithm is an experimental scheduler strategy introduced in TiDB v6.3.0 and is in General Availability (GA) in TiDB v6.4.0. This algorithm mainly focuses on improving the rate of the equitability between stores and factors in few side

effects. Compared with the `v1` algorithm with `strict-picking-store` being `true` ↪ , the `v2` algorithm pays more attention to the priority equalization of the first dimension. Compared with the `v1` algorithm with `strict-picking-store` being `false`, the `v2` algorithm considers the balance of the second dimension.

- The `v1` algorithm with `strict-picking-store` being `true` is conservative and scheduling can only be generated when there is a store with a high load in both dimensions. In certain scenarios, it might be impossible to continue balancing due to dimensional conflicts. To achieve better balancing in the first dimension, it is necessary to set the `strict-picking-store` to `false`. The `v2` algorithm can achieve better balancing in both dimensions and reduce invalid scheduling.

```
bash  scheduler config balance-hot-region-scheduler set rank-formula-
↪ version v2
```

- `enable-for-tiflash` controls whether hot Region scheduling takes effect for TiFlash instances. Usually, it is enabled. When it is disabled, the hot Region scheduling between TiFlash instances is not performed.

```
scheduler config balance-hot-region-scheduler set enable-for-tiflash
    ↪ true
```

14.9.2.4.27 `scheduler config evict-leader-scheduler`

Use this command to view and manage the configuration of the `evict-leader-` ↪ `scheduler`.

- When an `evict-leader-scheduler` already exists, use the `add-store` subcommand to add leader eviction scheduling for the specified store:

```
scheduler config evict-leader-scheduler add-store 2 // Add leader
    ↪ eviction scheduling for store 2
```

- When an `evict-leader-scheduler` already exists, use the `delete-store` subcommand to remove leader eviction scheduling for the specified store:

```
scheduler config evict-leader-scheduler delete-store 2 // Remove leader
    ↪  eviction scheduling for store 2
```

If all store configurations of an `evict-leader-scheduler` are removed, the scheduler itself is automatically removed.

- When an `evict-leader-scheduler` already exists, use the `set batch` subcommand to modify the `batch` value. `batch` controls the number of Operators generated during a single scheduling process. The default value is `3`, and the range is `[1, 10]`. The larger the `batch` value, the faster the scheduling speed.

```
scheduler config evict-leader-scheduler set batch 10 // Set the batch
    ↪ value to 10
```

14.9.2.4.28 `service-gc-safepoint`

Use this command to query the current GC safepoint and service GC safepoint. The output is as follows:

```
{
  "service_gc_safe_points": [
    {
      "service_id": "gc_worker",
      "expired_at": 9223372036854775807,
      "safe_point": 439923410637160448
    }
  ],
  "gc_safe_point": 0
}
```

14.9.2.4.29 `store [delete | cancel-delete | label | weight | remove-tombstone | limit ] <store_id> [--jq="<query string>"]`

For a jq formatted output, see jq-formatted-json-output-usage.

Get a store

To display the information of all stores, run the following command:

```
store
```

```
{
  "count": 3,
  "stores": [...]
}
```

To get the store with ID of 1, run the following command:

```
store 1
```

```
......
```

Delete a store

To delete the store with ID of 1, run the following command:

```
store delete 1
```

To cancel deleting `Offline` state stores which are deleted using `store delete`, run the `store cancel-delete` command. After canceling, the store changes from `Offline` to `Up`. Note that the `store cancel-delete` command cannot change a `Tombstone` state store to the `Up` state.

To cancel deleting the store with ID of 1, run the following command:

```
store cancel-delete 1
```

To delete all stores in `Tombstone` state, run the following command:

```
store remove-tombstone
```

Note:

If the PD leader changes during store deletion, you need to modify the store limit manually using the `store limit` command.

Manage store labels

To manage the labels of a store, run the `store label` command.

- To set a label with the key being `"zone"` and value being `"cn"` to the store with ID of 1, run the following command:

```
store label 1 zone=cn
```

- To update the label of a store, for example, changing the value of the key `"zone"` from `"cn"` to `"us"` for the store with ID of 1, run the following command:

```
store label 1 zone=us
```

- To rewrite all labels of a store with ID of 1, use the `--rewrite` option. Note that this option overwrites all existing labels:

```
store label 1 region=us-est-1 disk=ssd --rewrite
```

- To delete the `"disk"` label for the store with ID 1, use the `--delete` option:

```
store label 1 disk --delete
```

Note:

- The label of a store is updated by a merge strategy. After a TiKV process is restarted, the store labels in its configuration file will be merged with the store labels stored by PD, and the merged result will be persisted. During the merging process, if there are duplicate store labels

between the PD side and the TiKV configuration file, the TiKV store label configuration will overwrite the PD label. For example, if the store label for store 1 is set to `"zone=cn"` through `store label 1 zone=cn`, but TiKV's configuration file has `zone = "us"`, after TiKV restarts, the `"zone"` will be updated to `"us"`.

- To manage labels of a store using TiUP, you can run the `store label <id> --force` command to empty the labels stored in PD before restarting the cluster.

Configure store weight

To set the leader weight to `5` and Region weight to `10` for the store with ID of 1, run the following command:

```
store weight 1 5 10
```

Configure store scheduling speed

You can set the scheduling speed of stores by using `store limit`. For more details about the principles and usage of `store limit`, see store limit.

```
>> store limit                    // Show the speed limit of adding-peer
   ↪ operations and the limit of removing-peer operations per minute in
   ↪ all stores
>> store limit add-peer           // Show the speed limit of adding-peer
   ↪ operations per minute in all stores
>> store limit remove-peer        // Show the limit of removing-peer
   ↪ operations per minute in all stores
>> store limit all 5              // Set the limit of adding-peer
   ↪ operations to 5 and the limit of removing-peer operations to 5 per
   ↪ minute for all stores
>> store limit 1 5                // Set the limit of adding-peer
   ↪ operations to 5 and the limit of removing-peer operations to 5 per
   ↪ minute for store 1
>> store limit all 5 add-peer     // Set the limit of adding-peer
   ↪ operations to 5 per minute for all stores
>> store limit 1 5 add-peer       // Set the limit of adding-peer
   ↪ operations to 5 per minute for store 1
>> store limit 1 5 remove-peer    // Set the limit of removing-peer
   ↪ operations to 5 per minute for store 1
>> store limit all 5 remove-peer  // Set the limit of removing-peer
   ↪ operations to 5 per minute for all stores
```

Note:

You can use `pd-ctl` to check the state (`Up`, `Disconnect`, `Offline`, `Down`, or `Tombstone`) of a TiKV store. For the relationship between each state, see Relationship between each state of a TiKV store.

14.9.2.4.30 `log [fatal | error | warn | info | debug]`

Use this command to set the log level of the PD leader.

Usage:

```
log warn
```

14.9.2.4.31 `tso`

Use this command to parse the physical and logical time of TSO.

Usage:

```
>> tso 395181938313123110    // Parse TSO
system: 2017-10-09 05:50:59 +0800 CST
logic: 120102
```

14.9.2.4.32 `unsafe remove-failed-stores [store-ids | show]`

Warning:

- This feature is a lossy recovery, so TiKV cannot guarantee data integrity and data indexes integrity after using the feature.
- It is recommended to perform the feature-related operations with the support from the TiDB team. If any misoperation is performed, it might be hard to recover the cluster.

Use this command to perform lossy recovery operations when permanently damaged replicas cause data to be unavailable. See the following example. The details are described in Online Unsafe Recovery

Execute Online Unsafe Recovery to remove permanently damaged stores:

```
unsafe remove-failed-stores 101,102,103
```

```
Success!
```

Show the current or historical state of Online Unsafe Recovery:

```
unsafe remove-failed-stores show
```

```
[
  "Collecting cluster info from all alive stores, 10/12.",
  "Stores that have reports to PD: 1, 2, 3, ...",
  "Stores that have not reported to PD: 11, 12",
]
```

14.9.2.5 Jq formatted JSON output usage

14.9.2.5.1 Simplify the output of `store`

```
>> store --jq=".stores[].store | {id, address, state_name}"
{"id":1,"address":"127.0.0.1:20161","state_name":"Up"}
{"id":30,"address":"127.0.0.1:20162","state_name":"Up"}
...
```

14.9.2.5.2 Query the remaining space of the node

```
>> store --jq=".stores[] | {id: .store.id, available: .status.available}"
{"id":1,"available":"10 GiB"}
{"id":30,"available":"10 GiB"}
...
```

14.9.2.5.3 Query all nodes whose status is not `Up`

```
store --jq='.stores[].store | select(.state_name!="Up") | {id, address,
    ↪ state_name}'
```

```
{"id":1,"address":"127.0.0.1:20161""state_name":"Offline"}
{"id":5,"address":"127.0.0.1:20162""state_name":"Offline"}
...
```

14.9.2.5.4 Query all TiFlash nodes

```
store --jq='.stores[].store | select(.labels | length>0 and contains([{"key
    ↪ ":"engine","value":"tiflash"}])) | {id, address, state_name}'
```

```
{"id":1,"address":"127.0.0.1:20161""state_name":"Up"}
{"id":5,"address":"127.0.0.1:20162""state_name":"Up"}
...
```

14.9.2.5.5 Query the distribution status of the Region replicas

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id]}"
{"id":2,"peer_stores":[1,30,31]}
{"id":4,"peer_stores":[1,31,34]}
...
```

14.9.2.5.6 Filter Regions according to the number of replicas

For example, to filter out all Regions whose number of replicas is not 3:

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id] |
   ↪ select(length != 3)}"
{"id":12,"peer_stores":[30,32]}
{"id":2,"peer_stores":[1,30,31,32]}
```

14.9.2.5.7 Filter Regions according to the store ID of replicas

For example, to filter out all Regions that have a replica on store30:

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id] |
   ↪ select(any(.==30))}"
{"id":6,"peer_stores":[1,30,31]}
{"id":22,"peer_stores":[1,30,32]}
...
```

You can also find out all Regions that have a replica on store30 or store31 in the same way:

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id] |
   ↪ select(any(.==(30,31)))}"
{"id":16,"peer_stores":[1,30,34]}
{"id":28,"peer_stores":[1,30,32]}
{"id":12,"peer_stores":[30,32]}
...
```

14.9.2.5.8 Look for relevant Regions when restoring data

For example, when `[store1, store30, store31]` is unavailable at its downtime, you can find all Regions whose Down replicas are more than normal replicas:

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id] |
   ↪ select(length as $total | map(if .==(1,30,31) then . else empty end)
   ↪ | length>=$total-length) }"
{"id":2,"peer_stores":[1,30,31,32]}
{"id":12,"peer_stores":[30,32]}
{"id":14,"peer_stores":[1,30,32]}
...
```

Or when `[store1, store30, store31]` fails to start, you can find Regions where the data can be manually removed safely on store1. In this way, you can filter out all Regions that have a replica on store1 but don't have other DownPeers:

```
>> region --jq=".regions[] | {id: .id, peer_stores: [.peers[].store_id] |
   ↪ select(length>1 and any(.==1) and all(.!=(30,31)))}"
{"id":24,"peer_stores":[1,32,33]}
```

When `[store30, store31]` is down, find out all Regions that can be safely processed by creating the `remove-peer` Operator, that is, Regions with one and only DownPeer:

```
>> region --jq=".regions[] | {id: .id, remove_peer: [.peers[].store_id] |
   ↪ select(length>1) | map(if .==(30,31) then . else empty end) | select(
   ↪ length==1)}"
{"id":12,"remove_peer":[30]}
{"id":4,"remove_peer":[31]}
{"id":22,"remove_peer":[30]}
...
```

14.9.3 TiDB Control User Guide

TiDB Control is a command-line tool of TiDB, usually used to obtain the status information of TiDB for debugging. This document introduces the features of TiDB Control and how to use these features.

> **Note:**
>
> TiDB Control is specifically designed for debugging purposes and might not be fully compatible with future capabilities introduced in TiDB. It's not recommended to include this tool in applications or utilities development to get information.

14.9.3.1 Get TiDB Control

You can get TiDB Control by installing it using TiUP or by compiling it from source code.

> **Note:**
>
> It is recommended that the version of the Control tool you use is consistent with the version of the cluster.

14.9.3.1.1 Install TiDB Control using TiUP

After installing TiUP, you can use `tiup ctl:v<CLUSTER_VERSION> tidb` command to get and execute TiDB Control.

14.9.3.1.2 Compile from source code

- Compilation environment requirement: Go 1.23 or later
- Compilation procedures: Go to the root directory of the TiDB Control project, use the `make` command to compile, and generate `tidb-ctl`.
- Compilation documentation: you can find the help files in the `doc` directory; if the help files are lost or you want to update them, use the `make doc` command to generate the help files.

14.9.3.2 Usage introduction

This section describes how to use commands, subcommands, options, and flags in `tidb-ctl`.

- command: characters without `-` or `--`
- subcommand: characters without `-` or `--` that follow a command
- option: characters with `-` or `--`
- flag: characters exactly following a command/subcommand or option, passing value to the command/subcommand or option

Usage example: `tidb-ctl schema in mysql -n db`

- `schema`: the command
- `in`: the subcommand of `schema`
- `mysql`: the flag of `in`
- `-n`: the option
- `db`: the flag of `-n`

Currently, TiDB Control has the following subcommands:

- `tidb-ctl base64decode`: used for `BASE64` decoding
- `tidb-ctl decoder`: used for `KEY` decoding
- `tidb-ctl etcd`: used for operating etcd
- `tidb-ctl log`: used to format the log file to expand the single-line stack information
- `tidb-ctl mvcc`: used to get the MVCC information
- `tidb-ctl region`: used to get the Region information
- `tidb-ctl schema`: used to get the schema information
- `tidb-ctl table`: used to get the table information

14.9.3.2.1 Get help

Use `tidb-ctl -h/--help` to get usage information.

TiDB Control consists of multiple layers of commands. You can use `-h/--help` after each command/subcommand to get its respective usage information.

The following example shows how to obtain the schema information:

Use `tidb-ctl schema -h` to get usage details. The `schema` command itself has two subcommands: `in` and `tid`.

- `in` is used to obtain the table schema of all tables in the database through the database name.
- `tid` is used to obtain the table schema by using the unique `table_id` in the whole database.

14.9.3.2.2 Global options

`tidb-ctl` has the following connection-related global options:

- `--host`: TiDB Service address (default 127.0.0.1)
- `--port`: TiDB status port (default 10080)
- `--pdhost`: PD Service address (default 127.0.0.1)
- `--pdport`: PD Service port (default 2379)
- `--ca`: The CA file path used for the TLS connection
- `--ssl-key`: The key file path used for the TLS connection
- `--ssl-cert`: The certificate file path used for the TLS connection

`--pdhost` and `--pdport` are mainly used in the `etcd` subcommand. For example, `tidb-ctl etcd ddlinfo`. If you do not specify the address and the port, the following default value is used:

- The default service address of TiDB and PD: `127.0.0.1`. The service address must be an IP address.
- The default service port of TiDB: `10080`.
- The default service port of PD: `2379`.

14.9.3.2.3 The `schema` command

The `in` subcommand

`in` is used to obtain the table schema of all tables in the database through the database name.

```
tidb-ctl schema in <database name>
```

For example, running `tidb-ctl schema in mysql` returns the following result:

```
[
    {
        "id": 13,
        "name": {
            "O": "columns_priv",
            "L": "columns_priv"
        },
              ...
        "update_timestamp": 399494726837600268,
        "ShardRowIDBits": 0,
        "Partition": null
    }
]
```

The result is displayed in the JSON format. (The above output is truncated.)

- If you want to specify the table name, use `tidb-ctl schema in <database> -n <table name>` to filter.

  For example, `tidb-ctl schema in mysql -n db` returns the table schema of the `db` table in the `mysql` database:

  ```
  {
      "id": 9,
      "name": {
          "O": "db",
          "L": "db"
      },
      ...
      "Partition": null
  }
  ```

  (The above output is also truncated.)

  If you do not want to use the default TiDB service address and port, use the `--host` and `--port` options to configure. For example, `tidb-ctl --host 172.16.55.88 --port 8898 schema in mysql -n db`.

The `tid` subcommand

`tid` is used to obtain the table schema by using the unique `table_id` in the whole database. You can use the `in` subcommand to get all table IDs of certain schema and use the `tid` subcommand to get the detailed table information.

For example, the table ID of `mysql.stat_meta` is `21`. You can use `tidb-ctl schema tid -i 21` to obtain the detail of `mysql.stat_meta`.

```
{
 "id": 21,
 "name": {
  "O": "stats_meta",
  "L": "stats_meta"
 },
 "charset": "utf8mb4",
 "collate": "utf8mb4_bin",
  ...
}
```

Like the `in` subcommand, if you do not want to use the default TiDB service address and status port, use the `--host` and `--port` options to specify the host and port.

The `base64decode` command

`base64decode` is used to decode `base64` data.

```
tidb-ctl base64decode [base64_data]
tidb-ctl base64decode [db_name.table_name] [base64_data]
tidb-ctl base64decode [table_id] [base64_data]
```

1. Execute the following SQL statement to prepare the environment:

```
use test;
create table t (a int, b varchar(20),c datetime default current_
    ↪ timestamp , d timestamp default current_timestamp, unique index(
    ↪ a));
insert into t (a,b,c) values(1,"哈哈 hello",NULL);
alter table t add column e varchar(20);
```

2. Obtain MVCC data using the HTTP API interface:

```
$ curl "http://$IP:10080/mvcc/index/test/t/a/1?a=1"
{
 "info": {
  "writes": [
   {
    "start_ts": 407306449994645510,
```

```
    "commit_ts": 407306449994645513,
    "short_value": "AAAAAAAAAAE=" # The unique index a stores the
       ↪ handle id of the corresponding row.
   }
  ]
 }
}%

$ curl "http://$IP:10080/mvcc/key/test/t/1"
{
 "info": {
  "writes": [
   {
    "start_ts": 407306588892692486,
    "commit_ts": 407306588892692489,
    "short_value": "CAIIAggEAhjlk4jlk4ggaGVsbG8IBgAICAmAgIDwjYuu0Rk=" #
       ↪  Row data that handle id is 1.
   }
  ]
 }
}%
```

3. Decode `handle id (uint64)using `base64decode``.

```
$ tidb-ctl base64decode AAAAAAAAAAE=
hex: 0000000000000001
uint64: 1
```

4. Decode row data using `base64decode`.

```
$ ./tidb-ctl base64decode test.t
   ↪ CAIIAggEAhjlk4jlk4ggaGVsbG8IBgAICAmAgIDwjYuu0Rk=
a:     1
b:     哈哈 hello
c is NULL
d:     2019-03-28 05:35:30
e not found in data

# if the table id of test.t is 60, you can also use below command to do
   ↪  the same thing.
$ ./tidb-ctl base64decode 60
   ↪ CAIIAggEAhjlk4jlk4ggaGVsbG8IBgAICAmAgIDwjYuu0Rk=
a:     1
b:     哈哈 hello
c is NULL
```

```
d:     2019-03-28 05:35:30
e not found in data
```

14.9.3.2.4 The `decoder` command

- The following example shows how to decode the row key, similar to decoding the index key.

```
$ ./tidb-ctl decoder "t\x00\x00\x00\x00\x00\x00\x00\x1c_r\x00\x00\x00\
   ↪ x00\x00\x00\x00\xfa"
format: table_row
table_id: -9223372036854775780  table_id: -9223372036854775780
row_id: -9223372036854775558    row_id: -9223372036854775558
```

- The following example shows how to decode `value`.

```
$ ./tidb-ctl decoder AhZoZWxsbyB3b3JsZAiAEA==
format: index_value
type: bigint, value: 1024   index_value[0]: {type: bytes, value: hello
   ↪ world}
index_value[1]: {type: bigint, value: 1024}
```

14.9.3.2.5 The `etcd` command

- `tidb-ctl etcd ddlinfo` is used to obtain DDL information.
- `tidb-ctl etcd putkey KEY VALUE` is used to add KEY VALUE to etcd (All the KEYs are added to the `/tidb/ddl/all_schema_versions/` directory).

```
tidb-ctl etcd putkey "foo" "bar"
```

  In fact, a key-value pair is added to the etcd whose KEY is `/tidb/ddl/all_schema_` ↪ `versions/foo` and VALUE is `bar`.

- `tidb-ctl etcd delkey` deletes the KEY in etcd. Only those KEYs with the `/tidb/` ↪ `ddl/fg/owner/` or `/tidb/ddl/all_schema_versions/` prefix can be deleted.

```
tidb-ctl etcd delkey "/tidb/ddl/fg/owner/foo"
tidb-ctl etcd delkey "/tidb/ddl/all_schema_versions/bar"
```

14.9.3.2.6 The `log` command

The stack information for the TiDB error log is in one line format. You could use `tidb-ctl log` to change its format to multiple lines.

14.9.3.2.7 The `keyrange` command

The `keyrange` subcommand is used to query the global or table-related key range information, which is output in the hexadecimal form.

- Execute the `tidb-ctl keyrange` command to check the global key range information:

```
tidb-ctl keyrange
```

```
global ranges:
  meta: (6d, 6e)
  table: (74, 75)
```

- Add the `--encode` option to display encoded keys (in the same format as in TiKV and PD):

```
tidb-ctl keyrange --encode
```

```
global ranges:
  meta: (6d00000000000000f8, 6e00000000000000f8)
  table: (7400000000000000f8, 7500000000000000f8)
```

- Execute the `tidb-ctl keyrange --database={db} --table={tbl}` command to check the global and table-related key range information:

```
tidb-ctl keyrange --database test --table ttt
```

```
global ranges:
  meta: (6d, 6e)
  table: (74, 75)
table ttt ranges: (NOTE: key range might be changed after DDL)
  table: (748000000000002f, 748000000000000030)
  table indexes: (74800000000000002f5f69, 74800000000000002f5f72)
    index c2: (74800000000000002f5f698000000000000001,
       ↪ 74800000000000002f5f698000000000000002)
    index c3: (74800000000000002f5f698000000000000002,
       ↪ 74800000000000002f5f698000000000000003)
    index c4: (74800000000000002f5f698000000000000003,
       ↪ 74800000000000002f5f698000000000000004)
  table rows: (74800000000000002f5f72, 748000000000000030)
```

14.9.4 PD Recover User Guide

PD Recover is a disaster recovery tool of PD, used to recover the PD cluster which cannot start or provide services normally.

14.9.4.1 Compile from source code

- Go 1.23 or later is required because the Go modules are used.
- In the root directory of the PD project, use the `make pd-recover` command to compile and generate `bin/pd-recover`.

> **Note:**
>
> Generally, you do not need to compile source code because the PD Control tool already exists in the released binary or Docker. However, developer users can refer to the instructions above for compiling source code.

14.9.4.2 Download TiDB Toolkit

The PD Recover installation package is included in the TiDB Toolkit. To download the TiDB Toolkit, see Download TiDB Tools.

The following sections introduce two methods to recover a PD cluster: recover from a surviving PD node and rebuild a PD cluster entirely.

14.9.4.3 Method 1: Recover a PD cluster using a surviving PD node

When a majority of PD nodes in a cluster experience an unrecoverable error, the cluster becomes unable to provide services. If there are any surviving PD nodes, you can recover the service by selecting a surviving PD node and forcibly modifying the members of the Raft Group. The steps are as follows:

14.9.4.3.1 Step 1: Stop all nodes

To prevent data corruption or other unrecoverable errors caused by interactions with PD parameters during the recovery process, stop the TiDB, TiKV, and TiFlash processes in the cluster.

14.9.4.3.2 Step 2: Start the surviving PD node

Start the surviving PD node using the `--force-new-cluster` startup parameter. The following is an example:

```
./bin/pd-server --force-new-cluster --name=pd-127.0.0.10-2379 --client-urls=
    ↪ http://0.0.0.0:2379 --advertise-client-urls=http://127.0.0.1:2379 --
    ↪ peer-urls=http://0.0.0.0:2380 --advertise-peer-urls=http
    ↪ ://127.0.0.1:2380 --config=conf/pd.toml
```

14.9.4.3.3 Step 3: Repair metadata using `pd-recover`

Since this method relies on a minority PD node to recover the service, the node might contain outdated data. If the `alloc_id` and `tso` data roll back, the cluster data might be corrupted or unavailable. To prevent this, you need to use `pd-recover` to modify the metadata to ensure that the node can provide correct allocation IDs and TSO services. The following is an example:

```
./bin/pd-recover --from-old-member --endpoints=http://127.0.0.1:2379 #
    ↪ Specify the corresponding PD address
```

> **Note:**
>
> In this step, the `alloc_id` in the storage automatically increases by a safe value of `100000000`. As a result, the subsequent cluster will allocate larger IDs.
>
> Additionally, `pd-recover` does not modify the TSO. Therefore, before performing this step, make sure that the local time is later than the time when the failure occurs, and verify that the NTP clock synchronization service is enabled between the PD components before the failure. If it is not enabled, you need to adjust the local clock to a future time to prevent the TSO from rolling back.

14.9.4.3.4 Step 4: Restart the PD node

Once you see the prompt message `recovery is successful`, restart the PD node.

14.9.4.3.5 Step 5: Scale out PD and start the cluster

Scale out the PD cluster using the deployment tool and start the other components in the cluster. At this point, the PD service is available.

14.9.4.4 Method 2: Entirely rebuild a PD cluster

This method is applicable to scenarios in which all PD data is lost, but the data of other components, such as TiDB, TiKV, and TiFlash, still exists.

14.9.4.4.1 Step 1: Get cluster ID

The cluster ID can be obtained from the log of PD, TiKV, or TiDB. To get the cluster ID, you can view the log directly on the server.

Get cluster ID from PD log (recommended)

To get the cluster ID from the PD log, run the following command:

```
grep "init cluster id" {{/path/to}}/pd.log
```

```
[2019/10/14 10:35:38.880 +00:00] [INFO] [server.go:212] ["init cluster id"]
    ↪ [cluster-id=6747551640615446306]
...
```

Get cluster ID from TiDB log

To get the cluster ID from the TiDB log, run the following command:

```
grep "init cluster id" {{/path/to}}/tidb.log
```

```
2019/10/14 19:23:04.688 client.go:161: [info] [pd] init cluster id
    ↪ 6747551640615446306
...
```

Get cluster ID from TiKV log

To get the cluster ID from the TiKV log, run the following command:

```
grep "connect to PD cluster" {{/path/to}}/tikv.log
```

```
[2019/10/14 07:06:35.278 +00:00] [INFO] [tikv-server.rs:464] ["connect to PD
    ↪  cluster 6747551640615446306"]
...
```

14.9.4.4.2 Step 2: Get allocated ID

The allocated ID value you specify must be larger than the currently largest allocated ID value. To get allocated ID, you can either get it from the monitor, or view the log directly on the server.

Get allocated ID from the monitor (recommended)

To get allocated ID from the monitor, you need to make sure that the metrics you are viewing are the metrics of **the last PD leader**, and you can get the largest allocated ID from the **Current ID allocation** panel in PD dashboard.

Get allocated ID from PD log

To get the allocated ID from the PD log, you need to make sure that the log you are viewing is the log of **the last PD leader**, and you can get the maximum allocated ID by running the following command:

```
grep "idAllocator allocates a new id" {{/path/to}}/pd*.log | awk -F'=' '{
    ↪ print $2}' | awk -F']' '{print $1}' | sort -r -n | head -n 1
```

```
4000
...
```

Or you can simply run the above command in all PD servers to find the largest one.

14.9.4.4.3 Step 3: Deploy a new PD cluster

Before deploying a new PD cluster, you need to stop the existing PD cluster and then delete the previous data directory or specify a new data directory using `--data-dir`.

14.9.4.4.4 Step 4: Use pd-recover

You only need to run `pd-recover` on one PD node. Note that to avoid reallocation, it is recommended to set the `-alloc-id` parameter to a value larger than the allocated ID. For example, if the maximum allocated ID obtained from monitoring or logs is `9000`, it is recommended to pass `10000` or a larger value to the `-alloc-id` parameter.

```
./pd-recover -endpoints http://10.0.1.13:2379 -cluster-id
    ↪ 6747551640615446306 -alloc-id 10000
```

14.9.4.4.5 Step 5: Restart the whole cluster

When you see the prompted information that the recovery is successful, restart the whole cluster.

14.9.4.5 FAQ

14.9.4.5.1 Multiple cluster IDs are found when getting the cluster ID

When a PD cluster is created, a new cluster ID is generated. You can determine the cluster ID of the old cluster by viewing the log.

14.9.4.5.2 The error `dial tcp 10.0.1.13:2379: connect: connection refused` is returned when executing `pd-recover`

The PD service is required when you execute `pd-recover`. Deploy and start the PD cluster before you use PD Recover.

14.10 Command Line Flags

14.10.1 Configuration Options

When you start the TiDB cluster, you can use command-line options or environment variables to configure it. This document introduces TiDB's command options. The default TiDB ports are `4000` for client requests and `10080` for status report.

14.10.1.1 `--advertise-address`

- The IP address through which to log into the TiDB server
- Default: `""`
- This address must be accessible by the rest of the TiDB cluster and the user.

14.10.1.2 `--config`

- The configuration file
- Default: `""`
- If you have specified the configuration file, TiDB reads the configuration file. If the corresponding configuration also exists in the command line options, TiDB uses the configuration in the command line options to overwrite that in the configuration file. For detailed configuration information, see TiDB Configuration File Description.

14.10.1.3 `--config-check`

- Checks the validity of the configuration file and exits
- Default: `false`

14.10.1.4 `--config-strict`

- Enforces the validity of the configuration file
- Default: `false`

14.10.1.5 `--cors`

- Specifies the `Access-Control-Allow-Origin` value for Cross-Origin Request Sharing (CORS) request of the TiDB HTTP status service
- Default: `""`

14.10.1.6 `--host`

- The host address that the TiDB server monitors
- Default: `"0.0.0.0"`
- The TiDB server monitors this address.
- The `"0.0.0.0"` address monitors all network cards by default. If you have multiple network cards, specify the network card that provides service, such as `192.168.100.113`.

14.10.1.7 `--initialize-insecure`

- Bootstraps tidb-server in insecure mode
- Default: `true`

14.10.1.8 `--initialize-secure`

- Bootstraps tidb-server in secure mode
- Default: `false`

14.10.1.9 `--initialize-sql-file`

- The SQL script to be executed when the TiDB cluster is started for the first time. For details, see configuration item `initialize-sql-file`
- Default: `""`

14.10.1.10 `-L`

- The log level
- Default: `"info"`
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`

14.10.1.11 `--lease`

- The duration of the schema lease. It is **dangerous** to change the value unless you know what you do.
- Default: `45s`

14.10.1.12 `--log-file`

- The log file
- Default: `""`
- If this option is not set, logs are output to "stderr". If this option is set, logs are output to the corresponding file.

14.10.1.13 `--log-general`

- The filename of the General Log
- Default: `""`
- If this option is not set, the general log is written to the file specified by `--log-file` by default.

14.10.1.14 `--log-slow-query`

- The directory for the slow query log
- Default: `""`
- If this option is not set, logs are output to the file specified by `--log-file` by default.

14.10.1.15 `--metrics-addr`

- The Prometheus Pushgateway address
- Default: `""`
- Leaving it empty stops the Prometheus client from pushing.
- The format is `--metrics-addr=192.168.100.115:9091`.

14.10.1.16 `--metrics-interval`

- The Prometheus client push interval in seconds
- Default: `15s`
- Setting the value to 0 stops the Prometheus client from pushing.

14.10.1.17 `-P`

- The monitoring port of TiDB services
- Default: `"4000"`
- The TiDB server accepts MySQL client requests from this port.

14.10.1.18 `--path`

- The path to the data directory for local storage engine like "unistore"
- For `--store = tikv`, you must specify the path; for `--store = unistore`, the default value is used if you do not specify the path.
- For the distributed storage engine like TiKV, `--path` specifies the actual PD address. Assuming that you deploy the PD server on 192.168.100.113:2379, 192.168.100.114:2379 and 192.168.100.115:2379, the value of `--path` is "192.168.100.113:2379, 192.168.100.114:2379, 192.168.100.115:2379".
- Default: `"/tmp/tidb"`
- You can use `tidb-server --store=unistore --path=""` to enable a pure in-memory TiDB.

14.10.1.19 `--proxy-protocol-fallbackable`

- Controls whether to enable PROXY protocol fallback mode. When this parameter is set to `true`, TiDB accepts client connections that belong to `--proxy-protocol-networks` without using the PROXY protocol specification or without sending a PROXY protocol header. By default, TiDB only accepts client connections that belong to `--proxy-protocol-networks` and send a PROXY protocol header.
- Default value: `false`

14.10.1.20 `--proxy-protocol-networks`

- The list of proxy server's IP addresses allowed to connect to TiDB using the PROXY protocol.
- Default: `""`
- In general cases, when you access TiDB behind a reverse proxy, TiDB takes the IP address of the reverse proxy server as the IP address of the client. By enabling the PROXY protocol, reverse proxies that support this protocol such as HAProxy can pass the real client IP address to TiDB.

- After configuring this flag, TiDB allows the configured source IP address to connect to TiDB using the PROXY protocol; if a protocol other than PROXY is used, this connection will be denied; other addresses are allowed to connect to TiDB without the PROXY protocol. If this flag is left empty, no IP address can connect to TiDB using the PROXY protocol. The value can be the IP address (192.168.1.50) or CIDR (192.168.1.0/24) with `,` as the separator. `*` means any IP addresses.

> **Warning:**
>
> Use `*` with caution because it might introduce security risks by allowing a client of any IP address to report its IP address. In addition, using `*` ↪ might also cause the internal component that directly connects to TiDB (such as TiDB Dashboard) to be unavailable unless `--proxy-protocol-` ↪ `fallbackable` is set to `true`.

> **Note:**
>
> To use an AWS Network Load Balancer (NLB) with the PROXY protocol enabled, you need to configure the `target group` property of NLB. Specifically, set `proxy_protocol_v2.client_to_server.header_place` to `on_first_ack`. At the same time, you need to submit a ticket to AWS Support. Note that after the PROXY protocol is enabled, the client will fail to obtain handshake packets from the server and the packets are blocked until the client times out. This is because NLB sends proxy packets only after the client sends data. However, before the client sends any data packets, data packets sent by the server are dropped in the internal network.

14.10.1.21 `--proxy-protocol-header-timeout`

- Timeout for the PROXY protocol header read
- Default: `5` (seconds)

> **Warning:**
>
> Since v6.3.0, this parameter is deprecated. It is no longer used because the PROXY protocol header will be read upon the first time network data is read. Deprecating this parameter avoids affecting the timeout set when network data is read for the first time.

Note:

Do not set the value to `0`. Use the default value except for special situations.

14.10.1.22 `--report-status`

- Enables (`true`) or disables (`false`) the status report and pprof tool
- Default: `true`
- When set to `true`, this parameter enables metrics and pprof. When set to `false`, this parameter disables metrics and pprof.

14.10.1.23 `--run-ddl`

- To see whether the `tidb-server` runs DDL statements, and set when the number of `tidb-server` is over two in the cluster
- Default: `true`
- The value can be (true) or (false). (true) indicates the `tidb-server` runs DDL itself. (false) indicates the `tidb-server` does not run DDL itself.

14.10.1.24 `--socket string`

- The TiDB services use the unix socket file for external connections.
- Default: `""`
- Use `/tmp/tidb.sock` to open the unix socket file.

14.10.1.25 `--status`

- The status report port for TiDB server
- Default: `"10080"`
- This port is used to get server internal data. The data includes Prometheus metrics and pprof.
- Prometheus metrics can be accessed by `"http://host:status_port/metrics"`.
- pprof data can be accessed by `"http://host:status_port/debug/pprof"`.

14.10.1.26 `--status-host`

- The `HOST` used to monitor the status of TiDB service
- Default: `0.0.0.0`

14.10.1.27 `--store`

- Specifies the storage engine used by TiDB in the bottom layer
- Default: `"unistore"`
- You can choose "unistore" or "tikv". ("unistore" is the local storage engine; "tikv" is a distributed storage engine)

14.10.1.28 `--temp-dir`

- The temporary directory of TiDB
- Default: `"/tmp/tidb"`

14.10.1.29 `--tidb-service-scope`

- Specifies the initial value of `tidb_service_scope` for the current TiDB instance.
- Default: `""`

14.10.1.30 `--token-limit`

- The number of sessions allowed to run concurrently in TiDB. It is used for traffic control.
- Default: `1000`
- If the number of the concurrent sessions is larger than `token-limit`, the request is blocked and waiting for the operations which have been finished to release tokens.

14.10.1.31 `-V`

- Outputs the version of TiDB
- Default: `""`

14.10.1.32 `--plugin-dir`

- The storage directory for plugins.
- Default: `"/data/deploy/plugin"`

14.10.1.33 `--plugin-load`

- The names of the plugins to be loaded, each separated by a comma.
- Default: `""`

14.10.1.34 `--affinity-cpus`

- Sets the CPU affinity of TiDB servers, which is separated by commas. For example, "1,2,3".
- Default: `""`

14.10.1.35 `--redact`

- Determines whether the TiDB server desensitizes log files when using the subcommand `collect-log`.
- Default: false
- When the value is `true`, it is a masking operation, and all fields wrapped in `<` `>` mark symbols are replaced with `?`. When the value is `false`, it is a restore operation, and all mark symbols are removed. To use this feature, execute `./tidb-server --redact =xxx collect-log <input> <output>` to desensitize or restore the TiDB server log file specified by `<input>` and output it to `<output>`. For more information, see the system variable tidb_redact_log.

14.10.1.36 `--repair-mode`

- Determines whether to enable the repair mode, which is only used in the data repair scenario.
- Default: `false`

14.10.1.37 `--repair-list`

- The names of the tables to be repaired in the repair mode.
- Default: `""`

14.10.2 TiKV Configuration Flags

TiKV supports some readable unit conversions for command line parameters.

- File size (based on byte): KB, MB, GB, TB, PB (or lowercase)
- Time (based on ms): ms, s, m, h

14.10.2.1 `-A, --addr`

- The address that the TiKV server monitors
- Default: `"127.0.0.1:20160"`
- To deploy a cluster, you must use `--addr` to specify the IP address of the current host, such as `"192.168.100.113:20160"`. If the cluster is run on Docker, specify the IP address of Docker as `"0.0.0.0:20160"`.

14.10.2.2 `--advertise-addr`

- The server advertise address for client traffic from outside
- Default: `${addr}`
- If the client cannot connect to TiKV through the `--addr` address because of Docker or NAT network, you must manually set the `--advertise-addr` address.
- For example, the internal IP address of Docker is 172.17.0.1, while the IP address of the host is 192.168.100.113 and the port mapping is set to `-p 20160:20160`. In this case, you can set `--advertise-addr` to "192.168.100.113:20160". The client can find this service through 192.168.100.113:20160.

14.10.2.3 `--status-addr`

- The port through which the TiKV service status is listened
- Default: `"20180"`
- The Prometheus can access this status information via `http://host:status_port/metrics`.
- The Profile can access this status information via `http://host:status_port/debug/pprof/profile`.

14.10.2.4 `--advertise-status-addr`

- The address through which TiKV accesses service status from outside.
- Default: The value of `--status-addr` is used.
- If the client cannot connect to TiKV through the `--status-addr` address because of Docker or NAT network, you must manually set the `--advertise-status-addr` address.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 20180:20180`. In this case, set `--advertise-status-addr="192.168.100.113:20180"`. The client can find this service through `192.168.100.113:20180`.

14.10.2.5 `-C, --config`

- The config file
- Default: `""`
- If you set the configuration using the command line, the same setting in the config file will be overwritten.

14.10.2.6 `--capacity`

- The store capacity
- Default: `0` (unlimited)
- PD uses this flag to determine how to balance the TiKV servers. (Tip: you can use 10GB instead of 1073741824)

14.10.2.7 `--config-info <FORMAT>`

- When this flag is used, available configuration values are listed according to `FORMAT` and then exit.
- Value option for `FORMAT`: `json`. Currently, only JSON format is supported.
- Only the configuration name (Name), default value (DefaultValue) and current value (ValueInFile) are listed in the output JSON. If the `-C` or `--config` is specified, the current value and the default value of configuration items in the file are listed together, and other items without `-C` or `--config` specified only have default values. The following is an example:

```
{
"Component": "TiKV Server",
"Version": "6.2.0",
"Parameters": [
    {
    "Name": "log-level",
    "DefaultValue": "info",
    "ValueInFile": "warn"
    },
    {
    "Name": "log-file",
    "DefaultValue": ""
    },
    ...
]
}
```

14.10.2.8 `--data-dir`

- The path to the data directory
- Default: `"/tmp/tikv/store"`

14.10.2.9 `-L`

- The log level
- Default: `"info"`
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`

14.10.2.10 `--log-file`

- The log file
- Default: `""`
- If this flag is not set, logs will be written to "stderr". If this flag is set, logs are output to the corresponding file.

14.10.2.11 `--pd`

- The address list of PD servers
- Default: `""`
- To make TiKV work, you must use the value of `--pd` to connect the TiKV server to the PD server. Separate multiple PD addresses using comma, for example "192.168.100.113:2379, 192.168.100.114:2379, 192.168.100.115:2379".

14.10.3 TiFlash Command-Line Flags

This document introduces the command-line flags that you can use when you launch TiFlash.

14.10.3.1 `server --config-file`

- Specifies the path of the TiFlash configuration file
- Default: ""
- You must specify the configuration file. For detailed configuration items, refer to TiFlash configuration parameters.

14.10.3.2 `dttool migrate`

- Migrates the file format of DTFile (for testing or downgrading). Data is migrated in the unit of a single DTFile. If you want to migrate the whole table, you need to locate all the paths similar to `<data dir>/t_<table id>/stable/dmf_<file id>` and migrate them one by one. You can use scripts to automate the migration.
- User scenarios:
  - If you need to downgrade TiFlash from a version >= v5.4.0 that has enabled data validation to a version < v5.4.0, you can use this tool to downgrade the data format of the DTFile.
  - If you upgrade TiFlash to a version >= v5.4.0, and if you hope to enable data validation for existing data, you can use this tool to upgrade the data format of the DTFile.
  - Test the space usage and read speed of the DTFile in different configurations.

  - If you need to downgrade TiFlash from a version >= v7.3.0 that has enabled small file merging (that is, `storage.format_version` >= 5) to a version < v7.3.0, you can use this tool to downgrade the data format of the DTFile.

- Parameters:

  - `--imitative`: When you do not use the encryption feature of the DTFile, you can use this flag to avoid using the configuration file and connecting to PD.
  - `--version`: The target version of DTFile. The value options are `1`, `2` (default), and `3`. `1` is the old version, `2` is the version corresponding to the new checksum, and `3` is the version that supports merging small files.
  - `--algorithm`: The hash algorithm used for data validation. The value options are `xxh3` (default), `city128`, `crc32`, `crc64`, and `none`. This parameter is effective only when `version` is `2`.
  - `--frame`: The size of the validation frame. The default value is `1048576`. This parameter is effective only when `version` is `2`.
  - `--compression`: The target compression algorithm. The value options are `LZ4` (default), `LZ4HC`, `zstd`, and `none`.
  - `--level`: The target compression level. If not specified, the recommended compression level is used by default according to the compression algorithm. If `compression` is set to `LZ4` or `zstd`, the default level is 1. If `compression` is set to `LZ4HC`, the default level is 9.
  - `--config-file`: The configuration file of `dttool migrate` is the same as the configuration file of `server`. For more information, see `--imitative`.
  - `--file-id`: The ID of the DTFile. For example, the ID of the DTFile `dmf_123` is `123`.
  - `--workdir`: The parent directory of `dmf_xxx`.
  - `--dry`: The dry run mode. Only the migration process is output.
  - `--nokeep`: Does not keep the original data. When this option is not enabled, `dmf_xxx.old` files are created.

Warning:

TiFlash can read DTFile that uses custom compression algorithms and compression levels. However, only the `lz4` algorithm with the default compression level is officially supported. Custom compression parameters have not been thoroughly tested and are only experimental.

Note:

For security reasons, DTTool attempts to add a lock to the working directory in the migration mode. Therefore, in the same directory, only one DTTool can perform the migration task at the same time. If you forcibly stop DTTool where the lock is not released, then when you try to rerun DTTool later, it might refuse to perform the migration task.

If you encounter this situation, and if you are aware that removing the LOCK file does not cause any data corruption, you can manually delete the LOCK file in the working directory to release the lock.

14.10.3.3 `dttool bench`

- Provides a basic I/O speed test for the DTFile.
- Parameters:
  - `--version`: The version of DTFile. See `--version` in `dttool migrate`.
  - `--algorithm`: The hash algorithm used for data validation. See `--algorithm` in `dttool migrate`.
  - `--frame`: The size of the validation frame. See `--frame` in `dttool migrate`.
  - `--column`: The columns of the table to be tested. The default value is `100`.
  - `--size`: The rows of the table to be tested. The default value is `1000`.
  - `--field`: The field length limit of the table to be tested. The default value is `1024`.
  - `--random`: The random seed. If you do not specify this parameter, the random seed is drawn from the system entropy pool.
  - `--encryption`: Enables the encryption feature.
  - `--repeat`: The number of times to repeat the test. The default value is `5`.
  - `--workdir`: The temporary data directory, which points to a path in the file system to be tested. The default value is `/tmp/test`.

14.10.3.4 `dttool inspect`

- Checks the integrity of the DTFile. Data validation is performed in the unit of a single DTFile. If you want to validate the whole table, you need to locate all the paths similar to `<data dir>/t_<table id>/stable/dmf_<file id>` and validate them one by one. You can use scripts to automate the validation.
- User scenarios:
  - After you perform a format upgrade or downgrade, you can validate the data integrity of the DTFile.

    - After you migrate the DTFile to a new environment, you can validate the data integrity of the DTFile.

- Parameters:

    - `--config-file`: The configuration file of `dttool bench`. See `--config-file` in `dttool migrate`.
    - `--check`: Performs hash validation.
    - `--file-id`: The ID of the DTFile. See `--file-id` in `dttool migrate`.
    - `--imitative`: Imitates the database context. See `--imitative` in `dttool migrate`.
    - `--workdir`: The data directory. See `--workdir` in `dttool migrate`.

14.10.4 PD Configuration Flags

PD is configurable using command-line flags and environment variables.

14.10.4.1 `--advertise-client-urls`

- The list of advertise URLs for the client to access PD
- Default: `"${client-urls}"`
- In some situations such as in the Docker or NAT network environment, if a client cannot access PD through the default client URLs listened to by PD, you must manually set the advertise client URLs.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 2379:2379`. In this case, you can set `--advertise-client-urls` to `"http://192.168.100.113:2379"`. The client can find this service through `"http://192.168.100.113:2379"`.

14.10.4.2 `--advertise-peer-urls`

- The list of advertise URLs for other PD nodes (peers) to access a PD node
- Default: `"${peer-urls}"`
- In some situations such as in the Docker or NAT network environment, if the other nodes (peers) cannot access the PD node through the default peer URLs listened to by this PD node, you must manually set the advertise peer URLs.
- For example, the internal IP address of Docker is `172.17.0.1`, while the IP address of the host is `192.168.100.113` and the port mapping is set to `-p 2380:2380`. In this case, you can set `--advertise-peer-urls` to `"http://192.168.100.113:2380"`. The other PD nodes can find this service through `"http://192.168.100.113:2380"`.

14.10.4.3 `--client-urls`

- The list of client URLs to be listened to by PD
- Default: `"http://127.0.0.1:2379"`
- When you deploy a cluster, you must specify the IP address of the current host as `--client-urls` (for example, `"http://192.168.100.113:2379"`). If the cluster runs on Docker, specify the IP address of Docker as `"http://0.0.0.0:2379"`.

14.10.4.4 `--peer-urls`

- The list of peer URLs to be listened to by a PD node
- Default: `"http://127.0.0.1:2380"`
- When you deploy a cluster, you must specify `--peer-urls` as the IP address of the current host, such as `"http://192.168.100.113:2380"`. If the cluster runs on Docker, specify the IP address of Docker as `"http://0.0.0.0:2380"`.

14.10.4.5 `--config`

- The configuration file
- Default: `""`
- If you set the configuration using the command line, the same setting in the configuration file will be overwritten.

14.10.4.6 `--data-dir`

- The path to the data directory
- Default: `"default.${name}"`

14.10.4.7 `--initial-cluster`

- The initial cluster configuration for bootstrapping
- Default: `"{name}=http://{advertise-peer-url}"`
- For example, if `name` is "pd", and `advertise-peer-urls` is `"http://192.168.100.113:2380"` ↪ , the `initial-cluster` is `"pd=http://192.168.100.113:2380"`.
- If you need to start three PD servers, the `initial-cluster` might be:

```
pd1=http://192.168.100.113:2380, pd2=http://192.168.100.114:2380, pd3
    ↪ =192.168.100.115:2380
```

14.10.4.8 `--join`

- Join the cluster dynamically
- Default: `""`
- If you want to join an existing cluster, you can use `--join="${advertise-client-urls}"`, the `advertise-client-url` is any existing PD's, multiply advertise client urls are separated by comma.

14.10.4.9 `-L`

- The log level
- Default: `"info"`
- Optional values: `"debug"`, `"info"`, `"warn"`, `"error"`, `"fatal"`

14.10.4.10 `--log-file`

- The log file
- Default: `""`
- If this flag is not set, logs will be written to "stderr". If this flag is set, logs are output to the corresponding file.

14.10.4.11 `--log-rotate`

- To enable or disable log rotation
- Default: `true`
- When the value is true, follow the `[log.file]` in PD configuration files.

14.10.4.12 `--name`

- The human-readable unique name for this PD member
- Default: `"pd-${hostname}"`
- If you want to start multiply PDs, you must use different name for each one.

14.10.4.13 `--cacert`

- The file path of CA, used to enable TLS
- Default: `""`

14.10.4.14 `--cert`

- The path of the PEM file including the X509 certificate, used to enable TLS
- Default: `""`

14.10.4.15 `--key`

- The path of the PEM file including the X509 key, used to enable TLS
- Default: `""`

14.10.4.16 `--metrics-addr`

- The address of Prometheus Pushgateway, which does not push data to Prometheus by default.
- Default: `""`

14.11 Key Monitoring Metrics

14.11.1 Key Metrics

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see TiDB Monitoring Framework Overview.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, Node_exporter, Disk Performance, and Performance_overview. A lot of metrics are there to help you diagnose.

For routine operations, you can get an overview of the component (PD, TiDB, TiKV) status and the entire cluster from the Overview dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

14.11.1.1 Key metrics description

To understand the key metrics displayed on the Overview dashboard, check the following table:

Service	Panel Name	Description	Normal Range
Services Port Status	Services Up	The online nodes number of each service.	
PD	PD role	The role of the current PD.	
PD	Storage capacity	The total storage capacity of the TiDB cluster.	
PD	Current storage size	The occupied storage capacity of the TiDB cluster, including the space occupied by TiKV replicas.	
PD	Normal stores	The number of nodes in the normal state.	

Service	Panel Name	Description	Normal Range
PD	Abnormal stores	The number of nodes in the abnormal state.	0
PD	Number of Regions	The total number of Regions in the current cluster. Note that the number of Regions has nothing to do with the number of replicas.	
PD	99% completed_cmds_duration_seconds	The 99th percentile duration to complete a pd-server request.	less than 5ms
PD	Handle_requests_duration_seconds	The total duration of a PD request.	
PD	Region health	The state of each Region.	Generally, the number of pending peers is less than 100, and that of the missing peers cannot always be greater than `0`.
PD	Hot write Region's leader distribution	The total number of leaders who are the write hotspots on each TiKV instance.	
PD	Hot read Region's leader distribution	The total number of leaders who are the read hotspots on each TiKV instance.	
PD	Region heartbeat report	The count of heartbeats reported to PD per instance.	
PD	99% Region heartbeat latency	The heartbeat latency per TiKV instance (P99).	
TiDB	Statement OPS	The number of different types of SQL statements executed per second, which is counted according to `SELECT`, `INSERT`, `UPDATE`, and other types of statements.	

Service	Panel Name	Description	Normal Range
TiDB	Duration	The execution time.1. The duration between the time that the client's network request is sent to TiDB and the time that the request is returned to the client after TiDB has executed the request. In general, client requests are sent in the form of SQL statements; however, this duration can include the execution time of commands such as `COM_PING`, `COM_SLEEP`, `COM_STMT_FETCH`, and `COM_SEND_LONG_DATA`.2. Because TiDB supports Multi-Query, TiDB supports sending multiple SQL statements at one time, such as `select 1; select 1; select 1;`. In this case, the total execution time of this query includes the execution time of all SQL statements.	
TiDB	CPS By Instance	CPS By Instance: the command statistics on each TiDB instance, which is classified according to the success or failure of command execution results.	
TiDB	Failed Query OPM	The statistics of error types (such as syntax errors and primary key conflicts) based on the errors occurred when executing SQL statements per second on each TiDB instance. The module in which the error occurs and the error code are included.	
TiDB	Connection Count	The connection number of each TiDB instance.	
TiDB	Memory Usage	The memory usage statistics of each TiDB instance, which is divided into the memory occupied by processes and the memory applied by Golang on the heap.	
TiDB	Transaction OPS	The number of transactions executed per second.	

Service	Panel Name	Description	Normal Range
TiDB	Transaction Duration	The execution time of a transaction	
TiDB	KV Cmd OPS	The number of executed KV commands.	
TiDB	KV Cmd Duration 99	The execution time of the KV command.	
TiDB	PD TSO OPS	The number of gRPC requests per second that TiDB sends to PD (cmd) and the number of TSO requests (request); each gRPC request contains a batch of TSO requests.	
TiDB	PD TSO Wait Duration	The duration that TiDB waits for PD to return TSO.	
TiDB	TiClient Region Error OPS	The number of Region related errors returned by TiKV.	
TiDB	Lock Resolve OPS	The number of TiDB operations that resolve locks. When TiDB's read or write request encounters a lock, it tries to resolve the lock.	
TiDB	KV Backoff OPS	The number of errors returned by TiKV.	
TiKV	leader	The number of leaders on each TiKV node.	
TiKV	region	The number of Regions on each TiKV node.	
TiKV	CPU	The CPU usage ratio on each TiKV node.	
TiKV	Memory	The memory usage on each TiKV node.	
TiKV	store size	The size of storage space used by each TiKV instance.	
TiKV	cf size	The size of each column family (CF for short).	
TiKV	channel full	The number of "channel full" errors on each TiKV instance.	0
TiKV	server report failures	The number of error messages reported by each TiKV instance.	0
TiKV	scheduler pending commands	The number of pending commands on each TiKV instance.	

Service	Panel Name	Description	Normal Range
TiKV	coprocessor executor count	The number of coprocessor operations received by TiKV per second. Each type of coprocessor is counted separately.	
TiKV	coprocessor request duration	The time consumed to process read requests of coprocessor.	
TiKV	raft store CPU	The CPU usage ratio of the raftstore thread	The default number of threads is 2 (configured by `raftstore.store-pool-size`). A value of over 80% for a single thread indicates that the CPU usage ratio is very high.
TiKV	Coprocessor CPU	The CPU usage ratio of the coprocessor thread.	
System Info	Vcores	The number of CPU cores.	
System Info	Memory	The total memory.	
System Info	CPU Usage	The CPU usage ratio, 100% at a maximum.	
System Info	Load [1m]	The overload within 1 minute.	
System Info	Memory Available	The size of the available memory.	
System Info	Network Traffic	The statistics of the network traffic.	
System Info	TCP Retrans	The frequency of the TOC retransmission.	
System Info	IO Util	The disk usage ratio, 100% at a maximum; generally you need to consider adding a new node when the usage ratio is up to 80% ~ 90%.	

14.11.1.2 Interface of the Overview dashboard

Figure 563: overview

14.11.2 Key Metrics on Performance Overview

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see TiDB Monitoring Framework Overview.

The Grafana dashboard is divided into a series of sub dashboards which include PD, TiDB, TiKV, Node_exporter, Overview, and Performance Overview. A lot of metrics are there to help you diagnose.

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- Overview: Database time and SQL execution time summary. By checking different colors in the overview, you can quickly identify the database workload profile and the performance bottleneck.

- Load profile: Key metrics and resource usage, including database QPS, connection information, the MySQL command types the application interacts with TiDB, database internal TSO and KV request OPS, and resource usage of the TiKV and TiDB.
- Top-down latency breakdown: Query latency versus connection idle time ratio, query latency breakdown, TSO/KV request latency during execution, breakdown of write latency within TiKV.

With the Performance Overview Dashboard, you can analyze performance efficiently, and confirm whether the bottleneck of user response time is in the database. If the bottleneck is in the database, you can identify the bottleneck inside the database, with database time overview, workload profile and SQL latency breakdown. For details, see Performance Analysis and Tuning.

The following sections illustrate the metrics on the Performance Overview dashboard.

14.11.2.1 Performance Overview

14.11.2.1.1 Database Time by SQL Type

- database time: Total database time per second
- sql_type: Database time consumed by each type of SQL statements per second

14.11.2.1.2 Database Time by SQL Phase

- database time: Total database time per second
- get token/parse/compile/execute: Database time consumed in four SQL processing phases

The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required.

14.11.2.1.3 SQL Execute Time Overview

- execute time: Database time consumed during SQL execution per second
- tso_wait: Concurrent TSO waiting time per second during SQL execution
- kv request type: Time waiting for each KV request type per second during SQL execution. The total KV request wait time might exceed SQL execution time, because KV requests are concurrent.
- tiflash_mpp: Time of processing TiFlash requests per second during SQL execution.

Green metrics stand for common KV write requests (such as prewrite and commit), blue metrics stand for common read requests, purple metrics stand for TiFlash MPP requests, and metrics in other colors stand for unexpected situations which you need to pay attention to. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown.

If non-blue or non-green areas are large, it means there is a bottleneck during SQL execution. For example:

- If serious lock conflicts occur, the red area will take a large proportion.
- If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

14.11.2.1.4 QPS

Number of SQL statements executed per second in all TiDB instances, collected by type: such as `SELECT`, `INSERT`, and `UPDATE`

14.11.2.1.5 CPS By Type

Number of commands processed by all TiDB instances per second based on type

14.11.2.1.6 Queries Using Plan Cache OPS

- avg-hit: The number of queries using the execution plan cache per second for all TiDB instances
- avg-miss: The number of queries not using the execution plan cache per second for all TiDB instances

`avg-hit + avg-miss` is equal to `StmtExecute`, which is the number of all queries executed per second.

14.11.2.1.7 KV/TSO Request OPS

- kv request total: Total number of KV requests per second in all TiDB instances
- kv request by type: Number of KV requests per second in all TiDB instances based on such types as `Get`, `Prewrite`, and `Commit`
- tso - cmd: Number of gRPC requests per second that TiDB sends to PD in all TiDB instances; each gRPC request contains a batch of TSO requests
- tso - request: Number of TSO requests per second in all TiDB instances

Generally, `tso - request` divided by `tso - cmd` is the average size of TSO request batches per second.

14.11.2.1.8 KV Request Time By Source

- kv request total time: Total time of processing KV and TiFlash requests per second in all TiDB instances
- Each KV request and the corresponding request source form a stacked bar chart, in which `external` identifies normal business requests and `internal` identifies internal activity requests (such as DDL and auto analyze requests)

14.11.2.1.9 TiDB CPU

- avg: Average CPU utilization across all TiDB instances
- delta: Maximum CPU utilization of all TiDB instances minus minimum CPU utilization of all TiDB instances
- max: Maximum CPU utilization across all TiDB instances

14.11.2.1.10 TiKV CPU/IO MBps

- CPU-Avg: Average CPU utilization of all TiKV instances
- CPU-Delta: Maximum CPU utilization of all TiKV instances minus minimum CPU utilization of all TiKV instances
- CPU-MAX: Maximum CPU utilization among all TiKV instances
- IO-Avg: Average MBps of all TiKV instances
- IO-Delt: Maximum MBps of all TiKV instances minus minimum MBps of all TiKV instances
- IO-MAX: Maximum MBps of all TiKV instances

14.11.2.1.11 Duration

- Duration: Execution time
    - The duration from receiving a request from the client to TiDB till TiDB executing the request and returning the result to the client. In general, client requests are sent in the form of SQL statements; however, this duration can include the execution time of commands such as `COM_PING`, `COM_SLEEP`, `COM_STMT_FETCH`, and `COM_SEND_LONG_DATA`.
    - TiDB supports Multi-Query, which means the client can send multiple SQL statements at one time, such as `select 1; select 1; select 1;`. In this case, the total execution time of this query includes the execution time of all SQL statements.
- avg: Average time to execute all requests
- 99: P99 duration to execute all requests
- avg by type: Average time to execute all requests in all TiDB instances, collected by type: `SELECT`, `INSERT`, and `UPDATE`

14.11.2.1.12 Connection Idle Duration

Connection Idle Duration indicates the duration of a connection being idle.

- avg-in-txn: Average connection idle duration when the connection is within a transaction
- avg-not-in-txn: Average connection idle duration when the connection is not within a transaction
- 99-in-txn: P99 connection idle duration when the connection is within a transaction

14.11.2.1.13 Connection Count

- total: Number of connections to all TiDB instances
- active connections: Number of active connections to all TiDB instances
- tidb-{node-number}-peer: Number of connections to each TiDB instance
- disconnection/s: Number of disconnections in a TiDB cluster
- 99-not-in-txn: P99 connection idle duration when the connection is not within a transaction

14.11.2.1.14 Parse Duration, Compile Duration, and Execute Duration

- Parse Duration: Time consumed in parsing SQL statements
- Compile Duration: Time consumed in compiling the parsed SQL AST to execution plans
- Execution Duration: Time consumed in executing execution plans of SQL statements

All these three metrics include the average duration and the 99th percentile duration in all TiDB instances.

14.11.2.1.15 Avg TiDB KV Request Duration

Average time consumed in executing KV requests in all TiDB instances based on the type, including `Get`, `Prewrite`, and `Commit`.

14.11.2.1.16 Avg TiKV GRPC Duration

Average time consumed in executing gRPC requests in all TiKV instances based on the type, including `kv_get`, `kv_prewrite`, and `kv_commit`.

14.11.2.1.17 PD TSO Wait/RPC Duration

- wait - avg: Average duration of waiting for PD to return TSO in all TiDB instances
- rpc - avg: Average duration from the time that TiDB sends gRPC requests to PD to get TSO to the time that TiDB receives TSO in all TiDB instances
- wait - 99: P99 duration of waiting for PD to return TSO in all TiDB instances
- rpc - 99: P99 duration from the time that TiDB sends gRPC requests to PD to get TSO to the time that TiDB receives TSO in all TiDB instances

14.11.2.1.18 Storage Async Write Duration, Store Duration, and Apply Duration

- Storage Async Write Duration: Time consumed in asynchronous write
- Store Duration: Time consumed in store loop during asynchronously write
- Apply Duration: Time consumed in apply loop during asynchronously write

All these three metrics include the average duration and P99 duration in all TiKV instances.

Average storage async write duration = Average store duration + Average apply duration

14.11.2.1.19 Append Log Duration, Commit Log Duration, and Apply Log Duration

- Append Log Duration: Time consumed by Raft to append logs
- Commit Log Duration: Time consumed by Raft to commit logs
- Apply Log Duration: Time consumed by Raft to apply logs

All these three metrics include the average duration and P99 duration in all TiKV instances.

14.11.2.1.20 Interface of the Performance Overview panels

Figure 564: performance overview

14.11.2.2 TiFlash

- CPU: The CPU utilization per TiFlash instance.
- Memory: The memory usage per TiFlash instance.
- IO utilization: The IO utilization per TiFlash instance.
- MPP Query count: The number of TiFlash MPP queries per second per TiFlash instance.
- Request QPS: The number of coprocessor requests received by all TiFlash instances.
    - `batch`: Number of batch requests.
    - `batch_cop`: Number of coprocessor requests in the batch requests.
    - `cop`: Number of coprocessor requests that are sent directly via the coprocessor interface.
    - `cop_dag`: Number of dag requests in all coprocessor requests.
    - `super_batch`: Number of requests that enable the Super Batch feature.
- Executor QPS: The number of each type of dag executors in the requests received by all TiFlash instances. `table_scan` is the table scan executor. `selection` is the selection executor. `aggregation` is the aggregation executor. `top_n` is the `TopN` executor. `limit` is the limit executor.
- Request Duration Overview: Provides a stacked chart of total processing time per second for all request types in all TiFlash instances.
- Request Duration: The total processing duration for each MPP and coprocessor request type in all TiFlash instances. It is from the time that the coprocessor request is received to the time that the response of the request is completed, which includes the average latency and p99 latency.
- Request Handle Duration: The actual processing duration for each MPP and coprocessor request type in all TiFlash instances. It is from the start of executing the coprocessor request to the completion of the execution, which includes the average latency and p99 latency.
- Raft Wait Index Duration: The time used by `wait_index` for all TiFlash instances, namely the time used to wait until Region index >= `read_index` after the `read_index` request is received.
- Raft Batch Read Index Duration: The time used by `read_index` for all TiFlash instances. Most time is used for interaction with the Region leader and retry.
- Write Throughput By Instance: The throughput of write by instance. It includes the throughput by applying the Raft write commands and Raft snapshots.
- Write flow: The traffic of disk writes by all TiFlash instances.
- Read flow: The traffic of disk reads by all TiFlash instances.

14.11.2.3 CDC

- CPU usage: The CPU usage per TiCDC node.
- Memory usage: The memory usage per TiCDC node.
- Goroutine count: The number of goroutines per TiCDC node.
- Changefeed checkpoint lag: The progress lag of data replication (the unit is second) between the upstream and the downstream.
- Changefeed resolved ts lag: The progress lag of data replication (the unit is second) between the upstream and TiCDC nodes.
- The status of changefeeds:
    - 0: Normal
    - 1: Error
    - 2: Failed
    - 3: Stopped
    - 4: Finished
    - -1: Unknown
- Puller output events/s: The number of rows that the Puller module of TiCDC nodes sends to the Sorter module per second.
- Sorter output events/s: The number of rows that the Sorter module of TiCDC nodes sends to the Mounter module per second.
- Mounter output events/s: The number of rows that the Mounter module of TiCDC nodes sends to the Sink module per second.
- Table sink output events/s: The number of rows that the Table Sorter module of the TiCDC nodes sends to the Sink module per second.
- SinkV2 - Sink flush rows/s: The number of rows that the Sink module in the TiCDC node sends to the downstream per second.
- Transaction Sink Full Flush Duration: The average latency and p999 latency of writing downstream transactions by the MySQL Sink of TiCDC nodes.
- MQ Worker Send Message Duration Percentile: The latency of sending messages by MQ worker when the downstream is Kafka.
- Kafka Outgoing Bytes: The traffic of writing downstream transactions in MQ Workload.

14.11.3 TiDB Monitoring Metrics

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For the monitoring architecture, see TiDB Monitoring Framework Overview.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, Node_exporter, Disk Performance, and Performance_overview. The TiDB dashboard consists of the TiDB panel and the TiDB Summary panel. The differences between the two panels are different in the following aspects:

- TiDB panel: provides as comprehensive information as possible for troubleshooting cluster anomalies.
- TiDB Summary Panel: extracts parts of the TiDB panel information with which users are most concerned, with some modifications. It provides data (such as QPS, TPS, response delay) that users care about in the daily database operations, which serves as the monitoring information to be displayed or reported.

This document describes some key monitoring metrics displayed on the TiDB dashboard.

14.11.3.1 Key metrics description

To understand the key metrics displayed on the TiDB dashboard, check the following sections:

14.11.3.1.1 Query Summary

- Duration: execution time
    - The duration between the time that the client's network request is sent to TiDB and the time that the request is returned to the client after TiDB has executed it. In general, client requests are sent in the form of SQL statements, but can also include the execution time of commands such as `COM_PING`, `COM_SLEEP`, `COM_STMT_FETCH`, and `COM_SEND_LONG_DATA`
    - Because TiDB supports Multi-Query, it supports sending multiple SQL statements at one time, such as `select 1; select 1; select 1;`. In this case, the total execution time of this query includes the execution time of all SQL statements
- Command Per Second: the number of commands processed by TiDB per second, which is classified according to the success or failure of command execution results
- QPS: the number of SQL statements executed per second on all TiDB instances, which is counted according to `SELECT`, `INSERT`, `UPDATE`, and other types of statements
- CPS By Instance: the command statistics on each TiDB instance, which is classified according to the success or failure of command execution results

- Failed Query OPM: the statistics of error types (such as syntax errors and primary key conflicts) according to the errors occurred when executing SQL statements per minute on each TiDB instance. It contains the module in which the error occurs and the error code
- Slow query: the statistics of the processing time of slow queries (the time cost of the entire slow query, the time cost of Coprocessor, and the waiting time for Coprocessor scheduling). Slow queries are classified into internal and general SQL statements
- Connection Idle Duration: the duration of idle connections
- 999/99/95/80 Duration: the statistics of the execution time for different types of SQL statements (different percentiles)

14.11.3.1.2 Query Detail

- Duration 80/95/99/999 By Instance: the statistics of the execution time for SQL statements on each TiDB instance (different percentiles)
- Failed Query OPM Detail: the statistics of error types (such as syntax errors and primary key conflicts) according to the errors occurred when executing SQL statements per minute on each TiDB instance
- Internal SQL OPS: the internal SQL statements executed per second in the entire TiDB cluster. The internal SQL statements are internally executed and are generally triggered by user SQL statements or internally scheduled tasks.

14.11.3.1.3 Server

- Uptime: the runtime of each TiDB instance
- Memory Usage: the memory usage statistics of each TiDB instance, which is divided into the memory occupied by processes and the memory applied by Golang on the heap
- CPU Usage: the statistics of CPU usage of each TiDB instance
- Connection Count: the number of clients connected to each TiDB instance
- Open FD Count: the statistics of opened file descriptors of each TiDB instance
- Disconnection Count: the number of clients disconnected to each TiDB instance
- Events OPM: the statistics of key events, such as “start”, “close”, “graceful-shutdown”,“kill”, and “hang”
- Goroutine Count: the number of Goroutines on each TiDB instance
- Prepare Statement Count: the number of `Prepare` statements that are executed on each TiDB instance and the total count of them
- Keep Alive OPM: the number of times that the metrics are refreshed every minute on each TiDB instance. It usually needs no attention.
- Panic And Critical Error: the number of panics and critical errors occurred in TiDB
- Time Jump Back OPS: the number of times that the operating system rewinds every second on each TiDB instance
- Get Token Duration: the time cost of getting Token on each connection

- Skip Binlog Count: the number of binlog write failures in TiDB; starting from v8.4.0, TiDB Binlog is removed, and this metric has no value
- Client Data Traffic: data traffic statistics of TiDB and the client

14.11.3.1.4 Transaction

- Transaction OPS: the number of transactions executed per second
- Duration: the execution duration of a transaction
- Transaction Statement Num: the number of SQL statements in a transaction
- Transaction Retry Num: the number of times that a transaction retries
- Session Retry Error OPS: the number of errors encountered during the transaction retry per second. This metric includes two error types: retry failure and exceeding the maximum number of retries
- Commit Token Wait Duration: the wait duration in the flow control queue during the transaction commit. If the wait duration is long, it means that the transaction to commit is too large and the flow is controlled. If the system still has resources available, you can speed up the commit process by increasing the system variable `tidb_committer_concurrency`.
- KV Transaction OPS: the number of transactions executed per second within each TiDB instance
    - A user transaction might trigger multiple transaction executions in TiDB, including reading internal metadata and atomic retries of the user transaction
    - TiDB's internally scheduled tasks also operate on the database through transactions, which are also included in this panel
- KV Transaction Duration: the time spent on executing transactions within each TiDB
- Transaction Regions Num: the number of Regions operated in the transaction
- Transaction Write KV Num Rate and Sum: the rate at which KVs are written and the sum of these written KVs in the transaction
- Transaction Write KV Num: the number of KVs operated in the transaction
- Statement Lock Keys: the number of locks for a single statement
- Send HeartBeat Duration: the duration for the transaction to send heartbeats
- Transaction Write Size Bytes Rate and sum: the rate at which bytes are written and the sum of these written bytes in the transaction
- Transaction Write Size Bytes: the size of the data written in the transaction
- Acquire Pessimistic Locks Duration: the time consumed by adding locks
- TTL Lifetime Reach Counter: the number of transactions that reach the upper limit of TTL. The default value of the TTL upper limit is 1 hour. It means that 1 hour has passed since the first lock of a pessimistic transaction or the first prewrite of an optimistic transaction. The default value of the upper limit of TTL is 1 hour. The upper limit of TTL life can be changed by modifying `max-txn-TTL` in the TiDB configuration file
- Load Safepoint OPS: the number of times that `Safepoint` is loaded. `Safepoint` is to ensure that the data before `Safepoint` is not read when the transaction reads data, thus ensuring data safety. The data before `Safepoint` might be cleaned up by the GC

- Pessimistic Statement Retry OPS: the number of retry attempts for pessimistic statements. When the statement tries to add lock, it might encounter a write conflict. At this time, the statement will acquire a new snapshot and add lock again
- Transaction Types Per Seconds: the number of transactions committed per second using the two-phase commit (2PC), async commit, and one-phase commit (1PC) mechanisms, including both success and failure transactions

14.11.3.1.5 Executor

- Parse Duration: the statistics of the parsing time of SQL statements
- Compile Duration: the statistics of the time of compiling the parsed SQL AST to the execution plan
- Execution Duration: the statistics of the execution time for SQL statements
- Expensive Executor OPS: the statistics of the operators that consume many system resources per second, including `Merge Join`, `Hash Join`, `Index Look Up Join`, `Hash Agg`, `Stream Agg`, `Sort`, and `TopN`
- Queries Using Plan Cache OPS: the statistics of queries using the Plan Cache per second
- Plan Cache Miss OPS: the statistics of the number of times that the Plan Cache is missed per second
- Plan Cache Memory Usage: the total memory consumed by the execution plan cached in each TiDB instance
- Plan Cache Plan Num: the total number of execution plans cached in each TiDB instance

14.11.3.1.6 Distsql

- Distsql Duration: the processing time of Distsql statements
- Distsql QPS: the statistics of Distsql statements
- Distsql Partial QPS: the number of Partial results every second
- Scan Keys Num: the number of keys that each query scans
- Scan Keys Partial Num: the number of keys that each Partial result scans
- Partial Num: the number of Partial results for each SQL statement

14.11.3.1.7 KV Errors

- KV Backoff Duration: the total duration that a KV retry request lasts. TiDB might encounter an error when sending a request to TiKV. TiDB has a retry mechanism for every request to TiKV. This `KV Backoff Duration` item records the total time of a request retry.
- TiClient Region Error OPS: the number of Region related error messages returned by TiKV
- KV Backoff OPS: the number of error messages returned by TiKV

- Lock Resolve OPS: the number of TiDB operations to resolve locks. When TiDB's read or write request encounters a lock, it tries to resolve the lock
- Other Errors OPS: the number of other types of errors, including clearing locks and updating `SafePoint`

14.11.3.1.8 KV Request

The following metrics relate to requests sent to TiKV. Retry requests are counted multiple times.

- KV Request OPS: the execution times of a KV request, displayed according to TiKV
- KV Request Duration 99 by store: the execution time of a KV request, displayed according to TiKV
- KV Request Duration 99 by type: the execution time of a KV request, displayed according to the request type
- Stale Read Hit/Miss Ops
    - **hit**: the number of requests per second that successfully execute a stale read
    - **miss**: the number of requests per second that attempt a stale read but fail
- Stale Read Req Ops:
    - **cross-zone**: the number of requests per second that attempt a stale read in a remote zone
    - **local**: the number of requests per second that attempt a stale read in the local zone
- Stale Read Req Traffic:
    - **cross-zone-in**: the incoming traffic of responses to requests that attempt a stale read in a remote zone
    - **cross-zone-out**: the outgoing traffic of requests that attempt a stale read in a remote zone
    - **local-in**: the incoming traffic of responses to requests that attempt a stale read in the local zone
    - **local-out**: the outgoing traffic of requests that attempt a stale read in the local zone

14.11.3.1.9 PD Client

- PD Client CMD OPS: the statistics of commands executed by PD Client per second
- PD Client CMD Duration: the time it takes for PD Client to execute commands
- PD Client CMD Fail OPS: the statistics of failed commands executed by PD Client per second
- PD TSO OPS: the number of gRPC requests per second that TiDB sends to PD (cmd) and the number of TSO requests (request); each gRPC request contains a batch of TSO requests

- PD TSO Wait Duration: the time that TiDB waits for PD to return TSO
- PD TSO RPC duration: the duration from the time that TiDB sends gRPC requests to PD to get TSO to the time that TiDB receives the gRPC response from PD
- Async TSO Duration: the duration from the time that TiDB prepares to get TSO to the time that TiDB actually starts to wait for PD to return TSO

14.11.3.1.10 Schema Load

- Load Schema Duration: the time it takes TiDB to obtain the schema from TiKV
- Load Schema OPS: the statistics of the schemas that TiDB obtains from TiKV per second
- Schema Lease Error OPM: the Schema Lease errors include two types: `change` and `outdate`. `change` means that the schema has changed, and `outdate` means that the schema cannot be updated, which is a more serious error and triggers an alert.
- Load Privilege OPS: the statistics of the number of privilege information obtained by TiDB from TiKV per second

14.11.3.1.11 DDL

- DDL Duration 95: 95% quantile of DDL statement processing time
- Batch Add Index Duration 100: statistics of the maximum time spent by each Batch on creating an index
- DDL Waiting Jobs Count: the number of DDL tasks that are waiting
- DDL META OPM: the number of times that a DDL obtains META every minute
- DDL Worker Duration 99: 99% quantile of the execution time of each DDL worker
- Deploy Syncer Duration: the time consumed by Schema Version Syncer initialization, restart, and clearing up operations
- Owner Handle Syncer Duration: the time that it takes the DDL Owner to update, obtain, and check the Schema Version
- Update Self Version Duration: the time consumed by updating the version information of Schema Version Syncer
- DDL OPM: the number of DDL executions per second
- DDL backfill progress in percentage: the progress of backfilling DDL tasks

14.11.3.1.12 Statistics

- Auto Analyze Duration 95: the time consumed by automatic `ANALYZE`
- Auto Analyze QPS: the statistics of automatic `ANALYZE`
- Stats Inaccuracy Rate: the information of the statistics inaccuracy rate
- Pseudo Estimation OPS: the number of the SQL statements optimized using pseudo statistics
- Dump Feedback OPS: the number of stored statistical feedbacks

- Store Query Feedback QPS: the number of operations per second to store the feedback information of the union query, which is performed in TiDB memory
- Significant Feedback: the number of significant feedback pieces that update the statistics information
- Update Stats OPS: the number of operations of updating statistics with feedback

14.11.3.1.13 Owner

- New ETCD Session Duration 95: the time it takes to create a new etcd session. TiDB connects to etcd in PD through etcd client to save/read some metadata information. This records the time spent creating the session
- Owner Watcher OPS: the number of Goroutine operations per second of DDL owner watch PD's etcd metadata

14.11.3.1.14 Meta

- AutoID QPS: AutoID related statistics, including three operations (global ID allocation, a single table AutoID allocation, a single table AutoID Rebase)
- AutoID Duration: the time consumed by AutoID related operations
- Region Cache Error OPS: the number of errors encountered per second by the cached Region information in TiDB
- Meta Operations Duration 99: the latency of Meta operations

14.11.3.1.15 GC

- Worker Action OPM: the number of GC related operations, including `run_job`, `resolve_lock`, and `delete_range`
- Duration 99: the time consumed by GC related operations
- Config: the configuration of GC data life time and GC running interval
- GC Failure OPM: the number of failed GC related operations
- Delete Range Failure OPM: the number of times the `Delete Range` has failed
- Too Many Locks Error OPM: the number of the error that GC clears up too many locks
- Action Result OPM: the number of results of GC-related operations
- Delete Range Task Status: the task status of `Delete Range`, including completion and failure
- Push Task Duration 95: the time spent pushing GC subtasks to GC workers

14.11.3.1.16 Batch Client

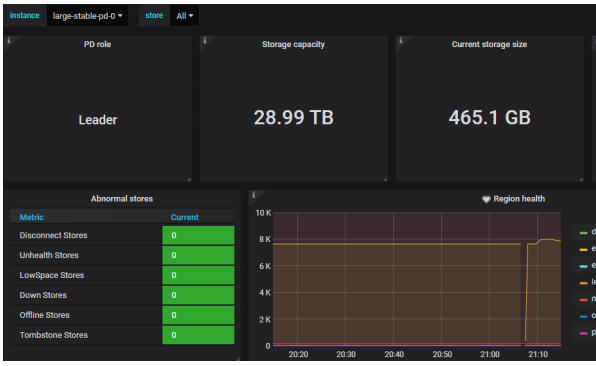
- Pending Request Count by TiKV: the number of Batch messages that are pending processing
- Batch Client Unavailable Duration 95: the unavailable time of the Batch client
- No Available Connection Counter: the number of times the Batch client cannot find an available link

14.11.3.1.17 TTL

- TiDB CPU Usage: the CPU usage of each TiDB instance.
- TiKV IO MBps: the total bytes of I/O in each TiKV instance.
- TiKV CPU: the CPU usage of each TiKV instance.
- TTL QPS By Type: the QPS information of different types of statements generated by TTL jobs.
- TTL Insert Rows Per Second: the number of rows inserted into TTL tables per second.
- TTL Processed Rows Per Second: the number of expired rows processed by TTL jobs per second.
- TTL Insert Rows Per Hour: the number of rows inserted into TTL tables for every hour.
- TTL Delete Rows Per Hour: the number of expired rows deleted by TTL jobs for every hour.
- TTL Scan/Delete Query Duration: the execution time of TTL scan/delete statements.
- TTL Scan/Delete Worker Time By Phase: the time consumed by different phases of TTL internal worker threads.
- TTL Job Count By Status: the number of TTL jobs currently being executed.
- TTL Task Count By Status: the number of TTL tasks currently being executed.

14.11.4 Key Monitoring Metrics of PD

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see Overview of the Monitoring Framework.



The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, Node_exporter, Disk Performance, and Performance_overview. A lot of metrics are there to help you diagnose.

You can get an overview of the component PD status from the PD dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

The following is the description of PD Dashboard metrics items:

- PD role: The role of the current PD instance
- Storage capacity: The total storage capacity for this TiDB cluster
- Current storage size: The storage size that is currently used by the TiDB cluster
- Current storage usage: The current storage usage rate
- Normal stores: The count of healthy storage instances
- Number of Regions: The total count of cluster Regions
- Abnormal stores: The count of unhealthy stores. The normal value is `0`. If the number is bigger than `0`, it means at least one instance is abnormal.
- Region health: The health status of Regions indicated via the count of unusual Regions including pending peers, down peers, extra peers, offline peers, missing peers, learner

peers and incorrect namespaces. Generally, the number of pending peers should be less than `100`. The missing peers should not be persistently greater than `0`. If many empty Regions exist, enable Region Merge in time.

- Current peer count: The current count of all cluster peers

14.11.4.1 Key metrics description

14.11.4.2 Cluster

- PD scheduler config: The list of PD scheduler configurations
- Cluster ID: The unique identifier of the cluster
- Current TSO: The physical part of current allocated TSO
- Current ID allocation: The maximum allocatable ID for new store/peer
- Region label isolation level: The number of Regions in different label levels
- Label distribution: The distribution status of the labels in the cluster
- Store Limit: The flow control limitation of scheduling on the Store

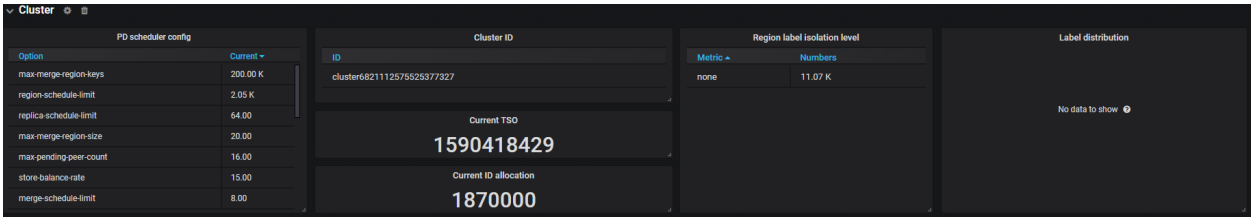


Figure 565: PD Dashboard - Cluster metrics

14.11.4.3 Operator

- Schedule operator create: The number of newly created operators per type
- Schedule operator check: The number of checked operator per type. It mainly checks whether the current step is finished; if yes, it returns the next step to be executed
- Schedule operator finish: The number of finished operators per type
- Schedule operator timeout: The number of timeout operators per type

- Schedule operator replaced or canceled: The number of replaced or canceled operators per type
- Schedule operators count by state: The number of operators per state
- Operator finish duration: The maximum duration of finished operators
- Operator step duration: The maximum duration of finished operator steps

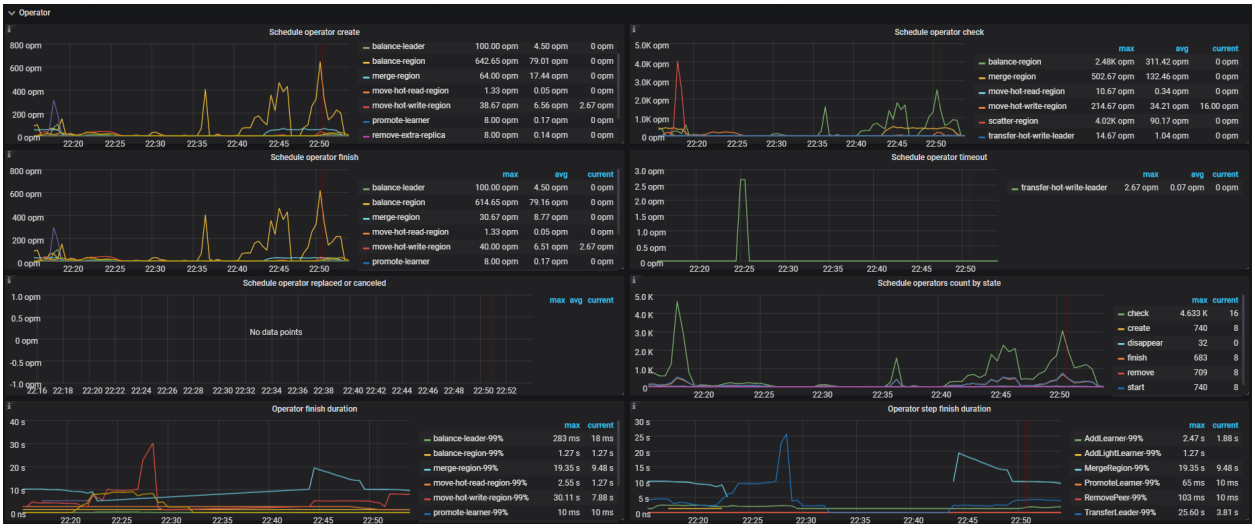

Figure 566: PD Dashboard - Operator metrics

14.11.4.4 Statistics - Balance

- Store capacity: The capacity size per TiKV instance
- Store available: The available capacity size per TiKV instance
- Store used: The used capacity size per TiKV instance
- Size amplification: The size amplification ratio per TiKV instance, which is equal to (Store Region size)/(Store used capacity size)
- Size available ratio: The size availability ratio per TiKV instance, which is equal to (Store available capacity size)/(Store capacity size)
- Store leader score: The leader score per TiKV instance
- Store Region score: The Region score per TiKV instance
- Store leader size: The total leader size per TiKV instance
- Store Region size: The total Region size per TiKV instance
- Store leader count: The leader count per TiKV instance
- Store Region count: The Region count per TiKV instance

Figure 567: PD Dashboard - Balance metrics

14.11.4.5 Statistics - hot write

- Hot Region's leader distribution: The total number of leader Regions that have become write hotspots on each TiKV instance
- Total written bytes on hot leader Regions: The total written bytes by leader Regions that have become write hotspots on each TiKV instance
- Hot write Region's peer distribution: The total number of peer Regions that have become write hotspots on each TiKV instance
- Total written bytes on hot peer Regions: The written bytes of all peer Regions that have become write hotspots on each TiKV instance
- Store Write rate bytes: The total written bytes on each TiKV instance
- Store Write rate keys: The total written keys on each TiKV instance
- Hot cache write entry number: The number of peers on each TiKV instance that are in the write hotspot statistics module
- Selector events: The event count of Selector in the hotspot scheduling module
- Direction of hotspot move leader: The direction of leader movement in the hotspot scheduling. The positive number means scheduling into the instance. The negative number means scheduling out of the instance

- Direction of hotspot move peer: The direction of peer movement in the hotspot scheduling. The positive number means scheduling into the instance. The negative number means scheduling out of the instance

Figure 568: PD Dashboard - Hot write metrics

14.11.4.6 Statistics - hot read

- Hot Region's peer distribution: The total number of peer Regions that have become read hotspots on each TiKV instance
- Total read bytes on hot peer Regions: The total read bytes of peers that have become read hotspots on each TiKV instance
- Store read rate bytes: The total read bytes of each TiKV instance
- Store read rate keys: The total read keys of each TiKV instance
- Hot cache read entry number: The number of peers that are in the read hotspot statistics module on each TiKV instance

Figure 569: PD Dashboard - Hot read metrics

14.11.4.7 Scheduler

- Scheduler is running: The current running schedulers
- Balance leader movement: The leader movement details among TiKV instances
- Balance Region movement: The Region movement details among TiKV instances
- Balance leader event: The count of balance leader events
- Balance Region event: The count of balance Region events
- Balance leader scheduler: The inner status of balance leader scheduler
- Balance Region scheduler: The inner status of balance Region scheduler
- Replica checker: The replica checker's status
- Rule checker: The rule checker's status
- Region merge checker: The merge checker's status
- Filter target: The number of attempts that the store is selected as the scheduling target but failed to pass the filter
- Filter source: The number of attempts that the store is selected as the scheduling source but failed to pass the filter
- Balance Direction: The number of times that the Store is selected as the target or source of scheduling

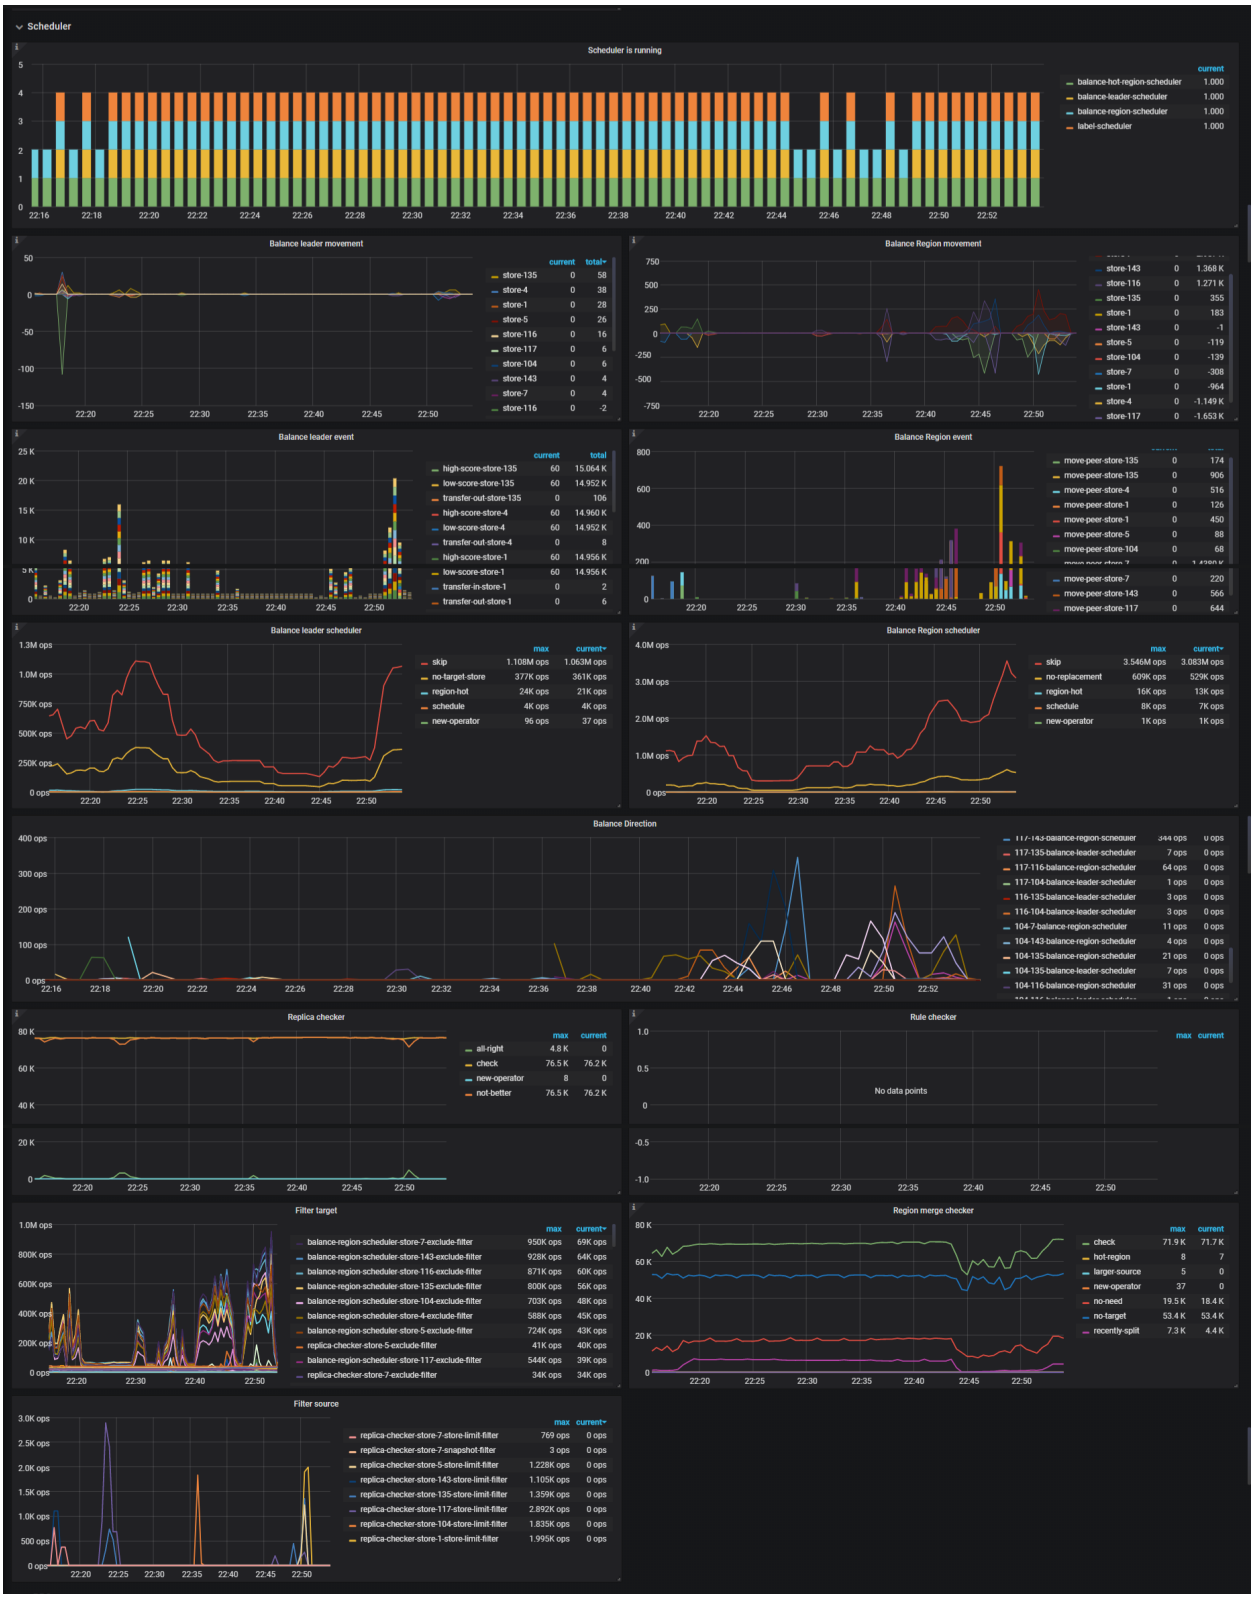

Figure 570: PD Dashboard - Scheduler metrics

14.11.4.8 gRPC

- Completed commands rate: The rate per command type at which gRPC commands are completed
- 99% Completed commands duration: The rate per command type at which gRPC commands are completed (P99)

Figure 571: PD Dashboard - gRPC metrics

14.11.4.9 etcd

- Handle transactions count: The rate at which etcd handles transactions
- 99% Handle transactions duration: The transaction handling rate (P99)
- 99% WAL fsync duration: The time consumed for writing WAL into the persistent storage. It is less than `1s` (P99)
- 99% Peer round trip time seconds: The network latency for etcd (P99) | The value is less than `1s`
- etcd disk WAL fsync rate: The rate of writing WAL into the persistent storage
- Raft term: The current term of Raft
- Raft committed index: The last committed index of Raft
- Raft applied index: The last applied index of Raft

Figure 572: PD Dashboard - etcd metrics

14.11.4.10 TiDB

- PD Server TSO handle time and Client recv time: The duration between PD receiving the TSO request and the PD client getting the TSO response
- Handle requests count: The count of TiDB requests
- Handle requests duration: The time consumed for handling TiDB requests. It should be less than `100ms` (P99)

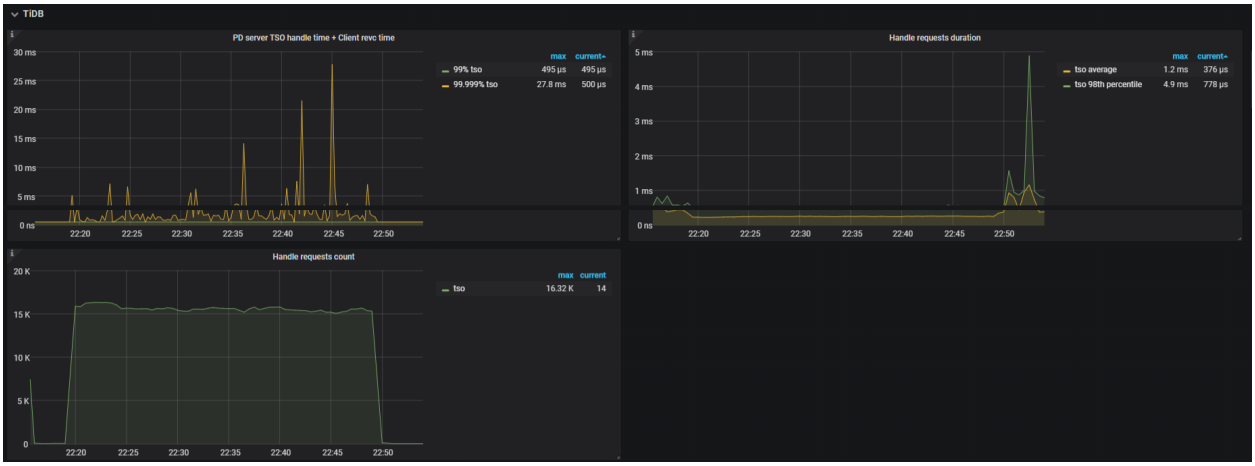

Figure 573: PD Dashboard - TiDB metrics

14.11.4.11 Heartbeat

- Heartbeat region event QPS: The QPS of handling heartbeat messages, including updating the cache and persisting data
- Region heartbeat report: The count of heartbeats reported to PD per instance
- Region heartbeat report error: The count of heartbeats with the `error` status
- Region heartbeat report active: The count of heartbeats with the `ok` status
- Region schedule push: The count of corresponding schedule commands sent from PD per TiKV instance
- 99% Region heartbeat latency: The heartbeat latency per TiKV instance (P99)

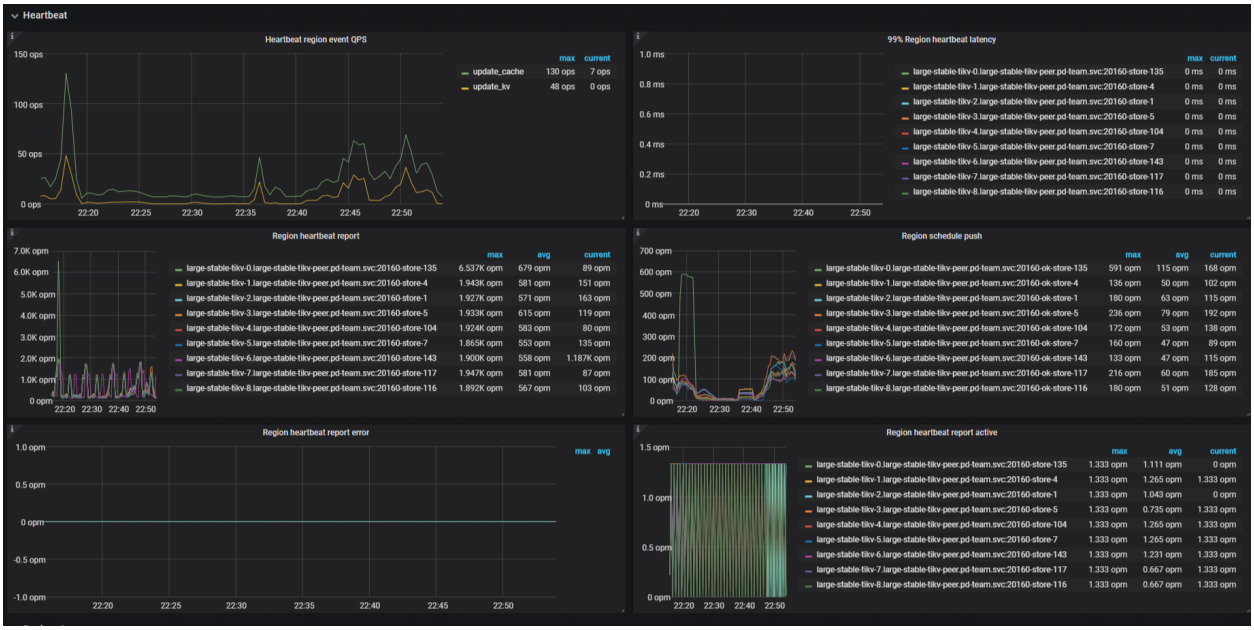

Figure 574: PD Dashboard - Heartbeat metrics

14.11.4.12 Region storage

- Syncer Index: The maximum index in the Region change history recorded by the leader
- history last index: The last index where the Region change history is synchronized successfully with the follower

Figure 575: PD Dashboard - Region storage

14.11.5 Key Monitoring Metrics of TiKV

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus/-Grafana) is deployed at the same time. For more information, see Overview of the Monitoring Framework.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, Node_exporter, and Performance_overview. A lot of metrics are there to help you diagnose.

14.11.5.1 TiKV-Details dashboard

You can get an overview of the component TiKV status from the **TiKV-Details** dashboard, where the key metrics are displayed. According to the Performance Map, you can check whether the status of the cluster is as expected.

This section provides a detailed description of these key metrics on the **TiKV-Details** dashboard.

14.11.5.1.1 Cluster

- Store size: The storage size per TiKV instance
- Available size: The available capacity per TiKV instance
- Capacity size: The capacity size per TiKV instance
- CPU: The CPU utilization per TiKV instance
- Memory: The memory usage per TiKV instance
- IO utilization: The I/O utilization per TiKV instance
- MBps: The total bytes of read and write in each TiKV instance
- QPS: The QPS per command in each TiKV instance
- Errps: The rate of gRPC message failures
- leader: The number of leaders per TiKV instance
- Region: The number of Regions per TiKV instance
- Uptime: The runtime of TiKV since last restart

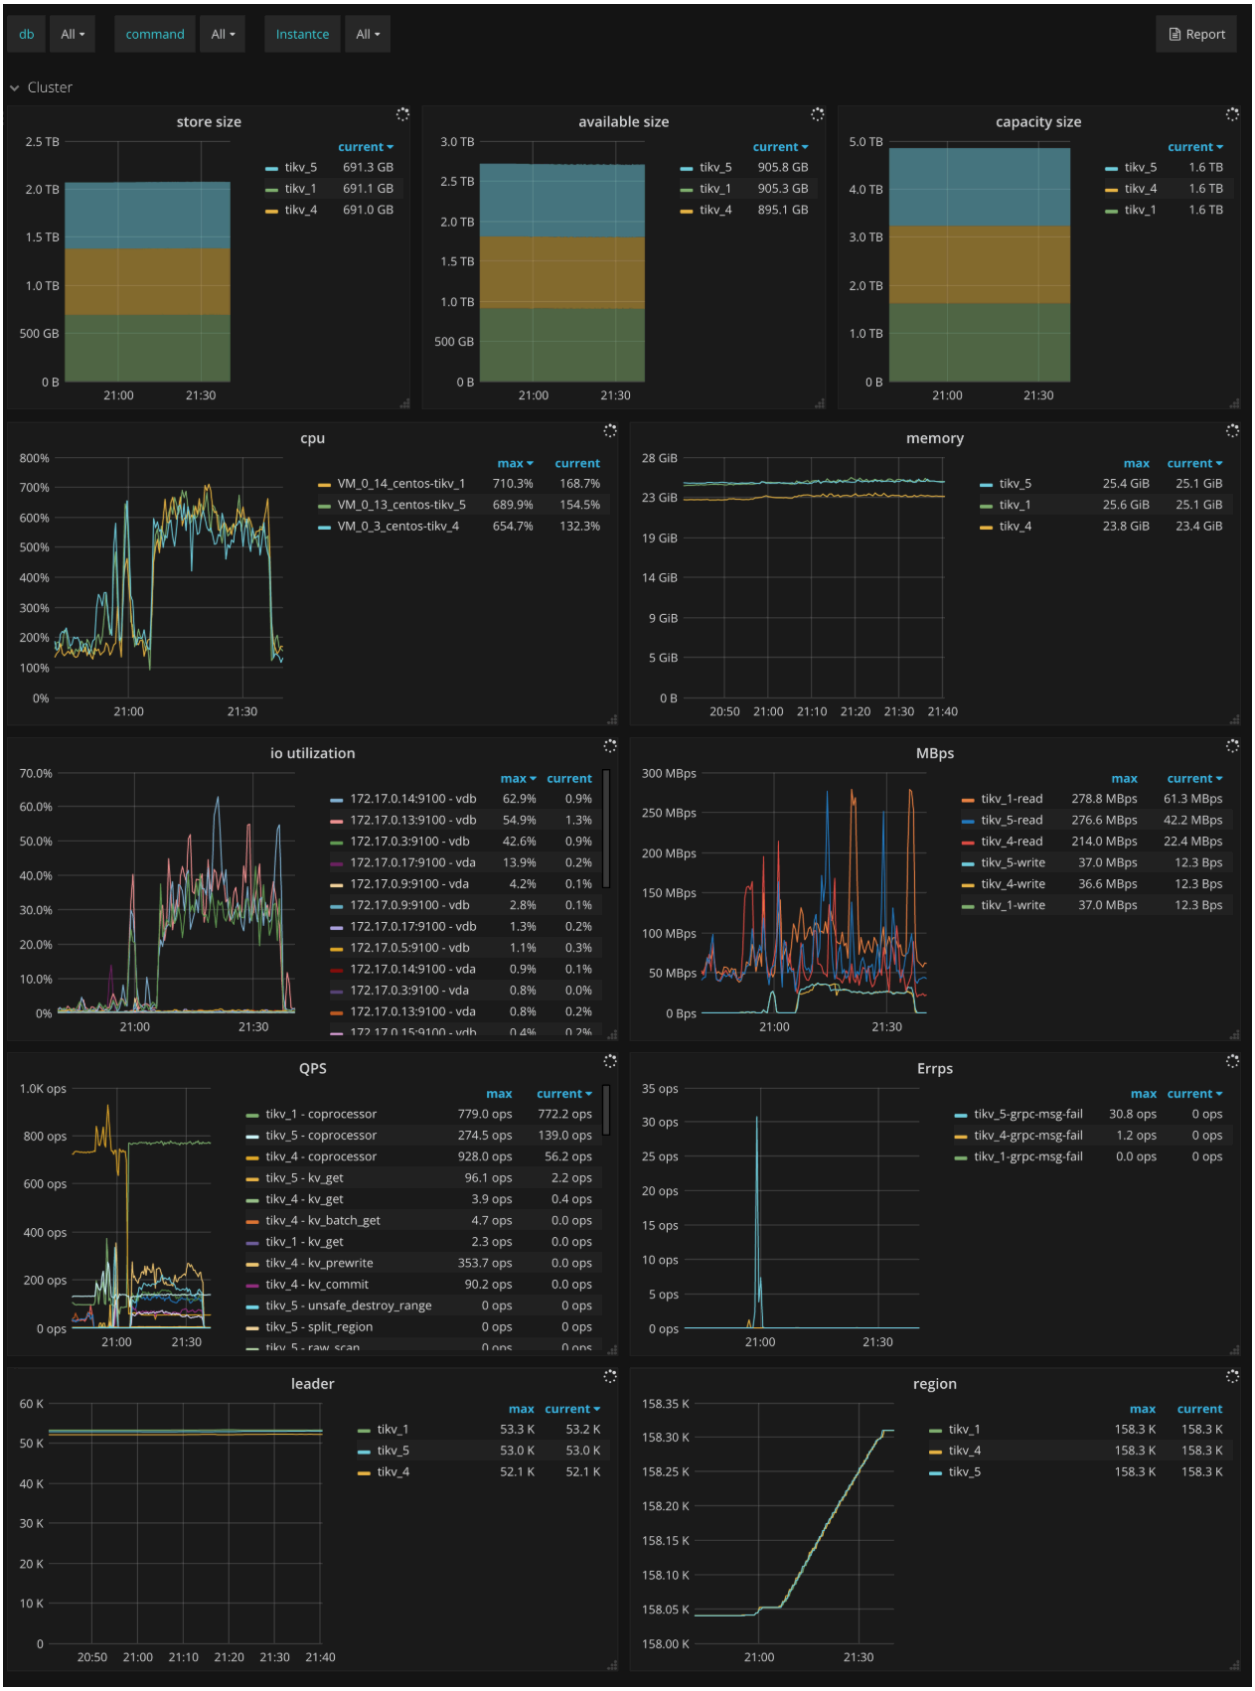

Figure 576: TiKV Dashboard - Cluster metrics

14.11.5.1.2 Errors

- Critical error: The number of critical errors
- Server is busy: Indicates occurrences of events that make the TiKV instance unavailable temporarily, such as Write Stall, and Channel Full. It should be `0` in normal case.
- Server report failures: The number of error messages reported by server. It should be `0` in normal case.
- Raftstore error: The number of Raftstore errors per type on each TiKV instance
- Scheduler error: The number of scheduler errors per type on each TiKV instance
- Coprocessor error: The number of coprocessor errors per type on each TiKV instance
- gRPC message error: The number of gRPC message errors per type on each TiKV instance
- Leader drop: The count of dropped leaders per TiKV instance
- Leader missing: The count of missing leaders per TiKV instance
- Log Replication Reject: The number of logappend messages rejected due to insufficient memory on each TiKV instance

Figure 577: TiKV Dashboard - Errors metrics

14.11.5.1.3 Server

- CF size: The size of each column family
- Store size: The storage size per TiKV instance
- Channel full: The number of Channel Full errors per TiKV instance. It should be `0` in normal case.
- Active written leaders: The number of leaders being written on each TiKV instance

- Approximate Region size: The approximate Region size
- Approximate Region size Histogram: The histogram of each approximate Region size
- Region average written keys: The average number of written keys to Regions per TiKV instance
- Region average written bytes: The average written bytes to Regions per TiKV instance

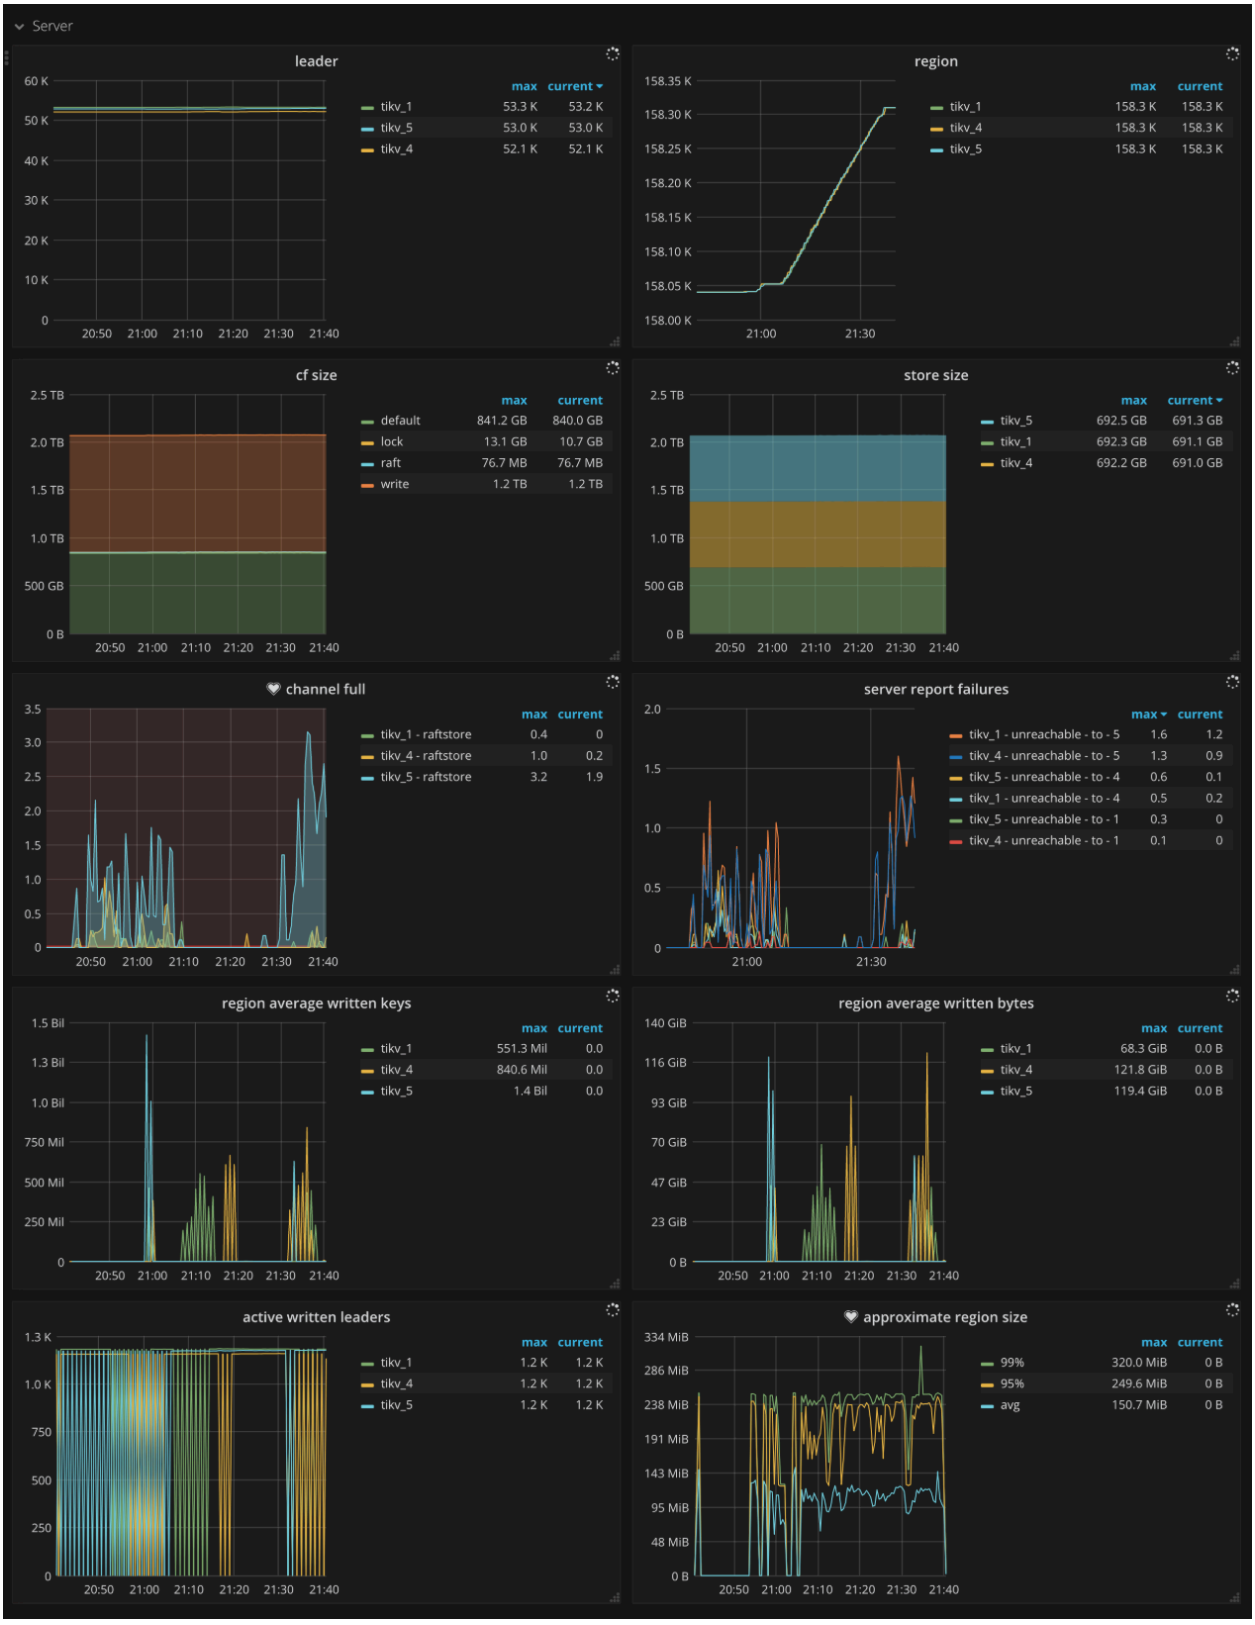

Figure 578: TiKV Dashboard - Server metrics

14.11.5.1.4 gRPC

- gRPC message count: The rate of gRPC messages per type
- gRPC message failed: The rate of failed gRPC messages
- 99% gRPC message duration: The gRPC message duration per message type (P99)
- Average gRPC message duration: The average execution time of gRPC messages
- gRPC batch size: The batch size of gRPC messages between TiDB and TiKV
- Raft message batch size: The batch size of Raft messages between TiKV instances
- gRPC request sources QPS: The QPS of gRPC request sources
- gRPC request sources duration: The execution time of gRPC request sources
- gRPC resource group QPS: The QPS of gRPC request sources by resource groups

14.11.5.1.5 Thread CPU

- Raft store CPU: The CPU utilization of the `raftstore` thread. The CPU utilization should be less than 80% * `raftstore.store-pool-size` in normal case.
- Async apply CPU: The CPU utilization of the `async apply` thread. The CPU utilization should be less than 90% * `raftstore.apply-pool-size` in normal cases.
- Store writer CPU: The CPU utilization of the async IO thread. The CPU utilization should be less than 90% * `raftstore.store-io-pool-size` in normal cases.
- gRPC poll CPU: The CPU utilization of the `gRPC` thread. The CPU utilization should be less than 80% * `server.grpc-concurrency` in normal cases.
- Scheduler worker CPU: The CPU utilization of the `scheduler worker` thread. The CPU utilization should be less than 90% * `storage.scheduler-worker-pool-size` in normal cases.
- Storage ReadPool CPU: The CPU utilization of the `storage read pool` thread
- Unified read pool CPU: The CPU utilization of the `unified read pool` thread
- RocksDB CPU: The CPU utilization of the RocksDB thread
- Coprocessor CPU: The CPU utilization of the `coprocessor` thread
- GC worker CPU: The CPU utilization of the `GC worker` thread
- BackGround worker CPU: The CPU utilization of the `background worker` thread
- Import CPU: The CPU utilization of the `import` thread
- Backup Worker CPU: The CPU utilization of the `backup` thread
- CDC Worker CPU: The CPU utilization of the `CDC worker` thread
- CDC endpoint CPU: The CPU utilization of the `CDC endpoint` thread
- Raftlog fetch worker CPU: The CPU utilization of the async raft log fetcher worker
- TSO Worker CPU: The CPU utilization of the `TSO worker` thread

14.11.5.1.6 PD

- PD requests: The rate at which TiKV sends to PD
- PD request duration (average): The average duration of processing requests that TiKV sends to PD

- PD heartbeats: The rate at which heartbeat messages are sent from TiKV to PD
- PD validate peers: The rate at which messages are sent from TiKV to PD to validate TiKV peers

14.11.5.1.7 Raft IO

- Apply log duration: The time consumed for Raft to apply logs
- Apply log duration per server: The time consumed for Raft to apply logs per TiKV instance
- Append log duration: The time consumed for Raft to append logs
- Append log duration per server: The time consumed for Raft to append logs per TiKV instance
- Commit log duration: The time consumed by Raft to commit logs
- Commit log duration per server: The time consumed by Raft to commit logs per TiKV instance

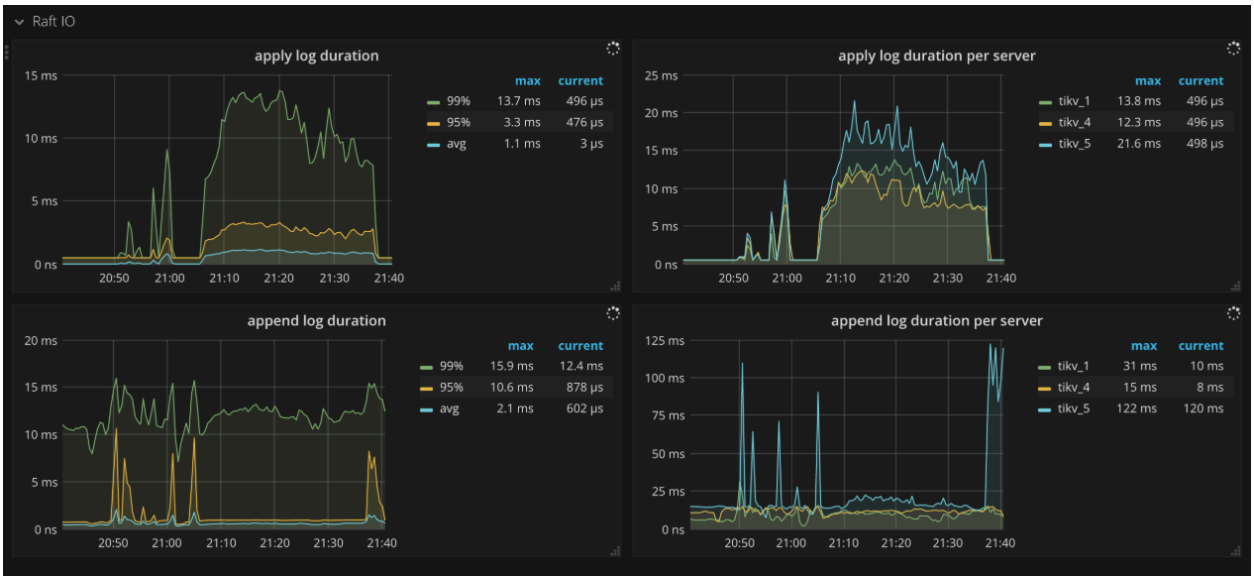

Figure 579: TiKV Dashboard - Raft IO metrics

14.11.5.1.8 Raft process

- Ready handled: The number of handled ready operations per type per second
    - count: The number of handled ready operations per second
    - has_ready_region: The number of Regions that have ready per second
    - pending_region: The operations per second of the Regions being checked for whether it has ready. This metric is deprecated since v3.0.0

  - message: The number of messages that the ready operations per second contain
  - append: The number of Raft log entries that the ready operations per second contain
  - commit: The number of committed Raft log entries that the ready operations per second contain
  - snapshot: The number of snapshots that the ready operations per second contains

- 0.99 Duration of Raft store events: The time consumed by Raftstore events (P99)
- Process ready duration: The time consumed for processes to be ready in Raft
- Process ready duration per server: The time consumed for peer processes to be ready in Raft per TiKV instance. It should be less than 2 seconds (P99.99).
- Max Duration of Raft store events: The time consumed by the slowest Raftstore event.
- Replica read lock checking duration: The time consumed for checking locks when processing Replica Read.
- Peer msg length distribution: The number of messages processed by each Region in each TiKV instance at a time. The more messages, the busier the peer is.

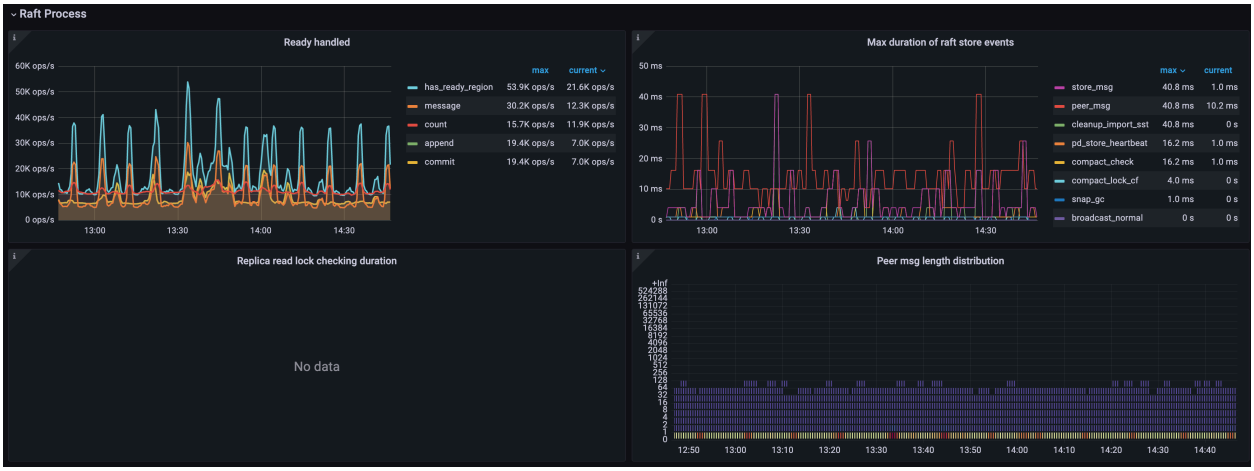

Figure 580: TiKV Dashboard - Raft process metrics

14.11.5.1.9 Raft message

- Sent messages per server: The number of Raft messages sent by each TiKV instance per second
- Flush messages per server: The number of Raft messages flushed by the Raft client in each TiKV instance per second
- Receive messages per server: The number of Raft messages received by each TiKV instance per second
- Messages: The number of Raft messages sent per type per second
- Vote: The number of Vote messages sent in Raft per second
- Raft dropped messages: The number of dropped Raft messages per type per second

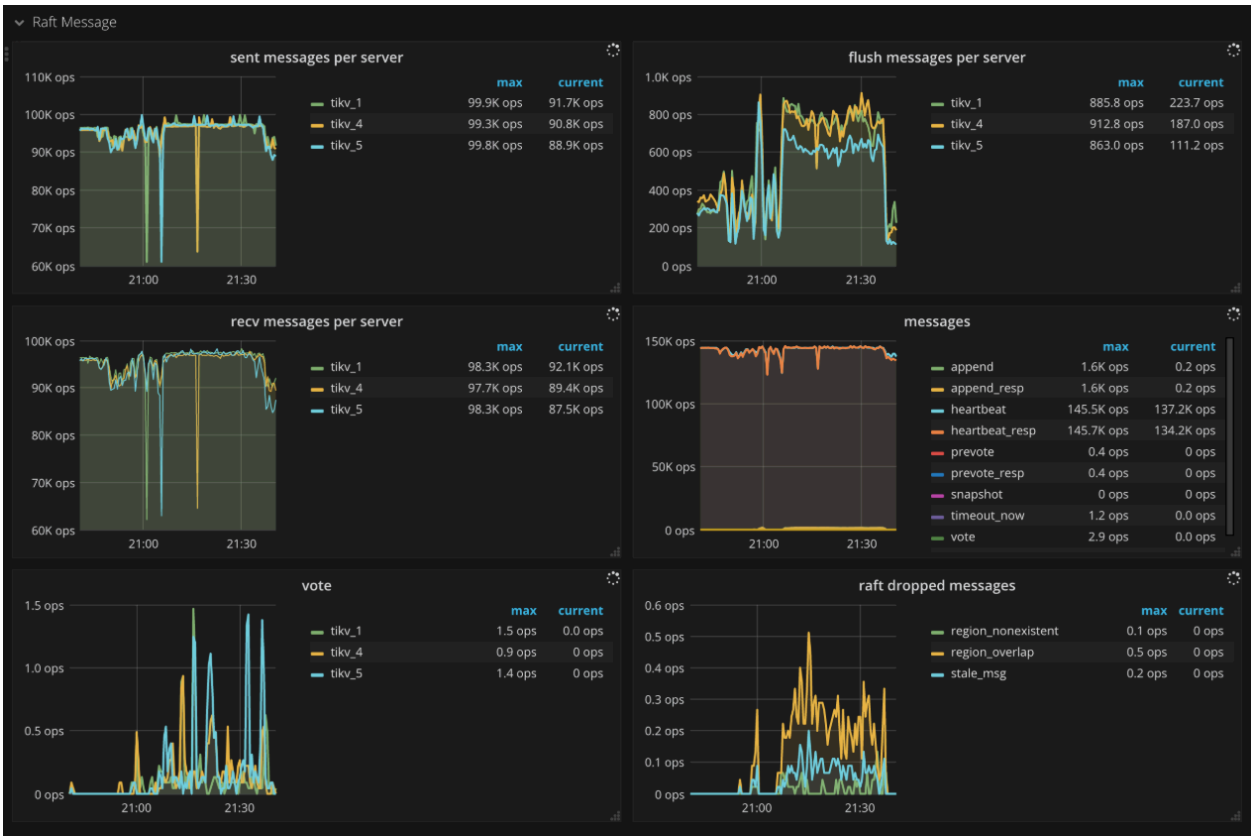

Figure 581: TiKV Dashboard - Raft message metrics

14.11.5.1.10 Raft propose

- Raft apply proposals per ready: The histogram of the number of proposals that each ready operation contains in a batch while applying proposal.
- Raft read/write proposals: The number of proposals per type per second
- Raft read proposals per server: The number of read proposals made by each TiKV instance per second
- Raft write proposals per server: The number of write proposals made by each TiKV instance per second
- Propose wait duration: The histogram of waiting time of each proposal
- Propose wait duration per server: The histogram of waiting time of each proposal per TiKV instance
- Apply wait duration: The histogram of apply time of each proposal
- Apply wait duration per server: The histogram of apply time of each proposal per TiKV instance
- Raft log speed: The average rate at which peers propose logs

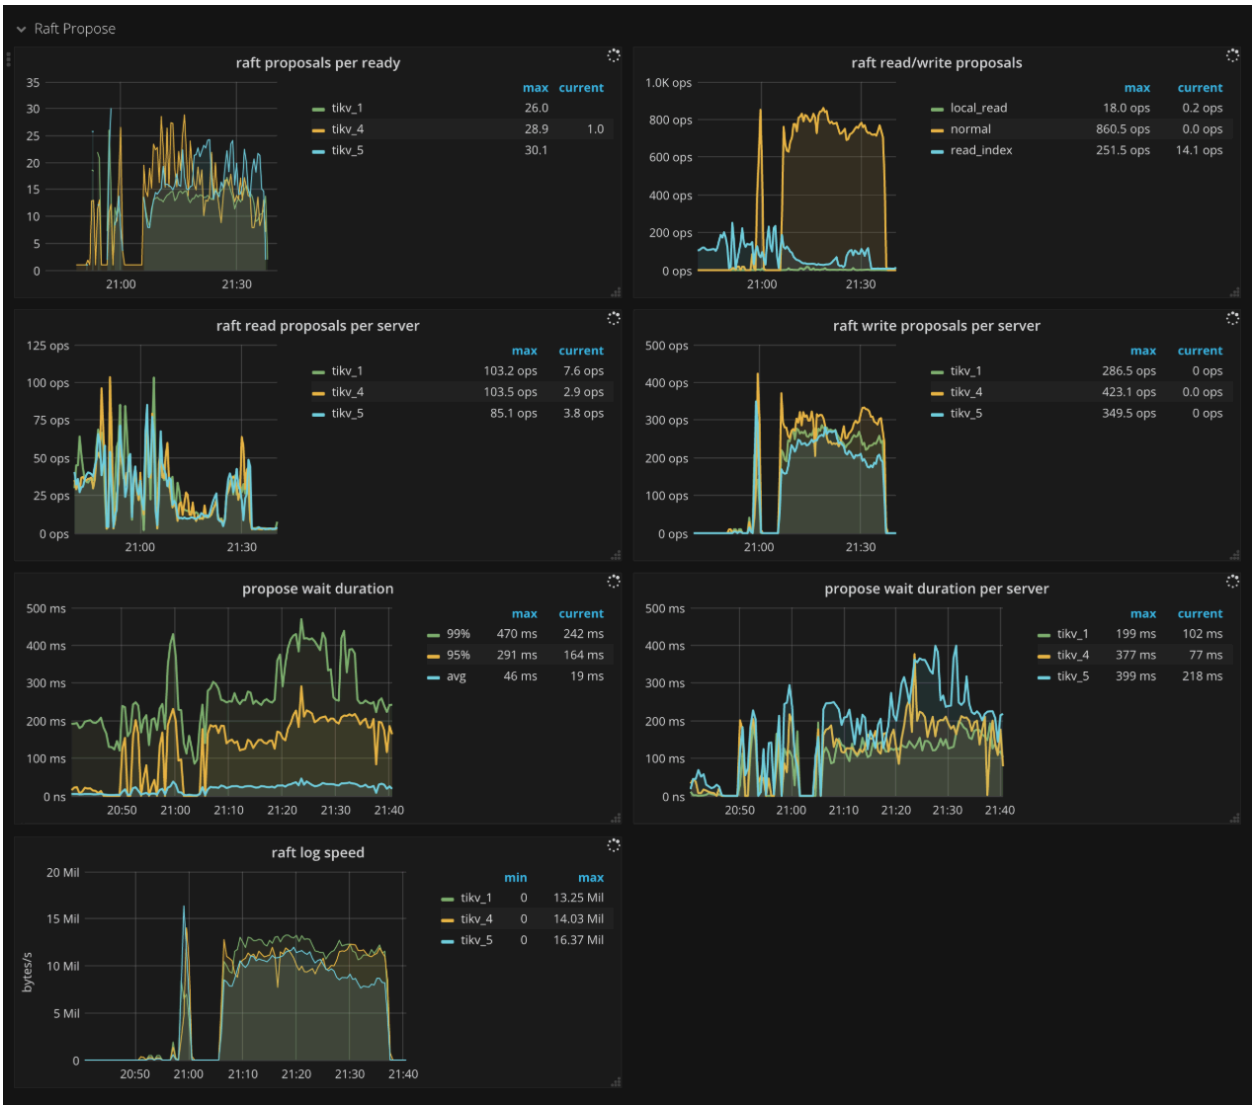

Figure 582: TiKV Dashboard - Raft propose metrics

14.11.5.1.11 Raft admin

- Admin proposals: The number of admin proposals per second
- Admin apply: The number of processed apply commands per second
- Check split: The number of Raftstore split check commands per second
- 99.99% Check split duration: The time consumed when running split check commands (P99.99)

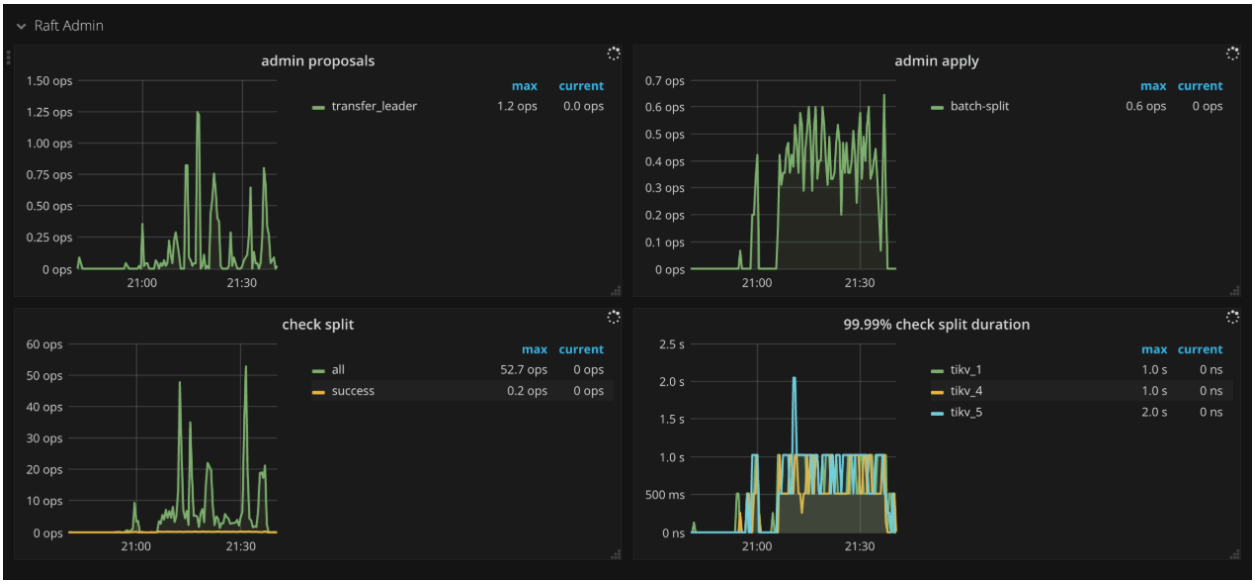

Figure 583: TiKV Dashboard - Raft admin metrics

14.11.5.1.12 Local reader

- Local reader requests: The number of total requests and the number of rejections from the local read thread

Figure 584: TiKV Dashboard - Local reader metrics

14.11.5.1.13 Unified Read Pool

- Time used by level: The time consumed for each level in the unified read pool. Level 0 means small queries.
- Level 0 chance: The proportion of level 0 tasks in unified read pool
- Running tasks: The number of tasks running concurrently in the unified read pool

14.11.5.1.14 Storage

- Storage command total: The number of received command by type per second
- Storage async request error: The number of engine asynchronous request errors per second
- Storage async snapshot duration: The time consumed by processing asynchronous snapshot requests. It should be less than `1s` in `.99`.
- Storage async write duration: The time consumed by processing asynchronous write requests. It should be less than `1s` in `.99`.

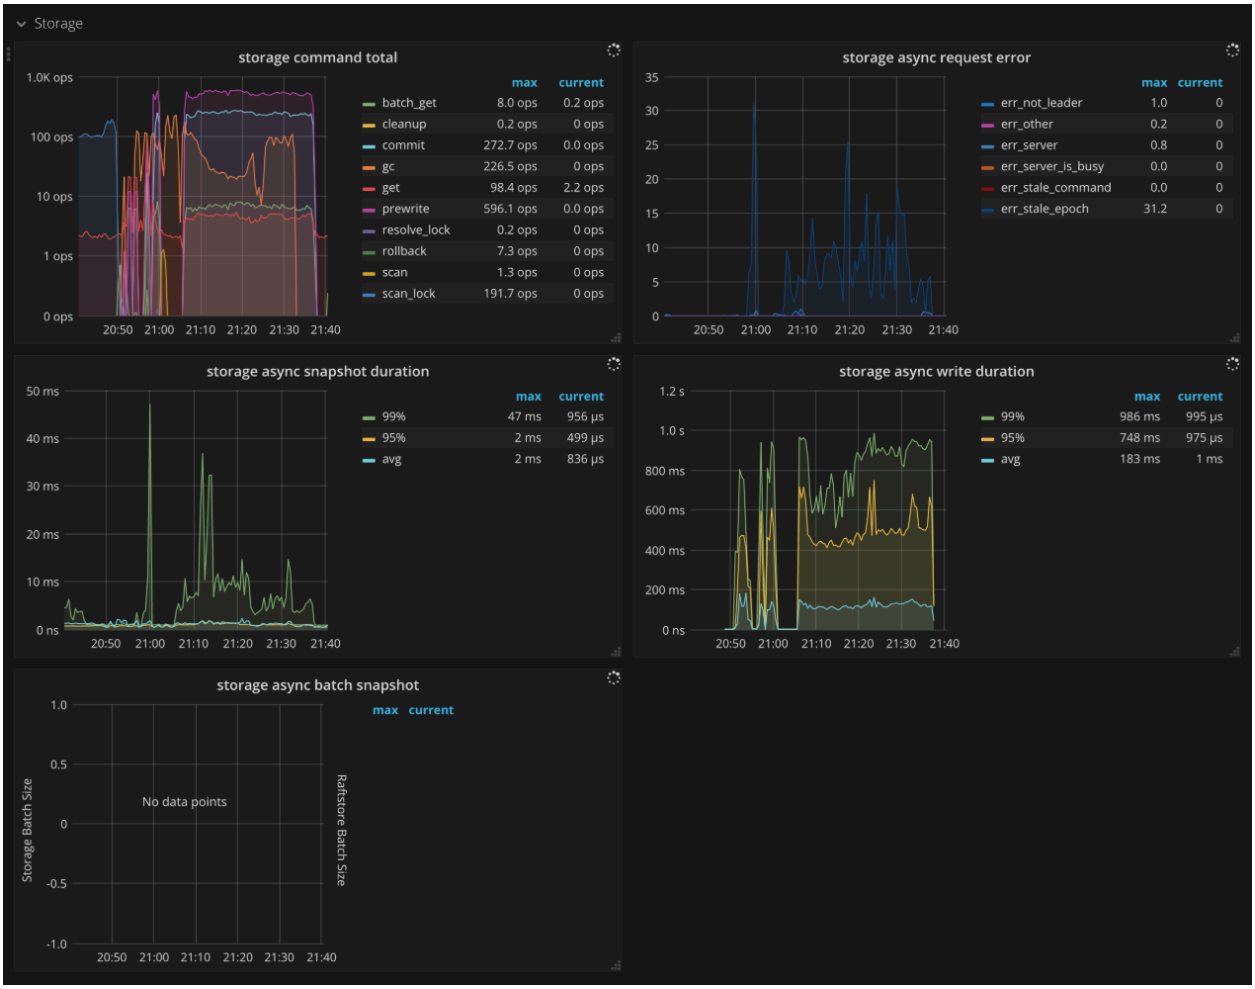

Figure 585: TiKV Dashboard - Storage metrics

14.11.5.1.15 Flow Control

- Scheduler flow: The scheduler traffic on each TiKV instance in real time.
- Scheduler discard ratio: The rejection ratio of scheduler requests on each TiKV instance. If this ratio is greater than 0, it indicates that flow control exists. When `Compaction pending bytes` exceeds its threshold, TiKV will linearly increase the `Scheduler discard ratio` based on the exceeded portion. The client will retry the rejected requests automatically.
- Throttle duration: The blocked duration for the execution of the scheduler requests when flow control is triggered due to too many L0 files. If this metric has values, it indicates that flow control exists.
- Scheduler throttled CF: The CF that triggers RocksDB throttling when the flow control threshold is reached.
- Flow controller actions: The actions that trigger RocksDB throttling when the flow control threshold is reached.

- Flush/L0 flow: The traffic of flush and L0 compaction for different CFs of RocksDB on each TiKV instance.
- Flow control factors: The factors related to triggering RocksDB throttling.
- Compaction pending bytes: The size of the RocksDB data awaiting compaction in real time on each TiKV instance.
- Txn command throttled duration: The blocked duration for commands related to transactions due to throttling. Under normal circumstances, this metric is 0.
- Non-txn command throttled duration: The blocked duration for other commands due to throttling. Under normal circumstances, this metric is 0.

Figure 586: TiKV Dashboard - Flow Control metrics

14.11.5.1.16 Scheduler

- Scheduler stage total: The number of commands at each stage per second. There should not be a lot of errors in a short time.
- Scheduler writing bytes: The total written bytes by commands processed on each TiKV instance
- Scheduler priority commands: The count of different priority commands per second

- Scheduler pending commands: The count of pending commands per TiKV instance per second

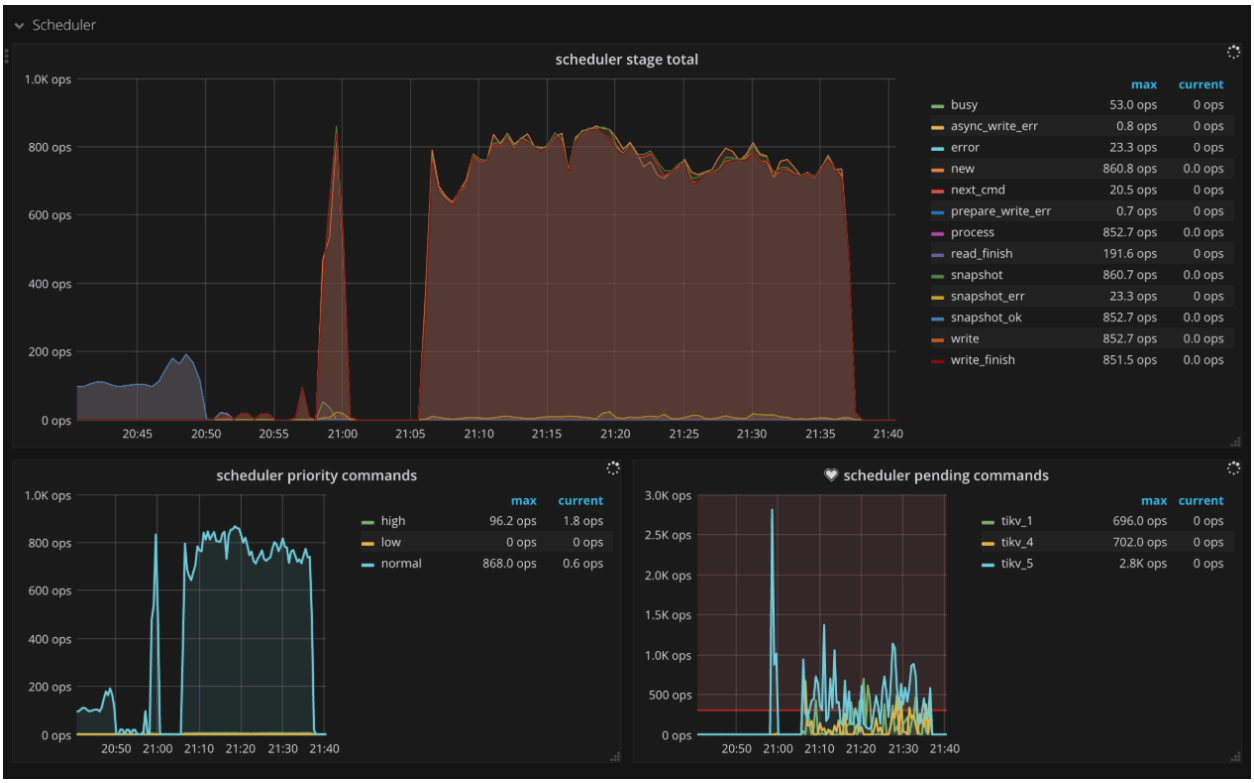

Figure 587: TiKV Dashboard - Scheduler metrics

14.11.5.1.17 Scheduler - commit

- Scheduler stage total: The number of commands at each stage per second when executing the commit command. There should not be a lot of errors in a short time.
- Scheduler command duration: The time consumed when executing the commit command. It should be less than `1s`.
- Scheduler latch wait duration: The waiting time caused by latch when executing the commit command. It should be less than `1s`.
- Scheduler keys read: The count of keys read by a commit command
- Scheduler keys written: The count of keys written by a commit command
- Scheduler scan details: The keys scan details of each CF when executing the commit command.
- Scheduler scan details lock: The keys scan details of lock CF when executing the commit command
- Scheduler scan details write: The keys scan details of write CF when executing the commit command

- Scheduler scan details [default]: The keys scan details of default CF when executing the commit command

Figure 588: TiKV Dashboard - Scheduler commit metrics

14.11.5.1.18 Scheduler - pessimistic_rollback

- Scheduler stage total: The number of commands at each stage per second when executing the `pessimistic_rollback` command. There should not be a lot of errors in a short time.

- Scheduler command duration: The time consumed when executing the `pessimistic_rollback` command. It should be less than `1s`.
- Scheduler latch wait duration: The waiting time caused by latch when executing the `pessimistic_rollback` command. It should be less than `1s`.
- Scheduler keys read: The count of keys read by a `pessimistic_rollback` command
- Scheduler keys written: The count of keys written by a `pessimistic_rollback` command
- Scheduler scan details: The keys scan details of each CF when executing the `pessimistic_rollback` command.
- Scheduler scan details lock: The keys scan details of lock CF when executing the `pessimistic_rollback` command
- Scheduler scan details write: The keys scan details of write CF when executing the `pessimistic_rollback` command
- Scheduler scan details [default]: The keys scan details of default CF when executing the `pessimistic_rollback` command

14.11.5.1.19 Scheduler - prewrite

- Scheduler stage total: The number of commands at each stage per second when executing the prewrite command. There should not be a lot of errors in a short time.
- Scheduler command duration: The time consumed when executing the prewrite command. It should be less than `1s`.
- Scheduler latch wait duration: The waiting time caused by latch when executing the prewrite command. It should be less than `1s`.
- Scheduler keys read: The count of keys read by a prewrite command
- Scheduler keys written: The count of keys written by a prewrite command
- Scheduler scan details: The keys scan details of each CF when executing the prewrite command.
- Scheduler scan details lock: The keys scan details of lock CF when executing the prewrite command
- Scheduler scan details write: The keys scan details of write CF when executing the prewrite command
- Scheduler scan details [default]: The keys scan details of default CF when executing the prewrite command

14.11.5.1.20 Scheduler - rollback

- Scheduler stage total: The number of commands at each stage per second when executing the rollback command. There should not be a lot of errors in a short time.
- Scheduler command duration: The time consumed when executing the rollback command. It should be less than `1s`.
- Scheduler latch wait duration: The waiting time caused by latch when executing the rollback command. It should be less than `1s`.
- Scheduler keys read: The count of keys read by a rollback command

- Scheduler keys written: The count of keys written by a rollback command
- Scheduler scan details: The keys scan details of each CF when executing the rollback command.
- Scheduler scan details lock: The keys scan details of lock CF when executing the rollback command
- Scheduler scan details write: The keys scan details of write CF when executing the rollback command
- Scheduler scan details [default]: The keys scan details of default CF when executing the rollback command

14.11.5.1.21 GC

- GC tasks: The count of GC tasks processed by gc_worker
- GC tasks Duration: The time consumed when executing GC tasks
- TiDB GC seconds: The GC duration
- TiDB GC worker actions: The count of TiDB GC worker actions
- ResolveLocks Progress: The progress of the first phase of GC (Resolve Locks)
- TiKV Auto GC Progress: The progress of the second phase of GC
- GC speed: The number of keys deleted by GC per second
- TiKV Auto GC SafePoint: The value of TiKV GC safe point. The safe point is the current GC timestamp
- GC lifetime: The lifetime of TiDB GC
- GC interval: The interval of TiDB GC
- GC in Compaction Filter: The count of filtered versions in the compaction filter of write CF.

14.11.5.1.22 Snapshot

- Rate snapshot message: The rate at which Raft snapshot messages are sent
- 99% Handle snapshot duration: The time consumed to handle snapshots (P99)
- Snapshot state count: The number of snapshots per state
- 99.99% Snapshot size: The snapshot size (P99.99)
- 99.99% Snapshot KV count: The number of KV within a snapshot (P99.99)

14.11.5.1.23 Task

- Worker handled tasks: The number of tasks handled by worker per second
- Worker pending tasks: Current number of pending and running tasks of worker per second. It should be less than `1000` in normal case.
- FuturePool handled tasks: The number of tasks handled by future pool per second
- FuturePool pending tasks: Current number of pending and running tasks of future pool per second

14.11.5.1.24 Coprocessor Overview

- Request duration: The total duration from the time of receiving the coprocessor request to the time of finishing processing the request
- Total Requests: The number of requests by type per second
- Handle duration: The histogram of time spent actually processing coprocessor requests per minute
- Total Request Errors: The number of request errors of Coprocessor per second. There should not be a lot of errors in a short time.
- Total KV Cursor Operations: The total number of the KV cursor operations by type per second, such as `select`, `index`, `analyze_table`, `analyze_index`, `checksum_table` ↪ , and `checksum_index`.
- KV Cursor Operations: The histogram of KV cursor operations by type per second
- Total RocksDB Perf Statistics: The statistics of RocksDB performance
- Total Response Size: The total size of coprocessor response

14.11.5.1.25 Coprocessor Detail

- Handle duration: The histogram of time spent actually processing coprocessor requests per minute
- 95% Handle duration by store: The time consumed to handle coprocessor requests per TiKV instance per second (P95)
- Wait duration: The time consumed when coprocessor requests are waiting to be handled. It should be less than `10s` (P99.99).
- 95% Wait duration by store: The time consumed when coprocessor requests are waiting to be handled per TiKV instance per second (P95)
- Total DAG Requests: The total number of DAG requests per second
- Total DAG Executors: The total number of DAG executors per second
- Total Ops Details (Table Scan): The number of RocksDB internal operations per second when executing select scan in coprocessor
- Total Ops Details (Index Scan): The number of RocksDB internal operations per second when executing index scan in coprocessor
- Total Ops Details by CF (Table Scan): The number of RocksDB internal operations for each CF per second when executing select scan in coprocessor
- Total Ops Details by CF (Index Scan): The number of RocksDB internal operations for each CF per second when executing index scan in coprocessor

14.11.5.1.26 Threads

- Threads state: The state of TiKV threads
- Threads IO: The I/O traffic of each TiKV thread
- Thread Voluntary Context Switches: The number of TiKV threads voluntary context switches
- Thread Nonvoluntary Context Switches: The number of TiKV threads nonvoluntary context switches

14.11.5.1.27 RocksDB - kv/raft

- Get operations: The count of get operations per second
- Get duration: The time consumed when executing get operations
- Seek operations: The count of seek operations per second
- Seek duration: The time consumed when executing seek operations
- Write operations: The count of write operations per second
- Write duration: The time consumed when executing write operations
- WAL sync operations: The count of WAL sync operations per second
- Write WAL duration: The time consumed for writing WAL
- WAL sync duration: The time consumed when executing WAL sync operations
- Compaction operations: The count of compaction and flush operations per second
- Compaction duration: The time consumed when executing the compaction and flush operations
- SST read duration: The time consumed when reading SST files
- Write stall duration: Write stall duration. It should be `0` in normal case.
- Memtable size: The memtable size of each column family
- Memtable hit: The hit rate of memtable
- Block cache size: The block cache size. Broken down by column family if shared block cache is disabled.
- Block cache hit: The hit rate of block cache
- Block cache flow: The flow rate of block cache operations per type
- Block cache operations: The count of block cache operations per type
- Keys flow: The flow rate of operations on keys per type
- Total keys: The count of keys in each column family
- Read flow: The flow rate of read operations per type
- Bytes / Read: The bytes per read operation
- Write flow: The flow rate of write operations per type
- Bytes / Write: The bytes per write operation
- Compaction flow: The flow rate of compaction operations per type
- Compaction pending bytes: The pending bytes to be compacted
- Compaction Job Size(files): The number of SST files involved in a single compaction job
- Read amplification: The read amplification per TiKV instance
- Compression ratio: The compression ratio of each level
- Number of snapshots: The number of snapshots per TiKV instance
- Oldest snapshots duration: The time that the oldest unreleased snapshot survivals
- Number files at each level: The number of SST files for different column families in each level
- Ingest SST duration seconds: The time consumed to ingest SST files
- Stall conditions changed of each CF: Stall conditions changed of each column family

14.11.5.1.28 Raft Engine

- Operations

    - write: the number of write operations by Raft Engine per second
    - read_entry: the number of raft log read operations by Raft Engine per second
    - read_message: the number of raft metadata read operations by Raft Engine per second

- Write duration: the duration of write operations by Raft Engine. This duration is close to the sum of the latency of disk IOs involved in writing these data.
- Flow
    - write: the write traffic of Raft Engine
    - rewrite append: the traffic of rewriting append logs
    - rewrite rewrite: the traffic of rewriting rewrite logs
- Write Duration Breakdown (99%)
    - wal: the latency of writing Raft Engine WAL
    - wait: the waiting time before writing
    - apply: the time consumed for applying data to memory
- Bytes/Written: the bytes written by Raft Engine every time
- WAL Duration Breakdown (P99%): the time consumed for each stage of writing Raft Engine WAL
- File Count
    - append: the number of files used for appending data by Raft Engine
    - rewrite: the number of files used for rewriting data by Raft Engine (rewrite is similar to RocksDB compaction)
- Entry Count
    - rewrite: the number of entries rewritten by Raft Engine
    - append: the number of entries appended by Raft Engine

14.11.5.1.29 Titan - All

- Blob file count: The number of Titan blob files
- Blob file size: The total size of Titan blob file
- Live blob size: The total size of valid blob record
- Blob cache hit: The hit rate of Titan block cache
- Iter touched blob file count: The number of blob file involved in a single iterator
- Blob file discardable ratio distribution: The ratio distribution of blob record failure of blob files
- Blob key size: The size of Titan blob keys
- Blob value size: The size of Titan blob values
- Blob get operations: The count of get operations in Titan blob
- Blob get duration: The time consumed when executing get operations in Titan blob
- Blob iter operations: The time consumed when executing iter operations in Titan blob
- Blob seek duration: The time consumed when executing seek operations in Titan blob

- Blob next duration: The time consumed when executing next operations in Titan blob
- Blob prev duration: The time consumed when executing prev operations in Titan blob
- Blob keys flow: The flow rate of operations on Titan blob keys
- Blob bytes flow: The flow rate of bytes on Titan blob keys
- Blob file read duration: The time consumed when reading Titan blob file
- Blob file write duration: The time consumed when writing Titan blob file
- Blob file sync operations: The count of blob file sync operations
- Blob file sync duration: The time consumed when synchronizing blob file
- Blob GC action: The count of Titan GC actions
- Blob GC duration: The Titan GC duration
- Blob GC keys flow: The flow rate of keys read and written by Titan GC
- Blob GC bytes flow: The flow rate of bytes read and written by Titan GC
- Blob GC input file size: The size of Titan GC input file
- Blob GC output file size: The size of Titan GC output file
- Blob GC file count: The count of blob files involved in Titan GC

14.11.5.1.30 In Memory Engine

The following metrics are related to TiKV MVCC In-Memory Engine (IME).

- Ops: The number of operations per second for column families
- Read MBps: The total bytes of read traffic in RocksDB and the in-memory engine
- Coprocessor Handle duration: The time consumed for handling coprocessor requests
- Region Cache Hit: The number of times data is successfully retrieved from the Region cache
- Region Cache Hit Rate: The hit rate of Region cache
- Region Cache Miss Reason: The reasons why data is not retrieved from the Region cache
- Memory Usage: The memory usage of the in-memory engine
- Region Count: The count of different types of Regions
- GC Filter: The information about the filtering process during garbage collection (GC)
- Region GC Duration: The time consumed for Region GC
- Region Load Duration: The time consumed for loading Regions
- Region Load Count: The number of Regions loaded per second
- Region Eviction Duration: The time consumed for evicting Regions
- Region Eviction Count: The number of Regions evicted per second
- Write duration: The time consumed for write operations in the Region cache engine
- 99% In-memory engine write duration per server: The 99th percentile of write duration per TiKV server for the in-memory engine
- Prepare for write duration: The time consumed for preparing write operations in the in-memory engine
- 99% In-memory engine prepare for write duration per server: The 99th percentile of time consumed for preparing write operations per TiKV server in the in-memory engine
- Iterator operations: The number of different types of iterator operations
- Seek duration: The time consumed for seek operations

- Oldest Auto GC SafePoint: The oldest automatic GC safepoint for Regions cached in the in-memory engine
- Newest Auto GC SafePoint: The newest automatic GC safepoint for Regions cached in the in-memory engine
- Auto GC SafePoint Gap: The time gap between the newest automatic GC safepoint and the oldest automatic GC safepoint for Regions cached in the in-memory engine
- Auto GC SafePoint Gap With TiKV: The gap between the TiKV automatic GC safepoint and the oldest automatic GC safepoint for Regions cached in the in-memory engine

14.11.5.1.31 Pessimistic Locking

- Lock Manager Thread CPU: The CPU utilization of the lock manager thread
- Lock Manager Handled tasks: The number of tasks handled by lock manager
- Waiter lifetime duration: The waiting time of the transaction for the lock to be released
- Wait table: The status information of wait table, including the number of locks and the number of transactions waiting for the lock
- Deadlock detect duration: The time consumed for detecting deadlock
- Detect error: The number of errors encountered when detecting deadlock, including the number of deadlocks
- Deadlock detector leader: The information of the node where the deadlock detector leader is located
- Total pessimistic locks memory size: The memory size occupied by the in-memory pessimistic locks
- In-memory pessimistic locking result: The result of only saving pessimistic locks to memory. `full` means the number of times that the pessimistic lock is not saved to memory because the memory limit is exceeded.

14.11.5.1.32 Resolved-TS

- Resolved-TS worker CPU: The CPU utilization of the resolved-ts worker threads
- Advance-TS worker CPU: The CPU utilization of the advance-ts worker threads
- Scan lock worker CPU: The CPU utilization of the scan lock worker threads
- Max gap of resolved-ts: The maximum time difference between the resolved-ts of all active Regions in this TiKV and the current time
- Max gap of safe-ts: The maximum time difference between the safe-ts of all active Regions in this TiKV and the current time
- Min Resolved TS Region: The ID of the Region whose resolved-ts is the minimal
- Min Safe TS Region: The ID of the Region whose safe-ts is the minimal
- Check Leader Duration: The distribution of time spent on processing leader requests. The duration is from sending requests to receiving responses in leader
- Max gap of resolved-ts in Region leaders: The maximum time difference between the resolved-ts of all active Regions in this TiKV and the current time, only for Region leaders

- Min Leader Resolved TS Region: The ID of the Region whose resolved-ts is the minimal, only for Region leaders
- Lock heap size: The size of the heap that tracks locks in the resolved-ts module

14.11.5.1.33 Memory

- Allocator Stats: The statistics of the memory allocator

14.11.5.1.34 Backup

- Backup CPU: The CPU utilization of the backup thread
- Range Size: The histogram of backup range size
- Backup Duration: The time consumed for backup
- Backup Flow: The total bytes of backup
- Disk Throughput: The disk throughput per instance
- Backup Range Duration: The time consumed for backing up a range
- Backup Errors: The number of errors encountered during a backup

14.11.5.1.35 Encryption

- Encryption data keys: The total number of encrypted data keys
- Encrypted files: The number of encrypted files
- Encryption initialized: Shows whether encryption is enabled. `1` means enabled.
- Encryption meta files size: The size of the encryption meta file
- Encrypt/decrypt data nanos: The histogram of duration on encrypting/decrypting data each time
- Read/write encryption meta duration: The time consumed for reading/writing encryption meta files

14.11.5.1.36 Log Backup

- Handle Event Rate: The speed of handling write events
- Initial Scan Generate Event Throughput: Incremental scanning speed when generating a new listener stream
- Abnormal Checkpoint TS Lag: The lag of the current checkpoint TS to the present time for each task
- Memory Of Events: An estimated amount of memory occupied by temporary data generated by incremental scanning
- Observed Region Count: The number of Regions currently listened to
- Errors: The number and type of retryable and non-fatal errors
- Fatal Errors: The number and type of fatal errors. Usually, fatal errors cause the task to be paused.

- Checkpoint TS of Tasks: Checkpoint TS for each task
- Flush Duration: The heat map of how long it takes for moving cached data to external storage
- Initial Scanning Duration: The heat map of how long it takes for incremental scanning when creating a new listening stream
- Convert Raft Event Duration: The heat map of how long it takes to transform a Raft log entry into backup data after creating a listening stream
- Command Batch Size: The batch size (within a single Raft group) of the listening Raft command
- Save to Temp File Duration: The heat map of how long it takes to temporarily store a batch of backup data (spanning several tasks) into the temporary file area
- Write to Temp File Duration: The heat map of how long it takes to temporarily store a batch of backup data (from a particular task) into the temporary file area
- System Write Call Duration: The heat map of how long it takes to write a batch of backup data (from a Region) to a temporary file
- Internal Message Type: The type of messages received by the actor responsible for the log backup within TiKV
- Internal Message Handling Duration (P90|P99): The speed of consuming and processing each type of messages
- Initial Scan RocksDB Throughput: The read traffic generated by RocksDB internal logging during incremental scanning
- Initial Scan RocksDB Operation: The number of individual operations logged internally by RocksDB during incremental scanning
- Initial Scanning Trigger Reason: The reason for triggering incremental scanning
- Region Checkpoint Key Putting: The number of checkpoint operations logged to the PD

> **Note:**
>
> The following monitoring metrics all use TiDB nodes as their data source, but they have some impact on the log backup process. Therefore, they are placed in the **TiKV Details** dashboard for ease of reference. TiKV actively pushes progress most of the time, but it is normal for some of the following monitoring metrics to occasionally not have sampled data.

- Request Checkpoint Batch Size: The request batch size when the log backup coordinator requests checkpoint information for each TiKV
- Tick Duration [P99|P90]: The time taken by the tick inside the coordinator
- Region Checkpoint Failure Reason: The reason why a Region checkpoint cannot advance within the coordinator
- Request Result: The record of the coordinator's success or failure in advancing the Region checkpoint

- Get Region Operation Count: The number of times the coordinator requests Region information from the PD
- Try Advance Trigger Time: The time taken for the coordinator to attempt to advance the checkpoint

14.11.5.1.37 Backup & Import

- Import CPU Utilization: The CPU utilization aggregated by SST importer.
- Import Thread Count: The number of threads used by SST importer.
- Import Errors: The number of errors encountered during SST import.
- Import RPC Duration: The time spent on various RPC calls in SST importer.
- Import RPC Ops: The total number of RPC calls in SST importer.
- Import RPC Count: The number of RPC calls being processed by SST importer.
- Import Write/Download RPC Duration: The RPC time for write or download operations in SST importer.
- Import Wait Duration: The time spent waiting in queue for download task execution.
- Import Read SST Duration: The time spent reading an SST file from external storage and downloading it to TiKV.
- Import Rewrite SST Duration: The time spent rewriting the SST file based on rewrite rules.
- Import Ingest RPC Duration: The time spent handling ingest RPC requests on TiKV.
- Import Ingest SST Duration: The time spent ingesting the SST file into RocksDB.
- Import Ingest SST Bytes: The number of bytes ingested.
- Import Download SST Throughput: The SST download throughput in bytes per second.
- cloud request: The number of requests to cloud providers.

14.11.5.1.38 Point In Time Restore

- CPU Usage: The CPU utilization by point-in-time recovery (PITR).
- P99 RPC Duration: The 99th percentile of RPC request duration.
- Import RPC Ops: The total number of RPC calls in SST importer.
- Import RPC Count: The number of RPC calls being processed by SST importer.
- Cache Events: The number of events in the file cache during SST import.
- Overall RPC Duration: The time spent on RPC calls.
- Read File into Memory Duration: The time spent downloading files from external storage and loading them into memory.
- Queuing Time: The time spent waiting to be scheduled on a thread.
- Apply Request Throughput: The rate of applying requests in bytes.
- Downloaded File Size: The size of downloaded file in bytes.
- Apply Batch Size: The number of bytes for applying to Raft store in one batch.
- Blocked by Concurrency Time: The time spent waiting for execution due to concurrency constraints.
- Apply Request Speed: The speed of applying request to Raft store.

- Cached File in Memory: The files cached by the applying requests of SST importer.
- Engine Requests Unfinished: The number of pending requests to Raft store.
- Apply Time: The time spent writing data to Raft store.
- Raft Store Memory Usage: The memory usage for Raft store.

14.11.5.1.39 Explanation of Common Parameters

gRPC Message Type

1. Transactional API:

    - kv_get: The command of getting the latest version of data specified by `ts`
    - kv_scan: The command of scanning a range of data
    - kv_prewrite: The command of prewriting the data to be committed at first phase of 2PC
    - kv_pessimistic_lock: The command of adding a pessimistic lock to the key to prevent other transaction from modifying this key
    - kv_pessimistic_rollback: The command of deleting the pessimistic lock on the key
    - kv_txn_heart_beat: The command of updating `lock_ttl` for pessimistic transactions or large transactions to prevent them from rolling back
    - kv_check_txn_status: The command of checking the status of the transaction
    - kv_commit: The command of committing the data written by the prewrite command
    - kv_cleanup: The command of rolling back a transaction, which is deprecated in v4.0
    - kv_batch_get: The command of getting the value of batch key at once, similar to `kv_get`
    - kv_batch_rollback: The command of batch rollback of multiple prewrite transactions
    - kv_scan_lock: The command of scanning all locks with a version number before `max_version` to clean up expired transactions
    - kv_resolve_lock: The command of committing or rollback the transaction lock, according to the transaction status.
    - kv_gc: The command of GC
    - kv_delete_range: The command of deleting a range of data from TiKV

2. Raw API:

    - raw_get: The command of getting the value of key
    - raw_batch_get: The command of getting the value of batch keys
    - raw_scan: The command of scanning a range of data
    - raw_batch_scan: The command of scanning multiple consecutive data range
    - raw_put: The command of writing a key/value pair
    - raw_batch_put: The command of writing a batch of key/value pairs

- raw_delete: The command of deleting a key/value pair
- raw_batch_delete: The command of a batch of key/value pairs
- raw_delete_range: The command of deleting a range of data

14.11.5.2 TiKV-FastTune dashboard

If performance issues of TiKV occur, such as QPS jitter, latency jitter, and latency increasing trend, you can check the **TiKV-FastTune** dashboard. This dashboard contains a set of panels that help you with diagnostics, especially when the write workload in your cluster is medium or large.

When write-related performance issues occur, you can first check the TiDB-related dashboards. If the issues are at the storage side, open the **TiKV-FastTune** page, browse and check every panel on it.

In the **TiKV-FastTune** dashboard, you can see a title that suggests a possible cause of the performance issues. To check whether the suggested cause is true, check the graph on the page.

The left-Y-axis of the graph represents the write-RPC QPS of the storage side, and a set of graphs on the right-Y-axis are drawn upside down. If the shape of the left graph matches that of the right graphs, the suggested cause is true.

For detailed metrics and descriptions, see the dashboard user manual.

14.11.6 Monitor the TiFlash Cluster

This document describes the monitoring items of TiFlash.

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see Overview of the Monitoring Framework.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, and Node_exporter. A lot of metrics are there to help you diagnose.

TiFlash has three dashboard panels: **TiFlash-Summary**, **TiFlash-Proxy-Summary**, and **TiFlash-Proxy-Details**. The metrics on these panels indicate the current status of TiFlash. The **TiFlash-Proxy-Summary** and **TiFlash-Proxy-Details** panels mainly show the information of the Raft layer and the metrics are detailed in Key Monitoring Metrics of TiKV.

> **Note:**
>
> It is recommended that you use TiDB v4.0.5 or later versions for improved monitor on TiFlash.

The following sections introduce the default monitoring information of **TiFlash-Summary**.

14.11.6.1 Server

- Store size: The storage size used by each TiFlash instance.
- Available size: The storage size available for each TiFlash instance.
- Capacity size: The storage capacity for each TiFlash instance.
- Uptime: The runtime of TiFlash since last restart.
- Memory: The memory usage per TiFlash instance.
- CPU Usage: The CPU utilization per TiFlash instance.
- FSync OPS: The number of fsync operations per TiFlash instance per second.
- File Open OPS: The number of `open` operations per TiFlash instance per second.
- Opened File Count: The number of file descriptors currently opened by each TiFlash instance.

> **Note:**
>
> Store size, FSync OPS, File Open OPS, and Opened File Count currently only cover the monitoring information of the TiFlash storage layer and do not cover that in TiFlash-Proxy.

14.11.6.2 Coprocessor

- Request QPS: The number of coprocessor requests received by all TiFlash instances. `batch` is the number of batch requests. `batch_cop` is the number of coprocessor requests in the batch requests. `cop` is the number of coprocessor requests that are sent directly via the coprocessor interface. `cop_dag` is the number of dag requests in all coprocessor requests. `super_batch` is the number of requests to enable the Super Batch feature.
- Executor QPS: The number of each type of dag executors in the requests received by all TiFlash instances. `table_scan` is the table scan executor. `selection` is the selection executor. `aggregation` is the aggregation executor. `top_n` is the `TopN` executor. `limit` is the limit executor.
- Request Duration: The total duration of all TiFlash instances processing coprocessor requests. The total duration is from the time that the coprocessor request is received to the time that the response to the request is completed.
- Error QPS: The number of errors of all TiFlash instances processing coprocessor requests. `meet_lock` means that the read data is locked. `region_not_found` means that the Region does not exist. `epoch_not_match` means the read Region epoch is inconsistent with the local epoch. `kv_client_error` means that the communication

with TiKV returns an error. `internal_error` is the internal system error of TiFlash. `other` is other types of errors.
- Request Handle Duration: The duration of all TiFlash instances processing coprocessor requests. The processing time is from starting to execute the coprocessor request to completing the execution.
- Response Bytes/Seconds: The total bytes of the response from all TiFlash instances.
- Cop task memory usage: The total memory usage of all TiFlash instances processing coprocessor requests.
- Handling Request Number: The total number of all TiFlash instances processing coprocessor requests. The classification of the requests is the same as that of Request QPS.
- Threads of RPC: The real-time number of RPC threads used in each TiFlash instance.
- Max Threads of RPC: The maximum number of RPC threads recently used in each TiFlash instance.
- Threads: The real-time number of threads used in each TiFlash instance.
- Max Threads: The maximum number of threads recently used in each TiFlash instance.

14.11.6.3 Task Scheduler

- Min TSO: The minimum TSO among all queries running on each TiFlash instance. This value ensures that queries with the minimum TSO can be scheduled to run. When no queries are running, this value is the maximum unsigned 64-bit integer.
- Estimated Thread Usage and Limit: The estimated amount of threads used by all queries running on each TiFlash instance, and the soft and hard limits on the amount.
- Active and Waiting Queries Count: The amount of running queries and that of waiting queries on each TiFlash instance.
- Active and Waiting Tasks Count: The amount of running tasks and that of waiting tasks on each TiFlash instance.
- Hard Limit Exceeded Count: Times that the estimated amount of threads used by queries running on each TiFlash instance exceeds the hard limit.
- Task Waiting Duration: The duration from task initialization to task scheduling on each TiFlash instance.

14.11.6.4 DDL

- Schema Version: The version of the schema currently cached in each TiFlash instance.
- Schema Apply OPM: The number of TiDB `schema diff` synchronized in `apply` operations by all TiFlash instances per minute. This item includes the count of three types of `apply`: `diff apply`, `full apply`, and `failed apply`. `diff apply` is the normal process of a single apply. If `diff apply` fails, `failed apply` increases by `1`, and TiFlash rolls back to `full apply` and pulls the latest schema information to update the schema version of TiFlash.
- Schema Internal DDL OPM: The number of specific DDL operations executed per minute in all TiFlash instances.

- Schema Apply Duration: The time used for a single `apply schema` operation in all TiFlash instances.

14.11.6.5 Storage

- Write Command OPS: The number of write requests received per second by the storage layer of all TiFlash instances.
- Write Amplification: Write amplification of each TiFlash instance (the actual bytes of disk writes divided by the written bytes of logical data). `total` is the write amplification since this start, and `5min` is the write amplification in the last 5 minutes.
- Read Tasks OPS: The number of read tasks in the storage layer per second for each TiFlash instance.
- Rough Set Filter Rate: The proportion of the number of packets read by each TiFlash instance in the last minute that are filtered by the rough set index of the storage layer.
- Internal Tasks OPS: The number of times that all TiFlash instances perform internal data sorting tasks per second.
- Internal Tasks Duration: The time consumed by all TiFlash instances for internal data sorting tasks.
- Page GC Tasks OPM: The number of times that all TiFlash instances perform Delta data sorting tasks per minute.
- Page GC Tasks Duration: The distribution of time consumed by all TiFlash instances to perform Delta data sorting tasks.
- Disk Write OPS: The number of disk writes per second by all TiFlash instances.
- Disk Read OPS: The number of disk reads per second by all TiFlash instances.
- Write flow: The traffic of disk writes by all TiFlash instances.
- Read flow: The traffic of disk reads by all TiFlash instances.

> **Note:**
>
> These metrics only cover the monitoring information of the TiFlash storage layer and do not cover that in TiFlash-Proxy.

14.11.6.6 Storage Write Stall

- Write & Delta Management Throughput: The throughput of write and data compaction for all instances.
  - `throughput_write` means the throughput of data synchronization through Raft.
  - `throughput_delta-management` means the throughput of data compaction.
  - `total_write` means the total bytes written since the last start.

    - `total_delta-management` means the total bytes of data compacted since the last start.

- Write Stall Duration: The stall duration of write and removing Region data (deleting ranges) by instance.
- Write Throughput By Instance: The throughput of write by instance. It includes the throughput by applying the Raft write commands and Raft snapshots.
- Write Command OPS By Instance: The total count of different kinds of commands received by instance.

    - `write block` means the data logs synchronized through Raft.
    - `delete_range` means that some Regions are removed from or moved to this instance.
    - `ingest` means some Region snapshots are applied to this instance.

14.11.6.7 Raft

- Read Index OPS: The number of times that each TiFlash instance triggers the `read_index` request per second, which equals to the number of Regions triggered.
- Read Index Duration: The time used by `read_index` for all TiFlash instances. Most time is used for interaction with the Region leader and retry.
- Wait Index Duration: The time used by `wait_index` for all TiFlash instances, namely the time used to wait until local index >= read_index after the `read_index` request is received.

14.11.7 Key Monitoring Metrics of Resource Control

If you use TiUP to deploy the TiDB cluster, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see Overview of the Monitoring Framework.

The Grafana dashboard is divided into a series of sub dashboards which include Overview, PD, TiDB, TiKV, Node_exporter, Disk Performance, and Performance_overview.

If your cluster has used the Resource Control feature, you can get an overview of the resource consumption status from the Resource Control dashboard.

TiDB uses the token bucket algorithm for flow control. As described in the RFC: Global Resource Control in TiDB, a TiDB node might have multiple Resource Groups, which are flow controlled by GAC (Global Admission Control) on the PD side. The Local Token Buckets in each TiDB node periodically (5 seconds by default) communicate with the GAC on the PD side to reconfigure the local tokens. In TiDB, the Local Token Buckets are implemented as Resource Controller Clients.

This document describes some key monitoring metrics displayed on the Resource Control dashboard.

14.11.7.1 Metrics about Request Unit

- RU: the Request Unit (RU) consumption information of each resource group, calculated in real time. `total` is the sum of the Request Units consumed by all Resource Groups. The Request Unit consumption of each resource group should be equal to the sum of its read consumption (Read Request Unit) and write consumption (Write Request Unit).
- RU Per Query: the average number of Request Units consumed by each SQL statement per second. It is obtained by dividing the above RU metric by the number of SQL statements executed per second.
- RRU: the Read Request Unit consumption information of each resource group, calculated in real time. `total` is the sum of the Read Request Units consumed by all Resource Groups.
- RRU Per Query: the average number of Read Request Units consumed by each SQL statement per second. It is obtained by dividing the above RRU metric by the number of SQL statements executed per second.
- WRU: the Write Request Unit consumption information of each resource group, calculated in real time. `total` is the sum of the Write Request Units consumed by all Resource Groups.
- WRU Per Query: the average number of Write Request Units consumed by each SQL statement per second. It is obtained by dividing the above WRU metric by the number of SQL statements executed per second.
- Available RU: the available tokens in the RU token bucket of each resource group. When it is `0`, this resource group consumes tokens at the rate of `RU_PER_SEC` and can be considered to be in a rate-limited state.
- Query Max Duration: the maximum Query Duration in terms of resource groups.

14.11.7.2 Metrics about resources

- KV Request Count: the number of KV requests for each resource group, calculated per second. The requests are divided into read and write types. `total` is the sum of the KV requests for all Resource Groups.
- KV Request Count Per Query: the average number of read and write KV requests by each SQL statement per second. It is obtained by dividing the above KV Request Count metric by the number of SQL statements executed per second.
- Bytes Read: the amount of data read by each Resource Group, calculated per second. `total` is the sum of the data read by all Resource Groups.
- Bytes Read Per Query: the average amount of data read by each SQL statement per second. It is obtained by dividing the above Bytes Read metric by the number of SQL statements executed per second.
- Bytes Written: the amount of data written by each Resource Group, calculated in real time. `total` is the sum of the data written by all Resource Groups.
- Bytes Written Per Query: the average amount of data written by each SQL statement per second. It is obtained by dividing the above Bytes Written metric by the number of SQL statements executed per second.

- KV CPU Time: the KV layer CPU time consumed by each Resource Group, calculated in real time. `total` is the sum of the KV layer CPU time consumed by all Resource Groups.
- SQL CPU Time: the SQL layer CPU time consumed by each Resource Group, calculated in real time. `total` is the sum of the SQL layer CPU time consumed by all Resource Groups.

14.11.7.3 Metrics about Resource Controller Client

- Active Resource Groups: the number of resource groups for each Resource Controller Client, calculated in real time.
- Total KV Request Count: the number of KV requests for each Resource Controller Client, calculated in real time and by resource groups. `total` is the sum of the KV requests for all Resource Controller Clients.
- Failed KV Request Count: the number of failed KV requests for each Resource Controller Client, calculated in real time and by resource groups. `total` is the sum of the failed KV requests for all Resource Controller Clients.
- Successful KV Request Count: the number of successful KV requests for each Resource Controller Client, calculated in real time and by resource groups. `total` is the sum of the successful KV requests for all Resource Controller Clients.
- Successful KV Request Wait Duration (99/90): the waiting time (at different percentiles) for successful KV requests for each Resource Controller Client, calculated in real time and by resource groups.
- Token Request Handle Duration (999/99): the waiting time (at different percentiles) for token requests from the server side for each Resource Controller Client, calculated in real time and by resource groups.
- Token Request Count: the number of token requests from the server side for each Resource Controller Client, calculated in real time and by resource groups. `successful` and `failed` are the sums of the successful and failed token requests for all Resource Controller Clients.

14.12 Privileges

14.12.1 Security Compatibility with MySQL

TiDB supports security features similar to MySQL 5.7, and also supports some security features of MySQL 8.0. The security features of TiDB are different from MySQL in implementation.

14.12.1.1 Unsupported security features

- Column level permissions.

- These permission attributes: `max_questions`, `max_updated`, and `max_user_connections`.
- Password verification policy, which requires you to verify the current password when you change it.
- Dual password policy.
- Random password generation.
- Multi-factor authentication.

14.12.1.2 Differences with MySQL

14.12.1.2.1 Password expiration policy

The password expiration policies of TiDB and MySQL have the following differences:

- MySQL supports password expiration policy in v5.7 and v8.0.
- TiDB supports password expiration policy starting from v6.5.0.

The expiration mechanism of TiDB is different from MySQL in the following aspects:

- In MySQL v5.7 and v8.0, the configuration of the client and the server combined together determines whether to enable "sandbox mode" for the client connection.
- In TiDB, the `security.disconnect-on-expired-password` configuration item alone determines whether to enable "sandbox mode" for the client connection.

14.12.1.2.2 Password complexity policy

The password complexity policies of TiDB and MySQL have the following differences:

- MySQL v5.7 implements the password complexity policy by using the `validate_password` plugin.
- MySQL v8.0 re-implements the password complexity policy by using the `validate_password` component.
- TiDB introduces a built-in password complexity management feature starting from v6.5.0.

The feature implementation has the following differences:

- Enable the feature:
    - In MySQL v5.7, the feature is implemented by using the `validate_password` plugin. You can enable the feature by installing the plugin.
    - In MySQL v8.0, the feature is implemented by using the `validate_password` component. You can enable the feature by installing the component.

    - For TiDB, this feature is built-in. You can enable the feature using the system variable `validate_password.enable`.

- Dictionary check:

    - In MySQL v5.7, you can specify a file path using the `validate_password_dictionary_file` variable. The file contains a list of words that are not allowed to exist in passwords.
    - In MySQL v8.0, you can specify a file path using the `validate_password.dictionary_file` variable. The file contains a list of words that are not allowed to exist in passwords.
    - In TiDB, you can specify a string using the `validate_password.dictionary` system variable. The string contains a list of words that are not allowed to exist in passwords.

14.12.1.2.3 Password failure tracking

The password failure tracking policies of TiDB and MySQL have the following differences:

- MySQL v5.7 does not support password failure tracking.
- MySQL v8.0 supports password failure tracking.
- TiDB supports password failure tracking starting from v6.5.0.

Because the number of failed attempts and lock status of accounts need to be globally consistent, and as a distributed database, TiDB cannot record the number of failed attempts and lock status in the server memory like MySQL, so the implementation mechanisms are different between TiDB and MySQL.

- For users that are not locked automatically, the count of failed attempts is reset in the following scenarios:

    - MySQL 8.0:
        - When the server is restarted, the count of failed attempts for all accounts is reset.
        - When `FLUSH PRIVILEGES` is executed, the count of failed attempts for all accounts is reset.
        - When you run `ALTER USER ... ACCOUNT UNLOCK` to unlock an account, the count is reset.
        - When an account logs in successfully, the count is reset.
    - TiDB:
        - When you run `ALTER USER ... ACCOUNT UNLOCK` to unlock an account, the count is reset.
        - When an account logs in successfully, the count is reset.

- For users that are locked automatically, the count of failed attempts is reset in the following scenarios:

    - MySQL 8.0:

        - When the server is restarted, the temporary locking for all accounts is reset.
        - When `FLUSH PRIVILEGES` is executed, the temporary locking for all accounts is reset.
        - If the lock time of an account ends, the temporary locking for the account is reset on the next login attempt.
        - When you run `ALTER USER ... ACCOUNT UNLOCK` to unlock an account, the temporary locking for the account is reset.

    - TiDB:

        - If the lock time of an account ends, the temporary locking for the account is reset on the next login attempt.
        - When you run `ALTER USER ... ACCOUNT UNLOCK` to unlock an account, the temporary locking for the account is reset.

14.12.1.2.4 Password reuse policy

The password reuse policies of TiDB and MySQL have the following differences:

- MySQL v5.7 does not support password reuse management.
- MySQL v8.0 supports password reuse management.
- TiDB supports password reuse management starting from v6.5.0.

The implementation mechanisms are consistent between TiDB and MySQL. Both use the `mysql.password_history` system table to implement the password reuse management feature. However, when deleting a user that does not exist in the `mysql.user` system table, TiDB and MySQL have different behaviors:

- Scenario: A user (`user01`) is not created in a normal way; instead, it is created by using the `INSERT INTO mysql.password_history VALUES (...)` statement to append a record of `user01` to the `mysql.password_history` system table. In such cases, because the record of `user01` does not exist in the `mysql.user` system table, when you run `DROP USER` on `user01`, TiDB and MySQL have different behaviors.

    - MySQL: When you run `DROP USER user01`, MySQL tries to find `user01` in `mysql.user` and `mysql.password_history`. If either system table contains `user01`, the `DROP USER` statement is executed successfully and no error is reported.
    - TiDB: When you run `DROP USER user01`, TiDB tries to find `user01` only in `mysql.user`. If no related record is found, the `DROP USER` statement fails and an error is reported. If you want to execute the statement successfully and delete the `user01` record from `mysql.password_history`, use `DROP USER IF EXISTS user01` instead.

14.12.1.3 Authentication plugin status

TiDB supports multiple authentication methods. These methods can be specified on a per user basis using `CREATE USER` and `ALTER USER`. These methods are compatible with the authentication methods of MySQL with the same names.

You can use one of the following supported authentication methods in the table. To specify a default method that the server advertises when the client-server connection is being established, set the `default_authentication_plugin` variable. `tidb_sm3_password` is the SM3 authentication method only supported in TiDB. Therefore, to authenticate using this method, you must connect to TiDB using TiDB-JDBC. `tidb_auth_token` is a JSON Web Token (JWT)-based authentication method used in TiDB Cloud, and you can also configure it for use in TiDB Self-Managed.

The support for TLS authentication is configured differently. For detailed information, see Enable TLS between TiDB Clients and Servers.

Authentication Method	Supported
`mysql_native_password`	Yes
`sha256_password`	No
`caching_sha2_password`	Yes, since 5.2.0
`auth_socket`	Yes, since 5.3.0
`tidb_sm3_password`	Yes, since 6.3.0
`tidb_auth_token`	Yes, since 6.4.0
`authentication_ldap_sasl`	Yes, since 7.1.0
`authentication_ldap_simple`	Yes, since 7.1.0
TLS Certificates	Yes
LDAP	Yes, since 7.1.0
PAM	No
ed25519 (MariaDB)	No
GSSAPI (MariaDB)	No
FIDO	No

14.12.1.3.1 `tidb_auth_token`

`tidb_auth_token` is a passwordless authentication method based on JSON Web Token (JWT). In v6.4.0, `tidb_auth_token` is only used for user authentication in TiDB Cloud. Starting from v6.5.0, you can also configure `tidb_auth_token` as a user authentication method for TiDB Self-Managed. Different from password-based authentication methods such as `mysql_native_password` and `caching_sha2_password`, when you create users using `tidb_auth_token`, there is no need to set or store custom passwords. To log into TiDB, users only need to use a signed token instead of a password, which simplifies the authentication process and improves security.

JWT

JWT consists of three parts: Header, Payload, and Signature. After being encoded using

base64, they are concatenated into a string separated by dots (`.`) for transmission between the client and server.

The Header describes the metadata of the JWT, including 3 parameters:

- `alg`: the algorithm for signature, which is `RS256` by default.
- `typ`: the type of token, which is `JWT`.
- `kid`: the key ID for generating token signature.

Here is an example for Header:

```
{
  "alg": "RS256",
  "kid": "the-key-id-0",
  "typ": "JWT"
}
```

Payload is the main part of JWT, which stores the user information. Each field in the Payload is called a claim. The claims required for TiDB user authentication are as follows:

- `iss`: if `TOKEN_ISSUER` is not specified or set to empty when `CREATE USER`, this claim is not required; otherwise, `iss` should use the same value as `TOKEN_ISSUER`.
- `sub`: this claim is required to be the same as the username to be authenticated.
- `iat`: it means `issued at`, the timestamp when the token is issued. In TiDB, this value must not be later than the authentication time or earlier than 15 minutes before authentication.
- `exp`: the timestamp when the token expires. If it is earlier than the time of authentication, the authentication fails.
- `email`: the email can be specified when creating a user by `ATTRIBUTE '{"email": "xxxx@pingcap.com"}`. If no email is specified when a user is created, this claim must be set as an empty string; otherwise, this claim must be the same as the specified value when the user is created.

Here is an example for Payload:

```
{
  "email": "user@pingcap.com",
  "exp": 1703305494,
  "iat": 1703304594,
  "iss": "issuer-abc",
  "sub": "user@pingcap.com"
}
```

Signature is used to sign the Header and Payload data.

Warning:

- The encoding of the Header and Payload in base64 is reversible. Do **Not** attach any sensitive information to them.
- The `tidb_auth_token` authentication method requires clients to support the `mysql_clear_password` plugin to send the token to TiDB in plain text. Therefore, you need to enable TLS between clients and servers before using `tidb_auth_token`.

Usage

To configure and use `tidb_auth_token` as the authentication method for TiDB Self-Managed users, take the following steps:

1. Configure `auth-token-jwks` and `auth-token-refresh-interval` in the TiDB configuration file.

   For example, you can get an example JWKS using the following command:

   ```
   wget https://raw.githubusercontent.com/CbcWestwolf/generate_jwt/master/
   ↪ JWKS.json
   ```

   Then, configure the path of the example JWKS in `config.toml`:

   ```
   [security]
   auth-token-jwks = "JWKS.json"
   ```

2. Start `tidb-server` and periodically update and save the JWKS to the path specified by `auth-token-jwks`.

3. Create a user with `tidb_auth_token`, and specify `iss` and `email` as needed using `REQUIRE TOKEN_ISSUER` and `ATTRIBUTE '{"email": "xxxx@pingcap.com"}`.

   For example, create a user `user@pingcap.com` with `tidb_auth_token`:

   ```
   CREATE USER 'user@pingcap.com' IDENTIFIED WITH 'tidb_auth_token'
   ↪ REQUIRE TOKEN_ISSUER 'issuer-abc' ATTRIBUTE '{"email": "
   ↪ user@pingcap.com"}';
   ```

4. Generate and sign a token for authentication, and authenticate using the `mysql_clear_text` plugin of the MySQL client.

   Install the JWT generation tool via `go install github.com/cbcwestwolf/generate_jwt` (this tool is only used for testing `tidb_auth_token`). For example:

```
generate_jwt --kid "the-key-id-0" --sub "user@pingcap.com" --email "
    ↪ user@pingcap.com" --iss "issuer-abc"
```

It prints the public key and token as follows:

```
-----BEGIN PUBLIC KEY-----
MIIBCgKCAQEAq8G5n9XBidxmBMVJKLOBsmdOHrCqGf17y9+VUXingwDUZxRp2Xbu

    ↪ LN4fAG9jZ6Zwvz7vb_s4TW7xccFf3dIhWTEwOQ5jDPCeYkwraRXU8NC6DPF_
    ↪ duSrYJc7d7Nu9Z2cr-E4i1Rt_IiRTuIIzzKlcQGg7jd9AGEfGe_SowsA-w
```

Copy the preceding token in the last line for login:

```
mycli -h 127.0.0.1 -P 4000 -u 'user@pingcap.com' -p '<the-token-
    ↪ generated>'
```

Ensure that the MySQL client here supports the `mysql_clear_password` plugin. mycli supports and enables this plugin by default. If you are using the mysql command-line client, you need to use the `--enable-cleartext-plugin` option to enable this plugin:

```
mysql -h 127.0.0.1 -P 4000 -u 'user@pingcap.com' -p'<the-token-
    ↪ generated>' --enable-cleartext-plugin
```

If an incorrect `--sub` is specified when the token is generated (such as `--sub "
↪ wronguser@pingcap.com"`), the authentication using this token would fail.

You can encode and decode a token using the debugger provided by jwt.io.

14.12.2 Privilege Management

TiDB supports MySQL 5.7's privilege management system, including the syntax and privilege types. The following features from MySQL 8.0 are also supported:

- SQL Roles, starting with TiDB 3.0.

- Dynamic privileges, starting with TiDB 5.1.

This document introduces privilege-related TiDB operations, privileges required for TiDB operations and implementation of the privilege system.

14.12.2.1 Privilege-related operations

14.12.2.1.1 Grant privileges

The GRANT statement grants privileges to the user accounts.

For example, use the following statement to grant the `xxx` user the privilege to read the `test` database.

```
GRANT SELECT ON test.* TO 'xxx'@'%';
```

Use the following statement to grant the `xxx` user all privileges on all databases:

```
GRANT ALL PRIVILEGES ON *.* TO 'xxx'@'%';
```

By default, GRANT statements will return an error if the user specified does not exist. This behavior depends on if the SQL mode `NO_AUTO_CREATE_USER` is specified:

```
SET sql_mode=DEFAULT;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT @@sql_mode;
```

```
+-------------------------------------------------------------------------------------------
    ↪
| @@sql_mode
    ↪
    ↪ |
+-------------------------------------------------------------------------------------------
    ↪
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_
    ↪ FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION |
+-------------------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

```
SELECT * FROM mysql.user WHERE user='idontexist';
```

```
Empty set (0.00 sec)
```

```
GRANT ALL PRIVILEGES ON test.* TO 'idontexist';
```

```
ERROR 1105 (HY000): You are not allowed to create a user with GRANT
```

```
SELECT user,host,authentication_string FROM mysql.user WHERE user='
    ↪ idontexist';
```

```
Empty set (0.00 sec)
```

In the following example, the user `idontexist` is automatically created with an empty password because the SQL Mode `NO_AUTO_CREATE_USER` was not set. This is **not recommended** since it presents a security risk: miss-spelling a username will result in a new user created with an empty password:

```
SET @@sql_mode='ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_
    ↪ ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_ENGINE_SUBSTITUTION';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT @@sql_mode;
```

```
+--------------------------------------------------------------------------------
    ↪
| @@sql_mode
    ↪
    ↪ |
+--------------------------------------------------------------------------------
    ↪
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_
    ↪ FOR_DIVISION_BY_ZERO,NO_ENGINE_SUBSTITUTION |
+--------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

```
SELECT * FROM mysql.user WHERE user='idontexist';
```

```
Empty set (0.00 sec)
```

```
GRANT ALL PRIVILEGES ON test.* TO 'idontexist';
```

```
Query OK, 1 row affected (0.05 sec)
```

```
SELECT user,host,authentication_string FROM mysql.user WHERE user='
    ↪ idontexist';
```

```
+------------+------+----------------------+
| user       | host | authentication_string |
+------------+------+----------------------+
| idontexist | %    |                      |
+------------+------+----------------------+
1 row in set (0.01 sec)
```

You can use fuzzy matching in GRANT to grant privileges to databases.

```
GRANT ALL PRIVILEGES ON `te%`.* TO genius;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT user,host,db FROM mysql.db WHERE user='genius';
```

```
+--------|------|-----+
| user   | host | db  |
+--------|------|-----+
| genius | %    | te% |
+--------|------|-----+
1 row in set (0.00 sec)
```

In this example, because of the % in te%, all the databases starting with te are granted the privilege.

14.12.2.1.2 Revoke privileges

The REVOKE statement enables system administrators to revoke privileges from the user accounts.

The REVOKE statement corresponds with the GRANT statement:

```
REVOKE ALL PRIVILEGES ON `test`.* FROM 'genius'@'localhost';
```

> **Note:**
>
> To revoke privileges, you need the exact match. If the matching result cannot be found, an error will be displayed:

```
REVOKE ALL PRIVILEGES ON `te%`.* FROM 'genius'@'%';
```

```
ERROR 1141 (42000): There is no such grant defined for user 'genius' on host
    ↪  '%'
```

About fuzzy matching, escape, string and identifier:

```
GRANT ALL PRIVILEGES ON `te\%`.* TO 'genius'@'localhost';
```

```
Query OK, 0 rows affected (0.00 sec)
```

This example uses exact match to find the database named `te%`. Note that the `%` uses the `\` escape character so that `%` is not considered as a wildcard.

A string is enclosed in single quotation marks(”), while an identifier is enclosed in backticks (“). See the differences below:

```
GRANT ALL PRIVILEGES ON 'test'.* TO 'genius'@'localhost';
```

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the
manual that corresponds to your MySQL server version for the right
syntax to use near ''test'.* to 'genius'@'localhost'' at line 1
```

```
GRANT ALL PRIVILEGES ON `test`.* TO 'genius'@'localhost';
```

```
Query OK, 0 rows affected (0.00 sec)
```

If you want to use special keywords as table names, enclose them in backticks (“). For example:

```
CREATE TABLE `select` (id int);
```

```
Query OK, 0 rows affected (0.27 sec)
```

14.12.2.1.3 Check privileges granted to users

You can use the `SHOW GRANTS` statement to see what privileges are granted to a user. For example:

```
SHOW GRANTS; -- show grants for the current user
```

```
+-------------------------------------------------------------+
| Grants for User                                             |
+-------------------------------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'%' WITH GRANT OPTION |
+-------------------------------------------------------------+
```

```
SHOW GRANTS FOR 'root'@'%'; -- show grants for a specific user
```

For example, create a user `rw_user@192.168.%` and grant the user with write privilege on the `test.write_table` table and global read privilege.

```
CREATE USER `rw_user`@`192.168.%`;
GRANT SELECT ON *.* TO `rw_user`@`192.168.%`;
GRANT INSERT, UPDATE ON `test`.`write_table` TO `rw_user`@`192.168.%`;
```

Show granted privileges of the `rw_user@192.168.%` user:

```
SHOW GRANTS FOR `rw_user`@`192.168.%`;
```

```
+-------------------------------------------------------------------+
| Grants for rw_user@192.168.%                                      |
+-------------------------------------------------------------------+
| GRANT Select ON *.* TO 'rw_user'@'192.168.%'                      |
| GRANT Insert,Update ON test.write_table TO 'rw_user'@'192.168.%' |
+-------------------------------------------------------------------+
```

14.12.2.1.4 Dynamic privileges

Since v5.1, TiDB features support dynamic privileges, a feature borrowed from MySQL 8.0. Dynamic privileges are intended to replace the `SUPER` privilege by implementing more fine-grained access to certain operations. For example, using dynamic privileges, system administrators can create a user account that can only perform `BACKUP` and `RESTORE` operations.

Dynamic privileges include:

- `BACKUP_ADMIN`
- `RESTORE_ADMIN`
- `SYSTEM_USER`
- `SYSTEM_VARIABLES_ADMIN`
- `ROLE_ADMIN`
- `CONNECTION_ADMIN`
- `PLACEMENT_ADMIN` allows privilege owners to create, modify, and remove placement policies.
- `DASHBOARD_CLIENT` allows privilege owners to log in to TiDB Dashboard.
- `RESTRICTED_TABLES_ADMIN` allows privilege owners to view system tables when SEM is enabled.
- `RESTRICTED_STATUS_ADMIN` allows privilege owners to view all status variables in `SHOW [GLOBAL|SESSION] STATUS` when SEM is enabled.
- `RESTRICTED_VARIABLES_ADMIN` allows privilege owners to view all system variables when SEM is enabled.

- `RESTRICTED_USER_ADMIN` prohibits privilege owners to have their access revoked by SUPER users when SEM is enabled.
- `RESTRICTED_CONNECTION_ADMIN` allows privilege owners to kill connections of `RESTRICTED_USER_ADMIN` users. This privilege affects `KILL` and `KILL TIDB` statements.
- `RESTRICTED_REPLICA_WRITER_ADMIN` allows privilege owners to perform write or update operations without being affected when the read-only mode is enabled in the TiDB cluster. For details, see `tidb_restricted_read_only`.

To see the full set of dynamic privileges, execute the `SHOW PRIVILEGES` statement. Because plugins are permitted to add new privileges, the list of privileges that are assignable might differ based on your TiDB installation.

14.12.2.2 `SUPER` privilege

- The `SUPER` privilege allows the user to perform almost any operation. By default, only the `root` user is granted with this privilege. Be careful when granting this privilege to other users.
- The `SUPER` privilege is considered deprecated in MySQL 8.0 and can be replaced by dynamic privileges to provide more fine-grained access control.

14.12.2.3 Privileges required for TiDB operations

You can check privileges of TiDB users in the `INFORMATION_SCHEMA.USER_PRIVILEGES` table. For example:

```
SELECT * FROM INFORMATION_SCHEMA.USER_PRIVILEGES WHERE grantee = "'root'@
    ↪ '%'";
```

```
+------------+---------------+-----------------------+--------------+
| GRANTEE    | TABLE_CATALOG | PRIVILEGE_TYPE        | IS_GRANTABLE |
+------------+---------------+-----------------------+--------------+
| 'root'@'%' | def           | Select                | YES          |
| 'root'@'%' | def           | Insert                | YES          |
| 'root'@'%' | def           | Update                | YES          |
| 'root'@'%' | def           | Delete                | YES          |
| 'root'@'%' | def           | Create                | YES          |
| 'root'@'%' | def           | Drop                  | YES          |
| 'root'@'%' | def           | Process               | YES          |

31 rows in set (0.00 sec)
```

14.12.2.3.1 ALTER

- For all `ALTER` statements, users must have the `ALTER` privilege for the corresponding table.
- For statements except `ALTER...DROP` and `ALTER...RENAME TO`, users must have the `INSERT` and `CREATE` privileges for the corresponding table.
- For the `ALTER...DROP` statement, users must have the `DROP` privilege for the corresponding table.
- For the `ALTER...RENAME TO` statement, users must have the `DROP` privilege for the table before renaming, and the `CREATE` and `INSERT` privileges for the table after renaming.

> **Note:**
>
> In MySQL 5.7 documentation, users need `INSERT` and `CREATE` privileges to perform the `ALTER` operation on a table. But in reality for MySQL 5.7.25, only the `ALTER` privilege is required in this case. Currently, the `ALTER` privilege in TiDB is consistent with the actual behavior in MySQL.

14.12.2.3.2 BACKUP

Requires the `SUPER` or `BACKUP_ADMIN` privilege.

14.12.2.3.3 CANCEL IMPORT JOB

Requires the `SUPER` privilege to cancel jobs created by other users. Otherwise, only jobs created by the current user can be canceled.

14.12.2.3.4 CREATE DATABASE

Requires the `CREATE` privilege for the database.

14.12.2.3.5 CREATE INDEX

Requires the `INDEX` privilege for the table.

14.12.2.3.6 CREATE TABLE

Requires the `CREATE` privilege for the table.

To execute the `CREATE TABLE...LIKE...` statement, the `SELECT` privilege for the table is required.

14.12.2.3.7 CREATE VIEW

Requires the `CREATE VIEW` privilege.

> **Note:**
>
> If the current user is not the user that creates the View, both the `CREATE VIEW` and `SUPER` privileges are required.

14.12.2.3.8 DROP DATABASE

Requires the `DROP` privilege for the database.

14.12.2.3.9 DROP INDEX

Requires the `INDEX` privilege for the table.

14.12.2.3.10 DROP TABLES

Requires the `DROP` privilege for the table.

14.12.2.3.11 IMPORT INTO

Requires the `SELECT`, `UPDATE`, `INSERT`, `DELETE`, and `ALTER` privileges for the target table. To import files stored locally in TiDB, the `FILE` privilege is also required.

14.12.2.3.12 LOAD DATA

Requires the `INSERT` privilege for the table. When you use `REPLACE INTO`, the `DELETE` privilege is also required.

14.12.2.3.13 TRUNCATE TABLE

Requires the `DROP` privilege for the table.

14.12.2.3.14 RENAME TABLE

Requires the `ALTER` and `DROP` privileges for the table before renaming and the `CREATE` and `INSERT` privileges for the table after renaming.

14.12.2.3.15 ANALYZE TABLE

Requires the `INSERT` and `SELECT` privileges for the table.

14.12.2.3.16 LOCK STATS

Requires the `INSERT` and `SELECT` privileges for the table.

14.12.2.3.17 UNLOCK STATS

Requires the `INSERT` and `SELECT` privileges for the table.

14.12.2.3.18 SHOW

`SHOW CREATE TABLE` requires any single privilege to the table.

`SHOW CREATE VIEW` requires the `SHOW VIEW` privilege.

`SHOW GRANTS` requires the `SELECT` privilege to the `mysql` database. If the target user is current user, `SHOW GRANTS` does not require any privilege.

`SHOW PROCESSLIST` requires the `PROCESS` privilege to show connections belonging to other users.

`SHOW IMPORT JOB` requires the `SUPER` privilege to show connections belonging to other users. Otherwise, it only shows jobs created by the current user.

`SHOW STATS_LOCKED` requires the `SELECT` privilege to the `mysql.stats_table_locked` table.

14.12.2.3.19 CREATE ROLE/USER

`CREATE ROLE` requires the `CREATE ROLE` privilege.

`CREATE USER` requires the `CREATE USER` privilege.

14.12.2.3.20 DROP ROLE/USER

`DROP ROLE` requires the `DROP ROLE` privilege.

`DROP USER` requires the `CREATE USER` privilege.

14.12.2.3.21 ALTER USER

Requires the `CREATE USER` privilege.

14.12.2.3.22 GRANT

Requires the `GRANT` privilege with the privileges granted by `GRANT`.

Requires additional `CREATE USER` privilege to create a user implicitly.

`GRANT ROLE` requires `SUPER` or `ROLE_ADMIN` privilege.

14.12.2.3.23 REVOKE

Requires the `GRANT` privilege and those privileges targeted by the `REVOKE` statement.

`REVOKE ROLE` requires `SUPER` or `ROLE_ADMIN` privilege.

14.12.2.3.24 SET GLOBAL

Requires `SUPER` or `SYSTEM_VARIABLES_ADMIN` privilege to set global variables.

14.12.2.3.25 ADMIN

Requires `SUPER` privilege.

14.12.2.3.26 SET DEFAULT ROLE

Requires `SUPER` privilege.

14.12.2.3.27 KILL

Requires `SUPER` or `CONNECTION_ADMIN` privilege to kill other user sessions.

14.12.2.3.28 CREATE RESOURCE GROUP

Requires `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.

14.12.2.3.29 ALTER RESOURCE GROUP

Requires `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.

14.12.2.3.30 DROP RESOURCE GROUP

Requires `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.

14.12.2.3.31 CALIBRATE RESOURCE

Requires `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.

14.12.2.3.32 SET RESOURCE GROUP

When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to execute this statement.

14.12.2.4 Implementation of the privilege system

14.12.2.4.1 Privilege table

The following `mysql` system tables are special because all the privilege-related data is stored in them:

- `mysql.user` (user account, global privilege)
- `mysql.db` (database-level privilege)
- `mysql.tables_priv` (table-level privilege)
- `mysql.columns_priv` (column-level privilege; not currently supported)

These tables contain the effective range and privilege information of the data. For example, in the `mysql.user` table:

```
SELECT User,Host,Select_priv,Insert_priv FROM mysql.user LIMIT 1;
```

```
+------|------|-------------|-------------+
| User | Host | Select_priv | Insert_priv |
+------|------|-------------|-------------+
| root | %    | Y           | Y           |
+------|------|-------------|-------------+
1 row in set (0.00 sec)
```

In this record, `Host` and `User` determine that the connection request sent by the `root` user from any host (`%`) can be accepted. `Select_priv` and `Insert_priv` mean that the user has global `Select` and `Insert` privilege. The effective range in the `mysql.user` table is global.

`Host` and `User` in `mysql.db` determine which databases users can access. The effective range is the database.

Note:

It is recommended to only update the privilege tables via the supplied syntax such as `GRANT`, `CREATE USER` and `DROP USER`. Making direct edits to the underlying privilege tables will not automatically update the privilege cache, leading to unpredictable behavior until `FLUSH PRIVILEGES` is executed.

14.12.2.4.2 Connection verification

When the client sends a connection request, TiDB server will verify the login operation. TiDB server first checks the `mysql.user` table. If a record of `User` and `Host` matches the connection request, TiDB server then verifies the `authentication_string`.

User identity is based on two pieces of information: `Host`, the host that initiates the connection, and `User`, the user name. If the user name is not empty, the exact match of user named is a must.

`User`+`Host` may match several rows in `user` table. To deal with this scenario, the rows in the `user` table are sorted. The table rows will be checked one by one when the client connects; the first matched row will be used to verify. When sorting, Host is ranked before User.

14.12.2.4.3 Request verification

When the connection is successful, the request verification process checks whether the operation has the privilege.

For database-related requests (`INSERT`, `UPDATE`), the request verification process first checks the user's global privileges in the `mysql.user` table. If the privilege is granted, you can access directly. If not, check the `mysql.db` table.

The `user` table has global privileges regardless of the default database. For example, the `DELETE` privilege in `user` can apply to any row, table, or database.

In the `db` table, an empty user is to match the anonymous user name. Wildcards are not allowed in the `User` column. The value for the `Host` and `Db` columns can use `%` and `_`, which can use pattern matching.

Data in the `user` and `db` tables is also sorted when loaded into memory.

The use of `%` in `tables_priv` and `columns_priv` is similar, but column value in `Db`, `Table_name` and `Column_name` cannot contain `%`. The sorting is also similar when loaded.

14.12.2.4.4 Time of effect

When TiDB starts, some privilege-check tables are loaded into memory, and then the cached data is used to verify the privileges. Executing privilege management statements such as `GRANT`, `REVOKE`, `CREATE USER`, `DROP USER` will take effect immediately.

Manually editing tables such as `mysql.user` with statements such as `INSERT`, `DELETE`, `UPDATE` will not take effect immediately. This behavior is compatible with MySQL, and privilege cache can be updated with the `FLUSH PRIVILEGES` statement.

14.12.3 TiDB User Account Management

This document describes how to manage a TiDB user account.

14.12.3.1 User names and passwords

TiDB stores the user accounts in the table of the `mysql.user` system table. Each account is identified by a user name and the client host. Each account may have a password.

You can connect to the TiDB server using the MySQL client, and use the specified account and password to login. For each user name, make sure that it contains no more than 32 characters.

```
mysql --port 4000 --user xxx --password
```

Or use the abbreviation of command line parameters:

```
mysql -P 4000 -u xxx -p
```

14.12.3.2 Add user accounts

You can create TiDB accounts in two ways:

- By using the standard account-management SQL statements intended for creating accounts and establishing their privileges, such as `CREATE USER` and `GRANT`.
- By manipulating the privilege tables directly with statements such as `INSERT`, `UPDATE`, or `DELETE` and running `FLUSH PRIVILEGES`. It is not recommended to use this method to create or modify accounts, because it might lead to incomplete updates.

You can also create accounts by using third party GUI tools.

```
CREATE USER [IF NOT EXISTS] user [IDENTIFIED BY 'auth_string'];
```

After you assign the password, TiDB hashes and stores the `auth_string` in the `mysql.user` table.

```
CREATE USER 'test'@'127.0.0.1' IDENTIFIED BY 'xxx';
```

The name of a TiDB account consists of a user name and a hostname. The syntax of the account name is 'user_name'@'host_name'.

- `user_name` is case sensitive.

- `host_name` is a hostname or IP address, which supports the wild card `%` or `_`. For example, the hostname `'%'` matches all hosts, and the hostname `'192.168.1.%'` matches all hosts in the subnet.

The host supports fuzzy matching:

```
CREATE USER 'test'@'192.168.10.%';
```

The `test` user is allowed to log in from any hosts on the `192.168.10` subnet.

If the host is not specified, the user is allowed to log in from any IP. If no password is specified, the default is empty password:

```
CREATE USER 'test';
```

Equivalent to:

```
CREATE USER 'test'@'%' IDENTIFIED BY '';
```

If the specified user does not exist, the behavior of automatically creating users depends on `sql_mode`. If the `sql_mode` includes `NO_AUTO_CREATE_USER`, the `GRANT` statement will not create users with an error returned.

For example, assume that the `sql_mode` does not include `NO_AUTO_CREATE_USER`, and you use the following `CREATE USER` and `GRANT` statements to create four accounts:

```
CREATE USER 'finley'@'localhost' IDENTIFIED BY 'some_pass';
```

```
GRANT ALL PRIVILEGES ON *.* TO 'finley'@'localhost' WITH GRANT OPTION;
```

```
CREATE USER 'finley'@'%' IDENTIFIED BY 'some_pass';
```

```
GRANT ALL PRIVILEGES ON *.* TO 'finley'@'%' WITH GRANT OPTION;
```

```
CREATE USER 'admin'@'localhost' IDENTIFIED BY 'admin_pass';
```

```
GRANT RELOAD,PROCESS ON *.* TO 'admin'@'localhost';
```

```
CREATE USER 'dummy'@'localhost';
```

To see the privileges granted for an account, use the `SHOW GRANTS` statement:

```
SHOW GRANTS FOR 'admin'@'localhost';
```

```
+-----------------------------------------------------+
| Grants for admin@localhost                          |
+-----------------------------------------------------+
| GRANT RELOAD, PROCESS ON *.* TO 'admin'@'localhost' |
+-----------------------------------------------------+
```

To see the account definition for an account, use the `SHOW CREATE USER` statement:

```
SHOW CREATE USER 'admin'@'localhost';
```

```
+-----------------------------------------------------------------------------------------
   ↪
| CREATE USER for admin@localhost
   ↪
   ↪ |
+-----------------------------------------------------------------------------------------
   ↪
| CREATE USER 'admin'@'localhost' IDENTIFIED WITH 'mysql_native_password' AS
   ↪  '*14E65567ABDB5135D0CFD9A70B3032C179A49EE7' REQUIRE NONE PASSWORD
   ↪ EXPIRE DEFAULT ACCOUNT UNLOCK PASSWORD HISTORY DEFAULT PASSWORD REUSE
   ↪  INTERVAL DEFAULT |
+-----------------------------------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

14.12.3.3 Remove user accounts

To remove a user account, use the `DROP USER` statement:

```
DROP USER 'test'@'localhost';
```

This operation clears the user's records in the `mysql.user` table and the related records in the privilege table.

14.12.3.4 Reserved user accounts

TiDB creates the `'root'@'%'` default account during the database initialization.

14.12.3.5 Set account resource limits

TiDB can limit the resources consumed by users using resource groups. For more information, see Use Resource Control to Achieve Resource Group Limitation and Flow Control.

14.12.3.6 Assign account passwords

TiDB stores passwords in the `mysql.user` system table. Operations that assign or update passwords are permitted only to users with the `CREATE USER` privilege, or, alternatively, privileges for the `mysql` database (`INSERT` privilege to create new accounts, `UPDATE` privilege to update existing accounts).

- To assign a password when you create a new account, use `CREATE USER` and include an `IDENTIFIED BY` clause:

```
CREATE USER 'test'@'localhost' IDENTIFIED BY 'mypass';
```

- To assign or change a password for an existing account, use `SET PASSWORD FOR` or `ALTER USER`:

```
SET PASSWORD FOR 'root'@'%' = 'xxx';
```

Or:

```
ALTER USER 'test'@'localhost' IDENTIFIED BY 'mypass';
```

14.12.3.7 Forget the root password

1. Modify the configuration file:

    1. Log in to the machine where one of the tidb-server instances is located.
    2. Enter the `conf` directory under the TiDB node deployment directory, and find the `tidb.toml` configuration file.
    3. Add the configuration item `skip-grant-table` in the `security` section of the configuration file. If there is no `security` section, add the following two lines to the end of the `tidb.toml` configuration file:

    ```
    [security]
    skip-grant-table = true
    ```

2. Stop the tidb-server process:

    1. View the tidb-server process:

    ```
    ps aux | grep tidb-server
    ```

    2. Find the process ID (PID) corresponding to tidb-server and use the `kill` command to stop the process:

    ```
    kill -9 <pid>
    ```

3. Start TiDB using the modified configuration:

> **Note:**
> If you set `skip-grant-table` before starting the TiDB process, a check on the operating system user will be initiated. Only the `root` user of the operating system can start the TiDB process.

1. Enter the `scripts` directory under the TiDB node deployment directory.
2. Switch to the `root` account of the operating system.
3. Run the `run_tidb.sh` script in the directory in the foreground.
4. Log in as `root` in a new terminal window and change the password.

```
mysql -h 127.0.0.1 -P 4000 -u root
```

4. Stop running the `run_tidb.sh` script, remove the content added in the TiDB configuration file in step 1, and wait for tidb-server to start automatically.

14.12.3.8 `FLUSH PRIVILEGES`

Information related to users and privileges is stored in the TiKV server, and TiDB caches this information inside the process. Generally, modification of the related information through `CREATE USER`, `GRANT`, and other statements takes effect quickly within the entire cluster. If the operation is affected by some factors such as temporarily unavailable network, the modification will take effect in about 15 minutes because TiDB will periodically reload the cache information.

If you modified the privilege tables directly, run the `FLUSH PRIVILEGES` to apply changes immediately.

For details, see Privilege Management.

14.12.4 TiDB Password Management

To protect the security of user passwords, TiDB supports the following password management policies starting from v6.5.0:

- Password complexity policy: require users to set strong passwords to prevent empty and weak passwords.
- Password expiration policy: require users to change their passwords periodically.
- Password reuse policy: prevent users from reusing old passwords.
- Failed-login tracking and temporary account locking policy: temporarily lock a user account to prevent the same user from trying to log in after multiple login failures caused by wrong passwords.

14.12.4.1 TiDB authentication credential storage

To ensure the authenticity of user identity, TiDB uses passwords as credentials to authenticate users when they log in to the TiDB server.

The *password* described in this document refers to the internal credentials generated, stored, and verified by TiDB. TiDB stores user passwords in the `mysql.user` system table.

The following authentication plugins are related to TiDB password management:

- `mysql_native_password`
- `caching_sha2_password`
- `tidb_sm3_password`

For more information about TiDB authentication plugins, see Authentication plugin status.

14.12.4.2 Password complexity policy

Password complexity check is disabled by default in TiDB. By configuring system variables related to password complexity, you can enable the password complexity check and make sure the user passwords comply with the password complexity policy.

The password complexity policy has the following features:

- For SQL statements that set user passwords in plaintext (including `CREATE USER`, `ALTER USER`, and `SET PASSWORD`), TiDB checks the passwords against the password complexity policy. If a password does not meet the requirements, the password is rejected.
- You can use the SQL function `VALIDATE_PASSWORD_STRENGTH()` to validate the password strength.

> **Note:**
>
> - For the `CREATE USER` statement, even if you can lock the account upon creation, you must set an acceptable password. Otherwise, when the account is unlocked, this account can log in to TiDB using a password that does not comply with the password complexity policy.
> - The modification to the password complexity policy does not affect the passwords that already exist and only affects the newly set passwords.

You can view all system variables related to the password complexity policy by executing the following SQL statement:

```
mysql> SHOW VARIABLES LIKE 'validate_password.%';

+--------------------------------------+--------+
| Variable_name                        | Value  |
+--------------------------------------+--------+
| validate_password.check_user_name    | ON     |
| validate_password.dictionary         |        |
| validate_password.enable             | OFF    |
```

```
| validate_password.length          | 8      |
| validate_password.mixed_case_count | 1   |
| validate_password.number_count    | 1      |
| validate_password.policy          | MEDIUM |
| validate_password.special_char_count | 1 |
+-------------------------------------+--------+
8 rows in set (0.00 sec)
```

For a detailed description of each system variable, see System Variables.

14.12.4.2.1 Configure password complexity policy

This section shows examples of configuring system variables related to the password complexity policy.

Enable the password complexity check:

```
SET GLOBAL validate_password.enable = ON;
```

Do not allow users to use a password that is the same as the user name:

```
SET GLOBAL validate_password.check_user_name = ON;
```

Set the password complexity level to `LOW`:

```
SET GLOBAL validate_password.policy = LOW;
```

Set the minimum password length to `10`:

```
SET GLOBAL validate_password.length = 10;
```

Require a password to contain at least two numbers, one uppercase letter, one lowercase letter, and one special character:

```
SET GLOBAL validate_password.number_count = 2;
SET GLOBAL validate_password.mixed_case_count = 1;
SET GLOBAL validate_password.special_char_count = 1;
```

Enable the dictionary check that prevents a password from containing words like `mysql` or `abcd`:

```
SET GLOBAL validate_password.dictionary = 'mysql;abcd';
```

Note:

- The value of `validate_password.dictionary` is a string, no longer than 1024 characters. It contains a list of words that must not exist in the password. Each word is separated by semicolon (;).
- The dictionary check is case-insensitive.

14.12.4.2.2 Password complexity check examples

When the system variable `validate_password.enable` is set to `ON`, TiDB enables the password complexity check. The following are examples of the check results:

TiDB checks the user's plaintext password against the default password complexity policy. If the set password does not meet the policy, the password is rejected.

```
mysql> ALTER USER 'test'@'localhost' IDENTIFIED BY 'abc';
ERROR 1819 (HY000): Require Password Length: 8
```

TiDB does not check the hashed password against the password complexity policy.

```
mysql> ALTER USER 'test'@'localhost' IDENTIFIED WITH mysql_native_password
    ↪ AS '*0D3CED9BEC10A777AEC23CCC353A8C08A633045E';
Query OK, 0 rows affected (0.01 sec)
```

When creating an account initially locked, you must also set a password that matches the password complexity policy, or the creation will fail.

```
mysql> CREATE USER 'user02'@'localhost' ACCOUNT LOCK;
ERROR 1819 (HY000): Require Password Length: 8
```

14.12.4.2.3 Password strength validation function

To check the password strength, you can use the `VALIDATE_PASSWORD_STRENGTH()` function. This function accepts a password argument and returns an integer from 0 (weak) to 100 (strong).

Note:

This function evaluates the password strength based on the current password complexity policy. If the password complexity policy is changed, the same password might get different evaluation results.

The following example shows how to use the `VALIDATE_PASSWORD_STRENGTH()` function:

```
mysql> SELECT VALIDATE_PASSWORD_STRENGTH('weak');
+-----------------------------------+
| VALIDATE_PASSWORD_STRENGTH('weak') |
+-----------------------------------+
|                                25 |
+-----------------------------------+
1 row in set (0.01 sec)

mysql> SELECT VALIDATE_PASSWORD_STRENGTH('lessweak$_@123');
+---------------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('lessweak$_@123') |
+---------------------------------------------+
|                                          50 |
+---------------------------------------------+
1 row in set (0.01 sec)

mysql> SELECT VALIDATE_PASSWORD_STRENGTH('NOTweak$_@123!');
+---------------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('NOTweak$_@123!') |
+---------------------------------------------+
|                                         100 |
+---------------------------------------------+
1 row in set (0.01 sec)
```

14.12.4.3 Password expiration policy

TiDB supports configuring a password expiration policy so that users must change their passwords periodically to improve password security. You can manually make account passwords expire or establish a policy for automatic password expiration.

The automatic password expiration policy can be set at the global level and at the account level. As a database administrator, you can establish an automatic password expiration policy at the global level, and also use an account-level policy to override the global policy.

The privileges for setting the password expiration policy are as follows:

- Database administrator with `SUPER` or `CREATE USER` privileges can manually make passwords expire.
- Database administrator with `SUPER` or `CREATE USER` privileges can set the account-level password expiration policy.
- Database administrator with `SUPER` or `SYSTEM_VARIABLES_ADMINR` privileges can set the global-level password expiration policy.

14.12.4.3.1 Manual expiration

To manually make an account password expire, use the `CREATE USER` or `ALTER USER` statements.

```
ALTER USER 'test'@'localhost' PASSWORD EXPIRE;
```

When the account password is set to expire by a database administrator, you must change the password before you can log in to TiDB. The manual expiration cannot be revoked.

For roles created using the `CREATE ROLE` statement, since the role does not require a password, the password field for the role is empty. In such case, TiDB sets the `password_expired` attribute to `'Y'`, which means that the role's password is manually expired. The purpose of this design is to prevent the role from being unlocked and logged into TiDB with an empty password. When the role is unlocked by the `ALTER USER ... ACCOUNT UNLOCK` statement, you can log in with this account even though the password is empty. Therefore, TiDB makes the password manually expired using the `password_expired` attribute so that the user must set a valid password for the account.

```
mysql> CREATE ROLE testrole;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT user,password_expired,Account_locked FROM mysql.user WHERE
    ↪ user = 'testrole';
+----------+------------------+----------------+
| user     | password_expired | Account_locked |
+----------+------------------+----------------+
| testrole | Y                | Y              |
+----------+------------------+----------------+
1 row in set (0.02 sec)
```

14.12.4.3.2 Automatic expiration

Automatic password expiration is based on the **password age** and the **password lifetime**.

- Password age: the time interval from the last password change date to the current date. The time of the last password change is recorded in the `mysql.user` system table.
- Password lifetime: the number of days the password can be used to log in to TiDB.

If a password is used for a longer period than it is allowed to live, the server automatically treats the password as expired.

TiDB supports automatic password expiration at the global level and at the account level.

- The global level

  You can set the system variable `default_password_lifetime` to control the password lifetime. The default value `0` indicates that the password never expires. If this system variable is set to a positive integer `N`, it means that the password lifetime is `N` days, and you must change your password every `N` days.

  The global automatic password expiration policy applies to all accounts that do not have an account-level override.

  The following example establishes a global automatic password expiration policy with a password lifetime of 180 days:

```
SET GLOBAL default_password_lifetime = 180;
```

- The account level

  To establish an automatic password expiration policy for an individual account, use the `PASSWORD EXPIRE` option in the `CREATE USER` or `ALTER USER` statement.

  The following examples require that the user password is changed every 90 days:

```
CREATE USER 'test'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
ALTER USER 'test'@'localhost' PASSWORD EXPIRE INTERVAL 90 DAY;
```

  The following examples disable the automatic password expiration policy for an individual account:

```
CREATE USER 'test'@'localhost' PASSWORD EXPIRE NEVER;
ALTER USER 'test'@'localhost' PASSWORD EXPIRE NEVER;
```

  Remove the account-level automatic password expiration policy for a specified account so that it follows the global automatic password expiration policy:

```
CREATE USER 'test'@'localhost' PASSWORD EXPIRE DEFAULT;
ALTER USER 'test'@'localhost' PASSWORD EXPIRE DEFAULT;
```

14.12.4.3.3 Password expiration check mechanism

When a client connects to the TiDB server, the server checks whether the password is expired in the following order:

1. The server checks whether the password has been set as expired manually.
2. If the password is not manually expired, the server checks whether the password age is longer than its configured lifetime. If so, the server treats the password as expired.

14.12.4.3.4 Handle an expired password

You can control the behavior of the TiDB server for password expiration. When a password is expired, the server either disconnects the client or restricts the client to the "sandbox mode". In a "sandbox mode", the TiDB server allows connections from the expired account. However, in such connections, the user is only allowed to reset the password.

The TiDB server can control whether to restrict the user with an expired password in the "sandbox mode". To control the behavior of the TiDB server when a password is expired, configure the `security.disconnect-on-expired-password` parameter in the TiDB configuration file:

```
[security]
disconnect-on-expired-password = true
```

- If `disconnect-on-expired-password` is set to `true` (default), the server disconnects the client when the password is expired.
- If `disconnect-on-expired-password` is set to `false`, the server enables the "sandbox mode" and allows the user to connect to the server. However, the user can only reset the password. After the password is reset, the user can execute SQL statements normally.

When `disconnect-on-expired-password` is enabled, if an account password is expired, TiDB rejects the connection from the account. In such cases, you can modify the password in the following ways:

- If the password for a normal account is expired, the administrator can change the password for the account by using SQL statements.
- If the password for an administrator account is expired, another administrator can change the password for the account by using SQL statements.
- If the password for an administrator account is expired and no other administrator is available to help change the password, you can use the `skip-grant-table` mechanism to change the password for the account. For details, see Forgot password process.

14.12.4.4 Password reuse policy

TiDB can limit the reuse of previous passwords. The password reuse policy can be based on the number of password changes or time elapsed, or both.

The password reuse policy can be set at the global level and at the account level. You can establish a password reuse policy at the global level, and also use an account-level policy to override the global policy.

TiDB records the password history for an account and limits the selection of a new password from the history:

- If a password reuse policy is based on the number of password changes, a new password must not be the same as any of the specified number of most recent passwords. For

example, if the minimum number of password changes is set to 3, the new password cannot be the same as any of the previous 3 passwords.

- If a password reuse policy is based on time elapsed, a new password must not be the same as any of the passwords used within the specified number of days. For example, if the password reuse interval is set to 60, the new password cannot be the same as any of the passwords used within the last 60 days.

> **Note:**
>
> Empty passwords are not recorded in the password history and can be reused at any time.

14.12.4.4.1 Global-level password reuse policy

To establish a global password reuse policy, use the `password_history` and `password_reuse_interval` system variables.

For example, to establish a global password reuse policy that prohibits the reuse of the last 6 passwords and passwords used within the last 365 days:

```
SET GLOBAL password_history = 6;
SET GLOBAL password_reuse_interval = 365;
```

The global password reuse policy applies to all accounts that do not have an account-level override.

14.12.4.4.2 Account-level password reuse policy

To establish an account-level password reuse policy, use the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options in the `CREATE USER` or `ALTER USER` statement.

For example:

To prohibit the reuse of the last 5 passwords:

```
CREATE USER 'test'@'localhost' PASSWORD HISTORY 5;
ALTER USER 'test'@'localhost' PASSWORD HISTORY 5;
```

To prohibit the reuse of passwords used within the last 365 days:

```
CREATE USER 'test'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'test'@'localhost' PASSWORD REUSE INTERVAL 365 DAY;
```

To combine the two types of reuse policies, use both `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL`:

```
CREATE USER 'test'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
ALTER USER 'test'@'localhost'
  PASSWORD HISTORY 5
  PASSWORD REUSE INTERVAL 365 DAY;
```

To remove the account-level password reuse policy for a specified account so that it follows the global password reuse policy:

```
CREATE USER 'test'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
ALTER USER 'test'@'localhost'
  PASSWORD HISTORY DEFAULT
  PASSWORD REUSE INTERVAL DEFAULT;
```

Note:

- If you set the password reuse policy multiple times, the last set value takes effect.
- The default value of the `PASSWORD HISTORY` and `PASSWORD REUSE INTERVAL` options is 0, which means that the reuse policy is disabled.
- When you modify a username, TiDB migrates the corresponding password history in the `mysql.password_history` system table from the original username to the new username.

14.12.4.5 Failed-login tracking and temporary account locking policy

TiDB can track the number of failed login attempts for an account. To prevent the password from being cracked by brute force, TiDB can lock the account after a specified number of failed login attempts.

Note:

- TiDB only supports failed-login tracking and temporary account locking at the account level, but not at the global level.

- Failed-login means that the client fails to provide the correct password during the connection attempt, and does not include connection failures due to unknown users or network issues.
- When you enable the failed-login tracking and temporary account locking for an account, the account is subject to additional checks when the account attempts to log in. This affects the performance of the login operation, especially in high-concurrency login scenarios.

14.12.4.5.1 Configure the login failure tracking policy

You can configure the number of failed login attempts and the lock time for each account by using the `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` options in the `CREATE USER` or `ALTER USER` statement. The available value options are as follows:

- `FAILED_LOGIN_ATTEMPTS`: N. The account is temporarily locked after `N` consecutive login failures. The value of N ranges from 0 to 32767.
- `PASSWORD_LOCK_TIME`: N | UNBOUNDED.
  - N means that the account will be temporarily locked for `N` days after consecutive failed login attempts. The value of N ranges from 0 to 32767.
  - `UNBOUNDED` means that the lock time is unlimited and the account must be manually unlocked. The value of N ranges from 0 to 32767.

Note:

- You can configure only `FAILED_LOGIN_ATTEMPTS` or `PASSWORD_LOCK_TIME` in a single SQL statement. In this case, the account locking does not take effect.
- The account locking takes effect only when both `FAILED_LOGIN_ATTEMPTS` and `PASSWORD_LOCK_TIME` are not 0.

You can configure the account locking policy as follows:

Create a user and configure the account locking policy. When the password is entered incorrectly for 3 consecutive times, the account will be temporarily locked for 3 days:

```
CREATE USER 'test1'@'localhost' IDENTIFIED BY 'password' FAILED_LOGIN_
    ↪ ATTEMPTS 3 PASSWORD_LOCK_TIME 3;
```

Modify the account locking policy for an existing user. When the password is entered incorrectly for 4 consecutive times, the account will be locked indefinitely until it is manually unlocked:

```
ALTER USER 'test2'@'localhost' FAILED_LOGIN_ATTEMPTS 4 PASSWORD_LOCK_TIME
    ↪ UNBOUNDED;
```

Disable the account locking policy for an existing user:

```
ALTER USER 'test3'@'localhost' FAILED_LOGIN_ATTEMPTS 0 PASSWORD_LOCK_TIME
    ↪ 0;
```

14.12.4.5.2 Unlock the locked account

In the following scenarios, the count of consecutive password errors can be reset:

- When you execute the `ALTER USER ... ACCOUNT UNLOCK` statement.
- When you log in successfully.

In the following scenarios, the locked account can be unlocked:

- When the lock time ends, the automatic lock flag of the account will be reset at the next login attempt.
- When you execute the `ALTER USER ... ACCOUNT UNLOCK` statement.

> **Note:**
>
> When an account is locked due to consecutive login failures, modifying the account locking policy has the following effects:
>
> - When you modify `FAILED_LOGIN_ATTEMPTS`, the lock status of the account does not change. The modified `FAILED_LOGIN_ATTEMPTS` takes effect after the account is unlocked and attempts to log in again.
> - When you modify `PASSWORD_LOCK_TIME`, the lock status of the account does not change. The modified `PASSWORD_LOCK_TIME` takes effect when the account attempts to log in again. At that time, TiDB checks whether the new lock time has reached. If yes, TiDB will unlock the user.

14.12.5 Role-Based Access Control

The implementation of TiDB's role-based access control (RBAC) system is similar to that of MySQL 8.0. TiDB is compatible with most RBAC syntax of MySQL.

This document introduces TiDB RBAC-related operations and implementation.

14.12.5.1 RBAC operations

A role is a collection of a series of privileges. You can do the following operations:

- Create a role.
- Delete a role.
- Grant a privilege to a role.
- Grant a role to another user. That user can obtain the privileges involved in the role, after enabling the role.

14.12.5.1.1 Create a role

For example, you can use the following statement to create the roles `app_developer`, `app_read`, and `app_write`:

```
CREATE ROLE 'app_developer', 'app_read', 'app_write';
```

For the role naming format and rule, see TiDB User Account Management.

Roles are stored in the `mysql.user` table and the host name part of the role name (if omitted) defaults to `'%'`. The name of the role you are trying to create must be unique; otherwise, an error is reported.

To create a role, you need the `CREATE ROLE` or `CREATE USER` privilege.

14.12.5.1.2 Grant a privilege to a role

The operation of granting a privilege to a role is the same with that of granting a privilege to a user. For details, see TiDB Privilege Management.

For example, you can use the following statement to grant the `app_read` role the privilege to read the `app_db` database:

```
GRANT SELECT ON app_db.* TO 'app_read'@'%';
```

You can use the following statement to grant the `app_write` role the privilege to write data to the `app_db` database:

```
GRANT INSERT, UPDATE, DELETE ON app_db.* TO 'app_write'@'%';
```

You can use the following statement to grant the `app_developer` role all privileges on the `app_db` database:

```
GRANT ALL ON app_db.* TO 'app_developer';
```

14.12.5.1.3 Grant a role to a user

Assume that a user `dev1` has the developer role with all the privileges on `app_db`; two users `read_user1` and `read_user2` have the read-only privilege on `app_db`; and a user `rw_user1` has read and write privileges on `app_db`.

Use `CREATE USER` to create the users:

```
CREATE USER 'dev1'@'localhost' IDENTIFIED BY 'dev1pass';
CREATE USER 'read_user1'@'localhost' IDENTIFIED BY 'read_user1pass';
CREATE USER 'read_user2'@'localhost' IDENTIFIED BY 'read_user2pass';
CREATE USER 'rw_user1'@'localhost' IDENTIFIED BY 'rw_user1pass';
```

Then use `GRANT` to grant roles to users

```
GRANT 'app_developer' TO 'dev1'@'localhost';
GRANT 'app_read' TO 'read_user1'@'localhost', 'read_user2'@'localhost';
GRANT 'app_read', 'app_write' TO 'rw_user1'@'localhost';
```

To grant a role to another user or revoke a role, you need the `SUPER` privilege.

Granting a role to a user does not mean enabling the role immediately. Enabling a role is another operation.

The following operations might form a "relation loop:"

```
CREATE USER 'u1', 'u2';
CREATE ROLE 'r1', 'r2';

GRANT 'u1' TO 'u1';
GRANT 'r1' TO 'r1';

GRANT 'r2' TO 'u2';
GRANT 'u2' TO 'r2';
```

TiDB supports this multi-level authorization relationship. You can use it to implement privilege inheritance.

14.12.5.1.4 Check a role's privileges

You can use the `SHOW GRANTS` statement to check what privileges have been granted to the user.

To check privilege-related information of another user, you need the `SELECT` privilege on the `mysql` database.

```
SHOW GRANTS FOR 'dev1'@'localhost';
```

```
+-------------------------------------------------+
| Grants for dev1@localhost                       |
+-------------------------------------------------+
| GRANT USAGE ON *.* TO `dev1`@`localhost`  |
| GRANT `app_developer`@`%` TO `dev1`@`localhost` |
+-------------------------------------------------+
```

You can use the `USING` option in `SHOW GRANTS` to check a role's privileges:

```
SHOW GRANTS FOR 'dev1'@'localhost' USING 'app_developer';
```

```
+-----------------------------------------------------------+
| Grants for dev1@localhost                                 |
+-----------------------------------------------------------+
| GRANT USAGE ON *.* TO `dev1`@`localhost`                  |
| GRANT ALL PRIVILEGES ON `app_db`.* TO `dev1`@`localhost` |
| GRANT `app_developer`@`%` TO `dev1`@`localhost`   |
+-----------------------------------------------------------+
```

```
SHOW GRANTS FOR 'rw_user1'@'localhost' USING 'app_read', 'app_write';
```

```
+-------------------------------------------------------------------------------+
   ↪
| Grants for rw_user1@localhost                                                 |
+-------------------------------------------------------------------------------+
   ↪
| GRANT USAGE ON *.* TO `rw_user1`@`localhost`                                  |
| GRANT SELECT, INSERT, UPDATE, DELETE ON `app_db`.* TO `rw_user1`@`
   ↪ localhost` |
| GRANT `app_read`@`%`,`app_write`@`%` TO `rw_user1`@`localhost`     |
+-------------------------------------------------------------------------------+
   ↪
```

```
SHOW GRANTS FOR 'read_user1'@'localhost' USING 'app_read';
```

```
+-----------------------------------------------------+
| Grants for read_user1@localhost                     |
+-----------------------------------------------------+
| GRANT USAGE ON *.* TO `read_user1`@`localhost`  |
| GRANT SELECT ON `app_db`.* TO `read_user1`@`localhost` |
| GRANT `app_read`@`%` TO `read_user1`@`localhost` |
+-----------------------------------------------------+
```

You can use `SHOW GRANTS` or `SHOW GRANTS FOR CURRENT_USER()` to check the current user's privileges. `SHOW GRANTS` and `SHOW GRANTS FOR CURRENT_USER()` are different in the following aspects:

- `SHOW GRANTS` shows the privilege of the enabled role for the current user.
- `SHOW GRANTS FOR CURRENT_USER()` does not show the enabled role's privilege.

14.12.5.1.5 Set the default role

After a role is granted to a user, it does not take effect immediately. Only after the user enables this role, he can use the privilege the role owns.

You can set default roles for a user. When the user logs in, the default roles are automatically enabled.

```
SET DEFAULT ROLE
    {NONE | ALL | role [, role ] ...}
    TO user [, user ]
```

For example, you can use the following statement to set default roles of `rw_user1@localhost` to `app_read` and `app_write`:

```
SET DEFAULT ROLE app_read, app_write TO 'rw_user1'@'localhost';
```

You can use the following statement to set default roles of `dev1@localhost` to all roles:

```
SET DEFAULT ROLE ALL TO 'dev1'@'localhost';
```

You can use the following statement to disable all default roles of `dev1@localhost`:

```
SET DEFAULT ROLE NONE TO 'dev1'@'localhost';
```

> **Note:**
>
> You need to grant the role to the user before you set the default role to this role.

14.12.5.1.6 Enable a role in the current session

You can enable some role(s) in the current session.

```
SET ROLE {
    DEFAULT
  | NONE
  | ALL
```

```
  | ALL EXCEPT role [, role ] ...
  | role [, role ] ...
}
```

For example, after `rw_user1` logs in, you can use the following statement to enable roles `app_read` and `app_write` that are valid only in the current session:

```
SET ROLE 'app_read', 'app_write';
```

You can use the following statement to enable the default role of the current user:

```
SET ROLE DEFAULT
```

You can use the following statement to enable all roles granted to the current user:

```
SET ROLE ALL
```

You can use the following statement to disable all roles:

```
SET ROLE NONE
```

You can use the following statement to enable roles except `app_read`:

```
SET ROLE ALL EXCEPT 'app_read'
```

> **Note:**
>
> If you use `SET ROLE` to enable a role, this role is valid only in the current session.

14.12.5.1.7 Check the current enabled role

The current user can use the `CURRENT_ROLE()` function to check which role has been enabled by the current user.

For example, you can grant default roles to `rw_user1'@'localhost`:

```
SET DEFAULT ROLE ALL TO 'rw_user1'@'localhost';
```

After `rw_user1@localhost` logs in, you can execute the following statement:

```
SELECT CURRENT_ROLE();
```

```
+--------------------------------+
| CURRENT_ROLE()                 |
+--------------------------------+
| `app_read`@`%`,`app_write`@`%` |
+--------------------------------+
```

```
SET ROLE 'app_read'; SELECT CURRENT_ROLE();
```

```
+----------------+
| CURRENT_ROLE() |
+----------------+
| `app_read`@`%` |
+----------------+
```

14.12.5.1.8 Revoke a role

You can use the following statement to revoke the `app_read` role granted to the users `read_user1@localhost` and `read_user2@localhost`:

```
REVOKE 'app_read' FROM 'read_user1'@'localhost', 'read_user2'@'localhost';
```

You can use the following statement to revoke the roles `app_read` and `app_write` granted to the `rw_user1@localhost` user:

```
REVOKE 'app_read', 'app_write' FROM 'rw_user1'@'localhost';
```

The operation of revoking a role from a user is atomic. If you fail to revoke a role, this operation rolls back.

14.12.5.1.9 Revoke a privilege

The `REVOKE` statement is reverse to `GRANT`. You can use `REVOKE` to revoke the privileges of `app_write`.

```
REVOKE INSERT, UPDATE, DELETE ON app_db.* FROM 'app_write';
```

For details, see TiDB Privilege Management.

14.12.5.1.10 Delete a role

You can use the following statement to delete roles `app_read` and `app_write`:

```
DROP ROLE 'app_read', 'app_write';
```

This operation deletes the role records of `app_read` and `app_write` in the `mysql.user` table and related records in the authorization table, and terminates the authorization related to the two roles.

To delete a role, you need the `DROP ROLE` or `DROP USER` privilege.

14.12.5.1.11 Authorization table

In addition to four system privilege tables, the RBAC system introduces two new system privilege tables:

- `mysql.role_edges`: records the authorization relationship of the role and user.
- `mysql.default_roles`: records default roles of each user.

`mysql.role_edges`

`mysql.role_edges` contains the following data:

```
SELECT * FROM mysql.role_edges;
```

```
+-----------+-----------+---------+---------+-------------------+
| FROM_HOST | FROM_USER | TO_HOST | TO_USER | WITH_ADMIN_OPTION |
+-----------+-----------+---------+---------+-------------------+
| %         | r_1       | %       | u_1     | N                 |
+-----------+-----------+---------+---------+-------------------+
1 row in set (0.00 sec)
```

- `FROM_HOST` and `FROM_USER` indicate the role's host name and user name respectively.
- `TO_HOST` and `TO_USER` indicate the host name and user name of the user to which a role is granted.

`mysql.default_roles`

`mysql.default_roles` shows which roles have been enabled by default for each user.

```
SELECT * FROM mysql.default_roles;
```

```
+------+------+--------------------+--------------------+
| HOST | USER | DEFAULT_ROLE_HOST | DEFAULT_ROLE_USER |
+------+------+--------------------+--------------------+
| %    | u_1 | %                  | r_1                |
| %    | u_1 | %                  | r_2                |
+------+------+--------------------+--------------------+
2 rows in set (0.00 sec)
```

- `HOST` and `USER` indicate the user's host name and user name respectively.
- `DEFAULT_ROLE_HOST` and `DEFAULT_ROLE_USER` indicate the host name and user name of the default role respectively.

14.12.5.1.12 References

Because RBAC, user management, and privilege management are closely related, you can refer to operation details in the following resources:

- TiDB Privilege Management
- TiDB User Account Management

14.12.6 Certificate-Based Authentication for Login

TiDB supports a certificate-based authentication method for users to log into TiDB. With this method, TiDB issues certificates to different users, uses encrypted connections to transfer data, and verifies certificates when users log in. This approach is more secure than the traditional password-based authentication method commonly used by MySQL users and is thus adopted by an increasing number of users.

To use certificate-based authentication, you might need to perform the following operations:

- Create security keys and certificates
- Configure certificates for TiDB and the client
- Configure the user certificate information to be verified when the user logs in
- Update and replace certificates

The rest of the document introduces in detail how to perform these operations.

14.12.6.1 Create security keys and certificates

It is recommended that you use OpenSSL to create keys and certificates. The certificate generation process is similar to the process described in Enable TLS Between TiDB Clients and Servers. The following paragraphs demonstrate how to configure more attribute fields that need to be verified in the certificate.

14.12.6.1.1 Generate CA key and certificate

1. Execute the following command to generate the CA key:

```
sudo openssl genrsa 2048 > ca-key.pem
```

The output of the above command:

```
Generating RSA private key, 2048 bit long modulus (2 primes)
.....................+++++
.............................................+++++
e is 65537 (0x010001)
```

2. Execute the following command to generate the certificate corresponding to the CA key:

```
sudo openssl req -new -x509 -nodes -days 365000 -key ca-key.pem -out ca
    ↪ -cert.pem
```

3. Enter detailed certificate information. For example:

```
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:California
Locality Name (e.g. city) []:San Francisco
Organization Name (e.g. company) [Internet Widgits Pty Ltd]:PingCAP Inc
    ↪ .
Organizational Unit Name (e.g. section) []:TiDB
Common Name (e.g. server FQDN or YOUR name) []:TiDB admin
Email Address []:s@pingcap.com
```

> **Note:**
> In the above certificate details, texts after : are the entered information.

14.12.6.1.2 Generate server key and certificate

1. Execute the following command to generate the server key:

```
sudo openssl req -newkey rsa:2048 -days 365000 -nodes -keyout server-
    ↪ key.pem -out server-req.pem
```

2. Enter detailed certificate information. For example:

```
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:California
Locality Name (e.g. city) []:San Francisco
Organization Name (e.g. company) [Internet Widgits Pty Ltd]:PingCAP Inc
    ↪ .
Organizational Unit Name (e.g. section) []:TiKV
Common Name (e.g. server FQDN or YOUR name) []:TiKV Test Server
Email Address []:k@pingcap.com

Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

3. Execute the following command to generate the RSA key of the server:

```
sudo openssl rsa -in server-key.pem -out server-key.pem
```

The output of the above command:

```
writing RSA key
```

4. Use the CA certificate signature to generate the signed server certificate:

```
sudo openssl x509 -req -in server-req.pem -days 365000 -CA ca-cert.pem
    ↪ -CAkey ca-key.pem -set_serial 01 -out server-cert.pem
```

The output of the above command (for example):

```
Signature ok
subject=C = US, ST = California, L = San Francisco, O = PingCAP Inc.,
    ↪ OU = TiKV, CN = TiKV Test Server, emailAddress = k@pingcap.com
Getting CA Private Key
```

> **Note:**
> When you log in, TiDB checks whether the information in the `subject` section of the above output is consistent or not.

14.12.6.1.3 Generate client key and certificate

After generating the server key and certificate, you need to generate the key and certificate for the client. It is often necessary to generate different keys and certificates for different users.

1. Execute the following command to generate the client key:

```
sudo openssl req -newkey rsa:2048 -days 365000 -nodes -keyout client-
    ↪ key.pem -out client-req.pem
```

2. Enter detailed certificate information. For example:

```
Country Name (2 letter code) [AU]:US
State or Province Name (full name) [Some-State]:California
Locality Name (e.g. city) []:San Francisco
Organization Name (e.g. company) [Internet Widgits Pty Ltd]:PingCAP Inc
    ↪ .
Organizational Unit Name (e.g. section) []:TiDB
Common Name (e.g. server FQDN or YOUR name) []:tpch-user1
Email Address []:zz@pingcap.com
```

```
Please enter the following 'extra' attributes
to be sent with your certificate request
A challenge password []:
An optional company name []:
```

3. Execute the following command to generate the RSA key of the client:

```
sudo openssl rsa -in client-key.pem -out client-key.pem
```

The output of the above command:

```
writing RSA key
```

4. Use the CA certificate signature to generate the client certificate:

```
sudo openssl x509 -req -in client-req.pem -days 365000 -CA ca-cert.pem
    ↪ -CAkey ca-key.pem -set_serial 01 -out client-cert.pem
```

The output of the above command (for example):

```
Signature ok
subject=C = US, ST = California, L = San Francisco, O = PingCAP Inc.,
    ↪ OU = TiDB, CN = tpch-user1, emailAddress = zz@pingcap.com
Getting CA Private Key
```

> **Note:**
> The information of the `subject` section in the above output is used for certificate configuration for login verification in the `require` section.

14.12.6.1.4 Verify certificate

Execute the following command to verify certificate:

```
openssl verify -CAfile ca-cert.pem server-cert.pem client-cert.pem
```

If the certificate is verified, you will see the following result:

```
server-cert.pem: OK
client-cert.pem: OK
```

14.12.6.2 Configure TiDB and the client to use certificates

After generating the certificates, you need to configure the TiDB server and the client to use the corresponding server certificate or client certificate.

14.12.6.2.1 Configure TiDB to use server certificate

Modify the `[security]` section in the TiDB configuration file. This step specifies the directory in which the CA certificate, the server key, and the server certificate are stored. You can replace `path/to/server-cert.pem`, `path/to/server-key.pem`, `path/to/ca-cert.pem` with your own directory.

```
[security]
ssl-cert ="path/to/server-cert.pem"
ssl-key ="path/to/server-key.pem"
ssl-ca="path/to/ca-cert.pem"
```

Start TiDB and check logs. If the following information is displayed in the log, the configuration is successful:

```
[INFO] [server.go:286] ["mysql protocol server secure connection is enabled
    ↪ "] ["client verification enabled"=true]
```

14.12.6.2.2 Configure the client to use client certificate

Configure the client so that the client uses the client key and certificate for login.

Taking the MySQL client as an example, you can use the newly created client certificate, client key and CA by specifying `ssl-cert`, `ssl-key`, and `ssl-ca`:

```
mysql -utest -h0.0.0.0 -P4000 --ssl-cert /path/to/client-cert.new.pem --ssl-
    ↪ key /path/to/client-key.new.pem --ssl-ca /path/to/ca-cert.pem
```

> **Note:**
>
> `/path/to/client-cert.new.pem`, `/path/to/client-key.new.pem`, and `/path/to/ca-cert.pem` are the directory of the CA certificate, client key, and client certificate. You can replace them with your own directory.

14.12.6.3 Configure the user certificate information for login verification

First, connect TiDB using the client to configure the login verification. Then, you can get and configure the user certificate information to be verified.

14.12.6.3.1 Get user certificate information

The user certificate information can be specified by `REQUIRE SUBJECT`, `REQUIRE ISSUER`, `REQUIRE SAN`, and `REQUIRE CIPHER`, which are used to check the X.509 certificate attributes.

- `REQUIRE SUBJECT`: Specifies the subject information of the client certificate when you log in. With this option specified, you do not need to configure `require ssl` or x509. The information to be specified is consistent with the entered subject information in Generate client keys and certificates.

  To get this option, execute the following command:

```
openssl x509 -noout -subject -in client-cert.pem | sed 's/.\{8\}//' |
    ↪ sed 's/, /\//g' | sed 's/ = /=/g' | sed 's/^/\//'
```

- `require issuer`: Specifies the `subject` information of the CA certificate that issues the user certificate. The information to be specified is consistent with the entered `subject` information in Generate CA key and certificate.

  To get this option, execute the following command:

```
openssl x509 -noout -subject -in ca-cert.pem | sed 's/.\{8\}//' | sed '
    ↪ s/, /\//g' | sed 's/ = /=/g' | sed 's/^/\//'
```

- `require san`: Specifies the `Subject Alternative Name` information of the CA certificate that issues the user certificate. The information to be specified is consistent with the `alt_names` of the `openssl.cnf` configuration file used to generate the client certificate.

  - Execute the following command to get the information of the `REQUIRE SAN` item in the generated certificate:

```
openssl x509 -noout -extensions subjectAltName -in client.crt
```

  - `REQUIRE SAN` currently supports the following `Subject Alternative Name` check items:

    - URI
    - IP
    - DNS

  - Multiple check items can be configured after they are connected by commas. For example, configure `REQUIRE SAN` as follows for the `u1` user:

```
CREATE USER 'u1'@'%' REQUIRE SAN 'DNS:d1,URI:spiffe://example.org/
    ↪ myservice1,URI:spiffe://example.org/myservice2';
```

    The above configuration only allows the `u1` user to log in to TiDB using the certificate with the URI item `spiffe://example.org/myservice1` or `spiffe://
    ↪ example.org/myservice2` and the DNS item `d1`.

- `REQUIRE CIPHER`: Checks the cipher method supported by the client. Use the following statement to check the list of supported cipher methods:

```
SHOW SESSION STATUS LIKE 'Ssl_cipher_list';
```

14.12.6.3.2 Configure user certificate information

After getting the user certificate information (`REQUIRE SUBJECT`, `REQUIRE ISSUER`, `REQUIRE SAN`, `REQUIRE CIPHER`), configure these information to be verified when creating a user, granting privileges, or altering a user. Replace `<replaceable>` with the corresponding information in the following statements.

You can configure one option or multiple options using the space or `and` as the separator.

- Configure user certificate when creating a user (`CREATE USER`):

```
CREATE USER 'u1'@'%' REQUIRE ISSUER '<replaceable>' SUBJECT '<
    ↪ replaceable>' SAN '<replaceable>' CIPHER '<replaceable>';
```

- Configure user certificate when altering a user:

```
ALTER USER 'u1'@'%' REQUIRE ISSUER '<replaceable>' SUBJECT '<
    ↪ replaceable>' SAN '<replaceable>' CIPHER '<replaceable>';
```

After the above configuration, the following items will be verified when you log in:

- SSL is used; the CA that issues the client certificate is consistent with the CA configured in the server.
- The `issuer` information of the client certificate matches the information specified in `REQUIRE ISSUER`.
- The `subject` information of the client certificate matches the information specified in `REQUIRE CIPHER`.
- The `Subject Alternative Name` information of the client certificate matches the information specified in `REQUIRE SAN`.

You can log into TiDB only after all the above items are verified. Otherwise, the `ERROR 1045 (28000): Access denied` error is returned. You can use the following command to check the TLS version, the cipher algorithm and whether the current connection uses the certificate for the login.

Connect the MySQL client and execute the following statement:

```
\s
```

The output:

```
--------------
mysql  Ver 8.5.1 for Linux on x86_64 (MySQL Community Server - GPL)

Connection id:    1
Current database: test
Current user:     root@127.0.0.1
SSL:              Cipher in use is TLS_AES_128_GCM_SHA256
```

Then execute the following statement:

```
SHOW VARIABLES LIKE '%ssl%';
```

The output:

```
+---------------+---------------------------------+
| Variable_name | Value                           |
+---------------+---------------------------------+
| have_openssl | YES                              |
| have_ssl     | YES                              |
| ssl_ca       | /path/to/ca-cert.pem             |
| ssl_cert     | /path/to/server-cert.pem         |
| ssl_cipher   |                                  |
| ssl_key      | /path/to/server-key.pem          |
+---------------+---------------------------------+
6 rows in set (0.06 sec)
```

14.12.6.4 Update and replace certificate

The key and certificate are updated regularly. The following sections introduce how to update the key and certificate.

The CA certificate is the basis for mutual verification between the client and server. To replace the CA certificate, generate a combined certificate that supports the authentication for both old and new certificates. On the client and server, first replace the CA certificate, then replace the client/server key and certificate.

14.12.6.4.1 Update CA key and certificate

1. Back up the old CA key and certificate (suppose that `ca-key.pem` is stolen):

   ```
   mv ca-key.pem ca-key.old.pem && \
   mv ca-cert.pem ca-cert.old.pem
   ```

2. Generate the new CA key:

   ```
   sudo openssl genrsa 2048 > ca-key.pem
   ```

3. Generate the new CA certificate using the newly generated CA key:

   ```
   sudo openssl req -new -x509 -nodes -days 365000 -key ca-key.pem -out ca
      ↪ -cert.new.pem
   ```

> **Note:**
>
> Generating the new CA certificate is to replace the keys and certificates on the client and server, and to ensure that online users are not affected. Therefore, the appended information in the above command must be consistent with the `require issuer` information.

4. Generate the combined CA certificate:

```
cat ca-cert.new.pem ca-cert.old.pem > ca-cert.pem
```

After the above operations, restart the TiDB server with the newly created combined CA certificate. Then the server accepts both the new and old CA certificates.

Also replace the old CA certificate with the combined certificate so that the client accepts both the old and new CA certificates.

14.12.6.4.2 Update client key and certificate

> **Note:**
>
> Perform the following steps **only after** you have replaced the old CA certificate on the client and server with the combined CA certificate.

1. Generate the new RSA key of the client:

```
sudo openssl req -newkey rsa:2048 -days 365000 -nodes -keyout client-
    ↪ key.new.pem -out client-req.new.pem && \
sudo openssl rsa -in client-key.new.pem -out client-key.new.pem
```

> **Note:**
>
> The above command is to replace the client key and certificate, and to ensure that the online users are not affected. Therefore, the appended information in the above command must be consistent with the `require subject` information.

2. Use the combined certificate and the new CA key to generate the new client certificate:

```
sudo openssl x509 -req -in client-req.new.pem -days 365000 -CA ca-cert.
    ↪ pem -CAkey ca-key.pem -set_serial 01 -out client-cert.new.pem
```

3. Make the client (for example, MySQL) connect TiDB with the new client key and certificate:

```
mysql -utest -h0.0.0.0 -P4000 --ssl-cert /path/to/client-cert.new.pem
    ↪ --ssl-key /path/to/client-key.new.pem --ssl-ca /path/to/ca-cert.
    ↪ pem
```

> **Note:**
>
> `/path/to/client-cert.new.pem`, `/path/to/client-key.new.pem`, and `/path/to/ca-cert.pem` specify the directory of the CA certificate, client key, and client certificate. You can replace them with your own directory.

14.12.6.4.3 Update the server key and certificate

1. Generate the new RSA key of the server:

```
sudo openssl req -newkey rsa:2048 -days 365000 -nodes -keyout server-
    ↪ key.new.pem -out server-req.new.pem && \
sudo openssl rsa -in server-key.new.pem -out server-key.new.pem
```

2. Use the combined CA certificate and the new CA key to generate the new server certificate:

```
sudo openssl x509 -req -in server-req.new.pem -days 365000 -CA ca-cert.
    ↪ pem -CAkey ca-key.pem -set_serial 01 -out server-cert.new.pem
```

3. Configure the TiDB server to use the new server key and certificate. See Configure TiDB server for details.

14.12.6.5 Policy-based access control for certificates

TiDB supports policy-based access control (PBAC) for certificates, leveraging policies defined by the underlying key management server. This enables fine-grained control over access based on various criteria, such as time-based policies (for example, certificates only valid during specific hours), location-based policies (for example, restricting access to certain geographic locations), and other customizable conditions, ensuring enhanced security and flexibility in certificate management.

14.13 SQL

14.13.1 SQL Language Structure and Syntax

14.13.1.1 Attributes

14.13.1.1.1 AUTO_INCREMENT

This document introduces the `AUTO_INCREMENT` column attribute, including its concept, implementation principles, auto-increment related features, and restrictions.

> **Note:**
>
> The `AUTO_INCREMENT` attribute might cause hotspot in production environments. See Troubleshoot HotSpot Issues for details. It is recommended to use `AUTO_RANDOM` instead.

You can also use the `AUTO_INCREMENT` parameter in the `CREATE TABLE` statement to specify the initial value of the increment field.

Concept

`AUTO_INCREMENT` is a column attribute that is used to automatically fill in default column values. When the `INSERT` statement does not specify values for the `AUTO_INCREMENT` column, the system automatically assigns values to this column.

For performance reasons, `AUTO_INCREMENT` numbers are allocated in a batch of values (30 thousand by default) to each TiDB server. This means that while `AUTO_INCREMENT` numbers are guaranteed to be unique, values assigned to an `INSERT` statement will only be monotonic on a per TiDB server basis.

> **Note:**
>
> If you want the `AUTO_INCREMENT` numbers to be monotonic on all TiDB servers and your TiDB version is v6.5.0 or later, it is recommended to enable the MySQL compatibility mode.

The following is a basic example of `AUTO_INCREMENT`:

```
CREATE TABLE t(id int PRIMARY KEY AUTO_INCREMENT, c int);
```

```
INSERT INTO t(c) VALUES (1);
INSERT INTO t(c) VALUES (2);
INSERT INTO t(c) VALUES (3), (4), (5);
```

```
mysql> SELECT * FROM t;
+----+---+
| id | c |
+----+---+
| 1  | 1 |
| 2  | 2 |
| 3  | 3 |
| 4  | 4 |
| 5  | 5 |
+----+---+
5 rows in set (0.01 sec)
```

In addition, `AUTO_INCREMENT` also supports the `INSERT` statements that explicitly specify column values. In such cases, TiDB stores the explicitly specified values:

```
INSERT INTO t(id, c) VALUES (6, 6);
```

```
mysql> SELECT * FROM t;
+----+---+
| id | c |
+----+---+
| 1  | 1 |
| 2  | 2 |
| 3  | 3 |
| 4  | 4 |
| 5  | 5 |
| 6  | 6 |
+----+---+
6 rows in set (0.01 sec)
```

The usage above is the same as that of `AUTO_INCREMENT` in MySQL. However, in terms of the specific value that is implicitly assigned, TiDB differs from MySQL significantly.

Implementation principles

TiDB implements the `AUTO_INCREMENT` implicit assignment in the following way:

For each auto-increment column, a globally visible key-value pair is used to record the maximum ID that has been assigned. In a distributed environment, communication between nodes has some overhead. Therefore, to avoid the issue of write amplification, each TiDB node applies for a batch of consecutive IDs as caches when assigning IDs, and then applies for the next batch of IDs after the first batch is assigned. Therefore, TiDB nodes do not apply to the storage node for IDs when assigning IDs each time. For example:

```
CREATE TABLE t(id int UNIQUE KEY AUTO_INCREMENT, c int);
```

Assume two TiDB instances, `A` and `B`, in the cluster. If you execute an `INSERT` statement on the `t` table on `A` and `B` respectively:

```
INSERT INTO t (c) VALUES (1)
```

Instance `A` might cache the auto-increment IDs of `[1,30000]`, and instance `B` might cache the auto-increment IDs of `[30001,60000]`. In `INSERT` statements to be executed, these cached IDs of each instance will be assigned to the `AUTO_INCREMENT` column as the default values.

Basic Features

Uniqueness

> **Warning:**
>
> When the cluster has multiple TiDB instances, if the table schema contains the auto-increment IDs, it is recommended not to use explicit insert and implicit assignment at the same time, which means using the default values of the auto-increment column and the custom values. Otherwise, it might break the uniqueness of implicitly assigned values.

In the example above, perform the following operations in order:

1. The client inserts a statement `INSERT INTO t VALUES (2, 1)` to instance `B`, which sets `id` to `2`. The statement is successfully executed.
2. The client sends a statement `INSERT INTO t (c)(1)` to instance `A`. This statement does not specify the value of `id`, so the ID is assigned by `A`. At present, because `A` caches the IDs of `[1, 30000]`, it might assign `2` as the value of the auto-increment ID, and increases the local counter by `1`. At this time, the data whose ID is `2` already exists in the database, so the `Duplicated Error` error is returned.

Monotonicity

TiDB guarantees that `AUTO_INCREMENT` values are monotonic (always increasing) on a per-server basis. Consider the following example where consecutive `AUTO_INCREMENT` values of 1-3 are generated:

```
CREATE TABLE t (a int PRIMARY KEY AUTO_INCREMENT, b timestamp NOT NULL
    ↪ DEFAULT NOW());
INSERT INTO t (a) VALUES (NULL), (NULL), (NULL);
SELECT * FROM t;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0

+---+---------------------+
| a | b                   |
+---+---------------------+
| 1 | 2020-09-09 20:38:22 |
| 2 | 2020-09-09 20:38:22 |
| 3 | 2020-09-09 20:38:22 |
+---+---------------------+
3 rows in set (0.00 sec)
```

Monotonicity is not the same guarantee as consecutive. Consider the following example:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a VARCHAR(10),
    ↪ cnt INT NOT NULL DEFAULT 1, UNIQUE KEY (a));
INSERT INTO t (a) VALUES ('A'), ('B');
SELECT * FROM t;
INSERT INTO t (a) VALUES ('A'), ('C') ON DUPLICATE KEY UPDATE cnt = cnt +
    ↪ 1;
SELECT * FROM t;
```

```
Query OK, 0 rows affected (0.00 sec)

Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0

+----+------+-----+
| id | a    | cnt |
+----+------+-----+
|  1 | A    |   1 |
|  2 | B    |   1 |
+----+------+-----+
2 rows in set (0.00 sec)

Query OK, 3 rows affected (0.00 sec)
Records: 2 Duplicates: 1 Warnings: 0

+----+------+-----+
| id | a    | cnt |
+----+------+-----+
|  1 | A    |   2 |
|  2 | B    |   1 |
```

```
| 4 | C    |   1 |
+----+------+-----+
3 rows in set (0.00 sec)
```

In this example, the AUTO_INCREMENT value of 3 is allocated for the INSERT of the key A in INSERT INTO t (a)VALUES ('A'), ('C')ON DUPLICATE KEY UPDATE cnt = cnt + 1; but never used because this INSERT statement contains a duplicate key A. This leads to a gap where the sequence is non-consecutive. This behavior is considered legal, even though it differs from MySQL. MySQL will also have gaps in the sequence in other scenarios such as transactions being aborted and rolled back.

AUTO_ID_CACHE

The AUTO_INCREMENT sequence might appear to *jump* dramatically if an INSERT operation is performed against a different TiDB server. This is caused by the fact that each server has its own cache of AUTO_INCREMENT values:

```
CREATE TABLE t (a int PRIMARY KEY AUTO_INCREMENT, b timestamp NOT NULL
    ↪ DEFAULT NOW());
INSERT INTO t (a) VALUES (NULL), (NULL), (NULL);
INSERT INTO t (a) VALUES (NULL);
SELECT * FROM t;
```

```
Query OK, 1 row affected (0.03 sec)

+---------+---------------------+
| a       | b                   |
+---------+---------------------+
|       1 | 2020-09-09 20:38:22 |
|       2 | 2020-09-09 20:38:22 |
|       3 | 2020-09-09 20:38:22 |
| 2000001 | 2020-09-09 20:43:43 |
+---------+---------------------+
4 rows in set (0.00 sec)
```

A new INSERT operation against the initial TiDB server generates the AUTO_INCREMENT value of 4. This is because the initial TiDB server still has space left in the AUTO_INCREMENT ↪ cache for allocation. In this case, the sequence of values cannot be considered globally monotonic, because the value of 4 is inserted after the value of 2000001:

```
mysql> INSERT INTO t (a) VALUES (NULL);
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t ORDER BY b;
+---------+---------------------+
| a       | b                   |
+---------+---------------------+
```

```
|      1 | 2020-09-09 20:38:22 |
|      2 | 2020-09-09 20:38:22 |
|      3 | 2020-09-09 20:38:22 |
| 2000001 | 2020-09-09 20:43:43 |
|      4 | 2020-09-09 20:44:43 |
+---------+---------------------+
5 rows in set (0.00 sec)
```

The `AUTO_INCREMENT` cache does not persist across TiDB server restarts. The following `INSERT` statement is performed after the initial TiDB server is restarted:

```
mysql> INSERT INTO t (a) VALUES (NULL);
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t ORDER BY b;
+---------+---------------------+
| a       | b                   |
+---------+---------------------+
|      1 | 2020-09-09 20:38:22 |
|      2 | 2020-09-09 20:38:22 |
|      3 | 2020-09-09 20:38:22 |
| 2000001 | 2020-09-09 20:43:43 |
|      4 | 2020-09-09 20:44:43 |
| 2030001 | 2020-09-09 20:54:11 |
+---------+---------------------+
6 rows in set (0.00 sec)
```

A high rate of TiDB server restarts might contribute to the exhaustion of `AUTO_INCREMENT` values. In the above example, the initial TiDB server still has values `[5-30000]` free in its cache. These values are lost, and will not be reallocated.

It is not recommended to rely on`AUTO_INCREMENT` values being continuous. Consider the following example, where a TiDB server has a cache of values `[2000001-2030000]`. By manually inserting the value `2029998`, you can see the behavior as a new cache range is retrieved:

```
mysql> INSERT INTO t (a) VALUES (2029998);
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t (a) VALUES (NULL);
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t (a) VALUES (NULL);
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t (a) VALUES (NULL);
```

```
Query OK, 1 row affected (0.02 sec)

mysql> INSERT INTO t (a) VALUES (NULL);
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM t ORDER BY b;
+---------+---------------------+
| a       | b                   |
+---------+---------------------+
|       1 | 2020-09-09 20:38:22 |
|       2 | 2020-09-09 20:38:22 |
|       3 | 2020-09-09 20:38:22 |
| 2000001 | 2020-09-09 20:43:43 |
|       4 | 2020-09-09 20:44:43 |
| 2030001 | 2020-09-09 20:54:11 |
| 2029998 | 2020-09-09 21:08:11 |
| 2029999 | 2020-09-09 21:08:11 |
| 2030000 | 2020-09-09 21:08:11 |
| 2060001 | 2020-09-09 21:08:11 |
| 2060002 | 2020-09-09 21:08:11 |
+---------+---------------------+
11 rows in set (0.00 sec)
```

After the value 2030000 is inserted, the next value is 2060001. This jump in sequence is due to another TiDB server obtaining the intermediate cache range of [2030001-2060000] ↪ . When multiple TiDB servers are deployed, there will be gaps in the AUTO_INCREMENT sequence because cache requests are interleaved.

Cache size control

In earlier versions of TiDB, the cache size of the auto-increment ID was transparent to users. Starting from v3.0.14, v3.1.2, and v4.0.rc-2, TiDB has introduced the AUTO_ID_CACHE table option to allow users to set the cache size for allocating the auto-increment ID.

```
CREATE TABLE t(a int AUTO_INCREMENT key) AUTO_ID_CACHE 100;
Query OK, 0 rows affected (0.02 sec)

INSERT INTO t values();
Query OK, 1 row affected (0.00 sec)

SELECT * FROM t;
+---+
| a |
+---+
| 1 |
+---+
1 row in set (0.01 sec)
```

```
SHOW CREATE TABLE t;
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int NOT NULL AUTO_INCREMENT,
  PRIMARY KEY (`a`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =101 /*T![auto_id_cache] AUTO_ID_CACHE=100 */ |
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

At this time, if you restart TiDB, the auto-increment ID cache will be lost, and new insert operations will allocate IDs starting from a higher value beyond the previously cached range.

```
INSERT INTO t VALUES();
Query OK, 1 row affected (0.00 sec)

SELECT * FROM t;
+-----+
| a   |
+-----+
|   1 |
| 101 |
+-----+
2 rows in set (0.01 sec)
```

The newly allocated value is `101`. This shows that the size of cache for allocating auto-increment IDs is `100`.

In addition, when the length of consecutive IDs in a batch `INSERT` statement exceeds the length of `AUTO_ID_CACHE`, TiDB increases the cache size accordingly to ensure that the statement can insert data properly.

Clear the auto-increment ID cache

In some scenarios, you might need to clear the auto-increment ID cache to ensure data

consistency. For example:

- In the scenario of incremental replication using Data Migration (DM), once the replication is complete, data writing to the downstream TiDB switches from DM to your application's write operations. Meanwhile, the ID writing mode of the auto-increment column usually switches from explicit insertion to implicit allocation.
- After TiDB Lightning completes the data import, it automatically clears the auto-increment ID cache. However, TiCDC does not automatically clear the cache after incremental data synchronization. Therefore, you need to manually clear the auto-increment ID cache in the downstream cluster after stopping TiCDC, and before performing the failover.

- When your application involves both explicit ID insertion and implicit ID allocation, you need to clear the auto-increment ID cache to avoid conflicts between future implicitly allocated IDs and previously explicitly inserted IDs, which could result in primary key conflict errors. For more information, see Uniqueness.

To clear the auto-increment ID cache on all TiDB nodes in the cluster, you can execute the `ALTER TABLE` statement with `AUTO_INCREMENT = 0`. For example:

```
CREATE TABLE t(a int AUTO_INCREMENT key) AUTO_ID_CACHE 100;
Query OK, 0 rows affected (0.02 sec)

INSERT INTO t VALUES();
Query OK, 1 row affected (0.02 sec)

INSERT INTO t VALUES(50);
Query OK, 1 row affected (0.00 sec)

SELECT * FROM t;
+----+
| a  |
+----+
|  1 |
| 50 |
+----+
2 rows in set (0.01 sec)
```

```
ALTER TABLE t AUTO_INCREMENT = 0;
Query OK, 0 rows affected, 1 warning (0.07 sec)

SHOW WARNINGS;
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
```

```
| Level   | Code | Message
   ↪                                                                |
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
| Warning | 1105 | Can't reset AUTO_INCREMENT to 0 without FORCE option,
   ↪ using 101 instead |
+---------+------+-----------------------------------------------------------------
   ↪
1 row in set (0.01 sec)

INSERT INTO t VALUES();
Query OK, 1 row affected (0.02 sec)

SELECT * FROM t;
+-----+
| a   |
+-----+
|   1 |
|  50 |
| 101 |
+-----+
3 rows in set (0.01 sec)
```

Auto-increment step size and offset

Starting from v3.0.9 and v4.0.0-rc.1, similar to the behavior of MySQL, the value implicitly assigned to the auto-increment column is controlled by the `@@auto_increment_increment` and `@@auto_increment_offset` session variables.

The value (ID) implicitly assigned to auto-increment columns satisfies the following equation:

```
(ID - auto_increment_offset)% auto_increment_increment == 0
```

MySQL compatibility mode

TiDB provides a MySQL-compatible mode for auto-increment columns that ensures strictly increasing IDs with minimal gaps. To enable this mode, set `AUTO_ID_CACHE` to `1` when creating a table:

```
CREATE TABLE t(a int AUTO_INCREMENT key) AUTO_ID_CACHE 1;
```

When `AUTO_ID_CACHE` is set to `1`, IDs are strictly increasing across all TiDB instances, each ID is guaranteed to be unique, and gaps between IDs are minimal compared to the default cache mode (`AUTO_ID_CACHE 0` with 30000 cached values).

For example, with `AUTO_ID_CACHE 1`, you might see a sequence as follows:

```
INSERT INTO t VALUES (); -- Returns ID 1
INSERT INTO t VALUES (); -- Returns ID 2
INSERT INTO t VALUES (); -- Returns ID 3
-- After failover
INSERT INTO t VALUES (); -- Might return ID 5
```

In contrast, with the default cache (`AUTO_ID_CACHE 0`), larger gaps can occur:

```
INSERT INTO t VALUES (); -- Returns ID 1
INSERT INTO t VALUES (); -- Returns ID 2
-- New TiDB instance allocates next batch
INSERT INTO t VALUES (); -- Returns ID 30001
```

While IDs are always increasing and without significant gaps like those seen with `AUTO_ID_CACHE 0`, small gaps in the sequence might still occur in the following scenarios. These gaps are necessary to maintain both uniqueness and the strictly increasing property of the IDs.

- During failover when the primary instance exits or crashes

  After you enable the MySQL compatibility mode, the allocated IDs are **unique** and **monotonically increasing**, and the behavior is almost the same as MySQL. Even when accessing across multiple TiDB instances, ID monotonicity is maintained. However, if the primary instance of the centralized service crashes, a few IDs might become non-continuous. This occurs because the secondary instance discards some IDs allocated by the primary instance during failover to ensure ID uniqueness.

- During rolling upgrades of TiDB nodes
- During normal concurrent transactions (similar to MySQL)

Note:

The behavior and performance of `AUTO_ID_CACHE 1` has evolved across TiDB versions:

- Before v6.4.0, each ID allocation requires a TiKV transaction, which affects performance.
- In v6.4.0, TiDB introduces a centralized allocating service that performs ID allocation as an in-memory operation, significantly improving performance.
- Starting from v8.1.0, TiDB removes the automatic `forceRebase` operation during primary node exits to enable faster restarts. While this might result in additional non-consecutive IDs during failover, it prevents potential write blocking when many tables use `AUTO_ID_CACHE 1`.

Restrictions

Currently, AUTO_INCREMENT has the following restrictions when used in TiDB:

- For TiDB v6.6.0 and earlier versions, the defined column must be either primary key or index prefixes.
- It must be defined on the column of INTEGER, FLOAT, or DOUBLE type.
- It cannot be specified on the same column with the DEFAULT column value.
- ALTER TABLE cannot be used to add or modify columns with the AUTO_INCREMENT attribute, including using ALTER TABLE ... MODIFY/CHANGE COLUMN to add the AUTO_INCREMENT attribute to an existing column, or using ALTER TABLE ... ADD COLUMN to add a column with the AUTO_INCREMENT attribute.
- ALTER TABLE can be used to remove the AUTO_INCREMENT attribute. However, starting from v2.1.18 and v3.0.4, TiDB uses the session variable @@tidb_allow_remove_auto_inc to control whether ALTER TABLE MODIFY or ALTER TABLE CHANGE can be used to remove the AUTO_INCREMENT attribute of a column. By default, you cannot use ALTER TABLE MODIFY or ALTER TABLE CHANGE to remove the AUTO_INCREMENT attribute.
- ALTER TABLE requires the FORCE option to set the AUTO_INCREMENT value to a smaller value.
- Setting the AUTO_INCREMENT to a value smaller than MAX(<auto_increment_column>) leads to duplicate keys because pre-existing values are not skipped.

14.13.1.1.2 AUTO_RANDOM New in v3.1.0

User scenario

Since the value of AUTO_RANDOM is random and unique, AUTO_RANDOM is often used in place of AUTO_INCREMENT to avoid write hotspot in a single storage node caused by TiDB assigning consecutive IDs. If the current AUTO_INCREMENT column is a primary key and the type is BIGINT, you can execute the ALTER TABLE t MODIFY COLUMN id BIGINT AUTO_RANDOM(5); statement to switch from AUTO_INCREMENT to AUTO_RANDOM.

For more information about how to handle highly concurrent write-heavy workloads in TiDB, see Highly concurrent write best practices.

The AUTO_RANDOM_BASE parameter in the CREATE TABLE statement is used to set the initial incremental part value of auto_random. This option can be considered as a part of the internal interface. You can ignore this parameter.

Basic concepts

AUTO_RANDOM is a column attribute that is used to automatically assign values to a BIGINT column. Values assigned automatically are **random** and **unique**.

To create a table with an AUTO_RANDOM column, you can use the following statements. The AUTO_RANDOM column must be included in a primary key, and the AUTO_RANDOM column is the first column in the primary key.

```
CREATE TABLE t (a BIGINT AUTO_RANDOM, b VARCHAR(255), PRIMARY KEY (a));
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b VARCHAR(255));
CREATE TABLE t (a BIGINT AUTO_RANDOM(6), b VARCHAR(255), PRIMARY KEY (a));
CREATE TABLE t (a BIGINT AUTO_RANDOM(5, 54), b VARCHAR(255), PRIMARY KEY (a
    ↪ ));
CREATE TABLE t (a BIGINT AUTO_RANDOM(5, 54), b VARCHAR(255), PRIMARY KEY (a
    ↪ , b));
```

You can wrap the keyword `AUTO_RANDOM` in an executable comment. For more details, refer to TiDB specific comment syntax.

```
CREATE TABLE t (a bigint /*T![auto_rand] AUTO_RANDOM */, b VARCHAR(255),
    ↪ PRIMARY KEY (a));
CREATE TABLE t (a bigint PRIMARY KEY /*T![auto_rand] AUTO_RANDOM */, b
    ↪ VARCHAR(255));
CREATE TABLE t (a BIGINT /*T![auto_rand] AUTO_RANDOM(6) */, b VARCHAR(255),
    ↪  PRIMARY KEY (a));
CREATE TABLE t (a BIGINT /*T![auto_rand] AUTO_RANDOM(5, 54) */, b VARCHAR
    ↪ (255), PRIMARY KEY (a));
```

When you execute an `INSERT` statement:

- If you explicitly specify the value of the `AUTO_RANDOM` column, it is inserted into the table as is.
- If you do not explicitly specify the value of the `AUTO_RANDOM` column, TiDB generates a random value and inserts it into the table.

```
tidb> CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b VARCHAR(255)) /*T
    ↪ ! PRE_SPLIT_REGIONS=2 */ ;
Query OK, 0 rows affected, 1 warning (0.01 sec)

tidb> INSERT INTO t(a, b) VALUES (1, 'string');
Query OK, 1 row affected (0.00 sec)

tidb> SELECT * FROM t;
+---+--------+
| a | b      |
+---+--------+
| 1 | string |
+---+--------+
1 row in set (0.01 sec)

tidb> INSERT INTO t(b) VALUES ('string2');
Query OK, 1 row affected (0.00 sec)
```

```
tidb> INSERT INTO t(b) VALUES ('string3');
Query OK, 1 row affected (0.00 sec)

tidb> SELECT * FROM t;
+--------------------+---------+
| a                  | b       |
+--------------------+---------+
|                  1 | string  |
| 1152921504606846978 | string2 |
| 4899916394579099651 | string3 |
+--------------------+---------+

```

The `AUTO_RANDOM(S, R)` column value automatically assigned by TiDB has a total of 64 bits:

- `S` is the number of shard bits. The value ranges from `1` to `15`. The default value is `5`.
- `R` is the total length of the automatic allocation range. The value ranges from `32` to `64`. The default value is `64`.

The structure of an `AUTO_RANDOM` value with a signed bit is as follows:

Signed bit	Reserved bits	Shard bits	Auto-increment bits
1 bit	`64-R` bits	`S` bits	`R-1-S` bits

The structure of an `AUTO_RANDOM` value without a signed bit is as follows:

Reserved bits	Shard bits	Auto-increment bits
`64-R` bits	`S` bits	`R-S` bits

- Whether a value has a signed bit depends on whether the corresponding column has the `UNSIGNED` attribute.
- The length of the sign bit is determined by the existence of an `UNSIGNED` attribute. If

there is an `UNSIGNED` attribute, the length is `0`. Otherwise, the length is `1`.
- The length of the reserved bits is `64-R`. The reserved bits are always `0`.
- The content of the shard bits is obtained by calculating the hash value of the starting time of the current transaction. To use a different length of shard bits (such as 10), you can specify `AUTO_RANDOM(10)` when creating the table.
- The value of the auto-increment bits is stored in the storage engine and allocated sequentially. Each time a new value is allocated, the value is incremented by 1. The auto-increment bits ensure that the values of `AUTO_RANDOM` are unique globally. When the auto-increment bits are exhausted, an error `Failed to read auto-increment value from storage engine` is reported when the value is allocated again.
- Value range: the maximum number of bits for the final generated value = shard bits + auto-increment bits. The range of a signed column is `[-(2^(R-1))+1, (2^(R-1))-1]`, and the range of an unsigned column is `[0, (2^R)-1]`.
- You can use `AUTO_RANDOM` with `PRE_SPLIT_REGIONS`. When a table is created successfully, `PRE_SPLIT_REGIONS` pre-splits data in the table into the number of Regions as specified by `2^(PRE_SPLIT_REGIONS)`.

Note:

Selection of shard bits (`S`):

- Since there is a total of 64 available bits, the shard bits length affects the auto-increment bits length. That is, as the shard bits length increases, the length of auto-increment bits decreases, and vice versa. Therefore, you need to balance the randomness of allocated values and available space.
- The best practice is to set the shard bits as `log(2, x)`, in which `x` is the current number of storage engines. For example, if there are 16 TiKV nodes in a TiDB cluster, you can set the shard bits as `log(2, 16)`, that is `4`. After all regions are evenly scheduled to each TiKV node, the load of bulk writes can be uniformly distributed to different TiKV nodes to maximize resource utilization.

Selection of range (`R`):

- Typically, the `R` parameter needs to be set when the numeric type of the application cannot represent a full 64-bit integer.
- For example, the range of JSON number is `[-(2^53)+1, (2^53)-1]`. TiDB can easily assign an integer beyond this range to a column defined as `AUTO_RANDOM(5)`, causing unexpected behaviors when the application reads the column. In such cases, you can replace `AUTO_RANDOM(5)` with `AUTO_RANDOM(5, 54)` for signed columns, and replace `AUTO_RANDOM(5)` with `AUTO_RANDOM(5, 53)` for unsigned columns, ensuring that TiDB

> does not assign integers greater than 9007199254740991 (2^53-1) to the column.

Values allocated implicitly to the AUTO_RANDOM column affect last_insert_id(). To get the ID that TiDB last implicitly allocates, you can use the SELECT last_insert_id () statement.

To view the shard bits number of the table with an AUTO_RANDOM column, you can execute the SHOW CREATE TABLE statement. You can also see the value of the PK_AUTO_RANDOM_BITS=x mode in the TIDB_ROW_ID_SHARDING_INFO column in the information_schema.tables system table. x is the number of shard bits.

After creating a table with an AUTO_RANDOM column, you can use SHOW WARNINGS to view the maximum implicit allocation times:

```
CREATE TABLE t (a BIGINT AUTO_RANDOM, b VARCHAR(255), PRIMARY KEY (a));
SHOW WARNINGS;
```

The output is as follows:

```
+-------+------+-----------------------------------------------------------+
| Level | Code | Message                                                   |
+-------+------+-----------------------------------------------------------+
| Note | 1105 | Available implicit allocation times: 288230376151711743 |
+-------+------+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Implicit allocation rules of IDs

TiDB implicitly allocates values to AUTO_RANDOM columns similarly to AUTO_INCREMENT columns. They are also controlled by the session-level system variables auto_increment_increment and auto_increment_offset. The auto-increment bits (ID) of implicitly allocated values conform to the equation (ID - auto_increment_offset)% auto_increment_increment == 0.

Clear the auto-increment ID cache

When you insert data with explicit values into an AUTO_RANDOM column in a deployment with multiple TiDB server instances, potential ID collisions can occur, similar to an AUTO_INCREMENT column. If explicit inserts happen to use ID values that conflict with the internal counter TiDB uses for automatic generation, this can lead to errors.

Here's how the collision can happen: each AUTO_RANDOM ID consists of random bits and an auto-incrementing part. TiDB uses an internal counter for this auto-incrementing part. If you explicitly insert an ID where the auto-incrementing part matches the counter's next value, a duplicate key error might occur when TiDB later attempts to generate the same ID automatically. For more details, see AUTO_INCREMENT Uniqueness.

With a single TiDB instance, this issue doesn't occur because the node automatically adjusts its internal counter when processing explicit insertions, preventing any future collisions. In contrast, with multiple TiDB nodes, each node maintains its own cache of IDs, which needs to be cleared to prevent collisions after explicit insertions. To clear these unallocated cached IDs and avoid potential collisions, you have two options:

Option 1: Automatically rebase (Recommended)

```
ALTER TABLE t AUTO_RANDOM_BASE=0;
```

This statement automatically determines an appropriate base value. Although it produces a warning message similar to `Can't reset AUTO_INCREMENT to 0 without FORCE option, using XXX instead`, the base value **will** change and you can safely ignore this warning.

> **Note:**
>
> You cannot set `AUTO_RANDOM_BASE` to `0` with the `FORCE` keyword. Attempting this results in an error.

Option 2: Manually set a specific base value

If you need to set a specific base value (for example, `1000`), use the `FORCE` keyword:

```
ALTER TABLE t FORCE AUTO_RANDOM_BASE = 1000;
```

This approach is less convenient because it requires you to determine an appropriate base value yourself.

> **Note:**
>
> When using `FORCE`, you must specify a non-zero positive integer.

Both commands modify the starting point for the auto-increment bits used in subsequent `AUTO_RANDOM` value generations across all TiDB nodes. They do not affect already allocated IDs.

Restrictions

Pay attention to the following restrictions when you use `AUTO_RANDOM`:

- To insert values explicitly, you need to set the value of the `@@allow_auto_random_explicit_insert` system variable to `1` (`0` by default). It is **not** recommended that

you explicitly specify a value for the column with the AUTO_RANDOM attribute when you insert data. Otherwise, the numeral values that can be automatically allocated for this table might be used up in advance.

- Specify this attribute for the primary key column **ONLY** as the BIGINT type. Otherwise, an error occurs. In addition, when the attribute of the primary key is NONCLUSTERED, AUTO_RANDOM is not supported even on the integer primary key. For more details about the primary key of the CLUSTERED type, refer to clustered index.
- You cannot use ALTER TABLE to modify the AUTO_RANDOM attribute, including adding or removing this attribute.
- You cannot use ALTER TABLE to change from AUTO_INCREMENT to AUTO_RANDOM if the maximum value is close to the maximum value of the column type.
- You cannot change the column type of the primary key column that is specified with AUTO_RANDOM attribute.
- You cannot specify AUTO_RANDOM and AUTO_INCREMENT for the same column at the same time.
- You cannot specify AUTO_RANDOM and DEFAULT (the default value of a column) for the same column at the same time.
- WhenAUTO_RANDOM is used on a column, it is difficult to change the column attribute back to AUTO_INCREMENT because the auto-generated values might be very large.

14.13.1.1.3 SHARD_ROW_ID_BITS

This document introduces the SHARD_ROW_ID_BITS table attribute, which is used to set the number of bits of the shards after the implicit _tidb_rowid is sharded.

Concept

For the tables with a non-clustered primary key or no primary key, TiDB uses an implicit auto-increment row ID. When a large number of INSERT operations are performed, the data is written into a single Region, causing a write hot spot.

To mitigate the hot spot issue, you can configure SHARD_ROW_ID_BITS. The row IDs are scattered and the data are written into multiple different Regions.

- SHARD_ROW_ID_BITS = 4 indicates 16 shards
- SHARD_ROW_ID_BITS = 6 indicates 64 shards
- SHARD_ROW_ID_BITS = 0 indicates the default 1 shard

For details on the usage, see the Troubleshoot Hotspot Issues guide.

Examples

```
CREATE TABLE t (
    id INT PRIMARY KEY NONCLUSTERED
) SHARD_ROW_ID_BITS = 4;
```

```
ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

14.13.1.2 Literal Values

TiDB literal values include character literals, numeric literals, time and date literals, hexadecimal, binary literals, and NULL literals. This document introduces each of these literal values.

This document describes String literals, Numeric literals, NULL values, Hexadecimal literals, Date and time literals, Boolean literals, and Bit-value literals.

14.13.1.2.1 String literals

A string is a sequence of bytes or characters, enclosed within either single quote `'` or double quote `"` characters. For example:

```
'example string'
"example string"
```

Quoted strings placed next to each other are concatenated to a single string. The following lines are equivalent:

```
'a string'
'a' ' ' 'string'
"a" ' ' "string"
```

If the `ANSI_QUOTES` SQL MODE is enabled, string literals can be quoted only within single quotation marks because a string quoted within double quotation marks is interpreted as an identifier.

The string is divided into the following two types:

- Binary string: It consists of a sequence of bytes, whose charset and collation are both `binary`, and uses **byte** as the unit when compared with each other.
- Non-binary string: It consists of a sequence of characters and has various charsets and collations other than `binary`. When compared with each other, non-binary strings use **characters** as the unit. A character might contain multiple bytes, depending on the charset.

A string literal may have an optional `character set introducer` and `COLLATE clause`, to designate it as a string that uses a specific character set and collation.

```
[_charset_name]'string' [COLLATE collation_name]
```

For example:

```
SELECT _latin1'string';
SELECT _binary'string';
SELECT _utf8'string' COLLATE utf8_bin;
```

You can use N'literal' (or n'literal') to create a string in the national character set. The following statements are equivalent:

```
SELECT N'some text';
SELECT n'some text';
SELECT _utf8'some text';
```

To represent some special characters in a string, you can use escape characters to escape:

Escape Characters	Meaning
\0	An ASCII NUL (X'00') character
\'	A single quote ' character
\"	A double quote " character
\b	A backspace character
\n	A line break (newline) character
\r	A carriage return character
\t	A tab character
\z	ASCII 26 (Ctrl + Z)
\\	A backslash \ character
\%	A % character
_	A _ character

If you want to represent " in the string surrounded by ', or ' in the string surrounded by ", you do not need to use escape characters.

For more information, see String Literals in MySQL.

14.13.1.2.2 Numeric literals

Numeric literals include integer and DECIMAL literals and floating-point literals.

Integer may include `.` as a decimal separator. Numbers may be preceded by `-` or `+` to indicate a negative or positive value respectively.

Exact-value numeric literals can be represented as `1, .2, 3.4, -5, -6.78, +9.10`.

Numeric literals can also be represented in scientific notation, such as `1.2E3, 1.2E-3, -1.2E3, -1.2E-3`.

For more information, see Numeric Literals in MySQL.

14.13.1.2.3 Date and time literals

Date and time literal values can be represented in several formats, such as quoted strings or as numbers. When TiDB expects a date, it interprets any of `'2017-08-24'`, `'20170824'` and `20170824` as a date.

TiDB supports the following date formats:

- `'YYYY-MM-DD'` or `'YY-MM-DD'`: The `-` delimiter here is not strict. It can be any punctuation. For example, `'2017-08-24'`, `'2017&08&24'`, `'2012@12^31'` are all valid date formats. The only special punctuation is '.', which is treated as a decimal point to separate the integer and fractional parts. Date and time can be separated by `T` or a white space. For example, `2017-8-24 10:42:00` and `2017-8-24T10:42:00` represents the same date and time.
- `'YYYYMMDDHHMMSS'` or `'YYMMDDHHMMSS'`: For example, `'20170824104520'` and `'170824104520'` are regarded as `'2017-08-24 10:45:20'`. However, if you provide a value out of range, such as `'170824304520'`, it is not treated as a valid date. Note that incorrect formats such as `YYYYMMDD HHMMSS`, `YYYYMMDD HH:MM:DD`, or `YYYY-MM-DD HHMMSS` will fail to insert.
- `YYYYMMDDHHMMSS` or `YYMMDDHHMMSS`: Note that these formats have no single or double quotes, but a number. For example, `20170824104520` is interpreted as `'2017-08-24 10:45:20'`.

DATETIME or TIMESTAMP values can be followed by a fractional part, used to represent microseconds precision (6 digits). The fractional part should always be separated from the rest of the time by a decimal point `.`.

The year value containing only two digits is ambiguous. It is recommended to use the four-digit year format. TiDB interprets the two-digit year value according to the following rules:

- If the year value is in the range of `70-99`, it is converted to `1970-1999`.
- If the year value is in the range of `00-69`, it is converted to `2000-2069`.

For month or day values less than 10, `'2017-8-4'` is the same as `'2017-08-04'`. The same is true for Time. For example, `'2017-08-24 1:2:3'` is the same as `'2017-08-24 01:02:03'`.

When the date or time value is required, TiDB selects the specified format according to the length of the value:

- 6 digits: `YYMMDD`.
- 12 digits: `YYMMDDHHMMSS`.
- 8 digits: `YYYYMMDD`.
- 14 digits: `YYYYMMDDHHMMSS`.

TiDB supports the following formats for time values:

- `'D HH:MM:SS'`, or `'HH:MM:SS'`, `'HH:MM'`, `'D HH:MM'`, `'D HH'`, `'SS'`: `D` means days and the valid value range is `0-34`.
- A number in `HHMMSS` format: For example, `231010` is interpreted as `'23:10:10'`.
- A number in any of `SS`, `MMSS`, and `HHMMSS`formats can be regarded as time.

The decimal point of the Time type is also `.`, with a precision of up to 6 digits after the decimal point.

See MySQL date and time literals for more details.

14.13.1.2.4 Boolean Literals

The constants `TRUE` and `FALSE` are equal to 1 and 0 respectively, which are not case sensitive.

```
SELECT TRUE, true, tRuE, FALSE, FaLsE, false;
```

```
+------+------+------+-------+-------+-------+
| TRUE | true | tRuE | FALSE | FaLsE | false |
+------+------+------+-------+-------+-------+
|    1 |    1 |    1 |     0 |     0 |     0 |
+------+------+------+-------+-------+-------+
1 row in set (0.00 sec)
```

14.13.1.2.5 Hexadecimal literals

Hexadecimal literal values are written using `X'val'` or `0xval` notation, where `val` contains hexadecimal digits. A leading `0x` is case sensitive and cannot be written as `0X`.

Legal hexadecimal literals:

```
X'ac12'
X'12AC'
x'ac12'
x'12AC'
0xac12
0x12AC
```

Illegal hexadecimal literals:

```
X'1z' (z is not a hexadecimal legal digit)
0X12AC (0X must be written as 0x)
```

Hexadecimal literals written using `X'val'` notation must contain an even number of digits. If the length of `val` is an odd number (for example, `X'A'` or `X'11A'`), to avoid the syntax error, pad the value with a leading zero:

```
mysql> select X'aff';
ERROR 1105 (HY000): line 0 column 13 near ""hex literal: invalid
    ↪ hexadecimal format, must even numbers, but 3 (total length 13)
mysql> select X'0aff';
+---------+
| X'0aff' |
+---------+
| 0x0aff |
+---------+
1 row in set (0.00 sec)
```

By default, a hexadecimal literal is a binary string.

To convert a string or a number to a string in hexadecimal format, use the `HEX()` function:

```
mysql> SELECT HEX('TiDB');
+-------------+
| HEX('TiDB') |
+-------------+
| 54694442    |
+-------------+
1 row in set (0.01 sec)

mysql> SELECT X'54694442';
+-------------+
| X'54694442' |
+-------------+
| TiDB        |
+-------------+
1 row in set (0.00 sec)
```

14.13.1.2.6 Bit-value literals

Bit-value literals are written using `b'val'` or `0bval` notation. The `val` is a binary value written using zeros and ones. A leading `0b` is case sensitive and cannot be written as `0B`.

Legal bit-value literals:

```
b'01'
B'01'
0b01
```

Illegal bit-value literals:

```
b'2' (2 is not a binary digit; it must be 0 or 1)
0B01 (0B must be written as 0b)
```

By default, a bit-value literal is a binary string.

Bit values are returned as binary values, which may not display well in the MySQL client. To convert a bit value to printable form, you can use a conversion function such as `BIN()` or `HEX()`.

```
CREATE TABLE t (b BIT(8));
INSERT INTO t SET b = b'00010011';
INSERT INTO t SET b = b'1110';
INSERT INTO t SET b = b'100101';

mysql> SELECT b+0, BIN(b), HEX(b) FROM t;
```

```
+------+--------+--------+
| b+0  | BIN(b) | HEX(b) |
+------+--------+--------+
|   19 | 10011  | 13     |
|   14 | 1110   | E      |
|   37 | 100101 | 25     |
+------+--------+--------+
3 rows in set (0.00 sec)
```

14.13.1.2.7 NULL Values

`NULL` means the data is empty, which is case-insensitive, and is synonymous with `\N` (case-sensitive).

> **Note:**
>
> `NULL` is not the same as `0`, nor the empty string `''`.

14.13.1.3 Schema Object Names

This document introduces schema object names in TiDB SQL statements.

Schema object names are used to name all schema objects in TiDB, including database, table, index, column, and alias. You can quote these objects using identifiers in SQL statements.

You can use backticks to enclose the identifier. For example, `SELECT * FROM t` can also be written as `SELECT * FROM `t``. But if the identifier includes one or more special characters or is a reserved keyword, it must be enclosed in backticks to quote the schema object it represents.

```
SELECT * FROM `table` WHERE `table`.id = 20;
```

If you set `ANSI_QUOTES` in SQL MODE, TiDB will recognize the string enclosed in double quotation marks `"` as an identifier.

```
CREATE TABLE "test" (a varchar(10));
```

```
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use
    ↪ line 1 column 19 near ""test" (a varchar(10))"
```

```
SET SESSION sql_mode='ANSI_QUOTES';
```

```
Query OK, 0 rows affected (0.000 sec)
```

```
CREATE TABLE "test" (a varchar(10));
```

```
Query OK, 0 rows affected (0.012 sec)
```

If you want to use the backtick character in the quoted identifier, repeat the backtick twice. For example, to create a table a‘b:

```
CREATE TABLE `a``b` (a int);
```

In a SELECT statement, you can use an identifier or a string to specify an alias:

```
SELECT 1 AS `identifier`, 2 AS 'string';
```

```
+------------+--------+
| identifier | string |
+------------+--------+
|          1 |      2 |
+------------+--------+
1 row in set (0.00 sec)
```

For more information, see MySQL Schema Object Names.

14.13.1.3.1 Identifier qualifiers

Object names can be unqualified or qualified. For example, the following statement creates a table without a qualified name:

```
CREATE TABLE t (i int);
```

If you have not used the USE statement or the connection parameter to configure the database, the ERROR 1046 (3D000): No database selected error is displayed. At this time, you can specify the database qualified name:

```
CREATE TABLE test.t (i int);
```

White spaces can exist around .. table_name.col_name and table_name . col_name are equivalent.

To quote this identifier, use:

```
`table_name`.`col_name`
```

Instead of:

```
`table_name.col_name`
```

For more information, see MySQL Identifier Qualifiers.

14.13.1.4 Keywords

This article introduces the keywords in TiDB, the differences between reserved words and non-reserved words and summarizes all keywords for the query.

Keywords are words that have special meanings in SQL statements, such as SELECT, UPDATE, and DELETE. Some of them can be used as identifiers directly, which are called **non-reserved keywords**. Some of them require special treatment before being used as identifiers, which are called **reserved keywords**.

To use the reserved keywords as identifiers, you must enclose them in backticks `:

```
CREATE TABLE select (a INT);
```

```
ERROR 1105 (HY000): line 0 column 19 near " (a INT)" (total length 27)
```

```
CREATE TABLE `select` (a INT);
```

```
Query OK, 0 rows affected (0.09 sec)
```

The non-reserved keywords do not require backticks, such as BEGIN and END, which can be successfully used as identifiers in the following statement:

```
CREATE TABLE `select` (BEGIN int, END int);
```

```
Query OK, 0 rows affected (0.09 sec)
```

In the special case, the reserved keywords do not need backticks if they are used with the . delimiter:

```
CREATE TABLE test.select (BEGIN int, END int);
```

```
Query OK, 0 rows affected (0.08 sec)
```

Starting from v7.5.3 and v7.6.0, TiDB provides a full list of keywords in the INFORMATION_SCHEMA.KEYWORDS table.

You can use the tidb_enable_window_function system variable to control whether the keywords in the window function take effect in the syntax tree. If you set tidb_enable_window_function to OFF, the words in the window function will no longer be treated as keywords.

14.13.1.4.1 Keyword list

The following list shows the keywords in TiDB. Reserved keywords are marked with (R). Reserved keywords for Window Functions are marked with (R-Window).

A

- ACCOUNT
- ACTION
- ADD (R)
- ADMIN
- ADVISE
- AFTER
- AGAINST
- AGO
- ALGORITHM
- ALL (R)
- ALTER (R)
- ALWAYS
- ANALYZE (R)
- AND (R)

14.13.1.5 User-Defined Variables

This document describes the concept of user-defined variables in TiDB and the methods to set and read the user-defined variables.

> **Warning:**
>
> User-defined variables are still an experimental feature. It is **NOT** recommended that you use them in the production environment.

The format of the user-defined variables is `@var_name`. The characters that compose `var_name` can be any characters that can compose an identifier, including the numbers `0-9` ↪ , the letters `a-zA-Z`, the underscore `_`, the dollar sign `$`, and the UTF-8 characters. In addition, it also includes the English period `.`. The user-defined variables are case-insensitive.

The user-defined variables are session-specific, which means a user variable defined by one client connection cannot be seen or used by other client connections.

14.13.1.5.1 Set the user-defined variables

You can use the SET statement to set a user-defined variable, and the syntax is `SET @var_name = expr [, @var_name = expr] ...;`. For example:

```
SET @favorite_db = 'TiDB';
```

```
SET @a = 'a', @b = 'b', @c = 'c';
```

For the assignment operator, you can also use `:=`. For example:

```
SET @favorite_db := 'TiDB';
```

The content to the right of the assignment operator can be any valid expression. For example:

```
SET @c = @a + @b;
```

```
SET @c = b'1000001' + b'1000001';
```

14.13.1.5.2 Read the user-defined variables

To read a user-defined variable, you can use the `SELECT` statement to query:

```
SELECT @a1, @a2, @a3
```

```
+------+------+------+
| @a1 | @a2 | @a3 |
+------+------+------+
|    1 |    2 |    4 |
+------+------+------+
```

You can also assign values in the `SELECT` statement:

```
SELECT @a1, @a2, @a3, @a4 := @a1+@a2+@a3;
```

```
+------+------+------+--------------------+
| @a1 | @a2 | @a3 | @a4 := @a1+@a2+@a3 |
+------+------+------+--------------------+
|    1 |    2 |    4 |                  7 |
+------+------+------+--------------------+
```

Before the variable `@a4` is modified or the connection is closed, its value is always `7`.

If a hexadecimal literal or binary literal is used when setting the user-defined variable, TiDB will treat it as a binary string. If you want to set it to a number, you can manually add the `CAST` conversion, or use the numeric operator in the expression:

```
SET @v1 = b'1000001';
SET @v2 = b'1000001'+0;
SET @v3 = CAST(b'1000001' AS UNSIGNED);
```

```
SELECT @v1, @v2, @v3;
```

```
+------+------+------+
| @v1 | @v2 | @v3 |
+------+------+------+
| A    | 65   | 65   |
+------+------+------+
```

If you refer to a user-defined variable that has not been initialized, it has a value of NULL and a type of string.

```
SELECT @not_exist;
```

```
+------------+
| @not_exist |
+------------+
| NULL       |
+------------+
```

In addition to using the `SELECT` statement to read the user-defined variables, another common usage is the `PREPARE` statement. For example:

```
SET @s = 'SELECT SQRT(POW(?,2) + POW(?,2)) AS hypotenuse';
PREPARE stmt FROM @s;
SET @a = 6;
SET @b = 8;
EXECUTE stmt USING @a, @b;
```

```
+------------+
| hypotenuse |
+------------+
|         10 |
+------------+
```

The contents of the user-defined variables are not recognized as identifiers in the SQL statements. For example:

```
SELECT * from t;
```

```
+---+
| a |
```

```
+---+
| 1 |
+---+
```

```
SET @col = "`a`";
SELECT @col FROM t;
```

```
+------+
| @col |
+------+
| `a` |
+------+
```

14.13.1.5.3 MySQL compatibility

Except for `SELECT ... INTO <variable>`, the syntax supported in MySQL and TiDB is identical.

For more information, see User-Defined Variables in MySQL.

14.13.1.6 Expression Syntax

An expression is a combination of one or more values, operators, or functions. In TiDB, expressions are mainly used in various clauses of the `SELECT` statement, including Group by clause, Where clause, Having clause, Join condition and window function. In addition, some DDL statements also use expressions, such as the setting of the default values, columns, and partition rules when creating tables.

The expressions can be divided into the following types:

- Identifier. For reference, see Schema object names.
- Predicates, numeric values, strings, date expressions. The Literal values of these types are also expressions.
- Function calls and window functions. For reference, see Functions and operators overview and Window functions
- ParamMarker (`?`), system variables, user variables and CASE expressions.

The following rules are the expression syntax, which is based on the `parser.y` rules of TiDB parser.

```
Expression ::=
    ( singleAtIdentifier assignmentEq | 'NOT' | Expression ( logOr | 'XOR' |
        ↪ logAnd ) ) Expression
```

```
|   'MATCH' '(' ColumnNameList ')' 'AGAINST' '(' BitExpr
    ↪ FulltextSearchModifierOpt ')'
|   PredicateExpr ( IsOrNotOp 'NULL' | CompareOp ( ( singleAtIdentifier
    ↪ assignmentEq )? PredicateExpr | AnyOrAll SubSelect ) )* ( IsOrNotOp (
    ↪  trueKwd | falseKwd | 'UNKNOWN' ) )?

PredicateExpr ::=
    BitExpr ( BetweenOrNotOp BitExpr 'AND' BitExpr )* ( InOrNotOp ( '('
        ↪ ExpressionList ')' | SubSelect ) | LikeOrNotOp SimpleExpr
        ↪ LikeEscapeOpt | RegexpOrNotOp SimpleExpr )?

BitExpr ::=
    BitExpr ( ( '|' | '&' | '<<' | '>>' | '*' | '/' | '%' | 'DIV' | 'MOD' |
        ↪ '^' ) BitExpr | ( '+' | '-' ) ( BitExpr | "INTERVAL" Expression
        ↪ TimeUnit ) )
|   SimpleExpr

SimpleExpr ::=
    SimpleIdent ( ( '->' | '->>' ) stringLit )?
|   FunctionCallKeyword
|   FunctionCallNonKeyword
|   FunctionCallGeneric
|   SimpleExpr ( 'COLLATE' CollationName | pipes SimpleExpr )
|   WindowFuncCall
|   Literal
|   paramMarker
|   Variable
|   SumExpr
|   ( '!' | '~' | '-' | '+' | 'NOT' | 'BINARY' ) SimpleExpr
|   'EXISTS'? SubSelect
|   ( ( '(' ( ExpressionList ',' )? | 'ROW' '(' ExpressionList ',' )
    ↪ Expression | builtinCast '(' Expression 'AS' CastType | ( 'DEFAULT' |
    ↪  'VALUES' ) '(' SimpleIdent | 'CONVERT' '(' Expression ( ',' CastType
    ↪  | 'USING' CharsetName ) ) ')'
|   'CASE' ExpressionOpt WhenClause+ ElseOpt 'END'
```

14.13.1.7 Comment Syntax

This document describes the comment syntax supported by TiDB.

TiDB supports three comment styles:

- Use # to comment a line:

```
SELECT 1+1;   # comments
```

```
+------+
| 1+1  |
+------+
|    2 |
+------+
1 row in set (0.00 sec)
```

- Use -- to comment a line:

```
SELECT 1+1;    -- comments
```

```
+------+
| 1+1  |
+------+
|    2 |
+------+
1 row in set (0.00 sec)
```

And this style requires at least one whitespace after --:

```
SELECT 1+1--1;
```

```
+--------+
| 1+1--1 |
+--------+
|      3 |
+--------+
1 row in set (0.01 sec)
```

- Use /* */ to comment a block or multiple lines:

```
SELECT 1 /* this is an in-line comment */ + 1;
```

```
+--------+
| 1  + 1 |
+--------+
|      2 |
+--------+
1 row in set (0.01 sec)
```

```
SELECT 1+
/*
/*> this is a
/*> multiple-line comment
/*> */
    1;
```

```
+-------------------+
| 1+
       1 |
+-------------------+
|               2 |
+-------------------+
1 row in set (0.001 sec)
```

14.13.1.7.1 MySQL-compatible comment syntax

The same as MySQL, TiDB supports a variant of C comment style:

```
/*! Specific code */
```

or

```
/*!50110 Specific code */
```

In this style, TiDB runs the statements in the comment.

For example:

```
SELECT /*! STRAIGHT_JOIN */ col1 FROM table1,table2 WHERE ...
```

In TiDB, you can also use another version:

```
SELECT STRAIGHT_JOIN col1 FROM table1,table2 WHERE ...
```

If the server version number is specified in the comment, for example, `/*!50110 KEY_BLOCK_SIZE=1024 */`, in MySQL it means that the contents in this comment are processed only when the MySQL version is or higher than 5.1.10. But in TiDB, the MySQL version number does not work and all contents in the comment are processed.

14.13.1.7.2 TiDB specific comment syntax

TiDB has its own comment syntax (that is, TiDB specific comment syntax), which can be divided into the following two types:

- `/*T! Specific code */`: This syntax can only be parsed and executed by TiDB, and be ignored in other databases.
- `/*T![feature_id] Specific code */`: This syntax is used to ensure compatibility between different versions of TiDB. TiDB can parse the SQL fragment in this comment only if it implements the corresponding feature of `feature_id` in the current version. For example, as the `AUTO_RANDOM` feature is introduced in v3.1.1, this version of TiDB can parse `/*T![auto_rand] auto_random */` into `auto_random`. Because the `AUTO_RANDOM` feature is not implemented in v3.0.0, the SQL statement fragment above is ignored. **Do not leave any space inside the `/*T![` characters**.

14.13.1.7.3 Optimizer comment syntax

Another type of comment is specially treated as an optimizer hint:

```
SELECT /*+ hint */ FROM ...;
```

For details about the optimizer hints that TiDB supports, see Optimizer hints.

> **Note:**
>
> In MySQL client, the TiDB-specific comment syntax is treated as comments and cleared by default. In MySQL client before 5.7.7, hints are also seen as comments and are cleared by default. It is recommended to use the `--comments` option when you start the client. For example, `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

For more information, see Comment Syntax.

14.13.2 SQL Statements

14.13.2.1 SQL Statement Overview

TiDB uses SQL statements that aim to follow ISO/IEC SQL standards, with extensions for MySQL and TiDB-specific statements where necessary.

14.13.2.1.1 Schema management / Data definition statements (DDL)

SQL Statement	Description
ALTER DATABASE	Modifies a database.
ALTER SEQUENCE	Modifies a sequence.
ALTER TABLE ... ADD COLUMN	Adds a column to an existing table.
ALTER TABLE ... ADD INDEX	Adds an index to an existing table.
ALTER TABLE ... ALTER INDEX	Changes an index definition.

SQL Statement	Description
`ALTER TABLE ... CHANGE COLUMN`	Changes a column definition.
`ALTER TABLE ... COMPACT`	Compacts a table.
`ALTER TABLE ... DROP COLUMN`	Drops a column from a table.
`ALTER TABLE ... MODIFY COLUMN`	Modifies a column definition.
`ALTER TABLE ... RENAME INDEX`	Renames an index.
`ALTER TABLE`	Changes a table definition.
`CREATE DATABASE`	Creates a new database.
`CREATE INDEX`	Creates a new index on a table.
`CREATE SEQUENCE`	Creates a new sequence object.
`CREATE TABLE LIKE`	Copies the definition of an existing table, without copying any data.
`CREATE TABLE`	Creates a new table.
`CREATE VIEW`	Creates a new view.
`DROP DATABASE`	Drops an existing database.
`DROP INDEX`	Drops an index from a table.

SQL Statement	Description
DROP SEQUENCE	Drops a sequence object.
DROP TABLE	Drops an existing table.
DROP VIEW	Drops an existing view.
RENAME TABLE	Renames a table.
SHOW COLUMNS ↪ FROM	Shows the columns from a table.
SHOW CREATE ↪ DATABASE	Shows the CREATE statement for a database.
SHOW CREATE ↪ SEQUENCE	Shows the CREATE statement for a sequence.
SHOW CREATE ↪ TABLE	Shows the CREATE statement for a table.
SHOW DATABASES	Shows a list of databases that the current user has privileges to.
SHOW FIELDS ↪ FROM	Shows columns of a table.
[SHOW INDEXES ↪](#show-indexes-[from	in])

SQL Statement	Description
SHOW SCHEMAS	An alias to SHOW ↪ DATABASES ↪ , which shows a list of databases that the current user has privileges to.
SHOW TABLE ↪ NEXT_ROW_ID	Shows the next row ID for a table.
SHOW TABLE ↪ REGIONS	Shows the Region information of a table in TiDB.
SHOW TABLE ↪ STATUS	Shows various statistics about tables in TiDB.
SHOW TABLES	Shows tables in a database.
TRUNCATE	Truncates all data from a table.

14.13.2.1.2 Data manipulation statements (DML)

SQL Statement	Description
BATCH	Splits a DML statement into multiple statements in TiDB for execution.
DELETE	Deletes rows from a table.
INSERT	Inserts new rows into a table.
REPLACE	Replaces existing rows or inserts new rows.
SELECT	Reads data from a table.
TABLE	Retrieves rows from a table.
UPDATE	Updates existing rows in a table.
WITH	Defines common table expressions.

14.13.2.1.3 Transaction statements

SQL Statement	Description
BEGIN	Begins a new transaction.
COMMIT	Commits the current transaction.
ROLLBACK	Rolls back the current transaction.
SAVEPOINT	Sets a savepoint within a transaction.
SET TRANSACTION	Changes the current isolation level on a GLOBAL or SESSION basis.
START TRANSACTION	Starts a new transaction.

14.13.2.1.4 Prepared statements

SQL Statement	Description
DEALLOCATE	Deallocates a prepared statement, freeing associated resources.
EXECUTE	Executes a prepared statement with specific parameter values.
PREPARE	Creates a prepared statement with placeholders.

14.13.2.1.5 Administrative statements

SQL Statement	Description
ADMIN ALTER DDL JOBS	Modifies the parameter of a single ru
ADMIN CANCEL DDL	Cancels a DDL job.
[ADMIN CHECK [TABLE|INDEX]](#admin-check-[table	index])
ADMIN CHECKSUM TABLE	Computes the checksum of a table.
ADMIN CLEANUP INDEX	Cleans up indexes from a table.
ADMIN PAUSE DDL	Pauses DDL operations.
ADMIN RESUME DDL	Resumes DDL operations.
[ADMIN SHOW DDL [JOBS|JOB QUERIES]](#admin-show-ddl-[jobs	job-queries])
ADMIN	Performs various administrative task
FLUSH TABLES	Included for MySQL compatibility. I
SET <variable>	Modifies a system variable or user va
[SET [NAMES|CHARACTER SET]](#set-[names	character-set])
SPLIT REGION	Splits a Region into smaller Regions.

14.13.2.1.6 Data import and export

SQL Statement	Description
CANCEL IMPORT ↪ JOB	Cancels an ongoing import job.

SQL Statement	Description
IMPORT INTO	Imports data into a table via the Physical Import Mode of TiDB Lightning.
LOAD DATA	Loads data into a table from Amazon S3 or Google Cloud Storage.
SHOW IMPORT ↪ JOB	Shows the status of an import job.

14.13.2.1.7 Backup & restore

SQL Statement	Description
BACKUP	Performs a distributed backup of the TiDB cluster.
FLASHBACK ↪ CLUSTER	Restores the cluster to a specific snapshot.
FLASHBACK ↪ DATABASE	Restores a database and its data deleted by the DROP statement.
FLASHBACK ↪ TABLE	Restore the tables and data dropped by the DROP or TRUNCATE operation.

SQL Statement	Description
RECOVER TABLE	Recovers a deleted table and the data on it.
RESTORE	Restores a database from a backup.
[SHOW BACKUPS ↪](#show-[backups	restores])
[SHOW RESTORES ↪](#show-[backups	restores])

14.13.2.1.8 Placement policy

SQL Statement	Description
ALTER PLACEMENT POLICY	Modifies a placement policy.
ALTER RANGE	Modifies the range of a placement policy.
CREATE PLACEMENT POLICY	Creates a new placement policy.
DROP PLACEMENT POLICY	Drops an existing placement policy.
SHOW CREATE PLACEMENT POLICY	Shows the CREATE statement for a placement policy.
SHOW PLACEMENT FOR	Shows placement rules for a specific table.
SHOW PLACEMENT LABELS	Shows available placement labels.
SHOW PLACEMENT	Shows placement rules.

14.13.2.1.9 Resource groups

SQL Statement	Description
ALTER RESOURCE ↪ GROUP	Modifies a resource group.
CALIBRATE ↪ RESOURCE	Estimates and outputs the Request Unit (RU) capacity of the current cluster.
CREATE ↪ RESOURCE ↪ GROUP	Creates a new resource group.

SQL Statement	Description
DROP RESOURCE ↪ GROUP	Drops a resource group.
QUERY WATCH	Manages the runaway query watch list.
SET RESOURCE ↪ GROUP	Sets a resource group.
SHOW CREATE ↪ RESOURCE ↪ GROUP	Shows the CREATE statement for a resource group.

14.13.2.1.10 Utility statements

SQL Statement	Description
DESC	An alias to DESCRIBE, which shows the structure of a table.
DESCRIBE	Shows the structure of a table.
DO	Executes an expression but does not return any results.
EXPLAIN	Shows the execution plan of a query.
TRACE	Provides detailed information about query execution.
USE	Sets the current database.

14.13.2.1.11 Show statements

SQL Statement	Description
SHOW BUILTINS	Lists builtin functions.
SHOW CHARACTER SET	Lists character sets.
SHOW COLLATIONS	Lists collations.
SHOW ERRORS	Shows errors from previously executed statements.
[SHOW STATUS](#show-[global	session]-status)
[SHOW VARIABLES](#show-[global	session]-variables)
SHOW WARNINGS	Shows warnings and notes from previously executed statements.

14.13.2.1.12 Instance management

SQL Statement	Description
`ALTER INSTANCE`	Modifies an instance.
`FLUSH STATUS`	Included for compatibility with MySQL. TiDB uses Prometheus and Grafana for centralized metrics collection instead of `SHOW STATUS` for most metrics.
`KILL`	Kills a connection in any TiDB instance in the current TiDB cluster.
`SHOW CONFIG`	Shows the configuration of various components of TiDB.
`SHOW ENGINES`	Shows available storage engines.
`SHOW PLUGINS`	Shows installed plugins.
`SHOW` ↪ `PROCESSLIST`	Shows the current sessions connected to the same TiDB server.

SQL Statement	Description
SHOW PROFILES	Included for compatibility with MySQL. Currently, it only returns an empty result.
SHUTDOWN	Stops the client-connected TiDB instance, not the entire TiDB cluster.

14.13.2.1.13 Locking statements

SQL Statement	Description
LOCK STATS	Locks statistics of tables or partitions.
LOCK TABLES	Locks tables for the current session.
UNLOCK STATS	Unlocks statistics of tables or partitions.
UNLOCK TABLES	Unlocks tables.

14.13.2.1.14 Account management / Data Control Language

SQL Statement	Description
ALTER USER	Modifies a user.
CREATE ROLE	Creates a role.
CREATE USER	Creates a new user.
DROP ROLE	Drops an existing role.
DROP USER	Drops an existing user.

SQL Statement	Description
FLUSH ↪ PRIVILEGES	Reloads the in-memory copy of privileges from the privilege tables.
GRANT < ↪ privileges>	Grants privileges.
GRANT <role>	Grants a role.
RENAME USER	Renames an existing user.
REVOKE < ↪ privileges>	Revokes privileges.
REVOKE <role>	Revokes a role.
SET DEFAULT ↪ ROLE	Sets a default role.
SET PASSWORD	Changes a password.
SET ROLE	Enables roles in the current session.
SHOW CREATE ↪ USER	Shows the CREATE statement for a user.
SHOW GRANTS	Shows privileges associated with a user.
SHOW ↪ PRIVILEGES	Shows available privileges.

14.13.2.1.15 TiCDC

SQL Statement	Description
[ADMIN [SET|SHOW|UNSET] BDR ROLE](#admin-[set	show
SHOW MASTER STATUS	Shows the latest TSO in the cluster.

14.13.2.1.16 Statistics and plan management

SQL Statement	Description
ANALYZE TABLE	Collects statistics about a table.
[CREATE ↪ BINDING ↪](#create-[global	session]-binding)
[DROP BINDING ↪](#drop-[global	session]-binding)
DROP STATS	Drops statistics from a table.
EXPLAIN ↪ ANALYZE	Works similar to EXPLAIN, with the major difference that it will execute the statement.
LOAD STATS	Loads statistics into TiDB.
SHOW ANALYZE ↪ STATUS	Shows statistics collection tasks.
[SHOW BINDINGS ↪](#show-[global	session]-bindings)
SHOW COLUMN_ ↪ STATS_USAGE	Shows the last usage time and collection time of column statistics.
SHOW STATS_ ↪ BUCKETS	Shows the bucket information in statistics.

SQL Statement	Description
`SHOW STATS_ HEALTHY`	Shows an estimation of how accurate statistics are believed to be.
`SHOW STATS_ HISTOGRAMS`	Shows the histogram information in statistics.
`SHOW STATS_ LOCKED`	Shows the tables whose statistics are locked.
`SHOW STATS_ META`	Shows how many rows are in a table and how many rows are changed in that table.
`SHOW STATS_ TOPN`	Shows the Top-N information in statistics.

14.13.2.2 ADMIN

This statement is a TiDB extension syntax, used to view the status of TiDB and check the data of tables in TiDB. This document introduces the following `ADMIN` related statements:

- `ADMIN RELOAD`
- `ADMIN PLUGINS`
- `ADMIN ... BINDINGS`
- `ADMIN REPAIR`
- `ADMIN SHOW NEXT_ROW_ID`
- `ADMIN SHOW SLOW`

14.13.2.2.1 DDL related statement

Statement	Description
`ADMIN CANCEL DDL JOBS`	Cancels a currently running DDL job
`ADMIN CHECKSUM TABLE`	Calculates the CRC64 of all rows + i

Statement	Description
[ADMIN CHECK [TABLE|INDEX]](#admin-check-[table	index])
[ADMIN SHOW DDL [JOBS|QUERIES]](#admin-show-ddl-[jobs	job-queries])

14.13.2.2.2 `ADMIN RELOAD` statement

```
ADMIN RELOAD expr_pushdown_blacklist;
```

The above statement is used to reload the blocklist pushed down by the expression.

```
ADMIN RELOAD opt_rule_blacklist;
```

The above statement is used to reload the blocklist of logic optimization rules.

14.13.2.2.3 `ADMIN PLUGINS` related statement

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

```
ADMIN PLUGINS ENABLE plugin_name [, plugin_name] ...;
```

The above statement is used to enable the `plugin_name` plugin.

```
ADMIN PLUGINS DISABLE plugin_name [, plugin_name] ...;
```

The above statement is used to disable the `plugin_name` plugin.

14.13.2.2.4 `ADMIN BINDINGS` related statement

```
ADMIN FLUSH BINDINGS;
```

The above statement is used to persist SQL Plan binding information.

```
ADMIN CAPTURE BINDINGS;
```

The above statement can generate the binding of SQL Plan from the `SELECT` statement that occurs more than once.

```
ADMIN EVOLVE BINDINGS;
```

After the automatic binding feature is enabled, the evolution of SQL Plan binding information is triggered every `bind-info-leave` (the default value is `3s`). The above statement is used to proactively trigger this evolution.

```
ADMIN RELOAD BINDINGS;
```

The above statement is used to reload SQL Plan binding information.

14.13.2.2.5 ADMIN REPAIR statement

To overwrite the metadata of the stored table in an untrusted way in extreme cases, use `ADMIN REPAIR TABLE`:

```
ADMIN REPAIR TABLE tbl_name CREATE TABLE STATEMENT;
```

Here "untrusted" means that you need to manually ensure that the metadata of the original table can be covered by the `CREATE TABLE STATEMENT` operation. To use this `REPAIR` statement, enable the `repair-mode` configuration item, and make sure that the tables to be repaired are listed in the `repair-table-list`.

14.13.2.2.6 ADMIN SHOW NEXT_ROW_ID statement

```
ADMIN SHOW t NEXT_ROW_ID;
```

The above statement is used to view the details of some special columns of a table. The output is the same as SHOW TABLE NEXT_ROW_ID.

14.13.2.2.7 ADMIN SHOW SLOW statement

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

```
ADMIN SHOW SLOW RECENT N;
```

```
ADMIN SHOW SLOW TOP [INTERNAL | ALL] N;
```

For details, refer to ADMIN SHOW SLOW command.

14.13.2.2.8 Synopsis

```
AdminStmt ::=
    'ADMIN' (
        'SHOW' (
            'DDL' (
                'JOBS' Int64Num? WhereClauseOptional
```

```
                | 'JOB' 'QUERIES' (NumList | AdminStmtLimitOpt)
            )?
            | TableName 'NEXT_ROW_ID'
            | 'SLOW' AdminShowSlow
            | 'BDR' 'ROLE'
        )
        | 'CHECK' (
            'TABLE' TableNameList
            | 'INDEX' TableName Identifier ( HandleRange ( ',' HandleRange )*
                ↪ )?
        )
        | 'RECOVER' 'INDEX' TableName Identifier
        | 'CLEANUP' (
            'INDEX' TableName Identifier
            | 'TABLE' 'LOCK' TableNameList )
        | 'CHECKSUM' 'TABLE' TableNameList | 'CANCEL' 'DDL' 'JOBS' NumList
        | ( 'CANCEL' | 'PAUSE' | 'RESUME' ) 'DDL' 'JOBS' NumList
        | 'RELOAD' (
            'EXPR_PUSHDOWN_BLACKLIST'
            | 'OPT_RULE_BLACKLIST'
            | 'BINDINGS'
            | 'STATS_EXTENDED'
            | 'STATISTICS'
        )
        | 'PLUGINS' ( 'ENABLE' | 'DISABLE' ) PluginNameList
        | 'REPAIR' 'TABLE' TableName CreateTableStmt
        | ( 'FLUSH' | 'CAPTURE' | 'EVOLVE' ) 'BINDINGS'
        | 'FLUSH' ('SESSION' | 'INSTANCE') 'PLAN_CACHE'
        | 'SET' 'BDR' 'ROLE' ( 'PRIMARY' | 'SECONDARY' )
        | 'UNSET' 'BDR' 'ROLE'
    )

NumList ::=
    Int64Num ( ',' Int64Num )*

AdminStmtLimitOpt ::=
    'LIMIT' LengthNum
|    'LIMIT' LengthNum ',' LengthNum
|    'LIMIT' LengthNum 'OFFSET' LengthNum

TableNameList ::=
    TableName ( ',' TableName )*
```

14.13.2.2.9 Examples

Run the following command to view the last 10 completed DDL jobs in the currently running DDL job queue. When `NUM` is not specified, only the last 10 completed DDL jobs is presented by default.

```
ADMIN SHOW DDL JOBS;
```

```
+--------+---------+-----------+---------------------+----------------+-----------+----
   ↪
| JOB_ID | DB_NAME | TABLE_NAME | JOB_TYPE      | SCHEMA_STATE | SCHEMA_ID |
   ↪  TABLE_ID | ROW_COUNT | START_TIME                | END_TIME

- `JOB_ID`: each DDL operation corresponds to one DDL job. `JOB_ID` is globally unique.
- `DB_NAME`: the name of the database on which the DDL operations are performed.
- `TABLE_NAME`: the name of the table on which the DDL operations are performed.
- `JOB_TYPE`: the type of the DDL operations.
- `SCHEMA_STATE`: the current state of the schema. If the `JOB_TYPE` is `add index`, it is the state of the index; if the `JOB_TYPE` is `add column`, it is the state of the column; if the `JOB_TYPE` is `create table`, it is the state of the table. The common states include:
    - `none`: it indicates not existing. When the `drop` or `create` operation fails and rolls back, it usually becomes the `none` state.
    - `delete only`, `write only`, `delete reorganization`, `write reorganization`: these four states are intermediate states. These states are not visible in common operations, because the conversion from the intermediate states is so quick. You

can see the `write reorganization` state only in `add index` operations, which means that the index data is being added.
- `public`: it indicates existing and usable. When operations like `create table` and `add index/column` are finished, it usually becomes the `public` state, which means that the created table/column/index can be normally read and written now.

- `SCHEMA_ID`: the ID of the database on which the DDL operations are performed.
- `TABLE_ID`: the ID of the table on which the DDL operations are performed.
- `ROW_COUNT`: the number of the data rows that have been added when running the `add index` operation.
- `START_TIME`: the start time of the DDL operations.
- `END_TIME`: the end time of the DDL operations.
- `STATE`: the state of the DDL operations. The common states include:
  - `none`: it indicates that the operation task has been put in the DDL job queue but has not been performed yet, because it is waiting for the previous tasks to complete. Another reason might be that it becomes the `none` state after running the drop operation, but it will soon be updated to the `synced` state, which means that all TiDB instances have been synced to this state.
  - `running`: it indicates that the operation is being performed.
  - `synced`: it indicates that the operation has been performed successfully and all TiDB instances have been synced to this state.
  - `rollback done`: it indicates that the operation has failed and has finished rolling back.
  - `rollingback`: it indicates that the operation has failed and is rolling back.
  - `cancelling`: it indicates that the operation is being cancelled. This state only occurs when you cancel DDL jobs using the `ADMIN CANCEL DDL JOBS` command.
  - `paused`: it indicates that the operation has been paused. This state only appears when you use the `ADMIN PAUSED DDL JOBS` command to pause the DDL job. You can use the `ADMIN RESUME DDL JOBS` command to resume the DDL job.

14.13.2.2.10 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.3 ADMIN ALTER DDL JOBS

The `ADMIN ALTER DDL JOBS` statement allows you to modify the parameter of a single running DDL job. For example:

```
ADMIN ALTER DDL JOBS 101 THREAD = 8;
```

- `101`: indicates the ID of the DDL job. You can obtain the ID by executing `ADMIN SHOW DDL JOBS`.

- `THREAD`: indicates the concurrency of the DDL job. You can configure its initial value using the system variable `tidb_ddl_reorg_worker_cnt`.

The DDL job types supported by the `ADMIN ALTER DDL JOBS` statement include `ADD INDEX`, `MODIFY COLUMN`, and `REORGANIZE PARTITION`. For other DDL job types, executing `ADMIN ALTER DDL JOBS` returns the `unsupported DDL operation` error.

Currently, you can only modify the parameters of a single DDL job by executing `ADMIN ALTER DDL JOBS`. Modifying the parameters of multiple DDL job IDs at the same time is not supported.

The following are the supported parameters for different DDL jobs and their corresponding system variables:

- `ADD INDEX`:
    - `THREAD`: the concurrency of the DDL job. The initial value is set by `tidb_ddl_reorg_worker_cnt`.
    - `BATCH_SIZE`: the batch size. The initial value is set by `tidb_ddl_reorg_batch_size`.
    - `MAX_WRITE_SPEED`: the maximum bandwidth limit for importing index records into each TiKV. The initial value is set by `tidb_ddl_reorg_max_write_speed`.

Currently, the preceding parameters only work for `ADD INDEX` jobs that are submitted and running after `tidb_enable_dist_task` is disabled.

- `MODIFY COLUMN`:
    - `THREAD`: the concurrency of the DDL job. The initial value is set by `tidb_ddl_reorg_worker_cnt`.
    - `BATCH_SIZE`: the batch size. The initial value is set by `tidb_ddl_reorg_batch_size`.
- `REORGANIZE PARTITION`:
    - `THREAD`: the concurrency of the DDL job. The initial value is set by `tidb_ddl_reorg_worker_cnt`.
    - `BATCH_SIZE`: the batch size. The initial value is set by `tidb_ddl_reorg_batch_size`.

The value ranges of the preceding parameters are consistent with those of the corresponding system variables.

`ADMIN ALTER DDL JOBS` takes effect only on running DDL jobs. If the DDL job does not exist or has already completed, executing this statement returns the `ddl job is not running` error.

The following are some examples of this statement:

```
ADMIN ALTER DDL JOBS 101 THREAD = 8;
ADMIN ALTER DDL JOBS 101 BATCH_SIZE = 256;
ADMIN ALTER DDL JOBS 101 MAX_WRITE_SPEED = '200MiB';
ADMIN ALTER DDL JOBS 101 THREAD = 8, BATCH_SIZE = 256;
```

To view the current parameter values for a specific DDL job, you can execute `ADMIN SHOW DDL JOBS`. The results are displayed in the `COMMENTS` column:

```
ADMIN SHOW DDL JOBS 1;
```

```
+--------+---------+-----------+----------+--------------+----------+----------+-----
    ↪
| JOB_ID | DB_NAME | TABLE_NAME | JOB_TYPE | SCHEMA_STATE | SCHEMA_ID |
    ↪ TABLE_ID | ROW_COUNT | CREATE_TIME | START_TIME              | END_
    ↪ TIME                | STATE | COMMENTS           |

1 row in set (0.01 sec)
```

14.13.2.3.1 Synopsis

```
AdminAlterDDLStmt ::=
    'ADMIN' 'ALTER' 'DDL' 'JOBS' Int64Num AlterJobOptionList

AlterJobOptionList ::=
    AlterJobOption ( ',' AlterJobOption )*

AlterJobOption ::=
    identifier "=" SignedLiteral
```

14.13.2.3.2 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.3.3 See also

- ADMIN SHOW DDL [JOBS|QUERIES]
- ADMIN CANCEL DDL
- ADMIN PAUSE DDL
- ADMIN RESUME DDL

14.13.2.4 ADMIN CANCEL DDL

The `ADMIN CANCEL DDL` statement allows you to cancel a running DDL job. The `job_id` can be found by running `ADMIN SHOW DDL JOBS`.

The `ADMIN CANCEL DDL` statement also allows you to cancel a DDL job that is committed but not yet completed executing. After the cancellation, the SQL statement that executes the DDL job returns the `ERROR 8214 (HY000): Cancelled DDL job` error. If you cancel a DDL job that has already been completed, you will see the `DDL Job:90 not found` error in the `RESULT` column, which indicates that the job has been removed from the DDL waiting queue.

14.13.2.4.1 Synopsis

```
AdminCancelDDLStmt ::=
    'ADMIN' 'CANCEL' 'DDL' 'JOBS' NumList

NumList ::=
    Int64Num ( ',' Int64Num )*
```

14.13.2.4.2 Examples

To cancel the currently running DDL jobs and return whether the corresponding jobs are successfully cancelled, use `ADMIN CANCEL DDL JOBS`:

```
ADMIN CANCEL DDL JOBS job_id [, job_id] ...;
```

If the operation fails to cancel the jobs, specific reasons are displayed.

Note:

- Before v6.2.0, only this operation can cancel DDL jobs, and all other operations and environment changes (such as machine restart and cluster restart) cannot cancel these jobs. Starting from v6.2.0, `KILL` statements can also be used to cancel ongoing DDL jobs by killing them.
- This operation can cancel multiple DDL jobs at the same time. You can get the ID of DDL jobs using the `ADMIN SHOW DDL JOBS` statement.
- If the jobs you want to cancel are finished, the cancellation operation fails.

14.13.2.4.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.4.4 See also

- ADMIN SHOW DDL [JOBS|JOB QUERIES]

14.13.2.5 ADMIN CHECKSUM TABLE

The `ADMIN CHECKSUM TABLE` statement calculates a CRC64 checksum for the data and indexes of a table.

The checksum is calculated based on table data and properties such as `table_id`. This means that two tables with the same data but different `table_id` values will get different checksums.

After importing a table using TiDB Lightning, TiDB Data Migration, or `IMPORT INTO`, `ADMIN CHECKSUM TABLE <table>` is executed by default to validate data integrity.

14.13.2.5.1 Synopsis

```
AdminChecksumTableStmt ::=
    'ADMIN' 'CHECKSUM' 'TABLE' TableNameList

TableNameList ::=
    TableName ( ',' TableName )*
```

14.13.2.5.2 Examples

Create table `t1`:

```
CREATE TABLE t1(id INT PRIMARY KEY);
```

Insert some data into `t1`:

```
INSERT INTO t1 VALUES (1),(2),(3);
```

Calculate the checksum for `t1`:

```
ADMIN CHECKSUM TABLE t1;
```

The output is as follows:

```
+---------+------------+---------------------+-----------+-------------+
| Db_name | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+---------+------------+---------------------+-----------+-------------+
| test    | t1         | 10909174369497628533 |     3 |         75 |
+---------+------------+---------------------+-----------+-------------+
1 row in set (0.00 sec)
```

14.13.2.5.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.6 ADMIN CHECK [TABLE|INDEX]

The `ADMIN CHECK [TABLE|INDEX]` statement checks for data consistency of tables and indexes.

It does not support the following:

- Checking FOREIGN KEY constraints.
- Checking the PRIMARY KEY index if a clustered primary key is used.

If `ADMIN CHECK [TABLE|INDEX]` finds any issues, you can resolve them by dropping and recreating the index. If the issue is not resolved, you can report a bug.

14.13.2.6.1 Principles

The `ADMIN CHECK TABLE` statement takes the following steps to check the table:

1. For each index, it checks if the number of records in the index is the same as that in the table.
2. For each index, it loops over the values in each row and compares the values with that in the table.

If you use the `ADMIN CHECK INDEX` statement, it only checks the specified index.

14.13.2.6.2 Synopsis

```
AdminCheckStmt ::=
    'ADMIN' 'CHECK' ( 'TABLE' TableNameList | 'INDEX' TableName Identifier (
       ↪ HandleRange ( ',' HandleRange )* )? )

TableNameList ::=
    TableName ( ',' TableName )*

HandleRange ::= '(' Int64Num ',' Int64Num ')'
```

14.13.2.6.3 Examples

To check the consistency of all the data and corresponding indexes in the `tbl_name` table, use `ADMIN CHECK TABLE`:

```
ADMIN CHECK TABLE tbl_name [, tbl_name] ...;
```

If the consistency check is passed, an empty result is returned. Otherwise, an error message is returned indicating that the data is inconsistent.

```
ADMIN CHECK INDEX tbl_name idx_name;
```

The above statement is used to check the consistency of the column data and index data corresponding to the `idx_name` index in the `tbl_name` table. If the consistency check is passed, an empty result is returned; otherwise, an error message is returned indicating that the data is inconsistent.

```
ADMIN CHECK INDEX tbl_name idx_name (lower_val, upper_val) [, (lower_val,
    ↪ upper_val)] ...;
```

The above statement is used to check the consistency of the column data and index data corresponding to the `idx_name` index in the `tbl_name` table, with the data range (to be checked) specified. If the consistency check is passed, an empty result is returned. Otherwise, an error message is returned indicating that the data is inconsistent.

14.13.2.6.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.6.5 See also

- ADMIN REPAIR

14.13.2.7 ADMIN CLEANUP INDEX

The `ADMIN CLEANUP INDEX` statement is used to delete redundant indexes from a table when the table has inconsistent data and index. Note that this syntax does not support foreign key constraints yet.

14.13.2.7.1 Synopsis

```
AdminCleanupStmt ::=
    'ADMIN' 'CLEANUP' ( 'INDEX' TableName IndexName | 'TABLE' 'LOCK'
       ↪ TableNameList )

TableNameList ::=
    TableName ( ',' TableName )*
```

14.13.2.7.2 Examples

Assume that the `tbl` table in a database has inconsistent data and index due to some reasons (for example, some row data is lost in the cluster in a disaster recovery scenario):

```
SELECT * FROM tbl;
ERROR 1105 (HY000): inconsistent index idx handle count 3 isn't equal to
    ↪ value count 2

ADMIN CHECK INDEX tbl idx ;
ERROR 1105 (HY000): handle &kv.CommonHandle{encoded:[]uint8{0x1, 0x0, 0x0, 0
    ↪ x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0xf8}, colEndOffsets:[]uint16{0xa}},
    ↪ index:types.Datum{k:0x5, decimal:0x0, length:0x0, i:0, collation:"
    ↪ utf8mb4_bin", b:[]uint8{0x0}, x:interface {}(nil)} != record:<nil>
```

It can be seen from the error message of the `SELECT` query that, the `tbl` table contains two rows of data and three rows of index data, which means inconsistent row and index data. At the same time, at least one index is in dangling state. In this case, you can use the `ADMIN CLEANUP INDEX` statement to delete the dangling index:

```
ADMIN CLEANUP INDEX tbl idx;
```

The execution result is as follows:

```
ADMIN CLEANUP INDEX tbl idx;
+---------------+
| REMOVED_COUNT |
+---------------+
|             1 |
+---------------+
```

You can execute the `ADMIN CHECK INDEX` statement again to check the consistency of data and index, and verify whether the data has been restored to a normal state:

```
ADMIN CHECK INDEX tbl idx;
Query OK, 0 rows affected (0.01 sec)
```

Note:

When the data and index are inconsistent due to the loss of replicas:

- There might be a loss of both row data and index data. To restore the consistency, use the `ADMIN CLEANUP INDEX` and `ADMIN RECOVER INDEX` statements together.

- The `ADMIN CLEANUP INDEX` statement is always executed in a single thread. When the table data is large, it is recommended to recover the index data by rebuilding the index.
- When you execute the `ADMIN CLEANUP INDEX` statement, the corresponding table or index is not locked and TiDB allows other sessions to modify the table records at the same time. However, in this case, `ADMIN CLEANUP INDEX` might not be able to handle all table records correctly. Therefore, when you execute `ADMIN CLEANUP INDEX`, avoid modifying the table data at the same time.
- If you use the enterprise edition of TiDB, you can submit a request to contact the support engineer for help.

The `ADMIN CLEANUP INDEX` statement is not atomic: if the statement is interrupted during execution, it is recommended to execute it again until it succeeds.

14.13.2.7.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.7.4 See also

- `ADMIN CHECK TABLE/INDEX`
- `ADMIN RECOVER INDEX`

14.13.2.8 ADMIN PAUSE DDL JOBS

`ADMIN PAUSE DDL` allows you to pause a running DDL job. The `job_id` can be found by running `ADMIN SHOW DDL JOBS`.

You can use this statement to pause a DDL job that is issued but not yet completed executing. After the pause, the SQL statement that executes the DDL job does not return immediately, but looks like it is still running. If you try to pause a DDL job that has already been completed, you will see the `DDL Job:90 not found` error in the `RESULT` column, which indicates that the job has been removed from the DDL waiting queue.

14.13.2.8.1 Synopsis

```
AdminPauseDDLStmt ::=
    'ADMIN' 'PAUSE' 'DDL' 'JOBS' NumList

NumList ::=
    Int64Num ( ',' Int64Num )*
```

14.13.2.8.2 Examples

`ADMIN PAUSE DDL JOBS` pauses the currently running DDL job and returns whether the job is paused successfully. The job can be resumed by `ADMIN RESUME DDL JOBS`.

```
ADMIN PAUSE DDL JOBS job_id [, job_id] ...;
```

If the pause fails, the specific reason for the failure is displayed.

Note:

- This statement can pause a DDL job, but other operations and environment changes (such as machine restarts and cluster restarts) do not pause DDL jobs except for cluster upgrades.
- During the cluster upgrade, the ongoing DDL jobs are paused, and the DDL jobs initiated during the upgrade are also paused. After the upgrade, all paused DDL jobs will resume. The pause and resume operations during the upgrade are taken automatically. For details, see TiDB Smooth Upgrade.
- This statement can pause multiple DDL jobs. You can use the `ADMIN SHOW DDL JOBS` statement to obtain the `job_id` of a DDL job.

14.13.2.8.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.8.4 See also

- `ADMIN SHOW DDL [JOBS|QUERIES]`
- `ADMIN CANCEL DDL`
- `ADMIN RESUME DDL`
- `ADMIN ALTER DDL`

14.13.2.9 ADMIN RECOVER INDEX

When the row data and index data are inconsistent, you can use the `ADMIN RECOVER INDEX` statement to recover the consistency based on the redundant indexes. Note that this syntax does not support foreign key constraints yet.

14.13.2.9.1 Synopsis

```
AdminRecoverStmt ::=
    'ADMIN' 'RECOVER' 'INDEX' TableName IndexName
```

14.13.2.9.2 Examples

Assume that the `tbl` table in a database has inconsistent row data and index due to some reasons (for example, some row data is lost in the cluster in a disaster recovery scenario):

```
SELECT * FROM tbl;
ERROR 1105 (HY000): inconsistent index idx handle count 2 isn't equal to
    ↪ value count 3

ADMIN CHECK INDEX tbl idx ;
ERROR 1105 (HY000): handle &kv.CommonHandle{encoded:[]uint8{0x1, 0x0, 0x0, 0
    ↪ x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0xf8}, colEndOffsets:[]uint16{0xa}},
    ↪ index:types.Datum{k:0x5, decimal:0x0, length:0x0, i:0, collation:"
    ↪ utf8mb4_bin", b:[]uint8{0x0}, x:interface {}(nil)} != record:<nil>
```

It can be seen from the error message of the `SELECT` query that, the `tbl` table contains three rows of data and two rows of index data, which means inconsistent row data and index data. At the same time, at least one row of data has no corresponding index. In this case, you can use the `ADMIN RECOVER INDEX` statement to supplement the missing index:

```
ADMIN RECOVER INDEX tbl idx;
```

The execution result is as follows:

```
ADMIN RECOVER INDEX tbl idx;
+-------------+------------+
| ADDED_COUNT | SCAN_COUNT |
+-------------+------------+
|           1 |          3 |
+-------------+------------+
1 row in set (0.00 sec)
```

You can execute the `ADMIN CHECK INDEX` statement again to check the consistency of data and index, and verify whether the data has been restored to normal state:

```
ADMIN CHECK INDEX tbl idx;
Query OK, 0 rows affected (0.01 sec)
```

Note:

When the data and index are inconsistent due to the loss of replicas:

- There might be a loss of both row data and index data. To address the issue, use the `ADMIN CLEANUP INDEX` and `ADMIN RECOVER INDEX` statements together to recover the consistency of row data and index data.

- The `ADMIN RECOVER INDEX` statement is always executed in a single thread. When the table data is large, it is recommended to recover the index data by rebuilding the index.
- When you execute the `ADMIN RECOVER INDEX` statement, the corresponding table or index is not locked and TiDB allows other sessions to modify the table records at the same time. However, in this case, `ADMIN RECOVER INDEX` might not be able to handle all table records correctly. Therefore, when you execute `ADMIN RECOVER INDEX`, avoid modifying the table data at the same time.
- If you use the enterprise edition of TiDB, you can submit a request to contact the support engineer for help.

The `ADMIN RECOVER INDEX` statement is not atomic: if the statement is interrupted during execution, it is recommended to execute it again until it succeeds.

14.13.2.9.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.9.4 See also

- ADMIN CHECK TABLE/INDEX
- ADMIN CLEANUP INDEX

14.13.2.10 ADMIN RESUME DDL JOBS

`ADMIN RESUME DDL` allows you to resume a paused DDL job. You can find the `job_id` by running ADMIN SHOW DDL JOBS.

You can use this statement to resume a paused DDL job. After the resume is completed, the SQL statement that executes the DDL job continues to show as being executed. If you try to resume a DDL job that has already been completed, you will see the `DDL Job:90 not found` error in the `RESULT` column, which indicates that the job has been removed from the DDL waiting queue.

14.13.2.10.1 Synopsis

```
AdminResumeDDLStmt ::=
    'ADMIN' 'RESUME' 'DDL' 'JOBS' NumList

NumList ::=
    Int64Num ( ',' Int64Num )*
```

14.13.2.10.2 Examples

`ADMIN RESUME DDL JOBS` resumes the currently paused DDL job and returns whether the job is resumed successfully.

```
ADMIN RESUME DDL JOBS job_id [, job_id] ...;
```

If the resume fails, the specific reason for the failure is displayed.

Note:

- During the cluster upgrade, the ongoing DDL jobs are paused, and the DDL jobs initiated during the upgrade are also paused. After the upgrade, all paused DDL jobs will resume. The pause and resume operations during the upgrade are taken automatically. For details, see TiDB Smooth Upgrade.
- This statement can resume multiple DDL jobs. You can use the `ADMIN SHOW DDL JOBS` statement to obtain the `job_id` of a DDL job.
- A DDL job in other status (other than `paused`) cannot be resumed and the resume operation will fail.
- If you try to resume a job more than once, TiDB reports an error `Error Number: 8261`.

14.13.2.10.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.10.4 See also

- `ADMIN SHOW DDL [JOBS|QUERIES]`
- `ADMIN CANCEL DDL`
- `ADMIN PAUSE DDL`
- `ADMIN ALTER DDL`

14.13.2.11 ADMIN [SET|SHOW|UNSET] BDR ROLE

- Use `ADMIN SET BDR ROLE` to set the BDR role of the cluster. Currently, you can set the following BDR roles for a TiDB cluster: `PRIMARY` and `SECONDARY`. For more information about BDR roles, see DDL Synchronization in TiCDC Bidirectional Replication.
- Use `ADMIN SHOW BDR ROLE` to show the BDR role of the cluster.
- Use `ADMIN UNSET BDR ROLE` to unset the BDR role of the cluster.

14.13.2.11.1 Synopsis

```
AdminShowBDRRoleStmt ::=
    'ADMIN' 'SHOW' 'BDR' 'ROLE'

AdminSetBDRRoleStmt ::=
    'ADMIN' 'SET' 'BDR' 'ROLE' ('PRIMARY' | 'SECONDARY')

AdminUnsetBDRRoleStmt ::=
    'ADMIN' 'UNSET' 'BDR' 'ROLE'
```

14.13.2.11.2 Examples

By default, a TiDB cluster has no BDR role. Run the following command to show the BDR role of the cluster.

```
ADMIN SHOW BDR ROLE;
```

```
+------------+
| BDR_ROLE   |
+------------+
|            |
+------------+
1 row in set (0.01 sec)
```

Run the following command to set the BDR role to `PRIMARY`.

```
ADMIN SET BDR ROLE PRIMARY;
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
ADMIN SHOW BDR ROLE;
+----------+
| BDR_ROLE |
+----------+
| primary  |
+----------+
1 row in set (0.00 sec)
```

Run the following command to unset the BDR role of the cluster.

```
ADMIN UNSET BDR ROLE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
ADMIN SHOW BDR ROLE;
+----------+
| BDR_ROLE |
+----------+
|          |
+----------+
1 row in set (0.01 sec)
```

14.13.2.11.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.12 ADMIN SHOW DDL [JOBS|JOB QUERIES]

The `ADMIN SHOW DDL [JOBS|JOB QUERIES]` statement shows information about running and recently completed DDL jobs.

14.13.2.12.1 Synopsis

```
AdminShowDDLStmt ::=
    'ADMIN' 'SHOW' 'DDL'
    (
        'JOBS' Int64Num? WhereClauseOptional
    |   'JOB' 'QUERIES' NumList
    |   'JOB' 'QUERIES' 'LIMIT' m ( ('OFFSET' | ',') n )?
    )?

NumList ::=
    Int64Num ( ',' Int64Num )*

WhereClauseOptional ::=
    WhereClause?
```

14.13.2.12.2 Examples

`ADMIN SHOW DDL`

To view the status of the currently running DDL jobs, use `ADMIN SHOW DDL`. The output includes the current schema version, the DDL ID and address of the owner, the running DDL jobs and SQL statements, and the DDL ID of the current TiDB instance. The returned result fields are described as follows:

- `SCHEMA_VER`: a number indicating the version of the schema.
- `OWNER_ID`: the UUID of the DDL owner. See also `TIDB_IS_DDL_OWNER()`.

- `OWNER_ADDRESS`: the IP address of the DDL owner.
- `RUNNING_JOBS`: details about the running DDL job.
- `SELF_ID`: the UUID of the TiDB node to which you are currently connected. If `SELF_ID` is the same as the `OWNER_ID`, it means that you are connected to the DDL owner.
- `QUERY`: the statements of the queries.

```
ADMIN SHOW DDL\G;
```

```
*************************** 1. row ***************************
   SCHEMA_VER: 26
     OWNER_ID: 2d1982af-fa63-43ad-a3d5-73710683cc63
OWNER_ADDRESS: 0.0.0.0:4000
 RUNNING_JOBS:
     SELF_ID: 2d1982af-fa63-43ad-a3d5-73710683cc63
       QUERY:
1 row in set (0.00 sec)
```

ADMIN SHOW DDL JOBS

The `ADMIN SHOW DDL JOBS` statement is used to view the 10 jobs in the current DDL job queue, including running and pending jobs (if any), and the last 10 jobs in the executed DDL job queue (if any). The returned result fields are described as follows:

- `JOB_ID`: each DDL operation corresponds to a DDL job. `JOB_ID` is globally unique.
- `DB_NAME`: the name of the database where the DDL operation is performed.
- `TABLE_NAME`: the name of the table where the DDL operation is performed.
- `JOB_TYPE`: the type of DDL operation. Common job types include the following:
  - `create schema`: for `CREATE SCHEMA` operations.
  - `create table`: for `CREATE TABLE` operations.
  - `create view`: for `CREATE VIEW` operations.
  - `add index`: for `ADD INDEX` operations.
- `SCHEMA_STATE`: the current state of the schema object that the DDL operates on. If `JOB_TYPE` is `ADD INDEX`, it is the state of the index; if `JOB_TYPE` is `ADD COLUMN`, it is the state of the column; if `JOB_TYPE` is `CREATE TABLE`, it is the state of the table. Common states include the following:
  - `none`: indicates that it does not exist. Generally, after the `DROP` operation or after the `CREATE` operation fails and rolls back, it will become the `none` state.
  - `delete only`, `write only`, `delete reorganization`, `write reorganization`: these four states are intermediate states. For their specific meanings, see How the Online DDL Asynchronous Change Works in TiDB. As the intermediate state conversion is fast, these states are generally not visible during operation. Only when performing `ADD INDEX` operation can the `write reorganization` state be seen, indicating that index data is being added.

    - `public`: indicates that it exists and is available to users. Generally, after `CREATE TABLE` and `ADD INDEX` (or `ADD COLUMN`) operations are completed, it will become the `public` state, indicating that the newly created table, column, and index can be read and written normally.

- `SCHEMA_ID`: the ID of the database where the DDL operation is performed.
- `TABLE_ID`: the ID of the table where the DDL operation is performed.
- `ROW_COUNT`: when performing the `ADD INDEX` operation, it is the number of data rows that have been added.
- `CREATE_TIME`: the creation time of the DDL operation.
- `START_TIME`: the start time of the DDL operation.
- `END_TIME`: the end time of the DDL operation.
- `STATE`: the state of the DDL operation. Common states include the following:

    - `none`: indicates that the operation has not started yet.
    - `queueing`: indicates that the operation job has entered the DDL job queue but has not been executed because it is still waiting for an earlier DDL job to complete. Another reason might be that after executing the `DROP` operation, the `queueing` state will become the `done` state, but it will soon be updated to the `synced` state, indicating that all TiDB instances have been synchronized to that state.
    - `running`: indicates that the operation is being executed.
    - `synced`: indicates that the operation has been executed successfully and all TiDB instances have been synchronized to this state.
    - `rollback done`: indicates that the operation has failed and the rollback has been completed.
    - `rollingback`: indicates that the operation has failed and is rolling back.
    - `cancelling`: indicates that the operation is being canceled. This state only appears when you use the `ADMIN CANCEL DDL JOBS` command to cancel the DDL job.
    - `cancelled`: indicates that the operation has been canceled.
    - `pausing`: indicates that the operation is being paused.
    - `paused`: indicates that the operation has been paused. This state only appears when you use the `ADMIN PAUSED DDL JOBS` command to pause the DDL job. You can use the `ADMIN RESUME DDL JOBS` command to resume the DDL job.
    - `done`: indicates that the operation has been successfully executed on the TiDB owner node, but other TiDB nodes have not yet synchronized the changes performed by this DDL job.

- `COMMENTS`: contains additional information for diagnostic purposes.

    - `ingest`: ingest tasks for accelerated adding index backfill configured via `tidb_ddl_enable_fast_reorg`.
    - `txn`: transaction-based index backfill after `tidb_ddl_enable_fast_reorg` is disabled.
    - `txn-merge`: transactional backfilling with a temporary index that gets merged with the original index when the backfilling is finished.

- `DXF`: tasks executed with Distributed eXecution Framework (DXF) configured via `tidb_enable_dist_task`.
- `service_scope`: the service scope of the TiDB node configured via `tidb_service_scope`.
- `thread`: the concurrency of backfill tasks. You can set the initial value by `tidb_ddl_reorg_worker_cnt`. It supports dynamic modification via `ADMIN ALTER DDL JOBS`.
- `batch_size`: the batch size of backfill tasks. You can set the initial value by `tidb_ddl_reorg_batch_size`. It supports dynamic modification via `ADMIN ALTER DDL JOBS`.
- `max_write_speed`: flow control during ingest task import. The initial value can be set with `tidb_ddl_reorg_max_write_speed`. It supports dynamic modification via `ADMIN ALTER DDL JOBS`.

The following example shows the results of `ADMIN SHOW DDL JOBS`:

```
ADMIN SHOW DDL JOBS;
```

```

+--
   ↪ ------+---------+-----------+---------------------------------+----------------
   ↪
14 rows in set (0.00 sec)
```

From the output above:

- Job 565 is currently in progress (`STATE` of `running`). The schema state is currently in `write reorganization`, but will switch to `public` once the job is completed to note

that the change can be observed publicly by user sessions. The `end_time` column is also `NULL` indicating that the completion time for the job is currently not known.

- The `STATE` for `job_id` 566 is shown as `queueing`, indicating that it is queuing. When job 565 completes and job 566 begins execution, the `STATE` for job 566 will change to `running`.
- For destructive changes such as dropping an index or dropping a table, the `SCHEMA_STATE` will change to `none` when the job is complete. For additive changes, the `SCHEMA_STATE` will change to `public`.

To limit the number of rows shown, specify a number and a where condition:

```
ADMIN SHOW DDL JOBS [NUM] [WHERE where_condition];
```

- `NUM`: to view the last `NUM` results in the completed DDL job queue. If not specified, `NUM` is by default 10.
- `WHERE`: to add filter conditions.

`ADMIN SHOW DDL JOB QUERIES`

To view the original SQL statements of the DDL job corresponding to `job_id`, use `ADMIN SHOW DDL JOB QUERIES`:

```
ADMIN SHOW DDL JOBS;
ADMIN SHOW DDL JOB QUERIES 51;
```

```
mysql> ADMIN SHOW DDL JOB QUERIES 51;
+-----------------------------------------------------------+
| QUERY                                                     |
+-----------------------------------------------------------+
| CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment) |
+-----------------------------------------------------------+
1 row in set (0.02 sec)
```

You can only search the running DDL job corresponding to `job_id` within the last ten results in the DDL history job queue.

`ADMIN SHOW DDL JOB QUERIES LIMIT m OFFSET n`

To view the original SQL statements of the DDL job within a specified range `[n+1, n+m]` corresponding to `job_id`, use `ADMIN SHOW DDL JOB QUERIES LIMIT m OFFSET n`:

```
sql ADMIN SHOW DDL JOB QUERIES LIMIT m; # Retrieve first m rows ADMIN
↪ SHOW DDL JOB QUERIES LIMIT n, m; # Retrieve rows [n+1, n+m] ADMIN SHOW
↪ DDL JOB QUERIES LIMIT m OFFSET n; # Retrieve rows [n+1, n+m]
```

where `n` and `m` are integers greater or equal to 0.

```
   sql  ADMIN SHOW DDL JOB QUERIES LIMIT 3; # Retrieve first 3 rows +--------+----------
↪  | JOB_ID | QUERY                                  |  +--------+----------------------
↪  | 59 | ALTER TABLE t1 ADD INDEX index2 (col2)          |  |     60 |
↪ ALTER TABLE t2 ADD INDEX index1 (col1)               |  |     58 | CREATE
↪ TABLE t2 (id INT NOT NULL PRIMARY KEY auto_increment)| +--------+--------------------
↪  3 rows in set (0.00 sec)

   sql  ADMIN SHOW DDL JOB QUERIES LIMIT 6, 2; # Retrieve rows 7-8 +--------+-----------
↪  | JOB_ID | QUERY                                          |  +--------+------------
↪  | 52 | ALTER TABLE t1 ADD INDEX index1 (col1)                |  |
↪    51 | CREATE TABLE IF NOT EXISTS t1 (id INT NOT NULL PRIMARY KEY auto_
↪ increment)| +--------+-------------------------------------------------------------
↪  3 rows in set (0.00 sec)

   sql  ADMIN SHOW DDL JOB QUERIES LIMIT 3 OFFSET 4; # Retrieve rows 5-7
↪ +--------+----------------------------------------+ | JOB_ID | QUERY
↪                | +--------+----------------------------------------+
↪ | 54 | DROP TABLE IF EXISTS t3        |  |     53 | ALTER TABLE t1 DROP
↪  INDEX index1  |  |     52 | ALTER TABLE t1 ADD INDEX index1 (col1)|
↪ +--------+----------------------------------------+ 3 rows in set (0.00
↪ sec)
```

You can search the running DDL job corresponding to `job_id` within an arbitrarily specified range of results in the DDL history job queue. This syntax does not have the limitation of the last ten results of `ADMIN SHOW DDL JOB QUERIES`.

14.13.2.12.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- DDL introduction
- `ADMIN CANCEL DDL`
- `ADMIN PAUSE DDL`
- `ADMIN RESUME DDL`
- `ADMIN ALTER DDL`
- `INFORMATION_SCHEMA.DDL_JOBS`

14.13.2.13 ALTER DATABASE

`ALTER DATABASE` is used to specify or modify the default character set and collation of the current database. `ALTER SCHEMA` has the same effect as `ALTER DATABASE`.

14.13.2.13.1 Synopsis

```
AlterDatabaseStmt ::=
    'ALTER' 'DATABASE' DBName? DatabaseOptionList

DatabaseOption ::=
    DefaultKwdOpt ( CharsetKw '='? CharsetName | 'COLLATE' '='?
        ↪ CollationName | 'ENCRYPTION' '='? EncryptionOpt )
```

14.13.2.13.2 Examples

Modify the test database schema to use the utf8mb4 character set:

```
ALTER DATABASE test DEFAULT CHARACTER SET = utf8mb4;
```

```
Query OK, 0 rows affected (0.00 sec)
```

Currently, TiDB only supports some character sets and collations. See Character Set and Collation Support for details.

14.13.2.13.3 MySQL compatibility

The `ALTER DATABASE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.13.4 See also

- CREATE DATABASE
- SHOW DATABASES

14.13.2.14 ALTER INSTANCE

The `ALTER INSTANCE` statement is used to make changes to a single TiDB instance. Currently, TiDB only supports the `RELOAD TLS` clause.

> **Note:**
>
> TiDB Cloud Serverless can automatically refresh the TLS certificate, so this feature is not applicable to TiDB Cloud Serverless clusters.

14.13.2.14.1 RELOAD TLS

You can execute the `ALTER INSTANCE RELOAD TLS` statement to reload the certificate (`ssl-cert`), the key (`ssl-key`), and the CA (`ssl-ca`) from the original configuration path.

The newly loaded certificate, key, and CA take effect on the connection that is established after the statement is successfully executed. The connection established before this statement execution is not affected.

When an error occurs during reloading, by default, this error message is returned and the previous key and certificate continue to be used. However, if you have added the optional `NO ROLLBACK ON ERROR`, when an error occurs during reloading, the error is not returned, and the subsequent requests are handled with the TLS security connection disabled.

14.13.2.14.2 Syntax diagram

AlterInstanceStmt:

```
AlterInstanceStmt ::=
    'ALTER' 'INSTANCE' InstanceOption

InstanceOption ::=
    'RELOAD' 'TLS' ('NO' 'ROLLBACK' 'ON' 'ERROR')?
```

14.13.2.14.3 Example

```
ALTER INSTANCE RELOAD TLS;
```

14.13.2.14.4 MySQL compatibility

The `ALTER INSTANCE RELOAD TLS` statement only supports reloading from the original configuration path. It does not support dynamically modifying the loading path or dynamically enabling the TLS encrypted connection feature when TiDB is started. This feature is disabled by default when you restart TiDB.

Enable TLS Between TiDB Clients and Servers.

Enable TLS Between TiDB Clients and Servers.

14.13.2.15 ALTER PLACEMENT POLICY

`ALTER PLACEMENT POLICY` is used to modify existing placement policies that have previously been created. All the tables and partitions which use the placement policy will automatically be updated.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

`ALTER PLACEMENT POLICY` *replaces* the previous policy with the new definition. It does not *merge* the old policy with the new one. In the following example, `FOLLOWERS=4` is lost when the `ALTER PLACEMENT POLICY` is executed:

```
CREATE PLACEMENT POLICY p1 FOLLOWERS=4;
ALTER PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us-
    ↪ west-1";
```

14.13.2.15.1 Synopsis

```
AlterPolicyStmt ::=
    "ALTER" "PLACEMENT" "POLICY" IfExists PolicyName PlacementOptionList

PolicyName ::=
    Identifier

PlacementOptionList ::=
    PlacementOption
|   PlacementOptionList PlacementOption
|   PlacementOptionList ',' PlacementOption

PlacementOption ::=
    CommonPlacementOption
|   SugarPlacementOption
|   AdvancedPlacementOption

CommonPlacementOption ::=
    "FOLLOWERS" EqOpt LengthNum

SugarPlacementOption ::=
    "PRIMARY_REGION" EqOpt stringLit
|   "REGIONS" EqOpt stringLit
|   "SCHEDULE" EqOpt stringLit

AdvancedPlacementOption ::=
    "LEARNERS" EqOpt LengthNum
|   "CONSTRAINTS" EqOpt stringLit
|   "LEADER_CONSTRAINTS" EqOpt stringLit
```

```
|   "FOLLOWER_CONSTRAINTS" EqOpt stringLit
|   "LEARNER_CONSTRAINTS" EqOpt stringLit
|   "SURVIVAL_PREFERENCES" EqOpt stringLit
```

14.13.2.15.2 Examples

> **Note:**
>
> To know which regions are available in your cluster, see SHOW PLACEMENT LABELS.
>
> If you do not see any available regions, your TiKV installation might not have labels set correctly.

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us
    -> -west-1";
CREATE TABLE t1 (i INT) PLACEMENT POLICY=p1; -- Assign policy p1 to table
    -> t1
ALTER PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us-
    -> west-1,us-west-2" FOLLOWERS=4; -- The rules of t1 will be updated
    -> automatically.
SHOW CREATE PLACEMENT POLICY p1\G
```

```
Query OK, 0 rows affected (0.08 sec)

Query OK, 0 rows affected (0.10 sec)

***************************[ 1. row ]***************************
Policy      | p1
Create Policy | CREATE PLACEMENT POLICY `p1` PRIMARY_REGION="us-east-1"
    -> REGIONS="us-east-1,us-west-1,us-west-2" FOLLOWERS=4
1 row in set (0.00 sec)
```

14.13.2.15.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.15.4 See also

- Placement Rules in SQL

- SHOW PLACEMENT
- CREATE PLACEMENT POLICY
- DROP PLACEMENT POLICY

14.13.2.16 ALTER RANGE

Currently, the `ALTER RANGE` statement can only be used to modify the range of a specific placement policy in TiDB.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.16.1 Synopsis

```
AlterRangeStmt ::=
    'ALTER' 'RANGE' Identifier PlacementPolicyOption
```

`ALTER RANGE` supports the following two parameters:

- `global`: indicates the range of all data in a cluster.
- `meta`: indicates the range of internal metadata stored in TiDB.

14.13.2.16.2 Examples

```
CREATE PLACEMENT POLICY `deploy111` CONSTRAINTS='{"+region=us-east-1":1, "+
    ↪ region=us-east-2": 1, "+region=us-west-1": 1}';
CREATE PLACEMENT POLICY `five_replicas` FOLLOWERS=4;

ALTER RANGE global PLACEMENT POLICY = "deploy111";
ALTER RANGE meta PLACEMENT POLICY = "five_replicas";
```

The preceding example creates two placement policies (`deploy111` and `five_replicas`), specifies constraints for different regions, and then applies the `deploy111` placement policy to all data in the cluster range and the `five_replicas` placement policy to the metadata range.

14.13.2.17 ALTER RESOURCE GROUP

The `ALTER RESOURCE GROUP` statement is used to modify a resource group in a database.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.17.1 Synopsis

```
AlterResourceGroupStmt ::=
   "ALTER" "RESOURCE" "GROUP" IfExists ResourceGroupName
      ↪ ResourceGroupOptionList

IfExists ::=
    ('IF' 'EXISTS')?

ResourceGroupName ::=
    Identifier
|   "DEFAULT"

ResourceGroupOptionList ::=
    DirectResourceGroupOption
|   ResourceGroupOptionList DirectResourceGroupOption
|   ResourceGroupOptionList ',' DirectResourceGroupOption

DirectResourceGroupOption ::=
    "RU_PER_SEC" EqOpt LengthNum
|   "PRIORITY" EqOpt ResourceGroupPriorityOption
|   "BURSTABLE"
|   "BURSTABLE" EqOpt Boolean
|   "QUERY_LIMIT" EqOpt '(' ResourceGroupRunawayOptionList ')'
|   "QUERY_LIMIT" EqOpt '(' ')'
|   "QUERY_LIMIT" EqOpt "NULL"
|   "BACKGROUND" EqOpt '(' BackgroundOptionList ')'
|   "BACKGROUND" EqOpt '(' ')'
|   "BACKGROUND" EqOpt "NULL"

ResourceGroupPriorityOption ::=
    LOW
|   MEDIUM
|   HIGH

ResourceGroupRunawayOptionList ::=
    DirectResourceGroupRunawayOption
|   ResourceGroupRunawayOptionList DirectResourceGroupRunawayOption
```

```
|   ResourceGroupRunawayOptionList ',' DirectResourceGroupRunawayOption

DirectResourceGroupRunawayOption ::=
    "EXEC_ELAPSED" EqOpt stringLit
|   "PROCESSED_KEYS" EqOpt intLit
|   "RU" EqOpt intLit
|   "ACTION" EqOpt ResourceGroupRunawayActionOption
|   "WATCH" EqOpt ResourceGroupRunawayWatchOption "DURATION" EqOpt stringLit

ResourceGroupRunawayWatchOption ::=
    EXACT
|   SIMILAR

ResourceGroupRunawayActionOption ::=
    DRYRUN
|   COOLDOWN
|   KILL
| "SWITCH_GROUP" '(' ResourceGroupName ')'

BackgroundOptionList ::=
    DirectBackgroundOption
|   BackgroundOptionList DirectBackgroundOption
|   BackgroundOptionList ',' DirectBackgroundOption

DirectBackgroundOption ::=
    "TASK_TYPES" EqOpt stringLit
|   "UTILIZATION_LIMIT" EqOpt LengthNum
```

TiDB supports the following `DirectResourceGroupOption`, where Request Unit (RU) is a unified abstraction unit in TiDB for CPU, IO, and other system resources.

Option	Description	Example
`RU_PER_SEC`	Rate of RU backfilling per second	`RU_PER_SEC = 500` indicates that this resource group is backfilled with 500 RUs per second
`PRIORITY`	The absolute priority of tasks to be processed on TiKV	`PRIORITY = HIGH` indicates that the priority is high. If not specified, the default value is `MEDIUM`.

Option	Description	Example
`BURSTABLE`	If the `BURSTABLE` attribute is set, TiDB allows the corresponding resource group to use the available system resources when the quota is exceeded.	
`QUERY_LIMIT`	When the query execution meets this condition, the query is identified as a runaway query and the corresponding action is executed.	`QUERY_LIMIT=(EXEC_ELAPSED='60s', ACTION=KILL, WATCH=EXACT DURATION='10m')` indicates that the query is identified as a runaway query when the execution time exceeds 60 seconds. The query is terminated. All SQL statements with the same SQL text will be terminated immediately in the coming 10 minutes. `QUERY_LIMIT=()` or `QUERY_LIMIT=NULL` means that runaway control is not enabled. See Runaway Queries.
`BACKGROUND`	Configure the background tasks. For more details, see Manage background tasks.	`BACKGROUND=(TASK_TYPES="br,stats", UTILIZATION_LIMIT=30)` indicates that the backup and restore and statistics collection related tasks are scheduled as background tasks, and background tasks can consume 30% of the TiKV resources at most.

Note:

- The `ALTER RESOURCE GROUP` statement can only be executed when the global variable `tidb_enable_resource_control` is set to `ON`.

- The `ALTER RESOURCE GROUP` statement supports incremental changes, leaving unspecified parameters unchanged. However, both `QUERY_LIMIT` and `BACKGROUND` are used as a whole and cannot be partially modified.
- Currently, only the `default` resource group supports modifying the `BACKGROUND` configuration.

14.13.2.17.2 Examples

Create a resource group named `rg1` and modify its properties.

```
DROP RESOURCE GROUP IF EXISTS rg1;
```

```
Query OK, 0 rows affected (0.22 sec)
```

```
CREATE RESOURCE GROUP IF NOT EXISTS rg1
  RU_PER_SEC = 100
  BURSTABLE;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='rg1';
```

```
+------+------------+----------+-----------+-------------+------------+
| NAME | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT | BACKGROUND |
+------+------------+----------+-----------+-------------+------------+
| rg1  | 100        | MEDIUM   | NO        | NULL        | NULL       |
+------+------------+----------+-----------+-------------+------------+
1 rows in set (1.30 sec)
```

```
ALTER RESOURCE GROUP rg1
  RU_PER_SEC = 200
  PRIORITY = LOW
  QUERY_LIMIT = (EXEC_ELAPSED='1s' ACTION=COOLDOWN WATCH=EXACT DURATION '30
    ↪ s');
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='rg1';
```

```
+--
  ↪ ----+------------+----------+-----------+-------------------------------------
  ↪
```

```
| NAME | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT
   ↪                                          | BACKGROUND |
+--
   ↪ ----+-----------+----------+-----------+-------------------------------------
   ↪
| rg1 | 200        | LOW      | NO        | EXEC_ELAPSED='1s', ACTION=COOLDOWN,
   ↪ WATCH=EXACT DURATION='30s' | NULL |
+--
   ↪ ----+-----------+----------+-----------+-------------------------------------
   ↪
1 rows in set (1.30 sec)
```

Modify the BACKGROUND option for the `default` resource group.

```
ALTER RESOURCE GROUP default BACKGROUND = (TASK_TYPES = "br,ddl",
   ↪ UTILIZATION_LIMIT=30);
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='default';
```

```
+--
   ↪ -------+-----------+----------+-----------+------------+---------------------
   ↪
| NAME    | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT | BACKGROUND
   ↪                      |
+--
   ↪ -------+-----------+----------+-----------+------------+---------------------
   ↪
| default | UNLIMITED | MEDIUM | YES     | NULL       | TASK_TYPES='br,ddl',
   ↪ UTILIZATION_LIMIT=30 |
+--
   ↪ -------+-----------+----------+-----------+------------+---------------------
   ↪
1 rows in set (1.30 sec)
```

14.13.2.17.3 MySQL compatibility

MySQL also supports ALTER RESOURCE GROUP. However, the acceptable parameters are different from that of TiDB so that they are not compatible.

14.13.2.17.4 See also

- DROP RESOURCE GROUP
- CREATE RESOURCE GROUP
- Request Unit (RU)

14.13.2.18 ALTER SEQUENCE

The `ALTER SEQUENCE` statement alters sequence objects in TiDB. The sequence is a database object that is on a par with the `Table` and the `View` object. The sequence is used to generate serialized IDs in a customized way.

14.13.2.18.1 Synopsis

```
CreateSequenceStmt ::=
    'ALTER' 'SEQUENCE' TableName CreateSequenceOptionListOpt

TableName ::=
    Identifier ('.' Identifier)?

CreateSequenceOptionListOpt ::=
    SequenceOption*

SequenceOptionList ::=
    SequenceOption

SequenceOption ::=
    ( 'INCREMENT' ( '='? | 'BY' ) | 'START' ( '='? | 'WITH' ) | ( 'MINVALUE'
       ↪  | 'MAXVALUE' | 'CACHE' ) '='? ) SignedNum
|   'COMMENT' '='? stringLit
|   'NOMINVALUE'
|   'NO' ( 'MINVALUE' | 'MAXVALUE' | 'CACHE' | 'CYCLE' )
|   'NOMAXVALUE'
|   'NOCACHE'
|   'CYCLE'
|   'NOCYCLE'
|   'RESTART' ( ( '='? | 'WITH' ) SignedNum )?
```

14.13.2.18.2 Syntax

```
ALTER SEQUENCE sequence_name
    [ INCREMENT [ BY | = ] increment ]
    [ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
    [ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
    [ START [ WITH | = ] start ]
    [ CACHE [=] cache | NOCACHE | NO CACHE]
    [ CYCLE | NOCYCLE | NO CYCLE]
    [table_options]
```

14.13.2.18.3 Parameters

Parameters	Default value	Description
`INCREMENT` ↪	`1`	Specifies the increment of a sequence. Its positive or negative values can control the growth direction of the sequence.

Parameters	Default value	Description
`MINVALUE` ↪	`1` or `-9223372036854775807` ↪	Specifies the minimum value of a sequence. When `INCREMENT` ↪ `> 0`, the default value is `1`. When `INCREMENT` ↪ `< 0`, the default value is `-922337203685477` ↪ .

Parameters	Default value	Description
`MAXVALUE` ↪	`9223372036854775806` ↪ or `-1`	Specifies the maximum value of a sequence. When `INCREMENT` ↪ `> 0`, the default value is `922337203685477` ↪ . When `INCREMENT` ↪ `< 0`, the default value is `-1`.

Parameters	Default value	Description
`START` ↪	`MINVALUE` ↪ or `MAXVALUE` ↪	Specifies the initial value of a sequence. When `INCREMENT` ↪ > 0, the default value is `MINVALUE` ↪ . When `INCREMENT` ↪ < 0, the default value is `MAXVALUE` ↪ .
`CACHE` ↪	`1000` ↪	Specifies the local cache size of a sequence in TiDB.

Parameters	Default value	Description
`CYCLE` ↪	`NO` ↪ `CYCLE` ↪	Specifies whether a sequence restarts from the minimum value (or maximum for the descending sequence). When `INCREMENT` ↪ > `0`, the default value is `MINVALUE` ↪ . When `INCREMENT` ↪ < `0`, the default value is `MAXVALUE` ↪ .

Parameters	Default value	Description

> **Note:**
>
> Changing the `START` value does not affect the generated values until you execute `ALTER SEQUENCE ... RESTART`.

14.13.2.18.4 `SEQUENCE` function

You can control a sequence through the following expression functions:

- `NEXTVAL` or `NEXT VALUE FOR`

  Essentially, both are the `NEXTVAL()` function that gets the next valid value of a sequence object. The parameter of the `NEXTVAL()` function is the `identifier` of the sequence.

- `LASTVAL`

  This function gets the last used value of this session. If the value does not exist, `NULL` is used. The parameter of this function is the `identifier` of the sequence.

- `SETVAL`

  This function sets the progression of the current value for a sequence. The first parameter of this function is the `identifier` of the sequence; the second parameter is `num`.

> **Note:**
>
> In the implementation of a sequence in TiDB, the `SETVAL` function cannot change the initial progression or cycle progression of this sequence. This function only returns the next valid value based on this progression.

14.13.2.18.5 Examples

Create a sequence named `s1`:

```
CREATE SEQUENCE s1;
```

```
Query OK, 0 rows affected (0.15 sec)
```

Get the next two values from the sequence by executing the following SQL statement twice:

```
SELECT NEXTVAL(s1);
```

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
1 row in set (0.01 sec)
```

```
SELECT NEXTVAL(s1);
```

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|           2 |
+-------------+
1 row in set (0.00 sec)
```

Change the increment of the sequence to 2:

```
ALTER SEQUENCE s1 INCREMENT=2;
```

```
Query OK, 0 rows affected (0.18 sec)
```

Now, get the next two values from the sequence again:

```
SELECT NEXTVAL(s1);
```

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|        1001 |
+-------------+
1 row in set (0.02 sec)
```

```
SELECT NEXTVAL(s1);
```

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|        1003 |
+-------------+
1 row in set (0.00 sec)
```

As you can see from the output, the values now increase by two, following the `ALTER SEQUENCE` statement.

You can also change other parameters of the sequence. For example, you can change the `MAXVALUE` of the sequence as follows:

```
CREATE SEQUENCE s2 MAXVALUE=10;
```

```
Query OK, 0 rows affected (0.17 sec)
```

```
ALTER SEQUENCE s2 MAXVALUE=100;
```

```
Query OK, 0 rows affected (0.15 sec)
```

```
SHOW CREATE SEQUENCE s2\G
```

```
*************************** 1. row ***************************
       Sequence: s2
Create Sequence: CREATE SEQUENCE `s2` start with 1 minvalue 1 maxvalue 100
    ↪ increment by 1 cache 1000 nocycle ENGINE=InnoDB
1 row in set (0.00 sec)
```

14.13.2.18.6 MySQL compatibility

This statement is a TiDB extension. The implementation is modeled on sequences available in MariaDB.

Except for the `SETVAL` function, all other functions have the same *progressions* as MariaDB. Here "progression" means that the numbers in a sequence follow a certain arithmetic progression rule defined by the sequence. Although you can use `SETVAL` to set the current value of a sequence, the subsequent values of the sequence still follow the original progression rule.

For example:

```
1, 3, 5, ...          // The sequence starts from 1 and increments by 2.
SELECT SETVAL(seq, 6) // Sets the current value of a sequence to 6.
7, 9, 11, ...         // Subsequent values still follow the progression rule.
```

In the `CYCLE` mode, the initial value of a sequence in the first round is the value of the `START` parameter, and the initial value in the subsequent rounds is the value of `MinValue` (`INCREMENT` > 0) or `MaxValue` (`INCREMENT` < 0).

14.13.2.19 ALTER TABLE

14.13.2.19.1 ALTER TABLE

This statement modifies an existing table to conform to a new table structure. The statement `ALTER TABLE` can be used to:

- `ADD`, `DROP`, or `RENAME` indexes
- `ADD`, `DROP`, `MODIFY` or `CHANGE` columns
- `COMPACT` table data

Synopsis

```
AlterTableStmt ::=
    'ALTER' IgnoreOptional 'TABLE' TableName (
        AlterTableSpecListOpt AlterTablePartitionOpt |
        'ANALYZE' 'PARTITION' PartitionNameList ( 'INDEX' IndexNameList )?
            ↪ AnalyzeOptionListOpt |
        'COMPACT' ( 'PARTITION' PartitionNameList )? 'TIFLASH' 'REPLICA'
    )

TableName ::=
    Identifier ('.' Identifier)?

AlterTableSpec ::=
    TableOptionList
|   'SET' 'TIFLASH' 'REPLICA' LengthNum LocationLabelList
|   'CONVERT' 'TO' CharsetKw ( CharsetName | 'DEFAULT' ) OptCollate
|   'ADD' ( ColumnKeywordOpt IfNotExists ( ColumnDef ColumnPosition | '('
    ↪ TableElementList ')' ) | Constraint | 'PARTITION' IfNotExists
    ↪ NoWriteToBinLogAliasOpt ( PartitionDefinitionListOpt | 'PARTITIONS'
    ↪ NUM ) )
|   ( ( 'CHECK' | 'TRUNCATE' ) 'PARTITION' | ( 'OPTIMIZE' | 'REPAIR' | '
    ↪ REBUILD' ) 'PARTITION' NoWriteToBinLogAliasOpt )

|   ( 'CACHE' | 'NOCACHE' )
|   (
        'TTL' EqOpt TimeColumnName '+' 'INTERVAL' Expression TimeUnit (
            ↪ TTLEnable EqOpt ( 'ON' | 'OFF' ))?
        | 'REMOVE' 'TTL'
        | TTLEnable EqOpt ( 'ON' | 'OFF' )
        | TTLJobInterval EqOpt stringLit
    )
|   PlacementPolicyOption

PlacementPolicyOption ::=
    "PLACEMENT" "POLICY" EqOpt PolicyName
|   "PLACEMENT" "POLICY" (EqOpt | "SET") "DEFAULT"
```

Examples

Create a table with some initial data:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT NOT
    ↪ NULL);
INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

The following query requires a full table scan because the column c1 is not indexed:

```
EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
```

```
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7         | 10.00   | root     |               | data:Selection_6
   ↪           |
| └─Selection_6         | 10.00   | cop[tikv] |              | eq(test.t1.c1,
   ↪ 3)          |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t1 | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

The statement ALTER TABLE .. ADD INDEX can be used to add an index on the table t1. EXPLAIN confirms that the original query now uses an index range scan, which is more efficient:

```
ALTER TABLE t1 ADD INDEX (c1);
EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
```

```
Query OK, 0 rows affected (0.30 sec)

+--
   ↪ ----------------------+---------+----------+-----------------------+---------
   ↪
| id                    | estRows | task     | access object         | operator
   ↪ info                           |
+--
   ↪ ----------------------+---------+----------+-----------------------+---------
   ↪
| IndexReader_6         | 10.00   | root     |                       | index:
   ↪ IndexRangeScan_5                |
| └─IndexRangeScan_5    | 10.00   | cop[tikv] | table:t1, index:c1(c1) | range
   ↪ :[3,3], keep order:false, stats:pseudo |
+--
   ↪ ----------------------+---------+----------+-----------------------+---------
   ↪
```

```
2 rows in set (0.00 sec)
```

TiDB supports the ability to assert that DDL changes use a particular `ALTER` algorithm. Note that this is only an assertion, and does not change the actual algorithm used to modify the table:

```
ALTER TABLE t1 DROP INDEX c1, ALGORITHM=INSTANT;
```

```
Query OK, 0 rows affected (0.24 sec)
```

Using the `ALGORITHM=INSTANT` assertion on an operation that requires the `INPLACE` algorithm results in a statement error:

```
ALTER TABLE t1 ADD INDEX (c1), ALGORITHM=INSTANT;
```

```
ERROR 1846 (0A000): ALGORITHM=INSTANT is not supported. Reason: Cannot
    ↪ alter table by INSTANT. Try ALGORITHM=INPLACE.
```

However, using the `ALGORITHM=COPY` assertion for an `INPLACE` operation generates a warning instead of an error. This is because TiDB interprets the assertion as *this algorithm or better*. This behavior difference is useful for MySQL compatibility because the algorithm TiDB uses might differ from MySQL:

```
ALTER TABLE t1 ADD INDEX (c1), ALGORITHM=COPY;
SHOW WARNINGS;
```

```
Query OK, 0 rows affected, 1 warning (0.25 sec)

+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Error | 1846 | ALGORITHM=COPY is not supported. Reason: Cannot alter
    ↪ table by COPY. Try ALGORITHM=INPLACE. |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

MySQL compatibility

The following major restrictions apply to `ALTER TABLE` in TiDB:

- When altering multiple schema objects in a single `ALTER TABLE` statement:
    - Modifying the same object in multiple changes is not supported.
    - TiDB validates statements according to the table schema **before execution**. For example, an error returns when `ALTER TABLE t ADD COLUMN c1 INT, ADD COLUMN c2 INT AFTER c1;` is executed because column `c1` does not exist in the table.
    - For an `ALTER TABLE` statement, the order of execution in TiDB is one change after another from left to right, which is incompatible with MySQL in some cases.
- Changes of the Reorg-Data types on primary key columns are not supported.
- Changes of column types on partitioned tables are not supported.
- Changes of column types on generated columns are not supported.
- Changes of some data types (for example, some TIME, Bit, Set, Enum, and JSON types) are not supported due to the compatibility issues of the `CAST` function's behavior between TiDB and MySQL.
- Spatial data types are not supported.
- `ALTER TABLE t CACHE | NOCACHE` is a TiDB extension to MySQL syntax. For details, see Cached Tables.

For further restrictions, see MySQL Compatibility.

14.13.2.19.2 ADD COLUMN

The `ALTER TABLE.. ADD COLUMN` statement adds a column to an existing table. This operation is online in TiDB, which means that neither reads or writes to the table are blocked by adding a column.

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName AddColumnSpec ( ','
           ↪ AddColumnSpec )*

TableName ::=
    Identifier ('.' Identifier)?

AddColumnSpec
        ::= 'ADD' 'COLUMN' 'IF NOT EXISTS'? ColumnName ColumnType
           ↪ ColumnOption+ ( 'FIRST' | 'AFTER' ColumnName )?

ColumnType
        ::= NumericType
          | StringType
          | DateAndTimeType
          | 'SERIAL'

ColumnOption
        ::= 'NOT'? 'NULL'
          | 'AUTO_INCREMENT'
          | 'PRIMARY'? 'KEY' ( 'CLUSTERED' | 'NONCLUSTERED' )? ( 'GLOBAL' |
             ↪ 'LOCAL' )?
          | 'UNIQUE' 'KEY'? ( 'GLOBAL' | 'LOCAL' )?
          | 'DEFAULT' ( NowSymOptionFraction | SignedLiteral |
             ↪ NextValueForSequence )
          | 'SERIAL' 'DEFAULT' 'VALUE'
          | 'ON' 'UPDATE' NowSymOptionFraction
          | 'COMMENT' stringLit
          | ( 'CONSTRAINT' Identifier? )? 'CHECK' '(' Expression ')' ( 'NOT
             ↪ '? ( 'ENFORCED' | 'NULL' ) )?
          | 'GENERATED' 'ALWAYS' 'AS' '(' Expression ')' ( 'VIRTUAL' | '
             ↪ STORED' )?
          | 'REFERENCES' TableName ( '(' IndexPartSpecificationList ')' )?
             ↪ Match? OnDeleteUpdateOpt
          | 'COLLATE' CollationName
          | 'COLUMN_FORMAT' ColumnFormat
          | 'STORAGE' StorageMedia
          | 'AUTO_RANDOM' ( '(' LengthNum ')' )?
```

Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 VALUES (NULL);
```

```
Query OK, 1 row affected (0.02 sec)

mysql> SELECT * FROM t1;
+----+
| id |
+----+
|  1 |
+----+
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 ADD COLUMN c1 INT NOT NULL;
Query OK, 0 rows affected (0.28 sec)

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  0 |
+----+----+
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 ADD c2 INT NOT NULL AFTER c1;
Query OK, 0 rows affected (0.28 sec)

mysql> SELECT * FROM t1;
+----+----+----+
| id | c1 | c2 |
+----+----+----+
|  1 |  0 |  0 |
+----+----+----+
1 row in set (0.00 sec)
```

MySQL compatibility

- Adding a new column and setting it to the `PRIMARY KEY` is not supported.
- Adding a new column and setting it to `AUTO_INCREMENT` is not supported.
- There are limitations on adding generated columns, refer to: generated column limitations.
- Setting a global index by specifying `PRIMARY KEY` or `UNIQUE INDEX` as `GLOBAL` when you add a new column is a TiDB extension for partitioned tables and is not compatible with MySQL.

See also

- ADD INDEX
- CREATE TABLE

14.13.2.19.3 ADD INDEX

The `ALTER TABLE.. ADD INDEX` statement adds an index to an existing table. This operation is online in TiDB, which means that neither reads or writes to the table are blocked by adding an index.

Tip:

The TiDB Distributed eXecution Framework (DXF) can be used to speed up the operation of this statement.

Warning:

- **DO NOT** upgrade a TiDB cluster when a DDL statement is being executed in the cluster (usually for the time-consuming DDL statements such as `ADD INDEX` and the column type changes).
- Before the upgrade, it is recommended to use the `ADMIN SHOW DDL` command to check whether the TiDB cluster has an ongoing DDL job. If the cluster has a DDL job, to upgrade the cluster, wait until the DDL execution is finished or use the `ADMIN CANCEL DDL` command to cancel the DDL job before you upgrade the cluster.
- In addition, during the cluster upgrade, **DO NOT** execute any DDL statement. Otherwise, the issue of undefined behavior might occur.

When you upgrade TiDB from v7.1.0 to a later version, you can ignore the preceding limitations. For details, see the limitations of TiDB smooth upgrade.

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName AddIndexSpec ( ','
           ↪ AddIndexSpec )*

AddIndexSpec
        ::= 'ADD' ( ( 'PRIMARY' 'KEY' | ( 'KEY' | 'INDEX' ) 'IF NOT EXISTS'?
           ↪  | 'UNIQUE' ( 'KEY' | 'INDEX' )? ) ( ( Identifier? 'USING' |
           ↪ Identifier 'TYPE' ) IndexType )? | 'FULLTEXT' ( 'KEY' | '
           ↪ INDEX' )? IndexName ) '(' IndexPartSpecification ( ','
           ↪ IndexPartSpecification )* ')' IndexOption*
```

```
IndexPartSpecification
        ::= ( ColumnName ( '(' LengthNum ')' )? | '(' Expression ')' ) ( '
           ↪ ASC' | 'DESC' )

IndexOption
        ::= 'KEY_BLOCK_SIZE' '='? LengthNum
          | 'USING' IndexType
          | 'WITH' 'PARSER' Identifier
          | 'COMMENT' stringLit
          | 'VISIBLE'
          | 'INVISIBLE'
          | 'GLOBAL'
          | 'LOCAL'

IndexType
        ::= 'BTREE'
          | 'HASH'
          | 'RTREE'
```

Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
   ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);

    ↪
2 rows in set (0.00 sec)
```

MySQL compatibility

- TiDB accepts index types such as `HASH`, `BTREE` and `RTREE` in syntax for compatibility with MySQL, but ignores them.
- `SPATIAL` indexes are not supported.
- TiDB supports parsing the `FULLTEXT` syntax but does not support using the `FULLTEXT` indexes.
- Descending indexes are not supported (similar to MySQL 5.7).
- Adding the primary key of the `CLUSTERED` type to a table is not supported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.
- Setting a `PRIMARY KEY` or `UNIQUE INDEX` as a global index with the `GLOBAL` index option is a TiDB extension for partitioned tables and is not compatible with MySQL.

14.13.2.19.4 ALTER INDEX

The `ALTER INDEX` statement is used to modify the visibility of the index to `Visible` or `Invisible`. Invisible indexes are maintained by DML statements, but will not be used by the query optimizer. This is useful in scenarios where you want to double-check before removing an index permanently. Starting from TiDB v8.0.0, you can make the optimizer select invisible indexes by modifying the system variable `tidb_opt_use_invisible_indexes`.

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName AlterIndexSpec ( ','
           ↪ AlterIndexSpec )*

AlterIndexSpec
        ::= 'ALTER' 'INDEX' Identifier ( 'VISIBLE' | 'INVISIBLE' )
```

Examples

You can modify the visibility of an index using the `ALTER TABLE ... ALTER INDEX ...` statement.

```
CREATE TABLE t1 (c1 INT, UNIQUE(c1));
ALTER TABLE t1 ALTER INDEX c1 INVISIBLE;
```

```
Query OK, 0 rows affected (0.02 sec)
```

```
SHOW CREATE TABLE t1;
```

```
+--
   ↪ -----+----------------------------------------------------------------------
   ↪
| Table | Create Table
                                  |
+--
   ↪ -----+----------------------------------------------------------------------
   ↪
| t1    | CREATE TABLE `t1` (
  `c1` int DEFAULT NULL,
```

```
  UNIQUE KEY `c1` (`c1`) /*!80000 INVISIBLE */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

The optimizer cannot use the **invisible index** of c1.

```
EXPLAIN SELECT c1 FROM t1 ORDER BY c1;
```

```
+--
    ↪ ----------------------+---------+----------+--------------+---------------
    ↪
| id                    | estRows | task     | access object | operator info
    ↪            |
+--
    ↪ ----------------------+---------+----------+--------------+---------------
    ↪
| Sort_4                | 10000.00 | root    |               | test.t1.c1:asc
    ↪             |
|  ─TableReader_8       | 10000.00 | root    |               | data:
    ↪ TableFullScan_7       |
|    ─TableFullScan_7   | 10000.00 | cop[tikv] | table:t1 | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+---------+----------+--------------+---------------
    ↪
3 rows in set (0.00 sec)
```

By comparison, c2 is a **visible index** and can be used by the optimizer.

```
EXPLAIN SELECT c2 FROM t1 ORDER BY c2;
```

```
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| id                    | estRows | task     | access object        | operator
    ↪ info             |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| IndexReader_13       | 10000.00 | root    |                      | index:
    ↪ IndexFullScan_12    |
|  ─IndexFullScan_12   | 10000.00 | cop[tikv] | table:t1, index:c2(c2) |
    ↪ keep order:true, stats:pseudo |
```

```
+--
    ↪ --------------------+----------+-----------+-----------------------+---------
    ↪
2 rows in set (0.00 sec)
```

Even if you use the `USE INDEX` SQL hint to forcibly use indexes, the optimizer still cannot use invisible indexes; otherwise, an error is returned.

```
SELECT * FROM t1 USE INDEX(c1);
```

```
ERROR 1176 (42000): Key 'c1' doesn't exist in table 't1'
```

> **Note:**
>
> "Invisible" here means invisible only to the optimizer. You can still modify or delete invisible indexes.

```
ALTER TABLE t1 DROP INDEX c1;
```

```
Query OK, 0 rows affected (0.02 sec)
```

MySQL compatibility

- Invisible indexes in TiDB are modeled on the equivalent feature from MySQL 8.0.
- Similar to MySQL, TiDB does not permit `PRIMARY KEY` indexes to be made invisible.

14.13.2.19.5 CHANGE COLUMN

The `ALTER TABLE.. CHANGE COLUMN` statement changes a column on an existing table. The change can include both renaming the column, and changing the data type to a compatible type.

Since v5.1.0, TiDB has supported changing the Reorg data type, including but not limited to:

- Changing `VARCHAR` to `BIGINT`
- Modifying the `DECIMAL` precision
- Compressing the length of `VARCHAR(10)` to `VARCHAR(5)`

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName ChangeColumnSpec ( ','
           ↪ ChangeColumnSpec )*

ChangeColumnSpec
        ::= 'CHANGE' ColumnKeywordOpt 'IF EXISTS' ColumnName ColumnName
           ↪ ColumnType ColumnOption* ( 'FIRST' | 'AFTER' ColumnName )?

ColumnType
        ::= NumericType
          | StringType
          | DateAndTimeType
          | 'SERIAL'

ColumnOption
        ::= 'NOT'? 'NULL'

          | 'COLLATE' CollationName
          | 'COLUMN_FORMAT' ColumnFormat
          | 'STORAGE' StorageMedia
          | 'AUTO_RANDOM' ( '(' LengthNum ')' )?

ColumnName ::=
    Identifier ( '.' Identifier ( '.' Identifier )? )?
```

Examples

```
CREATE TABLE t1 (id int not null primary key AUTO_INCREMENT, col1 INT);
```

```
Query OK, 0 rows affected (0.11 sec)
```

```
INSERT INTO t1 (col1) VALUES (1),(2),(3),(4),(5);
```

```
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

```
ALTER TABLE t1 CHANGE col1 col2 INT;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
ALTER TABLE t1 CHANGE col2 col3 BIGINT, ALGORITHM=INSTANT;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
ALTER TABLE t1 CHANGE col3 col4 BIGINT, CHANGE id id2 INT NOT NULL;
```

```
ERROR 1105 (HY000): can't run multi schema change
```

```
CREATE TABLE t (a int primary key);
ALTER TABLE t CHANGE COLUMN a a VARCHAR(10);
```

```
ERROR 8200 (HY000): Unsupported modify column: column has primary key flag
```

```
CREATE TABLE t (c1 INT, c2 INT, c3 INT) partition by range columns(c1) (
    ↪ partition p0 values less than (10), partition p1 values less than (
    ↪ maxvalue));
ALTER TABLE t CHANGE COLUMN c1 c1 DATETIME;
```

```
ERROR 8200 (HY000): Unsupported modify column: table is partition table
```

```
CREATE TABLE t (a INT, b INT as (a+1));
ALTER TABLE t CHANGE COLUMN b b VARCHAR(10);
```

```
ERROR 8200 (HY000): Unsupported modify column: column is generated
```

```
CREATE TABLE t (a DECIMAL(13, 7));
ALTER TABLE t CHANGE COLUMN a a DATETIME;
```

```
ERROR 8200 (HY000): Unsupported modify column: change from original type
    ↪ decimal(13,7) to datetime is currently unsupported yet
```

MySQL compatibility

- Changes of Reorg-Data types on primary key columns are not supported.
- Changes of column types on partitioned tables are not supported.
- Changes of column types on generated columns are not supported.
- Changes from some data types (for example, TIME, BIT, SET, ENUM, and JSON types) to some other types are not supported due to the compatibility issues of the `CAST` function's behavior between TiDB and MySQL.

14.13.2.19.6 ALTER TABLE ... COMPACT

To enhance read performance and reduce disk usage, TiDB automatically schedules data compaction on storage nodes in the background. During the compaction, storage nodes rewrite physical data, including cleaning up deleted rows and merging multiple versions of data caused by updates. The `ALTER TABLE ... COMPACT` statement allows you to initiate compaction for a specific table immediately, without waiting until compaction is triggered in the background.

The execution of this statement does not block existing SQL statements or affect any TiDB features, such as transactions, DDL, and GC. Data that can be selected via SQL statements will not be changed either. Executing this statement consumes some IO and CPU resources. Be careful to choose an appropriate timing for execution, such as when resources are available, to avoid negative impact on the business.

The compaction statement will be finished and returned when all replicas of a table are compacted. During the execution process, you can safely interrupt the compaction by executing the `KILL` statement. Interrupting a compaction does not break data consistency or lead to data loss, nor does it affect subsequent manual or background compactions.

This data compaction statement is currently supported only for TiFlash replicas, not for TiKV replicas.

Synopsis

```
AlterTableCompactStmt ::=
    'ALTER' 'TABLE' TableName 'COMPACT' ( 'PARTITION' PartitionNameList )? (
        ↪ 'TIFLASH' 'REPLICA' )?
```

Since v6.2.0, the `TIFLASH REPLICA` part of the syntax can be omitted. When omitted, the semantic of the statement remains unchanged, and takes effect only for TiFlash.

Examples

Compact TiFlash replicas in a table

The following takes an `employees` table as an example, which has 4 partitions with 2 TiFlash replicas:

```
CREATE TABLE employees (
    id INT NOT NULL,
    hired DATE NOT NULL DEFAULT '1970-01-01',
    store_id INT
)
PARTITION BY LIST (store_id) (
    PARTITION pNorth VALUES IN (1, 2, 3, 4, 5),
    PARTITION pEast VALUES IN (6, 7, 8, 9, 10),
    PARTITION pWest VALUES IN (11, 12, 13, 14, 15),
    PARTITION pCentral VALUES IN (16, 17, 18, 19, 20)
);
ALTER TABLE employees SET TIFLASH REPLICA 2;
```

You can execute the following statement to immediately initiate the compaction for the 2 TiFlash replicas for all partitions in the `employees` table:

```
ALTER TABLE employees COMPACT TIFLASH REPLICA;
```

Compact TiFlash replicas of specified partitions in a table

The following takes an `employees` table as an example, which has 4 partitions with 2 TiFlash replicas:

```
CREATE TABLE employees (
    id INT NOT NULL,
    hired DATE NOT NULL DEFAULT '1970-01-01',
    store_id INT
)
PARTITION BY LIST (store_id) (
    PARTITION pNorth VALUES IN (1, 2, 3, 4, 5),
    PARTITION pEast VALUES IN (6, 7, 8, 9, 10),
    PARTITION pWest VALUES IN (11, 12, 13, 14, 15),
    PARTITION pCentral VALUES IN (16, 17, 18, 19, 20)
);

ALTER TABLE employees SET TIFLASH REPLICA 2;
```

You can execute the following statement to immediately initiate the compaction for the 2 TiFlash replicas of the `pNorth` and `pEast` partitions in the `employees` table:

```
ALTER TABLE employees COMPACT PARTITION pNorth, pEast TIFLASH REPLICA;
```

Concurrency

The `ALTER TABLE ... COMPACT` statement compacts all replicas in a table simultaneously.

To avoid a significant impact on online business, each TiFlash instance only compacts data in one table at a time by default (except for the compaction triggered in the background). This means that if you execute the `ALTER TABLE ... COMPACT` statement on multiple tables at the same time, their executions will be queued on the same TiFlash instance, rather than being executed simultaneously.

To obtain greater table-level concurrency with higher resource usage, you can modify the TiFlash configuration `manual_compact_pool_size`. For example, when `manual_compact_pool_size` is set to 2, compaction for 2 tables can be processed simultaneously.

Observe data compaction progress

You can observe the progress of data compaction or determine whether to initiate compaction for a table by checking the `TOTAL_DELTA_ROWS` column in the `INFORMATION_SCHEMA.TIFLASH_TABLES` table. The larger the value of `TOTAL_DELTA_ROWS`, the more data that can be compacted. If `TOTAL_DELTA_ROWS` is `0`, all data in the table is in the best state and does not need to be compacted.

Example: Check the compaction state of a non-partitioned table

```
USE test;

CREATE TABLE foo(id INT);

ALTER TABLE foo SET TIFLASH REPLICA 1;

SELECT TOTAL_DELTA_ROWS, TOTAL_STABLE_ROWS FROM INFORMATION_SCHEMA.TIFLASH_
    ↪ TABLES
    WHERE IS_TOMBSTONE = 0 AND
    `TIDB_DATABASE` = "test" AND `TIDB_TABLE` = "foo";
+------------------+------------------+
| TOTAL_DELTA_ROWS | TOTAL_STABLE_ROWS |
+------------------+------------------+
|                0 |                0 |
+------------------+------------------+

INSERT INTO foo VALUES (1), (3), (7);

SELECT TOTAL_DELTA_ROWS, TOTAL_STABLE_ROWS FROM INFORMATION_SCHEMA.TIFLASH_
    ↪ TABLES
    WHERE IS_TOMBSTONE = 0 AND
```

```
    `TIDB_DATABASE` = "test" AND `TIDB_TABLE` = "foo";
+------------------+------------------+
| TOTAL_DELTA_ROWS | TOTAL_STABLE_ROWS |
+------------------+------------------+
|                3 |                0 |
+------------------+------------------+
-- Newly written data can be compacted

ALTER TABLE foo COMPACT TIFLASH REPLICA;

SELECT TOTAL_DELTA_ROWS, TOTAL_STABLE_ROWS FROM INFORMATION_SCHEMA.TIFLASH_
    ↪ TABLES
    WHERE IS_TOMBSTONE = 0 AND
    `TIDB_DATABASE` = "test" AND `TIDB_TABLE` = "foo";
+------------------+------------------+
| TOTAL_DELTA_ROWS | TOTAL_STABLE_ROWS |
+------------------+------------------+
|                0 |                3 |
+------------------+------------------+
-- All data is in the best state and no compaction is needed
```

Example: Check the compaction state of a partitioned table

```
USE test;

CREATE TABLE employees
    (id INT NOT NULL, store_id INT)
    PARTITION BY LIST (store_id) (
        PARTITION pNorth VALUES IN (1, 2, 3, 4, 5),
        PARTITION pEast VALUES IN (6, 7, 8, 9, 10),
        PARTITION pWest VALUES IN (11, 12, 13, 14, 15),
        PARTITION pCentral VALUES IN (16, 17, 18, 19, 20)
    );

ALTER TABLE employees SET TIFLASH REPLICA 1;

INSERT INTO employees VALUES (1, 1), (6, 6), (10, 10);

SELECT PARTITION_NAME, TOTAL_DELTA_ROWS, TOTAL_STABLE_ROWS
    FROM INFORMATION_SCHEMA.TIFLASH_TABLES t, INFORMATION_SCHEMA.PARTITIONS
        ↪ p
    WHERE t.IS_TOMBSTONE = 0 AND t.TABLE_ID = p.TIDB_PARTITION_ID AND
    p.TABLE_SCHEMA = "test" AND p.TABLE_NAME = "employees";
+----------------+------------------+------------------+
| PARTITION_NAME | TOTAL_DELTA_ROWS | TOTAL_STABLE_ROWS |
```

```
+---------------+-----------------+------------------+
| pNorth        |               1 |                0 |
| pEast         |               2 |                0 |
| pWest         |               0 |                0 |
| pCentral      |               0 |                0 |
+---------------+-----------------+------------------+
-- Some partitions can be compacted

ALTER TABLE employees COMPACT TIFLASH REPLICA;

SELECT PARTITION_NAME, TOTAL_DELTA_ROWS, TOTAL_STABLE_ROWS
    FROM INFORMATION_SCHEMA.TIFLASH_TABLES t, INFORMATION_SCHEMA.PARTITIONS
        ↪ p
    WHERE t.IS_TOMBSTONE = 0 AND t.TABLE_ID = p.TIDB_PARTITION_ID AND
    p.TABLE_SCHEMA = "test" AND p.TABLE_NAME = "employees";
+---------------+-----------------+------------------+
| PARTITION_NAME | TOTAL_DELTA_ROWS | TOTAL_STABLE_ROWS |
+---------------+-----------------+------------------+
| pNorth        |               0 |                1 |
| pEast         |               0 |                2 |
| pWest         |               0 |                0 |
| pCentral      |               0 |                0 |
+---------------+-----------------+------------------+
-- Data in all partitions is in the best state and no compaction is needed
```

Note:

- If data is updated during compaction, `TOTAL_DELTA_ROWS` might still be a non-zero value after compaction is done. This is normal and indicates that these updates have not been compacted. To compact these updates, execute the `ALTER TABLE ... COMPACT` statement again.
- `TOTAL_DELTA_ROWS` indicates the data version, not the number of rows. For example, if you insert a row and then delete it, `TOTAL_DELTA_ROWS` will increase by 2.

Compatibility

MySQL compatibility

The `ALTER TABLE ... COMPACT` syntax is TiDB specific, which is an extension to the standard SQL syntax. Although there is no equivalent MySQL syntax, you can still execute

this statement by using MySQL clients or various database drivers that comply with the MySQL protocol.

TiCDC compatibility

The `ALTER TABLE ... COMPACT` statement does not result in logical data changes and are therefore not replicated to downstream by TiCDC.

See also

- ALTER TABLE
- KILL TIDB

14.13.2.19.7 DROP COLUMN

This statement drops a column from a specified table. `DROP COLUMN` is online in TiDB, which means that it does not block read or write operations.

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName DropColumnSpec ( ','
           ↪ DropColumnSpec )*

DropColumnSpec
        ::= 'DROP' 'COLUMN'? 'IF EXISTS'? ColumnName ( 'RESTRICT' | 'CASCADE
           ↪ ' )?

ColumnName
        ::= Identifier ( '.' Identifier ( '.' Identifier )? )?
```

Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, col1
   ↪ INT NOT NULL, col2 INT NOT NULL);
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO t1 (col1,col2) VALUES (1,1),(2,2),(3,3),(4,4),(5,5);
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+------+------+
| id | col1 | col2 |
+----+------+------+
|  1 |    1 |    1 |
|  2 |    2 |    2 |
|  3 |    3 |    3 |
```

```
|  4 |    4 |    4 |
|  5 |    5 |    5 |
+----+------+------+
5 rows in set (0.01 sec)

mysql> ALTER TABLE t1 DROP COLUMN col1, DROP COLUMN col2;
ERROR 1105 (HY000): can't run multi schema change
mysql> SELECT * FROM t1;

|  1 |    1 |    1 |
|  2 |    2 |    2 |
|  3 |    3 |    3 |
|  4 |    4 |    4 |
|  5 |    5 |    5 |
+----+------+------+
5 rows in set (0.00 sec)

mysql> ALTER TABLE t1 DROP COLUMN col1;
Query OK, 0 rows affected (0.27 sec)

mysql> SELECT * FROM t1;
+----+------+
| id | col2 |
+----+------+
|  1 |    1 |
|  2 |    2 |
|  3 |    3 |
|  4 |    4 |
|  5 |    5 |
+----+------+
5 rows in set (0.00 sec)
```

MySQL compatibility

- Dropping primary key columns or columns covered by the composite index is not supported.

See also

- ADD COLUMN
- SHOW CREATE TABLE
- CREATE TABLE

14.13.2.19.8 DROP INDEX

This statement removes an index from a specified table, marking space as free in TiKV.

Synopsis

```
DropIndexStmt ::=
    "DROP" "INDEX" IfExists Identifier "ON" TableName
        ↪ IndexLockAndAlgorithmOpt

IfExists ::=
    ( 'IF' 'EXISTS' )?

IndexLockAndAlgorithmOpt ::=
    ( LockClause AlgorithmClause? | AlgorithmClause LockClause? )?
```

Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.10 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
| id                    | estRows | task      | access object | operator info
    ↪            |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪

    ↪           |
| └─Selection_6         | 10.00   | cop[tikv] |               | eq(test.t1.c1,
    ↪ 3)          |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t1 | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+---------------+----------------
    ↪
3 rows in set (0.00 sec)

mysql> CREATE INDEX c1 ON t1 (c1);
```

```
Query OK, 0 rows affected (0.30 sec)

mysql> EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
+--
    ↪ ---------------------+---------+----------+-----------------------+---------
    ↪
| id                    | estRows | task     | access object         | operator
    ↪ info                           |
+--
    ↪ ---------------------+---------+----------+-----------------------+---------
    ↪
| IndexReader_6         | 0.01    | root     |                       | index:
    ↪ IndexRangeScan_5                 |
|  ─IndexRangeScan_5    | 0.01    | cop[tikv] | table:t1, index:c1(c1) | range
    ↪ :[3,3], keep order:false, stats:pseudo |
+--
    ↪ ---------------------+---------+----------+-----------------------+---------
    ↪
2 rows in set (0.00 sec)

mysql> DROP INDEX c1 ON t1;
Query OK, 0 rows affected (0.30 sec)
```

MySQL compatibility

- Dropping the primary key of the `CLUSTERED` type is not supported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

- SHOW INDEXES
- CREATE INDEX
- ADD INDEX
- RENAME INDEX
- ALTER INDEX

14.13.2.19.9 MODIFY COLUMN

The `ALTER TABLE.. MODIFY COLUMN` statement modifies a column on an existing table. The modification can include changing the data type and attributes. To rename at the same time, use the `CHANGE COLUMN` statement instead.

Since v5.1.0, TiDB has supported changes of data types for Reorg data, including but not limited to:

- Changing `VARCHAR` to `BIGINT`
- Modifying the `DECIMAL` precision
- Compressing the length of `VARCHAR(10)` to `VARCHAR(5)`

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName ModifyColumnSpec ( ','
           ↪ ModifyColumnSpec )*

ModifyColumnSpec
        ::= 'MODIFY' ColumnKeywordOpt 'IF EXISTS' ColumnName ColumnType
           ↪ ColumnOption* ( 'FIRST' | 'AFTER' ColumnName )?

ColumnType
        ::= NumericType
          | StringType
          | DateAndTimeType
          | 'SERIAL'

ColumnOption
        ::= 'NOT'? 'NULL'
          | 'AUTO_INCREMENT'
          | 'PRIMARY'? 'KEY' ( 'CLUSTERED' | 'NONCLUSTERED' )?
          | 'UNIQUE' 'KEY'?
          | 'DEFAULT' ( NowSymOptionFraction | SignedLiteral |
             ↪ NextValueForSequence )
          | 'SERIAL' 'DEFAULT' 'VALUE'
          | 'ON' 'UPDATE' NowSymOptionFraction
          | 'COMMENT' stringLit
          | ( 'CONSTRAINT' Identifier? )? 'CHECK' '(' Expression ')' ( 'NOT
             ↪ '? ( 'ENFORCED' | 'NULL' ) )?
          | 'GENERATED' 'ALWAYS' 'AS' '(' Expression ')' ( 'VIRTUAL' | '
             ↪ STORED' )?
          | 'REFERENCES' TableName ( '(' IndexPartSpecificationList ')' )?
             ↪ Match? OnDeleteUpdateOpt
          | 'COLLATE' CollationName
          | 'COLUMN_FORMAT' ColumnFormat
          | 'STORAGE' StorageMedia
          | 'AUTO_RANDOM' ( '(' LengthNum ')' )?

ColumnName ::=
    Identifier ( '.' Identifier ( '.' Identifier )? )?
```

Examples

Meta-Only Change

```
CREATE TABLE t1 (id int not null primary key AUTO_INCREMENT, col1 INT);
```

```
Query OK, 0 rows affected (0.11 sec)
```

```
INSERT INTO t1 (col1) VALUES (1),(2),(3),(4),(5);
```

```
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

```
ALTER TABLE t1 MODIFY col1 BIGINT;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
SHOW CREATE TABLE t1\G
```

```
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int NOT NULL AUTO_INCREMENT,
  `col1` bigint DEFAULT NULL,
  PRIMARY KEY (`id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =30001
1 row in set (0.00 sec)
```

Reorg-Data Change

```
CREATE TABLE t1 (id int not null primary key AUTO_INCREMENT, col1 INT);
```

```
Query OK, 0 rows affected (0.11 sec)
```

```
INSERT INTO t1 (col1) VALUES (12345),(67890);
```

```
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
ALTER TABLE t1 MODIFY col1 VARCHAR(5);
```

```
Query OK, 0 rows affected (2.52 sec)
```

```
SHOW CREATE TABLE t1\G
```

```
*************************** 1. row ***************************
       Table: t1
CREATE TABLE `t1` (
  `id` int NOT NULL AUTO_INCREMENT,
  `col1` varchar(5) DEFAULT NULL,
  PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =30001
1 row in set (0.00 sec)
```

Note:

- TiDB returns an error when the changed data type conflicts with an existing data row. In the above example, TiDB returns the following error:

```
alter table t1 modify column col1 varchar(4); ERROR 1406
↪ (22001): Data Too Long, field len 4, data len 5
```

- Due to the compatibility with the Async Commit feature, the DDL statement waits for a period of time (about 2.5s) before starting to process into Reorg Data.

```
Query OK, 0 rows affected (2.52 sec)
```

MySQL compatibility

- Does not support modifying the Reorg-Data types on the primary key columns but supports modifying the Meta-Only types. For example:

```
CREATE TABLE t (a int primary key);
ALTER TABLE t MODIFY COLUMN a VARCHAR(10);
ERROR 8200 (HY000): Unsupported modify column: column has primary key
    ↪ flag
```

```
CREATE TABLE t (a int primary key);
ALTER TABLE t MODIFY COLUMN a int UNSIGNED;
ERROR 8200 (HY000): Unsupported modify column: column has primary key
    ↪ flag
```

```
CREATE TABLE t (a int primary key);
ALTER TABLE t MODIFY COLUMN a bigint;
Query OK, 0 rows affected (0.01 sec)
```

- Does not support modifying the column types on generated columns. For example:

```
CREATE TABLE t (a INT, b INT as (a+1));
ALTER TABLE t MODIFY COLUMN b VARCHAR(10);
ERROR 8200 (HY000): Unsupported modify column: column is generated
```

- Does not support modifying the column types on the partitioned tables. For example:

```
CREATE TABLE t (c1 INT, c2 INT, c3 INT) partition by range columns(c1)
    ↪  ( partition p0 values less than (10), partition p1 values less
    ↪ than (maxvalue));
ALTER TABLE t MODIFY COLUMN c1 DATETIME;
ERROR 8200 (HY000): Unsupported modify column: table is partition
    ↪ table
```

- Does not support modifying from some data types (for example, some TIME types, BIT, SET, ENUM, JSON) to some other types due to some compatibility issues of the `cast` function's behavior between TiDB and MySQL.

```
CREATE TABLE t (a DECIMAL(13, 7));
ALTER TABLE t MODIFY COLUMN a DATETIME;
ERROR 8200 (HY000): Unsupported modify column: change from original
    ↪ type decimal(13,7) to datetime is currently unsupported yet
```

See also

- CREATE TABLE
- SHOW CREATE TABLE
- ADD COLUMN
- DROP COLUMN
- CHANGE COLUMN

14.13.2.19.10 RENAME INDEX

The statement `ALTER TABLE .. RENAME INDEX` renames an existing index to a new name. This operation is instant in TiDB, and requires only a meta data change.

Synopsis

```
AlterTableStmt
        ::= 'ALTER' 'IGNORE'? 'TABLE' TableName RenameIndexSpec ( ','
           ↪ RenameIndexSpec )*

RenameIndexSpec
        ::= 'RENAME' ( 'KEY' | 'INDEX' ) Identifier 'TO' Identifier
```

Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
   ↪ NOT NULL, INDEX col1 (c1));
Query OK, 0 rows affected (0.11 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int NOT NULL AUTO_INCREMENT,
  `c1` int NOT NULL,
  PRIMARY KEY (`id`),
  KEY `col1` (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)

mysql> ALTER TABLE t1 RENAME INDEX col1 TO c1;
Query OK, 0 rows affected (0.09 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int NOT NULL AUTO_INCREMENT,
  `c1` int NOT NULL,
  PRIMARY KEY (`id`),
  KEY `c1` (`c1`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)
```

MySQL compatibility

The `RENAME INDEX` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

- SHOW CREATE TABLE

- CREATE INDEX
- DROP INDEX
- SHOW INDEXES
- ALTER INDEX

14.13.2.20 ALTER USER

This statement changes an existing user inside the TiDB privilege system. In the MySQL privilege system, a user is the combination of a username and the host from which they are connecting from. Thus, it is possible to create a user `'newuser2'@'192.168.1.1'` who is only able to connect from the IP address `192.168.1.1`. It is also possible to have two users have the same user-portion, and different permissions as they login from different hosts.

14.13.2.20.1 Synopsis

```
AlterUserStmt ::=
    'ALTER' 'USER' IfExists (UserSpecList RequireClauseOpt ConnectionOptions
       ↪  PasswordOption LockOption AttributeOption | 'USER' '(' ')' '
       ↪ IDENTIFIED' 'BY' AuthString) ResourceGroupNameOption

UserSpecList ::=
    UserSpec ( ',' UserSpec )*

UserSpec ::=
    Username AuthOption

RequireClauseOpt ::=
    ( 'REQUIRE' 'NONE' | 'REQUIRE' 'SSL' | 'REQUIRE' 'X509' | 'REQUIRE'
       ↪ RequireList )?

RequireList ::=
    ( "ISSUER" stringLit | "SUBJECT" stringLit | "CIPHER" stringLit | "SAN"
       ↪ stringLit | "TOKEN_ISSUER" stringLit )*

Username ::=
    StringName ('@' StringName | singleAtIdentifier)? | 'CURRENT_USER'
       ↪ OptionalBraces

AuthOption ::=
    ( 'IDENTIFIED' ( 'BY' ( AuthString | 'PASSWORD' HashString ) | 'WITH'
       ↪ StringName ( 'BY' AuthString | 'AS' HashString )? ) )?

PasswordOption ::= ( 'PASSWORD' 'EXPIRE' ( 'DEFAULT' | 'NEVER' | 'INTERVAL'
    ↪ N 'DAY' )? | 'PASSWORD' 'HISTORY' ( 'DEFAULT' | N ) | 'PASSWORD' '
    ↪ REUSE' 'INTERVAL' ( 'DEFAULT' | N 'DAY' ) | 'FAILED_LOGIN_ATTEMPTS' N
```

```
    ↪  | 'PASSWORD_LOCK_TIME' ( N | 'UNBOUNDED' ) )*

LockOption ::= ( 'ACCOUNT' 'LOCK' | 'ACCOUNT' 'UNLOCK' )?

AttributeOption ::= ( 'COMMENT' CommentString | 'ATTRIBUTE' AttributeString
    ↪ )?

ResourceGroupNameOption::= ( 'RESOURCE' 'GROUP' Identifier)?

RequireClauseOpt ::= ('REQUIRE' ('NONE' | 'SSL' | 'X509' |
    ↪ RequireListElement ('AND'? RequireListElement)*))?

RequireListElement ::= 'ISSUER' Issuer | 'SUBJECT' Subject | 'CIPHER' Cipher
    ↪  | 'SAN' SAN | 'TOKEN_ISSUER' TokenIssuer
```

14.13.2.20.2 Examples

```
mysql> CREATE USER 'newuser' IDENTIFIED BY 'newuserpassword';
Query OK, 1 row affected (0.01 sec)

mysql> SHOW CREATE USER 'newuser';
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER for newuser@%
    ↪
    ↪ |
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER 'newuser'@'%' IDENTIFIED WITH 'mysql_native_password' AS '
    ↪ *5806E04BBEE79E1899964C6A04D68BCA69B1A879' REQUIRE NONE PASSWORD
    ↪ EXPIRE DEFAULT ACCOUNT UNLOCK |
+--
    ↪ ------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Modify basic user information

Change the password for user `newuser`:

```
mysql> ALTER USER 'newuser' IDENTIFIED BY 'newnewpassword';
Query OK, 0 rows affected (0.02 sec)
```

```
mysql> SHOW CREATE USER 'newuser';
+-----------------------------------------------------------------------------------------
   ↪
| CREATE USER for newuser@%
   ↪
   ↪ |
+-----------------------------------------------------------------------------------------
   ↪
| CREATE USER 'newuser'@'%' IDENTIFIED WITH 'mysql_native_password' AS '*
   ↪ FB8A1EA1353E8775CA836233E367FBDFCB37BE73' REQUIRE NONE PASSWORD
   ↪ EXPIRE DEFAULT ACCOUNT UNLOCK |
+-----------------------------------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

Lock the user `newuser`:

```
ALTER USER 'newuser' ACCOUNT LOCK;
```

```
Query OK, 0 rows affected (0.02 sec)
```

Modify the attributes of `newuser`:

```
ALTER USER 'newuser' ATTRIBUTE '{"newAttr": "value", "deprecatedAttr": null
   ↪ }';
SELECT * FROM information_schema.user_attributes;
```

```
+----------+------+-------------------------+
| USER     | HOST | ATTRIBUTE               |
+----------+------+-------------------------+
| newuser  | %    | {"newAttr": "value"}  |
+----------+------+-------------------------+
1 rows in set (0.00 sec)
```

Modify the comment of `newuser` using `ALTER USER ... COMMENT`:

```
ALTER USER 'newuser' COMMENT 'Here is the comment';
SELECT * FROM information_schema.user_attributes;
```

```
+--
   ↪ ---------+------+-----------------------------------------------------------+
   ↪
| USER     | HOST | ATTRIBUTE                                                 |
+--
   ↪ ---------+------+-----------------------------------------------------------+
   ↪
```

```
| newuser  | %    | {"comment": "Here is the comment", "newAttr": "value"} |
+--
    ↪ ---------+------+--------------------------------------------------------+
    ↪
1 rows in set (0.00 sec)
```

Remove the comment of `newuser` using `ALTER USER ... ATTRIBUTE`:

```
ALTER USER 'newuser' ATTRIBUTE '{"comment": null}';
SELECT * FROM information_schema.user_attributes;
```

```
+-----------+------+---------------------------+
| USER      | HOST | ATTRIBUTE                 |
+-----------+------+---------------------------+
| newuser  | %    | {"newAttr": "value"}   |
+-----------+------+---------------------------+
1 rows in set (0.00 sec)
```

Change the automatic password expiration policy for `newuser` to never expire via `ALTER USER ... PASSWORD EXPIRE NEVER`:

```
ALTER USER 'newuser' PASSWORD EXPIRE NEVER;
```

```
Query OK, 0 rows affected (0.02 sec)
```

Modify the password reuse policy for `newuser` to disallow the reuse of any password used within the last 90 days using `ALTER USER ... PASSWORD REUSE INTERVAL ... DAY`:

```
ALTER USER 'newuser' PASSWORD REUSE INTERVAL 90 DAY;
```

```
Query OK, 0 rows affected (0.02 sec)
```

Modify the resource group bound to the user

Use `ALTER USER ... RESOURCE GROUP` to modify the resource group of the user `newuser` to `rg1`.

```
ALTER USER 'newuser' RESOURCE GROUP rg1;
```

```
Query OK, 0 rows affected (0.02 sec)
```

View the resource group bound to the current user:

```
SELECT USER, JSON_EXTRACT(User_attributes, "$.resource_group") FROM mysql.
    ↪ user WHERE user = "newuser";
```

```
+---------+-----------------------------------------------------+
| USER    | JSON_EXTRACT(User_attributes, "$.resource_group") |
+---------+-----------------------------------------------------+
| newuser | "rg1"                                               |
+---------+-----------------------------------------------------+
1 row in set (0.02 sec)
```

Unbind the user to a resource group, that is, bind the user to the `default` resource group.

```
ALTER USER 'newuser' RESOURCE GROUP `default`;
SELECT USER, JSON_EXTRACT(User_attributes, "$.resource_group") FROM mysql.
    ↪ user WHERE user = "newuser";
```

```
+---------+-----------------------------------------------------+
| USER    | JSON_EXTRACT(User_attributes, "$.resource_group") |
+---------+-----------------------------------------------------+
| newuser | "default"                                           |
+---------+-----------------------------------------------------+
1 row in set (0.02 sec)
```

14.13.2.21 ANALYZE

This statement updates the statistics that TiDB builds on tables and indexes. It is recommended to run `ANALYZE` after performing a large batch update or import of records, or when you notice that query execution plans are sub-optimal.

TiDB will also automatically update its statistics over time as it discovers that they are inconsistent with its own estimates.

Currently, TiDB collects statistical information as a full collection by using the `ANALYZE TABLE` statement. For more information, see Introduction to statistics.

14.13.2.21.1 Synopsis

```
AnalyzeTableStmt ::=
    'ANALYZE' ( 'TABLE' ( TableNameList ( 'ALL COLUMNS' | 'PREDICATE COLUMNS
       ↪ ' ) | TableName ( 'INDEX' IndexNameList? | AnalyzeColumnOption | '
       ↪ PARTITION' PartitionNameList ( 'INDEX' IndexNameList? |
       ↪ AnalyzeColumnOption )? )? ) ) AnalyzeOptionListOpt

AnalyzeOptionListOpt ::=
( WITH AnalyzeOptionList )?

AnalyzeOptionList ::=
AnalyzeOption ( ',' AnalyzeOption )*

AnalyzeOption ::=
( NUM ( 'BUCKETS' | 'TOPN' | ( 'CMSKETCH' ( 'DEPTH' | 'WIDTH' ) ) | 'SAMPLES
    ↪ ' ) ) | ( FLOATNUM 'SAMPLERATE' )

AnalyzeColumnOption ::=
( 'ALL COLUMNS' | 'PREDICATE COLUMNS' | 'COLUMNS' ColumnNameList )

TableNameList ::=
    TableName (',' TableName)*

TableName ::=
    Identifier ( '.' Identifier )?

ColumnNameList ::=
    Identifier ( ',' Identifier )*

IndexNameList ::=
    Identifier ( ',' Identifier )*

PartitionNameList ::=
    Identifier ( ',' Identifier )*
```

14.13.2.21.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)
```

```
mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

```
mysql> ALTER TABLE t1 ADD INDEX (c1);
Query OK, 0 rows affected (0.30 sec)
```

```
mysql> EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
| id                    | estRows | task     | access object         | operator
   ↪ info                            |
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
| IndexReader_6         | 10.00   | root     |                       | index:
   ↪ IndexRangeScan_5                |
| └─IndexRangeScan_5    | 10.00   | cop[tikv] | table:t1, index:c1(c1) | range
   ↪ :[3,3], keep order:false, stats:pseudo |
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
2 rows in set (0.00 sec)
```

The status of the current statistics is pseudo, which means the statistics is inaccurate.

```
mysql> ANALYZE TABLE t1;
Query OK, 0 rows affected (0.13 sec)

mysql> EXPLAIN SELECT * FROM t1 WHERE c1 = 3;
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
| id                    | estRows | task     | access object         | operator
   ↪ info              |
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
| IndexReader_6         | 1.00    | root     |                       | index:
   ↪ IndexRangeScan_5    |
| └─IndexRangeScan_5    | 1.00    | cop[tikv] | table:t1, index:c1(c1) | range
   ↪ :[3,3], keep order:false |
+--
   ↪ --------------------+---------+----------+-----------------------+----------
   ↪
2 rows in set (0.00 sec)
```

The statistics is now correctly updated and loaded.

14.13.2.21.3 MySQL compatibility

TiDB differs from MySQL in **both** the statistics it collects and how it makes use of statistics during query execution. While this statement is syntactically similar to MySQL, the following differences apply:

- TiDB might not include very recently committed changes when running `ANALYZE TABLE`. After a batch update of rows, you might need to `sleep(1)` before executing `ANALYZE TABLE` in order for the statistics update to reflect these changes. See #16570.
- `ANALYZE TABLE` takes significantly longer to execute in TiDB than MySQL.

14.13.2.21.4 See also

- EXPLAIN
- EXPLAIN ANALYZE

14.13.2.22 BACKUP

This statement is used to perform a distributed backup of the TiDB cluster.

> - This feature is not available on TiDB Cloud Serverless clusters.

The `BACKUP` statement uses the same engine as the BR tool does, except that the backup process is driven by TiDB itself rather than a separate BR tool. All benefits and warnings of BR also apply to this statement.

Executing `BACKUP` requires either the `BACKUP_ADMIN` or `SUPER` privilege. Additionally, both the TiDB node executing the backup and all TiKV nodes in the cluster must have read or write permission to the destination. Local storage (storage paths starting with `local://`) is not permitted when Security Enhanced Mode is enabled.

The `BACKUP` statement is blocked until the entire backup task is finished, failed, or canceled. A long-lasting connection should be prepared for executing `BACKUP`. The task can be canceled using the `KILL TIDB QUERY` statement.

Only one `BACKUP` and `RESTORE` task can be executed at a time. If a `BACKUP` or `RESTORE` statement is already being executed on the same TiDB server, the new `BACKUP` execution will wait until all previous tasks are finished.

`BACKUP` can only be used with "tikv" storage engine. Using `BACKUP` with the "unistore" engine will fail.

14.13.2.22.1 Synopsis

```
BackupStmt ::=
    "BACKUP" BRIETables "TO" stringLit BackupOption*

BRIETables ::=
    "DATABASE" ( '*' | DBName (',' DBName)* )
|   "TABLE" TableNameList

BackupOption ::=
    "CHECKSUM" '='? Boolean
|   "CHECKSUM_CONCURRENCY" '='? LengthNum
|   "COMPRESSION_LEVEL" '='? LengthNum
|   "COMPRESSION_TYPE" '='? stringLit
|   "CONCURRENCY" '='? LengthNum
|   "IGNORE_STATS" '='? Boolean
|   "LAST_BACKUP" '='? BackupTSO
|   "RATE_LIMIT" '='? LengthNum "MB" '/' "SECOND"
|   "SEND_CREDENTIALS_TO_TIKV" '='? Boolean
|   "SNAPSHOT" '='? ( BackupTSO | LengthNum TimestampUnit "AGO" )

Boolean ::=
    NUM | "TRUE" | "FALSE"

BackupTSO ::=
    LengthNum | stringLit
```

14.13.2.22.2 Examples

Back up databases

```
BACKUP DATABASE `test` TO 'local:///mnt/backup/2020/04/';
```

```
+--
    ↪ ----------------------------+----------+----------------+--------------------
    ↪
| Destination                | Size     | BackupTS       | Queue Time         |
    ↪ Execution Time    |
+--
    ↪ ----------------------------+----------+----------------+--------------------
    ↪
```

```
| local:///mnt/backup/2020/04/ | 248665063 | 416099531454472 | 2020-04-12
    ↪ 23:09:48 | 2020-04-12 23:09:48 |
+--
    ↪ ----------------------------+----------+----------------+--------------------
    ↪
1 row in set (58.453 sec)
```

In the example above, the `test` database is backed up into the local filesystem. The data is saved as SST files in the `/mnt/backup/2020/04/` directories distributed among all TiDB and TiKV nodes.

The first row of the result above is described as follows:

Column	Description
`Destination` ↪	The destination URL
`Size`	The total size of the backup archive, in bytes
`BackupTS`	The TSO of the snapshot when the backup is created (useful for incremental backup)
`Queue` ↪ `Time`	The timestamp (in current time zone) when the `BACKUP` task is queued.

Column	Description
`Execution Time`	The timestamp (in current time zone) when the `BACKUP` task starts to run.

Back up tables

```
BACKUP TABLE `test`.`sbtest01` TO 'local:///mnt/backup/sbtest01/';
```

```
BACKUP TABLE sbtest02, sbtest03, sbtest04 TO 'local:///mnt/backup/sbtest/';
```

Back up the entire cluster

```
BACKUP DATABASE * TO 'local:///mnt/backup/full/';
```

Note that the system tables (`mysql.*`, `INFORMATION_SCHEMA.*`, `PERFORMANCE_SCHEMA.*`, …) will not be included into the backup.

External storages

BR supports backing up data to S3 or GCS:

```
BACKUP DATABASE `test` TO 's3://example-bucket-2020/backup-05/?access-key={YOUR_ACCESS_KEY}&secret-access-key={YOUR_SECRET_KEY}';
```

The URL syntax is further explained in URI Formats of External Storage Services.

When running on cloud environment where credentials should not be distributed, set the `SEND_CREDENTIALS_TO_TIKV` option to `FALSE`:

```
BACKUP DATABASE `test` TO 's3://example-bucket-2020/backup-05/'
    SEND_CREDENTIALS_TO_TIKV = FALSE;
```

Performance fine-tuning

Use `RATE_LIMIT` to limit the average upload speed per TiKV node to reduce network bandwidth.

Before the backup is completed, `BACKUP` would perform a checksum against the data on the cluster to verify correctness by default. The default concurrency for checksum tasks on a single table is 4, which you can adjust using the `CHECKSUM_CONCURRENCY` parameter. If you are confident that the data verification is unnecessary, you can disable the check by setting the `CHECKSUM` parameter to `FALSE`.

To specify the number of concurrent tasks that BR can execute for backing up tables and indices, use the `CONCURRENCY` parameter. This parameter controls the thread pool size within BR, optimizing the performance and efficiency of backup operations.

One task represents one table range or one index range, according to the backup schemas. For one table with one index, two tasks are used to back up this table. The default value of `CONCURRENCY` is `4`. If you need to back up lots of tables or indices, increase its value.

Statistics are not backed up by default. To back up statistics, you need to set the `IGNORE_STATS` parameter to `FALSE`.

By default, the SST files generated by backup use the `zstd` compression algorithm. If needed, you can specify a different compression algorithm using the `COMPRESSION_TYPE` parameter. Supported algorithms include `lz4`, `zstd`, and `snappy`. You can also adjust the compression level with the `COMPRESSION_LEVEL` parameter; the higher the level number, the higher the compression ratio, but the higher the CPU consumption.

```
BACKUP DATABASE `test` TO 's3://example-bucket-2020/backup-06/'
    RATE_LIMIT = 120 MB/SECOND
    CONCURRENCY = 8
    CHECKSUM = FALSE;
```

Snapshot

Specify a timestamp, TSO or relative time to backup historical data.

```
-- relative time
BACKUP DATABASE `test` TO 'local:///mnt/backup/hist01'
    SNAPSHOT = 36 HOUR AGO;

-- timestamp (in current time zone)
BACKUP DATABASE `test` TO 'local:///mnt/backup/hist02'
    SNAPSHOT = '2020-04-01 12:00:00';

-- timestamp oracle
BACKUP DATABASE `test` TO 'local:///mnt/backup/hist03'
    SNAPSHOT = 415685305958400;
```

The supported units for relative time are:

- MICROSECOND
- SECOND
- MINUTE
- HOUR
- DAY
- WEEK

Note that, following SQL standard, the units are always singular.

Incremental backup

Supply the `LAST_BACKUP` option to only backup the changes between the last backup to the current snapshot.

```
-- timestamp (in current time zone)
BACKUP DATABASE `test` TO 'local:///mnt/backup/hist02'
    LAST_BACKUP = '2020-04-01 12:00:00';

-- timestamp oracle
BACKUP DATABASE `test` TO 'local:///mnt/backup/hist03'
    LAST_BACKUP = 415685305958400;
```

14.13.2.22.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.22.4 See also

- RESTORE
- SHOW BACKUPS

14.13.2.23 BATCH

The `BATCH` syntax splits a DML statement into multiple statements in TiDB for execution. This means that there are **no guarantees** of transactional atomicity and isolation. Therefore, it is a "non-transactional" statement.

Currently, `INSERT`, `REPLACE`, `UPDATE`, and `DELETE` are supported in `BATCH`.

Based on a column, the `BATCH` syntax divides a DML statement into multiple ranges of scope for execution. In each range, a single SQL statement is executed.

For details about the usage and restrictions, see Non-transactional DML statements.

When you use multi-table join in a `BATCH` statement, you need to specify the full path of the column to avoid ambiguity:

```
BATCH ON test.t2.id LIMIT 1 INSERT INTO t SELECT t2.id, t2.v, t3.v FROM t2
    ↪ JOIN t3 ON t2.k = t3.k;
```

The preceding statement specifies the column to be split as `test.t2.id`, which is unambiguous. If you use the `id` as follows, an error is reported:

```
BATCH ON id LIMIT 1 INSERT INTO t SELECT t2.id, t2.v, t3.v FROM t2 JOIN t3
    ↪ ON t2.k = t3.k;

Non-transactional DML, shard column must be fully specified
```

14.13.2.23.1 Synopsis

```
NonTransactionalDMLStmt ::=
    'BATCH' ( 'ON' ColumnName )? 'LIMIT' NUM DryRunOptions? ShardableStmt

DryRunOptions ::=
    'DRY' 'RUN' 'QUERY'?

ShardableStmt ::=
    DeleteFromStmt
|   UpdateStmt
|   InsertIntoStmt
|   ReplaceIntoStmt
```

14.13.2.23.2 MySQL compatibility

The `BATCH` syntax is TiDB-specific and not compatible with MySQL.

14.13.2.23.3 See also

- Non-transactional DML statements

14.13.2.24 BEGIN

This statement starts a new transaction inside of TiDB. It is similar to the statements `START TRANSACTION` and `SET autocommit=0`.

In the absence of a `BEGIN` statement, every statement will by default autocommit in its own transaction. This behavior ensures MySQL compatibility.

14.13.2.24.1 Synopsis

```
BeginTransactionStmt ::=
    'BEGIN' ( 'PESSIMISTIC' | 'OPTIMISTIC' )?
|   'START' 'TRANSACTION' ( 'READ' ( 'WRITE' | 'ONLY' ( 'WITH' 'TIMESTAMP' '
    ↪ BOUND' TimestampBound )? ) | 'WITH' 'CONSISTENT' 'SNAPSHOT' )?
```

14.13.2.24.2 Examples

```
mysql> CREATE TABLE t1 (a int NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.12 sec)

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT;
Query OK, 0 rows affected (0.01 sec)
```

14.13.2.24.3 MySQL compatibility

TiDB supports the syntax extension of `BEGIN PESSIMISTIC` or `BEGIN OPTIMISTIC`. This enables you to override the default transactional model for your transaction.

14.13.2.24.4 See also

- COMMIT
- ROLLBACK
- START TRANSACTION
- TiDB optimistic transaction model
- TiDB pessimistic transaction mode

14.13.2.25 `CALIBRATE RESOURCE`

The `CALIBRATE RESOURCE` statement is used to estimate and output the 'Request Unit (RU)' capacity of the current cluster.

> **Note:**
>
> This feature is only applicable to TiDB Self-Managed and not available on TiDB Cloud.

14.13.2.25.1 Synopsis

```
CalibrateResourceStmt ::= 'CALIBRATE' 'RESOURCE' WorkloadOption

WorkloadOption ::=
( 'WORKLOAD' ('TPCC' | 'OLTP_READ_WRITE' | 'OLTP_READ_ONLY' | 'OLTP_WRITE_
   ↪ ONLY') )
| ( 'START_TIME' 'TIMESTAMP' ('DURATION' stringLit | 'END_TIME' 'TIMESTAMP')
   ↪ ?)?
```

14.13.2.25.2 Privileges

To execute this command, make sure that the following requirements are met:

- You have enabled `tidb_enable_resource_control`.
- The user has `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.
- To estimate capacity based on actual workload, the user must have the `SELECT` privilege for all tables in the `METRICS_SCHEMA` schema.

14.13.2.25.3 Methods for estimating capacity

TiDB provides two methods for estimation:

Estimate capacity based on actual workload

If your application is already running in a production environment, or you can run actual business tests, it is recommended to use the actual workload over a period of time to estimate the total capacity. To improve the accuracy of the estimation, observe the following constraints:

- Use the `START_TIME` parameter to specify the time point at which the estimation starts, in the format of `2006-01-02 15:04:05`. The default estimation end time is the current time.
- After specifying the `START_TIME` parameter, you can use the `END_TIME` parameter to specify the estimation end time, or use the `DURATION` parameter to specify the estimation time window from `START_TIME`.
- The time window ranges from 10 minutes to 24 hours.
- In the specified time window, if the CPU utilization of TiDB and TiKV is too low, you cannot estimate the capacity.

> **Note:**
>
> TiKV does not monitor CPU usage metrics on macOS. It does not support capacity estimation based on the actual workload on macOS.

Estimate capacity based on hardware deployment

This method mainly estimates capacity based on the current cluster configuration, combined with the empirical values observed for different workloads. Because different types of workloads require different ratios of hardware, the output capacity of the same configuration of hardware might be different. The `WORKLOAD` parameter here accepts the following different workload types. The default value is `TPCC`.

- `TPCC`: applies to workloads with heavy data write. It is estimated based on a workload model similar to `TPC-C`.

- `OLTP_WRITE_ONLY`: applies to workloads with heavy data write. It is estimated based on a workload model similar to `sysbench oltp_write_only`.
- `OLTP_READ_WRITE`: applies to workloads with even data read and write. It is estimated based on a workload model similar to `sysbench oltp_read_write`.
- `OLTP_READ_ONLY`: applies to workloads with heavy data read. It is estimated based on a workload model similar to `sysbench oltp_read_only`.
- `TPCH_10`: applies to AP queries. It is estimated based on 22 queries from `TPCH-10G`.

> **Note:**
>
> The RU capacity of a cluster varies with the topology of the cluster and the hardware and software configuration of each component. The actual RU that each cluster can provide is also related to the actual workload. The estimated value based on hardware deployment is for reference only and might differ from the actual maximum value. It is recommended to estimate capacity based on actual workload.

14.13.2.25.4 Examples

Specify the start time `START_TIME` and the time window `DURATION` to view the RU capacity according to the actual workload.

```
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' DURATION '20m';
+-------+
| QUOTA |
+-------+
| 27969 |
+-------+
1 row in set (0.01 sec)
```

Specify the start time `START_TIME` and the end time `END_TIME` to view the RU capacity according to the actual workload.

```
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' END_TIME '2023-04-18
    ↪ 08:20:00';
+-------+
| QUOTA |
+-------+
| 27969 |
+-------+
1 row in set (0.01 sec)
```

When the time window range `DURATION` does not fall between 10 minutes and 24 hours, an error occurs.

```
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' DURATION '25h';
ERROR 1105 (HY000): the duration of calibration is too long, which could
    ↪ lead to inaccurate output. Please make the duration between 10m0s and
    ↪  24h0m0s
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' DURATION '9m';
ERROR 1105 (HY000): the duration of calibration is too short, which could
    ↪ lead to inaccurate output. Please make the duration between 10m0s and
    ↪  24h0m0s
```

The monitoring metrics for the capacity estimation based on the actual workload feature include `tikv_cpu_quota`, `tidb_server_maxprocs`, `resource_manager_resource_unit`, `process_cpu_usage`, `tiflash_cpu_quota`, `tiflash_resource_manager_resource_unit`, and `tiflash_process_cpu_usage`. If the CPU quota monitoring data is empty, there will be an error with the corresponding monitoring metric name, as shown in the following example:

```
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' DURATION '60m';
Error 1105 (HY000): There is no CPU quota metrics, metrics 'tikv_cpu_quota'
    ↪  is empty
```

If the workload in the time window is too low, or the `resource_manager_resource_unit` and `process_cpu_usage` monitoring data is missing, the following error will be reported. In addition, because TiKV does not monitor CPU utilization on macOS, it does not support capacity estimation based on the actual workload, and will also report this error.

```
CALIBRATE RESOURCE START_TIME '2023-04-18 08:00:00' DURATION '60m';
ERROR 1105 (HY000): The workload in selected time window is too low, with
    ↪ which TiDB is unable to reach a capacity estimation; please select
    ↪ another time window with higher workload, or calibrate resource by
    ↪ hardware instead
```

Specify `WORKLOAD` to view the RU capacity. The default value is `TPCC`.

```
CALIBRATE RESOURCE;
+-------+
| QUOTA |
+-------+
| 190470 |
+-------+
1 row in set (0.01 sec)

CALIBRATE RESOURCE WORKLOAD OLTP_WRITE_ONLY;
+-------+
| QUOTA |
+-------+
| 27444 |
```

```
+-------+
1 row in set (0.01 sec)
```

14.13.2.26 CANCEL IMPORT

The `CANCEL IMPORT` statement is used to cancel a data import job created in TiDB.

14.13.2.26.1 Required privileges

To cancel a data import job, you need to be the creator of the import job or have the `SUPER` privilege.

14.13.2.26.2 Synopsis

```
CancelImportJobsStmt ::=
    'CANCEL' 'IMPORT' 'JOB' JobID
```

14.13.2.26.3 Example

To cancel an import job with the ID as `1`, execute the following statement:

```
CANCEL IMPORT JOB 1;
```

The output is as follows:

```
Query OK, 0 rows affected (0.01 sec)
```

14.13.2.26.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.26.5 See also

- `IMPORT INTO`
- `SHOW IMPORT JOB`

14.13.2.27 COMMIT

This statement commits a transaction inside of the TiDB server.

In the absence of a `BEGIN` or `START TRANSACTION` statement, the default behavior of TiDB is that every statement will be its own transaction and autocommit. This behavior ensures MySQL compatibility.

14.13.2.27.1 Synopsis

```
CommitStmt ::=
    'COMMIT' CompletionTypeWithinTransaction?

CompletionTypeWithinTransaction ::=
    'AND' ( 'CHAIN' ( 'NO' 'RELEASE' )? | 'NO' 'CHAIN' ( 'NO'? 'RELEASE' )?
       ↪ )
|   'NO'? 'RELEASE'
```

14.13.2.27.2 Examples

```
mysql> CREATE TABLE t1 (a int NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.12 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT;
Query OK, 0 rows affected (0.01 sec)
```

14.13.2.27.3 MySQL compatibility

- Currently, TiDB use Metadata Locking (MDL) to prevent DDL statements from modifying tables used by transactions by default. The behavior of metadata lock is different between TiDB and MySQL. For more details, see Metadata Lock.
- By default, TiDB 3.0.8 and later versions use Pessimistic Locking. When using Optimistic Locking, it is important to consider that a `COMMIT` statement might fail because rows have been modified by another transaction.
- When Optimistic Locking is enabled, `UNIQUE` and `PRIMARY KEY` constraint checks are deferred until statement commit. This results in additional situations where a `COMMIT` statement might fail. This behavior can be changed by setting `tidb_constraint_check_in_place=ON`.
- TiDB parses but ignores the syntax `ROLLBACK AND [NO] RELEASE`. This functionality is used in MySQL to disconnect the client session immediately after committing the transaction. In TiDB, it is recommended to instead use the `mysql_close()` functionality of your client driver.
- TiDB parses but ignores the syntax `ROLLBACK AND [NO] CHAIN`. This functionality is used in MySQL to immediately start a new transaction with the same isolation level while the current transaction is being committed. In TiDB, it is recommended to instead start a new transaction.

14.13.2.27.4 See also

- START TRANSACTION
- ROLLBACK
- BEGIN
- Lazy checking of constraints

14.13.2.28 CREATE [GLOBAL|SESSION] BINDING

This statement creates a new execution plan binding in TiDB. Binding can be used to inject a hint into a statement without requiring changes to the underlying query.

A `BINDING` can be on either a `GLOBAL` or `SESSION` basis. The default is `SESSION`.

The bound SQL statement is parameterized and stored in the system table. When a SQL query is processed, as long as the parameterized SQL statement and a bound one in the system table are consistent and the system variable `tidb_use_plan_baselines` is set to `ON` (default), the corresponding optimizer hint is available. If multiple execution plans are available, the optimizer chooses to bind the plan with the least cost. For more information, see Create a binding.

14.13.2.28.1 Synopsis

```
CreateBindingStmt ::=
    'CREATE' GlobalScope 'BINDING' ( 'FOR' BindableStmt 'USING' BindableStmt
|   'FROM' 'HISTORY' 'USING' 'PLAN' 'DIGEST' StringLiteralOrUserVariableList
    ↪  )

GlobalScope ::=
    ( 'GLOBAL' | 'SESSION' )?

BindableStmt ::=
    ( SelectStmt | UpdateStmt | InsertIntoStmt | ReplaceIntoStmt |
       ↪ DeleteStmt )

StringLiteralOrUserVariableList ::=
    ( StringLitOrUserVariable | StringLiteralOrUserVariableList ','
       ↪ StringLitOrUserVariable )

StringLiteralOrUserVariable ::=
    ( stringLiteral | UserVariable )
```

14.13.2.28.2 Examples

You can create a binding according to a SQL statement or a historical execution plan.

When you create a binding according to a historical execution plan, you need to specify the corresponding Plan Digest:

- You can use either the string literal or user variable of the string type to specify the Plan Digest.
- You can specify multiple Plan Digests to create bindings for multiple statements at the same time. In this case, you can specify multiple strings, and include multiple digests in each string. Note that the strings or digests need to be separated by commas.

The following example shows how to create a binding according to a SQL statement.

```
mysql> CREATE TABLE t1 (
    id INT NOT NULL PRIMARY KEY auto_increment,
    b INT NOT NULL,
    pad VARBINARY(255),
    INDEX(b)
   );
Query OK, 0 rows affected (0.07 sec)

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM dual;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 1 row affected (0.00 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 1000 rows affected (0.04 sec)
Records: 1000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (1.74 sec)
```

```
Records: 100000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (2.15 sec)
Records: 100000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (2.64 sec)
Records: 100000 Duplicates: 0 Warnings: 0

mysql> SELECT SLEEP(1);
+----------+
| SLEEP(1) |
+----------+
|        0 |
+----------+
1 row in set (1.00 sec)

mysql> ANALYZE TABLE t1;
Query OK, 0 rows affected (1.33 sec)

mysql> EXPLAIN ANALYZE SELECT * FROM t1 WHERE b = 123;

14.13.2.28.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.28.4 See also

- DROP [GLOBAL|SESSION] BINDING
- SHOW [GLOBAL|SESSION] BINDINGS
- ANALYZE TABLE
- Optimizer Hints
- SQL Plan Management

14.13.2.29 CREATE DATABASE

This statement creates a new database in TiDB. The MySQL terminology for 'database' most closely maps to a schema in the SQL standard.

14.13.2.29.1 Synopsis

```
CreateDatabaseStmt ::=
    'CREATE' 'DATABASE' IfNotExists DBName DatabaseOptionListOpt

IfNotExists ::=
    ( 'IF' 'NOT' 'EXISTS' )?

DBName ::=
    Identifier

DatabaseOptionListOpt ::=
    DatabaseOptionList?

DatabaseOptionList ::=
    DatabaseOption ( ','? DatabaseOption )*

DatabaseOption ::=
    DefaultKwdOpt ( CharsetKw '='? CharsetName | 'COLLATE' '='?
        ↪ CollationName | 'ENCRYPTION' '='? EncryptionOpt )
|   DefaultKwdOpt PlacementPolicyOption

PlacementPolicyOption ::=
    "PLACEMENT" "POLICY" EqOpt PolicyName
|   "PLACEMENT" "POLICY" (EqOpt | "SET") "DEFAULT"
```

14.13.2.29.2 Syntax

The `CREATE DATABASE` statement is used to create a database, and to specify the default properties of the database, such as the default character set and collation. `CREATE SCHEMA` is a synonym for `CREATE DATABASE`.

```
CREATE {DATABASE | SCHEMA} [IF NOT EXISTS] db_name
    [create_specification] ...

create_specification:
    [DEFAULT] CHARACTER SET [=] charset_name
  | [DEFAULT] COLLATE [=] collation_name
```

If you create an existing database and does not specify `IF NOT EXISTS`, an error is displayed.

The `create_specification` option is used to specify the specific `CHARACTER SET` and `COLLATE` in the database. Currently, TiDB only supports some of the character sets and collations. For details, see Character Set and Collation Support.

14.13.2.29.3 Examples

```
mysql> CREATE DATABASE mynewdatabase;
Query OK, 0 rows affected (0.09 sec)

mysql> USE mynewdatabase;
Database changed
mysql> CREATE TABLE t1 (a int);
Query OK, 0 rows affected (0.11 sec)

mysql> SHOW TABLES;
+------------------------+
| Tables_in_mynewdatabase |
+------------------------+
| t1                     |
+------------------------+
1 row in set (0.00 sec)
```

14.13.2.29.4 MySQL compatibility

The `CREATE DATABASE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.29.5 See also

- USE
- ALTER DATABASE
- DROP DATABASE
- SHOW DATABASES

14.13.2.30 CREATE INDEX

This statement adds a new index to an existing table. It is an alternative syntax to `ALTER TABLE .. ADD INDEX`, and included for MySQL compatibility.

14.13.2.30.1 Synopsis

```
CreateIndexStmt ::=
    'CREATE' IndexKeyTypeOpt 'INDEX' IfNotExists Identifier IndexTypeOpt 'ON
       ↪ ' TableName '(' IndexPartSpecificationList ')' IndexOptionList
       ↪ IndexLockAndAlgorithmOpt

IndexKeyTypeOpt ::=
    ( 'UNIQUE' | 'SPATIAL' | 'FULLTEXT' )?
```

```
IfNotExists ::=
    ( 'IF' 'NOT' 'EXISTS' )?

IndexTypeOpt ::=
    IndexType?

IndexPartSpecificationList ::=
    IndexPartSpecification ( ',' IndexPartSpecification )*

IndexOptionList ::=
    IndexOption*

IndexLockAndAlgorithmOpt ::=
    ( LockClause AlgorithmClause? | AlgorithmClause LockClause? )?

IndexType ::=
    ( 'USING' | 'TYPE' ) IndexTypeName

IndexPartSpecification ::=
    ( ColumnName OptFieldLen | '(' Expression ')' ) Order

IndexOption ::=
    'KEY_BLOCK_SIZE' '='? LengthNum
|   IndexType
|   'WITH' 'PARSER' Identifier
|   'COMMENT' stringLit
|   ("VISIBLE" | "INVISIBLE")
|   ("GLOBAL" | "LOCAL")

IndexTypeName ::=
    'BTREE'
|   'HASH'
|   'RTREE'

ColumnName ::=
    Identifier ( '.' Identifier ( '.' Identifier )? )?

OptFieldLen ::=
    FieldLen?

IndexNameList ::=
    ( Identifier | 'PRIMARY' )? ( ',' ( Identifier | 'PRIMARY' ) )*

KeyOrIndex ::=
    'Key' | 'Index'
```

2 rows in set (0.00 sec)

mysql> ALTER TABLE t1 DROP INDEX c1;
Query OK, 0 rows affected (0.30 sec)

mysql> CREATE UNIQUE INDEX c1 ON t1 (c1);
Query OK, 0 rows affected (0.31 sec)
```

14.13.2.30.3 Expression index

In some scenarios, the filtering condition of a query is based on a certain expression. In these scenarios, the query performance is relatively poor because ordinary indexes cannot take effect, the query can only be executed by scanning the entire table. The expression index is a type of special index that can be created on an expression. Once an expression index is created, TiDB can use the index for the expression-based query, which significantly improves the query performance.

For example, if you want to create an index based on `LOWER(col1)`, execute the following SQL statement:

```
CREATE INDEX idx1 ON t1 ((LOWER(col1)));
```

Or you can execute the following equivalent statement:

```
ALTER TABLE t1 ADD INDEX idx1((LOWER(col1)));
```

You can also specify the expression index when you create the table:

```
CREATE TABLE t1 (
    col1 CHAR(10),
    col2 CHAR(10),
    INDEX ((LOWER(col1)))
);
```

> **Note:**
>
> The expression in an expression index must be surrounded by `(` and `)`. Otherwise, a syntax error is reported.

You can drop an expression index in the same way as dropping an ordinary index:

```
DROP INDEX idx1 ON t1;
```

Expression index involves various kinds of expressions. To ensure correctness, only some fully tested functions are allowed for creating an expression index. This means that only these functions are allowed in expressions in a production environment. You can get these functions by querying the `tidb_allow_function_for_expression_index` variable. Currently, the allowed functions are as follows:

- `JSON_ARRAY()`
- `JSON_ARRAY_APPEND()`
- `JSON_ARRAY_INSERT()`
- `JSON_CONTAINS()`
- `JSON_CONTAINS_PATH()`
- `JSON_DEPTH()`
- `JSON_EXTRACT()`
- `JSON_INSERT()`
- `JSON_KEYS()`
- `JSON_LENGTH()`
- `JSON_MERGE_PATCH()`
- `JSON_MERGE_PRESERVE()`
- `JSON_OBJECT()`
- `JSON_PRETTY()`
- `JSON_QUOTE()`
- `JSON_REMOVE()`
- `JSON_REPLACE()`
- `JSON_SCHEMA_VALID()`
- `JSON_SEARCH()`
- `JSON_SET()`
- `JSON_STORAGE_SIZE()`
- `JSON_TYPE()`
- `JSON_UNQUOTE()`
- `JSON_VALID()`
- `LOWER()`
- `MD5()`
- `REVERSE()`
- `TIDB_SHARD()`
- `UPPER()`
- `VITESS_HASH()`

For the functions that are not included in the above list, those functions are not fully tested and not recommended for a production environment, which can be seen as experimental. Other expressions such as operators, `CAST`, and `CASE WHEN` are also seen as experimental and not recommended for production.

If you still want to use those expressions, you can make the following configuration in the TiDB configuration file:

```
allow-expression-index = true
```

Note:

An expression index cannot be created on a primary key.

The expression in an expression index cannot contain the following content:

- Volatile functions, such as `RAND()` and `NOW()`.
- System variables and user variables.
- Subqueries.
- `AUTO_INCREMENT` columns. You can remove this restriction by setting the value of `tidb_enable_auto_increment_in_generated` (system variable) to `true`.
- Window functions.
- ROW functions, such as `CREATE TABLE t (j JSON, INDEX k (((j,j) ↪ )));`.
- Aggregate functions.

An expression index implicitly takes up a name (for example, `_V$_{index ↪ _name}_{index_offset}`). If you try to create a new expression index with the name that a column has already had, an error occurs. In addition, if you add a new column with the same name, an error also occurs.

Make sure that the number of function parameters in the expression of an expression index is correct.

When the expression of an index contains a string-related function, affected by the returned type and the length, creating the expression index might fail. In this situation, you can use the `CAST()` function to explicitly specify the returned type and the length. For example, to create an expression index based on the `REPEAT(a, 3)` expression, you need to modify this expression to `CAST(REPEAT(a, 3)AS CHAR(20))`.

When the expression in a query statement matches the expression in an expression index, the optimizer can choose the expression index for the query. In some cases, the optimizer might not choose an expression index depending on statistics. In this situation, you can force the optimizer to select an expression index by using optimizer hints.

In the following examples, suppose that you create the expression index `idx` on the expression `LOWER(col1)`:

If the results of the query statement are the same expressions, the expression index applies. Take the following statement as an example:

```
SELECT LOWER(col1) FROM t;
```

If the same expression is included in the filtering conditions, the expression index applies. Take the following statements as an example:

```
SELECT * FROM t WHERE LOWER(col1) = "a";
SELECT * FROM t WHERE LOWER(col1) > "a";
SELECT * FROM t WHERE LOWER(col1) BETWEEN "a" AND "b";
SELECT * FROM t WHERE LOWER(col1) IN ("a", "b");
SELECT * FROM t WHERE LOWER(col1) > "a" AND LOWER(col1) < "b";
SELECT * FROM t WHERE LOWER(col1) > "b" OR LOWER(col1) < "a";
```

When the queries are sorted by the same expression, the expression index applies. Take the following statement as an example:

```
SELECT * FROM t ORDER BY LOWER(col1);
```

If the same expression is included in the aggregate (`GROUP BY`) functions, the expression index applies. Take the following statements as an example:

```
SELECT MAX(LOWER(col1)) FROM t;
SELECT MIN(col1) FROM t GROUP BY LOWER(col1);
```

To see the expression corresponding to the expression index, execute `SHOW INDEX`, or check the system tables `information_schema.tidb_indexes` and the table `information_schema.STATISTICS`. The `Expression` column in the output indicates the corresponded expression. For the non-expression indexes, the column shows `NULL`.

The cost of maintaining an expression index is higher than that of maintaining other indexes, because the value of the expression needs to be calculated whenever a row is inserted or updated. The value of the expression is already stored in the index, so this value does not require recalculation when the optimizer selects the expression index.

Therefore, when the query performance outweighs the insert and update performance, you can consider indexing the expressions.

Expression indexes have the same syntax and limitations as in MySQL. They are implemented by creating indexes on generated virtual columns that are invisible, so the supported expressions inherit all limitations of virtual generated columns.

14.13.2.30.4 Multi-valued indexes

Multi-valued indexes are a kind of secondary index defined on an array column. In a normal index, one index record corresponds to one data record (1:1). In a multi-valued index, multiple index records correspond to one data record (N:1). Multi-valued indexes are used to index JSON arrays. For example, a multi-valued index defined on the `zipcode` field will generate one index record for each element in the `zipcode` array.

```
{
    "user":"Bob",
    "user_id":31,
    "zipcode":[94477,94536]
}
```

Create multi-valued indexes

You can create multi-valued indexes by using the `CAST(... AS ... ARRAY)` function in the index definition, as creating an expression index.

```
mysql> CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name CHAR(10),
    custinfo JSON,
    INDEX zips((CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)))
);
```

You can define a multi-valued index as a unique index.

```
mysql> CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name CHAR(10),
    custinfo JSON,
    UNIQUE INDEX zips( (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)))
);
```

When a multi-valued index is defined as a unique index, an error is reported if you try to insert duplicate data.

```
mysql> INSERT INTO customers VALUES (1, 'pingcap', '{"zipcode": [1,2]}');
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO customers VALUES (1, 'pingcap', '{"zipcode": [2,3]}');
ERROR 1062 (23000): Duplicate entry '2' for key 'customers.zips'
```

The same record can have duplicate values, but when different records have duplicate values, an error is reported.

```
-- Insert succeeded
mysql> INSERT INTO t1 VALUES('[1,1,2]');
mysql> INSERT INTO t1 VALUES('[3,3,3,4,4,4]');

-- Insert failed
mysql> INSERT INTO t1 VALUES('[1,2]');
mysql> INSERT INTO t1 VALUES('[2,3]');
```

You can also define a multi-valued index as a composite index:

```
mysql> CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name CHAR(10),
    custinfo JSON,
    INDEX zips(name, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)))
);
```

When a multi-valued index is defined as a composite index, the multi-valued part can appear in any position, but only once.

```
mysql> CREATE TABLE customers (
    id BIGINT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name CHAR(10),
    custinfo JSON,
    INDEX zips(name, (CAST(custinfo->'$.zipcode' AS UNSIGNED ARRAY)), (CAST(
        ↪ custinfo->'$.zipcode' AS UNSIGNED ARRAY)))
);
ERROR 1235 (42000): This version of TiDB doesn't yet support 'more than one
    ↪ multi-valued key part per index'.
```

The written data must exactly match the type defined by the multi-valued index; otherwise, the data write fails:

```
-- All elements in the zipcode field must be the UNSIGNED type.
mysql> INSERT INTO customers VALUES (1, 'pingcap', '{"zipcode": [-1]}');
ERROR 3752 (HY000): Value is out of range for expression index 'zips' at
    ↪ row 1

mysql> INSERT INTO customers VALUES (1, 'pingcap', '{"zipcode": ["1"]}');
    ↪ -- Incompatible with MySQL
ERROR 3903 (HY000): Invalid JSON value for CAST for expression index 'zips'

mysql> INSERT INTO customers VALUES (1, 'pingcap', '{"zipcode": [1]}');
Query OK, 1 row affected (0.00 sec)
```

Use multi-valued indexes

See Index Selection - Use multi-valued indexes for more details.

Limitations

- For an empty JSON array, no corresponding index record is generated.
- The target type in `CAST(... AS ... ARRAY)` cannot be any of `BINARY`, `JSON`, `YEAR`, `FLOAT`, and `DECIMAL`. The source type must be JSON.
- You cannot use multi-valued indexes for sorting.

- You can only create multi-valued indexes on a JSON array.
- A multi-valued index cannot be a primary key or a foreign key.
- The extra storage space used by a multi-valued index = the average number of array elements per row * the space used by a normal secondary index.
- Compared with normal indexes, DML operations will modify more index records for multi-valued indexes, so multi-valued indexes will have a greater performance impact than normal indexes.
- Because multi-valued indexes are a special type of expression index, multi-valued indexes have the same limitations as expression indexes.
- If a table uses multi-valued indexes, you cannot back up, replicate, or import the table using BR, TiCDC, or TiDB Lightning to a TiDB cluster earlier than v6.6.0.
- For a query with complex conditions, TiDB might not be able to select multi-valued indexes. For information on the condition patterns supported by multi-valued indexes, refer to Use multi-valued indexes.

14.13.2.30.5 Invisible index

By default, invisible indexes are indexes that are ignored by the query optimizer:

```
CREATE TABLE t1 (c1 INT, c2 INT, UNIQUE(c2));
CREATE UNIQUE INDEX c1 ON t1 (c1) INVISIBLE;
```

Starting from TiDB v8.0.0, you can make the optimizer select invisible indexes by modifying the system variable `tidb_opt_use_invisible_indexes`.

For details, see `ALTER INDEX`.

14.13.2.30.6 Associated system variables

The system variables associated with the `CREATE INDEX` statement are `tidb_ddl_enable_fast_reorg`, `tidb_ddl_reorg_worker_cnt`, `tidb_ddl_reorg_batch_size`, `tidb_enable_auto_increment_in_generated`, and `tidb_ddl_reorg_priority`. Refer to system variables for details.

14.13.2.30.7 MySQL compatibility

- TiDB supports parsing the `FULLTEXT` syntax but does not support using the `FULLTEXT`, `HASH`, and `SPATIAL` indexes.
- TiDB accepts index types such as `HASH`, `BTREE` and `RTREE` in syntax for compatibility with MySQL, but ignores them.
- Descending indexes are not supported (similar to MySQL 5.7).
- Adding the primary key of the `CLUSTERED` type to a table is not supported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.
- Expression indexes are incompatible with views. When a query is executed using a view, the expression index cannot be used at the same time.

- Expression indexes have compatibility issues with bindings. When the expression of an expression index has a constant, the binding created for the corresponding query expands its scope. For example, suppose that the expression in the expression index is `a+1`, and the corresponding query condition is `a+1 > 2`. In this case, the created binding is `a+? > ?`, which means that the query with the condition such as `a+2 > 2` is also forced to use the expression index and results in a poor execution plan. In addition, this also affects the baseline capturing and baseline evolution in SQL Plan Management (SPM).
- The data written with multi-valued indexes must exactly match the defined data type. Otherwise, data writes fail. For details, see create multi-valued indexes.
- Setting a `UNIQUE KEY` as a global index with the `GLOBAL` index option is a TiDB extension for partitioned tables and is not compatible with MySQL.

14.13.2.31 CREATE PLACEMENT POLICY

`CREATE PLACEMENT POLICY` is used to create a named placement policy that can later be assigned to tables, partitions, or database schemas.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.31.1 Synopsis

```
CreatePolicyStmt ::=
    "CREATE" "PLACEMENT" "POLICY" IfNotExists PolicyName PlacementOptionList

PolicyName ::=
    Identifier
```

```
PlacementOptionList ::=
    PlacementOption
|   PlacementOptionList PlacementOption
|   PlacementOptionList ',' PlacementOption

PlacementOption ::=
    CommonPlacementOption
|   SugarPlacementOption
|   AdvancedPlacementOption

CommonPlacementOption ::=
    "FOLLOWERS" EqOpt LengthNum

SugarPlacementOption ::=
    "PRIMARY_REGION" EqOpt stringLit
|   "REGIONS" EqOpt stringLit
|   "SCHEDULE" EqOpt stringLit

AdvancedPlacementOption ::=
    "LEARNERS" EqOpt LengthNum
|   "CONSTRAINTS" EqOpt stringLit
|   "LEADER_CONSTRAINTS" EqOpt stringLit
|   "FOLLOWER_CONSTRAINTS" EqOpt stringLit
|   "LEARNER_CONSTRAINTS" EqOpt stringLit
|   "SURVIVAL_PREFERENCES" EqOpt stringLit
```

14.13.2.31.2 Examples

> **Note:**
>
> To know which regions are available in your cluster, see SHOW PLACEMENT LABELS.
>
> If you do not see any available regions, your TiKV installation might not have labels set correctly.

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us
    -west-1" FOLLOWERS=4;
CREATE TABLE t1 (a INT) PLACEMENT POLICY=p1;
SHOW CREATE PLACEMENT POLICY p1;
```

```
Query OK, 0 rows affected (0.08 sec)

Query OK, 0 rows affected (0.10 sec)

+--------+-------------------------------------------------------------------------------
    ↪
| Policy | Create Policy
    ↪
    ↪ |
+--------+-------------------------------------------------------------------------------
    ↪
| p1     | CREATE PLACEMENT POLICY `p1` PRIMARY_REGION="us-east-1" REGIONS="
    ↪ us-east-1,us-west-1" FOLLOWERS=4 |
+--------+-------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.2.31.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- Placement Rules in SQL
- SHOW PLACEMENT
- ALTER PLACEMENT POLICY
- DROP PLACEMENT POLICY

14.13.2.32 CREATE RESOURCE GROUP

You can use the `CREATE RESOURCE GROUP` statement to create a resource group.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.32.1 Synopsis

```
CreateResourceGroupStmt ::=
   "CREATE" "RESOURCE" "GROUP" IfNotExists ResourceGroupName
      ↪ ResourceGroupOptionList
```

```
IfNotExists ::=
    ('IF' 'NOT' 'EXISTS')?

ResourceGroupName ::=
    Identifier
|   "DEFAULT"

ResourceGroupOptionList ::=
    DirectResourceGroupOption
|   ResourceGroupOptionList DirectResourceGroupOption
|   ResourceGroupOptionList ',' DirectResourceGroupOption

DirectResourceGroupOption ::=
    "RU_PER_SEC" EqOpt stringLit
|   "PRIORITY" EqOpt ResourceGroupPriorityOption
|   "BURSTABLE"
|   "BURSTABLE" EqOpt Boolean
|   "QUERY_LIMIT" EqOpt '(' ResourceGroupRunawayOptionList ')'
|   "QUERY_LIMIT" EqOpt '(' ')'
|   "QUERY_LIMIT" EqOpt "NULL"
|   "BACKGROUND" EqOpt '(' BackgroundOptionList ')'
|   "BACKGROUND" EqOpt '(' ')'
|   "BACKGROUND" EqOpt "NULL"

ResourceGroupPriorityOption ::=
    LOW
|   MEDIUM
|   HIGH

ResourceGroupRunawayOptionList ::=
    DirectResourceGroupRunawayOption
|   ResourceGroupRunawayOptionList DirectResourceGroupRunawayOption
|   ResourceGroupRunawayOptionList ',' DirectResourceGroupRunawayOption

DirectResourceGroupRunawayOption ::=
    "EXEC_ELAPSED" EqOpt stringLit
|   "PROCESSED_KEYS" EqOpt intLit
|   "RU" EqOpt intLit
|   "ACTION" EqOpt ResourceGroupRunawayActionOption
|   "WATCH" EqOpt ResourceGroupRunawayWatchOption WatchDurationOption

WatchDurationOption ::=
    ("DURATION" EqOpt stringLit | "DURATION" EqOpt "UNLIMITED")?
```

```
ResourceGroupRunawayWatchOption ::=
    EXACT
|   SIMILAR
|   PLAN

ResourceGroupRunawayActionOption ::=
    DRYRUN
|   COOLDOWN
|   KILL
| "SWITCH_GROUP" '(' ResourceGroupName ')'
```

The resource group name parameter (`ResourceGroupName`) must be globally unique.

TiDB supports the following `DirectResourceGroupOption`, where Request Unit (RU) is a unified abstraction unit in TiDB for CPU, IO, and other system resources.

Option	Description	Example
`RU_PER_SEC`	Rate of RU backfilling per second	`RU_PER_SEC = 500` indicates that this resource group is backfilled with 500 RUs per second
`PRIORITY`	The absolute priority of tasks to be processed on TiKV	`PRIORITY = HIGH` indicates that the priority is high. If not specified, the default value is `MEDIUM`.
`BURSTABLE`	If the `BURSTABLE` attribute is set, TiDB allows the corresponding resource group to use the available system resources when the quota is exceeded.	

Option	Description	Example
`QUERY_LIMIT`	When the query execution meets this condition, the query is identified as a runaway query and the corresponding action is executed.	`QUERY_LIMIT=(EXEC_ELAPSED='60s', ACTION=KILL, WATCH=EXACT DURATION='10m')` indicates that the query is identified as a runaway query when the execution time exceeds 60 seconds. The query is terminated. All SQL statements with the same SQL text will be terminated immediately in the coming 10 minutes. `QUERY_LIMIT=()` or `QUERY_LIMIT=NULL` means that runaway control is not enabled. See Runaway Queries.

Note:

- The `CREATE RESOURCE GROUP` statement can only be executed when the global variable `tidb_enable_resource_control` is set to `ON`. TiDB automatically creates a `default` resource group during cluster initialization. For this resource group, the default value of `RU_PER_SEC` is `UNLIMITED` (equivalent to the maximum value of the `INT` type, that is, `2147483647`) and it is in `BURSTABLE` mode. All requests that are not bound to any resource group are automatically bound to this `default` resource group. When you create a new configuration for another resource group, it is recommended to modify the `default` resource group configuration as needed.
- Currently, only the `default` resource group supports modifying the `BACKGROUND` configuration.

14.13.2.32.2 Examples

Create two resource groups `rg1` and `rg2`.

```
DROP RESOURCE GROUP IF EXISTS rg1;
```

```
Query OK, 0 rows affected (0.22 sec)
```

```
CREATE RESOURCE GROUP IF NOT EXISTS rg1
  RU_PER_SEC = 100
  PRIORITY = HIGH
  BURSTABLE;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
CREATE RESOURCE GROUP IF NOT EXISTS rg2
  RU_PER_SEC = 200 QUERY_LIMIT=(EXEC_ELAPSED='100ms', ACTION=KILL);
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='rg1' or NAME
    ↪ = 'rg2';
```

```
+--
    ↪ ----+------------+----------+-----------+------------------------------+
    ↪
| NAME | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT                  |
+--
    ↪ ----+------------+----------+-----------+------------------------------+
    ↪
| rg1  | 100        | HIGH     | YES       | NULL                         |
| rg2  | 200        | MEDIUM   | NO        | EXEC_ELAPSED=100ms, ACTION=KILL |
+--
    ↪ ----+------------+----------+-----------+------------------------------+
    ↪
2 rows in set (1.30 sec)
```

14.13.2.32.3 MySQL compatibility

MySQL also supports CREATE RESOURCE GROUP. However, the acceptable parameters are different from that of TiDB so that they are not compatible.

14.13.2.32.4 See also

- DROP RESOURCE GROUP
- ALTER RESOURCE GROUP
- ALTER USER RESOURCE GROUP
- Request Unit (RU)

14.13.2.33 CREATE ROLE

This statement creates a new role, which can be assigned to users as part of role-based access control.

14.13.2.33.1 Synopsis

```
CreateRoleStmt ::=
    'CREATE' 'ROLE' IfNotExists RoleSpec (',' RoleSpec)*

IfNotExists ::=
    ('IF' 'NOT' 'EXISTS')?

RoleSpec ::=
    Rolename
```

14.13.2.33.2 Examples

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Create a new role `analyticsteam` and a new user `jennifer`:

```
CREATE ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)

GRANT SELECT ON test.* TO analyticsteam;
Query OK, 0 rows affected (0.02 sec)

CREATE USER jennifer;
Query OK, 0 rows affected (0.01 sec)

GRANT analyticsteam TO jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Note that by default `jennifer` needs to execute `SET ROLE analyticsteam` in order to be able to use the privileges associated with the `analyticsteam` role:

```
SHOW GRANTS;
+-----------------------------------------+
| Grants for User                         |
+-----------------------------------------+
```

```
| GRANT USAGE ON *.* TO 'jennifer'@'%'  |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+---------------------------------------------+
2 rows in set (0.00 sec)

SHOW TABLES in test;
ERROR 1044 (42000): Access denied for user 'jennifer'@'%' to database 'test'
SET ROLE analyticsteam;
Query OK, 0 rows affected (0.00 sec)

SHOW GRANTS;
+---------------------------------------------+
| Grants for User                             |
+---------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'  |
| GRANT SELECT ON test.* TO 'jennifer'@'%' |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+---------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

The statement `SET DEFAULT ROLE` can be used to associate the role `analyticsteam` to `jennifer`:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
Query OK, 0 rows affected (0.02 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

After this, the user `jennifer` has the privileges associated with the role `analyticsteam` and `jennifer` does not have to execute the statement `SET ROLE`:

```
SHOW GRANTS;
+---------------------------------------------+
```

```
| Grants for User                                |
+------------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'           |
| GRANT SELECT ON test.* TO 'jennifer'@'%'       |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%'    |
+------------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

14.13.2.33.3 MySQL compatibility

The `CREATE ROLE` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.33.4 See also

- DROP ROLE
- GRANT <role>
- REVOKE <role>
- SET ROLE
- SET DEFAULT ROLE

- Role-Based Access Control

14.13.2.34 CREATE SEQUENCE

The `CREATE SEQUENCE` statement creates sequence objects in TiDB. The sequence is a database object that is on a par with the table and the `View` object. The sequence is used to generate serialized IDs in a customized way.

14.13.2.34.1 Synopsis

```
CreateSequenceStmt ::=
    'CREATE' 'SEQUENCE' IfNotExists TableName CreateSequenceOptionListOpt

IfNotExists ::=
    ('IF' 'NOT' 'EXISTS')?
```

```
TableName ::=
    Identifier ('.' Identifier)?

CreateSequenceOptionListOpt ::=
    SequenceOption*

SequenceOptionList ::=
    SequenceOption

SequenceOption ::=
    ( 'INCREMENT' ( '='? | 'BY' ) | 'START' ( '='? | 'WITH' ) | ( 'MINVALUE'
       ↪  | 'MAXVALUE' | 'CACHE' ) '='? ) SignedNum
|   'COMMENT' '='? stringLit
|   'NOMINVALUE'
|   'NO' ( 'MINVALUE' | 'MAXVALUE' | 'CACHE' | 'CYCLE' )
|   'NOMAXVALUE'
|   'NOCACHE'
|   'CYCLE'
|   'NOCYCLE'
```

14.13.2.34.2 Syntax

```
CREATE [TEMPORARY] SEQUENCE [IF NOT EXISTS] sequence_name
    [ INCREMENT [ BY | = ] increment ]
    [ MINVALUE [=] minvalue | NO MINVALUE | NOMINVALUE ]
    [ MAXVALUE [=] maxvalue | NO MAXVALUE | NOMAXVALUE ]
    [ START [ WITH | = ] start ]
    [ CACHE [=] cache | NOCACHE | NO CACHE]
    [ CYCLE | NOCYCLE | NO CYCLE]
    [table_options]
```

14.13.2.34.3 Parameters

Parameters	Default value	Description
`TEMPORARY` ↪	`false` ↪	TiDB currently does not support the `TEMPORARY` ↪ option and provides only syntax compatibility for it.

Parameters	Default value	Description
`INCREMENT` ↪	`1`	Specifies the increment of a sequence. Its positive or negative values can control the growth direction of the sequence.

Parameters	Default value	Description
`MINVALUE` ↪	`1` or `-9223372036854775807` ↪	Specifies the minimum value of a sequence. When `INCREMENT` ↪ `> 0`, the default value is `1`. When `INCREMENT` ↪ `< 0`, the default value is `-922337203685477` ↪ .

Parameters	Default value	Description
`MAXVALUE` ↪	`9223372036854775806` ↪ or `-1`	Specifies the maximum value of a sequence. When `INCREMENT` ↪ `> 0`, the default value is `922337203685477` ↪ . When `INCREMENT` ↪ `< 0`, the default value is `-1`.

Parameters	Default value	Description
`START` ↪	`MINVALUE` ↪ or `MAXVALUE` ↪	Specifies the initial value of a sequence. When `INCREMENT` ↪ > 0, the default value is `MINVALUE` ↪ . When `INCREMENT` ↪ < 0, the default value is `MAXVALUE` ↪ .
`CACHE` ↪	`1000` ↪	Specifies the local cache size of a sequence in TiDB.

Parameters	Default value	Description
`CYCLE` ↪	`NO` ↪ `CYCLE` ↪	Specifies whether a sequence restarts from the minimum value (or maximum for the descending sequence). When `INCREMENT` ↪ > `0`, the default value is `MINVALUE` ↪ . When `INCREMENT` ↪ < `0`, the default value is `MAXVALUE` ↪ .

Parameters	Default value	Description

14.13.2.34.4 `SEQUENCE` function

You can control a sequence through the following expression functions:

- `NEXTVAL` or `NEXT VALUE FOR`

  Essentially, both are the `NEXTVAL()` function that gets the next valid value of a sequence object. The parameter of the `NEXTVAL()` function is the `identifier` of the sequence.

- `LASTVAL`

  This function gets the last used value of this session. If the value does not exist, `NULL` is used. The parameter of this function is the `identifier` of the sequence.

- `SETVAL`

  This function sets the progression of the current value for a sequence. The first parameter of this function is the `identifier` of the sequence; the second parameter is `num`.

> **Note:**
>
> In the implementation of a sequence in TiDB, the `SETVAL` function cannot change the initial progression or cycle progression of this sequence. This function only returns the next valid value based on this progression.

14.13.2.34.5 Examples

- Create a sequence object with the default parameter:

```
CREATE SEQUENCE seq;
```

```
Query OK, 0 rows affected (0.06 sec)
```

- Use the `NEXTVAL()` function to get the next value of the sequence object:

```
SELECT NEXTVAL(seq);
```

```
+--------------+
| NEXTVAL(seq) |
+--------------+
|            1 |
+--------------+
1 row in set (0.02 sec)
```

- Use the `LASTVAL()` function to get the value generated by the last call to a sequence object in this session:

```
SELECT LASTVAL(seq);
```

```
+--------------+
| LASTVAL(seq) |
+--------------+
|            1 |
+--------------+
1 row in set (0.02 sec)
```

- Use the `SETVAL()` function to set the current value (or the current position) of the sequence object:

```
SELECT SETVAL(seq, 10);
```

```
+-----------------+
| SETVAL(seq, 10) |
+-----------------+
|              10 |
+-----------------+
1 row in set (0.01 sec)
```

- You can also use the `next value for` syntax to get the next value of the sequence:

```
SELECT next value for seq;
```

```
+--------------------+
| next value for seq |
+--------------------+
|                 11 |
+--------------------+
1 row in set (0.00 sec)
```

- Create a sequence object with default custom parameters:

```
CREATE SEQUENCE seq2 start 3 increment 2 minvalue 1 maxvalue 10 cache
    ↪ 3;
```

```
Query OK, 0 rows affected (0.01 sec)
```

- When the sequence object has not been used in this session, the `LASTVAL()` function returns a `NULL` value.

```
SELECT LASTVAL(seq2);
```

```
+---------------+
| LASTVAL(seq2) |
+---------------+
|          NULL |
+---------------+
1 row in set (0.01 sec)
```

- The first valid value of the `NEXTVAL()` function for the sequence object is the value of `START` parameter.

```
SELECT NEXTVAL(seq2);
```

```
+---------------+
| NEXTVAL(seq2) |
+---------------+
|             3 |
+---------------+
1 row in set (0.00 sec)
```

- Although the `SETVAL()` function can change the current value of the sequence object, it cannot change the arithmetic progression rule for the next value.

```
SELECT SETVAL(seq2, 6);
```

```
+-----------------+
| SETVAL(seq2, 6) |
+-----------------+
|               6 |
+-----------------+
1 row in set (0.00 sec)
```

- When you use `NEXTVAL()` to get the next value, the next value will follow the arithmetic progression rule defined by the sequence.

```
SELECT next value for seq2;
```

```
+---------------------+
| next value for seq2 |
+---------------------+
|                   7 |
+---------------------+
1 row in set (0.00 sec)
```

- You can use the next value of the sequence as the default value for the column, as in the following example.

```
CREATE table t(a int default next value for seq2);
```

```
Query OK, 0 rows affected (0.02 sec)
```

- In the following example, the value is not specified, so the default value of `seq2` is used.

```
INSERT into t values();
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT * from t;
```

```
+------+
| a    |
+------+
|    9 |
+------+
1 row in set (0.00 sec)
```

- In the following example, the value is not specified, so the default value of `seq2` is used. But the next value of `seq2` is not within the range defined in the above example (`CREATE SEQUENCE seq2 start 3 increment 2 minvalue 1 maxvalue 10 cache 3;`), so an error is returned.

```
INSERT into t values();
```

```
ERROR 4135 (HY000): Sequence 'test.seq2' has run out
```

14.13.2.34.6 MySQL compatibility

This statement is a TiDB extension. The implementation is modeled on sequences available in MariaDB.

Except for the `SETVAL` function, all other functions have the same *progressions* as MariaDB. Here "progression" means that the numbers in a sequence follow a certain arithmetic

progression rule defined by the sequence. Although you can use `SETVAL` to set the current value of a sequence, the subsequent values of the sequence still follow the original progression rule.

For example:

```
1, 3, 5, ...          // The sequence starts from 1 and increments by 2.
select SETVAL(seq, 6) // Sets the current value of a sequence to 6.
7, 9, 11, ...         // Subsequent values still follow the progression rule.
```

In the `CYCLE` mode, the initial value of a sequence in the first round is the value of the `START` parameter, and the initial value in the subsequent rounds is the value of `MinValue` (`INCREMENT` > 0) or `MaxValue` (`INCREMENT` < 0).

14.13.2.35 CREATE TABLE LIKE

This statement copies the definition of an existing table, without copying any data.

14.13.2.35.1 Synopsis

```
CreateTableLikeStmt ::=
    'CREATE' OptTemporary 'TABLE' IfNotExists TableName
       ↪ LikeTableWithOrWithoutParen OnCommitOpt

OptTemporary ::=
    ( 'TEMPORARY' | ('GLOBAL' 'TEMPORARY') )?

LikeTableWithOrWithoutParen ::=
    'LIKE' TableName
|   '(' 'LIKE' TableName ')'

OnCommitOpt ::=
    ('ON' 'COMMIT' 'DELETE' 'ROWS')?
```

14.13.2.35.2 Examples

```
mysql> CREATE TABLE t1 (a INT NOT NULL);
Query OK, 0 rows affected (0.13 sec)
```

```
mysql> INSERT INTO t1 VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+---+
5 rows in set (0.00 sec)

mysql> CREATE TABLE t2 LIKE t1;
Query OK, 0 rows affected (0.10 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

14.13.2.35.3 Pre-split region

If the table to be copied is defined with the `PRE_SPLIT_REGIONS` attribute, the table created using the `CREATE TABLE LIKE` statement inherits this attribute, and the Region on the new table will be split. For details of `PRE_SPLIT_REGIONS`, see `CREATE TABLE` Statement.

14.13.2.35.4 MySQL compatibility

The `CREATE TABLE LIKE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.35.5 See also

- CREATE TABLE
- SHOW CREATE TABLE

14.13.2.36 CREATE TABLE

This statement creates a new table in the currently selected database. It behaves similarly to the `CREATE TABLE` statement in MySQL.

14.13.2.36.1 Synopsis

```
CreateTableStmt ::=
    'CREATE' OptTemporary 'TABLE' IfNotExists TableName (
       ↪ TableElementListOpt CreateTableOptionListOpt PartitionOpt

|   "REPLACE" '(' ExpressionList ')'

NowSymOptionFractionParentheses ::=
    '(' NowSymOptionFractionParentheses ')'
|   NowSymOptionFraction

NowSymOptionFraction ::=
    NowSym
|   NowSymFunc '(' ')'
|   NowSymFunc '(' NUM ')'
|   CurdateSym '(' ')'
|   "CURRENT_DATE"

NextValueForSequenceParentheses ::=
    '(' NextValueForSequenceParentheses ')'
|   NextValueForSequence

NextValueForSequence ::=
    "NEXT" "VALUE" forKwd TableName
|   "NEXTVAL" '(' TableName ')'
```

The following *table_options* are supported. Other options such as `AVG_ROW_LENGTH`, `CHECKSUM`, `COMPRESSION`, `CONNECTION`, `DELAY_KEY_WRITE`, `ENGINE`, `KEY_BLOCK_SIZE`, `MAX_ROWS`, `MIN_ROWS`, `ROW_FORMAT` and `STATS_PERSISTENT` are parsed but ignored.

Options	Description	Example
`AUTO_INCREMENT`	The initial value of the increment field	`AUTO_INCREMENT = 5`
`SHARD_ROW_ID_BITS`	To set the number of bits for the implicit `_tidb_rowid` shards	`SHARD_ROW_ID_BITS = 4`

Options	Description	Example
PRE_SPLIT ↪ _ ↪ REGIONS ↪	To pre-split 2^(PRE_ ↪ SPLIT_ ↪ REGIONS ↪) Regions when creating a table	PRE_ ↪ SPLIT ↪ _ ↪ REGIONS ↪ = 4
AUTO_ID_ ↪ CACHE	To set the auto ID cache size in a TiDB instance. By default, TiDB automatically changes this size according to allocation speed of auto ID	AUTO_ ↪ ID_ ↪ CACHE ↪ = 200
AUTO_ ↪ RANDOM ↪ _BASE	To set the initial incremental part value of auto_random. This option can be considered as a part of the internal interface. Users can ignore this parameter	AUTO_ ↪ RANDOM ↪ _ ↪ BASE ↪ = 0

Options	Description	Example
CHARACTER SET	To specify the character set for the table	CHARACTER SET = 'utf8mb4'
COMMENT	The comment information	COMMENT = 'comment info'

Note:

The `split-table` configuration option is enabled by default. When it is enabled, a separate Region is created for each newly created table. For details, see TiDB configuration file.

14.13.2.36.2 Examples

Creating a simple table and inserting one row:

```
CREATE TABLE t1 (a int);
DESC t1;
SHOW CREATE TABLE t1\G
INSERT INTO t1 (a) VALUES (1);
SELECT * FROM t1;
```

```
mysql> drop table if exists t1;
Query OK, 0 rows affected (0.23 sec)

mysql> CREATE TABLE t1 (a int);
Query OK, 0 rows affected (0.09 sec)

mysql> DESC t1;
+-------+------+------+------+---------+-------+
| Field | Type | Null | Key | Default | Extra |
+-------+------+------+------+---------+-------+
| a     | int | YES |     | NULL   |       |
+-------+------+------+------+---------+-------+
1 row in set (0.00 sec)
```

```
mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `a` int DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.03 sec)

mysql> SELECT * FROM t1;
+------+
| a    |
+------+
|    1 |
+------+
1 row in set (0.00 sec)
```

Dropping a table if it exists, and conditionally creating a table if it does not exist:

```
DROP TABLE IF EXISTS t1;
CREATE TABLE IF NOT EXISTS t1 (
 id BIGINT NOT NULL PRIMARY KEY auto_increment,
 b VARCHAR(200) NOT NULL
);
DESC t1;
```

```
mysql> DROP TABLE IF EXISTS t1;
Query OK, 0 rows affected (0.22 sec)

mysql> CREATE TABLE IF NOT EXISTS t1 (
        id BIGINT NOT NULL PRIMARY KEY auto_increment,
        b VARCHAR(200) NOT NULL
       );
Query OK, 0 rows affected (0.08 sec)

mysql> DESC t1;
+-------+--------------+------+------+---------+----------------+
| Field | Type         | Null | Key | Default | Extra          |
+-------+--------------+------+------+---------+----------------+
| id    | bigint       | NO   | PRI | NULL    | auto_increment |
| b     | varchar(200) | NO |     | NULL    |                |
+-------+--------------+------+------+---------+----------------+
2 rows in set (0.00 sec)
```

14.13.2.36.3 MySQL compatibility

- All of the data types except spatial types are supported.
- TiDB accepts index types such as `HASH`, `BTREE` and `RTREE` in syntax for compatibility with MySQL, but ignores them.
- TiDB supports parsing the `FULLTEXT` syntax but does not support using the `FULLTEXT` indexes.
- Setting a `PRIMARY KEY` or `UNIQUE INDEX` as a global index with the `GLOBAL` index option is a TiDB extension for partitioned tables and is not compatible with MySQL.

- For compatibility, the `index_col_name` attribute supports the length option with a maximum length limit of 3072 bytes by default. The length limit can be changed through the `max-index-length` configuration option. For details, see TiDB configuration file.

- The `[ASC | DESC]` in `index_col_name` is currently parsed but ignored (MySQL 5.7 compatible behavior).
- The `COMMENT` attribute does not support the `WITH PARSER` option.
- TiDB supports 1017 columns in a single table by default and 4096 columns at most. The corresponding number limit in InnoDB is 1017 columns, and the hard limit in MySQL is 4096 columns. For details, see TiDB Limitations.
- TiDB supports `HASH`, `RANGE`, `LIST`, and `KEY` partitioning types. For an unsupported partition type, TiDB returns `Warning: Unsupported partition type %s, treat` ↪ `as normal table`, where `%s` is the specific unsupported partition type.

14.13.2.37 CREATE USER

This statement creates a new user, specified with a password. In the MySQL privilege system, a user is the combination of a username and the host from which they are connecting from. Thus, it is possible to create a user `'newuser2'@'192.168.1.1'` who is only able to connect from the IP address `192.168.1.1`. It is also possible to have two users have the same user-portion, and different permissions as they login from different hosts.

14.13.2.37.1 Synopsis

```
CreateUserStmt ::=
    'CREATE' 'USER' IfNotExists UserSpecList RequireClauseOpt
       ↪ ConnectionOptions PasswordOption LockOption AttributeOption
       ↪ ResourceGroupNameOption

IfNotExists ::=
    ('IF' 'NOT' 'EXISTS')?

UserSpecList ::=
    UserSpec ( ',' UserSpec )*

RequireClauseOpt ::=
    ( 'REQUIRE' 'NONE' | 'REQUIRE' 'SSL' | 'REQUIRE' 'X509' | 'REQUIRE'
       ↪ RequireList )?

RequireList ::=
    ( "ISSUER" stringLit | "SUBJECT" stringLit | "CIPHER" stringLit | "SAN"
       ↪ stringLit | "TOKEN_ISSUER" stringLit )*

UserSpec ::=
    Username AuthOption

AuthOption ::=
    ( 'IDENTIFIED' ( 'BY' ( AuthString | 'PASSWORD' HashString ) | 'WITH'
       ↪ StringName ( 'BY' AuthString | 'AS' HashString )? ) )?

StringName ::=
    stringLit
|   Identifier

PasswordOption ::= ( 'PASSWORD' 'EXPIRE' ( 'DEFAULT' | 'NEVER' | 'INTERVAL'
    ↪ N 'DAY' )?
| 'PASSWORD' 'HISTORY' ( 'DEFAULT' | N )
| 'PASSWORD' 'REUSE' 'INTERVAL' ( 'DEFAULT' | N 'DAY' )
| 'PASSWORD' 'REQUIRE' 'CURRENT' 'DEFAULT'
| 'FAILED_LOGIN_ATTEMPTS' N
| 'PASSWORD_LOCK_TIME' ( N | 'UNBOUNDED' ) )*

LockOption ::= ( 'ACCOUNT' 'LOCK' | 'ACCOUNT' 'UNLOCK' )?

AttributeOption ::= ( 'COMMENT' CommentString | 'ATTRIBUTE' AttributeString
    ↪ )?

ResourceGroupNameOption::= ( 'RESOURCE' 'GROUP' Identifier)?
```

```
RequireClauseOpt ::= ('REQUIRE' ('NONE' | 'SSL' | 'X509' |
    ↪ RequireListElement ('AND'? RequireListElement)*))?

RequireListElement ::= 'ISSUER' Issuer | 'SUBJECT' Subject | 'CIPHER' Cipher
    ↪  | 'SAN' SAN | 'TOKEN_ISSUER' TokenIssuer
```

14.13.2.37.2 Examples

Create a user with the `newuserpassword` password.

```
mysql> CREATE USER 'newuser' IDENTIFIED BY 'newuserpassword';
Query OK, 1 row affected (0.04 sec)
```

Create a user who can only log in to `192.168.1.1`.

```
mysql> CREATE USER 'newuser2'@'192.168.1.1' IDENTIFIED BY 'newuserpassword'
    ↪ ;
Query OK, 1 row affected (0.02 sec)
```

Create a user who is enforced to log in using TLS connection.

```
CREATE USER 'newuser3'@'%' IDENTIFIED BY 'newuserpassword' REQUIRE SSL;
Query OK, 1 row affected (0.02 sec)
```

Create a user who is required to use X.509 certificate at login.

```
CREATE USER 'newuser4'@'%' IDENTIFIED BY 'newuserpassword' REQUIRE ISSUER '
    ↪ /C=US/ST=California/L=San Francisco/O=PingCAP';
Query OK, 1 row affected (0.02 sec)
```

Create a user who is locked upon creation.

```
CREATE USER 'newuser5'@'%' ACCOUNT LOCK;
```

```
Query OK, 1 row affected (0.02 sec)
```

Create a user with a comment.

```
CREATE USER 'newuser6'@'%' COMMENT 'This user is created only for test';
SELECT * FROM information_schema.user_attributes;
```

```
+-----------+------+-----------------------------------------------------+
| USER      | HOST | ATTRIBUTE                                           |
+-----------+------+-----------------------------------------------------+
| newuser6 | %    | {"comment": "This user is created only for test"} |
+-----------+------+-----------------------------------------------------+
1 rows in set (0.00 sec)
```

Create a user with an `email` attribute.

```
CREATE USER 'newuser7'@'%' ATTRIBUTE '{"email": "user@pingcap.com"}';
SELECT * FROM information_schema.user_attributes;
```

```
+----------+------+-----------------------------------------------------+
| USER     | HOST | ATTRIBUTE                                           |
+----------+------+-----------------------------------------------------+
| newuser7 | %    | {"email": "user@pingcap.com"}                       |
+----------+------+-----------------------------------------------------+
1 rows in set (0.00 sec)
```

Create a user who is not allowed to reuse the last 5 passwords:

```
CREATE USER 'newuser8'@'%' PASSWORD HISTORY 5;
```

```
Query OK, 1 row affected (0.02 sec)
```

Create a user whose password is manually expired:

```
CREATE USER 'newuser9'@'%' PASSWORD EXPIRE;
```

```
Query OK, 1 row affected (0.02 sec)
```

Create a user that uses the resource group `rg1`.

```
CREATE USER 'newuser7'@'%' RESOURCE GROUP rg1;
SELECT USER, HOST, USER_ATTRIBUTES FROM MYSQL.USER WHERE USER='newuser7';
```

```
+----------+------+--------------------------+
| USER     | HOST | USER_ATTRIBUTES          |
+----------+------+--------------------------+
| newuser7 | %    | {"resource_group": "rg1"} |
+----------+------+--------------------------+

```

14.13.2.37.3 MySQL compatibility

The following `CREATE USER` options are not yet supported by TiDB, and will be parsed but ignored:

- `PASSWORD REQUIRE CURRENT DEFAULT`
- `WITH MAX_QUERIES_PER_HOUR`
- `WITH MAX_UPDATES_PER_HOUR`
- `WITH MAX_USER_CONNECTIONS`

The following `CREATE USER` options are not supported by TiDB either, and are *not* accepted by the parser:

- `DEFAULT ROLE`
- `PASSWORD REQUIRE CURRENT OPTIONAL`

14.13.2.37.4 See also

- Security Compatibility with MySQL
- Privilege Management

- DROP USER
- SHOW CREATE USER
- ALTER USER

14.13.2.38 CREATE VIEW

The `CREATE VIEW` statement saves a `SELECT` statement as a queryable object, similar to a table. Views in TiDB are non-materialized. This means that as a view is queried, TiDB will internally rewrite the query to combine the view definition with the SQL query.

14.13.2.38.1 Synopsis

```
CreateViewStmt ::=
    'CREATE' OrReplace ViewAlgorithm ViewDefiner ViewSQLSecurity 'VIEW'
       ↪ ViewName ViewFieldList 'AS' CreateViewSelectOpt ViewCheckOption

OrReplace ::=
    ( 'OR' 'REPLACE' )?

ViewAlgorithm ::=
    ( 'ALGORITHM' '=' ( 'UNDEFINED' | 'MERGE' | 'TEMPTABLE' ) )?

ViewDefiner ::=
    ( 'DEFINER' '=' Username )?

ViewSQLSecurity ::=
    ( 'SQL' 'SECURITY' ( 'DEFINER' | 'INVOKER' ) )?

ViewName ::= TableName

ViewFieldList ::=
    ( '(' Identifier ( ',' Identifier )* ')' )?
```

```
ViewCheckOption ::=
    ( 'WITH' ( 'CASCADED' | 'LOCAL' ) 'CHECK' 'OPTION' )?
```

14.13.2.38.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE c1 > 2;
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM v1;
+----+----+
| id | c1 |
+----+----+
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
3 rows in set (0.00 sec)

mysql> INSERT INTO t1 (c1) VALUES (6);
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM v1;
+----+----+
| id | c1 |
```

```
+----+----+
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
|  6 |  6 |
+----+----+
4 rows in set (0.00 sec)

mysql> INSERT INTO v1 (c1) VALUES (7);
ERROR 1105 (HY000): insert into view v1 is not supported now.
```

14.13.2.38.3 MySQL compatibility

- Currently, any view in TiDB cannot be inserted or updated (that is, `INSERT VIEW` and `UPDATE VIEW` are not supported). `WITH CHECK OPTION` is only syntactically compatible but does not take effect.
- Currently, the view in TiDB does not support `ALTER VIEW`, but you can use `CREATE OR REPLACE` instead.
- Currently, the `ALGORITHM` field is only syntactically compatible in TiDB but does not take effect. TiDB currently only supports the MERGE algorithm.

14.13.2.38.4 See also

- DROP VIEW
- CREATE TABLE
- SHOW CREATE TABLE
- DROP TABLE

14.13.2.39 DEALLOCATE

The `DEALLOCATE` statement provides an SQL interface to server-side prepared statements.

14.13.2.39.1 Synopsis

```
DeallocateStmt ::=
    DeallocateSym 'PREPARE' Identifier

DeallocateSym ::=
    'DEALLOCATE'
|   'DROP'

Identifier ::=
    identifier
```

```
|   UnReservedKeyword
|   NotKeywordToken
|   TiDBKeyword
```

14.13.2.39.2 Examples

```
mysql> PREPARE mystmt FROM 'SELECT ? as num FROM DUAL';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @number = 5;
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE mystmt USING @number;
+------+
| num |
+------+
| 5   |
+------+
1 row in set (0.00 sec)

mysql> DEALLOCATE PREPARE mystmt;
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.39.3 MySQL compatibility

The `DEALLOCATE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.39.4 See also

- PREPARE
- EXECUTE

14.13.2.40 DELETE

The `DELETE` statement removes rows from a specified table.

14.13.2.40.1 Synopsis

```
DeleteFromStmt ::=
    'DELETE' TableOptimizerHints PriorityOpt QuickOptional IgnoreOptional (
        ↪ 'FROM' ( TableName TableAsNameOpt IndexHintListOpt
        ↪ WhereClauseOptional OrderByOptional LimitClause |
        ↪ TableAliasRefList 'USING' TableRefs WhereClauseOptional ) |
        ↪ TableAliasRefList 'FROM' TableRefs WhereClauseOptional )
```

14.13.2.40.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
5 rows in set (0.00 sec)

mysql> DELETE FROM t1 WHERE id = 4;
Query OK, 1 row affected (0.02 sec)

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
|  5 |  5 |
+----+----+
4 rows in set (0.00 sec)
```

14.13.2.40.3 MySQL compatibility

The `DELETE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.40.4 See also

- INSERT

- SELECT
- UPDATE
- REPLACE

14.13.2.41 DESC

This statement is an alias to `EXPLAIN`. It is included for compatibility with MySQL.

14.13.2.42 DESCRIBE

This statement is an alias to `EXPLAIN`. It is included for compatibility with MySQL.

14.13.2.43 DO

`DO` executes the expressions but does not return any results. In most cases, `DO` is equivalent to `SELECT expr, ...` that does not return a result.

> **Note:**
>
> `DO` only executes expressions. It cannot be used in all cases where `SELECT` can be used. For example, `DO id FROM t1` is invalid because it references a table.

In MySQL, a common use case is to execute stored procedure or trigger. Since TiDB does not provide stored procedure or trigger, this function has a limited use.

14.13.2.43.1 Synopsis

```
DoStmt  ::= 'DO' ExpressionList

ExpressionList ::=
    Expression ( ',' Expression )*

Expression ::=
    ( singleAtIdentifier assignmentEq | 'NOT' | Expression ( logOr | 'XOR' |
       ↪  logAnd ) ) Expression
|   'MATCH' '(' ColumnNameList ')' 'AGAINST' '(' BitExpr
    ↪ FulltextSearchModifierOpt ')'
|   PredicateExpr ( IsOrNotOp 'NULL' | CompareOp ( ( singleAtIdentifier
    ↪ assignmentEq )? PredicateExpr | AnyOrAll SubSelect ) )* ( IsOrNotOp (
    ↪  trueKwd | falseKwd | 'UNKNOWN' ) )?
```

14.13.2.43.2 Examples

This SELECT statement pauses, but also produces a result set.

```
mysql> SELECT SLEEP(5);
+----------+
| SLEEP(5) |
+----------+
|        0 |
+----------+
1 row in set (5.00 sec)
```

DO, on the other hand, pauses without producing a result set.

```
mysql> DO SLEEP(5);
Query OK, 0 rows affected (5.00 sec)

mysql> DO SLEEP(1), SLEEP(1.5);
Query OK, 0 rows affected (2.50 sec)
```

14.13.2.43.3 MySQL compatibility

The `DO` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.43.4 See also

- SELECT

14.13.2.44 DROP [GLOBAL|SESSION] BINDING

This statement removes a binding from a specific SQL statement. Bindings can be used to inject a hint into a statement without requiring changes to the underlying query.

A `BINDING` can be on either a `GLOBAL` or `SESSION` basis. The default is `SESSION`.

14.13.2.44.1 Synopsis

```
DropBindingStmt ::=
    'DROP' GlobalScope 'BINDING' 'FOR' ( BindableStmt ( 'USING' BindableStmt
       ↪ )?
|   'SQL' 'DIGEST' StringLiteralOrUserVariableList )

GlobalScope ::=
    ( 'GLOBAL' | 'SESSION' )?
```

```
BindableStmt ::=
    ( SelectStmt | UpdateStmt | InsertIntoStmt | ReplaceIntoStmt |
       ↪ DeleteStmt )

StringLiteralOrUserVariableList ::=
    ( StringLitOrUserVariable | StringLiteralOrUserVariableList ','
       ↪ StringLitOrUserVariable )

StringLiteralOrUserVariable ::=
    ( stringLiteral | UserVariable )
```

14.13.2.44.2 Examples

You can remove a binding according to a SQL statement or SQL Digest.

When you remove a binding according to SQL Digest, you need to specify the corresponding SQL Digest:

- You can use either the string literal or user variable of the string type to specify the Plan Digest.
- You can specify multiple string values, and include multiple digests in each string. Note that the strings or digests need to be separated by commas.

The following example shows how to remove a binding according to a SQL statement.

```
mysql> CREATE TABLE t1 (
        id INT NOT NULL PRIMARY KEY auto_increment,
        b INT NOT NULL,
        pad VARBINARY(255),
        INDEX(b)
       );
Query OK, 0 rows affected (0.07 sec)

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM dual;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 1 row affected (0.00 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
```

```
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 1000 rows affected (0.04 sec)
Records: 1000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (1.74 sec)
Records: 100000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (2.15 sec)
Records: 100000 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    ↪ FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 100000 rows affected (2.64 sec)

3 rows in set (0.01 sec)

mysql> SHOW SESSION BINDINGS\G
Empty set (0.00 sec)
```

The following example shows how to remove a binding according to SQL Digest.

```
CREATE TABLE t1(a INT, b INT, c INT, INDEX ia(a));
CREATE TABLE t2(a INT, b INT, c INT, INDEX ia(a));
CREATE GLOBAL BINDING FOR SELECT * FROM t1 WHERE a > 1 USING SELECT * FROM
    ↪ t1 USE INDEX (ia) WHERE a > 1;
CREATE GLOBAL BINDING FOR SELECT * FROM t2 WHERE a < 1 USING SELECT * FROM
    ↪ t2 USE INDEX (ia) WHERE a < 1;
CREATE GLOBAL BINDING FOR SELECT * FROM t1 JOIN t2 ON t1.b = t2.a USING
    ↪ SELECT /*+ HASH_JOIN(t1) */ * FROM t1 JOIN t2 ON t1.b = t2.a;
SHOW GLOBAL BINDINGS;
```

Method 1:

```
DROP GLOBAL BINDING FOR SQL DIGEST '31026623
    ↪ c8f22264fe0dfc26f29c69c5c457d6b85960c578ebcf17a967ed7893', '0
    ↪ f38b2e769927ae37981c66f0988c6299b602e03f029e38aa071e656fc321593', '3

14.13.2.45 DROP DATABASE

The `DROP DATABASE` statement permanently removes a specified database schema, and all of the tables and views that were created inside. User privileges that are associated with the dropped database remain unaffected.

14.13.2.45.1 Synopsis

```
DropDatabaseStmt ::=
    'DROP' 'DATABASE' IfExists DBName

IfExists ::= ( 'IF' 'EXISTS' )?
```

14.13.2.45.2 Examples

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| mysql              |
| test               |
+--------------------+
4 rows in set (0.00 sec)

mysql> DROP DATABASE test;
Query OK, 0 rows affected (0.25 sec)

mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
```

```
| PERFORMANCE_SCHEMA |
| mysql              |
+--------------------+
3 rows in set (0.00 sec)
```

14.13.2.45.3 MySQL compatibility

The `DROP DATABASE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.45.4 See also

- CREATE DATABASE
- ALTER DATABASE

14.13.2.46 DROP PLACEMENT POLICY

`DROP PLACEMENT POLICY` is used to drop a previously created placement policy.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.46.1 Synopsis

```
DropPolicyStmt ::=
    "DROP" "PLACEMENT" "POLICY" IfExists PolicyName

PolicyName ::=
    Identifier
```

14.13.2.46.2 Examples

Placement policies can only be dropped when they are not referenced by any tables or partitions.

```
CREATE PLACEMENT POLICY p1 FOLLOWERS=4;
CREATE TABLE t1 (a INT PRIMARY KEY) PLACEMENT POLICY=p1;
DROP PLACEMENT POLICY p1; -- This statement fails because the placement
    ↪ policy p1 is referenced.

-- Finds which tables and partitions reference the placement policy.
```

```
SELECT table_schema, table_name FROM information_schema.tables WHERE tidb_
    ↪ placement_policy_name='p1';
SELECT table_schema, table_name FROM information_schema.partitions WHERE
    ↪ tidb_placement_policy_name='p1';

ALTER TABLE t1 PLACEMENT POLICY=default; -- Removes the placement policy
    ↪ from t1.
DROP PLACEMENT POLICY p1; -- Succeeds.
```

```
Query OK, 0 rows affected (0.10 sec)

Query OK, 0 rows affected (0.11 sec)

ERROR 8241 (HY000): Placement policy 'p1' is still in use

+--------------+------------+
| table_schema | table_name |
+--------------+------------+
| test         | t1         |
+--------------+------------+
1 row in set (0.00 sec)

Empty set (0.01 sec)

Query OK, 0 rows affected (0.08 sec)

Query OK, 0 rows affected (0.21 sec)
```

14.13.2.46.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.46.4 See also

- Placement Rules in SQL
- SHOW PLACEMENT
- CREATE PLACEMENT POLICY
- ALTER PLACEMENT POLICY

14.13.2.47 DROP RESOURCE GROUP

You can use the `DROP RESOURCE GROUP` statement to drop a resource group.

Note:

This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.47.1 Synopsis

```
DropResourceGroupStmt ::=
    "DROP" "RESOURCE" "GROUP" IfExists ResourceGroupName

IfExists ::=
    ('IF' 'EXISTS')?

ResourceGroupName ::=
    Identifier
|   "DEFAULT"
```

Note:

- The `DROP RESOURCE GROUP` statement can only be executed when the global variable `tidb_enable_resource_control` is set to `ON`.
- The `default` resource group is reserved and cannot be dropped.

14.13.2.47.2 Examples

Drop a resource group named `rg1`.

```
DROP RESOURCE GROUP IF EXISTS rg1;
```

```
Query OK, 0 rows affected (0.22 sec)
```

```
CREATE RESOURCE GROUP IF NOT EXISTS rg1 RU_PER_SEC = 500 BURSTABLE;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='rg1';
```

```
+------+------------+----------+-----------+-------------+
| NAME | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT |
```

```
+------+------------+----------+----------+-------------+
| rg1  | 500        | MEDIUM   | YES      | NULL        |
+------+------------+----------+----------+-------------+
1 row in set (0.01 sec)
```

```
DROP RESOURCE GROUP IF EXISTS rg1;
```

```
Query OK, 1 rows affected (0.09 sec)
```

```
SELECT * FROM information_schema.resource_groups WHERE NAME ='rg1';
```

```
Empty set (0.00 sec)
```

14.13.2.47.3 MySQL compatibility

MySQL also supports DROP RESOURCE GROUP, but TiDB does not support the `FORCE` parameter.

14.13.2.47.4 See also

- ALTER RESOURCE GROUP
- CREATE RESOURCE GROUP
- Request Unit (RU)

14.13.2.48 DROP ROLE

This statement removes a role, that was previously created with `CREATE ROLE`.

14.13.2.48.1 Synopsis

```
DropRoleStmt ::=
    'DROP' 'ROLE' ( 'IF' 'EXISTS' )? RolenameList

RolenameList ::=
    Rolename ( ',' Rolename )*
```

14.13.2.48.2 Examples

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Create a new role `analyticsteam` and a new user `jennifer`:

```
CREATE ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)

GRANT SELECT ON test.* TO analyticsteam;
Query OK, 0 rows affected (0.02 sec)

CREATE USER jennifer;
Query OK, 0 rows affected (0.01 sec)

GRANT analyticsteam TO jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Note that by default `jennifer` needs to execute `SET ROLE analyticsteam` in order to be able to use the privileges associated with the `analyticsteam` role:

```
SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%'   |
+-----------------------------------------------+
2 rows in set (0.00 sec)

SHOW TABLES in test;
ERROR 1044 (42000): Access denied for user 'jennifer'@'%' to database 'test'
SET ROLE analyticsteam;
Query OK, 0 rows affected (0.00 sec)

SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT SELECT ON test.* TO 'jennifer'@'%'      |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%'   |
+-----------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
```

```
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

The statement `SET DEFAULT ROLE` can be used to associate the role `analyticsteam` to `jennifer`:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
Query OK, 0 rows affected (0.02 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

After this, the user `jennifer` has the privileges associated with the role `analyticsteam` and `jennifer` does not have to execute the statement `SET ROLE`:

```
SHOW GRANTS;
+-------------------------------------------+
| Grants for User                           |
+-------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'      |
| GRANT SELECT ON test.* TO 'jennifer'@'%'  |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Drop the role for the `analyticsteam`:

```
DROP ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)
```

`jennifer` no longer has the default role of `analyticsteam` associated, nor can set the role to `analyticsteam`.

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Show the privileges of `jennifer`:

```
SHOW GRANTS;
+-------------------------------------+
| Grants for User                     |
+-------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%' |
+-------------------------------------+
1 row in set (0.00 sec)

SET ROLE analyticsteam;
ERROR 3530 (HY000): `analyticsteam`@`%` is is not granted to jennifer@%
```

14.13.2.48.3 MySQL compatibility

The `DROP ROLE` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.48.4 See also

- CREATE ROLE
- GRANT <role>
- REVOKE <role>
- SET ROLE
- SET DEFAULT ROLE

- Role-Based Access Control

14.13.2.49 DROP SEQUENCE

The `DROP SEQUENCE` statement drops the sequence object in TiDB.

14.13.2.49.1 Synopsis

```
DropSequenceStmt ::=
    'DROP' 'SEQUENCE' IfExists TableNameList

IfExists ::= ( 'IF' 'EXISTS' )?

TableNameList ::=
    TableName ( ',' TableName )*

TableName ::=
    Identifier ('.' Identifier)?
```

14.13.2.49.2 Examples

```
DROP SEQUENCE seq;
```

```
Query OK, 0 rows affected (0.10 sec)
```

```
DROP SEQUENCE seq, seq2;
```

```
Query OK, 0 rows affected (0.03 sec)
```

14.13.2.49.3 MySQL compatibility

This statement is a TiDB extension. The implementation is modeled on sequences available in MariaDB.

14.13.2.49.4 See also

- CREATE SEQUENCE
- ALTER SEQUENCE
- SHOW CREATE SEQUENCE

14.13.2.50 DROP STATS

The `DROP STATS` statement is used to delete the statistics of the selected table from the selected database.

14.13.2.50.1 Synopsis

```
DropStatsStmt ::=
    'DROP' 'STATS' TableName ("PARTITION" partition | "GLOBAL")? ( ','
       ↪ TableName )*

TableName ::=
    Identifier ('.' Identifier)?
```

14.13.2.50.2 Usage

The following statement deletes all statistics of `TableName`. If a partitioned table is specified, this statement deletes statistics of all partitions in this table as well as global statistics generated in dynamic pruning mode.

```
DROP STATS TableName
```

```
Query OK, 0 rows affected (0.00 sec)
```

The following statement only deletes statistics of the specified partitions in `PartitionNameList` ↪ .

```
DROP STATS TableName PARTITION PartitionNameList;
```

```
Query OK, 0 rows affected (0.00 sec)
```

The following statement only deletes global statistics generated in dynamic pruning mode of the specified table.

```
DROP STATS TableName GLOBAL;
```

```
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.50.3 Examples

```
CREATE TABLE t(a INT);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
SHOW STATS_META WHERE db_name='test' and table_name='t';
```

```
+---------+------------+----------------+---------------------+--------------+----------
   ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_
   ↪ count |
```

```
+---------+-----------+---------------+---------------------+-------------+---------
    ↪
| test    | t         |               | 2020-05-25 20:34:33 |        0 |
    ↪        0 |
+---------+-----------+---------------+---------------------+-------------+---------
    ↪
1 row in set (0.00 sec)
```

```
DROP STATS t;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SHOW STATS_META WHERE db_name='test' and table_name='t';
```

```
Empty set (0.00 sec)
```

14.13.2.50.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.50.5 See also

- Introduction to Statistics

14.13.2.51 DROP TABLE

This statement drops a table from the currently selected database. An error is returned if the table does not exist, unless the `IF EXISTS` modifier is used.

14.13.2.51.1 Synopsis

```
DropTableStmt ::=
    'DROP' OptTemporary TableOrTables IfExists TableNameList
        ↪ RestrictOrCascadeOpt

OptTemporary ::=
    ( 'TEMPORARY' | ('GLOBAL' 'TEMPORARY') )?

TableOrTables ::=
    'TABLE'
|   'TABLES'

TableNameList ::=
    TableName ( ',' TableName )*
```

14.13.2.51.2 Drop temporary tables

You can use the following syntax to drop ordinary tables and temporary tables:

- Use `DROP TEMPORARY TABLE` to drop local temporary tables.
- Use `DROP GLOBAL TEMPORARY TABLE` to drop global temporary tables.
- Use `DROP TABLE` to drop ordinary tables or temporary tables.

14.13.2.51.3 Examples

```
mysql> CREATE TABLE t1 (a INT);
Query OK, 0 rows affected (0.11 sec)

mysql> DROP TABLE t1;
Query OK, 0 rows affected (0.22 sec)

mysql> DROP TABLE table_not_exists;
ERROR 1051 (42S02): Unknown table 'test.table_not_exists'

mysql> DROP TABLE IF EXISTS table_not_exists;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+-------+------+----------------------------------------+
| Level | Code | Message                                |
+-------+------+----------------------------------------+
| Note | 1051 | Unknown table 'test.table_not_exists' |
+-------+------+----------------------------------------+
1 row in set (0.01 sec)

mysql> CREATE VIEW v1 AS SELECT 1;
Query OK, 0 rows affected (0.10 sec)

mysql> DROP TABLE v1;
Query OK, 0 rows affected (0.23 sec)
```

14.13.2.51.4 MySQL compatibility

Currently, `RESTRICT` and `CASCADE` are only supported syntactically.

14.13.2.51.5 See also

- CREATE TABLE
- SHOW CREATE TABLE
- SHOW TABLES

14.13.2.52 DROP USER

This statement removes a user from the TiDB system database. The optional keyword `IF EXISTS` can be used to silence an error if the user does not exist. This statement requires the `CREATE USER` privilege.

14.13.2.52.1 Synopsis

```
DropUserStmt ::=
    'DROP' 'USER' ( 'IF' 'EXISTS' )? UsernameList

Username ::=
    StringName ('@' StringName | singleAtIdentifier)? | 'CURRENT_USER'
        ↪ OptionalBraces
```

14.13.2.52.2 Examples

```
mysql> DROP USER idontexist;
ERROR 1396 (HY000): Operation DROP USER failed for idontexist@%

mysql> DROP USER IF EXISTS 'idontexist';
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE USER 'newuser' IDENTIFIED BY 'mypassword';
Query OK, 1 row affected (0.02 sec)

mysql> GRANT ALL ON test.* TO 'newuser';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GRANTS FOR 'newuser';
+-------------------------------------------------+
| Grants for newuser@%                            |
+-------------------------------------------------+
| GRANT USAGE ON *.* TO 'newuser'@'%'             |
| GRANT ALL PRIVILEGES ON test.* TO 'newuser'@'%' |
+-------------------------------------------------+
2 rows in set (0.00 sec)

mysql> REVOKE ALL ON test.* FROM 'newuser';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GRANTS FOR 'newuser';
+---------------------------------+
| Grants for newuser@%            |
+---------------------------------+
```

```
| GRANT USAGE ON *.* TO 'newuser'@'%' |
+-------------------------------------+
1 row in set (0.00 sec)

mysql> DROP USER 'newuser';
Query OK, 0 rows affected (0.14 sec)

mysql> SHOW GRANTS FOR 'newuser';
ERROR 1141 (42000): There is no such grant defined for user 'newuser' on
    ↪ host '%'
```

14.13.2.52.3 MySQL compatibility

- Dropping a user that does not exist with `IF EXISTS` will not create a warning in TiDB. Issue #10196.

14.13.2.52.4 See also

- CREATE USER
- ALTER USER
- SHOW CREATE USER

- Privilege Management

14.13.2.53 DROP VIEW

This statement drops a view object from the currently selected database. It does not affect any base tables that a view references.

14.13.2.53.1 Synopsis

```
DropViewStmt ::=
    'DROP' 'VIEW' ( 'IF' 'EXISTS' )? TableNameList RestrictOrCascadeOpt

TableNameList ::=
    TableName ( ',' TableName )*

TableName ::=
    Identifier ('.' Identifier)?
```

14.13.2.53.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> CREATE VIEW v1 AS SELECT * FROM t1 WHERE c1 > 2;
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
5 rows in set (0.00 sec)

mysql> SELECT * FROM v1;
+----+----+
| id | c1 |
+----+----+
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
3 rows in set (0.00 sec)

mysql> DROP VIEW v1;
Query OK, 0 rows affected (0.23 sec)

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
```

```
|  4 |  4 |
|  5 |  5 |
+----+----+
5 rows in set (0.00 sec)
```

14.13.2.53.3 MySQL compatibility

The `DROP VIEW` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.53.4 See also

- CREATE VIEW
- DROP TABLE

14.13.2.54 EXECUTE

The `EXECUTE` statement provides an SQL interface to server-side prepared statements.

14.13.2.54.1 Synopsis

```
ExecuteStmt ::=
    'EXECUTE' Identifier ( 'USING' UserVariable ( ',' UserVariable )* )?
```

14.13.2.54.2 Examples

```
mysql> PREPARE mystmt FROM 'SELECT ? as num FROM DUAL';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @number = 5;
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE mystmt USING @number;
+------+
| num |
+------+
| 5   |
+------+
1 row in set (0.00 sec)

mysql> DEALLOCATE PREPARE mystmt;
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.54.3 MySQL compatibility

The `EXECUTE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.54.4 See also

- PREPARE
- DEALLOCATE

14.13.2.55 EXPLAIN ANALYZE

The `EXPLAIN ANALYZE` statement works similar to `EXPLAIN`, with the major difference being that it will actually execute the statement. This allows you to compare the estimates used as part of query planning to actual values encountered during execution. If the estimates differ significantly from the actual values, you should consider running `ANALYZE TABLE` on the affected tables.

> **Note:**
>
> When you use `EXPLAIN ANALYZE` to execute DML statements, modification to data is normally executed. Currently, the execution plan for DML statements **cannot** be shown yet.

14.13.2.55.1 Synopsis

```
ExplainSym ::=
    'EXPLAIN'
|   'DESCRIBE'
|    'DESC'

ExplainStmt ::=
    ExplainSym ( TableName ColumnName? | 'ANALYZE'? ExplainableStmt | 'FOR'
        ↪ 'CONNECTION' NUM | 'FORMAT' '=' ( stringLit | ExplainFormatType )
        ↪ ( 'FOR' 'CONNECTION' NUM | ExplainableStmt ) )

ExplainableStmt ::=
    SelectStmt
|   DeleteFromStmt
|   UpdateStmt
|   InsertIntoStmt
|   ReplaceIntoStmt
|   UnionStmt
```

14.13.2.55.2 EXPLAIN ANALYZE output format

Different from `EXPLAIN`, `EXPLAIN ANALYZE` executes the corresponding SQL statement, records its runtime information, and returns the information together with the execution plan. Therefore, you can regard `EXPLAIN ANALYZE` as an extension of the `EXPLAIN` statement. Compared to `EXPLAIN` (for debugging query execution), the return results of `EXPLAIN ANALYZE` also include columns of information such as `actRows`, `execution info`, `memory`, and `disk`. The details of these columns are shown as follows:

attribute name	description
actRows	Number of rows output by the operator.
execution info	Execution information of the operator. `time` represents the total `wall time` from entering the operator to leaving the operator, including the total execution time of all sub-operators. If the operator is called many times by the parent operator (in loops), then the time refers to the accumulated time. `loops` is the number of times the current operator is called by the parent operator.
memory	Memory space occupied by the operator.
disk	Disk space occupied by the operator.

14.13.2.55.3 Examples

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT NOT
    ↪ NULL);
```

```
Query OK, 0 rows affected (0.12 sec)
```

```
INSERT INTO t1 (c1) VALUES (1), (2), (3);
```

```
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
EXPLAIN ANALYZE SELECT * FROM t1 WHERE id = 1;
```

```
+--
    ↪ ----------+---------+---------+------+--------------+----------------------
    ↪
```

```

14.13.2.55.4 Execution information of operators

In addition to the basic `time` and `loop` execution information, `execution info` also contains operator-specific execution information, which mainly includes the time consumed for the operator to send RPC requests and the duration of other steps.

Point_Get

The execution information from a `Point_Get` operator will typically contain the following information:

- `Get:{num_rpc:1, total_time:697.051µs}`: The number of the `Get` RPC requests (`num_rpc`) sent to TiKV and the total duration (`total_time`) of all RPC requests.
- `ResolveLock:{num_rpc:1, total_time:12.117495ms}`: If TiDB encounters a lock when reading data, it has to resolve the lock first, which generally occurs in the scenario of read-write conflict. This information indicates the duration of resolving locks.
- `regionMiss_backoff:{num:11, total_time:2010 ms},tikvRPC_backoff:{num :11, total_time:10691 ms}`: When an RPC request fails, TiDB will wait the backoff time before retrying the request. Backoff statistics include the type of backoff (such as `regionMiss` and `tikvRPC`), the total waiting time (`total_time`), and the total number of backoffs (`num`).

Batch_Point_Get

The execution information of the `Batch_Point_Get` operator is similar to that of the `Point_Get` operator, but `Batch_Point_Get` generally sends `BatchGet` RPC requests to TiKV to read data.

`BatchGet:{num_rpc:2, total_time:83.13µs}`: The number of RPC requests (`num_rpc`) of the `BatchGet` type sent to TiKV and the total time consumed (`total_time`) for all RPC requests.

TableReader

The execution information of a `TableReader` operator is typically as follows:

```
cop_task: {num: 6, max: 1.07587ms, min: 844.312µs, avg: 919.601µs, p95:
    ↪ 1.07587ms, max_proc_keys: 16, p95_proc_keys: 16, tot_proc: 1ms, tot_
    ↪ wait: 1ms, copr_cache_hit_ratio: 0.00}, rpc_info:{Cop:{num_rpc:6,
    ↪ total_time:5.313996ms}}
```

- `cop_task`: Contains the execution information of `cop` tasks. For example:
  - `num`: The number of cop tasks.
  - `max`, `min`, `avg`, `p95`: The maximum, minimum, average, and P95 values of the execution time consumed for executing cop tasks.
  - `max_proc_keys` and `p95_proc_keys`: The maximum and P95 key-values scanned by TiKV in all cop tasks. If the difference between the maximum value and the P95 value is large, the data distribution might be imbalanced.
  - `copr_cache_hit_ratio`: The hit rate of Coprocessor Cache for `cop` task requests.
- `rpc_info`: The total number and total time of RPC requests sent to TiKV aggregated by request type.
- `backoff`: Contains different types of backoff and the total waiting time of backoff.

Insert

The execution information of an `Insert` operator is typically as follows:

```
prepare:109.616µs, check_insert:{total_time:1.431678ms, mem_insert_time
    ↪ :667.878µs, prefetch:763.8µs, rpc:{BatchGet:{num_rpc:1, total_time
    ↪ :699.166µs},Get:{num_rpc:1, total_time:378.276µs }}}
```

- `prepare`: The time consumed for preparing to write, including expression, default value and auto-increment value calculations.
- `check_insert`: This information generally appears in `insert ignore` and `insert ↪ on duplicate` statements, including conflict checking and the time consumed for writing data to TiDB transaction cache. Note that this time consumption does not include the time consumed for transaction commit. It contains the following information:
    - `total_time`: The total time spent on the `check_insert` step.
    - `mem_insert_time`: The time consumed for writing data to the TiDB transaction cache.
    - `prefetch`: The duration of retrieving the data that needs to be checked for conflicts from TiKV. This step sends a `Batch_Get` RPC request to TiKV to retrieve data.
    - `rpc`: The total time consumed for sending RPC requests to TiKV, which generally includes two types of RPC time, `BatchGet` and `Get`, among which:
        - `BatchGet` RPC request is sent in the `prefetch` step.
        - `Get` RPC request is sent when the `insert on duplicate` statement executes `duplicate update`.
- `backoff`: Contains different types of backoff and the total waiting time of backoff.

IndexJoin

The `IndexJoin` operator has 1 outer worker and N inner workers for concurrent execution. The join result preserves the order of the outer table. The detailed execution process is as follows:

1. The outer worker reads N outer rows, then wraps it into a task, and sends it to the result channel and the inner worker channel.
2. The inner worker receives the task, build key ranges from the task, and fetches inner rows according to the key ranges. It then builds the inner row hash table.
3. The main `IndexJoin` thread receives the task from the result channel and waits for the inner worker to finish handling the task.
4. The main `IndexJoin` thread joins each outer row by looking up to the inner rows' hash table.

The `IndexJoin` operator contains the following execution information:

```
inner:{total:4.297515932s, concurrency:5, task:17, construct:97.96291ms,
    ↪ fetch:4.164310088s, build:35.219574ms}, probe:53.574945ms
```

- `Inner`: The execution information of inner worker:
  - `total`: The total time consumed by the inner worker.
  - `concurrency`: The number of concurrent inner workers.
  - `task`: The total number of tasks processed by the inner worker.
  - `construct`: The preparation time before the inner worker reads the inner table rows corresponding to the task.
  - `fetch`: The total time consumed for it takes for the inner worker to read inner table rows.
  - `Build`: The total time consumed for it takes for the inner worker to construct the hash table of the corresponding inner table rows.
- `probe`: The total time consumed by the main `IndexJoin` thread to perform join operations with the hash table of the outer table rows and the inner table rows.

IndexHashJoin

The execution process of the `IndexHashJoin` operator is similar to that of the `IndexJoin` operator. `IndexHashJoin` operator also has 1 outer worker and N inner workers to execute in parallel, but the output order is not guaranteed to be consistent with that of the outer table. The detailed execution process is as follows:

1. The outer worker reads N outer rows, builds a task, and sends it to the inner worker channel.
2. The inner worker receives the tasks from the inner worker channel and performs the following three operations in order for every task:

a. Build a hash table from the outer rows
b. Build key ranges from outer rows and fetches inner rows
c. Probe the hash table and sends the join result to the result channel. Note: step a and step b are running concurrently.

3. The main thread of `IndexHashJoin` receives the join results from the result channel.

The `IndexHashJoin` operator contains the following execution information:

```
inner:{total:4.429220003s, concurrency:5, task:17, construct:96.207725ms,
    ↪ fetch:4.239324006s, build:24.567801ms, join:93.607362ms}
```

- `Inner`: the execution information of inner worker:

- `total`: the total time consumed by the inner worker.
- `concurrency`: the number of inner workers.
- `task`: The total number of tasks processed by the inner worker.
- `construct`: The preparation time before the inner worker reads the inner table rows.
- `fetch`: The total time consumed for inner worker to read inner table rows.
- `Build`: The total time consumed for inner worker to construct the hash table of the outer table rows.
- `join`: The total time consumed for inner worker to do join with the inner table rows and the hash table of outer table rows.

HashJoin

The `HashJoin` operator has an inner worker, an outer worker, and N join workers. The detailed execution process is as follows:

1. The inner worker reads inner table rows and constructs a hash table.
2. The outer worker reads the outer table rows, then wraps it into a task and sends it to the join worker.
3. The join worker waits for the hash table construction in step 1 to finish.
4. The join worker uses the outer table rows and hash table in the task to perform join operations, and then sends the join result to the result channel.
5. The main thread of `HashJoin` receives the join result from the result channel.

The `HashJoin` operator contains the following execution information:

```
build_hash_table:{total:146.071334ms, fetch:110.338509ms, build:35.732825ms
    ↪ }, probe:{concurrency:5, total:857.162518ms, max:171.48271ms, probe
    ↪ :125.341665ms, fetch:731.820853ms}
```

- `build_hash_table`: Reads the data of the inner table and constructs the execution information of the hash table:
    - `total`: The total time consumption.
    - `fetch`: The total time spent reading inner table data.
    - `build`: The total time spent constructing a hash table.
- `probe`: The execution information of join workers:
    - `concurrency`: The number of join workers.
    - `total`: The total time consumed by all join workers.
    - `max`: The longest time for a single join worker to execute.
    - `probe`: The total time consumed for joining with outer table rows and the hash table.
    - `fetch`: The total time that the join worker waits to read the outer table rows data.

TableFullScan (TiFlash)

The `TableFullScan` operator executed on a TiFlash node contains the following execution information:

```
tiflash_scan: {
  dtfile: {
    total_scanned_packs: 2,
    total_skipped_packs: 1,
    total_scanned_rows: 16000,
    total_skipped_rows: 8192,
    total_rough_set_index_load_time: 2ms,
    total_read_time: 20ms
  },
  total_create_snapshot_time: 1ms
}
```

- `dtfile`: the DTFile (DeltaTree File) related information during the table scan, which reflects the data scan status of the TiFlash Stable layer.
    - `total_scanned_packs`: the total number of packs that have been scanned in the DTFile. A pack is the minimum unit that can be read in the TiFlash DTFile. By default, every 8192 rows constitute a pack.
    - `total_skipped_packs`: the total number of packs that have been skipped by the scan in the DTFile. When a `WHERE` clause hits rough set indexes or matches the range filtering of a primary key, the irrelevant packs are skipped.
    - `total_scanned_rows`: the total number of rows that have been scanned in the DTFile. If there are multiple versions of updates or deletions because of MVCC, each version is counted independently.
    - `total_skipped_rows`: the total number of rows that are skipped by the scan in the DTFile.
    - `total_rs_index_load_time`: the total time used to read DTFile rough set indexes.
    - `total_read_time`: the total time used to read DTFile data.
- `total_create_snapshot_time`: the total time used to create snapshots during the table scan.

lock_keys execution information

When a DML statement is executed in a pessimistic transaction, the execution information of the operator might also include the execution information of `lock_keys`. For example:

```
lock_keys: {time:94.096168ms, region:6, keys:8, lock_rpc:274.503214ms, rpc_
    ↪ count:6}
```

- `time`: The total duration of executing the `lock_keys` operation.
- `region`: The number of Regions involved in executing the `lock_keys` operation.
- `keys`: The number of `Keys` that need `Lock`.
- `lock_rpc`: The total time spent sending an RPC request of the `Lock` type to TiKV. Because multiple RPC requests can be sent in parallel, the total RPC time consumption might be greater than the total time consumption of the `lock_keys` operation.
- `rpc_count`: The total number of RPC requests of the `Lock` type sent to TiKV.

commit_txn execution information

When a write-type DML statement is executed in a transaction with `autocommit=1`, the execution information of the write operator will also include the duration information of the transaction commit. For example:

```
commit_txn: {prewrite:48.564544ms, wait_prewrite_binlog:47.821579, get_
    ↪ commit_ts:4.277455ms, commit:50.431774ms, region_num:7, write_keys
    ↪ :16, write_byte:536}
```

- `prewrite`: The time consumed for the `prewrite` phase of the 2PC commit of the transaction.
- `wait_prewrite_binlog`:: The time consumed for waiting to write the prewrite Binlog.
- `get_commit_ts`: The time consumed for getting the transaction commit timestamp.
- `commit`: The time consumed for the `commit` phase during the 2PC commit of the transaction.
- `write_keys`: The total `keys` written in the transaction.
- `write_byte`: The total bytes of `key-value` written in the transaction, and the unit is byte.

RU (Request Unit) consumption

Request Unit (RU) is a unified abstraction unit of system resources, which is defined in TiDB resource control. The `execution info` of the top-level operator shows the overall RU consumption of this particular SQL statement.

```
RU:273.842670
```

> **Note:**
>
> This value shows the actual RUs consumed by this execution. The same SQL statement might consume different amounts of RUs each time it is executed due to the effects of caching (for example, coprocessor cache).

You can calculate the RU from the other values in `EXPLAIN ANALYZE`, specifically the `execution info` column. For example:

```
'executeInfo':
  time:2.55ms,
  loops:2,
  RU:0.329460,
  Get:{
      num_rpc:1,
      total_time:2.13ms
  },
  total_process_time: 231.5µs,
  total_wait_time: 732.9µs,
  tikv_wall_time: 995.8µs,
  scan_detail: {
     total_process_keys: 1,
     total_process_keys_size: 150,
     total_keys: 1,
     get_snapshot_time: 691.7µs,
     rocksdb: {
         block: {
             cache_hit_count: 2,
             read_count: 1,
             read_byte: 8.19 KB,
             read_time: 10.3µs
         }
     }
 },
```

The base costs are defined in the `tikv/pd` source code and the calculations are performed in the `model.go` file.

If you are using TiDB v7.1, the calculation is the sum of `BeforeKVRequest()` and `AfterKVRequest()` in `pd/pd-client/model.go`, that is:

```
before key/value request is processed:
     consumption.RRU += float64(kc.ReadBaseCost) -> kv.ReadBaseCost * rpc_
        ↪ nums

after key/value request is processed:
     consumption.RRU += float64(kc.ReadBytesCost) * readBytes -> kc.
        ↪ ReadBytesCost * total_process_keys_size
     consumption.RRU += float64(kc.CPUMsCost) * kvCPUMs -> kc.CPUMsCost *
        ↪ total_process_time
```

For writes and batch gets, the calculation is similar with different base costs.

Other common execution information

The Coprocessor operators usually contain two parts of execution time information: `cop_task` and `tikv_task`. `cop_task` is the time recorded by TiDB, and it is from the moment that the request is sent to the server to the moment that the response is received. `tikv_task` is the time recorded by TiKV Coprocessor itself. If there is much difference between the two, it might indicate that the time spent waiting for the response is too long, or the time spent on gRPC or network is too long.

14.13.2.55.5 MySQL compatibility

`EXPLAIN ANALYZE` is a feature of MySQL 8.0, but both the output format and the potential execution plans in TiDB differ substantially from MySQL.

14.13.2.55.6 See also

- Understanding the Query Execution Plan
- EXPLAIN
- ANALYZE TABLE
- TRACE

14.13.2.56 `EXPLAIN`

The `EXPLAIN` statement shows the execution plan for a query without executing it. It complements the `EXPLAIN ANALYZE` statement, which executes the query. If the output of `EXPLAIN` does not match the expected result, consider executing `ANALYZE TABLE` on each table in the query to make sure the table statistics are up to date.

> **Note:**
>
> Certain subqueries are pre-executed during the optimization phase to generate optimal execution plans, even in the `EXPLAIN` statement. For more information on this behavior and how to disable it, see `tidb_opt_enable_non_eval_scalar_subquery` and Disable the early execution of subqueries.

The statements `DESC` and `DESCRIBE` are aliases of the `EXPLAIN` statement. The alternative usage of `EXPLAIN <tableName>` is documented in `SHOW [FULL] COLUMNS FROM`.

TiDB supports the `EXPLAIN [options] FOR CONNECTION connection_id` statement. However, this statement is different from the `EXPLAIN FOR` statement in MySQL. For more details, see `EXPLAIN FOR CONNECTION`.

14.13.2.56.1 Synopsis

```
ExplainSym ::=
    'EXPLAIN'
|   'DESCRIBE'
|   'DESC'

ExplainStmt ::=
    ExplainSym ( TableName ColumnName? | 'ANALYZE'? ExplainableStmt | 'FOR'
        ↪ 'CONNECTION' NUM | 'FORMAT' '=' ( stringLit | ExplainFormatType )
        ↪ ( 'FOR' 'CONNECTION' NUM | ExplainableStmt ) )

ExplainableStmt ::=
    SelectStmt
|   DeleteFromStmt
|   UpdateStmt
|   InsertIntoStmt
|   ReplaceIntoStmt
|   UnionStmt
```

14.13.2.56.2 `EXPLAIN` output format

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow → button on your keyboard to horizontally scroll through the output.

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0. You can find details in TiDB Query Execution Plan Overview.

Currently, `EXPLAIN` in TiDB outputs 5 columns: `id`, `estRows`, `task`, `access object`, `operator info`. Each operator in the execution plan is described by these attributes, with

each row in the `EXPLAIN` output describing an operator. The description of each attribute is as follows:

Attribute name	Description
id	The operator ID is the unique identifier of the operator in the entire execution plan. In TiDB 2.1, the ID is formatted to display the tree structure of the operator. Data flows from the child node to the parent node. One and only one parent node for each operator.
estRows	The number of rows that the operator is expected to output. This number is estimated according to the statistics and the operator's logic. `estRows` is called `count` in the earlier versions of TiDB 4.0.
task	The type of task the operator belongs to. Currently, the execution plans are divided into two tasks: **root** task, which is executed on tidb-server, and **cop** task, which is performed in parallel on TiKV or TiFlash. The topology of the execution plan at the task level is that a root task followed by many cop tasks. The root task uses the output of cop tasks as input. The cop tasks refer to tasks that TiDB pushes down to TiKV or TiFlash. Each cop task is distributed in the TiKV cluster or the TiFlash cluster, and is executed by multiple processes.
access object	Data item information accessed by the operator. The information includes `table`, `partition`, and `index` (if any). Only operators that directly access the data have such information.
operator info	Other information about the operator. `operator info` of each operator is different. You can refer to the following examples.

14.13.2.56.3 Examples

```
EXPLAIN SELECT 1;
```

    ↪
4 rows in set (0.01 sec)
```

To specify the format of the `EXPLAIN` output, you can use the `FORMAT = xxx` syntax. Currently, TiDB supports the following formats:

FORMAT	Description
Not specified	If the format is not specified, `EXPLAIN` uses the default format `row`.
`brief`	The operator IDs in the output of the `EXPLAIN` statement are simplified, compared with those when `FORMAT` is left unspecified.

FORMAT	Description
`dot`	The `EXPLAIN` statement outputs DOT execution plans, which can be used to generate PNG files through a `dot` program (in the `graphviz` package).

FORMAT	Description
`row`	The `EXPLAIN` statement outputs results in a tabular format. See Understand the Query Execution Plan for more information.

FORMAT	Description
`tidb_json`	The `EXPLAIN` statement outputs execution plans in JSON and stores the operator information in a JSON array.

FORMAT	Description
`verbose` ↪	The `EXPLAIN` ↪ statement outputs results in the `row` format, with an additional `estCost` ↪ column for the estimated cost of the query in the results. For more information about how to use this format, see SQL Plan Management.

FORMAT	Description
plan_cache	The EXPLAIN statement outputs results in the row format, with the Plan Cache information as a warning.

The following is an example when FORMAT is "brief" in EXPLAIN:

```
EXPLAIN FORMAT = "brief" DELETE FROM t1 WHERE c1 = 3;
```

```
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| Delete                | N/A     | root      |               | N/A
   ↪                        |
|  -TableReader         | 0.00    | root      |               | data:Selection
   ↪              |
|    -Selection         | 0.00    | cop[tikv] |               | eq(test.t1.c1, 3)
   ↪           |
|      -TableFullScan   | 3.00    | cop[tikv] | table:t1      | keep order:false,
   ↪  stats:pseudo |
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
```

```
4 rows in set (0.001 sec)
```

In addition to the MySQL standard result format, TiDB also supports DotGraph and you need to specify `FORMAT = "dot"` as in the following example:

```
CREATE TABLE t(a bigint, b bigint);
EXPLAIN format = "dot" SELECT A.a, B.b FROM t A JOIN t B ON A.a > B.b WHERE
    ↪  A.a < 10;
```

```
+--
    ↪ ------------------------------------------------------------------------------
    ↪
| dot contents
    ↪
    ↪ |
+--
    ↪ ------------------------------------------------------------------------------
    ↪
|
digraph Projection_8 {
subgraph cluster8{
node [style=filled, color=lightgrey]
color=black
label = "root"
"Projection_8" -> "HashJoin_9"
"HashJoin_9" -> "TableReader_13"
"HashJoin_9" -> "Selection_14"
"Selection_14" -> "TableReader_17"
}
subgraph cluster12{
node [style=filled, color=lightgrey]
color=black
label = "cop"
"Selection_12" -> "TableFullScan_11"
}
subgraph cluster16{
node [style=filled, color=lightgrey]
color=black
label = "cop"
"Selection_16" -> "TableFullScan_15"
}
"TableReader_13" -> "Selection_12"
"TableReader_17" -> "Selection_16"
}
 |
```

```
+--
    ↪ ----------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

If your computer has a `dot` program, you can generate a PNG file using the following method:

```
dot xx.dot -T png -O

The xx.dot is the result returned by the above statement.
```

If your computer has no `dot` program, copy the result to this website to get a tree diagram:

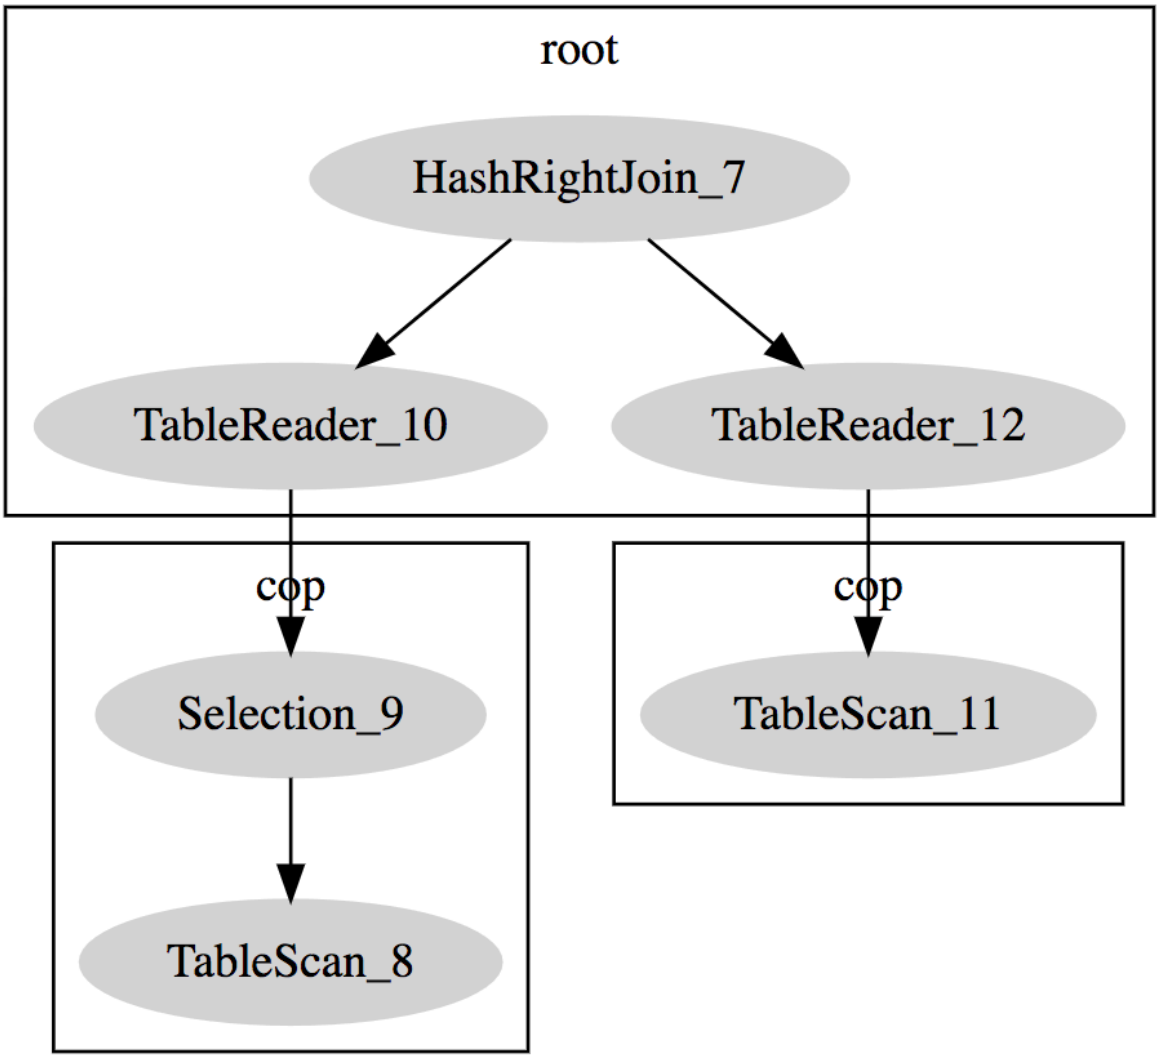

Figure 589: Explain Dot

To get the output in JSON, specify `FORMAT = "tidb_json"` in the `EXPLAIN` statement. The following is an example:

```
CREATE TABLE t(id int primary key, a int, b int, key(a));
EXPLAIN FORMAT = "tidb_json" SELECT id FROM t WHERE a = 1;
```

```
+-------------------------------------------------------------------------------------------------
    ↪
| TiDB_JSON
    ↪
    ↪ |
```

```
+-------------------------------------------------------------------------------------------
    ↪
| [
    {
        "id": "Projection_4",
        "estRows": "10.00",
        "taskType": "root",
        "operatorInfo": "test.t.id",
        "subOperators": [
            {
                "id": "IndexReader_6",
                "estRows": "10.00",
                "taskType": "root",
                "operatorInfo": "index:IndexRangeScan_5",
                "subOperators": [
                    {
                        "id": "IndexRangeScan_5",
                        "estRows": "10.00",
                        "taskType": "cop[tikv]",
                        "accessObject": "table:t, index:a(a)",
                        "operatorInfo": "range:[1,1], keep order:false, stats:
                            ↪ pseudo"
                    }
                ]
            }
        ]
    }
]
 |
+-------------------------------------------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

In the output, `id`, `estRows`, `taskType`, `accessObject`, and `operatorInfo` have the same meaning as the columns in the default format. `subOperators` is an array that stores the sub-nodes. The fields and meanings of the sub-nodes are the same as the parent node. If a field is missing, it means that the field is empty.

14.13.2.56.4 MySQL compatibility

- Both the format of `EXPLAIN` and the potential execution plans in TiDB differ substantially from MySQL.
- TiDB does not support the `FORMAT=JSON` or `FORMAT=TREE` options.
- `FORMAT=tidb_json` in TiDB is the JSON format output of the default `EXPLAIN` result. The format and fields are different from the `FORMAT=JSON` output in MySQL.

`EXPLAIN FOR CONNECTION`

`EXPLAIN FOR CONNECTION` is used to get the execution plan of the currently executed SQL query or the last executed SQL query in a connection. The output format is the same as that of `EXPLAIN`. However, the implementation of `EXPLAIN FOR CONNECTION` in TiDB is different from that in MySQL. Their differences (apart from the output format) are listed as follows:

- If the connection is sleeping, MySQL returns an empty result, while TiDB returns the last executed query plan.
- If you try to get the execution plan of the current session, MySQL returns an error, while TiDB returns the result normally.
- MySQL requires the login user to be the same as the connection being queried, or the login user has the **`PROCESS`** privilege; while TiDB requires the login user to be the same as the connection being queried, or the login user has the **`SUPER`** privilege.

14.13.2.57 FLASHBACK CLUSTER

TiDB v6.4.0 introduces the `FLASHBACK CLUSTER TO TIMESTAMP` syntax. You can use it to restore a cluster to a specific point in time. When specifying the timestamp, you can either set a datetime value or use a time function. The format of datetime is like '2016-10-08 16:45:26.999', with millisecond as the minimum time unit. But in most cases, specifying the timestamp with second as the time unit is sufficient, for example, '2016-10-08 16:45:26'.

Starting from v6.5.6, v7.1.3, v7.5.1, and v7.6.0, TiDB introduces the `FLASHBACK CLUSTER TO TSO` syntax. This syntax enables you to use TSO to specify a more precise recovery point in time, thereby enhancing flexibility in data recovery.

> **Warning:**
>
> The `FLASHBACK CLUSTER TO [TIMESTAMP|TSO]` syntax is not applicable to TiDB Cloud Serverless clusters. To avoid unexpected results, do not execute this statement on TiDB Cloud Serverless clusters.

Warning:

- When specifying a recovery point in time, make sure to check the validity of your target timestamp or TSO and avoid specifying a future time that exceeds the maximum TSO currently allocated by PD (see `Current TSO` ↪ on the Grafana PD panel). Otherwise, concurrent processing linear consistency and transaction isolation levels might be violated, leading to serious data correctness issues.
- During `FLASHBACK CLUSTER` execution, the data cleanup process does not guarantee transaction consistency. After `FLASHBACK CLUSTER` completes, if you intend to use any historical version reading features in TiDB (such as Stale Read or `tidb_snapshot`), make sure that the specified historical timestamp falls outside the `FLASHBACK CLUSTER` execution period. Reading a historical version that includes data not fully restored by FLASHBACK might violate concurrent processing linear consistency and transaction isolation levels, leading to serious data correctness issues.

Warning:

When you use this feature in TiDB v7.1.0, some Regions might remain in the FLASHBACK process even after the completion of the FLASHBACK operation. It is recommended to avoid using this feature in v7.1.0. For more information, see issue #44292.

If you have encountered this issue, you can use the TiDB snapshot backup and restore feature to restore data.

Note:

The working principle of `FLASHBACK CLUSTER TO [TIMESTAMP|TSO]` is to write the old data of a specific point in time with the latest timestamp, and will not delete the current data. So before using this feature, you need to ensure that there is enough storage space for the old data and the current data.

14.13.2.57.1 Syntax

```
FLASHBACK CLUSTER TO TIMESTAMP '2022-09-21 16:02:50';
FLASHBACK CLUSTER TO TSO 445494839813079041;
```

Synopsis

```
FlashbackToTimestampStmt
        ::= 'FLASHBACK' 'CLUSTER' 'TO' ('TIMESTAMP' stringLit | 'TSO'
           ↪ LengthNum)
```

14.13.2.57.2 Notes

- The time specified in the `FLASHBACK` statement must be within the Garbage Collection (GC) lifetime. The system variable `tidb_gc_life_time` (default: `10m0s`) defines the retention time of earlier versions of rows. The current `safePoint` of where garbage collection has been performed up to can be obtained with the following query:

  ```
  SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point';
  ```

- Only a user with the `SUPER` privilege can execute the `FLASHBACK CLUSTER` SQL statement.
- `FLASHBACK CLUSTER` does not support rolling back DDL statements that modify PD-related information, such as `ALTER TABLE ATTRIBUTE`, `ALTER TABLE REPLICA`, and `CREATE PLACEMENT POLICY`.
- At the time specified in the `FLASHBACK` statement, there cannot be a DDL statement that is not completely executed. If such a DDL exists, TiDB will reject it.
- Before executing `FLASHBACK CLUSTER`, TiDB disconnects all related connections and prohibits read and write operations on these tables until the `FLASHBACK CLUSTER` statement is completed.
- The `FLASHBACK CLUSTER` statement cannot be canceled after being executed. TiDB will keep retrying until it succeeds.
- During the execution of `FLASHBACK CLUSTER`, if you need to back up data, you can only use Backup & Restore and specify a `BackupTS` that is earlier than the start time of `FLASHBACK CLUSTER`. In addition, during the execution of `FLASHBACK CLUSTER`, enabling log backup will fail. Therefore, try to enable log backup after `FLASHBACK CLUSTER` is completed.
- If the `FLASHBACK CLUSTER` statement causes the rollback of metadata (table structure, database structure), the related modifications will **not** be replicated by TiCDC. Therefore, you need to pause the task manually, wait for the completion of `FLASHBACK CLUSTER`, and manually replicate the schema definitions of the upstream and downstream to make sure that they are consistent. After that, you need to recreate the TiCDC changefeed.

14.13.2.57.3 Example

The following example shows how to flashback a cluster to a specific timestamp to restore newly inserted data:

```
mysql> CREATE TABLE t(a INT);
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT * FROM t;
Empty set (0.01 sec)

mysql> SELECT now();
+---------------------+
| now()               |
+---------------------+
| 2022-09-28 17:24:16 |
+---------------------+
1 row in set (0.02 sec)

mysql> INSERT INTO t VALUES (1);
Query OK, 1 row affected (0.02 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
|    1 |
+------+
1 row in set (0.01 sec)

mysql> FLASHBACK CLUSTER TO TIMESTAMP '2022-09-28 17:24:16';
Query OK, 0 rows affected (0.20 sec)

mysql> SELECT * FROM t;
Empty set (0.00 sec)
```

The following example shows how to flashback a cluster to a specific TSO to precisely restore mistakenly deleted data:

```
mysql> INSERT INTO t VALUES (1);
Query OK, 1 row affected (0.02 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
|    1 |
```

```
+------+
1 row in set (0.01 sec)

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT @@tidb_current_ts; -- Get the current TSO
+--------------------+
| @@tidb_current_ts |
+--------------------+
| 446113975683252225 |
+--------------------+
1 row in set (0.00 sec)

mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)

mysql> DELETE FROM t;
Query OK, 1 rows affected (0.00 sec)

mysql> FLASHBACK CLUSTER TO TSO 446113975683252225;
Query OK, 0 rows affected (0.20 sec)

mysql> SELECT * FROM t;
+------+
| a    |
+------+
|    1 |
+------+
1 row in set (0.01 sec)
```

If there is a DDL statement that is not completely executed at the time specified in the `FLASHBACK` statement, the `FLASHBACK` statement fails:

```
mysql> ALTER TABLE t ADD INDEX k(a);
Query OK, 0 rows affected (0.56 sec)

mysql> ADMIN SHOW DDL JOBS 1;
+--
    ↪ ------+---------+----------------------+----------------------+-------------
    ↪
| JOB_ID | DB_NAME | TABLE_NAME       | JOB_TYPE             | SCHEMA_STATE |
```

```
    ↪  SCHEMA_ID | TABLE_ID | ROW_COUNT | CREATE_TIME | START_TIME      |
    ↪ END_TIME          | STATE |
+--
    ↪ ------+---------+---------------------+---------------------+-------------
    ↪
|    84 | test   | t                   | add index /* ingest */ | public  |
    ↪        2 |      82 |        0 | 2023-01-29 14:33:11 | 2023-01-29
    ↪ 14:33:11 | 2023-01-29 14:33:12 | synced |
+--
    ↪ ------+---------+---------------------+---------------------+-------------
    ↪
1 rows in set (0.01 sec)

mysql> FLASHBACK CLUSTER TO TIMESTAMP '2023-01-29 14:33:12';
ERROR 1105 (HY000): Detected another DDL job at 2023-01-29 14:33:12 +0800
    ↪ CST, can't do flashback
```

Through the log, you can obtain the execution progress of `FLASHBACK`. The following is an example:

```
[2022/10/09 17:25:59.316 +08:00] [INFO] [cluster.go:463] ["flashback cluster
    ↪  stats"] ["complete regions"=9] ["total regions"=10] []
```

14.13.2.57.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.58 FLASHBACK DATABASE

TiDB v6.4.0 introduces the `FLASHBACK DATABASE` syntax. You can use `FLASHBACK ↪ DATABASE` to restore a database and its data that are deleted by the `DROP` statement within the Garbage Collection (GC) life time.

You can set the retention time of historical data by configuring the `tidb_gc_life_time` system variable. The default value is `10m0s`. You can query the current `safePoint`, that is, the time point GC has been performed up to, using the following SQL statement:

```
SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point';
```

As long as a database is deleted by `DROP` after the `tikv_gc_safe_point` time, you can use `FLASHBACK DATABASE` to restore the database.

14.13.2.58.1 Syntax

```
FLASHBACK DATABASE DBName [TO newDBName]
```

Synopsis

```
FlashbackDatabaseStmt ::=
    'FLASHBACK' DatabaseSym DBName FlashbackToNewName
FlashbackToNewName ::=
    ( 'TO' Identifier )?
```

14.13.2.58.2 Notes

- If the database is deleted before the `tikv_gc_safe_point` time, you cannot restore the data using the `FLASHBACK DATABASE` statement. The `FLASHBACK DATABASE` statement returns an error similar to `ERROR 1105 (HY000): Can't find dropped database ' ↪ test' in GC safe point 2022-11-06 16:10:10 +0800 CST`.
- You cannot restore the same database multiple times using the `FLASHBACK DATABASE` ↪ statement. Because the database restored by `FLASHBACK DATABASE` has the same schema ID as the original database, restoring the same database multiple times leads to duplicate schema IDs. In TiDB, the database schema ID must be globally unique.

14.13.2.58.3 Example

- Restore the `test` database that is deleted by `DROP`:

```
DROP DATABASE test;
```

```
FLASHBACK DATABASE test;
```

- Restore the `test` database that is deleted by `DROP` and rename it to `test1`:

```
DROP DATABASE test;
```

```
FLASHBACK DATABASE test TO test1;
```

14.13.2.58.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.59 FLASHBACK TABLE

The `FLASHBACK TABLE` syntax is introduced since TiDB 4.0. You can use the `FLASHBACK` ↪ `TABLE` statement to restore the tables and data dropped by the `DROP` or `TRUNCATE` operation within the Garbage Collection (GC) lifetime.

The system variable `tidb_gc_life_time` (default: `10m0s`) defines the retention time of earlier versions of rows. The current `safePoint` of where garbage collection has been performed up to can be obtained with the following query:

```
SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point';
```

As long as the table is dropped by `DROP` or `TRUNCATE` statements after the `tikv_gc_safe_point` time, you can restore the table using the `FLASHBACK TABLE` statement.

14.13.2.59.1 Syntax

```
FLASHBACK TABLE table_name [TO other_table_name]
```

14.13.2.59.2 Synopsis

```
FlashbackTableStmt ::=
    'FLASHBACK' 'TABLE' TableName FlashbackToNewName

TableName ::=
    Identifier ( '.' Identifier )?

FlashbackToNewName ::=
    ( 'TO' Identifier )?
```

14.13.2.59.3 Notes

If a table is dropped and the GC lifetime has passed, you can no longer use the `FLASHBACK TABLE` statement to recover the dropped data. Otherwise, an error like `Can't find dropped / truncated table 't' in GC safe point 2020-03-16 16:34:52 +0800 CST` will be returned.

14.13.2.59.4 Example

- Recover the table data dropped by the `DROP` operation:

```
DROP TABLE t;
```

```
FLASHBACK TABLE t;
```

- Recover the table data dropped by the `TRUNCATE` operation. Because the truncated table `t` still exists, you need to rename the table `t` to be recovered. Otherwise, an error will be returned because the table `t` already exists.

```
TRUNCATE TABLE t;
```

```
FLASHBACK TABLE t TO t1;
```

14.13.2.59.5 Implementation principle

When deleting a table, TiDB only deletes the table metadata, and writes the table data (row data and index data) to be deleted to the `mysql.gc_delete_range` table. The GC Worker in the TiDB background periodically removes from the `mysql.gc_delete_range` table the keys that exceed the GC lifetime.

Therefore, to recover a table, you only need to recover the table metadata and delete the corresponding row record in the `mysql.gc_delete_range` table before the GC Worker deletes the table data. You can use a snapshot read of TiDB to recover the table metadata. For details of snapshot read, refer to Read Historical Data.

The following is the working process of `FLASHBACK TABLE t TO t1`:

1. TiDB searches the recent DDL history jobs and locates the first DDL operation of the `DROP TABLE` or the `truncate table` type on table `t`. If TiDB fails to locate one, an error is returned.
2. TiDB checks whether the starting time of the DDL job is before `tikv_gc_safe_point`. If it is before `tikv_gc_safe_point`, it means that the table dropped by the `DROP` or `TRUNCATE` operation has been cleaned up by the GC and an error is returned.
3. TiDB uses the starting time of the DDL job as the snapshot to read historical data and read table metadata.
4. TiDB deletes GC tasks related to table `t` in `mysql.gc_delete_range`.
5. TiDB changes `name` in the table's metadata to `t1`, and uses this metadata to create a new table. Note that only the table name is changed but not the table ID. The table ID is the same as that of the previously dropped table `t`.

From the above process, you can see that TiDB always operates on the metadata of the table, and the user data of the table has never been modified. The restored table `t1` has the same ID as the previously dropped table `t`, so `t1` can read the user data of `t`.

> **Note:**
>
> You cannot use `FLASHBACK` statements to restore the same deleted table multiple times, because the ID of the restored table is the same ID of the dropped table, and TiDB requires that all existing tables must have a globally unique table ID.

The `FLASHBACK TABLE` operation is done by TiDB obtaining the table metadata through snapshot read, and then going through the process of table creation similar to `CREATE TABLE`. Therefore, `FLASHBACK TABLE` is, in essence, a kind of DDL operation.

14.13.2.59.6 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.60 FLUSH PRIVILEGES

The statement `FLUSH PRIVILEGES` instructs TiDB to reload the in-memory copy of privileges from the privilege tables. You must execute this statement after manually editing tables such as `mysql.user`. However, executing this statement is not necessary after using privilege statements like `GRANT` or `REVOKE`. To execute this statement, the `RELOAD` privilege is required.

14.13.2.60.1 Synopsis

```
FlushStmt ::=
    'FLUSH' NoWriteToBinLogAliasOpt FlushOption

NoWriteToBinLogAliasOpt ::=
    ( 'NO_WRITE_TO_BINLOG' | 'LOCAL' )?

FlushOption ::=
    'PRIVILEGES'
|   'STATUS'
|    'TIDB' 'PLUGINS' PluginNameList
|    'HOSTS'
|   LogTypeOpt 'LOGS'
|   TableOrTables TableNameListOpt WithReadLockOpt
```

14.13.2.60.2 Examples

```
mysql> FLUSH PRIVILEGES;
Query OK, 0 rows affected (0.01 sec)
```

14.13.2.60.3 MySQL compatibility

The `FLUSH PRIVILEGES` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.60.4 See also

- SHOW GRANTS
- Privilege Management

14.13.2.61 FLUSH STATUS

This statement is included for compatibility with MySQL. It has no effect on TiDB, which uses Prometheus and Grafana for centralized metrics collection instead of `SHOW STATUS`.

14.13.2.61.1 Synopsis

```
FlushStmt ::=
    'FLUSH' NoWriteToBinLogAliasOpt FlushOption

NoWriteToBinLogAliasOpt ::=
    ( 'NO_WRITE_TO_BINLOG' | 'LOCAL' )?

FlushOption ::=
    'PRIVILEGES'
|   'STATUS'
|    'TIDB' 'PLUGINS' PluginNameList
|    'HOSTS'
|   LogTypeOpt 'LOGS'
|   TableOrTables TableNameListOpt WithReadLockOpt
```

14.13.2.61.2 Examples

```
mysql> show status;
+-------------------+--------------------------------------+
| Variable_name     | Value                                |
+-------------------+--------------------------------------+
| Ssl_cipher_list   |                                      |

14.13.2.61.3 MySQL compatibility

- This statement is compatible with MySQL.

14.13.2.61.4 See also

- SHOW [GLOBAL|SESSION] STATUS
- Server Status Variables

14.13.2.62 FLUSH TABLES

This statement is included for compatibility with MySQL. It has no effective usage in TiDB.

14.13.2.62.1 Synopsis

```
FlushStmt ::=
    'FLUSH' NoWriteToBinLogAliasOpt FlushOption

NoWriteToBinLogAliasOpt ::=
    ( 'NO_WRITE_TO_BINLOG' | 'LOCAL' )?

FlushOption ::=
    'PRIVILEGES'
|   'STATUS'
|    'TIDB' 'PLUGINS' PluginNameList
|    'HOSTS'
|    LogTypeOpt 'LOGS'
```

```
|    TableOrTables TableNameListOpt WithReadLockOpt

LogTypeOpt ::=
    ( 'BINARY' | 'ENGINE' | 'ERROR' | 'GENERAL' | 'SLOW' )?

TableOrTables ::=
    'TABLE'
|   'TABLES'

TableNameListOpt ::=
    TableNameList?

WithReadLockOpt ::=
    ( 'WITH' 'READ' 'LOCK' )?
```

14.13.2.62.2 Examples

```
mysql> FLUSH TABLES;
Query OK, 0 rows affected (0.00 sec)

mysql> FLUSH TABLES WITH READ LOCK;
ERROR 1105 (HY000): FLUSH TABLES WITH READ LOCK is not supported. Please
    ↪ use @@tidb_snapshot
```

14.13.2.62.3 MySQL compatibility

- TiDB does not have a concept of table cache as in MySQL. Thus, `FLUSH TABLES` is parsed but ignored in TiDB for compatibility.
- The statement `FLUSH TABLES WITH READ LOCK` produces an error, as TiDB does not currently support locking tables. It is recommended to use Historical reads for this purpose instead.

14.13.2.62.4 See also

- Read historical data

14.13.2.63 `GRANT <privileges>`

This statement allocates privileges to a pre-existing user in TiDB. The privilege system in TiDB follows MySQL, where credentials are assigned based on a database/table pattern. Executing this statement requires the `GRANT OPTION` privilege and all privileges you allocate.

14.13.2.63.1 Synopsis

```
GrantStmt ::=
    'GRANT' PrivElemList 'ON' ObjectType PrivLevel 'TO' UserSpecList
       ↪ RequireClauseOpt WithGrantOptionOpt

PrivElemList ::=
    PrivElem ( ',' PrivElem )*

PrivElem ::=
    PrivType ( '(' ColumnNameList ')' )?

PrivType ::=
    'ALL' 'PRIVILEGES'?
|    'ALTER' 'ROUTINE'?
|   'CREATE' ( 'USER' | 'TEMPORARY' 'TABLES' | 'VIEW' | 'ROLE' | 'ROUTINE' )
    ↪ ?
|   'TRIGGER'
|   'DELETE'
|   'DROP' 'ROLE'?
|    'PROCESS'
|   'EXECUTE'
|   'INDEX'
|   'INSERT'
|   'SELECT'
|   'SUPER'
|   'SHOW' ( 'DATABASES' | 'VIEW' )
|   'UPDATE'
|    'GRANT' 'OPTION'
|    'REFERENCES'
|    'REPLICATION' ( 'SLAVE' | 'CLIENT' )
|    'USAGE'
|   'RELOAD'
|   'FILE'
|   'CONFIG'
|   'LOCK' 'TABLES'
|   'EVENT'
|   'SHUTDOWN'

ObjectType ::=
    'TABLE'?

PrivLevel ::=
    '*' ( '.' '*' )?
|    Identifier ( '.' ( '*' | Identifier ) )?
```

```
UserSpecList ::=
    UserSpec ( ',' UserSpec )*

RequireClauseOpt ::= ('REQUIRE' ('NONE' | 'SSL' | 'X509' |
    ↪ RequireListElement ('AND'? RequireListElement)*))?

RequireListElement ::= 'ISSUER' Issuer | 'SUBJECT' Subject | 'CIPHER' Cipher
    ↪  | 'SAN' SAN | 'TOKEN_ISSUER' TokenIssuer
```

14.13.2.63.2 Examples

```
mysql> CREATE USER 'newuser' IDENTIFIED BY 'mypassword';
Query OK, 1 row affected (0.02 sec)

mysql> GRANT ALL ON test.* TO 'newuser';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GRANTS FOR 'newuser';
+-------------------------------------------------+
| Grants for newuser@%                            |
+-------------------------------------------------+
| GRANT USAGE ON *.* TO 'newuser'@'%'             |
| GRANT ALL PRIVILEGES ON test.* TO 'newuser'@'%' |
+-------------------------------------------------+
2 rows in set (0.00 sec)
```

14.13.2.63.3 MySQL compatibility

- Similar to MySQL, the `USAGE` privilege denotes the ability to log into a TiDB server.
- Column level privileges are not currently supported.
- Similar to MySQL, when the `NO_AUTO_CREATE_USER` sql mode is not present, the `GRANT` statement will automatically create a new user with an empty password when a user does not exist. Removing this sql-mode (it is enabled by default) presents a security risk.
- In TiDB, after the `GRANT <privileges>` statement is executed successfully, the execution result takes effect immediately on the current connection. Whereas in MySQL, for some privileges, the execution results take effect only on subsequent connections. See TiDB #39356 for details.

14.13.2.63.4 See also

- GRANT <role>

- REVOKE <privileges>
- SHOW GRANTS

- Privilege Management

14.13.2.64 GRANT <role>

Assigns a previously created role to an existing user. The user can use then use the statement SET ROLE <rolename> to assume the privileges of the role, or SET ROLE ALL to assume all roles that have been assigned.

14.13.2.64.1 Synopsis

```
GrantRoleStmt ::=
    'GRANT' RolenameList 'TO' UsernameList

RolenameList ::=
    Rolename ( ',' Rolename )*

UsernameList ::=
    Username ( ',' Username )*
```

14.13.2.64.2 Examples

Connect to TiDB as the root user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Create a new role analyticsteam and a new user jennifer:

```
CREATE ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)

GRANT SELECT ON test.* TO analyticsteam;
Query OK, 0 rows affected (0.02 sec)

CREATE USER jennifer;
Query OK, 0 rows affected (0.01 sec)

GRANT analyticsteam TO jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the jennifer user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Note that by default `jennifer` needs to execute `SET ROLE analyticsteam` in order to be able to use the privileges associated with the `analyticsteam` role:

```
SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-----------------------------------------------+
2 rows in set (0.00 sec)

SHOW TABLES in test;
ERROR 1044 (42000): Access denied for user 'jennifer'@'%' to database 'test'
SET ROLE analyticsteam;
Query OK, 0 rows affected (0.00 sec)

SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT SELECT ON test.* TO 'jennifer'@'%' |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-----------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

The statement `SET DEFAULT ROLE` can be used to associate the role `analyticsteam` to `jennifer`:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
Query OK, 0 rows affected (0.02 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

After this, the user `jennifer` has the privileges associated with the role `analyticsteam` and `jennifer` does not have to execute the statement `SET ROLE`:

```
SHOW GRANTS;
+-------------------------------------------+
| Grants for User                           |
+-------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'      |
| GRANT SELECT ON test.* TO 'jennifer'@'%'  |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

14.13.2.64.3 MySQL compatibility

The `GRANT <role>` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.64.4 See also

- `GRANT <privileges>`
- `CREATE ROLE`
- `DROP ROLE`
- `REVOKE <role>`
- `SET ROLE`
- `SET DEFAULT ROLE`

- Role-Based Access Control

14.13.2.65 IMPORT INTO

The `IMPORT INTO` statement lets you import data to TiDB via the Physical Import Mode of TiDB Lightning. You can use `IMPORT INTO` in the following two ways:

- `IMPORT INTO ... FROM FILE`: imports data files in formats such as `CSV`, `SQL`, and `PARQUET` into an empty table in TiDB.
- `IMPORT INTO ... FROM SELECT`: imports the query result of a `SELECT` statement into an empty table in TiDB. You can also use it to import historical data queried with `AS OF TIMESTAMP`.

> **Note:**
>
> Compared with TiDB Lightning, `IMPORT INTO` can be directly executed on TiDB nodes, supports automated distributed task scheduling and TiDB Global Sort, and offers significant improvements in deployment, resource utilization, task configuration convenience, ease of invocation and integration, high availability, and scalability. It is recommended that you consider using `IMPORT INTO` instead of TiDB Lightning in appropriate scenarios.

14.13.2.65.1 Restrictions

- `IMPORT INTO` only supports importing data into existing empty tables in the database.
- `IMPORT INTO` does not support importing data into an empty partition if other partitions of the same table already contain data. The target table must be completely empty for import operations.
- `IMPORT INTO` does not support importing data into a temporary table or a cached table.
- `IMPORT INTO` does not support transactions or rollback. Executing `IMPORT INTO` within an explicit transaction (`BEGIN`/`END`) will return an error.
- `IMPORT INTO` does not support working simultaneously with features such as Backup & Restore, `FLASHBACK CLUSTER`, acceleration of adding indexes, data import using TiDB Lightning, data replication using TiCDC, or Point-in-Time Recovery (PITR). For more compatibility information, see Compatibility of TiDB Lightning and `IMPORT INTO` with TiCDC and Log Backup.
- During the data import process, do not perform DDL or DML operations on the target table, and do not execute `FLASHBACK DATABASE` for the target database. These operations can lead to import failures or data inconsistencies. In addition, it is **NOT** recommended to perform read operations during the import process, as the data being read might be inconsistent. Perform read and write operations only after the import is completed.
- The import process consumes system resources significantly. For TiDB Self-Managed, to get better performance, it is recommended to use TiDB nodes with at least 32 cores and 64 GiB of memory. TiDB writes sorted data to the TiDB temporary directory during import, so it is recommended to configure high-performance storage media for TiDB Self-Managed, such as flash memory. For more information, see Physical Import Mode limitations.

- For TiDB Self-Managed, the TiDB temporary directory is expected to have at least 90 GiB of available space. It is recommended to allocate storage space that is equal to or greater than the volume of data to be imported.
- One import job supports importing data into one target table only.
- `IMPORT INTO` is not supported during TiDB cluster upgrades.
- Ensure that the data to be imported does not contain any records with primary key or non-null unique index conflicts. Otherwise, the conflicts can result in import task failures.
- Known issue: the `IMPORT INTO` task might fail if the PD address in the TiDB node configuration file is inconsistent with the current PD topology of the cluster. This inconsistency can arise in situations such as that PD was scaled in previously, but the TiDB configuration file was not updated accordingly or the TiDB node was not restarted after the configuration file update.

`IMPORT INTO ... FROM FILE` restrictions

- For TiDB Self-Managed, each `IMPORT INTO` task supports importing data within 10 TiB. If you enable the Global Sort feature, each `IMPORT INTO` task supports importing data within 40 TiB.
- For TiDB Cloud Dedicated, if your data to be imported exceeds 500 GiB, it is recommended to use TiDB nodes with at least 16 cores and enable the Global Sort feature, then each `IMPORT INTO` task supports importing data within 40 TiB. If your data to be imported is within 500 GiB or if the cores of your TiDB nodes are less than 16, it is not recommended to enable the Global Sort feature.
- The execution of `IMPORT INTO ... FROM FILE` blocks the current connection until the import is completed. To execute the statement asynchronously, you can add the `DETACHED` option.
- Up to 16 `IMPORT INTO` tasks can run simultaneously on each cluster (see TiDB Distributed eXecution Framework (DXF) usage limitations). When a cluster lacks sufficient resources or reaches the maximum number of tasks, newly submitted import tasks are queued for execution.
- When the Global Sort feature is used for data import, the value of the `THREAD` option must be at least `8`.
- When the Global Sort feature is used for data import, the data size of a single row after encoding must not exceed 32 MiB.
- All `IMPORT INTO` tasks that are created when TiDB Distributed eXecution Framework (DXF) is not enabled run directly on the nodes where the tasks are submitted, and these tasks will not be scheduled for execution on other TiDB nodes even after DXF is enabled later. After DXF is enabled, only newly created `IMPORT INTO` tasks that import data from S3 or GCS are automatically scheduled or failed over to other TiDB nodes for execution.

`IMPORT INTO ... FROM SELECT` restrictions

- `IMPORT INTO ... FROM SELECT` can only be executed on the TiDB node that the current user is connected to, and it blocks the current connection until the import is complete.
- `IMPORT INTO ... FROM SELECT` only supports two import options: `THREAD` and `DISABLE_PRECHECK`.
- `IMPORT INTO ... FROM SELECT` does not support the task management statements such as `SHOW IMPORT JOB(s)` and `CANCEL IMPORT JOB <job-id>`.
- The temporary directory of TiDB requires sufficient space to store the entire query result of the `SELECT` statement (configuring the `DISK_QUOTA` option is not supported currently).
- Importing historical data using `tidb_snapshot` is not supported.
- Because the syntax of the `SELECT` clause is complex, the `WITH` parameter in `IMPORT INTO` might conflict with it and cause parsing errors, such as `GROUP BY ... [WITH ROLLUP]`. It is recommended to create a view for complex `SELECT` statements and then use `IMPORT INTO ... FROM SELECT * FROM view_name` for importing. Alternatively, you can clarify the scope of the `SELECT` clause with parentheses, such as `IMPORT INTO ... FROM (SELECT ...)WITH ....`

14.13.2.65.2 Prerequisites for import

Before using `IMPORT INTO` to import data, make sure the following requirements are met:

- The target table to be imported is already created in TiDB and it is empty.
- The target cluster has sufficient space to store the data to be imported.
- For TiDB Self-Managed, the temporary directory of the TiDB node connected to the current session has at least 90 GiB of available space. If `tidb_enable_dist_task` is enabled and the data for import is from S3 or GCS, also make sure that the temporary directory of each TiDB node in the cluster has sufficient disk space.

14.13.2.65.3 Required privileges

Executing `IMPORT INTO` requires the `SELECT`, `UPDATE`, `INSERT`, `DELETE`, and `ALTER` privileges on the target table. To import files in TiDB local storage, the `FILE` privilege is also required.

14.13.2.65.4 Synopsis

```
ImportIntoStmt ::=
    'IMPORT' 'INTO' TableName ColumnNameOrUserVarList? SetClause? FROM
       ↪ fileLocation Format? WithOptions?
    |
    'IMPORT' 'INTO' TableName ColumnNameList? FROM SelectStatement
       ↪ WithOptions?

ColumnNameOrUserVarList ::=
```

```
    '(' ColumnNameOrUserVar (',' ColumnNameOrUserVar)* ')'

ColumnNameList ::=
    '(' ColumnName (',' ColumnName)* ')'

SetClause ::=
    'SET' SetItem (',' SetItem)*

SetItem ::=
    ColumnName '=' Expr

Format ::=
    'CSV' | 'SQL' | 'PARQUET'

WithOptions ::=
    'WITH' OptionItem (',' OptionItem)*

OptionItem ::=
    optionName '=' optionVal | optionName
```

14.13.2.65.5 Parameter description

ColumnNameOrUserVarList

It specifies how each field in the data file corresponds to the columns in the target table. You can also use it to map fields to variables to skip certain fields for the import, or use it in `SetClause`.

- If this parameter is not specified, the number of fields in each row of the data file must match the number of columns in the target table, and the fields will be imported to the corresponding columns in order.
- If this parameter is specified, the number of specified columns or variables must match the number of fields in each row of the data file.

SetClause

It specifies how the values of target columns are calculated. In the right side of the `SET` expression, you can reference the variables specified in `ColumnNameOrUserVarList`.

In the left side of the `SET` expression, you can only reference a column name that is not included in `ColumnNameOrUserVarList`. If the target column name already exists in `ColumnNameOrUserVarList`, the `SET` expression is invalid.

fileLocation

It specifies the storage location of the data file, which can be an Amazon S3 or GCS URI path, or a TiDB local file path.

- Amazon S3 or GCS URI path: for URI configuration details, see URI Formats of External Storage Services.
- TiDB local file path: it must be an absolute path, and the file extension must be `.csv`, `.sql`, or `.parquet`. Make sure that the files corresponding to this path are stored on the TiDB node connected by the current user, and the user has the `FILE` privilege.

> **Note:**
>
> If SEM is enabled in the target cluster, the `fileLocation` cannot be specified as a local file path.

In the `fileLocation` parameter, you can specify a single file, or use the `*` and `[]` wildcards to match multiple files for import. Note that the wildcard can only be used in the file name, because it does not match directories or recursively match files in subdirectories. Taking files stored on Amazon S3 as examples, you can configure the parameter as follows:

- Import a single file: `s3://<bucket-name>/path/to/data/foo.csv`
- Import all files in a specified path: `s3://<bucket-name>/path/to/data/*`
- Import all files with the `.csv` suffix in a specified path: `s3://<bucket-name>/path/to/data/*.csv`
- Import all files with the `foo` prefix in a specified path: `s3://<bucket-name>/path/to/data/foo*`
- Import all files with the `foo` prefix and the `.csv` suffix in a specified path: `s3://<bucket-name>/path/to/data/foo*.csv`
- Import `1.csv` and `2.csv` in a specified path: `s3://<bucket-name>/path/to/data/[12].csv`

Format

The `IMPORT INTO` statement supports three data file formats: `CSV`, `SQL`, and `PARQUET`. If not specified, the default format is `CSV`.

WithOptions

You can use `WithOptions` to specify import options and control the data import process. For example, to execute the import of data files asynchronously in the backend, you can enable the `DETACHED` mode for the import by adding the `WITH DETACHED` option to the `IMPORT INTO` statement.

The supported options are described as follows:

Option name	Supported data sources and formats	Description
`CHARACTER_SET='string'`	CSV	Specifies the character set of the data file. The default character set is `utf8mb4`. The supported character sets include `binary`, `utf8`, `utf8mb4`, `gb18030`, `gbk`, `latin1`, and `ascii`.

Option name	Supported data sources and formats	Description
`FIELDS ↪ _ ↪ TERMINATED ↪ _ ↪ BY ↪ ='< ↪ string ↪ >' ↪`	CSV	Specifies the field separator. The default separator is `,`.
`FIELDS ↪ _ ↪ ENCLOSED ↪ _ ↪ BY ↪ ='< ↪ char ↪ >' ↪`	CSV	Specifies the field delimiter. The default delimiter is `"`.

Option name	Supported data sources and formats	Description
`FIELDS ESCAPED BY '<char>'`	CSV	Specifies the escape character for fields. The default escape character is \.
`FIELDS DEFINED BY '<string>'`	CSV	Specifies the value that represents `NULL` in the fields. The default value is `\N`.

Option name	Supported data sources and formats	Description
`LINES_TERMINATED_BY='string'`	CSV	Specifies the line terminator. By default, `IMPORT INTO` automatically identifies `\n`, `\r`, or `\r\n` as line terminators. If the line terminator is one of these three, you do not need to explicitly

Option name	Supported data sources and formats	Description
`SKIP_ROWS=number`	CSV	Specifies the number of rows to skip. The default value is `0`. You can use this option to skip the header in a CSV file. If you use a wildcard to specify the source files for import, this option

Option name	Supported data sources and formats	Description
`SPLIT_FILE`	CSV	Splits a single CSV file into multiple smaller chunks of around 256 MiB for parallel processing to improve import efficiency. This parameter only works for **non-compressed** CSV files and has the same usage

Option name	Supported data sources and formats	Description
`DISK_QUOTA='<string>'`	All file formats	Specifies the disk space threshold that can be used during data sorting. The default value is 80% of the disk space in the TiDB temporary directory. If the total disk size cannot be obtained, the

Option name	Supported data sources and formats	Description
`DISABLE_TIKV_IMPORT_MODE`	All file formats	Specifies whether to disable switching TiKV to import mode during the import process. By default, switching TiKV to import mode is not disabled. If there are ongoing read-write operations

Option name	Supported data sources and formats	Description
`THREAD` ↪ `=<` ↪ `number` ↪ `>`	All file formats and query results of `SELECT` ↪	Specifies the concurrency for import. For `IMPORT` ↪ ↪ `INTO` ↪ ↪ `...` ↪ ↪ `FROM` ↪ ↪ `FILE` ↪ , the default value of `THREAD` ↪ is 50% of the number of CPU cores on the TiDB node, the minimum value

Option name	Supported data sources and formats	Description
`MAX_WRITE_SPEED='string'`	All file formats	Controls the write speed to a TiKV node. By default, there is no speed limit. For example, you can specify this option as `1MiB` to limit the write speed to 1 MiB/s.

Option name	Supported data sources and formats	Description
`CHECKSUM_TABLE='string'`	All file formats	Configures whether to perform a checksum check on the target table after the import to validate the import integrity. The supported values include `"required"` (default), `"optional"`, and `"off"`

Option name	Supported data sources and formats	Description
`DETACHED` ↪	All file formats	Controls whether to execute `IMPORT` ↪ ↪ `INTO` ↪ asynchronously. When this option is enabled, executing `IMPORT` ↪ ↪ `INTO` ↪ immediately returns the information of the import job (such as the `Job_` ↪ `ID` ↪),

Option name	Supported data sources and formats	Description
`CLOUD_STORAGE_URI`	All file formats	Specifies the target address where encoded KV data for Global Sort is stored. When `CLOUD_STORAGE_URI` is not specified, `IMPORT INTO` determines whether to use Global Sort based on the value of

Option name	Supported data sources and formats	Description
`DISABLE_PRECHECK`	All file formats and query results of `SELECT`	Setting this option disables prechecks of non-critical items, such as checking whether there are CDC or PITR tasks.

14.13.2.65.6 `IMPORT INTO ... FROM FILE` usage

For TiDB Self-Managed, `IMPORT INTO ... FROM FILE` supports importing data from files stored in Amazon S3, GCS, and the TiDB local storage. For TiDB Cloud Dedicated, `IMPORT INTO ... FROM FILE` supports importing data from files stored in Amazon S3 and GCS. For TiDB Cloud Serverless, `IMPORT INTO ... FROM FILE` supports importing data from files stored in Amazon S3 and Alibaba Cloud OSS.

- For data files stored in Amazon S3 or GCS, `IMPORT INTO ... FROM FILE` supports running in the TiDB Distributed eXecution Framework (DXF).
    - When the DXF is enabled (tidb_enable_dist_task is `ON`), `IMPORT INTO` splits a data import job into multiple sub-jobs and distributes these sub-jobs to different TiDB nodes for execution to improve the import efficiency.

    - When the DXF is disabled, `IMPORT INTO ... FROM FILE` only supports running on the TiDB node where the current user is connected.

- For data files stored locally in TiDB, `IMPORT INTO ... FROM FILE` only supports running on the TiDB node where the current user is connected. Therefore, the data files need to be placed on the TiDB node where the current user is connected. If you access TiDB through a proxy or load balancer, you cannot import data files stored locally in TiDB.

Compressed files

`IMPORT INTO ... FROM FILE` supports importing compressed `CSV` and `SQL` files. It can automatically determine whether a file is compressed and the compression format based on the file extension:

Extension	Compression format
`.gz`, `.gzip`	gzip compression format
`.zstd`, `.zst`	ZStd compression format
`.snappy`	snappy compression format

Note:

- The Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.
- Because TiDB Lightning cannot concurrently decompress a single large compressed file, the size of the compressed file affects the import speed. It is recommended that a source file is no greater than 256 MiB after decompression.

Global Sort

Note:

Global Sort is not available on TiDB Cloud Serverless clusters.

`IMPORT INTO ... FROM FILE` splits the data import job of a source data file into multiple sub-jobs, each sub-job independently encoding and sorting data before importing. If the encoded KV ranges of these sub-jobs have significant overlap (to learn how TiDB encodes

data to KV, see TiDB computing), TiKV needs to keep compaction during import, leading to a decrease in import performance and stability.

In the following scenarios, there can be significant overlap in KV ranges:

- If rows in the data file assigned to each sub-job have overlapping primary key ranges, the data KV generated by the encoding of each sub-job will also overlap.
    - `IMPORT INTO` splits sub-jobs based on the traversal order of data files, usually sorted by file name in lexicographic order.
- If the target table has many indexes, or the index column values are scattered in the data file, the index KV generated by the encoding of each sub-job will also overlap.

When the TiDB Distributed eXecution Framework (DXF) is enabled, you can enable Global Sort by specifying the `CLOUD_STORAGE_URI` option in the `IMPORT INTO` statement or by specifying the target storage address for encoded KV data using the system variable `tidb_cloud_storage_uri`. Currently, Global Sort supports using Amazon S3 as the storage address. When Global Sort is enabled, `IMPORT INTO` writes encoded KV data to the cloud storage, performs Global Sort in the cloud storage, and then parallelly imports the globally sorted index and table data into TiKV. This prevents problems caused by KV overlap and enhances import stability and performance.

Global Sort consumes a significant amount of memory resources. Before the data import, it is recommended to configure the `tidb_server_memory_limit_gc_trigger` and `tidb_server_memory_limit` variables, which avoids golang GC being frequently triggered and thus affecting the import efficiency.

```
SET GLOBAL tidb_server_memory_limit_gc_trigger=1;
SET GLOBAL tidb_server_memory_limit='75%';
```

Note:

- If the KV range overlap in a source data file is low, enabling Global Sort might decrease import performance. This is because when Global Sort is enabled, TiDB needs to wait for the completion of local sorting in all sub-jobs before proceeding with the Global Sort operations and subsequent import.
- After an import job using Global Sort completes, the files stored in the cloud storage for Global Sort are cleaned up asynchronously in a background thread.

Output

When `IMPORT INTO ... FROM FILE` completes the import or when the `DETACHED` mode is enabled, TiDB returns the current job information in the output, as shown in the following examples. For the description of each field, see `SHOW IMPORT JOB(s)`.

When `IMPORT INTO ... FROM FILE` completes the import, the example output is as follows:

```
IMPORT INTO t FROM '/path/to/small.csv';
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
| Job_ID | Data_Source     | Target_Table | Table_ID | Phase | Status |
   ↪ Source_File_Size | Imported_Rows | Result_Message | Create_Time  |
   ↪ Start_Time              | End_Time                   | Created_By |
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
|  60002 | /path/to/small.csv | `test`.`t` |  363 |      | finished | 16B
   ↪           |            2 |              | 2023-06-08 16:01:22.095698 |
   ↪ 2023-06-08 16:01:22.394418 | 2023-06-08 16:01:26.531821 | root@% |
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
```

When the `DETACHED` mode is enabled, executing the `IMPORT INTO ... FROM FILE` statement will immediately return the job information in the output. From the output, you can see that the status of the job is `pending`, which means waiting for execution.

```
IMPORT INTO t FROM '/path/to/small.csv' WITH DETACHED;
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
| Job_ID | Data_Source     | Target_Table | Table_ID | Phase | Status |
   ↪ Source_File_Size | Imported_Rows | Result_Message | Create_Time |
   ↪ Start_Time | End_Time | Created_By |
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
|  60001 | /path/to/small.csv | `test`.`t` |  361 |      | pending | 16B
   ↪           |         NULL |              | 2023-06-08 15:59:37.047703 |
   ↪ NULL  | NULL    | root@%    |
+--
   ↪ ------+--------------------+-------------+---------+-------+----------+-------
   ↪
```

View and manage import jobs

For an import job with the DETACHED mode enabled, you can use SHOW IMPORT to view its current job progress.

After an import job is started, you can cancel it using CANCEL IMPORT JOB <job-id>.

Examples

Import a CSV file with headers

```
IMPORT INTO t FROM '/path/to/file.csv' WITH skip_rows=1;
```

Import a file asynchronously in the DETACHED mode

```
IMPORT INTO t FROM '/path/to/file.csv' WITH DETACHED;
```

Skip importing a specific field in your data file

Assume that your data file is in the CSV format and its content is as follows:

```
id,name,age
1,Tom,23
2,Jack,44
```

And assume that the target table schema for the import is CREATE TABLE t(id int primary key, name varchar(100)). To skip importing the age field in the data file to the table t, you can execute the following SQL statement:

```
IMPORT INTO t(id, name, @1) FROM '/path/to/file.csv' WITH skip_rows=1;
```

Import multiple data files using wildcards

Assume that there are three files named file-01.csv, file-02.csv, and file-03.csv in the /path/to/ directory. To import these three files into a target table t using IMPORT INTO, you can execute the following SQL statement:

```
IMPORT INTO t FROM '/path/to/file-*.csv';
```

If you only need to import file-01.csv and file-03.csv into the target table, execute the following SQL statement:

```
IMPORT INTO t FROM '/path/to/file-0[13].csv';
```

Import data files from Amazon S3 or GCS

- Import data files from Amazon S3:

```
IMPORT INTO t FROM 's3://bucket-name/test.csv?access-key=XXX&secret-access-key=XXX';
```

- Import data files from GCS:

```
IMPORT INTO t FROM 'gs://import/test.csv?credentials-file=${credentials
    ↪ -file-path}';
```

For details about the URI path configuration for Amazon S3 or GCS, see URI Formats of External Storage Services.

Calculate column values using SetClause

Assume that your data file is in the CSV format and its content is as follows:

```
id,name,val
1,phone,230
2,book,440
```

And assume that the target table schema for the import is `CREATE TABLE t(id int ↪ primary key, name varchar(100), val int)`. If you want to multiply the `val` column values by 100 during the import, you can execute the following SQL statement:

```
IMPORT INTO t(id, name, @1) SET val=@1*100 FROM '/path/to/file.csv' WITH
    ↪ skip_rows=1;
```

Import a data file in the SQL format

```
IMPORT INTO t FROM '/path/to/file.sql' FORMAT 'sql';
```

Limit the write speed to TiKV

To limit the write speed to a TiKV node to 10 MiB/s, execute the following SQL statement:

```
IMPORT INTO t FROM 's3://bucket/path/to/file.parquet?access-key=XXX&secret-
    ↪ access-key=XXX' FORMAT 'parquet' WITH MAX_WRITE_SPEED='10MiB';
```

14.13.2.65.7 `IMPORT INTO ... FROM SELECT` usage

`IMPORT INTO ... FROM SELECT` lets you import the query result of a `SELECT` statement to an empty table in TiDB. You can also use it to import historical data queried with `AS OF TIMESTAMP`.

Import the query result of `SELECT`

To import the `UNION` result to the target table `t`, with the import concurrency specified as `8` and precheck of non-critical items configured as disabled, execute the following SQL statement:

```
IMPORT INTO t FROM SELECT * FROM src UNION SELECT * FROM src2 WITH THREAD =
    ↪  8, DISABLE_PRECHECK;
```

Import historical data at a specified time point

To import historical data at a specified time point to the target table `t`, execute the following SQL statement:

```
IMPORT INTO t FROM SELECT * FROM src AS OF TIMESTAMP '2024-02-27 11:38:00';
```

14.13.2.65.8 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- SHOW IMPORT JOB(s)
- TiDB Distributed eXecution Framework (DXF)

14.13.2.66 INSERT

This statement inserts new rows into a table.

14.13.2.66.1 Synopsis

```
InsertIntoStmt ::=
    'INSERT' TableOptimizerHints PriorityOpt IgnoreOptional IntoOpt
       ↪ TableName PartitionNameListOpt InsertValues OnDuplicateKeyUpdate

TableOptimizerHints ::=
    hintComment?

PriorityOpt ::=
    ( 'LOW_PRIORITY' | 'HIGH_PRIORITY' | 'DELAYED' )?

IgnoreOptional ::=
    'IGNORE'?

IntoOpt ::= 'INTO'?

TableName ::=
    Identifier ( '.' Identifier )?

PartitionNameListOpt ::=
    ( 'PARTITION' '(' Identifier ( ',' Identifier )* ')' )?
```

```
InsertValues ::=
    '(' ( ColumnNameListOpt ')' ( ValueSym ValuesList | SelectStmt | '('
       ↪ SelectStmt ')' | UnionStmt ) | SelectStmt ')' )
|   ValueSym ValuesList
|   SelectStmt
|   UnionStmt
|   'SET' ColumnSetValue? ( ',' ColumnSetValue )*

OnDuplicateKeyUpdate ::=
    ( 'ON' 'DUPLICATE' 'KEY' 'UPDATE' AssignmentList )?
```

Note:

Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority (`PriorityOpt`) will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.13.2.66.2 Examples

```
mysql> CREATE TABLE t1 (a INT);
Query OK, 0 rows affected (0.11 sec)

mysql> CREATE TABLE t2 LIKE t1;
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.02 sec)

mysql> INSERT INTO t1 (a) VALUES (1);
Query OK, 1 row affected (0.01 sec)

mysql> INSERT INTO t2 SELECT * FROM t1;
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+------+
| a    |
```

```
+------+
|    1 |
|    1 |
+------+
2 rows in set (0.00 sec)

mysql> SELECT * FROM t2;
+------+
| a    |
+------+
|    1 |
|    1 |
+------+
2 rows in set (0.00 sec)

mysql> INSERT INTO t2 VALUES (2),(3),(4);
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t2;
+------+
| a    |
+------+
|    1 |
|    1 |
|    2 |
|    3 |
|    4 |
+------+
5 rows in set (0.00 sec)
```

14.13.2.66.3 MySQL compatibility

The `INSERT` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

- REPLACE

14.13.2.67 KILL

The KILL statement is used to terminate a connection in any TiDB instance in the current TiDB cluster. Starting from TiDB v6.2.0, you can also use the KILL statement to terminate ongoing DDL jobs.

14.13.2.67.1 Synopsis

```
KillStmt ::= 'KILL' 'TIDB'? ( 'CONNECTION' | 'QUERY' )? CONNECTION_ID
```

14.13.2.67.2 Examples

The following example shows how to get all active queries in the current cluster and terminate any one of them.

```
SELECT ID, USER, INSTANCE, INFO FROM INFORMATION_SCHEMA.CLUSTER_PROCESSLIST
    ↪ ;
```

```
+--------------------+------+-----------------+-------------------------------------
    ↪
| ID                 | USER | INSTANCE        | INFO
    ↪                                                                              |
+--------------------+------+-----------------+-------------------------------------
    ↪
| 8306449708033769879 | root | 127.0.0.1:10082 | select sleep(30), 'foo'
    ↪                                                 |
| 5857102839209263511 | root | 127.0.0.1:10080 | select sleep(50)
    ↪                                                  |
| 5857102839209263513 | root | 127.0.0.1:10080 | SELECT ID, USER, INSTANCE,
    ↪ INFO FROM INFORMATION_SCHEMA.CLUSTER_PROCESSLIST |
+--------------------+------+-----------------+-------------------------------------
    ↪
```

```
KILL 5857102839209263511;
```

```
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.67.3 MySQL compatibility

- The KILL statement of MySQL can only terminate a connection in the currently connected MySQL instance, while the KILL statement of TiDB can terminate a connection in any TiDB instance in the entire cluster.
- In v7.2.0 and earlier versions, using the MySQL command line Control+C to terminate a query or connection in TiDB is not supported.

14.13.2.67.4 Behavior change descriptions

Starting from v7.3.0, TiDB supports generating 32-bit connection IDs, which is enabled by default and controlled by the `enable-32bits-connection-id` configuration item. When both the Global Kill feature and 32-bit connection ID are enabled, TiDB generates a 32-bit connection ID and you can terminate queries or connections in the MySQL command-line using Control+C.

> **Warning:**
>
> When the number of TiDB instances in the cluster exceeds 2048 or the concurrent connection count of a single TiDB instance exceeds 1048576, the 32-bit connection ID space becomes insufficient and is automatically upgraded to 64-bit connection IDs. During the upgrade process, existing business and established connections are unaffected. However, subsequent new connections cannot be terminated using Control+C in the MySQL command-line.

Starting from v6.1.0, TiDB supports the Global Kill feature, which is enabled by default and controlled by the `enable-global-kill` configuration.

When the Global Kill feature is enabled, both `KILL` and `KILL TIDB` statements can terminate queries or connections across instances so you do not need to worry about erroneously terminating queries or connections. When you use a client to connect to any TiDB instance and execute the `KILL` or `KILL TIDB` statement, the statement will be forwarded to the target TiDB instance. If there is a proxy between the client and the TiDB cluster, the `KILL` and `KILL TIDB` statements will also be forwarded to the target TiDB instance for execution.

If the Global Kill feature is not enabled or you are using a TiDB version earlier than v6.1.0, note the following:

- By default, `KILL` is not compatible with MySQL. This helps prevent against a case of a connection being terminated by a wrong TiDB server, because it is common to place multiple TiDB servers behind a load balancer. To terminate other connections on the currently connected TiDB instance, you need to add the `TIDB` suffix explicitly by executing the `KILL TIDB` statement.

- It is **STRONGLY NOT RECOMMENDED** to set `compatible-kill-query = true` in your configuration file UNLESS you are certain that clients will be always connected to the same TiDB instance. This is because pressing Control+C in the default MySQL client opens a new connection in which `KILL` is executed. If there is a proxy between the client and the TiDB cluster, the new connection might be routed to a different TiDB instance, which possibly kills a different session by mistake.

- The `KILL TIDB` statement is a TiDB extension. The feature of this statement is similar to the MySQL `KILL [CONNECTION|QUERY]` command and the MySQL command line Control+C. It is safe to use `KILL TIDB` on the same TiDB instance.

- SHOW [FULL] PROCESSLIST
- CLUSTER_PROCESSLIST

14.13.2.68 LOAD DATA

The `LOAD DATA` statement batch loads data into a TiDB table.

Starting from TiDB v7.0.0, the `LOAD DATA` SQL statement supports the following features:

- Support importing data from S3 and GCS
- Add a new parameter `FIELDS DEFINED NULL BY`

> **Warning:**
>
> The new parameter `FIELDS DEFINED NULL BY` and support for importing data from S3 and GCS are experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

14.13.2.68.1 Synopsis

```
LoadDataStmt ::=
    'LOAD' 'DATA' LocalOpt 'INFILE' stringLit DuplicateOpt 'INTO' 'TABLE'
       ↪ TableName CharsetOpt Fields Lines IgnoreLines
       ↪ ColumnNameOrUserVarListOptWithBrackets LoadDataSetSpecOpt

LocalOpt ::= ('LOCAL')?

Fields ::=
    ('TERMINATED' 'BY' stringLit
    | ('OPTIONALLY')? 'ENCLOSED' 'BY' stringLit
    | 'ESCAPED' 'BY' stringLit
    | 'DEFINED' 'NULL' 'BY' stringLit ('OPTIONALLY' 'ENCLOSED')?)?
```

14.13.2.68.2 Parameters

`LOCAL`

You can use `LOCAL` to specify data files on the client to be imported, where the file parameter must be the file system path on the client.

If you are using TiDB Cloud, to use the `LOAD DATA` statement to load local data files, you need to add the `--local-infile` option to the connection string when you connect to TiDB Cloud.

- The following is an example connection string for TiDB Cloud Serverless:

```
mysql --connect-timeout 15 -u '<user_name>' -h <host_name> -P 4000 -D
    ↪ test --ssl-mode=VERIFY_IDENTITY --ssl-ca=/etc/ssl/cert.pem -p<
    ↪ your_password> --local-infile
```

- The following is an example connection string for TiDB Cloud Dedicated:

```
mysql --connect-timeout 15 --ssl-mode=VERIFY_IDENTITY --ssl-ca=<CA_path
    ↪ > --tls-version="TLSv1.2" -u root -h <host_name> -P 4000 -D test
    ↪ -p<your_password> --local-infile
```

S3 and GCS storage

If you do not specify `LOCAL`, the file parameter must be a valid S3 or GCS path, as detailed in external storage.

When the data files are stored on S3 or GCS, you can import individual files or use the wildcard character `*` to match multiple files to be imported. Note that wildcards do not recursively process files in subdirectories. The following are some examples:

- Import a single file: `s3://<bucket-name>/path/to/data/foo.csv`
- Import all files in the specified path: `s3://<bucket-name>/path/to/data/*`
- Import all files ending with `.csv` under the specified path: `s3://<bucket-name>/path ↪ /to/data/*.csv`
- Import all files prefixed with `foo` under the specified path: `s3://<bucket-name>/path ↪ /to/data/foo*`
- Import all files prefixed with `foo` and ending with `.csv` under the specified path: `s3://<bucket-name>/path/to/data/foo*.csv`

`Fields`, `Lines`, and `Ignore Lines`

You can use the `Fields` and `Lines` parameters to specify how to handle the data format.

- `FIELDS TERMINATED BY`: specifies the data delimiter.
- `FIELDS ENCLOSED BY`: specifies the enclosing character of the data.

- `LINES TERMINATED BY`: specifies the line terminator, if you want to end a line with a certain character.

You can use `DEFINED NULL BY` to specify how NULL values are represented in the data file.

- Consistent with MySQL behavior, if `ESCAPED BY` is not null, for example, if the default value `\` is used, then `\N` will be considered a NULL value.
- If you use `DEFINED NULL BY`, such as `DEFINED NULL BY 'my-null'`, `my-null` is considered a NULL value.
- If you use `DEFINED NULL BY ... OPTIONALLY ENCLOSED`, such as `DEFINED NULL BY 'my-null' OPTIONALLY ENCLOSED`, `my-null` and `"my-null"` (assuming `ENCLOSED BY '"'`) are considered NULL values.
- If you do not use `DEFINED NULL BY` or `DEFINED NULL BY ... OPTIONALLY ENCLOSED`, but use `ENCLOSED BY`, such as `ENCLOSED BY '"'`, then `NULL` is considered a NULL value. This behavior is consistent with MySQL.
- In other cases, it is not considered a NULL value.

Take the following data format as an example:

```
"bob","20","street 1"\r\n
"alice","33","street 1"\r\n
```

If you want to extract `bob`, `20`, and `street 1`, specify the field delimiter as `','`, and the enclosing character as `'\"'`:

```
FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n'
```

If you do not specify the preceding parameters, the imported data is processed in the following way by default:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY '' ESCAPED BY '\\'
LINES TERMINATED BY '\n' STARTING BY ''
```

You can ignore the first `number` lines of a file by configuring the `IGNORE <number> LINES` parameter. For example, if you configure `IGNORE 1 LINES`, the first line of a file is ignored.

14.13.2.68.3 Examples

The following example imports data using `LOAD DATA`. Comma is specified as the field delimiter. The double quotation marks that enclose the data are ignored. The first line of the file is ignored.

If you see `ERROR 1148 (42000): the used command is not allowed with this TiDB version`, refer to ERROR 1148 (42000): the used command is not allowed with this TiDB version for troubleshooting.

```
LOAD DATA LOCAL INFILE '/mnt/evo970/data-sets/bikeshare-data/2017Q4-
    ↪ capitalbikeshare-tripdata.csv' INTO TABLE trips FIELDS TERMINATED BY
    ↪ ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n' IGNORE 1 LINES (
    ↪ duration, start_date, end_date, start_station_number, start_station,
    ↪ end_station_number, end_station, bike_number, member_type);
```

```
Query OK, 815264 rows affected (39.63 sec)
Records: 815264 Deleted: 0 Skipped: 0 Warnings: 0
```

`LOAD DATA` also supports using hexadecimal ASCII character expressions or binary ASCII character expressions as the parameters for `FIELDS ENCLOSED BY` and `FIELDS TERMINATED BY`. See the following example:

```
LOAD DATA LOCAL INFILE '/mnt/evo970/data-sets/bikeshare-data/2017Q4-
    ↪ capitalbikeshare-tripdata.csv' INTO TABLE trips FIELDS TERMINATED BY
    ↪ x'2c' ENCLOSED BY b'100010' LINES TERMINATED BY '\r\n' IGNORE 1 LINES
    ↪  (duration, start_date, end_date, start_station_number, start_station
    ↪ , end_station_number, end_station, bike_number, member_type);
```

In the above example, `x'2c'` is the hexadecimal representation of the `,` character, and `b'100010'` is the binary representation of the `"` character.

14.13.2.68.4 MySQL compatibility

The syntax of the `LOAD DATA` statement is compatible with that of MySQL, except for character set options which are parsed but ignored. If you find any syntax compatibility difference, you can report a bug.

Note:

- For versions earlier than TiDB v4.0.0, `LOAD DATA` commits every 20000 rows, which cannot be configured.
- For versions from TiDB v4.0.0 to v6.6.0, TiDB commits all rows in one transaction by default. But if you need the `LOAD DATA` statement to commit every fixed number of rows, you can set `tidb_dml_batch_size` to the desired number of rows.
- Starting from TiDB v7.0.0, `tidb_dml_batch_size` no longer takes effect on `LOAD DATA`, and TiDB commits all rows in one transaction.
- After upgrading from TiDB v4.0.0 or earlier versions, `ERROR 8004 (HY000)at line 1: Transaction is too large, size: 100000058` might occur. The recommended way to resolve this error is to increase the `txn-total-size-limit` value in your `tidb.toml` file.

- For versions earlier than TiDB v7.6.0, no matter how many rows are committed in a transaction, `LOAD DATA` is not rolled back by the `ROLLBACK` statement in an explicit transaction.
- For versions earlier than TiDB v7.6.0, the `LOAD DATA` statement is always executed in optimistic transaction mode, regardless of the TiDB transaction mode configuration.
- Starting from v7.6.0, TiDB processes `LOAD DATA` in transactions in the same way as other DML statements:
  - The `LOAD DATA` statement does not commit the current transaction or start a new transaction.
  - The `LOAD DATA` statement is affected by the TiDB transaction mode setting (optimistic or pessimistic transaction).
  - The `LOAD DATA` statement in a transaction can be rolled back by the `ROLLBACK` statement in the transaction.

14.13.2.68.5 See also

- INSERT
- TiDB Optimistic Transaction Model
- TiDB Pessimistic Transaction Mode

14.13.2.69 LOAD STATS

The `LOAD STATS` statement is used to load the statistics into TiDB.

Note:

This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.69.1 Synopsis

```
LoadStatsStmt ::=
    'LOAD' 'STATS' stringLit
```

14.13.2.69.2 Examples

You can access the address `http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_name}/${table_name}` to download the TiDB instance's statistics.

You can also use `LOAD STATS ${stats_path}` to load the specific statistics file.

The `${stats_path}` can be an absolute path or a relative path. If you use a relative path, the corresponding file is found starting from the path where `tidb-server` is started. Here is an example:

```
LOAD STATS '/tmp/stats.json';
```

```
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.69.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.69.4 See also

- Statistics

14.13.2.70 LOCK STATS

`LOCK STATS` is used to lock the statistics of tables or partitions. When the statistics is locked, TiDB does not automatically update the statistics of the table or partition. For details on the behavior, see Behaviors of locking statistics.

14.13.2.70.1 Synopsis

```
LockStatsStmt ::=
    'LOCK' 'STATS' (TableNameList) | (TableName 'PARTITION'
       ↪ PartitionNameList)

TableNameList ::=
    TableName (',' TableName)*

TableName ::=
    Identifier ( '.' Identifier )?

PartitionNameList ::=
    Identifier ( ',' Identifier )*
```

14.13.2.70.2 Examples

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT);
Query OK, 0 rows affected (0.03 sec)
```

```
mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Level | Code | Message
   ↪
   ↪ |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t, reason to use this rate is "Row count in stats_meta is much
   ↪ smaller compared with the row count got by PD, use min(1, 15000/4) as
   ↪  the sample-rate=1" |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `ANALYZE`. From the output of `SHOW STATS_LOCKED`, you can see that the statistics of table `t` have been locked. The warning message shows that the `ANALYZE` statement has skipped table `t`.

```
mysql> LOCK STATS t;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW STATS_LOCKED;
+---------+------------+----------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+------------+----------------+--------+
| test    | t          |                | locked |
+---------+------------+----------------+--------+
1 row in set (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
    ↪ sample-rate=1" |
| Warning | 1105 | skip analyze locked table: test.t
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
2 rows in set (0.00 sec)
```

In addition, you can also lock the statistics of a partition using `LOCK STATS`. For example:

Create a partition table `t`, and insert data into it. When the statistics of partition `p1` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT) PARTITION BY RANGE (a) (PARTITION p0
    ↪ VALUES LESS THAN (10), PARTITION p1 VALUES LESS THAN (20), PARTITION
    ↪ p2 VALUES LESS THAN (30));
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 6 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
```

```
   ↪
| Warning | 1105 | disable dynamic pruning due to t has no global stats
   ↪
   ↪ |
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t's partition p0, reason to use this rate is "Row count in stats
   ↪ _meta is much smaller compared with the row count got by PD, use min
   ↪ (1, 15000/4) as the sample-rate=1" |
| Warning | 1105 | disable dynamic pruning due to t has no global stats
   ↪
   ↪ |
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t's partition p1, reason to use this rate is "TiDB assumes that
   ↪ the table is empty, use sample-rate=1"
   ↪                                          |
| Warning | 1105 | disable dynamic pruning due to t has no global stats
   ↪
   ↪ |
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t's partition p2, reason to use this rate is "TiDB assumes that
   ↪ the table is empty, use sample-rate=1"
   ↪                                          |
+---------+------+-----------------------------------------------------------------------
   ↪
6 rows in set (0.01 sec)
```

Lock the statistics of partition `p1` and execute `ANALYZE`. The warning message shows that the `ANALYZE` statement has skipped partition `p1`.

```
mysql> LOCK STATS t PARTITION p1;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW STATS_LOCKED;
+---------+------------+----------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+------------+----------------+--------+
| test    | t          | p1             | locked |
+---------+------------+----------------+--------+
1 row in set (0.00 sec)

mysql> ANALYZE TABLE t PARTITION p1;
Query OK, 0 rows affected, 2 warnings (0.01 sec)

mysql> SHOW WARNINGS;
+--
```

```
    ↪ -------+------+-----------------------------------------------------------------
    ↪

14.13.2.71 LOCK TABLES and UNLOCK TABLES

> **Warning:**
>
> `LOCK TABLES` and `UNLOCK TABLES` are experimental features for the current version. It is not recommended to use it in the production environment.

TiDB enables client sessions to acquire table locks for the purpose of cooperating with other sessions for access to tables, or to prevent other sessions from modifying tables. A session can acquire or release locks only for itself. One session cannot acquire locks for another session or release locks held by another session.

`LOCK TABLES` acquires table locks for the current client session. If you have the `LOCK TABLES` and `SELECT` privileges for each object to be locked, you can acquire table locks for common tables.

`UNLOCK TABLES` explicitly releases any table locks held by the current session. `LOCK TABLES` implicitly releases all table locks held by the current session before acquiring new locks.

A table lock protects against reads or writes by other sessions. A session that holds a `WRITE` lock can perform table-level operations such as `DROP TABLE` or `TRUNCATE TABLE`.

> **Note:**
>
> The table locks feature is disabled by default.
>
> - For TiDB Self-Managed, to enable the table locks feature, you need to set `enable-table-lock` to `true` in the configuration files of all TiDB instances.
> - For TiDB Cloud Dedicated, to enable the table locks feature, you need to contact TiDB Cloud Support to set `enable-table-lock` to `true`.
> - For TiDB Cloud Serverless, setting `enable-table-lock` to `true` is not supported.

14.13.2.71.1 Synopsis

```
LockTablesDef
        ::= 'LOCK' ( 'TABLES' | 'TABLE' ) TableName LockType ( ',' TableName
            ↪  LockType)*

UnlockTablesDef
        ::= 'UNLOCK' 'TABLES'

LockType
        ::= 'READ' ('LOCAL')?
          | 'WRITE' ('LOCAL')?
```

14.13.2.71.2 Acquire table locks

You can acquire table locks within the current session by using the `LOCK TABLES` statement. The following lock types are available:

`READ` lock:

- The session that holds this lock can read the table, but cannot write it.
- Multiple sessions can acquire a `READ` lock from the same table at the same time.
- Other sessions can read the table without explicitly acquiring a `READ` lock.

The `READ LOCAL` lock is only for syntax compatibility with MySQL and is not supported.

`WRITE` lock:

- The session that holds this lock can read and write the table.
- Only the session that holds this lock can access the table. No other sessions can access it until the lock is released.

`WRITE LOCAL` lock:

- The session that holds this lock can read and write the table.
- Only the session that holds this lock can access the table. Other sessions can read the table, but cannot write it.

If the lock that the `LOCK TABLES` statement needs is held by another session, the `LOCK TABLES` statement must wait, and an error is returned upon the execution of this statement, for example:

```
> LOCK TABLES t1 READ;
ERROR 8020 (HY000): Table 't1' was locked in WRITE by server: f4799bcb-cad7
    ↪ -4285-8a6d-23d3555173f1_session: 2199023255959
```

The preceding error message indicates that the session with ID `2199023255959` in TiDB `f4799bcb-cad7-4285-8a6d-23d3555173f1` already holds a `WRITE` lock on table `t1`. Therefore, the current session cannot acquire a `READ` lock on table `t1`.

You cannot acquire the same table lock multiple times in a single `LOCK TABLES` statement.

```
> LOCK TABLES t WRITE, t READ;
ERROR 1066 (42000): Not unique table/alias: 't'
```

14.13.2.71.3 Release table locks

When the table locks held by a session are released, they are all released at the same time. A session can release its locks explicitly or implicitly.

- A session can release its locks explicitly with `UNLOCK TABLES`.
- If a session issues a `LOCK TABLES` statement to acquire a lock while already holding locks, its existing locks are released implicitly before the new locks are acquired.

If the connection for a client session terminates, whether normally or abnormally, TiDB implicitly releases all table locks held by the session. If the client reconnects, the locks are no longer in effect. For this reason, it is not recommended to enable auto-reconnection on the client. If you enable auto-reconnection, the client is not notified when reconnection occurs, and all table locks or current transactions are lost. By contrast, with auto-reconnection disabled, if the connection drops, an error occurs when the next statement is issued. The client can detect the error and take appropriate action such as reacquiring the locks or redoing the transaction.

14.13.2.71.4 Table-locking restrictions and conditions

You can safely use `KILL` to terminate a session that holds a table lock.

You cannot acquire table locks on tables in the following databases:

- `INFORMATION_SCHEMA`
- `PERFORMANCE_SCHEMA`
- `METRICS_SCHEMA`
- `mysql`

14.13.2.71.5 MySQL compatibility

Table lock acquisition

- In TiDB, if session A has already held a table lock, an error is returned if session B attempts to write to the table. In MySQL, the write request of session B is blocked until session A releases the table lock, and requests for locking the table from other sessions are blocked until the current session releases the `WRITE` lock.
- In TiDB, if the lock that the `LOCK TABLES` statement needs is held by another session, the `LOCK TABLES` statement must wait, and an error is returned upon the execution of this statement. In MySQL, this statement is blocked until the lock is acquired.
- In TiDB, the `LOCK TABLES` statement is effective in the whole cluster. In MySQL, this statement is effective only in the current MySQL server, and is not compatible with the NDB cluster.

Table lock release

When a transaction is explicitly started in a TiDB session (for example, with the `BEGIN` statement), TiDB does not implicitly release the table locks held by the session; but MySQL does.

14.13.2.72 PREPARE

The `PREPARE` statement provides an SQL interface to server-side prepared statements.

14.13.2.72.1 Synopsis

```
PreparedStmt ::=
    'PREPARE' Identifier 'FROM' PrepareSQL

PrepareSQL ::=
    stringLit
|   UserVariable
```

> **Note:**
>
> For each `PREPARE` statement, the maximum number of placeholders is 65535.

To limit the number of `PREPARE` statements in the current TiDB instance, you can use the `max_prepared_stmt_count` system variable.

14.13.2.72.2 Examples

```
mysql> PREPARE mystmt FROM 'SELECT ? as num FROM DUAL';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @number = 5;
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE mystmt USING @number;
+------+
| num |
+------+
| 5   |
+------+
1 row in set (0.00 sec)

mysql> DEALLOCATE PREPARE mystmt;
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.72.3 MySQL compatibility

The `PREPARE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.72.4 See also

- EXECUTE
- DEALLOCATE

14.13.2.73 QUERY WATCH

The `QUERY WATCH` statement is used to manually manage the watch list of runaway queries in a resource group.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.73.1 Synopsis

```
AddQueryWatchStmt ::=
    "QUERY" "WATCH" "ADD" QueryWatchOptionList

QueryWatchOptionList ::=
    QueryWatchOption
|   QueryWatchOptionList QueryWatchOption
|   QueryWatchOptionList ',' QueryWatchOption

QueryWatchOption ::=
    "RESOURCE" "GROUP" ResourceGroupName
|   "RESOURCE" "GROUP" UserVariable
|   "ACTION" EqOpt ResourceGroupRunawayActionOption
|   QueryWatchTextOption

ResourceGroupName ::=
    Identifier
|   "DEFAULT"

ResourceGroupRunawayActionOption ::=
    DRYRUN
|   COOLDOWN
|   KILL
|   "SWITCH_GROUP" '(' ResourceGroupName ')'

QueryWatchTextOption ::=
    "SQL" "DIGEST" SimpleExpr
```

```
|   "PLAN" "DIGEST" SimpleExpr
|   "SQL" "TEXT" ResourceGroupRunawayWatchOption "TO" SimpleExpr

ResourceGroupRunawayWatchOption ::=
    "EXACT"
|   "SIMILAR"
|   "PLAN"

DropQueryWatchStmt ::=
    "QUERY" "WATCH" "REMOVE" NUM
```

14.13.2.73.2 Parameters

See QUERY WATCH parameters.

14.13.2.73.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.73.4 See also

- Runaway Queries

14.13.2.74 RECOVER TABLE

`RECOVER TABLE` is used to recover a deleted table and the data on it within the GC (Garbage Collection) life time after the `DROP TABLE` statement is executed.

14.13.2.74.1 Syntax

```
RECOVER TABLE table_name;
```

```
RECOVER TABLE BY JOB JOB_ID;
```

14.13.2.74.2 Synopsis

```
RecoverTableStmt ::=
    'RECOVER' 'TABLE' ( 'BY' 'JOB' Int64Num | TableName Int64Num? )

TableName ::=
    Identifier ( '.' Identifier )?

Int64Num ::= NUM

NUM ::= intLit
```

Note:

If a table is deleted and the GC lifetime is out, the table cannot be recovered with `RECOVER TABLE`. Execution of `RECOVER TABLE` in this scenario returns an error like: `snapshot is older than GC safe point 2019-07-10 13:45:57 +0800 CST`.

14.13.2.74.3 Examples

- Recover the deleted table according to the table name.

```
DROP TABLE t;
```

```
RECOVER TABLE t;
```

This method searches the recent DDL job history and locates the first DDL operation of the `DROP TABLE` type, and then recovers the deleted table with the name identical to the one table name specified in the `RECOVER TABLE` statement.

- Recover the deleted table according to the table's `DDL JOB ID` used.

Suppose that you had deleted the table `t` and created another `t`, and again you deleted the newly created `t`. Then, if you want to recover the `t` deleted in the first place, you must use the method that specifies the `DDL JOB ID`.

```
DROP TABLE t;
```

```
ADMIN SHOW DDL JOBS 1;
```

The second statement above is used to search for the table's `DDL JOB ID` to delete `t`. In the following example, the ID is `53`.

```
+--------+---------+------------+------------+--------------+-----------+----------
   ↪
| JOB_ID | DB_NAME | TABLE_NAME | JOB_TYPE | SCHEMA_STATE | SCHEMA_ID |
   ↪  TABLE_ID | ROW_COUNT | START_TIME          | STATE |
+--------+---------+------------+------------+--------------+-----------+----------
   ↪
| 53     | test    |            | drop table | none         | 1         | 41
   ↪      | 0         | 2019-07-10 13:23:18.277 +0800 CST | synced |
+--------+---------+------------+------------+--------------+-----------+----------
   ↪
```

```
RECOVER TABLE BY JOB 53;
```

This method recovers the deleted table via the `DDL JOB ID`. If the corresponding DDL job is not of the `DROP TABLE` type, an error occurs.

14.13.2.74.4 Implementation principle

When deleting a table, TiDB only deletes the table metadata, and writes the table data (row data and index data) to be deleted to the `mysql.gc_delete_range` table. The GC Worker in the TiDB background periodically removes from the `mysql.gc_delete_range` table the keys that exceed the GC life time.

Therefore, to recover a table, you only need to recover the table metadata and delete the corresponding row record in the `mysql.gc_delete_range` table before the GC Worker deletes the table data. You can use a snapshot read of TiDB to recover the table metadata. Refer to Read Historical Data for details.

Table recovery is done by TiDB obtaining the table metadata through snapshot read, and then going through the process of table creation similar to `CREATE TABLE`. Therefore, `RECOVER TABLE` itself is, in essence, a kind of DDL operation.

14.13.2.74.5 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.75 RENAME USER

`RENAME USER` is used to rename an existing user.

14.13.2.75.1 Synopsis

```
RenameUserStmt ::=
    'RENAME' 'USER' UserToUser ( ',' UserToUser )*
UserToUser ::=
    Username 'TO' Username
Username ::=
    StringName ('@' StringName | singleAtIdentifier)? | 'CURRENT_USER'
        ↪ OptionalBraces
```

14.13.2.75.2 Examples

```
CREATE USER 'newuser' IDENTIFIED BY 'mypassword';
```

```
Query OK, 1 row affected (0.02 sec)
```

```
SHOW GRANTS FOR 'newuser';
```

```
+-----------------------------------+
| Grants for newuser@%              |
+-----------------------------------+
| GRANT USAGE ON *.* TO 'newuser'@'%' |
+-----------------------------------+
1 row in set (0.00 sec)
```

```
RENAME USER 'newuser' TO 'testuser';
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SHOW GRANTS FOR 'testuser';
```

```
+-------------------------------------+
| Grants for testuser@%               |
+-------------------------------------+
| GRANT USAGE ON *.* TO 'testuser'@'%' |
+-------------------------------------+
1 row in set (0.00 sec)
```

```
SHOW GRANTS FOR 'newuser';
```

```
ERROR 1141 (42000): There is no such grant defined for user 'newuser' on
    ↪ host '%'
```

14.13.2.75.3 MySQL compatibility

`RENAME USER` is expected to be fully compatible with MySQL. If you find any compatibility difference, you can report a bug.

14.13.2.75.4 See also

- CREATE USER
- SHOW GRANTS
- DROP USER

14.13.2.76 RENAME TABLE

This statement is used to rename existing tables and views, supporting renaming multiple tables at once and renaming across databases.

14.13.2.76.1 Synopsis

```
RenameTableStmt ::=
    'RENAME' 'TABLE' TableToTable ( ',' TableToTable )*

TableToTable ::=
    TableName 'TO' TableName
```

14.13.2.76.2 Examples

```
CREATE TABLE t1 (a int);
```

```
Query OK, 0 rows affected (0.12 sec)
```

```
SHOW TABLES;
```

```
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

```
RENAME TABLE t1 TO t2;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
SHOW TABLES;
```

```
+----------------+
| Tables_in_test |
+----------------+
| t2             |
+----------------+
1 row in set (0.00 sec)
```

The following example demonstrates how to rename multiple tables across databases, assuming that the databases `db1`, `db2`, `db3`, and `db4` already exist, and that the tables `db1.t1` and `db3.t3` already exist:

```
RENAME TABLE db1.t1 To db2.t2, db3.t3 To db4.t4;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
USE db1; SHOW TABLES;
```

```
Database changed
Empty set (0.00 sec)
```

```
USE db2; SHOW TABLES;
```

```
Database changed
+---------------+
| Tables_in_db2 |
+---------------+
| t2            |
+---------------+
1 row in set (0.00 sec)
```

```
USE db3; SHOW TABLES;
```

```
Database changed
Empty set (0.00 sec)
```

```
USE db4; SHOW TABLES;
```

```
Database changed
+---------------+
| Tables_in_db4 |
+---------------+
| t4            |
+---------------+
1 row in set (0.00 sec)
```

The atomic rename can be used to swap out a table without having any moment in which the table does not exist.

```
CREATE TABLE t1(id int PRIMARY KEY);
```

```
Query OK, 0 rows affected (0.04 sec)
```

```
CREATE TABLE t1_new(id int PRIMARY KEY, n CHAR(0));
```

```
Query OK, 0 rows affected (0.04 sec)
```

```
RENAME TABLE t1 TO t1_old, t1_new TO t1;
```

```
Query OK, 0 rows affected (0.07 sec)
```

```
SHOW CREATE TABLE t1\G
```

```
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `id` int NOT NULL,
  `n` char(0) DEFAULT NULL,
  PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)
```

14.13.2.76.3 MySQL compatibility

The `RENAME TABLE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.76.4 See also

- CREATE TABLE
- SHOW TABLES
- ALTER TABLE

14.13.2.77 REPLACE

The `REPLACE` statement is semantically a combined `DELETE`+`INSERT` statement. It can be used to simplify application code.

14.13.2.77.1 Synopsis

```
ReplaceIntoStmt ::=
    'REPLACE' PriorityOpt IntoOpt TableName PartitionNameListOpt
       ↪ InsertValues

PriorityOpt ::=
    ( 'LOW_PRIORITY' | 'HIGH_PRIORITY' | 'DELAYED' )?

IntoOpt ::= 'INTO'?

TableName ::=
    Identifier ( '.' Identifier )?
```

```
PartitionNameListOpt ::=
    ( 'PARTITION' '(' Identifier ( ',' Identifier )* ')' )?

InsertValues ::=
    '(' ( ColumnNameListOpt ')' ( ValueSym ValuesList | SelectStmt | '('
        ↪ SelectStmt ')' | UnionStmt ) | SelectStmt ')' )
|   ValueSym ValuesList
|   SelectStmt
|   UnionStmt
|   'SET' ColumnSetValue? ( ',' ColumnSetValue )*
```

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority (`PriorityOpt`) will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.13.2.77.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.12 sec)

mysql> INSERT INTO t1 (c1) VALUES (1), (2), (3);
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
+----+----+
3 rows in set (0.00 sec)

mysql> REPLACE INTO t1 (id, c1) VALUES(3, 99);
```

```

14.13.2.77.3 MySQL compatibility

The `REPLACE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.77.4 See also

- DELETE
- INSERT
- SELECT
- UPDATE

14.13.2.78 RESTORE

This statement performs a distributed restore from a backup archive previously produced by a `BACKUP` statement.

> **Warning:**
>
> - This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.
> - This feature is not available on TiDB Cloud Serverless clusters.

The `RESTORE` statement uses the same engine as the BR tool, except that the restore process is driven by TiDB itself rather than a separate BR tool. All benefits and caveats of BR also apply here. In particular, **`RESTORE` is currently not ACID-compliant**. Before running `RESTORE`, ensure that the following requirements are met:

- The cluster is "offline", and the current TiDB session is the only active SQL connection to access all tables being restored.
- When a full restore is being performed, the tables being restored should not already exist, because existing data might be overridden and causes inconsistency between the data and indices.
- When an incremental restore is being performed, the tables should be at the exact same state as the `LAST_BACKUP` timestamp when the backup is created.

Running `RESTORE` requires either the `RESTORE_ADMIN` or `SUPER` privilege. Additionally, both the TiDB node executing the restore and all TiKV nodes in the cluster must have read permission from the destination.

The `RESTORE` statement is blocking, and will finish only after the entire restore task is finished, failed, or canceled. A long-lasting connection should be prepared for running `RESTORE`. The task can be canceled using the `KILL TIDB QUERY` statement.

Only one `BACKUP` and `RESTORE` task can be executed at a time. If a `BACKUP` or `RESTORE` task is already running on the same TiDB server, the new `RESTORE` execution will wait until all previous tasks are done.

`RESTORE` can only be used with "tikv" storage engine. Using `RESTORE` with the "unistore" engine will fail.

14.13.2.78.1 Synopsis

```
RestoreStmt ::=
    "RESTORE" BRIETables "FROM" stringLit RestoreOption*

BRIETables ::=
    "DATABASE" ( '*' | DBName (',' DBName)* )
|   "TABLE" TableNameList

RestoreOption ::=
    "CHECKSUM_CONCURRENCY" '='? LengthNum
|   "CONCURRENCY" '='? LengthNum
|   "CHECKSUM" '='? Boolean
|   "LOAD_STATS" '='? Boolean
|   "RATE_LIMIT" '='? LengthNum "MB" '/' "SECOND"
|   "SEND_CREDENTIALS_TO_TIKV" '='? Boolean
|   "WAIT_TIFLASH_READY" '='? Boolean
|   "WITH_SYS_TABLE" '='? Boolean

Boolean ::=
    NUM | "TRUE" | "FALSE"
```

14.13.2.78.2 Examples

Restore from backup archive

```
RESTORE DATABASE * FROM 'local:///mnt/backup/2020/04/';
```

```
+--
    ↪ ---------------------------+----------+---------+--------------------+------
    ↪
| Destination                | Size     | BackupTS | Queue Time         |
    ↪ Execution Time    |
+--
    ↪ ---------------------------+----------+---------+--------------------+------
    ↪
| local:///mnt/backup/2020/04/ | 248665063 | 0 | 2020-04-21 17:16:55 |
    ↪ 2020-04-21 17:16:55 |
+--
    ↪ ---------------------------+----------+---------+--------------------+------
    ↪
1 row in set (28.961 sec)
```

In the example above, all data is restored from a backup archive at the local filesystem. The data is read as SST files from the `/mnt/backup/2020/04/` directories distributed among all TiDB and TiKV nodes.

The first row of the result above is described as follows:

Column	Description
`Destination` ↪	The destination URL to read from
`Size`	The total size of the backup archive, in bytes
`BackupTS`	(not used)
`Queue` ↪ `Time`	The timestamp (in current time zone) when the `RESTORE` task was queued.

Column	Description
`Execution Time`	The timestamp (in current time zone) when the `RESTORE` task starts to run.

Partial restore

You can specify which databases or tables to restore. If some databases or tables are missing from the backup archive, they will be ignored, and thus `RESTORE` would complete without doing anything.

```
RESTORE DATABASE `test` FROM 'local:///mnt/backup/2020/04/';
```

```
RESTORE TABLE `test`.`sbtest01`, `test`.`sbtest02` FROM 'local:///mnt/
    ↪ backup/2020/04/';
```

External storages

BR supports restoring data from S3 or GCS:

```
RESTORE DATABASE * FROM 's3://example-bucket-2020/backup-05/';
```

The URL syntax is further explained in URI Formats of External Storage Services.

When running on cloud environment where credentials should not be distributed, set the `SEND_CREDENTIALS_TO_TIKV` option to `FALSE`:

```
RESTORE DATABASE * FROM 's3://example-bucket-2020/backup-05/'
    SEND_CREDENTIALS_TO_TIKV = FALSE;
```

Performance fine-tuning

Use `RATE_LIMIT` to limit the average download speed per TiKV node to reduce network bandwidth.

Before the restore is completed, `RESTORE` would perform a checksum against the data in the backup files to verify correctness by default. The default concurrency for checksum tasks on a single table is 4, which you can adjust using the `CHECKSUM_CONCURRENCY` parameter. If you are confident that the data verification is unnecessary, you can disable the check by setting the `CHECKSUM` parameter to `FALSE`.

If statistics have been backed up, they are restored by default during the restore. If you do not need to restore the statistics, you can set the `LOAD_STATS` parameter to `FALSE`.

System privilege tables are restored by default. If you do not need to restore system privilege tables, you can set the `WITH_SYS_TABLE` parameter to `FALSE`.

By default, the restore task does not wait for TiFlash replicas to be fully created before completing. If you need the restore task to wait, you can set the `WAIT_TIFLASH_READY` parameter to `TRUE`.

```
RESTORE DATABASE * FROM 's3://example-bucket-2020/backup-06/'
    RATE_LIMIT = 120 MB/SECOND
    CONCURRENCY = 64
    CHECKSUM = FALSE;
```

Incremental restore

There is no special syntax to perform incremental restore. TiDB will recognize whether the backup archive is full or incremental and take appropriate action. You only need to apply each incremental restore in correct order.

For instance, if a backup task is created as follows:

```
BACKUP DATABASE `test` TO 's3://example-bucket/full-backup' SNAPSHOT =
    ↪ 413612900352000;
BACKUP DATABASE `test` TO 's3://example-bucket/inc-backup-1' SNAPSHOT =
    ↪ 414971854848000 LAST_BACKUP = 413612900352000;
BACKUP DATABASE `test` TO 's3://example-bucket/inc-backup-2' SNAPSHOT =
    ↪ 416353458585600 LAST_BACKUP = 414971854848000;
```

then the same order should be applied in the restore:

```
RESTORE DATABASE * FROM 's3://example-bucket/full-backup';
RESTORE DATABASE * FROM 's3://example-bucket/inc-backup-1';
RESTORE DATABASE * FROM 's3://example-bucket/inc-backup-2';
```

14.13.2.78.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- BACKUP
- SHOW RESTORES

14.13.2.79 `REVOKE <privileges>`

This statement removes privileges from an existing user. Executing this statement requires the `GRANT OPTION` privilege and all privileges you revoke.

14.13.2.79.1 Synopsis

```
RevokeStmt ::=
    'REVOKE' PrivElemList 'ON' ObjectType PrivLevel 'FROM' UserSpecList

PrivElemList ::=
    PrivElem ( ',' PrivElem )*

PrivElem ::=
    PrivType ( '(' ColumnNameList ')' )?

PrivType ::=
    'ALL' 'PRIVILEGES'?
|   'ALTER' 'ROUTINE'?
|   'CREATE' ( 'USER' | 'TEMPORARY' 'TABLES' | 'VIEW' | 'ROLE' | 'ROUTINE' )
    ↪ ?
|    'TRIGGER'
|   'DELETE'
|    'DROP' 'ROLE'?
|    'PROCESS'
|    'EXECUTE'
|   'INDEX'
|   'INSERT'
|   'SELECT'
|   'SUPER'
|    'SHOW' ( 'DATABASES' | 'VIEW' )
|   'UPDATE'
|   'GRANT' 'OPTION'
|   'REFERENCES'
|   'REPLICATION' ( 'SLAVE' | 'CLIENT' )
|   'USAGE'
|    'RELOAD'
|   'FILE'
|   'CONFIG'
|   'LOCK' 'TABLES'
|    'EVENT'
|   'SHUTDOWN'

ObjectType ::=
    'TABLE'?

PrivLevel ::=
    '*' ( '.' '*' )?
|    Identifier ( '.' ( '*' | Identifier ) )?
```

```
UserSpecList ::=
    UserSpec ( ',' UserSpec )*
```

14.13.2.79.2 Examples

```
mysql> CREATE USER 'newuser' IDENTIFIED BY 'mypassword';
Query OK, 1 row affected (0.02 sec)

mysql> GRANT ALL ON test.* TO 'newuser';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GRANTS FOR 'newuser';
+-------------------------------------------------+
| Grants for newuser@%                            |
+-------------------------------------------------+
| GRANT USAGE ON *.* TO 'newuser'@'%'             |
| GRANT ALL PRIVILEGES ON test.* TO 'newuser'@'%' |
+-------------------------------------------------+
2 rows in set (0.00 sec)

mysql> REVOKE ALL ON test.* FROM 'newuser';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GRANTS FOR 'newuser';
+-----------------------------------+
| Grants for newuser@%              |
+-----------------------------------+
| GRANT USAGE ON *.* TO 'newuser'@'%' |
+-----------------------------------+
1 row in set (0.00 sec)

mysql> DROP USER 'newuser';
Query OK, 0 rows affected (0.14 sec)

mysql> SHOW GRANTS FOR 'newuser';
ERROR 1141 (42000): There is no such grant defined for user 'newuser' on
    ↪ host '%'
```

14.13.2.79.3 MySQL compatibility

- In TiDB, after the `REVOKE <privileges>` statement is executed successfully, the execution result takes effect immediately on the current connection. Whereas in MySQL, for some privileges, the execution results take effect only on subsequent connections. See TiDB #39356 for details.

14.13.2.79.4 See also

- GRANT <privileges>
- SHOW GRANTS

- Privilege Management

14.13.2.80 REVOKE <role>

This statement removes a previously assigned role from a specified user (or list of users).

14.13.2.80.1 Synopsis

```
RevokeRoleStmt ::=
    'REVOKE' RolenameList 'FROM' UsernameList

RolenameList ::=
    Rolename ( ',' Rolename )*

UsernameList ::=
    Username ( ',' Username )*
```

14.13.2.80.2 Examples

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Create a new role `analyticsteam` and a new user `jennifer`:

```
CREATE ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)

GRANT SELECT ON test.* TO analyticsteam;
Query OK, 0 rows affected (0.02 sec)

CREATE USER jennifer;
Query OK, 0 rows affected (0.01 sec)

GRANT analyticsteam TO jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Note that by default `jennifer` needs to execute `SET ROLE analyticsteam` in order to be able to use the privileges associated with the `analyticsteam` role:

```
SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-----------------------------------------------+
2 rows in set (0.00 sec)

SHOW TABLES in test;
ERROR 1044 (42000): Access denied for user 'jennifer'@'%' to database 'test'
SET ROLE analyticsteam;
Query OK, 0 rows affected (0.00 sec)

SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT SELECT ON test.* TO 'jennifer'@'%' |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-----------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

The statement `SET DEFAULT ROLE` can be used to associate the role `analyticsteam` to `jennifer`:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
Query OK, 0 rows affected (0.02 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

After this, the user `jennifer` has the privileges associated with the role `analyticsteam` and `jennifer` does not have to execute the statement `SET ROLE`:

```
SHOW GRANTS;
+-----------------------------------------------+
| Grants for User                               |
+-----------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'          |
| GRANT SELECT ON test.* TO 'jennifer'@'%'      |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%'   |
+-----------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Revoke the role of analyticsteam from `jennifer`:

```
REVOKE analyticsteam FROM jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Show the privileges of `jennifer`:

```
SHOW GRANTS;
+--------------------------------------+
| Grants for User                      |
+--------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%' |
+--------------------------------------+
1 row in set (0.00 sec)
```

14.13.2.80.3 MySQL compatibility

The `REVOKE <role>` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.80.4 See also

- `CREATE ROLE`
- `DROP ROLE`
- `GRANT <role>`
- `SET ROLE`
- `SET DEFAULT ROLE`

- Role-Based Access Control

14.13.2.81 ROLLBACK

This statement reverts all changes in the current transaction inside of TiDB. It is the opposite of a `COMMIT` statement.

14.13.2.81.1 Synopsis

```
RollbackStmt ::=
    'ROLLBACK' CompletionTypeWithinTransaction?

CompletionTypeWithinTransaction ::=
    'AND' ( 'CHAIN' ( 'NO' 'RELEASE' )? | 'NO' 'CHAIN' ( 'NO'? 'RELEASE' )?
       ↪ )
|   'NO'? 'RELEASE'
```

14.13.2.81.2 Examples

```
mysql> CREATE TABLE t1 (a INT NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.12 sec)

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> ROLLBACK;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM t1;
Empty set (0.01 sec)
```

14.13.2.81.3 MySQL compatibility

- TiDB parses but ignores the syntax `ROLLBACK AND [NO] RELEASE`. This functionality is used in MySQL to disconnect the client session immediately after rolling back the transaction. In TiDB, it is recommended to instead use the `mysql_close()` functionality of your client driver.
- TiDB parses but ignores the syntax `ROLLBACK AND [NO] CHAIN`. This functionality is used in MySQL to immediately start a new transaction with the same isolation level while the current transaction is being rolled back. In TiDB, it is recommended to instead start a new transaction.

14.13.2.81.4 See also

- SAVEPOINT
- COMMIT
- BEGIN
- START TRANSACTION

14.13.2.82 SAVEPOINT

`SAVEPOINT` is a feature introduced in TiDB v6.2.0. The syntax is as follows:

```
SAVEPOINT identifier
ROLLBACK TO [SAVEPOINT] identifier
RELEASE SAVEPOINT identifier
```

> **Warning:**
>
> You cannot use `SAVEPOINT` in pessimistic transactions when `tidb_constraint_check_in_place_pessimistic` is disabled.

- `SAVEPOINT` is used to set a savepoint of a specified name in the current transaction. If a savepoint with the same name already exists, it will be deleted and a new savepoint with the same name will be set.
- `ROLLBACK TO SAVEPOINT` rolls back a transaction to the savepoint of a specified name and does not terminate the transaction. Data changes made to the table data after the savepoint will be reverted in the rollback, and all savepoints after the savepoint are deleted. In a pessimistic transaction, the locks held by the transaction are not rolled back. Instead, the locks will be released when the transaction ends.

  If the savepoint specified in the `ROLLBACK TO SAVEPOINT` statement does not exist, the statement returns the following error:

```
ERROR 1305 (42000): SAVEPOINT identifier does not exist
```

- `RELEASE SAVEPOINT` statement removes the named savepoint and **all savepoints** after this savepoint from the current transaction, without committing or rolling back the current transaction. If the savepoint of the specified name does not exist, the following error is returned:

  ```
  ERROR 1305 (42000): SAVEPOINT identifier does not exist
  ```

  After the transaction is committed or rolled back, all savepoints in the transaction will be deleted.

14.13.2.82.1 Synopsis

```
SavepointStmt ::=
    "SAVEPOINT" Identifier

RollbackToStmt ::=
    "ROLLBACK" "TO" "SAVEPOINT"? Identifier

ReleaseSavepointStmt ::=
    "RELEASE" "SAVEPOINT" Identifier
```

14.13.2.82.2 Examples

Create a table `t1`:

```
CREATE TABLE t1 (a INT NOT NULL PRIMARY KEY);
```

```
Query OK, 0 rows affected (0.12 sec)
```

Start the current transaction:

```
BEGIN;
```

```
Query OK, 0 rows affected (0.00 sec)
```

Insert data into the table and set a savepoint `sp1`:

```
INSERT INTO t1 VALUES (1);
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SAVEPOINT sp1;
```

```
Query OK, 0 rows affected (0.01 sec)
```

Insert data into the table again and set a savepoint `sp2`:

```
INSERT INTO t1 VALUES (2);
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SAVEPOINT sp2;
```

```
Query OK, 0 rows affected (0.01 sec)
```

Release the savepoint `sp2`:

```
RELEASE SAVEPOINT sp2;
```

```
Query OK, 0 rows affected (0.01 sec)
```

Roll back to the savepoint `sp1`:

```
ROLLBACK TO SAVEPOINT sp1;
```

```
Query OK, 0 rows affected (0.01 sec)
```

Commit the transaction and query the table. Only the data inserted before `sp1` is returned.

```
COMMIT;
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
SELECT * FROM t1;
```

```
+---+
| a |
+---+
| 1 |
+---+
1 row in set
```

14.13.2.82.3 MySQL compatibility

When `ROLLBACK TO SAVEPOINT` is used to roll back a transaction to a specified savepoint, MySQL releases the locks held only after the specified savepoint, while in TiDB pessimistic transaction, TiDB does not immediately release the locks held after the specified savepoint. Instead, TiDB releases all locks when the transaction is committed or rolled back.

TiDB does not support the MySQL syntax `ROLLBACK WORK TO SAVEPOINT ...`.

14.13.2.83 SELECT

The `SELECT` statement is used to read data from TiDB.

14.13.2.83.1 Synopsis

```
SelectStmt ::=
    ( SelectStmtBasic | SelectStmtFromDualTable | SelectStmtFromTable )
    OrderBy? SelectStmtLimit? SelectLockOpt? SelectStmtIntoOption

SelectStmtBasic ::=
    "SELECT" SelectStmtOpts Field ("," Field)* ( "HAVING" Expression)?

SelectStmtFromDualTable ::=
    "SELECT" SelectStmtOpts Field ("," Field)* "FROM" "DUAL" WhereClause?

SelectStmtFromTable ::=
    "SELECT" SelectStmtOpts Field ("," Field)* "FROM" TableRefsClause
    WhereClause? GroupByClause? ( "HAVING" Expression)? WindowClause?

SelectStmtOpts ::=
    TableOptimizerHints DefaultFalseDistictOpt PriorityOpt
       ↪ SelectStmtSQLSmallResult
    SelectStmtSQLBigResult SelectStmtSQLBufferResult SelectStmtSQLCache
       ↪ SelectStmtCalcFoundRows
    SelectStmtStraightJoin

TableRefsClause ::=
    TableRef ( ',' TableRef )*

TableRef ::=
    TableFactor
|   JoinTable

TableFactor ::=
    TableName ( "PARTITION" "(" Identifier ("," Identifier)* ")" )? ("AS"
       ↪ TableAlias)? AsOfClause? TableSample?
```

```
JoinTable ::=
    TableRef
    (
        ("INNER" | "CROSS")? "JOIN" TableRef JoinClause?
        | "STRAIGHT_JOIN" TableRef "ON" Expression
        | ("LEFT" | "RIGHT") "OUTER"? "JOIN" TableRef JoinClause
        | "NATURAL" ("LEFT" | "RIGHT") "OUTER"? "JOIN" TableFactor
    )

JoinClause ::=
    ("ON" Expression
    | "USING" "(" ColumnNameList ")" )

AsOfClause ::=
    'AS' 'OF' 'TIMESTAMP' Expression

SelectStmtLimit ::=
    ("LIMIT" LimitOption ( "," | "OFFSET") LimitOption )?
| "FETCH" ("FIRST" | "NEXT") LimitOption? ("ROW" | "ROWS") "ONLY" )

SelectLockOpt ::=
    ( 'FOR' 'UPDATE' ( 'OF' TableList )? 'NOWAIT'?
|   'LOCK' 'IN' 'SHARE' 'MODE' )

TableList ::=
    TableName ( ',' TableName )*

WhereClause ::=
    "WHERE" Expression

GroupByClause ::=
    "GROUP" "BY" Expression

OrderBy ::=
    "ORDER" "BY" Expression

WindowClause ::=
    "WINDOW" WindowDefinition ("," WindowDefinition)*

TableSample ::=
    'TABLESAMPLE' 'REGIONS' '(' ')'
```

14.13.2.83.2 Description of the syntax elements

Syntax Element	Description
`TableOptimizerHints`	This is the hint to control the behavior of TiDB's optimizer. For more information, refer to Optimizer Hints.
`ALL`, `DISTINCT`, `DISTINCTROW`	The `ALL`, `DISTINCT`/`DISTINCTROW` modifiers specify whether duplicate rows should be returned. ALL (the default) specifies that all matching rows should be returned.
`HIGH_PRIORITY`	`HIGH_PRIORITY` gives the current statement higher priority than other statements.
`SQL_CALC_FOUND_ROWS`	TiDB does not support this feature, and will return an error unless `tidb_enable_noop_functions=1` is set.
`SQL_CACHE`, `SQL_NO_CACHE`	`SQL_CACHE` and `SQL_NO_CACHE` are used to control whether to cache the request results to the `BlockCache` of TiKV (RocksDB). For a one-time query on a large amount of data, such as the `count(*)` query, it is recommended to fill in `SQL_NO_CACHE` to avoid flushing the hot user data in `BlockCache`.
`STRAIGHT_JOIN`	`STRAIGHT_JOIN` forces the optimizer to do a union query in the order of the tables used in the `FROM` clause. When the optimizer chooses a join order that is not good, you can use this syntax to speed up the execution of the query.
`select_expr`	Each `select_expr` indicates a column to retrieve. including the column names and expressions. `\*` represents all the columns.
`FROM table_references`	The `FROM table_references` clause indicates the table (such as `select * from t;`), or tables (such as `select * from t1 join t2;`) or even 0 tables (such as `select 1+1 from dual;` which is equivalent to `select 1+1;`) from which to retrieve rows.
`WHERE where_condition`	The `WHERE` clause, if given, indicates the condition or conditions that rows must satisfy to be selected. The result contains only the data that meets the condition(s).
`GROUP BY`	The `GROUP BY` statement is used to group the result-set.
`HAVING where_condition`	The `HAVING` clause and the `WHERE` clause are both used to filter the results. The `HAVING` clause filters the results of `GROUP BY`, while the `WHERE` clause filter the results before aggregation.
`ORDER BY`	The `ORDER BY` clause is used to sort the data in ascending or descending order, based on columns, expressions or items in the `select_expr` list.

Syntax Element	Description
`LIMIT`	The `LIMIT` clause can be used to constrain the number of rows. `LIMIT` takes one or two numeric arguments. With one argument, the argument specifies the maximum number of rows to return, the first row to return is the first row of the table by default; with two arguments, the first argument specifies the offset of the first row to return, and the second specifies the maximum number of rows to return. TiDB also supports the `FETCH FIRST/NEXT n ROW/ROWS ONLY` syntax, which has the same effect as `LIMIT n`. You can omit `n` in this syntax and its effect is the same as `LIMIT 1`.
`Window window_definition`	This is the syntax for window function, which is usually used to do some analytical computation. For more information, refer to Window Function.
`FOR UPDATE`	The `SELECT FOR UPDATE` clause locks all the data in the result sets to detect concurrent updates from other transactions. Data that match the query conditions but do not exist in the result sets are not read-locked, such as the row data written by other transactions after the current transaction is started. When TiDB uses the Optimistic Transaction Mode, the transaction conflicts are not detected in the statement execution phase. Therefore, the current transaction does not block other transactions from executing `UPDATE`, `DELETE` or `SELECT FOR UPDATE` like other databases such as PostgreSQL. In the committing phase, the rows read by `SELECT FOR UPDATE` are committed in two phases, which means they can also join the conflict detection. If write conflicts occur, the commit fails for all transactions that include the `SELECT FOR UPDATE` clause. If no conflict is detected, the commit succeeds. And a new version is generated for the locked rows, so that write conflicts can be detected when other uncommitted transactions are being committed later. When TiDB uses the Pessimistic Transaction Mode, the behavior is basically the same as other databases. Refer to Differences from MySQL InnoDB to see the details. TiDB supports the `NOWAIT` modifier for `FOR UPDATE`. See TiDB Pessimistic Transaction Mode for details.
`LOCK IN SHARE MODE`	To guarantee compatibility, TiDB parses these three modifiers, but will ignore them.
`TABLESAMPLE`	To get a sample of rows from the table.

Note:

Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority (`HIGH_PRIORITY`) will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.13.2.83.3 Examples

SELECT

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.03 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
|  4 |  4 |
|  5 |  5 |
+----+----+
5 rows in set (0.00 sec)
```

```
mysql> SELECT AVG(s_quantity), COUNT(s_quantity) FROM stock TABLESAMPLE
    ↪ REGIONS();
+----------------+------------------+
| AVG(s_quantity) | COUNT(s_quantity) |
+----------------+------------------+
|        59.5000 |                4 |
+----------------+------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT AVG(s_quantity), COUNT(s_quantity) FROM stock;
+----------------+------------------+
| AVG(s_quantity) | COUNT(s_quantity) |
+----------------+------------------+
|        54.9729 |          1000000 |
+----------------+------------------+
1 row in set (0.52 sec)
```

The above example uses data generated with `tiup bench tpcc prepare`. The first query shows the use of `TABLESAMPLE`.

SELECT … INTO OUTFILE

The `SELECT ... INTO OUTFILE` statement is used to write the result of a query to a file.

> **Note:**
>
> - This statement is only applicable to TiDB Self-Managed and not available on TiDB Cloud.
> - This statement does not support writing query results to any external storages such as Amazon S3 or GCS.

In the statement, you can specify the format of the output file by using the following clauses:

- `FIELDS TERMINATED BY`: specifies the field delimiter in the file. For example, you can specify it as `','` to output comma-separated values (CSV) or `'\t'` to output tab-separated values (TSV).
- `FIELDS ENCLOSED BY`: specifies the enclosing character that wraps around each field in the file.
- `LINES TERMINATED BY`: specifies the line terminator in the file, if you want to end a line with a certain character.

Assume that there is a table `t` with three columns as follows:

```
mysql> CREATE TABLE t (a INT, b VARCHAR(10), c DECIMAL(10,2));
Query OK, 0 rows affected (0.02 sec)

mysql> INSERT INTO t VALUES (1, 'a', 1.1), (2, 'b', 2.2), (3, 'c', 3.3);
Query OK, 3 rows affected (0.01 sec)
```

The following examples show how to use the `SELECT ... INTO OUTFILE` statement to write the query result to a file.

Example 1:

```
mysql> SELECT * FROM t INTO OUTFILE '/tmp/tmp_file1';
Query OK, 3 rows affected (0.00 sec)
```

In this example, you can find the query result in `/tmp/tmp_file1` as follows:

```
1       a       1.10
2       b       2.20
3       c       3.30
```

Example 2:

```
mysql> SELECT * FROM t INTO OUTFILE '/tmp/tmp_file2' FIELDS TERMINATED BY '
    ↪ ,' ENCLOSED BY '"';
Query OK, 3 rows affected (0.00 sec)
```

In this example, you can find the query result in `/tmp/tmp_file2` as follows:

```
"1","a","1.10"
"2","b","2.20"
"3","c","3.30"
```

Example 3:

```
mysql> SELECT * FROM t INTO OUTFILE '/tmp/tmp_file3'
    -> FIELDS TERMINATED BY ',' ENCLOSED BY '\'' LINES TERMINATED BY '<<<\n'
       ↪ ;
Query OK, 3 rows affected (0.00 sec)
```

In this example, you can find the query result in `/tmp/tmp_file3` as follows:

```
'1','a','1.10'<<<
'2','b','2.20'<<<
'3','c','3.30'<<<
```

14.13.2.83.4 MySQL compatibility

- The syntax `SELECT ... INTO @variable` is not supported.
- The syntax `SELECT ... INTO DUMPFILE` is not supported.
- The syntax `SELECT .. GROUP BY expr` does not imply `GROUP BY expr ORDER BY expr` as it does in MySQL 5.7. TiDB instead matches the behavior of MySQL 8.0 and does not imply a default order.
- The syntax `SELECT ... TABLESAMPLE ...` is a TiDB extension designed for compatibility with other database systems and the ISO/IEC 9075-2 standard, but currently it is not supported by MySQL.

14.13.2.83.5 See also

- INSERT
- DELETE
- UPDATE
- REPLACE

14.13.2.84 SET DEFAULT ROLE

This statement sets a specific role to be applied to a user by default. Thus, they will automatically have the permissions associated with a role without having to execute `SET ROLE <rolename>` or `SET ROLE ALL`.

14.13.2.84.1 Synopsis

```
SetDefaultRoleStmt ::=
    "SET" "DEFAULT" "ROLE" ( "NONE" | "ALL" | Rolename ("," Rolename)* ) "TO
        ↪ " Username ("," Username)*
```

14.13.2.84.2 Examples

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

Create a new role `analyticsteam` and a new user `jennifer`:

```
CREATE ROLE analyticsteam;
Query OK, 0 rows affected (0.02 sec)

GRANT SELECT ON test.* TO analyticsteam;
Query OK, 0 rows affected (0.02 sec)

CREATE USER jennifer;
Query OK, 0 rows affected (0.01 sec)

GRANT analyticsteam TO jennifer;
Query OK, 0 rows affected (0.01 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

Note that by default `jennifer` needs to execute `SET ROLE analyticsteam` in order to be able to use the privileges associated with the `analyticsteam` role:

```
SHOW GRANTS;
+-------------------------------------------+
| Grants for User                           |
+-------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'      |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-------------------------------------------+
2 rows in set (0.00 sec)

SHOW TABLES in test;
ERROR 1044 (42000): Access denied for user 'jennifer'@'%' to database 'test'
SET ROLE analyticsteam;
Query OK, 0 rows affected (0.00 sec)

SHOW GRANTS;
+-------------------------------------------+
| Grants for User                           |
+-------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'      |
| GRANT Select ON test.* TO 'jennifer'@'%'  |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

Connect to TiDB as the `root` user:

```
mysql -h 127.0.0.1 -P 4000 -u root
```

The statement `SET DEFAULT ROLE` can be used to associate the role `analyticsteam` to `jennifer`:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
Query OK, 0 rows affected (0.02 sec)
```

Connect to TiDB as the `jennifer` user:

```
mysql -h 127.0.0.1 -P 4000 -u jennifer
```

After this, the user `jennifer` has the privileges associated with the role `analyticsteam` and `jennifer` does not have to execute the statement `SET ROLE`:

```
SHOW GRANTS;
+-------------------------------------------+
| Grants for User                           |
+-------------------------------------------+
| GRANT USAGE ON *.* TO 'jennifer'@'%'      |
| GRANT Select ON test.* TO 'jennifer'@'%'  |
| GRANT 'analyticsteam'@'%' TO 'jennifer'@'%' |
+-------------------------------------------+
3 rows in set (0.00 sec)

SHOW TABLES IN test;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
+----------------+
1 row in set (0.00 sec)
```

`SET DEFAULT ROLE` will not automatically `GRANT` the associated role to the user. Attempting to `SET DEFAULT ROLE` for a role that `jennifer` does not have granted results in the following error:

```
SET DEFAULT ROLE analyticsteam TO jennifer;
ERROR 3530 (HY000): `analyticsteam`@`%` is is not granted to jennifer@%
```

14.13.2.84.3 MySQL compatibility

The `SET DEFAULT ROLE` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.85 SET [NAMES|CHARACTER SET]

The statements `SET NAMES`, `SET CHARACTER SET` and `SET CHARSET` modify the variables `character_set_client`, `character_set_results` and `character_set_connection` for the current connection.

14.13.2.85.1 Synopsis

```
SetNamesStmt ::=
    "SET" ("NAMES" ("DEFAULT" | CharsetName ("COLLATE" ("DEFAULT" |
        ↪ CollationName))?) | ("CHARSET" | ("CHAR" | "CHARACTER") "SET") ("
        ↪ DEFAULT" | CharsetName))
```

14.13.2.85.2 Examples

```
mysql> SHOW VARIABLES LIKE 'character_set%';
+--
    ↪ ----------------------+-----------------------------------------------------
    ↪
| Variable_name        | Value                                                 |
+--
    ↪ ----------------------+-----------------------------------------------------

- SHOW [GLOBAL|SESSION] VARIABLES
- SET <variable>
- Character Set and Collation Support

14.13.2.86 SET PASSWORD

This statement changes the user password for a user account in the TiDB system database.

14.13.2.86.1 Synopsis

```
SetPasswordStmt ::=
    "SET" "PASSWORD" ( "FOR" Username )? "=" ( stringLit | "PASSWORD" "("
       ↪ stringLit ")" )
```

14.13.2.86.2 Examples

```
mysql> SET PASSWORD='test'; -- change my password
Query OK, 0 rows affected (0.01 sec)

mysql> CREATE USER 'newuser' IDENTIFIED BY 'test';
Query OK, 1 row affected (0.00 sec)

mysql> SHOW CREATE USER 'newuser';
+--
   ↪ ------------------------------------------------------------------------
   ↪
| CREATE USER for newuser@%
   ↪
   ↪ |
+--
   ↪ ------------------------------------------------------------------------
   ↪
| CREATE USER 'newuser'@'%' IDENTIFIED WITH 'mysql_native_password' AS '*94
   ↪ BDCEBE19083CE2A1F959FD02F964C7AF4CFC29' REQUIRE NONE PASSWORD EXPIRE
   ↪ DEFAULT ACCOUNT UNLOCK |
+--
   ↪ ------------------------------------------------------------------------
   ↪
```

```
1 row in set (0.00 sec)

mysql> SET PASSWORD FOR newuser = 'test';
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW CREATE USER 'newuser';
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER for newuser@%
    ↪
    ↪ |
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER 'newuser'@'%' IDENTIFIED WITH 'mysql_native_password' AS '*94
    ↪ BDCEBE19083CE2A1F959FD02F964C7AF4CFC29' REQUIRE NONE PASSWORD EXPIRE
    ↪ DEFAULT ACCOUNT UNLOCK |
+--
    ↪ ------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> SET PASSWORD FOR newuser = PASSWORD('test'); -- deprecated syntax
    ↪ from earlier MySQL releases
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW CREATE USER 'newuser';
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER for newuser@%
    ↪
    ↪ |
+--
    ↪ ------------------------------------------------------------------------
    ↪
| CREATE USER 'newuser'@'%' IDENTIFIED WITH 'mysql_native_password' AS '*94
    ↪ BDCEBE19083CE2A1F959FD02F964C7AF4CFC29' REQUIRE NONE PASSWORD EXPIRE
    ↪ DEFAULT ACCOUNT UNLOCK |
+--
    ↪ ------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.2.86.3 MySQL compatibility

The `SET PASSWORD` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.86.4 See also

- CREATE USER
- Privilege Management

14.13.2.87 SET RESOURCE GROUP

`SET RESOURCE GROUP` is used to set the resource group for the current session.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.87.1 Synopsis

SetResourceGroupStmt:

```
SetResourceGroupStmt ::=
    "SET" "RESOURCE" "GROUP" ResourceGroupName

ResourceGroupName ::=
    Identifier
|   "DEFAULT"
```

14.13.2.87.2 Privilege

Executing this statement requires the following configuration and privilege:

1. The system variable `tidb_enable_resource_control` is set to `ON`.
2. When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege; when it is set to `OFF`, none of these privileges are required.

14.13.2.87.3 Examples

Create a user `user1`, create two resource groups `rg1` and `rg2`, and bind the user `user1` to the resource group `rg1`.

```
CREATE USER 'user1';
CREATE RESOURCE GROUP 'rg1' RU_PER_SEC = 1000;
ALTER USER 'user1' RESOURCE GROUP `rg1`;
```

Use `user1` to log in and view the resource group bound to the current user.

```
SELECT CURRENT_RESOURCE_GROUP();
```

```
+--------------------------+
| CURRENT_RESOURCE_GROUP() |
+--------------------------+
| rg1                      |
+--------------------------+
1 row in set (0.00 sec)
```

Execute `SET RESOURCE GROUP` to set the resource group for the current session to `rg2`.

```
SET RESOURCE GROUP `rg2`;
SELECT CURRENT_RESOURCE_GROUP();
```

```
+--------------------------+
| CURRENT_RESOURCE_GROUP() |
+--------------------------+
| rg2                      |
+--------------------------+
1 row in set (0.00 sec)
```

Execute `SET RESOURCE GROUP` to specify the current session to use the default resource group.

```
SET RESOURCE GROUP `default`;
SELECT CURRENT_RESOURCE_GROUP();
```

```
+--------------------------+
| CURRENT_RESOURCE_GROUP() |
+--------------------------+
| default                  |
+--------------------------+
1 row in set (0.00 sec)
```

14.13.2.87.4 MySQL compatibility

MySQL also supports SET RESOURCE GROUP. But the accepted parameters are different from that of TiDB. They are not compatible.

14.13.2.87.5 See also

- CREATE RESOURCE GROUP
- DROP RESOURCE GROUP
- ALTER RESOURCE GROUP
- Resource Control

14.13.2.88 SET ROLE

The `SET ROLE` statement is used to enable roles in the current session. After enabling roles, users can use the privileges of the role(s).

14.13.2.88.1 Synopsis

```
SetRoleStmt ::=
    "SET" "ROLE" ( "DEFAULT" | "ALL" ( "EXCEPT" Rolename ("," Rolename)* )?
       ↪ | "NONE" | Rolename ("," Rolename)* )?
```

14.13.2.88.2 Examples

Create a user `'u1'@'%'` and three roles: `'r1'@'%'`, `'r2'@'%'` and `'r3'@'%'`. Grant these roles to `'u1'@'%'` and set `'r1'@'%'` as the default role of `'u1'@'%'`.

```
CREATE USER 'u1'@'%';
CREATE ROLE 'r1', 'r2', 'r3';
GRANT 'r1', 'r2', 'r3' TO 'u1'@'%';
SET DEFAULT ROLE 'r1' TO 'u1'@'%';
```

Log in as `'u1'@'%'` and execute the following `SET ROLE` statement to enable all roles.

```
SET ROLE ALL;
SELECT CURRENT_ROLE();
```

```
+----------------------------+
| CURRENT_ROLE()             |
+----------------------------+
| `r1`@`%`,`r2`@`%`,`r3`@`%` |
+----------------------------+
1 row in set (0.000 sec)
```

Execute the following `SET ROLE` statement to enable `'r2'` and `'r3'`.

```
SET ROLE 'r2', 'r3';
SELECT CURRENT_ROLE();
```

```
+-------------------+
| CURRENT_ROLE()  |
+-------------------+
| `r2`@`%`,`r3`@`%` |
+-------------------+
1 row in set (0.000 sec)
```

Execute the following `SET ROLE` statement to enable the default role(s).

```
SET ROLE DEFAULT;
SELECT CURRENT_ROLE();
```

```
+----------------+
| CURRENT_ROLE() |
+----------------+
| `r1`@`%`     |
+----------------+
1 row in set (0.000 sec)
```

Execute the following `SET ROLE` statement to cancel all enabled role(s).

```
SET ROLE NONE;
SELECT CURRENT_ROLE();
```

```
+----------------+
| CURRENT_ROLE() |
+----------------+
|              |
+----------------+
1 row in set (0.000 sec)
```

14.13.2.88.3 MySQL compatibility

The `SET ROLE` statement in TiDB is fully compatible with the roles feature in MySQL 8.0. If you find any compatibility differences, report a bug.

14.13.2.88.4 See also

- CREATE ROLE
- DROP ROLE
- GRANT <role>

- REVOKE <role>
- SET DEFAULT ROLE

- Role-Based Access Control

14.13.2.89 SET TRANSACTION

The SET TRANSACTION statement can be used to change the current isolation level on a GLOBAL or SESSION basis. This syntax is an alternative to SET transaction_isolation='new-value' and is included for compatibility with both MySQL, and the SQL standards.

14.13.2.89.1 Synopsis

```
SetStmt ::=
    'SET' ( VariableAssignmentList |
    'PASSWORD' ('FOR' Username)? '=' PasswordOpt |
    ( 'GLOBAL'| 'SESSION' )? 'TRANSACTION' TransactionChars |
    'CONFIG' ( Identifier | stringLit) ConfigItemName EqOrAssignmentEq
       ↪ SetExpr )

TransactionChars ::=
    ( 'ISOLATION' 'LEVEL' IsolationLevel | 'READ' 'WRITE' | 'READ' 'ONLY'
       ↪ AsOfClause? )

IsolationLevel ::=
    ( 'REPEATABLE' 'READ' | 'READ' ( 'COMMITTED' | 'UNCOMMITTED' ) | '
       ↪ SERIALIZABLE' )

AsOfClause ::=
    ( 'AS' 'OF' 'TIMESTAMP' Expression)
```

14.13.2.89.2 Examples

```
mysql> SHOW SESSION VARIABLES LIKE 'transaction_isolation';
+-----------------------+----------------+
| Variable_name         | Value          |
+-----------------------+----------------+
| transaction_isolation | REPEATABLE-READ |
+-----------------------+----------------+
1 row in set (0.00 sec)

mysql> SET SESSION TRANSACTION ISOLATION LEVEL READ COMMITTED;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW SESSION VARIABLES LIKE 'transaction_isolation';
```

```
+----------------------+----------------+
| Variable_name        | Value          |
+----------------------+----------------+
| transaction_isolation | READ-COMMITTED |
+----------------------+----------------+
1 row in set (0.01 sec)

mysql> SET SESSION transaction_isolation = 'REPEATABLE-READ';
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW SESSION VARIABLES LIKE 'transaction_isolation';
+----------------------+-----------------+
| Variable_name        | Value           |
+----------------------+-----------------+
| transaction_isolation | REPEATABLE-READ |
+----------------------+-----------------+
1 row in set (0.00 sec)
```

14.13.2.89.3 MySQL compatibility

- TiDB supports the ability to set a transaction as read-only in syntax only.
- The isolation levels `READ-UNCOMMITTED` and `SERIALIZABLE` are not supported.
- The `REPEATABLE-READ` isolation level is achieved through using the snapshot isolation technology, which is partly compatible with MySQL.
- In pessimistic transactions, TiDB supports two isolation levels compatible with MySQL: `REPEATABLE-READ` and `READ-COMMITTED`. For a detailed description, see Isolation Levels.

14.13.2.89.4 See also

- SET [GLOBAL|SESSION] <variable>
- Isolation Levels

14.13.2.90 SET [GLOBAL|SESSION] <variable>

The statement `SET [GLOBAL|SESSION]` modifies one of TiDB's built in variables. These variables can be system variables of either `SESSION` or `GLOBAL` scope or user variables.

> **Warning:**
>
> User-defined variables are still an experimental feature. It is **NOT** recommended that you use them in the production environment.

> **Note:**
>
> Similar to MySQL, changes to `GLOBAL` variables do not apply to either existing connections, or the local connection. Only new sessions reflect the changes to the value.

14.13.2.90.1 Synopsis

```
SetVariableStmt ::=
    "SET" Variable "=" Expression ("," Variable "=" Expression )*

Variable ::=
    ("GLOBAL" | "SESSION") SystemVariable
|   UserVariable
```

14.13.2.90.2 Examples

Get the value of `sql_mode`.

```
mysql> SHOW GLOBAL VARIABLES LIKE 'sql_mode';
+--
    ↪ -------------+-----------------------------------------------------------------
    ↪
| Variable_name | Value
    ↪
    ↪ |
+--
    ↪ -------------+-----------------------------------------------------------------
    ↪
| sql_mode      | ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_
    ↪ ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_
    ↪ SUBSTITUTION |
+--
    ↪ -------------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> SHOW SESSION VARIABLES LIKE 'sql_mode';
+--
    ↪ -------------+-----------------------------------------------------------------
    ↪
```

```
| Variable_name | Value
    ↪
    ↪ |
+--
    ↪ -------------+-------------------------------------------------------------
    ↪
| sql_mode     | ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_
    ↪ ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_
    ↪ SUBSTITUTION |
+--
    ↪ -------------+-------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Update the value of `sql_mode` globally. If you check the value of `SQL_mode` after the update, you can see that the value of `SESSION` level has not been updated:

```
mysql> SET GLOBAL sql_mode = 'STRICT_TRANS_TABLES,NO_AUTO_CREATE_USER';
Query OK, 0 rows affected (0.03 sec)

mysql> SHOW GLOBAL VARIABLES LIKE 'sql_mode';
+---------------+-----------------------------------------+
| Variable_name | Value                                   |
+---------------+-----------------------------------------+
| sql_mode      | STRICT_TRANS_TABLES,NO_AUTO_CREATE_USER |
+---------------+-----------------------------------------+
1 row in set (0.00 sec)

mysql> SHOW SESSION VARIABLES LIKE 'sql_mode';
+--
    ↪ -------------+-------------------------------------------------------------
    ↪
| Variable_name | Value
    ↪
    ↪ |
+--
    ↪ -------------+-------------------------------------------------------------
    ↪
| sql_mode     | ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_
    ↪ ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_
    ↪ SUBSTITUTION |
+--
    ↪ -------------+-------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Using `SET SESSION` takes effect immediately:

```
mysql> SET SESSION sql_mode = 'STRICT_TRANS_TABLES,NO_AUTO_CREATE_USER';
Query OK, 0 rows affected (0.01 sec)

mysql> SHOW SESSION VARIABLES LIKE 'sql_mode';
+---------------+-----------------------------------------+
| Variable_name | Value                                   |
+---------------+-----------------------------------------+
| sql_mode      | STRICT_TRANS_TABLES,NO_AUTO_CREATE_USER |
+---------------+-----------------------------------------+
1 row in set (0.00 sec)
```

User variables start with a `@`.

```
SET @myvar := 5;
Query OK, 0 rows affected (0.00 sec)

SELECT @myvar, @myvar + 1;
+--------+------------+
| @myvar | @myvar + 1 |
+--------+------------+
|      5 |          6 |
+--------+------------+
1 row in set (0.00 sec)
```

14.13.2.90.3 MySQL compatibility

The following behavior differences apply:

- Changes made with `SET GLOBAL` will be propagated to all TiDB instances in the cluster. This differs from MySQL, where changes do not propagate to replicas.
- TiDB presents several variables as both readable and settable. This is required for MySQL compatibility, because it is common for both applications and connectors to read MySQL variables. For example: JDBC connectors both read and set query cache settings, despite not relying on the behavior.
- Changes made with `SET GLOBAL` will persist through TiDB server restarts. This means that `SET GLOBAL` in TiDB behaves more similar to `SET PERSIST` as available in MySQL 8.0 and above.
- TiDB does not support `SET PERSIST` and `SET PERSIST_ONLY`, because TiDB persists global variables.

14.13.2.90.4 See also

- SHOW [GLOBAL|SESSION] VARIABLES

14.13.2.91 SHOW ANALYZE STATUS

The `SHOW ANALYZE STATUS` statement shows the statistics collection tasks being executed by TiDB and a limited number of historical task records.

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

Starting from TiDB v7.3.0, you can view the progress of the current `ANALYZE` task through the system table `mysql.analyze_jobs` or `SHOW ANALYZE STATUS`.

Currently, the `SHOW ANALYZE STATUS` statement returns the following columns:

Column name	Description
`Table_schema`	The database name
`Table_name`	The table name
`Partition_name`	The partition name
`Job_info`	The task information. If an index is analyzed, this information will include the index name. When `tidb_analyze_version =2`, this information will include configuration items such as sample rate.
`Processed_rows`	The number of rows that have been analyzed
`Start_time`	The time at which the task starts

Column name	Description
`State`	The state of a task, including `pending`, `running`, `finished`, and `failed`
`Fail_reason`	The reason why the task fails. If the execution is successful, the value is `NULL`.
`Instance`	The TiDB instance that executes the task
`Process_id`	The process ID that executes the task

14.13.2.91.1 Synopsis

```
ShowAnalyzeStatusStmt ::= 'SHOW' 'ANALYZE' 'STATUS' ShowLikeOrWhereOpt

ShowLikeOrWhereOpt ::= 'LIKE' SimpleExpr | 'WHERE' Expression
```

14.13.2.91.2 Examples

```
mysql> create table t(x int, index idx(x)) partition by hash(x) partitions
    ↪ 2;
Query OK, 0 rows affected (0.69 sec)

mysql> set @@tidb_analyze_version = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> analyze table t;
Query OK, 0 rows affected (0.20 sec)

mysql> show analyze status;
+--

14.13.2.91.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.91.4 See also

- ANALYZE_STATUS table

14.13.2.92 SHOW [BACKUPS|RESTORES]

These statements show a list of all queued, running and recently finished `BACKUP` and `RESTORE` tasks that were executed on a TiDB instance.

Both statements require `SUPER` privilege to run.

Use `SHOW BACKUPS` to query `BACKUP` tasks and use `SHOW RESTORES` to query `RESTORE` tasks.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

Backups and restores that were started with the `br` commandline tool are not shown.

14.13.2.92.1 Synopsis

```
ShowBRIEStmt ::=
    "SHOW" ("BACKUPS" | "RESTORES") ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.92.2 Examples

In one connection, execute the following statement:

```
BACKUP DATABASE `test` TO 's3://example-bucket/backup-01';
```

Before the backup completes, run `SHOW BACKUPS` in a new connection:

```
SHOW BACKUPS;
```

```
+--
    ↪ ----------------------------+---------+----------+--------------------+------
    ↪
| Destination                | State   | Progress | Queue_time         |
    ↪ Execution_time    | Finish_time | Connection | Message |
+--
    ↪ ----------------------------+---------+----------+--------------------+------
    ↪
| s3://example-bucket/backup-01/ | Backup | 98.38 | 2020-04-12 23:09:03 |
    ↪ 2020-04-12 23:09:25 | NULL |      4 | NULL    |
+--
    ↪ ----------------------------+---------+----------+--------------------+------
    ↪
1 row in set (0.00 sec)
```

The first row of the result above is described as follows:

Column	Description
`Destination`	The destination URL (with all parameters stripped to avoid leaking secret keys)
`State`	State of the task
`Progress`	Estimated progress in the current state as a percentage
`Queue_time`	When the task was queued
`Execution_time`	When the task was started; the value is `0000-00-00 00:00:00` for queueing tasks
`Finish_time`	The timestamp when the task finished; the value is `0000-00-00 00:00:00` for queueing and running tasks

Column	Description
`Connection ID`	Connection ID running this task
`Message`	Message with details

The possible states are:

State	Description
Backup	Making a backup
Wait	Waiting for execution
Checksum	Running a checksum operation

The connection ID can be used to cancel a backup/restore task via the `KILL TIDB QUERY` statement.

```
KILL TIDB QUERY 4;
```

```
Query OK, 0 rows affected (0.00 sec)
```

Filtering

Use the `LIKE` clause to filter out tasks by matching the destination URL against a wildcard expression.

```
SHOW BACKUPS LIKE 's3://%';
```

Use the `WHERE` clause to filter by columns.

```
SHOW BACKUPS WHERE `Progress` < 25.0;
```

14.13.2.92.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- RESTORE

14.13.2.93 SHOW [GLOBAL|SESSION] BINDINGS

The `SHOW BINDINGS` statement is used to display information about created SQL bindings. A `BINDING` can be on either a `GLOBAL` or `SESSION` basis. The default is `SESSION`.

14.13.2.93.1 Synopsis

```
ShowBindingsStmt ::=
    "SHOW" ("GLOBAL" | "SESSION")? "BINDINGS" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.93.2 Syntax description

This statement outputs the execution plan bindings at the GLOBAL or SESSION level. The default scope is SESSION. Currently `SHOW BINDINGS` outputs eight columns, as shown below:

Column Name	Description
original_sql	Original SQL statement after parameterization
bind_sql	Bound SQL statement with hints
default_db	Default database
status	Status including 'Using', 'Deleted', 'Invalid', 'Rejected', and 'Pending verification'
create_time	Created time
update_time	Updated time
charset	Character set
collation	Sorting rule

Column Name	Description
source	The way in which a binding is created, including `manual` (created by the `create [global] binding` SQL statement), `capture` (captured automatically by TiDB), and `evolve` (evolved automatically by TiDB)

14.13.2.93.3 Examples

```
mysql> CREATE TABLE t1 (
         id INT NOT NULL PRIMARY KEY auto_increment,
         b INT NOT NULL,
         pad VARBINARY(255),
         INDEX(b)
        );
Query OK, 0 rows affected (0.07 sec)

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    -> FROM dual;
Query OK, 1 row affected (0.01 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    -> FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 1 row affected (0.00 sec)
Records: 1 Duplicates: 0 Warnings: 0

mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)
    -> FROM t1 a JOIN t1 b JOIN t1 c LIMIT 100000;
Query OK, 8 rows affected (0.00 sec)
Records: 8 Duplicates: 0 Warnings: 0
```

```
mysql> INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255)

14.13.2.94 SHOW BUILTINS

`SHOW BUILTINS` is used to list all supported builtin functions in TiDB.

14.13.2.94.1 Synopsis

```
ShowBuiltinsStmt ::=
    "SHOW" "BUILTINS"
```

14.13.2.94.2 Examples

```
SHOW BUILTINS;
```

```

14.13.2.94.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.95 SHOW CHARACTER SET

This statement provides a static list of available character sets in TiDB. The output does not reflect any attributes of the current connection or user.

14.13.2.95.1 Synopsis

```
ShowCharsetStmt ::=
    "SHOW" ( ("CHARACTER" | "CHAR") "SET" | "CHARSET" ) ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.95.2 Examples

```
SHOW CHARACTER SET;
```

```
+---------+---------------------------------------+--------------------+--------+
    ↪

14.13.2.95.3 MySQL compatibility

The usage of `SHOW CHARACTER SET` statement in TiDB is fully compatible with MySQL. However, charsets in TiDB might have different default collations compared with MySQL. For details, refer to Compatibility with MySQL. If you find any compatibility differences, report a bug.

14.13.2.95.4 See also

- SHOW COLLATION
- Character Set and Collation

14.13.2.96 SHOW COLLATION

This statement provides a static list of collations, and is included to provide compatibility with MySQL client libraries.

> **Note:**
>
> Results of `SHOW COLLATION` vary when the "new collation framework" is enabled. For new collation framework details, refer to Character Set and Collation.

14.13.2.96.1 Synopsis

```
ShowCollationStmt ::=
    "SHOW" "COLLATION" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.96.2 Examples

When the new collation framework is enabled (the default), the example output is as follows:

```
SHOW COLLATION;
```

```
+--------------------+---------+-----+---------+----------+---------+---------------+
   ↪
| Collation        | Charset | Id | Default | Compiled | Sortlen | Pad_
   ↪ attribute |
+--------------------+---------+-----+---------+----------+---------+---------------+
   ↪
| ascii_bin        | ascii   |  65 | Yes     | Yes      |       1 | PAD SPACE     |
| binary           | binary  |  63 | Yes     | Yes      |       1 | NO PAD        |
| gbk_bin          | gbk     |  87 |         | Yes      |       1 | PAD SPACE     |
| gbk_chinese_ci   | gbk     |  28 | Yes     | Yes      |       1 | PAD SPACE     |
```

```
| latin1_bin         | latin1 |  47 | Yes    | Yes     |       1 | PAD SPACE   |
| utf8_bin           | utf8   |  83 | Yes    | Yes     |       1 | PAD SPACE   |
| utf8_general_ci    | utf8   |  33 |        | Yes     |       1 | PAD SPACE   |
| utf8_unicode_ci    | utf8   | 192 |        | Yes     |       8 | PAD SPACE   |
| utf8mb4_0900_ai_ci | utf8mb4 | 255 |    | Yes     |       0 | NO PAD      |
| utf8mb4_0900_bin | utf8mb4 | 309 |      | Yes     |       1 | NO PAD      |
| utf8mb4_bin      | utf8mb4 | 46 | Yes   | Yes     |       1 | PAD SPACE   |
| utf8mb4_general_ci | utf8mb4 | 45 |    | Yes     |       1 | PAD SPACE   |
| utf8mb4_unicode_ci | utf8mb4 | 224 |   | Yes     |       8 | PAD SPACE   |
+--------------------+---------+-----+--------+---------+---------+---------------+
   ↪
13 rows in set (0.00 sec)
```

When the new collation framework is disabled, only binary collations are listed.

```
SHOW COLLATION;
```

```
+-------------+---------+----+---------+----------+---------+---------------+
   ↪
| Collation | Charset | Id | Default | Compiled | Sortlen | Pad_attribute |
+-------------+---------+----+---------+----------+---------+---------------+
   ↪
| utf8mb4_bin | utf8mb4 | 46 | Yes | Yes    |       1 | PAD SPACE   |
| latin1_bin | latin1 | 47 | Yes  | Yes     |       1 | PAD SPACE   |
| binary     | binary | 63 | Yes  | Yes     |       1 | NO PAD      |
| ascii_bin  | ascii  | 65 | Yes  | Yes     |       1 | PAD SPACE   |
| utf8_bin   | utf8   | 83 | Yes  | Yes     |       1 | PAD SPACE   |
| gbk_bin    | gbk    | 87 | Yes  | Yes     |       1 | PAD SPACE   |
+-------------+---------+----+---------+----------+---------+---------------+
   ↪
6 rows in set (0.00 sec)
```

To filter on the character set, you can add a `WHERE` clause.

```
SHOW COLLATION WHERE Charset="utf8mb4";
```

```
+--
   ↪ -----------------+---------+-----+---------+----------+---------+-------------
   ↪
| Collation       | Charset | Id | Default | Compiled | Sortlen | Pad_
   ↪ attribute |

14.13.2.97 SHOW COLUMN_STATS_USAGE

The `SHOW COLUMN_STATS_USAGE` statement shows the last usage time and collection time of column statistics. You can also use it to locate `PREDICATE COLUMNS` and columns on which statistics have been collected.

Currently, the `SHOW COLUMN_STATS_USAGE` statement returns the following columns:

Column name	Description
`Db_name`	The database name
`Table_ ↪ name`	The table name
`Partition ↪ _name`	The partition name
`Column_ ↪ name`	The column name
`Last_ ↪ used_ ↪ at`	The last time when the column statistics were used in the query optimization

Column name	Description
Last_analyzed_at	The last time when the column statistics were collected

14.13.2.97.1 Synopsis

```
ShowColumnStatsUsageStmt ::=
    "SHOW" "COLUMN_STATS_USAGE" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.97.2 Examples

```
SHOW COLUMN_STATS_USAGE;
```

```

14.13.2.98 SHOW [FULL] COLUMNS FROM

The statement `SHOW [FULL] COLUMNS FROM <table_name>` describes the columns of a table or view in a useful tabular format. The optional keyword `FULL` displays the privileges the current user has to that column, and the `comment` from the table definition.

The statements `SHOW [FULL] FIELDS FROM <table_name>`, `DESC <table_name>`, `DESCRIBE <table_name>`, and `EXPLAIN <table_name>` are aliases of this statement.

> **Note:**
>
> `DESC TABLE <table_name>`, `DESCRIBE TABLE <table_name>`, and `EXPLAIN TABLE <table_name>` are not equivalent to the above statements. They are aliases of `DESC SELECT * FROM <table_name>`.

14.13.2.98.1 Synopsis

```
ShowColumnsFromStmt ::=
    "SHOW" "FULL"? ("COLUMNS" | "FIELDS") ("FROM" | "IN") TableName ( ("FROM
        ↪ " | "IN") SchemaName)? ShowLikeOrWhere?

TableName ::=
    (Identifier ".")? Identifier

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.98.2 Examples

```
mysql> CREATE VIEW v1 AS SELECT 1;
Query OK, 0 rows affected (0.11 sec)

mysql> SHOW COLUMNS FROM v1;
+-------+--------+------+------+---------+-------+
| Field | Type | Null | Key | Default | Extra |
+-------+--------+------+------+---------+-------+
```

```
| 1     | bigint | YES |     | NULL    |       |
+-------+--------+-----+-----+---------+-------+
1 row in set (0.00 sec)

mysql> DESC v1;

14.13.2.98.3 MySQL compatibility

The `SHOW [FULL] COLUMNS FROM` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.98.4 See also

- SHOW CREATE TABLE

14.13.2.99 SHOW CONFIG

The `SHOW CONFIG` statement is used to show the current configuration of various components of TiDB. Note that the configuration and system variables act on different dimensions and should not be mixed up. If you want to obtain the system variable information, use the SHOW VARIABLES syntax.

> **Note:**
>
> This feature is only applicable to TiDB Self-Managed and not available on TiDB Cloud.

14.13.2.99.1 Synopsis

```
ShowConfigStmt ::=
    "SHOW" "CONFIG" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.99.2 Examples

Show all configurations:

```
SHOW CONFIG;
```

```

   ↪                                                                |
| tidb | 127.0.0.1:4000 | binlog.binlog-socket                                 |
   ↪                                                                  |
| tidb | 127.0.0.1:4000 | binlog.enable                                        | false
   ↪                                                                  |
...
120 rows in set (0.01 sec)
```

Show the configuration where the `type` is `tidb`:

```
SHOW CONFIG WHERE type = 'tidb' AND name = 'advertise-address';
```

```
+------+---------------+------------------+-----------+
| Type | Instance    | Name             | Value     |
+------+---------------+------------------+-----------+
| tidb | 127.0.0.1:4000 | advertise-address | 127.0.0.1 |
+------+---------------+------------------+-----------+
1 row in set (0.05 sec)
```

You can also use the `LIKE` clause to show the configuration where the `type` is `tidb`:

```
SHOW CONFIG LIKE 'tidb';
```

```
+------+---------------+-------------------------------------------------------+-------------
   ↪
| Type | Instance    | Name                                                  | Value
   ↪                                                                  |
+------+---------------+-------------------------------------------------------+-------------
   ↪
| tidb | 127.0.0.1:4000 | advertise-address                                    | 127.0.0.1
   ↪                                                                |
| tidb | 127.0.0.1:4000 | binlog.binlog-socket                                 |
   ↪                                                                  |
| tidb | 127.0.0.1:4000 | binlog.enable                                        | false
   ↪                                                                  |
...
40 rows in set (0.01 sec)
```

14.13.2.99.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.99.4 See also

- SHOW VARIABLES

14.13.2.100 SHOW CREATE DATABASE

`SHOW CREATE DATABASE` is used to show the exact SQL statement for re-creating an existing database. `SHOW CREATE SCHEMA` is a synonym for it.

14.13.2.100.1 Synopsis

ShowCreateDatabaseStmt:

```
ShowCreateDatabaseStmt ::=
    "SHOW" "CREATE" ("DATABASE" | "SCHEMA") ("IF" "NOT" "EXISTS")? DBName
```

14.13.2.100.2 Examples

```
CREATE DATABASE test;
```

```
Query OK, 0 rows affected (0.12 sec)
```

```
SHOW CREATE DATABASE test;
```

```
+--
    ↪ --------+-----------------------------------------------------------------+
    ↪
| Database | Create Database                                                  |
+--
    ↪ --------+-----------------------------------------------------------------+
    ↪
| test     | CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4
    ↪ */ |
+--
    ↪ --------+-----------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

```
SHOW CREATE SCHEMA IF NOT EXISTS test;
```

```
+--
    ↪ --------+-----------------------------------------------------------------------
    ↪
| Database | Create Database
    ↪                                                                          |
+--
    ↪ --------+-----------------------------------------------------------------------
    ↪
| test     | CREATE DATABASE /*!32312 IF NOT EXISTS*/ `test` /*!40100
    ↪ DEFAULT CHARACTER SET utf8mb4 */ |
+--
    ↪ --------+-----------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.2.100.3 MySQL compatibility

`SHOW CREATE DATABASE` is expected to be fully compatible with MySQL. If you find any compatibility differences, you can report a bug.

14.13.2.100.4 See also

- CREATE TABLE
- DROP TABLE
- SHOW TABLES
- SHOW COLUMNS FROM

14.13.2.101 SHOW CREATE PLACEMENT POLICY

`SHOW CREATE PLACEMENT POLICY` is used to show the definition of a placement policy. This can be used to see the current definition of a placement policy and recreate it in another TiDB cluster.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.101.1 Synopsis

```
ShowCreatePlacementPolicyStmt ::=
    "SHOW" "CREATE" "PLACEMENT" "POLICY" PolicyName

PolicyName ::=
    Identifier
```

14.13.2.101.2 Examples

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us
    ↪ -west-1" FOLLOWERS=4;
CREATE TABLE t1 (a INT) PLACEMENT POLICY=p1;
SHOW CREATE PLACEMENT POLICY p1\G
```

```
Query OK, 0 rows affected (0.08 sec)

Query OK, 0 rows affected (0.10 sec)

***************************[ 1. row ]***************************
Policy      | p1
Create Policy | CREATE PLACEMENT POLICY `p1` PRIMARY_REGION="us-east-1"
    ↪ REGIONS="us-east-1,us-west-1" FOLLOWERS=4
1 row in set (0.00 sec)
```

14.13.2.101.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.101.4 See also

- Placement Rules in SQL
- SHOW PLACEMENT
- CREATE PLACEMENT POLICY
- ALTER PLACEMENT POLICY
- DROP PLACEMENT POLICY

14.13.2.102 SHOW CREATE RESOURCE GROUP

You can use the `SHOW CREATE RESOURCE GROUP` statement to view the current definition of a resource group.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.102.1 Synopsis

```
ShowCreateResourceGroupStmt ::=
    "SHOW" "CREATE" "RESOURCE" "GROUP" ResourceGroupName

ResourceGroupName ::=
    Identifier
|   "DEFAULT"
```

14.13.2.102.2 Examples

Create a resource group `rg1`.

```
CREATE RESOURCE GROUP rg1 RU_PER_SEC=100;
Query OK, 0 rows affected (0.10 sec)
```

View the definition of `rg1`.

```
SHOW CREATE RESOURCE GROUP rg1;
***************************[ 1. row ]***************************
+--
    ↪ --------------+-------------------------------------------------------------+
    ↪
| Resource_Group | Create Resource Group                                      |
+--
    ↪ --------------+-------------------------------------------------------------+
    ↪
| rg1            | CREATE RESOURCE GROUP `rg1` RU_PER_SEC=100 PRIORITY=MEDIUM
    ↪  |
+--
    ↪ --------------+-------------------------------------------------------------+
    ↪
1 row in set (0.01 sec)
```

14.13.2.102.3 MySQL compatibility

This statement is a TiDB extension for MySQL.

14.13.2.102.4 See also

- TiDB RESOURCE CONTROL
- CREATE RESOURCE GROUP
- ALTER RESOURCE GROUP
- DROP RESOURCE GROUP

14.13.2.103 SHOW CREATE SEQUENCE

The `SHOW CREATE SEQUENCE` shows the detailed information of a sequence, which is similar to `SHOW CREATE TABLE`.

14.13.2.103.1 Synopsis

```
ShowCreateSequenceStmt ::=
    "SHOW" "CREATE" "SEQUENCE" ( SchemaName "." )? TableName
```

14.13.2.103.2 Examples

```
CREATE SEQUENCE seq;
```

```
Query OK, 0 rows affected (0.03 sec)
```

```
SHOW CREATE SEQUENCE seq;
```

```
+-------+-------------------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+-------+-------------------------------------------------------------------------------
    ↪
| seq   | CREATE SEQUENCE `seq` start with 1 minvalue 1 maxvalue
    ↪ 9223372036854775806 increment by 1 cache 1000 nocycle ENGINE=InnoDB |
+-------+-------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.2.103.3 MySQL compatibility

This statement is a TiDB extension. The implementation is modeled on sequences available in MariaDB.

14.13.2.103.4 See also

- CREATE SEQUENCE
- ALTER SEQUENCE
- DROP SEQUENCE

14.13.2.104 SHOW CREATE TABLE

This statement shows the exact statement to recreate an existing table using SQL.

14.13.2.104.1 Synopsis

```
ShowCreateTableStmt ::=
    "SHOW" "CREATE" "TABLE" (SchemaName ".")? TableName
```

14.13.2.104.2 Examples

```
mysql> CREATE TABLE t1 (a INT);
Query OK, 0 rows affected (0.12 sec)

mysql> SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `a` int DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)
```

14.13.2.104.3 MySQL compatibility

The `SHOW CREATE TABLE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.104.4 See also

- CREATE TABLE
- DROP TABLE
- SHOW TABLES
- SHOW COLUMNS FROM

14.13.2.105 SHOW CREATE USER

This statement shows how to re-create a user using the `CREATE USER` syntax.

14.13.2.105.1 Synopsis

```
ShowCreateUserStmt ::=
    "SHOW" "CREATE" "USER" (Username ("@" Hostname)? | "CURRENT_USER" ( "("
        ↪ ")" )? )
```

14.13.2.105.2 Examples

```
mysql> SHOW CREATE USER 'root';
+--
    ↪ ------------------------------------------------------------------------------
    ↪
| CREATE USER for root@%
    ↪
    ↪ |
+--
    ↪ ------------------------------------------------------------------------------
    ↪
| CREATE USER 'root'@'%' IDENTIFIED WITH 'mysql_native_password' AS ''
    ↪ REQUIRE NONE PASSWORD EXPIRE DEFAULT ACCOUNT UNLOCK |
+--
    ↪ ------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> SHOW GRANTS FOR 'root';
+-----------------------------------------+
| Grants for root@%                       |
+-----------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'%' |
+-----------------------------------------+
1 row in set (0.00 sec)
```

14.13.2.105.3 MySQL compatibility

- The output of `SHOW CREATE USER` is designed to match MySQL, but several of the `CREATE` options are not yet supported by TiDB. Not yet supported options will be parsed but ignored. See Security compatibility for more details.

14.13.2.105.4 See also

- CREATE USER
- SHOW GRANTS
- DROP USER

14.13.2.106 SHOW DATABASES

This statement shows a list of databases that the current user has privileges to. Databases which the current user does not have access to will appear hidden from the list. The `information_schema` database always appears first in the list of databases.

`SHOW SCHEMAS` is an alias of this statement.

14.13.2.106.1 Synopsis

```
ShowDatabasesStmt ::=
    "SHOW" "DATABASES" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.106.2 Examples

```
mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| mysql              |
| test               |
+--------------------+
4 rows in set (0.00 sec)

mysql> CREATE DATABASE mynewdb;
Query OK, 0 rows affected (0.10 sec)

mysql> SHOW DATABASES;
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| mynewdb            |
| mysql              |
| test               |
+--------------------+
5 rows in set (0.00 sec)
```

14.13.2.106.3 MySQL compatibility

The `SHOW DATABASES` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.106.4 See also

- SHOW SCHEMAS
- DROP DATABASE
- CREATE DATABASE
- INFORMATION_SCHEMA.SCHEMATA

14.13.2.107 SHOW ENGINES

This statement is used to list all supported storage engines. The syntax is included only for compatibility with MySQL.

14.13.2.107.1 Synopsis

```
ShowEnginesStmt ::=
    "SHOW" "ENGINES" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.107.2 Examples

```
mysql> SHOW ENGINES;
+--
    ↪ ------+---------+----------------------------------------------------------------+--
    ↪
| Engine | Support | Comment                                                        |
    ↪ Transactions | XA | Savepoints |
+--
    ↪ ------+---------+----------------------------------------------------------------+--
    ↪
| InnoDB | DEFAULT | Supports transactions, row-level locking, and foreign
    ↪ keys | YES | YES | YES    |
+--
    ↪ ------+---------+----------------------------------------------------------------+--
    ↪
1 row in set (0.00 sec)
```

14.13.2.107.3 MySQL compatibility

- This statement will always only return InnoDB as the supported engine. Internally, TiDB will typically use TiKV as the storage engine.

14.13.2.108 SHOW ERRORS

This statement shows errors from previously executed statements. The error buffer is cleared as soon as a statement executes successfully. In which case, `SHOW ERRORS` will return an empty set.

The behavior of which statements generate errors vs. warnings is highly influenced by the current `sql_mode`.

14.13.2.108.1 Synopsis

```
ShowErrorsStmt ::=
    "SHOW" "ERRORS" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.108.2 Examples

```
mysql> select invalid;
ERROR 1054 (42S22): Unknown column 'invalid' in 'field list'
mysql> create invalid;
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use
    ↪ line 1 column 14 near "invalid"
mysql> SHOW ERRORS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Error | 1054 | Unknown column 'invalid' in 'field list'
    ↪
    ↪ |
| Error | 1064 | You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use
    ↪ line 1 column 14 near "invalid" |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
2 rows in set (0.00 sec)
```

```
mysql> CREATE invalid2;
ERROR 1064 (42000): You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your TiDB version for the right syntax to use
    ↪ line 1 column 15 near "invalid2"
mysql> SELECT 1;
+------+
| 1    |
+------+
|    1 |
+------+
1 row in set (0.00 sec)

mysql> SHOW ERRORS;
Empty set (0.00 sec)
```

14.13.2.108.3 MySQL compatibility

The `SHOW ERRORS` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.108.4 See also

- SHOW WARNINGS

14.13.2.109 SHOW [FULL] FIELDS FROM

This statement is an alias to `SHOW [FULL] COLUMNS FROM`. It is included for compatibility with MySQL.

14.13.2.110 SHOW GRANTS

This statement shows a list of privileges associated with a user. As in MySQL, the `USAGE` privileges denotes the ability to login to TiDB.

14.13.2.110.1 Synopsis

```
ShowGrantsStmt ::=
    "SHOW" "GRANTS" ("FOR" Username ("USING" RolenameList)?)?

Username ::=
    "CURRENT_USER" ( "(" ")" )?
| Username ("@" Hostname)?
```

```
RolenameList ::=
    Rolename ("@" Hostname)? ("," Rolename ("@" Hostname)? )*
```

14.13.2.110.2 Examples

```
mysql> SHOW GRANTS;
+----------------------------------------+
| Grants for User                        |
+----------------------------------------+
| GRANT ALL PRIVILEGES ON *.* TO 'root'@'%' |
+----------------------------------------+
1 row in set (0.00 sec)

mysql> SHOW GRANTS FOR 'u1';
ERROR 1141 (42000): There is no such grant defined for user 'u1' on host '%
    ↪ '
mysql> CREATE USER u1;
Query OK, 1 row affected (0.04 sec)

mysql> GRANT SELECT ON test.* TO u1;
Query OK, 0 rows affected (0.04 sec)

mysql> SHOW GRANTS FOR u1;
+-----------------------------------+
| Grants for u1@%                   |
+-----------------------------------+
| GRANT USAGE ON *.* TO 'u1'@'%' |
| GRANT Select ON test.* TO 'u1'@'%' |
+-----------------------------------+
2 rows in set (0.00 sec)
```

14.13.2.110.3 MySQL compatibility

The `SHOW GRANTS` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.110.4 See also

- SHOW CREATE USER
- GRANT

14.13.2.111 SHOW IMPORT

The `SHOW IMPORT` statement is used to show the IMPORT jobs created in TiDB. This statement can only show jobs created by the current user.

14.13.2.111.1 Required privileges

- `SHOW IMPORT JOBS`: if a user has the `SUPER` privilege, this statement shows all import jobs in TiDB. Otherwise, this statement only shows jobs created by the current user.
- `SHOW IMPORT JOB <job-id>`: only the creator of an import job or users with the `SUPER` privilege can use this statement to view a specific job.

14.13.2.111.2 Synopsis

```
ShowImportJobsStmt ::=
    'SHOW' 'IMPORT' 'JOBS'

ShowImportJobStmt ::=
    'SHOW' 'IMPORT' 'JOB' JobID
```

The output fields of the `SHOW IMPORT` statement are described as follows:

Column	Description
Job_ID	The ID of the task
Data_Source	Information about the data source
Target_Table	The name of the target table
Phase	The current phase of the job, including `importing`, `validating`, and `add-index`
Status	The current status of the job, including `pending` (means created but not started yet), `running`, `canceled`, `failed`, and `finished`
Source_File_Size	The size of the source file
Imported_Rows	The number of data rows that have been read and written to the target table
Result_Message	If the import fails, this field returns the error message. Otherwise, it is empty.
Create_Time	The time when the task is created
Start_Time	The time when the task is started

Column	Description
End_Time	The time when the task is ended
Created_By	The name of the database user who creates the task

14.13.2.111.3 Example

```
SHOW IMPORT JOBS;
```

```
+--------+-------------------+-------------+----------+-------+----------+-------------
   ↪
| Job_ID | Data_Source    | Target_Table | Table_ID | Phase | Status |
   ↪ Source_File_Size | Imported_Rows | Result_Message | Create_Time  |
   ↪ Start_Time              | End_Time                | Created_By |
+--------+-------------------+-------------+----------+-------+----------+-------------
   ↪
|      1 | /path/to/file.csv | `test`.`foo` | 116 |      | finished | 11GB
   ↪          |       950000 |              | 2023-06-26 11:23:59.281257 |

   ↪           |         NULL |              | 2023-06-08 15:59:37.047703 |
   ↪ NULL  | NULL    | root@%    |
+--------+-------------------+-------------+----------+-------+---------+-------------
   ↪
1 row in set (0.01 sec)
```

14.13.2.111.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.111.5 See also

- IMPORT INTO
- CANCEL IMPORT JOB

14.13.2.112 SHOW INDEXES [FROM|IN]

The statement `SHOW INDEXES [FROM|IN]` lists the indexes on a specified table. The statements `SHOW INDEX [FROM|IN]`, `SHOW KEYS [FROM|IN]` are aliases of this statement, and included for compatibility with MySQL.

14.13.2.112.1 Synopsis

```
ShowIndexStmt ::=
    "SHOW" ( "INDEX" | "INDEXES" | "KEYS" ) ("FROM" | "IN" ) TableName (("
        ↪ FROM" | "IN") SchemaName )? ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.112.2 Examples

```
mysql> CREATE TABLE t1 (id int not null primary key AUTO_INCREMENT, col1
    ↪ INT, INDEX(col1));
Query OK, 0 rows affected (0.12 sec)

mysql> SHOW INDEXES FROM t1;
+--
    ↪ -----+------------+----------+--------------+-------------+-----------+---------
    ↪
| Table | Non_unique | Key_name | Seq_in_index | Column_name | Collation |
    ↪ Cardinality | Sub_part | Packed | Null | Index_type | Comment | Index
    ↪ _comment | Visible | Expression |
+--
    ↪ -----+------------+----------+--------------+-------------+-----------+---------
    ↪
| t1    |          0 | PRIMARY |            1 | id          | A         |           0

```

```
+--
    ↪ -----+-----------+---------+-------------+------------+---------+--------
    ↪
2 rows in set (0.00 sec)
```

Note that TiDB accepts index types such as `HASH`, `BTREE` and `RTREE` in syntax for compatibility with MySQL, but ignores them.

14.13.2.112.3 MySQL compatibility

The `SHOW INDEXES [FROM|IN]` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.112.4 See also

- SHOW CREATE TABLE
- DROP INDEX
- CREATE INDEX
- `information_schema.TIDB_INDEXES`
- `information_schema.TIDB_INDEX_USAGE`
- `information_schema.KEY_COLUMN_USAGE`
- `sys.schema_unused_indexes`

14.13.2.113 SHOW MASTER STATUS

The `SHOW MASTER STATUS` statement displays the latest TSO in the cluster.

14.13.2.113.1 Examples

```
SHOW MASTER STATUS;
```

```
+--
    ↪ ----------+-------------------+-------------+-----------------+-----------
    ↪
| File       | Position          | Binlog_Do_DB | Binlog_Ignore_DB | Executed_
    ↪ Gtid_Set |
+--
    ↪ ----------+-------------------+-------------+-----------------+-----------
    ↪
| tidb-binlog | 416916363252072450 |              |                  |
    ↪                  |
+--
    ↪ ----------+-------------------+-------------+-----------------+-----------
    ↪
1 row in set (0.00 sec)
```

14.13.2.113.2 MySQL compatibility

The output of `SHOW MASTER STATUS` is designed to match MySQL. However, the execution results are different in that the MySQL result is the binlog location information and the TiDB result is the latest TSO information.

The `SHOW BINARY LOG STATUS` statement was added in TiDB as an alias for `SHOW MASTER STATUS`, which has been deprecated in MySQL 8.2.0 and newer versions.

14.13.2.114 SHOW PLACEMENT

`SHOW PLACEMENT` summarizes all placement options from placement policies, and presents them in canonical form.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

The statement returns a result set in which the `Scheduling_State` field indicates the current progress that the Placement Driver (PD) has made in scheduling the placement:

- `PENDING`: The PD has not yet started scheduling the placement. This might indicate that the placement rules are semantically correct, but cannot currently be satisfied by the cluster. For example, if `FOLLOWERS=4` but there are only 3 TiKV stores which are candidates for followers.
- `INPROGRESS`: The PD is currently scheduling the placement.
- `SCHEDULED`: The PD has successfully scheduled the placement.

14.13.2.114.1 Synopsis

```
ShowStmt ::=
    "SHOW" "PLACEMENT" ShowLikeOrWhere?
```

14.13.2.114.2 Examples

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us
    ↪ -west-1" FOLLOWERS=4;
CREATE TABLE t1 (a INT) PLACEMENT POLICY=p1;
SHOW PLACEMENT;
```

```
Query OK, 0 rows affected (0.01 sec)

Query OK, 0 rows affected (0.00 sec)
```

```

14.13.2.115 SHOW PLACEMENT FOR

`SHOW PLACEMENT FOR` summarizes all placement options, and presents them in the canonical form for a specific table, database schema, or partition.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

The statement returns a result set in which the `Scheduling_State` field indicates the current progress that the Placement Driver (PD) has made in scheduling the placement:

- `PENDING`: The PD has not yet started scheduling the placement. This might indicate that the placement rules are semantically correct, but cannot currently be satisfied by the cluster. For example, if `FOLLOWERS=4` but there are only 3 TiKV stores that are candidates for followers.
- `INPROGRESS`: The PD is currently scheduling the placement.
- `SCHEDULED`: The PD has successfully scheduled the placement.

14.13.2.115.1 Synopsis

```
ShowStmt ::=
    "SHOW" "PLACEMENT" "FOR" ShowPlacementTarget

ShowPlacementTarget ::=

+-----------------------------+-----------------------------------------+-------------
   ↪
50 rows in set (0.00 sec)
```

14.13.2.118.3 MySQL compatibility

The `SHOW PRIVILEGES` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.118.4 See also

- SHOW GRANTS
- Privilege Management
- `GRANT <privileges>`

14.13.2.119 SHOW [FULL] PROCESSLIST

This statement lists the current sessions connected to the same TiDB server. The `Info` column contains the query text, which will be truncated unless the optional keyword `FULL` is specified.

14.13.2.119.1 Synopsis

```
ShowProcesslistStmt ::=
    "SHOW" "FULL"? "PROCESSLIST"
```

14.13.2.119.2 Examples

```
mysql> SHOW PROCESSLIST;
+--
    ↪ ----+------+----------------+------+---------+------+-----------+------------
    ↪
| Id   | User | Host          | db   | Command | Time | State   | Info
    ↪           |
+--
    ↪ ----+------+----------------+------+---------+------+-----------+------------
    ↪
|    5 | root | 127.0.0.1:45970 | test | Query | 0 | autocommit | SHOW
    ↪ PROCESSLIST |
+--
    ↪ ----+------+----------------+------+---------+------+-----------+------------
    ↪
1 rows in set (0.00 sec)
```

14.13.2.119.3 MySQL compatibility

- The `State` column in TiDB is non-descriptive. Representing state as a single value is more complex in TiDB, since queries are executed in parallel and each goroutine will have a different state at any one time.

14.13.2.119.4 See also

- KILL [TIDB]
- `INFORMATION_SCHEMA.PROCESSLIST`

14.13.2.120 SHOW PROFILES

The `SHOW PROFILES` statement currently only returns an empty result.

14.13.2.120.1 Synopsis

```
ShowProfilesStmt ::=
    "SHOW" "PROFILES" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.120.2 Examples

```
SHOW PROFILES;
```

```
Empty set (0.00 sec)
```

14.13.2.120.3 MySQL compatibility

This statement is included only for compatibility with MySQL. Executing `SHOW PROFILES` always returns an empty result.

As an alternative, TiDB provides statement summary tables to help understand SQL performance issues.

14.13.2.121 SHOW SCHEMAS

This statement is an alias to `SHOW DATABASES`. It is included for compatibility with MySQL.

14.13.2.122 SHOW STATS_BUCKETS

The `SHOW STATS_BUCKETS` statement shows the bucket information in statistics.

Currently, the `SHOW STATS_BUCKETS` statement returns the following columns:

Column name	Description
`Db_name`	The database name
`Table_name`	The table name
`Partition_name`	The partition name

Column name	Description
`Column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`Is_index`	Whether it is an index column or not
`Bucket_id`	The ID of a bucket
`Count`	The number of all the values that falls on the bucket and the previous buckets
`Repeats`	The occurrence number of the maximum value
`Lower_bound`	The minimum value
`Upper_bound`	The maximum value
`Ndv`	The number of distinct values in the bucket. This field is deprecated and always shows `0` due to its inaccurate value.

14.13.2.122.1 Synopsis

```
ShowStatsBucketsStmt ::=
    "SHOW" "STATS_BUCKETS" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.122.2 Examples

```
SHOW STATS_BUCKETS WHERE Table_name='t';
```

```

   ↪
6 rows in set (0.00 sec)
```

14.13.2.122.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.122.4 See also

- ANALYZE
- Introduction to Statistics

14.13.2.123 SHOW STATS_HEALTHY

The `SHOW STATS_HEALTHY` statement shows an estimation of how accurate statistics are believed to be. Tables with a low percentage health may generate sub-optimal query execution plans.

The health of a table can be improved by running the `ANALYZE` statement. `ANALYZE` runs automatically when the health drops below the `tidb_auto_analyze_ratio` threshold.

Currently, the `SHOW STATS_HEALTHY` statement returns the following columns:

Column name	Description
Db_name	The database name
Table_name	The table name
Partition_name	The partition name
Healthy	The healthy percentage between 0 and 100

14.13.2.123.1 Synopsis

```
ShowStatsHealthyStmt ::=
    "SHOW" "STATS_HEALTHY" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.123.2 Examples

Load example data and run `ANALYZE`:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 b INT NOT NULL,
 pad VARBINARY(255),
 INDEX(b)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM dual
    ↪ ;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(255) FROM t1 a
    ↪  JOIN t1 b JOIN t1 c LIMIT 100000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
SHOW STATS_HEALTHY; # should be 100% healthy
```

```
...
mysql> SHOW STATS_HEALTHY;
+---------+------------+----------------+---------+
| Db_name | Table_name | Partition_name | Healthy |
+---------+------------+----------------+---------+
| test    | t1         |                |     100 |
+---------+------------+----------------+---------+
1 row in set (0.00 sec)
```

Perform a bulk update deleting approximately 30% of the records. Check the health of the statistics:

```
DELETE FROM t1 WHERE id BETWEEN 101010 AND 201010; # delete about 30% of
    ↪ records
SHOW STATS_HEALTHY;
```

```
mysql> SHOW STATS_HEALTHY;
+---------+------------+----------------+---------+
| Db_name | Table_name | Partition_name | Healthy |
+---------+------------+----------------+---------+
| test    | t1         |                |      50 |
+---------+------------+----------------+---------+
1 row in set (0.00 sec)
```

14.13.2.123.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.124 SHOW STATS_HISTOGRAMS

This statement shows the histogram information collected by the `ANALYZE` statement as part of database statistics.

Currently, the `SHOW STATS_HISTOGRAMS` statement returns the following columns:

Column name	Description
`Db_name`	Database name

Column name	Description
`Table_name`	The table name
`Partition_name`	The partition name
`Column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`Is_index`	Whether it is an index column or not
`Update_time`	The update time
`Distinct_count`	The distinct count
`Null_count`	NULL count
`Avg_col_size`	The average col size
`Correlation`	Pearson correlation coefficient between this column and the integer primary key column, indicating the degree of association between the two columns
`Load_status`	Load status, such as `allEvicted` and `allLoaded`

Column name	Description
Total_mem_usage	The total memory usage
Hist_mem_usage	The historical memory usage
Topn_mem_usage	The TopN memory usage
Cms_mem_usage	The CMS memory usage

14.13.2.124.1 Synopsis

14.13.2.125 SHOW STATS_LOCKED

`SHOW STATS_LOCKED` shows the tables whose statistics are locked.

Currently, the `SHOW STATS_LOCKED` statement returns the following columns:

Column name	Description
`Db_name`	The database name
`Table_name`	The table name
`Partition_name`	The partition name
`Status`	The statistics status, such as `locked`

14.13.2.125.1 Synopsis

```
ShowStatsLockedStmt ::= 'SHOW' 'STATS_LOCKED' ShowLikeOrWhereOpt

ShowLikeOrWhereOpt ::= 'LIKE' SimpleExpr | 'WHERE' Expression
```

14.13.2.125.2 Examples

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Level | Code | Message
   ↪
   ↪ |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t, reason to use this rate is "Row count in stats_meta is much
   ↪ smaller compared with the row count got by PD, use min(1, 15000/4) as
   ↪  the sample-rate=1" |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `SHOW STATS_LOCKED`. The output shows that the statistics of table `t` have been locked.

```
mysql> LOCK STATS t;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW STATS_LOCKED;
```

```
+---------+-----------+---------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+-----------+---------------+--------+
| test    | t         |               | locked |
+---------+-----------+---------------+--------+
1 row in set (0.01 sec)
```

14.13.2.125.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

- UNLOCK STATS

14.13.2.126 SHOW STATS_META

You can use `SHOW STATS_META` to view how many rows are in a table and how many rows are changed in that table. When using this statement, you can filter the needed information by the `ShowLikeOrWhere` clause.

Currently, the `SHOW STATS_META` statement outputs 6 columns:

Column name	Description
db_name	Database name
table_name	Table name
partition_name	Partition name
update_time	Last updated time
modify_count	The number of rows modified
row_count	The total row count

Note:

The `update_time` is updated when TiDB updates the `modify_count` and `row ↪ _count` fields according to DML statements. So `update_time` is not the last execution time of the `ANALYZE` statement.

14.13.2.126.1 Synopsis

```
ShowStatsMetaStmt ::=
    "SHOW" "STATS_META" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.126.2 Examples

```
SHOW STATS_META;
```

```

14.13.2.127 SHOW STATS_TOPN

The `SHOW STATS_TOPN` statement shows the Top-N information in statistics.

Currently, the `SHOW STATS_TOPN` statement returns the following columns:

Column name	Description
`Db_name`	The database name
`Table_name`	The table name
`Partition_name`	The partition name

Column name	Description
`Column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`Is_index`	Whether it is an index column or not
`Value`	The value of this column
`Count`	How many times the value appears

14.13.2.127.1 Synopsis

```
ShowStatsTopnStmt ::=
    "SHOW" "STATS_TOPN" ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.127.2 Example

```
SHOW STATS_TOPN WHERE Table_name='t';
```

```
+---------+------------+----------------+-------------+----------+----------------------

14.13.2.128 SHOW [GLOBAL|SESSION] STATUS

This statement is included for compatibility with MySQL. TiDB uses Prometheus and Grafana for centralized metrics collection instead of `SHOW STATUS` for most metrics.

A full description of the variables can be found here: status variables

14.13.2.128.1 Synopsis

```
ShowStatusStmt ::=
    'SHOW' Scope? 'STATUS' ShowLikeOrWhere?

Scope ::=
    ( 'GLOBAL' | 'SESSION' )

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.128.2 Examples

```
mysql> SHOW SESSION STATUS;
+-----------------------------+--------------------------------------+
| Variable_name               | Value                                |

- Server Status Variables

14.13.2.129 SHOW TABLE NEXT_ROW_ID

`SHOW TABLE NEXT_ROW_ID` is used to show the details of some special columns of a table, including:

- `AUTO_INCREMENT` column automatically created by TiDB, namely, `_tidb_rowid` column.
- `AUTO_INCREMENT` column created by users.
- `AUTO_RANDOM` column created by users.
- `SEQUENCE` created by users.

14.13.2.129.1 Synopsis

```
ShowTableNextRowIDStmt ::=
    "SHOW" "TABLE" (SchemaName ".")? TableName "NEXT_ROW_ID"
```

14.13.2.129.2 Examples

For newly created tables, `NEXT_GLOBAL_ROW_ID` is `1` because no Row ID is allocated.

```
CREATE TABLE t(a int);
Query OK, 0 rows affected (0.06 sec)
```

```
SHOW TABLE t NEXT_ROW_ID;
+---------+------------+-------------+--------------------+
| DB_NAME | TABLE_NAME | COLUMN_NAME | NEXT_GLOBAL_ROW_ID |
+---------+------------+-------------+--------------------+
| test    | t          | _tidb_rowid |                  1 |
+---------+------------+-------------+--------------------+
1 row in set (0.00 sec)
```

Data have been written to the table. The TiDB server that inserts the data allocates and caches 30000 IDs at once. Thus, NEXT_GLOBAL_ROW_ID is 30001 now. The number of IDs is controlled by AUTO_ID_CACHE.

```
INSERT INTO t VALUES (), (), ();
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
SHOW TABLE t NEXT_ROW_ID;
+---------+------------+-------------+--------------------+
| DB_NAME | TABLE_NAME | COLUMN_NAME | NEXT_GLOBAL_ROW_ID |
+---------+------------+-------------+--------------------+
| test    | t          | _tidb_rowid |              30001 |
+---------+------------+-------------+--------------------+
1 row in set (0.00 sec)
```

14.13.2.129.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.130 SHOW TABLE REGIONS

The `SHOW TABLE REGIONS` statement is used to show the Region information of a table in TiDB.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.130.1 Syntax

```
SHOW TABLE [table_name] REGIONS [WhereClauseOptional];
SHOW TABLE [table_name] INDEX [index_name] REGIONS [WhereClauseOptional];
```

14.13.2.130.2 Synopsis

```
ShowTableRegionStmt ::=
    "SHOW" "TABLE" TableName PartitionNameList? ("INDEX" IndexName)? "
        ↪ REGIONS" ("WHERE" Expression)?

TableName ::=
    (SchemaName ".")? Identifier
```

Executing `SHOW TABLE REGIONS` returns the following columns:

- `REGION_ID`: The Region ID.
- `START_KEY`: The start key of the Region.
- `END_KEY`: The end key of the Region.
- `LEADER_ID`: The Leader ID of the Region.
- `LEADER_STORE_ID`: The ID of the store (TiKV) where the Region leader is located.
- `PEERS`: The IDs of all Region replicas.
- `SCATTERING`: Whether the Region is being scheduled. `1` means true.
- `WRITTEN_BYTES`: The estimated amount of data written into the Region within one heartbeat cycle. The unit is byte.
- `READ_BYTES`: The estimated amount of data read from the Region within one heartbeat cycle. The unit is byte.
- `APPROXIMATE_SIZE(MB)`: The estimated amount of data in the Region. The unit is megabytes (MB).
- `APPROXIMATE_KEYS`: The estimated number of Keys in the Region.

- `SCHEDULING_CONSTRAINTS`: The placement policy settings associated with the table or partition to which a Region belongs.

- `SCHEDULING_STATE`: The scheduling state of the Region which has a placement policy.

> **Note:**
>
> The values of `WRITTEN_BYTES`, `READ_BYTES`, `APPROXIMATE_SIZE(MB)`, `APPROXIMATE_KEYS` are not accurate data. They are estimated data from PD based on the heartbeat information that PD receives from the Region.

14.13.2.130.3 Examples

Create an example table with enough data that fills a few Regions:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 b INT NOT NULL,
 pad1 VARBINARY(1024),
 pad2 VARBINARY(1024),
 pad3 VARBINARY(1024)
);
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1000), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT
    ↪ 10000;
```

```
SELECT SLEEP(5);
SHOW TABLE t1 REGIONS;
```

The output should show that the table is split into Regions. The `REGION_ID`, `START_KEY` and `END_KEY` may not match exactly:

```
...
mysql> SHOW TABLE t1 REGIONS;
+--
   ↪ ---------+-------------+-------------+----------+----------------+-------+--
   ↪
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS |
   ↪  SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
   ↪ APPROXIMATE_KEYS | SCHEDULING_CONSTRAINTS | SCHEDULING_STATE |
+--
   ↪ ---------+-------------+-------------+----------+----------------+-------+--
   ↪
|       94 | t_75_      | t_75_r_31717 |     95 |             1 | 95    |
   ↪         0 |           0 |         0 |                112 |
   ↪ 207465 |                     |                |
|       96 | t_75_r_31717 | t_75_r_63434 |   97 |             1 | 97    |
   ↪         0 |           0 |         0 |                 97 |
   ↪ 0 |                       |                 |
|        2 | t_75_r_63434 |          |        3 |             1 | 3     |
   ↪         0 |    269323514 | 66346110 |                245 |
   ↪ 162020 |                     |                |
+--
   ↪ ---------+-------------+-------------+----------+----------------+-------+--
   ↪
3 rows in set (0.00 sec)
```

In the output above, a `START_KEY` of `t_75_r_31717` and `END_KEY` of `t_75_r_63434` shows that data with a PRIMARY KEY between `31717` and `63434` is stored in this Region. The prefix `t_75_` indicates that this is the Region for a table (`t`) which has an internal table ID of `75`. An empty key value for `START_KEY` or `END_KEY` indicates negative infinity or positive infinity respectively.

TiDB automatically rebalances Regions as needed. For manual rebalancing, use the `SPLIT TABLE REGION` statement:

```
mysql> SPLIT TABLE t1 BETWEEN (31717) AND (63434) REGIONS 2;
+--------------------+----------------------+
| TOTAL_SPLIT_REGION | SCATTER_FINISH_RATIO |
+--------------------+----------------------+
|                  1 |                    1 |
+--------------------+----------------------+
```

```
1 row in set (42.34 sec)

mysql> SHOW TABLE t1 REGIONS;
+--
    ↪ ---------+-------------+-------------+----------+----------------+-------+--
    ↪
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS |
    ↪  SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
    ↪ APPROXIMATE_KEYS | SCHEDULING_CONSTRAINTS | SCHEDULING_STATE |
+--
    ↪ ---------+-------------+-------------+----------+----------------+-------+--
    ↪
|       94 | t_75_      | t_75_r_31717 |     95 |             1 | 95    |
    ↪         0 |           0 |         0 |                112 |
    ↪ 207465 |                     |                |
|       98 | t_75_r_31717 | t_75_r_47575 |   99 |             1 | 99    |
    ↪         0 |         1325 |         0 |                 53 |
    ↪ 12052 |                     |                |
|       96 | t_75_r_47575 | t_75_r_63434 |   97 |             1 | 97    |
    ↪         0 |         1526 |         0 |                 48 |
    ↪ 0 |                     |                |
|        2 | t_75_r_63434 |          |        3 |             1 | 3     |
    ↪         0 |           0 |   55752049 |                 60 |
    ↪ 0 |                     |                |
+--
    ↪ ---------+-------------+-------------+----------+----------------+-------+--
    ↪
4 rows in set (0.00 sec)
```

The above output shows that Region 96 was split, with a new Region 98 being created. The remaining Regions in the table were unaffected by the split operation. This is confirmed by the output statistics:

- `TOTAL_SPLIT_REGION` indicates the number of newly split Regions. In this example, the number is 1.
- `SCATTER_FINISH_RATIO` indicates the rate at which the newly split Regions are successfully scattered. `1.0` means that all Regions are scattered.

For a more detailed example:

```
mysql> SHOW TABLE t REGIONS;
+--
    ↪ ---------+-------------+-------------+----------+----------------+----------
    ↪
```

```
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS
   ↪    | SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
   ↪ APPROXIMATE_KEYS | SCHEDULING_CONSTRAINTS | SCHEDULING_STATE |
+--
   ↪ ---------+-------------+-------------+----------+----------------+---------
   ↪
| 102       | t_43_r      | t_43_r_20000 | 118    | 7              | 105, 118,
   ↪ 119 | 0       | 0            | 0         | 1                | 0
   ↪               |                       |                |
| 106       | t_43_r_20000 | t_43_r_40000 | 120  | 7              | 107, 108,
   ↪ 120 | 0       | 23           | 0         | 1                | 0
   ↪               |                       |                |
| 110       | t_43_r_40000 | t_43_r_60000 | 112  | 9              | 112, 113,
   ↪ 121 | 0       | 0            | 0         | 1                | 0
   ↪               |                       |                |
| 114       | t_43_r_60000 | t_43_r_80000 | 122  | 7              | 115, 122,
   ↪ 123 | 0       | 35           | 0         | 1                | 0
   ↪               |                       |                |
| 3         | t_43_r_80000 |           | 93       | 8              | 5, 73, 93
   ↪   | 0         | 0            | 0         | 1                | 0
   ↪               |                       |                |
| 98        | t_43_       | t_43_r      | 99       | 1              | 99, 100,
   ↪ 101 | 0        | 0            | 0         | 1                 | 0
   ↪               |                       |                |
+--
   ↪ ---------+-------------+-------------+----------+----------------+---------
   ↪
6 rows in set
```

In the above example:

- Table t corresponds to six Regions. In these Regions, 102, 106, 110, 114, and 3 store the row data and 98 stores the index data.
- For START_KEY and END_KEY of Region 102, t_43 indicates the table prefix and ID. _r is the prefix of the record data in table t. _i is the prefix of the index data.
- In Region 102, START_KEY and END_KEY mean that record data in the range of [-inf, ↪ 20000) is stored. In similar way, the ranges of data storage in Regions (106, 110, 114, 3) can also be calculated.
- Region 98 stores the index data. The start key of table t's index data is t_43_i, which is in the range of Region 98.

To check the Region that corresponds to table t in store 1, use the WHERE clause:

```
test> SHOW TABLE t REGIONS WHERE leader_store_id =1;
```

```
+--
   ↪ ---------+-----------+---------+-----------+-----------------+---------------+---
   ↪
| REGION_ID | START_KEY | END_KEY | LEADER_ID | LEADER_STORE_ID | PEERS |
   ↪ SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
   ↪ APPROXIMATE_KEYS | SCHEDULING_CONSTRAINTS | SCHEDULING_STATE |
+--
   ↪ ---------+-----------+---------+-----------+-----------------+---------------+---
   ↪
| 98       | t_43_    | t_43_r | 99       | 1               | 99, 100, 101 | 0
   ↪       | 0           | 0         | 1                 | 0              |
   ↪                     |                 |
+--
   ↪ ---------+-----------+---------+-----------+-----------------+---------------+---
   ↪
```

Use `SPLIT TABLE REGION` to split the index data into Regions. In the following example, the index data `name` of table t is split into two Regions in the range of `[a,z]`.

```
test> SPLIT TABLE t INDEX name BETWEEN ("a") AND ("z") REGIONS 2;
+--------------------+----------------------+
| TOTAL_SPLIT_REGION | SCATTER_FINISH_RATIO |
+--------------------+----------------------+
| 2                  | 1.0                  |
+--------------------+----------------------+
1 row in set
```

Now table t corresponds to seven Regions. Five of them (`102`, `106`, `110`, `114`, `3`) store the record data of table t and another two (`135`, `98`) store the index data `name`.

```
test> SHOW TABLE t REGIONS;
+--
   ↪ ---------+----------------------------+----------------------------+-----------
   ↪
| REGION_ID | START_KEY                | END_KEY                    | LEADER_ID |
   ↪  LEADER_STORE_ID | PEERS    | SCATTERING | WRITTEN_BYTES | READ_BYTES
   ↪ | APPROXIMATE_SIZE(MB) | APPROXIMATE_KEYS | SCHEDULING_CONSTRAINTS |
   ↪ SCHEDULING_STATE |
+--
   ↪ ---------+----------------------------+----------------------------+-----------
   ↪
| 102      | t_43_r                   | t_43_r_20000               | 118       |
   ↪ 7                | 105, 118, 119 | 0          | 0             | 0           | 1
   ↪                    | 0               |                       |
   ↪                  |
```

```
| 106      | t_43_r_20000              | t_43_r_40000                | 120      |
   ↪ 7             | 108, 120, 126 | 0       | 0           | 0         | 1
   ↪                 | 0             |                       |
   ↪                |
| 110      | t_43_r_40000              | t_43_r_60000                | 112      |
   ↪ 9             | 112, 113, 121 | 0       | 0           | 0         | 1
   ↪                 | 0             |                       |
   ↪                |
| 114      | t_43_r_60000              | t_43_r_80000                | 122      |
   ↪ 7             | 115, 122, 123 | 0       | 35          | 0         | 1
   ↪                 | 0             |                       |
   ↪                |
| 3        | t_43_r_80000              |                             | 93       |
   ↪ 8             | 73, 93, 128 | 0         | 0           | 0         | 1
   ↪                 | 0             |                       |
   ↪                |
| 135      | t_43_i_1_                 | t_43_i_1_016d80000000000000 | 139      |
   ↪ 2             | 138, 139, 140 | 0       | 35          | 0         | 1
   ↪                 | 0             |                       |
   ↪                |

14.13.2.130.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.130.5 See also

- SPLIT REGION
- CREATE TABLE

14.13.2.131 SHOW TABLE STATUS

This statement shows various statistics about tables in TiDB. If the statistics appear out of date, it is recommended to run `ANALYZE TABLE`.

14.13.2.131.1 Synopsis

```
ShowTableStatusStmt ::=
    "SHOW" "TABLE" "STATUS" ("FROM" Identifier | "IN" Identifier )?
        ↪ ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.131.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.02 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SHOW TABLE STATUS LIKE 't1'\G
*************************** 1. row ***************************
           Name: t1
         Engine: InnoDB
        Version: 10
     Row_format: Compact
           Rows: 0
 Avg_row_length: 0
    Data_length: 0
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: 30001
    Create_time: 2019-04-19 08:32:06
    Update_time: NULL
     Check_time: NULL
      Collation: utf8mb4_bin
       Checksum:
 Create_options:
        Comment:
1 row in set (0.00 sec)

mysql> ANALYZE TABLE t1;
Query OK, 0 rows affected (0.12 sec)
```

```
mysql> SHOW TABLE STATUS LIKE 't1'\G
*************************** 1. row ***************************
           Name: t1
         Engine: InnoDB
        Version: 10
     Row_format: Compact
           Rows: 5
 Avg_row_length: 16
    Data_length: 80
Max_data_length: 0
   Index_length: 0
      Data_free: 0
 Auto_increment: 30001
    Create_time: 2019-04-19 08:32:06
    Update_time: NULL
     Check_time: NULL
      Collation: utf8mb4_bin
       Checksum:
 Create_options:
        Comment:
1 row in set (0.00 sec)
```

14.13.2.131.3 MySQL compatibility

The `SHOW TABLE STATUS` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.131.4 See also

- SHOW TABLES
- CREATE TABLE
- DROP TABLE
- SHOW CREATE TABLE

14.13.2.132 SHOW [FULL] TABLES

This statement shows a list of tables and views in the currently selected database. The optional keyword `FULL` indicates if a table is of type `BASE TABLE`, `SEQUENCE`, or `VIEW`.

To show tables in a different database, use `SHOW TABLES IN DatabaseName`.

14.13.2.132.1 Synopsis

```
ShowTableStmt ::=
    "SHOW" "FULL"? "TABLES" ("FROM" Identifier | "IN" Identifier )?
        ↪ ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.132.2 Examples

```
mysql> CREATE TABLE t1 (a int);
Query OK, 0 rows affected (0.12 sec)

mysql> CREATE VIEW v1 AS SELECT 1;
Query OK, 0 rows affected (0.10 sec)

mysql> SHOW TABLES;
+----------------+
| Tables_in_test |
+----------------+
| t1             |
| v1             |
+----------------+
2 rows in set (0.00 sec)

mysql> SHOW FULL TABLES;
+----------------+------------+
| Tables_in_test | Table_type |

20 rows in set (0.00 sec)
```

14.13.2.132.3 MySQL compatibility

The `SHOW [FULL] TABLES` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.132.4 See also

- CREATE TABLE
- DROP TABLE
- SHOW CREATE TABLE
- `INFORMATION_SCHEMA.TABLES`

14.13.2.133 SHOW [GLOBAL|SESSION] VARIABLES

This statement shows a list of variables for the scope of either `GLOBAL` or `SESSION`. If no scope is specified, the default scope of `SESSION` will apply.

14.13.2.133.1 Synopsis

```
ShowVariablesStmt ::=
    "SHOW" ("GLOBAL" | "SESSION")? VARIABLES ShowLikeOrWhere?

ShowLikeOrWhere ::=
    "LIKE" SimpleExpr
|   "WHERE" Expression
```

14.13.2.133.2 Examples

List all TiDB specific variables. For detailed description, refer to System Variables.

```
mysql> SHOW GLOBAL VARIABLES LIKE 'tidb%';
+-----------------------------------+--------------------+
| Variable_name                     | Value              |

14.13.2.133.3 MySQL compatibility

The `SHOW [GLOBAL|SESSION] VARIABLES` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.133.4 See also

- `SET [GLOBAL|SESSION]`

14.13.2.134 SHOW WARNINGS

This statement shows a list of warnings that occurred for previously executed statements in the current client connection. As in MySQL, the `sql_mode` impacts which statements will cause errors vs. warnings considerably.

14.13.2.134.1 Synopsis

```
ShowWarningsStmt ::=
    "SHOW" "WARNINGS"
```

14.13.2.134.2 Examples

```
mysql> CREATE TABLE t1 (a INT UNSIGNED);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 VALUES (0);
Query OK, 1 row affected (0.02 sec)

mysql> SELECT 1/a FROM t1;
+------+
| 1/a  |
+------+
| NULL |
+------+
```

```
1 row in set, 1 warning (0.00 sec)

mysql> SHOW WARNINGS;
+---------+------+---------------+
| Level   | Code | Message       |
+---------+------+---------------+
| Warning | 1365 | Division by 0 |
+---------+------+---------------+
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES (-1);
ERROR 1264 (22003): Out of range value for column 'a' at row 1
mysql> SELECT * FROM t1;
+------+
| a    |
+------+
|    0 |
+------+
1 row in set (0.00 sec)

mysql> SET sql_mode='';
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (-1);
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+---------+------+--------------------------+
| Level   | Code | Message                  |
+---------+------+--------------------------+
| Warning | 1690 | constant -1 overflows int |
+---------+------+--------------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM t1;
+------+
| a    |
+------+
|    0 |
|    0 |
+------+
2 rows in set (0.00 sec)
```

14.13.2.134.3 MySQL compatibility

The `SHOW WARNINGS` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.134.4 See also

- SHOW ERRORS

14.13.2.135 SHUTDOWN

The `SHUTDOWN` statement is used to perform a shutdown operation in TiDB. Execution of the `SHUTDOWN` statement requires the user to have `SHUTDOWN privilege`.

> **Note:**
>
> This feature is only applicable to TiDB Self-Managed and not available on TiDB Cloud.

14.13.2.135.1 Synopsis

```
ShutdownStmt ::=
    "SHUTDOWN"
```

14.13.2.135.2 Examples

```
SHUTDOWN;
```

```
Query OK, 0 rows affected (0.00 sec)
```

14.13.2.135.3 MySQL compatibility

> **Note:**
>
> Because TiDB is a distributed database, the shutdown operation in TiDB stops the client-connected TiDB instance, not the entire TiDB cluster.

The `SHUTDOWN` statement is partly compatible with MySQL. If you encounter any compatibility issues, you can report a bug.

14.13.2.136 Split Region

For each new table created in TiDB, one Region is segmented by default to store the data of this table. This default behavior is controlled by `split-table` in the TiDB configuration file. When the data in this Region exceeds the default Region size limit, the Region starts to split into two.

In the above case, because there is only one Region at the beginning, all write requests occur on the TiKV where the Region is located. If there are a large number of writes for the newly created table, hotspots are caused.

To solve the hotspot problem in the above scenario, TiDB introduces the pre-split function, which can pre-split multiple Regions for a certain table according to the specified parameters and scatter them to each TiKV node.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.2.136.1 Synopsis

```
SplitRegionStmt ::=
    "SPLIT" SplitSyntaxOption "TABLE" TableName PartitionNameList? ("INDEX"
       ↪ IndexName)? SplitOption

SplitSyntaxOption ::=
    ("REGION" "FOR")? "PARTITION"?

TableName ::=
    (SchemaName ".")? Identifier

PartitionNameList ::=
    "PARTITION" "(" PartitionName ("," PartitionName)* ")"

SplitOption ::=
    ("BETWEEN" RowValue "AND" RowValue "REGIONS" NUM
|   "BY" RowValue ("," RowValue)* )

RowValue ::=
    "(" ValuesOpt ")"
```

14.13.2.136.2 Usage of Split Region

There are two types of Split Region syntax:

- The syntax of even split:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (
    ↪ upper_value) REGIONS region_num
```

`BETWEEN lower_value AND upper_value REGIONS region_num` defines the upper boundary, the lower boundary, and the Region amount. Then the current region will be evenly spilt into the number of regions (as specified in `region_num`) between the upper and lower boundaries.

- The syntax of uneven split:

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_
    ↪ list)] ...
```

`BY value_list⋯` specifies a series of points manually, based on which the current Region is spilt. It is suitable for scenarios with unevenly distributed data.

The following example shows the result of the `SPLIT` statement:

```
+--------------------+----------------------+
| TOTAL_SPLIT_REGION | SCATTER_FINISH_RATIO |
+--------------------+----------------------+
| 4                  | 1.0                  |
+--------------------+----------------------+
```

- `TOTAL_SPLIT_REGION`: the number of newly split Regions.
- `SCATTER_FINISH_RATIO`: the completion rate of scattering for newly split Regions. `1.0` means that all Regions are scattered. `0.5` means that only half of the Regions are scattered and the rest are being scattered.

Note:

The following two session variables might affect the behavior of the `SPLIT` statement:

- `tidb_wait_split_region_finish`: It might take a while to scatter the Regions. This duration depends on PD scheduling and TiKV loads. This variable is used to control when executing the `SPLIT REGION` statement whether to return the results to the client until all Regions are scattered. If its value is set to `1` (by default), TiDB returns the results only after the scattering is completed. If its value is set to `0`, TiDB returns the results regardless of the scattering status.

- `tidb_wait_split_region_timeout`: This variable is to set the execution timeout of the `SPLIT REGION` statement, in seconds. The default value is 300s. If the `split` operation is not completed within the duration, TiDB returns a timeout error.

Split Table Region

The key of row data in each table is encoded by `table_id` and `row_id`. The format is as follows:

```
t[table_id]_r[row_id]
```

For example, when `table_id` is 22 and `row_id` is 11:

```
t22_r11
```

Row data in the same table have the same `table_id`, but each row has its unique `row_id` that can be used for Region split.

Even Split

Because `row_id` is an integer, the value of the key to be split can be calculated according to the specified `lower_value`, `upper_value`, and `region_num`. TiDB first calculates the step value (`step = (upper_value - lower_value)/region_num`). Then split will be done evenly per each "step" between `lower_value` and `upper_value` to generate the number of Regions as specified by `region_num`.

For example, if you want 16 evenly split Regions split from key range`minInt64~maxInt64` for table t, you can use this statement:

```
SPLIT TABLE t BETWEEN (-9223372036854775808) AND (9223372036854775807)
    ↪ REGIONS 16;
```

This statement splits table t into 16 Regions between minInt64 and maxInt64. If the given primary key range is smaller than the specified one, for example, 0~1000000000, you can use 0 and 1000000000 take place of minInt64 and maxInt64 respectively to split Regions.

```
SPLIT TABLE t BETWEEN (0) AND (1000000000) REGIONS 16;
```

Uneven split

If the known data is unevenly distributed, and you want a Region to be split respectively in key ranges -inf ~ 10000, 10000 ~ 90000, and 90000 ~ +inf, you can achieve this by setting fixed points, as shown below:

```
SPLIT TABLE t BY (10000), (90000);
```

Split index Region

The key of the index data in the table is encoded by `table_id`, `index_id`, and the value of the index column. The format is as follows:

```
t[table_id]_i[index_id][index_value]
```

For example, when `table_id` is 22, `index_id` is 5, and `index_value` is abc:

```
t22_i5abc
```

The `table_id` and `index_id` of the same index data in one table is the same. To split index Regions, you need to split Regions based on `index_value`.

Even Spilt

The way to split index evenly works the same as splitting data evenly. However, calculating the value of step is more complicated, because `index_value` might not be an integer.

The values of `upper` and `lower` are encoded into a byte array firstly. After removing the longest common prefix of `lower` and `upper` byte array, the first 8 bytes of `lower` and `upper` are converted into the uint64 format. Then `step = (upper - lower)/num` is calculated. After that, the calculated step is encoded into a byte array, which is appended to the longest common prefix of the `lower` and `upper` byte array for index split. Here is an example:

If the column of the `idx` index is of the integer type, you can use the following SQL statement to split index data:

```
SPLIT TABLE t INDEX idx BETWEEN (-9223372036854775808) AND
    ↪ (9223372036854775807) REGIONS 16;
```

This statement splits the Region of index idx in table t into 16 Regions from `minInt64` to `maxInt64`.

If the column of index idx1 is of varchar type, and you want to split index data by prefix letters.

```
SPLIT TABLE t INDEX idx1 BETWEEN ("a") AND ("z") REGIONS 25;
```

This statement splits index idx1 into 25 Regions from a~z. The range of Region 1 is `[minIndexValue, b)`; the range of Region 2 is `[b, c)`; … the range of Region 25 is `[y,
↪ minIndexValue]`. For the `idx` index, data with the `a` prefix is written into Region 1, and data with the `b` prefix is written into Region 2.

In the split method above, both data with the `y` and `z` prefixes are written into Region 25, because the upper bound is not `z`, but `{` (the character next to `z` in ASCII). Therefore, a more accurate split method is as follows:

```
SPLIT TABLE t INDEX idx1 BETWEEN ("a") AND ("{") REGIONS 26;
```

This statement splits index idx1 of the table `t` into 26 Regions from a~{. The range of Region 1 is `[minIndexValue, b)`; the range of Region 2 is `[b, c)`; … the range of Region 25 is `[y, z)`, and the range of Region 26 is `[z, maxIndexValue)`.

If the column of index `idx2` is of time type like timestamp/datetime, and you want to split index Region by year:

```
SPLIT TABLE t INDEX idx2 BETWEEN ("2010-01-01 00:00:00") AND ("2020-01-01
    ↪ 00:00:00") REGIONS 10;
```

This statement splits the Region of index `idx2` in table `t` into 10 Regions from `2010-01-01 00:00:00` to `2020-01-01 00:00:00`. The range of Region 1 is `[minIndexValue , 2011-01-01 00:00:00)`; the range of Region 2 is `[2011-01-01 00:00:00, 2012-01-01 00:00:00)`.

If you want to split the index Region by day, see the following example:

```
SPLIT TABLE t INDEX idx2 BETWEEN ("2020-06-01 00:00:00") AND ("2020-07-01
    ↪ 00:00:00") REGIONS 30;
```

This statement splits the data of June 2020 of index `idex2` in table `t` into 30 Regions, each Region representing 1 day.

Region split methods for other types of index columns are similar.

For data Region split of joint indexes, the only difference is that you can specify multiple columns values.

For example, index `idx3 (a, b)` contains 2 columns, with column `a` of timestamp type and column `b` int. If you just want to do a time range split according to column `a`, you can use the SQL statement for splitting time index of a single column. In this case, do not specify the value of column `b` in `lower_value` and `upper_velue`.

```
SPLIT TABLE t INDEX idx3 BETWEEN ("2010-01-01 00:00:00") AND ("2020-01-01
    ↪ 00:00:00") REGIONS 10;
```

Within the same range of time, if you want to do one more split according to column b column. Just specify the value for column b when splitting.

```
SPLIT TABLE t INDEX idx3 BETWEEN ("2010-01-01 00:00:00", "a") AND ("
    ↪ 2010-01-01 00:00:00", "z") REGIONS 10;
```

This statement splits 10 Regions in the range of a~z according to the value of column b, with the same time prefix as column a. If the value specified for column a is different, the value of column b might not be used in this case.

If the primary key of the table is a non-clustered index, you need to use backticks ` to escape the `PRIMARY` keyword when splitting Regions. For example:

```
SPLIT TABLE t INDEX `PRIMARY` BETWEEN (-9223372036854775808) AND
    ↪ (9223372036854775807) REGIONS 16;
```

Uneven Split

Index data can also be split by specified index values.

For example, there is `idx4 (a,b)`, with column `a` of the varchar type and column `b` of the timestamp type.

```
SPLIT TABLE t1 INDEX idx4 BY ("a", "2000-01-01 00:00:01"), ("b", "
    ↪ 2019-04-17 14:26:19"), ("c", "");
```

This statement specifies 3 values to split 4 Regions. The range of each Region is as follows:

```
region1 [ minIndexValue           , ("a", "2000-01-01 00:00:01"))
region2 [("a", "2000-01-01 00:00:01") , ("b", "2019-04-17 14:26:19"))
region3 [("b", "2019-04-17 14:26:19") , ("c", "")           )
region4 [("c", "")                , maxIndexValue           )
```

Split Regions for partitioned tables

Splitting Regions for partitioned tables is the same as splitting Regions for ordinary tables. The only difference is that the same split operation is performed for every partition.

- The syntax of even split:

```
SPLIT [PARTITION] TABLE t [PARTITION] [(partition_name_list...)] [INDEX
    ↪  index_name] BETWEEN (lower_value) AND (upper_value) REGIONS
    ↪ region_num
```

- The syntax of uneven split:

```
SPLIT [PARTITION] TABLE table_name [PARTITION (partition_name_list...)]
    ↪  [INDEX index_name] BY (value_list) [, (value_list)] ...
```

Examples of Split Regions for partitioned tables

1. Create a partitioned table `t`. Suppose that you want to create a Hash table divided into two partitions. The example statement is as follows:

```
CREATE TABLE t (a INT, b INT, INDEX idx(a)) PARTITION BY HASH(a)
    ↪ PARTITIONS 2;
```

After creating the table `t`, a Region is split for each partition. Use the `SHOW TABLE ↪ REGIONS` syntax to view the Regions of this table:

```
SHOW TABLE t REGIONS;
```

```
+--
    ↪ --------+----------+--------+----------+----------------+------------
    ↪
| REGION_ID | START_KEY | END_KEY | LEADER_ID | LEADER_STORE_ID | PEERS
    ↪   | SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB
    ↪ ) | APPROXIMATE_KEYS |
+--
    ↪ --------+----------+--------+----------+----------------+------------
    ↪
| 1978     | t_1400_  | t_1401_ | 1979    | 4              | 1979, 1980,
    ↪ 1981 | 0       | 0            | 0         | 1                    | 0
    ↪                |
| 6        | t_1401_  |         | 17       | 4              | 17, 18, 21
    ↪      | 0         | 223          | 0         | 1                    | 0
    ↪                |
+--
    ↪ --------+----------+--------+----------+----------------+------------
    ↪
```

2. Use the `SPLIT` syntax to split a Region for each partition. Suppose that you want to split the data in the `[0,10000]` range of each partition into four Regions. The example statement is as follows:

```
split partition table t between (0) and (10000) regions 4;
```

In the above statement, `0` and `10000` respectively represent the `row_id` of the upper and lower boundaries corresponding to the hotspot data you want to scatter.

> **Note:**
>
> This example only applies to scenarios where hotspot data is evenly distributed. If the hotspot data is unevenly distributed in a specified data range, refer to the syntax of uneven split in Split Regions for partitioned tables.

3. Use the `SHOW TABLE REGIONS` syntax to view the Regions of this table again. You can see that this table now has ten Regions, each partition with five Regions, four of which are the row data and one is the index data.

```
SHOW TABLE t REGIONS;
```

```
+--
    ↪ --------+--------------+--------------+----------+-----------------+---
    ↪
```

```
| REGION_ID | START_KEY  | END_KEY     | LEADER_ID | LEADER_STORE_ID |
   ↪ PEERS      | SCATTERING | WRITTEN_BYTES | READ_BYTES |
   ↪ APPROXIMATE_SIZE(MB) | APPROXIMATE_KEYS |
+--
   ↪ --------+--------------+--------------+----------+-----------------+---
   ↪
| 1998     | t_1400_r     | t_1400_r_2500 | 2001   | 5               |
   ↪ 2000, 2001, 2015 | 0      | 132          | 0         | 1
   ↪                  | 0              |
| 2006     | t_1400_r_2500 | t_1400_r_5000 | 2016 | 1               |
   ↪ 2007, 2016, 2017 | 0      | 35           | 0         | 1
   ↪                  | 0              |
| 2010     | t_1400_r_5000 | t_1400_r_7500 | 2012 | 2               |
   ↪ 2011, 2012, 2013 | 0      | 35           | 0         | 1
   ↪                  | 0              |
| 1978     | t_1400_r_7500 | t_1401_    | 1979     | 4               |
   ↪ 1979, 1980, 1981 | 0      | 621          | 0         | 1

+--
   ↪ --------+--------------+--------------+----------+-----------------+---
   ↪
```

4. You can also split Regions for the index of each partition. For example, you can split the `[1000,10000]` range of the `idx` index into two Regions. The example statement is as follows:

```
SPLIT PARTITION TABLE t INDEX idx BETWEEN (1000) AND (10000) REGIONS
```

```
    ↪ 2;
```

Examples of Split Region for a single partition

You can specify the partition to be split.

1. Create a partitioned table. Suppose that you want to create a Range partitioned table split into three partitions. The example statement is as follows:

```
CREATE TABLE t ( a INT, b INT, INDEX idx(b)) PARTITION BY RANGE( a ) (
    PARTITION p1 VALUES LESS THAN (10000),
    PARTITION p2 VALUES LESS THAN (20000),
    PARTITION p3 VALUES LESS THAN (MAXVALUE) );
```

2. Suppose that you want to split the data in the `[0,10000]` range of the `p1` partition into two Regions. The example statement is as follows:

```
SPLIT PARTITION TABLE t PARTITION (p1) BETWEEN (0) AND (10000) REGIONS
    ↪  2;
```

3. Suppose that you want to split the data in the `[10000,20000]` range of the `p2` partition into two Regions. The example statement is as follows:

```
SPLIT PARTITION TABLE t PARTITION (p2) BETWEEN (10000) AND (20000)
    ↪ REGIONS 2;
```

4. You can use the `SHOW TABLE REGIONS` syntax to view the Regions of this table:

```
SHOW TABLE t REGIONS;
```

```
+--
    ↪ ---------+---------------+---------------+----------+-----------------+-
    ↪
| REGION_ID | START_KEY   | END_KEY       | LEADER_ID | LEADER_STORE_ID |
    ↪  PEERS       | SCATTERING | WRITTEN_BYTES | READ_BYTES |
    ↪ APPROXIMATE_SIZE(MB) | APPROXIMATE_KEYS |
+--
    ↪ ---------+---------------+---------------+----------+-----------------+-
    ↪
| 2040     | t_1406_       | t_1406_r_5000 | 2045    | 3             |
    ↪ 2043, 2045, 2044 | 0       | 0            | 0         | 1
    ↪                  | 0              |
| 2032     | t_1406_r_5000 | t_1407_      | 2033     | 4             |
    ↪ 2033, 2034, 2035 | 0       | 0            | 0         | 1
    ↪                  | 0              |
```

```
| 2046     | t_1407_       | t_1407_r_15000 | 2048   | 2              |
    ↪ 2047, 2048, 2050 | 0       | 35           | 0         | 1
    ↪                  | 0              |
| 2036     | t_1407_r_15000 | t_1408_     | 2037     | 4              |
    ↪ 2037, 2038, 2039 | 0       | 0            | 0         | 1
    ↪                  | 0              |
| 6        | t_1408_       |               | 17       | 4              |
    ↪ 17, 18, 21     | 0         | 214          | 0         | 1
    ↪                  | 0              |
+--
    ↪ ---------+----------------+----------------+----------+--------------------+-
    ↪
```

5. Suppose that you want to split the `[0,20000]` range of the `idx` index of the `p1` and `p2` partitions into two Regions. The example statement is as follows:

```
SPLIT PARTITION TABLE t PARTITION (p1,p2) INDEX idx BETWEEN (0) AND
    ↪ (20000) REGIONS 2;
```

14.13.2.136.3 pre_split_regions

When creating a table with the `AUTO_RANDOM` or `SHARD_ROW_ID_BITS` attribute, you can also specify the `PRE_SPLIT_REGIONS` option if you want to evenly pre-split the table into Regions immediately after the table is created. The number of pre-split Regions for a table is `2^(PRE_SPLIT_REGIONS)`.

> **Note:**
>
> The value of `PRE_SPLIT_REGIONS` must be less than or equal to that of `SHARD_ROW_ID_BITS` or `AUTO_RANDOM`.

The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`. This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to `global`, then TiDB scatters the Regions of newly created tables according to the data distribution of the entire cluster. Otherwise, TiDB writes the data before the scattering is completed, which will have a significant impact on write performance.

Examples of pre_split_regions

```
CREATE TABLE t (a INT, b INT, INDEX idx1(a)) SHARD_ROW_ID_BITS = 4 PRE_
    ↪ SPLIT_REGIONS=2;
```

After building the table, this statement splits `4 + 1` Regions for table t. `4 (2^2)` Regions are used to save table row data, and 1 Region is for saving the index data of `idx1`.

The ranges of the 4 table Regions are as follows:

```
region1:  [ -inf     ,  1<<61 )
region2:  [ 1<<61    ,  2<<61 )
region3:  [ 2<<61    ,  3<<61 )
region4:  [ 3<<61    ,  +inf  )
```

Note:

The Region split by the Split Region statement is controlled by the Region merge scheduler in PD. To avoid PD re-merging the newly split Region soon after, you need to use table attributes or dynamically modify configuration items related to the Region merge feature.

14.13.2.136.4 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.136.5 See also

- SHOW TABLE REGIONS
- Session variables: `tidb_scatter_region`, `tidb_wait_split_region_finish` and `tidb_wait_split_region_timeout`.

14.13.2.137 START TRANSACTION

This statement starts a new transaction inside of TiDB. It is similar to the statement `BEGIN`.

In the absence of a `START TRANSACTION` statement, every statement will by default autocommit in its own transaction. This behavior ensures MySQL compatibility.

14.13.2.137.1 Synopsis

BeginTransactionStmt:

```
BeginTransactionStmt ::=
    'BEGIN' ( 'PESSIMISTIC' | 'OPTIMISTIC' )?
|   'START' 'TRANSACTION' ( 'READ' ( 'WRITE' | 'ONLY' ( ( 'WITH' 'TIMESTAMP'
    ↪  'BOUND' TimestampBound )? | AsOfClause ) ) | 'WITH' 'CONSISTENT' '
    ↪ SNAPSHOT' | 'WITH' 'CAUSAL' 'CONSISTENCY' 'ONLY' )?
```

```
AsOfClause ::=
    ( 'AS' 'OF' 'TIMESTAMP' Expression)
```

14.13.2.137.2 Examples

```
mysql> CREATE TABLE t1 (a int NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.12 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT;
Query OK, 0 rows affected (0.01 sec)
```

14.13.2.137.3 MySQL compatibility

- `START TRANSACTION` immediately starts a transaction inside TiDB. This differs from MySQL, where `START TRANSACTION` lazily creates a transaction. But `START TRANSACTION` in TiDB is equivalent to MySQL's `START TRANSACTION WITH CONSISTENT SNAPSHOT`.
- The statement `START TRANSACTION READ ONLY` is parsed for compatibility with MySQL, but still allows write operations.

14.13.2.137.4 See also

- COMMIT
- ROLLBACK
- BEGIN
- START TRANSACTION WITH CAUSAL CONSISTENCY ONLY

14.13.2.138 TABLE

The `TABLE` statement can be used instead of `SELECT * FROM` when no aggregation or complex filtering is needed.

14.13.2.138.1 Synopsis

```
TableStmt ::=
    "TABLE" Table ( "ORDER BY" Column )? ( "LIMIT" NUM )?
```

14.13.2.138.2 Examples

Create table `t1`:

```
CREATE TABLE t1(id INT PRIMARY KEY);
```

Insert some data into `t1`:

```
INSERT INTO t1 VALUES (1),(2),(3);
```

View the data in table `t1`:

```
TABLE t1;
```

```
+----+
| id |
+----+
|  1 |
|  2 |
|  3 |
+----+
3 rows in set (0.01 sec)
```

Query `t1` and sort the result by the `id` field in descending order:

```
TABLE t1 ORDER BY id DESC;
```

```
+----+
| id |
+----+
|  3 |
|  2 |
|  1 |
+----+
3 rows in set (0.01 sec)
```

Query the first record in `t1`:

```
TABLE t1 LIMIT 1;
```

```
+----+
| id |
+----+
|  1 |
+----+
1 row in set (0.01 sec)
```

14.13.2.138.3 MySQL compatibility

The `TABLE` statement was introduced in MySQL 8.0.19.

- TABLE statements in MySQL

14.13.2.139 TRACE

The `TRACE` statement provides detailed information about query execution. It is intended to be viewed through a Graphical interface exposed by the TiDB server's status port.

14.13.2.139.1 Synopsis

```
TraceStmt ::=
    "TRACE" ( "FORMAT" "=" stringLit )? TracableStmt

TracableStmt ::=
    ( SelectStmt | DeleteFromStmt | UpdateStmt | InsertIntoStmt |
        ↪ ReplaceIntoStmt | UnionStmt | LoadDataStmt | BeginTransactionStmt
        ↪ | CommitStmt | RollbackStmt | SetStmt )
```

Format	Description
row	Output in a tree format
json	Structured output in JSON format
log	Log based output

14.13.2.139.2 Examples

14.13.2.139.4 See also

- EXPLAIN ANALYZE

14.13.2.140 TRUNCATE

The `TRUNCATE` statement removes all data from the table in a non-transactional way. `TRUNCATE` can be thought of as semantically the same as `DROP TABLE` + `CREATE TABLE` with the previous definition.

Both `TRUNCATE TABLE tableName` and `TRUNCATE tableName` are valid syntax.

14.13.2.140.1 Synopsis

```
TruncateTableStmt ::=
    "TRUNCATE" ( "TABLE" )? TableName

TableName ::=
    (Identifier ".")? Identifier
```

14.13.2.140.2 Examples

```
mysql> CREATE TABLE t1 (a INT NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+---+
5 rows in set (0.00 sec)

mysql> TRUNCATE t1;
Query OK, 0 rows affected (0.11 sec)

mysql> SELECT * FROM t1;
Empty set (0.00 sec)

mysql> INSERT INTO t1 VALUES (1),(2),(3),(4),(5);
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

mysql> TRUNCATE TABLE t1;
Query OK, 0 rows affected (0.11 sec)
```

14.13.2.140.3 MySQL compatibility

The `TRUNCATE` statement in TiDB is fully compatible with MySQL. If you find any compatibility differences, report a bug.

14.13.2.140.4 See also

- DELETE
- CREATE TABLE
- SHOW CREATE TABLE

14.13.2.141 UNLOCK STATS

`UNLOCK STATS` is used to unlock the statistics of a table or tables.

14.13.2.141.1 Synopsis

```
UnlockStatsStmt ::=
    'UNLOCK' 'STATS' (TableNameList | TableName 'PARTITION'
       ↪ PartitionNameList)

TableNameList ::=
    TableName (',' TableName)*

TableName ::=
    Identifier ( '.' Identifier )?

PartitionNameList ::=
    Identifier ( ',' Identifier )*
```

14.13.2.141.2 Examples

Refer to the examples in LOCK STATS and create a table `t` and lock its statistics.

Unlock the statistics of table `t`, and `ANALYZE` can be successfully executed.

```
mysql> UNLOCK STATS t;
Query OK, 0 rows affected (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.03 sec)

mysql> SHOW WARNINGS;
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Level | Code | Message
   ↪
   ↪ |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
   ↪ sample-rate=1" |
+--
   ↪ -----+------+-----------------------------------------------------------------
   ↪
```

```
1 row in set (0.00 sec)
```

Refer to examples in LOCK STATS and create a table `t` and lock the statistics of its partition `p1`.

Unlock the statistics of partition `p1`, and `ANALYZE` can be successfully executed.

```
mysql> UNLOCK STATS t PARTITION p1;
Query OK, 0 rows affected (0.00 sec)

mysql> ANALYZE TABLE t PARTITION p1;
Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t's partition p1, reason to use this rate is "TiDB assumes that
    ↪ the table is empty, use sample-rate=1" |
+-------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.2.141.3 MySQL compatibility

This statement is a TiDB extension to MySQL syntax.

14.13.2.142 UPDATE

The `UPDATE` statement is used to modify data in a specified table.

14.13.2.142.1 Synopsis

```
UpdateStmt ::=
    "UPDATE" UpdateOption
(   TableRef "SET" Assignment ("," Assignment)* WhereClause? OrderBy? Limit?
|   TableRefs "SET" Assignment ("," Assignment)* WhereClause?
)

UpdateOption ::=
    OptimizerHints? ("LOW_PRIORITY" | "HIGH_PRIORITY" | "DELAYED")? "IGNORE
        ↪ "?

TableRef ::=
    ( TableFactor | JoinTable )

TableRefs ::=
    EscapedTableRef ("," EscapedTableRef)*
```

> **Note:**
>
> Starting from v6.6.0, TiDB supports Resource Control. You can use this feature to execute SQL statements with different priorities in different resource groups. By configuring proper quotas and priorities for these resource groups, you can gain better scheduling control for SQL statements with different priorities. When resource control is enabled, statement priority (`LOW_PRIORITY` and `HIGH_PRIORITY`) will no longer take effect. It is recommended that you use Resource Control to manage resource usage for different SQL statements.

14.13.2.142.2 Examples

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY AUTO_INCREMENT, c1 INT
    ↪ NOT NULL);
Query OK, 0 rows affected (0.11 sec)

mysql> INSERT INTO t1 (c1) VALUES (1), (2), (3);
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
```

```
|  1 |  1 |
|  2 |  2 |
|  3 |  3 |
+----+----+
3 rows in set (0.00 sec)

mysql> UPDATE t1 SET c1=5 WHERE c1=3;
Query OK, 1 row affected (0.01 sec)
Rows matched: 1 Changed: 1 Warnings: 0

mysql> SELECT * FROM t1;
+----+----+
| id | c1 |
+----+----+
|  1 |  1 |
|  2 |  2 |
|  3 |  5 |
+----+----+
3 rows in set (0.00 sec)
```

14.13.2.142.3 MySQL compatibility

TiDB always uses the original value of a column when evaluating expressions. For example:

```
CREATE TABLE t (a int, b int);
INSERT INTO t VALUES (1,2);
UPDATE t SET a = a+1,b=a;
```

In MySQL, the column `b` is updated to 2 because it is set to the value of `a`, and the value of `a` (which is 1) is updated to `a+1` (which is 2) in the same statement.

TiDB follows the more standard SQL behavior, and updates `b` to 1.

- CREATE DATABASE
- SHOW TABLES

14.13.2.144 WITH

A Common Table Expression (CTE) is a temporary result set that can be referred multiple times within a SQL statement to improve the statement's readability and execution efficiency. You can apply the `WITH` statement to use Common Table Expressions.

14.13.2.144.1 Synopsis

WithClause:

```
WithClause ::=
        "WITH" WithList
|       "WITH" "RECURSIVE" WithList
```

WithList:

```
WithList ::=
        WithList ',' CommonTableExpr
|       CommonTableExpr
```

CommonTableExpr:

```
CommonTableExpr ::=
       Identifier IdentListWithParenOpt "AS" SubSelect
```

IdentListWithParenOpt:

```
IdentListWithParenOpt ::=
( '(' IdentList ')' )?
```

14.13.2.144.2 Examples

Non-recursive CTE:

```
WITH cte AS (SELECT 1, 2) SELECT * FROM cte t1, cte t2;
```

```
+---+---+---+---+
| 1 | 2 | 1 | 2 |
+---+---+---+---+
| 1 | 2 | 1 | 2 |
+---+---+---+---+
1 row in set (0.00 sec)
```

Recursive CTE:

```
WITH RECURSIVE cte(a) AS (SELECT 1 UNION SELECT a+1 FROM cte WHERE a < 5)
    ↪ SELECT * FROM cte;
```

```
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+---+
5 rows in set (0.00 sec)
```

14.13.2.144.3 MySQL compatibility

- In strict mode, when the data length recursively calculated exceeds the data length of the seed part, TiDB returns a warning while MySQL returns an error. In non-strict mode, the behavior of TiDB is consistent with that of MySQL.

- The data type for recursive CTE is determined by the seed part. The data type of the seed part is not completely consistent with MySQL in some cases (such as functions).
- In the case of multiple `UNION` / `UNION ALL` operators, MySQL does not allow `UNION` to be followed by `UNION ALL`, but TiDB does.
- If there is a problem with the definition of a CTE, TiDB will report an error, while MySQL will not if the CTE is not referred.

- REPLACE

14.13.3 Data Types

14.13.3.1 Data Types

TiDB supports all the data types in MySQL except the `SPATIAL` type. This includes all the numeric types, string types, date & time types, and the JSON type.

The definitions used for datatypes are specified as `T(M[, D])`. Where by:

- `T` indicates the specific data type.
- `M` indicates the maximum display width for integer types. For floating-point and fixed-point types, `M` is the total number of digits that can be stored (the precision). For string types, `M` is the maximum length. The maximum permissible value of M depends on the data type.

> **Warning:**
>
> Starting from v8.5.0, integer display width is deprecated (`deprecate-integer-display-length` is `true` by default). Specifying display width for integer types is NOT recommended.

- `D` applies to floating-point and fixed-point types and indicates the number of digits following the decimal point (the scale).
- `fsp` applies to the `TIME`, `DATETIME`, and `TIMESTAMP` types and represents the fractional seconds precision. The `fsp` value, if given, must be in the range 0 to 6. A value of 0 signifies that there is no fractional part. If omitted, the default precision is 0.

14.13.3.2 Default Values

The DEFAULT value clause in a data type specification indicates a default value for a column.

You can set default values for all data types. Typically, default values must be constants and cannot be functions or expressions, but there are some exceptions:

- For time types, you can use NOW, CURRENT_TIMESTAMP, LOCALTIME, and LOCALTIMESTAMP ↪ functions as default values for TIMESTAMP and DATETIME columns.
- For integer types, you can use the NEXT VALUE FOR function to set the next value of a sequence as the default value for a column, and use the RAND() function to generate a random floating-point value as the default value for a column.
- For string types, you can use the UUID() function to generate a universally unique identifier (UUID) as the default value for a column.
- For binary types, you can use the UUID_TO_BIN() function to convert a UUID to the binary format and set the converted value as the default value for a column.
- Starting from v8.0.0, TiDB additionally supports specifying the default values for BLOB ↪ , TEXT, and JSON data types, but you can only use expressions to set the default values for them.

If a column definition includes no explicit DEFAULT value, TiDB determines the default value as follows:

- If the column can take NULL as a value, the column is defined with an explicit DEFAULT ↪ NULL clause.
- If the column cannot take NULL as the value, TiDB defines the column with no explicit DEFAULT clause.

For data entry into a NOT NULL column that has no explicit DEFAULT clause, if an INSERT or REPLACE statement includes no value for the column, TiDB handles the column according to the SQL mode in effect at the time:

- If strict SQL mode is enabled, an error occurs for transactional tables, and the statement is rolled back. For nontransactional tables, an error occurs.
- If strict mode is not enabled, TiDB sets the column to the implicit default value for the column data type.

Implicit defaults are defined as follows:

- For numeric types, the default is 0. If declared with the AUTO_INCREMENT attribute, the default is the next value in the sequence.
- For date and time types other than TIMESTAMP, the default is the appropriate "zero" value for the type. For TIMESTAMP, the default value is the current date and time.
- For string types other than ENUM, the default value is the empty string. For ENUM, the default is the first enumeration value.

14.13.3.2.1 Specify expressions as default values

Starting from 8.0.13, MySQL supports specifying expressions as default values in the `DEFAULT` clause. For more information, see Explicit default handling as of MySQL 8.0.13.

TiDB supports specifying the following expressions as default values in the `DEFAULT` clause.

- `UPPER(SUBSTRING_INDEX(USER(), '@', 1))`
- `REPLACE(UPPER(UUID()), '-', '')`
- `DATE_FORMAT` expressions in the following formats:
  - `DATE_FORMAT(NOW(), '%Y-%m')`
  - `DATE_FORMAT(NOW(), '%Y-%m-%d')`
  - `DATE_FORMAT(NOW(), '%Y-%m-%d %H.%i.%s')`
  - `DATE_FORMAT(NOW(), '%Y-%m-%d %H:%i:%s')`
- `STR_TO_DATE('1980-01-01', '%Y-%m-%d')`
- `CURRENT_TIMESTAMP()`, `CURRENT_DATE()`: both use the default fractional seconds precision (fsp)
- `JSON_OBJECT()`, `JSON_ARRAY()`, `JSON_QUOTE()`
- `NEXTVAL()`
- `RAND()`
- `UUID()`, `UUID_TO_BIN()`
- `VEC_FROM_TEXT()`

TiDB supports assigning default values to `BLOB`, `TEXT`, and `JSON` data types. However, you can only use expressions, not literals, to define default values for these data types. The following is an example of `BLOB`:

```
CREATE TABLE t2 (
  b BLOB DEFAULT (RAND())
);
```

An example for using a UUID:

```
CREATE TABLE t3 (
  uuid BINARY(16) DEFAULT (UUID_TO_BIN(UUID())),
  name VARCHAR(255)
);
```

For more information on how to use UUID, see UUID best practices.

An example for using `JSON`:

```
CREATE TABLE t4 (
  id bigint AUTO_RANDOM PRIMARY KEY,
  j json DEFAULT (JSON_OBJECT("a", 1, "b", 2))
);
```

An example for what is not allowed for `JSON`:

```
CREATE TABLE t5 (
  id bigint AUTO_RANDOM PRIMARY KEY,
  j json DEFAULT ('{"a": 1, "b": 2}')
);
```

The last two examples show similar defaults, but only the first one is valid because it uses an expression rather than a literal.

14.13.3.3 Numeric Types

TiDB supports all the MySQL numeric types, including:

- Integer Types (Exact Value)
- Floating-Point Types (Approximate Value)
- Fixed-Point Types (Exact Value)

14.13.3.3.1 Integer types

TiDB supports all the MySQL integer types, including `INTEGER/INT`, `TINYINT`, `SMALLINT` ↪ , `MEDIUMINT`, and `BIGINT`. For more information, see Integer Data Type Syntax in MySQL.

The following table summarizes field descriptions:

> **Warning:**
>
> Starting from v8.5.0, integer display width is deprecated (`deprecate-` ↪ `integer-display-length` is `true` by default). Specifying display width for integer types is NOT recommended.

Syntax Element	Description
M	the display width of the type. Optional.
UNSIGNED	UNSIGNED. If omitted, it is SIGNED.
ZEROFILL	If you specify ZEROFILL for a numeric column, TiDB automatically adds the UNSIGNED attribute to the column.

The following table summarizes the required storage and range for integer types supported by TiDB:

Data Type	Storage Required (bytes)	Minimum Value (signed/unsigned)	Maximum value (signed/unsigned)
`TINYINT`	1	-128 / 0	127 / 255
`SMALLINT`	2	-32768 / 0	32767 / 65535
`MEDIUMINT`	3	-8388608 / 0	8388607 / 16777215
`INT`	4	-2147483648 / 0	2147483647 / 4294967295
`BIGINT`	8	-9223372036854775808 / 0	9223372036854775807 / 18446744073709551615

`BIT` type

The BIT data type. A type of BIT(M) enables the storage of M-bit values. M can range from 1 to 64, with the default value of 1:

```
BIT[(M)]
```

`BOOLEAN` type

The `BOOLEAN` type and its alias `BOOL` are equivalent to `TINYINT(1)`. If the value is `0`, it is considered as `False`; otherwise, it is considered `True`. As in MySQL, `True` is `1` and `False` is `0`:

```
BOOLEAN
```

`TINYINT` type

The `TINYINT` data type stores signed values of range [-128, 127] and unsigned values of range [0, 255]:

```
TINYINT[(M)] [UNSIGNED] [ZEROFILL]
```

`SMALLINT` type

The `SMALLINT` data type stores signed values of range [-32768, 32767], and unsigned values of range [0, 65535]:

```
SMALLINT[(M)] [UNSIGNED] [ZEROFILL]
```

`MEDIUMINT` type

The `MEDIUMINT` data type stores signed values of range [-8388608, 8388607], and unsigned values of range [0, 16777215]:

```
MEDIUMINT[(M)] [UNSIGNED] [ZEROFILL]
```

`INTEGER` type

The `INTEGER` type and its alias `INT` stores signed values of range [-2147483648, 2147483647], and unsigned values of range [0, 4294967295]:

```
INT[(M)] [UNSIGNED] [ZEROFILL]
```

You can also use another form:

```
INTEGER[(M)] [UNSIGNED] [ZEROFILL]
```

`BIGINT` type

The `BIGINT` data type stores signed values of range [-9223372036854775808, 9223372036854775807], and unsigned values of range [0, 18446744073709551615]:

```
BIGINT[(M)] [UNSIGNED] [ZEROFILL]
```

14.13.3.3.2 Floating-point types

TiDB supports all the MySQL floating-point types, including `FLOAT`, and `DOUBLE`. For more information, see Floating-Point Types (Approximate Value) - FLOAT, DOUBLE in MySQL.

The following table summarizes field descriptions:

Syntax Element	Description
M	the total number of digits
D	the number of digits following the decimal point
UNSIGNED	UNSIGNED. If omitted, it is SIGNED.
ZEROFILL	If you specify ZEROFILL for a numeric column, TiDB automatically adds the UNSIGNED attribute to the column.

The following table summarizes the required storage for floating-point types supported by TiDB:

Data Type	Storage Required (bytes)
`FLOAT`	4
`FLOAT(p)`	If 0 <= p <= 24, it is 4; if 25 <= p <= 53, it is 8
`DOUBLE`	8

`FLOAT` type

The `FLOAT` type stores a single-precision floating-point number. Permissible values are -3.402823466E+38 to -1.175494351E-38, 0, and 1.175494351E-38 to 3.402823466E+38. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

`FLOAT(p)` can be used to represent the required precision in bits. TiDB uses this value only to determine whether to use `FLOAT` or `DOUBLE` for the resulting data type. If p is from 0 to 24, the data type becomes FLOAT with no M or D values. If p is from 25 to 53, the data type becomes `DOUBLE` with no M or D values. The range of the resulting column is the same as for the single-precision `FLOAT` or double-precision `DOUBLE` data type.

```
FLOAT[(M,D)] [UNSIGNED] [ZEROFILL]
FLOAT(p) [UNSIGNED] [ZEROFILL]
```

Note:

As in MySQL, the `FLOAT` data type stores approximate values. For values such as currency, it is recommended to use the `DECIMAL` type instead.

In TiDB, the default precision of the `FLOAT` data type is 8 digits, but in MySQL, the default precision is 6 digits. For example, assuming that you insert `123456789` and `1.23456789` into columns of the `FLOAT` type in both TiDB and MySQL, when you query the corresponding values in MySQL, you get `123457000` and `1.23457`, while in TiDB, you get `123456790` and `1.2345679`.

`DOUBLE` type

The `DOUBLE` type, and its alias `DOUBLE PRECISION` stores a double-precision floating-point number. Permissible values are -1.7976931348623157E+308 to -2.2250738585072014E-308, 0, and 2.2250738585072014E-308 to 1.7976931348623157E+308. These are the theoretical limits, based on the IEEE standard. The actual range might be slightly smaller depending on your hardware or operating system.

```
DOUBLE[(M,D)] [UNSIGNED] [ZEROFILL]
DOUBLE PRECISION [(M,D)] [UNSIGNED] [ZEROFILL], REAL[(M,D)] [UNSIGNED] [
    ↪ ZEROFILL]
```

Warning:

As in MySQL, the `DOUBLE` data type stores approximate values. For values such as currency, it is recommended to use the `DECIMAL` type instead.

Note:

When TiDB converts a double-precision floating-point number represented in scientific notation to the `CHAR` type, the result is displayed inconsistently with that in MySQL. See Cast functions and operators for details.

14.13.3.3.3 Fixed-point types

TiDB supports all the MySQL floating-point types, including DECIMAL, and NUMERIC. For more information, Fixed-Point Types (Exact Value) - DECIMAL, NUMERIC in MySQL.

The meaning of the fields:

Syntax Element	Description
M	the total number of decimal digits
D	the number of digits after the decimal point
UNSIGNED	UNSIGNED. If omitted, it is SIGNED.
ZEROFILL	If you specify ZEROFILL for a numeric column, TiDB automatically adds the UNSIGNED attribute to the column.

`DECIMAL` type

`DECIMAL` and its alias `NUMERIC` store a packed "exact" fixed-point number. M is the total number of decimal digits (the precision), and D is the number of digits after the decimal point (the scale). The decimal point and (for negative numbers) the - sign are not counted in M. If D is 0, values have no decimal point or fractional part. The maximum number of digits (M) for DECIMAL is 65. The maximum number of supported decimals (D) is 30. If

D is omitted, the default is 0. If M is omitted, the default is 10.

```
DECIMAL[(M[,D])] [UNSIGNED] [ZEROFILL]
NUMERIC[(M[,D])] [UNSIGNED] [ZEROFILL]
```

14.13.3.4 Date and Time Types

TiDB supports all MySQL date and time data types to store temporal values: `DATE`, `TIME`, `DATETIME`, `TIMESTAMP`, and `YEAR`. For more information, see Date and Time Data Types in MySQL.

Each of these types has its range of valid values, and uses a zero value to indicate that it is an invalid value. In addition, the `TIMESTAMP` and `DATETIME` types can automatically generate new time values on modification.

When dealing with date and time value types, note:

- Although TiDB tries to interpret different formats, the date-portion must be in the format of year-month-day (for example, '1998-09-04'), rather than month-day-year or day-month-year.
- If the year-portion of a date is specified as 2 digits, TiDB converts it based on specific rules.
- If a numeric value is needed in the context, TiDB automatically converts the date or time value into a numeric type. For example:

```
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+---------------------+---------------+--------------------+
| NOW()               | NOW()+0       | NOW(3)+0           |
+---------------------+---------------+--------------------+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+---------------------+---------------+--------------------+
```

- TiDB might automatically convert invalid values or values beyond the supported range to a zero value of that type. This behavior is dependent on the SQL Mode set. For example:

```
mysql> show create table t1;
+--
   ↪ -----+-----------------------------------------------------------------
   ↪
| Table | Create Table
   ↪
   ↪ |
+--
   ↪ -----+-----------------------------------------------------------------
   ↪
```

```
| t1    | CREATE TABLE `t1` (
  `a` time DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> select @@sql_mode;
+--
    ↪ ----------------------------------------------------------------------
    ↪
| @@sql_mode
    ↪
    ↪ |
+--
    ↪ ----------------------------------------------------------------------
    ↪
| ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,
    ↪ ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_
    ↪ SUBSTITUTION |
+--
    ↪ ----------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)

mysql> insert into t1 values ('2090-11-32:22:33:44');
ERROR 1292 (22007): Truncated incorrect time value: '
    ↪ 2090-11-32:22:33:44'
mysql> set @@sql_mode='';
    ↪
    ↪ Query OK, 0 rows affected (0.01 sec)

mysql> insert into t1 values ('2090-11-32:22:33:44');
Query OK, 1 row affected, 1 warning (0.01 sec)

mysql> select * from t1;
+----------+
| a        |
+----------+
| 00:00:00 |
+----------+
1 row in set (0.01 sec)
```

- Setting different SQL modes can change TiDB behaviors.
- If the SQL mode `NO_ZERO_DATE` is not enabled, TiDB allows month or day in the columns of `DATE` and `DATETIME` to be zero value, for example, '2009-00-00' or '2009-01-00'. If this date type is to be calculated in a function, for example, in `DATE_SUB()` or `DATE_ADD()`, the result can be incorrect.
- By default, TiDB enables the SQL mode `NO_ZERO_DATE`. This mode prevents storing zero values such as '0000-00-00'.

Different types of zero value are shown in the following table:

Date Type	"Zero" Value
DATE	'0000-00-00'
TIME	'00:00:00'
DATETIME	'0000-00-00 00:00:00'
TIMESTAMP	'0000-00-00 00:00:00'
YEAR	0000

Invalid `DATE`, `DATETIME`, `TIMESTAMP` values are automatically converted to the corresponding type of zero value ('0000-00-00' or '0000-00-00 00:00:00') if the SQL mode permits such usage.

14.13.3.4.1 Supported types

`DATE` type

`DATE` only contains date-portion and no time-portion, displayed in `YYYY-MM-DD` format. The supported range is '0000-01-01' to '9999-12-31':

```
DATE
```

`TIME` type

For the `TIME` type, the format is `HH:MM:SS[.fraction]` and valid values range from '-838:59:59.000000' to '838:59:59.000000'. `TIME` is used not only to indicate the time within a day but also to indicate the time interval between 2 events. An optional `fsp` value in the range from 0 to 6 may be given to specify fractional seconds precision. If omitted, the default precision is 0:

```
TIME[(fsp)]
```

Note:

> Pay attention to the abbreviated form of `TIME`. For example, '11:12' means '11:12:00' instead of '00:11:12'. However, '1112' means '00:11:12'. These differences are caused by the presence or absence of the `:` character.

`DATETIME` type

`DATETIME` contains both date-portion and time-portion. Valid values range from '0000-01-01 00:00:00.000000' to '9999-12-31 23:59:59.999999'.

TiDB displays `DATETIME` values in `YYYY-MM-DD HH:MM:SS[.fraction]` format, but permits assignment of values to `DATETIME` columns using either strings or numbers. An optional fsp value in the range from 0 to 6 may be given to specify fractional seconds precision. If omitted, the default precision is 0:

```
DATETIME[(fsp)]
```

`TIMESTAMP` type

`TIMESTAMP` contains both date-portion and time-portion. Valid values range from '1970-01-01 00:00:01.000000' to '2038-01-19 03:14:07.999999' in UTC time. An optional fsp value in the range from 0 to 6 may be given to specify fractional seconds precision. If omitted, the default precision is 0.

In `TIMESTAMP`, zero is not permitted to appear in the month-portion or day-portion. The only exception is zero value itself '0000-00-00 00:00:00'.

```
TIMESTAMP[(fsp)]
```

Timezone Handling

When `TIMESTAMP` is to be stored, TiDB converts the `TIMESTAMP` value from the current time zone to UTC time zone. When `TIMESTAMP` is to be retrieved, TiDB converts the stored `TIMESTAMP` value from UTC time zone to the current time zone (Note: `DATETIME` is not handled in this way). The default time zone for each connection is the server's local time zone, which can be modified by the environment variable `time_zone`.

> **Warning:**
>
> As in MySQL, the `TIMESTAMP` data type suffers from the Year 2038 Problem. For storing values that may span beyond 2038, please consider using the `DATETIME` type instead.

`YEAR` type

The YEAR type is specified in the format 'YYYY'. Supported values range from 1901 to 2155, or the zero value of 0000:

```
YEAR[(4)]
```

YEAR follows the following format rules:

- Four-digit numeral ranges from 1901 to 2155
- Four-digit string ranges from '1901' to '2155'
- One-digit or two-digit numeral ranges from 1 to 99. Accordingly, 1-69 is converted to 2001-2069 and 70-99 is converted to 1970-1999
- One-digit or two-digit string ranges from '0' to '99'
- Value 0 is taken as 0000 whereas the string '0' or '00' is taken as 2000

Invalid YEAR value is automatically converted to 0000 (if users are not using the NO_ZERO
↪ _DATE SQL mode).

14.13.3.4.2 Automatic initialization and update of TIMESTAMP and DATETIME

Columns with TIMESTAMP or DATETIME value type can be automatically initialized or updated to the current time.

For any column with TIMESTAMP or DATETIME value type in the table, you can set the default or auto-update value as current timestamp.

These properties can be set by setting DEFAULT CURRENT_TIMESTAMP and ON UPDATE
↪ CURRENT_TIMESTAMP when the column is being defined. DEFAULT can also be set as a specific value, such as DEFAULT 0 or DEFAULT '2000-01-01 00:00:00'.

```
CREATE TABLE t1 (
    ts TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP,
    dt DATETIME DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_TIMESTAMP
);
```

The default value for DATETIME is NULL unless it is specified as NOT NULL. For the latter situation, if no default value is set, the default value is be 0.

```
CREATE TABLE t1 (
    dt1 DATETIME ON UPDATE CURRENT_TIMESTAMP,   -- default NULL
    dt2 DATETIME NOT NULL ON UPDATE CURRENT_TIMESTAMP -- default 0
);
```

14.13.3.4.3 Decimal part of time value

DATETIME and TIMESTAMP values can contain a fractional part of up to 6 digits which is accurate to microseconds. In any column of DATETIME or TIMESTAMP types, a fractional part is stored instead of being discarded. With a fractional part, the value is in the format of

'YYYY-MM-DD HH:MM:SS[.fraction]', and the fraction ranges from 000000 to 999999. A decimal point must be used to separate the fraction from the rest.

- Use `type_name(fsp)` to define a column that supports fractional precision, where `type_name` can be `TIME`, `DATETIME` or `TIMESTAMP`. For example,

```
CREATE TABLE t1 (t TIME(3), dt DATETIME(6));
```

`fsp` must range from 0 to 6.

`0` means there is no fractional part. If `fsp` is omitted, the default is 0.

- When inserting `TIME`, `DATETIME` or `TIMESTAMP` which contain a fractional part, if the number of digit of the fraction is too few, or too many, rounding might be needed in the situation. For example:

```
mysql> CREATE TABLE fractest( c1 TIME(2), c2 DATETIME(2), c3 TIMESTAMP
    ↪ (2) );
Query OK, 0 rows affected (0.33 sec)

mysql> INSERT INTO fractest VALUES
    > ('17:51:04.777', '2014-09-08 17:51:04.777', '2014-09-08
       ↪ 17:51:04.777');
Query OK, 1 row affected (0.03 sec)

mysql> SELECT * FROM fractest;
+-------------/-----------------------/-----------------------+
| c1          | c2                    | c3                    |
+-------------/-----------------------/-----------------------+
| 17:51:04.78 | 2014-09-08 17:51:04.78 | 2014-09-08 17:51:04.78 |
+-------------/-----------------------/-----------------------+
1 row in set (0.00 sec)
```

14.13.3.4.4 Conversions between date and time types

Sometimes we need to make conversions between date and time types. But some conversions might lead to information loss. For example, `DATE`, `DATETIME` and `TIMESTAMP` values all have their own respective ranges. `TIMESTAMP` should be no earlier than the year 1970 in UTC time or no later than UTC time '2038-01-19 03:14:07'. Based on this rule, '1968-01-01' is a valid date value of `DATE` or `DATETIME`, but becomes 0 when it is converted to `TIMESTAMP`.

The conversions of `DATE`:

- When `DATE` is converted to `DATETIME` or `TIMESTAMP`, a time-portion '00:00:00' is added, because DATE does not contain any time information

- When DATE is converted to TIME, the result is '00:00:00'

Conversions of DATETIME or TIMESTAMP:

- When DATETIME or TIMESTAMP is converted to DATE, the time and fractional part is discarded. For example, '1999-12-31 23:59:59.499' is converted to '1999-12-31'
- When DATETIME or TIMESTAMP is converted to TIME, the date-portion is discarded, because TIME does not contain any date information

When we convert TIME to other time and date formats, the date-portion is automatically specified as CURRENT_DATE(). The final converted result is a date that consists of TIME and CURRENT_DATE(). This is to say that if the value of TIME is beyond the range from '00:00:00' to '23:59:59', the converted date-portion does not indicate the current day.

When TIME is converted to DATE, the process is similar, and the time-portion is discarded.

Using the CAST() function can explicitly convert a value to a DATE type. For example:

```
date_col = CAST(datetime_col AS DATE)
```

Converting TIME and DATETIME to numeric format. For example:

```
mysql> SELECT CURTIME(), CURTIME()+0, CURTIME(3)+0;
+-----------/-------------/--------------+
| CURTIME() | CURTIME()+0 | CURTIME(3)+0 |
+-----------/-------------/--------------+
| 09:28:00 |      92800 |   92800.887 |
+-----------/-------------/--------------+
mysql> SELECT NOW(), NOW()+0, NOW(3)+0;
+---------------------/----------------/--------------------+
| NOW()               | NOW()+0       | NOW(3)+0           |
+---------------------/----------------/--------------------+
| 2012-08-15 09:28:00 | 20120815092800 | 20120815092800.889 |
+---------------------/----------------/--------------------+
```

14.13.3.4.5 Two-digit year-portion contained in the date

The two-digit year-portion contained in date does not explicitly indicate the actual year and is ambiguous.

For DATETIME, DATE and TIMESTAMP types, TiDB follows the following rules to eliminate ambiguity:

- Values between 01 and 69 is converted to a value between 2001 and 2069
- Values between 70 and 99 is converted to a value between 1970 and 1999

These rules also apply to the YEAR type, with one exception:

When numeral 00 is inserted to YEAR(4), the result is 0000 rather than 2000.

If you want the result to be 2000, specify the value to be 2000.

The two-digit year-portion might not be properly calculated in some functions such MIN() and MAX(). For these functions, the four-digit format suites better.

14.13.3.5 String Types

TiDB supports all the MySQL string types, including CHAR, VARCHAR, BINARY, VARBINARY , BLOB, TEXT, ENUM, and SET. For more information, see String Types in MySQL.

14.13.3.5.1 Supported types

CHAR type

CHAR is a fixed length string. M represents the column-length in characters (not bytes). The range of M is 0 to 255. Different from the VARCHAR type, when data is inserted into a CHAR column, the trailing spaces are truncated.

```
[NATIONAL] CHAR[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

VARCHAR type

VARCHAR is a string of variable-length. M represents the maximum column length in characters (not bytes). The maximum size of VARCHAR cannot exceed 65,535 bytes. The maximum row length and the character set being used determine the VARCHAR length.

The space occupied by a single character might differ for different character sets. The following table shows the bytes consumed by a single character, and the range of the VARCHAR column length in each character set:

Character Set	Byte(s) per Character	Range of the Maximum VARCHAR Column Length
ascii	1	(0, 65535]
latin1	1	(0, 65535]
binary	1	(0, 65535]
utf8	3	(0, 21845]
utf8mb4	4	(0, 16383]

```
[NATIONAL] VARCHAR(M) [CHARACTER SET charset_name] [COLLATE collation_name]
```

TEXT type

TEXT is a string of variable-length. The maximum column length is 65,535 bytes. The optional M argument is in characters and is used to automatically select the fittest type of a TEXT column. For example TEXT(60) will yield a TINYTEXT data type that can hold up to 255 bytes, which fits a 60-character UTF-8 string that has up to 4 bytes per character

(4×60=240). Using the M argument is not recommended.

```
TEXT[(M)] [CHARACTER SET charset_name] [COLLATE collation_name]
```

`TINYTEXT` type

The `TINYTEXT` type is similar to the `TEXT` type. The difference is that the maximum column length of `TINYTEXT` is 255.

```
TINYTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

`MEDIUMTEXT` type

The `MEDIUMTEXT` type is similar to the `TEXT` type. The difference is that the maximum column length of `MEDIUMTEXT` is 16,777,215. But due to the limitation of `txn-entry-size-limit`, the maximum storage size of a single row in TiDB is 6 MiB by default and can be increased to 120 MiB by changing the configuration.

```
MEDIUMTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

`LONGTEXT` type

The `LONGTEXT` type is similar to the `TEXT` type. The difference is that the maximum column length of `LONGTEXT` is 4,294,967,295. But due to the limitation of `txn-entry-size-limit`, the maximum storage size of a single row in TiDB is 6 MiB by default and can be increased to 120 MiB by changing the configuration.

```
LONGTEXT [CHARACTER SET charset_name] [COLLATE collation_name]
```

`BINARY` type

The `BINARY` type is similar to the `CHAR` type. The difference is that `BINARY` stores binary byte strings.

```
BINARY(M)
```

`VARBINARY` type

The `VARBINARY` type is similar to the `VARCHAR` type. The difference is that the `VARBINARY` stores binary byte strings.

```
VARBINARY(M)
```

`BLOB` type

`BLOB` is a large binary file. M represents the maximum column length in bytes, ranging from 0 to 65,535.

```
BLOB[(M)]
```

`TINYBLOB` type

The `TINYBLOB` type is similar to the `BLOB` type. The difference is that the maximum column length of `TINYBLOB` is 255.

```
TINYBLOB
```

`MEDIUMBLOB` type

The `MEDIUMBLOB` type is similar to the BLOB type. The difference is that the maximum column length of `MEDIUMBLOB` is 16,777,215. But due to the limitation of `txn-entry-size-limit`, the maximum storage size of a single row in TiDB is 6 MiB by default and can be increased to 120 MiB by changing the configuration.

```
MEDIUMBLOB
```

`LONGBLOB` type

The `LONGBLOB` type is similar to the BLOB type. The difference is that the maximum column length of `LONGBLOB` is 4,294,967,295. But due to the limitation of `txn-entry-size-limit`, the maximum storage size of a single row in TiDB is 6 MiB by default and can be increased to 120 MiB by changing the configuration.

```
LONGBLOB
```

`ENUM` type

An `ENUM` is a string object with a value chosen from a list of permitted values that are enumerated explicitly in the column specification when the table is created. The syntax is:

```
ENUM('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_name]

#### For example:
ENUM('apple', 'orange', 'pear')
```

The value of the `ENUM` data type is stored as numbers. Each value is converted to a number according the definition order. In the previous example, each string is mapped to a number:

Value	Number
NULL	NULL
”	0
‘apple’	1
‘orange’	2
‘pear’	3

For more information, see the ENUM type in MySQL.

`SET` type

A `SET` is a string object that can have zero or more values, each of which must be chosen from a list of permitted values specified when the table is created. The syntax is:

```
SET('value1','value2',...) [CHARACTER SET charset_name] [COLLATE collation_
    ↪ name]

#### For example:
SET('1', '2') NOT NULL
```

In the example, any of the following values can be valid:

```
''
'1'
'2'
'1,2'
```

In TiDB, the values of the `SET` type is internally converted to `Int64`. The existence of each element is represented using a binary: 0 or 1. For a column specified as `SET('a','b ↪ ','c','d')`, the members have the following decimal and binary values.

Member	Decimal Value	Binary Value
'a'	1	0001
'b'	2	0010
'c'	4	0100
'd'	8	1000

In this case, for an element of `('a', 'c')`, it is `0101` in binary.

For more information, see the SET type in MySQL.

14.13.3.6 JSON Data Type

TiDB supports the `JSON` (JavaScript Object Notation) data type, which is useful for storing semi-structured data. The `JSON` data type provides the following advantages over storing `JSON`-format strings in a string column:

- Use the Binary format for serialization. The internal format permits quick read access to `JSON` document elements.
- Automatic validation of the JSON documents stored in `JSON` columns. Only valid documents can be stored.

`JSON` columns, like columns of other binary types, are not indexed directly, but you can index the fields in the `JSON` document in the form of generated column:

```
CREATE TABLE city (
    id INT PRIMARY KEY,
    detail JSON,
```

```
    population INT AS (JSON_EXTRACT(detail, '$.population')),
    index index_name (population)
    );
INSERT INTO city (id,detail) VALUES (1, '{"name": "Beijing", "population":
    ↪ 100}');
SELECT id FROM city WHERE population >= 100;
```

For more information, see JSON Functions and Generated Columns.

14.13.3.6.1 JSON value types

The values inside a JSON document have types. This is visible in the output of JSON_ ↪ TYPE().

Type	Example
ARRAY	`[]`
BIT	
BLOB	`0x616263`
BOOLEAN	`true`
DATE	`"2025-06-14"`
DATETIME	`"2025-06-14 09:05:10.000000"`
DOUBLE	`1.14`
INTEGER	`5`
NULL	`null`
OBJECT	`{}`
OPAQUE	
STRING	`"foobar"`
TIME	`"09:10:00.000000"`
UNSIGNED INTEGER	`9223372036854776000`

14.13.3.6.2 Restrictions

- Currently, TiDB only supports pushing down limited `JSON` functions to TiFlash. For more information, see Push-down expressions.
- TiDB Backup & Restore (BR) changes how JSON column data is encoded in v6.3.0. Therefore, it is not recommended to use BR to restore data containing JSON columns to a TiDB cluster earlier than v6.3.0.
- Do not use any replication tool to replicate data containing non-standard `JSON` data types, such as `DATE`, `DATETIME`, and `TIME`.

14.13.3.6.3 MySQL compatibility

- When you create JSON columns with data in the `BINARY` type, MySQL mislabels the data as the `STRING` type currently, while TiDB processes it as the `BINARY` type

correctly.

```
CREATE TABLE test(a json);
INSERT INTO test SELECT json_objectagg('a', b'01010101');

-- In TiDB, executing the following SQL statement returns `0, 0`. In
   ↪ MySQL, executing the following SQL statement returns `0, 1`.
mysql> SELECT JSON_EXTRACT(JSON_OBJECT('a', b'01010101'), '$.a') = "
   ↪ base64:type15:VQ==" AS r1, JSON_EXTRACT(a, '$.a') = "base64:
   ↪ type15:VQ==" AS r2 FROM test;
+------+------+
| r1   | r2   |
+------+------+
|    0 |    0 |
+------+------+
1 row in set (0.01 sec)
```

For more information, see issue #37443.

- When converting the data type from `ENUM` or `SET` to `JSON`, TiDB checks the correctness of data format. For example, executing the following SQL statements in TiDB will return an error.

```
CREATE TABLE t(e ENUM('a'));
INSERT INTO t VALUES ('a');
mysql> SELECT CAST(e AS JSON) FROM t;
ERROR 3140 (22032): Invalid JSON text: The document root must not be
   ↪ followed by other values.
```

For more information, see issue #9999.

- In TiDB, you can use `ORDER BY` to sort JSON arrays or JSON objects.

  In MySQL, if you use `ORDER BY` to sort JSON arrays or JSON objects, MySQL returns a warning and the sorting result does not match the result of the comparison operation:

```
CREATE TABLE t(j JSON);
INSERT INTO t VALUES ('[1,2,3,4]');
INSERT INTO t VALUES ('[5]');

mysql> SELECT j FROM t WHERE j < JSON_ARRAY(5);
+--------------+
| j            |
+--------------+
| [1, 2, 3, 4] |
+--------------+
1 row in set (0.00 sec)
```

```
-- In TiDB, executing the following SQL statement returns the correct
   ↪  sorting result. In MySQL, executing the following SQL
   ↪ statement returns the "This version of MySQL doesn't yet
   ↪ support 'sorting of non-scalar JSON values'." warning and the
   ↪ sorting result is inconsistent with the comparison result of
   ↪ `<`.
mysql> SELECT j FROM t ORDER BY j;
+--------------+
| j            |
+--------------+
| [1, 2, 3, 4] |
| [5]          |
+--------------+
2 rows in set (0.00 sec)
```

For more information, see issue #37506.

- When you insert data to a JSON column, TiDB implicitly converts the value of the data to the `JSON` type.

```
CREATE TABLE t(col JSON);

-- In TiDB, the following INSERT statement is executed successfully.
   ↪ In MySQL, executing the following INSERT statement returns the
   ↪ "Invalid JSON text" error.
INSERT INTO t VALUES (3);
```

For more information about the `JSON` data type, see JSON functions and Generated Columns.

14.13.3.7 Vector Data Types

A vector is a sequence of floating-point numbers, such as `[0.3, 0.5, -0.1, ...]`. TiDB offers Vector data types, specifically optimized for efficiently storing and querying vector embeddings widely used in AI applications.

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> Vector data types are only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

The following Vector data types are currently available:

- `VECTOR`: A sequence of single-precision floating-point numbers with any dimension.
- `VECTOR(D)`: A sequence of single-precision floating-point numbers with a fixed dimension `D`.

Using vector data types provides the following advantages over using the `JSON` type:

- Vector index support: You can build a vector search index to speed up vector searching.
- Dimension enforcement: You can specify a dimension to forbid inserting vectors with different dimensions.
- Optimized storage format: Vector data types are optimized for handling vector data, offering better space efficiency and performance compared to `JSON` types.

14.13.3.7.1 Syntax

You can use a string in the following syntax to represent a Vector value:

```
'[<float>, <float>, ...]'
```

Example:

```
CREATE TABLE vector_table (
    id INT PRIMARY KEY,
    embedding VECTOR(3)
);

INSERT INTO vector_table VALUES (1, '[0.3, 0.5, -0.1]');

INSERT INTO vector_table VALUES (2, NULL);
```

Inserting vector values with invalid syntax will result in an error:

```
[tidb]> INSERT INTO vector_table VALUES (3, '[5, ]');
ERROR 1105 (HY000): Invalid vector text: [5, ]
```

In the following example, because dimension `3` is enforced for the `embedding` column when the table is created, inserting a vector with a different dimension will result in an error:

```
[tidb]> INSERT INTO vector_table VALUES (4, '[0.3, 0.5]');
ERROR 1105 (HY000): vector has 2 dimensions, does not fit VECTOR(3)
```

For available functions and operators over the vector data types, see Vector Functions and Operators.

For more information about building and using a vector search index, see Vector Search Index.

14.13.3.7.2 Store vectors with different dimensions

You can store vectors with different dimensions in the same column by omitting the dimension parameter in the `VECTOR` type:

```
CREATE TABLE vector_table (
    id INT PRIMARY KEY,
    embedding VECTOR
);

INSERT INTO vector_table VALUES (1, '[0.3, 0.5, -0.1]'); -- 3 dimensions
    ↪ vector, OK
INSERT INTO vector_table VALUES (2, '[0.3, 0.5]'); -- 2 dimensions vector,
    ↪ OK
```

However, note that you cannot build a vector search index for this column, as vector distances can be only calculated between vectors with the same dimensions.

14.13.3.7.3 Comparison

You can compare vector data types using comparison operators such as `=`, `!=`, `<`, `>`, `<=`, and `>=`. For a complete list of comparison operators and functions for vector data types, see Vector Functions and Operators.

Vector data types are compared element-wise numerically. For example:

- `[1] < [12]`
- `[1,2,3] < [1,2,5]`
- `[1,2,3] = [1,2,3]`
- `[2,2,3] > [1,2,3]`

Two vectors with different dimensions are compared using lexicographical comparison, with the following rules:

- Two vectors are compared element by element from the start, and each element is compared numerically.

- The first mismatching element determines which vector is lexicographically *less* or *greater* than the other.
- If one vector is a prefix of another, the shorter vector is lexicographically *less* than the other. For example, `[1,2,3] < [1,2,3,0]`.
- Vectors of the same length with identical elements are lexicographically *equal*.
- An empty vector is lexicographically *less* than any non-empty vector. For example, `[] < [1]`.
- Two empty vectors are lexicographically *equal*.

When comparing vector constants, consider performing an explicit cast from string to vector to avoid comparisons based on string values:

```
-- Because string is given, TiDB is comparing strings:
[tidb]> SELECT '[12.0]' < '[4.0]';
+--------------------+
| '[12.0]' < '[4.0]' |
+--------------------+
|                  1 |
+--------------------+
1 row in set (0.01 sec)

-- Cast to vector explicitly to compare by vectors:
[tidb]> SELECT VEC_FROM_TEXT('[12.0]') < VEC_FROM_TEXT('[4.0]');
+-------------------------------------------------+
| VEC_FROM_TEXT('[12.0]') < VEC_FROM_TEXT('[4.0]') |
+-------------------------------------------------+
|                                               0 |
+-------------------------------------------------+
1 row in set (0.01 sec)
```

14.13.3.7.4 Arithmetic

Vector data types support arithmetic operations `+` (addition) and `-` (subtraction). However, arithmetic operations between vectors with different dimensions are not supported and will result in an error.

Examples:

```
[tidb]> SELECT VEC_FROM_TEXT('[4]') + VEC_FROM_TEXT('[5]');
+-------------------------------------------+
| VEC_FROM_TEXT('[4]') + VEC_FROM_TEXT('[5]') |
+-------------------------------------------+
| [9]                                       |
+-------------------------------------------+
1 row in set (0.01 sec)
```

```
[tidb]> SELECT VEC_FROM_TEXT('[2,3,4]') - VEC_FROM_TEXT('[1,2,3]');
+---------------------------------------------------+
| VEC_FROM_TEXT('[2,3,4]') - VEC_FROM_TEXT('[1,2,3]') |
+---------------------------------------------------+
| [1,1,1]                                           |
+---------------------------------------------------+
1 row in set (0.01 sec)

[tidb]> SELECT VEC_FROM_TEXT('[4]') + VEC_FROM_TEXT('[1,2,3]');
ERROR 1105 (HY000): vectors have different dimensions: 1 and 3
```

14.13.3.7.5 Cast

Cast between Vector String

To cast between Vector and String, use the following functions:

- `CAST(... AS VECTOR)`: String Vector
- `CAST(... AS CHAR)`: Vector String
- `VEC_FROM_TEXT`: String Vector
- `VEC_AS_TEXT`: Vector String

To improve usability, if you call a function that only supports vector data types, such as a vector correlation distance function, you can also just pass in a format-compliant string. TiDB automatically performs an implicit cast in this case.

```
-- The VEC_DIMS function only accepts VECTOR arguments, so you can
   ↪ directly pass in a string for an implicit cast.
[tidb]> SELECT VEC_DIMS('[0.3, 0.5, -0.1]');
+------------------------------+
| VEC_DIMS('[0.3, 0.5, -0.1]') |
+------------------------------+
|                            3 |
+------------------------------+
1 row in set (0.01 sec)

-- You can also explicitly cast a string to a vector using VEC_FROM_TEXT
   ↪ and then pass the vector to the VEC_DIMS function.
[tidb]> SELECT VEC_DIMS(VEC_FROM_TEXT('[0.3, 0.5, -0.1]'));
+-------------------------------------------+
| VEC_DIMS(VEC_FROM_TEXT('[0.3, 0.5, -0.1]')) |
+-------------------------------------------+
|                                         3 |
+-------------------------------------------+
1 row in set (0.01 sec)
```

```
-- You can also cast explicitly using CAST(... AS VECTOR):
[tidb]> SELECT VEC_DIMS(CAST('[0.3, 0.5, -0.1]' AS VECTOR));
+-----------------------------------------------+
| VEC_DIMS(CAST('[0.3, 0.5, -0.1]' AS VECTOR)) |
+-----------------------------------------------+
|                                             3 |
+-----------------------------------------------+
1 row in set (0.01 sec)
```

When using an operator or function that accepts multiple data types, you need to explicitly cast the string type to the vector type before passing the string to that operator or function, because TiDB does not perform implicit casts in this case. For example, before performing comparison operations, you need to explicitly cast strings to vectors; otherwise, TiDB compares them as string values rather than as vector numeric values:

```
-- Because string is given, TiDB is comparing strings:
[tidb]> SELECT '[12.0]' < '[4.0]';
+--------------------+
| '[12.0]' < '[4.0]' |
+--------------------+
|                  1 |
+--------------------+
1 row in set (0.01 sec)

-- Cast to vector explicitly to compare by vectors:
[tidb]> SELECT VEC_FROM_TEXT('[12.0]') < VEC_FROM_TEXT('[4.0]');
+-------------------------------------------------------+
| VEC_FROM_TEXT('[12.0]') < VEC_FROM_TEXT('[4.0]') |
+-------------------------------------------------------+
|                                                     0 |
+-------------------------------------------------------+
1 row in set (0.01 sec)
```

You can also explicitly cast a vector to its string representation. Take using the `VEC_AS_TEXT()` function as an example:

```
-- The string is first implicitly cast to a vector, and then the vector is explicitly cast to a string, thus returning a string in the normalized format:
[tidb]> SELECT VEC_AS_TEXT('[0.3, 0.5, -0.1]');
+-------------------------------------+
| VEC_AS_TEXT('[0.3,  0.5, -0.1]') |
+-------------------------------------+
| [0.3,0.5,-0.1]                    |
+-------------------------------------+
```

```
1 row in set (0.01 sec)
```

For additional cast functions, see Vector Functions and Operators.

Cast between Vector other data types

Currently, direct casting between Vector and other data types (such as `JSON`) is not supported. To work around this limitation, use String as an intermediate data type for casting in your SQL statement.

Note that vector data type columns stored in a table cannot be converted to other data types using `ALTER TABLE ... MODIFY COLUMN ...`.

14.13.3.7.6 Restrictions

For restrictions on vector data types, see Vector search limitations and Vector index restrictions.

14.13.3.7.7 MySQL compatibility

Vector data types are TiDB specific, and are not supported in MySQL.

- Improve Vector Search Performance

14.13.4 Functions and Operators

14.13.4.1 Function and Operator Reference

The usage of the functions and operators in TiDB is similar to MySQL. See Functions and Operators in MySQL.

In SQL statements, expressions can be used on the `ORDER BY` and `HAVING` clauses of the `SELECT` statement, the `WHERE` clause of `SELECT`/`DELETE`/`UPDATE` statements, and `SET` statements.

You can write expressions using literals, column names, `NULL`, built-in functions, operators, and so on.

- For expressions that TiDB supports pushing down to TiKV, see List of expressions for pushdown.
- For expressions that TiDB supports pushing down to TiFlash, see Push-down expressions.

14.13.4.2 Type Conversion in Expression Evaluation

TiDB behaves the same as MySQL: https://dev.mysql.com/doc/refman/8.0/en/type-conversion.html

14.13.4.3 Operators

This document describes the operators precedence, comparison functions and operators, logical operators, and assignment operators.

- Operator precedence
- Comparison functions and operators
- Logical operators
- Assignment operators

Name	Description
AND, &&	Logical AND
=	Assign a value (as part of a `SET` statement, or as part of the `SET` clause in an `UPDATE` statement)
:=	Assign a value
BETWEEN ... AND ...	Check whether a value is within a range of values
BINARY	Cast a string to a binary string
&	Bitwise AND
~	Bitwise inversion
|	Bitwise OR
[^](https://dev.mysql.com/doc/refman/8.0/en/bit-functions.html#operator_bitwise-xor)	Bitwise XOR
CASE	Case operator
DIV	Integer division
/	Division operator
=	Equal operator
`<=>`	NULL-safe equal to operator
>	Greater than operator
>=	Greater than or equal operator
IS	Test a value against a boolean
IS NOT	Test a value against a boolean
IS NOT NULL	NOT NULL value test
IS NULL	NULL value test
->	Return value from JSON column after evaluating path; equivalent to `JSON_EXTRACT()`

Name	Description
->>	Return value from JSON column after evaluating path and unquoting the result; equivalent to `JSON_UNQUOTE(JSON_EXTRACT())`
<<	Left shift
<	Less than operator
<=	Less than or equal operator
LIKE	Simple pattern matching
ILIKE	Simple pattern matching with case insensitive (Supported in TiDB, but not supported in MySQL)
-	Minus operator
%, MOD	Modulo operator
NOT, !	Negates value
NOT BETWEEN … AND …	Check whether a value is not within a range of values
!=, <>	Not equal operator
NOT LIKE	Negation of simple pattern matching
NOT REGEXP	Negation of REGEXP
||, OR	Logical OR
+	Addition operator
REGEXP	Pattern matching using regular expressions
>>	Right shift
RLIKE	Synonym for REGEXP
*	Multiplication operator
-	Change the sign of the argument
XOR	Logical XOR

14.13.4.3.1 Unsupported operators

- `SOUNDS LIKE`

14.13.4.3.2 Operator precedence

Operator precedences are shown in the following list, from highest precedence to the lowest. Operators that are shown together on a line have the same precedence.

```
INTERVAL
BINARY, COLLATE
!
- (unary minus), ~ (unary bit inversion)
^
*, /, DIV, %, MOD
```

```
-, +
<<, >>
&
|
= (comparison), <=>, >=, >, <=, <, <>, !=, IS, LIKE, REGEXP, IN
BETWEEN, CASE, WHEN, THEN, ELSE
NOT
AND, &&
XOR
OR, ||
= (assignment), :=
```

For details, see Operator Precedence.

14.13.4.3.3 Comparison functions and operators

Name	Description
BETWEEN … AND …	Check whether a value is within a range of values
COALESCE()	Return the first non-NULL argument
=	Equal operator
<=>	NULL-safe equal to operator
>	Greater than operator
>=	Greater than or equal operator
GREATEST()	Return the largest argument
IN()	Check whether a value is within a set of values
INTERVAL()	Return the index of the argument that is less than the first argument
IS	Test a value against a boolean
IS NOT	Test a value against a boolean
IS NOT NULL	NOT NULL value test
IS NULL	NULL value test
ISNULL()	Test whether the argument is NULL
LEAST()	Return the smallest argument
<	Less than operator
<=	Less than or equal operator
LIKE	Simple pattern matching
ILIKE	Simple pattern matching with case insensitive (Supported in TiDB, but not supported in MySQL)
NOT BETWEEN … AND …	Check whether a value is not within a range of values
!=, <>	Not equal operator

Name	Description
NOT IN()	Check whether a value is not within a set of values
NOT LIKE	Negation of simple pattern matching
STRCMP()	Compare two strings

For details, see Comparison Functions and Operators.

14.13.4.3.4 Logical operators

Name	Description
AND, &&	Logical AND
NOT, !	Negates value
||, OR	Logical OR
XOR	Logical XOR

For details, see MySQL Handling of GROUP BY.

14.13.4.3.5 Assignment operators

Name	Description
=	Assign a value (as part of a `SET` statement, or as part of the `SET` clause in an `UPDATE` statement)
:=	Assign a value

For details, see Detection of Functional Dependence.

14.13.4.3.6 MySQL compatibility

- MySQL does not support the `ILIKE` operator.

14.13.4.4 Control Flow Functions

TiDB supports all of the control flow functions available in MySQL 8.0.

Name	Description
`CASE`	Case operator
`IF()`	If/else construct
`IFNULL()`	Null if/else construct
`NULLIF()`	Return `NULL` if expr1 = expr2

14.13.4.4.1 CASE

The CASE operator enables you to perform conditional logic and customize query results based on specified conditions.

Syntax:

```
CASE
    WHEN condition1 THEN result1
    WHEN condition2 THEN result2
    ...
    ELSE default_result
END
```

Example:

```
WITH RECURSIVE d AS (SELECT 1 AS n UNION ALL SELECT n+1 FROM d WHERE n<10)
SELECT n, CASE WHEN n MOD 2 THEN "odd" ELSE "even" END FROM d;
```

```
+----+-----------------------------------------------+
| n  | CASE WHEN n MOD 2 THEN "odd" ELSE "even" END  |
+----+-----------------------------------------------+
|  1 | odd                                           |
|  2 | even                                          |
|  3 | odd                                           |
|  4 | even                                          |
|  5 | odd                                           |
|  6 | even                                          |
|  7 | odd                                           |
|  8 | even                                          |
|  9 | odd                                           |
| 10 | even                                          |
+----+-----------------------------------------------+
10 rows in set (0.00 sec)
```

14.13.4.4.2 IF()

The IF() function enables you to perform different actions based on whether a value or expression is true or not.

Syntax:

```
IF(condition, value_if_true, value_if_false)
```

Example:

```
WITH RECURSIVE d AS (SELECT 1 AS n UNION ALL SELECT n+1 FROM d WHERE n<10)
SELECT n, IF(n MOD 2, "odd", "even") FROM d;
```

```
+----+----------------------------+
| n  | IF(n MOD 2, "odd", "even") |
+----+----------------------------+
|  1 | odd                        |
|  2 | even                       |
|  3 | odd                        |
|  4 | even                       |
|  5 | odd                        |
|  6 | even                       |
|  7 | odd                        |
|  8 | even                       |
|  9 | odd                        |
| 10 | even                       |
+----+----------------------------+
10 rows in set (0.00 sec)
```

14.13.4.4.3 IFNULL()

The IFNULL(expr1,expr2) function is used to handle NULL values in queries. If expr1 is not NULL, it returns expr1; otherwise, it returns expr2.

Example:

```
WITH data AS (SELECT NULL AS x UNION ALL SELECT 1 )
SELECT x, IFNULL(x,'x has no value') FROM data;
```

```
+------+----------------------------+
| x    | IFNULL(x,'x has no value') |
+------+----------------------------+
| NULL | x has no value             |
|    1 | 1                          |
+------+----------------------------+
2 rows in set (0.0006 sec)
```

14.13.4.4.4 NULLIF()

The NULLIF(expr1,expr2) function returns NULL if both arguments are the same or if the first argument is NULL. Otherwise, it returns the first argument.

Example:

```
WITH RECURSIVE d AS (SELECT 1 AS n UNION ALL SELECT n+1 FROM d WHERE n<10)
SELECT n, NULLIF(n+n, n+2) FROM d;
```

```
+----+------------------+
| n  | NULLIF(n+n, n+2) |
+----+------------------+
|  1 |                2 |
|  2 |             NULL |
|  3 |                6 |
|  4 |                8 |
|  5 |               10 |
|  6 |               12 |
|  7 |               14 |
|  8 |               16 |
|  9 |               18 |
| 10 |               20 |
+----+------------------+
10 rows in set (0.00 sec)
```

In this example, when `n` equals `2`, both `n+n` and `n+2` equal `4`, making both arguments the same and causing the function to return `NULL`.

14.13.4.5 String Functions

TiDB supports most of the string functions available in MySQL 8.0, and some of the functions available in Oracle 21.

For comparisons between functions and syntax of Oracle and TiDB, see Comparisons between Functions and Syntax of Oracle and TiDB.

14.13.4.5.1 Supported functions

`ASCII()`

The `ASCII(str)` function is used to get the ASCII value of the leftmost character in the given argument. The argument can be either a string or a number.

- If the argument is not empty, the function returns the ASCII value of the leftmost character.
- If the argument is an empty string, the function returns `0`.
- If the argument is `NULL`, the function returns `NULL`.

> **Note:**
>
> `ASCII(str)` only works for characters represented using 8 bits of binary digits (one byte).

Example:

```
SELECT ASCII('A'), ASCII('TiDB'), ASCII(23);
```

Output:

```
+-----------+--------------+-----------+
| ASCII('A') | ASCII('TiDB') | ASCII(23) |
+-----------+--------------+-----------+
|        65 |           84 |        50 |
+-----------+--------------+-----------+
```

BIN()

The `BIN()` function is used to convert the given argument into a string representation of its binary value. The argument can be either a string or a number.

- If the argument is a positive number, the function returns a string representation of its binary value.
- If the argument is a negative number, the function converts the absolute value of the argument to its binary representation, inverts each bit of the binary value (changing `0` to `1` and `1` to `0`), and then adds `1` to the inverted value.
- If the argument is a string containing only digits, the function returns the result according to those digits. For example, the results for `"123"` and `123` are the same.
- If the argument is a string and its first character is not a digit (such as `"q123"`), the function returns `0`.
- If the argument is a string that consists of digits and non-digits, the function returns the result according to the consecutive digits at the beginning of the argument. For example, the results for `"123q123"` and `123` are the same, but `BIN('123q123')` generates a warning like `Truncated incorrect INTEGER value: '123q123'`.
- If the argument is `NULL`, the function returns `NULL`.

Example 1:

```
SELECT BIN(123), BIN('123q123');
```

Output 1:

```
+----------+----------------+
| BIN(123) | BIN('123q123') |
+----------+----------------+
| 1111011 | 1111011      |
+----------+----------------+
```

Example 2:

```
SELECT BIN(-7);
```

Output 2:

```
+-----------------------------------------------------------------------+
| BIN(-7)                                                               |
+-----------------------------------------------------------------------+
| 1111111111111111111111111111111111111111111111111111111111111001 |
+-----------------------------------------------------------------------+
```

BIT_LENGTH()

The BIT_LENGTH() function is used to return the length of a given argument in bits.

Examples:

```
SELECT BIT_LENGTH("TiDB");

+--------------------+
| BIT_LENGTH("TiDB") |
+--------------------+
|                 32 |
+--------------------+
```

8 bits per character x 4 characters = 32 bits

```
SELECT BIT_LENGTH("PingCAP 123");

+--------------------------+
| BIT_LENGTH("PingCAP 123") |
+--------------------------+
|                       88 |
+--------------------------+
```

8 bits per character (space is counted because it is a non-alphanumeric character) x 11 characters = 88 bits

```
SELECT CustomerName, BIT_LENGTH(CustomerName) AS BitLengthOfName FROM
    ↪ Customers;

+-------------------+-----------------+
| CustomerName      | BitLengthOfName |
+-------------------+-----------------+
| Albert Einstein   |             120 |
| Robert Oppenheimer |            144 |
+-------------------+-----------------+
```

> **Note:**
>
> The preceding example operates under the assumption that there is a database with a table named `Customers` and a column inside the table named `CustomerName`.

CHAR()

The `CHAR()` function is used to get the corresponding character of a specific ASCII value. It performs the opposite operation of `ASCII()`, which returns the ASCII value of a specific character. If multiple arguments are supplied, the function works on all arguments and are then concatenated together.

Examples:

```
SELECT CHAR(65);

+------------+
| CHAR(65) |
+------------+
|          A |
+------------+
```

```
SELECT CHAR(84);

+------------+
| CHAR(84) |
+------------+
|          T |
+------------+
```

The `CHAR()` function can also be used to get the corresponding character of ASCII values that extend beyond the standard ASCII range (`0 - 127`).

```
/*For extended ASCII: */

SELECT CHAR(128);

+------------+
| CHAR(128) |
+------------+
|       0x80 |
+------------+
```

The `CHAR()` function can also get the corresponding character value of a unicode value.

```
/* For Unicode: */

--skip-binary-as-hex

SELECT CHAR(50089);

+--------------+
|  CHAR(50089) |
+--------------+
|           é |
+--------------+
```

```
SELECT CHAR(65,66,67);
```

```
+----------------+
| CHAR(65,66,67) |
+----------------+
| ABC            |
+----------------+
1 row in set (0.00 sec)
```

CHAR_LENGTH()

The CHAR_LENGTH() function is used to get the total number of characters in a given argument as an integer.

Examples:

```
SELECT CHAR_LENGTH("TiDB") AS LengthOfString;

+----------------+
| LengthOfString |
+----------------+
|              4 |
+----------------+
```

```
SELECT CustomerName, CHAR_LENGTH(CustomerName) AS LengthOfName FROM
    ↪ Customers;

+--------------------+--------------+
| CustomerName       | LengthOfName |
+--------------------+--------------+
| Albert Einstein    |           15 |
| Robert Oppenheimer |           18 |
+--------------------+--------------+
```

> **Note:**
>
> The preceding example operates under the assumption that there is a database with a table named `Customers` and a column inside the table named `CustomerName`.

CHARACTER_LENGTH()

The `CHARACTER_LENGTH()` function is the same as the `CHAR_LENGTH()` function. Both functions can be used synonymously because they generate the same output.

CONCAT()

The `CONCAT()` function concatenates one or more arguments into a single string.

Syntax:

```
CONCAT(str1,str2,...)
```

`str1, str2, ...` is a list of arguments to be concatenated. Each argument can be a string or a number.

Example:

```
SELECT CONCAT('TiDB', ' ', 'Server', '-', 1, TRUE);
```

Output:

```
+-------------------------------------------+
| CONCAT('TiDB', ' ', 'Server', '-', 1, TRUE) |
+-------------------------------------------+
| TiDB Server-11                            |
+-------------------------------------------+
```

If any of the arguments is `NULL`, `CONCAT()` returns `NULL`.

Example:

```
SELECT CONCAT('TiDB', NULL, 'Server');
```

Output:

```
+------------------------------+
| CONCAT('TiDB', NULL, 'Server') |
+------------------------------+
| NULL                         |
+------------------------------+
```

In addition to the `CONCAT()` function, you can concatenate strings by placing them adjacent to each other as in the following example. Note that this method does not support numeric types.

```
SELECT 'Ti' 'DB' ' ' 'Server';
```

Output:

```
+-------------+
| Ti          |
+-------------+
| TiDB Server |
+-------------+
```

CONCAT_WS()

The `CONCAT_WS()` function is a form of `CONCAT()` with a separator, which returns a string concatenated by the specified separator.

Syntax:

```
CONCAT_WS(separator,str1,str2,...)
```

- `separator`: the first argument is the separator, which concatenates the remaining arguments that are not `NULL`.
- `str1, str2, ...`: a list of arguments to be concatenated. Each argument can be a string or a number.

Example:

```
SELECT CONCAT_WS(',', 'TiDB Server', 'TiKV', 'PD');
```

Output:

```
+--------------------------------------------+
| CONCAT_WS(',', 'TiDB Server', 'TiKV', 'PD') |
+--------------------------------------------+
| TiDB Server,TiKV,PD                        |
+--------------------------------------------+
```

- If the separator is an empty string, `CONCAT_WS()` is equivalent to `CONCAT()` and returns the concatenated string of the remaining arguments.

  Example:

  ```
  SELECT CONCAT_WS('', 'TiDB Server', 'TiKV', 'PD');
  ```

  Output:

```
+-----------------------------------------+
| CONCAT_WS('', 'TiDB Server', 'TiKV', 'PD') |
+-----------------------------------------+
| TiDB ServerTiKVPD                       |
+-----------------------------------------+
```

- If the separator is `NULL`, `CONCAT_WS()` returns `NULL`.

  Example:

```
SELECT CONCAT_WS(NULL, 'TiDB Server', 'TiKV', 'PD');
```

  Output:

```
+-------------------------------------------+
| CONCAT_WS(NULL, 'TiDB Server', 'TiKV', 'PD') |
+-------------------------------------------+
| NULL                                      |
+-------------------------------------------+
```

- If only one of the arguments to be concatenated is not `NULL`, `CONCAT_WS()` returns that argument.

  Example:

```
SELECT CONCAT_WS(',', 'TiDB Server', NULL);
```

  Output:

```
+-----------------------------------+
| CONCAT_WS(',', 'TiDB Server', NULL) |
+-----------------------------------+
| TiDB Server                       |
+-----------------------------------+
```

- If there are `NULL` arguments to be concatenated, `CONCAT_WS()` skips these `NULL` arguments.

  Example:

```
SELECT CONCAT_WS(',', 'TiDB Server', NULL, 'PD');
```

  Output:

```
+---------------------------------------+
| CONCAT_WS(',', 'TiDB Server', NULL, 'PD') |
+---------------------------------------+
| TiDB Server,PD                        |
+---------------------------------------+
```

- If there are empty strings to be concatenated, `CONCAT_WS()` does not skip empty strings.

  Example:

```
SELECT CONCAT_WS(',', 'TiDB Server', '', 'PD');
```

  Output:

```
+----------------------------------------+
| CONCAT_WS(',', 'TiDB Server', '', 'PD') |
+----------------------------------------+
| TiDB Server,,PD                        |
+----------------------------------------+
```

ELT()

The `ELT()` function returns the element at the index number.

```
SELECT ELT(3, 'This', 'is', 'TiDB');
```

```
+-----------------------------+
| ELT(3, 'This', 'is', 'TiDB') |
+-----------------------------+
| TiDB                        |
+-----------------------------+
1 row in set (0.00 sec)
```

The preceding example returns the third element, which is `'TiDB'`.

EXPORT_SET()

The `EXPORT_SET()` function returns a string that consists of a specified number (`number_of_bits`) of `on`/`off` values, optionally separated by `separator`. These values are based on whether the corresponding bit in the `bits` argument is `1`, where the first value corresponds to the rightmost (lowest) bit of `bits`.

Syntax:

```
EXPORT_SET(bits, on, off, [separator[, number_of_bits]])
```

- `bits`: an integer representing the bit value.
- `on`: the string to be returned if the corresponding bit is `1`.
- `off`: the string to be returned if the corresponding bit is `0`.
- `separator` (optional): the separator character in the result string.
- `number_of_bits` (optional): the number of bits to be processed. If it is not set, `64` (the max size of bits) is used by default, which means that `bits` is treated as an unsigned 64-bit integer.

Examples:

In the following example, `number_of_bits` is set to `5`, resulting in 5 values, separated by `|`. Because only 3 bits are given, the other bits are considered unset. Therefore, setting `number_of_bits` to either `101` or `00101` results in the same output.

```
SELECT EXPORT_SET(b'101',"ON",'off','|',5);
```

```
+-----------------------------------+
| EXPORT_SET(b'101',"ON",'off','|',5) |
+-----------------------------------+
| ON|off|ON|off|off                |
+-----------------------------------+
1 row in set (0.00 sec)
```

In the following example, `bits` is set to `00001111`, `on` is set to `x`, and `off` is set to `_`. This causes the function to return `____` for the `0` bits and `xxxx` for the `1` bits. Therefore, when processing with the bits in `00001111` from right to left, the function returns `xxxx____`.

```
SELECT EXPORT_SET(b'00001111', 'x', '_', '', 8);
```

```
+---------------------------------------+
| EXPORT_SET(b'00001111', 'x', '_', '', 8) |
+---------------------------------------+
| xxxx____                              |
+---------------------------------------+
1 row in set (0.00 sec)
```

In the following example, `bits` is set to `00001111`, `on` is set to `x`, and `off` is set to `_`. This causes the function to return `x` for each `1` bit and `_` for each `0` bit. Therefore, when processing with the bits in `01010101` from right to left, the function returns `x_x_x_x_`.

```
SELECT EXPORT_SET(b'01010101', 'x', '_', '', 8);
```

```
+---------------------------------------+
| EXPORT_SET(b'01010101', 'x', '_', '', 8) |
+---------------------------------------+
| x_x_x_x_                              |
+---------------------------------------+
1 row in set (0.00 sec)
```

FIELD()

Return the index (position) of the first argument in the subsequent arguments.

In the following example, the first argument of `FIELD()` is `needle`, and it matches the second argument in the following list, so the function returns `2`.

```
SELECT FIELD('needle', 'A', 'needle', 'in', 'a', 'haystack');
+-----------------------------------------------------+
| FIELD('needle', 'A', 'needle', 'in', 'a', 'haystack') |
+-----------------------------------------------------+
|                                                   2 |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

FIND_IN_SET()

Return the index position of the first argument within the second argument.

This function is often used with the SET data type.

In the following example, `Go` is the fourth element in the set `COBOL,BASIC,Rust,Go,Java,Fortran`, so the function returns `4`.

```
SELECT FIND_IN_SET('Go', 'COBOL,BASIC,Rust,Go,Java,Fortran');
+-------------------------------------------------------+
| FIND_IN_SET('Go', 'COBOL,BASIC,Rust,Go,Java,Fortran') |
+-------------------------------------------------------+
|                                                     4 |
+-------------------------------------------------------+
1 row in set (0.00 sec)
```

FORMAT()

The `FORMAT(X,D[,locale])` function is used to format the number `X` to a format similar to `"#,###,###. ##"`, rounded to `D` decimal places, and return the result as a string.

Arguments:

- `X`: the number to be formatted. It can be a direct numeric value, a numeric string, or a number in scientific notation.
- `D`: the number of decimal places for the returned value. The function rounds the number `X` to `D` decimal places. If `D` is greater than the actual number of decimal places in `X`, the result is padded with zeros to the corresponding length.
- `[locale]`: specifies a locale setting to be used for grouping between decimal points, thousands separators, and separators for resultant numbers. A valid locale value is the same as the valid value of the `lc_time_names` system variable. If not specified or the region setting is `NULL`, the `'en_US'` region setting is used by default. This argument is optional.

Behaviors:

- If the first argument is a string and contains only numbers, the function returns a result based on that numeric value. For example, `FORMAT('12.34', 1)` and `FORMAT(12.34, 1)` return the same result.

- If the first argument is a number represented in scientific notation (using `E/e`), the function returns the result based on that number. For example, `FORMAT('1E2', 3)` returns `100.000`.
- If the first argument is a string starting with non-numeric characters, the function returns zero and a warning `(Code 1292)`. For example, `FORMAT('q12.36', 5)` returns `0.00000`, but also includes a warning `Warning (Code 1292): Truncated incorrect DOUBLE value: 'q12.36'`.
- If the first argument is a string mixing numbers and non-numbers, the function returns a result based on the consecutive numeric part at the beginning of the argument, and also includes a warning `(Code 1292)`. For example, `FORMAT('12.36q56.78', 1)` returns the same numeric result as `FORMAT('12.36', 1)`, but includes a warning `Warning (Code 1292): Truncated incorrect DOUBLE value: '12.36q56.78'`.
- If the second argument is zero or a negative number, the function truncates the decimal part and returns an integer.
- If any of the arguments is `NULL`, the function returns `NULL`.

Examples:

The following examples show how to format the number 12.36 to different decimal places:

```
mysql> SELECT FORMAT(12.36, 1);
+------------------+
| FORMAT(12.36, 1) |
+------------------+
| 12.4             |
+------------------+
```

```
mysql> SELECT FORMAT(12.36, 5);
+------------------+
| FORMAT(12.36, 5) |
+------------------+
| 12.36000         |
+------------------+
```

```
mysql> SELECT FORMAT(12.36, 2);
+------------------+
| FORMAT(12.36, 2) |
+------------------+
| 12.36            |
+------------------+
```

FROM_BASE64()

The `FROM_BASE64()` function is used to decode a Base64 encoded string and return the decoded result in its hexadecimal form.

- This function accepts a single argument, that is, the Base64 encoded string to be decoded.
- If the argument is `NULL` or not a valid Base64 encoded string, the `FROM_BASE64()` function returns `NULL`.

Examples:

The following example shows how to decode the Base64 encoded string `'SGVsbG8gVGlEQg==`. This string is the result of encoding `'Hello TiDB'`, using the `TO_BASE64()` function.

```
mysql> SELECT TO_BASE64('Hello TiDB');
+-------------------------+
| TO_BASE64('Hello TiDB') |
+-------------------------+
| SGVsbG8gVGlEQg==        |
+-------------------------+

mysql> SELECT FROM_BASE64('SGVsbG8gVGlEQg==');
+-----------------------------------------------------------------------+
| FROM_BASE64('SGVsbG8gVGlEQg==')                                       |
+-----------------------------------------------------------------------+
| 0x48656C6C6F2054694442                                                |
+-----------------------------------------------------------------------+
```

```
mysql> SELECT CONVERT(FROM_BASE64('SGVsbG8gVGlEQg==') USING utf8mb4);
+-----------------------------------------------------------+
| CONVERT(FROM_BASE64('SGVsbG8gVGlEQg==') USING utf8mb4) |
+-----------------------------------------------------------+
| Hello TiDB                                                |
+-----------------------------------------------------------+
```

The following example shows how to decode the Base64 encoded number `MTIzNDU2`. This string is the result of encoding `123456`, which can be done using the `TO_BASE64()` function.

```
mysql> SELECT FROM_BASE64('MTIzNDU2');
+-------------------------------------------------+
| FROM_BASE64('MTIzNDU2')                         |
+-------------------------------------------------+
| 0x313233343536                                  |
+-------------------------------------------------+
```

HEX()

The `HEX()` function is used to convert the given argument into a string representation of its hexadecimal value. The argument can be either a string or a number.

- If the argument is a string, `HEX(str)` returns a hexadecimal string representation of `str`. The function converts each byte of each character in `str` into two hexadecimal digits. For example, the character `a` in a UTF-8 or ASCII character set is represented as a binary value of `00111101`, or `61` in hexadecimal notation.
- If the argument is a number, `HEX(n)` returns a hexadecimal string representation of `n` ↪ . The function treats the argument `n` as a `BIGINT` number, equivalent to using `CONV(n, 10, 16)`.
- If the argument is `NULL`, the function returns `NULL`.

> **Note:**
>
> In the MySQL client, the `--binary-as-hex` option is enabled by default in interactive mode, causing the client to display data with an unknown character set as a hexadecimal literal. You can use the `--skip-binary-as-hex` option to disable this behavior.

Examples (with `mysql --skip-binary-as-hex`):

```
SELECT X'616263', HEX('abc'), UNHEX(HEX('abc')), 0x616263;
+----------+-----------+------------------+----------+
| X'616263' | HEX('abc') | UNHEX(HEX('abc')) | 0x616263 |
+----------+-----------+------------------+----------+
| abc      | 616263    | abc              | abc      |
+----------+-----------+------------------+----------+
```

```
SELECT X'F09F8DA3', HEX('🍣'), UNHEX(HEX('🍣')), 0xF09F8DA3;
+------------+------------+-------------------+------------+
| X'F09F8DA3' | HEX('🍣') | UNHEX(HEX('🍣'))  | 0xF09F8DA3 |
+------------+------------+-------------------+------------+
| 🍣          | F09F8DA3   | 🍣                | 🍣         |
+------------+------------+-------------------+------------+
```

```
SELECT HEX(255), CONV(HEX(255), 16, 10);
+----------+-----------------------+
| HEX(255) | CONV(HEX(255), 16, 10) |
+----------+-----------------------+
| FF       | 255                   |
+----------+-----------------------+
```

```
SELECT HEX(NULL);
+-----------+
| HEX(NULL) |
```

```
+-----------+
| NULL      |
+-----------+
```

INSERT()

The `INSERT(str, pos, len, newstr)` function is used to replace a substring in `str` (that starts at position `pos` and is `len` characters long) with the string `newstr`. This function is multibyte safe.

- If `pos` exceeds the length of `str`, the function returns the original string `str` without modification.
- If `len` exceeds the remaining length of `str` from position `pos`, the function replaces the rest of the string from position `pos`.
- If any argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT INSERT('He likes tennis', 4, 5, 'plays');
+-----------------------------------------+
| INSERT('He likes tennis', 4, 5, 'plays') |
+-----------------------------------------+
| He plays tennis                         |
+-----------------------------------------+
```

```
SELECT INSERT('He likes tennis', -1, 5, 'plays');
+------------------------------------------+
| INSERT('He likes tennis', -1, 5, 'plays') |
+------------------------------------------+
| He likes tennis                          |
+------------------------------------------+
```

```
SELECT INSERT('He likes tennis', 4, 100, 'plays');
+-------------------------------------------+
| INSERT('He likes tennis', 4, 100, 'plays') |
+-------------------------------------------+
| He plays                                  |
+-------------------------------------------+
```

```
SELECT INSERT('He likes tenis', 10, 100, '□');
+----------------------------------------+
| INSERT('He likes tenis', 10, 100, '□') |
+----------------------------------------+
| He likes □                             |
+----------------------------------------+
```

```
SELECT INSERT('あああああああ', 2, 3, 'いいいい');
+-----------------------------------------------+
| INSERT('あああああああ', 2, 3, 'いいいい')     |
+-----------------------------------------------+
| あいいいいああ                                 |
+-----------------------------------------------+
```

```
SELECT INSERT('あああああああ', 2, 3, 'xx');
+-----------------------------------------+
| INSERT('あああああああ', 2, 3, 'xx')   |
+-----------------------------------------+
| あxxああ                                 |
+-----------------------------------------+
```

INSTR()

The `INSTR(str, substr)` function is used to get the position of the first occurrence of `substr` in `str`. Each argument can be either a string or a number. This function is the same as the two-argument version of `LOCATE(substr, str)`, but with the order of the arguments reversed.

> **Note:**
>
> The case sensitivity of `INSTR(str, substr)` is determined by the collations used in TiDB. Binary collations (with the suffix `_bin`) are case-sensitive, while general collations (with the suffix `_general_ci` or `_ai_ci`, and) are case-insensitive.

- If either argument is a number, the function treats the number as a string.
- If `substr` is not in `str`, the function returns `0`. Otherwise, it returns the position of the first occurrence of `substr` in `str`.
- If either argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT INSTR("pingcap.com", "tidb");

+-----------------------------+
| INSTR("pingcap.com", "tidb") |
+-----------------------------+
|                           0 |
+-----------------------------+
```

```
SELECT INSTR("pingcap.com/tidb", "tidb");

+-----------------------------------+
| INSTR("pingcap.com/tidb", "tidb") |
+-----------------------------------+
|                                13 |
+-----------------------------------+
```

```
SELECT INSTR("pingcap.com/tidb" COLLATE utf8mb4_bin, "TiDB");

+-------------------------------------------------------+
| INSTR("pingcap.com/tidb" COLLATE utf8mb4_bin, "TiDB") |
+-------------------------------------------------------+
|                                                     0 |
+-------------------------------------------------------+
```

```
SELECT INSTR("pingcap.com/tidb" COLLATE utf8mb4_general_ci, "TiDB");

+-----------------------------------------------------------------+
| INSTR("pingcap.com/tidb" COLLATE utf8mb4_general_ci, "TiDB") |
+-----------------------------------------------------------------+
|                                                              13 |
+-----------------------------------------------------------------+
```

```
SELECT INSTR(0123, "12");

+-------------------+
| INSTR(0123, "12") |
+-------------------+
|                 1 |
+-------------------+
```

LCASE()

The `LCASE(str)` function is a synonym for `LOWER(str)`, which returns the lowercase of the given argument.

LEFT()

The `LEFT()` function returns a specified number of characters from the left side of a string.

Syntax:

```
LEFT(`str`, `len`)
```

- `str`: the original string to extract characters. If `str` contains a multibyte character, the function counts it as a single code point.
- `len`: the length of characters to be returned.
    - If `len` is equal to or less than 0, the function returns an empty string.
    - If `len` is equal to or greater than the length of `str`, the function returns the original `str`.
- If any argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT LEFT('ABCED', 3);
+------------------+
| LEFT('ABCED', 3) |
+------------------+
| ABC              |
+------------------+

SELECT LEFT('ABCED', 6);
+------------------+
| LEFT('ABCED', 6) |
+------------------+
| ABCED            |
+------------------+
```

```
SELECT LEFT('ABCED', 0);
+------------------+
| LEFT('ABCED', 0) |
+------------------+
|                  |
+------------------+

SELECT LEFT('ABCED', -1);
+-------------------+
| LEFT('ABCED', -1) |
+-------------------+
|                   |
+-------------------+
```

```
SELECT LEFT('□ABC', 3);
+--------------------+
| LEFT('□ABC', 3)    |
+--------------------+
| □AB                |
+--------------------+
```

```
SELECT LEFT('ABC', NULL);
+-------------------+
| LEFT('ABC', NULL) |
+-------------------+
| NULL              |
+-------------------+

SELECT LEFT(NULL, 3);
+------------------------------+
| LEFT(NULL, 3)                |
+------------------------------+
| NULL                         |
+------------------------------+
```

LENGTH()

The `LENGTH()` function returns the length of a string in bytes.

`LENGTH()` counts a multibyte character as multiple bytes while `CHAR_LENGTH()` counts a multibyte character as a single code point.

If the argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT LENGTH('ABC');
+---------------+
| LENGTH('ABC') |
+---------------+
|             3 |
+---------------+

SELECT LENGTH('□ABC');
+--------------------+
| LENGTH('□ABC')   |
+--------------------+
|                  7 |
+--------------------+

SELECT CHAR_LENGTH('□ABC');
+-----------------------+
| CHAR_LENGTH('□ABC')  |
+-----------------------+
|                     4 |
+-----------------------+
```

```
SELECT LENGTH(NULL);
```

```
+--------------+
| LENGTH(NULL) |
+--------------+
|         NULL |
+--------------+
```

LIKE

The `LIKE` operator is used for simple string matching. The expression `expr LIKE pat [ESCAPE 'escape_char']` returns `1` (`TRUE`) or `0` (`FALSE`). If either `expr` or `pat` is `NULL`, the result is `NULL`.

You can use the following two wildcard parameters with `LIKE`:

- `%` matches any number of characters, including zero characters.
- `_` matches exactly one character.

The following examples use the `utf8mb4_bin` collation:

```
SET collation_connection='utf8mb4_bin';
SHOW VARIABLES LIKE 'collation_connection';
+----------------------+-------------+
| Variable_name        | Value       |
+----------------------+-------------+
| collation_connection | utf8mb4_bin |
+----------------------+-------------+
```

```
SELECT NULL LIKE '%' as result;
+--------+
| result |
+--------+
|   NULL |
+--------+
```

```
SELECT 'sushi!!!' LIKE 'sushi_' AS result;
+--------+
| result |
+--------+
|      0 |
+--------+
```

```
SELECT '□ □sushi□ □' LIKE '%sushi%' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

```
SELECT '□□sushi□□' LIKE '%SUSHI%' AS result;
+--------+
| result |
+--------+
|      0 |
+--------+
```

```
SELECT '□□sushi□□' LIKE '%□%' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

The default escape character is \:

```
SELECT 'sushi!!!' LIKE 'sushi\_' AS result;
+--------+
| result |
+--------+
|      0 |
+--------+
```

```
SELECT 'sushi_' LIKE 'sushi\_' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

To specify a different escape character, such as `*`, you can use the `ESCAPE` clause:

```
SELECT 'sushi_' LIKE 'sushi*_' ESCAPE '*' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

```
SELECT 'sushi!' LIKE 'sushi*_' ESCAPE '*' AS result;
+--------+
| result |
+--------+
|      0 |
+--------+
```

You can use the `LIKE` operator to match a numeric value:

```
SELECT 10 LIKE '1%' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

```
SELECT 10000 LIKE '12%' AS result;
+--------+
| result |
+--------+
|      0 |
+--------+
```

To specify a collation explicitly, such as `utf8mb4_unicode_ci`, you can use `COLLATE`:

```
SELECT '□ □Sushi□ □' COLLATE utf8mb4_unicode_ci LIKE '%SUSHI%' AS result;
+--------+
| result |
+--------+
|      1 |
+--------+
```

LOCATE()

The `LOCATE(substr, str[, pos])` function is used to get the position of the first occurrence of a specified substring `substr` in a string `str`. The `pos` argument is optional and specifies the starting position for the search.

- If the substring `substr` is not present in `str`, the function returns `0`.
- If any argument is `NULL`, the function returns `NULL`.
- This function is multibyte safe and performs a case-sensitive search only if at least one argument is a binary string.

The following examples use the `utf8mb4_bin` collation:

```
SET collation_connection='utf8mb4_bin';
SHOW VARIABLES LIKE 'collation_connection';
+----------------------+-------------+
| Variable_name        | Value       |
+----------------------+-------------+
| collation_connection | utf8mb4_bin |
+----------------------+-------------+
```

```
SELECT LOCATE('bar', 'foobarbar');
+----------------------------+
| LOCATE('bar', 'foobarbar') |
+----------------------------+
|                          4 |
+----------------------------+
```

```
SELECT LOCATE('baz', 'foobarbar');
+----------------------------+
| LOCATE('baz', 'foobarbar') |
+----------------------------+
|                          0 |
+----------------------------+
```

```
SELECT LOCATE('bar', 'fooBARBAR');
+----------------------------+
| LOCATE('bar', 'fooBARBAR') |
+----------------------------+
|                          0 |
+----------------------------+
```

```
SELECT LOCATE('bar', 'foobarBAR', 100);
+---------------------------------+
| LOCATE('bar', 'foobarBAR', 100) |
+---------------------------------+
|                               0 |
+---------------------------------+
```

```
SELECT LOCATE('bar', 'foobarbar', 5);
+-----------------------------+
| LOCATE('bar', 'foobarbar', 5) |
+-----------------------------+
|                           7 |
+-----------------------------+
```

```
SELECT LOCATE('bar', NULL);
+---------------------+
| LOCATE('bar', NULL) |
+---------------------+
|                NULL |
+---------------------+
```

```
SELECT LOCATE('い', 'たいでぃーびー');
+--------------------------------------+
```

```
| LOCATE('い', 'たいでぃーびー')     |
+-----------------------------------+
|                                 2 |
+-----------------------------------+
```

```
SELECT LOCATE('い', 'たいでぃーびー', 3);
+--------------------------------------+
| LOCATE('い', 'たいでぃーびー', 3)    |
+--------------------------------------+
|                                    0 |
+--------------------------------------+
```

The following examples use the `utf8mb4_unicode_ci` collation:

```
SET collation_connection='utf8mb4_unicode_ci';
SHOW VARIABLES LIKE 'collation_connection';
+----------------------+--------------------+
| Variable_name        | Value              |
+----------------------+--------------------+
| collation_connection | utf8mb4_unicode_ci |
+----------------------+--------------------+
```

```
SELECT LOCATE('い', 'たいでぃーびー', 3);
+--------------------------------------+
| LOCATE('い', 'たいでぃーびー', 3)    |
+--------------------------------------+
|                                    4 |
+--------------------------------------+
```

```
SELECT LOCATE('□', '□□□□□□');
+-----------------------------------+
| LOCATE('□', '□□□□□□')       |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
```

The following multibyte and binary string examples use the `utf8mb4_bin` collation:

```
SET collation_connection='utf8mb4_bin';
SHOW VARIABLES LIKE 'collation_connection';
+----------------------+-------------+
| Variable_name        | Value       |
+----------------------+-------------+
| collation_connection | utf8mb4_bin |
+----------------------+-------------+
```

```
SELECT LOCATE('□', '□ □ □ □ □');
+---------------------------------------+
| LOCATE('□', '□ □ □ □ □')                  |
+---------------------------------------+
|                                     4 |
+---------------------------------------+
```

```
SELECT LOCATE('b', _binary'aBcde');
+-----------------------------+
| LOCATE('b', _binary'aBcde') |
+-----------------------------+
|                           0 |
+-----------------------------+
```

```
SELECT LOCATE('B', _binary'aBcde');
+-----------------------------+
| LOCATE('B', _binary'aBcde') |
+-----------------------------+
|                           2 |
+-----------------------------+
```

```
SELECT LOCATE(_binary'b', 'aBcde');
+-----------------------------+
| LOCATE(_binary'b', 'aBcde') |
+-----------------------------+
|                           0 |
+-----------------------------+
```

```
SELECT LOCATE(_binary'B', 'aBcde');
+-----------------------------+
| LOCATE(_binary'B', 'aBcde') |
+-----------------------------+
|                           2 |
+-----------------------------+
```

LOWER()

The `LOWER(str)` function is used to convert all characters in the given argument `str` to lowercase. The argument can be either a string or a number.

- If the argument is a string, the function returns the string in lowercase.
- If the argument is a number, the function returns the number without leading zeros.
- If the argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT LOWER("TiDB");

+---------------+
| LOWER("TiDB") |
+---------------+
| tidb          |
+---------------+
```

```
SELECT LOWER(-012);

+-------------+
| LOWER(-012) |
+-------------+
| -12         |
+-------------+
```

LPAD()

The `LPAD(str, len, padstr)` function returns the string argument, left-padded with the specified string `padstr` to a length of `len` characters.

- If `len` is less than the length of the string `str`, the function truncates the string `str` to the length of `len`.
- If `len` is a negative number, the function returns `NULL`.
- If any argument is `NULL`, the function returns `NULL`.

Examples:

```
SELECT LPAD('TiDB',8,'>');
+--------------------+
| LPAD('TiDB',8,'>') |
+--------------------+
| >>>>TiDB           |
+--------------------+
1 row in set (0.00 sec)
```

```
SELECT LPAD('TiDB',2,'>');
+--------------------+
| LPAD('TiDB',2,'>') |
+--------------------+
| Ti                 |
+--------------------+
1 row in set (0.00 sec)
```

```
SELECT LPAD('TiDB',-2,'>');
+---------------------+
| LPAD('TiDB',-2,'>') |
+---------------------+
| NULL                |
+---------------------+
1 row in set (0.00 sec)
```

LTRIM()

The `LTRIM()` function removes leading spaces from a given string.

If the argument is `NULL`, this function returns `NULL`.

> **Note:**
>
> This function only removes the space character (U+0020) and does not remove other space-like characters such as tab (U+0009) or non-breaking space (U+00A0).

Examples:

In the following example, the `LTRIM()` function removes the leading spaces from `'  hello'` and returns `hello`.

```
SELECT LTRIM('  hello');
```

```
+--------------------+
| LTRIM('  hello') |
+--------------------+
| hello            |
+--------------------+
1 row in set (0.00 sec)
```

In the following example, `CONCAT()` is used to enclose the result of `LTRIM('  hello')` with « and ». This formatting makes it a bit easier to see that all leading spaces are removed.

```
SELECT CONCAT('«',LTRIM('  hello'),'»');
```

```
+-----------------------------------+
| CONCAT('«',LTRIM('  hello'),'») |
+-----------------------------------+
| «hello»                           |
+-----------------------------------+
1 row in set (0.00 sec)
```

MAKE_SET()

The MAKE_SET() function returns a set of comma-separated strings based on whether a corresponding bit in the bits argument is set to 1.

Syntax:

```
MAKE_SET(bits, str1, str2, ...)
```

- bits: controls which subsequent string arguments to include in the result set. If bits is set to NULL, the function returns NULL.
- str1, str2, ...: a list of strings. Each string corresponds to a bit in the bits argument from right to left. str1 corresponds to the first bit from the right, str2 corresponds to the second bit from the right, and so on. If the corresponding bit is 1, the string is included in the result; otherwise, it is not included.

Examples:

In the following example, because all bits are set to 0 in the bits argument, the function does not include any subsequent strings in the result and returns an empty string.

```
SELECT MAKE_SET(b'000','foo','bar','baz');
```

```
+-----------------------------------+
| MAKE_SET(b'000','foo','bar','baz') |
+-----------------------------------+
|                                   |
+-----------------------------------+
1 row in set (0.00 sec)
```

In the following example, because only the first bit from the right is 1, the function only returns the first string foo.

```
SELECT MAKE_SET(b'001','foo','bar','baz');
```

```
+-----------------------------------+
| MAKE_SET(b'001','foo','bar','baz') |
+-----------------------------------+
| foo                               |
+-----------------------------------+
1 row in set (0.00 sec)
```

In the following example, because only the second bit from the right is 1, the function only returns the second string bar.

```
SELECT MAKE_SET(b'010','foo','bar','baz');
```

```
+-----------------------------------+
| MAKE_SET(b'010','foo','bar','baz') |
+-----------------------------------+
| bar                               |
+-----------------------------------+
1 row in set (0.00 sec)
```

In the following example, because only the third bit from the right is `1`, the function only returns the third string `baz`.

```
SELECT MAKE_SET(b'100','foo','bar','baz');
```

```
+-----------------------------------+
| MAKE_SET(b'100','foo','bar','baz') |
+-----------------------------------+
| baz                               |
+-----------------------------------+
1 row in set (0.00 sec)
```

In the following example, because all bits are `1`, the function returns all three strings in a comma-separated result set.

```
SELECT MAKE_SET(b'111','foo','bar','baz');
```

```
+-----------------------------------+
| MAKE_SET(b'111','foo','bar','baz') |
+-----------------------------------+
| foo,bar,baz                       |
+-----------------------------------+
1 row in set (0.0002 sec)
```

MID()

The `MID(str, pos[, len])` function returns a substring starting from the specified `pos` position with the `len` length.

Starting from v8.4.0, TiDB supports the two-argument variant `MID(str, pos)`. If `len` is not specified, this function returns all remaining characters from the specified `pos` position to the end of the string.

If any of the arguments are `NULL`, the function returns `NULL`.

Examples:

In the following example, `MID()` returns the substring of the input string starting from the second character (`b`) with a length of `3` characters.

```
SELECT MID('abcdef',2,3);
```

```
+-------------------+
| MID('abcdef',2,3) |
+-------------------+
| bcd               |
+-------------------+
1 row in set (0.00 sec)
```

In the following example, `MID()` returns the substring of the input string starting from the second character (`b`) to the end of the string.

```
SELECT MID('abcdef',2);
```

```
+-------------------+
| MID('abcdef',2) |
+-------------------+
| bcdef           |
+-------------------+
1 row in set (0.00 sec)
```

`NOT LIKE`

Negation of simple pattern matching.

This function performs the inverse operation of `LIKE`.

Examples:

In the following example, `NOT LIKE` returns `0` (False) because `aaa` matches the `a%` pattern.

```
SELECT 'aaa' LIKE 'a%', 'aaa' NOT LIKE 'a%';
```

```
+-----------------+---------------------+
| 'aaa' LIKE 'a%' | 'aaa' NOT LIKE 'a%' |
+-----------------+---------------------+
|               1 |                   0 |
+-----------------+---------------------+
1 row in set (0.00 sec)
```

In the following example, `NOT LIKE` returns `1` (True) because `aaa` does not match the `b%` pattern.

```
SELECT 'aaa' LIKE 'b%', 'aaa' NOT LIKE 'b%';
```

```
+-----------------+---------------------+
| 'aaa' LIKE 'b%' | 'aaa' NOT LIKE 'b%' |
+-----------------+---------------------+
|               0 |                   1 |
+-----------------+---------------------+
1 row in set (0.00 sec)
```

`NOT REGEXP`

Negation of `REGEXP`.

`OCT()`

Return a string containing octal (base 8) representation of a number.

Examples:

The following example generates a sequence of numbers from 0 to 20 using a recursive common table expression (CTE) and then uses the `OCT()` function to convert each number to its octal representation. Decimal values from 0 to 7 have identical representations in octal. Decimal numbers from 8 to 15 correspond to octal numbers from 10 to 17.

```
WITH RECURSIVE nr(n) AS (
    SELECT 0 AS n
    UNION ALL
    SELECT n+1 FROM nr WHERE n<20
)
SELECT n, OCT(n) FROM nr;
```

```
+------+--------+
| n    | OCT(n) |
+------+--------+
|    0 | 0      |
|    1 | 1      |
|    2 | 2      |
|    3 | 3      |
|    4 | 4      |
|    5 | 5      |
|    6 | 6      |
|    7 | 7      |
|    8 | 10     |
|    9 | 11     |
|   10 | 12     |
|   11 | 13     |
|   12 | 14     |
|   13 | 15     |
|   14 | 16     |
|   15 | 17     |
|   16 | 20     |
|   17 | 21     |
|   18 | 22     |
|   19 | 23     |
|   20 | 24     |
+------+--------+
20 rows in set (0.00 sec)
```

`OCTET_LENGTH()`

Synonym for `LENGTH()`.

`ORD()`

Return the character code for the leftmost character of the given argument.

This function is similar to `CHAR()` but works the other way around.

Examples:

Taking `a` and `A` as an example, `ORD()` returns `97` for `a` and `65` for `A`.

```
SELECT ORD('a'), ORD('A');
```

```
+----------+----------+
| ORD('a') | ORD('A') |
+----------+----------+
|       97 |       65 |
+----------+----------+
1 row in set (0.00 sec)
```

If you take the character code obtained from `ORD()` as input, you can get the original characters back using the `CHAR()` function. Note that the output format might vary depending on whether the `binary-as-hex` option is enabled in your MySQL client.

```
SELECT CHAR(97), CHAR(65);
```

```
+----------+----------+
| CHAR(97) | CHAR(65) |
+----------+----------+
| a        | A        |
+----------+----------+
1 row in set (0.01 sec)
```

The following example shows how `ORD()` handles multibyte characters. Here, both `101` and `0x65` are the UTF-8 encoded values for the `e` character, but in different formats. And both `50091` and `0xC3AB` represent the same values, but for the `ë` character.

```
SELECT ORD('e'), ORD('ë'), HEX('e'), HEX('ë');
```

```
+----------+-----------+----------+-----------+
| ORD('e') | ORD('ë') | HEX('e') | HEX('ë') |
+----------+-----------+----------+-----------+
|      101 |     50091 | 65       | C3AB      |
+----------+-----------+----------+-----------+
1 row in set (0.00 sec)
```

`POSITION()`

Synonym for `LOCATE()`.

`QUOTE()`

Escape the argument for use in an SQL statement.

If the argument is `NULL`, the function returns `NULL`.

Example:

To display the result directly instead of showing a hexadecimal-encoded value, you need to start the MySQL client with the `--skip-binary-as-hex` option.

The following example shows that the ASCII NULL character is escaped as `\0` and the single quote character `'` is escaped as `\'`:

```
SELECT QUOTE(0x002774657374);
```

```
+-----------------------+
| QUOTE(0x002774657374) |
+-----------------------+
| '\0\'test'            |
+-----------------------+
1 row in set (0.00 sec)
```

`REGEXP`

Pattern matching using regular expressions.

Examples:

In this example a number of strings are matched against two regular expressions.

```
WITH vals AS (
    SELECT 'TiDB' AS v
    UNION ALL
    SELECT 'Titanium'
    UNION ALL
    SELECT 'Tungsten'
    UNION ALL
    SELECT 'Rust'
)
SELECT
    v,
    v REGEXP '^Ti' AS 'starts with "Ti"',
    v REGEXP '^.{4}$' AS 'Length is 4 characters'
FROM
    vals;
```

```
+----------+-----------------+-----------------------+
| v        | starts with "Ti" | Length is 4 characters |
+----------+-----------------+-----------------------+
| TiDB     |               1 |                     1 |
| Titanium |               1 |                     0 |
| Tungsten |               0 |                     0 |
| Rust     |               0 |                     1 |
+----------+-----------------+-----------------------+
4 rows in set (0.00 sec)
```

The following example demonstrates that `REGEXP` is not limited to the `SELECT` clause. For example, you can also use it in the `WHERE` clause of the query.

```
SELECT
    v
FROM (
        SELECT 'TiDB' AS v
    ) AS vals
WHERE
    v REGEXP 'DB$';
```

```
+------+
| v    |
+------+
| TiDB |
+------+
1 row in set (0.01 sec)
```

REGEXP_INSTR()

Return the starting index of the substring that matches the regular expression (Partly compatible with MySQL. For more details, see Regular expression compatibility with MySQL).

The `REGEXP_INSTR(str, regexp, [start, [match, [ret, [match_type]]]])` function returns the position of the match if the regular expression (`regexp`) matches the string (`str`).

If either the `str` or `regexp` is `NULL`, then the function returns `NULL`.

Examples:

In the example below you can see that the `^.b.$` matches `abc`.

```
SELECT REGEXP_INSTR('abc','^.b.$');
```

```
+---------------------------+
| REGEXP_INSTR('abc','^.b.$') |
```

```
+-----------------------------+
|                           1 |
+-----------------------------+
1 row in set (0.00 sec)
```

The following example uses the third argument to look for a match with a different start position in the string.

```
SELECT REGEXP_INSTR('abcabc','a');
```

```
+-----------------------------+
| REGEXP_INSTR('abcabc','a') |
+-----------------------------+
|                           1 |
+-----------------------------+
1 row in set (0.00 sec)
```

```
SELECT REGEXP_INSTR('abcabc','a',2);
```

```
+-------------------------------+
| REGEXP_INSTR('abcabc','a',2) |
+-------------------------------+
|                             4 |
+-------------------------------+
1 row in set (0.00 sec)
```

The following example uses the 4th argument to look for the second match.

```
SELECT REGEXP_INSTR('abcabc','a',1,2);
```

```
+---------------------------------+
| REGEXP_INSTR('abcabc','a',1,2) |
+---------------------------------+
|                               4 |
+---------------------------------+
1 row in set (0.00 sec)
```

The following example uses the 5th argument to return the value *after* the mach, instead of the value of the match.

```
SELECT REGEXP_INSTR('abcabc','a',1,1,1);
```

```
+---------------------------------+
| REGEXP_INSTR('abcabc','a',1,1,1) |
+---------------------------------+
|                               2 |
```

```
+----------------------------------+
1 row in set (0.00 sec)
```

The following example uses the 6th argument to add the `i` flag to get a case insensitive match. For more details about regular expression `match_type`, see `match_type` compatibility.

```
SELECT REGEXP_INSTR('abcabc','A',1,1,0,'');
```

```
+-----------------------------------+
| REGEXP_INSTR('abcabc','A',1,1,0,'') |
+-----------------------------------+
|                                 0 |
+-----------------------------------+
1 row in set (0.00 sec)
```

```
SELECT REGEXP_INSTR('abcabc','A',1,1,0,'i');
```

```
+------------------------------------+
| REGEXP_INSTR('abcabc','A',1,1,0,'i') |
+------------------------------------+
|                                  1 |
+------------------------------------+
1 row in set (0.00 sec)
```

Besides `match_type`, the collation also influences the matching. The following example uses a case-sensitive and a case-insensitive collation to demonstrate this.

```
SELECT REGEXP_INSTR('abcabc','A' COLLATE utf8mb4_general_ci);
```

```
+-------------------------------------------------------+
| REGEXP_INSTR('abcabc','A' COLLATE utf8mb4_general_ci) |
+-------------------------------------------------------+
|                                                     1 |
+-------------------------------------------------------+
1 row in set (0.01 sec)
```

```
SELECT REGEXP_INSTR('abcabc','A' COLLATE utf8mb4_bin);
```

```
+-----------------------------------------------+
| REGEXP_INSTR('abcabc','A' COLLATE utf8mb4_bin) |
+-----------------------------------------------+
|                                             0 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

REGEXP_LIKE()

Whether the string matches the regular expression (Partly compatible with MySQL. For more details, see Regular expression compatibility with MySQL).

The `REGEXP_LIKE(str, regex, [match_type])` function is used to test if a regular expression matches a string. Optionally the `match_type` can be used to change the matching behavior.

Examples:

The following example shows that `^a` matches `abc`.

```
SELECT REGEXP_LIKE('abc','^a');
```

```
+-------------------------+
| REGEXP_LIKE('abc','^a') |
+-------------------------+
|                       1 |
+-------------------------+
1 row in set (0.00 sec)
```

This following example shows that `^A` does not match `abc`.

```
SELECT REGEXP_LIKE('abc','^A');
```

```
+-------------------------+
| REGEXP_LIKE('abc','^A') |
+-------------------------+
|                       0 |
+-------------------------+
1 row in set (0.00 sec)
```

This example matches `^A` against `abc`, which now matches because of the `i` flag which enabled case insensitive matching. For more details about the regular expression `match_type`, see `match_type` compatibility.

```
SELECT REGEXP_LIKE('abc','^A','i');
```

```
+----------------------------+
| REGEXP_LIKE('abc','^A','i') |
+----------------------------+
|                          1 |
+----------------------------+
1 row in set (0.00 sec)
```

REGEXP_REPLACE()

Replace substrings that match the regular expression (Partly compatible with MySQL. For more details, see Regular expression compatibility with MySQL).

The `REGEXP_REPLACE(str, regexp, replace, [start, [match, [match_type]]])` function can be used to replace strings based on regular expressions.

Examples:

In the following example, two o's are replaced by `i`.

```
SELECT REGEXP_REPLACE('TooDB', 'o{2}', 'i');
```

```
+-------------------------------------+
| REGEXP_REPLACE('TooDB', 'o{2}', 'i') |
+-------------------------------------+
| TiDB                                |
+-------------------------------------+
1 row in set (0.00 sec)
```

The following example starts the match at the third character, causing the regular expression not to match and not do any replacement.

```
SELECT REGEXP_REPLACE('TooDB', 'o{2}', 'i',3);
```

```
+---------------------------------------+
| REGEXP_REPLACE('TooDB', 'o{2}', 'i',3) |
+---------------------------------------+
| TooDB                                 |
+---------------------------------------+
1 row in set (0.00 sec)
```

In the following example, the 5th argument is used to set if the first or the second match is used for the replacement.

```
SELECT REGEXP_REPLACE('TooDB', 'o', 'i',1,1);
```

```
+-------------------------------------+
| REGEXP_REPLACE('TooDB', 'o', 'i',1,1) |
+-------------------------------------+
| TioDB                               |
+-------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT REGEXP_REPLACE('TooDB', 'o', 'i',1,2);
```

```
+-------------------------------------+
| REGEXP_REPLACE('TooDB', 'o', 'i',1,2) |
+-------------------------------------+
| ToiDB                               |
+-------------------------------------+
1 row in set (0.00 sec)
```

The following example uses the 6th argument to set the `match_type` for case insensitive matching. For more details about the regular expression `match_type`, see match_type compatibility.

```
SELECT REGEXP_REPLACE('TooDB', 'O{2}','i',1,1);
```

```
+----------------------------------------+
| REGEXP_REPLACE('TooDB', 'O{2}','i',1,1) |
+----------------------------------------+
| TooDB                                  |
+----------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT REGEXP_REPLACE('TooDB', 'O{2}','i',1,1,'i');
```

```
+-----------------------------------------------+
| REGEXP_REPLACE('TooDB', 'O{2}','i',1,1,'i') |
+-----------------------------------------------+
| TiDB                                          |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

REGEXP_SUBSTR()

Return the substring that matches the regular expression (Partly compatible with MySQL. For more details, see Regular expression compatibility with MySQL).

The `REGEXP_SUBSTR(str, regexp, [start, [match, [match_type]]])` function is used to get a substring based on a regular expression.

The following example uses the `Ti.{2}` regular expression to get the `TiDB` substring of the `This is TiDB` string.

```
SELECT REGEXP_SUBSTR('This is TiDB','Ti.{2}');
```

```
+---------------------------------------+
| REGEXP_SUBSTR('This is TiDB','Ti.{2}') |
+---------------------------------------+
| TiDB                                  |
+---------------------------------------+
1 row in set (0.00 sec)
```

REPEAT()

Repeat a string the specified number of times.

Examples:

The following example generates a sequence of numbers from 1 to 20 using a recursive common table expression (CTE). For each number in the sequence, the character `x` is repeated the number of times equal to the number itself.

```
WITH RECURSIVE nr(n) AS (
    SELECT 1 AS n
    UNION ALL
    SELECT n+1 FROM nr WHERE n<20
)
SELECT n, REPEAT('x',n) FROM nr;
```

```
+------+----------------------+
| n    | REPEAT('x',n)        |
+------+----------------------+
|    1 | x                    |
|    2 | xx                   |
|    3 | xxx                  |
|    4 | xxxx                 |
|    5 | xxxxx                |
|    6 | xxxxxx               |
|    7 | xxxxxxx              |
|    8 | xxxxxxxx             |
|    9 | xxxxxxxxx            |
|   10 | xxxxxxxxxx           |
|   11 | xxxxxxxxxxx          |
|   12 | xxxxxxxxxxxx         |
|   13 | xxxxxxxxxxxxx        |

|   15 | xxxxxxxxxxxxxxx      |
|   16 | xxxxxxxxxxxxxxxx     |
|   17 | xxxxxxxxxxxxxxxxx    |
|   18 | xxxxxxxxxxxxxxxxxx   |
|   19 | xxxxxxxxxxxxxxxxxxx  |
|   20 | xxxxxxxxxxxxxxxxxxxx |
+------+----------------------+
20 rows in set (0.01 sec)
```

The following example demonstrates that `REPEAT()` can operate on strings consisting of multiple characters.

```
SELECT REPEAT('ha',3);
```

```
+----------------+
| REPEAT('ha',3) |
+----------------+
| hahaha         |
```

```
+----------------+
1 row in set (0.00 sec)
```

`REPLACE()`

Replace occurrences of a specified string.

`REVERSE()`

Reverse the characters in a string.

`RIGHT()`

Return the specified rightmost number of characters.

`RLIKE`

Synonym for `REGEXP`.

`RPAD()`

Append string the specified number of times.

`RTRIM()`

Remove trailing spaces.

`SPACE()`

Return a string of the specified number of spaces.

`STRCMP()`

Compare two strings.

`SUBSTR()`

Return the substring as specified.

`SUBSTRING()`

Return the substring as specified.

`SUBSTRING_INDEX()`

The `SUBSTRING_INDEX()` function is used to extract a substring from a string based on a specified delimiter and count. This function is particularly useful when dealing with data separated by a specific delimiter, such as parsing CSV data or processing log files.

Syntax:

```
SUBSTRING_INDEX(str, delim, count)
```

- `str`: specifies the string to be processed.
- `delim`: specifies the delimiter in the string, which is case-sensitive.
- `count`: specifies the number of occurrences of the delimiter.

- If `count` is a positive number, the function returns the substring before the `count` occurrences (counting from the left of the string) of the delimiter.
- If `count` is a negative number, the function returns the substring after the `count` occurrences (counting from the right of the string) of the delimiter.
- If `count` is `0`, the function returns an empty string.

Example 1:

```
SELECT SUBSTRING_INDEX('www.tidbcloud.com', '.', 2);
```

Output 1:

```
+-----------------------------------------+
| SUBSTRING_INDEX('www.tidbcloud.com', '.', 2) |
+-----------------------------------------+
| www.tidbcloud                           |
+-----------------------------------------+
```

Example 2:

```
SELECT SUBSTRING_INDEX('www.tidbcloud.com', '.', -1);
```

Output 2:

```
+-----------------------------------------+
| SUBSTRING_INDEX('www.tidbcloud.com', '.', -1) |
+-----------------------------------------+
| com                                     |
+-----------------------------------------+
```

TO_BASE64()

The `TO_BASE64()` function is used to convert the given argument to a string in the base-64 encoded form and return the result according to the character set and collation of the current connection. A base-64 encoded string can be decoded using the `FROM_BASE64()` function.

Syntax:

```
TO_BASE64(str)
```

- If the argument is not a string, the function converts it to a string before base-64 encoding.
- If the argument is `NULL`, the function returns `NULL`.

Example 1:

```
SELECT TO_BASE64('abc');
```

Output 1:

```
+------------------+
| TO_BASE64('abc') |
+------------------+
| YWJj             |
+------------------+
```

Example 2:

```
SELECT TO_BASE64(6);
```

Output 2:

```
+--------------+
| TO_BASE64(6) |
+--------------+
| Ng==         |
+--------------+
```

`TRANSLATE()`

Replace all occurrences of characters by other characters in a string. It does not treat empty strings as `NULL` as Oracle does.

`TRIM()`

Remove leading and trailing spaces.

`UCASE()`

The `UCASE()` function is used to convert a string to uppercase letters. This function is equivalent to the `UPPER()` function.

> **Note:**
>
> When the string is null, the `UCASE()` function returns `NULL`.

Example:

```
SELECT UCASE('bigdata') AS result_upper, UCASE(null) AS result_null;
```

Output:

```
+--------------+-------------+
| result_upper | result_null |
+--------------+-------------+
| BIGDATA      | NULL        |
+--------------+-------------+
```

UNHEX()

The UNHEX() function performs the reverse operation of the HEX() function. It treats each pair of characters in the argument as a hexadecimal number and converts it to the character represented by that number, returning the result as a binary string.

> **Note:**
>
> - The argument must be a valid hexadecimal value that contains 0–9, A–F, or a–f. If the argument is NULL or falls outside this range, the function returns NULL.
> - In the MySQL client, the --binary-as-hex option is enabled by default in interactive mode, causing the client to display data with an unknown character set as a hexadecimal literal. You can use the --skip-binary ↪ -as-hex option to disable this behavior.

Example:

```
SELECT UNHEX('54694442');
```

Output:

```
+------------------------------------+
| UNHEX('54694442')                  |
+------------------------------------+
| 0x54694442                         |
+------------------------------------+
```

UPPER()

The UPPER() function is used to convert a string to uppercase letters. This function is equivalent to the UCASE() function.

> **Note:**
>
> When the string is null, the UPPER() function returns NULL.

Example:

```
SELECT UPPER('bigdata') AS result_upper, UPPER(null) AS result_null;
```

Output:

```
+--------------+-------------+
| result_upper | result_null |
+--------------+-------------+
| BIGDATA      | NULL        |
+--------------+-------------+
```

WEIGHT_STRING()

The `WEIGHT_STRING()` function returns the weight string (binary characters) for the input string, primarily used for sorting and comparison operations in multi-character set scenarios. If the argument is `NULL`, it returns `NULL`. The syntax is as follows:

```
WEIGHT_STRING(str [AS {CHAR|BINARY}(N)])
```

- `str`: the input string expression. If it is a non-binary string, such as a `CHAR`, `VARCHAR`, or `TEXT` value, the return value contains the collation weights for the string. If it is a binary string, such as a `BINARY`, `VARBINARY`, or `BLOB` value, the return value is the same as the input.
- `AS {CHAR|BINARY}(N)`: optional parameters used to specify the type and length of the output. `CHAR` represents the character data type, and `BINARY` represents the binary data type. `N` specifies the output length, which is an integer greater than or equal to 1.

> **Note:**
>
> If `N` is less than the string length, the string is truncated. If `N` exceeds the string length, `AS CHAR(N)` pads the string with spaces to the specified length, and `AS BINARY(N)` pads the string with `0x00` to the specified length.

Example:

```
SET NAMES 'utf8mb4';
SELECT HEX(WEIGHT_STRING('ab' AS CHAR(3))) AS char_result, HEX(WEIGHT_
    ↪ STRING('ab' AS BINARY(3))) AS binary_result;
```

Output:

```
+-------------+---------------+
| char_result | binary_result |
+-------------+---------------+
| 6162        | 616200        |
+-------------+---------------+
```

14.13.4.5.2 Unsupported functions

- `LOAD_FILE()`
- `MATCH()`
- `SOUNDEX()`

14.13.4.5.3 Regular expression compatibility with MySQL

The following sections describe the regular expression compatibility with MySQL, including `REGEXP_INSTR()`, `REGEXP_LIKE()`, `REGEXP_REPLACE()`, and `REGEXP_SUBSTR()`.

Syntax compatibility

MySQL implements regular expression using International Components for Unicode (ICU), and TiDB uses RE2. To learn the syntax differences between the two libraries, you can refer to the ICU documentation and RE2 Syntax.

`match_type` compatibility

The value options of `match_type` between TiDB and MySQL are:

- Value options in TiDB are `"c"`, `"i"`, `"m"`, and `"s"`, and value options in MySQL are `"c"`, `"i"`, `"m"`, `"n"`, and `"u"`.
- The `"s"` in TiDB corresponds to `"n"` in MySQL. When `"s"` is set in TiDB, the `.` character also matches line terminators (`\n`).

  For example, the `SELECT REGEXP_LIKE(a, b, "n")FROM t1` in MySQL is the same as the `SELECT REGEXP_LIKE(a, b, "s")FROM t1` in TiDB.
- TiDB does not support `"u"`, which means Unix-only line endings in MySQL.

`match_type`	MySQL	TiDB	Description
c	Yes	Yes	Case-sensitive matching
i	Yes	Yes	Case-insensitive matching
m	Yes	Yes	Multi-line mode
s	No	Yes	Matches newlines, same as `n` in MySQL
n	Yes	No	Matches newlines, same as `s` in TiDB
u	Yes	No	UNIX™ line endings

Data type compatibility

The difference between TiDB and MySQL support for the binary string type:

- MySQL does not support binary strings in regular expression functions since 8.0.22. For more details, refer to MySQL documentation. But in practice, regular functions

can work in MySQL when all parameters or return types are binary strings. Otherwise, an error will be reported.
- Currently, TiDB prohibits using binary strings and an error will be reported under any circumstances.

Other compatibility

- The behavior of replacing empty strings in TiDB is different from MySQL. Taking `REGEXP_REPLACE("", "^$", "123")` as an example:
  - MySQL does not replace the empty string and returns `""` as the result.
  - TiDB replaces the empty string and returns `"123"` as the result.
- The keyword used for capturing groups in TiDB is different from MySQL. MySQL uses `$` as the keyword, while TiDB uses `\\` as the keyword. In addition, TiDB only supports capturing groups numbered from `0` to `9`.

  For example, the following SQL statement returns `ab` in TiDB:

```
SELECT REGEXP_REPLACE('abcd','(.*)(.{2})$','\\1') AS s;
```

Known issues

- GitHub Issue #37981

14.13.4.6 Numeric Functions and Operators

TiDB supports all of the numeric functions and operators available in MySQL 8.0.

14.13.4.6.1 Arithmetic operators

Name	Description
+	Addition operator
-	Minus operator
*	Multiplication operator
/	Division operator
DIV	Integer division
lstinlineMOD!	Modulo operator
-	Change the sign of the argument

14.13.4.6.2 Mathematical functions

Name	Description
ABS()	Return the absolute value
ACOS()	Return the arc cosine
ASIN()	Return the arc sine
ATAN()	Return the arc tangent
ATAN2(), ATAN()	Return the arc tangent of the two arguments
CEIL()	Return the smallest integer value not less than the argument
CEILING()	Return the smallest integer value not less than the argument
CONV()	Convert numbers between different number bases
COS()	Return the cosine
COT()	Return the cotangent
CRC32()	Compute a cyclic redundancy check value
DEGREES()	Convert radians to degrees
EXP()	Raise to the power of
FLOOR()	Return the largest integer value not greater than the argument
LN()	Return the natural logarithm of the argument
LOG()	Return the natural logarithm of the first argument
LOG10()	Return the base-10 logarithm of the argument
LOG2()	Return the base-2 logarithm of the argument
MOD()	Return the remainder
PI()	Return the value of pi
POW()	Return the argument raised to the specified power
POWER()	Return the argument raised to the specified power
RADIANS()	Return argument converted to radians
RAND()	Return a random floating-point value
ROUND()	Round the argument
SIGN()	Return the sign of the argument
SIN()	Return the sine of the argument
SQRT()	Return the square root of the argument
TAN()	Return the tangent of the argument
TRUNCATE()	Truncate to specified number of decimal places

14.13.4.6.3 Related system variables

`div_precision_increment` is used to set the precision for the `/` operator.

14.13.4.7 Date and Time Functions

TiDB supports all of the date and time functions available in MySQL 8.0.

Note:

- MySQL will often accept the incorrectly formatted date and time values. For example, `'2020-01-01\n\t01:01:01'` and `'2020-01_01\n\t01:01'` are treated as valid date and time values.
- TiDB makes the best effort to match MySQL's behavior, but it might not match in all instances. It is recommended to correctly format dates, because the intended behavior for incorrectly formatted values is not documented, and is often inconsistent.

Date/Time functions:

Name	Description
ADDDATE()	Add time values (intervals) to a date value
ADDTIME()	Add time
CONVERT_TZ()	Convert from one time zone to another
CURDATE()	Return the current date
CURRENT_DATE(), CURRENT_DATE	Synonyms for CURDATE()
CURRENT_TIME(), CURRENT_TIME	Synonyms for CURTIME()
CURRENT_TIMESTAMP(), CURRENT_TIMESTAMP	Synonyms for NOW()
CURTIME()	Return the current time
DATE()	Extract the date part of a date or datetime expression
DATE_ADD()	Add time values (intervals) to a date value
DATE_FORMAT()	Format date as specified
DATE_SUB()	Subtract a time value (interval) from a date
DATEDIFF()	Subtract two dates
DAY()	Synonym for DAYOFMONTH()
DAYNAME()	Return the name of the weekday
DAYOFMONTH()	Return the day of the month (0-31)
DAYOFWEEK()	Return the weekday index of the argument
DAYOFYEAR()	Return the day of the year (1-366)
EXTRACT()	Extract part of a date
FROM_DAYS()	Convert a day number to a date
FROM_UNIXTIME()	Format Unix timestamp as a date
GET_FORMAT()	Return a date format string
HOUR()	Extract the hour
LAST_DAY	Return the last day of the month for the argument
LOCALTIME(), LOCALTIME	Synonym for NOW()
LOCALTIMESTAMP, LOCALTIMESTAMP()	Synonym for NOW()
MAKEDATE()	Create a date from the year and day of year

Name	Description
MAKETIME()	Create time from hour, minute, second
MICROSECOND()	Return the microseconds from argument
MINUTE()	Return the minute from the argument
MONTH()	Return the month from the date passed
MONTHNAME()	Return the name of the month
NOW()	Return the current date and time
PERIOD_ADD()	Add a period to a year-month
PERIOD_DIFF()	Return the number of months between periods
QUARTER()	Return the quarter from a date argument
SEC_TO_TIME()	Converts seconds to 'HH:MM:SS' format
SECOND()	Return the second (0-59)
STR_TO_DATE()	Convert a string to a date
SUBDATE()	Synonym for DATE_SUB() when invoked with three arguments
SUBTIME()	Subtract times
SYSDATE()	Return the time at which the function executes
TIME()	Extract the time portion of the expression passed
TIME_FORMAT()	Format as time
TIME_TO_SEC()	Return the argument converted to seconds
TIMEDIFF()	Subtract time
TIMESTAMP()	With a single argument, this function returns the date or datetime expression; with two arguments, the sum of the arguments
TIMESTAMPADD()	Add an interval to a datetime expression
TIMESTAMPDIFF()	Subtract an interval from a datetime expression
TO_DAYS()	Return the date argument converted to days
TO_SECONDS()	Return the date or datetime argument converted to seconds since Year 0
UNIX_TIMESTAMP()	Return a Unix timestamp
UTC_DATE()	Return the current UTC date
UTC_TIME()	Return the current UTC time
UTC_TIMESTAMP()	Return the current UTC date and time
WEEK()	Return the week number
WEEKDAY()	Return the weekday index
WEEKOFYEAR()	Return the calendar week of the date (1-53)
YEAR()	Return the year

Name	Description
YEARWEEK()	Return the year and week

For details, see Date and Time Functions.

14.13.4.7.1 MySQL compatibility

The function STR_TO_DATE() is supported by TiDB, but is unable to parse all date and time values. In addition, the following date and time formatting options are **not implemented**:

Format	Description
"%a"	Abbreviated weekday name (Sun..Sat)
"%D"	Day of the month with English suffix (0th, 1st, 2nd, 3rd)
"%U"	Week (00..53), where Sunday is the first day of the week; WEEK() mode 0
"%u"	Week (00..53), where Monday is the first day of the week; WEEK() mode 1
"%V"	Week (01..53), where Sunday is the first day of the week; WEEK() mode 2; used with %X
"%v"	Week (01..53), where Monday is the first day of the week; WEEK() mode 3; used with %x
"%W"	Weekday name (Sunday..Saturday)
"%w"	Day of the week (0=Sunday..6=Saturday)
"%X"	Year for the week where Sunday is the first day of the week, numeric, four digits.
"%x"	Year for the week, where Monday is the first day of the week, numeric, four digits.

See issue #30082 for more details.

14.13.4.7.2 Related system variables

The default_week_format variable affects the WEEK() function.

14.13.4.8 Bit Functions and Operators

TiDB supports all of the bit functions and operators available in MySQL 8.0.

Bit functions and operators:

Name	Description
BIT_COUNT()	Return the number of bits that are set as 1
&	Bitwise AND
~	Bitwise inversion
|	Bitwise OR

Name	Description
^	Bitwise XOR
<<	Left shift
>>	Right shift

14.13.4.8.1 BIT_COUNT()

The `BIT_COUNT(expr)` function returns the number of bits that are set as 1 in `expr`.

```
SELECT BIT_COUNT(b'00101001');
```

```
+------------------------+
| BIT_COUNT(b'00101001') |
+------------------------+
|                      3 |
+------------------------+
1 row in set (0.00 sec)
```

Note:

If the argument `expr` is a binary number, you need to specify `b` explicitly before the number, such as `b'00101001'`. Otherwise, this function treats it as a string and returns a different result. For example, `BIT_COUNT ↪ ('00101001')` returns `7` because it converts the string `'00101001'` as the decimal number `101001` and counts the number of `1` bits in its binary format `11000100001010001`.

The following example is similar to the preceding one, but it uses a hex-literal instead of a bit-literal as the argument. The `CONV()` function converts `0x29` from hexadecimal (base 16) to binary (base 2), showing that it equals `00101001` in binary.

```
SELECT BIT_COUNT(0x29), CONV(0x29,16,2);
```

```
+-----------------+-----------------+
| BIT_COUNT(0x29) | CONV(0x29,16,2) |
+-----------------+-----------------+
|               3 | 101001          |
+-----------------+-----------------+
1 row in set (0.01 sec)
```

A practical use of the `BIT_COUNT(expr)` function is to convert a netmask to a CIDR notation. In the following example, the netmask `255.255.255.0` is converted to its CIDR representation `24`.

```
SELECT BIT_COUNT(INET_ATON('255.255.255.0'));
```

```
+-------------------------------------+
| BIT_COUNT(INET_ATON('255.255.255.0')) |
+-------------------------------------+
|                                  24 |
+-------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.8.2 & (bitwise AND)

The `&` operator performs a bitwise AND operation. It compares the corresponding bits of two numbers: if both corresponding bits are 1, the corresponding bit of the result is 1; otherwise, it is 0.

For example, a bitwise AND operation between `1010` and `1100` returns `1000`, because only the leftmost bit is set as 1 in both numbers.

```
  1010
& 1100
  ----
  1000
```

In SQL, you can use the `&` operator as follows:

```
SELECT CONV(b'1010' & b'1000',10,2);
```

```
+-----------------------------+
| CONV(b'1010' & b'1000',10,2) |
+-----------------------------+
| 1000                        |
+-----------------------------+
1 row in set (0.00 sec)
```

You can use the `&` operator with `INET_NTOA()` and `INET_ATON()` functions to perform a bitwise AND operation on an IP address and a network mask to get the network address. This is useful to determine whether multiple IP addresses belong to the same network or not.

In the following two examples, the IP addresses `192.168.1.1` and `192.168.1.2` are in the same network `192.168.1.0/24` when masked with `255.255.255.0`.

```
SELECT INET_NTOA(INET_ATON('192.168.1.1') & INET_ATON('255.255.255.0'));
```

```
+-----------------------------------------------------------------+
| INET_NTOA(INET_ATON('192.168.1.1') & INET_ATON('255.255.255.0')) |
```

```
+-----------------------------------------------------------------+
| 192.168.1.0                                                     |
+-----------------------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT INET_NTOA(INET_ATON('192.168.1.2') & INET_ATON('255.255.255.0'));
```

```
+-----------------------------------------------------------------+
| INET_NTOA(INET_ATON('192.168.1.2') & INET_ATON('255.255.255.0')) |
+-----------------------------------------------------------------+
| 192.168.1.0                                                     |
+-----------------------------------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.8.3 ~ (bitwise inversion)

The ~ operator performs a bitwise inversion (or bitwise NOT) operation on a given value. It inverts each bit of the given value: bits that are 0 become 1, and bits that are 1 become 0.

Before the operation, the value is expanded to 64 bits.

Take the binary number `1111000011110000` as an example. When expanded to 64 bits and inverted, it looks like this:

```
Original (16 bits):
    ↪ 1111000011110000
Expanded and inverted (64 bits):
    ↪ 1111111111111111111111111111111111111111111111110000111100001111
```

In SQL, you can use the ~ operator as follows:

```
SELECT CONV(~ b'1111000011110000',10,2);
+-----------------------------------------------------------------+
| CONV(~ b'1111000011110000',10,2)                                |
+-----------------------------------------------------------------+
| 1111111111111111111111111111111111111111111111110000111100001111 |
+-----------------------------------------------------------------+
1 row in set (0.00 sec)
```

You can reverse the inversion by applying the ~ operator again to the result:

```
SELECT CONV(~ b'
    ↪ 1111111111111111111111111111111111111111111111110000111100001111'
    ↪ ,10,2);
```

```
+-------------------------------------------------------------------------------------+
   ↪
| CONV(~ b
   ↪ '1111111111111111111111111111111111111111111111110000111100001111',10,2)
   ↪  |
+-------------------------------------------------------------------------------------+
   ↪
| 1111000011110000                                                      |
+-------------------------------------------------------------------------------------+
   ↪
1 row in set (0.00 sec)
```

14.13.4.8.4 | (bitwise OR)

The | operator performs a bitwise OR operation. It compares the corresponding bits of two numbers: if at least one of the corresponding bits is 1, the corresponding bit in the result is 1.

For example, a bitwise OR operation between `1010` and `1100` returns `1110`, because among the first three bits of the two numbers, at least one of the corresponding bits is set as 1.

```
  1010
| 1100
  ----
  1110
```

In SQL, you can use the | operator as follows:

```
SELECT CONV(b'1010' | b'1100',10,2);
```

```
+-----------------------------+
| CONV(b'1010' | b'1100',10,2) |
+-----------------------------+
| 1110                        |
+-----------------------------+
1 row in set (0.00 sec)
```

14.13.4.8.5 ^ (bitwise XOR)

The ^ operator performs a bitwise XOR (exclusive OR) operation. It compares the corresponding bits of two numbers: if the corresponding bits are different, the corresponding bit in the result is 1.

For example, a bitwise XOR operation between `1010` and `1100` returns `0110`, because the second and the third bits of the two numbers are different.

```
  1010
^ 1100
  ----
  0110
```

In SQL, you can use the ^ operator as follows:

```
SELECT CONV(b'1010' ^ b'1100',10,2);
```

```
+------------------------------+
| CONV(b'1010' ^ b'1100',10,2) |
+------------------------------+
| 110                          |
+------------------------------+
1 row in set (0.00 sec)
```

Note that the result is shown as `110` instead of `0110` because the leading zero is removed.

14.13.4.8.6 << (left shift)

The `<<` operator performs a left shift operation, which shifts the bits of a number to the left by a specified number of positions, filling the vacated bits with zeros on the right.

For example, the following statement uses `1<<n` to shift the binary value `1` to the left by `n` positions:

```
WITH RECURSIVE cte(n) AS (
    SELECT 0 AS n
    UNION ALL
    SELECT 1+n FROM cte WHERE n<10
)
SELECT n,1<<n,LPAD(CONV(1<<n,10,2),11,0) FROM cte;
```

```
+------+------+----------------------------+
| n    | 1<<n | LPAD(CONV(1<<n,10,2),11,0) |
+------+------+----------------------------+
|    0 |    1 | 00000000001                |
|    1 |    2 | 00000000010                |
|    2 |    4 | 00000000100                |
|    3 |    8 | 00000001000                |
|    4 |   16 | 00000010000                |
|    5 |   32 | 00000100000                |
|    6 |   64 | 00001000000                |
|    7 |  128 | 00010000000                |
|    8 |  256 | 00100000000                |
|    9 |  512 | 01000000000                |
```

```
|   10 | 1024 | 10000000000              |
+------+------+--------------------------+
11 rows in set (0.00 sec)
```

14.13.4.8.7 >> (right shift)

The `>>` operator performs a right shift operation, which shifts the bits of a number to the right by a specified number of positions, filling the vacated bits with zeros on the left.

For example, the following statement uses `1024>>n` to shift a value of `1024` (`10000000000` in binary) to the right by `n` positions:

```
WITH RECURSIVE cte(n) AS (
    SELECT 0 AS n
    UNION ALL
    SELECT n+1 FROM cte WHERE n<11
)
SELECT n,1024>>n,LPAD(CONV(1024>>n,10,2),11,0) FROM cte;
```

```
+------+---------+-------------------------------+
| n    | 1024>>n | LPAD(CONV(1024>>n,10,2),11,0) |
+------+---------+-------------------------------+
|    0 |    1024 | 10000000000                   |
|    1 |     512 | 01000000000                   |
|    2 |     256 | 00100000000                   |
|    3 |     128 | 00010000000                   |
|    4 |      64 | 00001000000                   |
|    5 |      32 | 00000100000                   |
|    6 |      16 | 00000010000                   |
|    7 |       8 | 00000001000                   |
|    8 |       4 | 00000000100                   |
|    9 |       2 | 00000000010                   |
|   10 |       1 | 00000000001                   |
|   11 |       0 | 00000000000                   |
+------+---------+-------------------------------+
12 rows in set (0.00 sec)
```

The `>>` operator can also be useful for extracting specific parts of a larger number, such as extracting a UNIX timestamp from a TiDB TSO timestamp.

14.13.4.8.8 MySQL compatibility

There are some differences between MySQL 8.0 and earlier versions of MySQL in handling bit functions and operators. TiDB aims to follow the behavior of MySQL 8.0.

14.13.4.8.9 Known issues

In the following cases, the query results in TiDB are the same as MySQL 5.7 but different from MySQL 8.0.

- Bitwise operations with binary arguments. For more information, see #30637.
- The result of the `BIT_COUNT()` function. For more information, see #44621.

14.13.4.9 Cast Functions and Operators

Cast functions and operators enable conversion of values from one data type to another. TiDB supports all of the cast functions and operators available in MySQL 8.0.

Name	Description
`BINARY`	Cast a string to a binary string
`CAST()`	Cast a value as a certain type
`CONVERT()`	Cast a value as a certain type

Note:

TiDB and MySQL display inconsistent results for `SELECT CAST(MeN AS CHAR ↪ )` (or its equivalent form `SELECT CONVERT(MeM, CHAR)`), where `MeN` represents a double-precision floating-point number in scientific notation. MySQL displays the complete numeric value when `-15 <= N <= 14` and the scientific notation when `N < -15` or `N > 14`. However, TiDB always displays the complete numeric value. For example, MySQL displays the result of `SELECT ↪ CAST(3.1415e15 AS CHAR)` as `3.1415e15`, while TiDB displays the result as `3141500000000000`.

14.13.4.9.1 BINARY

The `BINARY` operator has been deprecated since MySQL 8.0.27. It is recommended to use `CAST(... AS BINARY)` instead both in TiDB and MySQL.

14.13.4.9.2 CAST

The `CAST(<expression> AS <type> [ARRAY])` function is used to cast an expression to a specific type.

This function is also used to create Multi-valued indexes.

The following types are supported:

Type	Description	Whether it can be used with multi-valued indexes
`BINARY(n)`	Binary string	No
`CHAR(n)`	Character string	Yes, but only if a length is specified
`DATE`	Date	Yes
`DATETIME(fsp)`	Date/time, where `fsp` is optional	Yes
`DECIMAL(n, m)`	Decimal number, where `n` and `m` are optional and are `10` and `0` if not specified	No
`DOUBLE`	Double precision floating-point number	No
`FLOAT(n)`	Floating-point number, where `n` is optional and should be between `0` and `53`	No
`JSON`	JSON	No
`REAL`	Floating-point number	Yes
`SIGNED [INTEGER ↪ ]`	Signed integer	Yes
`TIME(fsp)`	Time	Yes
`UNSIGNED [ ↪ INTEGER]`	Unsigned integer	Yes
`VECTOR`	Vector	No
`YEAR`	Year	No

Examples:

The following statement converts a binary string from a HEX literal to a `CHAR`.

```
SELECT CAST(0x54694442 AS CHAR);
```

```
+-------------------------+
| CAST(0x54694442 AS CHAR) |
+-------------------------+
```

```
| TiDB                     |
+--------------------------+
1 row in set (0.0002 sec)
```

The following statement casts the values of the `a` attribute extracted from the JSON column to an unsigned array. Note that casting to an array is only supported as part of an index definition for multi-valued indexes.

```
CREATE TABLE t (
    id INT PRIMARY KEY,
    j JSON,
    INDEX idx_a ((CAST(j->'$.a' AS UNSIGNED ARRAY)))
);
INSERT INTO t VALUES (1, JSON_OBJECT('a',JSON_ARRAY(1,2,3)));
INSERT INTO t VALUES (2, JSON_OBJECT('a',JSON_ARRAY(4,5,6)));
INSERT INTO t VALUES (3, JSON_OBJECT('a',JSON_ARRAY(7,8,9)));
ANALYZE TABLE t;
```

```
 EXPLAIN SELECT * FROM t WHERE 1 MEMBER OF(j->'$.a')\G
*************************** 1. row ***************************
          id: IndexMerge_10
      estRows: 2.00
        task: root
access object:
operator info: type: union
*************************** 2. row ***************************
          id:  ─IndexRangeScan_8(Build)
      estRows: 2.00
        task: cop[tikv]
access object: table:t, index:idx_a(cast(json_extract(`j`, _utf8mb4'$.a')
    ↪ as unsigned array))
operator info: range:[1,1], keep order:false, stats:partial[j:unInitialized
    ↪ ]
*************************** 3. row ***************************
          id:  ─TableRowIDScan_9(Probe)
      estRows: 2.00
        task: cop[tikv]
access object: table:t
operator info: keep order:false, stats:partial[j:unInitialized]
3 rows in set (0.00 sec)
```

14.13.4.9.3 CONVERT

The `CONVERT()` function is used to convert between character sets.

Example:

```
SELECT CONVERT(0x616263 USING utf8mb4);
```

```
+--------------------------------+
| CONVERT(0x616263 USING utf8mb4) |
+--------------------------------+
| abc                            |
+--------------------------------+
1 row in set (0.0004 sec)
```

14.13.4.9.4 MySQL compatibility

- TiDB does not support cast operations on `SPATIAL` types. For more information, see #6347.
- TiDB does not support `AT TIME ZONE` for `CAST()`. For more information, see #51742.
- `CAST(24 AS YEAR)` returns 2 digits in TiDB and 4 digits in MySQL. For more information, see #29629.

14.13.4.10 Encryption and Compression Functions

TiDB supports most of the encryption and compression functions available in MySQL 8.0.

14.13.4.10.1 Supported functions

Name	Description
AES_DECRYPT()	Decrypt using AES
AES_ENCRYPT()	Encrypt using AES
COMPRESS()	Compress and return result as a binary string
MD5()	Calculate MD5 checksum
PASSWORD()	Calculate and return a password string
RANDOM_BYTES()	Return a random byte vector
SHA()	Calculate an SHA-1 160-bit checksum
SHA1()	Calculate an SHA-1 160-bit checksum
SHA2()	Calculate an SHA-2 checksum
SM3()	Calculate an SM3 checksum
UNCOMPRESS()	Uncompress a compressed string
UNCOMPRESSED_LENGTH()	Return the length of a string before compression
VALIDATE_PASSWORD_STRENGTH()	Validate the password strength

AES_DECRYPT()

The `AES_DECRYPT(data, key [,iv])` function decrypts `data` that was previously en-

crypted using the AES_ENCRYPT() function with the same key.

You can use the block_encryption_mode system variable to select the Advanced Encryption Standard (AES) encryption mode.

For encryption modes that require an initialization vector, set it with the iv argument. The default value is NULL.

```
SELECT AES_DECRYPT(0x28409970815CD536428876175F1A4923, 'secret');
```

```
+-------------------------------------------------------------------------------
   ↪
| AES_DECRYPT(0x28409970815CD536428876175F1A4923, 'secret')
   ↪                                                      |
+-------------------------------------------------------------------------------
   ↪
| 0x616263
   ↪
   ↪ |
+-------------------------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

AES_ENCRYPT()

The AES_ENCRYPT(data, key [,iv]) function encrypts data with key using the Advanced Encryption Standard (AES) algorithm.

You can use the block_encryption_mode system variable to select the AES encryption mode.

For encryption modes that require an initialization vector, set it with the iv argument. The default value is NULL.

```
SELECT AES_ENCRYPT(0x616263,'secret');
```

```
+------------------------------------------------------------+
| AES_ENCRYPT(0x616263,'secret')                             |
+------------------------------------------------------------+
| 0x28409970815CD536428876175F1A4923                         |
+------------------------------------------------------------+
1 row in set (0.00 sec)
```

COMPRESS()

The COMPRESS(expr) function returns a compressed version of the input data expr.

- If the argument is NULL, the function returns NULL.
- If the argument is an empty string, the function returns a zero-length value.

For non-zero length argument, the function returns a binary string with the following structure:

- Bytes 0 to 3: the uncompressed length
- Bytes 4 to the end: the zlib compressed data

```
SELECT COMPRESS(0x414243);
```

```
+----------------------------------------+
| COMPRESS(0x414243)                     |
+----------------------------------------+
| 0x03000000789C72747206040000FFFF018D00C7 |
+----------------------------------------+
1 row in set (0.00 sec)
```

In this output, `0x03000000` represents the uncompressed length (3) and `0x789C72747206040000FFFF01`
↪ is the zlib compressed data.

An example of using Python to decode this outside of TiDB:

```
import codecs
import zlib

data = codecs.decode('03000000789C72747206040000FFFF018D00C7','hex')
print(int.from_bytes(data[:4], byteorder='little')) # 3
print(zlib.decompress(data[4:])) # b'ABC'
```

For short strings, `COMPRESS()` might return more bytes than the input. The following example shows that a string of 100 `a` characters compresses to 19 bytes.

```
WITH x AS (SELECT REPEAT('a',100) 'a')
SELECT LENGTH(a),LENGTH(COMPRESS(a)) FROM x;
```

```
+-----------+---------------------+
| LENGTH(a) | LENGTH(COMPRESS(a)) |
+-----------+---------------------+
|       100 |                  19 |
+-----------+---------------------+
1 row in set (0.00 sec)
```

MD5()

The `MD5(expr)` function calculates a 128-bit MD5 hash for the given argument `expr`.

```
SELECT MD5('abc');
```

```
+----------------------------------+
| MD5('abc')                       |
+----------------------------------+
| 900150983cd24fb0d6963f7d28e17f72 |
+----------------------------------+
1 row in set (0.00 sec)
```

PASSWORD()

> **Warning:**
>
> This function is deprecated in MySQL 5.7 and removed in MySQL 8.0. It is deprecated in TiDB. It is not recommended to use this function.

The `PASSWORD(str)` function calculates a password hash that can be used with the `mysql_native_password` authentication method.

```
SELECT PASSWORD('secret');
```

```
+-------------------------------------------+
| PASSWORD('secret')                        |
+-------------------------------------------+
| *14E65567ABDB5135D0CFD9A70B3032C179A49EE7 |
+-------------------------------------------+
1 row in set, 1 warning (0.00 sec)

Warning (Code 1681): PASSWORD is deprecated and will be removed in a future
    ↪ release.
```

RANDOM_BYTES()

The `RANDOM_BYTES(n)` function returns `n` random bytes.

```
SELECT RANDOM_BYTES(3);
```

```
+----------------------------------+
| RANDOM_BYTES(3)                  |
+----------------------------------+
| 0x1DBC0D                         |
+----------------------------------+
1 row in set (0.00 sec)
```

SHA()

The `SHA()` function is an alias for `SHA1`.

SHA1()

The `SHA1(expr)` function calculates a 160-bit SHA-1 hash for the given argument `expr`.

```
SELECT SHA1('abc');
```

```
+------------------------------------------+
| SHA1('abc')                              |
+------------------------------------------+
| a9993e364706816aba3e25717850c26c9cd0d89d |
+------------------------------------------+
1 row in set (0.00 sec)
```

SHA2()

The `SHA2(str, n)` function calculates a hash using an algorithm from the SHA-2 family. The `n` argument is used to select the algorithm. `SHA2()` returns `NULL` if any of the arguments are `NULL` or if the algorithm selected by `n` is unknown or unsupported.

The following lists supported algorithms:

n	Algorithm
0	SHA-256
224	SHA-224
256	SHA-256
384	SHA-384
512	SHA-512

```
SELECT SHA2('abc',224);
```

```
+----------------------------------------------------------+
| SHA2('abc',224)                                          |
+----------------------------------------------------------+
| 23097d223405d8228642a477bda255b32aadbce4bda0b3f7e36c9da7 |
+----------------------------------------------------------+
1 row in set (0.00 sec)
```

SM3()

> **Note:**
>
> The `SM3()` function is a TiDB extension and is not implemented in MySQL.

The `SM3(str)` function calculates a 256-bit ShangMi 3 (SM3) hash for the given argument `str`.

```
SELECT SM3('abc');
```

```
+------------------------------------------------------------------+
| SM3('abc')                                                       |
+------------------------------------------------------------------+
| 66c7f0f462eeedd9d1f2d46bdc10e4e24167c4875cf2f7a2297da02b8f4ba8e0 |
+------------------------------------------------------------------+
1 row in set (0.00 sec)
```

UNCOMPRESS()

The `UNCOMPRESS(data)` function decompresses the data that was compressed with the `COMPRESS()` function.

```
SELECT UNCOMPRESS(0x03000000789C72747206040000FFFF018D00C7);
```

```
+-------------------------------------------------------------------------------------------
   ↪
| UNCOMPRESS(0x03000000789C72747206040000FFFF018D00C7)
   ↪                                                  |
+-------------------------------------------------------------------------------------------
   ↪
| 0x414243
   ↪
   ↪ |
+-------------------------------------------------------------------------------------------
   ↪
1 row in set (0.00 sec)
```

UNCOMPRESSED_LENGTH()

The `UNCOMPRESSED_LENGTH(data)` function returns the first 4 bytes of the compressed data, which store the length that the compressed string had before being compressed with the `COMPRESS()` function.

```
SELECT UNCOMPRESSED_LENGTH(0x03000000789C72747206040000FFFF018D00C7);
```

```
+-----------------------------------------------------------+
| UNCOMPRESSED_LENGTH(0x03000000789C72747206040000FFFF018D00C7) |
+-----------------------------------------------------------+
|                                                         3 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

VALIDATE_PASSWORD_STRENGTH()

The VALIDATE_PASSWORD_STRENGTH(str) function is used as part of password management. It calculates the strength of a password and returns a value between 0 and 100.

The validate_password.* system variables affect the behavior of the VALIDATE_PASSWORD_STRENGTH() function.

Examples:

- To enable the password complexity check, set the validate_password.enable system variable to ON:

```
SET GLOBAL validate_password.enable=ON;
```

- View password validation-related system variables:

```
SHOW VARIABLES LIKE 'validate_password.%';
```

```
+--------------------------------------+--------+
| Variable_name                        | Value  |
+--------------------------------------+--------+
| validate_password.check_user_name    | ON     |
| validate_password.dictionary         |        |
| validate_password.enable             | ON     |
| validate_password.length             | 8      |
| validate_password.mixed_case_count   | 1      |
| validate_password.number_count       | 1      |
| validate_password.policy             | MEDIUM |
| validate_password.special_char_count | 1      |
+--------------------------------------+--------+
8 rows in set (0.01 sec)
```

- Check the password strength of an empty string, which returns 0:

```
SELECT VALIDATE_PASSWORD_STRENGTH('');
```

```
+-----------------------------------+
| VALIDATE_PASSWORD_STRENGTH('') |
+-----------------------------------+
|                                 0 |
+-----------------------------------+
1 row in set (0.00 sec)
```

- Check the password strength of a short string abcdef, which returns 25:

```
SELECT VALIDATE_PASSWORD_STRENGTH('abcdef');
```

```
+-------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('abcdef') |
+-------------------------------------+
|                                  25 |
+-------------------------------------+
1 row in set (0.00 sec)
```

- Check the password strength of a longer string `abcdefghi`, which returns `50`. This string is longer than the default value of `validate_password.length`:

```
SELECT VALIDATE_PASSWORD_STRENGTH('abcdefghi');
```

```
+----------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('abcdefghi') |
+----------------------------------------+
|                                    50 |
+----------------------------------------+
1 row in set (0.00 sec)
```

- Adding an upper-case character to the string does not improve the password strength:

```
SELECT VALIDATE_PASSWORD_STRENGTH('Abcdefghi');
```

```
+----------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('Abcdefghi') |
+----------------------------------------+
|                                    50 |
+----------------------------------------+
1 row in set (0.01 sec)
```

- Adding numbers to the string also does not improve the password strength:

```
SELECT VALIDATE_PASSWORD_STRENGTH('Abcdefghi123');
```

```
+-----------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('Abcdefghi123') |
+-----------------------------------------+
|                                      50 |
+-----------------------------------------+
1 row in set (0.00 sec)
```

- Finally, adding special characters to the string brings the password strength to `100`, indicating a strong password:

```
SELECT VALIDATE_PASSWORD_STRENGTH('Abcdefghi123%$#');
```

```
+-----------------------------------------------+
| VALIDATE_PASSWORD_STRENGTH('Abcdefghi123%$#') |
+-----------------------------------------------+
|                                           100 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.10.2 Unsupported functions

- TiDB does not support the functions only available in MySQL Enterprise Issue #2632.

14.13.4.10.3 MySQL compatibility

- TiDB does not support the `STATEMENT_DIGEST()` and `STATEMENT_DIGEST_TEXT()` functions.
- TiDB does not support the `kdf_name`, `salt`, and `iterations` arguments for `AES_ENCRYPT()` and `AES_DECRYPT` that MySQL added in MySQL 8.0.30.
- MySQL does not implement the `SM3()` function.

14.13.4.11 Locking Functions

TiDB supports most of the user-level locking functions available in MySQL 8.0.

14.13.4.11.1 Supported functions

Name	Description
`GET_LOCK(lockName, timeout)`	Acquires an advisory lock. The `lockName` parameter must be NO longer than 64 characters. Waits maximum `timeout` seconds before timing out and returns a failure.
`IS_FREE_LOCK(lockName)`	Checks if a lock is free.
`IS_USED_LOCK(lockName)`	Checks if a lock is in use. If true, it returns the corresponding connection ID.
`RELEASE_ALL_LOCKS()`	Releases all locks held by the current session.
`RELEASE_LOCK(lockName)`	Releases a previously acquired lock. The `lockName` parameter must be NO longer than 64 characters.

14.13.4.11.2 MySQL compatibility

- The minimum timeout permitted by TiDB is 1 second, and the maximum timeout is 1 hour (3600 seconds). This differs from MySQL, where both 0 second and unlimited timeouts (`timeout=-1`) are permitted. TiDB will automatically convert out-of-range values to the nearest permitted value and convert `timeout=-1` to 3600 seconds.
- TiDB does not automatically detect deadlocks caused by user-level locks. Deadlocked sessions will time out after a maximum of 1 hour, but can also be manually resolved by using `KILL` on one of the affected sessions. You can also prevent deadlocks by always acquiring user-level locks in the same order.
- Locks take effect on all TiDB servers in the cluster. This differs from MySQL Cluster and Group Replication where locks are local to a single server.
- `IS_USED_LOCK()` returns `1` if it is called from another session and is unable to return the ID of the process that is holding the lock.

14.13.4.12 Information Functions

TiDB supports most of the information functions available in MySQL 8.0.

14.13.4.12.1 TiDB supported MySQL functions

Name	Description
`BENCHMARK` `↪ ()`	Execute an expression in a loop
`CONNECTION` `↪ _ID` `↪ ()`	Return the connection ID (thread ID) for the connection
`CURRENT` `↪ _` `↪ ROLE` `↪ ()`	Return the role that is in use by the connection
`CURRENT` `↪ _` `↪ USER` `↪ (),` `CURRENT` `↪ _` `↪ USER` `↪`	Return the authenticated user name and host name

Name	Description
DATABASE ↪ ()	Return the default (current) database name
FOUND_ ↪ ROWS ↪ ()	For a SELECT with a LIMIT clause, the number of the rows that are returned if there is no LIMIT clause
LAST_ ↪ INSERT ↪ _ID ↪ ()	Return the value of the AUTOINCREMENT ↪ column for the last INSERT
ROW_ ↪ COUNT ↪ ()	The number of rows affected
SCHEMA ↪ ()	Synonym for DATABASE()
SESSION ↪ _ ↪ USER ↪ ()	Synonym for USER()
SYSTEM ↪ _ ↪ USER ↪ ()	Synonym for USER()
USER()	Return the user name and host name provided by the client
VERSION ↪ ()	Return a string that indicates the MySQL server version

BENCHMARK()

The `BENCHMARK()` function executes the given expression a specified number of times.

Syntax:

```
BENCHMARK(count, expression)
```

- `count`: the number of times the expression to be executed.
- `expression`: the expression to be executed repeatedly.

Example:

```
SELECT BENCHMARK(5, SLEEP(2));
```

```
+------------------------+
| BENCHMARK(5, SLEEP(2)) |
+------------------------+
|                      0 |
+------------------------+
1 row in set (10.00 sec)
```

CONNECTION_ID()

The `CONNECTION_ID()` function returns the ID of the connection. Based on the value of the `enable-32bits-connection-id` configuration item for TiDB, this function returns a 32-bit or 64-bit connection ID.

If `enable-global-kill` is enabled, the connection ID can be used to kill queries across multiple TiDB instances of the same cluster.

```
SELECT CONNECTION_ID();
```

```
+-----------------+
| CONNECTION_ID() |
+-----------------+
|      322961414 |
+-----------------+
1 row in set (0.00 sec)
```

CURRENT_ROLE()

The `CURRENT_ROLE()` function returns the current role for the current session.

```
SELECT CURRENT_ROLE();
```

```
+----------------+
| CURRENT_ROLE() |
+----------------+
| NONE           |
+----------------+
1 row in set (0.00 sec)
```

CURRENT_USER()

The `CURRENT_USER()` function returns the account that is used in the current session.

```
SELECT CURRENT_USER();
```

```
+----------------+
| CURRENT_USER() |
+----------------+
| root@%         |
+----------------+
1 row in set (0.00 sec)
```

DATABASE()

The `DATABASE()` function returns the database schema that the current session is using.

```
SELECT DATABASE();
```

```
+------------+
| DATABASE() |
+------------+
| test       |
+------------+
1 row in set (0.00 sec)
```

FOUND_ROWS()

The `FOUND_ROWS()` function returns the number of rows in the result set of the last executed `SELECT` statement.

```
SELECT 1 UNION ALL SELECT 2;
```

```
+------+
| 1    |
+------+
|    2 |
|    1 |
+------+
2 rows in set (0.01 sec)
```

```
SELECT FOUND_ROWS();
```

```
+--------------+
| FOUND_ROWS() |
+--------------+
|            2 |
+--------------+
1 row in set (0.00 sec)
```

> **Note:**
>
> The `SQL_CALC_FOUND_ROWS` query modifier, which calculates the total number of rows in a result set without considering the `LIMIT` clause, is only accepted if `tidb_enable_noop_functions` is enabled. This query modifier is deprecated starting from MySQL 8.0.17. It is recommended to use `COUNT(*)` instead.

LAST_INSERT_ID()

The `LAST_INSERT_ID()` function returns the ID of the last inserted row in a table that contains an `AUTO_INCREMENT` or `AUTO_RANDOM` column.

```
CREATE TABLE t1(id SERIAL);
Query OK, 0 rows affected (0.17 sec)

INSERT INTO t1() VALUES();
Query OK, 1 row affected (0.03 sec)

INSERT INTO t1() VALUES();
Query OK, 1 row affected (0.00 sec)

SELECT LAST_INSERT_ID();
+------------------+
| LAST_INSERT_ID() |
+------------------+
|                3 |
+------------------+
1 row in set (0.00 sec)

TABLE t1;
+----+
| id |
+----+
```

```
|  1 |
|  3 |
+----+
2 rows in set (0.00 sec)
```

Note

- In TiDB, AUTO_ID_CACHE might lead to results that differ from those returned by MySQL. This discrepancy arises because TiDB caches IDs on each node, potentially leading to IDs that are out of order or have gaps. If maintaining strict ID ordering is essential for your application, you can enable MySQL compatible mode.
- In the preceding example, IDs increase by 2 while MySQL would generate IDs incrementing by 1 in the same scenario. For more compatibility information, see Auto-increment ID.

The LAST_INSERT_ID(expr) function can accept an expression as an argument, storing the value for the next call to LAST_INSERT_ID(). You can use it as a MySQL-compatible method for generating sequences. Note that TiDB also supports proper sequence functions.

ROW_COUNT()

The ROW_COUNT() function returns the number of affected rows.

```
CREATE TABLE t1(id BIGINT UNSIGNED PRIMARY KEY AUTO_RANDOM);
Query OK, 0 rows affected, 1 warning (0.16 sec)

INSERT INTO t1() VALUES (),(),();
Query OK, 3 rows affected (0.02 sec)
Records: 3 Duplicates: 0 Warnings: 0

SELECT ROW_COUNT();
+-------------+
| ROW_COUNT() |
+-------------+
|           3 |
+-------------+
1 row in set (0.00 sec)
```

SCHEMA()

The SCHEMA() function is a synonym for DATABASE().

SESSION_USER()

The `SESSION_USER()` function is a synonym for `USER()`.

SYSTEM_USER()

The `SYSTEM_USER()` function is a synonym for `USER()`.

USER()

The `USER()` function returns the user of the current connection. This might differ slightly from the output of `CURRENT_USER()`, as `USER()` displays the actual IP address instead of a wildcard.

```
SELECT USER(), CURRENT_USER();
```

```
+----------------+----------------+
| USER()         | CURRENT_USER() |
+----------------+----------------+
| root@127.0.0.1 | root@%         |
+----------------+----------------+
1 row in set (0.00 sec)
```

VERSION()

The `VERSION()` function returns the TiDB version in a format that is compatible with MySQL. To get a more detailed result, you can use the `TIDB_VERSION()` function.

```
SELECT VERSION();
+--------------------+
| VERSION()          |
+--------------------+
| 8.0.11-TiDB-v7.5.1 |
+--------------------+
1 row in set (0.00 sec)
```

```
SELECT TIDB_VERSION()\G
*************************** 1. row ***************************
TIDB_VERSION(): Release Version: v7.5.1
Edition: Community
Git Commit Hash: 7d16cc79e81bbf573124df3fd9351c26963f3e70
Git Branch: heads/refs/tags/v7.5.1
UTC Build Time: 2024-02-27 14:28:32
GoVersion: go1.21.6
Race Enabled: false
Check Table Before Drop: false
Store: tikv
1 row in set (0.00 sec)
```

The preceding example is from TiDB v7.5.1, which identifies itself as MySQL 8.0.11.

If you want to change the returned version, you can modify the `server-version` configuration item.

14.13.4.12.2 TiDB specific functions

The following function is only supported by TiDB, and there is no equivalent function in MySQL.

Name	Description
`CURRENT_RESOURCE_GROUP()`	Return the name of the resource group that the current session is bound to

14.13.4.12.3 Unsupported functions

- `CHARSET()`
- `COERCIBILITY()`
- `COLLATION()`
- `ICU_VERSION()`
- `ROLES_GRAPHML()`

14.13.4.13 Vector Functions and Operators

This document lists the functions and operators available for Vector data types.

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> Vector data types and these vector functions are only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

14.13.4.13.1 Vector functions

The following functions are designed specifically for Vector data types.

Vector distance functions:

Function Name	Description
VEC_L2_DISTANCE	Calculates L2 distance (Euclidean distance) between two vectors
VEC_COSINE_DISTANCE	Calculates the cosine distance between two vectors
VEC_NEGATIVE_INNER_PRODUCT	Calculates the negative of the inner product between two vectors
VEC_L1_DISTANCE	Calculates L1 distance (Manhattan distance) between two vectors

Other vector functions:

Function Name	Description
VEC_DIMS	Returns the dimension of a vector
VEC_L2_NORM	Calculates the L2 norm (Euclidean norm) of a vector
VEC_FROM_TEXT	Converts a string into a vector
VEC_AS_TEXT	Converts a vector into a string

14.13.4.13.2 Extended built-in functions and operators

The following built-in functions and operators are extended to support operations on Vector data types.

Arithmetic operators:

Name	Description
+	Vector element-wise addition operator
-	Vector element-wise subtraction operator

For more information about how vector arithmetic works, see Vector Data Type | Arithmetic.

Aggregate (GROUP BY) functions:

Name	Description
COUNT()	Return a count of the number of rows returned
COUNT(DISTINCT)	Return the count of a number of different values
MAX()	Return the maximum value
MIN()	Return the minimum value

Comparison functions and operators:

Name	Description
`BETWEEN ... AND ...`	Check whether a value is within a range of values
`COALESCE()`	Return the first non-NULL argument
`=`	Equal operator
`<=>`	NULL-safe equal to operator
`>`	Greater than operator
`>=`	Greater than or equal operator
`GREATEST()`	Return the largest argument
`IN()`	Check whether a value is within a set of values
`IS NULL`	Test whether a value is `NULL`
`ISNULL()`	Test whether the argument is `NULL`
`LEAST()`	Return the smallest argument
`<`	Less than operator
`<=`	Less than or equal operator
`NOT BETWEEN ... AND ...`	Check whether a value is not within a range of values
`!=`, `<>`	Not equal operator
`NOT IN()`	Check whether a value is not within a set of values

For more information about how vectors are compared, see Vector Data Type | Comparison.

Control flow functions:

Name	Description
`CASE`	Case operator
`IF()`	If/else construct
`IFNULL()`	Null if/else construct
`NULLIF()`	Return `NULL` if expr1 = expr2

Cast functions:

Name	Description
`CAST()`	Cast a value as a string or vector
`CONVERT()`	Cast a value as a string

For more information about how to use `CAST()`, see Vector Data Type | Cast.

14.13.4.13.3 Full references

VEC_L2_DISTANCE

```
VEC_L2_DISTANCE(vector1, vector2)
```

Calculates the L2 distance (Euclidean distance) between two vectors using the following formula:

$$DISTANCE(p, q) = \sqrt{\sum_{i=1}^{n} (p_i - q_i)^2}$$

The two vectors must have the same dimension. Otherwise, an error is returned.

Example:

```
[tidb]> SELECT VEC_L2_DISTANCE('[0,3]', '[4,0]');
+---------------------------------+
| VEC_L2_DISTANCE('[0,3]', '[4,0]') |
+---------------------------------+
|                               5 |
+---------------------------------+
```

VEC_COSINE_DISTANCE

```
VEC_COSINE_DISTANCE(vector1, vector2)
```

Calculates the cosine distance between two vectors using the following formula:

$$DISTANCE(p, q) = 1.0 - \frac{\sum_{i=1}^{n} p_i q_i}{\sqrt{\sum_{i=1}^{n} p_i^2} \cdot \sqrt{\sum_{i=1}^{n} q_i^2}}$$

The two vectors must have the same dimension. Otherwise, an error is returned.

Example:

```
[tidb]> SELECT VEC_COSINE_DISTANCE('[1, 1]', '[-1, -1]');
+-----------------------------------------+
| VEC_COSINE_DISTANCE('[1, 1]', '[-1, -1]') |
+-----------------------------------------+
|                                       2 |
+-----------------------------------------+
```

VEC_NEGATIVE_INNER_PRODUCT

```
VEC_NEGATIVE_INNER_PRODUCT(vector1, vector2)
```

Calculates the distance by using the negative of the inner product between two vectors, using the following formula:

$$DISTANCE(p, q) = -INNER_PROD(p, q) = -\sum_{i=1}^{n} p_i q_i$$

The two vectors must have the same dimension. Otherwise, an error is returned.

Example:

```
[tidb]> SELECT VEC_NEGATIVE_INNER_PRODUCT('[1,2]', '[3,4]');
+-----------------------------------------------+
| VEC_NEGATIVE_INNER_PRODUCT('[1,2]', '[3,4]') |
+-----------------------------------------------+
|                                           -11 |
+-----------------------------------------------+
```

VEC_L1_DISTANCE

```
VEC_L1_DISTANCE(vector1, vector2)
```

Calculates the L1 distance (Manhattan distance) between two vectors using the following formula:

$$DISTANCE(p, q) = \sum_{i=1}^{n} |p_i - q_i|$$

The two vectors must have the same dimension. Otherwise, an error is returned.

Example:

```
[tidb]> SELECT VEC_L1_DISTANCE('[0,0]', '[3,4]');
+-----------------------------------+
| VEC_L1_DISTANCE('[0,0]', '[3,4]') |
+-----------------------------------+
|                                 7 |
+-----------------------------------+
```

VEC_DIMS

```
VEC_DIMS(vector)
```

Returns the dimension of a vector.

Examples:

```
[tidb]> SELECT VEC_DIMS('[1,2,3]');
+---------------------+
| VEC_DIMS('[1,2,3]') |
+---------------------+
|                   3 |
+---------------------+

[tidb]> SELECT VEC_DIMS('[]');
+----------------+
| VEC_DIMS('[]') |
+----------------+
|              0 |
+----------------+
```

VEC_L2_NORM

```
VEC_L2_NORM(vector)
```

Calculates the L2 norm (Euclidean norm) of a vector using the following formula:

$$NORM(p) = \sqrt{\sum_{i=1}^{n} p_i^2}$$

Example:

```
[tidb]> SELECT VEC_L2_NORM('[3,4]');
+----------------------+
| VEC_L2_NORM('[3,4]') |
+----------------------+
|                    5 |
+----------------------+
```

VEC_FROM_TEXT

```
VEC_FROM_TEXT(string)
```

Converts a string into a vector.

Example:

```
[tidb]> SELECT VEC_FROM_TEXT('[1,2]') + VEC_FROM_TEXT('[3,4]');
+-------------------------------------------------+
| VEC_FROM_TEXT('[1,2]') + VEC_FROM_TEXT('[3,4]') |
+-------------------------------------------------+
| [4,6]                                           |
+-------------------------------------------------+
```

VEC_AS_TEXT

```
VEC_AS_TEXT(vector)
```

Converts a vector into a string.

Example:

```
[tidb]> SELECT VEC_AS_TEXT('[1.000, 2.5]');
+------------------------------+
| VEC_AS_TEXT('[1.000, 2.5]') |
+------------------------------+
| [1,2.5]                      |
+------------------------------+
```

14.13.4.13.4 MySQL compatibility

The vector functions and the extended usage of built-in functions and operators over vector data types are TiDB specific, and are not supported in MySQL.

14.13.4.13.5 See also

- Vector Data Types

14.13.4.14 JSON Functions

14.13.4.14.1 JSON Functions

You can use JSON functions to work with data in the JSON data type.

Functions that create JSON values

Function Name	Description
JSON_ARRAY()	Evaluates a (possibly empty) list of values and returns a JSON array containing those values
JSON_OBJECT()	Evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs
JSON_QUOTE()	Returns a string as a JSON value with quotes

Functions that search JSON values

Function Name	Description
JSON_CONTAINS()	Indicates by returning 1 or 0 whether a given candidate JSON document is contained within a target JSON document
JSON_CONTAINS_PATH()	Returns 0 or 1 to indicate whether a JSON document contains data at a given path or paths
JSON_EXTRACT()	Returns data from a JSON document, selected from the parts of the document matched by the `path` arguments

Function Name	Description
->	Returns the value from a JSON column after the evaluating path; an alias for `JSON_EXTRACT(doc, path_literal)`
->>	Returns the value from a JSON column after the evaluating path and unquoting the result; an alias for `JSON_UNQUOTE(JSON_EXTRACT(doc, path_literal))`

Function Name	Description
JSON_KEYS()	Returns the keys from the top-level value of a JSON object as a JSON array, or, if a path argument is given, the top-level keys from the selected path
JSON_SEARCH()	Search a JSON document for one or all matches of a string
MEMBER OF()	If the passed value is an element of the JSON array, returns 1. Otherwise, returns 0.
JSON_OVERLAPS()	Indicates whether two JSON documents have overlapping part. If yes, returns 1. If not, returns 0.

Functions that modify JSON values

Function Name	Description
JSON_APPEND()	An alias to `JSON_ARRAY_APPEND()`
JSON_ARRAY_APPEND()	Appends values to the end of the indicated arrays within a JSON document and returns the result
JSON_ARRAY_INSERT()	Insert values into the specified locations of a JSON document and returns the result
JSON_INSERT()	Inserts data into a JSON document and returns the result
JSON_MERGE_PATCH()	Merges two or more JSON documents, without preserving values of duplicate keys
JSON_MERGE_PRESERVE()	Merges two or more JSON documents by preserving all values

Function Name	Description
JSON_MERGE()	A deprecated alias for `JSON_MERGE_PRESERVE()`
JSON_REMOVE()	Removes data from a JSON document and returns the result
JSON_REPLACE()	Replaces existing values in a JSON document and returns the result
JSON_SET()	Inserts or updates data in a JSON document and returns the result
JSON_UNQUOTE()	Unquotes a JSON value and returns the result as a string

Functions that return JSON value attributes

Function Name	Description
JSON_DEPTH()	Returns the maximum depth of a JSON document

Function Name	Description
JSON_LENGTH()	Returns the length of a JSON document, or, if a path argument is given, the length of the value within the path
JSON_TYPE()	Returns a string indicating the type of a JSON value
JSON_VALID()	Checks if a json_doc is valid JSON.

Utility functions

Function Name	Description
JSON_PRETTY()	Pretty formatting of a JSON document
JSON_STORAGE_FREE()	Returns how much storage space was freed in the binary representation of the JSON value after it was updated in place.

Function Name	Description
JSON_STORAGE_SIZE()	Returns an approximate size of bytes required to store the json value. As the size does not account for TiKV using compression, the output of this function is not strictly compatible with MySQL.

Aggregate functions

Function Name	Description
JSON_ARRAYAGG()	Provides an aggregation of keys.
JSON_OBJECTAGG()	Provides an aggregation of values for a given key.

Validation functions

Function Name	Description
JSON_SCHEMA_VALID()	Validates a JSON document against a schema to ensure data integrity and consistency.

JSONPath

Many of JSON functions use JSONPath to select parts of a JSON document.

Symbol	Description
$	Document root
.	Member selection
[]	Array selection
*	Wildcard
**	Path wildcard
[<n> to <n>]	Array range selection

The subsequent content takes the following JSON document as an example to demonstrate how to use JSONPath:

```
{
    "database": {
        "name": "TiDB",
        "features": [
            "distributed",
            "scalable",
            "relational",
            "cloud native"
        ],
        "license": "Apache-2.0 license",
        "versions": [
            {
                "version": "v8.1.0",
                "type": "lts",
                "release_date": "2024-05-24"
            },
            {
                "version": "v8.0.0",
                "type": "dmr",
                "release_date": "2024-03-29"
            }
        ]
    },
    "migration_tool": {
        "name": "TiDB Data Migration",
        "features": [
            "MySQL compatible",
            "Shard merging"
        ],
        "license": "Apache-2.0 license"
    }
}
```

JSONPath	Description	Example with JSON_EXTRACT()
$	The root of the document	Returns the full document
$.database	The database object	Returns the full structure starting with "database". It does not include "migration_tool" and the structure below that.
$.database.name	The name of the database.	"TiDB"
$.database.features	All database features	["distributed", " ↪ scalable", " ↪ relational", " ↪ cloud native"]
$.database.features[0]	The first database feature.	"distributed"
$.database.features[2]	The third database feature.	"relational"
$.database.versions[0]. ↪ type	The type of the first database version.	"lts"
$.database.versions[*]. ↪ release_date	The release date for all versions.	["2024-05-24","2024-03-29"] ↪
$.*.features	Two array's of features	[["distributed", " ↪ scalable", " ↪ relational", " ↪ cloud native"], ↪ ["MySQL ↪ compatible", " ↪ Shard merging"]]
$**.version	All versions, with path wildcard	["v8.1.0","v8.0.0"]
$.database.features[0 ↪ to 2]	Range of database features from the first to the third.	["scalable"," ↪ relational"]

For more information, see the IETF draft for JSONPath.

See also

- JSON Data Type

Unsupported functions

- JSON_SCHEMA_VALIDATION_REPORT()
- JSON_TABLE()

- `JSON_VALUE()`

For more information, see #14486.

MySQL compatibility

- TiDB supports most of the JSON functions available in MySQL 8.0.

14.13.4.14.2 JSON Functions That Create JSON Values

This document describes JSON functions that create JSON values.

JSON_ARRAY()

The `JSON_ARRAY([val[, val] ...])` function evaluates a (possibly empty) list of values and returns a JSON array containing those values.

```
SELECT JSON_ARRAY(1,2,3,4,5), JSON_ARRAY("foo", "bar");
```

```
+----------------------+--------------------------+
| JSON_ARRAY(1,2,3,4,5) | JSON_ARRAY("foo", "bar") |
+----------------------+--------------------------+
| [1, 2, 3, 4, 5]    | ["foo", "bar"]        |
+----------------------+--------------------------+
1 row in set (0.00 sec)
```

JSON_OBJECT()

The `JSON_OBJECT([key, val[, key, val] ...])` function evaluates a (possibly empty) list of key-value pairs and returns a JSON object containing those pairs.

```
SELECT JSON_OBJECT("database", "TiDB", "distributed", TRUE);
```

```
+-----------------------------------------------------+
| JSON_OBJECT("database", "TiDB", "distributed", TRUE) |
+-----------------------------------------------------+
| {"database": "TiDB", "distributed": true}     |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_QUOTE()

The `JSON_QUOTE(str)` function returns a string as a JSON value with quotes.

```
SELECT JSON_QUOTE('The name is "O\'Neil"');
```

```
+-----------------------------------+
| JSON_QUOTE('The name is "O\'Neil"') |
+-----------------------------------+
| "The name is \"O'Neil\""          |
+-----------------------------------+
1 row in set (0.00 sec)
```

14.13.4.14.3 JSON Functions That Search JSON Values

This document describes JSON functions that search JSON values.

JSON_CONTAINS()

By returning `1` or `0`, the `JSON_CONTAINS(json_doc, candidate [,path])` function indicates whether a given `candidate` JSON document is contained within a target JSON document.

Examples:

Here `a` is contained in the target document.

```
SELECT JSON_CONTAINS('["a","b","c"]','"a"');
```

```
+-----------------------------------+
| JSON_CONTAINS('["a","b","c"]','"a"') |
+-----------------------------------+
|                                 1 |
+-----------------------------------+
1 row in set (0.00 sec)
```

Here `e` is not contained in the target document.

```
SELECT JSON_CONTAINS('["a","b","c"]','"e"');
```

```
+-----------------------------------+
| JSON_CONTAINS('["a","b","c"]','"e"') |
+-----------------------------------+
|                                 0 |
+-----------------------------------+
1 row in set (0.00 sec)
```

Here `{"foo": "bar"}` is contained in the target document.

```
SELECT JSON_CONTAINS('{"foo": "bar", "aaa": 5}','{"foo": "bar"}');
```

```
+-----------------------------------------------------------+
| JSON_CONTAINS('{"foo": "bar", "aaa": 5}','{"foo": "bar"}') |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Here `"bar"` is not contained in the root of the target document.

```
SELECT JSON_CONTAINS('{"foo": "bar", "aaa": 5}','"bar"');
```

```
+-------------------------------------------------+
| JSON_CONTAINS('{"foo": "bar", "aaa": 5}','"bar"') |
+-------------------------------------------------+
|                                               0 |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

Here `"bar"` is contained in the `$.foo` attribute of the target document.

```
SELECT JSON_CONTAINS('{"foo": "bar", "aaa": 5}','"bar"', '$.foo');
```

```
+-----------------------------------------------------------+
| JSON_CONTAINS('{"foo": "bar", "aaa": 5}','"bar"', '$.foo') |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_CONTAINS_PATH()

The `JSON_CONTAINS_PATH(json_doc, all_or_one, path [,path, ...])` function returns `0` or `1` to indicate whether a JSON document contains data at a given path or paths.

Examples:

Here the document contains `$.foo`.

```
SELECT JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.foo');
```

```
+-----------------------------------------------------------+
| JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.foo') |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Here the document does not contain `$.bar`.

```
SELECT JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.bar');
```

```
+-----------------------------------------------------------+
| JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.bar') |
+-----------------------------------------------------------+
|                                                         0 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Here the document contains both `$.foo` and `$.aaa`.

```
SELECT JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.foo', '$.aaa'
    ↪ );
```

```
+-----------------------------------------------------------------------+
| JSON_CONTAINS_PATH('{"foo": "bar", "aaa": 5}','all','$.foo', '$.aaa') |
+-----------------------------------------------------------------------+
|                                                                     1 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_EXTRACT()

The `JSON_EXTRACT(json_doc, path[, path] ...)` function extracts data from a JSON document, selected from the parts of the document matched by the `path` arguments.

```
SELECT JSON_EXTRACT('{"foo": "bar", "aaa": 5}', '$.foo');
```

```
+-------------------------------------------------+
| JSON_EXTRACT('{"foo": "bar", "aaa": 5}', '$.foo') |
+-------------------------------------------------+
| "bar"                                           |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

->

The `column->path` function returns the data in `column` that matches the `path` argument. It is an alias for JSON_EXTRACT().

```
SELECT
    j->'$.foo',
    JSON_EXTRACT(j, '$.foo')
FROM (
    SELECT
        '{"foo": "bar", "aaa": 5}' AS j
    ) AS tbl;
```

```
+------------+--------------------------+
| j->'$.foo' | JSON_EXTRACT(j, '$.foo') |
+------------+--------------------------+
| "bar"      | "bar"                    |
+------------+--------------------------+
1 row in set (0.00 sec)
```

->>

The `column->>path` function unquotes data in `column` that matches the `path` argument. It is an alias for `JSON_UNQUOTE(JSON_EXTRACT(doc, path_literal))`.

```
SELECT
    j->'$.foo',
    JSON_EXTRACT(j, '$.foo')
    j->>'$.foo',
    JSON_UNQUOTE(JSON_EXTRACT(j, '$.foo'))
FROM (
    SELECT
        '{"foo": "bar", "aaa": 5}' AS j
    ) AS tbl;
```

```
+------------+--------------------------+------------+-------------------------------
    ↪
| j->'$.foo' | JSON_EXTRACT(j, '$.foo') | j->>'$.foo' | JSON_UNQUOTE(JSON_
    ↪ EXTRACT(j, '$.foo')) |
+------------+--------------------------+------------+-------------------------------
    ↪
| "bar"      | "bar"                    | bar        | bar
    ↪                                  |
+------------+--------------------------+------------+-------------------------------
    ↪
1 row in set (0.00 sec)
```

JSON_KEYS()

The `JSON_KEYS(json_doc [,path])` function returns the top-level keys of a JSON object as a JSON array. If a `path` argument is given, it returns the top-level keys from the selected path.

Examples:

The following example returns the two top-level keys in the JSON document.

```
SELECT JSON_KEYS('{"name": {"first": "John", "last": "Doe"}, "type": "
    ↪ Person"}');
```

```
+-------------------------------------------------------------------------------+
   ↪
| JSON_KEYS('{"name": {"first": "John", "last": "Doe"}, "type": "Person"}')
   ↪ |
+-------------------------------------------------------------------------------+
   ↪
| ["name", "type"]                                                              |
+-------------------------------------------------------------------------------+
   ↪
1 row in set (0.00 sec)
```

The following example returns the top-level keys that are in the `$.name` path of the JSON document.

```
SELECT JSON_KEYS('{"name": {"first": "John", "last": "Doe"}, "type": "
   ↪ Person"}', '$.name');
```

```
+-------------------------------------------------------------------------------------+
   ↪
| JSON_KEYS('{"name": {"first": "John", "last": "Doe"}, "type": "Person"}',
   ↪ '$.name') |
+-------------------------------------------------------------------------------------+
   ↪
| ["first", "last"]
   ↪ |
+-------------------------------------------------------------------------------------+
   ↪
1 row in set (0.00 sec)
```

JSON_SEARCH()

The `JSON_SEARCH(json_doc, one_or_all, str)` function searches a JSON document for one or all matches of a string.

Examples:

In the following example, you can search for the first result for `cc`, which is at the position of index 2 in the `a` array.

```
SELECT JSON_SEARCH('{"a": ["aa", "bb", "cc"], "b": ["cc", "dd"]}','one','cc
   ↪ ');
```

```
+-----------------------------------------------------------------------+
| JSON_SEARCH('{"a": ["aa", "bb", "cc"], "b": ["cc", "dd"]}','one','cc') |
+-----------------------------------------------------------------------+
| "$.a[2]"                                                              |
+-----------------------------------------------------------------------+
```

```
1 row in set (0.00 sec)
```

Now you do the same, but set `one_or_all` to `all` to get not just the first result, but all results.

```
SELECT JSON_SEARCH('{"a": ["aa", "bb", "cc"], "b": ["cc", "dd"]}','all','cc
    ↪ ');
```

```
+-----------------------------------------------------------------------+
| JSON_SEARCH('{"a": ["aa", "bb", "cc"], "b": ["cc", "dd"]}','all','cc') |
+-----------------------------------------------------------------------+
| ["$.a[2]", "$.b[0]"]                                                  |
+-----------------------------------------------------------------------+
1 row in set (0.01 sec)
```

MEMBER OF()

The `str MEMBER OF (json_array)` function tests if the passed value `str` is an element of the `json_array`, it returns `1`. Otherwise, it returns `0`. It returns `NULL` if any of the arguments is `NULL`.

```
SELECT '□' MEMBER OF ('["□","","","□"]') AS 'Contains pineapple';
```

```
+--------------------+
| Contains pineapple |
+--------------------+
|                  1 |
+--------------------+
1 row in set (0.00 sec)
```

JSON_OVERLAPS()

The `JSON_OVERLAPS(json_doc, json_doc)` function indicates whether two JSON documents have overlapping part. If yes, it returns `1`. If not, it returns `0`. It returns `NULL` if any of the arguments is `NULL`.

Examples:

The following example shows that there is no overlap because the array value does not have the same number of elements.

```
SELECT JSON_OVERLAPS(
    '{"languages": ["Go","Rust","C#"]}',
    '{"languages": ["Go","Rust"]}'
) AS 'Overlaps';
```

```
+----------+
| Overlaps |
```

```
+----------+
|        0 |
+----------+
1 row in set (0.00 sec)
```

The following example shows that both JSON documents overlap as they are identical.

```
SELECT JSON_OVERLAPS(
    '{"languages": ["Go","Rust","C#"]}',
    '{"languages": ["Go","Rust","C#"]}'
) AS 'Overlaps';
```

```
+----------+
| Overlaps |
+----------+
|        1 |
+----------+
1 row in set (0.00 sec)
```

The following example shows that there is an overlap, while the second document has an extra attribute.

```
SELECT JSON_OVERLAPS(
    '{"languages": ["Go","Rust","C#"]}',
    '{"languages": ["Go","Rust","C#"], "arch": ["arm64"]}'
) AS 'Overlaps';
```

```
+----------+
| Overlaps |
+----------+
|        1 |
+----------+
1 row in set (0.00 sec)
```

14.13.4.14.4 JSON Functions That Modify JSON Values

This document describes JSON functions that modify JSON values.

JSON_APPEND()

An alias to JSON_ARRAY_APPEND().

JSON_ARRAY_APPEND()

The `JSON_ARRAY_APPEND(json_array, path, value [,path, value] ...)` function appends values to the end of the indicated arrays within a JSON document at the specified `path` and returns the result.

This function takes arguments in pairs, where each pair is a `path` and a `value`.

Examples:

The following example adds an item to an array, which is the root of the JSON document.

```
SELECT JSON_ARRAY_APPEND('["Car", "Boat", "Train"]', '$', "Airplane") AS "
    ↪ Transport options";
```

```
+-------------------------------------+
| Transport options                   |
+-------------------------------------+
| ["Car", "Boat", "Train", "Airplane"] |
+-------------------------------------+
1 row in set (0.00 sec)
```

The following example adds an item to an array at the specified path.

```
SELECT JSON_ARRAY_APPEND('{"transport_options": ["Car", "Boat", "Train"]}',
    ↪  '$.transport_options', "Airplane") AS "Transport options";
```

```
+-------------------------------------------------------------+
| Transport options                                           |
+-------------------------------------------------------------+
| {"transport_options": ["Car", "Boat", "Train", "Airplane"]} |
+-------------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_ARRAY_INSERT()

The `JSON_ARRAY_INSERT(json_array, path, value [,path, value] ...)` function inserts a `value` into the specified position of the `json_array` in the `path` and returns the result.

This function takes arguments in pairs, where each pair is a `path` and a `value`.

Examples:

The following example inserts a value at the position of index 0 in the array.

```
SELECT JSON_ARRAY_INSERT('["Car", "Boat", "Train"]', '$[0]', "Airplane") AS
    ↪  "Transport options";
```

```
+-------------------------------------+
| Transport options                   |
+-------------------------------------+
| ["Airplane", "Car", "Boat", "Train"] |
+-------------------------------------+
1 row in set (0.01 sec)
```

The following example inserts a value at the position of index 1 in the array.

```
SELECT JSON_ARRAY_INSERT('["Car", "Boat", "Train"]', '$[1]', "Airplane") AS
    ↪  "Transport options";
```

```
+-------------------------------------+
| Transport options                   |
+-------------------------------------+
| ["Car", "Airplane", "Boat", "Train"] |
+-------------------------------------+
1 row in set (0.00 sec)
```

JSON_INSERT()

The `JSON_INSERT(json_doc, path, value [,path, value] ...)` function inserts one or more values into a JSON document and returns the result.

This function takes arguments in pairs, where each pair is a `path` and a `value`.

```
SELECT JSON_INSERT(
    '{"language": ["Go", "Rust", "C++"]}',
    '$.architecture', 'riscv',
    '$.os', JSON_ARRAY("linux","freebsd")
) AS "Demo";
```

```
+-------------------------------------------------------------------------------
    ↪
| Demo
    ↪
    ↪ |
+-------------------------------------------------------------------------------
    ↪
| {"architecture": "riscv", "language": ["Go", "Rust", "C++"], "os": ["linux
    ↪ ", "freebsd"]} |
+-------------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Note that this function does not overwrite values of existing attributes. For example, the following statement appears to overwrite the `"a"` attribute, but it does not actually do so.

```
SELECT JSON_INSERT('{"a": 61, "b": 62}', '$.a', 41, '$.c', 63);
```

```
+-----------------------------------------------------------+
| JSON_INSERT('{"a": 61, "b": 62}', '$.a', 41, '$.c', 63) |
+-----------------------------------------------------------+
| {"a": 61, "b": 62, "c": 63}                               |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_MERGE_PATCH()

The `JSON_MERGE_PATCH(json_doc, json_doc [,json_doc] ...)` function merges two or more JSON documents into a single JSON document, without preserving values of duplicate keys. For `json_doc` arguments with duplicated keys, only the values from the later specified `json_doc` argument are preserved in the merged result.

Examples:

In the following example, you can see that the value of `a` gets overwritten by argument 2 and that `c` is added as a new attribute in the merged result.

```
SELECT JSON_MERGE_PATCH(
    '{"a": 1, "b": 2}',
    '{"a": 100}',
    '{"c": 300}'
);
```

```
+-------------------------------------------------------------------+
| JSON_MERGE_PATCH('{"a": 1, "b": 2}','{"a": 100}', '{"c": 300}') |
+-------------------------------------------------------------------+
| {"a": 100, "b": 2, "c": 300}                                      |
+-------------------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_MERGE_PRESERVE()

The `JSON_MERGE_PRESERVE(json_doc, json_doc [,json_doc] ...)` function merges two or more JSON documents while preserving all values associated with each key and returns the merged result.

Examples:

In the following example, you can see that the value of argument 2 is appended to `a` and that `c` is added as a new attribute.

```
SELECT JSON_MERGE_PRESERVE('{"a": 1, "b": 2}','{"a": 100}', '{"c": 300}');
```

```
+-----------------------------------------------------------------------+
| JSON_MERGE_PRESERVE('{"a": 1, "b": 2}','{"a": 100}', '{"c": 300}') |
+-----------------------------------------------------------------------+
| {"a": [1, 100], "b": 2, "c": 300}                                     |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_MERGE()

> **Warning:**
>
> This function is deprecated.

A deprecated alias for JSON_MERGE_PRESERVE().

JSON_REMOVE()

The JSON_REMOVE(json_doc, path [,path] ...) function removes data of the specified path from a JSON document and returns the result.

Examples:

This example removes the b attribute from the JSON document.

```
SELECT JSON_REMOVE('{"a": 61, "b": 62, "c": 63}','$.b');
```

```
+-------------------------------------------------+
| JSON_REMOVE('{"a": 61, "b": 62, "c": 63}','$.b') |
+-------------------------------------------------+
| {"a": 61, "c": 63}                              |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

This example removes the b and c attributes from the JSON document.

```
SELECT JSON_REMOVE('{"a": 61, "b": 62, "c": 63}','$.b','$.c');
```

```
+-----------------------------------------------------------+
| JSON_REMOVE('{"a": 61, "b": 62, "c": 63}','$.b','$.c') |
+-----------------------------------------------------------+
| {"a": 61}                                                 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_REPLACE()

The `JSON_REPLACE(json_doc, path, value [, path, value] ...)` function replaces values in specified paths of a JSON document and returns the result. If a specified path does not exist, the value corresponding to the path is not added to the result.

This function takes arguments in pairs, where each pair is a `path` and a `value`.

Examples:

In the following example, you change the value at `$.b` from `62` to `42`.

```
SELECT JSON_REPLACE('{"a": 41, "b": 62}','$.b',42);
```

```
+-------------------------------------------+
| JSON_REPLACE('{"a": 41, "b": 62}','$.b',42) |
+-------------------------------------------+
| {"a": 41, "b": 42}                        |
+-------------------------------------------+
1 row in set (0.00 sec)
```

In the following example, you can change the value at `$.b` from `62` to `42`. In addition, this statement tries to replace the value at `$.c` with `43`, but it does not work because the `$.c` path does not exist in `{"a": 41, "b": 62}`.

```
SELECT JSON_REPLACE('{"a": 41, "b": 62}','$.b',42,'$.c',43);
```

```
+-----------------------------------------------------+
| JSON_REPLACE('{"a": 41, "b": 62}','$.b',42,'$.c',43) |
+-----------------------------------------------------+
| {"a": 41, "b": 42}                                  |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

JSON_SET()

The `JSON_SET(json_doc, path, value [,path, value] ...)` function inserts or updates data in a JSON document and returns the result.

This function takes arguments in pairs, where each pair is a `path` and a `value`.

Examples:

In the following example, you can update the `$.version` from `1.1` to `1.2`.

```
SELECT JSON_SET('{"version": 1.1, "name": "example"}','$.version',1.2);
```

```
+-------------------------------------------------------------+
| JSON_SET('{"version": 1.1, "name": "example"}','$.version',1.2) |
+-------------------------------------------------------------+
| {"name": "example", "version": 1.2}                         |
```

```
+-------------------------------------------------------------------+
1 row in set (0.00 sec)
```

In the following example, you can update the `$.version` from `1.1` to `1.2`. And you can update `$.branch`, which does not exist before, to `main`.

```
SELECT JSON_SET('{"version": 1.1, "name": "example"}','$.version',1.2,'$.
    ↪ branch', "main");
```

```
+-------------------------------------------------------------------------------------+
    ↪
| JSON_SET('{"version": 1.1, "name": "example"}','$.version',1.2,'$.branch',
    ↪  "main") |
+-------------------------------------------------------------------------------------+
    ↪
| {"branch": "main", "name": "example", "version": 1.2}                    |
+-------------------------------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

JSON_UNQUOTE()

The `JSON_UNQUOTE(json)` function unquotes a JSON value and returns the result as a string. This is the opposite of the `JSON_QUOTE()` function.

Examples:

In the example, `"foo"` is unquoted to `foo`.

```
SELECT JSON_UNQUOTE('"foo"');
```

```
+----------------------+
| JSON_UNQUOTE('"foo"') |
+----------------------+
| foo                  |
+----------------------+
1 row in set (0.00 sec)
```

This function is often used together with `JSON_EXTRACT()`. For the following examples, you can extract a JSON value with quotes in the first example and then use the two functions together to unquote the value in the second example. Note that instead of `JSON_UNQUOTE(
↪ JSON_EXTRACT(...))`, you can use the `->>` operator.

```
SELECT JSON_EXTRACT('{"database": "TiDB"}', '$.database');
```

```
+-------------------------------------------------+
| JSON_EXTRACT('{"database": "TiDB"}', '$.database') |
+-------------------------------------------------+
```

```
| "TiDB"                                              |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_UNQUOTE(JSON_EXTRACT('{"database": "TiDB"}', '$.database'));
```

```
+-------------------------------------------------------------------+
| JSON_UNQUOTE(JSON_EXTRACT('{"database": "TiDB"}', '$.database')) |
+-------------------------------------------------------------------+
| TiDB                                                              |
+-------------------------------------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.14.5 JSON Functions That Return JSON Values

This document describes JSON functions that return JSON values.

JSON_DEPTH()

The `JSON_DEPTH(json_doc)` function returns the maximum depth of a JSON document.

Examples:

In the following example, `JSON_DEPTH()` returns `3` because there are three levels:

- root (`$`)
- weather (`$.weather`)
- weather current (`$.weather.sunny`)

```
SELECT JSON_DEPTH('{"weather": {"current": "sunny"}}');
```

```
+-----------------------------------------------+
| JSON_DEPTH('{"weather": {"current": "sunny"}}') |
+-----------------------------------------------+
|                                             3 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

JSON_LENGTH()

The `JSON_LENGTH(json_doc [,path])` function returns the length of a JSON document. If a `path` argument is given, it returns the length of the value within the path.

Examples:

In the following example, the returned value is `1` because the only item at the root of the document is `weather`.

```
SELECT JSON_LENGTH('{"weather": {"current": "sunny", "tomorrow": "cloudy"}}
    ↪ ','$');
```

```
+-----------------------------------------------------------------------------+
    ↪
| JSON_LENGTH('{"weather": {"current": "sunny", "tomorrow": "cloudy"}}','$')
    ↪  |
+-----------------------------------------------------------------------------+
    ↪
|                                                                           1 |
+-----------------------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

In the following example, the returned value is `2` because there are two items at `$.weather`: `current` and `tomorrow`.

```
SELECT JSON_LENGTH('{"weather": {"current": "sunny", "tomorrow": "cloudy"}}
    ↪ ','$.weather');
```

```
+-----------------------------------------------------------------------------+
    ↪
| JSON_LENGTH('{"weather": {"current": "sunny", "tomorrow": "cloudy"}}','$.
    ↪ weather') |
+-----------------------------------------------------------------------------+
    ↪
|                                                                           2 |
+-----------------------------------------------------------------------------+
    ↪
1 row in set (0.01 sec)
```

JSON_TYPE()

The `JSON_TYPE(json_val)` function returns a string indicating the type of a JSON value.

Example:

```
WITH demo AS (
    SELECT 'null' AS 'v'
    UNION SELECT '"foobar"'
    UNION SELECT 'true'
    UNION SELECT '5'
```

```
    UNION SELECT '1.14'
    UNION SELECT '[]'
    UNION SELECT '{}'
    UNION SELECT POW(2,63)
)
SELECT v, JSON_TYPE(v) FROM demo ORDER BY 2;
```

```
+----------------------+-------------+
| v                    | JSON_TYPE(v) |
+----------------------+-------------+
| []                   | ARRAY       |
| true                 | BOOLEAN     |
| 1.14                 | DOUBLE      |
| 9.223372036854776e18 | DOUBLE      |
| 5                    | INTEGER     |
| null                 | NULL        |
| {}                   | OBJECT      |
| "foobar"             | STRING      |
+----------------------+-------------+
8 rows in set (0.00 sec)
```

Note that values that look the same might not have the same type, as demonstrated in the following example.

```
SELECT '"2025-06-14"',CAST(CAST('2025-06-14' AS date) AS json);
```

```
+--------------+-----------------------------------------+
| "2025-06-14" | CAST(CAST('2025-06-14' AS date) AS json) |
+--------------+-----------------------------------------+
| "2025-06-14" | "2025-06-14"                            |
+--------------+-----------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_TYPE('"2025-06-14"'),JSON_TYPE(CAST(CAST('2025-06-14' AS date)
    ↪ AS json));
```

```
+--------------------------+-----------------------------------------------------+
    ↪
| JSON_TYPE('"2025-06-14"') | JSON_TYPE(CAST(CAST('2025-06-14' AS date) AS
    ↪ json)) |
+--------------------------+-----------------------------------------------------+
    ↪
| STRING                   | DATE                                                |
+--------------------------+-----------------------------------------------------+
    ↪
```

```
1 row in set (0.00 sec)
```

JSON_VALID()

The `JSON_VALID(str)` function checks if the argument is valid JSON. This can be useful for checking a column before converting it to the `JSON` type.

```
SELECT JSON_VALID('{"foo"="bar"}');
```

```
+-----------------------------+
| JSON_VALID('{"foo"="bar"}') |
+-----------------------------+
|                           0 |
+-----------------------------+
1 row in set (0.01 sec)
```

```
SELECT JSON_VALID('{"foo": "bar"}');
```

```
+------------------------------+
| JSON_VALID('{"foo": "bar"}') |
+------------------------------+
|                            1 |
+------------------------------+
1 row in set (0.01 sec)
```

14.13.4.14.6 JSON Utility Functions

This document describes JSON utility functions.

JSON_PRETTY()

The `JSON_PRETTY(json_doc)` function does pretty formatting of a JSON document.

```
SELECT JSON_PRETTY('{"person":{"name":{"first":"John","last":"Doe"},"age
    ↪ ":23}}')\G
```

```
*************************** 1. row ***************************
JSON_PRETTY('{"person":{"name":{"first":"John","last":"Doe"},"age":23}}'): {
  "person": {
    "age": 23,
    "name": {
      "first": "John",
```

```
      "last": "Doe"
    }
  }
}
1 row in set (0.00 sec)
```

JSON_STORAGE_FREE()

The `JSON_STORAGE_FREE(json_doc)` function returns how much storage space is freed in the binary representation of the JSON value after it is updated in place.

> **Note:**
>
> Because TiDB has a different storage architecture from MySQL, this function always returns `0` for a valid JSON value, and it is implemented for compatibility with MySQL 8.0. Note that TiDB does not do in-place updates. For more information, see RocksDB space usage.

```
SELECT JSON_STORAGE_FREE('{}');
```

```
+-------------------------+
| JSON_STORAGE_FREE('{}') |
+-------------------------+
|                       0 |
+-------------------------+
1 row in set (0.00 sec)
```

JSON_STORAGE_SIZE()

The `JSON_STORAGE_SIZE(json_doc)` function returns an approximate size of bytes required to store the JSON value. Because the size does not account for TiKV using compression, the output of this function is not strictly compatible with MySQL.

```
SELECT JSON_STORAGE_SIZE('{}');
```

```
+-------------------------+
| JSON_STORAGE_SIZE('{}') |
+-------------------------+
|                       9 |
+-------------------------+
1 row in set (0.00 sec)
```

14.13.4.14.7 JSON Functions That Aggregate JSON Values

The functions listed on this page are part of the aggregate functions that TiDB supports, but are specific to working with JSON.

JSON_ARRAYAGG()

The `JSON_ARRAYAGG(key)` function aggregates values of keys into a JSON array according to the given `key`. `key` is typically an expression or a column name.

Example:

Here the two rows in one column of a table get aggregated into a JSON array.

```
SELECT JSON_ARRAYAGG(v) FROM (SELECT 1 'v' UNION SELECT 2);
```

```
+------------------+
| JSON_ARRAYAGG(v) |
+------------------+
| [2, 1]           |
+------------------+
1 row in set (0.00 sec)
```

JSON_OBJECTAGG()

The `JSON_OBJECTAGG(key,value)` function aggregates keys and values of keys into a JSON object according to the given `key` and `value`. Both `key` or `value` are typically an expression or a column name.

Example:

First, create two tables and add a few rows to them.

```
CREATE TABLE plants (
    id INT PRIMARY KEY,
    name VARCHAR(255)
);

CREATE TABLE plant_attributes (
    id INT PRIMARY KEY AUTO_INCREMENT,
    plant_id INT, attribute VARCHAR(255),
    value VARCHAR(255),
    FOREIGN KEY (plant_id) REFERENCES plants(id)
);

INSERT INTO plants
VALUES
```

```
(1,"rose"),
(2,"tulip"),
(3,"orchid");

INSERT INTO plant_attributes(plant_id,attribute,value)
VALUES
(1,"color","red"),
(1,"thorns","yes"),
(2,"color","orange"),
(2,"thorns","no"),
(2,"grows_from","bulb"),
(3,"color","white"),
(3, "thorns","no");
```

Now you can check what the created tables look like.

```
TABLE plants;
```

```
+----+--------+
| id | name   |
+----+--------+
|  1 | rose   |
|  2 | tulip  |
|  3 | orchid |
+----+--------+
3 rows in set (0.00 sec)
```

```
TABLE plant_attributes;
```

```
+----+----------+-----------+--------+
| id | plant_id | attribute | value  |
+----+----------+-----------+--------+
|  1 |        1 | color     | red    |
|  2 |        1 | thorns    | yes    |
|  3 |        2 | color     | orange |
|  4 |        2 | thorns    | no     |
|  5 |        2 | grows_from | bulb  |
|  6 |        3 | color     | white  |
|  7 |        3 | thorns    | no     |
+----+----------+-----------+--------+
7 rows in set (0.00 sec)
```

You can use the `JSON_OBJECTAGG()` function with this data. Here you can see that for every group multiple key/value pairs are aggregated into a JSON object.

```
SELECT
    p.name,
    JSON_OBJECTAGG(attribute,value)
FROM
    plant_attributes pa
    LEFT JOIN plants p ON pa.plant_id=p.id
GROUP BY
    plant_id;
```

```
+--------+-------------------------------------------------------------+
| name   | JSON_OBJECTAGG(attribute,value)                             |
+--------+-------------------------------------------------------------+
| rose   | {"color": "red", "thorns": "yes"}                           |
| orchid | {"color": "white", "thorns": "no"}                          |
| tulip | {"color": "orange", "grows_from": "bulb", "thorns": "no"} |
+--------+-------------------------------------------------------------+
3 rows in set (0.00 sec)
```

14.13.4.14.8 JSON Functions That Validate JSON Documents

This document describes JSON functions that validate JSON documents.

JSON_SCHEMA_VALID()

The `JSON_SCHEMA_VALID(schema, json_doc)` function validate a JSON document against a schema to ensure data integrity and consistency.

This can be used together with a CHECK constraint to do automatic schema validation when a table is modified.

This function follows the JSON Schema specification.

The supported validation keywords are as follows:

Validation keyword	Applied type	Description
`type` ↪	Any	Tests the type (such as `array` ↪ and `string` ↪)
`enum` ↪	Any	Tests if a value is in the specified array of values
`const` ↪	Any	Similar to `enum` ↪ , but for a single value
`allOf` ↪	Any	Matches all of the specified schemas

Validation keyword	Applied type	Description
`anyOf`	Any	Matches any of the specified schemas
`multipleOf`	`number` ↪ `/integer`	Tests if the value is a multiple of the specified value
`maximum`	`number` ↪ `/integer`	Tests if the value is below the maximum (inclusive)

Validation keyword	Applied type	Description
`exclusiveMaximum`	`number` ↪ `/integer` ↪	Tests if the value is below the maximum (exclusive)
`minimum` ↪	`number` ↪ `/integer` ↪	Tests if the value is above the minimum (inclusive)
`exclusiveMinimum` ↪	`number` ↪ `/integer` ↪	Tests if the value is above the minimum (exclusive)

Validation keyword	Applied type	Description
`maxlength` ↪	`string` ↪	Tests if the length of the value is not exceeding the specified value
`minLength` ↪	`string` ↪	Tests if the length of the value is at least the specified value
`format` ↪	`string` ↪	Tests if a string matches a named format

Validation keyword	Applied type	Description
`pattern` ↪	`string` ↪	Tests if a string matches a pattern
`items` ↪	`array` ↪	Schema to apply to the items of an array
`prefixItems` ↪	`array` ↪	Schema to apply to positional items of an array

Validation keyword	Applied type	Description
`maxItems` ↪	`array` ↪	Tests if the number of items in the array is not exceeding the specified value
`minItems` ↪	`array` ↪	Tests if the number of items in the array is at least the specified value

Validation keyword	Applied type	Description
`uniqueItems`	`array`	Tests if the items in the array are unique, `true` /`false`
`contains`	`array`	Sets schema for items contained in the array
`maxContains`	`array`	Used together with `contains` to test the maximum times an item can be present

Validation keyword	Applied type	Description
`minContains` ↪	`array` ↪	Used together with `contains` ↪ to test the minimum times an item can be present
`properties` ↪	`object` ↪	Schema to apply to the properties of an object

Validation keyword	Applied type	Description
`patternProperties` ↪	`object` ↪	Schema to apply to certain properties based on pattern matching of the property name
`additionalProperties` ↪	`object` ↪	Whether additional properties are allowed or not, `true` ↪ /`false` ↪

Validation keyword	Applied type	Description
`minProperties` ↪	`object` ↪	Tests the minimum number of properties that an object can have
`maxProperties` ↪	`object` ↪	Tests the maximum number of properties that an object can have

Validation keyword	Applied type	Description
`required` ↪	`object` ↪	Tests if the specified property names exist in an object

Examples:

For some of the examples, use this JSON document:

```
{
    "fruits": [
        "orange",
        "apple",
        "pear"
    ],
    "vegetables": [
        "carrot",
        "pepper",
        "kale"]
}
```

Use a user defined variable to hold the JSON document.

```
SET @j := '{"fruits": ["orange", "apple", "pear"], "vegetables": ["carrot",
    ↪  "pepper", "kale"]}';
```

Start by testing the type:

```
SELECT JSON_SCHEMA_VALID('{"type": "object"}',@j);
```

```
+-----------------------------------------+
| JSON_SCHEMA_VALID('{"type": "object"}',@j) |
+-----------------------------------------+
```

```
|                                          1 |
+--------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"type": "array"}',@j);
```

```
+-------------------------------------------+
| JSON_SCHEMA_VALID('{"type": "array"}',@j) |
+-------------------------------------------+
|                                         0 |
+-------------------------------------------+
1 row in set (0.00 sec)
```

```
mysql> SELECT JSON_TYPE(@j);
```

```
+---------------+
| JSON_TYPE(@j) |
+---------------+
| OBJECT        |
+---------------+
1 row in set (0.00 sec)
```

As you can see in the preceding output, the type of `@j` is `object`. This matches with the output of `JSON_TYPE()`.

Now validate the presence of certain attributes.

```
SELECT JSON_SCHEMA_VALID('{"required": ["fruits","vegetables"]}',@j);
```

```
+-----------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"required": ["fruits","vegetables"]}',@j) |
+-----------------------------------------------------------------+
|                                                               1 |
+-----------------------------------------------------------------+
1 row in set (0.00 sec)
```

In the preceding output, you can see that the validation of the presence of the `fruits` and `vegetables` attributes succeeds.

```
SELECT JSON_SCHEMA_VALID('{"required": ["fruits","vegetables","grains"]}',
    ↪ @j);
```

```
+------------------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"required": ["fruits","vegetables","grains"]}',@j) |
+------------------------------------------------------------------------+
|                                                                      0 |
```

```
+------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

In the preceding output, you can see that the validation of the presence of the `fruits`, `vegetables` and `grains` attributes fails because `grains` is not present.

Now validate that `fruits` is an array.

```
SELECT JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "array"}}}',@j
    ↪ );
```

```
+------------------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "array"}}}',@j) |
+------------------------------------------------------------------------+
|                                                                      1 |
+------------------------------------------------------------------------+
1 row in set (0.01 sec)
```

The preceding output confirms that `fruits` is an array.

```
SELECT JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "string"}}}',
    ↪ @j);
```

```
+------------------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "string"}}}',@j) |
+------------------------------------------------------------------------+
|                                                                      0 |
+------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

The preceding output shows that `fruits` is **not** a string.

Now verify the number of items in the array.

```
SELECT JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "array", "
    ↪ minItems": 3}}}',@j);
```

```
+------------------------------------------------------------------------
```

The preceding output shows that `fruits` is an array with at least 3 items.

```
SELECT JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "array", "
    ↪ minItems": 4}}}',@j);
```

```
+-------------------------------------------------------------------------------+
    ↪
| JSON_SCHEMA_VALID('{"properties": {"fruits": {"type": "array", "minItems":
    ↪  4}}}',@j) |
+-------------------------------------------------------------------------------+
    ↪
|                                                                             0
    ↪  |
+-------------------------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

The preceding output shows that `fruits` is **not** an array with at least 4 items. This is because it does not meet the minimum number of items.

For integers values, you can check if they are in a certain range.

```
SELECT JSON_SCHEMA_VALID('{"type": "integer", "minimum": 40, "maximum": 45}
    ↪ ', '42');
+--
    ↪ ------------------------------------------------------------------------+
    ↪
| JSON_SCHEMA_VALID('{"type": "integer", "minimum": 40, "maximum": 45}', '42
    ↪ ') |
+--
    ↪ ------------------------------------------------------------------------+
    ↪
|                                                                           1 |
+--
    ↪ ------------------------------------------------------------------------+
    ↪
1 row in set (0.01 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"type": "integer", "minimum": 40, "maximum": 45}
    ↪ ', '123');
```

```
+-------------------------------------------------------------------------+
    ↪
| JSON_SCHEMA_VALID('{"type": "integer", "minimum": 40, "maximum": 45}',
    ↪ '123') |
+-------------------------------------------------------------------------+
    ↪
```

```
|                                                                                0 |
+----------------------------------------------------------------------------------+
   ↪
1 row in set (0.00 sec)
```

For a string, you can validate whether it matches a certain pattern.

```
SELECT JSON_SCHEMA_VALID('{"type": "string", "pattern": "^Ti"}', '"TiDB"');
```

```
+-----------------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"type": "string", "pattern": "^Ti"}', '"TiDB"') |
+-----------------------------------------------------------------------+
|                                                                     1 |
+-----------------------------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"type": "string", "pattern": "^Ti"}', '"PingCAP"
   ↪ ');
```

```
+-------------------------------------------------------------------------+
| JSON_SCHEMA_VALID('{"type": "string", "pattern": "^Ti"}', '"PingCAP"') |
+-------------------------------------------------------------------------+
|                                                                       0 |
+-------------------------------------------------------------------------+
1 row in set (0.00 sec)
```

You can check whether a value matches a certain named format. The formats that can be validated include `ipv4`, `ipv6`, `time`, `date`, `duration`, `email`, `hostname`, `uuid`, and `uri`.

```
SELECT JSON_SCHEMA_VALID('{"format": "ipv4"}', '"127.0.0.1"');
```

```
+-----------------------------------------------------+
| JSON_SCHEMA_VALID('{"format": "ipv4"}', '"127.0.0.1"') |
+-----------------------------------------------------+
|                                                   1 |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"format": "ipv4"}', '"327.0.0.1"');
```

```
+-----------------------------------------------------+
| JSON_SCHEMA_VALID('{"format": "ipv4"}', '"327.0.0.1"') |
+-----------------------------------------------------+
|                                                   0 |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

You can also use `enum` to check if a string is in an array.

```
SELECT JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"TiDB"');
```

```
+-----------------------------------------------------------+
| JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"TiDB"') |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"MySQL"');
```

```
+-----------------------------------------------------------+
| JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"MySQL"') |
+-----------------------------------------------------------+
|                                                         1 |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"SQLite"');
```

```
+-----------------------------------------------------------+
| JSON_SCHEMA_VALID('{"enum": ["TiDB", "MySQL"]}', '"SQLite"') |
+-----------------------------------------------------------+

+-------------------------------------------------------------------------------+
    ↪
1 row in set (0.00 sec)
```

MySQL compatibility

- If the schema to be validated in `JSON_SCHEMA_VALID()` is invalid (such as `{"type": "sting"}`), MySQL might accept it, but TiDB returns an error. Note that there is a spelling mistake in `"sting"`, which should be `"string"`.
- MySQL uses an older draft version of the JSON Schema standard.

14.13.4.15 Aggregate (GROUP BY) Functions

This document describes details about the supported aggregate functions in TiDB.

14.13.4.15.1 Supported aggregate functions

This section describes the supported MySQL `GROUP BY` aggregate functions in TiDB.

Name	Description
`COUNT()`	Return a count of the number of rows returned
`COUNT(DISTINCT)`	Return the count of a number of different values
`SUM()`	Return the sum
`AVG()`	Return the average value of the argument
`MAX()`	Return the maximum value
`MIN()`	Return the minimum value
`GROUP_CONCAT()`	Return a concatenated string
`VARIANCE()`, `VAR_POP()`	Return the population standard variance
`STD()`, `STDDEV()`, `STDDEV_POP`	Return the population standard deviation
`VAR_SAMP()`	Return the sample variance
`STDDEV_SAMP()`	Return the sample standard deviation
`JSON_ARRAYAGG()`	Return the result set as a single JSON array
`JSON_OBJECTAGG()`	Return the result set as a single JSON object containing key-value pairs

- Unless otherwise stated, group functions ignore `NULL` values.
- If you use a group function in a statement containing no `GROUP BY` clause, it is equivalent to grouping on all rows.

In addition, TiDB also provides the following aggregate functions:

- `APPROX_PERCENTILE(expr, constant_integer_expr)`

  This function returns the percentile of `expr`. The `constant_integer_expr` argument indicates the percentage value which is a constant integer in the range of `[1,100]`. A percentile Pk (`k` represents percentage) indicates that there are at least `k%` values in the data set that are less than or equal to Pk.

This function only supports the numeric type and the date and time type as the returned type of `expr`. For other returned types, `APPROX_PERCENTILE` only returns `NULL`.

The following example shows how to calculate the fiftieth percentile of a `INT` column:

```
DROP TABLE IF EXISTS t;
CREATE TABLE t(a INT);
INSERT INTO t VALUES(1), (2), (3);
```

```
SELECT APPROX_PERCENTILE(a, 50) FROM t;
```

```
+--------------------------+
| APPROX_PERCENTILE(a, 50) |
+--------------------------+
|                        2 |
+--------------------------+
1 row in set (0.00 sec)
```

- `APPROX_COUNT_DISTINCT(expr, [expr...])`

  This function is similar to `COUNT(DISTINCT)` in counting the number of distinct values but returns an approximate result. It uses the `BJKST` algorithm, significantly reducing memory consumption when processing large datasets with a power-law distribution. Moreover, for low-cardinality data, this function provides high accuracy while maintaining efficient CPU utilization.

  The following example shows how to use this function:

```
DROP TABLE IF EXISTS t;
CREATE TABLE t(a INT, b INT, c INT);
INSERT INTO t VALUES(1, 1, 1), (2, 1, 1), (2, 2, 1), (3, 1, 1), (5, 1,
    ↪ 2), (5, 1, 2), (6, 1, 2), (7, 1, 2);
```

```
SELECT APPROX_COUNT_DISTINCT(a, b) FROM t GROUP BY c;
```

```
+-----------------------------+
| approx_count_distinct(a, b) |
+-----------------------------+
|                           3 |
|                           4 |
+-----------------------------+
2 rows in set (0.00 sec)
```

Except for the `GROUP_CONCAT()`, `APPROX_PERCENTILE()`, and `APPROX_COUNT_DISTINCT` functions, all the preceding functions can serve as Window functions.

14.13.4.15.2 GROUP BY modifiers

Starting from v7.4.0, the `GROUP BY` clause of TiDB supports the `WITH ROLLUP` modifier. For more information, see GROUP BY modifiers.

14.13.4.15.3 SQL mode support

TiDB supports the SQL Mode `ONLY_FULL_GROUP_BY`, and when enabled TiDB will refuse queries with ambiguous non-aggregated columns. For example, this query is illegal with `ONLY_FULL_GROUP_BY` enabled because the non-aggregated column "b" in the `SELECT` list does not appear in the `GROUP BY` statement:

```
drop table if exists t;
create table t(a bigint, b bigint, c bigint);
insert into t values(1, 2, 3), (2, 2, 3), (3, 2, 3);

mysql> select a, b, sum(c) from t group by a;
+------+------+--------+
| a    | b    | sum(c) |
+------+------+--------+
|    1 |    2 |      3 |
|    2 |    2 |      3 |
|    3 |    2 |      3 |
+------+------+--------+
3 rows in set (0.01 sec)

mysql> set sql_mode = 'ONLY_FULL_GROUP_BY';
Query OK, 0 rows affected (0.00 sec)

mysql> select a, b, sum(c) from t group by a;
ERROR 1055 (42000): Expression #2 of SELECT list is not in GROUP BY clause
    ↪ and contains nonaggregated column 'b' which is not functionally
    ↪ dependent on columns in GROUP BY clause; this is incompatible with
    ↪ sql_mode=only_full_group_by
```

TiDB currently enables the `ONLY_FULL_GROUP_BY` mode by default.

Differences from MySQL

The current implementation of `ONLY_FULL_GROUP_BY` is less strict than that in MySQL 5.7. For example, suppose that we execute the following query, expecting the results to be ordered by "c":

```
drop table if exists t;
create table t(a bigint, b bigint, c bigint);
insert into t values(1, 2, 1), (1, 2, 2), (1, 3, 1), (1, 3, 2);
select distinct a, b from t order by c;
```

To order the result, duplicates must be eliminated first. But to do so, which row should we keep? This choice influences the retained value of "c", which in turn influences ordering and makes it arbitrary as well.

In MySQL, a query that has `DISTINCT` and `ORDER BY` is rejected as invalid if any `ORDER BY` expression does not satisfy at least one of these conditions:

- The expression is equal to one in the `SELECT` list
- All columns referenced by the expression and belonging to the query's selected tables are elements of the `SELECT` list

But in TiDB, the above query is legal, for more information see #4254.

Another TiDB extension to standard SQL permits references in the `HAVING` clause to aliased expressions in the `SELECT` list. For example, the following query returns "name" values that occur only once in table "orders":

```
select name, count(name) from orders
group by name
having count(name) = 1;
```

The TiDB extension permits the use of an alias in the `HAVING` clause for the aggregated column:

```
select name, count(name) as c from orders
group by name
having c = 1;
```

Standard SQL permits only column expressions in `GROUP BY` clauses, so a statement such as this is invalid because "FLOOR(value/100)" is a noncolumn expression:

```
select id, floor(value/100)
from tbl_name
group by id, floor(value/100);
```

TiDB extends standard SQL to permit noncolumn expressions in `GROUP BY` clauses and considers the preceding statement valid.

Standard SQL also does not permit aliases in `GROUP BY` clauses. TiDB extends standard SQL to permit aliases, so another way to write the query is as follows:

```
select id, floor(value/100) as val
from tbl_name
group by id, val;
```

14.13.4.15.4 Related system variables

The `group_concat_max_len` variable sets the maximum number of items for the `GROUP_CONCAT()` function.

14.13.4.16 GROUP BY Modifiers

Starting from v7.4.0, the `GROUP BY` clause of TiDB supports the `WITH ROLLUP` modifier.

In the `GROUP BY` clause, you can specify one or more columns as a group list and append the `WITH ROLLUP` modifier after the list. Then, TiDB will conduct multidimensional descending grouping based on the columns in the group list and provide you with summary results for each group in the output.

- Grouping method:
    - The first grouping dimension includes all columns in the group list.
    - Subsequent grouping dimensions start from the right end of the grouping list and exclude one more column at a time to form new groups.
- Aggregation summaries: for each dimension, the query performs aggregation operations, and then aggregates the results of this dimension with the results of all previous dimensions. This means that you can get aggregated data at different dimensions, from detailed to overall.

With this grouping method, if there are `N` columns in the group list, TiDB aggregates the query results on `N+1` groups.

For example:

```
SELECT count(1) FROM t GROUP BY a,b,c WITH ROLLUP;
```

In this example, TiDB will aggregate the calculation results of `count(1)` on 4 groups (that is, `{a, b, c}`, `{a, b}`, `{a}`, and `{}`) and output the summary results for each group.

> **Note:**
>
> Currently, TiDB does not support the Cube syntax.

14.13.4.16.1 Use cases

Aggregating and summarizing data from multiple columns is commonly used in OLAP (Online Analytical Processing) scenarios. By using the `WITH ROLLUP` modifier, you can get additional rows that display super summary information from other high-level dimensions in your aggregated results. Then, you can use the super summary information for advanced data analysis and report generation.

14.13.4.16.2 Prerequisites

Before v8.3.0, TiDB only supports generating valid execution plans for the `WITH ROLLUP` syntax in TiFlash MPP mode. Therefore, your TiDB cluster needs to contain TiFlash nodes, and the target table must be configured with the correct TiFlash replica. For more information, see Scale out a TiFlash cluster.

Starting from v8.3.0, the preceding limitation is removed. Regardless of whether your TiDB cluster contains TiFlash nodes, TiDB supports generating valid execution plans for the `WITH ROLLUP` syntax.

To identify whether TiDB or TiFlash executes the `Expand` operator, you can check the `task` attribute of the `Expand` operator in the execution plan. For more information, see How to interpret the ROLLUP execution plan.

14.13.4.16.3 Examples

Suppose you have a profit table named `bank` with the `year`, `month`, `day`, and `profit` columns.

```
CREATE TABLE bank
(
    year   INT,
    month  VARCHAR(32),
    day    INT,
    profit DECIMAL(13, 7)
);

ALTER TABLE bank SET TIFLASH REPLICA 1; -- Add a TiFlash replica for the
    ↪ table in TiFlash MPP mode.

INSERT INTO bank VALUES(2000, "Jan", 1, 10.3),(2001, "Feb", 2, 22.4),(2000,
    ↪ "Mar", 3, 31.6)
```

To get the profit for the bank per year, you can use a simple `GROUP BY` clause as follows:

```
SELECT year, SUM(profit) AS profit FROM bank GROUP BY year;
+------+--------------------+
| year | profit             |
+------+--------------------+
| 2001 | 22.399999618530273 |
| 2000 | 41.90000057220459 |
+------+--------------------+
2 rows in set (0.15 sec)
```

In addition to yearly profits, bank reports usually also need to include the overall profit for all years or monthly divided profits for detailed profit analysis. Before v7.4.0, you have to use different `GROUP BY` clauses in multiple queries and join the results using UNION to obtain

aggregated summaries. Starting from v7.4.0, you can simply achieve the desired results in a single query by appending the `WITH ROLLUP` modifier to the `GROUP BY` clause.

```
SELECT year, month, SUM(profit) AS profit from bank GROUP BY year, month
    ↪ WITH ROLLUP ORDER BY year desc, month desc;
+------+-------+--------------------+
| year | month | profit             |
+------+-------+--------------------+
| 2001 | Feb   | 22.399999618530273 |
| 2001 | NULL  | 22.399999618530273 |
| 2000 | Mar   | 31.600000381469727 |
| 2000 | Jan   | 10.300000190734863 |
| 2000 | NULL  | 41.90000057220459  |
| NULL | NULL  | 64.30000019073486  |
+------+-------+--------------------+
6 rows in set (0.025 sec)
```

The preceding results include aggregated data at different dimensions: by both year and month, by year, and overall. In the results, a row without `NULL` values indicates that the `profit` in that row is calculated by grouping both year and month. A row with a `NULL` value in the `month` column indicates that `profit` in that row is calculated by aggregating all months in a year, while a row with a `NULL` value in the `year` column indicates that `profit` in that row is calculated by aggregating all years.

Specifically:

- The `profit` value in the first row comes from the 2-dimensional group `{year, month}`, representing the aggregation result for the fine-grained `{2000, "Jan"}` group.
- The `profit` value in the second row comes from the 1-dimensional group `{year}`, representing the aggregation result for the mid-level `{2001}` group.
- The `profit` value in the last row comes from the 0-dimensional grouping `{}`, representing the overall aggregation result.

`NULL` values in the `WITH ROLLUP` results are generated just before the Aggregate operator is applied. Therefore, you can use `NULL` values in `SELECT`, `HAVING`, and `ORDER BY` clauses to further filter the aggregated results.

For example, you can use `NULL` in the `HAVING` clause to filter and view the aggregated results of 2-dimensional groups only:

```
SELECT year, month, SUM(profit) AS profit FROM bank GROUP BY year, month
    ↪ WITH ROLLUP HAVING year IS NOT null AND month IS NOT null;
+------+-------+--------------------+
| year | month | profit             |
+------+-------+--------------------+
| 2000 | Mar   | 31.600000381469727 |
| 2000 | Jan   | 10.300000190734863 |
```

```
| 2001 | Feb | 22.399999618530273 |
+------+-------+--------------------+
3 rows in set (0.02 sec)
```

Note that if a column in the `GROUP BY` list contains native `NULL` values, the aggregation results of `WITH ROLLUP` might mislead the query results. To address this issue, you can use the `GROUPING()` function to distinguish native `NULL` values from `NULL` values generated by `WITH ROLLUP`. This function takes a grouping expression as a parameter and returns `0` or `1` to indicate whether the grouping expression is aggregated in the current result. `1` represents aggregated, and `0` represents not aggregated.

The following example shows how to use the `GROUPING()` function:

```
SELECT year, month, SUM(profit) AS profit, grouping(year) as grp_year,
    ↪ grouping(month) as grp_month FROM bank GROUP BY year, month WITH
    ↪ ROLLUP ORDER BY year DESC, month DESC;
+------+-------+--------------------+----------+-----------+
| year | month | profit             | grp_year | grp_month |
+------+-------+--------------------+----------+-----------+
| 2001 | Feb | 22.399999618530273 |    0 |        0 |
| 2001 | NULL | 22.399999618530273 |    0 |        1 |
| 2000 | Mar | 31.600000381469727 |    0 |        0 |
| 2000 | Jan | 10.300000190734863 |    0 |        0 |
| 2000 | NULL | 41.90000057220459 |    0 |        1 |
| NULL | NULL | 64.30000019073486 |    1 |        1 |
+------+-------+--------------------+----------+-----------+
6 rows in set (0.028 sec)
```

From this output, you can get an understanding of the aggregation dimension of a row directly from the results of `grp_year` and `grp_month`, which prevents interference from native `NULL` values in the `year` and `month` grouping expressions.

The `GROUPING()` function can accept up to 64 grouping expressions as parameters. In the output of multiple parameters, each parameter generates a result of `0` or `1`, and these parameters collectively form a 64-bit `UNSIGNED LONGLONG` with each bit as `0` or `1`. You can use the following formula to get the bit position of each parameter as follows:

```
GROUPING(day, month, year):
  result for GROUPING(year)
+ result for GROUPING(month) << 1
+ result for GROUPING(day) << 2
```

By using multiple parameters in the `GROUPING()` function, you can efficiently filter aggregate results at any high dimension. For example, you can quickly filter the aggregate results for each year and all years by using `GROUPING(year, month)`.

```
SELECT year, month, SUM(profit) AS profit, grouping(year) as grp_year,
    ↪ grouping(month) as grp_month FROM bank GROUP BY year, month WITH
    ↪ ROLLUP HAVING GROUPING(year, month) <> 0 ORDER BY year DESC, month
    ↪ DESC;
+------+-------+--------------------+---------+-----------+
| year | month | profit             | grp_year | grp_month |
+------+-------+--------------------+---------+-----------+
| 2001 | NULL | 22.399999618530273 |    0 |        1 |
| 2000 | NULL | 41.90000057220459 |    0 |        1 |
| NULL | NULL | 64.30000019073486 |    1 |        1 |
+------+-------+--------------------+---------+-----------+
3 rows in set (0.023 sec)
```

14.13.4.16.4 How to interpret the ROLLUP execution plan

Multidimensional data aggregation uses the `Expand` operator to copy data to meet the needs of multidimensional grouping. Each data copy corresponds to a grouping of a specific dimension. In MPP mode, the `Expand` operator can facilitate data shuffle to quickly reorganize and calculate a large amount of data between multiple nodes, making full use of the computing capacity of each node. In a TiDB cluster without TiFlash nodes, because the `Expand` operator is only executed on a single TiDB node, data redundancy will increase as the number of dimension groupings (`grouping set`) increases.

The implementation of the `Expand` operator is similar to that of the `Projection` operator. The difference is that `Expand` is a multi-level `Projection`, which contains multiple levels of projection operation expressions. For each row of the raw data, the `Projection` operator generates only one row in results, whereas the `Expand` operator generates multiple rows in results (the number of rows is equal to the number of levels in projection operation expressions).

The following example shows the execution plan for a TiDB cluster without TiFlash nodes, where the `task` of the `Expand` operator is `root`, indicating that the `Expand` operator is executed in TiDB:

```
EXPLAIN SELECT year, month, grouping(year), grouping(month), SUM(profit) AS
    ↪  profit FROM bank GROUP BY year, month WITH ROLLUP;
+--
    ↪ ------------------------------+---------+----------+---------------+----------
    ↪
| id                           | estRows | task    | access object | operator
    ↪ info
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+----------+---------------+----------
    ↪
```

```
| Projection_7                | 2.40   | root     |              | Column#6->
    ↪ Column#12, Column#7->Column#13, grouping(gid)->Column#14, grouping(
    ↪ gid)->Column#15, Column#9->Column#16
    ↪
    ↪ |
|  ─HashAgg_8                 | 2.40   | root     |              | group by:
    ↪ Column#6, Column#7, gid, funcs:sum(test.bank.profit)->Column#9, funcs
    ↪ :firstrow(Column#6)->Column#6, funcs:firstrow(Column#7)->Column#7,
    ↪ funcs:firstrow(gid)->gid                                  |
|    ─Expand_12               | 3.00   | root     |              | level-
    ↪ projection:[test.bank.profit, <nil>->Column#6, <nil>->Column#7, 0->
    ↪ gid],[test.bank.profit, Column#6, <nil>->Column#7, 1->gid],[test.bank
    ↪ .profit, Column#6, Column#7, 3->gid]; schema: [test.bank.profit,
    ↪ Column#6,Column#7,gid] |
|      ─Projection_14         | 3.00   | root     |              | test.bank.
    ↪ profit, test.bank.year->Column#6, test.bank.month->Column#7
    ↪
    ↪ |
|        ─TableReader_16      | 3.00   | root     |              | data:
    ↪ TableFullScan_15
    ↪
    ↪ |
|          ─TableFullScan_15  | 3.00   | cop[tikv] | table:bank | keep order
    ↪ :false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ----------------------------+---------+-----------+--------------+-----------
    ↪
6 rows in set (0.00 sec)
```

The following example shows the execution plan in TiFlash MPP mode, where the `task` of the `Expand` operator is `mpp[tiflash]`, indicating that the `Expand` operator is executed in TiFlash:

```
EXPLAIN SELECT year, month, grouping(year), grouping(month), SUM(profit) AS
    ↪  profit FROM bank GROUP BY year, month WITH ROLLUP;
+--
    ↪ ------------------------------------+---------+-------------+---------------+
    ↪
| id                                  | estRows | task      | access object |
    ↪ operator info
    ↪
    ↪ |
+--
```

```
    ↪ ------------------------------------+--------+-------------+---------------+
    ↪
| TableReader_44                      | 2.40   | root        |               |
    ↪ MppVersion: 2, data:ExchangeSender_43
    ↪
    ↪ |
|  ─ExchangeSender_43                 | 2.40   | mpp[tiflash] |              |
    ↪ ExchangeType: PassThrough
    ↪
    ↪ |
|    ─Projection_8                    | 2.40   | mpp[tiflash] |              |
    ↪ Column#6->Column#12, Column#7->Column#13, grouping(gid)->Column#14,
    ↪ grouping(gid)->Column#15, Column#9->Column#16
    ↪
    ↪ |
|      ─Projection_38                 | 2.40   | mpp[tiflash] |              |
    ↪ Column#9, Column#6, Column#7, gid
    ↪
    ↪ |
|        ─HashAgg_36                  | 2.40   | mpp[tiflash] |              |

    ↪ ------------------------------------+--------+-------------+--------------+
    ↪
10 rows in set (0.05 sec)
```

In this example execution plan, you can view the multiple-level expression of the `Expand` operator in the `operator info` column of the `Expand_20` row. It consists of 2-dimensional expressions, and you can view the schema information of the `Expand` operator at the end of the row, which is `schema: [test.bank.profit, Column#6, Column#7, gid]`.

In the schema information of the `Expand` operator, `GID` is generated as an additional column. Its value is calculated by the `Expand` operator based on the grouping logic of different dimensions, and the value reflects the relationship between the current data replica and the `grouping set`. In most cases, the `Expand` operator uses a Bit-And operation, which can represent 63 combinations of grouping items for ROLLUP, corresponding to 64 dimensions of grouping. In this mode, TiDB generates the `GID` value depending on whether the `grouping set` of the required dimension contains grouping expressions when the current data replica is replicated, and it fills a 64-bit UINT64 value in the order of columns to be grouped.

In the preceding example, the order of columns in the grouping list is `[year, month]`, and the dimension groups generated by the ROLLUP syntax are `{year, month}`, `{year}` ↪ , and `{}`. For the dimension group `{year, month}`, both `year` and `month` are required columns, so TiDB fills the bit positions for them with 1 and 1 correspondingly. This forms a UINT64 of `11...0`, which is 3 in decimal. Therefore, the projection expression is `[test.` ↪ `bank.profit, Column#6, Column#7, 3->gid]` (where `column#6` corresponds to `year`, and `column#7` corresponds to `month`).

The following is an example row of the raw data:

```
+------+-------+-----+------------+
| year | month | day | profit  |
+------+-------+-----+------------+
| 2000 | Jan |   1 | 10.3000000 |
+------+-------+-----+------------+
```

After the `Expand` operator is applied, you can get the following three rows of results:

```
+------------+------+-------+-----+
| profit    | year | month | gid |
+------------+------+-------+-----+
| 10.3000000 | 2000 | Jan | 3 |
+------------+------+-------+-----+
| 10.3000000 | 2000 | NULL | 1 |
+------------+------+-------+-----+
| 10.3000000 | NULL | NULL | 0 |
+------------+------+-------+-----+
```

Note that the SELECT clause in the query uses the GROUPING function. When the GROUPING function is used in the SELECT, HAVING, or ORDER BY clauses, TiDB rewrites it during the logical optimization phase, transforms the relationship between the GROUPING function and the GROUP BY items into a GID related to the logic of dimension group (also known as grouping set), and fills this GID as metadata into the new GROUPING function.

14.13.4.17 Window Functions

The usage of window functions in TiDB is similar to that in MySQL 8.0. For details, see MySQL Window Functions.

In TiDB, you can control window functions using the following system variables:

- tidb_enable_window_function: because window functions reserve additional keywords in the parser, TiDB provides this variable to disable window functions. If you receive errors parsing SQL statements after upgrading TiDB, try setting this variable to OFF.
- tidb_enable_pipelined_window_function: you can use this variable to disable pipeline execution algorithm for window functions.
- windowing_use_high_precision: you can use this variable to disable high precision mode for window functions.

The window functions listed here can be pushed down to TiFlash.

Except for GROUP_CONCAT() and APPROX_PERCENTILE(), TiDB supports using all GROUP BY aggregate functions as window functions. In addition, TiDB supports the following window functions:

Function name	Feature description
CUME_DIST()	Returns the cumulative distribution of a value within a group of values.
DENSE_RANK()	Returns the rank of the current row within the partition, and the rank is without gaps.
FIRST_VALUE()	Returns the expression value of the first row in the current window.
LAG()	Returns the expression value from the row that precedes the current row by N rows within the partition.
LAST_VALUE()	Returns the expression value of the last row in the current window.
LEAD()	Returns the expression value from the row that follows the current row by N rows within the partition.
NTH_VALUE()	Returns the expression value from the N-th row of the current window.

Function name	Feature description
NTILE()	Divides a partition into N buckets, assigns the bucket number to each row in the partition, and returns the bucket number of the current row within the partition.
PERCENT_RANK()	Returns the percentage of partition values that are less than the value in the current row.
RANK()	Returns the rank of the current row within the partition. The rank might have gaps.
ROW_NUMBER()	Returns the number of the current row in the partition.

14.13.4.17.1 CUME_DIST()

CUME_DIST() calculates the cumulative distribution of a value within a group of values. Note that you need to use the ORDER BY clause with CUME_DIST() to sort the group of values. Otherwise, this function will not return the expected values.

```
WITH RECURSIVE cte(n) AS (
    SELECT 1
    UNION
    SELECT
        n+2
    FROM
        cte
    WHERE
        n<6
)
SELECT
    *,
    CUME_DIST() OVER(ORDER BY n)
FROM
    cte;
```

```
+------+------------------------------+
| n    | CUME_DIST() OVER(ORDER BY n) |
+------+------------------------------+
|    1 |                         0.25 |
|    3 |                          0.5 |
|    5 |                         0.75 |
|    7 |                            1 |
+------+------------------------------+
4 rows in set (0.00 sec)
```

14.13.4.17.2 DENSE_RANK()

The DENSE_RANK() function returns the rank of the current row. It is similar to RANK() ↪ but does not leave any gaps in case of ties (rows that share the same values and order conditions).

```
SELECT
    *,
    DENSE_RANK() OVER (ORDER BY n)
FROM (
    SELECT 5 AS 'n'
    UNION ALL
    SELECT 8
    UNION ALL
    SELECT 5
    UNION ALL
    SELECT 30
    UNION ALL
    SELECT 31
    UNION ALL
    SELECT 32) a;
```

```
+----+---------------------------------+
| n  | DENSE_RANK() OVER (ORDER BY n) |
+----+---------------------------------+
|  5 |                               1 |
|  5 |                               1 |
|  8 |                               2 |
| 30 |                               3 |
| 31 |                               4 |
| 32 |                               5 |
+----+---------------------------------+
6 rows in set (0.00 sec)
```

14.13.4.17.3 FIRST_VALUE()

The FIRST_VALUE(expr) returns the first value in a window.

The following example uses two different window definitions:

- PARTITION BY n MOD 2 ORDER BY n partitions the data in table a into two groups: 1, 3 and 2, 4. So it returns either 1 or 2 as those are the first values of those groups.

- `PARTITION BY n <= 2 ORDER BY n` partitions the data in table `a` into two groups: `1, 2` and `3, 4` So it returns either `1` or `3` depending on which group `n` belongs to.

```
SELECT
    n,
    FIRST_VALUE(n) OVER (PARTITION BY n MOD 2 ORDER BY n),
    FIRST_VALUE(n) OVER (PARTITION BY n <= 2 ORDER BY n)
FROM (
    SELECT 1 AS 'n'
    UNION
    SELECT 2
    UNION
    SELECT 3
    UNION
    SELECT 4
) a
ORDER BY
    n;
```

```
+------+-------------------------------------------------------+-----------------------
    ↪
| n    | FIRST_VALUE(n) OVER (PARTITION BY n MOD 2 ORDER BY n) | FIRST_VALUE
    ↪ (n) OVER (PARTITION BY n <= 2 ORDER BY n) |
+------+-------------------------------------------------------+-----------------------
    ↪
|    1 |                                                     1 |
    ↪                                                     1 |
|    2 |                                                     2 |
    ↪                                                     1 |
|    3 |                                                     1 |
    ↪                                                     3 |
|    4 |                                                     2 |
    ↪                                                     3 |
+------+-------------------------------------------------------+-----------------------
    ↪
4 rows in set (0.00 sec)
```

14.13.4.17.4 LAG()

The `LAG(expr [, num [, default]])` function returns the value of `expr` from the row that is `num` rows preceding the current row. If such row does not exist, `default` is returned. By default, `num` is `1` and `default` is `NULL` when they are not specified.

In the following example, because `num` is not specified, `LAG(n)` returns the value of `n` in the previous row. When `n` is 1, because the previous row does not exist and `default` is not specified, `LAG(1)` returns `NULL`.

```
WITH RECURSIVE cte(n) AS (
    SELECT 1
    UNION
    SELECT
        n+1
    FROM
        cte
    WHERE
        n<10
)
SELECT
    n,
    LAG(n) OVER ()
FROM
    cte;
```

```
+------+----------------+
| n    | LAG(n) OVER () |
+------+----------------+
|    1 |           NULL |
|    2 |              1 |
|    3 |              2 |
|    4 |              3 |
|    5 |              4 |
|    6 |              5 |
|    7 |              6 |
|    8 |              7 |
|    9 |              8 |
|   10 |              9 |
+------+----------------+
10 rows in set (0.01 sec)
```

14.13.4.17.5 LAST_VALUE()

The LAST_VALUE() function returns the last value in the window.

```
WITH RECURSIVE cte(n) AS (
    SELECT
        1
    UNION
    SELECT
        n+1
    FROM
        cte
```

```
    WHERE
        n<10
)
SELECT
    n,
    LAST_VALUE(n) OVER (PARTITION BY n<=5)
FROM
    cte
ORDER BY
    n;
```

```
+------+----------------------------------------+
| n    | LAST_VALUE(n) OVER (PARTITION BY n<=5) |
+------+----------------------------------------+
|    1 |                                      5 |
|    2 |                                      5 |
|    3 |                                      5 |
|    4 |                                      5 |
|    5 |                                      5 |
|    6 |                                     10 |
|    7 |                                     10 |
|    8 |                                     10 |
|    9 |                                     10 |
|   10 |                                     10 |
+------+----------------------------------------+
10 rows in set (0.00 sec)
```

14.13.4.17.6 LEAD()

The `LEAD(expr [, num [,default]])` function returns the value of `expr` from the row that is `num` rows following the current row. If such row does not exist, `default` is returned. By default, `num` is `1` and `default` is `NULL` when they are not specified.

In the following example, because `num` is not specified, `LEAD(n)` returns the value of `n` in the next row following the current row. When `n` is 10, because the next row does not exist and `default` is not specified, `LEAD(10)` returns `NULL`.

```
WITH RECURSIVE cte(n) AS (
    SELECT
        1
    UNION
    SELECT
        n+1
    FROM
        cte
```

```
    WHERE
        n<10
)
SELECT
    n,
    LEAD(n) OVER ()
FROM
    cte;
```

```
+------+-----------------+
| n    | LEAD(n) OVER () |
+------+-----------------+
|    1 |               2 |
|    2 |               3 |
|    3 |               4 |
|    4 |               5 |
|    5 |               6 |
|    6 |               7 |
|    7 |               8 |
|    8 |               9 |
|    9 |              10 |
|   10 |            NULL |
+------+-----------------+
10 rows in set (0.00 sec)
```

14.13.4.17.7 NTH_VALUE()

The NTH_VALUE(expr, n) function returns the n-th value of the window.

```
WITH RECURSIVE cte(n) AS (
    SELECT
        1
    UNION
    SELECT
        n+1
    FROM
        cte
    WHERE
        n<10
)
SELECT
    n,
    FIRST_VALUE(n) OVER w AS 'First',
    NTH_VALUE(n, 2) OVER w AS 'Second',
    NTH_VALUE(n, 3) OVER w AS 'Third',
```

```
    LAST_VALUE(n) OVER w AS 'Last'
FROM
    cte
WINDOW
    w AS (PARTITION BY n<=5)
ORDER BY
    n;
```

```
+------+-------+--------+-------+------+
| n    | First | Second | Third | Last |
+------+-------+--------+-------+------+
|    1 |     1 |      2 |     3 |    5 |
|    2 |     1 |      2 |     3 |    5 |
|    3 |     1 |      2 |     3 |    5 |
|    4 |     1 |      2 |     3 |    5 |
|    5 |     1 |      2 |     3 |    5 |
|    6 |     6 |      7 |     8 |   10 |
|    7 |     6 |      7 |     8 |   10 |
|    8 |     6 |      7 |     8 |   10 |
|    9 |     6 |      7 |     8 |   10 |
|   10 |     6 |      7 |     8 |   10 |
+------+-------+--------+-------+------+
10 rows in set (0.00 sec)
```

14.13.4.17.8 NTILE()

The `NTILE(n)` function divides the window into `n` groups and returns the group number of each row.

```
WITH RECURSIVE cte(n) AS (
    SELECT
        1
    UNION
    SELECT
        n+1
    FROM
        cte
    WHERE
    n<10
)
SELECT
    n,
    NTILE(5) OVER (),
    NTILE(2) OVER ()
FROM
```

```
    cte;
```

```
+------+-----------------+-----------------+
| n    | NTILE(5) OVER () | NTILE(2) OVER () |
+------+-----------------+-----------------+
|    1 |               1 |               1 |
|    2 |               1 |               1 |
|    3 |               2 |               1 |
|    4 |               2 |               1 |
|    5 |               3 |               1 |
|    6 |               3 |               2 |
|    7 |               4 |               2 |
|    8 |               4 |               2 |
|    9 |               5 |               2 |
|   10 |               5 |               2 |
+------+-----------------+-----------------+
10 rows in set (0.00 sec)
```

14.13.4.17.9 PERCENT_RANK()

The PERCENT_RANK() function returns a number between 0 and 1 indicating the percentage of rows with a value less than the value of the current row.

```
SELECT
    *,
    PERCENT_RANK() OVER (ORDER BY n),
    PERCENT_RANK() OVER (ORDER BY n DESC)
FROM (
    SELECT 5 AS 'n'
    UNION ALL
    SELECT 8
    UNION ALL
    SELECT 5
    UNION ALL
    SELECT 30
    UNION ALL
    SELECT 31
    UNION ALL
    SELECT 32) a;
```

```
+----+---------------------------------+-----------------------------------
    ↪
| n  | PERCENT_RANK() OVER (ORDER BY n) | PERCENT_RANK() OVER (ORDER BY n
    ↪ DESC) |
```

```
+----+---------------------------------+-------------------------------------+
    ↪
|  5 |                               0 |                                 0.8 |
|  5 |                               0 |                                 0.8 |
|  8 |                             0.4 |                                 0.6 |
| 30 |                             0.6 |                                 0.4 |
| 31 |                             0.8 |                                 0.2 |
| 32 |                               1 |                                   0 |
+----+---------------------------------+-------------------------------------+
    ↪
6 rows in set (0.00 sec)
```

14.13.4.17.10 RANK()

The RANK() function is similar to DENSE_RANK() but will leave gaps in case of ties (rows that share the same values and order conditions). This means it provides an absolute ranking. For example, a rank of 7 means that there are 6 rows with lower ranks.

```
SELECT
    *,
    RANK() OVER (ORDER BY n),
    DENSE_RANK() OVER (ORDER BY n)
FROM (
    SELECT 5 AS 'n'
    UNION ALL
    SELECT 8
    UNION ALL
    SELECT 5
    UNION ALL
    SELECT 30
    UNION ALL
    SELECT 31
    UNION ALL
    SELECT 32) a;
```

```
+----+-------------------------+---------------------------------+
| n  | RANK() OVER (ORDER BY n) | DENSE_RANK() OVER (ORDER BY n) |
+----+-------------------------+---------------------------------+
|  5 |                       1 |                               1 |
|  5 |                       1 |                               1 |
|  8 |                       3 |                               2 |
| 30 |                       4 |                               3 |
| 31 |                       5 |                               4 |
| 32 |                       6 |                               5 |
+----+-------------------------+---------------------------------+
```

```
6 rows in set (0.00 sec)
```

14.13.4.17.11 ROW_NUMBER()

The ROW_NUMBER() returns the row number of the current row in the result set.

```
WITH RECURSIVE cte(n) AS (
    SELECT
        1
    UNION
    SELECT
        n+3
    FROM
        cte
    WHERE
        n<30
)
SELECT
    n,
    ROW_NUMBER() OVER ()
FROM
    cte;
```

```
+------+----------------------+
| n    | ROW_NUMBER() OVER () |
+------+----------------------+
|    1 |                    1 |
|    4 |                    2 |
|    7 |                    3 |
|   10 |                    4 |
|   13 |                    5 |
|   16 |                    6 |
|   19 |                    7 |
|   22 |                    8 |
|   25 |                    9 |
|   28 |                   10 |
|   31 |                   11 |
+------+----------------------+
11 rows in set (0.00 sec)
```

14.13.4.18 Sequence Functions

Sequence functions in TiDB are used to return or set values of sequence objects created using the CREATE SEQUENCE statement.

Function name	Description
NEXTVAL()	Returns the next value of a sequence.
NEXT VALUE FOR	Returns the next value of a sequence (alias for NEXTVAL()).
SETVAL()	Sets the current value of a sequence.
LASTVAL()	Returns the last value generated by a sequence in the current session.

14.13.4.18.1 NEXTVAL()

The NEXTVAL() function returns the next value of a sequence.

Example:

Create a sequence named s1:

```
CREATE SEQUENCE s1;
```

Get the next value from s1:

```
SELECT NEXTVAL(s1);
```

The output is as follows:

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|           1 |
+-------------+
1 row in set (0.00 sec)
```

14.13.4.18.2 NEXT VALUE FOR

The NEXT VALUE FOR function is an alias for NEXTVAL().

Example:

Get the next value from s1 using NEXTVAL():

```
SELECT NEXTVAL(s1);
```

The output is as follows:

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|           2 |
+-------------+
1 row in set (0.00 sec)
```

Get the next value from s1 using NEXT VALUE FOR:

```
SELECT NEXT VALUE FOR s1;
```

The output is as follows:

```
+------------------+
| NEXT VALUE FOR s1 |
+------------------+
|                3 |
+------------------+
1 row in set (0.00 sec)
```

14.13.4.18.3 SETVAL()

The `SETVAL(n)` function sets the current value of a sequence.

Example:

Get the next value from `s1`:

```
SELECT NEXTVAL(s1);
```

The output is as follows:

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|           4 |
+-------------+
1 row in set (0.00 sec)
```

Set the current value of `s1` to `10`:

```
SELECT SETVAL(s1, 10);
```

The output is as follows:

```
+----------------+
| SETVAL(s1, 10) |
+----------------+
|             10 |
+----------------+
1 row in set (0.00 sec)
```

Verify the next value after setting it to `10`:

```
SELECT NEXTVAL(s1);
```

The output is as follows:

```
+-------------+
| NEXTVAL(s1) |
+-------------+
|          11 |
+-------------+
1 row in set (0.00 sec)
```

14.13.4.18.4 `LASTVAL()`

The `LASTVAL()` function returns the last value generated by a sequence **in the current session**.

Example:

Get the last value generated by `s1` in the current session:

```
SELECT LASTVAL(s1);
```

The output is as follows:

```
+-------------+
| LASTVAL(s1) |
+-------------+
|          11 |
+-------------+
1 row in set (0.00 sec)
```

14.13.4.18.5 MySQL compatibility

MySQL does not support the functions and statements for creating and manipulating sequences as defined in ISO/IEC 9075-2.

14.13.4.19 Utility Functions

This document introduces utility functions supported in TiDB, designed to simplify common data conversions for better readability.

14.13.4.19.1 `FORMAT_BYTES()`

The `FORMAT_BYTES()` function converts a number of bytes into a human-readable format.

```
SELECT FORMAT_BYTES(10*1024*1024);
```

```
+---------------------------+
| FORMAT_BYTES(10*1024*1024) |
+---------------------------+
```

```
| 10.00 MiB                |
+--------------------------+
1 row in set (0.001 sec)
```

14.13.4.19.2 FORMAT_NANO_TIME()

The FORMAT_NANO_TIME() function converts a number of nanoseconds into a human-readable time format.

```
SELECT FORMAT_NANO_TIME(1000000);
```

```
+--------------------------+
| FORMAT_NANO_TIME(1000000) |
+--------------------------+
| 1.00 ms                  |
+--------------------------+
1 row in set (0.001 sec)
```

14.13.4.20 Miscellaneous Functions

TiDB supports most of the miscellaneous functions available in MySQL 8.0.

14.13.4.20.1 Supported functions

Name	Description
ANY_VALUE()	Suppress ONLY_FULL_GROUP_BY value rejection
BIN_TO_UUID()	Convert UUID from binary format to text format
DEFAULT()	Returns the default value for a table column
GROUPING()	Modifier for GROUP BY operations
INET_ATON()	Return the numeric value of an IP address
INET_NTOA()	Return the IP address from a numeric value
INET6_ATON()	Return the numeric value of an IPv6 address
INET6_NTOA()	Return the IPv6 address from a numeric value
IS_IPV4()	Whether argument is an IPv4 address
IS_IPV4_COMPAT()	Whether argument is an IPv4-compatible address

Name	Description
IS_IPV4_MAPPED()	Whether argument is an IPv4-mapped address
IS_IPV6()	Whether argument is an IPv6 address
IS_UUID()	Whether argument is an UUID
NAME_CONST()	Can be used to rename a column name
SLEEP()	Sleep for a number of seconds. Note that for TiDB Cloud Serverless clusters, the SLEEP() function has a limitation wherein it can only support a maximum sleep time of 300 seconds.
UUID()	Return a Universal Unique Identifier (UUID)
UUID_TO_BIN()	Convert UUID from text format to binary format
VALUES()	Defines the values to be used during an INSERT

ANY_VALUE()

The ANY_VALUE() function returns any value from a group of values. Typically, it is used in scenarios where you need to include non-aggregated columns in your SELECT statement along with a GROUP BY clause.

```
CREATE TABLE fruits (id INT PRIMARY KEY, name VARCHAR(255));
Query OK, 0 rows affected (0.14 sec)

INSERT INTO fruits VALUES (1,'apple'),(2,'apple'),(3,'pear'),(4,'banana')
    ↪ ,(5, 'pineapple');
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

SELECT id,name FROM fruits GROUP BY name;
ERROR 1055 (42000): Expression #1 of SELECT list is not in GROUP BY clause
    ↪ and contains nonaggregated column 'test.fruits.id' which is not
    ↪ functionally dependent on columns in GROUP BY clause; this is
    ↪ incompatible with sql_mode=only_full_group_by

SELECT ANY_VALUE(id),GROUP_CONCAT(id),name FROM fruits GROUP BY name;
+---------------+-----------------+-----------+
| ANY_VALUE(id) | GROUP_CONCAT(id) | name |
+---------------+-----------------+-----------+
|           1 | 1,2             | apple     |
|           3 | 3               | pear      |
|           4 | 4               | banana    |
|           5 | 5               | pineapple |
```

```
+--------------+------------------+----------+
4 rows in set (0.00 sec)
```

In the preceding example, TiDB returns an error for the first `SELECT` statement because the `id` column is non-aggregated and not included in the `GROUP BY` clause. To address the issue, the second `SELECT` query uses `ANY_VALUE()` to get any value from each group and uses `GROUP_CONCAT()` to concatenate all values of the `id` column within each group into a single string. This approach enables you to get one value from each group and all values of the group without changing the SQL mode for non-aggregated columns.

BIN_TO_UUID()

`BIN_TO_UUID()` and `UUID_TO_BIN()` can be used to convert between a textual format UUID and a binary format. Both functions accept two arguments.

- The first argument specifies the value to be converted.
- The second argument (optional) controls the ordering of the fields in the binary format.

```
SET @a := UUID();
Query OK, 0 rows affected (0.00 sec)

SELECT @a;
+--------------------------------------+
| @a                                   |
+--------------------------------------+
| 9a17b457-eb6d-11ee-bacf-5405db7aad56 |
+--------------------------------------+
1 row in set (0.00 sec)

SELECT UUID_TO_BIN(@a);
+----------------------------------+
| UUID_TO_BIN(@a)                  |
+----------------------------------+
| 0x9A17B457EB6D11EEBACF5405DB7AAD56 |
+----------------------------------+
1 row in set (0.00 sec)

SELECT BIN_TO_UUID(0x9A17B457EB6D11EEBACF5405DB7AAD56);
+-------------------------------------------------+
| BIN_TO_UUID(0x9A17B457EB6D11EEBACF5405DB7AAD56) |
+-------------------------------------------------+
| 9a17b457-eb6d-11ee-bacf-5405db7aad56      |
+-------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT UUID_TO_BIN(@a, 1);
+--------------------------------------+
| UUID_TO_BIN(@a, 1)                   |
+--------------------------------------+
| 0x11EEEB6D9A17B457BACF5405DB7AAD56 |
+--------------------------------------+
1 row in set (0.00 sec)

SELECT BIN_TO_UUID(0x11EEEB6D9A17B457BACF5405DB7AAD56, 1);
+-----------------------------------------------------+
| BIN_TO_UUID(0x11EEEB6D9A17B457BACF5405DB7AAD56, 1) |
+-----------------------------------------------------+
| 9a17b457-eb6d-11ee-bacf-5405db7aad56         |
+-----------------------------------------------------+
1 row in set (0.00 sec)
```

See also UUID() and Best practices for UUID.

DEFAULT()

The `DEFAULT()` function is used to get the default value of a column.

```
CREATE TABLE t1 (id INT PRIMARY KEY, c1 INT DEFAULT 5);
Query OK, 0 rows affected (0.15 sec)

INSERT INTO t1 VALUES (1, 1);
Query OK, 1 row affected (0.01 sec)

UPDATE t1 SET c1=DEFAULT(c1)+3;
Query OK, 1 row affected (0.02 sec)
Rows matched: 1 Changed: 1 Warnings: 0

TABLE t1;
+----+------+
| id | c1   |
+----+------+
|  1 |    8 |
+----+------+
1 row in set (0.00 sec)
```

In the preceding example, the `UPDATE` statement sets the value of the `c1` column to the default value of the column (which is `5`) plus `3`, resulting in a new value of `8`.

GROUPING()

See `GROUP BY` modifiers.

INET_ATON()

The `INET_ATON()` function converts an IPv4 address in dotted-quad notation into a binary version that can be stored efficiently.

```
SELECT INET_ATON('127.0.0.1');
```

```
+------------------------+
| INET_ATON('127.0.0.1') |
+------------------------+
|             2130706433 |
+------------------------+
1 row in set (0.00 sec)
```

INET_NTOA()

The `INET_NTOA()` function converts a binary IPv4 address into a dotted-quad notation.

```
SELECT INET_NTOA(2130706433);
```

```
+-----------------------+
| INET_NTOA(2130706433) |
+-----------------------+
| 127.0.0.1             |
+-----------------------+
1 row in set (0.00 sec)
```

INET6_ATON()

The `INET6_ATON()` function is similar to `INET_ATON()`, but `INET6_ATON()` can also handle IPv6 addresses.

```
SELECT INET6_ATON('::1');
```

```
+------------------------------------+
| INET6_ATON('::1')                  |
+------------------------------------+
| 0x00000000000000000000000000000001 |
+------------------------------------+
1 row in set (0.00 sec)
```

INET6_NTOA()

The `INET6_NTOA()` function is similar to `INET_NTOA()`, but `INET6_NTOA()` can also handle IPv6 addresses.

```
SELECT INET6_NTOA(0x00000000000000000000000000000001);
```

```
+--------------------------------------------+
| INET6_NTOA(0x00000000000000000000000000000001) |
```

```
+-----------------------------------------------+
| ::1                                           |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

IS_IPV4()

The `IS_IPV4()` function tests whether the given argument is an IPv4 address or not.

```
SELECT IS_IPV4('127.0.0.1');
```

```
+----------------------+
| IS_IPV4('127.0.0.1') |
+----------------------+
|                    1 |
+----------------------+
1 row in set (0.00 sec)
```

```
SELECT IS_IPV4('300.0.0.1');
```

```
+----------------------+
| IS_IPV4('300.0.0.1') |
+----------------------+
|                    0 |
+----------------------+
1 row in set (0.00 sec)
```

IS_IPV4_COMPAT()

The `IS_IPV4_COMPAT()` function tests whether the given argument is an IPv4-compatible address.

```
SELECT IS_IPV4_COMPAT(INET6_ATON('::127.0.0.1'));
```

```
+-----------------------------------------+
| IS_IPV4_COMPAT(INET6_ATON('::127.0.0.1')) |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+
1 row in set (0.00 sec)
```

IS_IPV4_MAPPED()

The `IS_IPV4_MAPPED()` function tests whether the given argument is an IPv4-mapped address.

```
SELECT IS_IPV4_MAPPED(INET6_ATON('::ffff:127.0.0.1'));
```

```
+-----------------------------------------------+
| IS_IPV4_MAPPED(INET6_ATON('::ffff:127.0.0.1')) |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

IS_IPV6()

The `IS_IPV6()` function tests whether the given argument is an IPv6 address.

```
SELECT IS_IPV6('::1');
```

```
+----------------+
| IS_IPV6('::1') |
+----------------+
|              1 |
+----------------+
1 row in set (0.00 sec)
```

IS_UUID()

The `IS_UUID()` function tests whether the given argument is a UUID.

```
SELECT IS_UUID('eb48c08c-eb71-11ee-bacf-5405db7aad56');
```

```
+-----------------------------------------------+
| IS_UUID('eb48c08c-eb71-11ee-bacf-5405db7aad56') |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

NAME_CONST()

The `NAME_CONST()` function is used to name columns. It is recommended to use column aliases instead.

```
SELECT NAME_CONST('column name', 'value') UNION ALL SELECT 'another value';
```

```
+---------------+
| column name |
+---------------+
| another value |
| value       |
+---------------+
2 rows in set (0.00 sec)
```

The preceding statement uses `NAME_CONST()` and the following statement uses the recommended way of aliasing columns.

```
SELECT 'value' AS 'column name' UNION ALL SELECT 'another value';
```

```
+--------------+
| column name |
+--------------+
| value        |
| another value |
+--------------+
2 rows in set (0.00 sec)
```

SLEEP()

The `SLEEP()` function is used to pause the execution of queries for a specified number of seconds.

```
SELECT SLEEP(1.5);
```

```
+------------+
| SLEEP(1.5) |
+------------+
|          0 |
+------------+
1 row in set (1.50 sec)
```

UUID()

The `UUID()` function returns a universally unique identifier (UUID) version 1 as defined in RFC 4122.

```
SELECT UUID();
```

```
+--------------------------------------+
| UUID()                               |
+--------------------------------------+
| cb4d5ae6-eb6b-11ee-bacf-5405db7aad56 |
+--------------------------------------+
1 row in set (0.00 sec)
```

See also Best practices for UUID.

UUID_TO_BIN

See BIN_TO_UUID().

VALUES()

The `VALUES(col_name)` function is used to reference the value of a specific column in the `ON DUPLICATE KEY UPDATE` clause of an `INSERT` statement.

```
CREATE TABLE t1 (id INT PRIMARY KEY, c1 INT);
Query OK, 0 rows affected (0.17 sec)

INSERT INTO t1 VALUES (1,51),(2,52),(3,53),(4,54),(5,55);
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

INSERT INTO t1 VALUES(2,22),(4,44) ON DUPLICATE KEY UPDATE c1=VALUES(id)
    ↪ +100;
Query OK, 4 rows affected (0.01 sec)
Records: 2 Duplicates: 2 Warnings: 0

TABLE t1;
+----+------+
| id | c1   |
+----+------+
|  1 |   51 |
|  2 |  102 |
|  3 |   53 |
|  4 |  104 |
|  5 |   55 |
+----+------+
5 rows in set (0.00 sec)
```

14.13.4.20.2 Unsupported functions

Name	Description
UUID_ ↪ SHORT ↪ ()	Provides a UUID that is unique given certain assumptions not present in TiDB TiDB #4620

14.13.4.21 TiDB Specific Functions

The following functions are TiDB extensions, and are not present in MySQL:

Function name	Function description
CURRENT_ ↪ RESOURCE_ ↪ GROUP()	Returns the name of the resource group that the current session is bound to. See Use Resource Control to Achieve Resource Group Limitation and Flow Control.

Function name	Function description
TIDB_BOUNDED_STALENESS()	Instructs TiDB to read the most recent data within a specified time range. See reading historical data using the AS OF TIMESTAMP clause.
TIDB_CURRENT_TSO()	Returns the current TimeStamp Oracle (TSO) in TiDB.
TIDB_DECODE_BINARY_PLAN()	Decodes binary plans.
TIDB_DECODE_KEY()	Decodes a TiDB-encoded key entry into a JSON structure containing `_tidb_rowid` and `table_id`. These encoded keys can be found in some system tables and logging outputs.
TIDB_DECODE_PLAN()	Decodes a TiDB execution plan.
TIDB_DECODE_SQL_DIGESTS()	Queries the normalized SQL statements (a form without formats and arguments) corresponding to a set of SQL digests in the cluster.
TIDB_ENCODE_INDEX_KEY()	Encodes an index key.
TIDB_ENCODE_RECORD_KEY()	Encodes a record key.
TIDB_ENCODE_SQL_DIGEST()	Gets a digest for a query string.
TIDB_IS_DDL_OWNER()	Checks whether or not the TiDB instance you are connected to is the DDL Owner. The DDL Owner is the TiDB instance that is tasked with executing DDL statements on behalf of all other nodes in the cluster.
TIDB_MVCC_INFO()	Returns the MVCC (Multi-Version Concurrency Control) information about a key.
TIDB_PARSE_TSO()	Extracts the physical timestamp from a TiDB TSO timestamp. See also: tidb_current_ts.
TIDB_PARSE_TSO_LOGICAL()	Extracts the logical timestamp from a TiDB TSO timestamp.

Function name	Function description
TIDB_ROW_ ↪ CHECKSUM()	Queries the checksum value of a row. This function can only be used in SELECT statements within the FastPlan process. That is, you can query through statements like SELECT TIDB_ROW_ ↪ CHECKSUM()FROM t WHERE id = ? or SELECT TIDB_ROW_CHECKSUM()FROM t ↪ WHERE id IN (?, ?, ...). See also: Data integrity validation for single-row data.
TIDB_SHARD()	Creates a shard index to scatter the index hotspot. A shard index is an expression index with a TIDB_SHARD function as the prefix.
TIDB_VERSION()	Returns the TiDB version with additional build information.
VITESS_HASH()	Returns the hash of a number. This function is compatible with the HASH function of Vitess, and is intended to help the data migration from Vitess.

14.13.4.21.1 CURRENT_RESOURCE_GROUP

The CURRENT_RESOURCE_GROUP() function is used to show the resource group name that the current session is bound to. When the Resource control feature is enabled, the available resources that can be used by SQL statements are restricted by the resource quota of the bound resource group.

When a session is established, TiDB binds the session to the resource group that the login user is bound to by default. If the user is not bound to any resource groups, the session is bound to the default resource group. Once the session is established, the bound resource group will not change by default, even if the bound resource group of the user is changed via modifying the resource group bound to the user. To change the bound resource group of the current session, you can use SET RESOURCE GROUP.

Examples:

Create a user user1, create two resource groups rg1 and rg2, and bind the user user1 to the resource group rg1:

```
CREATE USER 'user1';
CREATE RESOURCE GROUP rg1 RU_PER_SEC = 1000;
CREATE RESOURCE GROUP rg2 RU_PER_SEC = 2000;
ALTER USER 'user1' RESOURCE GROUP `rg1`;
```

Use user1 to log in and view the resource group bound to the current user:

```
SELECT CURRENT_RESOURCE_GROUP();
```

```
+--------------------------+
| CURRENT_RESOURCE_GROUP() |
+--------------------------+
| rg1                      |
+--------------------------+
1 row in set (0.00 sec)
```

Execute `SET RESOURCE GROUP` to set the resource group for the current session to `rg2`, and then view the resource group bound to the current user:

```
SET RESOURCE GROUP `rg2`;
SELECT CURRENT_RESOURCE_GROUP();
```

```
+--------------------------+
| CURRENT_RESOURCE_GROUP() |

```

14.13.4.21.2 TIDB_BOUNDED_STALENESS

The `TIDB_BOUNDED_STALENESS()` function is used as part of `AS OF TIMESTAMP` syntax.

14.13.4.21.3 TIDB_CURRENT_TSO

The `TIDB_CURRENT_TSO()` function returns the TSO for the current transaction. This is similar to the `tidb_current_ts` system variable.

```
BEGIN;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT TIDB_CURRENT_TSO();
```

```
+--------------------+
| TIDB_CURRENT_TSO() |
+--------------------+

```

14.13.4.21.4 TIDB_DECODE_BINARY_PLAN

The `TIDB_DECODE_BINARY_PLAN(binary_plan)` function decodes binary plans, like the ones in the `BINARY_PLAN` column of the `STATEMENTS_SUMMARY` table.

The `tidb_generate_binary_plan` variable must be set to `ON` for the binary plans to be available.

Example:

```
SELECT BINARY_PLAN,TIDB_DECODE_BINARY_PLAN(BINARY_PLAN) FROM information_
    ↪ schema.STATEMENTS_SUMMARY LIMIT 1\G
```

```
*************************** 1. row ***************************
                      BINARY_PLAN:

1 row in set (0.00 sec)
```

14.13.4.21.5 TIDB_DECODE_KEY

The `TIDB_DECODE_KEY()` function decodes a TiDB-encoded key entry into a JSON structure containing `_tidb_rowid` and `table_id`. These encoded keys exist in some system tables and logging outputs.

In the following example, the table `t1` has a hidden `rowid` that is generated by TiDB. The `TIDB_DECODE_KEY()` function is used in the statement. From the result, you can see that the hidden `rowid` is decoded and output, which is a typical result for the non-clustered primary key.

```
SELECT START_KEY, TIDB_DECODE_KEY(START_KEY) FROM information_schema.tikv_
    ↪ region_status WHERE table_name='t1' AND REGION_ID=2\G
```

```
*************************** 1. row ***************************
               START_KEY: 7480000000000000
                   ↪ FF3B5F728000000000FF1DE3F10000000000FA
TIDB_DECODE_KEY(START_KEY): {"_tidb_rowid":1958897,"table_id":"59"}
1 row in set (0.00 sec)
```

In the following example, the table `t2` has a compound clustered primary key. From the JSON output, you can see a `handle` that contains the name and value for both of the columns that are part of the primary key.

```
SHOW CREATE TABLE t2\G
```

```
*************************** 1. row ***************************
       Table: t2
Create Table: CREATE TABLE `t2` (
  `id` binary(36) NOT NULL,
  `a` tinyint unsigned NOT NULL,
  `v` varchar(512) DEFAULT NULL,
  PRIMARY KEY (`a`,`id`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.001 sec)
```

```
SELECT * FROM information_schema.tikv_region_status WHERE table_name='t2'
    ↪ LIMIT 1\G
```

```
*************************** 1. row ***************************

TIDB_DECODE_KEY returns valid JSON on success and returns the argument value if it fails to decode.

14.13.4.21.6 TIDB_DECODE_PLAN

You can find TiDB execution plans in encoded form in the slow query log. The TIDB_
↪ DECODE_PLAN() function is then used to decode the encoded plans into a human-readable form.

This function is useful because a plan is captured at the time the statement is executed. Re-executing the statement in EXPLAIN might produce different results as data distribution and statistics evolves over time.

```
SELECT tidb_decode_plan('8
    ↪ QIYMAkzMV83CQEH8E85LjA0CWRhdGE6U2VsZWN0aW9uXzYJOTYwCXRpbWU6NzEzLjHCtXMsIGxvb3BzOj1

      ↪ stats:pseudo 960     tikv_task:{time:153µs, loops:960}
      ↪
      ↪ N/A       N/A
```

14.13.4.21.7 TIDB_DECODE_SQL_DIGESTS

The `TIDB_DECODE_SQL_DIGESTS()` function is used to query the normalized SQL statements (a form without formats and arguments) corresponding to the set of SQL digests in the cluster. This function accepts 1 or 2 arguments:

- `digests`: A string. This parameter is in the format of a JSON string array, and each string in the array is a SQL digest.
- `stmtTruncateLength`: An integer (optional). It is used to limit the length of each SQL statement in the returned result. If a SQL statement exceeds the specified length, the statement is truncated. `0` means that the length is unlimited.

This function returns a string, which is in the format of a JSON string array. The i-th item in the array is the normalized SQL statement corresponding to the i-th element in the `digests` parameter. If an element in the `digests` parameter is not a valid SQL digest or the system cannot find the corresponding SQL statement, the corresponding item in the returned result is `null`. If the truncation length is specified (`stmtTruncateLength > 0`), for each statement in the returned result that exceeds this length, the first `stmtTruncateLength` characters are retained and the suffix `"..."` is added at the end to indicate the truncation. If the `digests` parameter is `NULL`, the returned value of the function is `NULL`.

Note:

- Only users with the PROCESS privilege can use this function.
- When `TIDB_DECODE_SQL_DIGESTS` is executed, TiDB queries the statement corresponding to each SQL digest from the statement summary tables, so there is no guarantee that the corresponding statement can always be found for any SQL digest. Only the statements that have been executed in the cluster can be found, and whether these SQL statements

can be queried or not is also affected by the related configuration of the statement summary tables. For the detailed description of the statement summary table, see Statement Summary Tables.

- This function has a high overhead. In queries with a large number of rows (for example, querying the full table of `information_schema.cluster_tidb_trx` on a large and busy cluster), using this function might cause the queries to run for too long. Use it with caution.
    - This function has a high overhead because every time it is called, it internally queries the `STATEMENTS_SUMMARY`, `STATEMENTS_SUMMARY_HISTORY`, `CLUSTER_STATEMENTS_SUMMARY`, and `CLUSTER_STATEMENTS_SUMMARY_HISTORY` tables, and the query involves the `UNION` operation. This function currently does not support vectorization, that is, when calling this function for multiple rows of data, the above query is performed separately for each row.

```
SET @digests = '["
    ↪ e6f07d43b5c21db0fbb9a31feac2dc599787763393dd5acbfad80e247eb02ad5","38
    ↪ b03afa5debbdf0326a014dbe5012a62c51957f1982b3093e748460f8b00821","
    ↪ e5796985ccafe2f71126ed6c0ac939ffa015a8c0744a24b7aee6d587103fd2f7"]';

SELECT TIDB_DECODE_SQL_DIGESTS(@digests);
```

```
+----------------------------------+
| TIDB_DECODE_SQL_DIGESTS(@digests) |
+----------------------------------+
| ["begin",null,"select * from `t`"] |
+----------------------------------+
1 row in set (0.00 sec)
```

In the above example, the parameter is a JSON array containing 3 SQL digests, and the corresponding SQL statements are the three items in the query results. But the SQL statement corresponding to the second SQL digest cannot be found from the cluster, so the second item in the result is `null`.

```
SELECT TIDB_DECODE_SQL_DIGESTS(@digests, 10);
```

```
+-------------------------------------+
| TIDB_DECODE_SQL_DIGESTS(@digests, 10) |
+-------------------------------------+
| ["begin",null,"select * f..."]    |
+-------------------------------------+
1 row in set (0.01 sec)
```

The above call specifies the second parameter (that is, the truncation length) as 10, and the length of the third statement in the query result is greater than 10. Therefore, only the first 10 characters are retained, and `"..."` is added at the end, which indicates the truncation.

See also:

- Statement summary tables
- `INFORMATION_SCHEMA.TIDB_TRX`

14.13.4.21.8 TIDB_ENCODE_SQL_DIGEST

The `TIDB_ENCODE_SQL_DIGEST(query_str)` returns the SQL digest for a query string.

In the following example you can see that both queries get the same query digest, which is because the digest will be `select ?` for both of them.

```
SELECT TIDB_ENCODE_SQL_DIGEST('SELECT 1');
```

```
+------------------------------------------------------------------+
| TIDB_ENCODE_SQL_DIGEST('SELECT 1')                               |
+------------------------------------------------------------------+
| e1c71d1661ae46e09b7aaec1c390957f0d6260410df4e4bc71b9c8d681021471 |
+------------------------------------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT TIDB_ENCODE_SQL_DIGEST('SELECT 2');
```

```
+------------------------------------------------------------------+
| TIDB_ENCODE_SQL_DIGEST('SELECT 2')                               |
+------------------------------------------------------------------+
| e1c71d1661ae46e09b7aaec1c390957f0d6260410df4e4bc71b9c8d681021471 |
+------------------------------------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.21.9 TIDB_IS_DDL_OWNER

The `TIDB_IS_DDL_OWNER()` function returns `1` if the instance you are connected to is the DDL owner.

```
SELECT TIDB_IS_DDL_OWNER();
```

```
+---------------------+
| TIDB_IS_DDL_OWNER() |
+---------------------+
|                   1 |
+---------------------+
1 row in set (0.00 sec)
```

14.13.4.21.10 TIDB_PARSE_TSO

The `TIDB_PARSE_TSO()` function extracts the physical timestamp from a TiDB TSO timestamp. TSO stands for Time Stamp Oracle and is a monotonically increasing timestamp given out by PD (Placement Driver) for every transaction.

A TSO is a number that consists of two parts:

- A physical timestamp
- A logical counter

```
BEGIN;
SELECT TIDB_PARSE_TSO(@@tidb_current_ts);
ROLLBACK;
```

```
+----------------------------------+
| TIDB_PARSE_TSO(@@tidb_current_ts) |
+----------------------------------+
| 2021-05-26 11:33:37.776000    |
+----------------------------------+
1 row in set (0.0012 sec)
```

Here `TIDB_PARSE_TSO` is used to extract the physical timestamp from the timestamp number that is available in the `tidb_current_ts` session variable. Because timestamps are given out per transaction, this function is running in a transaction.

14.13.4.21.11 TIDB_PARSE_TSO_LOGICAL

The `TIDB_PARSE_TSO_LOGICAL(tso)` function returns the logical part of a TSO timestamp.

```
SELECT TIDB_PARSE_TSO_LOGICAL(450456244814610433);
```

```
+-----------------------------------------+
| TIDB_PARSE_TSO_LOGICAL(450456244814610433) |
+-----------------------------------------+
|                                       1 |
+-----------------------------------------+
1 row in set (0.00 sec)
```

```
SELECT TIDB_PARSE_TSO_LOGICAL(450456244814610434);
```

```
+-----------------------------------------+
| TIDB_PARSE_TSO_LOGICAL(450456244814610434) |
+-----------------------------------------+
|                                       2 |
```

```
+-----------------------------------------+
1 row in set (0.00 sec)
```

14.13.4.21.12 TIDB_ROW_CHECKSUM

The `TIDB_ROW_CHECKSUM()` function is used to query the checksum value of a row. This function can only be used in `SELECT` statements within the FastPlan process. That is, you can query through statements like `SELECT TIDB_ROW_CHECKSUM()FROM t WHERE id = ?` or `SELECT TIDB_ROW_CHECKSUM()FROM t WHERE id IN (?, ?, ...)`.

To enable the checksum feature of single-row data in TiDB (controlled by the system variable `tidb_enable_row_level_checksum`), run the following statement:

```
SET GLOBAL tidb_enable_row_level_checksum = ON;
```

This configuration only takes effect for newly created sessions, so you need to reconnect to TiDB.

Create table `t` and insert data:

```
USE test;
CREATE TABLE t (id INT PRIMARY KEY, k INT, c CHAR(1));
INSERT INTO t VALUES (1, 10, 'a');
```

The following statement shows how to query the checksum value of the row where `id = 1` in table `t`:

```
SELECT *, TIDB_ROW_CHECKSUM() FROM t WHERE id = 1;
```

The output is as follows:

```
+----+------+------+--------------------+
| id | k    | c    | TIDB_ROW_CHECKSUM() |
+----+------+------+--------------------+
|  1 |   10 | a    | 3813955661         |
+----+------+------+--------------------+
1 row in set (0.000 sec)
```

14.13.4.21.13 TIDB_SHARD

The `TIDB_SHARD()` function creates a shard index to scatter the index hotspot. A shard index is an expression index prefixed with a `TIDB_SHARD()` function.

- Creation:

  To create a shard index for the index field `a`, you can use `uk((tidb_shard(a)), a))`. When there is a hotspot caused by monotonically increasing or decreasing data on the index field `a` in the unique secondary index `uk((tidb_shard(a)), a))`, the index's prefix `tidb_shard(a)` can scatter the hotspot to improve the scalability of the cluster.

- Scenarios:

  - There is a write hotspot caused by monotonically increasing or decreasing keys on the unique secondary index, and the index contains integer type fields.
  - The SQL statement executes an equality query based on all fields of the secondary index, either as a separate `SELECT` or as an internal query generated by `UPDATE`, `DELETE` and so on. The equality query includes two ways: `a = 1` or `a IN (1, 2, ...)`.

- Limitations:

  - Cannot be used in inequality queries.
  - Cannot be used in queries that contain `OR` mixed with an outmost `AND` operator.
  - Cannot be used in the `GROUP BY` clause.
  - Cannot be used in the `ORDER BY` clause.
  - Cannot be used in the `ON` clause.
  - Cannot be used in the `WHERE` subquery.
  - Can be used to scatter unique indexes of only the integer fields.
  - Might not take effect in composite indexes.
  - Cannot go through FastPlan process, which affects optimizer performance.
  - Cannot be used to prepare the execution plan cache.

The following example shows how to use the `TIDB_SHARD()` function.

- Use the `TIDB_SHARD()` function to calculate the SHARD value.

  The following statement shows how to use the `TIDB_SHARD()` function to calculate the SHARD value of `12373743746`:

```
SELECT TIDB_SHARD(12373743746);
```

- The SHARD value is:

```
+--------------------------+
| TIDB_SHARD(12373743746) |
+--------------------------+
|                      184 |
+--------------------------+
1 row in set (0.00 sec)
```

- Create a shard index using the `TIDB_SHARD()` function:

```
CREATE TABLE test(id INT PRIMARY KEY CLUSTERED, a INT, b INT, UNIQUE
    ↪ KEY uk((tidb_shard(a)), a));
```

14.13.4.21.14 TIDB_VERSION

The `TIDB_VERSION()` function is used to get the version and build details of the TiDB server that you are connected to. You can use this function when reporting issues on GitHub.

```
SELECT TIDB_VERSION()\G
```

```
*************************** 1. row ***************************

14.13.4.21.15 VITESS_HASH

The `VITESS_HASH(num)` function is used to hash a number in the same way Vitess does this. This is to aid migration from Vitess to TiDB.

Example:

```
SELECT VITESS_HASH(123);
```

```
+---------------------+
| VITESS_HASH(123)  |
+---------------------+
| 1155070131015363447 |
+---------------------+
1 row in set (0.00 sec)
```

14.13.4.21.16 TIDB_ENCODE_INDEX_KEY

Encodes an index key.

```
CREATE TABLE t(id int PRIMARY KEY, a int, KEY `idx` (a));
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
INSERT INTO t VALUES(1,1);
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT TIDB_ENCODE_INDEX_KEY('test', 't', 'idx', 1, 1);
```

```
+-------------------------------------------------------------------------------+
   ↪
| TIDB_ENCODE_INDEX_KEY('test', 't', 'idx', 1, 1)                   |

14.13.4.22 Precision Math

The precision math support in TiDB is consistent with MySQL. For more information, see Precision Math in MySQL.

14.13.4.22.1 Numeric types

The scope of precision math for exact-value operations includes the exact-value data types (integer and DECIMAL types) and exact-value numeric literals. Approximate-value data types and numeric literals are handled as floating-point numbers.

Exact-value numeric literals have an integer part or fractional part, or both. They may be signed. Examples: `1`, `.2`, `3.4`, `-5`, `-6.78`, `+9.10`.

Approximate-value numeric literals are represented in scientific notation (power-of-10) with a mantissa and exponent. Either or both parts may be signed. Examples: `1.2E3`, `1.2E-3`, `-1.2E3`, `-1.2E-3`.

Two numbers that look similar might be treated differently. For example, `2.34` is an exact-value (fixed-point) number, whereas `2.34E0` is an approximate-value (floating-point) number.

The DECIMAL data type is a fixed-point type and the calculations are exact. The FLOAT and DOUBLE data types are floating-point types and calculations are approximate.

14.13.4.22.2 DECIMAL data type characteristics

This section discusses the following topics of the characteristics of the DECIMAL data type (and its synonyms):

- Maximum number of digits
- Storage format
- Storage requirements

The declaration syntax for a DECIMAL column is `DECIMAL(M,D)`. The ranges of values for the arguments are as follows:

- M is the maximum number of digits (the precision). 1<= M <= 65.
- D is the number of digits to the right of the decimal point (the scale). 1 <= D <= 30 and D must be no larger than M.

The maximum value of 65 for M means that calculations on DECIMAL values are accurate up to 65 digits. This limit of 65 digits of precision also applies to exact-value numeric literals.

Values for DECIMAL columns are stored using a binary format that packs 9 decimal digits into 4 bytes. The storage requirements for the integer and fractional parts of each value are determined separately. Each multiple of 9 digits requires 4 bytes, and any remaining digits left over require some fraction of 4 bytes. The storage required for remaining digits is given by the following table.

Leftover Digits	Number of Bytes
0	0
1–2	1
3–4	2
5–6	3
7–9	4

For example, a `DECIMAL(18,9)` column has 9 digits on each side of the decimal point, so the integer part and the fractional part each require 4 bytes. A `DECIMAL(20,6)` column has 14 integer digits and 6 fractional digits. The integer digits require 4 bytes for 9 of the digits and 3 bytes for the remaining 5 digits. The 6 fractional digits require 3 bytes.

DECIMAL columns do not store a leading `+` character or `-` character or leading `0` digits. If you insert `+0003.1` into a `DECIMAL(5,1)` column, it is stored as `3.1`. For negative numbers, a literal `-` character is not stored.

DECIMAL columns do not permit values larger than the range implied by the column definition. For example, a `DECIMAL(3,0)` column supports a range of `-999` to `999`. A `DECIMAL(M,D)` column permits at most `M - D` digits to the left of the decimal point.

For more information about the internal format of the DECIMAL values, see `mydecimal ↪ .go` in TiDB source code.

14.13.4.22.3 Expression handling

For expressions with precision math, TiDB uses the exact-value numbers as given whenever possible. For example, numbers in comparisons are used exactly as given without a change in value. In strict SQL mode, if you add an exact data type into a column, a number is inserted with its exact value if it is within the column range. When retrieved, the value is the same as what is inserted. If strict SQL mode is not enabled, truncation for INSERT is permitted in TiDB.

How to handle a numeric expression depends on the values of the expression:

- If the expression contains any approximate values, the result is approximate. TiDB evaluates the expression using floating-point arithmetic.
- If the expression contains no approximate values are present, which means only exact values are contained, and if any exact value contains a fractional part, the expression is evaluated using DECIMAL exact arithmetic and has a precision of 65 digits.
- Otherwise, the expression contains only integer values. The expression is exact. TiDB evaluates the expression using integer arithmetic and has a precision the same as BIGINT (64 bits).

If a numeric expression contains strings, the strings are converted to double-precision floating-point values and the result of the expression is approximate.

Inserts into numeric columns are affected by the SQL mode. The following discussions mention strict mode and `ERROR_FOR_DIVISION_BY_ZERO`. To turn on all the restrictions, you can simply use the `TRADITIONAL` mode, which includes both strict mode values and `ERROR_FOR_DIVISION_BY_ZERO`:

```
SET sql_mode = 'TRADITIONAL`;
```

If a number is inserted into an exact type column (DECIMAL or integer), it is inserted with its exact value if it is within the column range. For this number:

- If the value has too many digits in the fractional part, rounding occurs and a warning is generated.
- If the value has too many digits in the integer part, it is too large and is handled as follows:
    - If strict mode is not enabled, the value is truncated to the nearest legal value and a warning is generated.
    - If strict mode is enabled, an overflow error occurs.

To insert strings into numeric columns, TiDB handles the conversion from string to number as follows if the string has nonnumeric contents:

- In strict mode, a string (including an empty string) that does not begin with a number cannot be used as a number. An error, or a warning occurs.
- A string that begins with a number can be converted, but the trailing nonnumeric portion is truncated. In strict mode, if the truncated portion contains anything other than spaces, an error, or a warning occurs.

By default, the result of the division by 0 is NULL and no warning. By setting the SQL mode appropriately, division by 0 can be restricted. If you enable the `ERROR_FOR_DIVISION_BY_ZERO` SQL mode, TiDB handles division by 0 differently:

- In strict mode, inserts and updates are prohibited, and an error occurs.
- If it's not in the strict mode, a warning occurs.

In the following SQL statement:

```
INSERT INTO t SET i = 1/0;
```

The following results are returned in different SQL modes:

`sql_mode` Value	Result
''	No warning, no error; i is set to NULL.
strict	No warning, no error; i is set to NULL.
`ERROR_FOR_DIVISION_BY_ZERO`	Warning, no error; i is set to NULL.
strict, `ERROR_FOR_DIVISION_BY_ZERO`	Error; no row is inserted.

14.13.4.22.4 Rounding behavior

The result of the `ROUND()` function depends on whether its argument is exact or approximate:

- For exact-value numbers, the `ROUND()` function uses the "round half up" rule.

- For approximate-value numbers, the results in TiDB differs from that in MySQL:

```
TiDB > SELECT ROUND(2.5), ROUND(25E-1);
+------------+--------------+
| ROUND(2.5) | ROUND(25E-1) |
+------------+--------------+
|          3 |            3 |
+------------+--------------+
1 row in set (0.00 sec)
```

For inserts into a DECIMAL or integer column, the rounding uses round half away from zero.

```
TiDB > CREATE TABLE t (d DECIMAL(10,0));
Query OK, 0 rows affected (0.01 sec)

TiDB > INSERT INTO t VALUES(2.5),(2.5E0);
Query OK, 2 rows affected, 2 warnings (0.00 sec)

TiDB > SELECT d FROM t;
+------+
| d    |
+------+
|    3 |
|    3 |
+------+
2 rows in set (0.00 sec)
```

14.13.4.23 Set Operations

TiDB supports three set operations using the UNION, EXCEPT, and INTERSECT operators. The smallest unit of a set is a SELECT statement.

14.13.4.23.1 UNION operator

In mathematics, the union of two sets A and B consists of all elements that are in A or in B. For example:

```
SELECT 1 UNION SELECT 2;
+---+
| 1 |
+---+
| 2 |
| 1 |
+---+
2 rows in set (0.00 sec)
```

TiDB supports both `UNION DISTINCT` and `UNION ALL` operators. `UNION DISTINCT` removes duplicate records from the result set, while `UNION ALL` keeps all records including duplicates. `UNION DISTINCT` is used by default in TiDB.

```
CREATE TABLE t1 (a int);
CREATE TABLE t2 (a int);
INSERT INTO t1 VALUES (1),(2);
INSERT INTO t2 VALUES (1),(3);
```

Examples for `UNION DISTINCT` and `UNION ALL` queries are respectively as follows:

```
SELECT * FROM t1 UNION DISTINCT SELECT * FROM t2;
+---+
| a |
+---+
| 1 |
| 2 |
| 3 |
+---+
3 rows in set (0.00 sec)

SELECT * FROM t1 UNION ALL SELECT * FROM t2;
+---+
| a |
+---+
| 1 |
| 2 |
| 1 |
| 3 |
+---+
4 rows in set (0.00 sec)
```

14.13.4.23.2 EXCEPT operator

If A and B are two sets, EXCEPT returns the difference set of A and B which consists of elements that are in A but not in B.

```
SELECT * FROM t1 EXCEPT SELECT * FROM t2;
+---+
| a |
+---+
| 2 |
+---+
1 rows in set (0.00 sec)
```

`EXCEPT ALL` operator is not yet supported.

14.13.4.23.3 INTERSECT operator

In mathematics, the intersection of two sets A and B consists of all elements that are both in A and B, and no other elements.

```
SELECT * FROM t1 INTERSECT SELECT * FROM t2;
+---+
| a |
+---+
| 1 |
+---+
1 rows in set (0.00 sec)
```

`INTERSECT ALL` operator is not yet supported. INTERSECT operator has higher precedence over EXCEPT and UNION operators.

```
SELECT * FROM t1 UNION ALL SELECT * FROM t1 INTERSECT SELECT * FROM t2;
+---+
| a |
+---+
| 1 |
| 1 |
| 2 |
+---+
3 rows in set (0.00 sec)
```

14.13.4.23.4 Parentheses

TiDB supports using parentheses to specify the precedence of set operations. Expressions in parentheses are processed first.

```
(SELECT * FROM t1 UNION ALL SELECT * FROM t1) INTERSECT SELECT * FROM t2;
+---+
| a |
+---+
| 1 |
+---+
1 rows in set (0.00 sec)
```

14.13.4.23.5 Use `ORDER BY` and `LIMIT`

TiDB supports using `ORDER BY` or `LIMIT` clause on the entire result of set operations. These two clauses must be at the end of the entire statement.

```
(SELECT * FROM t1 UNION ALL SELECT * FROM t1 INTERSECT SELECT * FROM t2)
    ↪ ORDER BY a LIMIT 2;
+---+
```

```
| a |
+---+
| 1 |
| 1 |
+---+
2 rows in set (0.00 sec)
```

14.13.4.24 List of Expressions for Pushdown

When TiDB reads data from TiKV, TiDB tries to push down some expressions (including calculations of functions or operators) to be processed to TiKV. This reduces the amount of transferred data and offloads processing from a single TiDB node. This document introduces the expressions that TiDB already supports pushing down and how to prohibit specific expressions from being pushed down using blocklist.

TiFlash also supports pushdown for the functions and operators listed on this page.

> **Note:**
>
> The Aggregate functions do not support pushdown to TiKV when used as window functions.

14.13.4.24.1 Supported expressions for pushdown to TiKV

Expression Type	Operations
Logical operators	AND (&&) OR (||) NOT (!) XOR
Bit operators	& ~ | ^ << >>
Comparison functions and operators	< <= = != (<>) > >= <=> BETWEEN … AND … COALESCE() IN() INTERVAL() IS NOT NULL IS NOT IS NULL IS ISNULL() LIKE NOT BETWEEN … AND … NOT IN() NOT LIKE STRCMP()
Numeric functions and operators	+ - * / DIV % (MOD) - ABS() ACOS() ASIN() ATAN() ATAN2() ATAN() CEIL() CEILING() CONV() COS() COT() CRC32() DEGREES() EXP() FLOOR() LN() LOG() LOG10() LOG2() MOD() PI() POW() POWER() RADIANS() RAND() ROUND() SIGN() SIN() SQRT()

Expression Type	Operations
Control flow functions	CASE IF() IFNULL()
JSON functions	JSON_ARRAY_APPEND() JSON_ARRAY() JSON_CONTAINS() JSON_EXTRACT() JSON_INSERT() JSON_LENGTH() JSON_MERGE_PATCH() JSON_MERGE() JSON_OBJECT() JSON_REMOVE() JSON_REPLACE() JSON_SET() JSON_TYPE() JSON_UNQUOTE() JSON_VALID() MEMBER OF()
Date and time functions	DATE() DATE_FORMAT() DATEDIFF() DAYOFMONTH() DAYOFWEEK() DAYOFYEAR() FROM_DAYS() HOUR() MAKEDATE() MAKETIME() MICROSECOND() MINUTE() MONTH() MONTHNAME() PERIOD_ADD() PERIOD_DIFF() SEC_TO_TIME() SECOND() SYSDATE() TIME_TO_SEC() TIMEDIFF() WEEK() WEEKOFYEAR() YEAR() DATE_ADD() DATE_SUB() ADDDATE() SUBDATE()
String functions	ASCII() BIT_LENGTH() CHAR() CHAR_LENGTH() CONCAT() CONCAT_WS() ELT() FIELD() HEX() LENGTH() LIKE LOWER() LTRIM() MID() NOT LIKE NOT REGEXP REGEXP REGEXP_LIKE() REGEXP_REPLACE() REGEXP_SUBSTR() REPLACE() REVERSE() RIGHT(), RLIKE RTRIM() SPACE() STRCMP() SUBSTR() SUBSTRING() UPPER()
Aggregation functions	COUNT() COUNT(DISTINCT) SUM() AVG() MAX() MIN() VARIANCE() VAR_POP() STD() STDDEV() STDDEV_POP VAR_SAMP() STDDEV_SAMP() JSON_ARRAYAGG(key) JSON_OBJECTAGG(key, value)

Expression Type	Operations
Encryption and compression functions	MD5() SHA1(), SHA() UNCOMPRESSED_LENGTH()
Cast functions and operators	CAST() CONVERT()
Miscellaneous functions	UUID()
Window Functions	None

14.13.4.24.2 Blocklist specific expressions

If unexpected behavior occurs in the calculation process when pushing down the supported expressions or specific data types (**only** the `ENUM` type and the `BIT` type), you can restore the application quickly by prohibiting the pushdown of the corresponding functions, operators, or data types. Specifically, you can prohibit the functions, operators, or data types from being pushed down by adding them to the blocklist `mysql.expr_pushdown_blacklist`. For details, refer to Add to the blocklist.

14.13.4.25 Comparisons between Functions and Syntax of Oracle and TiDB

This document describes the comparisons between functions and syntax of Oracle and TiDB. It helps you find the corresponding TiDB functions based on the Oracle functions, and understand the syntax differences between Oracle and TiDB.

> **Note:**
>
> The functions and syntax in this document are based on Oracle 12.2.0.1.0 and TiDB v5.4.0. They might be different in other versions.

14.13.4.25.1 Comparisons of functions

The following table shows the comparisons between some Oracle and TiDB functions.

Function	Oracle syntax	TiDB syntax	Note
Cast a value as a certain type	`TO_NUMBER(key)`	`TO_CHAR(key)`	

| CONVERT(key,dataType) | TiDB supports casting a value as one of the following types: BINARY, CHAR, DATE, DATETIME, TIME, SIGNED INTEGER, UNSIGNED INTEGER and DECIMAL. | | Convert a date to a string |

TO_CHAR(SYSDATE,'yyyy-MM-dd hh24:mi:ss')

TO_CHAR(SYSDATE,'yyyy-MM-dd')

|

DATE_FORMAT(NOW(),'%Y-%m-%d %H:%i:%s')

DATE_FORMAT(NOW(),'%Y-%m-%d')

| The format string of TiDB is case-sensitive. | | Convert a string to a date |

TO_DATE('2021-05-28 17:31:37','yyyy-MM-dd hh24:mi:ss')

TO_DATE('2021-05-28','yyyy-MM-dd hh24:mi:ss')

|

STR_TO_DATE('2021-05-28 17:31:37','%Y-%m-%d %H:%i:%s')

STR_TO_DATE('2021-05-28','%Y-%m-%d%T')

| The format string of TiDB is case-sensitive. | | Get the current system time in second precision | SYSDATE | NOW() | | | Get the current system time in microsecond precision | SYSTIMESTAMP | CURRENT_TIMESTAMP(6) | | | Get the number of days between two dates | date1 - date2 | DATEDIFF(date1, date2) | | | Get the number of months between two dates | MONTHS_BETWEEN(ENDDATE,SYSDATE) | TIMESTAMPDIFF(MONTH,SYSDATE,ENDDATE) | The results of MONTHS_BETWEEN() in Oracle and TIMESTAMPDIFF() in TiDB are different. TIMESTAMPDIFF() returns an integer. Note that the parameters in the two functions are swapped. | | Add n days to a date | DATEVAL + n | DATE_ADD(dateVal,INTERVAL n DAY) | n can be a negative value.| | Add n months to a date | ADD_MONTHS(dateVal,n)| DATE_ADD ↪ (dateVal,INTERVAL n MONTH) | n can be a negative value. | | Get the day of a date | TRUNC(SYSDATE) |

CAST(NOW()AS DATE)

DATE_FORMAT(NOW(),'%Y-%m-%d')

| In TiDB, CAST and DATE_FORMAT return the same result. | | Get the month of a date | TRUNC(SYSDATE,'mm') | DATE_ADD(CURDATE(),interval - day(CURDATE())+ 1 day) | | | Truncate a value | TRUNC(2.136)= 2 TRUNC(2.136,2)= 2.13 | TRUNCATE(2.136,0)= 2 ↪ TRUNCATE(2.136,2)= 2.13 | Data precision is preserved. Truncate the corresponding decimal places without rounding. | | Get the next value in a sequence | sequence_name ↪ .NEXTVAL | NEXTVAL(sequence_name) | | | Get a random sequence value | SYS_GUID ↪ () | UUID() | TiDB returns a Universal Unique Identifier (UUID). | | Left join or right join | SELECT * FROM a, b WHERE a.id = b.id(+);SELECT * FROM a, b WHERE a ↪ .id(+)= b.id; | SELECT * FROM a LEFT JOIN b ON a.id = b.id;SELECT * FROM a ↪ RIGHT JOIN b ON a.id = b.id; | In a correlated query, TiDB does not support using (+) to left join or right join. You can use LEFT JOIN or RIGHT JOIN instead. | | NVL() | NVL(key,val) | IFNULL(key,val) | If the value of the field is NULL, it returns val; otherwise,

it returns the value of the field. | | NVL2() | NVL2(key, val1, val2) | IF(key is NOT ↪ NULL, val1, val2) | If the value of the field is not NULL, it returns val1; otherwise, it returns val2. | | DECODE() |

DECODE(key,val1,val2,val3)

DECODE(value,if1,val1,if2,val2,...,ifn,valn,val)

|

IF(key=val1,val2,val3)

CASE WHEN value=if1 THEN val1 WHEN value=if2 THEN val2,...,WHEN value= ↪ ifn THEN valn ELSE val END

|

If the value of the field is val1, then it returns val2; otherwise it returns val3.

When the value of the field satisfies condition 1 (if1), it returns val1. When it satisfies condition 2 (if2), it returns val2. When it satisfies condition 3 (if3), it returns val3.

| | Concatenate the string a and b | 'a' || 'b' | CONCAT('a','b') | | | Get the length of a string | LENGTH(str) | CHAR_LENGTH(str) | | | Get the substring as specified | SUBSTR(' ↪ abcdefg',0,2)= 'ab' SUBSTR('abcdefg',1,2)= 'ab' | SUBSTRING('abcdefg',0,2) ↪ = ''SUBSTRING('abcdefg',1,2)= 'ab' |

In Oracle, the starting position 0 has the same effect as 1.

In TiDB, the starting position 0 returns an empty string. If you want to get a substring from the beginning, the starting position should be 1.

| | Get the position of a substring | INSTR('abcdefg','b',1,1) | INSTR('abcdefg ↪ ','b') | Search from the first character of 'abcdefg' and return the position of the first occurrence of 'b'. | | Get the position of a substring | INSTR('stst','s',1,2) | LENGTH(SUBSTRING_INDEX('stst','s',2))+ 1 | Search from the first character of 'stst ↪ ' and return the position of the second occurrence of 's'. | | Get the position of a substring | INSTR('abcabc','b',2,1) | LOCATE('b','abcabc',2) | Search from the second character of abcabc and return the position of the first occurrence of b. | | Concatenate values of a column | LISTAGG(CONCAT(E.dimensionid,'---',E.DIMENSIONNAME),'***')within ↪ GROUP(ORDER BY DIMENSIONNAME) | GROUP_CONCAT(CONCAT(E.dimensionid,'---',E. ↪ DIMENSIONNAME)ORDER BY DIMENSIONNAME SEPARATOR '***') | Concatenate values of a specified column to one row with the *** delimiter. | | Convert an ASCII code to a character | CHR(n) | CHAR(n) | The Tab (CHR(9)), LF (CHR(10)), and CR (CHR(13)) characters in Oracle correspond to CHAR(9), CHAR(10), and CHAR(13) in TiDB. |

14.13.4.25.2 Comparisons of syntax

This section describes some syntax differences between Oracle and TiDB.

String syntax

In Oracle, a string can only be enclosed in single quotes (''). For example 'a'.

In TiDB, a string can be enclosed in single quotes (') or double quotes (""). For example, `'a'` and `"a"`.

Difference between `NULL` and an empty string

Oracle does not distinguish between `NULL` and an empty string `''`, that is, `NULL` is equivalent to `''`.

TiDB distinguishes between `NULL` and an empty string `''`.

Read and write to the same table in an `INSERT` statement

Oracle supports reading and writing to the same table in an `INSERT` statement. For example:

```
INSERT INTO table1 VALUES (field1,(SELECT field2 FROM table1 WHERE...))
```

TiDB does not support reading and writing to the same table in a `INSERT` statement. For example:

```
INSERT INTO table1 VALUES (field1,(SELECT T.fields2 FROM table1 T WHERE...)
    ↪ )
```

Get the first n rows from a query

In Oracle, to get the first n rows from a query, you can use the `ROWNUM <= n` clause. For example `ROWNUM <= 10`.

In TiDB, to get the first n rows from a query, you can use the `LIMIT n` clause. For example `LIMIT 10`. The Hibernate Query Language (HQL) running SQL statements with `LIMIT` results in an error. You need to change the Hibernate statements to SQL statements.

Update multiple tables in an `UPDATE` statement

In Oracle, it is not necessary to list the specific field update relationship when updating multiple tables. For example:

```
UPDATE test1 SET(test1.name,test1.age) = (SELECT test2.name,test2.age FROM
    ↪ test2 WHERE test2.id=test1.id)
```

In TiDB, when updating multiple tables, you need to list all the specific field update relationships in `SET`. For example:

```
UPDATE test1,test2 SET test1.name=test2.name,test1.age=test2.age WHERE
    ↪ test1.id=test2.id
```

Derived table alias

In Oracle, when querying multiple tables, it is unnecessary to add an alias to the derived table. For example:

```
SELECT * FROM (SELECT * FROM test)
```

In TiDB, when querying multiple tables, every derived table must have its own alias. For example:

```
SELECT * FROM (SELECT * FROM test) t
```

Set operations

In Oracle, to get the rows that are in the first query result but not in the second, you can use the `MINUS` set operation. For example:

```
SELECT * FROM t1 MINUS SELECT * FROM t2
```

TiDB does not support the `MINUS` operation. You can use the `EXCEPT` set operation. For example:

```
SELECT * FROM t1 EXCEPT SELECT * FROM t2
```

Comment syntax

In Oracle, the comment syntax is `--Comment`.

In TiDB, the comment syntax is `-- Comment`. Note that there is a white space after `--` in TiDB.

Pagination

In Oracle, you can use the `OFFSET m ROWS` to skip `m` rows and use the `FETCH NEXT n ROWS ONLY`to fetch `n` rows. For example:

```
SELECT * FROM tables OFFSET 0 ROWS FETCH NEXT 2000 ROWS ONLY
```

In TiDB, you can use the `LIMIT n OFFSET m` to replace `OFFSET m ROWS FETCH NEXT n ROWS ONLY`. For example:

```
SELECT * FROM tables LIMIT 2000 OFFSET 0
```

Sorting order on `NULL` values

In Oracle, `NULL` values are sorted by the `ORDER BY` clause in the following cases:

- In the `ORDER BY column ASC` statement, `NULL` values are returned last.
- In the `ORDER BY column DESC` statement, `NULL` values are returned first.
- In the `ORDER BY column [ASC|DESC] NULLS FIRST` statement, `NULL` values are returned before non-NULL values. Non-NULL values are returned in ascending order or descending order specified in `ASC|DESC`.
- In the `ORDER BY column [ASC|DESC] NULLS LAST` statement, `NULL` values are returned after non-NULL values. Non-NULL values are returned in ascending order or descending order specified in `ASC|DESC`.

In TiDB, `NULL` values are sorted by the `ORDER BY` clause in the following cases:

- In the `ORDER BY column ASC` statement, `NULL` values are returned first.
- In the `ORDER BY column DESC` statement, `NULL` values are returned last.

The following table shows some examples of equivalent `ORDER BY` statements in Oracle and TiDB:

`ORDER BY` in Oracle	Equivalent statements in TiDB
`SELECT * FROM t1 ↪ ORDER BY name ↪ NULLS FIRST;`	`SELECT * FROM t1 ↪ ORDER BY ↪ name;`
`SELECT * FROM t1 ↪ ORDER BY name ↪ DESC NULLS LAST ↪ ;`	`SELECT * FROM t1 ↪ ORDER BY ↪ name DESC;`
`SELECT * FROM t1 ↪ ORDER BY name ↪ DESC NULLS ↪ FIRST;`	`SELECT * FROM t1 ↪ ORDER BY ↪ ISNULL(name) ↪ DESC, name ↪ DESC;`
`SELECT * FROM t1 ↪ ORDER BY name ↪ ASC NULLS LAST;`	`SELECT * FROM t1 ↪ ORDER BY ↪ ISNULL(name), ↪ name;`

14.13.5 Clustered Indexes

TiDB supports the clustered index feature since v5.0. This feature controls how data is stored in tables containing primary keys. It provides TiDB the ability to organize tables in a way that can improve the performance of certain queries.

The term *clustered* in this context refers to the *organization of how data is stored* and not *a group of database servers working together*. Some database management systems refer to clustered index tables as *index-organized tables* (IOT).

Currently, tables containing primary keys in TiDB are divided into the following two categories:

- `NONCLUSTERED`: The primary key of the table is non-clustered index. In tables with non-clustered indexes, the keys for row data consist of internal `_tidb_rowid` implicitly assigned by TiDB. Because primary keys are essentially unique indexes, tables with non-clustered indexes need at least two key-value pairs to store a row, which are:

    - `_tidb_rowid` (key) - row data (value)
    - Primary key data (key) - `_tidb_rowid` (value)

- `CLUSTERED`: The primary key of the table is clustered index. In tables with clustered indexes, the keys for row data consist of primary key data given by the user. Therefore, tables with clustered indexes need only one key-value pair to store a row, which is:

    - Primary key data (key) - row data (value)

> **Note:**
>
> TiDB supports clustering only by a table's `PRIMARY KEY`. With clustered indexes enabled, the terms *the* `PRIMARY KEY` and *the clustered index* might be used interchangeably. `PRIMARY KEY` refers to the constraint (a logical property), and clustered index describes the physical implementation of how the data is stored.

14.13.5.1 User scenarios

Compared to tables with non-clustered indexes, tables with clustered indexes offer greater performance and throughput advantages in the following scenarios:

- When data is inserted, the clustered index reduces one write of the index data from the network.
- When a query with an equivalent condition only involves the primary key, the clustered index reduces one read of index data from the network.
- When a query with a range condition only involves the primary key, the clustered index reduces multiple reads of index data from the network.
- When a query with an equivalent or range condition only involves the primary key prefix, the clustered index reduces multiple reads of index data from the network.

On the other hand, tables with clustered indexes have certain disadvantages. See the following:

- There might be write hotspot issues when inserting a large number of primary keys with close values.
- The table data takes up more storage space if the data type of the primary key is larger than 64 bits, especially when there are multiple secondary indexes.

14.13.5.2 Usages

14.13.5.2.1 Create a table with clustered indexes

Since TiDB v5.0, you can add non-reserved keywords `CLUSTERED` or `NONCLUSTERED` after `PRIMARY KEY` in a `CREATE TABLE` statement to specify whether the table's primary key is a clustered index. For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY CLUSTERED, b VARCHAR(255));
CREATE TABLE t (a BIGINT PRIMARY KEY NONCLUSTERED, b VARCHAR(255));
CREATE TABLE t (a BIGINT KEY CLUSTERED, b VARCHAR(255));
CREATE TABLE t (a BIGINT KEY NONCLUSTERED, b VARCHAR(255));
CREATE TABLE t (a BIGINT, b VARCHAR(255), PRIMARY KEY(a, b) CLUSTERED);
CREATE TABLE t (a BIGINT, b VARCHAR(255), PRIMARY KEY(a, b) NONCLUSTERED);
```

Note that keywords `KEY` and `PRIMARY KEY` have the same meaning in the column definition.

You can also use the comment syntax in TiDB to specify the type of the primary key. For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY /*T![clustered_index] CLUSTERED */, b
    ↪  VARCHAR(255));
CREATE TABLE t (a BIGINT PRIMARY KEY /*T![clustered_index] NONCLUSTERED */
    ↪ , b VARCHAR(255));
CREATE TABLE t (a BIGINT, b VARCHAR(255), PRIMARY KEY(a, b) /*T![clustered_
    ↪ index] CLUSTERED */);
CREATE TABLE t (a BIGINT, b VARCHAR(255), PRIMARY KEY(a, b) /*T![clustered_
    ↪ index] NONCLUSTERED */);
```

For statements that do not explicitly specify the keyword `CLUSTERED`/`NONCLUSTERED`, the default behavior is controlled by the system variable `@@global.tidb_enable_clustered_index`. Supported values for this variable are as follows:

- `OFF` indicates that primary keys are created as non-clustered indexes by default.
- `ON` indicates that primary keys are created as clustered indexes by default.
- `INT_ONLY` indicates that the behavior is controlled by the configuration item `alter-primary-key`. If `alter-primary-key` is set to `true`, primary keys are created as non-clustered indexes by default. If it is set to `false`, only the primary keys which consist of an integer column are created as clustered indexes.

The default value of `@@global.tidb_enable_clustered_index` is `ON`.

14.13.5.2.2 Add or drop clustered indexes

TiDB does not support adding or dropping clustered indexes after tables are created. Nor does it support the mutual conversion between clustered indexes and non-clustered indexes. For example:

```
ALTER TABLE t ADD PRIMARY KEY(b, a) CLUSTERED; -- Currently not supported.
ALTER TABLE t DROP PRIMARY KEY; -- If the primary key is a clustered index
    ↪ , then not supported.
ALTER TABLE t DROP INDEX `PRIMARY`; -- If the primary key is a clustered
    ↪ index, then not supported.
```

14.13.5.2.3 Add or drop non-clustered indexes

TiDB supports adding or dropping non-clustered indexes after tables are created. You can explicitly specify the keyword `NONCLUSTERED` or omit it. For example:

```
ALTER TABLE t ADD PRIMARY KEY(b, a) NONCLUSTERED;
ALTER TABLE t ADD PRIMARY KEY(b, a); -- If you omit the keyword, the
    ↪ primary key is a non-clustered index by default.
ALTER TABLE t DROP PRIMARY KEY;
ALTER TABLE t DROP INDEX `PRIMARY`;
```

14.13.5.2.4 Check whether the primary key is a clustered index

You can check whether the primary key of a table is a clustered index using one of the following methods:

- Execute the command `SHOW CREATE TABLE`.
- Execute the command `SHOW INDEX FROM`.
- Query the `TIDB_PK_TYPE` column in the system table `information_schema.tables`.

By running the command `SHOW CREATE TABLE`, you can see whether the attribute of `PRIMARY KEY` is `CLUSTERED` or `NONCLUSTERED`. For example:

```
mysql> SHOW CREATE TABLE t;
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` bigint NOT NULL,
  `b` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`a`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
```

```
+--
    ↪ -----+-------------------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

By running the command `SHOW INDEX FROM`, you can check whether the result in the column `Clustered` shows `YES` or `NO`. For example:

```
mysql> SHOW INDEX FROM t;
+--
    ↪ -----+------------+---------+-------------+------------+---------+--------
    ↪
| Table | Non_unique | Key_name | Seq_in_index | Column_name | Collation |
    ↪ Cardinality | Sub_part | Packed | Null | Index_type | Comment | Index
    ↪ _comment | Visible | Expression | Clustered |
+--
    ↪ -----+------------+---------+-------------+------------+---------+--------
    ↪
| t     |          0 | PRIMARY |           1 | a          | A         |           0
    ↪  |     NULL | NULL |      | BTREE      |         |               | YES     |
    ↪ NULL       | YES       |
+--
    ↪ -----+------------+---------+-------------+------------+---------+--------
    ↪
1 row in set (0.01 sec)
```

You can also query the column `TIDB_PK_TYPE` in the system table `information_schema` ↪ `.tables` to see whether the result is `CLUSTERED` or `NONCLUSTERED`. For example:

```
mysql> SELECT TIDB_PK_TYPE FROM information_schema.tables WHERE table_
    ↪ schema = 'test' AND table_name = 't';
+--------------+
| TIDB_PK_TYPE |
+--------------+
| CLUSTERED    |
+--------------+
1 row in set (0.03 sec)
```

14.13.5.3 Limitations

Currently, there are several different types of limitations for the clustered index feature. See the following:

- Situations that are not supported and not in the support plan:

    - Using clustered indexes together with the attribute SHARD_ROW_ID_BITS is not supported. Also, the attribute PRE_SPLIT_REGIONS does not take effect on tables with clustered indexes that are not AUTO_RANDOM.
    - Downgrading tables with clustered indexes is not supported. If you need to downgrade such tables, use logical backup tools to migrate data instead.
- Situations that are not supported yet but in the support plan:
    - Adding, dropping, and altering clustered indexes using ALTER TABLE statements are not supported.

If you use clustered indexes together with the attribute SHARD_ROW_ID_BITS, TiDB reports the following error:

```
mysql> CREATE TABLE t (a VARCHAR(255) PRIMARY KEY CLUSTERED) SHARD_ROW_ID_
    ↪ BITS = 3;
ERROR 8200 (HY000): Unsupported shard_row_id_bits for table with primary
    ↪ key as row id
```

14.13.5.4 Compatibility

14.13.5.4.1 Compatibility with earlier and later TiDB versions

TiDB supports upgrading tables with clustered indexes but not downgrading such tables, which means that data in tables with clustered indexes on a later TiDB version is not available on an earlier one.

The clustered index feature is partially supported in TiDB v3.0 and v4.0. It is enabled by default when the following requirements are fully met:

- The table contains a PRIMARY KEY.
- The PRIMARY KEY consists of only one column.
- The PRIMARY KEY is an INTEGER.

Since TiDB v5.0, the clustered index feature is fully supported for all types of primary keys, but the default behavior is consistent with TiDB v3.0 and v4.0. To change the default behavior, you can configure the system variable @@tidb_enable_clustered_index to ON or OFF. For more details, see Create a table with clustered indexes.

14.13.5.4.2 Compatibility with MySQL

TiDB specific comment syntax supports wrapping the keywords CLUSTERED and NONCLUSTERED in a comment. The result of SHOW CREATE TABLE also contains TiDB specific SQL comments. MySQL databases and TiDB databases of an earlier version will ignore these comments.

14.13.5.4.3 Compatibility with TiDB migration tools

The clustered index feature is only compatible with the following migration tools in v5.0 and later versions:

- Backup and restore tools: BR, Dumpling, and TiDB Lightning.
- Data migration and replication tools: DM and TiCDC.

However, you cannot convert a table with non-clustered indexes to a table with clustered indexes by backing up and restoring the table using the v5.0 BR tool, and vice versa.

14.13.5.4.4 Compatibility with other TiDB features

For a table with a combined primary key or a single non-integer primary key, if you change the primary key from a non-clustered index to a clustered index, the keys of its row data change as well. Therefore, `SPLIT TABLE BY/BETWEEN` statements that are executable in TiDB versions earlier than v5.0 are no longer workable in v5.0 and later versions of TiDB. If you want to split a table with clustered indexes using `SPLIT TABLE BY/BETWEEN`, you need to provide the value of the primary key column, instead of specifying an integer value. See the following example:

```
mysql> create table t (a int, b varchar(255), primary key(a, b) clustered);
Query OK, 0 rows affected (0.01 sec)
mysql> split table t between (0) and (1000000) regions 5;
ERROR 1105 (HY000): Split table region lower value count should be 2
mysql> split table t by (0), (50000), (100000);
ERROR 1136 (21S01): Column count doesn't match value count at row 0
mysql> split table t between (0, 'aaa') and (1000000, 'zzz') regions 5;
+--------------------+----------------------+
| TOTAL_SPLIT_REGION | SCATTER_FINISH_RATIO |
+--------------------+----------------------+
|                  4 |                    1 |
+--------------------+----------------------+
1 row in set (0.00 sec)
mysql> split table t by (0, ''), (50000, ''), (100000, '');
+--------------------+----------------------+
| TOTAL_SPLIT_REGION | SCATTER_FINISH_RATIO |
+--------------------+----------------------+
|                  3 |                    1 |
+--------------------+----------------------+
1 row in set (0.01 sec)
```

The attribute `AUTO_RANDOM` can only be used on clustered indexes. Otherwise, TiDB returns the following error:

```
mysql> create table t (a bigint primary key nonclustered auto_random);
ERROR 8216 (HY000): Invalid auto random: column a is not the integer
    ↪ primary key, or the primary key is nonclustered
```

14.13.6 Vector Search Index

As described in the Vector Search document, vector search identifies the Top K-Nearest Neighbors (KNN) to a given vector by calculating the distance between the given vector and all vectors stored in the database. While this approach provides accurate results, it can be slow when the table contains a large number of vectors because it involves a full table scan. [8]

To improve search efficiency, you can create vector search indexes in TiDB for approximate KNN (ANN) search. When using vector indexes for vector search, TiDB can greatly improve query performance with only a slight reduction in accuracy, generally maintaining a search recall rate above 90%.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

Currently, TiDB supports the HNSW (Hierarchical Navigable Small World) vector search index algorithm.

14.13.6.1 Restrictions

- TiFlash nodes must be deployed in your cluster in advance.
- Vector search indexes cannot be used as primary keys or unique indexes.

[8] The explanation of KNN search is adapted from the Approximate Nearest Neighbor Search Indexes document authored by rschu1ze in ClickHouse documentation, licensed under the Apache License 2.0.

- Vector search indexes can only be created on a single vector column and cannot be combined with other columns (such as integers or strings) to form composite indexes.
- A distance function must be specified when creating and using vector search indexes. Currently, only cosine distance `VEC_COSINE_DISTANCE()` and L2 distance `VEC_L2_DISTANCE()` functions are supported.
- For the same column, creating multiple vector search indexes using the same distance function is not supported.
- Directly dropping columns with vector search indexes is not supported. You can drop such a column by first dropping the vector search index on that column and then dropping the column itself.
- Modifying the type of a column with a vector index is not supported.
- Setting vector search indexes as invisible is not supported.
- Building vector search indexes on TiFlash nodes with encryption at rest enabled is not supported.

14.13.6.2 Create the HNSW vector index

HNSW is one of the most popular vector indexing algorithms. The HNSW index provides good performance with relatively high accuracy, up to 98% in specific cases.

In TiDB, you can create an HNSW index for a column with a vector data type in either of the following ways:

- When creating a table, use the following syntax to specify the vector column for the HNSW index:

```
CREATE TABLE foo (
    id      INT PRIMARY KEY,
    embedding   VECTOR(5),
    VECTOR INDEX idx_embedding ((VEC_COSINE_DISTANCE(embedding)))
);
```

- For an existing table that already contains a vector column, use the following syntax to create an HNSW index for the vector column:

```
CREATE VECTOR INDEX idx_embedding ON foo ((VEC_COSINE_DISTANCE(
    ↪ embedding)));
ALTER TABLE foo ADD VECTOR INDEX idx_embedding ((VEC_COSINE_DISTANCE(
    ↪ embedding)));

-- You can also explicitly specify "USING HNSW" to build the vector
    ↪ search index.
CREATE VECTOR INDEX idx_embedding ON foo ((VEC_COSINE_DISTANCE(
    ↪ embedding))) USING HNSW;
ALTER TABLE foo ADD VECTOR INDEX idx_embedding ((VEC_COSINE_DISTANCE(
    ↪ embedding))) USING HNSW;
```

Note:

The vector search index feature relies on TiFlash replicas for tables.

- If a vector search index is defined when a table is created, TiDB automatically creates a TiFlash replica for the table.
- If no vector search index is defined when a table is created, and the table currently does not have a TiFlash replica, you need to manually create a TiFlash replica before adding a vector search index to the table. For example: `ALTER TABLE 'table_name' SET TIFLASH REPLICA 1;`.

When creating an HNSW vector index, you need to specify the distance function for the vector:

- Cosine Distance: `((VEC_COSINE_DISTANCE(embedding)))`
- L2 Distance: `((VEC_L2_DISTANCE(embedding)))`

The vector index can only be created for fixed-dimensional vector columns, such as a column defined as `VECTOR(3)`. It cannot be created for non-fixed-dimensional vector columns (such as a column defined as `VECTOR`) because vector distances can only be calculated between vectors with the same dimension.

For restrictions and limitations of vector search indexes, see Restrictions.

14.13.6.3 Use the vector index

The vector search index can be used in K-nearest neighbor search queries by using the `ORDER BY ... LIMIT` clause as follows:

```
SELECT *
FROM foo
ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3, 4, 5]')
LIMIT 10
```

To use an index in a vector search, make sure that the `ORDER BY ... LIMIT` clause uses the same distance function as the one specified when creating the vector index.

14.13.6.4 Use the vector index with filters

Queries that contain a pre-filter (using the `WHERE` clause) cannot utilize the vector index because they are not querying for K-Nearest neighbors according to the SQL semantics. For example:

```
-- For the following query, the `WHERE` filter is performed before KNN, so
   ↪  the vector index cannot be used:

SELECT * FROM vec_table
WHERE category = "document"
ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]')
LIMIT 5;
```

To use the vector index with filters, query for the K-Nearest neighbors first using vector search, and then filter out unwanted results:

```
-- For the following query, the `WHERE` filter is performed after KNN, so
   ↪ the vector index cannot be used:

SELECT * FROM
(
  SELECT * FROM vec_table
  ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]')
  LIMIT 5
) t
WHERE category = "document";

-- Note that this query might return fewer than 5 results if some are
   ↪ filtered out.
```

14.13.6.5 View index build progress

After you insert a large volume of data, some of it might not be instantly persisted to TiFlash. For vector data that has already been persisted, the vector search index is built synchronously. For data that has not yet been persisted, the index will be built once the data is persisted. This process does not affect the accuracy and consistency of the data. You can still perform vector searches at any time and get complete results. However, performance will be suboptimal until vector indexes are fully built.

To view the index build progress, you can query the `INFORMATION_SCHEMA.TIFLASH_INDEXES` table as follows:

```
SELECT * FROM INFORMATION_SCHEMA.TIFLASH_INDEXES;
+--
   ↪ -------------+------------+----------+-------------+--------------+-----------+
   ↪
| TIDB_DATABASE | TIDB_TABLE | TABLE_ID | COLUMN_NAME | INDEX_NAME | COLUMN
   ↪ _ID | INDEX_ID | INDEX_KIND | ROWS_STABLE_INDEXED | ROWS_STABLE_NOT_
   ↪ INDEXED | ROWS_DELTA_INDEXED | ROWS_DELTA_NOT_INDEXED | ERROR_MESSAGE
   ↪  | TIFLASH_INSTANCE |
```

```
+--
    ↪ ------------+-----------+---------+------------+--------------+----------+
    ↪
| test        | tcff1d827 |     219 | col1fff    | 0a452311     |        7 |
    ↪       1 | HNSW      |             29646 |                     0 |
    ↪                 0 |                   0 |             | 127.0.0.1:3930
    ↪ |
| test        | foo       |     717 | embedding | idx_embedding |      2 |
    ↪       1 | HNSW      |                 0 |                     0 |
    ↪                 0 |                   3 |             | 127.0.0.1:3930
    ↪ |
+--
    ↪ ------------+-----------+---------+------------+--------------+----------+
    ↪
```

- You can check the `ROWS_STABLE_INDEXED` and `ROWS_STABLE_NOT_INDEXED` columns for the index build progress. When `ROWS_STABLE_NOT_INDEXED` becomes 0, the index build is complete.

  As a reference, indexing a 500 MiB vector dataset with 768 dimensions might take up to 20 minutes. The indexer can run in parallel for multiple tables. Currently, adjusting the indexer priority or speed is not supported.

- You can check the `ROWS_DELTA_NOT_INDEXED` column for the number of rows in the Delta layer. Data in the storage layer of TiFlash is stored in two layers: Delta layer and Stable layer. The Delta layer stores recently inserted or updated rows and is periodically merged into the Stable layer according to the write workload. This merge process is called Compaction.

  The Delta layer is always not indexed. To achieve optimal performance, you can force the merge of the Delta layer into the Stable layer so that all data can be indexed:

  ```
  ALTER TABLE <TABLE_NAME> COMPACT;
  ```

  For more information, see `ALTER TABLE ... COMPACT`.

In addition, you can monitor the execution progress of the DDL job by executing `ADMIN SHOW DDL JOBS;` and checking the `row count`. However, this method is not fully accurate, because the `row count` value is obtained from the `rows_stable_indexed` field in `TIFLASH_INDEXES`. You can use this approach as a reference for tracking the progress of indexing.

14.13.6.6 Check whether the vector index is used

Use the `EXPLAIN` or `EXPLAIN ANALYZE` statement to check whether a query is using the vector index. When `annIndex:` is presented in the `operator info` column for the `TableFullScan` executor, it means this table scan is utilizing the vector index.

Example: the vector index is used

```
[tidb]> EXPLAIN SELECT * FROM vector_table_with_index
ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]')
LIMIT 10;
+--
   ↪ ---+-------------------------------------------------------------------------
   ↪
| ... | operator info
   ↪                                                                  |
+--
   ↪ ---+-------------------------------------------------------------------------
   ↪
| ... | ...
   ↪                                                                              |
| ... | Column#5, offset:0, count:10
   ↪                                                  |
| ... | ..., vec_cosine_distance(test.vector_table_with_index.embedding,
   ↪ [1,2,3])->Column#5 |
| ... | MppVersion: 1, data:ExchangeSender_16
   ↪                                          |
| ... | ExchangeType: PassThrough
   ↪                                                    |
| ... | ...
   ↪                                                                              |
| ... | Column#4, offset:0, count:10
   ↪                                                  |
| ... | ..., vec_cosine_distance(test.vector_table_with_index.embedding,
   ↪ [1,2,3])->Column#4 |
| ... | annIndex:COSINE(test.vector_table_with_index.embedding..[1,2,3],
   ↪ limit:10), ... |
+--
   ↪ ---+-------------------------------------------------------------------------
   ↪
9 rows in set (0.01 sec)
```

Example: The vector index is not used because of not specifying a Top K

```
[tidb]> EXPLAIN SELECT * FROM vector_table_with_index
    -> ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]');
+--
   ↪ ----------------------------+-----+-----------------------------------------
   ↪
| id                           | ... | operator info
   ↪                                |
+--
```

```
    ↪ ------------------------------+-----+-----------------------------------------
    ↪
| Projection_15                | ... | ...
    ↪                                          |
|  ─Sort_4                     | ... | Column#4

    ↪
6 rows in set, 1 warning (0.01 sec)
```

When the vector index cannot be used, a warning occurs in some cases to help you learn the cause:

```
-- Using a wrong distance function:
[tidb]> EXPLAIN SELECT * FROM vector_table_with_index
ORDER BY VEC_L2_DISTANCE(embedding, '[1, 2, 3]')
LIMIT 10;

[tidb]> SHOW WARNINGS;
ANN index not used: not ordering by COSINE distance

-- Using a wrong order:
[tidb]> EXPLAIN SELECT * FROM vector_table_with_index
ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]') DESC
LIMIT 10;

[tidb]> SHOW WARNINGS;
ANN index not used: index can be used only when ordering by vec_cosine_
    ↪ distance() in ASC order
```

14.13.6.7 Analyze vector search performance

To learn detailed information about how a vector index is used, you can execute the `EXPLAIN ANALYZE` statement and check the `execution info` column in the output:

```
[tidb]> EXPLAIN ANALYZE SELECT * FROM vector_table_with_index
```

```
ORDER BY VEC_COSINE_DISTANCE(embedding, '[1, 2, 3]')
LIMIT 10;
+-----+-----------------------------------------------------+-----+
|     | execution info                                      |     |
+-----+-----------------------------------------------------+-----+
| ... | time:339.1ms, loops:2, RU:0.000000, Concurrency:OFF | ... |
| ... | time:339ms, loops:2                                 | ... |
| ... | time:339ms, loops:3, Concurrency:OFF                | ... |
| ... | time:339ms, loops:3, cop_task: {...}                | ... |
| ... | tiflash_task:{time:327.5ms, loops:1, threads:4}     | ... |
| ... | tiflash_task:{time:327.5ms, loops:1, threads:4}     | ... |
| ... | tiflash_task:{time:327.5ms, loops:1, threads:4}     | ... |
| ... | tiflash_task:{time:327.5ms, loops:1, threads:4}     | ... |
| ... | tiflash_task:{...}, vector_idx:{                    | ... |
|     |   load:{total:68ms,from_s3:1,from_disk:0,from_cache:0},| |
|     |   search:{total:0ms,visited_nodes:2,discarded_nodes:0},| |
|     |   read:{vec_total:0ms,others_total:0ms}},...}       |     |
+-----+-----------------------------------------------------+-----+
```

Note:

The execution information is internal. Fields and formats are subject to change without any notification. Do not rely on them.

Explanation of some important fields:

- `vector_index.load.total`: The total duration of loading index. This field might be larger than the actual query time because multiple vector indexes might be loaded in parallel.
- `vector_index.load.from_s3`: Number of indexes loaded from S3.
- `vector_index.load.from_disk`: Number of indexes loaded from disk. The index was already downloaded from S3 previously.
- `vector_index.load.from_cache`: Number of indexes loaded from cache. The index was already downloaded from S3 previously.
- `vector_index.search.total`: The total duration of searching in the index. Large latency usually means the index is cold (never accessed before, or accessed long ago) so that there are heavy I/O operations when searching through the index. This field might be larger than the actual query time because multiple vector indexes might be searched in parallel.
- `vector_index.search.discarded_nodes`: Number of vector rows visited but discarded during the search. These discarded vectors are not considered in the search

result. Large values usually indicate that there are many stale rows caused by `UPDATE` or `DELETE` statements.

See `EXPLAIN`, `EXPLAIN ANALYZE`, and EXPLAIN Walkthrough for interpreting the output.

14.13.7 Constraints

TiDB supports almost the same constraints as MySQL.

14.13.7.1 NOT NULL

NOT NULL constraints supported by TiDB are the same as those supported by MySQL.

For example:

```
CREATE TABLE users (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 age INT NOT NULL,
 last_login TIMESTAMP
);
```

```
INSERT INTO users (id,age,last_login) VALUES (NULL,123,NOW());
```

```
Query OK, 1 row affected (0.02 sec)
```

```
INSERT INTO users (id,age,last_login) VALUES (NULL,NULL,NOW());
```

```
ERROR 1048 (23000): Column 'age' cannot be null
```

```
INSERT INTO users (id,age,last_login) VALUES (NULL,123,NULL);
```

```
Query OK, 1 row affected (0.03 sec)
```

- The first `INSERT` statement succeeds because it is possible to assign `NULL` to the `AUTO_INCREMENT` column. TiDB generates sequence numbers automatically.
- The second `INSERT` statement fails because the `age` column is defined as `NOT NULL`.
- The third `INSERT` statement succeeds because the `last_login` column is not explicitly defined as `NOT NULL`. NULL values are allowed by default.

14.13.7.2 CHECK

> **Note:**
>
> The `CHECK` constraint feature is disabled by default. To enable it, you need to set the `tidb_enable_check_constraint` variable to `ON`.

A `CHECK` constraint restricts the values of a column in a table to meet your specified conditions. When the `CHECK` constraint is added to a table, TiDB checks whether the constraint is satisfied during the insertion or updates of data into the table. If the constraint is not met, an error is returned.

The syntax for the `CHECK` constraint in TiDB is the same as that in MySQL:

```
[CONSTRAINT [symbol]] CHECK (expr) [[NOT] ENFORCED]
```

Syntax explanation:

- `[]`: the content within `[]` is optional.
- `CONSTRAINT [symbol]`: specifies the name of the `CHECK` constraint.
- `CHECK (expr)`: specifies the constraint condition, where `expr` needs to be a boolean expression. For each row in the table, the calculation result of this expression must be one of `TRUE`, `FALSE`, or `UNKNOWN` (for `NULL` values). If the calculation result is `FALSE` for a row, it indicates that the constraint is violated.
- `[NOT] ENFORCED`: specifies whether to implement the constraint check. You can use it to enable or disable a `CHECK` constraint.

14.13.7.2.1 Add `CHECK` constraints

In TiDB, you can add a `CHECK` constraint to a table using either the `CREATE TABLE` or the `ALTER TABLE` statement.

- Example of adding a `CHECK` constraint using the `CREATE TABLE` statement:

```
CREATE TABLE t(a INT CHECK(a > 10) NOT ENFORCED, b INT, c INT,
    ↪ CONSTRAINT c1 CHECK (b > c));
```

- Example of adding a `CHECK` constraint using the `ALTER TABLE` statement:

```
ALTER TABLE t ADD CONSTRAINT CHECK (1 < c);
```

When adding or enabling a `CHECK` constraint, TiDB checks the existing data in the table. If any data violates the constraint, the operation of adding the `CHECK` constraint will fail and return an error.

When adding a `CHECK` constraint, you can either specify a constraint name or leave the name unspecified. If no constraint name is specified, TiDB automatically generates a constraint name in the `<tableName>_chk_<1, 2, 3...>` format.

14.13.7.2.2 View `CHECK` constraints

You can view the constraint information in a table using the `SHOW CREATE TABLE` statement. For example:

```
SHOW CREATE TABLE t;
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int DEFAULT NULL,
  `b` int DEFAULT NULL,
  `c` int DEFAULT NULL,
CONSTRAINT `c1` CHECK ((`b` > `c`)),
CONSTRAINT `t_chk_1` CHECK ((`a` > 10)) /*!80016 NOT ENFORCED */,
CONSTRAINT `t_chk_2` CHECK ((1 < `c`))
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+----------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.7.2.3 Delete `CHECK` constraints

When deleting a `CHECK` constraint, you need to specify the name of the constraint to be deleted. For example:

```
ALTER TABLE t DROP CONSTRAINT t_chk_1;
```

14.13.7.2.4 Enable or disable `CHECK` constraints

When adding a `CHECK` constraint to a table, you can specify whether TiDB needs to implement the constraint check during data insertion or updates.

- If `NOT ENFORCED` is specified, TiDB does not check the constraint conditions during data insertion or updates.
- If `NOT ENFORCED` is not specified or `ENFORCED` is specified, TiDB checks the constraint conditions during data insertion or updates.

In addition to specifying `[NOT] ENFORCED` when adding the constraint, you can also enable or disable a `CHECK` constraint using the `ALTER TABLE` statement. For example:

```
ALTER TABLE t ALTER CONSTRAINT c1 NOT ENFORCED;
```

14.13.7.2.5 MySQL compatibility

- It is not supported to add a `CHECK` constraint while adding a column (for example, `ALTER TABLE t ADD COLUMN a CHECK(a > 0)`). In this case, only the column is added successfully, and TiDB ignores the `CHECK` constraint without reporting any error.
- It is not supported to use `ALTER TABLE t CHANGE a b int CHECK(b > 0)` to add a `CHECK` constraint. When this statement is executed, TiDB reports an error.

14.13.7.3 UNIQUE KEY

Unique constraints mean that all non-null values in a unique index and a primary key column are unique.

14.13.7.3.1 Optimistic transactions

By default, for optimistic transactions, TiDB checks unique constraints lazily in the execution phase and strictly in the commit phase, which helps reduce network overhead and improve performance.

For example:

```
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 username VARCHAR(60) NOT NULL,
 UNIQUE KEY (username)
);
INSERT INTO users (username) VALUES ('dave'), ('sarah'), ('bill');
```

With optimistic locking and `tidb_constraint_check_in_place=OFF`:

```
BEGIN OPTIMISTIC;
INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill');
```

```
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
INSERT INTO users (username) VALUES ('steve'),('elizabeth');
```

```
Query OK, 2 rows affected (0.00 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
COMMIT;
```

```
ERROR 1062 (23000): Duplicate entry 'bill' for key 'users.username'
```

In the preceding optimistic example, the unique check was deferred until the transaction is committed. This resulted in a duplicate key error, because the value `bill` was already present.

You can disable this behavior by setting `tidb_constraint_check_in_place` to `ON`. When `tidb_constraint_check_in_place=ON`, the unique constraint is checked when a statement is executed. Note that this variable is only applicable to optimistic transactions. For pessimistic transactions, you can control this behavior using the `tidb_constraint_check_in_place_pessimistic` variable.

For example:

```
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 username VARCHAR(60) NOT NULL,
 UNIQUE KEY (username)
);
INSERT INTO users (username) VALUES ('dave'), ('sarah'), ('bill');
```

```
SET tidb_constraint_check_in_place = ON;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
BEGIN OPTIMISTIC;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill');
```

```
ERROR 1062 (23000): Duplicate entry 'bill' for key 'users.username'
```

The first `INSERT` statement caused a duplicate key error. This causes additional network communication overhead and may reduce the throughput of insert operations.

14.13.7.3.2 Pessimistic transactions

In pessimistic transactions, by default, TiDB checks `UNIQUE` constraints when a SQL statement that requires inserting or updating unique indexes is executed.

```
DROP TABLE IF EXISTS users;
CREATE TABLE users (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 username VARCHAR(60) NOT NULL,
 UNIQUE KEY (username)
);
INSERT INTO users (username) VALUES ('dave'), ('sarah'), ('bill');

BEGIN PESSIMISTIC;
INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill');
```

```
ERROR 1062 (23000): Duplicate entry 'bill' for key 'users.username'
```

To achieve better performance of pessimistic transactions, you can set the `tidb_constraint_check_in_place_pessimistic` variable to `OFF`, which allows TiDB to defer the unique constraint check of a unique index (to the next time when this index requires a lock or to the time when the transaction is committed) and skip the corresponding pessimistic lock. When using this variable, pay attention to the following:

- Due to the deferred unique constraint check, TiDB might read results that do not meet the unique constraints and return a `Duplicate entry` error when you commit a pessimistic transaction. When this error occurs, TiDB rolls back the current transaction.

  The following example skips the lock to `bill`, so TiDB might get results that do not satisfy the uniqueness constraints.

  ```
  SET tidb_constraint_check_in_place_pessimistic = OFF;
  BEGIN PESSIMISTIC;
  INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill'); --
      ↪ Query OK, 3 rows affected
  SELECT * FROM users FOR UPDATE;
  ```

As in the following example output, the query results of TiDB contain two `bills`, which does not satisfy the uniqueness constraints.

```
```sql
+----+----------+
| id | username |
+----+----------+
| 1  | dave     |
| 2  | sarah    |
```
```

```
| 3  | bill    |
| 7  | jane    |
| 8  | chris   |
| 9  | bill    |
+----+----------+
```

At this time, if the transaction is committed, TiDB will perform a unique constraint check, report a `Duplicate entry` error, and roll back the transaction.

```sql
COMMIT;
```

```
ERROR 1062 (23000): Duplicate entry 'bill' for key 'users.username'
```

- When this variable is disabled, committing a pessimistic transaction that needs to write data might return a `Write conflict` error. When this error occurs, TiDB rolls back the current transaction.

  As in the following example, if two concurrent transactions need to insert data to the same table, skipping the pessimistic lock causes TiDB to return a `Write conflict` error when you commit a transaction. And the transaction will be rolled back.

  ```
  DROP TABLE IF EXISTS users;
  CREATE TABLE users (
  id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
  username VARCHAR(60) NOT NULL,
  UNIQUE KEY (username)
  );

  SET tidb_constraint_check_in_place_pessimistic = OFF;
  BEGIN PESSIMISTIC;
  INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill'); -- Query OK, 3 rows affected
  ```

  At the same time, another session inserts `bill` to the same table.

  ```
  INSERT INTO users (username) VALUES ('bill'); -- Query OK, 1 row affected
  ```

  Then, when you commit the transaction in the first session, TiDB reports a `Write conflict` error.

```
COMMIT;
```

```
ERROR 9007 (HY000): Write conflict, txnStartTS=435688780611190794,
    ↪ conflictStartTS=435688783311536129, conflictCommitTS
    ↪ =435688783311536130, key={tableID=74, indexID=1, indexValues={
    ↪ bill, }} primary={tableID=74, indexID=1, indexValues={bill, }},
    ↪ reason=LazyUniquenessCheck [try again later]
```

- When this variable is disabled, if there is a write conflict among multiple pessimistic transactions, the pessimistic lock might be forced to roll back when other pessimistic transactions are committed, thus resulting in a `Pessimistic lock not found` error. When this error occurs, it means that deferring the unique constraint check of the pessimistic transaction is not suitable for your application scenario. In this case, consider adjusting the application logic to avoid the conflict or retrying the transaction after an error occurs.
- When this variable is disabled, executing a DML statement in a pessimistic transaction might return an error `8147: LazyUniquenessCheckFailure`.

> **Note:**
> When the `8147` error occurs, TiDB rolls back the current transaction.

As in the following example, at the execution of the `INSERT` statement, TiDB skips a lock. Then, at the execution of the `DELETE` statement, TiDB locks the unique index and checks the unique constraints, so you will see an error is reported at the `DELETE` statement.

```
SET tidb_constraint_check_in_place_pessimistic = OFF;
BEGIN PESSIMISTIC;
INSERT INTO users (username) VALUES ('jane'), ('chris'), ('bill'); --
    ↪ Query OK, 3 rows affected
DELETE FROM users where username = 'bill';
```

```
ERROR 8147 (23000): transaction aborted because lazy uniqueness check
    ↪ is enabled and an error occurred: [kv:1062]Duplicate entry 'bill'
    ↪  for key 'users.username'
```

- When this variable is disabled, the `1062 Duplicate entry` error might be not from the current SQL statement. Therefore, when a transaction operates on multiple tables that have indexes with the same name, you need to check the `1062` error message to find which index the error is actually from.

14.13.7.4 PRIMARY KEY

Like MySQL, primary key constraints contain unique constraints, that is, creating a primary key constraint is equivalent to having a unique constraint. In addition, other primary key constraints of TiDB are also similar to those of MySQL.

For example:

```
CREATE TABLE t1 (a INT NOT NULL PRIMARY KEY);
```

```
Query OK, 0 rows affected (0.12 sec)
```

```
CREATE TABLE t2 (a INT NULL PRIMARY KEY);
```

```
ERROR 1171 (42000): All parts of a PRIMARY KEY must be NOT NULL; if you need
    ↪  NULL in a key, use UNIQUE instead
```

```
CREATE TABLE t3 (a INT NOT NULL PRIMARY KEY, b INT NOT NULL PRIMARY KEY);
```

```
ERROR 1068 (42000): Multiple primary key defined
```

```
CREATE TABLE t4 (a INT NOT NULL, b INT NOT NULL, PRIMARY KEY (a,b));
```

```
Query OK, 0 rows affected (0.10 sec)
```

- Table `t2` failed to be created, because column `a` is defined as the primary key and does not allow NULL values.
- Table `t3` failed to be created, because a table can only have one primary key.
- Table `t4` was created successfully, because even though there can be only one primary key, TiDB supports defining multiple columns as the composite primary key.

In addition to the rules above, TiDB currently only supports adding and deleting the primary keys of the `NONCLUSTERED` type. For example:

```
CREATE TABLE t5 (a INT NOT NULL, b INT NOT NULL, PRIMARY KEY (a,b)
    ↪ CLUSTERED);
ALTER TABLE t5 DROP PRIMARY KEY;
```

```
ERROR 8200 (HY000): Unsupported drop primary key when the table is using
    ↪ clustered index
```

```
CREATE TABLE t5 (a INT NOT NULL, b INT NOT NULL, PRIMARY KEY (a,b)
    ↪ NONCLUSTERED);
ALTER TABLE t5 DROP PRIMARY KEY;
```

```
Query OK, 0 rows affected (0.10 sec)
```

For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

14.13.7.5 FOREIGN KEY

> **Note:**
>
> Starting from v6.6.0, TiDB supports the FOREIGN KEY constraints. Before v6.6.0, TiDB supports creating and deleting foreign key constraints, but the constraints are not actually effective. After upgrading TiDB to v6.6.0 or later, you can delete the invalid foreign key and create a new one to make the foreign key constraints effective. This feature becomes generally available in v8.5.0.

TiDB supports creating `FOREIGN KEY` constraints in DDL commands.

For example:

```
CREATE TABLE users (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 doc JSON
);
CREATE TABLE orders (
 id INT NOT NULL PRIMARY KEY AUTO_INCREMENT,
 user_id INT NOT NULL,
 doc JSON,
 FOREIGN KEY fk_user_id (user_id) REFERENCES users(id)
);
```

```
SELECT table_name, column_name, constraint_name, referenced_table_name,
    ↪ referenced_column_name
FROM information_schema.key_column_usage WHERE table_name IN ('users', '
    ↪ orders');
```

```
+------------+-------------+-----------------+-----------------------+-----------------
    ↪
| table_name | column_name | constraint_name | referenced_table_name |
    ↪ referenced_column_name |
+------------+-------------+-----------------+-----------------------+-----------------
    ↪
| users      | id          | PRIMARY         | NULL                  | NULL
    ↪                 |
| orders     | id          | PRIMARY         | NULL                  | NULL
    ↪                 |
| orders     | user_id     | fk_user_id      | users                 | id
    ↪                   |
```

```
+------------+------------+-----------------+----------------------+-------------------
    ↪
3 rows in set (0.00 sec)
```

TiDB also supports the syntax to `DROP FOREIGN KEY` and `ADD FOREIGN KEY` via the `ALTER TABLE` command.

```
ALTER TABLE orders DROP FOREIGN KEY fk_user_id;
ALTER TABLE orders ADD FOREIGN KEY fk_user_id (user_id) REFERENCES users(id
    ↪ );
```

14.13.8 Generated Columns

This document introduces the concept and usage of generated columns.

14.13.8.1 Basic concepts

Unlike general columns, the value of the generated column is calculated by the expression in the column definition. When inserting or updating a generated column, you cannot assign a value, but only use `DEFAULT`.

There are two kinds of generated columns: virtual and stored. A virtual generated column occupies no storage and is computed when it is read. A stored generated column is computed when it is written (inserted or updated) and occupies storage. Compared with the virtual generated columns, the stored generated columns have better read performance, but take up more disk space.

You can create an index on a generated column whether it is virtual or stored.

14.13.8.2 Usage

One of the main usage of generated columns is to extract data from the JSON data type and indexing the data.

In both MySQL 8.0 and TiDB, columns of type JSON cannot be indexed directly. That is, the following table schema is **not supported**:

```
CREATE TABLE person (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(255) NOT NULL,
    address_info JSON,
    KEY (address_info)
);
```

To index a JSON column, you must extract it as a generated column first.

Using the `city` field in `address_info` as an example, you can create a virtual generated column and add an index for it:

```
CREATE TABLE person (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(255) NOT NULL,
    address_info JSON,
    city VARCHAR(64) AS (JSON_UNQUOTE(JSON_EXTRACT(address_info, '$.city')))
       ↪ , -- virtual generated column
    -- city VARCHAR(64) AS (JSON_UNQUOTE(JSON_EXTRACT(address_info, '$.city
       ↪ '))) VIRTUAL, -- virtual generated column
    -- city VARCHAR(64) AS (JSON_UNQUOTE(JSON_EXTRACT(address_info, '$.city
       ↪ '))) STORED, -- stored generated column
    KEY (city)
);
```

In this table, the `city` column is a **virtual generated column** and has an index. The following query can use the index to speed up the execution:

```
SELECT name, id FROM person WHERE city = 'Beijing';
```

```
EXPLAIN SELECT name, id FROM person WHERE city = 'Beijing';
```

```
+--
   ↪ ------------------------------+---------+-----------+-------------------------
   ↪
| id                            | estRows | task    | access object
   ↪              | operator info                                          |
+--
   ↪ ------------------------------+---------+-----------+-------------------------
   ↪
| Projection_4                  | 10.00   | root      |
   ↪                               | test.person.name, test.person.id
   ↪                       |
| └─IndexLookUp_10              | 10.00   | root      |
   ↪                               |
   ↪                                                       |
|   ├─IndexRangeScan_8(Build)   | 10.00   | cop[tikv] | table:person, index:
   ↪ city(city) | range:["Beijing","Beijing"], keep order:false, stats:
   ↪ pseudo |
|   └─TableRowIDScan_9(Probe)   | 10.00   | cop[tikv] | table:person
   ↪              | keep order:false, stats:pseudo                         |
+--
   ↪ ------------------------------+---------+-----------+-------------------------
   ↪
```

From the query execution plan, it can be seen that the `city` index is used to read the `HANDLE` of the row that meets the condition `city ='Beijing'`, and then it uses this `HANDLE`

to read the data of the row.

If no data exists at path `$.city`, `JSON_EXTRACT` returns `NULL`. If you want to enforce a constraint that `city` must be `NOT NULL`, you can define the virtual generated column as follows:

```
CREATE TABLE person (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    name VARCHAR(255) NOT NULL,
    address_info JSON,
    city VARCHAR(64) AS (JSON_UNQUOTE(JSON_EXTRACT(address_info, '$.city')))
        ↪  NOT NULL,
    KEY (city)
);
```

14.13.8.3 Validation of generated columns

Both `INSERT` and `UPDATE` statements check virtual column definitions. Rows that do not pass validation return errors:

```
mysql> INSERT INTO person (name, address_info) VALUES ('Morgan', JSON_
    ↪ OBJECT('Country', 'Canada'));
ERROR 1048 (23000): Column 'city' cannot be null
```

14.13.8.4 Generated columns index replacement rule

When an expression in a query is strictly equivalent to a generated column with an index, TiDB replaces the expression with the corresponding generated column, so that the optimizer can take that index into account during execution plan construction.

The following example creates a generated column for the expression `a+1` and adds an index. The column type of `a` is int and the column type of `a+1` is bigint. If the type of the generated column is set to int, the replacement will not occur. For type conversion rules, see Type Conversion of Expression Evaluation.

```
create table t(a int);
desc select a+1 from t where a+1=3;
```

```
+--
    ↪ ------------------------+----------+-----------+--------------+--------------
    ↪
| id                        | estRows | task    | access object | operator info
    ↪             |
+--
    ↪ ------------------------+----------+-----------+--------------+--------------
    ↪
```

```
| Projection_4          | 8000.00 | root    |              | plus(test.t.a,
    ↪ 1)->Column#3 |
|  ─TableReader_7       | 8000.00 | root    |              | data:Selection
    ↪ _6           |
|    ─Selection_6       | 8000.00 | cop[tikv] |            | eq(plus(test.t
    ↪ .a, 1), 3)   |
|      ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t  | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+--------------+-------------
    ↪
4 rows in set (0.00 sec)
```

```
alter table t add column b bigint as (a+1) virtual;
alter table t add index idx_b(b);
desc select a+1 from t where a+1=3;
```

```
+--
    ↪ ---------------------+---------+----------+-----------------------+--------
    ↪
| id                   | estRows | task    | access object         | operator
    ↪ info                          |
+--
    ↪ ---------------------+---------+----------+-----------------------+--------
    ↪
| IndexReader_6        | 10.00   | root     |                       | index:
    ↪ IndexRangeScan_5                |
|  ─IndexRangeScan_5   | 10.00   | cop[tikv] | table:t, index:idx_b(b) |
    ↪ range:[3,3], keep order:false, stats:pseudo |
+--
    ↪ ---------------------+---------+----------+-----------------------+--------
    ↪
2 rows in set (0.01 sec)
```

Note:

If the expression to be replaced and the generated column are both the string type but with different lengths, you can still replace the expression by setting the system variable `tidb_enable_unsafe_substitute` to `ON`. When configuring this system variable, ensure that the value calculated by the generated column strictly satisfies the definition of the generated column. Otherwise, the data might be truncated due to the difference in length, resulting in an incorrect result. See GitHub issue #35490.

14.13.8.5 Limitations

The current limitations of JSON and generated columns are as follows:

- You cannot add a stored generated column through `ALTER TABLE`.
- You can neither convert a stored generated column to a normal column through the `ALTER TABLE` statement nor convert a normal column to a stored generated column.
- You cannot modify the expression of a stored generated column through the `ALTER TABLE` statement.
- Not all JSON functions are supported.
- The `NULLIF()` function is not supported. You can use the `CASE` function instead.
- Currently, the generated column index replacement rule is valid only when the generated column is a virtual generated column. It is not valid on the stored generated column, but the index can still be used by directly using the generated column itself.
- The following functions and expressions are not allowed in generated column definitions, and TiDB returns errors if they are used:
    - Non-deterministic functions and expressions, such as `RAND`, `UUID`, and `CURRENT_TIMESTAMP`.
    - Functions that depend on session-specific or global state, such as `CONNECTION_ID` and `CURRENT_USER`.
    - Functions that affect the system state or perform system interactions, such as `GET_LOCK`, `RELEASE_LOCK`, and `SLEEP`.

— title: SQL Mode summary: Learn SQL mode. —

14.13.9 SQL Mode

TiDB servers operate in different SQL modes and apply these modes differently for different clients. SQL mode defines the SQL syntaxes that TiDB supports and the type of data validation check to perform, as described below:

After TiDB is started, you can use the `SET [ SESSION | GLOBAL ] sql_mode='modes'` statement to set SQL mode.

- Ensure that you have `SUPER` privilege when setting SQL mode at `GLOBAL` level, and your setting at this level only affects the connections established afterwards.
- Changes to SQL mode at `SESSION` level only affect the current client.

In this statement, `modes` is a set of modes separated by commas (','). You can use the `SELECT @@sql_mode` statement to check the current SQL mode. The default value of SQL mode: `ONLY_FULL_GROUP_BY, STRICT_TRANS_TABLES, NO_ZERO_IN_DATE, NO_ZERO_DATE, ERROR_FOR_DIVISION_BY_ZERO, NO_AUTO_CREATE_USER, NO_ENGINE_SUBSTITUTION`.

14.13.9.1 Important `sql_mode` values

- `ANSI`: This mode complies with standard SQL. In this mode, data is checked. If data does not comply with the defined type or length, the data type is adjusted or trimmed and a `warning` is returned.
- `STRICT_TRANS_TABLES`: Strict mode, where data is strictly checked. If any data is incorrect, it cannot be inserted into a table and an error is returned.
- `TRADITIONAL`: In this mode, TiDB behaves like a "traditional" SQL database system. An error instead of a warning is returned when any incorrect value is inserted into a column. Then, the `INSERT` or `UPDATE` statement is immediately stopped.

14.13.9.2 SQL mode table

Name	Description
`PIPES_AS_CONCAT`	Treats "||" as a string concatenation operator (+) (the same as `CONCAT()`), not as an `OR` (full support)

Name	Description
`ANSI_QUOTES`	Treats `"` as an identifier. If `ANSI_QUOTES` is enabled, only single quotes are treated as string literals, and double quotes are treated as identifiers. Therefore, double quotes cannot be used to quote strings. (full support)

Name	Description
`IGNORE_SPACE`	If this mode is enabled, the system ignores space. For example: “user” and “user” are the same. (full support)

Name	Description
`ONLY_FULL_GROUP_BY`	A SQL statement is invalid if it refers to a column in `SELECT`, `HAVING`, or `ORDER BY` that is neither aggregated nor included in the `GROUP BY` clause. This is because displaying such a column in

Name	Description
`NO_UNSIGNED_SUBTRACTION`	Does not mark the result as `UNSIGNED` if an operand has no symbol in subtraction. (full support)

Name	Description
NO_ ↪ DIR ↪ _ ↪ IN ↪ _ ↪ CREATE ↪	Ignores all INDEX ↪ ↪ DIRECTORY ↪ and DATA ↪ ↪ DIRECTORY ↪ direc- tives when a table is cre- ated. This op- tion is only use- ful for sec- ondary repli- ca- tion servers (syn- tax sup- port only)

Name	Description
NO_KEY_OPTIONS	When you use the SHOW CREATE TABLE statement, MySQL-specific syntaxes such as ENGINE are not exported. Consider this option when migrating across DB types using mysqldump. (syntax support only)

Name	Description
NO_ ↪ FIELD ↪ _ ↪ OPTIONS ↪	When you use the SHOW ↪ ↪ CREATE ↪ ↪ TABLE ↪ statement, MySQL-specific syntaxes such as ENGINE ↪ are not exported. Consider this option when migrating across DB types using mysqldump. (syntax support only)

Name	Description
`NO_TABLE_OPTIONS`	When you use the `SHOW CREATE TABLE` statement, MySQL-specific syntaxes such as `ENGINE` are not exported. Consider this option when migrating across DB types using mysqldump. (syntax support only)

Name	Description
NO_ ↪ AUTO ↪ _ ↪ VALUE ↪ _ ↪ ON ↪ _ ↪ ZERO ↪	If this mode is enabled, when the value passed in the AUTO ↪ _ ↪ INCREMENT ↪ column is 0 or a specific value, the system directly writes this value to this column. When NULL is passed, the system automatically generates the

Name	Description
NO_ ↪ BACKSLASH ↪ _ ↪ ESCAPES ↪	If this mode is enabled, the \ backslash symbol only stands for itself. (full support)

Name	Description
`STRICT_TRANS_TABLES`	Enables the strict mode for the transaction storage engine and rolls back the entire statement after an illegal value is inserted. (full support)

Name	Description
`STRICT` ↪ `_` ↪ `ALL` ↪ `_` ↪ `TABLES` ↪	For transactional tables, rolls back the entire transaction statement after an illegal value is inserted. (full support)

Name	Description
`NO_ZERO_IN_DATE`	Strict mode, where dates with a month or day part of `0` are not accepted. If you use the `IGNORE` option, TiDB inserts '0000-00-00' for a similar date. In non-strict mode, this date is accepted but a warning is returned. (full sup-

Name	Description
`NO_ZERO_DATE`	Does not use '0000-00-00' as a legal date in strict mode. You can still insert a zero date with the `IGNORE` option. In non-strict mode, this date is accepted but a warning is returned. (full support)

Name	Description
`ALLOW_INVALID_DATES`	In this mode, the system does not check the validity of all dates. It only checks the month value ranging from `1` to `12` and the date value ranging from `1` to `31`. The mode only applies to `DATE` and `DATATIME` columns. All `TIMESTAMP`

Name	Description
`ERROR_FOR_DIVISION_BY_ZERO`	If this mode is enabled, the system returns an error when handling division by `0` in data-change operations (`INSERT` or `UPDATE`). If this mode is not enabled, the system returns a warning and `NULL` is used

Name	Description
NO_ ↪ AUTO ↪ _ ↪ CREATE ↪ _ ↪ USER ↪	Prevents GRANT ↪ ↪ from automatically creating new users, except for the specified password (full support)

Name	Description
`HIGH_NOT_PRECEDENCE`	The precedence of the NOT operator is such that expressions such as `NOT a BETWEEN b AND c` are parsed as `NOT ( a BETWEEN b AND c )`. In some older versions of MySQL,

Name	Description
NO_ ↪ ENGINE ↪ _ ↪ SUBSTITUTION ↪	Prevents the automatic replacement of storage engines if the required storage engine is disabled or not compiled. (syntax support only)

Name	Description
`PAD_` ↪ `CHAR` ↪ `_` ↪ `TO` ↪ `_` ↪ `FULL` ↪ `_` ↪ `LENGTH` ↪	If this mode is enabled, the system does not trim the trailing spaces for `CHAR` types. (syntax support only. This mode has been deprecated in MySQL 8.0.)

Name	Description
`REAL` ↪ `_` ↪ `AS` ↪ `_` ↪ `FLOAT` ↪	Treats `REAL` as the synonym of `FLOAT` ↪ , not the synonym of `DOUBLE` ↪ (full support)

Name	Description
POSTGRESQL ↪	Equivalent to PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS ↪ (syntax support only)

Name	Description
MSSQL ↪	Equivalent to PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS (syntax support only)

Name	Description
DB2	Equivalent to PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE, NO_KEY_OPTIONS, NO_TABLE_OPTIONS, NO_FIELD_OPTIONS (syntax support only)

Name	Description
MAXDB ↪	Equivalent to PIPES ↪ _ ↪ AS ↪ _ ↪ CONCAT ↪ , ANSI ↪ _ ↪ QUOTES ↪ , IGNORE ↪ _ ↪ SPACE ↪ , NO_ ↪ KEY ↪ _ ↪ OPTIONS ↪ , NO_ ↪ TABLE ↪ _ ↪ OPTIONS ↪ , NO_ ↪ FIELD ↪ _ ↪ OPTIONS ↪ , NO_ ↪ AUTO ↪ _ ↪ CREATE ↪ _ ↪ USER ↪ (full sup- port)

Name	Description
MySQL323 ↪	Equivalent to NO_ ↪ FIELD ↪ _ ↪ OPTIONS ↪ , HIGH ↪ _ ↪ NOT ↪ _ ↪ PRECEDENCE ↪ (syntax support only)
MYSQL40 ↪	Equivalent to NO_ ↪ FIELD ↪ _ ↪ OPTIONS ↪ , HIGH ↪ _ ↪ NOT ↪ _ ↪ PRECEDENCE ↪ (syntax support only)

Name	Description
ANSI	Equivalent to REAL_AS_FLOAT, PIPES_AS_CONCAT, ANSI_QUOTES, IGNORE_SPACE (syntax support only)

Name	Description

14.13.10 Table Attributes

The Table Attributes feature is introduced in TiDB v5.3.0. Using this feature, you can add specific attributes to a table or partition to perform the operations corresponding to the attributes. For example, you can use table attributes to control the Region merge behavior.

Currently, TiDB only supports adding the `merge_option` attribute to a table or partition to control the Region merge behavior. The `merge_option` attribute is only part of how to deal with hotspots. For more information, refer to Troubleshoot Hotspot Issues.

> **Note:**
>
> When you use TiCDC to perform replication or use BR to perform incremental backup, the replication or backup operations skip the DDL statement that sets table attributes. To use table attributes in the downstream or in the backup cluster, you need to manually execute the DDL statement in the downstream or in the backup cluster.

14.13.10.1 Usage

The table attribute is in the form of `key=value`. Multiple attributes are separated by commas. In the following examples, `t` is the name of the table to be modified, `p` is the name of the partition to be modified. Items in `[]` are optional.

- Set attributes for a table or partition:

```
ALTER TABLE t [PARTITION p] ATTRIBUTES [=] 'key=value[, key1=value1...]
    ↪ ';
```

- Reset attributes for a table or partition:

```
ALTER TABLE t [PARTITION p] ATTRIBUTES [=] DEFAULT;
```

- See the attributes of all tables and partitions:

```
SELECT * FROM information_schema.attributes;
```

- See the attribute configured to a table or partition:

```
SELECT * FROM information_schema.attributes WHERE id='schema/t[/p]';
```

- See all tables and partitions that have a specific attribute:

```
SELECT * FROM information_schema.attributes WHERE attributes LIKE '%
    ↪ key%';
```

14.13.10.2 Attribute override rules

The attribute configured to a table takes effect on all partitions of the table. However, there is one exception: If the table and partition are configured with the same attribute but different attribute values, the partition attribute overrides the table attribute. For example, suppose that the table `t` is configured with the `key=value` attribute, and the partition `p` is configured with `key=value1`.

```
ALTER TABLE t ATTRIBUTES[=]'key=value';
ALTER TABLE t PARTITION p ATTRIBUTES[=]'key=value1';
```

In this case, `key=value1` is the attribute that actually takes effect on the `p1` partition.

14.13.10.3 Control the Region merge behavior using table attributes

14.13.10.3.1 User scenarios

If there is a write hotspot or read hotspot, you can use table attributes to control the Region merge behavior. You can first add the `merge_option` attribute to a table or partition and then set its value to `deny`. The two scenarios are as follows.

Write hotspot on a newly created table or partition

If a hotspot issue occurs when data is written to a newly created table or partition, you usually need to split and scatter Regions. However, if there is a certain time interval between the split/scatter operation and writes, these operations do not truly avoid the write hotspot. This is because the split operation performed when the table or partition is created produces empty Regions, so if the time interval exists, the split Regions might be merged. To handle this case, you can add the `merge_option` attribute to the table or partition and set the attribute value to `deny`.

Periodic read hotspot in read-only scenarios

Suppose that in a read-only scenario, you try to reduce the periodic read hotspot that occurs on a table or partition by manually splitting Regions, and you do not want the manually split Regions to be merged after the hotspot issue is resolved. In this case, you can add the `merge_option` attribute to the table or partition and set its value to `deny`.

14.13.10.3.2 Usage

- Prevent the Regions of a table from merging:

```
ALTER TABLE t ATTRIBUTES 'merge_option=deny';
```

- Allow merging Regions belonging to a table:

```
ALTER TABLE t ATTRIBUTES 'merge_option=allow';
```

- Reset attributes of a table:

```
ALTER TABLE t ATTRIBUTES DEFAULT;
```

- Prevent the Regions of a partition from merging:

```
ALTER TABLE t PARTITION p ATTRIBUTES 'merge_option=deny';
```

- Allow merging Regions belonging to a partition:

```
ALTER TABLE t PARTITION p ATTRIBUTES 'merge_option=allow';
```

- See all tables or partitions configured the `merge_option` attribution:

```
SELECT * FROM information_schema.attributes WHERE attributes LIKE '%
    ↪ merge_option%';
```

14.13.10.3.3 Attribute override rules

```
ALTER TABLE t ATTRIBUTES 'merge_option=deny';
ALTER TABLE t PARTITION p ATTRIBUTES 'merge_option=allow';
```

When the above two attributes are configured at the same time, the Regions belonging to the partition `p` can actually be merged. When the attribute of the partition is reset, the partition `p` inherits the attribute from the table `t`, and the Regions cannot be merged.

Note:

- For a table with partitions, if the `merge_option` attribute is configured at the table level only, even if `merge_option=allow`, the table is still split into multiple Regions by default according to the actual number of partitions. To merge all Regions, you need to reset the attribute of the table.
- When using the `merge_option` attribute, you need to pay attention to the PD configuration parameter `split-merge-interval`. Suppose that the `merge_option` attribute is not configured. In this case, if Regions meet conditions, Regions can be merged after the interval specified by `split-merge-interval`. If the `merge_option` attribute is configured, PD decides whether to merge Regions after the specified interval according to the `merge_option` configuration.

Note:

- For a table with partitions, if the `merge_option` attribute is configured at the table level only, even if `merge_option=allow`, the table is still split into multiple Regions by default according to the actual number of partitions. To merge all Regions, you need to reset the attribute of the table.
- Suppose that the `merge_option` attribute is not configured. In this case, if Regions meet conditions, Regions can be merged after one hour. If the `merge_option` attribute is configured, PD decides whether to merge Regions after one hour according to the `merge_option` configuration.

14.13.11 Transactions

14.13.11.1 Transactions

TiDB supports distributed transactions using either pessimistic or optimistic transaction mode. Starting from TiDB 3.0.8, TiDB uses the pessimistic transaction mode by default.

This document introduces commonly used transaction-related statements, explicit and implicit transactions, isolation levels, lazy check for constraints, and transaction sizes.

The common variables include `autocommit`, `tidb_disable_txn_auto_retry`, `tidb_retry_limit`, and `tidb_txn_mode`.

Note:

The `tidb_disable_txn_auto_retry` and `tidb_retry_limit` variables only apply to optimistic transactions, not to pessimistic transactions.

14.13.11.1.1 Common statements

Starting a transaction

The statements `BEGIN` and `START TRANSACTION` can be used interchangeably to explicitly start a new transaction.

Syntax:

```
BEGIN;
```

```
START TRANSACTION;
```

```
START TRANSACTION WITH CONSISTENT SNAPSHOT;
```

```
START TRANSACTION WITH CAUSAL CONSISTENCY ONLY;
```

If the current session is in the process of a transaction when one of these statements is executed, TiDB automatically commits the current transaction before starting a new transaction.

> **Note:**
>
> Unlike MySQL, TiDB takes a snapshot of the current database after executing the statements above. MySQL's `BEGIN` and `START TRANSACTION` take a snapshot after executing the first `SELECT` statement (not `SELECT FOR UPDATE` ↪) that reads data from InnoDB after a transaction is started. `START` ↪ `TRANSACTION WITH CONSISTENT SNAPSHOT` takes a snapshot during the execution of the statement. As a result, `BEGIN`, `START TRANSACTION`, and `START TRANSACTION WITH CONSISTENT SNAPSHOT` are equivalent to `START` ↪ `TRANSACTION WITH CONSISTENT SNAPSHOT` in MySQL.

Committing a transaction

The statement `COMMIT` instructs TiDB to apply all changes made in the current transaction.

Syntax:

```
COMMIT;
```

> **Tip:**
>
> Make sure that your application correctly handles that a `COMMIT` statement could return an error before enabling optimistic transactions. If you are unsure of how your application handles this, it is recommended to instead use the default of pessimistic transactions.

Rolling back a transaction

The statement `ROLLBACK` rolls back and cancels all changes in the current transaction.

Syntax:

```
ROLLBACK;
```

Transactions are also automatically rolled back if the client connection is aborted or closed.

14.13.11.1.2 Autocommit

As required for MySQL compatibility, TiDB will by default *autocommit* statements immediately following their execution.

For example:

```
mysql> CREATE TABLE t1 (
    id INT NOT NULL PRIMARY KEY auto_increment,
    pad1 VARCHAR(100)
   );
Query OK, 0 rows affected (0.09 sec)

mysql> SELECT @@autocommit;
+--------------+
| @@autocommit |
+--------------+
| 1            |
+--------------+
1 row in set (0.00 sec)

mysql> INSERT INTO t1 VALUES (1, 'test');
Query OK, 1 row affected (0.02 sec)

mysql> ROLLBACK;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM t1;
+----+------+
| id | pad1 |
+----+------+
|  1 | test |
+----+------+
1 row in set (0.00 sec)
```

In the above example, the `ROLLBACK` statement has no effect. This is because the `INSERT` ↪ statement is executed in autocommit. That is, it was the equivalent of the following single-statement transaction:

```
START TRANSACTION;
INSERT INTO t1 VALUES (1, 'test');
```

```
COMMIT;
```

Autocommit will not apply if a transaction has been explicitly started. In the following example, the `ROLLBACK` statement successfully reverts the `INSERT` statement:

```
mysql> CREATE TABLE t2 (
     id INT NOT NULL PRIMARY KEY auto_increment,
     pad1 VARCHAR(100)
    );
Query OK, 0 rows affected (0.10 sec)

mysql> SELECT @@autocommit;
+--------------+
| @@autocommit |
+--------------+
| 1            |
+--------------+
1 row in set (0.00 sec)

mysql> START TRANSACTION;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t2 VALUES (1, 'test');
Query OK, 1 row affected (0.02 sec)

mysql> ROLLBACK;
Query OK, 0 rows affected (0.00 sec)

mysql> SELECT * FROM t2;
Empty set (0.00 sec)
```

The `autocommit` system variable can be changed on either a global or session basis.

For example:

```
SET autocommit = 0;
```

```
SET GLOBAL autocommit = 0;
```

14.13.11.1.3 Explicit and implicit transaction

Note:

> Some statements are committed implicitly. For example, executing `[BEGIN|START TRANSACTION]` implicitly commits the last transaction and starts a new transaction. This behavior is required for MySQL compatibility. Refer to implicit commit for more details.

TiDB supports explicit transactions (use `[BEGIN|START TRANSACTION]` and `COMMIT` to define the start and end of the transaction) and implicit transactions (`SET autocommit = 1`).

If you set the value of `autocommit` to `1` and start a new transaction through the `[BEGIN|START TRANSACTION]` statement, the autocommit is disabled before `COMMIT` or `ROLLBACK` which makes the transaction becomes explicit.

For DDL statements, the transaction is committed automatically and does not support rollback. If you run the DDL statement while the current session is in the process of a transaction, the DDL statement is executed after the current transaction is committed.

14.13.11.1.4 Lazy check of constraints

By default, optimistic transactions will not check the primary key or unique constraints when a DML statement is executed. These checks are instead performed on transaction `COMMIT`.

For example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY);
INSERT INTO t1 VALUES (1);
BEGIN OPTIMISTIC;
INSERT INTO t1 VALUES (1); -- MySQL returns an error; TiDB returns success
    ↪ .
INSERT INTO t1 VALUES (2);
COMMIT; -- It is successfully committed in MySQL; TiDB returns an error
    ↪ and the transaction rolls back.
SELECT * FROM t1; -- MySQL returns 1 2; TiDB returns 1.
```

```
mysql> CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.10 sec)

mysql> INSERT INTO t1 VALUES (1);
Query OK, 1 row affected (0.02 sec)

mysql> BEGIN OPTIMISTIC;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (1); -- MySQL returns an error; TiDB returns
    ↪ success.
```

```
Query OK, 1 row affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (2);
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT; -- It is successfully committed in MySQL; TiDB returns an
    ↪ error and the transaction rolls back.
ERROR 1062 (23000): Duplicate entry '1' for key 't1.PRIMARY'
mysql> SELECT * FROM t1; -- MySQL returns 1 2; TiDB returns 1.
+----+
| id |
+----+
|  1 |
+----+
1 row in set (0.01 sec)
```

The lazy check optimization improves performance by batching constraint checks and reducing network communication. The behavior can be disabled by setting `tidb_constraint_check_in_place=ON`.

Note:

- This optimization only applies to optimistic transactions.
- This optimization does not take effect for `INSERT IGNORE` and `INSERT ON DUPLICATE KEY UPDATE`, but only for normal `INSERT` statements.

14.13.11.1.5 Statement rollback

TiDB supports atomic rollback after statement execution failure. If a statement results in an error, the changes it made will not take effect. The transaction will remain open, and additional changes can be made before issuing a `COMMIT` or `ROLLBACK` statement.

```
CREATE TABLE test (id INT NOT NULL PRIMARY KEY);
BEGIN;
INSERT INTO test VALUES (1);
INSERT INTO tset VALUES (2); -- Statement does not take effect because "
    ↪ test" is misspelled as "tset".
INSERT INTO test VALUES (1),(2); -- Entire statement does not take effect
    ↪ because it violates a PRIMARY KEY constraint
INSERT INTO test VALUES (3);
COMMIT;
SELECT * FROM test;
```

```
mysql> CREATE TABLE test (id INT NOT NULL PRIMARY KEY);
Query OK, 0 rows affected (0.09 sec)

mysql> BEGIN;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO test VALUES (1);
Query OK, 1 row affected (0.02 sec)

mysql> INSERT INTO tset VALUES (2); -- Statement does not take effect
    ↪ because "test" is misspelled as "tset".
ERROR 1146 (42S02): Table 'test.tset' doesn't exist
mysql> INSERT INTO test VALUES (1),(2); -- Entire statement does not take
    ↪ effect because it violates a PRIMARY KEY constraint
ERROR 1062 (23000): Duplicate entry '1' for key 'test.PRIMARY'
mysql> INSERT INTO test VALUES (3);
Query OK, 1 row affected (0.00 sec)

mysql> COMMIT;
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM test;
+----+
| id |
+----+
|  1 |
|  3 |
+----+
2 rows in set (0.00 sec)
```

In the above example, the transaction remains open after the failed `INSERT` statements. The final insert statement is then successful and changes are committed.

14.13.11.1.6 Transaction size limit

Due to the limitations of the underlying storage engine, TiDB requires a single row to be no more than 6 MB. All columns of a row are converted to bytes according to their data types and summed up to estimate the size of a single row.

TiDB supports both optimistic and pessimistic transactions, and optimistic transactions are the basis for pessimistic transactions. Because optimistic transactions first cache the changes in private memory, TiDB limits the size of a single transaction.

By default, TiDB sets the total size of a single transaction to no more than 100 MB. You can modify this default value via `txn-total-size-limit` in the configuration file. The

maximum value of `txn-total-size-limit` is 1 TB. The individual transaction size limit also depends on the size of remaining memory available in the server. This is because when a transaction is executed, the memory usage of the TiDB process is scaled up comparing with the transaction size, up to two to three times or more of the transaction size.

TiDB previously limited the total number of key-value pairs for a single transaction to 300,000. This restriction was removed in TiDB v4.0.

14.13.11.1.7 Causal consistency

> **Note:**
>
> Transactions with causal consistency take effect only when the async commit and one-phase commit features are enabled. For details of the two features, see `tidb_enable_async_commit` and `tidb_enable_1pc`.

TiDB supports enabling causal consistency for transactions. Transactions with causal consistency, when committed, do not need to get timestamp from PD and have lower commit latency. The syntax to enable causal consistency is as follows:

```
START TRANSACTION WITH CAUSAL CONSISTENCY ONLY;
```

By default, TiDB guarantees linear consistency. In the case of linear consistency, if transaction 2 is committed after transaction 1 is committed, logically, transaction 2 should occur after transaction 1. Causal consistency is weaker than linear consistency. In the case of causal consistency, the commit order and occurrence order of two transactions can be guaranteed consistent only when the data locked or written by transaction 1 and transaction 2 have an intersection, which means that the two transactions have a causal relationship known to the database. Currently, TiDB does not support passing in external causal relationship.

Two transactions with causal consistency enabled have the following characteristics:

- Transactions with potential causal relationship have the consistent logical order and physical commit order
- Transactions with no causal relationship do not guarantee consistent logical order and physical commit order
- Reads without lock do not create causal relationship

Transactions with potential causal relationship have the consistent logical order and physical commit order

Assume that both transaction 1 and transaction 2 adopt causal consistency and have the following statements executed:

Transaction 1	Transaction 2
START TRANSACTION WITH CAUSAL CONSISTENCY ONLY	START TRANSACTION WITH CAUSAL CONSISTENCY ONLY
x = SELECT v FROM t WHERE id = 1 FOR UPDATE	
UPDATE t set v = $(x + 1) WHERE id = 2	
COMMIT	
	UPDATE t SET v = 2 WHERE id = 1
	COMMIT

In the example above, transaction 1 locks the `id = 1` record and transaction 2 modifies the `id = 1` record. Therefore, transaction 1 and transaction 2 have a potential causal relationship. Even with the causal consistency enabled, as long as transaction 2 is committed after transaction 1 is successfully committed, logically, transaction 2 must occur after transaction 1. Therefore, it is impossible that a transaction reads transaction 2's modification on the `id = 1` record without reading transaction 1's modification on the `id = 2` record.

Transactions with no causal relationship do not guarantee consistent logical order and physical commit order

Assume that the initial values of `id = 1` and `id = 2` are both `0`. Assume that both transaction 1 and transaction 2 adopt causal consistency and have the following statements executed:

Transaction 1	Transaction 2	Transaction 3
START TRANSACTION WITH CAUSAL CONSISTENCY ONLY	START TRANSACTION WITH CAUSAL CONSISTENCY ONLY	
UPDATE t set v = 3 WHERE id = 2		
	UPDATE t SET v = 2 WHERE id = 1	
		BEGIN
COMMIT		
	COMMIT	
		SELECT v FROM t WHERE id IN (1, 2)

In the example above, transaction 1 does not read the `id = 1` record, so transaction 1 and transaction 2 have no causal relationship known to the database. With causal consistency enabled for the transactions, even if transaction 2 is committed after transaction 1 is committed in terms of physical time order, TiDB does not guarantee that transaction 2 logically occurs after transaction 1.

If transaction 3 begins before transaction 1 is committed, and if transaction 3 reads the `id = 1` and `id = 2` records after transaction 2 is committed, transaction 3 might read the

value of `id = 1` to be `2` but the value of `id = 2` to be `0`.

Reads without lock do not create causal relationship

Assume that both transaction 1 and transaction 2 adopt causal consistency and have the following statements executed:

Transaction 1	Transaction 2
START TRANSACTION WITH CAUSAL CONSISTENCY ONLY	START TRANSACTION WITH CAUSAL CONSISTENCY ONLY
	UPDATE t SET v = 2 WHERE id = 1
SELECT v FROM t WHERE id = 1	
UPDATE t set v = 3 WHERE id = 2	
	COMMIT
COMMIT	

In the example above, reads without lock do not create causal relationship. Transaction 1 and transaction 2 have created write skew. In this case, it would have been unreasonable if the two transactions still had causal relationship. Therefore, the two transactions with causal consistency enabled have no definite logical order.

14.13.11.2 TiDB Transaction Isolation Levels

Transaction isolation is one of the foundations of database transaction processing. Isolation is one of the four key properties of a transaction (commonly referred as ACID).

The SQL-92 standard defines four levels of transaction isolation: Read Uncommitted, Read Committed, Repeatable Read, and Serializable. See the following table for details:

Isolation Level	Dirty Write	Dirty Read	Fuzzy Read	Phantom
READ UNCOMMITTED	Not Possible	Possible	Possible	Possible
READ COMMITTED	Not Possible	Not possible	Possible	Possible
REPEATABLE READ	Not Possible	Not possible	Not possible	Possible
SERIALIZABLE	Not Possible	Not possible	Not possible	Not possible

TiDB implements Snapshot Isolation (SI) consistency, which it advertises as `REPEATABLE-READ` for compatibility with MySQL. This differs from the ANSI Repeatable Read isolation level and the MySQL Repeatable Read level.

> **Note:**
>
> Starting from TiDB v3.0, the automatic retry of transactions is disabled by default. It is not recommended to enable the automatic retry because it might **break the transaction isolation level**. Refer to Transaction Retry for details.
>
> Starting from TiDB v3.0.8, newly created TiDB clusters use the pessimistic transaction mode by default. The current read (`for update` read) is **non-repeatable read**. Refer to pessimistic transaction mode for details.

14.13.11.2.1 Repeatable Read isolation level

The Repeatable Read isolation level only sees data committed before the transaction begins, and it never sees either uncommitted data or changes committed during transaction execution by concurrent transactions. However, the transaction statement does see the effects of previous updates executed within its own transaction, even though they are not yet committed.

For transactions running on different nodes, the start and commit order depends on the order that the timestamp is obtained from PD.

Transactions of the Repeatable Read isolation level cannot concurrently update a same row. When committing, if the transaction finds that the row has been updated by another transaction after it starts, then the transaction rolls back. For example:

```
create table t1(id int);
insert into t1 values(0);
```

```
start transaction;          |            start transaction;
select * from t1;           |            select * from t1;
update t1 set id=id+1;      |            update t1 set id=id+1; -- In
   ↪ pessimistic transactions, the `update` statement executed later
   ↪ waits for the lock until the transaction holding the lock commits or
   ↪  rolls back and releases the row lock.
commit;                     |
                            |            commit; -- The transaction commit
                               ↪  fails and rolls back. Pessimistic
                               ↪ transactions can commit successfully.
```

Difference between TiDB and ANSI Repeatable Read

The Repeatable Read isolation level in TiDB differs from ANSI Repeatable Read isolation level, though they sharing the same name. According to the standard described in the A Critique of ANSI SQL Isolation Levels paper, TiDB implements the Snapshot Isolation level. This isolation level does not allow strict phantoms (A3) but allows broad phantoms (P3) and write skews. In contrast, the ANSI Repeatable Read isolation level allows phantom reads but does not allow write skews.

Difference between TiDB and MySQL Repeatable Read

The Repeatable Read isolation level in TiDB differs from that in MySQL. The MySQL Repeatable Read isolation level does not check whether the current version is visible when updating, which means it can continue to update even if the row has been updated after the transaction starts. In contrast, if the row has been updated after the transaction starts, the TiDB optimistic transaction is rolled back and retried. Transaction retries in TiDB's optimistic concurrency control might fail, leading to a final failure of the transaction, while in TiDB's pessimistic concurrency control and MySQL, the updating transaction can be successful.

14.13.11.2.2 Read Committed isolation level

Starting from TiDB v4.0.0-beta, TiDB supports the Read Committed isolation level.

For historical reasons, the Read Committed isolation level of current mainstream databases is essentially the Consistent Read isolation level defined by Oracle. In order to adapt to this situation, the Read Committed isolation level in TiDB pessimistic transactions is also a consistent read behavior in essence.

> **Note:**
>
> The Read Committed isolation level only takes effect in the pessimistic transaction mode. In the optimistic transaction mode, setting the transaction

isolation level to `Read Committed` does not take effect and transactions still use the Repeatable Read isolation level.

Starting from v6.0.0, TiDB supports using the `tidb_rc_read_check_ts` system variable to optimize the timestamp acquisition in scenarios where read-write conflicts are rare. After enabling this variable, TiDB will try to use the previous valid timestamp to read data when `SELECT` is executed. The initial value of this variable is the `start_ts` of the transaction.

- If TiDB does not encounter any data update during the read process, it returns the result to the client and the `SELECT` statement is successfully executed.
- If TiDB encounters data update during the read process:
    - If TiDB has not yet sent the result to the client, TiDB tries to acquire a new timestamp and retry this statement.
    - If TiDB has already sent partial data to the client, TiDB reports an error to the client. The amount of data sent to the client each time is controlled by `tidb_init_chunk_size` and `tidb_max_chunk_size`.

In scenarios where the `READ-COMMITTED` isolation level is used, the `SELECT` statements are many, and read-write conflicts are rare, enabling this variable can avoid the latency and cost of getting the global timestamp.

Since v6.3.0, TiDB supports optimizing the acquisition of timestamps by enabling the system variable `tidb_rc_write_check_ts` in scenarios where point-write conflicts are few. After enabling this variable, during the execution of point-write statements, TiDB will try to use valid timestamps of the current transaction to read and lock data. TiDB will read data in the same way when `tidb_rc_read_check_ts` is enabled.

Currently, the applicable types of point-write statements include `UPDATE`, `DELETE`, and `SELECT ..... FOR UPDATE`. A point-write statement refers to a write statement that uses the primary key or unique key as a filter condition and the final execution operator contains `POINT-GET`. Currently, the three types of point-write statements have these in common: they first perform a point query based on the key value. If the key exists, they lock the key. If the key does not exist, they return an empty set.

- If the entire read process of a point-write statement does not encounter an updated data version, TiDB continues to use the timestamp of the current transaction to lock the data.
    - If a write conflict occurs due to an old timestamp during the lock acquisition process, TiDB retries the lock acquisition process by obtaining the latest global timestamp.
    - If no write conflicts or other errors occur during the lock acquisition process, the lock is acquired successfully.

- If an updated data version is encountered during the read process, TiDB tries to acquire a new timestamp and retries this statement.

In transactions with many point-write statements but a few point-write conflicts in the `READ-COMMITTED` isolation level, enabling this variable can avoid the latency and overhead of getting the global timestamp.

14.13.11.2.3 Difference between TiDB and MySQL Read Committed

The MySQL Read Committed isolation level is in line with the Consistent Read features in most cases. There are also exceptions, such as semi-consistent read. This special behavior is not supported in TiDB.

14.13.11.2.4 View and modify transaction isolation levels

You can view and modify the transaction isolation level as follows.

View the transaction isolation level of the current session:

```
SHOW VARIABLES LIKE 'transaction_isolation';
```

Modify the transaction isolation level of the current session:

```
SET SESSION transaction_isolation = 'READ-COMMITTED';
```

For more information on configuring and using transaction isolation levels, see the following documents:

- The system variable `transaction_isolation`
- Isolation level
- `SET TRANSACTION`

14.13.11.3 TiDB Optimistic Transaction Model

With optimistic transactions, conflicting changes are detected as part of a transaction commit. This helps improve the performance when concurrent transactions are infrequently modifying the same rows, because the process of acquiring row locks can be skipped. In the case that concurrent transactions frequently modify the same rows (a conflict), optimistic transactions may perform worse than Pessimistic Transactions.

Before enabling optimistic transactions, make sure that your application correctly handles that a `COMMIT` statement could return errors. If you are unsure of how your application handles this, it is recommended to instead use Pessimistic Transactions.

Note:

Starting from v3.0.8, TiDB uses the pessimistic transaction mode by default. However, this does not affect your existing cluster if you upgrade it from v3.0.7 or earlier to v3.0.8 or later. In other words, **only newly created clusters default to using the pessimistic transaction mode**.

14.13.11.3.1 Principles of optimistic transactions

To support distributed transactions, TiDB adopts two-phase commit (2PC) in optimistic transactions. The procedure is as follows:

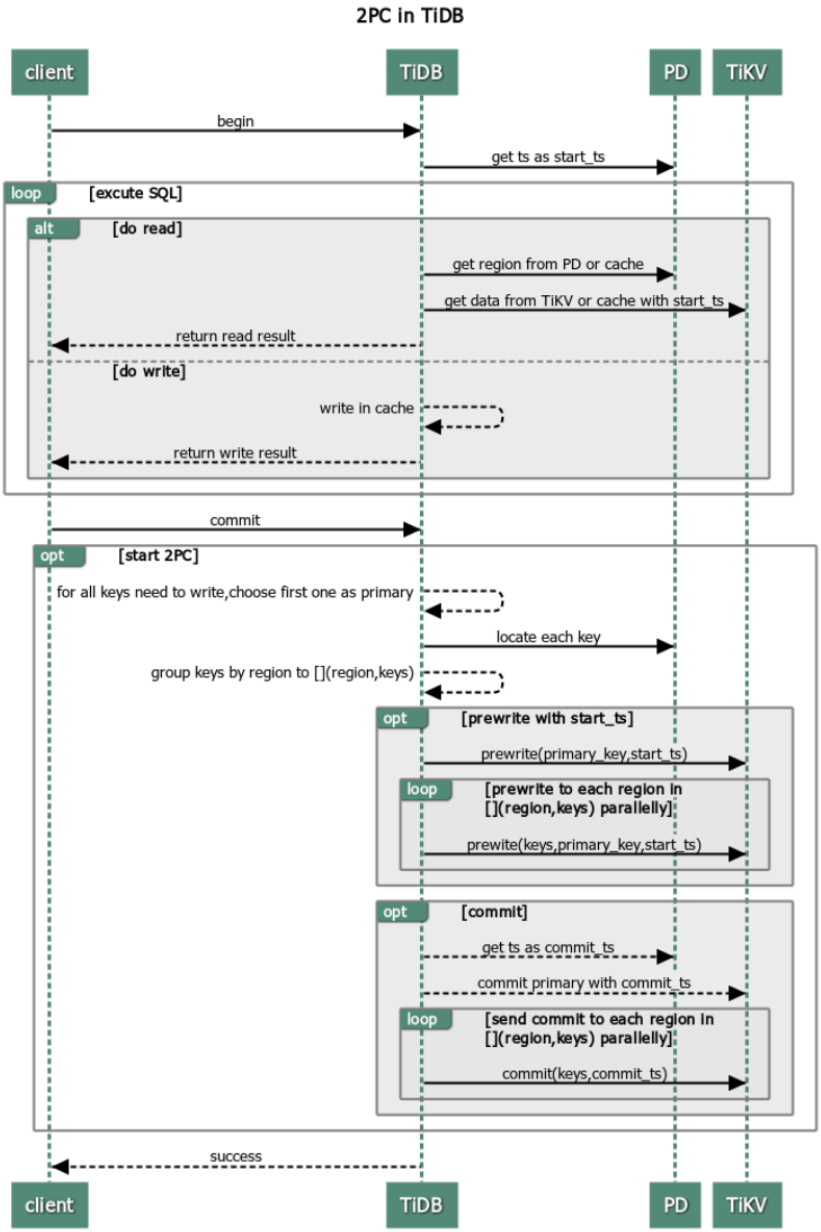

Figure 592: 2PC in TiDB

1. The client begins a transaction.

   TiDB gets a timestamp (monotonically increasing in time and globally unique) from PD as the unique transaction ID of the current transaction, which is called `start_ts`. TiDB implements multi-version concurrency control, so `start_ts` also serves as the version of the database snapshot obtained by this transaction. This means that the transaction can only read the data from the database at `start_ts`.

2. The client issues a read request.

    1. TiDB receives routing information (how data is distributed among TiKV nodes) from PD.
    2. TiDB receives the data of the `start_ts` version from TiKV.

3. The client issues a write request.

   TiDB checks whether the written data satisfies constraints (to ensure the data types are correct, the NOT NULL constraint is met). **Valid data is stored in the private memory of this transaction in TiDB**.

4. The client issues a commit request.

5. TiDB begins 2PC, and persists data in store while guaranteeing the atomicity of transactions.

    1. TiDB selects a Primary Key from the data to be written.
    2. TiDB receives the information of Region distribution from PD, and groups all keys by Region accordingly.
    3. TiDB sends prewrite requests to all TiKV nodes involved. Then, TiKV checks whether there are conflict or expired versions. Valid data is locked.
    4. TiDB receives all responses in the prewrite phase and the prewrite is successful.
    5. TiDB receives a commit version number from PD and marks it as `commit_ts`.
    6. TiDB initiates the second commit to the TiKV node where Primary Key is located. TiKV checks the data, and cleans the locks left in the prewrite phase.
    7. TiDB receives the message that reports the second phase is successfully finished.

6. TiDB returns a message to inform the client that the transaction is successfully committed.

7. TiDB asynchronously cleans the locks left in this transaction.

14.13.11.3.2 Advantages and disadvantages

From the process of transactions in TiDB above, it is clear that TiDB transactions have the following advantages:

- Simple to understand
- Implement cross-node transaction based on single-row transaction
- Decentralized lock management

However, TiDB transactions also have the following disadvantages:

- Transaction latency due to 2PC
- In need of a centralized timestamp allocation service
- OOM (out of memory) when extensive data is written in the memory

14.13.11.3.3 Transaction retries

> **Note:**
>
> Starting from v8.0.0, the `tidb_disable_txn_auto_retry` system variable is deprecated, and TiDB no longer supports automatic retries of optimistic transactions. It is recommended to use the Pessimistic transaction mode. If you encounter optimistic transaction conflicts, you can capture the error and retry transactions in your application.

In the optimistic transaction model, transactions might fail to be committed because of write–write conflict in heavy contention scenarios. TiDB uses optimistic concurrency control by default, whereas MySQL applies pessimistic concurrency control. This means that MySQL adds locks during the execution of write-type SQL statements, and its Repeatable Read isolation level allows for current reads, so commits generally do not encounter exceptions. To lower the difficulty of adapting applications, TiDB provides an internal retry mechanism.

Automatic retry

If a write-write conflict occurs during the transaction commit, TiDB automatically retries the SQL statement that includes write operations. You can enable the automatic retry by setting `tidb_disable_txn_auto_retry` to `OFF` and set the retry limit by configuring `tidb_retry_limit`:

```
#### Whether to disable automatic retry. ("on" by default)
tidb_disable_txn_auto_retry = OFF
#### Set the maximum number of the retires. ("10" by default)
#### When "tidb_retry_limit = 0", automatic retry is completely disabled.
tidb_retry_limit = 10
```

You can enable the automatic retry in either session level or global level:

1. Session level:

```
SET tidb_disable_txn_auto_retry = OFF;
```

```
SET tidb_retry_limit = 10;
```

2. Global level:

```
SET GLOBAL tidb_disable_txn_auto_retry = OFF;
```

```
SET GLOBAL tidb_retry_limit = 10;
```

Note:

The `tidb_retry_limit` variable decides the maximum number of retries. When this variable is set to `0`, none of the transactions automatically retries, including the implicit single statement transactions that are automatically committed. This is the way to completely disable the automatic retry mechanism in TiDB. After the automatic retry is disabled, all conflicting transactions report failures (including the `try again later` message) to the application layer in the fastest way.

Limits of retry

By default, TiDB will not retry transactions because this might lead to lost updates and damaged `REPEATABLE READ` isolation.

The reason can be observed from the procedures of retry:

1. Allocate a new timestamp and mark it as `start_ts`.
2. Retry the SQL statements that contain write operations.
3. Implement the two-phase commit.

In Step 2, TiDB only retries SQL statements that contain write operations. However, during retrying, TiDB receives a new version number to mark the beginning of the transaction. This means that TiDB retries SQL statements with the data in the new `start_ts` version. In this case, if the transaction updates data using other query results, the results might be inconsistent because the `REPEATABLE READ` isolation is violated.

If your application can tolerate lost updates, and does not require `REPEATABLE READ` isolation consistency, you can enable this feature by setting `tidb_disable_txn_auto_retry = OFF`.

14.13.11.3.4 Conflict detection

As a distributed database, TiDB performs in-memory conflict detection in the TiKV layer, mainly in the prewrite phase. TiDB instances are stateless and unaware of each other, which means they cannot know whether their writes result in conflicts across the cluster. Therefore, conflict detection is performed in the TiKV layer.

The configuration is as follows:

```
#### Controls the number of slots. ("2048000" by default)
scheduler-concurrency = 2048000
```

In addition, TiKV supports monitoring the time spent on waiting latches in the scheduler.

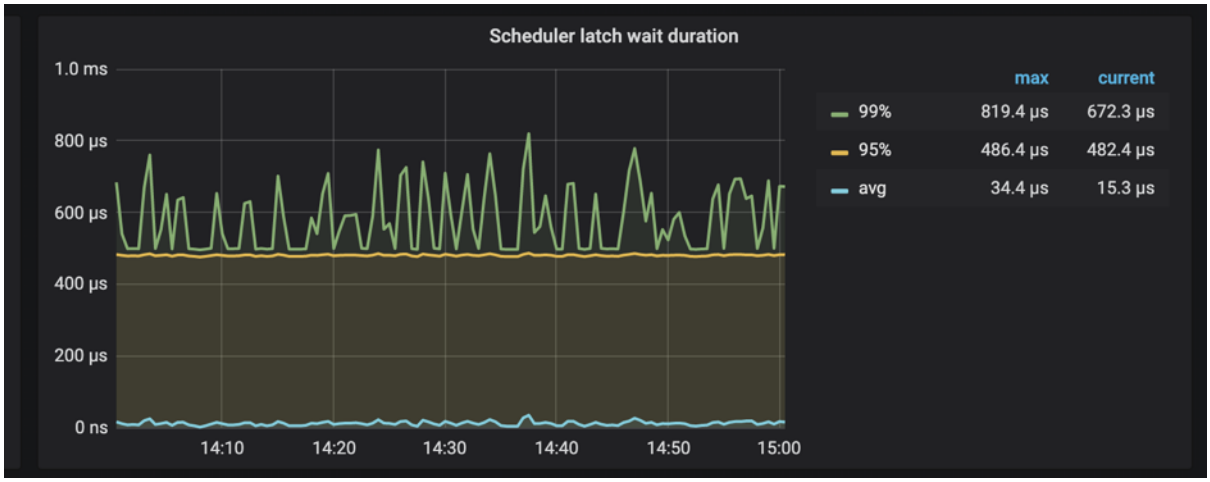

Figure 593: Scheduler latch wait duration

When `Scheduler latch wait duration` is high and there are no slow writes, it can be safely concluded that there are many write conflicts at this time.

14.13.11.4 TiDB Pessimistic Transaction Mode

To make the usage of TiDB closer to traditional databases and reduce the cost of migration, starting from v3.0, TiDB supports the pessimistic transaction mode on top of the optimistic transaction model. This document describes the features of the TiDB pessimistic transaction mode.

> **Note:**
>
> Starting from v3.0.8, newly created TiDB clusters use the pessimistic transaction mode by default. However, this does not affect your existing cluster if you upgrade it from v3.0.7 or earlier to v3.0.8 or later. In other words, **only newly created clusters default to using the pessimistic transaction mode**.

14.13.11.4.1 Switch transaction mode

You can set the transaction mode by configuring the `tidb_txn_mode` system variable. The following command sets all explicit transactions (that is, non-autocommit transactions) executed by newly created sessions in the cluster to the pessimistic transaction mode:

```
SET GLOBAL tidb_txn_mode = 'pessimistic';
```

You can also explicitly enable the pessimistic transaction mode by executing the following SQL statements:

```
BEGIN PESSIMISTIC;
```

```
BEGIN /*T! PESSIMISTIC */;
```

The `BEGIN PESSIMISTIC;` and `BEGIN OPTIMISTIC;` statements take precedence over the `tidb_txn_mode` system variable. Transactions started with these two statements ignore the system variable and support using both the pessimistic and optimistic transaction modes.

14.13.11.4.2 Behaviors

Pessimistic transactions in TiDB behave similarly to those in MySQL. See the minor differences in Differences from MySQL InnoDB.

- For pessimistic transactions, TiDB introduces snapshot read and current read.
    - Snapshot read: it is an unlocked read that reads a version committed before the transaction starts. The read in the `SELECT` statement is a snapshot read.
    - Current read: it is a locked read that reads the latest committed version. The read in the `UPDATE`, `DELETE`, `INSERT`, or `SELECT FOR UPDATE` statement is a current read.

    The following examples provide a detailed description of snapshot read and current read.

Session 1	Session 2	Session 3
CREATE TABLE t (a INT);		
INSERT INTO T VALUES(1);		
BEGIN PESSIMISTIC;		
UPDATE t SET a = a + 1;		

Session 1	Session 2	Session 3
	BEGIN PESSIMISTIC; SELECT * FROM t; – Use the snapshot read to read the version committed before the current transaction starts. The result returns a=1.	
		BEGIN PESSIMISTIC;

Session 1	Session 2	Session 3
		SELECT * FROM t FOR UPDATE; – Use the current read. Wait for the lock.

Session 1	Session 2	Session 3
COMMIT; – Release the lock. The SELECT FOR UPDATE operation of session 3 obtains the lock and TiDB uses the current read to read the latest committed version. The result returns a=2.		

Session 1	Session 2	Session 3
	SELECT * FROM t; – Use the snapshot read to read the version committed before the current transaction starts. The result returns a=1.	

- When you execute `UPDATE`, `DELETE` or `INSERT` statements, the **latest** committed data is read, data is modified, and a pessimistic lock is applied on the modified rows.
- For `SELECT FOR UPDATE` statements, a pessimistic lock is applied on the latest version of the committed data, instead of on the modified rows.
- Locks will be released when the transaction is committed or rolled back. Other transactions attempting to modify the data are blocked and have to wait for the lock to be released. Transactions attempting to *read* the data are not blocked, because TiDB uses multi-version concurrency control (MVCC).
- You can set the system variable `tidb_constraint_check_in_place_pessimistic` to control whether to skip the pessimistic locks with unique constraint checks. See con-

straints for details.

- If several transactions are trying to acquire each other's respective locks, a deadlock will occur. This is automatically detected, and one of the transactions will randomly be terminated with a MySQL-compatible error code `1213` returned.
- Transactions will wait up to `innodb_lock_wait_timeout` seconds (default: 50) to acquire new locks. When this timeout is reached, a MySQL-compatible error code `1205` is returned. If multiple transactions are waiting for the same lock, the order of priority is approximately based on the `start ts` of the transaction.
- TiDB supports both the optimistic transaction mode and pessimistic transaction mode in the same cluster. You can specify either mode for transaction execution.
- TiDB supports the `FOR UPDATE NOWAIT` syntax and does not block and wait for locks to be released. Instead, a MySQL-compatible error code `3572` is returned.
- If the `Point Get` and `Batch Point Get` operators do not read data, they still lock the given primary key or unique key, which blocks other transactions from locking or writing data to the same primary key or unique key.
- TiDB supports the `FOR UPDATE OF TABLES` syntax. For a statement that joins multiple tables, TiDB only applies pessimistic locks on the rows that are associated with the tables in `OF TABLES`.

14.13.11.4.3 Differences from MySQL InnoDB

1. When TiDB executes DML or `SELECT FOR UPDATE` statements that use range in the WHERE clause, concurrent DML statements within the range are not blocked.

   For example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad1 VARCHAR(100)
);
INSERT INTO t1 (id) VALUES (1),(5),(10);
```

```
BEGIN /*T! PESSIMISTIC */;
SELECT * FROM t1 WHERE id BETWEEN 1 AND 10 FOR UPDATE;
```

```
BEGIN /*T! PESSIMISTIC */;
INSERT INTO t1 (id) VALUES (6); -- blocks only in MySQL
UPDATE t1 SET pad1='new value' WHERE id = 5; -- blocks waiting in both
    ↪ MySQL and TiDB
```

   This behavior is because TiDB does not currently support *gap locking*.

2. TiDB does not support `SELECT LOCK IN SHARE MODE`.

   TiDB does not support the `SELECT LOCK IN SHARE MODE` syntax by default. You can enable `tidb_enable_noop_functions` to make TiDB compatible with the `SELECT LOCK IN SHARE MODE` syntax. Executing `SELECT LOCK IN SHARE MODE` has the same effect as that without the lock, so it does not block read or write operations of other transactions.

   Starting from v8.3.0, TiDB supports using the `tidb_enable_shared_lock_promotion` system variable to enable the `SELECT LOCK IN SHARE MODE` statement to add locks. However, note that the lock added at this time is not a true shared lock, but an exclusive lock, which is consistent with `SELECT FOR UPDATE`. If you want to block writes to prevent data from being modified by write transactions in parallel during reads while keeping TiDB compatible with the `SELECT LOCK IN SHARE MODE` syntax, you can enable this variable. Enabling this variable takes effect on the `SELECT LOCK IN SHARE MODE` statement, regardless of whether `tidb_enable_noop_functions` is enabled or not.

3. DDL may result in failure of the pessimistic transaction commit.

   When DDL is executed in MySQL, it might be blocked by the transaction that is being executed. However, in this scenario, the DDL operation is not blocked in TiDB, which leads to failure of the pessimistic transaction commit: `ERROR 1105 (HY000) : Information schema is changed. [try again later]`. TiDB executes the `TRUNCATE TABLE` statement during the transaction execution, which might result in the `table doesn't exist` error.

4. After executing `START TRANSACTION WITH CONSISTENT SNAPSHOT`, MySQL can still read the tables that are created later in other transactions, while TiDB cannot.

5. The autocommit transactions prefer the optimistic locking.

   When using the pessimistic model, the autocommit transactions first try to commit the statement using the optimistic model that has less overhead. If a write conflict occurs, the pessimistic model is used for transaction retry. Therefore, if `tidb_retry_limit` is set to `0`, the autocommit transaction still reports the `Write Conflict` error when a write conflict occurs.

   The autocommit `SELECT FOR UPDATE` statement does not wait for lock.

6. The data read by `EMBEDDED SELECT` in the statement is not locked.

7. Open transactions in TiDB do not block garbage collection (GC). By default, this limits the maximum execution time of pessimistic transactions to 1 hour. You can modify this limit by editing `max-txn-ttl` under `[performance]` in the TiDB configuration file.

14.13.11.4.4 Isolation level

TiDB supports the following two isolation levels in the pessimistic transaction mode:

- Repeatable Read by default, which is the same as MySQL.

> **Note:**
> In this isolation level, DML operations are performed based on the latest committed data. The behavior is the same as MySQL, but differs from the optimistic transaction mode in TiDB. See Difference between TiDB and MySQL Repeatable Read.

- Read Committed. You can set this isolation level using the `SET TRANSACTION` statement.

14.13.11.4.5 Pessimistic transaction commit process

In the transaction commit process, pessimistic transactions and optimistic transactions have the same logic. Both transactions adopt the two-phase commit (2PC) mode. The important adaptation of pessimistic transactions is DML execution.

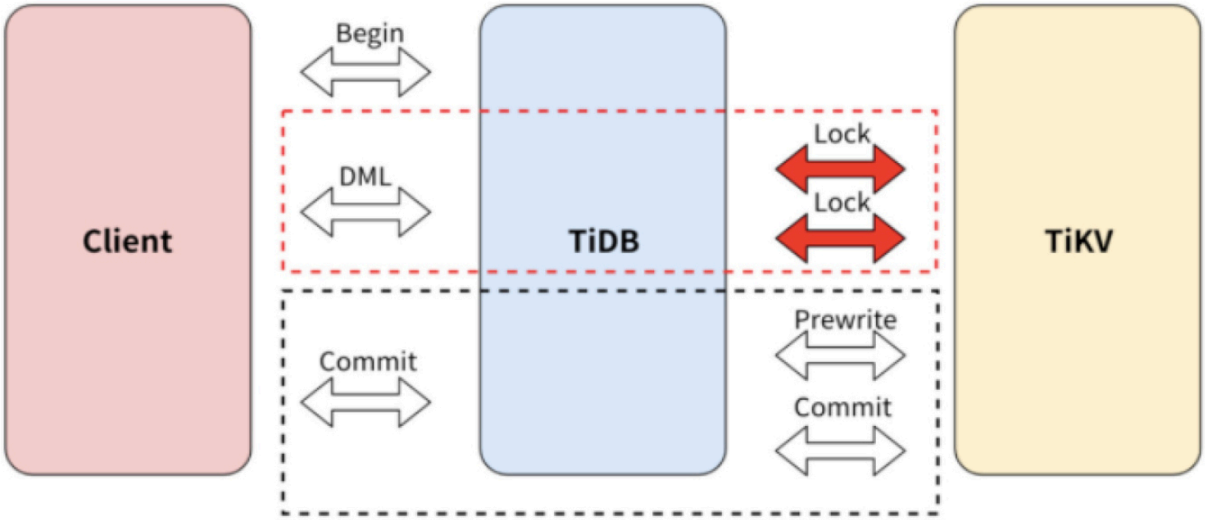

Figure 594: TiDB pessimistic transaction commit process

The pessimistic transaction adds an `Acquire Pessimistic Lock` phase before 2PC. This phase includes the following steps:

1. (Same as the optimistic transaction mode) TiDB receives the `begin` request from the client, and the current timestamp is this transaction's start_ts.
2. When the TiDB server receives a writing request from the client, the TiDB server initiates a pessimistic lock request to the TiKV server, and the lock is persisted to the TiKV server.

3. (Same as the optimistic transaction mode) When the client sends the commit request, TiDB starts to perform the two-phase commit similar to the optimistic transaction mode.

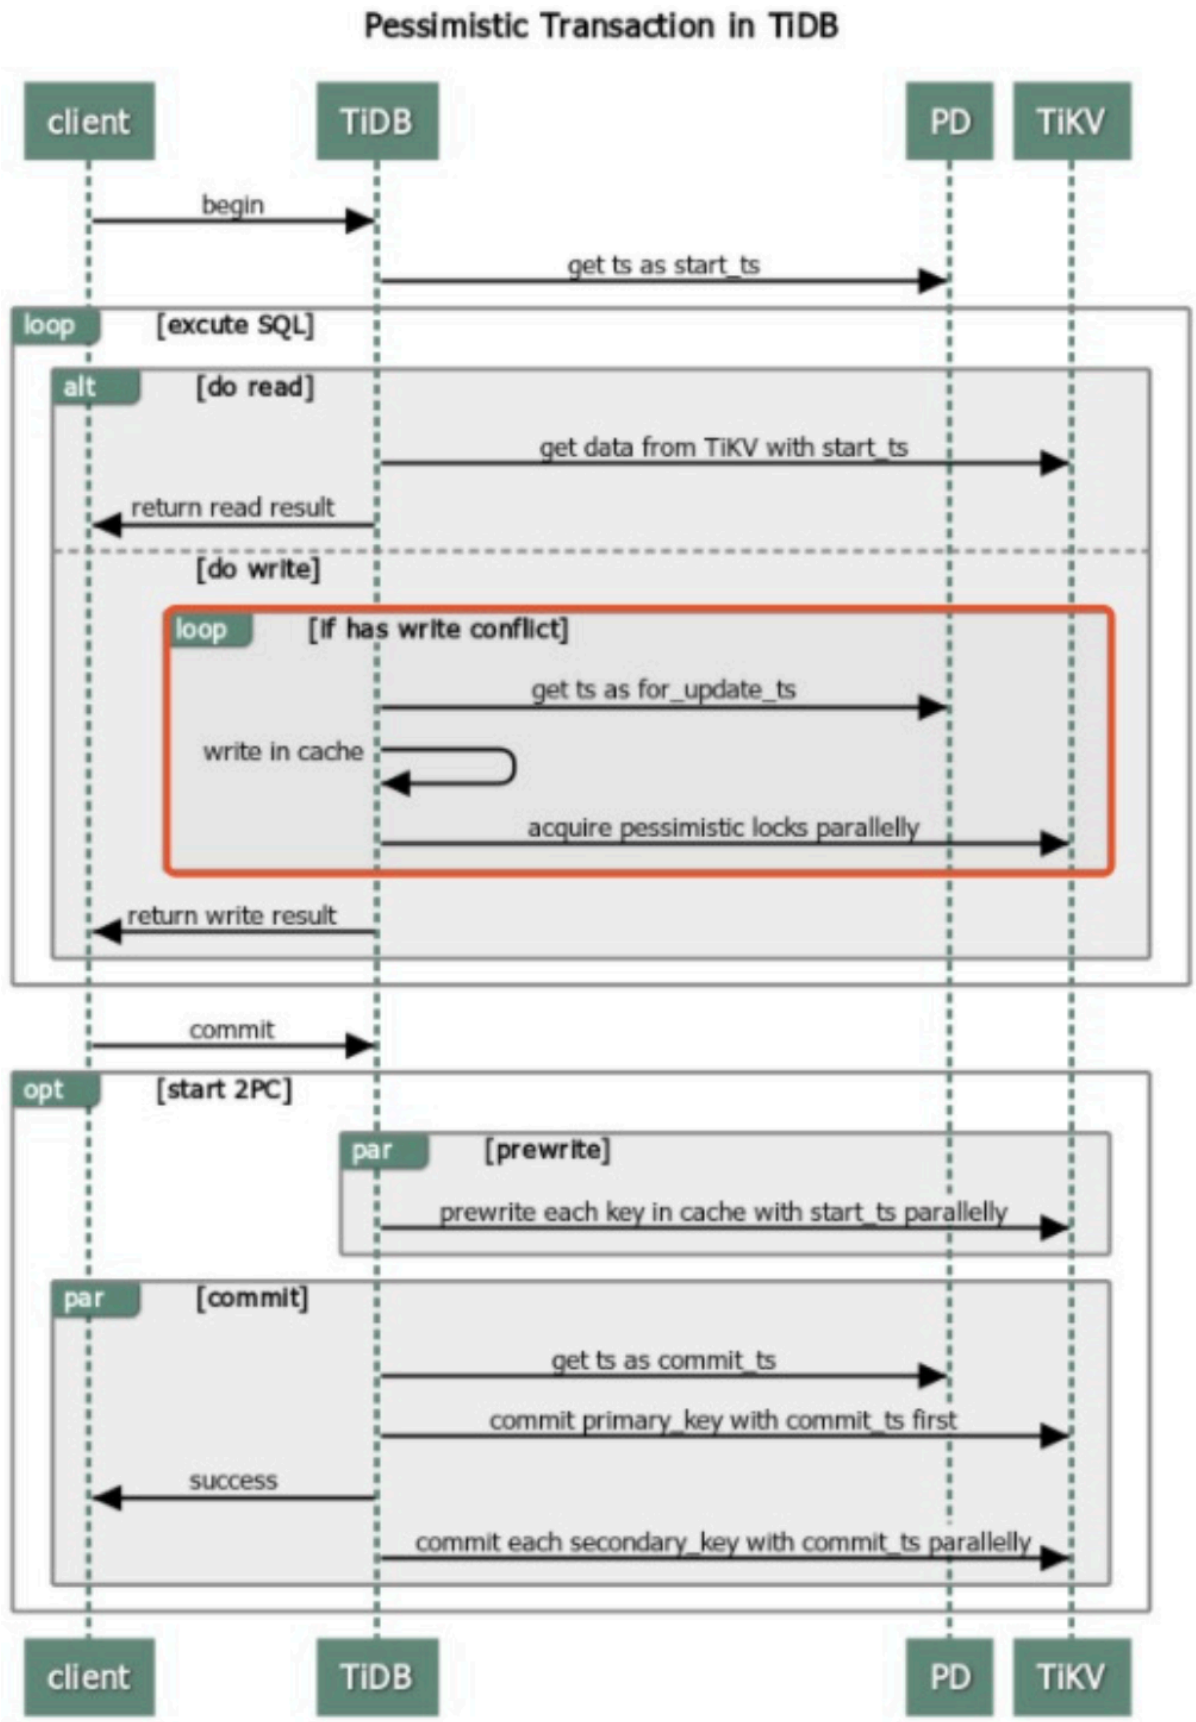

Figure 595: Pessimistic transactions in TiDB

14.13.11.4.6 Pipelined locking process

Adding a pessimistic lock requires writing data into TiKV. The response of successfully adding a lock can only be returned to TiDB after commit and apply through Raft. Therefore, compared with optimistic transactions, the pessimistic transaction mode inevitably has higher latency.

To reduce the overhead of locking, TiKV implements the pipelined locking process: when the data meets the requirements for locking, TiKV immediately notifies TiDB to execute subsequent requests and writes into the pessimistic lock asynchronously. This process reduces most latency and significantly improves the performance of pessimistic transactions. However, when network partition occurs in TiKV or a TiKV node is down, the asynchronous write into the pessimistic lock might fail and affect the following aspects:

- Other transactions that modify the same data cannot be blocked. If the application logic relies on locking or lock waiting mechanisms, the correctness of the application logic is affected.
- There is a low probability that the transaction commit fails, but it does not affect the correctness of the transactions.

If the application logic relies on the locking or lock waiting mechanisms, or if you want to guarantee as much as possible the success rate of transaction commits even in the case of TiKV cluster anomalies, you should disable the pipelined locking feature.

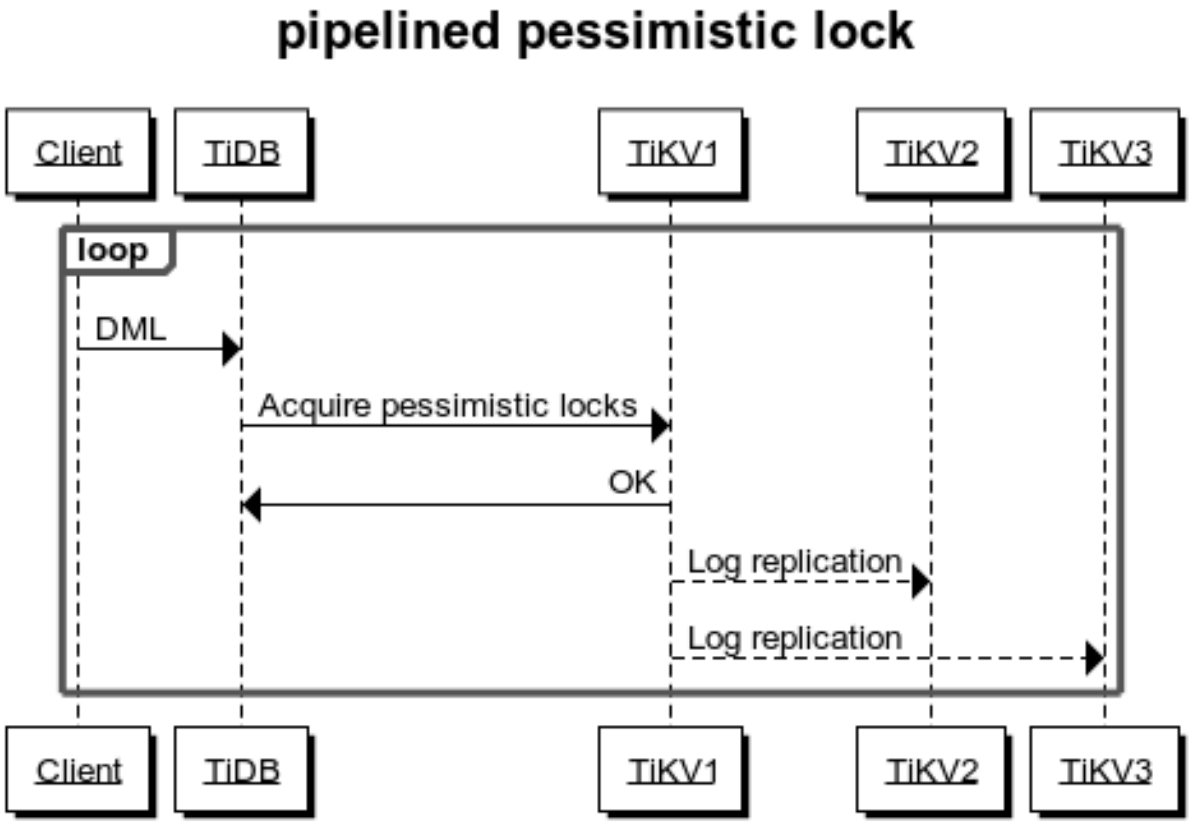

Figure 596: Pipelined pessimistic lock

This feature is enabled by default. To disable it, modify the TiKV configuration:

```
[pessimistic-txn]
pipelined = false
```

If the TiKV cluster is v4.0.9 or later, you can also dynamically disable this feature by modifying TiKV configuration dynamically:

```
set config tikv pessimistic-txn.pipelined='false';
```

14.13.11.4.7 In-memory pessimistic lock

In v6.0.0, TiKV introduces the feature of in-memory pessimistic lock. When this feature is enabled, pessimistic locks are usually stored in the memory of the Region leader only, and are not persisted to disk or replicated through Raft to other replicas. This feature can greatly reduce the overhead of acquiring pessimistic locks and improve the throughput of pessimistic transactions.

When the memory usage of in-memory pessimistic locks exceeds the memory threshold of the Region or the TiKV node, the acquisition of pessimistic locks turns to the pipelined locking process. When the Region is merged or the leader is transferred, to avoid the loss of the pessimistic lock, TiKV writes the in-memory pessimistic lock to disk and replicates it to other replicas.

The in-memory pessimistic lock performs similarly to the pipelined locking process, which does not affect the lock acquisition when the cluster is healthy. However, when network isolation occurs in TiKV or a TiKV node is down, the acquired pessimistic lock might be lost.

If the application logic relies on the lock acquiring or lock waiting mechanism, or if you want to guarantee as much as possible the success rate of transaction commits even when the cluster is in an abnormal state, you need to **disable** the in-memory pessimistic lock feature.

This feature is enabled by default. To disable it, modify the TiKV configuration:

```
[pessimistic-txn]
in-memory = false
```

To dynamically disable this feature, modify the TiKV configuration dynamically:

```
set config tikv pessimistic-txn.in-memory='false';
```

Starting from v8.4.0, you can configure the memory usage limit for in-memory pessimistic locks in a Region or a TiKV instance using `pessimistic-txn.in-memory-peer-size-limit` or `pessimistic-txn.in-memory-instance-size-limit`:

```
[pessimistic-txn]
in-memory-peer-size-limit = "512KiB"
in-memory-instance-size-limit = "100MiB"
```

To dynamically modify these limits, modify TiKV configuration dynamically as follows:

```
SET CONFIG tikv `pessimistic-txn.in-memory-peer-size-limit`="512KiB";
SET CONFIG tikv `pessimistic-txn.in-memory-instance-size-limit`="100MiB";
```

14.13.11.5 Non-Transactional DML Statements

This document describes the usage scenarios, usage methods, and restrictions of non-transactional DML statements in TiDB. In addition, the implementation principle and common issues are also explained.

A non-transactional DML statement is a DML statement split into multiple SQL statements (which is, multiple batches) to be executed in sequence. It enhances the performance and ease of use in batch data processing at the expense of transactional atomicity and isolation.

Usually, memory-consuming transactions need to be split into multiple SQL statements to bypass the transaction size limit. Non-transactional DML statements integrate this process into the TiDB kernel to achieve the same effect. It is helpful to understand the effect of non-transactional DML statements by splitting SQL statements. The `DRY RUN` syntax can be used to preview the split statements.

Non-transactional DML statements include:

- `INSERT INTO ... SELECT`
- `REPLACE INTO .. SELECT`
- `UPDATE`
- `DELETE`

For detailed syntax, see `BATCH`.

Note:

- A non-transactional DML statement does not guarantee the atomicity and isolation of the statement, and is not equivalent to the original DML statement.
- After a DML statement is rewritten into a non-transactional DML statement, you cannot assume that its behavior is consistent with that of the original statement.
- Before using a non-transactional DML, you need to analyze whether the split statements will affect each other.

14.13.11.5.1 Usage scenarios

In the scenarios of large data processing, you might often need to perform same operations on a large batch of data. If the operation is performed directly using a single SQL statement, the transaction size might exceed the limit and affect the execution performance.

Batch data processing often has no overlap of time or data with the online application operations. Isolation (I in ACID) is unnecessary when no concurrent operations exist. Atomicity is also unnecessary if bulk data operations are idempotent or easily retryable. If your application needs neither data isolation nor atomicity, you can consider using non-transactional DML statements.

Non-transactional DML statements are used to bypass the size limit on large transactions in certain scenarios. One statement is used to complete tasks that would otherwise require manually splitting of transactions, with higher execution efficiency and less resource consumption.

For example, to delete expired data, if you ensure that no application will access the expired data, you can use a non-transactional DML statement to improve the `DELETE` performance.

14.13.11.5.2 Prerequisites

Before using non-transactional DML statements, make sure that the following conditions are met:

- The statement does not require atomicity, which permits some rows to be modified and some rows to remain unmodified in the execution result.
- The statement is idempotent, or you are prepared to retry on a part of the data according to the error message. If the system variables are set to `tidb_redact_log = 1` and `tidb_nontransactional_ignore_error = 1`, this statement must be idempotent. Otherwise, when the statement partially fails, the failed part cannot be accurately located.
- The data to be operated on has no other concurrent writes, which means it is not updated by other statements at the same time. Otherwise, unexpected results such as missing writes, wrong writes, and modifying the same line multiple times might occur.
- The statement does not modify the data to be read by the statement itself. Otherwise, the following batch will read the data written by the previous batch and easily causes unexpected results.
    - Avoid modifying the shard column when you select from and modify the same table within a non-transactional `INSERT INTO ... SELECT` statement. Otherwise, multiple batches might read the same row and insert data multiple times:
        - It is not recommended to use `BATCH ON test.t.id LIMIT 10000 INSERT INTO t SELECT id+1, value FROM t;`.
        - It is recommended to use `BATCH ON test.t.id LIMIT 10000 INSERT INTO t SELECT id, value FROM t;`.
        - If the shard column `id` has the `AUTO_INCREMENT` attribute, it is recommended to use `BATCH ON test.t.id LIMIT 10000 INSERT INTO t(value)SELECT value FROM t;`.
    - Avoid updating the shard column in the non-transactional `UPDATE`, `INSERT ... ON DUPLICATE KEY UPDATE`, or `REPLACE INTO` statement:
        - For example, for a non-transactional `UPDATE` statement, the split SQL statements are executed in sequence. The modification of the previous batch is read by the next batch after the previous batch is committed, which causes the same line of data to be modified multiple times.
        - These statements do not support `BATCH ON test.t.id LIMIT 10000 UPDATE t SET test.t.id = test.t.id-1;`.

- It is not recommended to use `BATCH ON test.t.id LIMIT 1 INSERT INTO t SELECT id+1, value FROM t ON DUPLICATE KEY UPDATE id = id + 1;`.

- The shard column should not be used as a Join key. For example, the following example uses the shard column `test.t.id` as a Join key, which causes a non-transactional `UPDATE` statement to modify the same line multiple times:

```
CREATE TABLE t(id int, v int, key(id));
CREATE TABLE t2(id int, v int, key(id));
INSERT INTO t VALUES (1, 1), (2, 2), (3, 3);
INSERT INTO t2 VALUES (1, 1), (2, 2), (4, 4);
BATCH ON test.t.id LIMIT 1 UPDATE t JOIN t2 ON t.id = t2.id SET t2
    ↪ .id = t2.id+1;
SELECT * FROM t2; -- (4, 1) (4, 2) (4, 4)
```

- The statement meets the restrictions.

- It is not recommended to perform concurrent DDL operations on the table to be read or written by this DML statement.

> **Warning:**
>
> If `tidb_redact_log` and `tidb_nontransactional_ignore_error` are enabled at the same time, you might not get the complete error information of each batch, and you cannot retry the failed batch only. Therefore, if both of the system variables are turned on, the non-transactional DML statement must be idempotent.

14.13.11.5.3 Usage examples

Use a non-transactional DML statement

The following sections describe the use of non-transactional DML statements with examples:

Create a table `t` with the following schema:

```
CREATE TABLE t (id INT, v INT, KEY(id));
```

```
Query OK, 0 rows affected
```

Insert some data into table `t`.

```
INSERT INTO t VALUES (1, 2), (2, 3), (3, 4), (4, 5), (5, 6);
```

```
Query OK, 5 rows affected
```

The following operation uses a non-transactional DML statement to delete rows with values less than the integer 6 on column `v` of table `t`. This statement is split into two SQL statements, with a batch size of 2, sharded by the `id` column and executed.

```
BATCH ON id LIMIT 2 DELETE FROM t WHERE v < 6;
```

```
+---------------+--------------+
| number of jobs | job status |
+---------------+--------------+
| 2             | all succeeded |
+---------------+--------------+
1 row in set
```

Check the deletion results of the above non-transactional DML statement.

```
SELECT * FROM t;
```

```
+----+---+
| id | v |
+----+---+
| 5  | 6 |
+----+---+
1 row in set
```

The following example describes how to use multiple table joins. First, create table `t2` and insert data:

```
CREATE TABLE t2(id int, v int, key(id));
INSERT INTO t2 VALUES (1,1), (3,3), (5,5);
```

Then, update the data of table `t2` by joining table `t` and `t2`. Note that you need to specify the shard column along with the complete database name, table name, and column name (`test.t.id`):

```
BATCH ON test.t._tidb_rowid LIMIT 1 UPDATE t JOIN t2 ON t.id = t2.id SET t2
    ↪ .id = t2.id+1;
```

Query the results:

```
SELECT * FROM t2;
```

```
+----+---+
| id | v |
+----+---+
```

```
| 1  | 1 |
| 3  | 3 |
| 6  | 5 |
+----+---+
```

Check the execution progress

During the execution of a non-transactional DML statement, you can view the progress using `SHOW PROCESSLIST`. The `Time` field in the returned result indicates the time consumption of the current batch execution. Logs and slow logs also record the progress of each split statement throughout the non-transactional DML execution. For example:

```
SHOW PROCESSLIST;
```

```
+--
    ↪ ----+------+--------------------+--------+---------+------+-----------+--------
    ↪
| Id   | User | Host              | db     | Command | Time | State   | Info
    ↪
    ↪ |
+--
    ↪ ----+------+--------------------+--------+---------+------+-----------+--------
    ↪
| 1203 | root | 100.64.10.62:52711 | test | Query | 0 | autocommit | /* job
    ↪  506/500000 */ DELETE FROM `test`.`t1` WHERE `test`.`t1`.`_tidb_rowid
    ↪ ` BETWEEN 2271 AND 2273 |
| 1209 | root | 100.64.10.62:52735 | <null> | Query | 0 | autocommit | show
    ↪  full processlist
    ↪                                                                    |
+--
    ↪ ----+------+--------------------+--------+---------+------+-----------+--------
    ↪
```

Terminate a non-transactional DML statement

To terminate a non-transactional DML statement, you can use `KILL TIDB <processlist_id>`. Then TiDB will cancel all batches after the batch that is currently being executed. You can get the execution result from the log.

For more information about `KILL TIDB`, see the reference KILL.

Query the batch-dividing statement

During the execution of a non-transactional DML statement, a statement is internally used to divide the DML statement into multiple batches. To query this batch-dividing statement, you can add `DRY RUN QUERY` to this non-transactional DML statement. Then TiDB will not execute this query and the subsequent DML operations.

The following statement queries the batch-dividing statement during the execution of `BATCH ON id LIMIT 2 DELETE FROM t WHERE v < 6`:

```
BATCH ON id LIMIT 2 DRY RUN QUERY DELETE FROM t WHERE v < 6;
```

```
+--
    ↪ ----------------------------------------------------------------------------+
    ↪
| query statement                                                                 |
+--
    ↪ ----------------------------------------------------------------------------+
    ↪
| SELECT `id` FROM `test`.`t` WHERE (`v` < 6) ORDER BY IF(ISNULL(`id`),0,1)
    ↪ ,`id` |
+--
    ↪ ----------------------------------------------------------------------------+
    ↪
1 row in set
```

Query the statements corresponding to the first and the last batches

To query the actual DML statements corresponding to the first and the last batches in a non-transactional DML statement, you can add `DRY RUN` to this non-transactional DML statement. Then, TiDB only divides batches and does not execute these SQL statements. Because there might be many batches, not all batches are displayed, and only the first one and the last one are displayed.

```
BATCH ON id LIMIT 2 DRY RUN DELETE FROM t WHERE v < 6;
```

```
+-----------------------------------------------------------------+
| split statement examples                                        |
+-----------------------------------------------------------------+
| DELETE FROM `test`.`t` WHERE (`id` BETWEEN 1 AND 2 AND (`v` < 6)) |
| DELETE FROM `test`.`t` WHERE (`id` BETWEEN 3 AND 4 AND (`v` < 6)) |
+-----------------------------------------------------------------+
2 rows in set
```

Use the optimizer hint

If an optimizer hint is originally supported in the `DELETE` statement, the optimizer hint is also supported in the non-transactional `DELETE` statement. The position of the hint is the same as that in the ordinary `DELETE` statement:

```
BATCH ON id LIMIT 2 DELETE /*+ USE_INDEX(t)*/ FROM t WHERE v < 6;
```

14.13.11.5.4 Best practices

To use a non-transactional DML statement, the following steps are recommended:

1. Select an appropriate shard column. Integer or string types are recommended.
2. Add `DRY RUN QUERY` to the non-transactional DML statement, execute the query manually, and confirm whether the data range affected by the DML statement is roughly correct.
3. Add `DRY RUN` to the non-transactional DML statement, execute the query manually, and check the split statements and the execution plans. You need to pay attention to the following points:

    - Whether the split statement can read the result written by the previous statement, which might cause an anomaly.
    - The index selectivity.
    - Whether the shard column automatically selected by TiDB will be modified.

4. Execute the non-transactional DML statement.
5. If an error is reported, get the specific failed data range from the error message or log, and retry or handle it manually.

14.13.11.5.5 Parameter description

Parameter	Description	Default value	Required or not	Recommended value

Parameter	Description	Default value	Required or not	Recommended value
Shard column	The column used to shard batches, such as the `id` column in the above non-transactional DML statement `BATCH ON id LIMIT 2 DELETE FROM t WHERE v < 5140`	TiDB tries to automatically select a shard column (not recommended).	No	Select a column that can meet the `WHERE` condition in the most efficient way.

Parameter	Description	Default value	Required or not	Recommended value
Batch size	Used to control the size of each batch. The number of batches is the number of SQL statements into which DML operations are split, such as `LIMIT ↪ ↪ 2 ↪` in the above non-transactional DML statement `BATCH ↪`	N/A	Yes	1000-1000000. Too small or too large a batch will lead to performance degradation.

Parameter	Description	Default value	Required or not	Recommended value

How to select a shard column

A non-transactional DML statement uses a column as the basis for data batching, which is the shard column. For higher execution efficiency, a shard column is required to use index. The execution efficiency brought by different indexes and shard columns might vary by dozens of times. When choosing the shard column, consider the following suggestions:

- If you know the application data distribution, according to the `WHERE` condition, choose the column that divides data with smaller ranges after the batching.
    - Ideally, the `WHERE` condition can take advantage of the index of the shard column to reduce the amount of data to be scanned per batch. For example, there is a transaction table that records the start and end time of each transaction, and you want to delete all transaction records whose end time is before one month. If there is an index on the start time of the transaction, and the start and end times of the transaction are relatively close, then you can choose the start time column as the shard column.
    - In a less-than-ideal case, the data distribution of the shard column is completely independent of the `WHERE` condition, and the index of the shard column cannot be used to reduce the scope of the data scan.
- When a clustered index exists, it is recommended to use the primary key (including an `INT` primary key and `_tidb_rowid`) as the shard column, so that the execution efficiency is higher.
- Choose the column with fewer duplicate values.

You can also choose not to specify a shard column. Then, TiDB will use the first column of `handle` as the shard column by default. But if the first column of the primary key of the clustered index is of a data type not supported by non-transactional DML statements (which is `ENUM`, `BIT`, `SET`, `JSON`), TiDB will report an error. You can choose an appropriate shard column according to your application needs.

How to set batch size

In non-transactional DML statements, the larger the batch size, the fewer SQL statements are split and the slower each SQL statement is executed. The optimal batch size depends on the workload. It is recommended to start from 50000. Either too small or too large batch sizes will cause decreased execution efficiency.

The information of each batch is stored in memory, so too many batches can significantly increase memory consumption. This explains why the batch size cannot be too small. The upper limit of memory consumed by non-transactional statements for storing batch information is the same as `tidb_mem_quota_query`, and the action triggered when this limit is exceeded is determined by the configuration item `tidb_mem_oom_action`.

14.13.11.5.6 Restrictions

The following are hard restrictions on non-transactional DML statements. If these restrictions are not met, TiDB will report an error.

- The DML statements cannot contain `ORDER BY` or `LIMIT` clauses.
- Subqueries or set operations are not supported.
- The shard column must be indexed. The index can be a single-column index, or the first column of a joint index.
- Must be used in the `autocommit` mode.
- Cannot be used when batch-dml is enabled.
- Cannot be used when `tidb_snapshot` is set.
- Cannot be used with the `prepare` statement.
- `ENUM`, `BIT`, `SET`, `JSON` types are not supported as the shard columns.
- Not supported for temporary tables.
- Common Table Expression is not supported.

14.13.11.5.7 Control batch execution failure

Non-transactional DML statements do not satisfy atomicity. Some batches might succeed and some might fail. The system variable `tidb_nontransactional_ignore_error` controls how the non-transactional DML statements handle errors.

An exception is that if the first batch fails, there is a high probability that the statement itself is wrong. In this case, the entire non-transactional statement will directly return an error.

14.13.11.5.8 How it works

The working principle of non-transactional DML statements is to build into TiDB the automatic splitting of SQL statements. Without non-transactional DML statements, you will need to manually split the SQL statements. To understand the behavior of a non-transactional DML statement, think of it as a user script doing the following tasks:

For the non-transactional DML `BATCH ON $C$ LIMIT $N$ DELETE FROM ... WHERE $P$`, C is the column used for dividing, N is the batch size, and P is the filter condition.

1. According to the filter condition P of the original statement and the specified column C for dividing, TiDB queries all C that satisfy P. TiDB sorts these C into groups $B_1 \dots B_k$ according to N. For each of all B_i, TiDB keeps its first and last C as S_i and E_i. The query statement executed in this step can be viewed through `DRY RUN QUERY`.
2. The data involved in B_i is a subset that satisfies P_i: C BETWEEN S_i AND E_i. You can use P_i to narrow down the range of data that each batch needs to process.
3. For B_i, TiDB embeds the above condition into the `WHERE` condition of the original statement, which makes it WHERE (P_i) AND (P). The execution result of this step can be viewed through `DRY RUN`.

4. For all batches, execute new statements in sequence. The errors for each grouping are collected and combined, and returned as the result of the entire non-transactional DML statement after all groupings are complete.

14.13.11.5.9 Comparison with batch-dml

batch-dml is a mechanism for splitting a transaction into multiple transaction commits during the execution of a DML statement.

> **Note:**
>
> It is not recommended to use batch-dml which has been deprecated. When the batch-dml feature is not properly used, there is a risk of data index inconsistency.

Non-transactional DML statements are not yet a replacement for all batch-dml usage scenarios. Their main differences are as follows:

- Performance: When the shard column is efficient, the performance of non-transactional DML statements is close to that of batch-dml. When the shard column is less efficient, the performance of non-transactional DML statements is significantly lower than that of batch-dml.
- Stability: batch-dml is prone to data index inconsistencies due to improper use. Non-transactional DML statements do not cause data index inconsistencies. However, when used improperly, non-transactional DML statements are not equivalent to the original statements, and the applications might observe unexpected behavior. See the common issues section for details.

14.13.11.5.10 Common issues

Executing a multiple table joins statement results in the `Unknown column xxx in 'where clause'` error

This error occurs when the `WHERE` clause concatenated in a query involves tables other than the table in which the shard column is defined. For example, in the following SQL statement, the shard column is `t2.id` and it is defined in table `t2`, but the `WHERE` clause involves table `t2` and `t3`.

```
BATCH ON test.t2.id LIMIT 1
INSERT INTO t
SELECT t2.id, t2.v, t3.id FROM t2, t3 WHERE t2.id = t3.id
```

```
(1054, "Unknown column 't3.id' in 'where clause'")
```

If the error occurs, you can print the query statement for confirmation by using `DRY RUN QUERY`. For example:

```
BATCH ON test.t2.id LIMIT 1
DRY RUN QUERY INSERT INTO t
SELECT t2.id, t2.v, t3.id FROM t2, t3 WHERE t2.id = t3.id
```

To avoid the error, you can move the condition related to other tables in the `WHERE` clause to the `ON` condition in the `JOIN` clause. For example:

```
BATCH ON test.t2.id LIMIT 1
INSERT INTO t
SELECT t2.id, t2.v, t3.id FROM t2 JOIN t3 ON t2.id = t3.id
```

```
+----------------+---------------+
| number of jobs | job status |
+----------------+---------------+
| 0              | all succeeded |
+----------------+---------------+
```

The actual batch size is not the same as the specified batch size

During the execution of a non-transactional DML statement, the size of data to be processed in the last batch might be smaller than the specified batch size.

When **duplicated values exist in the shard column**, each batch will contain all the duplicated values of the last element of the shard column in this batch. Therefore, the number of rows in this batch might be greater than the specified batch size.

In addition, when other concurrent writes occur, the number of rows processed in each batch might be different from the specified batch size.

The `Failed to restore the delete statement, probably because of unsupported type of the shard column` error occurs during execution

The shard column does not support `ENUM`, `BIT`, `SET`, `JSON` types. Try to specify a new shard column. It is recommended to use an integer or string type column.

If the error occurs when the selected shard column is not one of these unsupported types, get support from PingCAP or the community.

Non-transactional `DELETE` has "exceptional" behavior that is not equivalent to ordinary `DELETE`

A non-transactional DML statement is not equivalent to the original form of this DML statement, which might have the following reasons:

- There are other concurrent writes.

- The non-transactional DML statement modifies a value that the statement itself will read.
- The SQL statement executed in each batch might cause a different execution plan and expression calculation order because the `WHERE` condition is changed. Therefore, the execution result might be different from the original statement.
- The DML statements contain non-deterministic operations.

14.13.11.5.11 MySQL compatibility

Non-transactional statements are TiDB-specific and are not compatible with MySQL.

14.13.11.6 Pipelined DML

> **Warning:**
>
> Pipelined DML is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

This document introduces the use cases, methods, limitations, and common issues related to Pipelined DML.

14.13.11.6.1 Overview

Pipelined DML is an experimental feature introduced in TiDB v8.0.0 to improve the performance of large-scale data write operations. When this feature is enabled, TiDB streams data directly to the storage layer during DML operations, instead of buffering it entirely in memory. This pipeline-like approach simultaneously reads data (input) and writes it to the storage layer (output), effectively resolving common challenges in large-scale DML operations as follows:

- Memory limits: traditional DML operations might encounter out-of-memory (OOM) errors when handling large datasets.
- Performance bottlenecks: large transactions are often inefficient and is prone to causing workload fluctuations.

With pipelined DML enabled, you can achieve the following:

- Perform large-scale data operations without being constrained by TiDB memory limits.
- Maintain smoother workloads and lower operation latency.
- Keep transaction memory usage predictable, typically within 1 GiB.

It is recommended to enable Pipelined DML in the following scenarios:

- Processing data writes involving millions of rows or more.
- Encountering memory insufficient errors during DML operations.
- Experiencing noticeable workload fluctuations during large-scale data operations.

Note that although Pipelined DML significantly reduces memory usage during transaction processing, you still need to configure a reasonable memory threshold (at least 2 GiB recommended) to ensure other components (such as executors) function properly during large-scale data operations.

14.13.11.6.2 Limitations

Currently, Pipelined DML has the following limitations:

- Pipelined DML is currently incompatible with TiCDC, TiFlash, or BR. Avoid using Pipelined DML on tables associated with these components, as it might lead to issues such as blocking or OOM in these components.
- Pipelined DML is not suitable for scenarios with write conflicts, because it might lead to significant performance degradation or operation failures that require rollback.
- Make sure that the metadata lock is enabled during Pipelined DML operations.
- When executing DML statements with Pipelined DML enabled, TiDB checks the following conditions. If any condition is not met, TiDB falls back to standard DML execution and generates a warning:
    - Only autocommit statements are supported.
    - Only `INSERT`, `UPDATE`, `REPLACE`, and `DELETE` statements are supported.
    - Target tables must not include temporary tables or cached tables.
    - When foreign key constraints are enabled (`foreign_key_checks = ON`), target tables must not include foreign key relationships.
- When executing `INSERT IGNORE ... ON DUPLICATE KEY UPDATE` statements, conflicting updates might result in `Duplicate entry` errors.

14.13.11.6.3 Usage

This section describes how to enable Pipelined DML and verify whether it takes effect.

Enable Pipelined DML

You can enable Pipelined DML in one of the following methods:

- To enable Pipelined DML for the current session, set the `tidb_dml_type` variable to `"bulk"`:

```
SET tidb_dml_type = "bulk";
```

- To enable Pipelined DML for a specific statement, add the `SET_VAR` hint in the statement.
    - Data archiving example:

```
INSERT /*+ SET_VAR(tidb_dml_type='bulk') */ INTO target_table
    ↪ SELECT * FROM source_table;
```

    - Bulk data update example:

```
UPDATE /*+ SET_VAR(tidb_dml_type='bulk') */ products
SET price = price * 1.1
WHERE category = 'electronics';
```

    - Bulk deletion example:

```
DELETE /*+ SET_VAR(tidb_dml_type='bulk') */ FROM logs WHERE log_
    ↪ time < '2023-01-01';
```

Verify Pipelined DML

After executing a DML statement, you can verify whether Pipelined DML is used for the statement execution by checking the `tidb_last_txn_info` variable:

```
SELECT @@tidb_last_txn_info;
```

If the `pipelined` field in the output is `true`, it indicates that Pipelined DML is successfully used.

14.13.11.6.4 Best practices

- Increase the value of `tidb_mem_quota_query` slightly to ensure that memory usage for components such as executors does not exceed the limit. A value of at least 2 GiB is recommended. For environments with sufficient TiDB memory, you can increase this value further.
- In scenarios where data is inserted into new tables, the performance of Pipelined DML might be affected by hotspots. To achieve optimal performance, it is recommended to address hotspots in advance. For more information, see Troubleshoot Hotspot Issues.

14.13.11.6.5 Related configurations

- The `tidb_dml_type` system variable controls whether Pipelined DML is enabled at the session level.
- When `tidb_dml_type` is set to `"bulk"`, the `pessimistic-auto-commit` configuration item behaves as if it is set to `false`.
- Transactions executed using Pipelined DML are not subject to the size limit specified by the TiDB configuration item `txn-total-size-limit`.
- For large transactions executed using Pipelined DML, transaction duration might increase. In such cases, the maximum TTL for the transaction lock is the larger value of `max-txn-ttl` or 24 hours.
- If the execution time of a transaction exceeds the value set by `tidb_gc_max_wait_time`, garbage collection (GC) might force the transaction to roll back, causing it to fail.

14.13.11.6.6 Monitor Pipelined DML

You can monitor the execution of Pipelined DML using the following methods:

- Check the `tidb_last_txn_info` system variable to get information about the last transaction executed in the current session, including whether Pipelined DML was used.
- Look for lines containing `"[pipelined dml]"` in TiDB logs to understand the execution process and progress of Pipelined DML, including the current stage and the amount of data written.
- View the `affected rows` field in the `expensive query` logs to track the progress of long-running statements.
- Query the `INFORMATION_SCHEMA.PROCESSLIST` table to view transaction execution progress. Pipelined DML is typically used for large transactions, so you can use this table to monitor their execution progress.

14.13.11.6.7 FAQs

Why wasn't my query executed using Pipelined DML?

When TiDB rejects to execute a statement using Pipelined DML, it generates a warning message accordingly. You can execute `SHOW WARNINGS;` to check the warning and identify the cause.

Common reasons:

- The DML statement is not autocommitted.
- The statement involves unsupported table types, such as temporary tables or cached tables.
- The operation involves foreign keys, and foreign key checks are enabled.

Does Pipelined DML affect the isolation level of transactions?

No. Pipelined DML only changes the data-writing mechanism during transactions and does not affect isolation guarantees of TiDB transactions.

Why do I still encounter out-of-memory (OOM) errors after enabling Pipelined DML?

Even with Pipelined DML enabled, you might still encounter query termination caused by memory limit issues:

```
The query has been canceled due to exceeding the memory limit allowed for a
    ↪ single SQL query. Please try to narrow the query scope or increase
    ↪ the tidb_mem_quota_query limit, and then try again.
```

This error occurs because Pipelined DML only controls the memory usage by data during transaction execution. However, the total memory consumed during statement execution also includes memory used by other components, such as executors. If the total memory required exceeds the TiDB memory limit, out-of-memory (OOM) errors might still occur.

In most cases, you can increase the system variable `tidb_mem_quota_query` to a higher value to resolve this issue. A value of at least 2 GiB is recommended. For SQL statements with complex operators or involving large datasets, you might need to increase this value further.

14.13.12 Views

TiDB supports views. A view acts as a virtual table, whose schema is defined by the `SELECT` statement that creates the view. Using views has the following benefits:

- Exposing only safe fields and data to users to ensure security of sensitive fields and data stored in the underlying table.
- Defining complex queries that frequently appear as views to make complex queries easier and more convenient.

14.13.12.1 Query views

Querying a view is similar to querying an ordinary table. However, when TiDB queries a view, it actually queries the `SELECT` statement associated with the view.

14.13.12.2 Show metadata

To obtain the metadata of views, choose any of the following methods.

14.13.12.2.1 Use the SHOW CREATE TABLE view_name or SHOW CREATE VIEW view_name statement

Usage example:

```
show create view v;
```

This statement shows the CREATE VIEW statement corresponding to this view and the value of the character_set_client and collation_connection system variables when the view was created.

```
+--
    ↪ ----+-------------------------------------------------------------------------
    ↪
| View | Create View
    ↪
    ↪ | character_set_client | collation_connection |
+--
    ↪ ----+-------------------------------------------------------------------------
    ↪
| v    | CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`127.0.0.1` SQL SECURITY
    ↪ DEFINER VIEW `v` (`a`) AS SELECT `s`.`a` FROM `test`.`t` LEFT JOIN `
    ↪ test`.`s` ON `t`.`a`=`s`.`a` | utf8 | utf8_general_ci |
+--
    ↪ ----+-------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.12.2.2 Query the INFORMATION_SCHEMA.VIEWS table

Usage example:

```
select * from information_schema.views;
```

You can view the relevant meta information of the view by querying this table, such as TABLE_CATALOG, TABLE_SCHEMA, TABLE_NAME, VIEW_DEFINITION, CHECK_OPTION, IS_UPDATABLE, DEFINER, SECURITY_TYPE, CHARACTER_SET_CLIENT, and COLLATION_
↪ CONNECTION.

```
+--
    ↪ -------------+--------------+------------+-------------------------------------
    ↪
| TABLE_CATALOG | TABLE_SCHEMA | TABLE_NAME | VIEW_DEFINITION
    ↪                                          | CHECK_OPTION | IS_UPDATABLE
    ↪  | DEFINER  | SECURITY_TYPE | CHARACTER_SET_CLIENT | COLLATION_
    ↪ CONNECTION |
```

```
+--
    ↪ ------------+-------------+-----------+-----------------------------------
    ↪
| def          | test        | v         | SELECT `s`.`a` FROM `test`.`t` LEFT
    ↪  JOIN `test`.`s` ON `t`.`a`=`s`.`a` | CASCADED | NO  | root@127.0.0.1
    ↪ | DEFINER    | utf8                | utf8_general_ci    |
+--
    ↪ ------------+-------------+-----------+-----------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.12.2.3 Use the HTTP APIs

Usage example:

```
curl http://127.0.0.1:10080/schema/test/v
```

By visiting `http://{TiDBIP}:10080/schema/{db}/{view}`, you can get all the metadata for the view.

14.13.12.3 Example

The following example creates a view, queries this view, and delete this view:

```
create table t(a int, b int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values(1, 1),(2,2),(3,3);
```

```
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
create table s(a int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into s values(2),(3);
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
create view v as select s.a from t left join s on t.a = s.a;
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
select * from v;
```

```
+------+
| a    |
+------+
| NULL |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
drop view v;
```

```
Query OK, 0 rows affected (0.02 sec)
```

14.13.12.4 Limitations

Currently, views in TiDB are subject to the following limitations:

- Materialized views are not supported yet.
- Views in TiDB are read-only and do not support write operations such as `UPDATE`, `INSERT`, `DELETE`, and `TRUNCATE`.
- For created views, the only supported DDL operation is `DROP [VIEW | TABLE]`

- DROP VIEW

14.13.13 Partitioning

This document introduces TiDB's implementation of partitioning.

14.13.13.1 Partitioning types

This section introduces the types of partitioning in TiDB. Currently, TiDB supports Range partitioning, Range COLUMNS partitioning, List partitioning, List COLUMNS partitioning, Hash partitioning, and Key partitioning.

- Range partitioning, Range COLUMNS partitioning, List partitioning, and List COLUMNS partitioning are used to resolve the performance issues caused by a large number of deletions in the application, and support dropping partitions quickly.
- Hash partitioning and Key partitioning are used to distribute data in scenarios with a large number of writes. Compared with Hash partitioning, Key partitioning supports distributing data of multiple columns and partitioning by non-integer columns.

14.13.13.1.1 Range partitioning

When a table is partitioned by Range, each partition contains rows for which the partitioning expression value lies within a given Range. Ranges have to be contiguous but not overlapping. You can define it by using `VALUES LESS THAN`.

Assume you need to create a table that contains personnel records as follows:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT NOT NULL
);
```

You can partition a table by Range in various ways as needed. For example, you can partition it by using the `store_id` column:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT NOT NULL
)

PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN (21)
);
```

In this partition scheme, all rows corresponding to employees whose `store_id` is 1 through 5 are stored in the `p0` partition while all employees whose `store_id` is 6 through 10 are stored in `p1`. Range partitioning requires the partitions to be ordered, from lowest to highest.

If you insert a row of data `(72, 'Tom', 'John', '2015-06-25', NULL, NULL, 15)`, it falls in the `p2` partition. But if you insert a record whose `store_id` is larger than 20, an error is reported because TiDB cannot know which partition this record should be inserted into. In this case, you can use `MAXVALUE` when creating a table:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
```

```
    job_code INT,
    store_id INT NOT NULL
)

PARTITION BY RANGE (store_id) (
    PARTITION p0 VALUES LESS THAN (6),
    PARTITION p1 VALUES LESS THAN (11),
    PARTITION p2 VALUES LESS THAN (16),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

`MAXVALUE` represents an integer value that is larger than all other integer values. Now, all records whose `store_id` is equal to or larger than 16 (the highest value defined) are stored in the `p3` partition.

You can also partition a table by employees' job codes, which are the values of the `job_code` column. Assume that two-digit job codes stand for regular employees, three-digit codes stand for office and customer support personnel, and four-digit codes stand for managerial personnel. Then you can create a partitioned table like this:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT NOT NULL
)

PARTITION BY RANGE (job_code) (
    PARTITION p0 VALUES LESS THAN (100),
    PARTITION p1 VALUES LESS THAN (1000),
    PARTITION p2 VALUES LESS THAN (10000)
);
```

In this example, all rows relating to regular employees are stored in the `p0` partition, all office and customer support personnel in the `p1` partition, and all managerial personnel in the `p2` partition.

Besides splitting up the table by `store_id`, you can also partition a table by dates. For example, you can partition by employees' separation year:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
```

```
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY RANGE ( YEAR(separated) ) (
    PARTITION p0 VALUES LESS THAN (1991),
    PARTITION p1 VALUES LESS THAN (1996),
    PARTITION p2 VALUES LESS THAN (2001),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

In Range partitioning, you can partition based on the values of the `timestamp` column and use the `unix_timestamp()` function, for example:

```
CREATE TABLE quarterly_report_status (
    report_id INT NOT NULL,
    report_status VARCHAR(20) NOT NULL,
    report_updated TIMESTAMP NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
        ↪ CURRENT_TIMESTAMP
)

PARTITION BY RANGE ( UNIX_TIMESTAMP(report_updated) ) (
    PARTITION p0 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-01-01 00:00:00') ),
    PARTITION p1 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-04-01 00:00:00') ),
    PARTITION p2 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-07-01 00:00:00') ),
    PARTITION p3 VALUES LESS THAN ( UNIX_TIMESTAMP('2008-10-01 00:00:00') ),
    PARTITION p4 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-01-01 00:00:00') ),
    PARTITION p5 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-04-01 00:00:00') ),
    PARTITION p6 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-07-01 00:00:00') ),
    PARTITION p7 VALUES LESS THAN ( UNIX_TIMESTAMP('2009-10-01 00:00:00') ),
    PARTITION p8 VALUES LESS THAN ( UNIX_TIMESTAMP('2010-01-01 00:00:00') ),
    PARTITION p9 VALUES LESS THAN (MAXVALUE)
);
```

It is not allowed to use any other partitioning expression that contains the timestamp column.

Range partitioning is particularly useful when one or more of the following conditions are satisfied:

- You want to delete the old data. If you use the `employees` table in the previous example, you can delete all records of employees who left this company before the year 1991 by simply using `ALTER TABLE employees DROP PARTITION p0;`. It is faster than executing the `DELETE FROM employees WHERE YEAR(separated)<= 1990;` operation.

- You want to use a column that contains time or date values, or containing values arising from some other series.
- You need to frequently run queries on the columns used for partitioning. For example, when executing a query like `EXPLAIN SELECT COUNT(*)FROM employees WHERE separated BETWEEN '2000-01-01' AND '2000-12-31' GROUP BY store_id;`, TiDB can quickly know that only the data in the `p2` partition needs to be scanned, because the other partitions do not match the `WHERE` condition.

14.13.13.1.2 Range COLUMNS partitioning

Range COLUMNS partitioning is a variant of Range partitioning. You can use one or more columns as partitioning keys. The data types of partition columns can be integer, string (`CHAR` or `VARCHAR`), `DATE`, and `DATETIME`. Any expressions, such as non-COLUMNS partitioning, are not supported.

Like Range partitioning, Range COLUMNS partitioning also requires the partition ranges to be strictly increasing. The partition definition in the following example is not supported:

```
CREATE TABLE t(
    a int,
    b datetime,
    c varchar(8)
) PARTITION BY RANGE COLUMNS(`c`,`b`)
(PARTITION `p20240520A` VALUES LESS THAN ('A','2024-05-20 00:00:00'),
 PARTITION `p20240520Z` VALUES LESS THAN ('Z','2024-05-20 00:00:00'),
 PARTITION `p20240521A` VALUES LESS THAN ('A','2024-05-21 00:00:00'));
```

```
Error 1493 (HY000): VALUES LESS THAN value must be strictly increasing for
    ↪ each partition
```

Suppose that you want to partition by name, and drop old and invalid data, then you can create a table as follows:

```
CREATE TABLE t (
  valid_until datetime,
  name varchar(255) CHARACTER SET ascii,
  notes text
)
PARTITION BY RANGE COLUMNS(name, valid_until)
(PARTITION `p2022-g` VALUES LESS THAN ('G','2023-01-01 00:00:00'),
 PARTITION `p2023-g` VALUES LESS THAN ('G','2024-01-01 00:00:00'),
 PARTITION `p2022-m` VALUES LESS THAN ('M','2023-01-01 00:00:00'),
 PARTITION `p2023-m` VALUES LESS THAN ('M','2024-01-01 00:00:00'),
 PARTITION `p2022-s` VALUES LESS THAN ('S','2023-01-01 00:00:00'),
 PARTITION `p2023-s` VALUES LESS THAN ('S','2024-01-01 00:00:00'))
```

The preceding SQL statement will partition the data by year and by name in the ranges `[ ('', ''), ('G', '2023-01-01 00:00:00'))`, `[ ('G', '2023-01-01 00:00:00'), ('G', '2024-01-01 00:00:00'))`, `[ ('G', '2024-01-01 00:00:00'), ('M', '2023-01-01 00:00:00'))`, `[ ('M', '2023-01-01 00:00:00'), ('M', '2024-01-01 00:00:00'))`, `[ ('M', '2024-01-01 00:00:00'), ('S', '2023-01-01 00:00:00'))`, and `[ ('S', '2023-01-01 00:00:00'), ('S', '2024-01-01 00:00:00'))`. It allows you to easily drop invalid data while still benefit from partition pruning on both `name` and `valid_until` columns. In this example, `[,)` indicates a left-closed, right-open range. For example, `[ ('G', '2023-01-01 00:00:00'), ('G', '2024-01-01 00:00:00'))` indicates a range of data whose name is `'G'`, the year contains `2023-01-01 00:00:00` and is greater than `2023-01-01 00:00:00` but less than `2024-01-01 00:00:00`. It does not include `(G, 2024-01-01 00:00:00)`.

14.13.13.1.3 Range INTERVAL partitioning

Range INTERVAL partitioning is an extension of Range partitioning, which allows you to create partitions of a specified interval easily. Starting from v6.3.0, INTERVAL partitioning is introduced in TiDB as syntactic sugar.

The syntax is as follows:

```
PARTITION BY RANGE [COLUMNS] (<partitioning expression>)
INTERVAL (<interval expression>)
FIRST PARTITION LESS THAN (<expression>)
LAST PARTITION LESS THAN (<expression>)
[NULL PARTITION]
[MAXVALUE PARTITION]
```

For example:

```
CREATE TABLE employees (
    id int unsigned NOT NULL,
    fname varchar(30),
    lname varchar(30),
    hired date NOT NULL DEFAULT '1970-01-01',
    separated date DEFAULT '9999-12-31',
    job_code int,
    store_id int NOT NULL
) PARTITION BY RANGE (id)
INTERVAL (100) FIRST PARTITION LESS THAN (100) LAST PARTITION LESS THAN
    ↪ (10000) MAXVALUE PARTITION
```

It creates the following table:

```
CREATE TABLE `employees` (
  `id` int unsigned NOT NULL,
  `fname` varchar(30) DEFAULT NULL,
```

```
  `lname` varchar(30) DEFAULT NULL,
  `hired` date NOT NULL DEFAULT '1970-01-01',
  `separated` date DEFAULT '9999-12-31',
  `job_code` int DEFAULT NULL,
  `store_id` int NOT NULL
)
PARTITION BY RANGE (`id`)
(PARTITION `P_LT_100` VALUES LESS THAN (100),
 PARTITION `P_LT_200` VALUES LESS THAN (200),
...
 PARTITION `P_LT_9900` VALUES LESS THAN (9900),
 PARTITION `P_LT_10000` VALUES LESS THAN (10000),
 PARTITION `P_MAXVALUE` VALUES LESS THAN (MAXVALUE))
```

Range INTERVAL partitioning also works with Range COLUMNS partitioning.

For example:

```
CREATE TABLE monthly_report_status (
    report_id int NOT NULL,
    report_status varchar(20) NOT NULL,
    report_date date NOT NULL
)
PARTITION BY RANGE COLUMNS (report_date)
INTERVAL (1 MONTH) FIRST PARTITION LESS THAN ('2000-01-01') LAST PARTITION
    ↪ LESS THAN ('2025-01-01')
```

It creates this table:

```
CREATE TABLE `monthly_report_status` (
  `report_id` int NOT NULL,
  `report_status` varchar(20) NOT NULL,
  `report_date` date NOT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
PARTITION BY RANGE COLUMNS(`report_date`)
(PARTITION `P_LT_2000-01-01` VALUES LESS THAN ('2000-01-01'),
 PARTITION `P_LT_2000-02-01` VALUES LESS THAN ('2000-02-01'),
...
 PARTITION `P_LT_2024-11-01` VALUES LESS THAN ('2024-11-01'),
 PARTITION `P_LT_2024-12-01` VALUES LESS THAN ('2024-12-01'),
 PARTITION `P_LT_2025-01-01` VALUES LESS THAN ('2025-01-01'))
```

The optional parameter `NULL PARTITION` creates a partition with the definition as `PARTITION P_NULL VALUES LESS THAN (<minimum value of the column type>)`, only matching when the partitioning expression evaluates to `NULL`. See Handling of NULL with Range partitioning, which explains that `NULL` is considered to be less than any other value.

The optional parameter `MAXVALUE PARTITION` creates the last partition as `PARTITION P_MAXVALUE VALUES LESS THAN (MAXVALUE)`.

ALTER INTERVAL partitioned tables

INTERVAL partitioning also adds simpler syntaxes for adding and dropping partitions.

The following statement changes the first partition. It drops all partitions whose values are less than the given expression, and makes the matched partition the new first partition. It does not affect a NULL PARTITION.

```
ALTER TABLE table_name FIRST PARTITION LESS THAN (<expression>)
```

The following statement changes the last partition, meaning adding more partitions with higher ranges and room for new data. It will add new partitions with the current INTERVAL up to and including the given expression. It does not work if a `MAXVALUE PARTITION` exists, because it needs data reorganization.

```
ALTER TABLE table_name LAST PARTITION LESS THAN (<expression>)
```

INTERVAL partitioning details and limitations

- The INTERVAL partitioning feature only involves the `CREATE/ALTER TABLE` syntax. There is no change in metadata, so tables created or altered with the new syntax are still MySQL-compatible.
- There is no change in the output format of `SHOW CREATE TABLE` to keep MySQL compatibility.
- The new `ALTER` syntax applies to existing tables conforming to INTERVAL. You do not need to create these tables with the `INTERVAL` syntax.
- To use the `INTERVAL` syntax for `RANGE COLUMNS` partitioning, you can only specify a single column in the `INTEGER`, `DATE`, or `DATETIME` type as the partitioning key.

14.13.13.1.4 List partitioning

List partitioning is similar to Range partitioning. Unlike Range partitioning, in List partitioning, the partitioning expression values for all rows in each partition are in a given value set. This value set defined for each partition can have any number of values but cannot have duplicate values. You can use the `PARTITION ... VALUES IN (...)` clause to define a value set.

Suppose that you want to create a personnel record table. You can create a table as follows:

```
CREATE TABLE employees (
    id INT NOT NULL,
    hired DATE NOT NULL DEFAULT '1970-01-01',
    store_id INT
);
```

Suppose that there are 20 stores distributed in 4 districts, as shown in the table below:

```
| Region | Store ID Numbers  |
| ------- | ------------------- |
| North  | 1, 2, 3, 4, 5      |
| East   | 6, 7, 8, 9, 10     |
| West   | 11, 12, 13, 14, 15 |
| Central | 16, 17, 18, 19, 20 |
```

If you want to store the personnel data of employees of the same region in the same partition, you can create a List partitioned table based on `store_id`:

```
CREATE TABLE employees (
    id INT NOT NULL,
    hired DATE NOT NULL DEFAULT '1970-01-01',
    store_id INT
)
PARTITION BY LIST (store_id) (
    PARTITION pNorth VALUES IN (1, 2, 3, 4, 5),
    PARTITION pEast VALUES IN (6, 7, 8, 9, 10),
    PARTITION pWest VALUES IN (11, 12, 13, 14, 15),
    PARTITION pCentral VALUES IN (16, 17, 18, 19, 20)
);
```

After creating the partitions as above, you can easily add or delete records related to a specific region in the table. For example, suppose that all stores in the East region (East) are sold to another company. Then all the row data related to the store employees of this region can be deleted by executing `ALTER TABLE employees TRUNCATE PARTITION pEast`, which is much more efficient than the equivalent statement `DELETE FROM employees WHERE store_id IN (6, 7, 8, 9, 10)`.

You can also execute `ALTER TABLE employees DROP PARTITION pEast` to delete all related rows, but this statement also deletes the `pEast` partition from the table definition. In this situation, you must execute the `ALTER TABLE ... ADD PARTITION` statement to recover the original partitioning scheme of the table.

Default List partition

Starting from v7.3.0, you can add a default partition to a List or List COLUMNS partitioned table. The default partition acts as a fallback partition, where rows that do not match value sets of any partitions can be placed.

> **Note:**
>
> This feature is a TiDB extension to MySQL syntax. For a List or List COLUMNS partitioned table with a default partition, the data in the table cannot be directly replicated to MySQL.

Take the following List partitioned table as an example:

```
CREATE TABLE t (
  a INT,
  b INT
)
PARTITION BY LIST (a) (
  PARTITION p0 VALUES IN (1, 2, 3),
  PARTITION p1 VALUES IN (4, 5, 6)
);
Query OK, 0 rows affected (0.11 sec)
```

You can add a default list partition named `pDef` to the table as follows:

```
ALTER TABLE t ADD PARTITION (PARTITION pDef DEFAULT);
```

or

```
ALTER TABLE t ADD PARTITION (PARTITION pDef VALUES IN (DEFAULT));
```

In this way, newly inserted values that do not match value sets of any partitions can automatically go into the default partition.

```
INSERT INTO t VALUES (7, 7);
Query OK, 1 row affected (0.01 sec)
```

You can also add a default partition when creating a List or List COLUMNS partitioned table. For example:

```
CREATE TABLE employees (
    id INT NOT NULL,
    hired DATE NOT NULL DEFAULT '1970-01-01',
    store_id INT
)
PARTITION BY LIST (store_id) (
    PARTITION pNorth VALUES IN (1, 2, 3, 4, 5),
    PARTITION pEast VALUES IN (6, 7, 8, 9, 10),
    PARTITION pWest VALUES IN (11, 12, 13, 14, 15),
    PARTITION pCentral VALUES IN (16, 17, 18, 19, 20),
    PARTITION pDefault DEFAULT
);
```

For a List or List COLUMNS partitioned table without a default partition, the values to be inserted using an `INSERT` statement must match value sets defined in the `PARTITION ... VALUES IN (...)` clauses of the table. If the values to be inserted do not match value sets of any partitions, the statement will fail and an error is returned, as shown in the following example:

```
CREATE TABLE t (
  a INT,
  b INT
)
PARTITION BY LIST (a) (
  PARTITION p0 VALUES IN (1, 2, 3),
  PARTITION p1 VALUES IN (4, 5, 6)
);
Query OK, 0 rows affected (0.11 sec)

INSERT INTO t VALUES (7, 7);
ERROR 1525 (HY000): Table has no partition for value 7
```

To ignore the preceding error, you can add the `IGNORE` keyword to the `INSERT` statement. After this keyword is added, the `INSERT` statement will only insert rows that match the partition value sets and will not insert unmatched rows, without returning an error:

```
test> TRUNCATE t;
Query OK, 1 row affected (0.00 sec)

test> INSERT IGNORE INTO t VALUES (1, 1), (7, 7), (8, 8), (3, 3), (5, 5);
Query OK, 3 rows affected, 2 warnings (0.01 sec)
Records: 5 Duplicates: 2 Warnings: 2

test> select * from t;
+------+------+
| a    | b    |
+------+------+
|    5 |    5 |
|    1 |    1 |
|    3 |    3 |
+------+------+
3 rows in set (0.01 sec)
```

14.13.13.1.5 List COLUMNS partitioning

List COLUMNS partitioning is a variant of List partitioning. You can use multiple columns as partition keys. Besides the integer data type, you can also use the columns in the string, `DATE`, and `DATETIME` data types as partition columns.

Suppose that you want to divide the store employees from the following 12 cities into 4 regions, as shown in the following table:

```
| Region | Cities                        |
| :----- | ----------------------------- |
```

```
| 1     | LosAngeles,Seattle, Houston |
| 2     | Chicago, Columbus, Boston  |
| 3     | NewYork, LongIsland, Baltimore |
| 4     | Atlanta, Raleigh, Cincinnati |
```

You can use List COLUMNS partitioning to create a table and store each row in the partition that corresponds to the employee's city, as shown below:

```
CREATE TABLE employees_1 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT,
    city VARCHAR(15)
)
PARTITION BY LIST COLUMNS(city) (
    PARTITION pRegion_1 VALUES IN('LosAngeles', 'Seattle', 'Houston'),
    PARTITION pRegion_2 VALUES IN('Chicago', 'Columbus', 'Boston'),
    PARTITION pRegion_3 VALUES IN('NewYork', 'LongIsland', 'Baltimore'),
    PARTITION pRegion_4 VALUES IN('Atlanta', 'Raleigh', 'Cincinnati')
);
```

Unlike List partitioning, in List COLUMNS partitioning, you do not need to use the expression in the `COLUMNS()` clause to convert column values to integers.

List COLUMNS partitioning can also be implemented using columns of the `DATE` and `DATETIME` types, as shown in the following example. This example uses the same names and columns as the previous `employees_1` table, but uses List COLUMNS partitioning based on the `hired` column:

```
CREATE TABLE employees_2 (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT,
    city VARCHAR(15)
)
PARTITION BY LIST COLUMNS(hired) (
    PARTITION pWeek_1 VALUES IN('2020-02-01', '2020-02-02', '2020-02-03',
        '2020-02-04', '2020-02-05', '2020-02-06', '2020-02-07'),
```

```
    PARTITION pWeek_2 VALUES IN('2020-02-08', '2020-02-09', '2020-02-10',
        '2020-02-11', '2020-02-12', '2020-02-13', '2020-02-14'),
    PARTITION pWeek_3 VALUES IN('2020-02-15', '2020-02-16', '2020-02-17',
        '2020-02-18', '2020-02-19', '2020-02-20', '2020-02-21'),
    PARTITION pWeek_4 VALUES IN('2020-02-22', '2020-02-23', '2020-02-24',
        '2020-02-25', '2020-02-26', '2020-02-27', '2020-02-28')
);
```

In addition, you can also add multiple columns in the `COLUMNS()` clause. For example:

```
CREATE TABLE t (
    id int,
    name varchar(10)
)
PARTITION BY LIST COLUMNS(id,name) (
     partition p0 values IN ((1,'a'),(2,'b')),
     partition p1 values IN ((3,'c'),(4,'d')),
     partition p3 values IN ((5,'e'),(null,null))
);
```

14.13.13.1.6 Hash partitioning

Hash partitioning is used to make sure that data is evenly scattered into a certain number of partitions. With Range partitioning, you must specify the range of the column values for each partition when you use Range partitioning, while you just need to specify the number of partitions when you use Hash partitioning.

To create a Hash partitioned table, you need to append a `PARTITION BY HASH (expr)` clause to the `CREATE TABLE` statement. `expr` is an expression that returns an integer. It can be a column name if the type of this column is integer. In addition, you might also need to append `PARTITIONS num`, where `num` is a positive integer indicating how many partitions a table is divided into.

The following operation creates a Hash partitioned table, which is divided into 4 partitions by `store_id`:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY HASH(store_id)
```

```
PARTITIONS 4;
```

If `PARTITIONS num` is not specified, the default number of partitions is 1.

You can also use an SQL expression that returns an integer for `expr`. For example, you can partition a table by the hire year:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY HASH( YEAR(hired) )
PARTITIONS 4;
```

The most efficient Hash function is one which operates upon a single table column, and whose value increases or decreases consistently with the column value.

For example, `date_col` is a column whose type is `DATE`, and the value of the `TO_DAYS (date_col)` expression varies with the value of `date_col`. `YEAR(date_col)` is different from `TO_DAYS(date_col)`, because not every possible change in `date_col` produces an equivalent change in `YEAR(date_col)`.

In contrast, assume that you have an `int_col` column whose type is `INT`. Now consider about the expression `POW(5-int_col,3)+ 6`. It is not a good Hash function though, because as the value of `int_col` changes, the result of the expression does not change proportionally. A value change in `int_col` might result in a huge change in the expression result. For example, when `int_col` changes from 5 to 6, the change of the expression result is -1. But the result change might be -7 when `int_col` changes from 6 to 7.

In conclusion, when the expression has a form that is closer to `y = cx`, it is more suitable to be a Hash function. Because the more non-linear an expression is, the more unevenly scattered the data among the partitions tends to be.

In theory, pruning is also possible for expressions involving more than one column value, but determining which of such expressions are suitable can be quite difficult and time-consuming. For this reason, the use of hashing expressions involving multiple columns is not particularly recommended.

When using `PARTITION BY HASH`, TiDB decides which partition the data should fall into based on the modulus of the result of the expression. In other words, if a partitioning expression is `expr` and the number of partitions is `num`, `MOD(expr, num)` decides the partition in which the data is stored. Assume that `t1` is defined as follows:

```
CREATE TABLE t1 (col1 INT, col2 CHAR(5), col3 DATE)
    PARTITION BY HASH( YEAR(col3) )
    PARTITIONS 4;
```

When you insert a row of data into `t1` and the value of `col3` is '2005-09-15', then this row is inserted into partition 1:

```
MOD(YEAR('2005-09-01'),4)
=  MOD(2005,4)
=  1
```

14.13.13.1.7 Key partitioning

Starting from v7.0.0, TiDB supports Key partitioning. For TiDB versions earlier than v7.0.0, if you try creating a Key partitioned table, TiDB creates it as a non-partitioned table and returns a warning.

Both Key partitioning and Hash partitioning can evenly distribute data into a certain number of partitions. The difference is that Hash partitioning only supports distributing data based on a specified integer expression or an integer column, while Key partitioning supports distributing data based on a column list, and partitioning columns of Key partitioning are not limited to the integer type. The Hash algorithm of TiDB for Key partitioning is different from that of MySQL, so the table data distribution is also different.

To create a Key partitioned table, you need to append a `PARTITION BY KEY (` ↪ `columnList)` clause to the `CREATE TABLE` statement. `columnList` is a column list with one or more column names. The data type of each column in the list can be any type except `BLOB`, `JSON`, and `GEOMETRY` (Note that TiDB does not support `GEOMETRY`). In addition, you might also need to append `PARTITIONS num` (where `num` is a positive integer indicating how many partitions a table is divided into), or append the definition of the partition names. For example, adding `(PARTITION p0, PARTITION p1)` means dividing the table into two partitions named `p0` and `p1`.

The following operation creates a Key partitioned table, which is divided into 4 partitions by `store_id`:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY KEY(store_id)
```

```
PARTITIONS 4;
```

If `PARTITIONS num` is not specified, the default number of partitions is 1.

You can also create a Key partitioned table based on non-integer columns such as VARCHAR. For example, you can partition a table by the `fname` column:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY KEY(fname)
PARTITIONS 4;
```

You can also create a Key partitioned table based on multiple columns. For example, you can divide a table into 4 partitions based on `fname` and `store_id`:

```
CREATE TABLE employees (
    id INT NOT NULL,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
    store_id INT
)

PARTITION BY KEY(fname, store_id)
PARTITIONS 4;
```

Similar to MySQL, TiDB supports creating Key partitioned tables with an empty partition column list specified in `PARTITION BY KEY`. For example, the following statement creates a partitioned table using the primary key `id` as the partitioning key:

```
CREATE TABLE employees (
    id INT NOT NULL PRIMARY KEY,
    fname VARCHAR(30),
    lname VARCHAR(30),
    hired DATE NOT NULL DEFAULT '1970-01-01',
    separated DATE DEFAULT '9999-12-31',
    job_code INT,
```

```
    store_id INT
)

PARTITION BY KEY()
PARTITIONS 4;
```

If the table lacks a primary key but contains a unique key, the unique key is used as the partitioning key:

```
CREATE TABLE k1 (
    id INT NOT NULL,
    name VARCHAR(20),
    UNIQUE KEY (id)
)
PARTITION BY KEY()
PARTITIONS 2;
```

However, the previous statement will fail if the unique key column is not defined as `NOT NULL`.

How TiDB handles Linear Hash partitions

Before v6.4.0, if you execute DDL statements of MySQL Linear Hash partitions in TiDB, TiDB can only create non-partitioned tables. In this case, if you still want to use partitioned tables in TiDB, you need to modify the DDL statements.

Since v6.4.0, TiDB supports parsing the MySQL `PARTITION BY LINEAR HASH` syntax but ignores the `LINEAR` keyword in it. If you have some existing DDL and DML statements of MySQL Linear Hash partitions, you can execute them in TiDB without modification:

- For a `CREATE` statement of MySQL Linear Hash partitions, TiDB will create a non-linear Hash partitioned table (note that there is no Linear Hash partitioned table in TiDB). If the number of partitions is a power of 2, the rows in the TiDB Hash partitioned table are distributed the same as that in the MySQL Linear Hash partitioned table. Otherwise, the distribution of these rows in TiDB is different from MySQL. This is because non-linear partitioned tables use a simple "modulus number of partition", while linear partitioned tables use "modulus next power of 2 and fold the values between the number of partitions and the next power of 2". For details, see #38450.
- For all other statements of MySQL Linear Hash partitions, they work in TiDB the same as that in MySQL, except that the rows are distributed differently if the number of partitions is not a power of 2, which will give different results for partition selection, `TRUNCATE PARTITION`, and `EXCHANGE PARTITION`.

14.13.13.1.8 How TiDB handles Linear Key partitions

Starting from v7.0.0, TiDB supports parsing the MySQL `PARTITION BY LINEAR KEY` ↪ syntax for Key partitioning. However, TiDB ignores the `LINEAR` keyword and uses a non-linear hash algorithm instead.

Before v7.0.0, if you try creating a Key partitioned table, TiDB creates it as a non-partitioned table and returns a warning.

14.13.13.1.9 How TiDB partitioning handles NULL

It is allowed in TiDB to use `NULL` as the calculation result of a partitioning expression.

> **Note:**
>
> `NULL` is not an integer. TiDB's partitioning implementation treats `NULL` as being less than any other integer values, just as `ORDER BY` does.

Handling of NULL with Range partitioning

When you insert a row into a table partitioned by Range, and the column value used to determine the partition is `NULL`, then this row is inserted into the lowest partition.

```
CREATE TABLE t1 (
    c1 INT,
    c2 VARCHAR(20)
)

PARTITION BY RANGE(c1) (
    PARTITION p0 VALUES LESS THAN (0),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN MAXVALUE
);
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
select * from t1 partition(p0);
```

```
+------|--------+
| c1   | c2     |
+------|--------+
| NULL | mothra |
+------|--------+
1 row in set (0.00 sec)
```

```
select * from t1 partition(p1);
```

```
Empty set (0.00 sec)
```

```
select * from t1 partition(p2);
```

```
Empty set (0.00 sec)
```

Drop the p0 partition and verify the result:

```
alter table t1 drop partition p0;
```

```
Query OK, 0 rows affected (0.08 sec)
```

```
select * from t1;
```

```
Empty set (0.00 sec)
```

Handling of NULL with Hash partitioning

When partitioning tables by Hash, there is a different way of handling NULL value - if the calculation result of the partitioning expression is NULL, it is considered as 0.

```
CREATE TABLE th (
    c1 INT,
    c2 VARCHAR(20)
)

PARTITION BY HASH(c1)
PARTITIONS 2;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
INSERT INTO th VALUES (NULL, 'mothra'), (0, 'gigan');
```

```
Query OK, 2 rows affected (0.04 sec)
```

```
select * from th partition (p0);
```

```
+------|--------+
| c1   | c2     |
+------|--------+
| NULL | mothra |
|    0 | gigan  |
+------|--------+
2 rows in set (0.00 sec)
```

```
select * from th partition (p1);
```

```
Empty set (0.00 sec)
```

You can see that the inserted record `(NULL, 'mothra')` falls into the same partition as `(0, 'gigan')`.

> **Note:**
>
> `NULL` values by Hash partitions in TiDB are handled in the same way as described in How MySQL Partitioning Handles NULL, which, however, is not consistent with the actual behavior of MySQL. In other words, MySQL's implementation in this case is not consistent with its documentation.
>
> In this case, the actual behavior of TiDB is in line with the description of this document.

Handling of NULL with Key partitioning

For Key partitioning, the way of handling `NULL` value is consistent with that of Hash partitioning. If the value of a partitioning field is `NULL`, it is treated as `0`.

14.13.13.2 Partition management

For `RANGE`, `RANGE COLUMNS`, `LIST`, and `LIST COLUMNS` partitioned tables, you can manage the partitions as follows:

- Add partitions using the `ALTER TABLE <table name> ADD PARTITION (<partition specification>)` statement.
- Drop partitions using the `ALTER TABLE <table name> DROP PARTITION <list of partitions>` statement.
- Remove all data from specified partitions using the `ALTER TABLE <table name> TRUNCATE PARTITION <list of partitions>` statement. The logic of `TRUNCATE PARTITION` is similar to `TRUNCATE TABLE` but it is for partitions.
- Merge, split, or make other changes to the partitions using the `ALTER TABLE <table name> REORGANIZE PARTITION <list of partitions> INTO (<new partition definitions>)` statement.

For `HASH` and `KEY` partitioned tables, you can manage the partitions as follows:

- Decrease the number of partitions using the `ALTER TABLE <table name> COALESCE PARTITION <number of partitions to decrease by>` statement. This operation reorganizes the partitions by copying the whole table to the new number of partitions online.

- Increase the number of partitions using the `ALTER TABLE <table name> ADD PARTITION <number of partitions to increase by | (additional partition definitions)>` statement. This operation reorganizes the partitions by copying the whole table to the new number of partitions online.
- Remove all data from specified partitions using the `ALTER TABLE <table name> TRUNCATE PARTITION <list of partitions>` statement. The logic of `TRUNCATE PARTITION` is similar to `TRUNCATE TABLE` but it is for partitions.

`EXCHANGE PARTITION` works by swapping a partition and a non-partitioned table, similar to how renaming a table like `RENAME TABLE t1 TO t1_tmp, t2 TO t1, t1_tmp TO t2` works.

For example, `ALTER TABLE partitioned_table EXCHANGE PARTITION p1 WITH TABLE non_partitioned_table` swaps the `partitioned_table` table `p1` partition with the `non_partitioned_table` table.

Ensure that all rows that you are exchanging into the partition match the partition definition; otherwise, the statement will fail.

Note that TiDB has some specific features that might affect `EXCHANGE PARTITION`. When the table structure contains such features, you need to ensure that `EXCHANGE PARTITION` meets the MySQL's EXCHANGE PARTITION condition. Meanwhile, ensure that these specific features are defined the same for both partitioned and non-partitioned tables. These specific features include the following:

- Placement Rules in SQL: placement policies are the same.

- TiFlash: the numbers of TiFlash replicas are the same.
- Clustered Indexes: partitioned and non-partitioned tables are both `CLUSTERED`, or both `NONCLUSTERED`.

In addition, there are limitations on the compatibility of `EXCHANGE PARTITION` with other components. Both partitioned and non-partitioned tables must have the same definition.

- TiFlash: when the TiFlash replica definitions in partitioned and non-partitioned tables are different, the `EXCHANGE PARTITION` operation cannot be performed.
- TiCDC: TiCDC replicates the `EXCHANGE PARTITION` operation when both partitioned and non-partitioned tables have primary keys or unique keys. Otherwise, TiCDC will not replicate the operation.
- TiDB Lightning and BR: do not perform the `EXCHANGE PARTITION` operation during import using TiDB Lightning or during restore using BR.

14.13.13.2.1 Manage Range, Range COLUMNS, List, and List COLUMNS partitions

This section uses the partitioned tables created by the following SQL statements as examples to show you how to manage Range and List partitions.

```
CREATE TABLE members (
    id int,
    fname varchar(255),
    lname varchar(255),
    dob date,
    data json
)
PARTITION BY RANGE (YEAR(dob)) (
 PARTITION pBefore1950 VALUES LESS THAN (1950),
 PARTITION p1950 VALUES LESS THAN (1960),
 PARTITION p1960 VALUES LESS THAN (1970),
 PARTITION p1970 VALUES LESS THAN (1980),
 PARTITION p1980 VALUES LESS THAN (1990),
 PARTITION p1990 VALUES LESS THAN (2000));

CREATE TABLE member_level (
 id int,
 level int,
 achievements json
)
PARTITION BY LIST (level) (
 PARTITION l1 VALUES IN (1),
 PARTITION l2 VALUES IN (2),
 PARTITION l3 VALUES IN (3),
 PARTITION l4 VALUES IN (4),
 PARTITION l5 VALUES IN (5));
```

Drop partitions

```
ALTER TABLE members DROP PARTITION p1990;

ALTER TABLE member_level DROP PARTITION l5;
```

Truncate partitions

```
ALTER TABLE members TRUNCATE PARTITION p1980;

ALTER TABLE member_level TRUNCATE PARTITION l4;
```

Add partitions

```
ALTER TABLE members ADD PARTITION (PARTITION `p1990to2010` VALUES LESS THAN
    ↪  (2010));

ALTER TABLE member_level ADD PARTITION (PARTITION l5_6 VALUES IN (5,6));
```

For a Range partitioned table, `ADD PARTITION` will append new partitions after the last existing partition. Compared with the existing partitions, the value defined in `VALUES LESS ↪ THAN` for new partitions must be greater. Otherwise, an error is reported:

```
ALTER TABLE members ADD PARTITION (PARTITION p1990 VALUES LESS THAN (2000))
    ↪ ;
```

```
ERROR 1493 (HY000): VALUES LESS THAN value must be strictly increasing for
    ↪ each partition
```

Reorganize partitions

Split a partition:

```
ALTER TABLE members REORGANIZE PARTITION `p1990to2010` INTO
(PARTITION p1990 VALUES LESS THAN (2000),
 PARTITION p2000 VALUES LESS THAN (2010),
 PARTITION p2010 VALUES LESS THAN (2020),
 PARTITION p2020 VALUES LESS THAN (2030),
 PARTITION pMax VALUES LESS THAN (MAXVALUE));

ALTER TABLE member_level REORGANIZE PARTITION l5_6 INTO
(PARTITION l5 VALUES IN (5),
 PARTITION l6 VALUES IN (6));
```

Merge partitions:

```
ALTER TABLE members REORGANIZE PARTITION pBefore1950,p1950 INTO (PARTITION
    ↪ pBefore1960 VALUES LESS THAN (1960));

ALTER TABLE member_level REORGANIZE PARTITION l1,l2 INTO (PARTITION l1_2
    ↪ VALUES IN (1,2));
```

Change the partitioning scheme definition:

```
ALTER TABLE members REORGANIZE PARTITION pBefore1960,p1960,p1970,p1980,
    ↪ p1990,p2000,p2010,p2020,pMax INTO
(PARTITION p1800 VALUES LESS THAN (1900),
 PARTITION p1900 VALUES LESS THAN (2000),
 PARTITION p2000 VALUES LESS THAN (2100));

ALTER TABLE member_level REORGANIZE PARTITION l1_2,l3,l4,l5,l6 INTO
```

```
(PARTITION lOdd VALUES IN (1,3,5),
 PARTITION lEven VALUES IN (2,4,6));
```

When reorganizing partitions, you need to note the following key points:

- Reorganizing partitions (including merging or splitting partitions) can change the listed partitions into a new set of partition definitions but cannot change the type of partitioning (for example, change the List type to the Range type, or change the Range COLUMNS type to the Range type).
- For a Range partition table, you can reorganize only adjacent partitions in it.

```
ALTER TABLE members REORGANIZE PARTITION p1800,p2000 INTO (PARTITION
    ↪ p2000 VALUES LESS THAN (2100));
```

```
ERROR 8200 (HY000): Unsupported REORGANIZE PARTITION of RANGE; not
    ↪ adjacent partitions
```

- For a Range partitioned table, to modify the end of the range, the new end defined in `VALUES LESS THAN` must cover the existing rows in the last partition. Otherwise, existing rows no longer fit and an error is reported:

```
INSERT INTO members VALUES (313, "John", "Doe", "2022-11-22", NULL);
ALTER TABLE members REORGANIZE PARTITION p2000 INTO (PARTITION p2000
    ↪ VALUES LESS THAN (2050)); -- This statement will work as
    ↪ expected, because 2050 covers the existing rows.
ALTER TABLE members REORGANIZE PARTITION p2000 INTO (PARTITION p2000
    ↪ VALUES LESS THAN (2020)); -- This statement will fail with an
    ↪ error, because 2022 does not fit in the new range.
```

```
ERROR 1526 (HY000): Table has no partition for value 2022
```

- For a List partitioned table, to modify the set of values defined for a partition, the new definition must cover the existing values in that partition. Otherwise, an error is reported:

```
INSERT INTO member_level (id, level) values (313, 6);
ALTER TABLE member_level REORGANIZE PARTITION lEven INTO (PARTITION
    ↪ lEven VALUES IN (2,4));
```

```
ERROR 1526 (HY000): Table has no partition for value 6
```

- After partitions are reorganized, the statistics of the corresponding partitions are outdated, so you will get the following warning. In this case, you can use the `ANALYZE ↪ TABLE` statement to update the statistics.

```
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Warning | 1105 | The statistics of related partitions will be
    ↪ outdated after reorganizing partitions. Please use 'ANALYZE TABLE
    ↪ ' statement if you want to update it now |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

14.13.13.2.2 Manage Hash and Key partitions

This section uses the partitioned table created by the following SQL statement as examples to show you how to manage Hash partitions. For Key partitions, you can use the same management statements as well.

```
CREATE TABLE example (
  id INT PRIMARY KEY,
  data VARCHAR(1024)
)
PARTITION BY HASH(id)
PARTITIONS 2;
```

Increase the number of partitions

Increase the number of partitions for the `example` table by 1 (from 2 to 3):

```
ALTER TABLE example ADD PARTITION PARTITIONS 1;
```

You can also specify partition options by adding partition definitions. For example, you can use the following statement to increase the number of partitions from 3 to 5 and specify the names of the newly added partitions as `pExample4` and `pExample5`:

```
ALTER TABLE example ADD PARTITION
(PARTITION pExample4 COMMENT = 'not p3, but pExample4 instead',
 PARTITION pExample5 COMMENT = 'not p4, but pExample5 instead');
```

Decrease the number of partitions

Unlike Range and List partitioning, `DROP PARTITION` is not supported for Hash and Key partitioning, but you can decrease the number of partitions with `COALESCE PARTITION` or delete all data from specific partitions with `TRUNCATE PARTITION`.

Decrease the number of partitions for the `example` table by 1 (from 5 to 4):

```
ALTER TABLE example COALESCE PARTITION 1;
```

Note:

The process of changing the number of partitions for Hash or Key partitioned tables reorganizes the partitions by copying all data to the new number of partitions. Therefore, after changing the number of partitions for a Hash or Key partitioned table, you will get the following warning about the outdated statistics. In this case, you can use the `ANALYZE TABLE` statement to update the statistics.

```
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Warning | 1105 | The statistics of related partitions will be
    ↪  outdated after reorganizing partitions. Please use '
    ↪ ANALYZE TABLE' statement if you want to update it now |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

To better understand how the `example` table is organized now, you can show the SQL statement that is used to recreate the `example` table as follows:

```
SHOW CREATE TABLE\G
```

```
*************************** 1. row ***************************
       Table: example
Create Table: CREATE TABLE `example` (
  `id` int NOT NULL,
```

```
  `data` varchar(1024) DEFAULT NULL,
  PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
PARTITION BY HASH (`id`)
(PARTITION `p0`,
 PARTITION `p1`,
 PARTITION `p2`,
 PARTITION `pExample4` COMMENT 'not p3, but pExample4 instead')
1 row in set (0.01 sec)
```

Truncate partitions

Delete all data from a partition:

```
ALTER TABLE example TRUNCATE PARTITION p0;
```

```
Query OK, 0 rows affected (0.03 sec)
```

14.13.13.2.3 Convert a partitioned table to a non-partitioned table

To convert a partitioned table to a non-partitioned table, you can use the following statement, which removes the partitioning, copies all rows of the table, and recreates the indexes online for the table:

```
ALTER TABLE <table_name> REMOVE PARTITIONING
```

For example, to convert the `members` partitioned table to the non-partitioned table, you can execute the following statement:

```
ALTER TABLE members REMOVE PARTITIONING
```

14.13.13.2.4 Partition an existing table

To partition an existing non-partitioned table or modify the partition type of an existing partitioned table, you can use the following statement, which copies all rows and recreates the indexes online according to the new partition definitions:

```
ALTER TABLE <table_name> PARTITION BY <new partition type and definitions>
    ↪ [UPDATE INDEXES (<index name> {GLOBAL|LOCAL}[ , <index name> {GLOBAL|
    ↪ LOCAL}...])]
```

Examples:

To convert the existing `members` table to a HASH partitioned table with 10 partitions, you can execute the following statement:

```
ALTER TABLE members PARTITION BY HASH(id) PARTITIONS 10;
```

To convert the existing `member_level` table to a RANGE partitioned table, you can execute the following statement:

```
ALTER TABLE member_level PARTITION BY RANGE(level)
(PARTITION pLow VALUES LESS THAN (1),
 PARTITION pMid VALUES LESS THAN (3),
 PARTITION pHigh VALUES LESS THAN (7)
 PARTITION pMax VALUES LESS THAN (MAXVALUE));
```

When partitioning a non-partitioned table or repartitioning an already partitioned table, you can update the indexes to be global or local as needed:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY uidx12(col1, col2),
    UNIQUE KEY uidx3(col3)
);

ALTER TABLE t1 PARTITION BY HASH (col1) PARTITIONS 3 UPDATE INDEXES (uidx12
    ↪  LOCAL, uidx3 GLOBAL);
```

14.13.13.3 Partition pruning

Partition pruning is an optimization which is based on a very simple idea - do not scan the partitions that do not match.

Assume that you create a partitioned table `t1`:

```
CREATE TABLE t1 (
    fname VARCHAR(50) NOT NULL,
    lname VARCHAR(50) NOT NULL,
    region_code TINYINT UNSIGNED NOT NULL,
    dob DATE NOT NULL
)

PARTITION BY RANGE( region_code ) (
    PARTITION p0 VALUES LESS THAN (64),
    PARTITION p1 VALUES LESS THAN (128),
    PARTITION p2 VALUES LESS THAN (192),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

If you want to get the result of this `SELECT` statement:

```
SELECT fname, lname, region_code, dob
    FROM t1
    WHERE region_code > 125 AND region_code < 130;
```

It is evident that the result falls in either the `p1` or the `p2` partition, that is, you just need to search for the matching rows in `p1` and `p2`. Excluding the unneeded partitions is so-called "pruning". If the optimizer is able to prune a part of partitions, the execution of the query in the partitioned table will be much faster than that in a non-partitioned table.

The optimizer can prune partitions through `WHERE` conditions in the following two scenarios:

- partition_column = constant
- partition_column IN (constant1, constant2, ..., constantN)

Currently, partition pruning does not work with `LIKE` conditions.

14.13.13.3.1 Some cases for partition pruning to take effect

1. Partition pruning uses the query conditions on the partitioned table, so if the query conditions cannot be pushed down to the partitioned table according to the planner's optimization rules, partition pruning does not apply for this query.

   For example:

   ```
   create table t1 (x int) partition by range (x) (
          partition p0 values less than (5),
          partition p1 values less than (10));
   create table t2 (x int);
   ```

   ```
   explain select * from t1 left join t2 on t1.x = t2.x where t2.x > 5;
   ```

   In this query, the left out join is converted to the inner join, and then `t1.x > 5` is derived from `t1.x = t2.x` and `t2.x > 5`, so it could be used in partition pruning and only the partition `p1` remains.

   ```
   explain select * from t1 left join t2 on t1.x = t2.x and t2.x > 5;
   ```

   In this query, `t2.x > 5` cannot be pushed down to the `t1` partitioned table, so partition pruning would not take effect for this query.

2. Since partition pruning is done during the plan optimizing phase, it does not apply for those cases that filter conditions are unknown until the execution phase.

   For example:

```
create table t1 (x int) partition by range (x) (
       partition p0 values less than (5),
       partition p1 values less than (10));
```

```
explain select * from t2 where x < (select * from t1 where t2.x < t1.x
   ↪  and t2.x < 2);
```

This query reads a row from `t2` and uses the result for the subquery on `t1`. Theoretically, partition pruning could benefit from `t1.x > val` expression in the subquery, but it does not take effect there as that happens in the execution phase.

3. As a result of a limitation from current implementation, if a query condition cannot be pushed down to TiKV, it cannot be used by the partition pruning.

   Take the `fn(col)` expression as an example. If the TiKV coprocessor supports this `fn` ↪ function, `fn(col)` may be pushed down to the leaf node (that is, partitioned table) according to the predicate push-down rule during the plan optimizing phase, and partition pruning can use it.

   If the TiKV coprocessor does not support this `fn` function, `fn(col)` would not be pushed down to the leaf node. Instead, it becomes a `Selection` node above the leaf node. The current partition pruning implementation does not support this kind of plan tree.

4. For Hash and Key partition types, the only query supported by partition pruning is the equal condition.

5. For Range partition, for partition pruning to take effect, the partition expression must be in those forms: `col` or `fn(col)`, and the query condition must be one of `>`, `<`, `=`, `>=`, and `<=`. If the partition expression is in the form of `fn(col)`, the `fn` function must be monotonous.

   If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". In theory, all monotonous functions are supported by partition pruning.

   Currently, partition pruning in TiDB only support those monotonous functions:

   - `UNIX_TIMESTAMP()`
   - `TO_DAYS()`
   - `EXTRACT(<time unit> FROM <DATETIME/DATE/TIME column>)`. For `DATE` and `DATETIME` columns, `YEAR` and `YEAR_MONTH` time units are considered monotonous functions. For the `TIME` column, `HOUR`, `HOUR_MINUTE`, `HOUR_SECOND` and `HOUR_` ↪ `MICROSECOND` are considered monotonous functions. Note that `WEEK` is not supported as time unit in `EXTRACT` for partition pruning.

   For example, the partition expression is a simple column:

```
create table t (id int) partition by range (id) (
       partition p0 values less than (5),
       partition p1 values less than (10));
select * from t where id > 6;
```

Or the partition expression is in the form of `fn(col)` where `fn` is `to_days`:

```
create table t (dt datetime) partition by range (to_days(id)) (
       partition p0 values less than (to_days('2020-04-01')),
       partition p1 values less than (to_days('2020-05-01')));
select * from t where dt > '2020-04-18';
```

An exception is `floor(unix_timestamp())` as the partition expression. TiDB does some optimization for that case by case, so it is supported by partition pruning.

```
create table t (ts timestamp(3) not null default current_timestamp(3))
partition by range (floor(unix_timestamp(ts))) (
       partition p0 values less than (unix_timestamp('2020-04-01
          ↪ 00:00:00')),
       partition p1 values less than (unix_timestamp('2020-05-01
          ↪ 00:00:00')));
select * from t where ts > '2020-04-18 02:00:42.123';
```

14.13.13.4 Partition selection

`SELECT` statements support partition selection, which is implemented by using a `PARTITION` option.

```
SET @@sql_mode = '';

CREATE TABLE employees (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    fname VARCHAR(25) NOT NULL,
    lname VARCHAR(25) NOT NULL,
    store_id INT NOT NULL,
    department_id INT NOT NULL
)

PARTITION BY RANGE(id) (
    PARTITION p0 VALUES LESS THAN (5),
    PARTITION p1 VALUES LESS THAN (10),
    PARTITION p2 VALUES LESS THAN (15),
    PARTITION p3 VALUES LESS THAN MAXVALUE
);
```

```
INSERT INTO employees VALUES
    ('', 'Bob', 'Taylor', 3, 2), ('', 'Frank', 'Williams', 1, 2),
    ('', 'Ellen', 'Johnson', 3, 4), ('', 'Jim', 'Smith', 2, 4),
    ('', 'Mary', 'Jones', 1, 1), ('', 'Linda', 'Black', 2, 3),
    ('', 'Ed', 'Jones', 2, 1), ('', 'June', 'Wilson', 3, 1),
    ('', 'Andy', 'Smith', 1, 3), ('', 'Lou', 'Waters', 2, 4),
    ('', 'Jill', 'Stone', 1, 4), ('', 'Roger', 'White', 3, 2),
    ('', 'Howard', 'Andrews', 1, 2), ('', 'Fred', 'Goldberg', 3, 3),
    ('', 'Barbara', 'Brown', 2, 3), ('', 'Alice', 'Rogers', 2, 2),
    ('', 'Mark', 'Morgan', 3, 3), ('', 'Karen', 'Cole', 3, 2);
```

You can view the rows stored in the `p1` partition:

```
SELECT * FROM employees PARTITION (p1);
```

```
+----|-------|--------|----------|---------------+
| id | fname | lname | store_id | department_id |
+----|-------|--------|----------|---------------+
|  5 | Mary | Jones |       1 |             1 |
|  6 | Linda | Black |       2 |             3 |
|  7 | Ed   | Jones |       2 |             1 |
|  8 | June | Wilson |       3 |             1 |
|  9 | Andy | Smith |       1 |             3 |
+----|-------|--------|----------|---------------+
5 rows in set (0.00 sec)
```

If you want to get the rows in multiple partitions, you can use a list of partition names which are separated by commas. For example, `SELECT * FROM employees PARTITION (p1 ↪ , p2)` returns all rows in the `p1` and `p2` partitions.

When you use partition selection, you can still use `WHERE` conditions and options such as `ORDER BY` and `LIMIT`. It is also supported to use aggregation options such as `HAVING` and `GROUP BY`.

```
SELECT * FROM employees PARTITION (p0, p2)
    WHERE lname LIKE 'S%';
```

```
+----|-------|-------|----------|---------------+
| id | fname | lname | store_id | department_id |
+----|-------|-------|----------|---------------+
|  4 | Jim  | Smith |       2 |             4 |
| 11 | Jill | Stone |       1 |             4 |
+----|-------|-------|----------|---------------+
2 rows in set (0.00 sec)
```

```
SELECT id, CONCAT(fname, ' ', lname) AS name
    FROM employees PARTITION (p0) ORDER BY lname;
```

```
+----|----------------+
| id | name           |
+----|----------------+
|  3 | Ellen Johnson  |
|  4 | Jim Smith      |
|  1 | Bob Taylor     |
|  2 | Frank Williams |
+----|----------------+
4 rows in set (0.06 sec)
```

```
SELECT store_id, COUNT(department_id) AS c
    FROM employees PARTITION (p1,p2,p3)
    GROUP BY store_id HAVING c > 4;
```

```
+---|----------+
| c | store_id |
+---|----------+
| 5 |        2 |
| 5 |        3 |
+---|----------+
2 rows in set (0.00 sec)
```

Partition selection is supported for all types of table partitioning, including Range partitioning and Hash partitioning. For Hash partitions, if partition names are not specified, `p0`, `p1`, `p2`,..., or `pN-1` is automatically used as the partition name.

`SELECT` in `INSERT ... SELECT` can also use partition selection.

14.13.13.5 Restrictions and limitations on partitions

This section introduces some restrictions and limitations on partitioned tables in TiDB.

- Using the `ALTER TABLE ... CHANGE COLUMN` statement to change column types of partitioned tables is not supported.
- Using the `ALTER TABLE ... CACHE` statement to set partitioned tables to cached tables is not supported.
- Temporary tables in TiDB are **NOT** compatible with partitioned tables.
- Creating a foreign key on a partitioned table is not supported.
- The `ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint does not work for partitioned tables and their related indexes, because indexes on partitioned tables cannot be read in order.

14.13.13.5.1 Partitioning keys, primary keys and unique keys

This section discusses the relationship of partitioning keys with primary keys and unique keys. The rule governing this relationship is as follows: every unique key on the partitioned table, including the primary key, must use every column in the table's partitioning expression, because the primary key is also a unique key by definition.

> **Note:**
>
> You can ignore this rule when using global indexes.

For example, the following table creation statements are invalid:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2)
)

PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1),
    UNIQUE KEY (col3)
)

PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

In each case, the proposed table has at least one unique key that does not include all columns used in the partitioning expression.

The valid statements are as follows:

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
```

```
    UNIQUE KEY (col1, col2, col3)
)

PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3)
)

PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

The following example displays an error:

```
CREATE TABLE t3 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2),
    UNIQUE KEY (col3)
)

PARTITION BY HASH(col1 + col3)
PARTITIONS 4;
```

```
ERROR 8264 (HY000): Global Index is needed for index 'col1', since the
    ↪ unique index is not including all partitioning columns, and GLOBAL is
    ↪  not given as IndexOption
```

The `CREATE TABLE` statement fails because both `col1` and `col3` are included in the proposed partitioning key, but neither of these columns is part of both of unique keys on the table. After the following modifications, the `CREATE TABLE` statement becomes valid:

```
CREATE TABLE t3 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col2, col3),
    UNIQUE KEY (col1, col3)
```

```
)
PARTITION BY HASH(col1 + col3)
    PARTITIONS 4;
```

The following table cannot be partitioned at all, because there is no way to include in a partitioning key any columns that belong to both unique keys:

```
CREATE TABLE t4 (
    col1 INT NOT NULL,
    col2 INT NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY (col1, col3),
    UNIQUE KEY (col2, col4)
);
```

Because every primary key is by definition a unique key, so the next two statements are invalid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2)
)

PARTITION BY HASH(col3)
PARTITIONS 4;

CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col3),
    UNIQUE KEY(col2)
)

PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

In the above examples, the primary key does not include all columns referenced in the partitioning expression. After adding the missing column in the primary key, the `CREATE ↪ TABLE` statement becomes valid:

```
CREATE TABLE t5 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;
CREATE TABLE t6 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    PRIMARY KEY(col1, col2, col3),
    UNIQUE KEY(col2)
)
PARTITION BY HASH( YEAR(col2) )
PARTITIONS 4;
```

If a table has neither unique keys nor primary keys, then this restriction does not apply.

When you change tables using DDL statements, you also need to consider this restriction when adding a unique index. For example, when you create a partitioned table as shown below:

```
CREATE TABLE t_no_pk (c1 INT, c2 INT)
    PARTITION BY RANGE(c1) (
        PARTITION p0 VALUES LESS THAN (10),
        PARTITION p1 VALUES LESS THAN (20),
        PARTITION p2 VALUES LESS THAN (30),
        PARTITION p3 VALUES LESS THAN (40)
    );
```

```
Query OK, 0 rows affected (0.12 sec)
```

You can add a non-unique index by using `ALTER TABLE` statements. But if you want to add a unique index, the `c1` column must be included in the unique index.

When using a partitioned table, you cannot specify the prefix index as a unique attribute:

```
CREATE TABLE t (a varchar(20), b blob,
    UNIQUE INDEX (a(5)))
    PARTITION by range columns (a) (
    PARTITION p0 values less than ('aaaaa'),
    PARTITION p1 values less than ('bbbbb'),
```

```
    PARTITION p2 values less than ('ccccc'));
```

```
ERROR 8264 (HY000): Global Index is needed for index 'a', since the unique
    ↪ index is not including all partitioning columns, and GLOBAL is not
    ↪ given as IndexOption
```

Global indexes

Before the introduction of global indexes, TiDB created a local index for each partition, leading to a limitation that primary keys and unique keys had to include the partition key to ensure data uniqueness. Additionally, when querying data across multiple partitions, TiDB needed to scan the data of each partition to return results.

To address these issues, TiDB introduces the global indexes feature in v8.3.0. A global index covers the data of the entire table with a single index, allowing primary keys and unique keys to maintain global uniqueness without including all partition keys. Moreover, global indexes can access index data across multiple partitions in a single operation, significantly improving query performance for non-partitioned keys instead of looking up in one local index for each partition.

To create a global index for a primary key or unique key, you can add the `GLOBAL` keyword in the index definition.

> **Note:**
>
> Global indexes affect partition management. `DROP`, `TRUNCATE`, and `REORGANIZE PARTITION` operations also trigger updates to table-level global indexes, meaning that these DDL operations will only return results after the global indexes of the corresponding tables are fully updated.

```
CREATE TABLE t1 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    col3 INT NOT NULL,
    col4 INT NOT NULL,
    UNIQUE KEY uidx12(col1, col2) GLOBAL,
    UNIQUE KEY uidx3(col3)
)
PARTITION BY HASH(col3)
PARTITIONS 4;
```

In the preceding example, the unique index `uidx12` is a global index, while `uidx3` is a regular unique index.

Note that a **clustered index** cannot be a global index, as shown in the following example:

```
CREATE TABLE t2 (
    col1 INT NOT NULL,
    col2 DATE NOT NULL,
    PRIMARY KEY (col2) CLUSTERED GLOBAL
) PARTITION BY HASH(col1) PARTITIONS 5;
```

```
ERROR 1503 (HY000): A CLUSTERED INDEX must include all columns in the table'
    ↪ s partitioning function
```

The reason is that if the clustered index is a global index, the table will no longer be partitioned. This is because the key of the clustered index is also the record key at the partition level, but the global index is at the table level, which causes a conflict. If you need to set the primary key as a global index, you must explicitly define it as a non-clustered index, for example, `PRIMARY KEY(col1, col2)NONCLUSTERED GLOBAL`.

You can identify a global index by the `GLOBAL` index option in the `SHOW CREATE TABLE` output.

```
SHOW CREATE TABLE t1\G
```

```
       Table: t1
Create Table: CREATE TABLE `t1` (
  `col1` int NOT NULL,
  `col2` date NOT NULL,
  `col3` int NOT NULL,
  `col4` int NOT NULL,
  UNIQUE KEY `uidx12` (`col1`,`col2`) /*T![global_index] GLOBAL */,
  UNIQUE KEY `uidx3` (`col3`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
PARTITION BY HASH (`col3`) PARTITIONS 4
1 row in set (0.00 sec)
```

Alternatively, you can query the `INFORMATION_SCHEMA.TIDB_INDEXES` table and check the `IS_GLOBAL` column in the output.

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE table_name='t1';
```

```
+--------------+------------+------------+----------+--------------+-------------+------
    ↪
| TABLE_SCHEMA | TABLE_NAME | NON_UNIQUE | KEY_NAME | SEQ_IN_INDEX | COLUMN_
    ↪ NAME | SUB_PART | INDEX_COMMENT | Expression | INDEX_ID | IS_VISIBLE
    ↪ | CLUSTERED | IS_GLOBAL |
+--------------+------------+------------+----------+--------------+-------------+------
    ↪
```

```
| test        | t1        |          0 | uidx12 |           1 | col1       |
   ↪     NULL |             | NULL       |        1 | YES        | NO         |
   ↪         1 |
| test        | t1        |          0 | uidx12 |           2 | col2       |
   ↪     NULL |             | NULL       |        1 | YES        | NO         |
   ↪         1 |
| test        | t1        |          0 | uidx3  |           1 | col3       |
   ↪     NULL |             | NULL       |        2 | YES        | NO         |
   ↪         0 |
+--------------+-----------+------------+---------+-------------+------------+------
   ↪
3 rows in set (0.00 sec)
```

When partitioning a non-partitioned table or repartitioning an already partitioned table, you can update the indexes to be global indexes or revert them to local indexes as needed:

```
ALTER TABLE t1 PARTITION BY HASH (col1) PARTITIONS 3 UPDATE INDEXES (uidx12
   ↪  LOCAL, uidx3 GLOBAL);
```

Limitations of global indexes

- If the `GLOBAL` keyword is not explicitly specified in the index definition, TiDB creates a local index by default.
- The `GLOBAL` and `LOCAL` keywords only apply to partitioned tables and do not affect non-partitioned tables. In other words, there is no difference between a global index and a local index in non-partitioned tables.
- Currently, TiDB only supports creating unique global indexes on unique columns. If you need to create a global index on a non-unique column, you can include a primary key in the global index to create a composite index. For example, if the non-unique column is `col3` and the primary key is `col1`, you can use the following statement to create a global index on the non-unique column `col3`:

  ```
  ALTER TABLE ... ADD UNIQUE INDEX(col3, col1) GLOBAL;
  ```

- DDL operations such as `DROP PARTITION`, `TRUNCATE PARTITION`, and `REORGANIZE ↪ PARTITION` also trigger updates to global indexes. These DDL operations need to wait for the global index updates to complete before returning results, which increases the execution time accordingly. This is particularly evident in data archiving scenarios, such as `DROP PARTITION` and `TRUNCATE PARTITION`. Without global indexes, these operations can typically complete immediately. However, with global indexes, the execution time increases as the number of indexes that need to be updated grows.
- Tables with global indexes do not support the `EXCHANGE PARTITION` operation.

- By default, the primary key of a partitioned table is a clustered index and must include the partition key. If you require the primary key to exclude the partition key, you can explicitly specify the primary key as a non-clustered global index when creating the table, for example, `PRIMARY KEY(col1, col2)NONCLUSTERED GLOBAL`.
- If a global index is added to an expression column, or a global index is also a prefix index (for example `UNIQUE KEY idx_id_prefix (id(10))GLOBAL`), you need to collect statistics manually for this global index.

14.13.13.5.2 Partitioning limitations relating to functions

Only the functions shown in the following list are allowed in partitioning expressions:

```
ABS()
CEILING()
DATEDIFF()
DAY()
DAYOFMONTH()
DAYOFWEEK()
DAYOFYEAR()
EXTRACT() (see EXTRACT() function with WEEK specifier)
FLOOR()
HOUR()
MICROSECOND()
MINUTE()
MOD()
MONTH()
QUARTER()
SECOND()
TIME_TO_SEC()
TO_DAYS()
TO_SECONDS()
UNIX_TIMESTAMP() (with TIMESTAMP columns)
WEEKDAY()
YEAR()
YEARWEEK()
```

14.13.13.5.3 Compatibility with MySQL

Currently, TiDB supports Range partitioning, Range COLUMNS partitioning, List partitioning, List COLUMNS partitioning, Hash partitioning, and Key partitioning. Other partitioning types that are available in MySQL are not supported yet in TiDB.

For the unsupported partitioning types, when you create a table in TiDB, the partitioning information is ignored and the table is created in the regular form with a warning reported.

The `LOAD DATA` syntax does not support partition selection currently in TiDB.

```
create table t (id int, val int) partition by hash(id) partitions 4;
```

The regular `LOAD DATA` operation is supported:

```
load local data infile "xxx" into t ...
```

But `Load Data` does not support partition selection:

```
load local data infile "xxx" into t partition (p1)...
```

For a partitioned table, the result returned by `select * from t` is unordered between the partitions. This is different from the result in MySQL, which is ordered between the partitions but unordered inside the partitions.

```
create table t (id int, val int) partition by range (id) (
    partition p0 values less than (3),
    partition p1 values less than (7),
    partition p2 values less than (11));
```

```
Query OK, 0 rows affected (0.10 sec)
```

```
insert into t values (1, 2), (3, 4),(5, 6),(7,8),(9,10);
```

```
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0
```

TiDB returns a different result every time, for example:

```
select * from t;
```

```
+------|------+
| id   | val |
+------|------+
|    7 |    8 |
|    9 |   10 |
|    1 |    2 |
|    3 |    4 |
|    5 |    6 |
+------|------+
5 rows in set (0.00 sec)
```

The result returned in MySQL:

```
select * from t;
```

```
+------|------+
| id   | val  |
+------|------+
|    1 |    2 |
|    3 |    4 |
|    5 |    6 |
|    7 |    8 |
|    9 |   10 |
+------|------+
5 rows in set (0.00 sec)
```

14.13.13.5.4 Dynamic pruning mode

TiDB accesses partitioned tables in either `dynamic` or `static` mode. `dynamic` mode is used by default since v6.3.0. However, dynamic partitioning is effective only after the full table-level statistics, or global statistics, are collected. If you enable the `dynamic` pruning mode before global statistics collection is completed, TiDB remains in the `static` mode until global statistics are fully collected. For detailed information about global statistics, see Collect statistics of partitioned tables in dynamic pruning mode.

```
set @@session.tidb_partition_prune_mode = 'dynamic'
```

Manual ANALYZE and normal queries use the session-level `tidb_partition_prune_mode` setting. The `auto-analyze` operation in the background uses the global `tidb_partition_prune_mode` setting.

In `static` mode, partitioned tables use partition-level statistics. In `dynamic` mode, partitioned tables use table-level global statistics.

When switching from `static` mode to `dynamic` mode, you need to check and collect statistics manually. This is because after the switch to `dynamic` mode, partitioned tables have only partition-level statistics but no table-level statistics. Global statistics are collected only upon the next `auto-analyze` operation.

```
set session tidb_partition_prune_mode = 'dynamic';
show stats_meta where table_name like "t";
```

```
+---------+------------+----------------+---------------------+--------------+----------
   ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_
   ↪ count |
+---------+------------+----------------+---------------------+--------------+----------
   ↪
| test    | t          | p0             | 2022-05-27 20:23:34 |            1 |
   ↪            2 |
```

```
| test   | t         | p1            | 2022-05-27 20:23:34 |        2 |
   ↪        4 |
| test   | t         | p2            | 2022-05-27 20:23:34 |        2 |
   ↪        4 |
+--------+-----------+---------------+---------------------+----------+---------
   ↪
3 rows in set (0.01 sec)
```

To make sure that the statistics used by SQL statements are correct after you enable global `dynamic` pruning mode, you need to manually trigger `analyze` on the tables or on a partition of the table to obtain global statistics.

```
analyze table t partition p1;
show stats_meta where table_name like "t";
```

```
+--------+-----------+---------------+---------------------+-------------+---------
   ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_
   ↪ count |
+--------+-----------+---------------+---------------------+-------------+---------
   ↪
| test   | t         | global        | 2022-05-27 20:50:53 |        0 |
   ↪        5 |
| test   | t         | p0            | 2022-05-27 20:23:34 |        1 |
   ↪        2 |
| test   | t         | p1            | 2022-05-27 20:50:52 |        0 |
   ↪        2 |
| test   | t         | p2            | 2022-05-27 20:50:08 |        0 |
   ↪        2 |
+--------+-----------+---------------+---------------------+-------------+---------
   ↪
4 rows in set (0.00 sec)
```

If the following warning is displayed during the `analyze` process, partition statistics are inconsistent, and you need to collect statistics of these partitions or the entire table again.

```
| Warning | 8244 | Build table: `t` column: `a` global-level stats failed
   ↪ due to missing partition-level column stats, please run analyze table
   ↪  to refresh columns of all partitions
```

You can also use scripts to update statistics of all partitioned tables. For details, see Update statistics of partitioned tables in dynamic pruning mode.

After table-level statistics are ready, you can enable the global dynamic pruning mode, which is effective to all SQL statements and `auto-analyze` operations.

```
set global tidb_partition_prune_mode = dynamic
```

In `static` mode, TiDB accesses each partition separately using multiple operators, and then merges the results using `Union`. The following example is a simple read operation where TiDB merges the results of two corresponding partitions using `Union`:

```
mysql> create table t1(id int, age int, key(id)) partition by range(id) (
       partition p0 values less than (100),
       partition p1 values less than (200),
       partition p2 values less than (300),
       partition p3 values less than (400));
Query OK, 0 rows affected (0.01 sec)

mysql> explain select * from t1 where id < 150;
```

```
+-----------------------------+----------+-----------+-----------------------+--------
   ↪
| id                          | estRows | task    | access object       |
   ↪ operator info              |
+-----------------------------+----------+-----------+-----------------------+--------
   ↪
| PartitionUnion_9            | 6646.67 | root    |                       |
   ↪                             |
|  ─TableReader_12            | 3323.33 | root    |                       | data
   ↪ :Selection_11             |
|    ─Selection_11            | 3323.33 | cop[tikv] |                     | lt(
   ↪ test.t1.id, 150)          |
|      ─TableFullScan_10      | 10000.00 | cop[tikv] | table:t1, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_18            | 3323.33 | root    |                       | data
   ↪ :Selection_17             |
|    ─Selection_17            | 3323.33 | cop[tikv] |                     | lt(
   ↪ test.t1.id, 150)          |
|      ─TableFullScan_16      | 10000.00 | cop[tikv] | table:t1, partition:p1
   ↪ | keep order:false, stats:pseudo |
+-----------------------------+----------+-----------+-----------------------+--------
   ↪
7 rows in set (0.00 sec)
```

In `dynamic` mode, each operator supports direct access to multiple partitions, so TiDB no longer uses `Union`.

```
mysql> set @@session.tidb_partition_prune_mode = 'dynamic';
Query OK, 0 rows affected (0.00 sec)

mysql> explain select * from t1 where id < 150;
+--
   ↪ ----------------------+----------+-----------+----------------+--------------
```

```
    ↪
| id                    | estRows | task     | access object | operator info
    ↪              |
+--
    ↪ ----------------------+---------+----------+---------------+-------------
    ↪
| TableReader_7         | 3323.33 | root     | partition:p0,p1 | data:
    ↪ Selection_6         |
|  ─Selection_6         | 3323.33 | cop[tikv] |               | lt(test.t1.id,
    ↪  150)        |
|    ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t1    | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+---------------+-------------
    ↪
3 rows in set (0.00 sec)
```

From the above query results, you can see that the `Union` operator in the execution plan disappears while the partition pruning still takes effect and the execution plan only accesses `p0` and `p1`.

`dynamic` mode makes execution plans simpler and clearer. Omitting the Union operation can improve the execution efficiency and avoid the problem of Union concurrent execution. In addition, `dynamic` mode also allows execution plans with IndexJoin which cannot be used in `static` mode. (See examples below)

Example 1: In the following example, a query is performed in `static` mode using the execution plan with IndexJoin:

```
mysql> create table t1 (id int, age int, key(id)) partition by range(id)
    (partition p0 values less than (100),
     partition p1 values less than (200),
     partition p2 values less than (300),
     partition p3 values less than (400));
Query OK, 0 rows affected (0,08 sec)

mysql> create table t2 (id int, code int);
Query OK, 0 rows affected (0.01 sec)

mysql> set @@tidb_partition_prune_mode = 'static';
Query OK, 0 rows affected, 1 warning (0.00 sec)

mysql> explain select /*+ TIDB_INLJ(t1, t2) */ t1.* from t1, t2 where t2.
    ↪ code = 0 and t2.id = t1.id;
+--

   ↪ data:Selection_35                            |
|      ─Selection_35          | 9990.00 | cop[tikv] |                    |
   ↪ not(isnull(test.t1.id))                      |
|        ─TableFullScan_34    | 10000.00 | cop[tikv] | table:t1, partition:
   ↪ p3 | keep order:false, stats:pseudo     |
+--
   ↪ ----------------------------+---------+----------+---------------------+-
   ↪
17 rows in set, 1 warning (0.00 sec)

mysql> show warnings;
```

```
+--
    ↪ -------+------+-------------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                                |
+--
    ↪ -------+------+-------------------------------------------------------------------
    ↪
| Warning | 1815 | Optimizer Hint /*+ INL_JOIN(t1, t2) */ or /*+ TIDB_INLJ(
    ↪ t1, t2) */ is inapplicable |
+--
    ↪ -------+------+-------------------------------------------------------------------
    ↪
1 row in set (0,00 sec)
```

From example 1, you can see that even if the `TIDB_INLJ` hint is used, the query on the partitioned table cannot select the execution plan with IndexJoin.

Example 2: In the following example, the query is performed in `dynamic` mode using the execution plan with IndexJoin:

```
mysql> set @@tidb_partition_prune_mode = 'dynamic';
Query OK, 0 rows affected (0.00 sec)

    ↪
8 rows in set (0.00 sec)
```

From example 2, you can see that in `dynamic` mode, the execution plan with IndexJoin is selected when you execute the query.

Currently, `static` pruning mode does not support plan cache for both prepared and non-prepared statements.

Update statistics of partitioned tables in dynamic pruning mode

1. Locate all partitioned tables:

```
SELECT DISTINCT CONCAT(TABLE_SCHEMA,'.', TABLE_NAME)
    FROM information_schema.PARTITIONS
    WHERE TIDB_PARTITION_ID IS NOT NULL
    AND TABLE_SCHEMA NOT IN ('INFORMATION_SCHEMA', 'mysql', 'sys', '
        ↪ PERFORMANCE_SCHEMA', 'METRICS_SCHEMA');
```

```
+-------------------------------------+
| concat(TABLE_SCHEMA,'.',TABLE_NAME) |
+-------------------------------------+
| test.t                              |
+-------------------------------------+
1 row in set (0.02 sec)
```

2. Generate the statements for updating the statistics of all partitioned tables:

```
SELECT DISTINCT CONCAT('ANALYZE TABLE ',TABLE_SCHEMA,'.',TABLE_NAME,'
    ↪ ALL COLUMNS;')
    FROM information_schema.PARTITIONS
    WHERE TIDB_PARTITION_ID IS NOT NULL
    AND TABLE_SCHEMA NOT IN ('INFORMATION_SCHEMA','mysql','sys','
        ↪ PERFORMANCE_SCHEMA','METRICS_SCHEMA');
```

```
+-----------------------------------------------------------------------+
    ↪
| concat('ANALYZE TABLE ',TABLE_SCHEMA,'.',TABLE_NAME,' ALL COLUMNS;')
    ↪ |
+-----------------------------------------------------------------------+
    ↪
| ANALYZE TABLE test.t ALL COLUMNS;                                     |
+-----------------------------------------------------------------------+
    ↪
1 row in set (0.01 sec)
```

You can change `ALL COLUMNS` to the columns you need.

3. Export the batch update statements to a file:

```
mysql --host xxxx --port xxxx -u root -p -e "SELECT DISTINCT CONCAT('
    ↪ ANALYZE TABLE ',TABLE_SCHEMA,'.',TABLE_NAME,' ALL COLUMNS;') \
    FROM information_schema.PARTITIONS \
    WHERE TIDB_PARTITION_ID IS NOT NULL \
    AND TABLE_SCHEMA NOT IN ('INFORMATION_SCHEMA','mysql','sys','
        ↪ PERFORMANCE_SCHEMA','METRICS_SCHEMA');" | tee
        ↪ gatherGlobalStats.sql
```

4. Execute a batch update:

   Process SQL statements before executing the `source` command:

```
sed -i "" '1d' gatherGlobalStats.sql --- mac
sed -i '1d' gatherGlobalStats.sql --- linux
```

```
SET session tidb_partition_prune_mode = dynamic;
source gatherGlobalStats.sql
```

14.13.14 Temporary Tables

The temporary tables feature is introduced in TiDB v5.3.0. This feature solves the issue of temporarily storing the intermediate results of an application, which frees you from

frequently creating and dropping tables. You can store the intermediate calculation data in temporary tables. When the intermediate data is no longer needed, TiDB automatically cleans up and recycles the temporary tables. This avoids user applications being too complicated, reduces table management overhead, and improves performance.

This document introduces the user scenarios and the types of temporary tables, provides usage examples and instruction on how to limit the memory usage of temporary tables, and explains compatibility restrictions with other TiDB features.

14.13.14.1 User scenarios

You can use TiDB temporary tables in the following scenarios:

- Cache the intermediate temporary data of an application. After the calculation is completed, the data is dumped to the ordinary table, and the temporary table is automatically released.
- Perform multiple DML operations on the same data in a short period of time. For example, in an e-commerce shopping cart application, add, modify, and delete products, complete the payment, and remove the shopping cart information.
- Quickly import intermediate temporary data in batches to improve the performance of importing temporary data.
- Update data in batches. Import data into temporary tables in the database in batches, and export the data to files after finishing modify the data.

14.13.14.2 Types of temporary tables

Temporary tables in TiDB are divided into two types: local temporary tables and global temporary tables.

- For a local temporary table, the table definition and data in the table are visible only to the current session. This type is suitable for temporarily storing intermediate data in the session.
- For a global temporary table, the table definition is visible to the entire TiDB cluster, and the data in the table is visible only to the current transaction. This type is suitable for temporarily storing intermediate data in the transaction.

14.13.14.3 Local temporary tables

The semantics of the local temporary table in TiDB is consistent with that of the MySQL temporary table. The characteristics are as follows:

- The table definition of a local temporary table is not persistent. A local temporary table is visible only to the session in which the table is created, and other sessions cannot access the table.

- You can create local temporary tables with the same name in different sessions, and each session reads only from and writes only to the local temporary table created in the session.
- The data of a local temporary table is visible to all transactions in the session.
- After a session ends, the local temporary table created in the session is automatically dropped.
- A local temporary table can have the same name as an ordinary table. In this case, in the DDL and DML statements, the ordinary table is hidden until the local temporary table is dropped.

To create a local temporary table, you can use the `CREATE TEMPORARY TABLE` statement. To drop a local temporary table, you can use the `DROP TABLE` or `DROP TEMPORARY TABLE` statement.

Different from MySQL, the local temporary tables in TiDB are all external tables, and no internal temporary tables will be created automatically when SQL statements are executed.

14.13.14.3.1 Usage examples of local temporary tables

Note:

- Before you use the temporary table in TiDB, pay attention to the compatibility restrictions with other TiDB features and the compatibility with MySQL temporary tables.
- If you have created local temporary tables on a cluster earlier than TiDB v5.3.0, these tables are actually ordinary tables, and treated as ordinary tables after the cluster is upgraded to TiDB v5.3.0 or a later version.

Assume that there is an ordinary table `users`:

```
CREATE TABLE users (
    id BIGINT,
    name VARCHAR(100),
    PRIMARY KEY(id)
);
```

In session A, creating a local temporary table `users` does not conflict with the ordinary table `users`. When session A accesses the `users` table, it accesses the local temporary table `users`.

```
CREATE TEMPORARY TABLE users (
    id BIGINT,
    name VARCHAR(100),
```

```
    city VARCHAR(50),
    PRIMARY KEY(id)
);
```

```
Query OK, 0 rows affected (0.01 sec)
```

If you insert data into `users`, data is inserted to the local temporary table `users` in session A.

```
INSERT INTO users(id, name, city) VALUES(1001, 'Davis', 'LosAngeles');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT * FROM users;
```

```
+------+-------+------------+
| id   | name | city       |
+------+-------+------------+
| 1001 | Davis | LosAngeles |
+------+-------+------------+
1 row in set (0.00 sec)
```

In session B, creating a local temporary table `users` does not conflict with the ordinary table `users` or the local temporary table `users` in session A. When session B accesses the `users` table, it accesses the local temporary table `users` in session B.

```
CREATE TEMPORARY TABLE users (
    id BIGINT,
    name VARCHAR(100),
    city VARCHAR(50),
    PRIMARY KEY(id)
);
```

```
Query OK, 0 rows affected (0.01 sec)
```

If you insert data into `users`, data is inserted to the local temporary table `users` in session B.

```
INSERT INTO users(id, name, city) VALUES(1001, 'James', 'NewYork');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT * FROM users;
```

```
+------+-------+---------+
| id   | name | city    |
+------+-------+---------+
| 1001 | James | NewYork |
+------+-------+---------+
1 row in set (0.00 sec)
```

14.13.14.3.2 Compatibility with MySQL temporary tables

The following features and limitations of TiDB local temporary tables are the same with those of MySQL temporary tables:

- When you create or drop local temporary tables, the current transaction is not automatically committed.
- After dropping the schema where a local temporary table is located, the temporary table is not dropped and is still readable and writable.
- Creating a local temporary table requires the `CREATE TEMPORARY TABLES` permission. All subsequent operations on the table do not require any permission.
- Local temporary tables do not support foreign keys and partitioned tables.
- Does not support creating views based on local temporary tables.
- `SHOW [FULL] TABLES` does not show local temporary tables.

Local temporary tables in TiDB are incompatible with MySQL temporary tables in the following aspects:

- TiDB local temporary tables do not support `ALTER TABLE`.
- TiDB local temporary tables ignore the `ENGINE` table option, and always store temporary table data in TiDB memory with a memory limit.
- When `MEMORY` is declared as the storage engine, TiDB local temporary tables are not restricted by the `MEMORY` storage engine.
- When `INNODB` or `MYISAM` is declared as the storage engine, TiDB local temporary tables ignore the system variables specific to the InnoDB temporary tables.
- MySQL does not permit referencing to the same temporary table multiple times in the same SQL statement. TiDB local temporary tables do not have this restriction.
- The system table `information_schema.INNODB_TEMP_TABLE_INFO` that shows temporary tables in MySQL does not exist in TiDB. Currently, TiDB does not have a system table that shows local temporary tables.
- TiDB does not have internal temporary tables. The MySQL system variables for internal temporary tables do not take effect for TiDB.

14.13.14.4 Global temporary tables

The global temporary table is an extension of TiDB. The characteristics are as follows:

- The table definition of a global temporary table is persistent and visible to all sessions.
- The data of a global temporary table is visible only in the current transaction. When the transaction ends, the data is automatically cleared.
- A global temporary table cannot have the same name as an ordinary table.

To create a global temporary table, you can use the `CREATE GLOBAL TEMPORARY TABLE` statement ended with `ON COMMIT DELETE ROWS`. To drop a global temporary table, you can use the `DROP TABLE` or `DROP GLOBAL TEMPORARY TABLE` statement.

14.13.14.4.1 Usage examples of global temporary tables

> **Note:**
>
> - Before you use the temporary table in TiDB, pay attention to the compatibility restrictions with other TiDB features.
> - If you have created global temporary tables on a TiDB cluster of v5.3.0 or later, when the cluster is downgraded to a version earlier than v5.3.0, these tables are handled as ordinary tables. In this case, a data error occurs.

Create a global temporary table `users` in session A:

```
CREATE GLOBAL TEMPORARY TABLE users (
    id BIGINT,
    name VARCHAR(100),
    city VARCHAR(50),
    PRIMARY KEY(id)
) ON COMMIT DELETE ROWS;
```

```
Query OK, 0 rows affected (0.01 sec)
```

The data written to `users` is visible to the current transaction:

```
BEGIN;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
INSERT INTO users(id, name, city) VALUES(1001, 'Davis', 'LosAngeles');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT * FROM users;
```

```
+------+-------+------------+
| id   | name | city       |
+------+-------+------------+
| 1001 | Davis | LosAngeles |
+------+-------+------------+
1 row in set (0.00 sec)
```

After the transaction ends, the data is automatically cleared:

```
COMMIT;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT * FROM users;
```

```
Empty set (0.00 sec)
```

After `users` is created in session A, session B can also read from and write to the `users` table:

```
SELECT * FROM users;
```

```
Empty set (0.00 sec)
```

> **Note:**
>
> If the transaction is automatically committed, after the SQL statement is executed, the inserted data is automatically cleared and unavailable to subsequent SQL executions. Therefore, you should use non-autocommit transactions to read from and write to global temporary tables.

14.13.14.5 Limit the memory usage of temporary tables

No matter which storage engine is declared as `ENGINE` when you define a table, the data of local temporary tables and global temporary tables is only stored in the memory of TiDB instances. This data is not persisted.

To avoid memory overflow, you can limit the size of each temporary table using the `tidb_tmp_table_max_size` system variable. Once a temporary table is larger than the

`tidb_tmp_table_max_size` threshold value, TiDB reports an error. The default value of `tidb_tmp_table_max_size` is `64MB`.

For example, set the maximum size of a temporary table to `256MB`:

```
SET GLOBAL tidb_tmp_table_max_size=268435456;
```

14.13.14.6 Compatibility restrictions with other TiDB features

Local temporary tables and global temporary tables in TiDB are **NOT** compatible with the following TiDB features:

- `AUTO_RANDOM` columns
- `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` table options
- Partitioned tables
- `SPLIT REGION` statements
- `ADMIN CHECK TABLE` and `ADMIN CHECKSUM TABLE` statements
- `FLASHBACK TABLE` and `RECOVER TABLE` statements
- Executing `CREATE TABLE LIKE` statements based on a temporary table
- Stale Read
- Foreign keys
- SQL bindings
- TiFlash replicas
- Creating views on a temporary table
- Placement Rules
- Execution plans involving a temporary table are not cached by `prepare plan cache`.

Local temporary tables in TiDB do **NOT** support the following feature:

- Reading historical data using the `tidb_snapshot` system variable.

14.13.14.7 TiDB migration tool support

Local temporary tables are not exported, backed up or replicated by TiDB migration tools, because these tables are visible only to the current session.

Global temporary tables are exported, backed up, and replicated by TiDB migration tools, because the table definition is globally visible. Note that the data on the tables are not exported.

Note:

- Replicating temporary tables using TiCDC requires TiCDC v5.3.0 or later. Otherwise, the table definition of the downstream table is wrong.

- Backing up temporary tables using BR requires BR v5.3.0 or later. Otherwise, the table definitions of the backed temporary tables are wrong.
- The cluster to export, the cluster after data restore, and the downstream cluster of a replication should support global temporary tables. Otherwise, an error is reported.

14.13.14.8 See also

- CREATE TABLE
- CREATE TABLE LIKE
- DROP TABLE

14.13.15 Cached Tables

In v6.0.0, TiDB introduces the cached table feature for frequently accessed but rarely updated small hotspot tables. When this feature is used, the data of an entire table is loaded into the memory of the TiDB server, and TiDB directly gets the table data from the memory without accessing TiKV, which improves the read performance.

This document describes the usage scenarios of cached tables, the examples, and the compatibility restrictions with other TiDB features.

14.13.15.1 Usage scenarios

The cached table feature is suitable for tables with the following characteristics:

- The data volume of the table is small, for example, less than 4 MiB.
- The table is read-only or rarely updated, for example, with a write QPS (queries per second) of less than 10 times per minute.
- The table is frequently accessed, and you expect a better read performance, for example, when encountering hotspots on small tables during direct reads from TiKV.

When the data volume of the table is small but the data is frequently accessed, the data is concentrated on a Region in TiKV and makes it a hotspot Region, which affects the performance. Therefore, the typical usage scenarios of cached tables are as follows:

- Configuration tables, from which applications read the configuration information.
- The tables of exchange rates in the financial sector. These tables are updated only once a day but not in real-time.
- Bank branch or network information tables, which are rarely updated.

Take configuration tables as an example. When the application restarts, the configuration information is loaded in all connections, which causes a high read latency. In this case, you can solve this problem by using the cached tables feature.

14.13.15.2 Examples

This section describes the usage of cached tables by examples.

14.13.15.2.1 Set a normal table to a cached table

Suppose that there is a table `users`:

```
CREATE TABLE users (
    id BIGINT,
    name VARCHAR(100),
    PRIMARY KEY(id)
);
```

To set this table to a cached table, use the `ALTER TABLE` statement:

```
ALTER TABLE users CACHE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

14.13.15.2.2 Verify a cached table

To verify a cached table, use the `SHOW CREATE TABLE` statement. If the table is cached, the returned result contains the `CACHED ON` attribute:

```
SHOW CREATE TABLE users;
```

```
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
| users | CREATE TABLE `users` (
  `id` bigint NOT NULL,
  `name` varchar(100) DEFAULT NULL,
  PRIMARY KEY (`id`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin /* CACHED ON */
    ↪  |
+--
    ↪ -----+-----------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

After reading data from a cached table, TiDB loads the data in memory. You can use the TRACE statement to check whether the data is loaded into memory. When the cache is not loaded, the returned result contains the `regionRequest.SendReqCtx` attribute, which indicates that TiDB reads data from TiKV.

```
TRACE SELECT * FROM users;
```

```
+--
    ↪ ----------------------------------------------+-----------------+------------+
    ↪
| operation                                     | startTS       | duration  |
+--
    ↪ ----------------------------------------------+-----------------+------------+
    ↪
| trace                                         | 17:47:39.969980 | 827.73µs  |
|    ─session.ExecuteStmt                       | 17:47:39.969986 | 413.31µs  |
|      ─executor.Compile                        | 17:47:39.969993 | 198.29µs  |
|      ─session.runStmt                         | 17:47:39.970221 | 157.252µs |
|        ─TableReaderExecutor.Open              | 17:47:39.970294 | 47.068µs  |
|          ─distsql.Select                      | 17:47:39.970312 | 24.729µs  |
|            ─regionRequest.SendReqCtx          | 17:47:39.970454 | 189.601µs |
|    ─* executor.UnionScanExec.Next             | 17:47:39.970407 | 353.073µs |
|      ─* executor.TableReaderExecutor.Next     | 17:47:39.970411 | 301.106µs |
|      ─* executor.TableReaderExecutor.Next     | 17:47:39.970746 | 6.57µs    |
|    ─* executor.UnionScanExec.Next             | 17:47:39.970772 | 17.589µs  |
|      ─* executor.TableReaderExecutor.Next     | 17:47:39.970776 | 6.59µs    |
+--
    ↪ ----------------------------------------------+-----------------+------------+
    ↪
12 rows in set (0.01 sec)
```

After executing TRACE again, the returned result no longer contains the `regionRequest ↪ .SendReqCtx` attribute, which indicates that TiDB no longer reads data from TiKV but reads data from the memory instead.

```
+-----------------------------------------+-----------------+-----------+
| operation                               | startTS         | duration  |
+-----------------------------------------+-----------------+-----------+
| trace                                   | 17:47:40.533888 | 453.547µs |
|    ─session.ExecuteStmt                 | 17:47:40.533894 | 402.341µs |
|      ─executor.Compile                  | 17:47:40.533903 | 205.54µs  |
|      ─session.runStmt                   | 17:47:40.534141 | 132.084µs |
|        ─TableReaderExecutor.Open        | 17:47:40.534202 | 14.749µs  |
|    ─* executor.UnionScanExec.Next       | 17:47:40.534306 | 3.21µs    |
|    ─* executor.UnionScanExec.Next       | 17:47:40.534316 | 1.219µs   |
+-----------------------------------------+-----------------+-----------+
```

```
7 rows in set (0.00 sec)
```

Note that the `UnionScan` operator is used to read the cached tables, so you can see `UnionScan` in the execution plan of the cached tables through `explain`:

```
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪            |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
| UnionScan_5           | 1.00    | root     |               |
    ↪                               |
|  ─TableReader_7       | 1.00    | root     |               | data:
    ↪ TableFullScan_6       |
|    ─TableFullScan_6   | 1.00    | cop[tikv] | table:users | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+--------------+-----------------
    ↪
3 rows in set (0.00 sec)
```

14.13.15.2.3 Write data to a cached table

Cached tables support data writes. For example, you can insert a record into the `users` table:

```
INSERT INTO users(id, name) VALUES(1001, 'Davis');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
SELECT * FROM users;
```

```
+------+-------+
| id   | name |
+------+-------+
| 1001 | Davis |
+------+-------+
1 row in set (0.00 sec)
```

Note:

When you insert data to a cached table, second-level write latency might occur. The latency is controlled by the global environment variable `tidb_table_cache_lease`. You can decide whether to use the cached table feature by checking whether the latency is acceptable based on your application. For example, in a read-only scenario, you can increase the value of `tidb_table_cache_lease`:

```
set @@global.tidb_table_cache_lease = 10;
```

The write latency of cached tables is high, because the cached table feature is implemented with a complex mechanism that requires a lease to be set for each cache. When there are multiple TiDB instances, one instance does not know whether the other instances have cached data. If an instance modifies the table data directly, the other instances read the old cache data. To ensure correctness, the cached table implementation uses a lease mechanism to ensure that the data is not modified before the lease expires. That is why the write latency is high.

The metadata of cached tables is stored in the `mysql.table_cache_meta` table. This table records the IDs of all cached tables, the current lock status (`lock_type`), and the lock lease information (`lease`). This table is only internally used in TiDB and you are not recommended to modify it. Otherwise, unexpected errors might occur.

```
SHOW CREATE TABLE mysql.table_cache_meta\G
*************************** 1. row ***************************
       Table: table_cache_meta
Create Table: CREATE TABLE `table_cache_meta` (
  `tid` bigint NOT NULL DEFAULT '0',
  `lock_type` enum('NONE','READ','INTEND','WRITE') NOT NULL DEFAULT 'NONE',
  `lease` bigint NOT NULL DEFAULT '0',
  `oldReadLease` bigint NOT NULL DEFAULT '0',
  PRIMARY KEY (`tid`) /*T![clustered_index] CLUSTERED */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
1 row in set (0.00 sec)
```

14.13.15.2.4 Revert a cached table to a normal table

Note:

> Executing DDL statements on a cached table will fail. Before executing DDL statements on a cached table, you need to remove the cache attribute first and set the cached table back to a normal table.

```
TRUNCATE TABLE users;
```

```
ERROR 8242 (HY000): 'Truncate Table' is unsupported on cache tables.
```

```
mysql> ALTER TABLE users ADD INDEX k_id(id);
```

```
ERROR 8242 (HY000): 'Alter Table' is unsupported on cache tables.
```

To revert a cached table to a normal table, use `ALTER TABLE t NOCACHE`:

```
ALTER TABLE users NOCACHE;
```

```
Query OK, 0 rows affected (0.00 sec)
```

14.13.15.3 Size limit of cached tables

Cached tables are only suitable for scenarios with small tables, because TiDB loads the data of an entire table into memory, and the cached data becomes invalid after modification and needs to be reloaded.

Currently, the size limit of a cached table is 64 MiB in TiDB. If the table data exceeds 64 MiB, executing `ALTER TABLE t CACHE` will fail.

14.13.15.4 Compatibility restrictions with other TiDB features

Cached tables **DO NOT** support the following features:

- Performing the `ALTER TABLE t ADD PARTITION` operation on partitioned tables is not supported.
- Performing the `ALTER TABLE t CACHE` operation on temporary tables is not supported.
- Performing the `ALTER TABLE t CACHE` operation on views is not supported.
- Stale Read is not supported.
- Direct DDL operations on a cached table are not supported. You need to set the cached table back to a normal table first by using `ALTER TABLE t NOCACHE` before performing DDL operations.

Cached tables **CANNOT** be used in the following scenarios:

- Setting the system variable `tidb_snapshot` to read historical data.
- During modification, the cached data becomes invalid until the data is reloaded.

14.13.15.5 Compatibility with TiDB migration tools

The cached table is a TiDB extension to MySQL syntax. Only TiDB can recognize the `ALTER TABLE ... CACHE` statement. TiDB migration tools **DO NOT** support cached tables, including Backup & Restore (BR), TiCDC, and Dumpling. These tools treat cached tables as normal tables.

That is to say, when a cached table is backed up and restored, it becomes a normal table. If the downstream cluster is a different TiDB cluster and you want to continue using the cached table feature, you can manually enable cached tables on the downstream cluster by executing `ALTER TABLE ... CACHE` on the downstream table.

14.13.16 FOREIGN KEY Constraints

Foreign keys allow cross-table references of related data, while foreign key constraints ensure the consistency of related data. Starting from v6.6.0, TiDB supports foreign keys and foreign key constraints. Starting from v8.5.0, this feature becomes generally available.

> **Warning:**
>
> The foreign key feature is typically employed to enforce referential integrity constraint checks. It might cause performance degradation, so it is recommended to conduct thorough testing before using it in performance-sensitive scenarios.

The foreign key is defined in the child table. The syntax is as follows:

```
ForeignKeyDef
        ::= ( 'CONSTRAINT' Identifier )? 'FOREIGN' 'KEY'
            Identifier? '(' ColumnName ( ',' ColumnName )* ')'
            'REFERENCES' TableName '(' ColumnName ( ',' ColumnName )* ')'
            ( 'ON' 'DELETE' ReferenceOption )?
            ( 'ON' 'UPDATE' ReferenceOption )?

ReferenceOption
        ::= 'RESTRICT'
          | 'CASCADE'
          | 'SET' 'NULL'
```

```
        | 'SET' 'DEFAULT'
        | 'NO' 'ACTION'
```

14.13.16.1 Naming

The naming of a foreign key follows the following rules:

- If a name is specified in `CONSTRAINT identifier`, the specified name is used.
- If no name is specified in `CONSTRAINT identifier`, but a name is specified in `FOREIGN KEY identifier`, the name specified in the `FOREIGN KEY identifier` is used.
- If neither `CONSTRAINT identifier` nor `FOREIGN KEY identifier` specifies a name, a name is automatically generated, such as `fk_1`, `fk_2`, and `fk_3`.
- The foreign key name must be unique in the current table. Otherwise, an error `ERROR 1826: Duplicate foreign key constraint name 'fk'` is reported when the foreign key is created.

14.13.16.2 Restrictions

When creating a foreign key, the following conditions must be met:

- Neither the parent table nor the child table is a temporary table.
- The user has the `REFERENCES` privilege on the parent table.
- The columns referenced by the foreign key in the parent table and the child table are of the same data type and have the same size, precision, length, character set, and collation.
- The columns in the foreign key cannot reference themselves.
- The columns in the foreign key and the columns in the referenced parent table have the same index, and the order of the columns in the index matches that in the foreign key. This is to use the index to avoid full table scans when performing foreign key constraint checks.
    - If there is no corresponding foreign key index in the parent table, an error `ERROR 1822: Failed to add the foreign key constraint. Missing index for constraint 'fk' in the referenced table 't'` is reported.
    - If there is no corresponding foreign key index in the child table, an index is automatically created with the same name as the foreign key.
- It is not supported to create a foreign key on a column of the `BLOB` or `TEXT` type.
- It is not supported to create a foreign key on a partitioned table.
- It is not supported to create a foreign key on a virtual generated column.

14.13.16.3 Reference operations

If an `UPDATE` or `DELETE` operation affects a foreign key value in the parent table, the corresponding foreign key value in the child table is determined by the reference operation defined by the `ON UPDATE` or `ON DELETE` clause in the foreign key definition. The reference operations include the following:

- `CASCADE`: automatically updates or deletes the matching rows in the child table when the `UPDATE` or `DELETE` operation affects the parent table. The cascade operation is performed in a depth-first manner.
- `SET NULL`: automatically sets the matching foreign key columns in the child table to `NULL` when the `UPDATE` or `DELETE` operation affects the parent table.
- `RESTRICT`: denies the `UPDATE` or `DELETE` operation if the child table contains matching rows.
- `NO ACTION`: the same as `RESTRICT`.
- `SET DEFAULT`: the same as `RESTRICT`.

If there is no matching foreign key value in the parent table, the `INSERT` or `UPDATE` operation on the child table is denied.

If the foreign key definition does not specify `ON DELETE` or `ON UPDATE`, the default behavior is `NO ACTION`.

If the foreign key is defined on a `STORED GENERATED COLUMN`, the `CASCADE`, `SET NULL`, and `SET DEFAULT` references are not supported.

14.13.16.4 Usage examples of foreign keys

The following example uses a single-column foreign key to associate the parent table and the child table:

```
CREATE TABLE parent (
    id INT KEY
);

CREATE TABLE child (
    id INT,
    pid INT,
    INDEX idx_pid (pid),
    FOREIGN KEY (pid) REFERENCES parent(id) ON DELETE CASCADE
);
```

The following is a more complex example where the `product_order` table has two foreign keys that reference the other two tables. One foreign key references two indexes on the `product` table, and the other references a single index on the `customer` table:

```
CREATE TABLE product (
    category INT NOT NULL,
    id INT NOT NULL,
    price DECIMAL(20,10),
    PRIMARY KEY(category, id)
);

CREATE TABLE customer (
    id INT KEY
);

CREATE TABLE product_order (
    id INT NOT NULL AUTO_INCREMENT,
    product_category INT NOT NULL,
    product_id INT NOT NULL,
    customer_id INT NOT NULL,

    PRIMARY KEY(id),
    INDEX (product_category, product_id),
    INDEX (customer_id),

    FOREIGN KEY (product_category, product_id)
      REFERENCES product(category, id)
      ON UPDATE CASCADE ON DELETE RESTRICT,

    FOREIGN KEY (customer_id)
      REFERENCES customer(id)
);
```

14.13.16.5 Create a foreign key constraint

To create a foreign key constraint, you can use the following `ALTER TABLE` statement:

```
ALTER TABLE table_name
    ADD [CONSTRAINT [identifier]] FOREIGN KEY
    [identifier] (col_name, ...)
    REFERENCES tbl_name (col_name,...)
    [ON DELETE reference_option]
    [ON UPDATE reference_option]
```

The foreign key can be self-referencing, that is, referencing the same table. When you add a foreign key constraint to a table using `ALTER TABLE`, you need to first create an index on the parent table column that the foreign key references.

14.13.16.6 Delete a foreign key constraint

To delete a foreign key constraint, you can use the following `ALTER TABLE` statement:

```
ALTER TABLE table_name DROP FOREIGN KEY fk_identifier;
```

If the foreign key constraint is named when it is created, you can reference the name to delete the foreign key constraint. Otherwise, you have to use the constraint name automatically generated to delete the constraint. You can use `SHOW CREATE TABLE` to view the foreign key name:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
       Table: child
Create Table: CREATE TABLE `child` (
  `id` int DEFAULT NULL,
  `pid` int DEFAULT NULL,
  KEY `idx_pid` (`pid`),
  CONSTRAINT `fk_1` FOREIGN KEY (`pid`) REFERENCES `test`.`parent` (`id`)
    ↪ ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

14.13.16.7 Foreign key constraint check

TiDB supports foreign key constraint check, which is controlled by the system variable `foreign_key_checks`. By default, this variable is set to `ON`, meaning that the foreign key constraint check is enabled. This variable has two scopes: `GLOBAL` and `SESSION`. Keeping this variable enabled can ensure the integrity of foreign key reference relationships.

The effect of disabling foreign key constraint check is as follows:

- When you delete a parent table referenced by a foreign key, the deletion can succeed only when the foreign key constraint check is disabled.
- When you import data to a database, the order of creating tables might be different from the foreign key dependency order, which might cause the creation of tables to fail. Only when the foreign key constraint check is disabled can the tables be created successfully. In addition, disabling the foreign key constraint check can speed up data import.
- When you import data to a database, if the data of the child table is imported first, an error will be reported. Only when the foreign key constraint check is disabled can the data of the child table be imported successfully.
- If an `ALTER TABLE` operation to be executed involves a change of the foreign key, this operation succeeds only when the foreign key constraint check is disabled.

When the foreign key constraint check is disabled, the foreign key constraint check and reference operation are not executed, except for the following scenarios:

- If the execution of `ALTER TABLE` might result in wrong definition of the foreign key, an error is still reported during the execution.
- When deleting the index required by the foreign key, you should delete the foreign key first. Otherwise, an error is reported.
- When you create a foreign key but it does not meet related conditions or restrictions, an error is reported.

14.13.16.8 Locking

When `INSERT` or `UPDATE` a child table, the foreign key constraint checks whether the corresponding foreign key value exists in the parent table, and locks the row in the parent table to avoid the foreign key value being deleted by other operations violating the foreign key constraint. The locking behavior is equivalent to performing a `SELECT FOR UPDATE` operation on the row where the foreign key value is located in the parent table.

Because TiDB currently does not support `LOCK IN SHARE MODE`, if a child table accepts a large number of concurrent writes and most of the referenced foreign key values are the same, there might be serious locking conflicts. It is recommended to disable `foreign_key_checks` when writing a large number of child table data.

14.13.16.9 Definition and metadata of foreign keys

To view the definition of a foreign key constraint, execute the `SHOW CREATE TABLE` statement:

```
mysql> SHOW CREATE TABLE child\G
*************************** 1. row ***************************
       Table: child
Create Table: CREATE TABLE `child` (
  `id` int DEFAULT NULL,
  `pid` int DEFAULT NULL,
  KEY `idx_pid` (`pid`),
  CONSTRAINT `fk_1` FOREIGN KEY (`pid`) REFERENCES `test`.`parent` (`id`)
    ↪ ON DELETE CASCADE
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

You can also get information about foreign keys using either of the following system tables:

- `INFORMATION_SCHEMA.KEY_COLUMN_USAGE`
- `INFORMATION_SCHEMA.TABLE_CONSTRAINTS`
- `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS`

The following provides examples:

Get information about foreign keys from the `INFORMATION_SCHEMA.KEY_COLUMN_USAGE` system table:

```
mysql> SELECT TABLE_SCHEMA, TABLE_NAME, COLUMN_NAME, CONSTRAINT_NAME FROM
    ↪ INFORMATION_SCHEMA.KEY_COLUMN_USAGE WHERE REFERENCED_TABLE_SCHEMA IS
    ↪ NOT NULL;
+--------------+--------------+-----------------+----------------+
| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME   | CONSTRAINT_NAME |
+--------------+--------------+-----------------+----------------+
| test         | child        | pid             | fk_1           |
| test         | product_order | product_category | fk_1      |
| test         | product_order | product_id    | fk_1           |
| test         | product_order | customer_id   | fk_2           |
+--------------+--------------+-----------------+----------------+
```

Get information about foreign keys from the `INFORMATION_SCHEMA.TABLE_CONSTRAINTS` system table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.TABLE_CONSTRAINTS WHERE CONSTRAINT_
    ↪ TYPE='FOREIGN KEY'\G
***************************[ 1. row ]***************************
CONSTRAINT_CATALOG | def
CONSTRAINT_SCHEMA | test
CONSTRAINT_NAME  | fk_1
TABLE_SCHEMA     | test
TABLE_NAME       | child
CONSTRAINT_TYPE  | FOREIGN KEY
```

Get information about foreign keys from the `INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS` system table:

```
mysql> SELECT * FROM INFORMATION_SCHEMA.REFERENTIAL_CONSTRAINTS\G
***************************[ 1. row ]***************************
CONSTRAINT_CATALOG     | def
CONSTRAINT_SCHEMA      | test
CONSTRAINT_NAME        | fk_1
UNIQUE_CONSTRAINT_CATALOG | def
UNIQUE_CONSTRAINT_SCHEMA | test
UNIQUE_CONSTRAINT_NAME | PRIMARY
MATCH_OPTION           | NONE
UPDATE_RULE            | NO ACTION
DELETE_RULE            | CASCADE
TABLE_NAME             | child
REFERENCED_TABLE_NAME  | parent
```

14.13.16.10 View execution plans with foreign keys

You can use the `EXPLAIN` statement to view execution plans. The `Foreign_Key_Check` operator performs the foreign key constraint check on DML statements that are executed.

```
mysql> explain insert into child values (1,1);
+--
   ↪ --------------------+---------+------+-------------+-----------------------
   ↪
| id                    | estRows | task | access object | operator info
   ↪         |
+--
   ↪ --------------------+---------+------+-------------+-----------------------
   ↪
| Insert_1              | N/A     | root |             | N/A
   ↪                         |
|  ─Foreign_Key_Check_3 | 0.00 | root | table:parent | foreign_key:fk_1,
   ↪ check_exist |
+--
   ↪ --------------------+---------+------+-------------+-----------------------
   ↪
```

You can use the `EXPLAIN ANALYZE` statement to view the execution of the foreign key reference behavior. The `Foreign_Key_Cascade` operator performs foreign key referencing for DML statements that are executed.

```
mysql> explain analyze delete from parent where id = 1;
+--
   ↪ --------------------------------+---------+---------+----------+-------------
   ↪
| id                              | estRows | actRows | task   | access object
   ↪               | execution info
   ↪
   ↪ | operator info                              | memory   | disk |
+--
   ↪ --------------------------------+---------+---------+----------+-------------
   ↪
| Delete_2                        | N/A     | 0       | root     |
   ↪                                | time:117.3µs, loops:1
   ↪
   ↪ | N/A                                        | 380 Bytes | N/A |
|  ─Point_Get_1                   | 1.00    | 1       | root     | table:parent
   ↪                | time:63.6µs, loops:2, Get:{num_rpc:1, total_time
   ↪ :29.9µs}
   ↪
   ↪ | handle:1                                   | N/A       | N/A |
|  ─Foreign_Key_Cascade_3         | 0.00    | 0       | root     | table:child,
   ↪ index:idx_pid  | total:1.28ms, foreign_keys:1
```

```
    ↪
    ↪ | foreign_key:fk_1, on_delete:CASCADE   | N/A      | N/A |
|    └─Delete_7                  | N/A    | 0      | root     |
    ↪                              | time:904.8µs, loops:1
    ↪
    ↪ | N/A                                    | 1.11 KB  | N/A |
|      └─IndexLookUp_11          | 10.00  | 1      | root     |
    ↪                              | time:869.5µs, loops:2, index_task: {
    ↪ total_time: 371.1µs, fetch_handle: 357.3µs, build: 1.25µs, wait: 12.5
    ↪ µs}, table_task: {total_time: 382.6µs, num: 1, concurrency: 5} |
    ↪                                      | 9.13 KB  | N/A |

    ↪ : 0.00, distsql_concurrency: 15}, tikv_task:{time:145.6µs, loops:0} |
    ↪  keep order:false, stats:pseudo | N/A | N/A |
+--
    ↪ ------------------------------+---------+---------+-----------+-------------
    ↪
```

14.13.16.11 Compatibility

14.13.16.11.1 Compatibility between TiDB versions

Before v6.6.0, TiDB supports the syntax of creating foreign keys, but the created foreign keys are ineffective. If you upgrade a TiDB cluster created before v6.6.0 to v6.6.0 or later, the foreign keys created before the upgrade are still ineffective. Only the foreign keys created in v6.6.0 or later versions are effective. You can delete the invalid foreign key and create a new one to make the foreign key constraints effective. You can use the `SHOW CREATE TABLE` statement to check whether the foreign keys are effective. The invalid foreign key has a `/* FOREIGN KEY INVALID */` comment.

```
mysql> SHOW CREATE TABLE child\G
***************************[ 1. row ]***************************
Table       | child
Create Table | CREATE TABLE `child` (
  `id` int DEFAULT NULL,
  `pid` int DEFAULT NULL,
  KEY `idx_pid` (`pid`),
```

```
  CONSTRAINT `fk_1` FOREIGN KEY (`pid`) REFERENCES `test`.`parent` (`id`)
    ↪ ON DELETE CASCADE /* FOREIGN KEY INVALID */
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

14.13.16.11.2 Compatibility with TiDB tools

- DM does not support foreign keys. DM disables the `foreign_key_checks` of the downstream TiDB when replicating data to TiDB. Therefore, the cascading operations caused by foreign keys are not replicated from the upstream to the downstream, which might cause data inconsistency.
- TiCDC v6.6.0 is compatible with foreign keys. The previous versions of TiCDC might report an error when replicating tables with foreign keys. It is recommended to disable the `foreign_key_checks` of the downstream TiDB cluster when using a TiCDC version earlier than v6.6.0.
- BR v6.6.0 is compatible with foreign keys. The previous versions of BR might report an error when restoring tables with foreign keys to a v6.6.0 or later cluster. It is recommended to disable the `foreign_key_checks` of the downstream TiDB cluster before restoring the cluster when using a BR earlier than v6.6.0.
- When you use TiDB Lightning, if the target table uses a foreign key, it is recommended to disable the `foreign_key_checks` of the downstream TiDB cluster before importing data. For versions earlier than v6.6.0, disabling this system variable does not take effect, and you need to grant the `REFERENCES` privilege for the downstream database user, or manually create the target table in the downstream database in advance to ensure smooth data import.

- Dumpling is compatible with foreign keys.

- When you use sync-diff-inspector to compare data between the upstream and downstream databases, if the database versions are different and there is an invalid foreign key in the downstream TiDB, sync-diff-inspector might report a table schema inconsistent error. This is because TiDB v6.6.0 adds a `/* FOREIGN KEY INVALID */` comment for the invalid foreign key.

14.13.16.11.3 Compatibility with MySQL

When you create a foreign key without specifying a name, the name generated by TiDB is different from that generated by MySQL. For example, the foreign key name generated by TiDB is `fk_1`, `fk_2`, and `fk_3`, while the foreign key name generated by MySQL is `table_name_ibfk_1`, `table_name_ibfk_2`, and `table_name_ibfk_3`.

Both MySQL and TiDB parse but ignore "inline `REFERENCES` specifications". Only `REFERENCES` specifications that are part of `FOREIGN KEY` definitions are checked and enforced. The following example creates a foreign key constraint using a `REFERENCES` clause:

```
CREATE TABLE parent (
    id INT KEY
);

CREATE TABLE child (
    id INT,
    pid INT REFERENCES parent(id)
);

SHOW CREATE TABLE child;
```

The output shows that the `child` table does not contain any foreign keys:

```
+-------+-----------------------------------------------------------------+
| Table | Create Table                                                    |
+-------+-----------------------------------------------------------------+
| child | CREATE TABLE `child` (                                          |
|       |   `id` int DEFAULT NULL,                                        |
|       |   `pid` int DEFAULT NULL                                        |
|       | ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+-------+-----------------------------------------------------------------+
```

14.13.17 Character Set and Collation

14.13.17.1 Character Set and Collation

This document introduces the character sets and collations supported by TiDB.

14.13.17.1.1 Concepts

A character set is a set of symbols and encodings. The default character set in TiDB is `utf8mb4`, which matches the default character set in MySQL 8.0 and later.

A collation is a set of rules for comparing characters in a character set, and the sorting order of characters. For example in a binary collation `A` and `a` do not compare as equal:

```
SET NAMES utf8mb4 COLLATE utf8mb4_bin;
SELECT 'A' = 'a';
SET NAMES utf8mb4 COLLATE utf8mb4_general_ci;
SELECT 'A' = 'a';
```

```
SELECT 'A' = 'a';
```

```
+-----------+
| 'A' = 'a' |
```

```
+-----------+
|         0 |
+-----------+
1 row in set (0.00 sec)
```

```
SET NAMES utf8mb4 COLLATE utf8mb4_general_ci;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
SELECT 'A' = 'a';
```

```
+-----------+
| 'A' = 'a' |
+-----------+
|         1 |
+-----------+
1 row in set (0.00 sec)
```

The following example demonstrates how different Unicode collations compare the German ß with ss. You can see that only the more strict Unicode collations treat them as equivalent, returning 1 (which means TRUE).

```
SELECT
  'ss' COLLATE utf8mb4_general_ci = 'ß',
  'ss' COLLATE utf8mb4_unicode_ci = 'ß',
  'ss' COLLATE utf8mb4_0900_ai_ci = 'ß',
  'ss' COLLATE utf8mb4_0900_bin = 'ß'
\G
```

```
*************************** 1. row ***************************
'ss' COLLATE utf8mb4_general_ci = 'ß': 0
'ss' COLLATE utf8mb4_unicode_ci = 'ß': 1
'ss' COLLATE utf8mb4_0900_ai_ci = 'ß': 1
  'ss' COLLATE utf8mb4_0900_bin = 'ß': 0
1 row in set (0.01 sec)
```

Character set and collation naming

A character set can have multiple collations, named in the `<character_set>_<collation_properties>` format. For example, the `utf8mb4` character set has a collation called `utf8mb4_bin`, which is a binary collation for `utf8mb4`. Multiple collation properties can be included in the name, separated by underscores (_).

The following table shows the common collation properties and meanings.

Collation properties	Meaning
_bin	Binary
_ci	Case insensitive
_ai_ci	Accent insensitive, case insensitive
_0900_bin	Unicode UCA 9.0.0, binary
_unicode_ci	(Older) Unicode UCA collation, case insensitive
_general_ci	Less strict Unicode collation, case insensitive

14.13.17.1.2 Character sets and collations supported by TiDB

Currently, TiDB supports the following character sets:

```
SHOW CHARACTER SET;
```

```
+--
    ↪ -------+-----------------------------------+-------------------+--------+
    ↪
| Charset | Description                       | Default collation | Maxlen |
+--
    ↪ -------+-----------------------------------+-------------------+--------+
    ↪
| ascii  | US ASCII                          | ascii_bin         |      1 |
| binary | binary                            | binary            |      1 |
| gbk    | Chinese Internal Code Specification | gbk_chinese_ci  | 2 |
| latin1 | Latin1                            | latin1_bin        |      1 |
| utf8   | UTF-8 Unicode                     | utf8_bin          |      3 |
| utf8mb4 | UTF-8 Unicode                    | utf8mb4_bin       |      4 |
+--
    ↪ -------+-----------------------------------+-------------------+--------+
    ↪
6 rows in set (0.00 sec)
```

TiDB supports the following collations:

```
SHOW COLLATION;
```

```
+--
    ↪ -----------------+---------+-----+---------+----------+---------+-------------
    ↪
| Collation        | Charset | Id | Default | Compiled | Sortlen | Pad_
    ↪ attribute |
+--
    ↪ -----------------+---------+-----+---------+----------+---------+-------------
    ↪
| ascii_bin        | ascii  |  65 | Yes     | Yes      |       1 | PAD SPACE   |
```

```
| binary           | binary  |  63 | Yes    | Yes     |       1 | NO PAD     |
| gbk_bin          | gbk     |  87 |        | Yes     |       1 | PAD SPACE  |
| gbk_chinese_ci   | gbk     |  28 | Yes    | Yes     |       1 | PAD SPACE  |
| latin1_bin       | latin1  |  47 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8_bin         | utf8    |  83 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8_general_ci  | utf8    |  33 |        | Yes     |       1 | PAD SPACE  |
| utf8_unicode_ci  | utf8    | 192 |        | Yes     |       8 | PAD SPACE  |
| utf8mb4_0900_ai_ci | utf8mb4 | 255 |    | Yes     |       0 | NO PAD     |
| utf8mb4_0900_bin | utf8mb4 | 309 |      | Yes     |       1 | NO PAD     |
| utf8mb4_bin      | utf8mb4 |  46 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8mb4_general_ci | utf8mb4 | 45 |     | Yes     |       1 | PAD SPACE  |
| utf8mb4_unicode_ci | utf8mb4 | 224 |    | Yes     |       8 | PAD SPACE  |
+--
    ↪ -----------------+---------+-----+---------+---------+---------+-------------
    ↪
13 rows in set (0.00 sec)
```

Warning:

TiDB incorrectly treats latin1 as a subset of utf8. This can lead to unexpected behaviors when you store characters that differ between latin1 and utf8 encodings. It is strongly recommended to the utf8mb4 character set. See TiDB #18955 for more details.

Note:

The default collations in TiDB (binary collations, with the suffix `_bin`) are different than the default collations in MySQL (typically general collations, with the suffix `_general_ci` or `_ai_ci`). This can cause incompatible behavior when specifying an explicit character set but relying on the implicit default collation to be chosen.

However, the default collations in TiDB are also affected by the connection collation settings of your clients. For example, the MySQL 8.x client defaults to `utf8mb4_0900_ai_ci` as the connection collation for the `utf8mb4` character set.

- Before TiDB v7.4.0, if your client uses `utf8mb4_0900_ai_ci` as the connection collation, TiDB falls back to using the TiDB server default collation `utf8mb4_bin` because TiDB does not support the `utf8mb4_0900 ↪ _ai_ci` collation.

- Starting from v7.4.0, if your client uses `utf8mb4_0900_ai_ci` as the connection collation, TiDB follows the client's configuration to use `utf8mb4_0900_ai_ci` as the default collation.

You can use the following statement to view the collations (under the new framework for collations) that corresponds to the character set.

```
SHOW COLLATION WHERE Charset = 'utf8mb4';
```

```
+--
   ↪ -----------------+---------+-----+---------+----------+---------+--------------
   ↪
| Collation       | Charset | Id | Default | Compiled | Sortlen | Pad_
   ↪ attribute |
+--
   ↪ -----------------+---------+-----+---------+----------+---------+--------------
   ↪
| utf8mb4_0900_ai_ci | utf8mb4 | 255 |    | Yes     |       0 | NO PAD      |
| utf8mb4_0900_bin | utf8mb4 | 309 |     | Yes     |       1 | NO PAD      |
| utf8mb4_bin      | utf8mb4 | 46 | Yes   | Yes     |       1 | PAD SPACE   |
| utf8mb4_general_ci | utf8mb4 | 45 |    | Yes     |       1 | PAD SPACE   |
| utf8mb4_unicode_ci | utf8mb4 | 224 |   | Yes     |       8 | PAD SPACE   |
+--
   ↪ -----------------+---------+-----+---------+----------+---------+--------------
   ↪
5 rows in set (0.001 sec)
```

For details about the TiDB support of the GBK character set, see GBK.

14.13.17.1.3 `utf8` and `utf8mb4` in TiDB

In MySQL, the character set `utf8` is limited to a maximum of three bytes. This is sufficient to store characters in the Basic Multilingual Plane (BMP), but not enough to store characters such as emojis. For new installations, it is recommended to use `utf8mb4` and migrate away from `utf8`.

In both MySQL and TiDB, `utf8` and `utf8mb3` are aliases for the same character set.

By default, TiDB also limits the character set `utf8` to a maximum of three bytes to ensure that data created in TiDB can still safely be restored in MySQL. You can disable it by changing the value of the system variable `tidb_check_mb4_value_in_utf8` to `OFF`. However, it is recommended to use `utf8mb4` instead for full Unicode support and better compatibility.

The following demonstrates the default behavior when inserting a 4-byte emoji character into a table. The `INSERT` statement fails for the `utf8` character set, but succeeds for `utf8mb4`:

```
CREATE TABLE utf8_test (
    c char(1) NOT NULL
   ) CHARACTER SET utf8;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
CREATE TABLE utf8m4_test (
    c char(1) NOT NULL
   ) CHARACTER SET utf8mb4;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
INSERT INTO utf8_test VALUES ('');
```

```
ERROR 1366 (HY000): incorrect utf8 value f09f9889() for column c
```

```
INSERT INTO utf8m4_test VALUES ('');
```

```
Query OK, 1 row affected (0.02 sec)
```

```
SELECT char_length(c), length(c), c FROM utf8_test;
```

```
Empty set (0.01 sec)
```

```
SELECT char_length(c), length(c), c FROM utf8m4_test;
```

```
+----------------+-----------+------+
| char_length(c) | length(c) | c |
+----------------+-----------+------+
|              1 |         4 |      |
+----------------+-----------+------+
1 row in set (0.00 sec)
```

14.13.17.1.4 Character set and collation in different layers

The character set and collation can be set at different layers.

Database character set and collation

Each database has a character set and a collation. You can use the following statements to specify the database character set and collation:

```
CREATE DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]

ALTER DATABASE db_name
    [[DEFAULT] CHARACTER SET charset_name]
    [[DEFAULT] COLLATE collation_name]
```

`DATABASE` can be replaced with `SCHEMA` here.

Different databases can use different character sets and collations. Use the `character_set_database` and `collation_database` to see the character set and collation of the current database:

```
CREATE SCHEMA test1 CHARACTER SET utf8mb4 COLLATE utf8mb4_general_ci;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
USE test1;
```

```
Database changed
```

```
SELECT @@character_set_database, @@collation_database;
```

```
+--------------------------/----------------------+
| @@character_set_database | @@collation_database |
+--------------------------/----------------------+
| utf8mb4                  | utf8mb4_general_ci |
+--------------------------/----------------------+
1 row in set (0.00 sec)
```

```
CREATE SCHEMA test2 CHARACTER SET latin1 COLLATE latin1_bin;
```

```
Query OK, 0 rows affected (0.09 sec)
```

```
USE test2;
```

```
Database changed
```

```
SELECT @@character_set_database, @@collation_database;
```

```
+--------------------------/----------------------+
| @@character_set_database | @@collation_database |
+--------------------------/----------------------+
```

```
| latin1                  | latin1_bin        |
+-------------------------/---------------------+
1 row in set (0.00 sec)
```

You can also see the two values in INFORMATION_SCHEMA:

```
SELECT DEFAULT_CHARACTER_SET_NAME, DEFAULT_COLLATION_NAME
FROM INFORMATION_SCHEMA.SCHEMATA WHERE SCHEMA_NAME = 'db_name';
```

Table character set and collation

You can use the following statement to specify the character set and collation for tables:

```
CREATE TABLE tbl_name (column_list)
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]]

ALTER TABLE tbl_name
    [[DEFAULT] CHARACTER SET charset_name]
    [COLLATE collation_name]
```

For example:

```
CREATE TABLE t1(a int) CHARACTER SET utf8mb4 COLLATE utf8mb4_general_ci;
```

```
Query OK, 0 rows affected (0.08 sec)
```

If the table character set and collation are not specified, the database character set and collation are used as their default values. If you only specify the character set as `utf8mb4` ↪ without specifying the collation, the collation is determined by the value of the system variable `default_collation_for_utf8mb4`.

Column character set and collation

You can use the following statement to specify the character set and collation for columns:

```
col_name {CHAR | VARCHAR | TEXT} (col_length)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]

col_name {ENUM | SET} (val_list)
    [CHARACTER SET charset_name]
    [COLLATE collation_name]
```

If the column character set and collation are not specified, the table character set and collation are used as their default values. If you only specify the character set as `utf8mb4` ↪ without specifying the collation, the collation is determined by the value of the system variable `default_collation_for_utf8mb4`.

String character sets and collation

Each string corresponds to a character set and a collation. When you use a string, this option is available:

```
[_charset_name]'string' [COLLATE collation_name]
```

Example:

```
SELECT 'string';
SELECT _utf8mb4'string';
SELECT _utf8mb4'string' COLLATE utf8mb4_general_ci;
```

Rules:

- Rule 1: If you specify `CHARACTER SET charset_name` and `COLLATE collation_name` ↪ , then the `charset_name` character set and the `collation_name` collation are used directly.
- Rule 2: If you specify `CHARACTER SET charset_name` but do not specify `COLLATE` ↪ `collation_name`, the `charset_name` character set and the default collation of `charset_name` are used.
- Rule 3: If you specify neither `CHARACTER SET charset_name` nor `COLLATE collation` ↪ `_name`, the character set and collation given by the system variables `character_` ↪ `set_connection` and `collation_connection` are used.

Client connection character set and collation

- The server character set and collation are the values of the `character_set_server` and `collation_server` system variables.
- The character set and collation of the default database are the values of the `character` ↪ `_set_database` and `collation_database` system variables.

You can use `character_set_connection` and `collation_connection` to specify the character set and collation for each connection. The `character_set_client` variable is to set the client character set.

Before returning the result, the `character_set_results` system variable indicates the character set in which the server returns query results to the client, including the metadata of the result.

You can use the following statement to set the character set and collation that is related to the client:

- `SET NAMES 'charset_name' [COLLATE 'collation_name']`

`SET NAMES` indicates what character set the client will use to send SQL statements to the server. `SET NAMES utf8mb4` indicates that all the requests from the client use utf8mb4, as well as the results from the server.

The `SET NAMES 'charset_name'` statement is equivalent to the following statement combination:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection = charset_name;
```

`COLLATE` is optional, if absent, the default collation of the `charset_name` is used to set the `collation_connection`.

- `SET CHARACTER SET 'charset_name'`

  Similar to `SET NAMES`, the `SET NAMES 'charset_name'` statement is equivalent to the following statement combination:

```
SET character_set_client = charset_name;
SET character_set_results = charset_name;
SET character_set_connection=@@character_set_database;
SET collation_connection = @@collation_database;
```

14.13.17.1.5 Selection priorities of character sets and collations

String > Column > Table > Database > Server

14.13.17.1.6 General rules on selecting character sets and collation

- Rule 1: If you specify `CHARACTER SET charset_name` and `COLLATE collation_name` ↪ , then the `charset_name` character set and the `collation_name` collation are used directly.
- Rule 2: If you specify `CHARACTER SET charset_name` and do not specify `COLLATE` ↪ `collation_name`, then the `charset_name` character set and the default collation of `charset_name` are used.
- Rule 3: If you specify neither `CHARACTER SET charset_name` nor `COLLATE collation` ↪ `_name`, the character set and collation with higher optimization levels are used.

14.13.17.1.7 Validity check of characters

If the specified character set is `utf8` or `utf8mb4`, TiDB only supports the valid `utf8` characters. For invalid characters, TiDB reports the `incorrect utf8 value` error. This validity check of characters in TiDB is compatible with MySQL 8.0 but incompatible with MySQL 5.7 or earlier versions.

To disable this error reporting, use `set @@tidb_skip_utf8_check=1;` to skip the character check.

Note:

If the character check is skipped, TiDB might fail to detect illegal UTF-8 characters written by the application, cause decoding errors when `ANALYZE` is executed, and introduce other unknown encoding issues. If your application cannot guarantee the validity of the written string, it is not recommended to skip the character check.

14.13.17.1.8 Collation support framework

The syntax support and semantic support for the collation are influenced by the new_collations_enabled_on_first_bootstrap configuration item. The syntax support and semantic support are different. The former indicates that TiDB can parse and set collations. The latter indicates that TiDB can correctly use collations when comparing strings.

Before v4.0, TiDB provides only the old framework for collations. In this framework, TiDB supports syntactically parsing most of the MySQL collations but semantically takes all collations as binary collations.

Since v4.0, TiDB supports a new framework for collations. In this framework, TiDB semantically parses different collations and strictly follows the collations when comparing strings.

Old framework for collations

Before v4.0, you can specify most of the MySQL collations in TiDB, and these collations are processed according to the default collations, which means that the byte order determines the character order. Different from MySQL, TiDB does not handle the trailing spaces of a character, which causes the following behavior differences:

```
CREATE TABLE t(a varchar(20) charset utf8mb4 collate utf8mb4_general_ci
    ↪ PRIMARY KEY);
```

```
Query OK, 0 rows affected
```

```
INSERT INTO t VALUES ('A');
```

```
Query OK, 1 row affected
```

```
INSERT INTO t VALUES ('a');
```

```
Query OK, 1 row affected
```

In TiDB, the preceding statement is successfully executed. In MySQL, because `utf8mb4_general_ci` is case-insensitive, the `Duplicate entry 'a'` error is reported.

```
INSERT INTO t1 VALUES ('a ');
```

```
Query OK, 1 row affected
```

In TiDB, the preceding statement is successfully executed. In MySQL, because comparison is performed after the spaces are filled in, the `Duplicate entry 'a '` error is returned.

New framework for collations

Since TiDB v4.0, a complete framework for collations is introduced.

This new framework supports semantically parsing collations and introduces the `new_collations_enabled_on_first_bootstrap` configuration item to decide whether to enable the new framework when a cluster is first initialized. To enable the new framework, set `new_collations_enabled_on_first_bootstrap` to `true`. For details, see new_collations_enabled_on_first_bootstrap.

For a TiDB cluster that is already initialized, you can check whether the new collation is enabled through the `new_collation_enabled` variable in the `mysql.tidb` table:

> **Note:**
>
> If the query result of the `mysql.tidb` table is different from the value of `new_collations_enabled_on_first_bootstrap`, the result of the `mysql.tidb` table is the actual value.

```
SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME='new_collation_enabled';
```

```
+----------------+
| VARIABLE_VALUE |
+----------------+
| True           |
+----------------+
1 row in set (0.00 sec)
```

Under the new framework, TiDB supports the `utf8_general_ci`, `utf8mb4_general_ci`, `utf8_unicode_ci`, `utf8mb4_unicode_ci`, `utf8mb4_0900_bin`, `utf8mb4_0900_ai_ci`, `gbk_chinese_ci`, and `gbk_bin` collations, which is compatible with MySQL.

When one of `utf8_general_ci`, `utf8mb4_general_ci`, `utf8_unicode_ci`, `utf8mb4_unicode_ci`, `utf8mb4_0900_ai_ci` and `gbk_chinese_ci` is used, the string comparison

is case-insensitive and accent-insensitive. At the same time, TiDB also corrects the collation's `PADDING` behavior:

```
CREATE TABLE t(a varchar(20) charset utf8mb4 collate utf8mb4_general_ci
    ↪ PRIMARY KEY);
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
INSERT INTO t VALUES ('A');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
INSERT INTO t VALUES ('a');
```

```
ERROR 1062 (23000): Duplicate entry 'a' for key 't.PRIMARY' -- TiDB is
    ↪ compatible with the case-insensitive collation of MySQL.
```

```
INSERT INTO t VALUES ('a ');
```

```
ERROR 1062 (23000): Duplicate entry 'a ' for key 't.PRIMARY' -- TiDB
    ↪ modifies the `PADDING` behavior to be compatible with MySQL.
```

Note:

The implementation of padding in TiDB is different from that in MySQL. In MySQL, padding is implemented by filling in spaces. In TiDB, padding is implemented by cutting out the spaces at the end. The two approaches are the same in most cases. The only exception is when the end of the string contains characters that are less than spaces (0x20). For example, the result of `'a' < 'a\t'` in TiDB is `1`, but in MySQL, `'a' < 'a\t'` is equivalent to `'a ' < 'a\t'`, and the result is `0`.

14.13.17.1.9 Coercibility values of collations in expressions

If an expression involves multiple clauses of different collations, you need to infer the collation used in the calculation. The rules are as follows:

- The coercibility value of the explicit `COLLATE` clause is `0`.
- If the collations of two strings are incompatible, the coercibility value of the concatenation of two strings with different collations is `1`.
- The collation of the column, `CAST()`, `CONVERT()`, or `BINARY()` has a coercibility value of 2.

- The system constant (the string returned by `USER ()` or `VERSION ()`) has a coercibility value of `3`.
- The coercibility value of constants is `4`.
- The coercibility value of numbers or intermediate variables is `5`.
- `NULL` or expressions derived from `NULL` has a coercibility value of `6`.

When inferring collations, TiDB prefers using the collation of expressions with lower coercibility values. If the coercibility values of two clauses are the same, the collation is determined according to the following priority:

binary > utf8mb4_bin > (utf8mb4_general_ci = utf8mb4_unicode_ci) > utf8_bin > (utf8_general_ci = utf8_unicode_ci) > latin1_bin > ascii_bin

TiDB cannot infer the collation and reports an error in the following situations:

- If the collations of two clauses are different and the coercibility value of both clauses is `0`.
- If the collations of two clauses are incompatible and the returned type of expression is `String`.

14.13.17.1.10 `COLLATE` clause

TiDB supports using the `COLLATE` clause to specify the collation of an expression. The coercibility value of this expression is `0`, which has the highest priority. See the following example:

```
SELECT 'a' = _utf8mb4 'A' collate utf8mb4_general_ci;
```

```
+-----------------------------------------------+
| 'a' = _utf8mb4 'A' collate utf8mb4_general_ci |
+-----------------------------------------------+
|                                             1 |
+-----------------------------------------------+
1 row in set (0.00 sec)
```

For more details, see Connection Character Sets and Collations.

14.13.17.2 GBK

Starting from v5.4.0, TiDB supports the GBK character set. This document provides the TiDB support and compatibility information of the GBK character set.

Starting from v6.0.0, TiDB enables the new framework for collations by default. The default collation for TiDB GBK character set is `gbk_chinese_ci`, which is consistent with MySQL.

```
SHOW CHARACTER SET WHERE CHARSET = 'gbk';
```

```
+---------+-------------------------------------+-------------------+--------+
    ↪
| Charset | Description                         | Default collation | Maxlen |
+---------+-------------------------------------+-------------------+--------+
    ↪
| gbk     | Chinese Internal Code Specification | gbk_chinese_ci | 2 |
+---------+-------------------------------------+-------------------+--------+
    ↪
1 row in set (0.00 sec)
```

```
SHOW COLLATION WHERE CHARSET = 'gbk';
```

```
+----------------+---------+----+---------+----------+---------+--------------+
    ↪
| Collation      | Charset | Id | Default | Compiled | Sortlen | Pad_attribute
    ↪  |
+----------------+---------+----+---------+----------+---------+--------------+
    ↪
| gbk_bin        | gbk     | 87 |         | Yes      |       1 | PAD SPACE    |
| gbk_chinese_ci | gbk     | 28 | Yes     | Yes      |       1 | PAD SPACE    |
+----------------+---------+----+---------+----------+---------+--------------+
    ↪
2 rows in set (0.00 sec)
```

14.13.17.2.1 MySQL compatibility

This section provides the compatibility information between MySQL and TiDB.

Collations

The default collation of the GBK character set in MySQL is `gbk_chinese_ci`. The default collation for the GBK character set in TiDB depends on the value of the TiDB configuration item `new_collations_enabled_on_first_bootstrap`:

- By default, the TiDB configuration item `new_collations_enabled_on_first_bootstrap` is set to `true`, which means that the new framework for collations is enabled and the default collation for the GBK character set is `gbk_chinese_ci`.
- When the TiDB configuration item `new_collations_enabled_on_first_bootstrap` is set to `false`, the new framework for collations is disabled, and the default collation for the GBK character set is `gbk_bin`.

Additionally, because TiDB converts GBK to `utf8mb4` and then uses a binary collation, the `gbk_bin` collation in TiDB is not the same as the `gbk_bin` collation in MySQL.

Illegal character compatibility

- If the system variables character_set_client and character_set_connection are not set to gbk at the same time, TiDB handles illegal characters in the same way as MySQL.
- If character_set_client and character_set_connection are both set to gbk, TiDB handles illegal characters differently than MySQL.
    - MySQL handles illegal GBK character sets in reading and writing operations differently.
    - TiDB handles illegal GBK character sets in reading and writing operations in the same way. In the SQL strict mode, TiDB reports an error when either reading or writing illegal GBK characters. In the non-strict mode, TiDB replaces illegal GBK characters with ? when either reading or writing illegal GBK characters.

For example, after SET NAMES gbk, if you create a table using the CREATE TABLE gbk_table(a VARCHAR(32)CHARACTER SET gbk) statement in MySQL and TiDB respectively and then execute the SQL statements in the following table, you can see the detailed differences.

Database	If the configured SQL mode contains either STRICT_ALL_TABLES or STRICT_TRANS_TABLES	If the configured SQL mode contains neither STRICT_ALL_TABLES nor STRICT_TRANS_TABLES
MySQL	SELECT HEX('一a'); e4b88061INSERT INTO gbk_table values('一a'); Incorrect Error	SELECT HEX('一a'); e4b88061INSERT INTO gbk_table VALUES('一a'); SELECT HEX(a)FROM gbk_table; e4b8
TiDB	SELECT HEX('一a'); Incorrect ErrorINSERT INTO gbk_table VALUES('一a'); Incorrect Error	SELECT HEX('一a'); e4b83fINSERT INTO gbk_table VALUES('一a');SELECT HEX(a)FROM gbk_table; e4b83f

In the above table, the result of SELECT HEX('a'); in the utf8mb4 byte set is e4b88061.

Other MySQL compatibility

- Currently, TiDB does not support using the ALTER TABLE statement to convert other character set types to gbk or from gbk to other character set types.
- TiDB does not support the use of _gbk. For example:

```
sql  CREATE TABLE t(a CHAR(10)CHARSET BINARY); Query OK, 0 rows affected (0.00 sec)INSERT INTO t VALUES (_gbk'啊');
ERROR 1115 (42000): Unsupported character introducer: 'gbk'
```

- Currently, for binary characters of the ENUM and SET types, TiDB deals with them as the utf8mb4 character set.

14.13.17.2.2 Component compatibility

- Currently, TiFlash does not support the GBK character set.
- TiDB Data Migration (DM) does not support migrating `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- TiDB Lightning does not support importing `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- TiCDC versions earlier than v6.1.0 do not support replicating `charset=GBK` tables. No version of TiCDC supports replicating `charset=GBK` tables to TiDB clusters earlier than v6.1.0.
- Backup & Restore (BR) versions earlier than v5.4.0 do not support recovering `charset =GBK` tables. No version of BR supports recovering `charset=GBK` tables to TiDB clusters earlier than v5.4.0.

14.13.18 Placement Rules in SQL

Placement Rules in SQL is a feature that enables you to specify where data is stored in a TiKV cluster using SQL statements. With this feature, you can schedule data of clusters, databases, tables, or partitions to specific regions, data centers, racks, or hosts.

This feature can fulfill the following use cases:

- Deploy data across multiple data centers and configure rules to optimize high availability strategies.
- Merge multiple databases from different applications and isolate data of different users physically, which meets the isolation requirements of different users within an instance.
- Increase the number of replicas for important data to improve application availability and data reliability.

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

14.13.18.1 Overview

With the Placement Rules in SQL feature, you can create placement policies and configure desired placement policies for data at different levels, with granularity from coarse to fine as follows:

Level	Description
Cluster	By default, TiDB configures a policy of 3 replicas for a cluster. You can configure a global placement policy for your cluster. For more information, see Specify the number of replicas globally for a cluster.
Database	You can configure a placement policy for a specific database. For more information, see Specify a default placement policy for a database.
Table	You can configure a placement policy for a specific table. For more information, see Specify a placement policy for a table.
Partition	You can create partitions for different rows in a table and configure placement policies for partitions separately. For more information, see Specify a placement policy for a partitioned table.

> **Tip:**
>
> The implementation of *Placement Rules in SQL* relies on the *placement rules feature* of PD. For details, refer to Configure Placement Rules. In the context of Placement Rules in SQL, *placement rules* might refer to *placement policies* attached to other objects, or to rules that are sent from TiDB to PD.

14.13.18.2 Limitations

- To simplify maintenance, it is recommended to limit the number of placement policies within a cluster to 10 or fewer.
- It is recommended to limit the total number of tables and partitions attached with placement policies to 10,000 or fewer. Attaching policies to too many tables and partitions can increase computation workloads on PD, thereby affecting service performance.
- It is recommended to use the Placement Rules in SQL feature according to examples provided in this document rather than using other complex placement policies.

14.13.18.3 Prerequisites

Placement policies rely on the configuration of labels on TiKV nodes. For example, the `PRIMARY_REGION` placement option relies on the `region` label in TiKV.

When you create a placement policy, TiDB does not check whether the labels specified in the policy exist. Instead, TiDB performs the check when you attach the policy. Therefore,

before attaching a placement policy, make sure that each TiKV node is configured with correct labels. The configuration method for a TiDB Self-Managed cluster is as follows:

```
tikv-server --labels region=<region>,zone=<zone>,host=<host>
```

For detailed configuration methods, see the following examples:

Deployment method	Example
Manual deployment	Schedule replicas by topology labels
Deployment with TiUP	Geo-distributed deployment topology
Deployment with TiDB Operator	Configure a TiDB cluster in Kubernetes

> **Note:**
>
> For TiDB Cloud Dedicated clusters, you can skip these label configuration steps because the labels on TiKV nodes in TiDB Cloud Dedicated clusters are configured automatically.

To view all available labels in the current TiKV cluster, you can use the `SHOW PLACEMENT LABELS` statement:

```
SHOW PLACEMENT LABELS;
+--------+----------------+
| Key    | Values         |
+--------+----------------+
| disk   | ["ssd"]        |
| region | ["us-east-1"]  |
| zone   | ["us-east-1a"] |
+--------+----------------+
3 rows in set (0.00 sec)
```

14.13.18.4 Usage

This section describes how to create, attach, view, modify, and delete placement policies using SQL statements.

14.13.18.4.1 Create and attach placement policies

1. To create a placement policy, use the `CREATE PLACEMENT POLICY` statement:

```
CREATE PLACEMENT POLICY myplacementpolicy PRIMARY_REGION="us-east-1"
    ↪ REGIONS="us-east-1,us-west-1";
```

In this statement:

- The `PRIMARY_REGION="us-east-1"` option means placing Raft Leaders on nodes with the `region` label as `us-east-1`.
- The `REGIONS="us-east-1,us-west-1"` option means placing Raft Followers on nodes with the `region` label as `us-east-1` and nodes with the `region` label as `us-west-1`.

For more configurable placement options and their meanings, see the Placement options.

2. To attach a placement policy to a table or a partitioned table, use the `CREATE TABLE` or `ALTER TABLE` statement to specify the placement policy for that table or partitioned table:

```
CREATE TABLE t1 (a INT) PLACEMENT POLICY=myplacementpolicy;
CREATE TABLE t2 (a INT);
ALTER TABLE t2 PLACEMENT POLICY=myplacementpolicy;
```

`PLACEMENT POLICY` is not associated with any database schema and can be attached in a global scope. Therefore, specifying a placement policy using `CREATE TABLE` does not require any additional privileges.

14.13.18.4.2 View placement policies

- To view an existing placement policy, you can use the `SHOW CREATE PLACEMENT POLICY` statement:

```
SHOW CREATE PLACEMENT POLICY myplacementpolicy\G
*************************** 1. row ***************************
       Policy: myplacementpolicy
Create Policy: CREATE PLACEMENT POLICY myplacementpolicy PRIMARY_
    ↪ REGION="us-east-1" REGIONS="us-east-1,us-west-1"
1 row in set (0.00 sec)
```

- To view the placement policy attached to a specific table, you can use the `SHOW CREATE TABLE` statement:

```
SHOW CREATE TABLE t1\G
*************************** 1. row ***************************
       Table: t1
Create Table: CREATE TABLE `t1` (
  `a` int DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin /*T![
    ↪ placement] PLACEMENT POLICY=`myplacementpolicy` */
1 row in set (0.00 sec)
```

- To view the definitions of placement policies in a cluster, you can query the INFORMATION_SCHEMA.PLACEMENT_POLICIES system table:

```
SELECT * FROM information_schema.placement_policies\G
***************************[ 1. row ]***************************
POLICY_ID          | 1
CATALOG_NAME       | def
POLICY_NAME        | p1
PRIMARY_REGION     | us-east-1
REGIONS            | us-east-1,us-west-1
CONSTRAINTS        |
LEADER_CONSTRAINTS |
FOLLOWER_CONSTRAINTS |
LEARNER_CONSTRAINTS |
SCHEDULE           |
FOLLOWERS          | 4
LEARNERS           | 0
1 row in set
```

- To view all tables that are attached with placement policies in a cluster, you can query the `tidb_placement_policy_name` column of the `information_schema.tables` system table:

```
SELECT * FROM information_schema.tables WHERE tidb_placement_policy_
    ↪ name IS NOT NULL;
```

- To view all partitions that are attached with placement policies in a cluster, you can query the `tidb_placement_policy_name` column of the `information_schema.partitions` system table:

```
SELECT * FROM information_schema.partitions WHERE tidb_placement_
    ↪ policy_name IS NOT NULL;
```

- Placement policies attached to all objects are applied *asynchronously*. To check the scheduling progress of placement policies, you can use the SHOW PLACEMENT statement:

```
SHOW PLACEMENT;
```

14.13.18.4.3 Modify placement policies

To modify a placement policy, you can use the ALTER PLACEMENT POLICY statement. The modification will apply to all objects that are attached with the corresponding policy.

```
ALTER PLACEMENT POLICY myplacementpolicy FOLLOWERS=4;
```

In this statement, the `FOLLOWERS=4` option means configuring 5 replicas for the data, including 4 Followers and 1 Leader. For more configurable placement options and their meanings, see Placement option reference.

14.13.18.4.4 Drop placement policies

To drop a policy that is not attached to any table or partition, you can use the `DROP PLACEMENT POLICY` statement:

```
DROP PLACEMENT POLICY myplacementpolicy;
```

14.13.18.5 Placement option reference

When creating or modifying placement policies, you can configure placement options as needed.

> **Note:**
>
> The `PRIMARY_REGION`, `REGIONS`, and `SCHEDULE` options cannot be specified together with the `CONSTRAINTS` option, or an error will occur.

14.13.18.5.1 Regular placement options

Regular placement options can meet the basic requirements of data placement.

Option name	Description
`PRIMARY_REGION`	Specifies that placing Raft Leaders on nodes with a `region` label that matches the value of this option.
`REGIONS`	Specifies that placing Raft Followers on nodes with a `region` label that matches the value of this option.
`SCHEDULE`	Specifies the strategy for scheduling the placement of Followers. The value options are `EVEN` (default) or `MAJORITY_IN_PRIMARY`.
`FOLLOWERS`	Specifies the number of Followers. For example, `FOLLOWERS=2` means there will be 3 replicas of the data (2 Followers and 1 Leader).

14.13.18.5.2 Advanced placement options

Advanced configuration options provide more flexibility for data placement to meet the requirements of complex scenarios. However, configuring advanced options is more complex than regular options and requires you to have a deep understanding of the cluster topology and the TiDB data sharding.

Option name	Description
CONSTRAINTS	A list of constraints that apply to all roles. For example, CONSTRAINTS ↪ ="[+disk ↪ =ssd]".
LEADER_ ↪ CONSTRAINTS ↪	A list of constraints that only apply to Leader.
FOLLOWER_ ↪ CONSTRAINTS ↪	A list of constraints that only apply to Followers.
LEARNER_ ↪ CONSTRAINTS ↪	A list of constraints that only apply to learners.
LEARNERS	The number of learners.
SURVIVAL_ ↪ PREFERENCE	The replica placement priority according to the disaster tolerance level of the labels. For example, SURVIVAL_ ↪ PREFERENCE ↪ ="[↪ region, ↪ zone, ↪ host]".

14.13.18.5.3 CONSTRAINTS formats

You can configure `CONSTRAINTS`, `FOLLOWER_CONSTRAINTS`, and `LEARNER_CONSTRAINTS` placement options using either of the following formats:

CONSTRAINTS format	Description

| List format | If a constraint to be specified applies to all replicas, you can use a key-value list format. Each key starts with `+` or `-`. For example:

`[+region=us-east-1]` means placing data on nodes that have a `region` label as `us-east-1`.

`[+region=us-east-1,-type=fault]` means placing data on nodes that have a `region` label as `us-east-1` but do not have a `type` label as `fault`.

| | Dictionary format | If you need to specify different numbers of replicas for different constraints, you can use the dictionary format. For example:

`FOLLOWER_CONSTRAINTS="{+region=us-east-1: 1,+region=us-east-2: 1,+region=us-west-1: 1}";` means placing one Follower in `us-east-1`, one Follower in `us-east-2`, and one Follower in `us-west-1`.

`FOLLOWER_CONSTRAINTS='{"+region=us-east-1,+type=scale-node": 1,"+region=us-west-1": 1}';` means placing one Follower on a node that is located in the `us-east-1` region and has the `type` label as `scale-node`, and one Follower in `us-west-1`.

The dictionary format supports each key starting with `+` or `-` and allows you to configure the special `#evict-leader` attribute. For example, `FOLLOWER_CONSTRAINTS='{"+region=us-east-1":1, "+region=us-east-2": 2, "+region=us-west-1,#evict-leader": 1}'` means that the Leaders elected in `us-west-1` will be evicted as much as possible during disaster recovery.|

Note:

- The `LEADER_CONSTRAINTS` placement option only supports the list format.
- Both list and dictionary formats are based on the YAML parser, but YAML syntax might be incorrectly parsed in some cases. For example, `"{+region=east:1,+region=west:2}"` (no space after `:`) can be incorrectly parsed as `'{"+region=east:1": null, "+region=west:2": null}'`, which is unexpected. However, `"{+region=east: 1,+region=west: 2}"` (space after `:`) can be correctly parsed as `'{"+region=east": 1, "+region=west": 2}'`. Therefore, it is recommended to add a space after `:`.

14.13.18.6 Basic examples

14.13.18.6.1 Specify the number of replicas globally for a cluster

After a cluster is initialized, the default number of replicas is `3`. If a cluster needs more replicas, you can increase this number by configuring a placement policy, and then apply the policy at the cluster level using `ALTER RANGE`. For example:

```
CREATE PLACEMENT POLICY five_replicas FOLLOWERS=4;
ALTER RANGE global PLACEMENT POLICY five_replicas;
```

Note that because TiDB defaults the number of Leaders to `1`, `five replicas` means `4` Followers and `1` Leader.

14.13.18.6.2 Specify a default placement policy for a database

You can specify a default placement policy for a database. This works similarly to setting a default character set or collation for a database. If no other placement policy is specified for a table or partition in the database, the placement policy for the database will apply to the table and partition. For example:

```
CREATE PLACEMENT POLICY p1 PRIMARY_REGION="us-east-1" REGIONS="us-east-1,us
    ↪ -east-2"; -- Creates a placement policy

CREATE PLACEMENT POLICY p2 FOLLOWERS=4;

CREATE PLACEMENT POLICY p3 FOLLOWERS=2;

CREATE TABLE t1 (a INT); -- Creates a table t1 without specifying any
    ↪ placement policy.

ALTER DATABASE test PLACEMENT POLICY=p2; -- Changes the default placement
    ↪ policy of the database to p2, which does not apply to the existing
    ↪ table t1.

CREATE TABLE t2 (a INT); -- Creates a table t2. The default placement
    ↪ policy p2 applies to t2.

CREATE TABLE t3 (a INT) PLACEMENT POLICY=p1; -- Creates a table t3. Because
    ↪  this statement has specified another placement rule, the default
    ↪ placement policy p2 does not apply to table t3.

ALTER DATABASE test PLACEMENT POLICY=p3; -- Changes the default policy of
    ↪ the database again, which does not apply to existing tables.

CREATE TABLE t4 (a INT); -- Creates a table t4. The default placement
    ↪ policy p3 applies to t4.
```

```
ALTER PLACEMENT POLICY p3 FOLLOWERS=3; -- `FOLLOWERS=3` applies to the
    ↪ table attached with policy p3 (that is, table t4).
```

Note that the policy inheritance from a table to its partitions differs from the policy inheritance in the preceding example. When you change the default policy of a table, the new policy also applies to partitions in that table. However, a table inherits the policy from the database only if it is created without any policy specified. Once a table inherits the policy from the database, modifying the default policy of the database does not apply to that table.

14.13.18.6.3 Specify a placement policy for a table

You can specify a default placement policy for a table. For example:

```
CREATE PLACEMENT POLICY five_replicas FOLLOWERS=4;

CREATE TABLE t (a INT) PLACEMENT POLICY=five_replicas; -- Creates a table t
    ↪  and attaches the 'five_replicas' placement policy to it.

ALTER TABLE t PLACEMENT POLICY=default; -- Removes the placement policy '
    ↪ five_replicas' from the table t and resets the placement policy to
    ↪ the default one.
```

14.13.18.6.4 Specify a placement policy for a partitioned table

You can also specify a placement policy for a partitioned table or a partition. For example:

```
CREATE PLACEMENT POLICY storageforhistorydata CONSTRAINTS="[+node=history]"
    ↪ ;
CREATE PLACEMENT POLICY storagefornewdata CONSTRAINTS="[+node=new]";
CREATE PLACEMENT POLICY companystandardpolicy CONSTRAINTS="";

CREATE TABLE t1 (id INT, name VARCHAR(50), purchased DATE, UNIQUE INDEX idx
    ↪ (id) GLOBAL)
PLACEMENT POLICY=companystandardpolicy
PARTITION BY RANGE( YEAR(purchased) ) (
  PARTITION p0 VALUES LESS THAN (2000) PLACEMENT POLICY=
      ↪ storageforhistorydata,
  PARTITION p1 VALUES LESS THAN (2005),
  PARTITION p2 VALUES LESS THAN (2010),
  PARTITION p3 VALUES LESS THAN (2015),
  PARTITION p4 VALUES LESS THAN MAXVALUE PLACEMENT POLICY=storagefornewdata
);
```

If no placement policy is specified for a partition in a table, the partition attempts to inherit the policy (if any) from the table. If the table has a global index, the index will apply the same placement policy as the table. In the preceding example:

- The `p0` partition will apply the `storageforhistorydata` policy.
- The `p4` partition will apply the `storagefornewdata` policy.
- The `p1`, `p2`, and `p3` partitions will apply the `companystandardpolicy` placement policy inherited from the table `t1`.
- The global index `idx` will apply the same `companystandardpolicy` placement policy as the table `t1`.
- If no placement policy is specified for the table `t1`, then the `p1`, `p2`, and `p3` partitions and the global index `idx` will inherit the database default policy or the global default policy.

After placement policies are attached to these partitions, you can change the placement policy for a specific partition as in the following example:

```
ALTER TABLE t1 PARTITION p1 PLACEMENT POLICY=storageforhistorydata;
```

14.13.18.7 High availability examples

Assume that there is a cluster with the following topology, where TiKV nodes are distributed across 3 regions, with each region containing 3 available zones:

```
SELECT store_id,address,label from INFORMATION_SCHEMA.TIKV_STORE_STATUS;
+--
   ↪ --------+-----------------+-------------------------------------------------
   ↪
| store_id | address      | label
   ↪
   ↪ |
+--
   ↪ --------+-----------------+-------------------------------------------------
   ↪
|        1 | 127.0.0.1:20163 | [{"key": "region", "value": "us-east-1"}, {"
   ↪ key": "zone", "value": "us-east-1a"}, {"key": "host", "value": "host1
   ↪ "}] |
|        2 | 127.0.0.1:20162 | [{"key": "region", "value": "us-east-1"}, {"
   ↪ key": "zone", "value": "us-east-1b"}, {"key": "host", "value": "host2
   ↪ "}] |
|        3 | 127.0.0.1:20164 | [{"key": "region", "value": "us-east-1"}, {"
   ↪ key": "zone", "value": "us-east-1c"}, {"key": "host", "value": "host3
   ↪ "}] |
|        4 | 127.0.0.1:20160 | [{"key": "region", "value": "us-east-2"}, {"
   ↪ key": "zone", "value": "us-east-2a"}, {"key": "host", "value": "host4
   ↪ "}] |
```

```
|       5 | 127.0.0.1:20161 | [{"key": "region", "value": "us-east-2"}, {"
    ↪ key": "zone", "value": "us-east-2b"}, {"key": "host", "value": "host5
    ↪ "}] |
|       6 | 127.0.0.1:20165 | [{"key": "region", "value": "us-east-2"}, {"
    ↪ key": "zone", "value": "us-east-2c"}, {"key": "host", "value": "host6
    ↪ "}] |
|       7 | 127.0.0.1:20166 | [{"key": "region", "value": "us-west-1"}, {"
    ↪ key": "zone", "value": "us-west-1a"}, {"key": "host", "value": "host7
    ↪ "}] |
|       8 | 127.0.0.1:20167 | [{"key": "region", "value": "us-west-1"}, {"
    ↪ key": "zone", "value": "us-west-1b"}, {"key": "host", "value": "host8
    ↪ "}] |
|       9 | 127.0.0.1:20168 | [{"key": "region", "value": "us-west-1"}, {"
    ↪ key": "zone", "value": "us-west-1c"}, {"key": "host", "value": "host9
    ↪ "}] |
+--
    ↪ --------+-----------------+-------------------------------------------------------
    ↪
```

14.13.18.7.1 Specify survival preferences

If you are not particularly concerned about the exact data distribution but prioritize fulfilling disaster recovery requirements, you can use the `SURVIVAL_PREFERENCES` option to specify data survival preferences.

As in the preceding example, the TiDB cluster is distributed across 3 regions, with each region containing 3 zones. When creating placement policies for this cluster, assume that you configure the `SURVIVAL_PREFERENCES` as follows:

```
CREATE PLACEMENT POLICY multiaz SURVIVAL_PREFERENCES="[region, zone, host]"
    ↪ ;
CREATE PLACEMENT POLICY singleaz CONSTRAINTS="[+region=us-east-1]" SURVIVAL
    ↪ _PREFERENCES="[zone]";
```

After creating the placement policies, you can attach them to the corresponding tables as needed:

- For tables attached with the `multiaz` placement policy, data will be placed in 3 replicas in different regions, prioritizing to meet the cross-region survival goal of data isolation, followed by the cross-zone survival goal, and finally the cross-host survival goal.
- For tables attached with the `singleaz` placement policy, data will be placed in 3 replicas in the `us-east-1` region first, and then meet the cross-zone survival goal of data isolation.

> **Note:**
>
> `SURVIVAL_PREFERENCES` is equivalent to `location-labels` in PD. For more information, see Schedule Replicas by Topology Labels.

14.13.18.7.2 Specify a cluster with 5 replicas distributed 2:2:1 across multiple data centers

If you need a specific data distribution, such as a 5-replica distribution in the proportion of 2:2:1, you can specify different numbers of replicas for different constraints by configuring these `CONSTRAINTS` in the dictionary formats:

```
CREATE PLACEMENT POLICY `deploy221` CONSTRAINTS='{"+region=us-east-1":2, "+
    ↪ region=us-east-2": 2, "+region=us-west-1": 1}';

ALTER RANGE global PLACEMENT POLICY = "deploy221";

SHOW PLACEMENT;
+--
    ↪ ----------------+-----------------------------------------------------------
    ↪
| Target          | Placement
    ↪
    ↪ | Scheduling_State |
+--
    ↪ ----------------+-----------------------------------------------------------
    ↪
| POLICY deploy221 | CONSTRAINTS="{\"+region=us-east-1\":2, \"+region=us-
    ↪ east-2\": 2, \"+region=us-west-1\": 1}" | NULL |
| RANGE TiDB_GLOBAL | CONSTRAINTS="{\"+region=us-east-1\":2, \"+region=us-
    ↪ east-2\": 2, \"+region=us-west-1\": 1}" | SCHEDULED |
+--
    ↪ ----------------+-----------------------------------------------------------
    ↪
```

After the global `deploy221` placement policy is set for the cluster, TiDB distributes data according to this policy: placing two replicas in the `us-east-1` region, two replicas in the `us-east-2` region, and one replica in the `us-west-1` region.

14.13.18.7.3 Specify the distribution of Leaders and Followers

You can specify a specific distribution of Leaders and Followers using constraints or `PRIMARY_REGION`.

Use constraints

If you have specific requirements for the distribution of Raft Leaders among nodes, you can specify the placement policy using the following statement:

```
CREATE PLACEMENT POLICY deploy221_primary_east1 LEADER_CONSTRAINTS="[+
    ↪ region=us-east-1]" FOLLOWER_CONSTRAINTS='{"+region=us-east-1": 1, "+
    ↪ region=us-east-2": 2, "+region=us-west-1": 1}';
```

After this placement policy is created and attached to the desired data, the Raft Leader replicas of the data will be placed in the `us-east-1` region specified by the `LEADER_CONSTRAINTS` option, while other replicas of the data will be placed in regions specified by the `FOLLOWER_CONSTRAINTS` option. Note that if the cluster fails, such as a node outage in the `us-east-1` region, a new Leader will still be elected from other regions, even if these regions are specified in `FOLLOWER_CONSTRAINTS`. In other words, ensuring service availability takes the highest priority.

In the event of a failure in the `us-east-1` region, if you do not want to place new Leaders in `us-west-1`, you can configure a special `evict-leader` attribute to evict the newly elected Leaders in that region:

```
CREATE PLACEMENT POLICY deploy221_primary_east1 LEADER_CONSTRAINTS="[+
    ↪ region=us-east-1]" FOLLOWER_CONSTRAINTS='{"+region=us-east-1": 1, "+
    ↪ region=us-east-2": 2, "+region=us-west-1,#evict-leader": 1}';
```

Use `PRIMARY_REGION`

If the `region` label is configured in your cluster topology, you can also use the `PRIMARY_REGION` and `REGIONS` options to specify a placement policy for Followers:

```
CREATE PLACEMENT POLICY eastandwest PRIMARY_REGION="us-east-1" REGIONS="us-
    ↪ east-1,us-east-2,us-west-1" SCHEDULE="MAJORITY_IN_PRIMARY" FOLLOWERS
    ↪ =4;
CREATE TABLE t1 (a INT) PLACEMENT POLICY=eastandwest;
```

- `PRIMARY_REGION` specifies the distribution region of the Leaders. You can only specify one region in this option.
- The `SCHEDULE` option specifies how TiDB balances the distribution of Followers.
    - The default `EVEN` scheduling rule ensures a balanced distribution of Followers across all regions.
    - If you want to ensure a sufficient number of Follower replicas are placed in the `PRIMARY_REGION` (that is, `us-east-1`), you can use the `MAJORITY_IN_PRIMARY` scheduling rule. This scheduling rule provides lower latency transactions at the expense of some availability. If the primary region fails, `MAJORITY_IN_PRIMARY` does not provide automatic failover.

14.13.18.8 Data isolation examples

As in the following example, when creating placement policies, you can configure a constraint for each policy, which requires data to be placed on TiKV nodes with the specified `app` label.

```
CREATE PLACEMENT POLICY app_order CONSTRAINTS="[+app=order]";
CREATE PLACEMENT POLICY app_list CONSTRAINTS="[+app=list_collection]";
CREATE TABLE order (id INT, name VARCHAR(50), purchased DATE)
PLACEMENT POLICY=app_order
CREATE TABLE list (id INT, name VARCHAR(50), purchased DATE)
PLACEMENT POLICY=app_list
```

In this example, the constraints are specified using the list format, such as `[+app=order]`. You can also specify them using the dictionary format, such as `{+app=order: 3}`.

After executing the statements in the example, TiDB will place the `app_order` data on TiKV nodes with the `app` label as `order`, and place the `app_list` data on TiKV nodes with the `app` label as `list_collection`, thus achieving physical data isolation in storage.

14.13.18.9 Compatibility

14.13.18.10 Compatibility with other features

- Temporary tables do not support placement policies.
- Placement policies only ensure that data at rest resides on the correct TiKV nodes but do not guarantee that data in transit (via either user queries or internal operations) only occurs in a specific region.
- To configure TiFlash replicas for your data, you need to create TiFlash replicas rather than using placement policies.
- Syntactic sugar rules are permitted for setting `PRIMARY_REGION` and `REGIONS`. In the future, we plan to add varieties for `PRIMARY_RACK`, `PRIMARY_ZONE`, and `PRIMARY_HOST`. See issue #18030.

14.13.18.11 Compatibility with tools

Tool Name	Minimum supported version	Description

Tool Name	Minimum supported version	Description
Backup & Restore (BR)	6.0	Before v6.0, BR does not support backing up and restoring placement policies. For more information, see Why does an error occur when I restore placement rules to a clus-

Tool Name	Minimum supported version	Description
TiDB Lightning	Not compatible yet	An error is reported when TiDB Lightning imports backup data that contains placement policies
TiCDC	6.0	Ignores placement policies, and does not replicate the policies to the downstream

14.13.19 System Tables

14.13.19.1 `mysql` Schema

14.13.19.1.1 `mysql` Schema

The `mysql` schema contains TiDB system tables. The design is similar to the `mysql` schema in MySQL, where tables such as `mysql.user` can be edited directly. It also contains a number of tables which are extensions to MySQL.

> **Note:**
>
> In most scenarios, it is not recommended to change the content of system tables directly using `INSERT`, `UPDATE`, or `DELETE`. Instead, use statements such as `CREATE USER`, `ALTER USER`, `DROP USER`, `GRANT`, `REVOKE`, and `SHOW CREATE USER` to manage users and privileges. If direct modification of system tables is unavoidable, use `FLUSH PRIVILEGES` to make the changes take effect.

Grant system tables

These system tables contain grant information about user accounts and their privileges:

- `user`: user accounts, global privileges, and other non-privilege columns
- `db`: database-level privileges
- `tables_priv`: table-level privileges
- `columns_priv`: column-level privileges
- `password_history`: password change history
- `default_roles`: the default roles for a user
- `global_grants`: dynamic privileges
- `global_priv`: the authentication information based on certificates
- `role_edges`: the relationship between roles

Cluster status system tables

- The `tidb` table contains some global information about TiDB:
  - `bootstrapped`: whether the TiDB cluster has been initialized. Note that this value is read-only and cannot be modified.
  - `tidb_server_version`: the version information of TiDB when it is initialized. Note that this value is read-only and cannot be modified.
  - `system_tz`: the system time zone of TiDB.

- `new_collation_enabled`: whether TiDB has enabled the new framework for collations. Note that this value is read-only and cannot be modified.

Server-side help system tables

Currently, the `help_topic` is NULL.

Statistics system tables

- `stats_buckets`: the buckets of statistics
- `stats_histograms`: the histograms of statistics
- `stats_top_n`: the TopN of statistics
- `stats_meta`: the meta information of tables, such as the total number of rows and updated rows
- `stats_extended`: extended statistics, such as the order correlation between columns
- `stats_feedback`: the query feedback of statistics
- `stats_fm_sketch`: the FMSketch distribution of the histogram of the statistics column
- `stats_table_locked`: information about the locked statistics
- `stats_meta_history`: the meta information in the historical statistics
- `stats_history`: the other information in the historical statistics
- `analyze_options`: the default `analyze` options for each table
- `column_stats_usage`: the usage of column statistics
- `analyze_jobs`: the ongoing statistics collection tasks and the history task records within the last 7 days

Execution plan-related system tables

- `bind_info`: the binding information of execution plans
- `capture_plan_baselines_blacklist`: the blocklist for the automatic binding of the execution plan

System tables related to PLAN REPLAYER

- `plan_replayer_status`: the `PLAN REPLAYER CAPTURE` tasks registered by the user
- `plan_replayer_task`: the results of `PLAN REPLAYER CAPTURE` tasks

GC worker system tables

> **Note:**
>
> The GC worker system tables are only applicable to TiDB Self-Managed and not available on TiDB Cloud.

- `gc_delete_range`: the KV range to be deleted
- `gc_delete_range_done`: the deleted KV range

System tables related to cached tables

- `table_cache_meta` stores the metadata of cached tables.

TTL related system tables

- `tidb_ttl_table_status`: the previously executed TTL job and ongoing TTL job for all TTL tables
- `tidb_ttl_task`: the current ongoing TTL subtasks
- `tidb_ttl_job_history`: the execution history of TTL tasks in the last 90 days

System tables related to runaway queries

- `tidb_runaway_queries`: the history records of all identified runaway queries in the past 7 days
- `tidb_runaway_watch`: the watch list of runaway queries
- `tidb_runaway_watch_done`: a watch list of deleted or expired runaway queries

System tables related to metadata locks

- `tidb_mdl_view`: a view of metadata locks. You can use it to view the information about the currently blocked DDL statements. See also Metadata Lock.
- `tidb_mdl_info`: used internally by TiDB to synchronize metadata locks across nodes.

System tables related to DDL statements

- `tidb_ddl_history`: the history records of DDL statements
- `tidb_ddl_job`: the metadata of DDL statements that are currently being executed by TiDB
- `tidb_ddl_reorg`: the metadata of physical DDL statements (such as adding indexes) that are currently being executed by TiDB

System tables related to TiDB Distributed eXecution Framework (DXF)

- `dist_framework_meta`: the metadata of the Distributed eXecution Framework (DXF) task scheduler
- `tidb_global_task`: the metadata of the current DXF task
- `tidb_global_task_history`: the metadata of the historical DXF tasks, including both succeeded and failed tasks

- `tidb_background_subtask`: the metadata of the current DXF subtask
- `tidb_background_subtask_history`: the metadata of the historical DXF subtasks

System tables related to Resource Control

- `request_unit_by_group`: the history records of consumed resource units (RUs) of all resource groups

System tables related to backup and restore

- `tidb_pitr_id_map`: the ID mapping information for point-in-time recovery (PITR) operations

Miscellaneous system tables

> **Note:**
>
> The `tidb`, `expr_pushdown_blacklist`, `opt_rule_blacklist`, `table_cache_meta`, `tidb_import_jobs`, and `tidb_timers` system tables are only applicable to TiDB Self-Managed and not available on TiDB Cloud.

- `GLOBAL_VARIABLES`: global system variable table
- `expr_pushdown_blacklist`: the blocklist for expression pushdown
- `opt_rule_blacklist`: the blocklist for logical optimization rules
- `tidb_import_jobs`: the job information of `IMPORT INTO`
- `tidb_timers`: the metadata of internal timers
- `advisory_locks`: information related to Locking functions

- `GLOBAL_VARIABLES`: global system variable table

14.13.19.1.2 `mysql.tidb_mdl_view`

This table shows the information about the metadata lock views.

```
DESC mysql.tidb_mdl_view;
```

The output is as follows:

```
+------------+----------------+------+------+---------+-------+
| Field      | Type           | Null | Key | Default | Extra |
+------------+----------------+------+------+---------+-------+
| job_id     | bigint         | NO   | PRI | NULL    |       |
| db_name    | longtext       | YES |      | NULL    |       |
| table_name | longtext       | YES |      | NULL    |       |
| query      | longtext       | YES |      | NULL    |       |
| session_id | bigint unsigned | YES |   | NULL    |       |
| start_time | timestamp(6)   | YES |      | NULL    |       |
| SQL_DIGESTS | varchar(5)    | YES |      | NULL    |       |
+------------+----------------+------+------+---------+-------+
7 rows in set (0.00 sec)
```

Fields

- `job_id`: The identifier of the job.
- `db_name`: The database name.
- `table_name`: The table name.
- `query`: The query.
- `session_id`: The identifier of the session.
- `start_time`: The start time. This column was called `TxnStart` in earlier versions.
- `SQL_DIGESTS`: The digests of the SQL statements.

14.13.19.1.3 `mysql.user`

The `mysql.user` table provides information about user accounts and their privileges.

To view the structure of `mysql.user`, use the following SQL statement:

```
DESC mysql.user;
```

The output is as follows:

```
+-----------------------+------------------+------+------+-------------------+-------+
   ↪
| Field                 | Type             | Null | Key | Default           |
   ↪ Extra |
+-----------------------+------------------+------+------+-------------------+-------+
   ↪
| Host                  | char(255)        | NO   | PRI | NULL              |
   ↪       |
| User                  | char(32)         | NO   | PRI | NULL              |
   ↪       |
| authentication_string | text             | YES |      | NULL              |
   ↪       |
```

```
| plugin                | char(64)          | YES |     | NULL                |
   ↪       |
| Select_priv           | enum('N','Y')     | NO  |     | N                   |
   ↪       |

```

The `mysql.user` table contains several fields that can be categorized into three groups:

- Scope:

- `Host`: specifies the hostname of a TiDB account.
- `User`: specifies the username of a TiDB account.

- Privilege:

  The fields ending with `_priv` or `_Priv` define the permissions granted to a user account. For example, `Select_priv` means that the user has global `Select` privilege. For more information, see Privileges required for TiDB operations.

- Security:

  - `authentication_string` and `plugin`: `authentication_string` stores the credentials for the user account. The credentials are interpreted based on the authentication plugin specified in the `plugin` field.
  - `Account_locked`: indicates whether the user account is locked.
  - `Password_reuse_history` and `Password_reuse_time`: used for Password reuse policy.
  - `User_attributes`: provides information about user comments and user attributes.
  - `Token_issuer`: used for the `tidb_auth_token` authentication plugin.
  - `Password_expired`, `Password_last_changed`, and `Password_lifetime`: used for Password expiration policy.

Although most of the fields in the TiDB `mysql.user` table also exist in the MySQL `mysql.user` table, the `Token_issuer` field is specific to TiDB.

14.13.19.2 INFORMATION_SCHEMA

14.13.19.2.1 Information Schema

Information Schema provides an ANSI-standard way of viewing system metadata. TiDB also provides a number of custom `INFORMATION_SCHEMA` tables, in addition to the tables included for MySQL compatibility.

Many `INFORMATION_SCHEMA` tables have a corresponding `SHOW` statement. The benefit of querying `INFORMATION_SCHEMA` is that it is possible to join between tables.

Tables for MySQL compatibility

Table name	Description
`CHARACTER_SETS`	Provides a list of character sets the server supports.
`CHECK_CONSTRAINTS`	Provides information about `CHECK` constraints on tables.

Table name	Description
COLLATIONS	Provides a list of collations that the server supports.
COLLATION_CHARACTER_SET_APPLICABILITY	Explains which collations apply to which character sets.
COLUMNS	Provides a list of columns for all tables.
COLUMN_PRIVILEGES	Not implemented by TiDB. Returns zero rows.
COLUMN_STATISTICS	Not implemented by TiDB. Returns zero rows.
ENGINES	Provides a list of supported storage engines.
EVENTS	Not implemented by TiDB. Returns zero rows.
FILES	Not implemented by TiDB. Returns zero rows.
GLOBAL_STATUS	Not implemented by TiDB. Returns zero rows.
GLOBAL_VARIABLES	Not implemented by TiDB. Returns zero rows.
KEYWORDS	Provides a full list of keywords.
KEY_COLUMN_USAGE	Describes the key constraints of the columns, such as the primary key constraint.
OPTIMIZER_TRACE	Not implemented by TiDB. Returns zero rows.
PARAMETERS	Not implemented by TiDB. Returns zero rows.

Table name	Description
PARTITIONS	Provides a list of table partitions.
PLUGINS	Not implemented by TiDB. Returns zero rows.
PROCESSLIST	Provides similar information to the command `SHOW PROCESSLIST`.
PROFILING	Not implemented by TiDB. Returns zero rows.
REFERENTIAL_CONSTRAINTS	Provides information on `FOREIGN KEY` constraints.
ROUTINES	Not implemented by TiDB. Returns zero rows.
SCHEMATA	Provides similar information to `SHOW DATABASES`.
SCHEMA_PRIVILEGES	Not implemented by TiDB. Returns zero rows.
SESSION_STATUS	Not implemented by TiDB. Returns zero rows.
SESSION_VARIABLES	Provides similar functionality to the command `SHOW SESSION ↪ VARIABLES`
STATISTICS	Provides information on table indexes.
TABLES	Provides a list of tables that the current user has visibility of. Similar to `SHOW TABLES`.
TABLESPACES	Not implemented by TiDB. Returns zero rows.

Table name	Description
TABLE_CONSTRAINTS	Provides information on primary keys, unique indexes and foreign keys.
TABLE_PRIVILEGES	Not implemented by TiDB. Returns zero rows.
TRIGGERS	Not implemented by TiDB. Returns zero rows.
USER_ATTRIBUTES	Summarizes information about user comments and user attributes.
USER_PRIVILEGES	Summarizes the privileges associated with the current user.
VARIABLES_INFO	Provides information about TiDB system variables.
VIEWS	Provides a list of views that the current user has visibility of. Similar to running `SHOW FULL TABLES ↪ WHERE table_ ↪ type = 'VIEW'`

Tables that are TiDB extensions

> **Note:**
>
> Some of the following tables are only supported on TiDB Self-Managed and not supported on TiDB Cloud. To get a full list of unsupported tables on TiDB Cloud, see System tables.

Table name	Description
ANALYZE_STATUS	Provides information about tasks to collect statistics.
CLIENT_ERRORS_SUMMARY_BY_HOST	Provides a summary of errors and warnings generated by client requests and returned to clients.
CLIENT_ERRORS_SUMMARY_BY_USER	Provides a summary of errors and warnings generated by clients.
CLIENT_ERRORS_SUMMARY_GLOBAL	Provides a summary of errors and warnings generated by clients.
CLUSTER_CONFIG	Provides details about configuration settings for the entire TiDB cluster. This table is not applicable to TiDB Cloud.

Table name	Description
CLUSTER_DEADLOCKS	Provides a cluster-level view of the DEADLOCKS table.
CLUSTER_HARDWARE	Provides details on the underlying physical hardware discovered on each TiDB component. This table is not applicable to TiDB Cloud.
CLUSTER_INFO	Provides details on the current cluster topology. This table is not available on TiDB Cloud Serverless clusters.

Table name	Description
CLUSTER_LOAD	Provides current load information for TiDB servers in the cluster. This table is not applicable to TiDB Cloud.
CLUSTER_LOG	Provides a log for the entire TiDB cluster. This table is not applicable to TiDB Cloud.
CLUSTER_MEMORY_USAGE	Provides a cluster-level view of the MEMORY_USAGE table.
CLUSTER_MEMORY_USAGE_OPS_HISTORY	Provides a cluster-level view of the MEMORY_USAGE_OPS_HISTORY table.
CLUSTER_PROCESSLIST	Provides a cluster-level view of the PROCESSLIST table.

Table name	Description
CLUSTER_SLOW_QUERY	Provides a cluster-level view of the SLOW_QUERY table. This table is not available on TiDB Cloud Serverless clusters.
CLUSTER_STATEMENTS_SUMMARY	Provides a cluster-level view of the STATEMENTS_SUMMARY table. This table is not available on TiDB Cloud Serverless clusters.
CLUSTER_STATEMENTS_SUMMARY_HISTORY	Provides a cluster-level view of the STATEMENTS_SUMMARY_HISTORY table. This table is not available on TiDB Cloud Serverless clusters.

Table name	Description
CLUSTER_TIDB_INDEX_USAGE	Provides a cluster-level view of the TIDB_ ↪ INDEX_ ↪ USAGE table.
CLUSTER_TIDB_TRX	Provides a cluster-level view of the TIDB_TRX table.
CLUSTER_SYSTEMINFO	Provides details about kernel parameter configuration for servers in the cluster. This table is not applicable to TiDB Cloud.
DATA_LOCK_WAITS	Provides the lock-waiting information on the TiKV server.
DDL_JOBS	Provides similar output to ADMIN ↪ SHOW ↪ DDL ↪ JOBS

Table name	Description
DEADLOCKS	Provides the information of several deadlock errors that have recently occurred.
INSPECTION_RESULT	Triggers internal diagnostics checks. This table is not applicable to TiDB Cloud.
INSPECTION_RULES	A list of internal diagnostic checks performed. This table is not applicable to TiDB Cloud.
INSPECTION_SUMMARY	A summarized report of important monitoring metrics. This table is not applicable to TiDB Cloud.

Table name	Description
MEMORY_USAGE	The memory usage of the current TiDB instance.
MEMORY_USAGE_OPS_HISTORY	The history of memory-related operations and the execution basis of the current TiDB instance.
METRICS_SUMMARY	A summary of metrics extracted from Prometheus. This table is not applicable to TiDB Cloud.
METRICS_SUMMARY_BY_LABEL	See METRICS_SUMMARY table. This table is not applicable to TiDB Cloud.

Table name	Description
METRICS_TABLES	Provides the PromQL definitions for tables in METRICS_SCHEMA. This table is not applicable to TiDB Cloud.
PLACEMENT_POLICIES	Provides information on all placement policies. This table is not available on TiDB Cloud Serverless clusters.
SEQUENCES	The TiDB implementation of sequences is based on MariaDB.

Table name	Description
SLOW_QUERY	Provides information on slow queries on the current TiDB server. This table is not available on TiDB Cloud Serverless clusters.
STATEMENTS_SUMMARY	Similar to performance_schema statement summary in MySQL. This table is not available on TiDB Cloud Serverless clusters.
STATEMENTS_SUMMARY_HISTORY	Similar to performance_schema statement summary history in MySQL. This table is not available on TiDB Cloud Serverless clusters.

Table name	Description
TABLE_STORAGE_STATS	Provides details about table sizes in storage.
TIDB_HOT_REGIONS	Provides statistics about which regions are hot.
TIDB_HOT_REGIONS_HISTORY	Provides history statistics about which Regions are hot.
TIDB_INDEXES	Provides index information about TiDB tables.
TIDB_INDEX_USAGE	Provides the information of the index usage statistics on the TiDB node. |
TIDB_SERVERS_INFO	Provides a list of TiDB servers (namely, tidb-server component)

Table name	Description
TIDB_TRX	Provides the information of the transactions that are being executed on the TiDB node.
TIFLASH_REPLICA	Provides details about TiFlash replicas.
TIKV_REGION_PEERS	Provides details about where regions are stored.
TIKV_REGION_STATUS	Provides statistics about regions.
TIKV_STORE_STATUS	Provides basic information about TiKV servers.

14.13.19.2.2 ANALYZE_STATUS

The `ANALYZE_STATUS` table provides information about the running tasks that collect statistics and a limited number of history tasks.

Starting from TiDB v6.1.0, the `ANALYZE_STATUS` table supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the restart using this table. Before TiDB v6.1.0, the `ANALYZE_STATUS` table can only show instance-level tasks, and task records are cleared after a TiDB restart.

Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

```
USE information_schema;
```

```
DESC analyze_status;
```

Fields in the `ANALYZE_STATUS` table are described as follows:

- `TABLE_SCHEMA`: The name of the database to which the table belongs.
- `TABLE_NAME`: The name of the table.
- `PARTITION_NAME`: The name of the partitioned table.
- `JOB_INFO`: The information of the `ANALYZE` task. If an index is analyzed, this information will include the index name. When `tidb_analyze_version = 2`, this information will include configuration items such as sample rate.
- `PROCESSED_ROWS`: The number of rows that have been processed.
- `START_TIME`: The start time of the `ANALYZE` task.
- `END_TIME`: The end time of the `ANALYZE` task.
- `STATE`: The execution status of the `ANALYZE` task. Its value can be `pending`, `running` ↪ ,`finished` or `failed`.
- `FAIL_REASON`: The reason why the task fails. If the execution is successful, the value is `NULL`.
- `INSTANCE`: The TiDB instance that executes the task.

- PROCESS_ID: The process ID that executes the task.
- REMAINING_SECONDS: The estimated time (in seconds) remaining for the task to complete.
- PROGRESS: The progress of the task.
- ESTIMATED_TOTAL_ROWS: The total rows that need to be analyzed by the task.
