- `--concurrency`: controls how backup tasks are split into multiple requests and sent concurrently to the same TiKV node. This parameter primarily affects the granularity of request splitting from BR to TiKV, and no longer directly determines overall backup throughput. In most cases, you do not need to change this value. To improve backup performance, you should tune `tikv.backup.num-threads` instead.
- `--pitr-concurrency`: the number of concurrent tasks during log restore.
- `--tikv-max-restore-concurrency`: the maximum number of concurrent tasks per TiKV node during snapshot restore.
- `--compression`: determines the compression algorithm used for generating backup files. It supports `lz4`, `snappy`, and `zstd`, with the default being `zstd` (usually no need to modify). For guidance on choosing different compression algorithms, refer to this document.
- `--compression-level`: sets the compression level corresponding to the chosen compression algorithm for backup. The default compression level for `zstd` is 3. In most cases there is no need to set this option.

8.4.4.1.2 Commands of full backup

To back up cluster data, run the `tiup br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster (`full`) or a single table (`table`).

- Back up TiDB cluster snapshots
- Back up a database
- Back up a table
- Back up multiple tables with table filter
- Encrypt snapshots

8.4.4.1.3 Commands of log backup

To start log backup and manage log backup tasks, run the `tiup br log` command.

- Start a log backup task
- Query the log backup status
- Pause and resume a log backup task
- Stop and restart a log backup task
- Clean up the backup data
- View the backup metadata

8.4.4.1.4 Commands of restoring backup data

To restore cluster data, run the `tiup br restore` command. You can add the `full`, `db`, or `table` sub-command to specify the scope of your restore: the whole cluster (`full`), a single database (`db`), or a single table (`table`).

- Point-in-time recovery
- Restore cluster snapshots
- Restore a database
- Restore a table
- Restore multiple tables with table filter
- Restore encrypted snapshots

8.4.4.2 TiDB Snapshot Backup and Restore Command Manual

This document describes the commands of TiDB snapshot backup and restore according to the application scenarios, including:

- Back up cluster snapshots
- Back up a database or a table
    - Back up a database
    - Back up a table
    - Back up multiple tables with table filter
- Back up statistics
- Encrypt the backup data
- Restore cluster snapshots
- Restore a database or a table
    - Restore a database
    - Restore a table
    - Restore multiple tables with table filter
    - Restore execution plan bindings from the `mysql` schema
- Restore encrypted snapshots

For more information about snapshot backup and restore, refer to:

- Snapshot Backup and Restore Guide
- Backup and Restore Use Cases

8.4.4.2.1 Back up cluster snapshots

You can back up the latest or specified snapshot of the TiDB cluster using the `tiup br backup full` command. For more information about the command, run the `tiup br backup full --help` command.

```
tiup br backup full \
    --pd "${PD_IP}:2379" \
    --backupts '2024-06-28 13:30:00 +08:00' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file backupfull.log
```

In the preceding command:

- `--backupts`: The time point of the snapshot. The format can be TSO or timestamp, such as `400036290571534337` or `2024-06-28 13:30:00 +08:00`. If the data of this snapshot is garbage collected, the `tiup br backup` command returns an error and 'br' exits. If you leave this parameter unspecified, `br` picks the snapshot corresponding to the backup start time.
- `--log-file`: The target file where `br` log is written.

> **Note:**
>
> - Starting from v8.5.0, the BR tool disables the table-level checksum calculation during full backups by default (`--checksum=false`) to improve backup performance.
> - The BR tool already supports self-adapting to GC. It automatically registers `backupTS` (the latest PD timestamp by default) to PD's `safePoint` to ensure that TiDB's GC Safe Point does not move forward during the backup, thus avoiding manually setting GC configurations.

During backup, a progress bar is displayed in the terminal, as shown below. When the progress bar advances to 100%, the backup is complete.

```
Full Backup <---------/.....................................................>
    ↪ 17.12%.
```

8.4.4.2.2 Back up a database or a table

Backup & Restore (BR) supports backing up partial data of a specified database or table from a cluster snapshot or incremental data backup. This feature allows you to filter out unwanted data from snapshot backup and incremental data backup, and back up only business-critical data.

Back up a database

To back up a database in a cluster, run the `tiup br backup db` command.

The following example backs up the `test` database to Amazon S3:

```
tiup br backup db \
    --pd "${PD_IP}:2379" \
    --db test \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file backuptable.log
```

In the preceding command, `--db` specifies the database name, and other parameters are the same as those in Back up TiDB cluster snapshots.

Back up a table

To back up a table in a cluster, run the `tiup br backup table` command.

The following example backs up the `test.usertable` table to Amazon S3:

```
tiup br backup table \
    --pd "${PD_IP}:2379" \
    --db test \
    --table usertable \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file backuptable.log
```

In the preceding command, `--db` and `--table` specify the database name and table name respectively, and other parameters are the same as those in Back up TiDB cluster snapshots.

Back up multiple tables with table filter

To back up multiple tables with more criteria, run the `tiup br backup full` command and specify the table filters with `--filter` or `-f`.

The following example backs up tables that match the `db*.tbl*` filter rule to Amazon S3:

```
tiup br backup full \
    --pd "${PD_IP}:2379" \
    --filter 'db*.tbl*' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file backupfull.log
```

8.4.4.2.3 Back up statistics

Starting from TiDB v7.5.0, the `br` command-line tool introduces the `--ignore-stats` ↪ parameter. When you set this parameter to `false`, the `br` command-line tool supports backing up statistics of columns, indexes, and tables. In this case, you do not need to manually run the statistics collection task for the TiDB database restored from the backup, or wait for the completion of the automatic collection task. This feature simplifies the database maintenance work and improves the query performance.

If you do not set this parameter to `false`, the `br` command-line tool uses the default setting `--ignore-stats=true`, which means statistics are not backed up during data backup.

The following is an example of backing up cluster snapshot data and backing up table statistics with `--ignore-stats=false`:

```
tiup br backup full \
--storage local:///br_data/ --pd "${PD_IP}:2379" --log-file restore.log \
--ignore-stats=false
```

After backing up data with the preceding configuration, when you restore data, the `br` command-line tool automatically restores table statistics if table statistics are included in the backup (Starting from v8.0.0, the `br` command-line tool introduces the `--load-stats` parameter, which controls whether to restore backup statistics. The default behavior is to restore backup statistics. There is no need to set it to `false` in most cases):

```
tiup br restore full \
--storage local:///br_data/ --pd "${PD_IP}:2379" --log-file restore.log
```

When the backup and restore feature backs up data, it stores statistics in JSON format within the `backupmeta` file. When restoring data, it loads statistics in JSON format into the cluster. For more information, see LOAD STATS.

8.4.4.2.4 Encrypt the backup data

BR supports encrypting backup data at the backup side and at the storage side when backing up to Amazon S3. You can choose either encryption method as required.

Since TiDB v5.3.0, you can encrypt backup data by configuring the following parameters:

- `--crypter.method`: Encryption algorithm, which can be `aes128-ctr`, `aes192-ctr`, or `aes256-ctr`. The default value is `plaintext`, indicating that data is not encrypted.
- `--crypter.key`: Encryption key in hexadecimal string format. It is a 128-bit (16 bytes) key for the algorithm `aes128-ctr`, a 24-byte key for the algorithm `aes192-ctr`, and a 32-byte key for the algorithm `aes256-ctr`.
- `--crypter.key-file`: The key file. You can directly pass in the file path where the key is stored as a parameter without passing in the `crypter.key`.

The following is an example:

```
tiup br backup full\
    --pd ${PD_IP}:2379 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --crypter.method aes128-ctr \
    --crypter.key 0123456789abcdef0123456789abcdef
```

Note:

- If the key is lost, the backup data cannot be restored to the cluster.
- The encryption feature needs to be used on `br` and TiDB clusters v5.3.0 or later versions. The encrypted backup data cannot be restored on clusters earlier than v5.3.0.

8.4.4.2.5 Restore cluster snapshots

You can restore a TiDB cluster snapshot by running the `tiup br restore full` command.

```
tiup br restore full \
    --pd "${PD_IP}:2379" \
    --with-sys-table \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --ratelimit 128 \
    --log-file restorefull.log
```

In the preceding command:

- `--with-sys-table`: BR restores **data in some system tables**, including account permission data and SQL bindings, and statistics (see Back up statistics). However, it does not restore statistics tables (`mysql.stat_*`) and system variable tables (`mysql.
  ↪ tidb` and `mysql.global_variables`). For more information, see Restore tables in the `mysql` schema.
- `--ratelimit`: The maximum speed **per TiKV** performing restore tasks. The unit is in MiB/s.
- `--log-file`: The target file where the `br` log is written.

During restore, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the restore task is completed. Then `br` will verify the restored data to ensure data security.

```
Full Restore <---------/.....................................................>
    ↪ 17.12%.
```

8.4.4.2.6 Restore a database or a table

You can use `br` to restore partial data of a specified database or table from backup data. This feature allows you to filter out data that you do not need during the restore.

Restore a database

To restore a database to a cluster, run the `tiup br restore db` command.

The following example restores the `test` database from the backup data to the target cluster:

```
tiup br restore db \
    --pd "${PD_IP}:2379" \
    --db "test" \
    --ratelimit 128 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restore_db.log
```

In the preceding command, `--db` specifies the name of the database to be restored and other parameters are the same as those in Restore TiDB cluster snapshots.

> **Note:**
>
> When you restore the backup data, the database name specified by `--db` must be the same as the one specified by `-- db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, and you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

Restore a table

To restore a single table to a cluster, run the `tiup br restore table` command.

The following example restores the `test.usertable` table from Amazon S3 to the target cluster:

```
tiup br restore table \
    --pd "${PD_IP}:2379" \
    --db "test" \
    --table "usertable" \
    --ratelimit 128 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restore_table.log
```

In the preceding command, `--table` specifies the name of the table to be restored, and other parameters are the same as those in Restore a database.

Restore multiple tables with table filter

To restore multiple tables with more complex filter rules, run the `tiup br restore ↪ full` command and specify the table filters with `--filter` or `-f`.

The following example restores tables that match the `db*.tbl*` filter rule from Amazon S3 to the target cluster:

```
tiup br restore full \
    --pd "${PD_IP}:2379" \
    --filter 'db*.tbl*' \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restorefull.log
```

Restore execution plan bindings from the `mysql` schema

To restore execution plan bindings of a cluster, you can run the `tiup br restore full` command, including the `--with-sys-table` option and also the `--filter` or `-f` option to specify the `mysql` schema to be restored.

The following is an example of restoring the `mysql.bind_info` table:

```
tiup br restore full \
    --pd "${PD_IP}:2379" \
    --filter 'mysql.bind_info' \
    --with-sys-table \
    --ratelimit 128 \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --log-file restore_system_table.log
```

After the restore is completed, you can confirm the execution plan binding information with `SHOW GLOBAL BINDINGS`:

```
SHOW GLOBAL BINDINGS;
```

The dynamic loading of execution plan bindings after the restore is still undergoing optimization (related issues are #46527 and #46528). You need to manually reload the execution plan bindings after the restore.

```
-- Ensure that the mysql.bind_info table has only one record for builtin_
    ↪ pseudo_sql_for_bind_lock. If there are more records, you need to
    ↪ manually delete them.
SELECT count(*) FROM mysql.bind_info WHERE original_sql = 'builtin_pseudo_
    ↪ sql_for_bind_lock';
DELETE FROM bind_info WHERE original_sql = 'builtin_pseudo_sql_for_bind_
    ↪ lock' LIMIT 1;

-- Force to reload the binding information.
ADMIN RELOAD BINDINGS;
```

8.4.4.2.7 Restore encrypted snapshots

After encrypting the backup data, you need to pass in the corresponding decryption parameters to restore the data. Ensure that the decryption algorithm and key are correct. If the decryption algorithm or key is incorrect, the data cannot be restored. The following is an example:

```
tiup br restore full\
    --pd "${PD_IP}:2379" \
    --storage "s3://${backup_collection_addr}/snapshot-${date}?access-key=${
        ↪ access-key}&secret-access-key=${secret-access-key}" \
    --crypter.method aes128-ctr \
    --crypter.key 0123456789abcdef0123456789abcdef
```

8.4.4.3 TiDB Log Backup and PITR Command Manual

This document describes the commands used in TiDB log backup and point-in-time recovery (PITR).

For more information about log backup and PITR, refer to:

- Log Backup and PITR Guide
- Back up and Restore Use Cases

8.4.4.3.1 Perform log backup

You can start and manage log backup using the `tiup br log` command.

```
tiup br log --help

backup stream log from TiDB/TiKV cluster

Usage:
  br log [command]

Available Commands:
  metadata  get the metadata of log dir
  pause     pause a log backup task
  resume    resume a log backup task
  start     start a log backup task
  status    get status for the log backup task
  stop      stop a log backup task
  truncate  truncate the log data until sometime
```

Each subcommand is described as follows:

- `tiup br log start`: start a log backup task.

- `tiup br log status`: query the status of the log backup task.
- `tiup br log pause`: pause a log backup task.
- `tiup br log resume`: resume a paused log backup task.
- `tiup br log stop`: stop a log backup task and delete the task metadata.
- `tiup br log truncate`: clean up the log backup data from the backup storage.
- `tiup br log metadata`: query the metadata of the log backup data.

Start a log backup task

You can run the `tiup br log start` command to start a log backup task. This task runs in the background of your TiDB cluster and automatically backs up the change log of KV storage to the backup storage.

Run `tiup br log start --help` to see the help information:

```
tiup br log start --help
start a log backup task

Usage:
  br log start [flags]

Flags:
  -h, --help            help for start
  --start-ts string     usually equals last full backupTS, used for backup
     ↪ log. Default value is current ts. support TSO or datetime, e.g.
     ↪ '400036290571534337' or '2018-05-11 01:42:23+0800'.
  --task-name string    The task name for the backup log task.

Global Flags:
 --ca string              CA certificate path for TLS connection
 --cert string            Certificate path for TLS connection
 --key string             Private key path for TLS connection
 -u, --pd strings         PD address (default [127.0.0.1:2379])
 -s, --storage string     specify the url where backup storage, eg, "s3://
    ↪ bucket/path/prefix"
```

The example output only shows the common parameters. These parameters are described as follows:

- `--start-ts`: specifies the start timestamp for the log backup. If this parameter is not specified, the backup program uses the current time as `start-ts`.
- `task-name`: specifies the task name for the log backup. This name is also used to query, pause, and resume the backup task.
- `--ca`, `--cert`, `--key`: specifies the mTLS encryption method to communicate with TiKV and PD.
- `--pd`: specifies the PD address for the backup cluster. BR needs to access PD to start the log backup task.

- `--storage`: specifies the backup storage address. Currently, BR supports Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage as the storage for log backup. The preceding command uses Amazon S3 as an example. For details, see URI Formats of External Storage Services.

Usage example:

```
tiup br log start \
  --task-name=pitr \
  --pd="${PD_IP}:2379" \
  --storage='s3://backup-101/logbackup?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}'
```

Encrypt the log backup data

BR enables you to encrypt log backup data before uploading it to your backup storage.

Starting from TiDB v8.4.0, you can encrypt log backup data by passing the following parameters in the log backup command, which is similar to snapshot backup encryption:

- `--log.crypter.method`: Encryption algorithm, which can be `aes128-ctr`, `aes192-ctr`, or `aes256-ctr`. The default value is `plaintext`, indicating that data is not encrypted.
- `--log.crypter.key`: Encryption key in hexadecimal string format. It is a 128-bit (16 bytes) key for the algorithm `aes128-ctr`, a 24-byte key for the algorithm `aes192-ctr`, and a 32-byte key for the algorithm `aes256-ctr`.
- `--log.crypter.key-file`: The key file. You can directly pass in the file path where the key is stored as a parameter without passing in the `crypter.key`.

The following is an example:

```
tiup br log start \
    --task-name=pitr-with-encryption
    --pd ${PD_IP}:2379 \
    --storage "s3://${BACKUP_COLLECTION_ADDR}/snapshot-${DATE}?access-key=${
      ↪ AWS_ACCESS_KEY}&secret-access-key=${AWS_SECRET_ACCESS_KEY}" \
    --log.crypter.method aes128-ctr \
    --log.crypter.key 0123456789abcdef0123456789abcdef
```

However, in scenarios with higher security requirements, you might not want to pass a fixed encryption key directly in the command line. To further enhance security, you can use a master key based encryption system to manage encryption keys. This system generates different data keys to encrypt different log backup files and supports master key rotation. You can configure it using the following parameters:

- `--master-key-crypter-method`: Encryption algorithm based on the master key, which can be `aes128-ctr`, `aes192-ctr`, or `aes256-ctr`. The default value is `plaintext`, indicating that data is not encrypted.

- `--master-key`: Master key configuration. It can be a master key stored on a local disk or a master key managed by a cloud Key Management Service (KMS).

Encrypt using a master key stored on a local disk:

```
tiup br log start \
    --task-name=pitr-with-encryption \
    --pd ${PD_IP}:2379 \
    --storage "s3://${BACKUP_COLLECTION_ADDR}/snapshot-${DATE}?access-key=${
        ↪ AWS_ACCESS_KEY}&secret-access-key=${AWS_SECRET_ACCESS_KEY}" \
    --master-key-crypter-method aes128-ctr \
    --master-key "local:///path/to/master.key"
```

Encrypt using a master key managed by AWS KMS:

```
tiup br log start \
    --task-name=pitr-with-encryption \
    --pd ${PD_IP}:2379 \
    --storage "s3://${BACKUP_COLLECTION_ADDR}/snapshot-${DATE}?access-key=${
        ↪ AWS_ACCESS_KEY}&secret-access-key=${AWS_SECRET_ACCESS_KEY}" \
    --master-key-crypter-method aes128-ctr \
    --master-key "aws-kms:///${AWS_KMS_KEY_ID}?AWS_ACCESS_KEY_ID=${AWS_
        ↪ ACCESS_KEY}&AWS_SECRET_ACCESS_KEY=${AWS_SECRET_ACCESS_KEY}&REGION=
        ↪ ${AWS_REGION}"
```

Encrypt using a master key managed by Google Cloud KMS:

```
tiup br log start \
    --task-name=pitr-with-encryption \
    --pd ${PD_IP}:2379 \
    --storage "s3://${BACKUP_COLLECTION_ADDR}/snapshot-${DATE}?access-key=${
        ↪ AWS_ACCESS_KEY}&secret-access-key=${AWS_SECRET_ACCESS_KEY}" \
    --master-key-crypter-method aes128-ctr \
    --master-key "gcp-kms:///projects/$GCP_PROJECT_ID/locations/$GCP_
        ↪ LOCATION/keyRings/$GCP_KEY_RING/cryptoKeys/$GCP_KEY_NAME?AUTH=
        ↪ specified&CREDENTIALS=$GCP_CREDENTIALS_PATH"
```

Note:

- If the key is lost, the log backup data cannot be restored to the cluster.
- The encryption feature needs to be used on `br` and TiDB clusters v8.4.0 or later versions. The encrypted log backup data cannot be restored on clusters earlier than v8.4.0.

Query the log backup status

You can run the `tiup br log status` command to query the log backup status.

Run `tiup br log status --help` to see the help information:

```
tiup br log status --help
get status for the log backup task

Usage:
  br log status [flags]

Flags:
  -h, --help         help for status
  --json             Print JSON as the output.
  --task-name string The task name for backup stream log. If default, get
     ↪ status of all of tasks (default "*")

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

In the example output, `task-name` is used to specify the name of the backup task. The default value is `*`, which means querying the status of all tasks.

Usage example:

```
tiup br log status --task-name=pitr --pd="${PD_IP}:2379"
```

Expected output:

```
  Total 1 Tasks.
> #1 <
             name: pitr
           status:  NORMAL
            start: 2022-07-14 20:08:03.268 +0800
              end: 2090-11-18 22:07:45.624 +0800
          storage: s3://backup-101/logbackup
      speed(est.): 0.82 ops/s
checkpoint[global]: 2022-07-25 22:52:15.518 +0800; gap=2m52s
```

The output fields are described as follows:

- `status`: the status of the backup task, which can be `NORMAL`, `ERROR`, or `PAUSE`.
- `start`: the start time of the backup task. It is the `start-ts` value specified when the backup task is started.

- `storage`: the backup storage address.
- `speed`: the total QPS of the backup task. QPS means the number of logs backed per second.
- `checkpoint [global]`: all data before this checkpoint is backed up to the backup storage. This is the latest timestamp available for restoring the backup data.
- `error [store]`: the error the log backup program encounters on the storage node.

Pause and resume a log backup task

You can run the `tiup br log pause` command to pause a running log backup task.

Run `tiup br log pause --help` to see the help information:

```
tiup br log pause --help
pause a log backup task

Usage:
  br log pause [flags]

Flags:
  --gc-ttl int       the TTL (in seconds) that PD holds for BR's GC
     ↪ safepoint (default 86400)
  -h, --help         help for status
  --task-name string The task name for backup stream log.

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

Note:

- After the log backup task is paused, to prevent the MVCC data that generates the change log from being deleted, the backup program automatically sets the current backup checkpoint as the service safepoint, which retains MVCC data within the latest 24 hours. If the backup task is paused for more than 24 hours, the corresponding data is garbage collected and is not backed up.
- Retaining too much MVCC data has a negative impact on the storage capacity and performance of the TiDB cluster. Therefore, it is recommended to resume the backup task in time.

Usage example:

```
tiup br log pause --task-name=pitr --pd="${PD_IP}:2379"
```

You can run the `tiup br log resume` command to resume a paused backup task.

Run `tiup br log resume --help` to see the help information:

```
tiup br log resume --help
resume a log backup task

Usage:
  br log resume [flags]

Flags:
  -h, --help         help for status
  --task-name string The task name for backup stream log.

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

After the backup task is paused for more than 24 hours, running `tiup br log resume` reports an error, and BR prompts that backup data is lost. To handle this error, refer to Backup & Restore FAQs.

Usage example:

```
tiup br log resume --task-name=pitr --pd="${PD_IP}:2379"
```

Stop and restart a log backup task

You can stop a log backup task by running the `tiup br log stop` command and restart a log backup task that is stopped by using the original `--storage` directory.

Stop a log backup task

You can run the `tiup br log stop` command to stop a log backup task. This command cleans up the task metadata in the backup cluster.

Run `tiup br log stop --help` to see the help information:

```
tiup br log stop --help
stop a log backup task

Usage:
  br log stop [flags]
```

```
Flags:
  -h, --help         help for status
  --task-name string The task name for the backup log task.

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
```

> **Note:**
>
> Use this command with caution. If you need to pause a log backup task, use `tiup br log pause` and `tiup br log resume` instead.

Usage example:

```
tiup br log stop --task-name=pitr --pd="${PD_IP}:2379"
```

Restart a log backup task

After running the `tiup br log stop` command to stop a log backup task, you can create a new log backup task in another `--storage` directory or restart the log backup task in the original `--storage` directory by running the `tiup br log start` command. If you restart the task in the original `--storage` directory, pay attention to the following points:

- Parameters of the `--storage` directory for restarting a task must be the same as the task that is stopped.
- The `--start-ts` does not need to be specified. BR automatically starts the backup from the last backup checkpoint.
- If the task is stopped for a long time and multiple versions of the data have been garbage collected, the error `BR:Backup:ErrBackupGCSafepointExceeded` is reported when you attempt to restart the task. In this case, you have to create a new log backup task in another `--storage` directory.

Clean up log backup data

You can run the `tiup br log truncate` command to clean up the outdated or no longer needed log backup data.

Run `tiup br log truncate --help` to see the help information:

```
tiup br log truncate --help
truncate the incremental log until sometime.

Usage:
  br log truncate [flags]

Flags:
  --dry-run      Run the command but don't really delete the files.
  -h, --help     help for truncate
  --until string Remove all backup data until this TS.(support TSO or
     ↪ datetime, e.g. '400036290571534337' or '2018-05-11 01:42:23+0800'.)
  -y, --yes      Skip all prompts and always execute the command.

Global Flags:
  -s, --storage string     specify the url where backup storage, eg, "s3://
     ↪ bucket/path/prefix"
```

This command only accesses the backup storage and does not access the TiDB cluster. Some parameters are described as follows:

- `--dry-run`: run the command but do not really delete the files.
- `--until`: delete all log backup data before the specified timestamp.
- `--storage`: the backup storage address. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URI Formats of External Storage Services.

Usage example:

```
tiup br log truncate --until='2022-07-26 21:20:00+0800' \
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
   ↪ key=${secret-access-key}'
```

Expected output:

```
Reading Metadata... DONE; take = 277.911599ms
We are going to remove 9 files, until 2022-07-26 21:20:00.0000.
Sure? (y/N) y
Clearing data files... DONE; take = 43.504161ms, kv-count = 53, kv-size =
   ↪ 4573(4.573kB)
Removing metadata... DONE; take = 24.038962ms
```

View the log backup metadata

You can run the `tiup br log metadata` command to view the log backup metadata in the storage system, such as the earliest and latest timestamp that can be restored.

Run `tiup br log metadata --help` to see the help information:

```
tiup br log metadata --help
get the metadata of log backup storage

Usage:
  br log metadata [flags]

Flags:
  -h, --help     help for metadata

Global Flags:
  -s, --storage string     specify the url where backup storage, eg, "s3://
     ↪ bucket/path/prefix"
```

This command only accesses the backup storage and does not access the TiDB cluster.

The `--storage` parameter is used to specify the backup storage address. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URI Formats of External Storage Services.

Usage example:

```
tiup br log metadata --storage='s3://backup-101/logbackup?access-key=${
   ↪ access-key}&secret-access-key=${secret-access-key}'
```

Expected output:

```
[2022/07/25 23:02:57.236 +08:00] [INFO] [collector.go:69] ["log metadata"] [
   ↪ log-min-ts=434582449885806593] [log-min-date="2022-07-14 20:08:03.268
   ↪  +0800"] [log-max-ts=434834300106964993] [log-max-date="2022-07-25
   ↪ 23:00:15.618 +0800"]
```

8.4.4.3.2 Restore to a specified point in time (PITR)

> **Note:**
>
> If you specify `--full-backup-storage` as the incremental backup address for `restore point`, for restores of this backup and any previous incremental backups, you need to set the parameter `--allow-pitr-from-incremental` to `true` to make the incremental backups compatible with the subsequent log backups.

You can run the `tiup br restore point` command to perform a PITR on a new cluster or just restore the log backup data.

Run `tiup br restore point --help` to see the help information:

```
tiup br restore point --help
restore data from log until specify commit timestamp

Usage:
  br restore point [flags]

Flags:
  --full-backup-storage string specify the backup full storage. fill it if
     ↪ want restore full backup before restore log.
  -h, --help                help for point
  --restored-ts string      the point of restore, used for log restore.
     ↪ support TSO or datetime, e.g. '400036290571534337' or '2018-05-11
     ↪ 01:42:23+0800'
  --start-ts string         the start timestamp which log restore from.
     ↪ support TSO or datetime, e.g. '400036290571534337' or '2018-05-11
     ↪ 01:42:23+0800'

Global Flags:
 --ca string               CA certificate path for TLS connection
 --cert string             Certificate path for TLS connection
 --key string              Private key path for TLS connection
 -u, --pd strings          PD address (default [127.0.0.1:2379])
 -s, --storage string      specify the url where backup storage, eg, "s3://
    ↪ bucket/path/prefix"
```

The example output only shows the common parameters. These parameters are described as follows:

- `--full-backup-storage`: the storage address for the snapshot (full) backup. To use PITR, specify this parameter and choose the latest snapshot backup before the restore timestamp. To restore only log backup data, you can omit this parameter. Note that when initializing the recovery cluster for the first time, you must specify a snapshot backup. Currently, BR supports Amazon S3, GCS, and Azure Blob Storage as the storage for log backup. For details, see URI Formats of External Storage Services.
- `--restored-ts`: the timestamp that you want to restore data to. If this parameter is not specified, BR restores data to the latest timestamp available in the log backup, that is, the checkpoint of the backup data.
- `--start-ts`: the start timestamp that you want to restore log backup data from. If you only need to restore log backup data, you must specify this parameter.
- `--pd`: the PD address of the restore cluster.
- `--ca`, `--cert`, `--key`: specify the mTLS encryption method to communicate with TiKV and PD.

- `--storage`: the storage address for the log backup. Currently, BR supports Amazon S3, GCS, or Azure Blob Storage as the storage for log backup. For details, see URI Formats of External Storage Services.

Usage example:

```
tiup br restore point --pd="${PD_IP}:2379"
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}'
--full-backup-storage='s3://backup-101/snapshot-202205120000?access-key=${
    ↪ access-key}&secret-access-key=${secret-access-key}'

Full Restore
    ↪ <-----------------------------------------------------------------------------
    ↪  100.00%
*** ***["Full Restore success summary"] ****** [total-take=3.112928252s] [
    ↪ restore-data-size(after-compressed)=5.056kB] [Size=5056] [BackupTS
    ↪ =434693927394607136] [total-kv=4] [total-kv-size=290B] [average-speed
    ↪ =93.16B/s]
Restore Meta Files
    ↪ <-----------------------------------------------------------------------------
    ↪  100.00%
Restore KV Files
    ↪ <-----------------------------------------------------------------------------
    ↪  100.00%
"restore log success summary"] [total-take=192.955533ms] [restore-from
    ↪ =434693681289625602] [restore-to=434693753549881345] [total-kv-count
    ↪ =33] [total-size=21551]
```

Note:

- When you restore the cluster for the first time, you must specify the full snapshot data. Otherwise, some data in the newly created table might be incorrect due to rewriting Table ID rules. For more information, see GitHub issue #54418.
- You cannot restore the log backup data of a certain time period repeatedly. If you restore the log backup data of a range `[t1=10, t2=20)` repeatedly, the restored data might be inconsistent.
- When you restore log data of different time periods in multiple batches, ensure that the log data is restored in consecutive order. If you restore the log backup data of `[t1, t2)`, `[t2, t3)`, and `[t3, t4)` in consecutive order, the restored data is consistent. However, if you restore

> `[t1, t2)` and then skip `[t2, t3)` to restore `[t3, t4)`, the restored data might be inconsistent.

Restore encrypted log backup data

To restore encrypted log backup data, you need to pass the corresponding decryption parameters in the restore command. Make sure that the decryption parameters are the same as those used for encryption. If the decryption algorithm or key is incorrect, the data cannot be restored.

The following is an example:

```
tiup br restore point --pd="${PD_IP}:2379"
--storage='s3://backup-101/logbackup?access-key=${ACCESS-KEY}&secret-access-
    ↪ key=${SECRET-ACCESS-KEY}'
--full-backup-storage='s3://backup-101/snapshot-202205120000?access-key=${
    ↪ ACCESS-KEY}&secret-access-key=${SECRET-ACCESS-KEY}'
--crypter.method aes128-ctr
--crypter.key 0123456789abcdef0123456789abcdef
--log.crypter.method aes128-ctr
--log.crypter.key 0123456789abcdef0123456789abcdef
```

If a log backup is encrypted using a master key, you can decrypt and restore the backup data using the following command:

```
tiup br restore point --pd="${PD_IP}:2379"
--storage='s3://backup-101/logbackup?access-key=${ACCESS-KEY}&secret-access-
    ↪ key=${SECRET-ACCESS-KEY}'
--full-backup-storage='s3://backup-101/snapshot-202205120000?access-key=${
    ↪ ACCESS-KEY}&secret-access-key=${SECRET-ACCESS-KEY}'
--crypter.method aes128-ctr
--crypter.key 0123456789abcdef0123456789abcdef
--master-key-crypter-method aes128-ctr
--master-key "local:///path/to/master.key"
```

8.4.5 References

8.4.5.1 BR Features

8.4.5.1.1 Backup Auto-Tune New in v5.4.0

Before TiDB v5.4.0, when you back up data using Backup & Restore (BR), the number of threads used for backup makes up 75% of the logical CPU cores. Without a speed limit, the backup process can consume a lot of cluster resources, which has a considerable impact

on the performance of the online cluster. Although you can reduce the impact of backup by adjusting the size of the thread pool, it is a tedious task to observe the CPU load and manually adjust the thread pool size.

To reduce the impact of backup tasks on the cluster, TiDB v5.4.0 introduces the auto-tune feature, which is enabled by default. When the cluster resource utilization is high, BR automatically limits the resources used by backup tasks and thereby reduces their impact on the cluster. The auto-tune feature is enabled by default.

Usage scenario

If you want to reduce the impact of backup tasks on the cluster, you can enable the auto-tune feature. With this feature enabled, TiDB performs backup tasks as fast as possible without excessively affecting the cluster.

Alternatively, you can limit the backup speed by using the TiKV configuration item `backup.num-threads` or using the parameter `--ratelimit`. When `--ratelimit` is set, to avoid too many tasks causing the speed limit to fail, the `concurrency` parameter of br is automatically adjusted to `1`.

Use auto-tune

The auto-tune feature is enabled by default, without additional configuration.

> **Note:**
>
> For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To manually enable the auto-tune feature, you need to set the TiKV configuration item `backup.enable-auto-tune` to `true`.

TiKV supports dynamically configuring the auto-tune feature. You can enable or disable the feature without restarting your cluster. To dynamically enable or disable the auto-tune feature, run the following command:

```
tikv-ctl modify-tikv-config -n backup.enable-auto-tune -v <true|false>
```

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

Limitations

Auto-tune is a coarse-grained solution for limiting backup speed. It reduces the need for manual tuning. However, because of the lack of fine-grained control, auto-tune might not be able to completely remove the impact of backup on the cluster.

The auto-tune feature has the following issues and corresponding solutions:

- Issue 1: For **write-heavy clusters**, auto-tune might put the workload and backup tasks into a "positive feedback loop": the backup tasks take up too many resources, which causes the cluster to use fewer resources; at this point, auto-tune might mistakenly assume that the cluster is not under heavy workload and thus allowing backup to run faster. In such cases, auto-tune is ineffective.

    - Solution: Manually adjust `backup.num-threads` to a smaller number to limit the number of threads used by backup tasks. The working principle is as follows:

      The backup process includes lots of SST decoding, encoding, compression, and decompression, which consume CPU resources. In addition, previous test cases have shown that during the backup process, the CPU utilization of the thread pool used for backup is close to 100%. This means that the backup tasks take up a lot of CPU resources. By adjusting the number of threads used by the backup tasks, TiKV can limit the CPU cores used by backup tasks, thus reducing the impact of backup tasks on the cluster performance.

- Issue 2: For **clusters with hotspots**, backup tasks on the TiKV node that has hotspots might be excessively limited, which slows down the overall backup process.

    - Solution: Eliminate the hotspot node, or disable auto-tune on the hotspot node (this might reduce the cluster performance).

- Issue 3: For scenarios with **high traffic jitter**, because auto-tune adjusts the speed limit on a fixed interval (1 minute by default), it might not be able to handle high traffic jitter. For details, see `auto-tune-refresh-interval`.

    - Solution: Disable auto-tune.

Implementation

Auto-tune adjusts the size of the thread pool used by backup tasks to ensure that the overall CPU utilization of the cluster does not exceed a specific threshold.

This feature has two related configuration items not listed in the TiKV configuration file. These two configuration items are only for internal tuning. You do **not** need to configure these two configuration items when you perform backup tasks.

- `backup.auto-tune-remain-threads`:

    - Auto-tune controls the resources used by the backup tasks and ensures that at least `backup.auto-tune-remain-threads` cores are available for other tasks on the same node.
    - Default value: `round(0.2 * vCPU)`

- `backup.auto-tune-refresh-interval`:

- Every `backup.auto-tune-refresh-interval` minute(s), auto-tune refreshes the statistics and recalculates the maximum number of CPU cores that backup tasks can use.
- Default value: `1m`

The following is an example of how auto-tune works. `*` denotes a CPU core used by backup tasks. `^` denotes a CPU core used by other tasks. `-` denotes an idle CPU core.

```
|--------| The server has 8 logical CPU cores.
|*******-| By default, `backup.num-threads` is `4`. Note that auto-tune
   ↪ makes sure that the thread pool size is never larger than `backup.num
   ↪ -threads`.
|^^****--| By default, `auto-tune-remain-threads` = round(8 * 0.2) = 2. Auto
   ↪ -tune adjusts the size of the thread pool to `4`.
|^^^^**--| Because the cluster workload gets higher, auto-tune adjusts the
   ↪ size of the thread pool to `2`. After that, the cluster still has 2
   ↪ idle CPU cores.
```

In the **Backup CPU Utilization** panel, you can see the size of the thread pool adjusted by auto-tune:

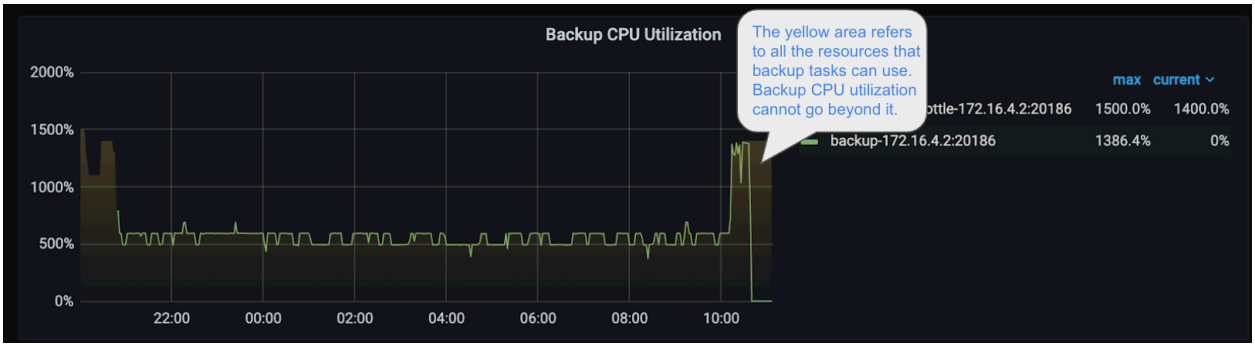

Figure 144: Grafana dashboard example of backup auto-tune metrics

In the image above, the yellow semi-transparent area represents the threads available for backup tasks. You can see the CPU utilization of backup tasks does not go beyond the yellow area.

8.4.5.1.2 Batch Create Table

When restoring data, Backup & Restore (BR) creates databases and tables in the target TiDB cluster and then restores the backup data to the tables. In versions earlier than TiDB v6.0.0, BR uses the serial execution implementation to create tables in the restore process. However, when BR restores data with a large number of tables (nearly 50000), this implementation takes much time on creating tables.

To speed up the table creation process and reduce the time for restoring data, the Batch Create Table feature is introduced in TiDB v6.0.0. This feature is enabled by default.

Note:

- To use the Batch Create Table feature, both TiDB and BR are expected to be of v6.0.0 or later. If either TiDB or BR is earlier than v6.0.0, BR uses the serial execution implementation.
- Suppose that you use a cluster management tool (for example, TiUP), and your TiDB and BR are of v6.0.0 or later versions, or your TiDB and BR are upgraded from a version earlier than v6.0.0 to v6.0.0 or later.

Usage scenario

If you need to restore data with a massive amount of tables, for example, 50000 tables, you can use the Batch Create Table feature to speed up the restore process.

For the detailed effect, see Test for the Batch Create Table Feature.

Use Batch Create Table

BR enables the Batch Create Table feature by default, with the default configuration of `--ddl-batch-size=128` in v6.0.0 or later to speed up the restore process. Therefore, you do not need to configure this parameter. `--ddl-batch-size=128` means creating tables in batches, each batch with 128 tables.

To disable this feature, you can set `--ddl-batch-size` to `1`. See the following example command:

```
tiup br restore full \
--storage local:///br_data/ --pd "${PD_IP}:2379" --log-file restore.log \
--ddl-batch-size=1
```

After this feature is disabled, BR uses the serial execution implementation instead.

Implementation

- Serial execution implementation before v6.0.0:

  When restoring data, BR creates databases and tables in the target TiDB cluster and then restores the backup data to the tables. To create tables, BR calls TiDB internal API first, and then processes table creation tasks, which works similarly to executing the `Create Table` statement. The TiDB DDL owner creates tables sequentially. Once the DDL owner creates a table, the DDL schema version changes correspondingly and each version change is synchronized to other TiDB DDL workers (including BR). Therefore, when restoring a large number of tables, the serial execution implementation is time-consuming.

- Batch create table implementation since v6.0.0:

  By default, BR creates tables in multiple batches, and each batch has 128 tables. Using this implementation, when BR creates one batch of tables, the TiDB schema version only changes once. This implementation significantly increases the speed of table creation.

Feature test

This section describes the test information about the Batch Create Table feature. The test environment is as follows:

- Cluster configurations:
  - 15 TiKV instances. Each TiKV instance is equipped with 16 CPU cores, 80 GB memory, and 16 threads to process RPC requests (`import.num-threads` = 16).
  - 3 TiDB instances. Each TiDB instance is equipped with 16 CPU cores, 32 GB memory.
  - 3 PD instances. Each PD instance is equipped with 16 CPU cores, 32 GB memory.
- The size of data to be restored: 16.16 TB

The test result is as follows:

```
'[2022/03/12 22:37:49.060 +08:00] [INFO] [collector.go:67] ["Full restore
    ↪ success summary"] [total-ranges=751760] [ranges-succeed=751760] [
    ↪ ranges-failed=0] [split-region=1h33m18.078448449s] [restore-ranges
    ↪ =542693] [total-take=1h41m35.471476438s] [restore-data-size(after-
    ↪ compressed)=8.337TB] [Size=8336694965072] [BackupTS
    ↪ =431773933856882690] [total-kv=148015861383] [total-kv-size=16.16TB]
    ↪ [average-speed=2.661GB/s]'
```

From the test result, you can see that the average speed of restoring one TiKV instance is as high as 181.65 MB/s (which equals to `average-speed/tikv_count`).

8.4.5.1.3 Checkpoint Backup

Snapshot backup might be interrupted due to recoverable errors, such as disk exhaustion and node crash. Before TiDB v6.5.0, data that is backed up before the interruption would be invalidated even after the error is addressed, and you need to start the backup from scratch. For large clusters, this incurs considerable extra cost.

In TiDB v6.5.0, Backup & Restore (BR) introduces the checkpoint backup feature to allow continuing an interrupted backup. This feature can retain most data of the interrupted backup.

Application scenarios

If your TiDB cluster is large and cannot afford to back up again after a failure, you can use the checkpoint backup feature. The br command-line tool (hereinafter referred to as `br`) periodically records the shards that have been backed up. In this way, the next backup retry can use the backup progress close to the abnormal exit.

Implementation details

During a snapshot backup, `br` encodes the tables into the corresponding key space, and generates backup RPC requests before sending them to TiKV nodes. After receiving the backup request, TiKV nodes back up the data within the requested range. Every time a TiKV node finishes backing up data of a Region, it returns the backup information of this range to `br`.

`br` records the information returned by TiKV nodes, which helps `br` get the key ranges that have been backed up. The checkpoint backup feature periodically uploads the new backup information to external storage so that the key ranges that have been backed up can be persisted.

When `br` retries the backup, it reads the key ranges that have been backed up from external storage, and compares them with the key ranges of the backup task. The differential data helps `br` to determine the key range that still needs to be backed up in checkpoint backup.

Usage limitations

Checkpoint backup relies on the GC mechanism and cannot recover all data that has been backed up. The following sections provide the details.

Backup retry must be prior to GC

During the backup, `br` periodically updates the `gc-safepoint` of the backup snapshot in PD to avoid data being garbage collected. When `br` exits, the `gc-safepoint` cannot be updated in time. As a result, before the next backup retry, the data might have been garbage collected.

To avoid this situation, `br` keeps the `gc-safepoint` for about one hour by default when `gcttl` is not specified. You can set the `gcttl` parameter to extend the retention period if needed .

The following example sets `gcttl` to 15 hours (54000 seconds) to extend the retention period of `gc-safepoint`:

```
tiup br backup full \
--storage local:///br_data/ --pd "${PD_IP}:2379" \
--gcttl 54000
```

> **Note:**
>
> The `gc-safepoint` created before backup is deleted after the snapshot backup is completed. You do not need to delete it manually.

Some data needs to be backed up again

When `br` retries backup, some data that has been backed up might need to be backed up again, including the data being backed up and the data not recorded by the checkpoint.

- If the interruption is caused by an error, `br` will persist the meta information of the data backed up before exit. In this case, only the data being backed up needs to be backed up again in the next retry.
- If the `br` process is interrupted by the system, `br` cannot persist the meta information of the data backed up to the external storage. Since `br` persists the meta information every 30 seconds, data backed up in the last 30 seconds before interruption cannot be persisted and needs to be backed up again in the next retry.

8.4.5.1.4 Checkpoint Restore

Snapshot restore or log restore might be interrupted due to recoverable errors, such as disk exhaustion and node crash. Before TiDB v7.1.0, the recovery progress before the interruption would be invalidated even after the error is addressed, and you need to start the restore from scratch. For large clusters, this incurs considerable extra cost.

Starting from TiDB v7.1.0, Backup & Restore (BR) introduces the checkpoint restore feature, which enables you to continue an interrupted restore. This feature can retain most recovery progress of the interrupted restore.

Application scenarios

If your TiDB cluster is large and cannot afford to restore again after a failure, you can use the checkpoint restore feature. The br command-line tool (hereinafter referred to as `br`) periodically records the shards that have been restored. In this way, the next restore retry can use a recovery progress point close to the abnormal exit.

Implementation principles

The implementation of checkpoint restore is divided into two parts: snapshot restore and log restore. For more information, see Implementation details.

Snapshot restore

The implementation of snapshot restore is similar to snapshot backup. `br` restores all SST files within a key range (Region) in batches. After completing a restore, `br` records this range and the table ID of the restored cluster table. The checkpoint restore feature periodically uploads the new restore information to external storage so that the key ranges that have been restored can be persisted.

When `br` retries a restore, it reads the key ranges that have been restored from external storage, and matches them with the corresponding table ID. During the restore, `br` skips any key ranges that overlap with those recorded in the checkpoint restore, and that have the same table ID.

If you delete tables before `br` retries the restore, the table ID of the newly created table during the retry will be different from the previously recorded table ID in the checkpoint

restore. In this case, `br` bypasses the previous checkpoint restore information and restores the table again. This means that the same table with a new ID disregards the old ID's checkpoint restore information and records the new checkpoint restore information corresponding to the new ID.

Due to the use of the MVCC (Multi-Version Concurrency Control) mechanism, data with specified timestamps can be written unordered and repeatedly.

When restoring database or table DDLs using snapshot restore, the `ifExists` parameter is added. For existing databases or tables that are already considered created, `br` automatically skips the restore.

Log restore

Log restore is the process of restoring data metadata backed up by TiKV nodes (meta-kv) in the order of timestamps. The checkpoint restore first establishes a one-to-one ID mapping relationship between the backup cluster and the restored cluster based on the meta-kv data. This ensures that the ID of meta-kv remains consistent across different restore retries, enabling meta-kv to be restored again.

Unlike snapshot backup files, the range of log backup files might overlap. Thus, the key range cannot be used directly as recovery progress metadata. Additionally, there might be a large number of log backup files. However, each log backup file has a fixed position in the log backup metadata. This means that a unique position in the log backup metadata can be assigned to each log backup file as recovery progress metadata.

The log backup metadata contains an array of file metadata. Each file metadata in the array represents a file composed of multiple log backup files. The file metadata records the offset and size of a log backup file in the concatenated file. Therefore, `br` can use the triple `(log backup metadata name, file metadata array offset, log backup file array offset)` to uniquely identify a log backup file.

Usage limitations

Checkpoint restore relies on the GC mechanism and cannot record all data that has been restored. The following sections provide the details.

GC will be paused

During a log restore, the order of the restored data is unordered, which means that the deletion record of a key might be restored before its write record. If GC is triggered at this time, all data of the key will be deleted and then GC cannot process subsequent write records of the key. To avoid this situation, `br` pauses GC during log restore. If `br` exits halfway, GC remains paused.

After the log restore is completed, GC is restarted automatically without manual startup. However, if you decide not to continue the restore, you can manually enable GC as follows:

The principle of `br` pausing GC is to execute `SET config tikv gc.ratio-threshold = -1.0` to set `gc.ratio-threshold` to a negative number, thus pausing GC. You can manually enable GC by modifying the value of `gc.ratio-threshold`. For example, to reset to its default value, you can execute `SET config tikv gc.ratio-threshold = 1.1`.

Some data needs to be restored again

When `br` retries a restore, some data that has been restored might need to be restored again, including the data being restored and the data not recorded by the checkpoint.

- If the interruption is caused by an error, `br` persists the meta information of the data restored before exit. In this case, only the data being restored needs to be restored again in the next retry.
- If the `br` process is interrupted by the system, `br` cannot persist the meta information of the data restored to the external storage. Since `br` persists the meta information every 30 seconds, data restored in the last 30 seconds before interruption cannot be persisted and needs to be restored again in the next retry.

Avoid modifying cluster data during the restore

After a restore failure, avoid writing, deleting, or creating tables in the cluster. This is because the backup data might contain DDL operations for renaming tables. If you modify the cluster data, the checkpoint restore cannot decide whether the deleted or existing table are resulted from external operations, which affects the accuracy of the next restore retry.

Cross-major-version checkpoint recovery is not recommended

Cross-major-version checkpoint recovery is not recommended. For clusters where `br` recovery fails using the Long-Term Support (LTS) versions prior to v8.5.0, recovery cannot be continued with v8.5.0 or later LTS versions, and vice versa.

Implementation details

Checkpoint restore operations are divided into two parts: snapshot restore and PITR restore.

Snapshot restore

During the initial restore, `br` creates a `__TiDB_BR_Temporary_Snapshot_Restore_Checkpoint` database in the target cluster. This database records checkpoint data, the upstream cluster ID, and the BackupTS of the backup data.

If the restore fails, you can retry it using the same command, and `br` will automatically read the checkpoint information from the `__TiDB_BR_Temporary_Snapshot_Restore_Checkpoint` database and resume from the last restore point.

If the restore fails and you try to restore backup data with different checkpoint information to the same cluster, `br` reports an error. It indicates that the current upstream cluster ID or BackupTS is different from the checkpoint record. If the restore cluster has been cleaned, you can manually delete the `__TiDB_BR_Temporary_Snapshot_Restore_Checkpoint` database and retry with a different backup.

PITR restore

PITR (Point-in-time recovery) consists of snapshot restore and log restore phases.

During the initial restore, `br` first enters the snapshot restore phase. This phase follows the same process as the preceding snapshot restore: BR records the checkpoint data, the upstream cluster ID, and BackupTS of the backup data (that is, the start time point `start-ts` of log restore) in the `__TiDB_BR_Temporary_Snapshot_Restore_Checkpoint` database. If restore fails during this phase, you cannot adjust the `start-ts` of log restore when resuming checkpoint restore.

When entering the log restore phase during the initial restore, `br` creates a `__TiDB_BR_Temporary_Log_Restore_Checkpoint` database in the target cluster. This database records checkpoint data, the upstream cluster ID, and the restore time range (`start-ts` and `restored-ts`). If restore fails during this phase, you need to specify the same `start-ts` and `restored-ts` as recorded in the checkpoint database when retrying. Otherwise, `br` will report an error and prompt that the current specified restore time range or upstream cluster ID is different from the checkpoint record. If the restore cluster has been cleaned, you can manually delete the `__TiDB_BR_Temporary_Log_Restore_Checkpoint` database and retry with a different backup.

Before entering the log restore phase during the initial restore, `br` constructs a mapping of upstream and downstream cluster database and table IDs at the `restored-ts` time point. This mapping is persisted in the system table `mysql.tidb_pitr_id_map` to prevent duplicate allocation of database and table IDs. Deleting data from `mysql.tidb_pitr_id_map` might lead to inconsistent PITR restore data.

8.4.5.2 Back up and Restore Data Using Dumpling and TiDB Lightning

This document introduces how to use Dumpling and TiDB Lightning to back up and restore full data of TiDB.

If you need to back up a small amount of data (for example, less than 50 GiB) and do not require high backup speed, you can use Dumpling to export data from the TiDB database and then use TiDB Lightning to restore the data into another TiDB database.

If you need to back up larger databases, the recommended method is to use BR. Note that Dumpling can be used to export large databases, but BR is a better tool for that.

8.4.5.2.1 Requirements

- Install Dumpling:

```
tiup install dumpling
```

- Install TiDB Lightning:

```
tiup install tidb-lightning
```

- Grant the source database privileges required for Dumpling
- Grant the target database privileges required for TiDB Lightning

8.4.5.2.2 Resource requirements

Operating system: The example in this document uses fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU: Because TiDB Lightning consumes high resources, it is recommended to allocate more than 64 GiB of memory and more than 32 CPU cores. To get the best performance, make sure that the CPU core to memory (GiB) ratio is greater than 1:2.

Disk space:

It is recommended to use Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage as the external storage. With such a cloud storage, you can store backup files quickly without being limited by the disk space.

If you need to save data of one backup task to the local disk, note the following limitations:

- Dumpling requires a disk space that can store the whole data source (or to store all upstream tables to be exported). To calculate the required space, see Downstream storage space requirements.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.

Note: It is difficult to calculate the exact data volume exported by Dumpling from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `DATA_LENGTH` field in the `information_schema.tables` table:

```
-- Calculate the size of all schemas
SELECT
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(DATA_LENGTH)) AS 'Data Size',
  FORMAT_BYTES(SUM(INDEX_LENGTH)) 'Index Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_SCHEMA;

-- Calculate the 5 largest tables
SELECT
  TABLE_NAME,
  TABLE_SCHEMA,
```

```
  FORMAT_BYTES(SUM(data_length)) AS 'Data Size',
  FORMAT_BYTES(SUM(index_length)) AS 'Index Size',
  FORMAT_BYTES(SUM(data_length+index_length)) AS 'Total Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_NAME,
  TABLE_SCHEMA
ORDER BY
  SUM(DATA_LENGTH+INDEX_LENGTH) DESC
LIMIT
  5;
```

Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Index might take extra space.
- RocksDB has a space amplification effect.

8.4.5.2.3 Use Dumpling to back up full data

1. Run the following command to export full data from TiDB to `s3://my-bucket/sql-backup` in Amazon S3:

   ```
   tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MiB -B my_db1 -f 'my_db1.table[12]' -o 's3://my-bucket/sql-backup'
   ```

   Dumpling exports data in SQL files by default. You can specify a different file format by adding the `--filetype` option.

   For more configurations of Dumpling, see Option list of Dumpling.

2. After the export is completed, you can view the backup files in the directory `s3://my-bucket/sql-backup`.

8.4.5.2.4 Use TiDB Lightning to restore full data

1. Edit the `tidb-lightning.toml` file to import full data backed up using Dumpling from `s3://my-bucket/sql-backup` to the target TiDB cluster:

```
[lightning]
# log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the
    ↪ target TiDB cluster cannot provide any service.
# "tidb": The "tidb" backend is recommended to import data less than 1
    ↪ TiB. During the import, the target TiDB cluster can provide
    ↪ service normally. For more information on the backends, refer to
    ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-backends.
backend = "local"
# Sets the temporary storage directory for the sorted Key-Value files.
    ↪ The directory must be empty, and the storage space must be
    ↪ greater than the size of the dataset to be imported. For better
    ↪ import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage, which can
    ↪  use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
# The data source directory. The same directory where Dumpling exports
    ↪ data in "Use Dumpling to back up full data".
data-source-dir = "${data-path}" # A local path or S3 path. For example
    ↪ , 's3://my-bucket/sql-backup'

[tidb]
# The target TiDB cluster information.
host = ${host}             # e.g.: 172.16.32.1
port = ${port}             # e.g.: 4000
user = "${user_name}"      # e.g.: "root"
password = "${password}"   # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs
    ↪ to obtain the table schema information from the TiDB status port.
    ↪  e.g.: 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD
    ↪ . When backend = "local", you must specify status-port and pd-
    ↪ addr correctly. Otherwise, the import will be abnormal.
```

For more information on TiDB Lightning configuration, refer to TiDB Lightning Configuration.

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

   If you import data from S3, pass the SecretKey and AccessKey that have access to the S3 storage path as environment variables to the TiDB Lightning node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can `grep` the keyword `progress` in the log to check the progress of the import. The progress is updated every 5 minutes by default.

4. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

8.4.5.3 Back Up and Restore RawKV

TiKV and PD can constitute a KV database when used without TiDB, which is called RawKV. TiKV-BR supports data backup and restore for products that use RawKV.

For more details, see TiKV-BR User Docs.

8.4.5.4 TiDB Incremental Backup and Restore Guide

Incremental data of a TiDB cluster is differentiated data between the starting snapshot and the end snapshot of time period, and the DDLs generated during this period. Compared with full (snapshot) backup data, incremental data is smaller and therefore it is a supplementary to snapshot backup, which reduces the volume of backup data. To perform incremental backup, ensure that MVCC data generated within the specified period is not

garbage collected by the TiDB GC mechanism. For example, to perform incremental backup hourly, you must set `tidb_gc_life_time` to a value greater than 1 hour.

> **Warning:**
>
> Development for this feature has stopped. It is recommended that you use log backup and PITR as an alternative.

8.4.5.4.1 Limitations

Because restoring the incremental backup relies on the snapshot of the database table at the backup time point to filter incremental DDL statements, the tables deleted during the incremental backup process might still exist after the data restore and need to be manually deleted.

The incremental backup does not support batch renaming of tables. If batch renaming of tables occurs during the incremental backup process, the data restore might fail. It is recommended to perform a full backup after batch renaming tables, and use the latest full backup to replace the incremental data during restore.

Starting from v8.3.0, the `--allow-pitr-from-incremental` configuration parameter is introduced to control whether incremental backups and subsequent log backups are compatible. The default value is `true`, which means that incremental backups are compatible with subsequent log backups.

- When you keep the default value `true`, the DDLs that need to be replayed are strictly checked before the incremental restore begins. This mode does not yet support `ADD INDEX`, `MODIFY COLUMN`, or `REORG PARTITION`. If you want to use incremental backups together with log backups, make sure that none of the preceding DDLs exist during the incremental backup process. Otherwise, these three DDLs cannot be replayed correctly.
- If you want to use incremental restores without log backups during the whole recovery process, you can set `--allow-pitr-from-incremental` to `false` to skip the checks in the incremental recovery phase.

8.4.5.4.2 Back up incremental data

To back up incremental data, run the `tiup br backup` command with **the last backup timestamp** `--lastbackupts` specified. In this way, br command-line tool automatically backs up incremental data generated between `lastbackupts` and the current time. To get `--lastbackupts`, run the `validate` command. The following is an example:

```
LAST_BACKUP_TS=`tiup br validate decode --field="end-version" --storage "s3
    ↪ ://backup-101/snapshot-202209081330?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"| tail -n1`
```

The following command backs up the incremental data between (`LAST_BACKUP_TS`, `current PD timestamp`] and the DDLs generated during this time period:

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330/incr?access-key=${access-
    ↪ key}&secret-access-key=${secret-access-key}" \
--lastbackupts ${LAST_BACKUP_TS} \
--ratelimit 128
```

- `--lastbackupts`: The last backup timestamp.
- `--ratelimit`: The maximum speed **per TiKV** performing backup tasks (in MiB/s).
- `storage`: The storage path of backup data. You need to save the incremental backup data under a different path from the previous snapshot backup. In the preceding example, incremental backup data is saved in the `incr` directory under the full backup data. For details, see URI Formats of External Storage Services.

8.4.5.4.3 Restore incremental data

When restoring incremental data, make sure that all the data backed up before `LAST_BACKUP_TS` has been restored to the target cluster. Also, because incremental restore updates data, you need to ensure that there are no other writes during the restore. Otherwise, conflicts might occur.

The following command restores the full backup data stored in the `backup-101/snapshot-202209081330` directory:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

The following command restores the incremental backup data stored in the `backup-101/snapshot-202209081330/incr` directory:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330/incr?access-key=${access-
    ↪ key}&secret-access-key=${secret-access-key}"
```

8.5 Cluster Disaster Recovery (DR)

8.5.1 Overview of TiDB Disaster Recovery Solutions

This document introduces the disaster recovery (DR) solutions provided by TiDB. The organization of this document is as follows:

- Describes the basic concepts in DR.
- Introduces the architecture of TiDB, TiCDC, and Backup & Restore (BR).
- Describes the DR solutions provided by TiDB.
- Compares these DR solutions.

8.5.1.1 Basic concepts

- RTO (Recovery Time Objective): The time required for the system to recover from a disaster.
- RPO (Recovery Point Objective): The maximum amount of data loss that the business can tolerate in a disaster.

The following figure illustrates these two concepts:

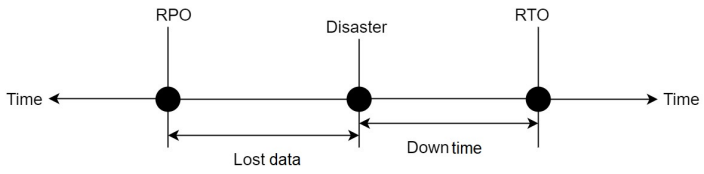

Figure 145: RTO and RPO

- Error tolerance objective: Because a disaster can affect different regions. In this document, the term error tolerance objective is used to describe the maximum range of a disaster that the system can tolerate.
- Region: This document focuses on regional DR and "region" mentioned here refers to a geographical area or city.

8.5.1.2 Component architecture

Before introducing specific DR solutions, this section introduces the architecture of TiDB components from the perspective of DR, including TiDB, TiCDC, and BR.

8.5.1.2.1 TiDB

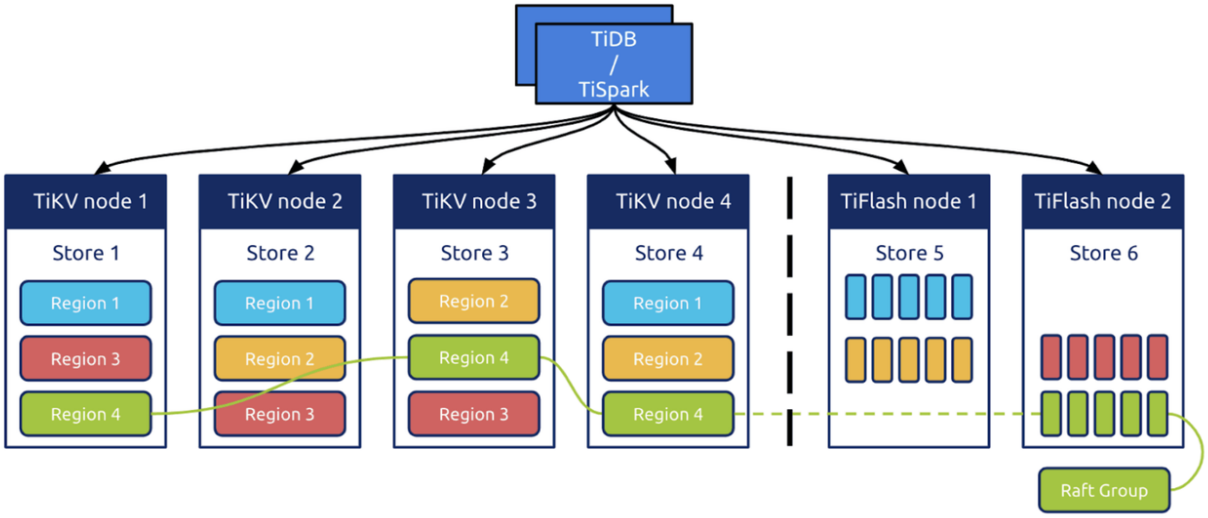

Figure 146: TiDB architecture

TiDB is designed with an architecture of separated computing and storage:

- TiDB is the SQL computing layer of the system.
- TiKV is the storage layer of the system, and is a row-based storage engine. Region is the basic unit for scheduling data in TiKV. A Region is a collection of sorted rows of data. The data in a Region is saved in at least three replicas, and data changes are replicated in the log layer through the Raft protocol.
- An optional component, TiFlash is a columnar storage engine that can be used to speed up analytical queries. Data is replicated from TiKV to TiFlash through the learner role in a Raft group.

TiDB stores three complete data replicas. Therefore, it is naturally capable of DR based on multiple replicas. At the same time, because TiDB uses Raft logs to replicate transaction logs, it can also provide DR based on transaction log replication.

8.5.1.2.2 TiCDC

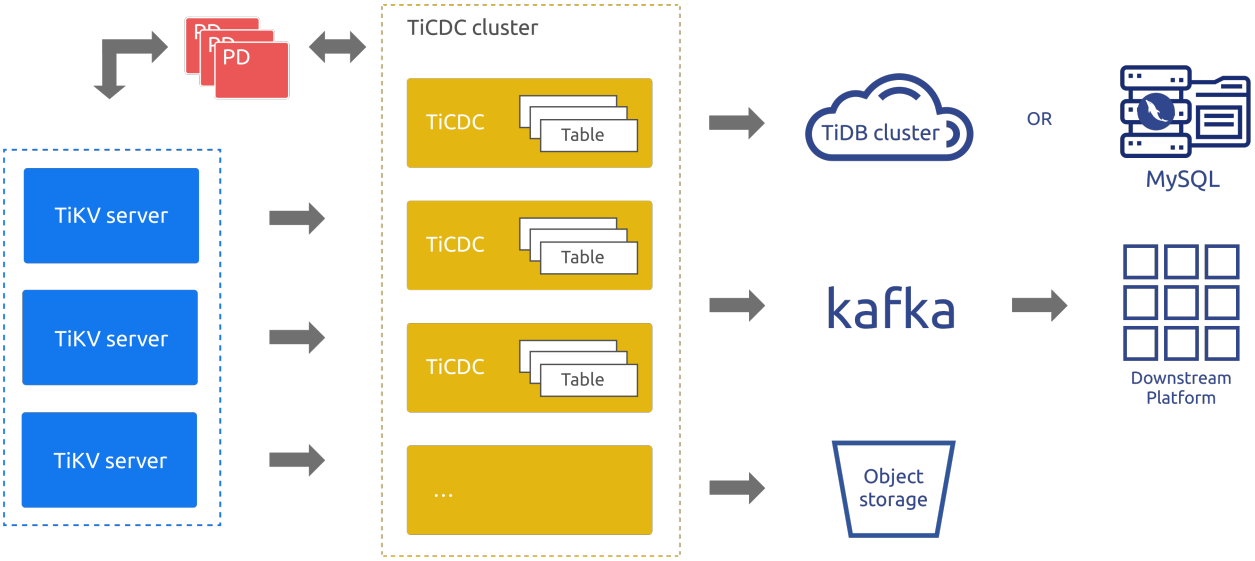

Figure 147: TiCDC architecture

As an incremental data replication tool for TiDB, TiCDC is highly available through PD's etcd. TiCDC pulls data changes from TiKV nodes through multiple Capture processes, and then sorts and merges data changes internally. After that, TiCDC replicates data to multiple downstream systems by using multiple replication tasks. In the preceding architecture diagram:

- TiKV server: sends data changes in the upstream to TiCDC nodes. When TiCDC nodes find the change logs not continuous, they will actively request the TiKV server to provide change logs.
- TiCDC: runs multiple Capture processes. Each Capture process pulls part of the KV change logs, and sorts the pulled data before replicating the changes to different downstream systems.

It can be seen from the preceding architecture diagram that, the architecture of TiCDC is similar to that of a transactional log replication system, but with better scalability and merits of logical data replication. Therefore, TiCDC is a good supplementation for TiDB in the DR scenario.

8.5.1.2.3 BR

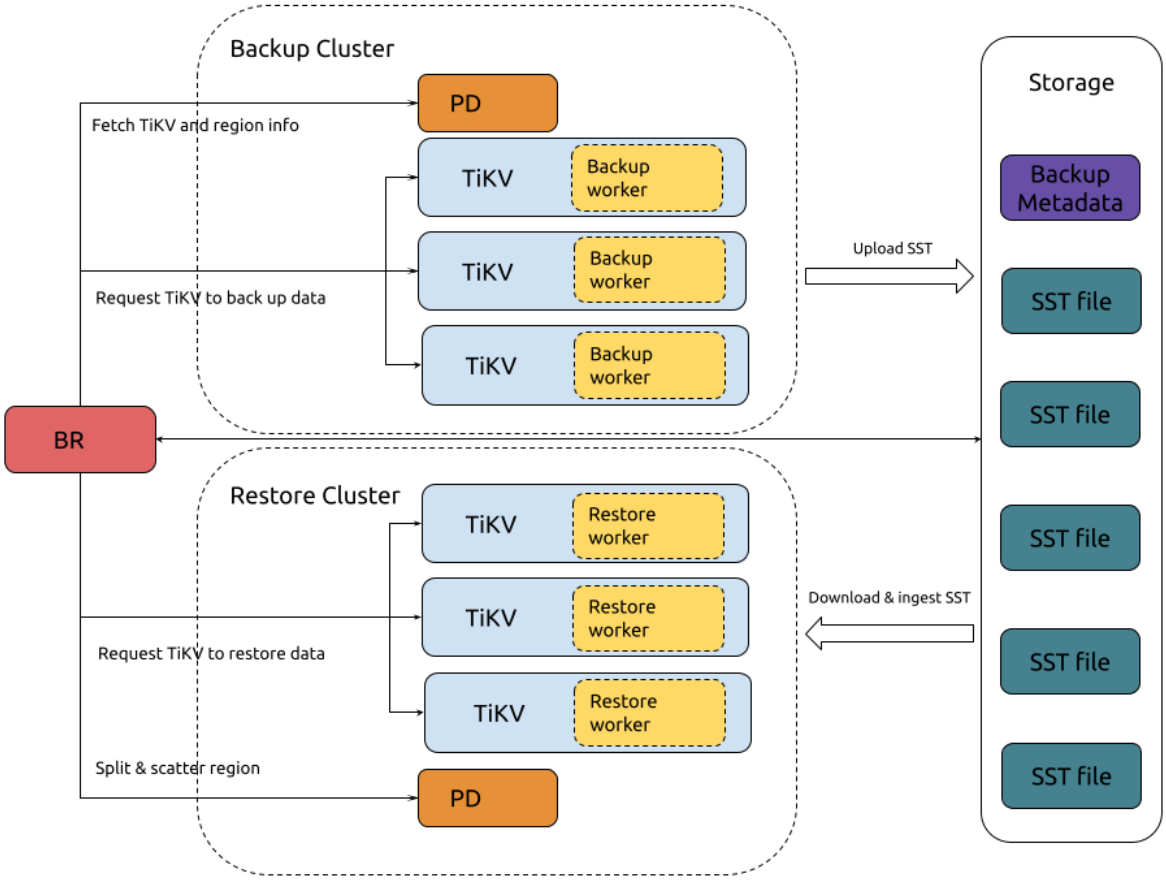

Figure 148: BR architecture

As a backup and restore tool for TiDB, BR can perform full snapshot backup based on a specific time point and continuous log backup of a TiDB cluster. When the TiDB cluster is completely unavailable, you can restore the backup files in a new cluster. BR is usually considered the last resort for data security.

8.5.1.3 Solutions introduction

8.5.1.3.1 DR solution based on primary and secondary clusters

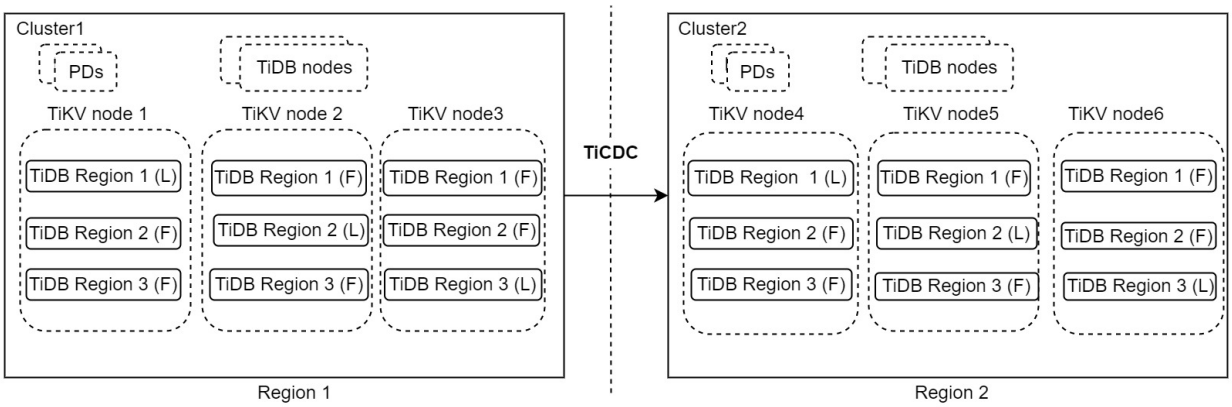

Figure 149: Primary-secondary cluster DR

The preceding architecture contains two TiDB clusters, cluster 1 runs in region 1 and handles read and write requests. Cluster 2 runs in region 2 and works as the secondary cluster. When cluster 1 encounters a disaster, cluster 2 takes over services. Data changes are replicated between the two clusters using TiCDC. This architecture is also called the "1:1" DR solution.

This architecture is simple and highly available with region-level error tolerance objective, scalable write capability, second-level RPO, and minute-level RTO or even lower. If a production system does not require the RPO to be zero, this DR solution is recommended. For more information about this solution, see DR solution based on primary and secondary clusters.

8.5.1.3.2 DR solution based on multiple replicas in a single cluster

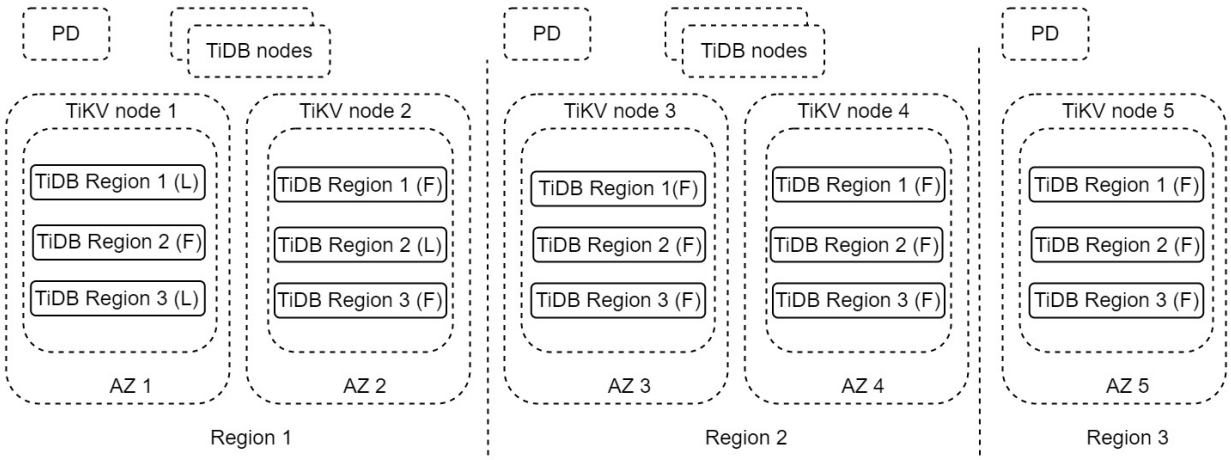

Figure 150: Multi-replica cluster DR

In the preceding architecture, each region has two complete data replicas located in different available zones (AZs). The entire cluster is across three regions. Region 1 is the primary region that handles read and write requests. When region 1 is completely unavailable due to a disaster, region 2 can be used as a DR region. Region 3 is a replica used to meet the majority protocol. This architecture is also called the "2-2-1" solution.

This solution provides region-level error tolerance, scalable write capability, zero RPO, and minute-level RTO or even lower. If a production system requires zero RPO, it is recommended to use this DR solution. For more information about this solution, see DR solution based on multiple replicas in a single cluster.

8.5.1.3.3 DR solution based on TiCDC and multiple replicas

The preceding two solutions provide regional DR. However, they fail to work if multiple regions are unavailable at the same time. If your system is very important and requires error tolerance objective to cover multiple regions, you need to combine these two solutions.

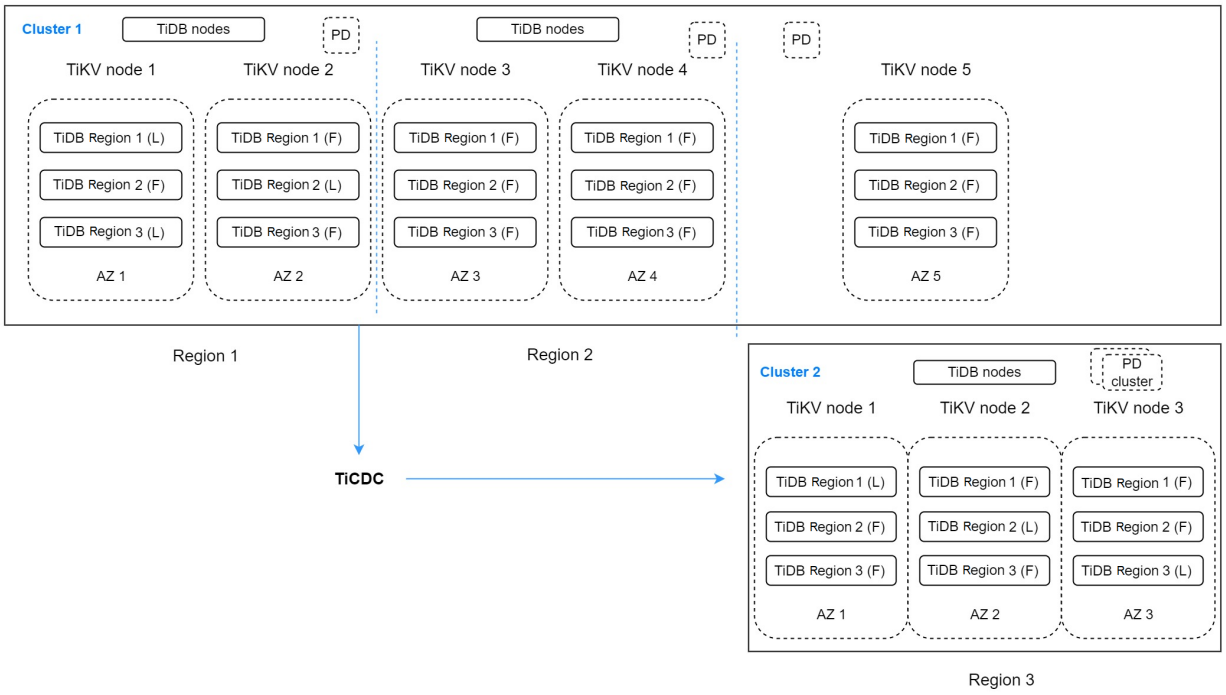

Figure 151: TiCDC-based multi-replica cluster DR

In the preceding architecture, there are two TiDB clusters. Cluster 1 has five replicas that span three regions. Region 1 contains two replicas that work as the primary region and handle write requests. Region 2 has two replicas that work as the DR region for region 1. This region provides read services that are not sensitive to latency. Located in Region 3, the last replica is used for voting.

As the DR cluster for region 1 and region 2, cluster 2 runs in region 3 and contains three replicas. TiCDC replicates data from cluster 1. This architecture looks complicated but it can increase the error tolerance objective to multiple regions. If the RPO is not required to be zero when multiple regions are unavailable at the same time, this architecture is a good choice. This architecture is also called the "2-2-1:1" solution.

Of course, if the error tolerance objective is multiple regions and RPO must be zero, you can also consider creating a cluster with at least nine replicas spanning five regions. This architecture is also called the "2-2-2-2-1" solution.

8.5.1.3.4 DR solution based on BR

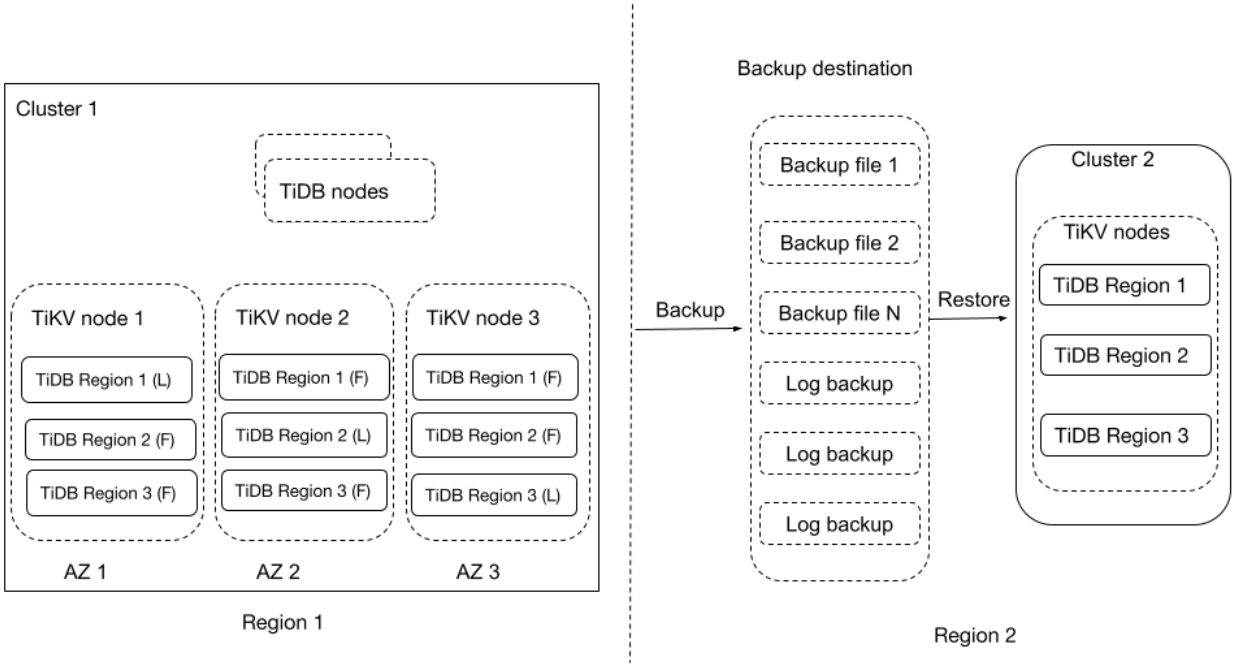

Figure 152: BR-based cluster DR

In this architecture, TiDB cluster 1 is deployed in region 1. BR regularly backs up the data of cluster 1 to region 2, and continuously backs up the data change logs of this cluster to region 2 as well. When region 1 encounters a disaster and cluster 1 cannot be recovered, you can use the backup data and data change logs to restore a new cluster (cluster 2) in region 2 to provide services.

The DR solution based on BR provides an RPO lower than 5 minutes and an RTO that varies with the size of the data to be restored. For BR v6.5.0, you can refer to Performance and impact of snapshot restore and Performance and impact of PITR to learn about the restore speed. Usually, the feature of backup across regions is considered the last resort of data security and also a must-have solution for most systems. For more information about this solution, see DR solution based on BR.

Meanwhile, starting from v6.5.0, BR supports restoring a TiDB cluster from EBS volume snapshots. If your cluster is running on Kubernetes and you want to restore the cluster as fast as possible without affecting the cluster, you can use this feature to reduce the RTO of your system.

8.5.1.3.5 Other DR solutions

Besides the preceding DR solutions, if zero RPO is a must in the same-city dual-center scenario, you can also use the DR-AUTO sync solution. For more information, see Two Data Centers in One City Deployment.

8.5.1.4 Solution comparison

This section compares the DR solutions mentioned in this document, based on which you can select an appropriate DR solution to satisfy your business needs.

DR solution	TCO	Error tolerance objective	RPO	RTO	Network latency requirement	Target system
DR solution based on multiple replicas in a single cluster (2-2-1)	High	Single region	0	Minute level	Less than 30 ms between regions	Production systems that have specific requirements on DR and response (RPO = 0)

DR solution	TCO	Error tolerance objective	RPO	RTO	Network latency requirement	Target system
DR solution based on primary and secondary clusters (1:1)	Medium	Single region	Less than 10 seconds	Less than 5 minutes	Less than 100 ms between regions	Production systems that have specific requirements on DR and response (RPO > 0)

DR solution	TCO	Error tolerance objective	RPO	RTO	Network latency requirement	Target system
DR solution based on TiCDC and multiple replicas (2-2-1:1)	High	Multiple regions	Less than 10 seconds	Less than 5 minutes	Less than 30 ms for regions that use multiple replicas for DR. Less than 100 ms for the third region and other regions	Production systems that have strict requirements on DR and response

DR solution	TCO	Error tolerance objective	RPO	RTO	Network latency requirement	Target system
DR solution based on BR	Low	Single region	Less than 5 minutes	Hour level	No special requirement	Production systems that accept an RPO of less than 5 minutes and an RTO of up to an hour

8.5.2 DR Solution Based on Primary and Secondary Clusters

Disaster recovery (DR) based on primary and secondary databases is a common solution. In this solution, the DR system has a primary cluster and a secondary cluster. The primary cluster handles user requests, while the secondary cluster backs up data from the primary cluster. When the primary cluster fails, the secondary cluster takes over services and continues to provide services using the backup data. This ensures that the business system continues to run normally without any interruptions caused by a failure.

The primary-secondary DR solution has the following benefits:

- High availability: The primary-secondary architecture enhances system availability, ensuring fast recovery from any failure.

- Fast switchover: When the primary cluster fails, the system can quickly switch to the secondary cluster and continue to provide services.
- Data consistency: The secondary cluster backs up the data from the primary cluster in almost real time. In this way, the data is basically up-to-date when the system switches to the secondary cluster due to a failure.

This document includes the following contents:

- Set up a primary cluster and a secondary cluster.
- Replicate data from the primary cluster to the secondary cluster.
- Monitor the clusters.
- Perform a DR switchover.

Meanwhile, this document also describes how to query business data on the secondary cluster and how to perform bidirectional replication between the primary and secondary clusters.

8.5.2.1 Set up primary and secondary clusters based on TiCDC

8.5.2.1.1 Architecture

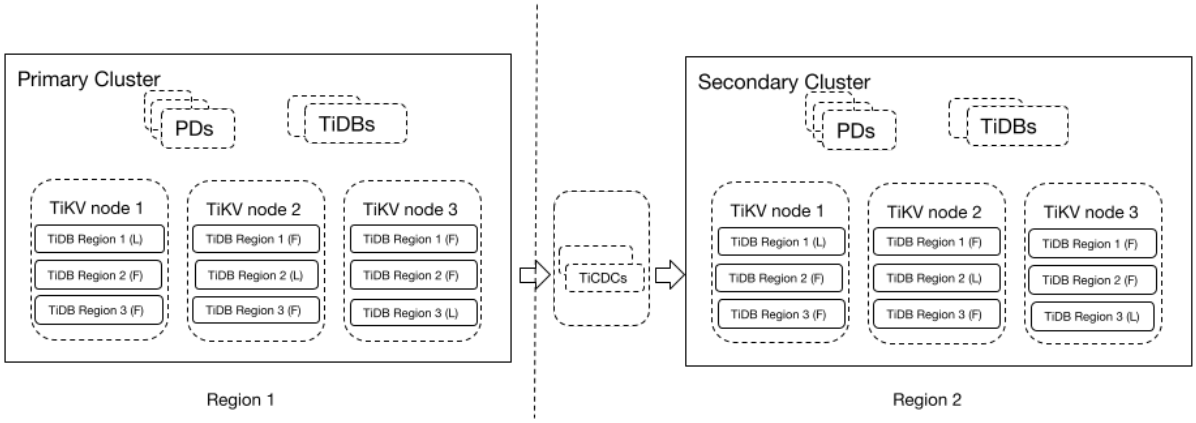

Figure 153: TiCDC secondary cluster architecture

The preceding architecture includes two TiDB clusters: a primary cluster and a secondary cluster.

- Primary cluster: The active cluster that runs in region 1 and has three replicas. This cluster handles read and write requests.
- Secondary cluster: The standby cluster that runs in region 2 and replicates data from the primary cluster through TiCDC.

This DR architecture is simple and easy to use. Being capable of tolerating regional failures, the DR system guarantees that the write performance of the primary cluster does not deteriorate, and the secondary cluster can handle some read-only business that is not latency-sensitive. The Recovery Point Objective (RPO) of this solution is in seconds, and the Recovery Time Objective (RTO) can be minutes or even lower. This is a solution recommended by many database vendors for important production systems.

Note:

- "Region" in TiKV means a range of data while the term "region" means a physical location. The two terms are not interchangeable.
- Do not run multiple changefeeds to replicate data to the secondary cluster, or run another secondary cluster with the presence of a secondary cluster already. Otherwise, the integrity of data transactions of the secondary cluster cannot be guaranteed.

8.5.2.1.2 Set up primary and secondary clusters

In this document, the TiDB primary and secondary clusters are deployed in two different regions (region 1 and region 2). TiCDC is deployed together with the secondary cluster, because there is a certain network latency between the primary and secondary clusters. Deploying TiCDC with the secondary cluster can avoid the impact of network latency, which helps achieve optimal replication performance. The deployment topology of the example provided in this document is as follows (one component node is deployed on one server):

Region	Host	Cluster	Component
Region 1	10.0.1.9	Primary	Monitor, Grafana, or AlterManager
Region 2	10.0.1.11	Secondary	Monitor, Grafana, or AlterManager
Region 1	10.0.1.1/10.0.1.2/10.0.1.3	Primary	PD
Region 2	10.1.1.1/10.1.1.2/10.1.1.3	Secondary	PD
Region 2	10.1.1.9/10.1.1.10	Primary	TiCDC
Region 1	10.0.1.4/10.0.1.5	Primary	TiDB
Region 2	10.1.1.4/10.1.1.5	Secondary	TiDB
Region 1	10.0.1.6/10.0.1.7/10.0.1.8	Primary	TiKV
Region 2	10.1.1.6/10.1.1.7/10.1.1.8	Secondary	TiKV

For server configurations, see the following documents:

- Software and hardware recommendations for TiDB
- Software and hardware recommendations for TiCDC

For details about how to deploy TiDB primary and secondary clusters, see Deploy a TiDB cluster.

When deploying TiCDC, note that the secondary cluster and TiCDC must be deployed and managed together, and the network between them must be connected.

- To deploy TiCDC on an existing primary cluster, see Deploy TiCDC.
- To deploy a new primary cluster and TiCDC, use the following deployment template and modify the configuration parameters as needed:

```
global:
user: "tidb"
ssh_port: 22
deploy_dir: "/tidb-deploy"
data_dir: "/tidb-data"
server_configs: {}
pd_servers:
- host: 10.0.1.1
- host: 10.0.1.2
- host: 10.0.1.3
tidb_servers:
- host: 10.0.1.4
- host: 10.0.1.5
tikv_servers:
- host: 10.0.1.6
- host: 10.0.1.7
- host: 10.0.1.8
monitoring_servers:
- host: 10.0.1.9
grafana_servers:
- host: 10.0.1.9
alertmanager_servers:
- host: 10.0.1.9
cdc_servers:
- host: 10.1.1.9
    gc-ttl: 86400
    data_dir: "/cdc-data"
    ticdc_cluster_id: "DR_TiCDC"
- host: 10.1.1.10
    gc-ttl: 86400
```

```
    data_dir: "/cdc-data"
    ticdc_cluster_id: "DR_TiCDC"
```

8.5.2.1.3 Replicate data from the primary cluster to the secondary cluster

After setting up the TiDB primary and secondary clusters, first migrate the data from the primary cluster to the secondary cluster, and then create a replication task to replicate real-time change data from the primary cluster to the secondary cluster.

Select an external storage

An external storage is used when migrating data and replicating real-time change data. Amazon S3 is a recommended choice. If the TiDB cluster is deployed in a self-built data center, the following methods are recommended:

- Build MinIO as the backup storage system, and use the S3 protocol to back up data to MinIO.
- Mount Network File System (NFS, such as NAS) disks to br command-line tool, TiKV, and TiCDC instances, and use the POSIX file system interface to write backup data to the corresponding NFS directory.

The following example uses MinIO as the storage system and is for reference only. Note that you need to prepare a separate server to deploy MinIO in region 1 or region 2.

```
wget https://dl.min.io/server/minio/release/linux-amd64/minio
chmod +x minio
### Configure access-key and access-secret-id to access MinIO
export HOST_IP='10.0.1.10' # Replace it with the IP address of MinIO
export MINIO_ROOT_USER='minio'
export MINIO_ROOT_PASSWORD='miniostorage'
### Create the redo and backup directories. `backup` and `redo` are bucket
    ↪ names.
mkdir -p data/redo
mkdir -p data/backup
### Start minio at port 6060
nohup ./minio server ./data --address :6060 &
```

The preceding command starts a MinIO server on one node to simulate Amazon S3 services. Parameters in the command are configured as follows:

- `endpoint`: `http://10.0.1.10:6060/`
- `access-key`: `minio`
- `secret-access-key`: `miniostorage`
- `bucket`: `redo/backup`

The link is as follows:

```
s3://backup?access-key=minio&secret-access-key=miniostorage&endpoint=http
    ↪ ://10.0.1.10:6060&force-path-style=true
```

Migrate data

Use the backup and restore feature to migrate data from the primary cluster to the secondary cluster.

1. Disable GC. To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before backup. In this way, history data is not deleted.

   Execute the following statement to disable GC:

   ```
   SET GLOBAL tidb_gc_enable=FALSE;
   ```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

   ```
   SELECT @@global.tidb_gc_enable;
   ```

   If the value is `0`, it means that GC is disabled:

   ```
   +--------------------------+
   | @@global.tidb_gc_enable |
   +--------------------------+
   |                        0 |
   +--------------------------+
   1 row in set (0.00 sec)
   ```

   Note:

   In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you back up data during off-peak hours, and set `RATE_LIMIT` to a proper value to avoid performance degradation.

2. Back up data. Execute the `BACKUP` statement in the upstream cluster to back up data:

   ```
   BACKUP DATABASE * TO '`s3://backup?access-key=minio&secret-access-key=
       ↪ miniostorage&endpoint=http://10.0.1.10:6060&force-path-style=true
       ↪ `';
   ```

   ```
   +---------------------+----------+--------------------+-------------------------+-----
       ↪
   | Destination         | Size     | BackupTS           | Queue Time              |
       ↪ Execution Time    |
   ```

```
+---------------------+---------+-------------------+-----------------------+-----
    ↪
| s3://backup         | 10315858 | 431434047157698561 | 2022-02-25
    ↪ 19:57:59 | 2022-02-25 19:57:59 |
+---------------------+---------+-------------------+-----------------------+-----
    ↪
1 row in set (2.11 sec)
```

After the `BACKUP` statement is executed, TiDB returns metadata about the backup data. Pay attention to `BackupTS`, because data generated before it is backed up. In this document, `BackupTS` is used as **the start of incremental migration**.

3. Restore data. Execute the `RESTORE` statement in the secondary cluster to restore data:

```
RESTORE DATABASE * FROM '`s3://backup?access-key=minio&secret-access-
    ↪ key=miniostorage&endpoint=http://10.0.1.10:6060&force-path-style=
    ↪ true`';
```

```
+---------------------+---------+---------+---------------------+--------------
    ↪
| Destination         | Size    | BackupTS | Queue Time         | Execution
    ↪ Time    |
+---------------------+---------+---------+---------------------+--------------
    ↪
| s3://backup         | 10315858 | 0       | 2022-02-25 20:03:59 |
    ↪ 2022-02-25 20:03:59 |
+---------------------+---------+---------+---------------------+--------------
    ↪
1 row in set (41.85 sec)
```

Replicate incremental data

After migrating data as described in the preceding section, you can replicate incremental data from the primary cluster to the secondary cluster starting from the **BackupTS**.

1. Create a changefeed.

   Create a changefeed configuration file `changefeed.toml`.

```
[consistent]
# eventual consistency: redo logs are used to ensure eventual
    ↪ consistency in disaster scenarios.
level = "eventual"
# The size of a single redo log, in MiB. The default value is 64, and
    ↪ the recommended value is less than 128.
max-log-size = 64
```

```
# The interval for refreshing or uploading redo logs to Amazon S3, in
    ↪ milliseconds. The default value is 1000, and the recommended
    ↪ value range is 500-2000.
flush-interval = 2000
# The path where redo logs are saved.
storage = "s3://redo?access-key=minio&secret-access-key=miniostorage&
    ↪ endpoint=http://10.0.1.10:6060&force-path-style=true"
```

In the primary cluster, run the following command to create a changefeed from the primary to the secondary cluster:

```
tiup cdc cli changefeed create --server=http://10.1.1.9:8300 \
--sink-uri="mysql://{username}:{password}@10.1.1.4:4000" \
--changefeed-id="dr-primary-to-secondary" --start-ts
    ↪ ="431434047157698561"
```

For more information about the changefeed configurations, see TiCDC Changefeed Configurations.

2. To check whether a changefeed task runs properly, run the `changefeed query` command. The query result includes the task information and the task state. You can specify the `--simple` or `-s` argument to display only the basic replication state and the checkpoint information. If you do not specify this argument, the output includes detailed task configuration, replication state, and replication table information.

```
tiup cdc cli changefeed query -s --server=http://10.1.1.9:8300 --
    ↪ changefeed-id="dr-primary-to-secondary"
```

```
{
"state": "normal",
"tso": 431434047157998561, # The TSO to which the changefeed has been
    ↪ replicated
"checkpoint": "2020-08-27 10:12:19.579", # The physical time
    ↪ corresponding to the TSO
"error": null
}
```

3. Enable GC.

   TiCDC ensures that history data is not garbage collected before it is replicated. Therefore, after creating a changefeed from the primary cluster to the secondary cluster, you can execute the following statement to enable GC again.

Execute the following statement to enable GC:

```
```sql
SET GLOBAL tidb_gc_enable=TRUE;
```
```

```
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```sql
SELECT @@global.tidb_gc_enable;
```

If the value is `1`, it means that GC is enabled:

```
+--------------------------+
| @@global.tidb_gc_enable |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```
```

#### 8.5.2.1.4 Monitor the primary and secondary clusters

Currently, no DR dashboard is available in TiDB. You can check the status of TiDB primary and secondary clusters using the following dashboards and decide whether to perform a DR switchover:

- TiDB Key Metrics
- Changefeed Metrics

#### 8.5.2.1.5 Perform DR switchover

This section describes how to perform a planned DR switchover, a DR switchover upon disasters, and the steps to rebuild a secondary cluster.

Planned primary and secondary switchover

It is important to conduct regular DR drills for critical business systems to test their reliability. The following are the recommended steps for DR drills. Note that simulated business writes and usage of proxy services to access databases are not considered, and therefore the steps might differ from actual application scenarios. You can modify the configurations as required.

1. Stop business writes on the primary cluster.
2. After there are no more writes, query the latest TSO (`Position`) of the TiDB cluster:

```
BEGIN; SELECT TIDB_CURRENT_TSO(); ROLLBACK;
```
```

```
Query OK, 0 rows affected (0.00 sec)

+--------------------+
| TIDB_CURRENT_TSO() |
+--------------------+
| 452654700157468673 |
+--------------------+
1 row in set (0.00 sec)

Query OK, 0 rows affected (0.00 sec)
```

3. Poll the changefeed `dr-primary-to-secondary` until it meets the condition `TSO >= Position`.

```
tiup cdc cli changefeed query -s --server=http://10.1.1.9:8300 --
    ↪ changefeed-id="dr-primary-to-secondary"

{
    "state": "normal",
    "tso": 438224029039198209, # The TSO to which the changefeed has
        ↪ been replicated
    "checkpoint": "2022-12-22 14:53:25.307", # The physical time
        ↪ corresponding to the TSO
    "error": null
}
```

4. Stop the changefeed `dr-primary-to-secondary`. You can pause the changefeed by removing it:

```
tiup cdc cli changefeed remove --server=http://10.1.1.9:8300 --
    ↪ changefeed-id="dr-primary-to-secondary"
```

5. Create a changefeed `dr-secondary-to-primary` without specifying the `start-ts` parameter. The changefeed starts replicating data from the current time.

6. Modify the database access configurations of business applications. Restart the business applications so that they can access the secondary cluster.

7. Check whether the business applications are running normally.

You can restore the previous primary and secondary cluster configurations by repeating the preceding steps.

Primary and secondary switchover upon disasters

When a disaster occurs, for example, power outage in the region where the primary cluster locates, the replication between the primary and secondary clusters might be interrupted suddenly. As a result, the data in the secondary cluster is inconsistent with the primary cluster.

1. Restore the secondary cluster to a transaction-consistent state. Specifically, run the following command on any TiCDC node in region 2 to apply the redo log to the secondary cluster:

```
tiup cdc redo apply --storage "s3://redo?access-key=minio&secret-access
    ↪ -key=miniostorage&endpoint=http://10.0.1.10:6060&force-path-style
    ↪ =true" --tmp-dir /tmp/redo --sink-uri "mysql://{username}:{
    ↪ password}@10.1.1.4:4000"
```

   The descriptions of parameters in this command are as follows:

   - `--storage`: The path where redo logs are stored in Amazon S3
   - `--tmp-dir`: The cache directory for downloading redo logs from Amazon S3
   - `--sink-uri`: The address of the secondary cluster

2. Modify the database access configurations of business applications. Restart the business applications so that they can access the secondary cluster.

3. Check whether the business applications are running normally.

Rebuild the primary and secondary clusters

After the disaster encountered by the primary cluster is resolved or the primary cluster cannot be recovered temporarily, the TiDB cluster is fragile because only the secondary cluster is in service as the primary cluster. To maintain the reliability of the system, you need to rebuild the DR cluster.

To rebuild the TiDB primary and secondary clusters, you can deploy a new cluster to form a new DR system. For details, see the following documents:

- Set up primary and secondary clusters
- Replicate data from the primary cluster to the secondary cluster
- After the preceding steps are completed, to make the new primary cluster, see Primary and secondary switchover.

> **Note:**
>
> If data inconsistency between the primary and secondary clusters can be resolved, you can use the repaired cluster to rebuild the DR system instead of deploying a new cluster.

8.5.2.1.6 Query business data on the secondary cluster

In a primary-secondary DR scenario, it is common that the secondary cluster is used as a read-only cluster to run some latency-insensitive queries. TiDB also provides this feature by its primary-secondary DR solution.

When creating the changefeed, enable the Syncpoint feature in the configuration file. Then the changefeed periodically (at `sync-point-interval`) sets the consistent snapshot point that has been replicated to the secondary cluster by executing `SET GLOBAL tidb_external_ts = @@tidb_current_ts` on the secondary cluster.

To query data from the secondary cluster, configure `SET GLOBAL|SESSION tidb_enable_external_ts_read = ON;` in the business application. Then you can get the data that is transactionally consistent with the primary cluster.

```
### Starting from v6.4.0, only the changefeed with the SYSTEM_VARIABLES_ADMIN or SUPER privilege can use the TiCDC Syncpoint feature.
enable-sync-point = true

### Specifies the interval at which Syncpoint aligns the primary and secondary snapshots. It also indicates the maximum latency at which you can read the complete transaction, for example, read the transaction data generated on the primary cluster two minutes ago from the secondary cluster.
### The format is in h m s. For example, "1h30m30s". The default value is "10m" and the minimum value is "30s".
sync-point-interval = "10m"

### Specifies how long the data is retained by Syncpoint in the downstream table. When this duration is exceeded, the data is cleaned up.
### The format is in h m s. For example, "24h30m30s". The default value is "24h".
sync-point-retention = "1h"

[consistent]
### eventual consistency: redo logs are used to ensure eventual consistency in disaster scenarios.
level = "eventual"
### The size of a single redo log, in MiB. The default value is 64, and the recommended value is less than 128.
max-log-size = 64
### Interval for refreshing or uploading redo logs to Amazon S3, in milliseconds. The default value is 1000, and the recommended value range is 500-2000.
flush-interval = 2000
### The path where redo logs are saved.
storage = "s3://redo?access-key=minio&secret-access-key=miniostorage&
```

```
    ↪ endpoint=http://10.0.1.10:6060&force-path-style=true"
```

Note:

In a primary-secondary DR architecture, a secondary cluster can only replicate data from one changefeed. Otherwise, the data transaction integrity of the secondary cluster cannot be guaranteed.

8.5.2.1.7 Perform bidirectional replication between the primary and secondary clusters

In this DR scenario, the TiDB clusters in two regions can act as each other's disaster recovery clusters: the business traffic is written to the corresponding TiDB cluster based on the region configuration, and the two TiDB clusters back up each other's data.

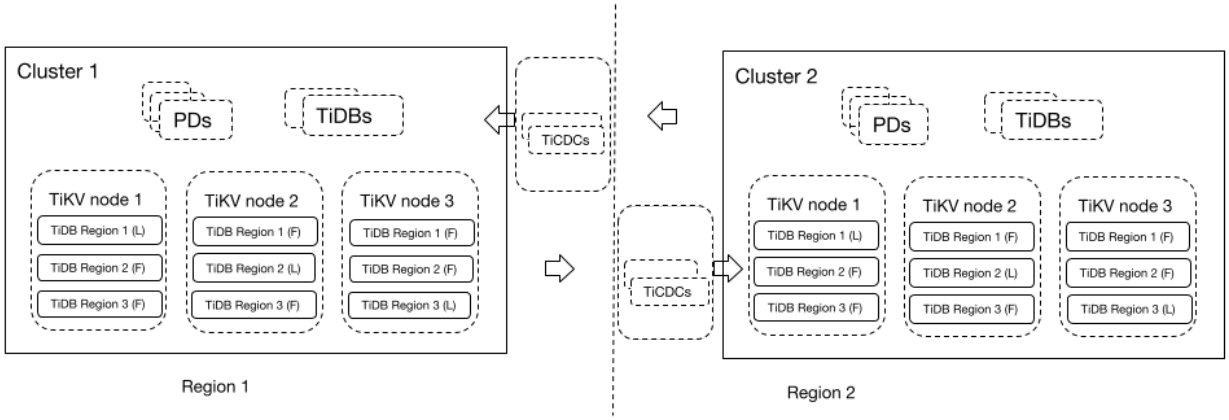

Figure 154: TiCDC bidirectional replication

With the bidirectional replication feature, the TiDB clusters in two regions can replicate each other's data. This DR solution guarantees data security and reliability, and also ensures the write performance of the database. In a planned DR switchover, you do not need to stop the running changefeeds before starting a new changefeed, which simplifies the operation and maintenance.

To build a bidirectional DR cluster, see TiCDC bidirectional replication.

8.5.2.2 Troubleshooting

If you encounter any problem in the preceding steps, you can first find the solution to the problem in TiDB FAQs. If the problem is not resolved, you can report a bug.

8.5.3 DR Solution Based on Multiple Replicas in a Single Cluster

This document describes the disaster recovery (DR) solution based on multiple replicas in a single cluster. The document is organized as follows:

- Solution introduction
- How to set up a cluster and configure replicas
- How to monitor the cluster
- How to perform a DR switchover

8.5.3.1 Introduction

Important production systems usually require regional DR with zero RPO and minute-level RTO. A Raft-based distributed database, TiDB provides multiple replicas, which allows it to support regional DR with data consistency and high availability guaranteed. Considering the small network latency between available zones (AZs) in the same region, we can dispatch business traffic to two AZs on the same region simultaneously, and achieve load balance among AZs on the same region by properly locating the Region leader and the PD leader.

> **Note:**
>
> "Region" in TiKV means a range of data while the term "region" means a physical location. The two terms are not interchangeable.

8.5.3.2 Set up a cluster and configure replicas

This section illustrates how to create a TiDB cluster across three regions with five replicas using TiUP, and how to achieve DR by properly distributing data and PD nodes.

In this example, TiDB contains five replicas and three regions. Region 1 is the primary region, region 2 is the secondary region, and region 3 is used for voting. Similarly, the PD cluster also contains 5 replicas, which function basically the same as the TiDB cluster.

1. Create a topology file similar to the following:

```
global:
  user: "root"
```

```
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["Region","AZ"] # PD schedules
       ↪ replicas according to the Region and AZ configuration of TiKV
       ↪  nodes.

pd_servers:
  - host: tidb-dr-test1
    name: "pd-1"
  - host: tidb-dr-test2
    name: "pd-2"
  - host: tidb-dr-test3
    name: "pd-3"
  - host: tidb-dr-test4
    name: "pd-4"
  - host: tidb-dr-test5
    name: "pd-5"

tidb_servers:
  - host: tidb-dr-test1
  - host: tidb-dr-test3

tikv_servers: # Label the Regions and AZs of each TiKV node through the
   ↪  labels option.
  - host: tidb-dr-test1
    config:
      server.labels: { Region: "Region1", AZ: "AZ1" }
  - host: tidb-dr-test2
    config:
      server.labels: { Region: "Region1", AZ: "AZ2" }
  - host: tidb-dr-test3
    config:
      server.labels: { Region: "Region2", AZ: "AZ3" }
  - host: tidb-dr-test4
    config:
      server.labels: { Region: "Region2", AZ: "AZ4" }
  - host: tidb-dr-test5
    config:
      server.labels: { Region: "Region3", AZ: "AZ5" }
```

```
    raftstore.raft-min-election-timeout-ticks: 50
    raftstore.raft-max-election-timeout-ticks: 60

monitoring_servers:
  - host: tidb-dr-test2

grafana_servers:
  - host: tidb-dr-test2

alertmanager_servers:
  - host: tidb-dr-test2
```

The preceding configurations use the following options to optimize toward cross-region DR:

- `server.grpc-compression-type: gzip` to enable gRPC message compression in TiKV, thus reducing network traffic.
- `raftstore.raft-min-election-timeout-ticks` and `raftstore.raft-max-election-timeout-ticks` to extend the time before region 3 participates in the election, thus preventing any replica in this region from being voted as the leader.

2. Create a cluster using the preceding configuration file:

```
tiup cluster deploy drtest v6.4.0 ./topo.yaml
tiup cluster start drtest --init
tiup cluster display drtest
```

Configure the number of replicas and the leader limit for the cluster:

```
tiup ctl:v6.4.0 pd config set max-replicas 5
tiup ctl:v6.4.0 pd config set label-property reject-leader Region
    ↪ Region3

# The following step adds some test data to the cluster, which is
    ↪ optional.
tiup bench tpcc prepare -H 127.0.0.1 -P 4000 -D tpcc --warehouses 1
```

Specify the priority of PD leader:

```
tiup ctl:v6.4.0 pd member leader_priority pd-1 4
tiup ctl:v6.4.0 pd member leader_priority pd-2 3
tiup ctl:v6.4.0 pd member leader_priority pd-3 2
tiup ctl:v6.4.0 pd member leader_priority pd-4 1
tiup ctl:v6.4.0 pd member leader_priority pd-5 0
```

> **Note:**
> In all available PD nodes, the node with the highest priority number becomes the leader.

3. Create placement rules and fix the primary replica of the test table to region 1:

```
-- Create two placement rules: the first rule specifies that region 1
   ↪  works as the primary region, and region 2 as the secondary
   ↪ region.
-- The second placement rule specifies that when region 1 is down,
   ↪ region 2 will become the primary region.
MySQL [(none)]> CREATE PLACEMENT POLICY primary_rule_for_region1
   ↪ PRIMARY_REGION="Region1" REGIONS="Region1, Region2,Region3";
MySQL [(none)]> CREATE PLACEMENT POLICY secondary_rule_for_region2
   ↪ PRIMARY_REGION="Region2" REGIONS="Region1,Region2,Region3";

-- Apply the rule primary_rule_for_region1 to the corresponding user
   ↪ tables.
ALTER TABLE tpcc.warehouse PLACEMENT POLICY=primary_rule_for_region1;
ALTER TABLE tpcc.district PLACEMENT POLICY=primary_rule_for_region1;

-- Note: You can modify the database name, table name, and placement
   ↪ rule name as needed.

-- Confirm whether the leaders have been transferred by executing the
   ↪  following query to check the number of leaders in each region.
SELECT STORE_ID, address, leader_count, label FROM TIKV_STORE_STATUS
   ↪ ORDER BY store_id;
```

The following SQL statement can generate a SQL script to configure the leader of all non-system schema tables to a specific region:

```
SET @region_name=primary_rule_for_region1;
SELECT CONCAT('ALTER TABLE ', table_schema, '.', table_name, '
   ↪ PLACEMENT POLICY=', @region_name, ';') FROM information_schema.
   ↪ tables WHERE table_schema NOT IN ('METRICS_SCHEMA', 'PERFORMANCE
   ↪ _SCHEMA', 'INFORMATION_SCHEMA','mysql');
```

8.5.3.3 Monitor the cluster

You can monitor the performance metrics of TiKV, TiDB, PD, and other components in the cluster by accessing Grafana or TiDB Dashboard. Based on the status of the components, you can determine whether to perform a DR switchover. For details, see the following documents:

- Key Monitoring Metrics of TiDB
- Key Monitoring Metrics of TiKV
- Key Monitoring Metrics of PD
- TiDB Dashboard Monitoring Page

8.5.3.4 Perform a DR switchover

This section describes how to perform a DR switchover, including planned switchover and unplanned switchover.

8.5.3.4.1 Planned switchover

A planned switchover is a scheduled switchover between the primary and secondary regions based on the maintenance needs. It can be used to verify whether the DR system works properly. This section describes how to perform a planned switchover.

1. Run the following command to switch all user tables and PD leaders to region 2:

```
-- Apply the rule secondary_rule_for_region2 to the corresponding
   ↪ user tables.
ALTER TABLE tpcc.warehouse PLACEMENT POLICY=secondary_rule_for_region2;
ALTER TABLE tpcc.district PLACEMENT POLICY=secondary_rule_for_region2;
```

   Note: You can modify the database name, table name, and placement rule name as needed.

   Run the following commands to lower the priority of PD nodes in region 1 and increase that of PD nodes in region 2.

```
tiup ctl:v6.4.0 pd member leader_priority pd-1 2
tiup ctl:v6.4.0 pd member leader_priority pd-2 1
tiup ctl:v6.4.0 pd member leader_priority pd-3 4
tiup ctl:v6.4.0 pd member leader_priority pd-4 3
```

2. Observe the PD and TiKV nodes in Grafana and ensure that leaders of the PD and user tables have been transferred to the target region. The steps for switching back to the original region are the same as the preceding steps and are therefore not covered in this document.

8.5.3.4.2 Unplanned switchover

An unplanned switchover means a switchover between primary and secondary regions when a disaster occurs. It can also be a primary-secondary region switchover initiated to simulate disaster scenarios so as to verify the effectiveness of DR systems.

1. Run the following command to stop all TiKV, TiDB, and PD nodes in region 1:

```
tiup cluster stop drtest -N tidb-dr-test1:20160,tidb-dr-test2:20160,
    ↪ tidb-dr-test1:2379,tidb-dr-test2:2379
```

2. Run the following commands to switch the leaders of all user tables to region 2:

```
-- Apply the rule secondary_rule_for_region2 to the corresponding
    ↪ user tables.
ALTER TABLE tpcc.warehouse PLACEMENT POLICY=secondary_rule_for_region2;
ALTER TABLE tpcc.district PLACEMENT POLICY=secondary_rule_for_region2;

--- Confirm whether the leaders have been transferred by executing
    ↪ the following query to check the number of leaders in each
    ↪ region.
SELECT STORE_ID, address, leader_count, label FROM TIKV_STORE_STATUS
    ↪ ORDER BY store_id;
```

After region 1 recovers, you can use commands similar to the preceding ones to switch the leaders of user tables back to region 1.

8.5.4 DR Solution Based on BR

A TiDB cluster has multiple replicas, which allows it to tolerate the failure of a single data center or region and continue to provide services. In the case of a natural disaster, software vulnerability, hardware failure, virus attack, or misoperations, which impacts an area larger than a single data center or region, TiDB's Backup & Restore (BR) feature can back up data to an independent disaster recovery (DR) storage device to protect user data from damage. Compared with other DR solutions, the BR feature is more flexible, reliable, recoverable, and cost-effective:

- Flexibility: You can back up data any time with any frequency. This makes backup and restore flexible and better adapts to different business scenarios.
- Reliability: Backup data is usually stored on an independent storage device and this means enhanced data security.
- Recoverability: Any loss or damage to the original data caused by any unexpected situation can be recovered by restoring the backup data. This makes the BR feature highly recoverable and ensures the normal use of your database.
- Cost effectiveness: You can get your database protected using BR without spending too much.

Generally speaking, BR is the last resort for data safety. It improves the safety and reliability of the databases without requiring too much cost. BR protects data in various unexpected situations so that you can use the database safely without worrying about the risk of data loss or damage.

8.5.4.1 Perform backup and restore

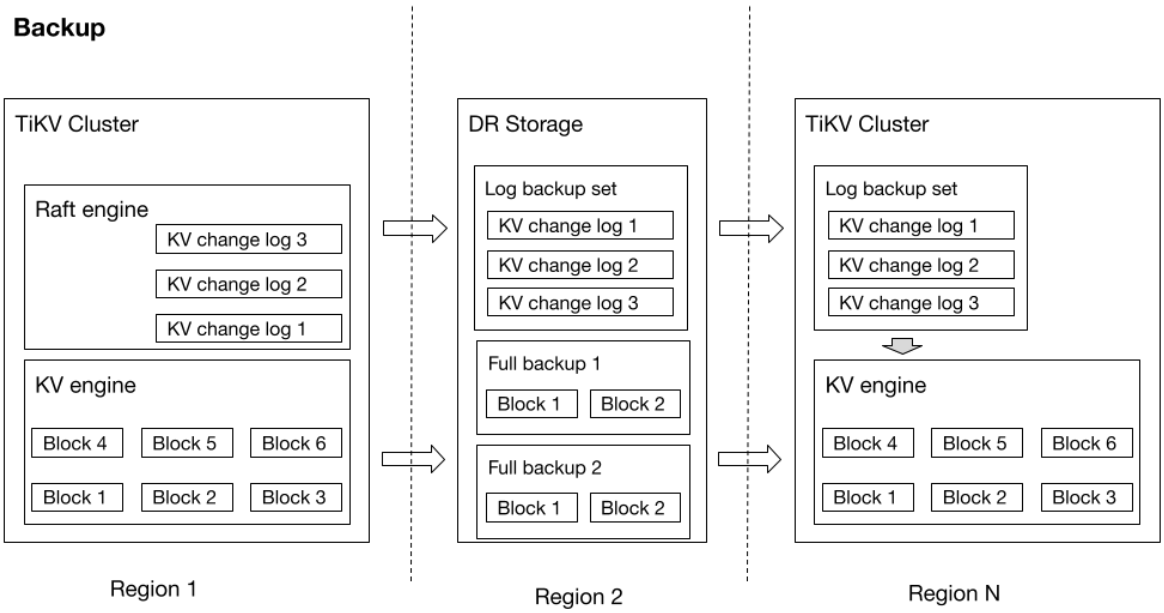

Figure 155: BR log backup and PITR architecture

As shown in the preceding architecture, you can back up data to a DR storage device located in other regions, and recover data from the backup data as needed. This means that the cluster can tolerate the failure of a single region with a Recovery Point Objective (RPO) of up to 5 minutes and a Recovery Time Objective (RTO) between tens of minutes and a few hours. However, if the database size is large, the RTO might be longer.

> **Note:**
>
> The term “region” in this document means a physical location.

Meanwhile, TiDB provides backup and restore based on block storage snapshots. This feature reduces the recovery time to hours or even less than one hour. TiDB is continuously improving and optimizing the backup and restore capabilities so as to provide you better services.

TiDB also provides detailed documentation to help you understand how to use the backup and restore feature in DR scenarios. Among them,

- Usage Overview of TiDB Backup and Restore is an overview of the BR feature, including the backup strategy and the organization of backup data.
- Backup & Restore FAQs lists the frequently asked questions (FAQs) and the solutions of TiDB Backup & Restore (BR).
- Overview of TiDB Backup & Restore Architecture describes the design architecture of the BR feature, including the backup and restore processes and the design of backup files.

8.6 Resource Manager

8.6.1 Use Resource Control to Achieve Resource Group Limitation and Flow Control

> **Note:**
>
> This feature is not available on TiDB Cloud Serverless clusters.

As a cluster administrator, you can use the resource control feature to create resource groups, set quotas for resource groups, and bind users to those groups.

The TiDB resource control feature provides two layers of resource management capabilities: the flow control capability at the TiDB layer and the priority scheduling capability at the TiKV layer. The two capabilities can be enabled separately or simultaneously. See the Parameters for resource control for details. This allows the TiDB layer to control the flow of user read and write requests based on the quotas set for the resource groups, and allows the TiKV layer to schedule the requests based on the priority mapped to the read and write quota. By doing this, you can ensure resource isolation for your applications and meet quality of service (QoS) requirements.

- TiDB flow control: TiDB flow control uses the token bucket algorithm. If there are not enough tokens in a bucket, and the resource group does not specify the `BURSTABLE` option, the requests to the resource group will wait for the token bucket to backfill the tokens and retry. The retry might fail due to timeout.
- TiKV scheduling: You can set the absolute priority (`PRIORITY`) as needed. Different resources are scheduled according to the `PRIORITY` setting. Tasks with high `PRIORITY` are scheduled first. If you do not set the absolute priority, TiKV uses the value of `RU_PER_SEC` of each resource group to determine the priority of the read and write requests for each resource group. Based on the priorities, the storage layer uses the priority queue to schedule and process requests.

Starting from v7.4.0, the resource control feature supports controlling TiFlash resources. Its principle is similar to that of TiDB flow control and TiKV scheduling:

- TiFlash flow control: With the TiFlash pipeline execution model, TiFlash can more accurately obtain the CPU consumption of different queries and convert it into Request Units (RU) for deduction. Traffic control is implemented using a token bucket algorithm.
- TiFlash scheduling: When system resources are insufficient, TiFlash schedules pipeline tasks among multiple resource groups based on their priorities. The specific logic is: First, TiFlash assesses the `PRIORITY` of the resource group, then considers the CPU usage and `RU_PER_SEC`. As a result, if `rg1` and `rg2` have the same `PRIORITY` but the `RU_PER_SEC` of `rg2` is twice that of `rg1`, the CPU usage of `rg2` is twice that of `rg1`.

For information on how to manage background tasks and handle resource-intensive queries (Runaway Queries), see the following documents:

- Use Resource Control to Managing Background Tasks
- Manage Queries That Consume More Resources Than Expected (Runaway Queries)

8.6.1.1 Scenarios for resource control

The introduction of the resource control feature is a milestone for TiDB. It can divide a distributed database cluster into multiple logical units. Even if an individual unit overuses resources, it does not crowd out the resources needed by other units.

With this feature, you can:

- Combine multiple small and medium-sized applications from different systems into a single TiDB cluster. When the workload of an application grows larger, it does not affect the normal operation of other applications. When the system workload is low, busy applications can still be allocated the required system resources even if they exceed the set quotas, so as to achieve the maximum utilization of resources.
- Choose to combine all test environments into a single TiDB cluster, or group the batch tasks that consume more resources into a single resource group. It can improve hardware utilization and reduce operating costs while ensuring that critical applications can always get the necessary resources.
- When there are mixed workloads in a system, you can put different workloads into separate resource groups. By using the resource control feature, you can ensure that the response time of transactional applications is not affected by data analysis or batch applications.
- When the cluster encounters an unexpected SQL performance issue, you can use SQL bindings along with resource groups to temporarily limit the resource consumption of a SQL statement.

In addition, the rational use of the resource control feature can reduce the number of clusters, ease the difficulty of operation and maintenance, and save management costs.

Note:

- To assess the effectiveness of resource management, it is recommended to deploy the cluster on independent computing and storage nodes. Scheduling and other cluster resource-sensitive features are hardly working properly on the deployment created by `tiup playground`, where the resources are shared across instances.

8.6.1.2 Limitations

Resource control incurs additional scheduling overhead. Therefore, there might be a slight performance degradation (less than 5%) when this feature is enabled.

8.6.1.3 What is Request Unit (RU)

Request Unit (RU) is a unified abstraction unit in TiDB for system resources, which currently includes CPU, IOPS, and IO bandwidth metrics. It is used to indicate the amount of resources consumed by a single request to the database. The number of RUs consumed by a request depends on a variety of factors, such as the type of operations, and the amount of data being queried or modified. Currently, the RU contains consumption statistics for the resources in the following table:

```
<thead>
    <tr>
        <th>Resource type</th>
        <th>RU consumption</th>
    </tr>
</thead>
<tbody>
    <tr>
        <td rowspan="3">Read</td>
        <td>2 storage read batches consume 1 RU</td>
    </tr>
    <tr>
        <td>8 storage read requests consume 1 RU</td>
    </tr>
    <tr>
        <td>64 KiB read request payload consumes 1 RU</td>
    </tr>
    <tr>
        <td rowspan="3">Write</td>
        <td>1 storage write batch consumes 1 RU</td>
```

```
    </tr>
    <tr>
        <td>1 storage write request consumes 1 RU</td>
    </tr>
    <tr>
        <td>1 KiB write request payload consumes 1 RU</td>
    </tr>
    <tr>
        <td>CPU</td>
        <td> 3 ms consumes 1 RU</td>
    </tr>
</tbody>
```

Note:

- Each write operation is eventually replicated to all replicas (by default, TiKV has 3 replicas). Each replication operation is considered a different write operation.
- The preceding table lists only the resources involved in RU calculation for TiDB Self-Managed clusters, excluding the network and storage consumption. For TiDB Cloud Serverless RUs, see TiDB Cloud Serverless Pricing Details.
- Currently, TiFlash resource control only considers SQL CPU, which is the CPU time consumed by the execution of pipeline tasks for queries, and read request payload.

8.6.1.4 Parameters for resource control

The resource control feature introduces the following system variables or parameters:

- TiDB: you can use the `tidb_enable_resource_control` system variable to control whether to enable flow control for resource groups.
- TiKV: you can use the `resource-control.enabled` parameter to control whether to use request scheduling based on resource groups.
- TiFlash: you can use the `tidb_enable_resource_control` system variable and the `enable_resource_control` configuration item (introduced in v7.4.0) to control whether to enable TiFlash resource control.

Starting from TiDB v7.0.0, `tidb_enable_resource_control` and `resource-control.enabled` are enabled by default. The results of the combinations of these two parameters are shown in the following table.

resource-control.enabled	tidb_enable_resource_control=ON	tidb_enable_resource_control=OFF
resource-control.enabled=true	Flow control and scheduling (recommended)	Invalid combination
resource-control.enabled=false	Only flow control (not recommended)	The feature is disabled.

Starting from v7.4.0, the TiFlash configuration item `enable_resource_control` is enabled by default. It works together with `tidb_enable_resource_control` to control the TiFlash resource control feature. TiFlash resource control only performs flow control and priority scheduling when both `enable_resource_control` and `tidb_enable_resource_control` are enabled. Additionally, when `enable_resource_control` is enabled, TiFlash uses the Pipeline execution model.

For more information about the resource control mechanism and parameters, see RFC: Global Resource Control in TiDB and TiFlash Resource Control.

8.6.1.5 How to use resource control

This section describes how to use the resource control feature to manage resource groups and control the resource allocation of each resource group.

8.6.1.5.1 Estimate cluster capacity

Before resource planning, you need to know the overall capacity of the cluster. TiDB provides the statement `CALIBRATE RESOURCE` to estimate the cluster capacity. You can use one of the following methods:

- Estimate capacity based on actual workload
- Estimate capacity based on hardware deployment

You can view the Resource Manager page in TiDB Dashboard. For more information, see `CALIBRATE RESOURCE`.

8.6.1.5.2 Manage resource groups

To create, modify, or delete a resource group, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` privilege.

You can create a resource group for a cluster by using `CREATE RESOURCE GROUP`.

For an existing resource group, you can modify the `RU_PER_SEC` option (the rate of RU backfilling per second) of the resource group by using `ALTER RESOURCE GROUP`. The changes to the resource group take effect immediately.

You can delete a resource group by using `DROP RESOURCE GROUP`.

8.6.1.5.3 Create a resource group

The following is an example of how to create a resource group.

1. Create a resource group `rg1`. The resource limit is 500 RUs per second and allows applications in this resource group to overrun resources.

```
CREATE RESOURCE GROUP IF NOT EXISTS rg1 RU_PER_SEC = 500 BURSTABLE;
```

2. Create a resource group `rg2`. The RU backfill rate is 600 RUs per second and does not allow applications in this resource group to overrun resources.

```
CREATE RESOURCE GROUP IF NOT EXISTS rg2 RU_PER_SEC = 600;
```

3. Create a resource group `rg3` with the absolute priority set to `HIGH`. The absolute priority currently supports `LOW|MEDIUM|HIGH`. The default value is `MEDIUM`.

```
CREATE RESOURCE GROUP IF NOT EXISTS rg3 RU_PER_SEC = 100 PRIORITY =
    ↪ HIGH;
```

8.6.1.5.4 Bind resource groups

TiDB supports three levels of resource group settings as follows.

- User level. Bind a user to a specific resource group via the `CREATE USER` or `ALTER USER` statement. After a user is bound to a resource group, sessions created by the user are automatically bound to the corresponding resource group.
- Session level. Set the resource group for the current session via `SET RESOURCE GROUP`.
- Statement level. Set the resource group for the current statement via `RESOURCE_GROUP ↪ ()` Optimizer Hint.

Bind users to a resource group

The following example creates a user `usr1` and binds the user to the resource group `rg1`. `rg1` is the resource group created in the example in Create Resource Group.

```
CREATE USER 'usr1'@'%' IDENTIFIED BY '123' RESOURCE GROUP rg1;
```

The following example uses `ALTER USER` to bind the user `usr2` to the resource group `rg2`. `rg2` is the resource group created in the example in Create Resource Group.

```
ALTER USER usr2 RESOURCE GROUP rg2;
```

After you bind users, the resource consumption of newly created sessions will be controlled by the specified quota (Request Unit, RU). If the system workload is relatively high and there is no spare capacity, the resource consumption rate of `usr2` will be strictly controlled not to exceed the quota. Because `usr1` is bound by `rg1` with `BURSTABLE` configured, the consumption rate of `usr1` is allowed to exceed the quota.

If there are too many requests that result in insufficient resources for the resource group, the client's requests will wait. If the wait time is too long, the requests will report an error.

Note:

- When you bind a user to a resource group by using `CREATE USER` or `ALTER USER`, it will not take effect for the user's existing sessions, but only for the user's new sessions.
- TiDB automatically creates a `default` resource group during cluster initialization. For this resource group, the default value of `RU_PER_SEC` ↪ is `UNLIMITED` (equivalent to the maximum value of the `INT` type, that is, `2147483647`) and it is in `BURSTABLE` mode. Statements that are not bound to a resource group are automatically bound to this resource group. This resource group does not support deletion, but you can modify the configuration of its RU.

To unbind users from a resource group, you can simply bind them to the `default` group again as follows:

```
ALTER USER 'usr3'@'%' RESOURCE GROUP `default`;
```

For more details, see `ALTER USER ... RESOURCE GROUP`.

Bind the current session to a resource group

You can use the `SET RESOURCE GROUP` statement to change the bound resource group of the current session. By binding a session to a resource group, the resource usage of the corresponding session is limited by the specified usage (RU).

When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to execute this statement.

The following example binds the current session to the resource group `rg1`.

```
SET RESOURCE GROUP rg1;
```

Bind the current statement to a resource group

By adding the `RESOURCE_GROUP(resource_group_name)` hint to a SQL statement, you can specify the resource group to which the statement is bound. This hint supports `SELECT`, `INSERT`, `UPDATE`, and `DELETE` statements.

When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to use this hint.

The following example binds the current statement to the resource group `rg1`.

```
SELECT /*+ RESOURCE_GROUP(rg1) */ * FROM t limit 10;
```

8.6.1.6 Disable resource control

1. Execute the following statement to disable the resource control feature.

   ```
   SET GLOBAL tidb_enable_resource_control = 'OFF';
   ```

2. Set the TiKV parameter `resource-control.enabled` to `false` to disable scheduling based on the RU of the resource group.

3. Set the TiFlash configuration item `enable_resource_control` to `false` to disable TiFlash resource control.

8.6.1.7 View RU consumption

You can view information about RU consumption.

8.6.1.7.1 View the RU consumption by SQL

You can view the RU consumption of SQL statements in the following ways:

- The system variable `tidb_last_query_info`
- `EXPLAIN ANALYZE`
- Slow queries and corresponding system table
- `statements_summary`

View the RUs consumed by the last SQL execution by querying the system variable `tidb_last_query_info`

TiDB provides the system variable `tidb_last_query_info`. This system variable records the information of the last DML statement executed, including the RUs consumed by the SQL execution.

Example:

1. Run the `UPDATE` statement:

```
UPDATE sbtest.sbtest1 SET k = k + 1 WHERE id = 1;
```

```
Query OK, 1 row affected (0.01 sec)
Rows matched: 1 Changed: 1 Warnings: 0
```

2. Query the system variable `tidb_last_query_info` to view the information of the last executed statement:

```
SELECT @@tidb_last_query_info;
```

```
+-------------------------------------------------------------------------------
    ↪
| @@tidb_last_query_info
    ↪
    ↪ |
+-------------------------------------------------------------------------------
    ↪
| {"txn_scope":"global","start_ts":446809472210829315,"for_update_ts
    ↪ ":446809472210829315,"ru_consumption":4.34885578125} |
+-------------------------------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

In the result, `ru_consumption` is the RUs consumed by the execution of this SQL statement.

View RUs consumed during SQL execution by `EXPLAIN ANALYZE`

You can use the `EXPLAIN ANALYZE` statement to get the amount of RUs consumed during SQL execution. Note that the amount of RUs is affected by the cache (for example, coprocessor cache). When the same SQL is executed multiple times, the amount of RUs consumed by each execution might be different. The RU value does not represent the exact value for each execution, but can be used as a reference for estimation.

Slow queries and the corresponding system table

When you enable resource control, the slow query log of TiDB and the corresponding system table `INFORMATION_SCHEMA.SLOW_QUERY` contain the resource group, RU consumption of the corresponding SQL, and the time spent waiting for available RUs.

View RU statistics by `statements_summary`

The system table `INFORMATION_SCHEMA.statements_summary` in TiDB stores the normalized and aggregated statistics of SQL statements. You can use the system table to view and analyze the execution performance of SQL statements. It also contains statistics about resource control, including the resource group name, RU consumption, and the time spent waiting for available RUs. For more details, see `statements_summary` fields description.

8.6.1.7.2 View the RU consumption of resource groups

Starting from v7.6.0, TiDB provides the system table `mysql.request_unit_by_group` to store the historical records of the RU consumption of each resource group.

Example:

```
SELECT * FROM request_unit_by_group LIMIT 5;
```

```
+----------------------------+----------------------------+----------------+----------+
    ↪
| start_time                 | end_time                   | resource_group | total_
    ↪ ru |
+----------------------------+----------------------------+----------------+----------+
    ↪
| 2024-01-01 00:00:00.000000 | 2024-01-02 00:00:00.000000 | default | 334147
    ↪  |
| 2024-01-01 00:00:00.000000 | 2024-01-02 00:00:00.000000 | rg1   |    4172
    ↪ |
| 2024-01-01 00:00:00.000000 | 2024-01-02 00:00:00.000000 | rg2   |   34028
    ↪ |
| 2024-01-02 00:00:00.000000 | 2024-01-03 00:00:00.000000 | default | 334088
    ↪  |
| 2024-01-02 00:00:00.000000 | 2024-01-03 00:00:00.000000 | rg1   |    3850
    ↪ |
+----------------------------+----------------------------+----------------+----------+
    ↪
5 rows in set (0.01 sec)
```

> **Note:**
>
> The data of `mysql.request_unit_by_group` is automatically imported by a TiDB scheduled task at the end of each day. If the RU consumption of a resource group is 0 on a certain day, no record is generated. By default, this table stores data for the last three months (up to 92 days). Data that exceeds this period is automatically cleared.

8.6.1.8 Monitoring metrics and charts

TiDB regularly collects runtime information about resource control and provides visual charts of the metrics in Grafana's **TiDB** > **Resource Control** dashboard. The metrics are detailed in the **Resource Control** section of TiDB Important Monitoring Metrics.

TiKV also records the request QPS from different resource groups. For more details, see TiKV Monitoring Metrics Detail.

You can view the data of resource groups in the current `RESOURCE_GROUPS` table in TiDB Dashboard. For more details, see Resource Manager page.

8.6.1.9 Tool compatibility

The resource control feature does not impact the regular usage of data import, export, and other replication tools. BR, TiDB Lightning, and TiCDC do not currently support processing DDL operations related to resource control, and their resource consumption is not limited by resource control.

8.6.1.10 FAQ

1. Do I have to disable resource control if I don't want to use resource groups?

   No. Users who do not specify any resource groups will be bound to the `default` resource group that has unlimited resources. When all users belong to the `default` ↪ resource group, the resource allocation method is the same as when the resource control is disabled.

2. Can a database user be bound to several resource groups?

   No. A database user can only be bound to one resource group. However, during the session runtime, you can use `SET RESOURCE GROUP` to set the resource group used by the current session. You can also use the optimizer hint `RESOURCE_GROUP()` to set the resource group for the running statement.

3. What happens when the total resource allocation (`RU_PER_SEC`) of all resource groups exceeds the system capacity?

   TiDB does not verify the capacity when you create a resource group. As long as the system has enough available resources, TiDB can meet the resource requirements of each resource group. When the system resources exceed the limit, TiDB prioritizes satisfying requests from resource groups with higher priority. If requests with the same priority cannot all be met, TiDB allocates resources proportionally according to the resource allocation (`RU_PER_SEC`).

- ALTER RESOURCE GROUP
- DROP RESOURCE GROUP
- RESOURCE GROUP RFC

8.6.2 Manage Queries That Consume More Resources Than Expected (Runaway Queries)

A runaway query is a query that consumes more time or resources than expected. The term **runaway queries** is used in the following to describe the feature of managing the runaway query.

- Starting from v7.2.0, the resource control feature introduces the management of runaway queries. You can set criteria for a resource group to identify runaway queries and automatically take actions to prevent them from exhausting resources and affecting other queries. You can manage runaway queries for a resource group by including the `QUERY_LIMIT` field in `CREATE RESOURCE GROUP` or `ALTER RESOURCE GROUP`.
- Starting from v7.3.0, the resource control feature introduces manual management of runaway watches, enabling quick identification of runaway queries for a given SQL statement or Digest. You can execute the statement `QUERY WATCH` to manually manage the runaway queries watch list in the resource group.

For more information about the resource control feature, see Use Resource Control to Achieve Resource Group Limitation and Flow Control.

8.6.2.1 `QUERY_LIMIT` parameters

If a query exceeds any of the following limits, it is identified as a runaway query:

- `EXEC_ELAPSED`: checks whether the query execution time exceeds the limit. This rule applies to read and write DML statements.
- `PROCESSED_KEYS`: checks whether the number of keys processed by the Coprocessor exceeds the limit. This rule only applies to read statements.
- `RU`: checks whether the total number of read and write RUs consumed by the statement exceeds the limit. This rule only applies to read statements.

Supported operations (`ACTION`):

- `DRYRUN`: no action is taken. The records are appended for the runaway queries. This is mainly used to observe whether the condition setting is reasonable.
- `COOLDOWN`: the execution priority of the query is lowered to the lowest level. The query continues to execute with the lowest priority and does not occupy resources of other operations.
- `KILL`: the identified query is automatically terminated and reports an error `Query execution was interrupted, identified as runaway query`.
- `SWITCH_GROUP`: introduced in v8.4.0, this parameter switches the identified query to the specified resource group for continued execution. After this query completes, subsequent SQL statements are executed in the original resource group. If the specified resource group does not exist, the query remains in the original resource group.

To avoid too many concurrent runaway queries that exhaust system resources, the resource control feature introduces a quick identification mechanism, which can quickly identify and isolate runaway queries. You can use this feature through the `WATCH` clause. When a query is identified as a runaway query, this mechanism extracts the matching feature (defined by the parameter after `WATCH`) of the query. In the next period of time (defined by `DURATION` ↪), the matching feature of the runaway query is added to the watch list, and the TiDB instance matches queries with the watch list. The matching queries are directly marked as runaway queries and isolated according to the corresponding action, instead of waiting for them to be identified by conditions. The `KILL` operation terminates the query and reports an error `Quarantined and interrupted because of being in runaway watch list`.

There are three methods for `WATCH` to match for quick identification:

- `EXACT` indicates that only SQL statements with exactly the same SQL text are quickly identified.
- `SIMILAR` indicates all SQL statements with the same pattern are matched by SQL Digest, and the literal values are ignored.
- `PLAN` indicates all SQL statements with the same pattern are matched by Plan Digest.

The `DURATION` option in `WATCH` indicates the duration of the identification item, which is infinite by default.

After a watch item is added, neither the matching feature nor the `ACTION` is changed or deleted whenever the `QUERY_LIMIT` configuration is changed or deleted. You can use `QUERY WATCH REMOVE` to remove a watch item.

The parameters of `QUERY_LIMIT` are as follows:

Parameter	Description	Note
`EXEC_ELAPSED`	When the query execution time exceeds this value, it is identified as a runaway query	EXEC_ELAPSED =`60s` means the query is identified as a runaway query if it takes more than 60 seconds to execute.
`PROCESSED_` ↪ `KEYS`	When the number of keys processed by the Coprocessor exceeds this value, the query is identified as a runaway query	`PROCESSED_KEYS = 1000` means the query is identified as a runaway query if the number of keys processed by the Coprocessor exceeds 1000.

Parameter	Description	Note
`RU`	When the total number of read and write RUs consumed by the query exceeds this value, this query is identified as a runaway query	`RU = 1000` means the query is identified as a runaway query if the total number of read and write RUs consumed by the query exceeds 1000.
`ACTION`	Action taken when a runaway query is identified	The optional values are `DRYRUN`, `COOLDOWN`, `KILL`, and `SWITCH_GROUP`.
`WATCH`	Quickly match the identified runaway query. If the same or similar query is encountered again within a certain period of time, the corresponding action is performed immediately.	Optional. For example, `WATCH=SIMILAR DURATION '60s'`, `WATCH=EXACT DURATION '1m'`, and `WATCH=PLAN`.

Note:

If you want to strictly limit runaway queries to a specific resource group, it is recommended to use `SWITCH_GROUP` together with the `QUERY WATCH` statement. Because `QUERY_LIMIT` only triggers the corresponding `ACTION` operation when the query meets the criteria, `SWITCH_GROUP` might not be able to switch the query to the target resource group in a timely manner in such scenarios.

8.6.2.2 Examples

1. Create a resource group `rg1` with a quota of 500 RUs per second, and define a runaway

query as one that exceeds 60 seconds, and lower the priority of the runaway query.

```
CREATE RESOURCE GROUP IF NOT EXISTS rg1 RU_PER_SEC = 500 QUERY_LIMIT=(
    ↪ EXEC_ELAPSED='60s', ACTION=COOLDOWN);
```

2. Change the `rg1` resource group to terminate the runaway queries, and mark the queries with the same pattern as runaway queries immediately in the next 10 minutes.

```
ALTER RESOURCE GROUP rg1 QUERY_LIMIT=(EXEC_ELAPSED='60s', ACTION=KILL,
    ↪  WATCH=SIMILAR DURATION='10m');
```

3. Change the `rg1` resource group to cancel the runaway query check.

```
ALTER RESOURCE GROUP rg1 QUERY_LIMIT=NULL;
```

8.6.2.3 `QUERY WATCH` parameters

For more information about the synopsis of `QUERY WATCH`, see QUERY WATCH.

The parameters are as follows:

- The `RESOURCE GROUP` specifies a resource group. The matching features of runaway queries added by this statement are added to the watch list of the resource group. This parameter can be omitted. If omitted, it applies to the `default` resource group.
- The meaning of `ACTION` is the same as `QUERY LIMIT`. This parameter can be omitted. If omitted, the corresponding action after identification adopts the `ACTION` configured by `QUERY LIMIT` in the resource group, and the action does not change with the `QUERY LIMIT` configuration. If there is no `ACTION` configured in the resource group, an error is reported.
- The `QueryWatchTextOption` parameter has three options: `SQL DIGEST`, `PLAN DIGEST`, and `SQL TEXT`.
    - `SQL DIGEST` is the same as that of `SIMILAR`. The following parameters accept strings, user-defined variables, or other expressions that yield string result. The string length must be 64, which is the same as the Digest definition in TiDB.
    - `PLAN DIGEST` is the same as `PLAN`. The following parameter is a Digest string.
    - `SQL TEXT` matches the input SQL as a raw string (`EXACT`), or parses and compiles it into `SQL DIGEST` (`SIMILAR`) or `PLAN DIGEST` (`PLAN`), depending on the following parameter.
- Add a matching feature to the runaway query watch list for the default resource group (you need to set `QUERY LIMIT` for the default resource group in advance).

```
QUERY WATCH ADD ACTION KILL SQL TEXT EXACT TO 'select * from test.t2';
```

- Add a matching feature to the runaway query watch list for the `rg1` resource group by parsing the SQL into SQL Digest. When `ACTION` is not specified, the `ACTION` option already configured for the `rg1` resource group is used.

```
QUERY WATCH ADD RESOURCE GROUP rg1 SQL TEXT SIMILAR TO 'select * from
    ↪ test.t2';
```

- Add a matching feature to the runaway query watch list for the `rg1` resource group by parsing the SQL into SQL Digest, and specify `ACTION` as `SWITCH_GROUP(rg2)`.

```
QUERY WATCH ADD RESOURCE GROUP rg1 ACTION SWITCH_GROUP(rg2) SQL TEXT
    ↪ SIMILAR TO 'select * from test.t2';
```

- Add a matching feature to the runaway query watch list for the `rg1` resource group using `PLAN DIGEST`, and specify `ACTION` as `KILL`.

```
QUERY WATCH ADD RESOURCE GROUP rg1 ACTION KILL PLAN DIGEST '
    ↪ d08bc323a934c39dc41948b0a073725be3398479b6fa4f6dd1db2a9b115f7f57'
    ↪ ;
```

- Get the watch item ID by querying `INFORMATION_SCHEMA.RUNAWAY_WATCHES` and delete the watch item.

```
SELECT * from information_schema.runaway_watches ORDER BY id\G
```

```
*************************** 1. row ***************************
                ID: 1
RESOURCE_GROUP_NAME: default
        START_TIME: 2024-09-09 03:35:31
          END_TIME: 2024-09-09 03:45:31
             WATCH: Exact
       WATCH_TEXT: SELECT variable_name, variable_value FROM mysql.
           ↪ global_variables
            SOURCE: 127.0.0.1:4000
            ACTION: Kill
            RULE: ProcessedKeys = 666(10)
1 row in set (0.00 sec)
```

```
QUERY WATCH REMOVE 1;
```

8.6.2.4 Observability

You can get more information about runaway queries from the following system tables and `INFORMATION_SCHEMA`:

- The `mysql.tidb_runaway_queries` table contains the history records of all runaway queries identified in the past 7 days. Take one of the rows as an example:

```
MySQL [(none)]> SELECT * FROM mysql.tidb_runaway_queries LIMIT 1\G
*************************** 1. row ***************************
resource_group_name: default
     start_time: 2024-09-09 17:43:42
        repeats: 2
     match_type: watch
         action: kill
     sample_sql: select sleep(2) from t
     sql_digest: 4
        ↪ adbc838b86c573265d4b39a3979d0a362b5f0336c91c26930c83ab187701a55
        ↪
    plan_digest: 5
        ↪ d094f78efbce44b2923733b74e1d09233cb446318293492901c5e5d92e27dbc
        ↪
    tidb_server: 127.0.0.1:4000
```

  Field description:

  - `start_time` indicates the time when the runaway query is identified.
  - `repeats` indicates the number of times the runaway query has been identified since `start_time`.
  - `match_type` indicates how the runaway query is identified. The value can be one of the following:
    - `identify` means that it matches the condition of the runaway query.
    - `watch` means that it matches the quick identification rule in the watch list.

- The `information_schema.runaway_watches` table contains records of quick identification rules for runaway queries. For more information, see RUNAWAY_WATCHES.

8.6.3 Use Resource Control to Manage Background Tasks

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.
>
> The background task management in resource control is based on TiKV's dynamic adjustment of resource quotas for CPU/IO utilization. Therefore, it relies on the available resource quota of each instance. If multiple components or instances are deployed on a single server, it is mandatory to set the

appropriate resource quota for each instance through `cgroup`. It is difficult to achieve the expected effect in deployment with shared resources such as TiUP Playground.

Background tasks, such as data backup and automatic statistics collection, are low-priority but consume many resources. These tasks are usually triggered periodically or irregularly. During execution, they consume a lot of resources, thus affecting the performance of online high-priority tasks.

Starting from v7.4.0, the TiDB resource control feature supports managing background tasks. When a task is marked as a background task, TiKV dynamically limits the resources used by this type of task to avoid the impact on the performance of other foreground tasks. TiKV monitors the CPU and IO resources consumed by all foreground tasks in real time, and calculates the resource threshold that can be used by background tasks based on the total resource limit of the instance. All background tasks are restricted by this threshold during execution.

8.6.3.1 `BACKGROUND` parameters

- `TASK_TYPES`: specifies the task types that need to be managed as background tasks. Use commas (`,`) to separate multiple task types.
- `UTILIZATION_LIMIT`: limits the maximum percentage (0-100) of resources that background tasks can consume on each TiKV node. By default, TiKV calculates the available resources for background tasks based on the total resources of the node and the resources currently occupied by the foreground tasks. If `UTILIZATION_LIMIT` is configured, the resource allocated to background tasks will not exceed this limit.

TiDB supports the following types of background tasks:

- `lightning`: perform import tasks using TiDB Lightning. Both physical and logical import modes of TiDB Lightning are supported.
- `br`: perform backup and restore tasks using BR. PITR is not supported.
- `ddl`: control the resource usage during the batch data write back phase of Reorg DDLs.
- `stats`: the collect statistics tasks that are manually executed or automatically triggered by TiDB.
- `background`: a reserved task type. You can use the `tidb_request_source_type` system variable to specify the task type of the current session as `background`.

By default, the task types that are marked as background tasks are `""`, and the management of background tasks is disabled. To enable background task management, you need to manually modify the background task type of the `default` resource group. After a background task is identified and matched, Resource Control is automatically performed. This

means that when system resources are insufficient, the background tasks are automatically reduced to the lowest priority to ensure the execution of foreground tasks.

> **Note:**
>
> Currently, background tasks for all resource groups are bound to the `default` resource group. You can manage background task types globally through `default`. Binding background tasks to other resource groups is currently not supported.

8.6.3.2 Examples

1. Modify the `default` resource group by marking `br` and `ddl` as background tasks and setting the resource limit of background tasks to 30%.

```
ALTER RESOURCE GROUP `default` BACKGROUND=(TASK_TYPES='br,ddl',
    ↪ UTILIZATION_LIMIT=30);
```

2. Change the `default` resource group to revert the background task type to its default value.

```
ALTER RESOURCE GROUP `default` BACKGROUND=NULL;
```

3. Change the `default` resource group to set the background task type to empty. In this case, all tasks of this resource group are not treated as background tasks.

```
ALTER RESOURCE GROUP `default` BACKGROUND=(TASK_TYPES="");
```

4. View the background task type of the `default` resource group.

```
SELECT * FROM information_schema.resource_groups WHERE NAME="default";
```

The output is as follows:

```
+---------+------------+----------+-----------+-------------+----------------------
    ↪
| NAME    | RU_PER_SEC | PRIORITY | BURSTABLE | QUERY_LIMIT | BACKGROUND
    ↪                       |
+---------+------------+----------+-----------+-------------+----------------------
    ↪
| default | UNLIMITED  | MEDIUM   | YES       | NULL        | TASK_TYPES='br,
    ↪ ddl', UTILIZATION_LIMIT=30 |
+---------+------------+----------+-----------+-------------+----------------------
    ↪
```

5. To explicitly mark tasks in the current session as the background type, you can use `tidb_request_source_type` to explicitly specify the task type. The following is an example:

```
SET @@tidb_request_source_type="background";
/* Add background task type */
ALTER RESOURCE GROUP `default` BACKGROUND=(TASK_TYPES="background");
/* Execute LOAD DATA in the current session */
LOAD DATA INFILE "s3://resource-control/Lightning/test.customer.aaaa.
    ↪ csv"
```

8.7 Time Zone Support

The time zone in TiDB is decided by the `time_zone` system variable. You can set it at the session or global level. The default value of `time_zone` is `SYSTEM`. The actual time zone corresponding to `SYSTEM` is configured when the TiDB cluster bootstrap is initialized. The detailed logic is as follows:

1. TiDB prioritizes the use of the `TZ` environment variable.
2. If the `TZ` environment variable fails, TiDB reads the time zone from the soft link at `/etc/localtime`.
3. If both of the preceding methods fail, TiDB uses `UTC` as the system time zone.

8.7.1 View time zone settings

To view the current values of the global, client-specific, and system time zones, execute the following statement:

```
SELECT @@global.time_zone, @@session.time_zone, @@global.system_time_zone;
```

8.7.2 Set the time zone

In TiDB, the value of the `time_zone` system variable can be set in one of the following formats:

- `SYSTEM` (default value), which indicates that the time zone should be the same as the system time zone.
- A UTC offset, such as `'+10:00'` or `'-6:00'`.
- A named time zone, such as `'Europe/Helsinki'`, `'US/Eastern'`, or `'MET'`.

Depending on your needs, you can set the time zone in TiDB at the global or session level as follows:

- Set the time zone in TiDB at the global level:

```
SET GLOBAL time_zone = ${time-zone-value};
```

For example, set the global time zone to UTC:

```
SET GLOBAL time_zone = 'UTC';
```

- Set the time zone in TiDB at the session level:

```
SET time_zone = ${time-zone-value};
```

For example, set the time zone of the current session to US/Pacific:

```
SET time_zone = 'US/Pacific';
```

8.7.3 Functions and data types affected by time zone settings

The current session time zone setting affects the display and interpretation of time values that are zone-sensitive, such as the values returned by `NOW()` and `CURTIME()` functions. To convert between time zones, use the `CONVERT_TZ()` function. To get a timestamp based on UTC, use the `UTC_TIMESTAMP()` function, which helps avoid time zone-related issues.

In TiDB, the displayed values of the `TIMESTAMP` data type are affected by time zone settings. This is because the `TIMESTAMP` data type uses the literal value and time zone information. Other data types, such as `DATETIME`, `DATE`, and `TIME`, do not have time zone information, thus their values are not affected by the changes of time zone.

For example:

```
create table t (ts timestamp, dt datetime);
```

```
Query OK, 0 rows affected (0.02 sec)
```

```
set @@time_zone = 'UTC';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
insert into t values ('2017-09-30 11:11:11', '2017-09-30 11:11:11');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
set @@time_zone = '+8:00';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+---------------------|---------------------+
| ts                  | dt                  |
+---------------------|---------------------+
| 2017-09-30 19:11:11 | 2017-09-30 11:11:11 |
+---------------------|---------------------+
1 row in set (0.00 sec)
```

In this example, no matter how you adjust the time zone value, the value of the `DATETIME` data type is not affected. However, the displayed value of the `TIMESTAMP` data type reflects changes in the time zone. In fact, the `TIMESTAMP` value stored in the database remains unchanged, but it is displayed differently according to different time zone settings.

8.7.4 Important considerations for time zone settings

- Time zone is involved during the conversion of the values of `TIMESTAMP` and `DATETIME`, which is handled based on the `time_zone` of the current session.
- For data migration, you need to pay special attention to whether the time zone settings of the primary database and the secondary database are consistent.
- To get accurate timestamps, it is strongly recommended that you configure a reliable clock using Network Time Protocol (NTP) or Precision Time Protocol (PTP) services. For information about how to check NTP services, see Check and install the NTP service.
- Be aware that using time zones that observe daylight saving time can result in ambiguous or nonexistent timestamps, especially when performing calculations with those timestamps.
- MySQL uses `mysql_tzinfo_to_sql` to convert the time zone database of the operating system into tables in the `mysql` database. In contrast, TiDB directly reads the time zone data files from the time zone database of the operating system, which leverages the built-in time zone handling capabilities of the Go programming language.

8.8 Daily Check

As a distributed database, TiDB is more complicated than the stand-alone database in terms of the mechanism, and monitoring items. To help operate and maintain TiDB in a more convenient way, this document introduces some key performance indicators.

8.8.1 Key indicators of TiDB Dashboard

Starting from v4.0, TiDB provides a new operation and maintenance management tool, TiDB Dashboard. This tool is integrated into the PD component. You can access TiDB Dashboard at the default address `http://${pd-ip}:${pd_port}/dashboard`.

TiDB Dashboard simplifies the operation and maintenance of the TiDB database. You can view the running status of the entire TiDB cluster through one interface. The following are descriptions of some performance indicators.

8.8.1.1 Instance panel

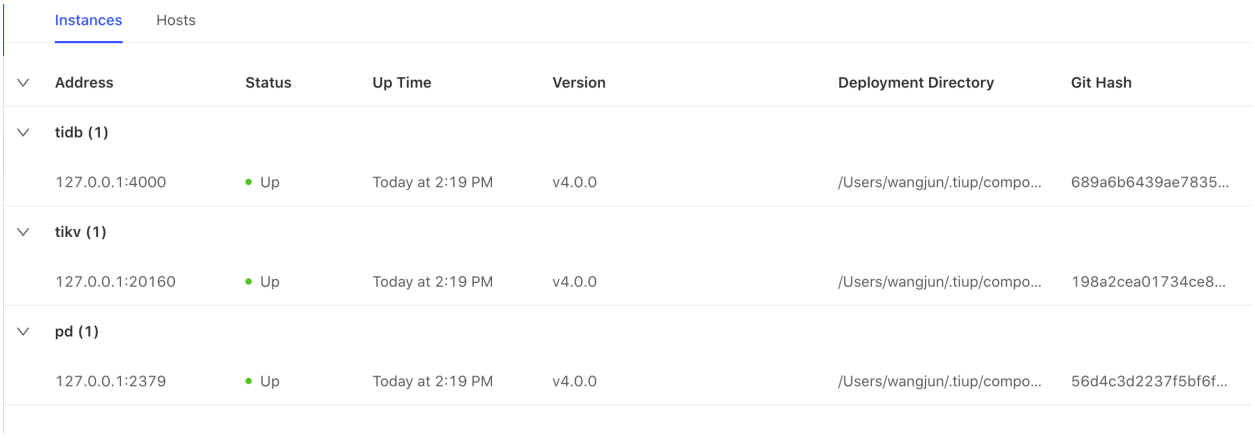

Figure 156: Instance panel

- **Status**: This indicator is used to check whether the status is normal. For an online node, this can be ignored.
- **Up Time**: The key indicator. If you find that the `Up Time` is changed, you need to locate the reason why the component is restarted.
- **Version**, **Deployment Directory**, **Git Hash**: These indicators need to be checked to avoid inconsistent or even incorrect version/deployment directory.

8.8.1.2 Host panel

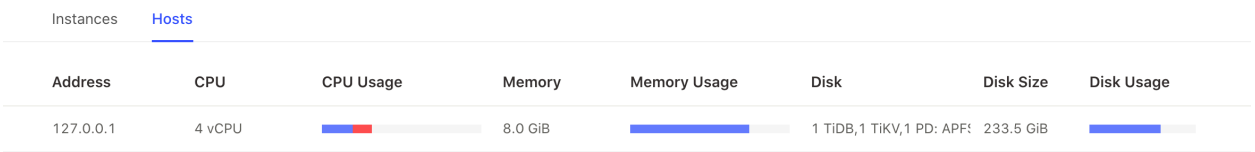

Figure 157: Host panel

You can view the usage of CPU, memory, and disk. When the usage of any resource exceeds 80%, it is recommended to scale out the capacity accordingly.

8.8.1.3 SQL analysis panel

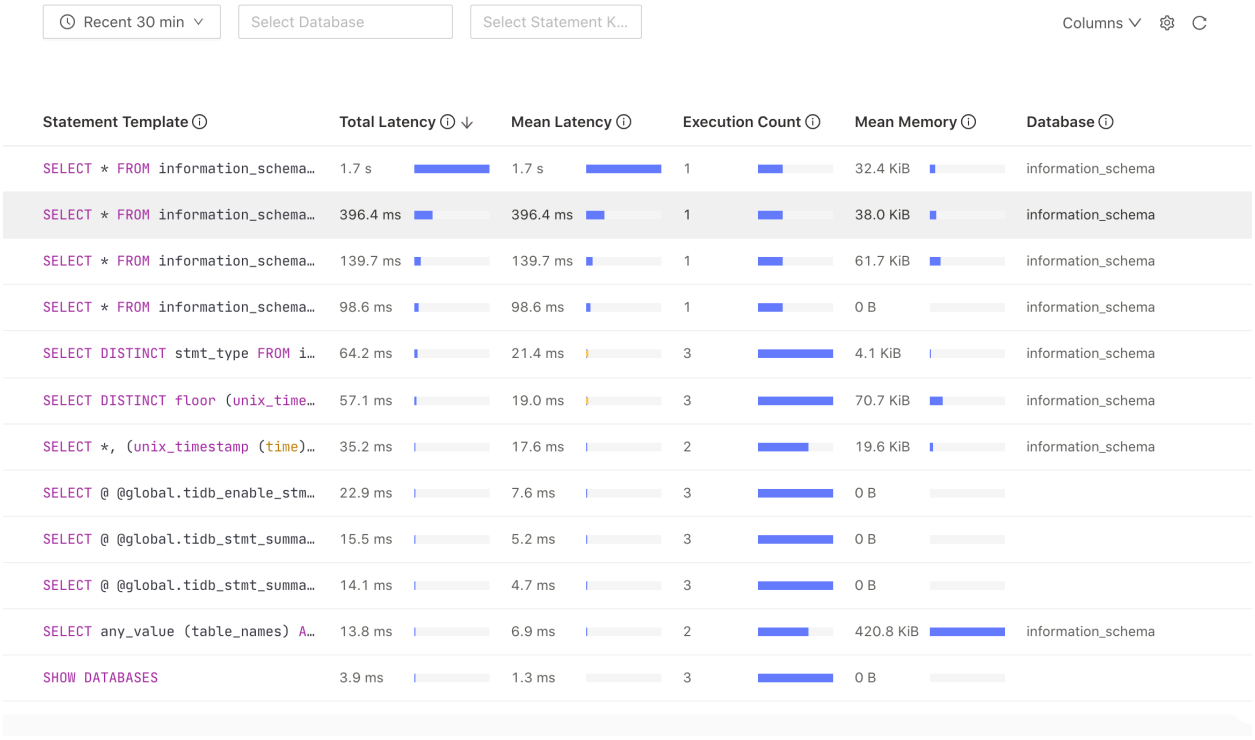

Figure 158: SQL analysis panel

You can locate the slow SQL statement executed in the cluster. Then you can optimize the specific SQL statement.

8.8.1.4 Region panel

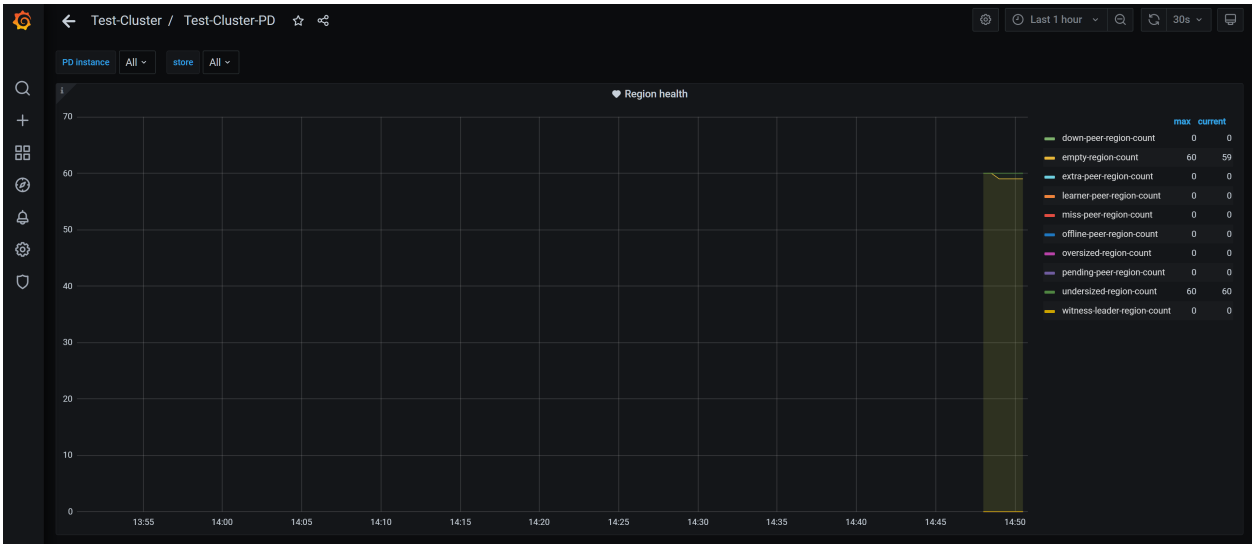

Figure 159: Region panel

- `down-peer-region-count`: The number of Regions with an unresponsive peer reported by the Raft leader.
- `empty-region-count`: The number of empty Regions, with a size of smaller than 1 MiB. These Regions are generated by executing the `TRUNCATE TABLE/DROP TABLE` statement. If this number is large, you can consider enabling `Region Merge` to merge Regions across tables.
- `extra-peer-region-count`: The number of Regions with extra replicas. These Regions are generated during the scheduling process.
- `learner-peer-region-count`: The number of Regions with the learner peer. The sources of learner peers can be various, for example, the learner peers in TiFlash, and the learner peers included in the configured Placement Rules.
- `miss-peer-region-count`: The number of Regions without enough replicas. This value is not always greater than `0`.
- `offline-peer-region-count`: The number of Regions during the peer offline process.
- `oversized-region-count`: The number of Regions with a size larger than `region-max-size` or `region-max-keys`.
- `pending-peer-region-count`: The number of Regions with outdated Raft logs. It is normal that a few pending peers are generated in the scheduling process. However, it is not normal if this value is large for a period of time (longer than 30 minutes).
- `undersized-region-count`: The number of Regions with a size smaller than `max-merge-region-size` or `max-merge-region-keys`.

Generally, it is normal that these values are not `0`. However, it is not normal that they are not `0` for quite a long time.

8.8.1.5 KV Request Duration

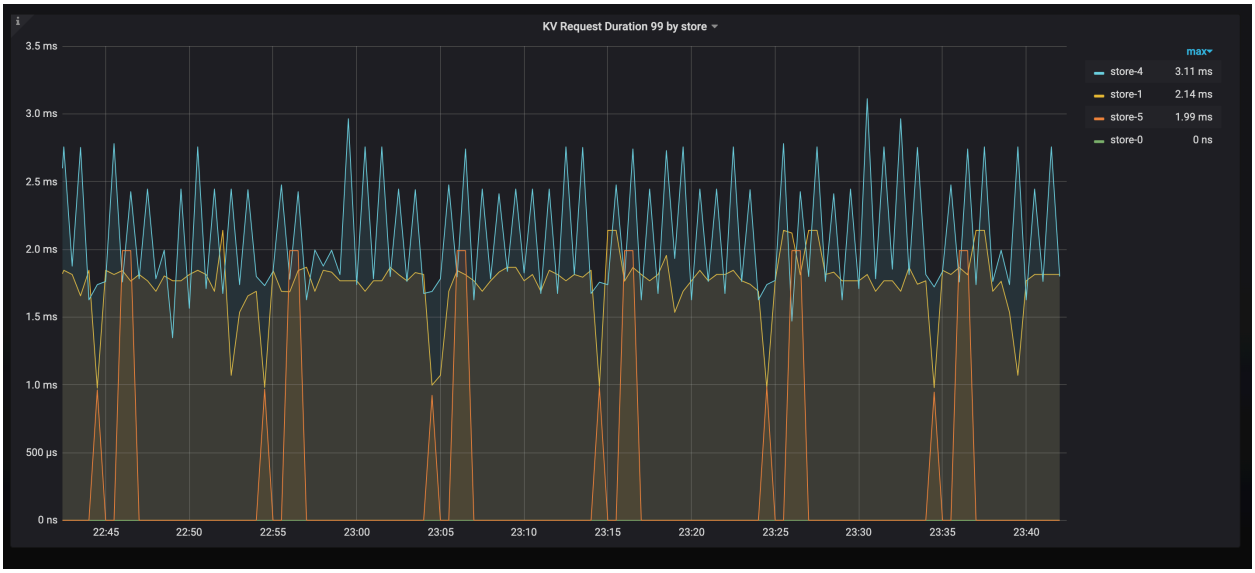

Figure 160: TiKV request duration

The KV request duration 99 in TiKV. If you find nodes with a long duration, check whether there are hot spots, or whether there are nodes with poor performance.

8.8.1.6 PD TSO Wait Duration

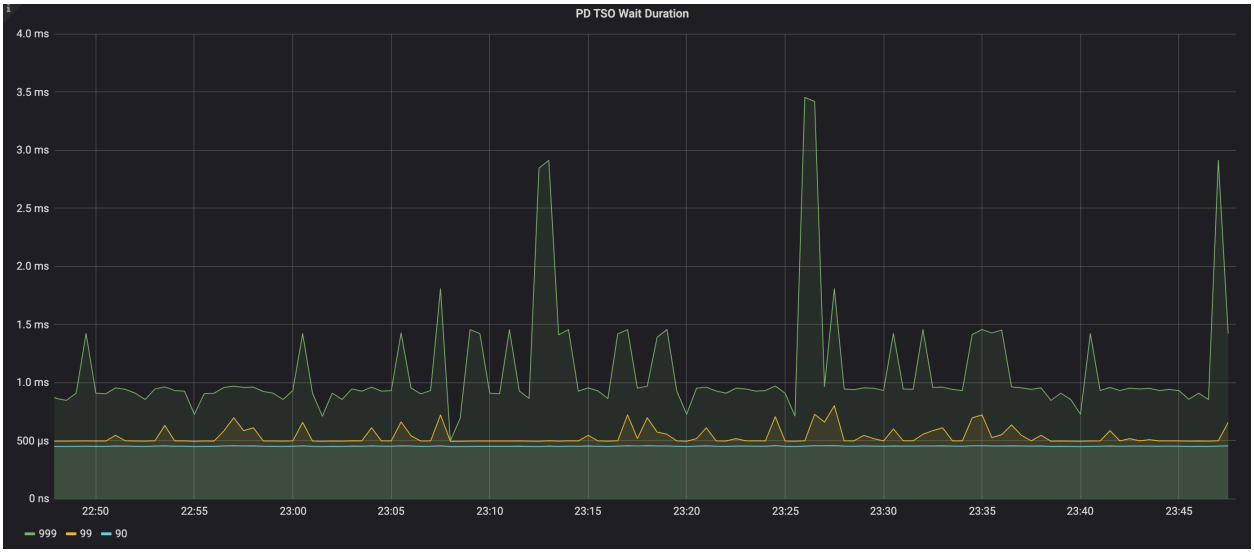

Figure 161: TiDB TSO Wait Duration

The time it takes for TiDB to obtain TSO from PD. The following are reasons for the long wait duration:

- High network latency from TiDB to PD. You can manually execute the ping command to test the network latency.
- High load for the TiDB server.
- High load for the PD server.

8.8.1.7 Overview panel

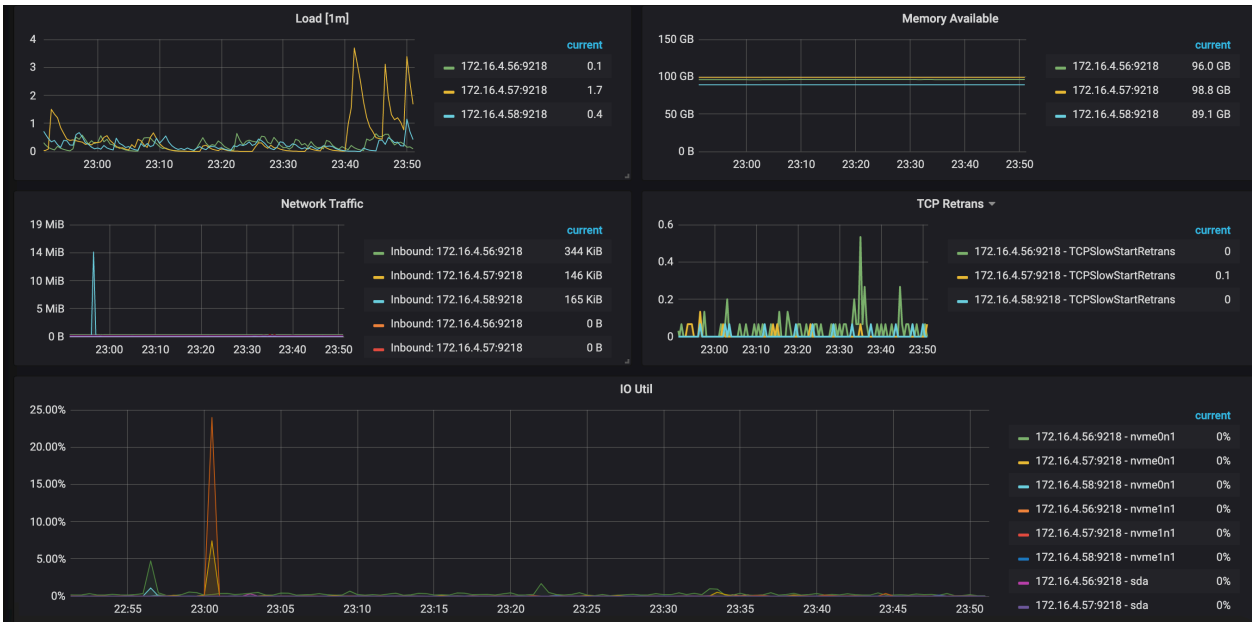

Figure 162: Overview panel

You can view the load, memory available, network traffic, and I/O utilities. When a bottleneck is found, it is recommended to scale out the capacity, or to optimize the cluster topology, SQL, and cluster parameters.

8.8.1.8 Exceptions

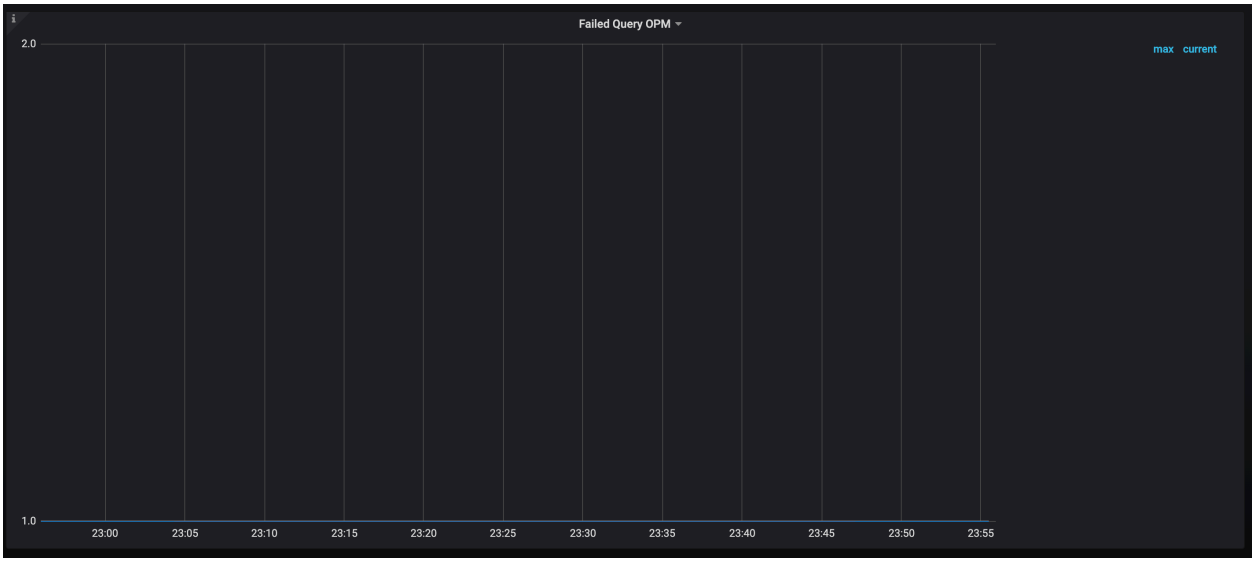

Figure 163: Exceptions

You can view the errors triggered by the execution of SQL statements on each TiDB instance. These include syntax error and primary key conflicts.

8.8.1.9 GC status

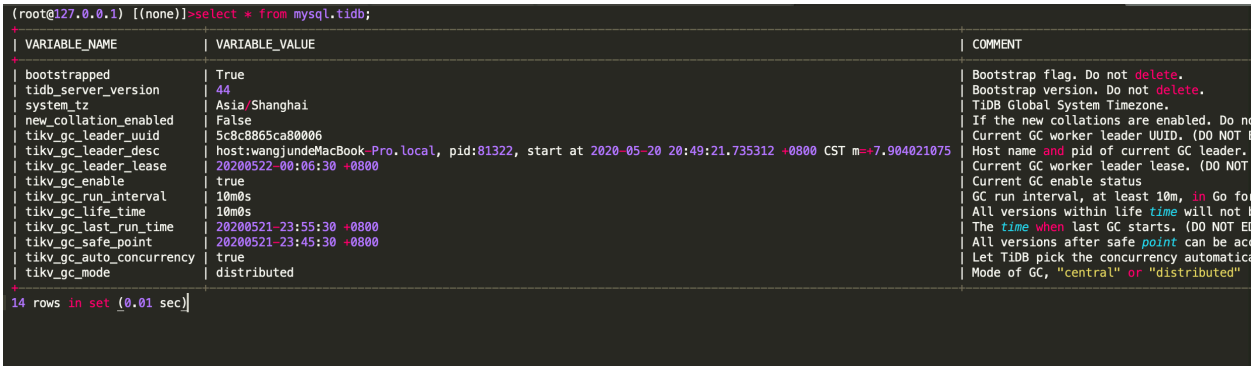

Figure 164: GC status

You can check whether the GC (Garbage Collection) status is normal by viewing the time when the last GC happens. If the GC is abnormal, it might lead to excessive historical data, thereby decreasing the access efficiency.

8.9 Maintain a TiFlash Cluster

This document describes how to perform common operations when you maintain a TiFlash cluster, including checking the TiFlash version. This document also introduces critical logs and a system table of TiFlash.

8.9.1 Check the TiFlash version

There are two ways to check the TiFlash version:

- If the binary file name of TiFlash is `tiflash`, you can check the version by executing the `./tiflash version` command.

  However, to execute the above command, you need to add the directory path which includes the `libtiflash_proxy.so` dynamic library to the `LD_LIBRARY_PATH` environment variable. This is because the running of TiFlash relies on the `libtiflash_proxy.so` dynamic library.

  For example, when `tiflash` and `libtiflash_proxy.so` are in the same directory, you can first switch to this directory, and then use the following command to check the TiFlash version:

```
LD_LIBRARY_PATH=./ ./tiflash version
```

- Check the TiFlash version by referring to the TiFlash log. For the log path, see the `[logger]` part in the `tiflash.toml` file. For example:

```
<information>: TiFlash version: TiFlash 0.2.0 master-375035282451103999
    ↪ f3863c691e2fc2
```

8.9.2 TiFlash critical logs

Log Information	Log Description
`[INFO] [<` `↪ unknown>]` `↪ ["KVStore:` `↪ Start to` `↪ persist [` `↪ region 47,` `↪ applied:` `↪ term 6` `↪ index 10]"]` `↪ [thread_id` `↪ =23]`	Data starts to be replicated (the number in the square brackets at the start of the log refers to the thread ID

Log Information	Log Description
`[DEBUG] [< unknown>] ["  CoprocessorHandler : grpc:: Status DB:: CoprocessorHandler ::execute() : Handling DAG request "] [thread_ id=30]`	Handling DAG request, that is, TiFlash starts to handle a Coprocessor request
`[DEBUG] [< unknown>] ["  CoprocessorHandler : grpc:: Status DB:: CoprocessorHandler ::execute() : Handle DAG request  done"] [ thread_id =30]`	Handling DAG request done, that is, TiFlash finishes handling a Coprocessor request

You can find the beginning or the end of a Coprocessor request, and then locate the related logs of the Coprocessor request through the thread ID printed at the start of the log.

8.9.3 TiFlash system table

The column names and their descriptions of the `information_schema.tiflash_replica` system table are as follows:

Column Name	Description
TABLE_SCHEMA	Database name
TABLE_NAME	Table name
TABLE_ID	Table ID
REPLICA_COUNT	Number of TiFlash replicas

Column Name	Description
LOCATION_LABELS	The hint for PD, based on which multiple replicas in a Region are scattered
AVAILABLE	Available or not (0/1)
PROGRESS	Replication progress [0.0~1.0]

8.10 TiUP Common Operations

This document describes the common operations when you operate and maintain a TiDB cluster using TiUP.

8.10.1 View the cluster list

You can manage multiple TiDB clusters using the TiUP cluster component. When a TiDB cluster is deployed, the cluster appears in the TiUP cluster list.

To view the list, run the following command:

```
tiup cluster list
```

8.10.2 Start the cluster

The components in the TiDB cluster are started in the following order:

PD > TiKV > TiDB > TiFlash > TiCDC > Prometheus > Grafana > Alertmanager

To start the cluster, run the following command:

```
tiup cluster start ${cluster-name}
```

> **Note:**
>
> Replace `${cluster-name}` with the name of your cluster. If you forget the cluster name, check it by running `tiup cluster list`.

You can start only some of the components by adding the `-R` or `-N` parameters in the command. For example:

- This command starts only the PD component:

```
tiup cluster start ${cluster-name} -R pd
```

- This command starts only the PD components on the `1.2.3.4` and `1.2.3.5` hosts:

```
tiup cluster start ${cluster-name} -N 1.2.3.4:2379,1.2.3.5:2379
```

> **Note:**
>
> If you start the specified component by using the `-R` or `-N` parameters, make sure the starting order is correct. For example, start the PD component before the TiKV component. Otherwise, the start might fail.

8.10.3 View the cluster status

After starting the cluster, check the status of each component to ensure that they work normally. TiUP provides the `display` command, so you do not have to log in to every machine to view the component status.

```
tiup cluster display ${cluster-name}
```

8.10.4 Modify the configuration

When the cluster is in operation, if you need to modify the parameters of a component, run the `edit-config` command. The detailed steps are as follows:

1. Open the configuration file of the cluster in the editing mode:

```
tiup cluster edit-config ${cluster-name}
```

2. Configure the parameters:

    - If the configuration is globally effective for a component, edit `server_configs`:

```
server_configs:
  tidb:
    log.slow-threshold: 300
```

- If the configuration takes effect on a specific node, edit the configuration in `config` of the node:

```
tidb_servers:
- host: 10.0.1.11
  port: 4000
  config:
      log.slow-threshold: 300
```

For the parameter format, see the TiUP parameter template.

Use `.` to represent the hierarchy of the configuration items.

For more information on the configuration parameters of components, refer to TiDB `config.toml.example`, TiKV `config.toml.example`, and PD `config.toml.example` ↪ .

3. Rolling update the configuration and restart the corresponding components by running the `reload` command:

```
tiup cluster reload ${cluster-name} [-N <nodes>] [-R <roles>]
```

8.10.4.1 Example

If you want to set the transaction size limit parameter (`txn-total-size-limit` in the performance module) to `1G` in tidb-server, edit the configuration as follows:

```
server_configs:
  tidb:
    performance.txn-total-size-limit: 1073741824
```

Then, run the `tiup cluster reload ${cluster-name} -R tidb` command to rolling restart the TiDB component.

8.10.5 Replace with a hotfix package

For normal upgrade, see Upgrade TiDB Using TiUP. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]
```

```
Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 600)

Global Flags:

      --native-ssh      Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

8.10.6 Rename the cluster

After deploying and starting the cluster, you can rename the cluster using the `tiup cluster rename` command:

```
tiup cluster rename ${cluster-name} ${new-name}
```

Note:

- The operation of renaming a cluster restarts the monitoring system (Prometheus and Grafana).
- After a cluster is renamed, some panels with the old cluster name might remain on Grafana. You need to delete them manually.

8.10.7 Stop the cluster

The components in the TiDB cluster are stopped in the following order (The monitoring component is also stopped):

Alertmanager > Grafana > Prometheus > TiCDC > TiFlash > TiDB > TiKV > PD

To stop the cluster, run the following command:

```
tiup cluster stop ${cluster-name}
```

Similar to the `start` command, the `stop` command supports stopping some of the components by adding the `-R` or `-N` parameters. For example:

- This command stops only the TiDB component:

  ```
  tiup cluster stop ${cluster-name} -R tidb
  ```

- This command stops only the TiDB components on the `1.2.3.4` and `1.2.3.5` hosts:

  ```
  tiup cluster stop ${cluster-name} -N 1.2.3.4:4000,1.2.3.5:4000
  ```

8.10.8 Clean up cluster data

The operation of cleaning up cluster data stops all the services and cleans up the data directory or/and log directory. The operation cannot be reverted, so proceed **with caution**.

- Clean up the data of all services in the cluster, but keep the logs:

  ```
  tiup cluster clean ${cluster-name} --data
  ```

- Clean up the logs of all services in the cluster, but keep the data:

  ```
  tiup cluster clean ${cluster-name} --log
  ```

- Clean up the data and logs of all services in the cluster:

  ```
  tiup cluster clean ${cluster-name} --all
  ```

- Clean up the logs and data of all services except Prometheus:

  ```
  tiup cluster clean ${cluster-name} --all --ignore-role prometheus
  ```

- Clean up the logs and data of all services except the `172.16.13.11:9000` instance:

  ```
  tiup cluster clean ${cluster-name} --all --ignore-node
  ↪ 172.16.13.11:9000
  ```

- Clean up the logs and data of all services except the `172.16.13.12` node:

```
tiup cluster clean ${cluster-name} --all --ignore-node 172.16.13.12
```

8.10.9 Destroy the cluster

The destroy operation stops the services and clears the data directory and deployment directory. The operation cannot be reverted, so proceed **with caution**.

```
tiup cluster destroy ${cluster-name}
```

8.10.10 Switch from Prometheus to VictoriaMetrics

In large-scale clusters, Prometheus might encounter performance bottlenecks when handling a large number of instances. Starting from TiUP v1.16.3, TiUP supports switching the monitoring component from Prometheus to VictoriaMetrics (VM) to provide better scalability, higher performance, and lower resource consumption.

8.10.10.1 Set up VictoriaMetrics for a new deployment

By default, TiUP uses Prometheus as the metrics monitoring component. To use VictoriaMetrics instead of Prometheus in a new deployment, configure the topology file as follows:

```
## Monitoring server configuration
monitoring_servers:
  # IP address of the monitoring server
  - host: ip_address
    ...
    prom_remote_write_to_vm: true
    enable_prom_agent_mode: true

## Grafana server configuration
grafana_servers:
  # IP address of the Grafana server
  - host: ip_address
    ...
    use_vm_as_datasource: true
```

8.10.10.2 Migrate an existing deployment to VictoriaMetrics

You can perform the migration without affecting running instances. Existing metrics will remain in Prometheus, while TiUP will write new metrics to VictoriaMetrics.

8.10.10.2.1 Enable VictoriaMetrics remote write

1. Edit the cluster configuration:

```
tiup cluster edit-config ${cluster-name}
```

2. Under `monitoring_servers`, set `prom_remote_write_to_vm` to `true`:

```
monitoring_servers:
  - host: ip_address
    ...
    prom_remote_write_to_vm: true
```

3. Reload the configuration to apply the changes:

```
tiup cluster reload ${cluster-name} -R prometheus
```

8.10.10.2.2 Switch the default data source to VictoriaMetrics

1. Edit the cluster configuration:

```
tiup cluster edit-config ${cluster-name}
```

2. Under `grafana_servers`, set `use_vm_as_datasource` to `true`:

```
grafana_servers:
  - host: ip_address
    ...
    use_vm_as_datasource: true
```

3. Reload the configuration to apply the changes:

```
tiup cluster reload ${cluster-name} -R grafana
```

8.10.10.2.3 View historical metrics generated before the switch (optional)

If you need to view historical metrics generated before the switch, switch the data source of Grafana as follows:

1. Edit the cluster configuration:

```
tiup cluster edit-config ${cluster-name}
```

2. Under `grafana_servers`, comment out `use_vm_as_datasource`:

```
grafana_servers:
  - host: ip_address
    ...
    # use_vm_as_datasource: true
```

3. Reload the configuration to apply the changes:

```
tiup cluster reload ${cluster-name} -R grafana
```

4. To switch back to VictoriaMetrics, repeat the steps in Switch the default data source to VictoriaMetrics.

8.10.10.3 Clean up old metrics and services

After confirming that the old metrics have expired, you can perform the following steps to remove redundant services and files. This does not affect the running cluster.

8.10.10.3.1 Set Prometheus to agent mode

1. Edit the cluster configuration:

```
tiup cluster edit-config ${cluster-name}
```

2. Under `monitoring_servers`, set `enable_prom_agent_mode` to `true`, and ensure you also set `prom_remote_write_to_vm` and `use_vm_as_datasource` correctly:

```
monitoring_servers:
  - host: ip_address
    ...
    prom_remote_write_to_vm: true
    enable_prom_agent_mode: true
grafana_servers:
  - host: ip_address
    ...
    use_vm_as_datasource: true
```

3. Reload the configuration to apply the changes:

```
tiup cluster reload ${cluster-name} -R prometheus
```

8.10.10.3.2 Remove expired data directories

1. In the configuration file, locate the `data_dir` path of the monitoring server:

```
monitoring_servers:
  - host: ip_address
    ...
    data_dir: "/tidb-data/prometheus-8249"
```

2. Remove the data directory:

```
rm -rf /tidb-data/prometheus-8249
```

8.11 Modify Configuration Dynamically

This document describes how to dynamically modify the cluster configuration.

You can dynamically update the configuration of components (including TiDB, TiKV, and PD) using SQL statements, without restarting the cluster components. Currently, the method of changing TiDB instance configuration is different from that of changing configuration of other components (such as TiKV and PD).

> **Note:**
>
> This feature is only applicable to TiDB Self-Managed and not available on TiDB Cloud. For TiDB Cloud, you need to contact TiDB Cloud Support to modify the configurations.

8.11.1 Common Operations

This section describes the common operations of dynamically modifying configuration.

8.11.1.1 View instance configuration

To view the configuration of all instances in the cluster, use the `show config` statement. The result is as follows:

```
show config;
```

```
+--
    ↪ ----+-----------------+-------------------------------------------------------
    ↪
```

```
| Type | Instance     | Name                                                          |
   ↪  Value
   ↪
   ↪ |
+--
   ↪ ----+----------------+---------------------------------------------------------
   ↪
| tidb | 127.0.0.1:4001 | advertise-address                                          |
   ↪  127.0.0.1
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.binlog-socket                                       |
   ↪
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.enable                                              |
   ↪  false
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.ignore-error                                        |
   ↪  false
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.strategy                                            |
   ↪  range
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.write-timeout                                       |
   ↪  15s
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | check-mb4-value-in-utf8                                    |
   ↪  true
   ↪
   ↪ |

...
```

You can filter the result by fields. For example:

```
show config where type='tidb'
show config where instance in (...)
show config where name like '%log%'
show config where type='tikv' and name='log.level'
```

8.11.1.2 Modify TiKV configuration dynamically

> **Note:**
>
> - After dynamically changing TiKV configuration items, the TiKV configuration file is automatically updated. However, you also need to modify the corresponding configuration items by executing `tiup edit-config`; otherwise, operations such as `upgrade` and `reload` will overwrite your changes. For details of modifying configuration items, refer to Modify configuration using TiUP.
> - After executing `tiup edit-config`, you do not need to execute `tiup reload`.

When using the `set config` statement, you can modify the configuration of a single instance or of all instances according to the instance address or the component type.

- Modify the configuration of all TiKV instances:

> **Note:**
>
> It is recommended to wrap variable names in backticks.

```
set config tikv `split.qps-threshold`=1000;
```

- Modify the configuration of a single TiKV instance:

```
set config "127.0.0.1:20180" `split.qps-threshold`=1000;
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If an error occurs during the batch modification, a warning is returned:

```
set config tikv `log-level`='warn';
```

```
Query OK, 0 rows affected, 1 warning (0.04 sec)
```

```
show warnings;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | bad request to http://127.0.0.1:20180/config: fail to
    ↪ update, error: "config log-level can not be changed" |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

The batch modification does not guarantee atomicity. The modification might succeed on some instances, while failing on others. If you modify the configuration of the entire TiKV cluster using `set tikv key=val`, your modification might fail on some instances. You can use `show warnings` to check the result.

If some modifications fail, you need to re-execute the corresponding statement or modify each failed instance. If some TiKV instances cannot be accessed due to network issues or machine failure, modify these instances after they are recovered.

If a configuration item is successfully modified, the result is persisted in the configuration file, which will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words, such as `limit` and `key`. For these configuration items, use backtick ` to enclose them. For example, `` `raftstore.raft-log-gc-size-limit` ``.

The following TiKV configuration items can be modified dynamically:

Configuration item	Description
log.level	The log level.

Configuration item	Description
`raftstore` ↪ `.` ↪ `raft` ↪ `-` ↪ `max` ↪ `-` ↪ `inflight` ↪ `-` ↪ `msgs` ↪	The number of Raft logs to be confirmed. If this number is exceeded, the Raft state machine slows down log sending.
`raftstore` ↪ `.` ↪ `raft` ↪ `-` ↪ `log` ↪ `-` ↪ `gc` ↪ `-` ↪ `tick` ↪ `-` ↪ `interval` ↪	The time interval at which the polling task of deleting Raft logs is scheduled

Configuration item	Description
`raftstore` ↪ `.` ↪ `raft` ↪ `-` ↪ `log` ↪ `-` ↪ `gc` ↪ `-` ↪ `threshold` ↪	The soft limit on the maximum allowable number of residual Raft logs
`raftstore` ↪ `.` ↪ `raft` ↪ `-` ↪ `log` ↪ `-` ↪ `gc` ↪ `-` ↪ `count` ↪ `-` ↪ `limit` ↪	The hard limit on the allowable number of residual Raft logs

Configuration item	Description
`raftstore ↪ . ↪ raft ↪ - ↪ log ↪ - ↪ gc ↪ - ↪ size ↪ - ↪ limit ↪`	The hard limit on the allowable size of residual Raft logs
`raftstore ↪ . ↪ raft ↪ - ↪ max ↪ - ↪ size ↪ - ↪ per ↪ - ↪ msg ↪`	The soft limit on the size of a single message packet that is allowed to be generated

Configuration item	Description
`raftstore ↪ . ↪ raft ↪ - ↪ entry ↪ - ↪ max ↪ - ↪ size ↪`	The hard limit on the maximum size of a single Raft log
`raftstore ↪ . ↪ raft ↪ - ↪ entry ↪ - ↪ cache ↪ - ↪ life ↪ - ↪ time ↪`	The maximum remaining time allowed for the log cache in memory

Configuration item	Description
`raftstore ↪ . ↪ max ↪ - ↪ apply ↪ - ↪ unpersisted ↪ - ↪ log ↪ - ↪ limit ↪`	The maximum number of committed but not persisted Raft logs that can be applied
`raftstore ↪ . ↪ split ↪ - ↪ region ↪ - ↪ check ↪ - ↪ tick ↪ - ↪ interval ↪`	The time interval at which to check whether the Region split is needed

Configuration item	Description
`raftstore` ↪ `.` ↪ `region` ↪ `-` ↪ `split` ↪ `-` ↪ `check` ↪ `-` ↪ `diff` ↪	The maximum value by which the Region data is allowed to exceed before Region split
`raftstore` ↪ `.` ↪ `region` ↪ `-` ↪ `compact` ↪ `-` ↪ `check` ↪ `-` ↪ `interval` ↪	The time interval at which to check whether it is necessary to manually trigger RocksDB compaction

Configuration item	Description
`raftstore` ↪ `.` ↪ `region` ↪ `-` ↪ `compact` ↪ `-` ↪ `check` ↪ `-` ↪ `step` ↪	The number of Regions checked at one time for each round of manual compaction
`raftstore` ↪ `.` ↪ `region` ↪ `-` ↪ `compact` ↪ `-` ↪ `min` ↪ `-` ↪ `tombstones` ↪	The number of tombstones required to trigger RocksDB compaction

Configuration item	Description
`raftstore` ↪ `.` ↪ `region` ↪ `-` ↪ `compact` ↪ `-` ↪ `tombstones` ↪ `-` ↪ `percent` ↪	The proportion of tombstone required to trigger RocksDB compaction
`raftstore` ↪ `.` ↪ `pd` ↪ `-` ↪ `heartbeat` ↪ `-` ↪ `tick` ↪ `-` ↪ `interval` ↪	The time interval at which a Region's heartbeat to PD is triggered

Configuration item	Description
raftstore ↪ . ↪ pd ↪ - ↪ store ↪ - ↪ heartbeat ↪ - ↪ tick ↪ - ↪ interval ↪	The time interval at which a store's heartbeat to PD is triggered
raftstore ↪ . ↪ snap ↪ - ↪ mgr ↪ - ↪ gc ↪ - ↪ tick ↪ - ↪ interval ↪	The time interval at which the recycle of expired snapshot files is triggered
raftstore ↪ . ↪ snap ↪ - ↪ gc ↪ - ↪ timeout ↪	The longest time for which a snapshot file is saved

Configuration item	Description
raftstore ↪ . ↪ lock ↪ - ↪ cf ↪ - ↪ compact ↪ - ↪ interval ↪	The time interval at which TiKV triggers a manual compaction for the Lock Column Family
raftstore ↪ . ↪ lock ↪ - ↪ cf ↪ - ↪ compact ↪ - ↪ bytes ↪ - ↪ threshold ↪	The size at which TiKV triggers a manual compaction for the Lock Column Family

Configuration item	Description
`raftstore ↪ . ↪ messages ↪ - ↪ per ↪ - ↪ tick ↪`	The maximum number of messages processed per batch
`raftstore ↪ . ↪ max ↪ - ↪ peer ↪ - ↪ down ↪ - ↪ duration ↪`	The longest inactive duration allowed for a peer

Configuration item	Description
`raftstore` ↪ `.` ↪ `max` ↪ `-` ↪ `leader` ↪ `-` ↪ `missing` ↪ `-` ↪ `duration` ↪	The longest duration allowed for a peer to be without a leader. If this value is exceeded, the peer verifies with PD whether it has been deleted.

Configuration item	Description
`raftstore` ↪ `.` ↪ `abnormal` ↪ `-` ↪ `leader` ↪ `-` ↪ `missing` ↪ `-` ↪ `duration` ↪	The normal duration allowed for a peer to be without a leader. If this value is exceeded, the peer is seen as abnormal and marked in metrics and logs.

Configuration item	Description
`raftstore` ↪ `.` ↪ `peer` ↪ `-` ↪ `stale` ↪ `-` ↪ `state` ↪ `-` ↪ `check` ↪ `-` ↪ `interval` ↪	The time interval to check whether a peer is without a leader
`raftstore` ↪ `.` ↪ `consistency` ↪ `-` ↪ `check` ↪ `-` ↪ `interval` ↪	The time interval to check consistency (**NOT** recommended because it is not compatible with the garbage collection in TiDB)

Configuration item	Description
raftstore ↪ . ↪ raft ↪ - ↪ store ↪ - ↪ max ↪ - ↪ leader ↪ - ↪ lease ↪	The longest trusted period of a Raft leader
raftstore ↪ . ↪ merge ↪ - ↪ check ↪ - ↪ tick ↪ - ↪ interval ↪	The time interval for merge check
raftstore ↪ . ↪ cleanup ↪ - ↪ import ↪ - ↪ sst ↪ - ↪ interval ↪	The time interval to check expired SST files

Configuration item	Description
`raftstore ↪ . ↪ local ↪ - ↪ read ↪ - ↪ batch ↪ - ↪ size ↪`	The maximum number of read requests processed in one batch
`raftstore ↪ . ↪ apply ↪ - ↪ yield ↪ - ↪ write ↪ - ↪ size ↪`	The maximum number of bytes that the Apply thread can write for one FSM (Finite-state Machine) in each round

Configuration item	Description
`raftstore` ↪ `.` ↪ `hibernate` ↪ `-` ↪ `timeout` ↪	The shortest wait duration before entering hibernation upon start. Within this duration, TiKV does not hibernate (not released).

Configuration item	Description
`raftstore` ↪ `.` ↪ `apply` ↪ `-` ↪ `pool` ↪ `-` ↪ `size` ↪	The number of threads in the pool that flushes data to the disk, which is the size of the Apply thread pool

Configuration item	Description
`raftstore` ↪ `.` ↪ `store` ↪ `-` ↪ `pool` ↪ `-` ↪ `size` ↪	The number of threads in the pool that processes Raft, which is the size of the Raftstore thread pool

Configuration item	Description
`raftstore` ↪ `.` ↪ `apply` ↪ `-` ↪ `max` ↪ `-` ↪ `batch` ↪ `-` ↪ `size` ↪	Raft state machines process data write requests in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can execute the requests in one batch.

Configuration item	Description
`raftstore` ↪ `.` ↪ `store` ↪ `-` ↪ `max` ↪ `-` ↪ `batch` ↪ `-` ↪ `size` ↪	Raft state machines process requests for flushing logs into the disk in batches by the BatchSystem. This configuration item specifies the maximum number of Raft state machines that can process the requests

Configuration item	Description
`raftstore` ↪ `.` ↪ `store` ↪ `-` ↪ `io` ↪ `-` ↪ `pool` ↪ `-` ↪ `size` ↪	The number of threads that process Raft I/O tasks, which is also the size of the StoreWriter thread pool (**DO NOT** modify this value from a non-zero value to 0 or from 0 to a non-zero value)

Configuration item	Description
`raftstore` ↪ `.` ↪ `periodic` ↪ `-` ↪ `full` ↪ `-` ↪ `compact` ↪ `-` ↪ `start` ↪ `-` ↪ `max` ↪ `-` ↪ `cpu` ↪	The CPU usage threshold at which TiKV performs periodic full compaction if full compaction is enabled

Configuration item	Description
`readpool` ↪ `.` ↪ `unified` ↪ `.` ↪ `max` ↪ `-` ↪ `thread` ↪ `-` ↪ `count` ↪	The maximum number of threads in the thread pool that uniformly processes read requests, which is the size of the UnifyReadPool thread pool

Configuration item	Description
`readpool` ↪ `.` ↪ `unified` ↪ `.` ↪ `max` ↪ `-` ↪ `tasks` ↪ `-` ↪ `per` ↪ `-` ↪ `worker` ↪	The maximum number of tasks allowed for a single thread in the unified read pool. `Server` ↪ ↪ `Is` ↪ ↪ `Busy` ↪ error is returned when the value is exceeded.

Configuration item	Description
`readpool` ↪ `.` ↪ `unified` ↪ `.` ↪ `auto` ↪ `-` ↪ `adjust` ↪ `-` ↪ `pool` ↪ `-` ↪ `size` ↪	Determines whether to auto-matically ad-just the Uni-fyRead-Pool thread pool size
`resource` ↪ `-` ↪ `control` ↪ `.` ↪ `priority` ↪ `-` ↪ `ctl` ↪ `-` ↪ `strategy` ↪	Configures the flow con-trol strat-egy of low-priority tasks.
`coprocessor` ↪ `.` ↪ `split` ↪ `-` ↪ `region` ↪ `-` ↪ `on` ↪ `-` ↪ `table` ↪	Enables to split Re-gion by table

Configuration item	Description
`coprocessor ↪ . ↪ batch ↪ - ↪ split ↪ - ↪ limit ↪`	The threshold of Region split in batches
`coprocessor ↪ . ↪ region ↪ - ↪ max ↪ - ↪ size ↪`	The maximum size of a Region
`coprocessor ↪ . ↪ region ↪ - ↪ split ↪ - ↪ size ↪`	The size of the newly split Region
`coprocessor ↪ . ↪ region ↪ - ↪ max ↪ - ↪ keys ↪`	The maximum number of keys allowed in a Region

Configuration item	Description
`coprocessor` ↪ `.` ↪ `region` ↪ `-` ↪ `split` ↪ `-` ↪ `keys` ↪	The number of keys in the newly split Region
`pessimistic` ↪ `-` ↪ `txn` ↪ `.` ↪ `wait` ↪ `-` ↪ `for` ↪ `-` ↪ `lock` ↪ `-` ↪ `timeout` ↪	The longest duration that a pessimistic transaction waits for the lock
`pessimistic` ↪ `-` ↪ `txn` ↪ `.` ↪ `wake` ↪ `-` ↪ `up` ↪ `-` ↪ `delay` ↪ `-` ↪ `duration` ↪	The duration after which a pessimistic transaction is woken up

Configuration item	Description
`pessimistic-txn.pipelined`	Determines whether to enable the pipelined pessimistic locking process
`pessimistic-txn.in-memory`	Determines whether to enable the in-memory pessimistic lock
`pessimistic-txn.in-memory.memory-limit-for-in-memory-peer`	Controls the memory usage limit for in-memory pessimistic locks in a Region

Configuration item	Description
`pessimistic-txn.in-memory.instance.size-limit`	Controls the memory usage limit for in-memory pessimistic locks in a TiKV instance
`quota.foreground-cpu-time`	The soft limit on the CPU resources used by TiKV foreground to process read and write requests

Configuration item	Description
`quota` ↪ `.` ↪ `foreground` ↪ `-` ↪ `write` ↪ `-` ↪ `bandwidth` ↪	The soft limit on the bandwidth with which foreground transactions write data
`quota` ↪ `.` ↪ `foreground` ↪ `-` ↪ `read` ↪ `-` ↪ `bandwidth` ↪	The soft limit on the bandwidth with which foreground transactions and the Coprocessor read data

Configuration item	Description
`quota` ↪ `.` ↪ `background` ↪ `-` ↪ `cpu` ↪ `-` ↪ `time` ↪	The soft limit on the CPU resources used by TiKV background to process read and write requests
`quota` ↪ `.` ↪ `background` ↪ `-` ↪ `write` ↪ `-` ↪ `bandwidth` ↪	The soft limit on the bandwidth with which background transactions write data

Configuration item	Description
`quota` ↪ `.` ↪ `background` ↪ `-` ↪ `read` ↪ `-` ↪ `bandwidth` ↪	The soft limit on the bandwidth with which background transactions and the Coprocessor read data

Configuration item	Description
`quota` ↪ `.` ↪ `enable` ↪ `-` ↪ `auto` ↪ `-` ↪ `tune` ↪	Whether to enable the auto-tuning of quota. If this configuration item is enabled, TiKV dynamically adjusts the quota for the background requests based on the load of TiKV instances.

Configuration item	Description
`quota` ↪ `.` ↪ `max` ↪ `-` ↪ `delay` ↪ `-` ↪ `duration` ↪	The maximum time that a single read or write request is forced to wait before it is processed in the foreground

Configuration item	Description
`gc.ratio-threshold`	The threshold at which Region GC is skipped (the number of GC versions/the number of keys)
`gc.batch-keys`	The number of keys processed in one batch

Configuration item	Description
gc. ↪ max ↪ - ↪ write ↪ - ↪ bytes ↪ - ↪ per ↪ - ↪ sec ↪	The maximum bytes that can be written into RocksDB per second
gc. ↪ enable ↪ - ↪ compaction ↪ - ↪ filter ↪	Whether to enable compaction filter
gc. ↪ compaction ↪ - ↪ filter ↪ - ↪ skip ↪ - ↪ version ↪ - ↪ check ↪	Whether to skip the cluster version check of compaction filter (not released)

Configuration item	Description
{db- ↪ name ↪ }. ↪ max ↪ - ↪ total ↪ - ↪ wal ↪ - ↪ size ↪	The maximum size of total WAL
{db- ↪ name ↪ }. ↪ max ↪ - ↪ background ↪ - ↪ jobs ↪	The number of background threads in RocksDB
{db- ↪ name ↪ }. ↪ max ↪ - ↪ background ↪ - ↪ flushes ↪	The maximum number of flush threads in RocksDB
{db- ↪ name ↪ }. ↪ max ↪ - ↪ open ↪ - ↪ files ↪	The total number of files that RocksDB can open

Configuration item	Description
{db- ↪ name ↪ }. ↪ compaction ↪ - ↪ readahead ↪ - ↪ size ↪	The size of readahead during compaction
{db- ↪ name ↪ }. ↪ bytes ↪ - ↪ per ↪ - ↪ sync ↪	The rate at which OS incremental synchronizes files to disk while these files are being written asynchronously

Configuration item	Description
{db- ↪ name ↪ }. ↪ wal ↪ - ↪ bytes ↪ - ↪ per ↪ - ↪ sync ↪	The rate at which OS incre-men-tally syn-chro-nizes WAL files to disk while the WAL files are being writ-ten
{db- ↪ name ↪ }. ↪ writable ↪ - ↪ file ↪ - ↪ max ↪ - ↪ buffer ↪ - ↪ size ↪	The maxi-mum buffer size used in Writable-FileWrite

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ block ↪ - ↪ cache ↪ - ↪ size ↪	The cache size of a block
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ write ↪ - ↪ buffer ↪ - ↪ size ↪	The size of a memtable
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ max ↪ - ↪ write ↪ - ↪ buffer ↪ - ↪ number ↪	The maximum number of memtables

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ max ↪ - ↪ bytes ↪ - ↪ for ↪ - ↪ level ↪ - ↪ base ↪	The maximum number of bytes at base level (L1)
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ target ↪ - ↪ file ↪ - ↪ size ↪ - ↪ base ↪	The size of the target file at base level

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ level0 ↪ - ↪ file ↪ - ↪ num ↪ - ↪ compaction ↪ - ↪ trigger ↪	The maximum number of files at L0 that trigger compaction
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ level0 ↪ - ↪ slowdown ↪ - ↪ writes ↪ - ↪ trigger ↪	The maximum number of files at L0 that trigger write stall

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ level0 ↪ - ↪ stop ↪ - ↪ writes ↪ - ↪ trigger ↪	The maximum number of files at L0 that completely block write
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ max ↪ - ↪ compaction ↪ - ↪ bytes ↪	The maximum number of bytes written into disk per compaction

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ max ↪ - ↪ bytes ↪ - ↪ for ↪ - ↪ level ↪ - ↪ multiplier ↪	The default amplification multiple for each layer
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ disable ↪ - ↪ auto ↪ - ↪ compactions ↪	Enables or disables automatic compaction

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ soft ↪ - ↪ pending ↪ - ↪ compaction ↪ - ↪ bytes ↪ - ↪ limit ↪	The soft limit on the pending compaction bytes
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ hard ↪ - ↪ pending ↪ - ↪ compaction ↪ - ↪ bytes ↪ - ↪ limit ↪	The hard limit on the pending compaction bytes

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ titan ↪ . ↪ blob ↪ - ↪ run ↪ - ↪ mode ↪	The mode of processing blob files
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ titan ↪ . ↪ min ↪ - ↪ blob ↪ - ↪ size ↪	The threshold at which data is stored in Titan. Data is stored in a Titan blob file when its value reaches this threshold.

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ titan ↪ . ↪ blob ↪ - ↪ file ↪ - ↪ compression ↪	The compression algorithm used by Titan blob files

Configuration item	Description
{db- ↪ name ↪ }.{ ↪ cf ↪ - ↪ name ↪ }. ↪ titan ↪ . ↪ discardable ↪ - ↪ ratio ↪	The threshold of garbage data ratio in Titan data files for GC. When the ratio of useless data in a blob file exceeds the threshold, Titan GC is triggered.

Configuration item	Description
`server` ↪ `.` ↪ `grpc` ↪ `-` ↪ `memory` ↪ `-` ↪ `pool` ↪ `-` ↪ `quota` ↪	Limits the memory size that can be used by gRPC
`server` ↪ `.` ↪ `max` ↪ `-` ↪ `grpc` ↪ `-` ↪ `send` ↪ `-` ↪ `msg` ↪ `-` ↪ `len` ↪	Sets the maximum length of a gRPC message that can be sent
`server` ↪ `.` ↪ `snap` ↪ `-` ↪ `io` ↪ `-` ↪ `max` ↪ `-` ↪ `bytes` ↪ `-` ↪ `per` ↪ `-` ↪ `sec` ↪	Sets the maximum allowable disk bandwidth when processing snapshots

Configuration item	Description
`server` ↪ `.` ↪ `concurrent` ↪ `-` ↪ `send` ↪ `-` ↪ `snap` ↪ `-` ↪ `limit` ↪	Sets the maximum number of snapshots sent at the same time
`server` ↪ `.` ↪ `concurrent` ↪ `-` ↪ `recv` ↪ `-` ↪ `snap` ↪ `-` ↪ `limit` ↪	Sets the maximum number of snapshots received at the same time

Configuration item	Description
`server` ↪ `.` ↪ `raft` ↪ `-` ↪ `msg` ↪ `-` ↪ `max` ↪ `-` ↪ `batch` ↪ `-` ↪ `size` ↪	Sets the maximum number of Raft messages that are contained in a single gRPC message
`server` ↪ `.` ↪ `simplify` ↪ `-` ↪ `metrics` ↪	Controls whether to simplify the sampling monitoring metrics

Configuration item	Description
`storage` ↪ `.` ↪ `block` ↪ `-` ↪ `cache` ↪ `.` ↪ `capacity` ↪	The size of shared block cache (supported since v4.0.3)
storage.flow-control.enable	Determines whether to enable the flow control mechanism
storage.flow-control.memtables-threshold	The maximum number of kvDB memtables that trigger flow control

Configuration item	Description
storage.flow-control.l0-files-threshold	The maximum number of kvDB L0 files that trigger flow control
storage.flow-control.soft-pending-compaction-bytes-limit	The threshold of kvDB pending compaction bytes that triggers flow control mechanism to reject some write requests

Configuration item	Description
storage.flow-control.hard-pending-compaction-bytes-limit	The threshold of kvDB pending compaction bytes that triggers flow control mechanism to reject all write requests
`storage.scheduler-worker-pool-size`	The number of threads in the Scheduler thread pool

Configuration item	Description
`import` ↪ `.` ↪ `num` ↪ `-` ↪ `threads` ↪	The number of threads to process restore or import RPC requests (dynamic modification is supported starting from v8.1.2)
`backup` ↪ `.` ↪ `num` ↪ `-` ↪ `threads` ↪	The number of backup threads (supported since v4.0.3)

Configuration item	Description
`split.qps-threshold`	The threshold to execute `load-base-split` on a Region. If the QPS of read requests for a Region exceeds `qps-threshold` for 10 consecutive seconds, this Region should be split.

Configuration item	Description
`split_byte_threshold`	The threshold to execute `load_base_split` on a Region. If the traffic of read requests for a Region exceeds the `byte_threshold` for 10 consecutive seconds, this Region should be split.

Configuration item	Description
`split` ↪ `.` ↪ `region` ↪ `-` ↪ `cpu` ↪ `-` ↪ `overload` ↪ `-` ↪ `threshold` ↪ `-` ↪ `ratio` ↪	The threshold to execute `load` ↪ `-` ↪ `base` ↪ `-` ↪ `split` ↪ on a Region. If the CPU usage in the Unified Read Pool for a Region exceeds the `region` ↪ `-` ↪ `cpu` ↪ `-` ↪ `overload` ↪ `-` ↪ `threshold` ↪ `-` ↪ `ratio` ↪ for 10 consecutive seconds, this

Configuration item	Description
`split` ↪ `.` ↪ `split` ↪ `-` ↪ `balance` ↪ `-` ↪ `score` ↪	The parameter of `load` ↪ `-` ↪ `base` ↪ `-` ↪ `split` ↪ , which ensures the load of the two split Regions is as balanced as possible. The smaller the value is, the more balanced the load is. But setting it too small might cause split

Configuration item	Description
`split` ↪ `.` ↪ `split` ↪ `-` ↪ `contained` ↪ `-` ↪ `score` ↪	The parameter of `load` ↪ `-` ↪ `base` ↪ `-` ↪ `split` ↪ `.` The smaller the value, the fewer cross-Region visits after Region split.
`cdc.` ↪ `min` ↪ `-` ↪ `ts` ↪ `-` ↪ `interval` ↪	The time interval at which Resolved TS is forwarded

Configuration item	Description
`cdc.` ↪ `old` ↪ `-` ↪ `value` ↪ `-` ↪ `cache` ↪ `-` ↪ `memory` ↪ `-` ↪ `quota` ↪	The upper limit of memory occupied by the TiCDC Old Value entries
`cdc.` ↪ `sink` ↪ `-` ↪ `memory` ↪ `-` ↪ `quota` ↪	The upper limit of memory occupied by TiCDC data change events

Configuration item	Description
`cdc.incremental-scan-speed-limit`	The upper limit on the speed of incremental scanning for historical data
`cdc.incremental-scan-concurrency`	The maximum number of concurrent incremental scanning tasks for historical data

In the table above, parameters with the `{db-name}` or `{db-name}.{cf-name}` prefix are configurations related to RocksDB. The optional values of `db-name` are `rocksdb` and `raftdb`.

- When `db-name` is `rocksdb`, the optional values of `cf-name` are `defaultcf`, `writecf`, `lockcf`, and `raftcf`.
- When `db-name` is `raftdb`, the value of `cf-name` can be `defaultcf`.

For detailed parameter description, refer to TiKV Configuration File.

8.11.1.3 Modify PD configuration dynamically

Currently, PD does not support the separate configuration for each instance. All PD instances share the same configuration.

You can modify the PD configurations using the following statement:

```
set config pd `log.level`='info';
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If a configuration item is successfully modified, the result is persisted in etcd instead of in the configuration file; the configuration in etcd will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words. For these configuration items, use backtick ` to enclose them. For example, `` `schedule.leader-schedule-limit` ``.

The following PD configuration items can be modified dynamically:

Configuration item	Description
`log.level`	The log level
`cluster-version`	The cluster version
`schedule.max-merge-region-size`	Controls the size limit of `Region` `Merge` (in MiB)

Configuration item	Description
`schedule` ↪ `.` ↪ `max` ↪ `-` ↪ `merge` ↪ `-` ↪ `region` ↪ `-` ↪ `keys` ↪	Specifies the maximum numbers of the `Region` ↪ ↪ `Merge` ↪ keys
`schedule` ↪ `.` ↪ `patrol` ↪ `-` ↪ `region` ↪ `-` ↪ `interval` ↪	Determines the frequency at which the checker inspects the health state of a Region

Configuration item	Description
`schedule` ↪ `.` ↪ `split` ↪ `-` ↪ `merge` ↪ `-` ↪ `interval` ↪	Determines the time interval of performing split and merge operations on the same Region
`schedule` ↪ `.` ↪ `max` ↪ `-` ↪ `snapshot` ↪ `-` ↪ `count` ↪	Determines the maximum number of snapshots that a single store can send or receive at the same time

Configuration item	Description
`schedule.max-pending-peer-count`	Determines the maximum number of pending peers in a single store
`schedule.max-store-down-time`	The downtime after which PD judges that the disconnected store cannot be recovered

Configuration item	Description
`schedule` ↪ `.` ↪ `max` ↪ `-` ↪ `store` ↪ `-` ↪ `preparing` ↪ `-` ↪ `time` ↪	Controls the maximum waiting time for the store to go online
`schedule` ↪ `.` ↪ `leader` ↪ `-` ↪ `schedule` ↪ `-` ↪ `policy` ↪	Determines the policy of Leader scheduling
`schedule` ↪ `.` ↪ `leader` ↪ `-` ↪ `schedule` ↪ `-` ↪ `limit` ↪	The number of Leader scheduling tasks performed at the same time

Configuration item	Description
`schedule` ↪ `.` ↪ `region` ↪ `-` ↪ `schedule` ↪ `-` ↪ `limit` ↪	The number of Region scheduling tasks performed at the same time
`schedule` ↪ `.` ↪ `replica` ↪ `-` ↪ `schedule` ↪ `-` ↪ `limit` ↪	The number of Replica scheduling tasks performed at the same time

Configuration item	Description
`schedule` ↪ `.` ↪ `merge` ↪ `-` ↪ `schedule` ↪ `-` ↪ `limit` ↪	The number of the `Region` ↪ ↪ `Merge` ↪ scheduling tasks performed at the same time
`schedule` ↪ `.` ↪ `hot` ↪ `-` ↪ `region` ↪ `-` ↪ `schedule` ↪ `-` ↪ `limit` ↪	The number of hot Region scheduling tasks performed at the same time

Configuration item	Description
`schedule` ↪ `.` ↪ `hot` ↪ `-` ↪ `region` ↪ `-` ↪ `cache` ↪ `-` ↪ `hits` ↪ `-` ↪ `threshold` ↪	Determines the threshold at which a Region is considered a hot spot
`schedule` ↪ `.` ↪ `high` ↪ `-` ↪ `space` ↪ `-` ↪ `ratio` ↪	The threshold ratio below which the capacity of the store is sufficient

Configuration item	Description
`schedule.low-space-ratio`	The threshold ratio above which the capacity of the store is insufficient
`schedule.tolerant-size-ratio`	Controls the `balance` buffer size
`schedule.enable-remove-down-replica`	Determines whether to enable the feature that automatically removes `DownReplica`

Configuration item	Description
`schedule.enable-replace-offline-replica`	Determines whether to enable the feature that migrates `OfflineReplica`
`schedule.enable-make-up-replica`	Determines whether to enable the feature that automatically supplements replicas
`schedule.enable-remove-extra-replica`	Determines whether to enable the feature that removes extra replicas

Configuration item	Description
`schedule ↪ . ↪ enable ↪ - ↪ location ↪ - ↪ replacement ↪`	Determines whether to enable isolation level check
`schedule ↪ . ↪ enable ↪ - ↪ cross ↪ - ↪ table ↪ - ↪ merge ↪`	Determines whether to enable cross-table merge
`schedule ↪ . ↪ enable ↪ - ↪ one ↪ - ↪ way ↪ - ↪ merge ↪`	Enables one-way merge, which only allows merging with the next adjacent Region

Configuration item	Description
`schedule ↪ . ↪ region ↪ - ↪ score ↪ - ↪ formula ↪ - ↪ version ↪`	Controls the version of the Region score formula
`schedule ↪ . ↪ scheduler ↪ - ↪ max ↪ - ↪ waiting ↪ - ↪ operator ↪`	Controls the number of waiting operators in each scheduler
`schedule ↪ . ↪ enable ↪ - ↪ debug ↪ - ↪ metrics ↪`	Enables the metrics for debugging

Configuration item	Description
`schedule` ↪ `.` ↪ `enable` ↪ `-` ↪ `heartbeat` ↪ `-` ↪ `concurrent` ↪ `-` ↪ `runner` ↪	Enables asynchronous concurrent processing for Region heartbeats
`schedule` ↪ `.` ↪ `enable` ↪ `-` ↪ `heartbeat` ↪ `-` ↪ `breakdown` ↪ `-` ↪ `metrics` ↪	Enables breakdown metrics for Region heartbeats to measure the time consumed in each stage of Region heartbeat processing

Configuration item	Description
`schedule . enable - joint - consensus`	Controls whether to use Joint Consensus for replica scheduling
`schedule . hot - regions - write - interval`	The time interval at which PD stores hot Region information
`schedule . hot - regions - reserved - days`	Specifies how many days the hot Region information is retained

Configuration item	Description
`schedule.max-movable-hot-peer-size`	Controls the maximum Region size that can be scheduled for hot Region scheduling.
`schedule.store-limit-version`	Controls the version of store limit

Configuration item	Description
`schedule` ↪ `.` ↪ `patrol` ↪ `-` ↪ `region` ↪ `-` ↪ `worker` ↪ `-` ↪ `count` ↪	Controls the number of concurrent operators created by the checker when inspecting the health state of a Region
`replication` ↪ `.` ↪ `max` ↪ `-` ↪ `replicas` ↪	Sets the maximum number of replicas

Configuration item	Description
`replication` ↪ `.` ↪ `location` ↪ `-` ↪ `labels` ↪	The topology information of a TiKV cluster
`replication` ↪ `.` ↪ `enable` ↪ `-` ↪ `placement` ↪ `-` ↪ `rules` ↪	Enables Placement Rules
`replication` ↪ `.` ↪ `strictly` ↪ `-` ↪ `match` ↪ `-` ↪ `label` ↪	Enables the label check
`replication` ↪ `.` ↪ `isolation` ↪ `-` ↪ `level` ↪	The minimum topological isolation level of a TiKV cluster

Configuration item	Description
pd-server.independent-region-storage	Enables independent Region storage
pd-server.max-gap-reset-ts	Sets the maximum interval of resetting timestamp (BR)
pd-server.key-type	Sets the cluster key type
pd-server.metric-storage	Sets the storage address of the cluster metrics

Configuration item	Description
`pd-server.dashboard-address`	Sets the dashboard address
`pd-server.flow-round-by-digit`	Specifies the number of lowest digits to round for the Region flow information

Configuration item	Description
pd-server.min-resolved-ts-persistence-interval	Determines the interval at which the minimum resolved ts is persistent to the PD
pd-server.server-memory-limit	The memory limit ratio for a PD instance
pd-server.server-memory-limit-gc-trigger	The threshold ratio at which PD tries to trigger GC

Configuration item	Description
pd-server.enable-gogc-tuner	Controls whether to enable the GOGC Tuner
pd-server.gc-tuner-threshold	The maximum memory threshold ratio for tuning GOGC
replication.-mode	Sets the backup mode
replication.replication-mode	

Configuration item	Description
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `label` ↪ `-` ↪ `key` ↪	Distinguishes different AZs and needs to match Placement Rules
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `primary` ↪	The primary AZ
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `dr` ↪	The disaster recovery (DR) AZ

Configuration item	Description
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `primary` ↪ `-` ↪ `replicas` ↪	The number of Voter replicas in the primary AZ
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `dr` ↪ `-` ↪ `replicas` ↪	The number of Voter replicas in the disaster recovery (DR) AZ

Configuration item	Description
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `wait` ↪ `-` ↪ `store` ↪ `-` ↪ `timeout` ↪	The waiting time for switching to asynchronous replication mode when network isolation or failure occurs

Configuration item	Description
`replication` ↪ `-` ↪ `mode` ↪ `.` ↪ `dr` ↪ `-` ↪ `auto` ↪ `-` ↪ `sync` ↪ `.` ↪ `wait` ↪ `-` ↪ `recover` ↪ `-` ↪ `timeout` ↪	The waiting time for switching back to the `sync` ↪ `-` ↪ `recover` ↪ status after the network recovers

Configuration item	Description
`replication-mode.dr-auto-sync.pause-region-split`	Controls whether to pause Region split operations in the `async_wait` and `async` statuses

For detailed parameter description, refer to PD Configuration File.

8.11.1.4 Modify TiDB configuration dynamically

Currently, the method of changing TiDB configuration is different from that of changing TiKV and PD configurations. You can modify TiDB configuration by using system variables.

The following example shows how to dynamically modify `slow-threshold` by using the `tidb_slow_log_threshold` variable.

The default value of `slow-threshold` is 300 ms. You can set it to 200 ms by using `tidb_slow_log_threshold`.

```
set tidb_slow_log_threshold = 200;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_slow_log_threshold;
```

```
+-----------------------------+
| @@tidb_slow_log_threshold |
```

```
+--------------------------+
| 200                      |
+--------------------------+
1 row in set (0.00 sec)
```

The following TiDB configuration items can be modified dynamically:

Configuration item	SQL variable	Description
instance.tidb_enable_slow_log	tidb_enable_slow_log	Controls whether to enable slow log
instance.tidb_slow_log_threshold	tidb_slow_log_threshold	Specifies the threshold of slow log
instance.tidb_expensive_query_time_threshold	tidb_expensive_query_time_threshold	Specifies the threshold of an expensive query

Configuration item	SQL variable	Description
instance ↪ . ↪ tidb ↪ _ ↪ enable ↪ _ ↪ collect ↪ _ ↪ execution ↪ _ ↪ info ↪	tidb ↪ _ ↪ enable ↪ _ ↪ collect ↪ _ ↪ execution ↪ _ ↪ info ↪	Controls whether to record the execution information of operators
instance ↪ . ↪ tidb ↪ _ ↪ record ↪ _ ↪ plan ↪ _ ↪ in ↪ _ ↪ slow ↪ _ ↪ log ↪	tidb ↪ _ ↪ record ↪ _ ↪ plan ↪ _ ↪ in ↪ _ ↪ slow ↪ _ ↪ log ↪	Controls whether to record execution plans in the slow log

Configuration item	SQL variable	Description
`instance` ↪ `.` ↪ `tidb` ↪ `_` ↪ `force` ↪ `_` ↪ `priority` ↪	`tidb` ↪ `_` ↪ `force` ↪ `_` ↪ `priority` ↪	Specifies the priority of statements that are submitted from this TiDB instance
`instance` ↪ `.` ↪ `max` ↪ `_` ↪ `connections` ↪	`max` ↪ `_` ↪ `connections` ↪	Specifies the maximum number of concurrent connections permitted for this TiDB instance

Configuration item	SQL variable	Description
`instance` ↪ `.` ↪ `tidb` ↪ `_` ↪ `enable` ↪ `_` ↪ `ddl` ↪	`tidb` ↪ `_` ↪ `enable` ↪ `_` ↪ `ddl` ↪	Controls whether this TiDB instance can become a DDL owner

Configuration item	SQL variable	Description
`pessimistic` ↪ `-` ↪ `txn` ↪ `.` ↪ `constraint` ↪ `-` ↪ `check` ↪ `-` ↪ `in` ↪ `-` ↪ `place` ↪ `-` ↪ `pessimistic` ↪	`tidb` ↪ `_` ↪ `constraint` ↪ `_` ↪ `check` ↪ `_` ↪ `in` ↪ `_` ↪ `place` ↪ `_` ↪ `pessimistic` ↪	Controls whether to defer the unique constraint check of a unique index to the next time when this index requires a lock or to the time when the transaction is committed

8.11.1.5 Modify TiFlash configuration dynamically

Currently, you can modify the TiFlash configuration `max_threads` by using the system variable `tidb_max_tiflash_threads`, which specifies the maximum concurrency for TiFlash to execute a request.

The default value of `tidb_max_tiflash_threads` is `-1`, indicating that this system variable is invalid and depends on the setting of the TiFlash configuration file. You can set `max_threads` to 10 by using `tidb_max_tiflash_threads`:

```
set tidb_max_tiflash_threads = 10;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_max_tiflash_threads;
```

```
+----------------------------+
| @@tidb_max_tiflash_threads |
+----------------------------+
| 10                         |
+----------------------------+
1 row in set (0.00 sec)
```

8.12 Online Unsafe Recovery

> **Warning:**
>
> Online Unsafe Recovery is a type of lossy recovery. If you use this feature, the integrity of data and data indexes cannot be guaranteed.

When permanently damaged replicas cause part of data on TiKV to be unreadable and unwritable, you can use the Online Unsafe Recovery feature to perform a lossy recovery operation.

8.12.1 Feature description

In TiDB, the same data might be stored in multiple stores at the same time according to the replica rules defined by users. This guarantees that data is still readable and writable even if a single or a few stores are temporarily offline or damaged. However, when most or all replicas of a Region go offline during a short period of time, the Region becomes temporarily unavailable and cannot be read or written.

Suppose that multiple replicas of a data range encounter issues like permanent damage (such as disk damage), and these issues cause the stores to stay offline. In this case, this data range is temporarily unavailable. If you want the cluster back in use and also accept data rewind or data loss, in theory, you can re-form the majority of replicas by manually removing the failed replicas from the group. This allows application-layer services to read and write this data range (might be stale or empty) again.

In this case, if some stores with loss-tolerant data are permanently damaged, you can perform a lossy recovery operation by using Online Unsafe Recovery. When you use this feature, PD automatically pauses Region scheduling (including split and merge), collects the metadata of data shards from all stores, and then, under its global perspective, generates a real-time and complete recovery plan. Then, PD distributes the plan to all surviving stores to make them perform data recovery tasks. In addition, once the data recovery plan is distributed, PD periodically monitors the recovery progress and re-send the plan when necessary.

8.12.2 User scenarios

The Online Unsafe Recovery feature is suitable for the following scenarios:

- The data for application services is unreadable and unwritable, because permanently damaged stores cause the stores to fail to restart.
- You can accept data loss and want the affected data to be readable and writable.
- You want to perform a one-stop online data recovery operation.

8.12.3 Usage

8.12.3.1 Prerequisites

Before using Online Unsafe Recovery, make sure that the following requirements are met:

- The offline stores indeed cause some pieces of data to be unavailable.
- The offline stores cannot be automatically recovered or restarted.

8.12.3.2 Step 1. Specify the stores that cannot be recovered

To trigger automatic recovery, use PD Control to execute `unsafe remove-failed-stores <store_id>[,<store_id>,...]` and specify **all** the TiKV and TiFlash nodes that cannot be recovered, separated by commas.

```
pd-ctl -u <pd_addr> unsafe remove-failed-stores <store_id1,store_id2,...>
```

Note:

- Make sure that **all** unrecoverable TiKV and TiFlash nodes are specified in the preceding command at once. Omitting any unrecoverable nodes might cause the recovery process to be blocked.
- If you have already performed Online Unsafe Recovery within a short period (such as within a day), make sure that the subsequent executions of this command still include the previously processed TiKV and TiFlash nodes.

To specify the longest allowable duration of a recovery task, use the `--timeout <seconds >` option. If this option is not specified, the longest duration is 5 minutes by default. When the timeout occurs, the recovery is interrupted and returns an error.

If the command returns `Success`, PD Control has successfully registered the task to PD. This only means that the request has been accepted, not that the recovery has been successfully performed. The recovery task is performed in the background. To see the recovery progress, use `show`.

If the command returns `Failed`, PD Control has failed to register the task to PD. The possible errors are as follows:

- `unsafe recovery is running`: There is already an ongoing recovery task.
- `invalid input store x doesn't exist`: The specified store ID does not exist.
- `invalid input store x is up and connected`: The specified store with the ID is still healthy and should not be recovered.

If PD loses store information for unrecoverable TiKV nodes after disaster recovery operations such as `pd-recover`, making the specific store IDs unknown, you can use the `--auto-detect` mode. This mode enables PD to automatically remove replicas from TiKV nodes that are either unregistered or previously registered but forcibly deleted.

```
pd-ctl -u <pd_addr> unsafe remove-failed-stores --auto-detect
```

Note:

- Because unsafe recovery needs to collect information from all peers, it might cause an increase in memory usage (100,000 peers are estimated to use 500 MiB of memory).
- If PD restarts when the command is running, the recovery is interrupted and you need to trigger the task again.
- Once the command is running, the specified stores will be set to the Tombstone status, and you cannot restart these stores.

- When the command is running, all scheduling tasks and split/merge are paused and will be resumed automatically after the recovery is successful or fails.

8.12.3.3 Step 2. Check the recovery progress and wait for the completion

When the above store removal command runs successfully, you can use PD Control to check the removal progress by running `unsafe remove-failed-stores show`.

```
pd-ctl -u <pd_addr> unsafe remove-failed-stores show
```

The recovery process has multiple possible stages:

- `collect report`: The initial stage in which PD collects reports from TiKV and gets global information.
- `tombstone tiflash learner`: Among the unhealthy Regions, delete the TiFlash learners that are newer than other healthy peers, to prevent such an extreme situation and the possible panic.
- `force leader for commit merge`: A special stage. When there is an uncompleted commit merge, `force leader` is first performed on the Regions with commit merge, in case of extreme situations.
- `force leader`: Forces unhealthy Regions to assign a Raft leader among the remaining healthy peers.
- `demote failed voter`: Demotes the Region's failed voters to learners, and then the Regions can select a Raft leader as normal.
- `create empty region`: Creates an empty Region to fill in the space in the key range. This is to resolve the case that the stores with all replicas of some Regions have been damaged.

Each of the above stages is output in the JSON format, including information, time, and a detailed recovery plan. For example:

```
[
    {
        "info": "Unsafe recovery enters collect report stage: failed stores
            ↪ 4, 5, 6",
        "time": "......"
    },
    {
        "info": "Unsafe recovery enters force leader stage",
        "time": "......",
        "actions": {
            "store 1": [
```

```
                "force leader on regions: 1001, 1002"
            ],
            "store 2": [
                "force leader on regions: 1003"
            ]
        }
    },
    {
        "info": "Unsafe recovery enters demote failed voter stage",
        "time": "......",
        "actions": {
            "store 1": [
                "region 1001 demotes peers { id:101 store_id:4 }, { id:102
                    ↪ store_id:5 }",
                "region 1002 demotes peers { id:103 store_id:5 }, { id:104
                    ↪ store_id:6 }",
            ],
            "store 2": [
                "region 1003 demotes peers { id:105 store_id:4 }, { id:106
                    ↪ store_id:6 }",
            ]
        }
    },
    {
        "info": "Collecting reports from alive stores(1/3)",
        "time": "......",
        "details": [
            "Stores that have not dispatched plan: ",
            "Stores that have reported to PD: 4",
            "Stores that have not reported to PD: 5, 6",
        ]
    }
]
```

After PD has successfully dispatched the recovery plan, it waits for TiKV to report the execution results. As you can see in `Collecting reports from alive stores`, the last stage of the above output, this part of the output shows the detailed statuses of PD dispatching recovery plan and receiving reports from TiKV.

The whole recovery process takes multiple stages and one stage might be retried multiple times. Usually, the estimated duration is 3 to 10 periods of store heartbeat (one period of store heartbeat is 10 seconds by default). After the recovery is completed, the last stage in the command output shows `"Unsafe recovery finished"`, the table IDs to which the affected Regions belong (if there is none or RawKV is used, the output does not show the table IDs), and the affected SQL meta Regions. For example:

```
{
    "info": "Unsafe recovery finished",
    "time": "......",
    "details": [
        "Affected table ids: 64, 27",
        "Affected meta regions: 1001",
    ]
}
```

After you get the affected table IDs, you can query `INFORMATION_SCHEMA.TABLES` to view the affected table names.

```
SELECT TABLE_SCHEMA, TABLE_NAME, TIDB_TABLE_ID FROM INFORMATION_SCHEMA.
    ↪ TABLES WHERE TIDB_TABLE_ID IN (64, 27);
```

Note:

- The recovery operation has turned some failed voters to failed learners. Then PD scheduling needs some time to remove these failed learners.
- It is recommended to add new stores in time.

If an error occurs during the task, the last stage in the output shows `"Unsafe recovery failed"` and the error message. For example:

```
{
    "info": "Unsafe recovery failed: <error>",
    "time": "......"
}
```

8.12.3.4 Step 3. Check the consistency of data and index (not required for RawKV)

Note:

Although the data can be read and written, it does not mean that there is no data loss.

After the recovery is completed, the data and index might be inconsistent. Use the SQL command `ADMIN CHECK` to check the data and index consistency of the affected tables

```
ADMIN CHECK TABLE table_name;
```

If there are inconsistent indexes, you can fix the index inconsistency by renaming the old index, creating a new index, and then dropping the old index.

1. Rename the old index:

```
ALTER TABLE table_name RENAME INDEX index_name TO index_name_lame_duck
    ↪ ;
```

2. Create a new index:

```
ALTER TABLE table_name ADD INDEX index_name (column_name);
```

3. Drop the old index:

```
ALTER TABLE table_name DROP INDEX index_name_lame_duck;
```

8.12.3.5 Step 4: Remove unrecoverable stores (optional)

1. Remove the unrecoverable nodes:

```
tiup cluster scale-in <cluster-name> -N <host> --force
```

2. Clean up Tombstone nodes:

```
tiup cluster prune <cluster-name>
```

1. Delete the `PersistentVolumeClaim`.

```
kubectl delete -n ${namespace} pvc ${pvc_name} --wait=false
```

2. Delete the TiKV Pod and wait for newly created TiKV Pods to join the cluster.

```
kubectl delete -n ${namespace} pod ${pod_name}
```

8.13 Replicate Data Between Primary and Secondary Clusters

This document describes how to configure a TiDB primary (upstream) cluster and a TiDB or MySQL secondary (downstream) cluster, and replicate incremental data from the primary cluster to the secondary cluster. The process includes the following steps:

1. Configure a TiDB primary cluster and a TiDB or MySQL secondary cluster.
2. Replicate incremental data from the primary cluster to the secondary cluster.
3. Recover data consistently by using Redo log when the primary cluster is down.

To replicate incremental data from a running TiDB cluster to its secondary cluster, you can use Backup & Restore BR and TiCDC.

8.13.1 Step 1. Set up the environment

1. Deploy TiDB clusters.

   Deploy two TiDB clusters, one upstream and the other downstream by using TiUP Playground. For production environments, deploy the clusters by referring to Deploy and Maintain an Online TiDB Cluster Using TiUP.

   In this document, we deploy the two clusters on two machines:

   - Node A: 172.16.6.123, for deploying the upstream TiDB cluster
   - Node B: 172.16.6.124, for deploying the downstream TiDB cluster

```
# Create an upstream cluster on Node A
tiup --tag upstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# Create a downstream cluster on Node B
tiup --tag downstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 0
# View cluster status
tiup status
```

2. Initialize data.

   By default, test databases are created in the newly deployed clusters. Therefore, you can use sysbench to generate test data and simulate data in real scenarios.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=10 --
    ↪ table-size=10000 prepare
```

   In this document, we use sysbench to run the `oltp_write_only` script. This script generates 10 tables in the upstream database, each with 10,000 rows. The tidb-config is as follows:

```
mysql-host=172.16.6.122 # Replace it with the IP address of your
    ↪ upstream cluster
mysql-port=4000
mysql-user=root
mysql-password=
db-driver=mysql      # Set database driver to MySQL
mysql-db=test        # Set the database as a test database
report-interval=10   # Set data collection period to 10s
threads=10           # Set the number of worker threads to 10
time=0               # Set the time required for executing the script.
    ↪ 0 indicates time unlimited
rate=100             # Set average TPS to 100
```

3. Simulate service workload.

   In real scenarios, service data is continuously written to the upstream cluster. In this document, we use sysbench to simulate this workload. Specifically, run the following command to enable 10 workers to continuously write data to three tables, sbtest1, sbtest2, and sbtest3, with a total TPS not exceeding 100.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=3 run
```

4. Prepare external storage.

   In full data backup, both the upstream and downstream clusters need to access backup files. It is recommended that you use External storage to store backup files. In this example, Minio is used to simulate an S3-compatible storage service.

```
wget https://dl.min.io/server/minio/release/linux-amd64/minio
chmod +x minio
# Configure access-key access-screct-id to access minio
export HOST_IP='172.16.6.123' # Replace it with the IP address of your
    ↪ upstream cluster
export MINIO_ROOT_USER='minio'
export MINIO_ROOT_PASSWORD='miniostorage'
# Create the redo and backup directories. `backup` and `redo` are
    ↪ bucket names.
mkdir -p data/redo
mkdir -p data/backup
# Start minio at port 6060
nohup ./minio server ./data --address :6060 &
```

   The preceding command starts a minio server on one node to simulate S3 services. Parameters in the command are configured as follows:

   - Endpoint: `http://${HOST_IP}:6060/`
   - Access-key: `minio`
   - Secret-access-key: `miniostorage`
   - Bucket: `redo`

   The link is as follows:

```
s3://backup?access-key=minio&secret-access-key=miniostorage&endpoint=
    ↪ http://${HOST_IP}:6060&force-path-style=true
```

8.13.2 Step 2. Migrate full data

After setting up the environment, you can use the backup and restore functions of BR to migrate full data. BR can be started in three ways. In this document, we use the SQL statements, `BACKUP` and `RESTORE`.

Note:

- `BACKUP` and `RESTORE` SQL statements are experimental. It is not recommended that you use them in the production environment. They might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.
- In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you back up data in off-peak hours, and set RATE_LIMIT to a proper value to avoid performance degradation.
- If the versions of the upstream and downstream clusters are different, you should check BR compatibility. In this document, we assume that the upstream and downstream clusters are the same version.

1. Disable GC.

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before backup. In this way, history data is not deleted.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+
| @@global.tidb_gc_enable |
+--------------------------+
|                        0 |
+--------------------------+
1 row in set (0.00 sec)
```

2. Back up data.

   Run the `BACKUP` statement in the upstream cluster to back up data:

```
MySQL [(none)]> BACKUP DATABASE * TO 's3://backup?access-key=minio&
    ↪ secret-access-key=miniostorage&endpoint=http://${HOST_IP}:6060&
    ↪ force-path-style=true' RATE_LIMIT = 120 MB/SECOND;
```

```
+---------------------+---------+-------------------+---------------------+-----
    ↪
| Destination         | Size    | BackupTS          | Queue Time          |
    ↪ Execution Time    |
+---------------------+---------+-------------------+---------------------+-----
    ↪
| local:///tmp/backup/ | 10315858 | 431434047157698561 | 2022-02-25
    ↪ 19:57:59 | 2022-02-25 19:57:59 |
+---------------------+---------+-------------------+---------------------+-----
    ↪
1 row in set (2.11 sec)
```

After the `BACKUP` command is executed, TiDB returns metadata about the backup data. Pay attention to `BackupTS`, because data generated before it is backed up. In this document, we use `BackupTS` as **the end of data check** and **the start of incremental migration scanning by TiCDC**.

3. Restore data.

   Run the `RESTORE` command in the downstream cluster to restore data:

```
mysql> RESTORE DATABASE * FROM 's3://backup?access-key=minio&secret-
    ↪ access-key=miniostorage&endpoint=http://${HOST_IP}:6060&force-
    ↪ path-style=true';
```

```
+---------------------+---------+-------------------+---------------------+-----
    ↪
| Destination         | Size    | BackupTS          | Queue Time          |
    ↪ Execution Time    |
+---------------------+---------+-------------------+---------------------+-----
    ↪
| local:///tmp/backup/ | 10315858 | 431434141450371074 | 2022-02-25
    ↪ 20:03:59 | 2022-02-25 20:03:59 |
+---------------------+---------+-------------------+---------------------+-----
    ↪
1 row in set (41.85 sec)
```

4. (Optional) Validate data.

   Use sync-diff-inspector to check data consistency between upstream and downstream at a certain time. The preceding `BACKUP` output shows that the upstream cluster finishes backup at 431434047157698561. The preceding `RESTORE` output shows that the downstream finishes restoration at 431434141450371074.

```
sync_diff_inspector -C ./config.yaml
```

For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Global config #########################
check-thread-count = 4
export-fix-sql = true
check-struct-only = false

######################### Datasource config #########################
[data-sources]
[data-sources.upstream]
       host = "172.16.6.123" # Replace it with the IP address of your
          ↪ upstream cluster
       port = 4000
       user = "root"
       password = ""
       snapshot = "431434047157698561" # Set snapshot to the actual
          ↪ backup time
[data-sources.downstream]
       host = "172.16.6.124" # Replace the value with the IP address of
          ↪  your downstream cluster
       port = 4000
       user = "root"
       password = ""
       snapshot = "431434141450371074" # Set snapshot to the actual
          ↪ restore time

######################### Task config #########################
[task]
       output-dir = "./output"
       source-instances = ["upstream"]
       target-instance = "downstream"
       target-check-tables = ["*.*"]
```

8.13.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test clusters. Therefore, we skip the step of deploying TiCDC and proceed with changefeed configuration.

2. Create a changefeed.

Create a changefeed configuration file `changefeed.toml`.

```
[consistent]
# Consistency level, eventual means enabling consistent replication
level = "eventual"
# Use S3 to store redo logs. Other options are local and nfs.
storage = "s3://redo?access-key=minio&secret-access-key=miniostorage&
    ↪ endpoint=http://172.16.6.125:6060&force-path-style=true"
```

In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

```
tiup cdc cli changefeed create --server=http://172.16.6.122:8300 --sink
    ↪ -uri="mysql://root:@172.16.6.125:4000" --changefeed-id="primary-
    ↪ to-secondary" --start-ts="431434047157698561"
```

In this command, the parameters are as follows:

- `--server`: IP address of any node in the TiCDC cluster
- `--sink-uri`: URI of the downstream cluster
- `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS mentioned in Step 2. Migrate full data)

For more information about the changefeed configurations, see TiCDC Changefeed Configurations.

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint?.

   To enable GC, run the following command:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+
| @@global.tidb_gc_enable |
+-------------------------+
|                       1 |
+-------------------------+
1 row in set (0.00 sec)
```

8.13.4 Step 4. Simulate a disaster in the upstream cluster

Create a disastrous event in the upstream cluster while it is running. For example, you can terminate the tiup playground process by pressing Ctrl+C.

8.13.5 Step 5. Use redo log to ensure data consistency

Normally, TiCDC concurrently writes transactions to downstream to increase throughout. When a changefeed is interrupted unexpectedly, the downstream may not have the latest data as it is in the upstream. To address inconsistency, run the following command to ensure that the downstream data is consistent with the upstream data.

```
tiup cdc redo apply --storage "s3://redo?access-key=minio&secret-access-key=
    ↪ miniostorage&endpoint=http://172.16.6.123:6060&force-path-style=true"
    ↪  --tmp-dir /tmp/redo --sink-uri "mysql://root:@172.16.6.124:4000"
```

- `--storage`: Location and credential of the redo log in S3
- `--tmp-dir`: Cache directory of the redo log downloaded from S3
- `--sink-uri`: URI of the downstream cluster

8.13.6 Step 6. Recover the primary cluster and its services

After the previous step, the downstream (secondary) cluster has data that is consistent with the upstream (primary) cluster at a specific time. You need to set up new primary and secondary clusters to ensure data reliability.

1. Deploy a new TiDB cluster on Node A as the new primary cluster.

   ```
   tiup --tag upstream playground v5.4.0 --host 0.0.0.0 --db 1 --pd 1 --kv
       ↪  1 --tiflash 0 --ticdc 1
   ```

2. Use BR to back up and restore data fully from the secondary cluster to the primary cluster.

   ```
   # Back up full data of the secondary cluster
   tiup br --pd http://172.16.6.124:2379 backup full --storage ./backup
   # Restore full data of the secondary cluster
   tiup br --pd http://172.16.6.123:2379 restore full --storage ./backup
   ```

3. Create a new changefeed to back up data from the primary cluster to the secondary cluster.

   ```
   # Create a changefeed
   tiup cdc cli changefeed create --server=http://172.16.6.122:8300 --sink
       ↪ -uri="mysql://root:@172.16.6.125:4000" --changefeed-id="primary-
       ↪ to-secondary"
   ```

9 Monitor and Alert

9.1 TiDB Monitoring Framework Overview

The TiDB monitoring framework adopts two open source projects: Prometheus and Grafana. TiDB uses Prometheus to store the monitoring and performance metrics and Grafana to visualize these metrics. TiDB also provides a built-in TiDB Dashboard for monitoring and diagnosing TiDB clusters.

9.1.1 About Prometheus in TiDB

As a time series database, Prometheus has a multi-dimensional data model and flexible query language. As one of the most popular open source projects, Prometheus has been adopted by many companies and organizations and has a very active community. PingCAP is one of the active developers and adopters of Prometheus for monitoring and alerting in TiDB, TiKV and PD.

Prometheus consists of multiple components. Currently, TiDB uses the following of them:

- The Prometheus Server to scrape and store time series data
- The client libraries to customize necessary metrics in the application
- An Alertmanager for the alerting mechanism

The diagram is as follows:

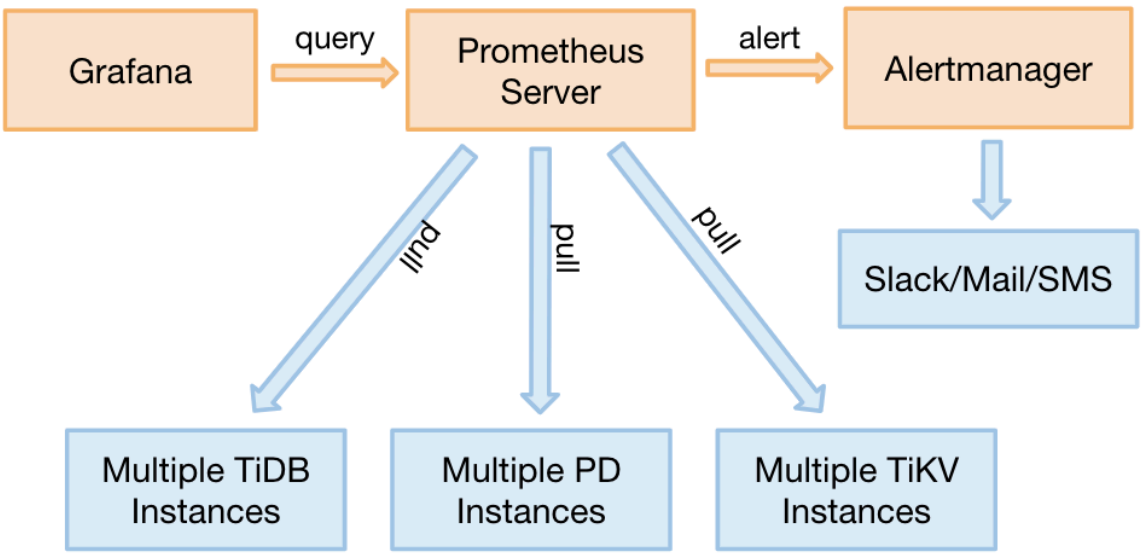

Figure 165: diagram

9.1.2 About Grafana in TiDB

Grafana is an open source project for analyzing and visualizing metrics. TiDB uses Grafana to display the performance metrics as follows:

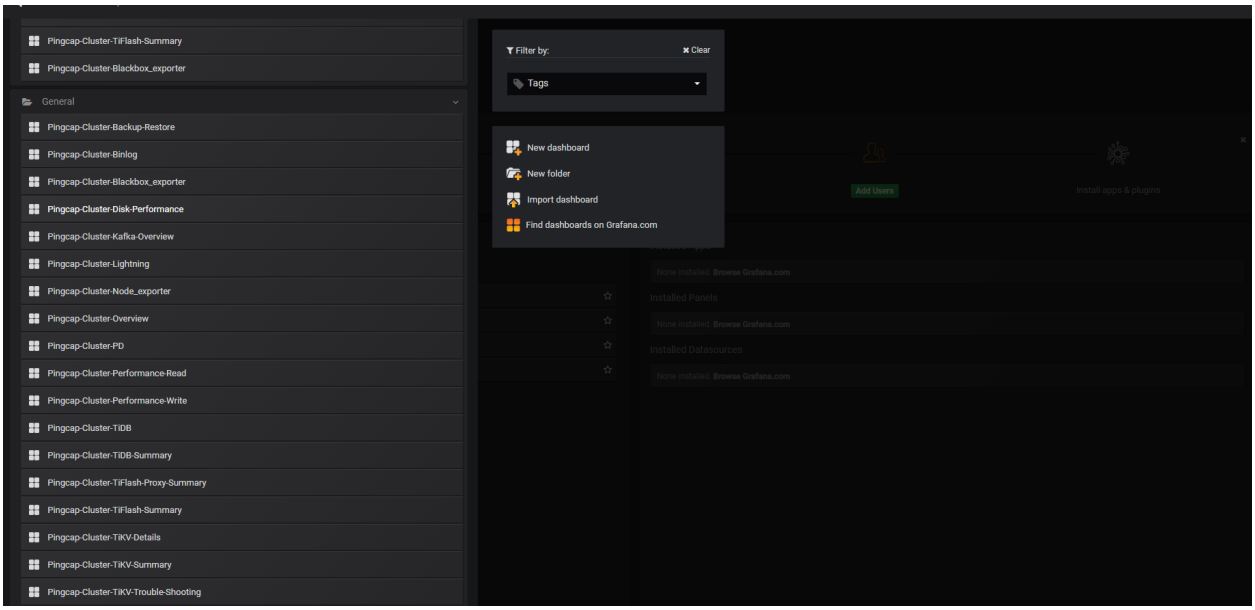

Figure 166: Grafana monitored_groups

- {TiDB_Cluster_name}-Backup-Restore: Monitoring metrics related to backup and restore.
- {TiDB_Cluster_name}-Blackbox_exporter: Monitoring metrics related to network probe.
- {TiDB_Cluster_name}-Disk-Performance: Monitoring metrics related to disk performance.
- {TiDB_Cluster_name}-Kafka-Overview: Monitoring metrics related to Kafka.
- {TiDB_Cluster_name}-Lightning: Monitoring metrics related to TiDB Lightning.
- {TiDB_Cluster_name}-Node_exporter: Monitoring metrics related to the operating system.
- {TiDB_Cluster_name}-Overview: Monitoring overview related to important components.
- {TiDB_Cluster_name}-PD: Monitoring metrics related to the PD server.
- {TiDB_Cluster_name}-Performance-Read: Monitoring metrics related to read performance.
- {TiDB_Cluster_name}-Performance-Write: Monitoring metrics related to write performance.
- {TiDB_Cluster_name}-TiDB: Detailed monitoring metrics related to the TiDB server.
- {TiDB_Cluster_name}-TiDB-Summary: Monitoring overview related to TiDB.

- {TiDB_Cluster_name}-TiFlash-Proxy-Summary: Monitoring overview of the proxy server that is used to replicate data to TiFlash.
- {TiDB_Cluster_name}-TiFlash-Summary: Monitoring overview related to TiFlash.
- {TiDB_Cluster_name}-TiKV-Details: Detailed monitoring metrics related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Summary: Monitoring overview related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Trouble-Shooting: Monitoring metrics related to the TiKV error diagnostics.
- {TiDB_Cluster_name}-TiCDC: Detailed monitoring metrics related to TiCDC.
- {TiDB_Cluster_name}-TiProxy-Summary: Monitoring overview related to TiProxy.

Each group has multiple panel labels of monitoring metrics, and each panel contains detailed information of multiple monitoring metrics. For example, the **Overview** monitoring group has five panel labels, and each labels corresponds to a monitoring panel. See the following UI:

Figure 167: Grafana Overview

9.1.3 TiDB Dashboard

TiDB Dashboard is a web UI for monitoring, diagnosing, and managing the TiDB cluster, which is introduced in v4.0. It is built into the PD component and does not require an independent deployment. For more information, see TiDB Dashboard introduction.

9.2 TiDB Monitoring API

You can use the following types of interfaces to monitor the TiDB cluster status:

- The status interface: this interface uses the HTTP interface to get the component information. Using this interface, you can get the running status of the current TiDB server and the storage information of a table.
- The metrics interface: this interface uses Prometheus to record the detailed information of the various operations in components and views these metrics using Grafana.

9.2.1 Use the status interface

The status interface monitors the basic information of a specific component in the TiDB cluster. It can also act as the monitor interface for Keepalive messages. In addition, the status interface for the Placement Driver (PD) can get the details of the entire TiKV cluster.

9.2.1.1 TiDB server

- TiDB API address: `http://${host}:${port}`
- Default port: `10080`

9.2.1.2 Running status

The following example uses `http://${host}:${port}/status` to get the current status of the TiDB server and to determine whether the server is alive. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/status
{
    connections: 0, # The current number of clients connected to the TiDB
        ↪ server.
    version: "8.0.11-TiDB-v8.5.1", # The TiDB version number.
    git_hash: "778c3f4a5a716880bcd1d71b257c8165685f0d70" # The Git Hash of
        ↪ the current TiDB code.
}
```

9.2.1.2.1 Storage information

The following example uses `http://${host}:${port}/schema_storage/${db}/${table}` to get the storage information of the specific data table. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/schema_storage/mysql/stats_histograms
```

```
{
    "table_schema": "mysql",
    "table_name": "stats_histograms",
    "table_rows": 0,
    "avg_row_length": 0,
    "data_length": 0,
    "max_data_length": 0,
    "index_length": 0,
    "data_free": 0
}
```

```
curl http://127.0.0.1:10080/schema_storage/test
```

```
[
    {

9.2.1.3 PD server

- PD API address: `http://${host}:${port}/pd/api/v1/${api_name}`
- Default port: 2379
- Details about API names: see PD API doc

The PD interface provides the status of all the TiKV servers and the information about load balancing. See the following example for the information about a single-node TiKV cluster:

```
curl http://127.0.0.1:2379/pd/api/v1/stores
{
  "count": 1, # The number of TiKV nodes.
  "stores": [ # The list of TiKV nodes.
    # The details about the single TiKV node.
    {
      "store": {
        "id": 1,
        "address": "127.0.0.1:20160",
        "version": "3.0.0-beta",
        "state_name": "Up"
      },
      "status": {
        "capacity": "20 GiB", # The total capacity.
        "available": "16 GiB", # The available capacity.
        "leader_count": 17,
        "leader_weight": 1,
        "leader_score": 17,
        "leader_size": 17,
        "region_count": 17,
        "region_weight": 1,
        "region_score": 17,
        "region_size": 17,
        "start_ts": "2019-03-21T14:09:32+08:00", # The starting timestamp.
        "last_heartbeat_ts": "2019-03-21T14:14:22.961171958+08:00", # The
            ↪ timestamp of the last heartbeat.
        "uptime": "4m50.961171958s"
      }
    }
  ]
```

9.2.2 Use the metrics interface

The metrics interface monitors the status and performance of the entire TiDB cluster.

- If you use other deployment ways, deploy Prometheus and Grafana before using this interface.

After Prometheus and Grafana are successfully deployed, configure Grafana.

9.3 Deploy Monitoring Services for the TiDB Cluster

This document is intended for users who want to manually deploy TiDB monitoring and alert services. If you deploy the TiDB cluster using TiUP, the monitoring and alert services

are automatically deployed, and no manual deployment is needed. TiDB Dashboard is built into the PD component and does not require an independent deployment.

9.3.1 Deploy Prometheus and Grafana

Assume that the TiDB cluster topology is as follows:

Name	Host IP	Services
Node1	192.168.199.113	PD1, TiDB, node_export, Prometheus, Grafana
Node2	192.168.199.114	PD2, node_export
Node3	192.168.199.115	PD3, node_export
Node4	192.168.199.116	TiKV1, node_export
Node5	192.168.199.117	TiKV2, node_export
Node6	192.168.199.118	TiKV3, node_export

9.3.1.1 Step 1: Download the binary package

```
## Downloads the package.
wget https://github.com/prometheus/prometheus/releases/download/v2.49.1/
    ↪ prometheus-2.49.1.linux-amd64.tar.gz
wget https://download.pingcap.org/node_exporter-v1.3.1-linux-amd64.tar.gz
wget https://download.pingcap.org/grafana-7.5.17.linux-amd64.tar.gz
```

```
## Extracts the package.
tar -xzf prometheus-2.49.1.linux-amd64.tar.gz
tar -xzf node_exporter-v1.3.1-linux-amd64.tar.gz
tar -xzf grafana-7.5.17.linux-amd64.tar.gz
```

9.3.1.2 Step 2: Start `node_exporter` on Node1, Node2, Node3, and Node4

```
cd node_exporter-v1.3.1-linux-amd64

## Starts the node_exporter service.
$ ./node_exporter --web.listen-address=":9100" \
    --log.level="info" &
```

9.3.1.3 Step 3: Start Prometheus on Node1

Edit the Prometheus configuration file:

```
cd prometheus-2.49.1.linux-amd64 &&
vi prometheus.yml
```

```
...

global:
  scrape_interval:  15s # By default, scrape targets every 15 seconds.
  evaluation_interval: 15s # By default, scrape targets every 15 seconds.
  # scrape_timeout is set to the global default value (10s).
  external_labels:
    cluster: 'test-cluster'
    monitor: "prometheus"

scrape_configs:
  - job_name: 'overwritten-nodes'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:9100'
      - '192.168.199.114:9100'
      - '192.168.199.115:9100'
      - '192.168.199.116:9100'
      - '192.168.199.117:9100'
      - '192.168.199.118:9100'

  - job_name: 'tidb'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:10080'

  - job_name: 'pd'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:2379'
      - '192.168.199.114:2379'
      - '192.168.199.115:2379'

  - job_name: 'tikv'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.116:20180'
      - '192.168.199.117:20180'
      - '192.168.199.118:20180'
```

```
...
```

To enable alarm rules for components such as TiDB, PD, and TiKV, download the alarm rule files of the corresponding components separately, and then add the configurations of alarm rule files to the Prometheus configuration file.

- TiDB: tidb.rules.yml
- PD: pd.rules.yml
- TiKV: tikv.rules.yml
- TiFlash: tiflash.rules.yml
- TiCDC: ticdc.rules.yml
- TiDB Lightning: lightning.rules.yml

```
rule_files:
  - 'tidb.rules.yml'
  - 'pd.rules.yml'
  - 'tikv.rules.yml'
  - 'tiflash.rules.yml'
  - 'ticdc.rules.yml'
  - 'lightning.rules.yml'
```

Start the Prometheus service:

```
$ ./prometheus \
    --config.file="./prometheus.yml" \
    --web.listen-address=":9090" \
    --web.external-url="http://192.168.199.113:9090/" \
    --web.enable-admin-api \
    --log.level="info" \
    --storage.tsdb.path="./data.metrics" \
    --storage.tsdb.retention="15d" &
```

9.3.1.4 Step 4: Start Grafana on Node1

Edit the Grafana configuration file:

```
cd grafana-7.5.17 &&
vi conf/grafana.ini

...

[paths]
data = ./data
logs = ./data/log
plugins = ./data/plugins
```

```
[server]
http_port = 3000
domain = 192.168.199.113
[database]
[session]
[analytics]
check_for_updates = true
[security]
admin_user = admin
admin_password = admin
[snapshots]
[users]
[auth.anonymous]
[auth.basic]
[auth.ldap]
[smtp]
[emails]
[log]
mode = file
[log.console]
[log.file]
level = info
format = text
[log.syslog]
[event_publisher]
[dashboards.json]
enabled = false
path = ./data/dashboards
[metrics]
[grafana_net]
url = https://grafana.net

...
```

Start the Grafana service:

```
./bin/grafana-server \
    --config="./conf/grafana.ini" &
```

9.3.2 Configure Grafana

This section describes how to configure Grafana.

9.3.2.1 Step 1: Add a Prometheus data source

1. Log in to the Grafana Web interface.

    - Default address: http://localhost:3000
    - Default account: admin
    - Default password: admin

> **Note:**
> For the **Change Password** step, you can choose **Skip**.

2. In the Grafana sidebar menu, click **Data Source** within the **Configuration**.
3. Click **Add data source**.
4. Specify the data source information.

    - Specify a **Name** for the data source.
    - For **Type**, select **Prometheus**.
    - For **URL**, specify the Prometheus address.
    - Specify other fields as needed.

5. Click **Add** to save the new data source.

9.3.2.2 Step 2: Import a Grafana dashboard

To import a Grafana dashboard for the PD server, the TiKV server, and the TiDB server, take the following steps respectively:

1. Click the Grafana logo to open the sidebar menu.
2. In the sidebar menu, click **Dashboards** -> **Import** to open the **Import Dashboard** window.
3. Click **Upload .json File** to upload a JSON file (Download TiDB Grafana configuration files from pingcap/tidb, tikv/tikv, and tikv/pd).

> **Note:**
> For the TiKV, PD, and TiDB dashboards, the corresponding JSON files are `tikv_summary.json`, `tikv_details.json`, `tikv_trouble_shooting.json`, `pd.json`, `tidb.json`, and `tidb_summary.json`.

4. Click **Load**.
5. Select a Prometheus data source.
6. Click **Import**. A Prometheus dashboard is imported.

9.3.3 View component metrics

Click **New dashboard** in the top menu and choose the dashboard you want to view.

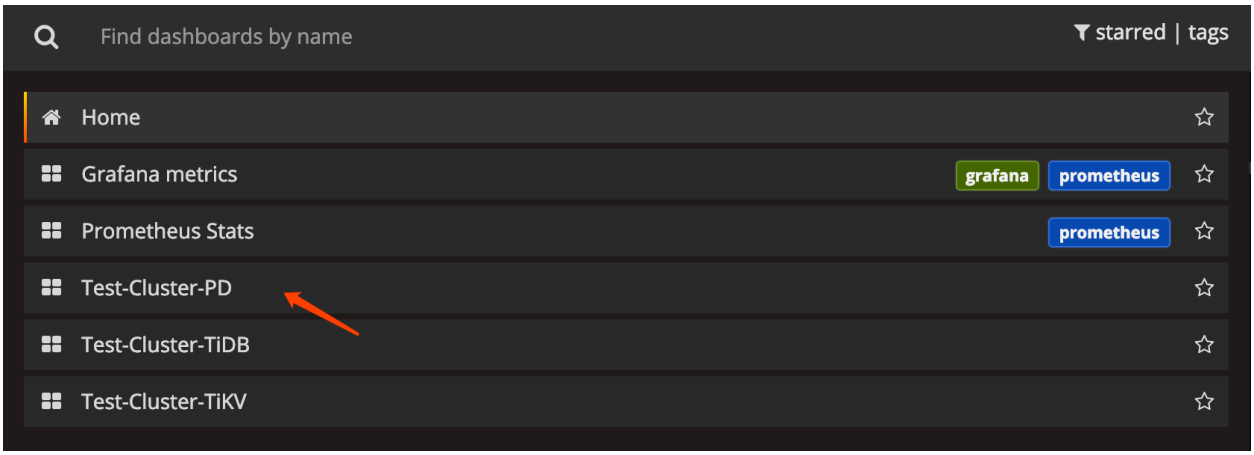

Figure 168: view dashboard

You can get the following metrics for cluster components:

- **TiDB server:**
    - Query processing time to monitor the latency and throughput
    - The DDL process monitoring
    - TiKV client related monitoring
    - PD client related monitoring
- **PD server:**
    - The total number of times that the command executes
    - The total number of times that a certain command fails
    - The duration that a command succeeds
    - The duration that a command fails
    - The duration that a command finishes and returns result
- **TiKV server:**
    - Garbage Collection (GC) monitoring
    - The total number of times that the TiKV command executes
    - The duration that Scheduler executes commands
    - The total number of times of the Raft propose command
    - The duration that Raft executes commands
    - The total number of times that Raft commands fail
    - The total number of times that Raft processes the ready state

9.4 Upgrade TiDB Cluster Monitoring Services

When deploying a TiDB cluster, TiUP automatically deploys monitoring services (such as Prometheus, Grafana, and Alertmanager) for the cluster. If you scale out this cluster, TiUP also automatically adds monitoring configurations for newly added nodes during the scaling. The monitoring services automatically deployed by TiUP are usually not the latest versions of these third-party monitoring services. To use the latest versions, you can follow this document to upgrade the monitoring services.

When managing a cluster, TiUP uses its own configurations to override the configurations of the monitoring services. If you directly upgrade the monitoring services by replacing their configuration files, any subsequent TiUP operations such as `deploy`, `scale-out`, `scale-in`, and `reload` on the cluster might overwrite your upgrade, leading to errors. To upgrade Prometheus, Grafana, and Alertmanager, follow the steps in this document rather than directly replacing configuration files.

Note:

- If your monitoring services are deployed manually instead of using TiUP, you can directly upgrade them without referring to this document.
- The TiDB compatibility with newer versions of monitoring services has not been tested, so some features might not work as expected after the upgrade. For any issues, create an issue on GitHub.
- The upgrade steps in this document are applicable for TiUP version 1.9.0 and later. Therefore, check your TiUP version before the upgrade.
- When you use TiUP to upgrade the TiDB cluster, TiUP will redeploy the monitoring services to the default version. You need to redo the upgrade for monitoring services after the TiDB upgrade.

9.4.1 Upgrade Prometheus

For better compatibility with TiDB, it is recommended to use the Prometheus installation package provided in the TiDB installation package. The version of Prometheus in the TiDB installation package is fixed. If you want to use a newer Prometheus version, refer to Prometheus Release Notes for new features of each version and choose a suitable version for your production environment. You can also consult with PingCAP technical staff for a recommended version.

In the following upgrade steps, you need to download the Prometheus installation package of your desired version from the Prometheus website, and then use it to create a Prometheus package that TiUP can use.

9.4.1.1 Step 1. Download a new Prometheus installation package from the Prometheus website

Download a new installation package from the Prometheus download page and extract it.

9.4.1.2 Step 2. Download the Prometheus installation package provided by TiDB

1. Download the TiDB server package and extract it. Note that your downloading means you agree to the Privacy Policy.

```
https://download.pingcap.org/tidb-community-server-{version}-linux-{
    ↪ arch}.tar.gz
```

> **Tip:**
>
> `{version}` in the link indicates the version number of TiDB and `{arch ↪ }` indicates the architecture of the system, which can be `amd64` or `arm64`. For example, the download link for `v8.5.1` in the `amd64` architecture is `https://download.pingcap.org/tidb-community-toolkit-v8 ↪ .5.1-linux-amd64.tar.gz`.

2. In the extracted files, locate `prometheus-v{version}-linux-amd64.tar.gz` and extract it.

```
tar -xzf prometheus-v{version}-linux-amd64.tar.gz
```

9.4.1.3 Step 3. Create a new Prometheus package that TiUP can use

1. Copy the files extracted in Step 1, and then use the copied files to replace the files in the `./prometheus-v{version}-linux-amd64/prometheus` directory extracted in Step 2.

2. Recompress the `./prometheus-v{version}-linux-amd64` directory and name the new compressed package as `prometheus-v{new-version}.tar.gz`, where `{new-version}` can be specified according to your need.

```
cd prometheus-v{version}-linux-amd64
tar -zcvf ../prometheus-v{new-version}.tar.gz ./
```

9.4.1.4 Step 4. Upgrade Prometheus using the newly created Prometheus package

Execute the following command to upgrade Prometheus:

```
tiup cluster patch <cluster-name> prometheus-v{new-version}.tar.gz -R
    ↪ prometheus --overwrite
```

After the upgrade, you can go to the home page of the Prometheus server (usually at `http://<Prometheus-server-host-name>:9090`), click **Status** in the top navigation menu, and then open the **Runtime & Build Information** page to check the Prometheus version and confirm whether the upgrade is successful.

9.4.2 Upgrade Grafana

For better compatibility with TiDB, it is recommended to use the Grafana installation package provided in the TiDB installation package. The version of Grafana in the TiDB installation package is fixed. If you want to use a newer Grafana version, refer to Grafana Release Notes for new features of each version and choose a suitable version for your production environment. You can also consult with PingCAP technical staff for a recommended version.

In the following upgrade steps, you need to download the Grafana installation package of your desired version from the Grafana website, and then use it to create a Grafana package that TiUP can use.

9.4.2.1 Step 1. Download a new Grafana installation package from the Grafana website

1. Download a new installation package from the Grafana download page. You can choose either the `OSS` or `Enterprise` edition according to your needs.
2. Extract the downloaded package.

9.4.2.2 Step 2. Download the Grafana installation package provided by TiDB

1. Download the TiDB server package and extract it. Note that your downloading means you agree to the Privacy Policy.

```
https://download.pingcap.org/tidb-community-server-{version}-linux-{
    ↪ arch}.tar.gz
```

> **Tip:**
> `{version}` in the link indicates the version number of TiDB and `{arch}` indicates the architecture of the system, which can be `amd64` or `arm64`. For example, the download link for `v8.5.1` in the `amd64` architecture is `https://download.pingcap.org/tidb-community-toolkit-v8.5.1-linux-amd64.tar.gz`.

2. In the extracted files, locate `grafana-v{version}-linux-amd64.tar.gz` and extract it.

```
tar -xzf grafana-v{version}-linux-amd64.tar.gz
```

9.4.2.3 Step 3. Create a new Grafana package that TiUP can use

1. Copy the files extracted in Step 1, and then use the copied files to replace the files in the `./grafana-v{version}-linux-amd64/` directory extracted in Step 2.
2. Recompress the `./grafana-v{version}-linux-amd64` directory and name the new compressed package as `grafana-v{new-version}.tar.gz`, where `{new-version}` can be specified according to your need.

```
cd grafana-v{version}-linux-amd64
tar -zcvf ../grafana-v{new-version}.tar.gz ./
```

9.4.2.4 Step 4. Upgrade Grafana using the newly created Grafana package

Execute the following command to upgrade Grafana:

```
tiup cluster patch <cluster-name> grafana-v{new-version}.tar.gz -R grafana
    ↪ --overwrite
```

After the upgrade, you can go to the home page of the Grafana server (usually at `http://<Grafana-server-host-name>:3000`), and then check the Grafana version on the page to confirm whether the upgrade is successful.

9.4.3 Upgrade Alertmanager

The Alertmanager package in the TiDB installation package is directly from the Prometheus website. Therefore, when upgrading Alertmanager, you only need to download and install a new version of Alertmanager from the Prometheus website.

9.4.3.1 Step 1. Download a new Alertmanager installation package from the Prometheus website

Download the `alertmanager` installation package from the Prometheus download page.

9.4.3.2 Step 2. Upgrade Alertmanager using the downloaded installation package

Execute the following command to upgrade Alertmanager:

```
tiup cluster patch <cluster-name> alertmanager-v{new-version}-linux-amd64.
    ↪ tar.gz -R alertmanager --overwrite
```

After the upgrade, you can go to the home page of the Alertmanager server (usually at `http://<Alertmanager-server-host-name>:9093`), click **Status** in the top navigation menu, and then check the Alertmanager version to confirm whether the upgrade is successful.

9.5 TiDB Dashboard

9.5.1 TiDB Dashboard Introduction

TiDB Dashboard is a Web UI for monitoring, diagnosing, and managing the TiDB cluster, which is available since v4.0. It is built into the PD component and does not require an independent deployment.

> **Note:**
>
> TiDB v6.5.0 (and later) and TiDB Operator v1.4.0 (and later) support deploying TiDB Dashboard as an independent Pod on Kubernetes. For details, see Deploy TiDB Dashboard independently in TiDB Operator.

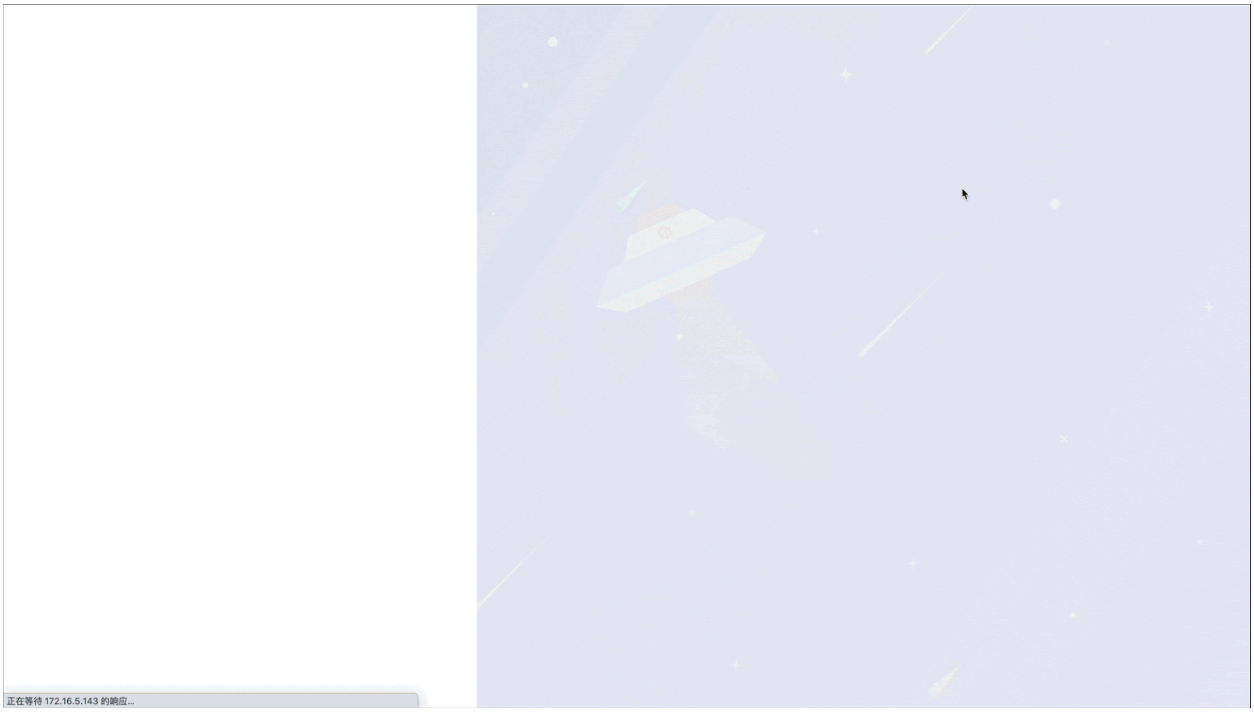

Figure 169: TiDB Dashboard interface

TiDB Dashboard is open-sourced on GitHub.

This document introduces the main features of TiDB Dashboard. You can click links in the following sections to learn more details.

9.5.1.1 Show the overall running status of the TiDB cluster

You can use TiDB Dashboard to learn the TiDB cluster's queries per second (QPS), execution time, the types of SQL statements that consume the most resources, and other overview information.

See TiDB Dashboard Overview for details.

9.5.1.2 Show the running status of components and hosts

You can use TiDB Dashboard to view the running status of TiDB, TiKV, PD, TiFlash components in the entire cluster and the running status of the host on which these components are located.

See TiDB Dashboard Cluster Information Page for details.

9.5.1.3 Show distribution and trends of read and write traffic

The Key Visualizer feature of TiDB Dashboard visually shows the change of read and write traffic over time in the entire cluster in the form of heatmap. You can use this feature to timely discover changes of application modes or locate hotspot issues with uneven performance.

See Key Visualizer Page for details.

9.5.1.4 Show a list of execution information of all SQL statements

The execution information of all SQL statements is listed on the SQL Statements page. You can use this page to learn the execution time and total executions at all stages, which helps you analyze and locate the SQL queries that consume the most resources and improve the overall cluster performance.

See SQL Statements Page of TiDB Dashboard for details.

9.5.1.5 Learn the detailed execution information of slow queries

The Slow Queries page of TiDB Dashboard shows a list of all SQL statements that take a long time to execute, including the SQL texts and execution information. This page helps you locate the cause of slow queries or performance jitter.

See Slow Queries Page for details.

9.5.1.6 Diagnose common cluster problems and generate reports

The diagnostic feature of TiDB Dashboard automatically determines whether some common risks (such as inconsistent configurations) or problems exist in the cluster, generates reports, and gives operation suggestions, or compares the status of each cluster metric in different time ranges for you to analyze possible problems.

See TiDB Dashboard Cluster Diagnostics Page for details.

9.5.1.7 Query logs of all components

On the Search Logs page of TiDB Dashboard, you can quickly search logs of all running instances in the cluster by keywords, time range, and other conditions, package these logs, and download them to your local machine.

See Search Logs Page for details.

9.5.1.8 Estimate cluster capacity for resource control

To implement resource isolation using the Resource Control feature, cluster administrators can create resource groups and set quotas for each group.

Before resource planning, you need to know the overall capacity of the cluster. For more details, see Resource Manager page.

9.5.1.9 Collect profiling data for each instance

This is an advanced debugging feature that lets you profile each instance online and analyze various internal operations an instance performed during the profiling data collection period and the proportion of the operation execution time in this period without third-party tools.

See Profile Instances Page for details.

9.5.2 Maintain

9.5.2.1 Deploy TiDB Dashboard

The TiDB Dashboard UI is built into the PD component for v4.0 or higher versions, and no additional deployment is required. Simply deploy a standard TiDB cluster, and TiDB Dashboard will be there.

> **Note:**
>
> TiDB v6.5.0 (and later) and TiDB Operator v1.4.0 (and later) support deploying TiDB Dashboard as an independent Pod on Kubernetes. For details, see Deploy TiDB Dashboard independently in TiDB Operator.

See the following documents to learn how to deploy a standard TiDB cluster:

- Quick Start with TiDB Self-Managed
- Deploy TiDB in Production Environment
- Kubernetes environment deployment

> **Note:**
>
> You cannot deploy TiDB Dashboard in a TiDB cluster earlier than v4.0.

9.5.2.1.1 Deployment with multiple PD instances

When multiple PD instances are deployed in the cluster, only one of these instances serves the TiDB Dashboard.

When PD instances are running for the first time, they automatically negotiate with each other to choose one instance to serve the TiDB Dashboard. TiDB Dashboard will not run on other PD instances. The TiDB Dashboard service will always be provided by the chosen

PD instance no matter PD instances are restarted or new PD instances are joined. However, there will be a re-negotiation when the PD instance that serves TiDB Dashboard is removed from the cluster (scaled-in). The negotiation process does not need user intervention.

When you access a PD instance that does not serve TiDB Dashboard, the browser will be redirected automatically to guide you to access the PD instance that serves the TiDB Dashboard, so that you can access the service normally. This process is illustrated in the image below.

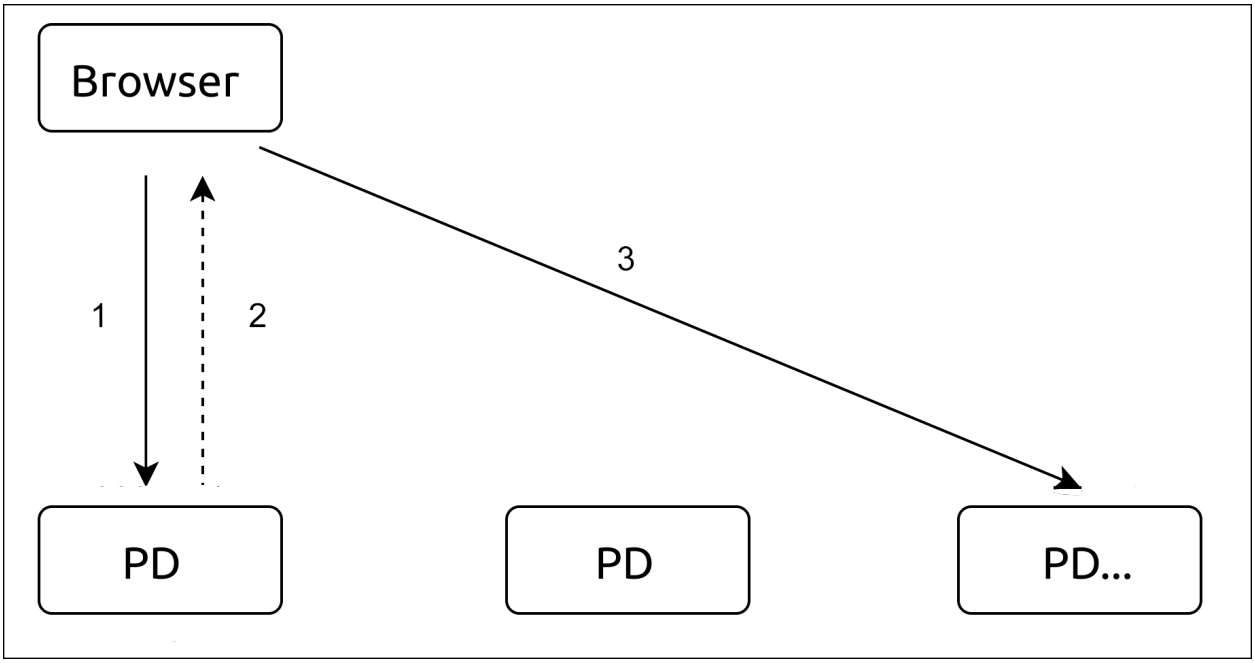

Figure 170: Process Schematic

Note:

The PD instance that serves TiDB Dashboard might not be a PD leader.

Check the PD instance that actually serves TiDB Dashboard

For a running cluster deployed using TiUP, you can use the `tiup cluster display` command to see which PD instance serves TiDB Dashboard. Replace `CLUSTER_NAME` with the cluster name.

```
tiup cluster display CLUSTER_NAME --dashboard
```

A sample output is as follows:

```
http://192.168.0.123:2379/dashboard/
```

Note:

This feature is available only in the later version of the `tiup cluster` deployment tool (v1.0.3 or later).

Upgrade TiUP Cluster

```
tiup update --self
tiup update cluster --force
```

Switch to another PD instance to serve TiDB Dashboard

For a running cluster deployed using TiUP, you can use the `tiup ctl:v<CLUSTER_VERSION> pd` command to change the PD instance that serves TiDB Dashboard, or re-specify a PD instance to serve TiDB Dashboard when it is disabled:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 config set
    ↪ dashboard-address http://9.9.9.9:2379
```

In the command above:

- Replace `127.0.0.1:2379` with the IP and port of any PD instance.
- Replace `9.9.9.9:2379` with the IP and port of the new PD instance that you desire to run the TiDB Dashboard service.

You can use the `tiup cluster display` command to see whether the modification is taking effect (replace `CLUSTER_NAME` with the cluster name):

```
tiup cluster display CLUSTER_NAME --dashboard
```

Warning:

If you change the instance to run TiDB Dashboard, the local data stored in the previous TiDB Dashboard instance will be lost, including the Key Visualize history and search history.

9.5.2.1.2 Disable TiDB Dashboard

For a running cluster deployed using TiUP, use the `tiup ctl:v<CLUSTER_VERSION> pd` command to disable TiDB Dashboard on all PD instances (replace `127.0.0.1:2379` with the IP and port of any PD instance):

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 config set
    ↪ dashboard-address none
```

After disabling TiDB Dashboard, checking which PD instance provides the TiDB Dashboard service will fail:

```
Error: TiDB Dashboard is disabled
```

Visiting the TiDB Dashboard address of any PD instance via the browser will also fail:

```
Dashboard is not started.
```

9.5.2.1.3 Re-enable TiDB Dashboard

For a running cluster deployed using TiUP, use the `tiup ctl:v<CLUSTER_VERSION> pd` ↪ command to request PD to renegotiate an instance to run TiDB Dashboard (replace `127.0.0.1:2379` with the IP and port of any PD instance):

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://127.0.0.1:2379 config set
    ↪ dashboard-address auto
```

After executing the command above, you can use the `tiup cluster display` command to view the TiDB Dashboard instance address automatically negotiated by PD (replace `CLUSTER_NAME` with the cluster name):

```
tiup cluster display CLUSTER_NAME --dashboard
```

You can also re-enable TiDB Dashboard by manually specifying the PD instance that serves TiDB Dashboard. See Switch to another PD instance to serve TiDB Dashboard.

> **Warning:**
>
> If the newly enabled TiDB Dashboard instance is different with the previous instance that served the TiDB Dashboard, the local data stored in the previous TiDB Dashboard instance will be lost, including Key Visualize history and search history.

9.5.2.1.4 What's next

- To learn how to access and log into the TiDB Dashboard UI, see Access TiDB Dashboard.
- To learn how to enhance the security of TiDB Dashboard, such as configuring a firewall, see Secure TiDB Dashboard.

9.5.2.2 Use TiDB Dashboard behind a Reverse Proxy

You can use a reverse proxy to safely expose the TiDB Dashboard service from the internal network to the external.

9.5.2.2.1 Procedures

Step 1: Get the actual TiDB Dashboard address

When multiple PD instances are deployed in the cluster, only one of the PD instances actually runs TiDB Dashboard. Therefore, you need to ensure that the upstream of the reverse proxy points to the correct address. For details of this mechanism, see Deployment with multiple PD instances.

When you use the TiUP tool for deployment, execute the following command to get the actual TiDB Dashboard address (replace `CLUSTER_NAME` with your cluster name):

```
tiup cluster display CLUSTER_NAME --dashboard
```

The output is the actual TiDB Dashboard address. A sample is as follows:

```
http://192.168.0.123:2379/dashboard/
```

Note:

This feature is available only in the later version of the `tiup cluster` deployment tool (v1.0.3 or later).

Upgrade TiUP Cluster

```
tiup update --self
tiup update cluster --force
```

Step 2: Configure the reverse proxy

Use HAProxy

When you use HAProxy as the reverse proxy, take the following steps:

1. Use reverse proxy for TiDB Dashboard on the `8033` port (for example). In the HAProxy configuration file, add the following configuration:

```
frontend tidb_dashboard_front
  bind *:8033
  use_backend tidb_dashboard_back if { path /dashboard } or { path_beg
     ↪ /dashboard/ }

backend tidb_dashboard_back
  mode http
  server tidb_dashboard 192.168.0.123:2379
```

   Replace `192.168.0.123:2379` with IP and port of the actual address of the TiDB Dashboard obtained in Step 1.

> **Warning:**
>
> You must retain the `if` part in the `use_backend` directive to ensure that services **only in this path** are behind reverse proxy; otherwise, security risks might be introduced. See Secure TiDB Dashboard.

2. Restart HAProxy for the configuration to take effect.

3. Test whether the reverse proxy is effective: access the `/dashboard/` address on the `8033` port of the machine where HAProxy is located (such as `http://example.com` ↪ `:8033/dashboard/`) to access TiDB Dashboard.

Use NGINX

When you use NGINX as the reverse proxy, take the following steps:

1. Use reverse proxy for TiDB Dashboard on the `8033` port (for example). In the NGINX configuration file, add the following configuration:

```
server {
    listen 8033;
    location /dashboard/ {
    proxy_pass http://192.168.0.123:2379/dashboard/;
    }
}
```

   Replace `http://192.168.0.123:2379/dashboard/` with the actual address of the TiDB Dashboard obtained in Step 1.

> **Warning:**
>
> You must keep the `/dashboard/` path in the `proxy_pass` directive to ensure that only the services under this path are reverse proxied. Otherwise, security risks will be introduced. See Secure TiDB Dashboard.

2. Reload NGINX for the configuration to take effect.

```
sudo nginx -s reload
```

3. Test whether the reverse proxy is effective: access the `/dashboard/` address on the `8033` port of the machine where NGINX is located (such as `http://example.com:8033/dashboard/`) to access TiDB Dashboard.

9.5.2.2.2 Customize path prefix

TiDB Dashboard provides services by default in the `/dashboard/` path, such as `http://example.com:8033/dashboard/`, which is the case even for reverse proxies. To configure the reverse proxy to provide the TiDB Dashboard service with a non-default path, such as `http://example.com:8033/foo/` or `http://example.com:8033/`, take the following steps.

Step 1: Modify PD configuration to specify the path prefix of TiDB Dashboard service

Modify the `public-path-prefix` configuration item in the `[dashboard]` category of the PD configuration to specify the path prefix of the TiDB Dashboard service. After this item is modified, restart the PD instance for the modification to take effect.

For example, if the cluster is deployed using TiUP and you want the service to run on `http://example.com:8033/foo/`, you can specify the following configuration:

```
server_configs:
  pd:
    dashboard.public-path-prefix: /foo
```

Modify configuration when deploying a new cluster using TiUP

If you are deploying a new cluster, you can add the configuration above to the `topology.yaml` TiUP topology file and deploy the cluster. For specific instruction, see TiUP deployment document.

Modify configuration of a deployed cluster using TiUP

For a deployed cluster:

1. Open the configuration file of the cluster in the edit mode (replace `CLUSTER_NAME` with the cluster name).

```
tiup cluster edit-config CLUSTER_NAME
```

2. Modify or add configuration items under the `pd` configuration of `server_configs`. If no `server_configs` exists, add it at the top level:

```
monitored:
  ...
server_configs:
  tidb: ...
  tikv: ...
  pd:
    dashboard.public-path-prefix: /foo
  ...
```

The configuration file after the modification is similar to the following file:

```
server_configs:
  pd:
    dashboard.public-path-prefix: /foo
  global:
    user: tidb
    ...
```

Or

```
monitored:
  ...
server_configs:
  tidb: ...
  tikv: ...
  pd:
    dashboard.public-path-prefix: /foo
```

3. Perform a rolling restart to all PD instances for the modified configuration to take effect (replace `CLUSTER_NAME` with your cluster name):

```
tiup cluster reload CLUSTER_NAME -R pd
```

See Common TiUP Operations - Modify the configuration for details.

If you want that the TiDB Dashboard service is run in the root path (such as `http://example.com:8033/`), use the following configuration:

```
server_configs:
  pd:
    dashboard.public-path-prefix: /
```

> **Warning:**
>
> After the modified and customized path prefix takes effect, you cannot directly access TiDB Dashboard. You can only access TiDB Dashboard through a reverse proxy that matches the path prefix.

Step 2: Modify the reverse proxy configuration

Use HAProxy

Taking `http://example.com:8033/foo/` as an example, the corresponding HAProxy configuration is as follows:

```
frontend tidb_dashboard_front
  bind *:8033
  use_backend tidb_dashboard_back if { path /foo } or { path_beg /foo/ }

backend tidb_dashboard_back
  mode http
  http-request set-path %[path,regsub(^/foo/?,/dashboard/)]
  server tidb_dashboard 192.168.0.123:2379
```

Replace `192.168.0.123:2379` with IP and port of the actual address of the TiDB Dashboard obtained in Step 1.

> **Warning:**
>
> You must retain the `if` part in the `use_backend` directive to ensure that services **only in this path** are behind reverse proxy; otherwise, security risks might be introduced. See Secure TiDB Dashboard.

If you want that the TiDB Dashboard service is run in the root path (such as `http://example.com:8033/`), use the following configuration:

```
frontend tidb_dashboard_front
  bind *:8033
  use_backend tidb_dashboard_back
backend tidb_dashboard_back
  mode http
  http-request set-path /dashboard%[path]
  server tidb_dashboard 192.168.0.123:2379
```

Modify the configuration and restart HAProxy for the modified configuration to take effect.

Use NGINX

Taking `http://example.com:8033/foo/` as an example, the corresponding NGINX configuration is as follows:

```
server {
  listen 8033;
  location /foo/ {
    proxy_pass http://192.168.0.123:2379/dashboard/;
  }
}
```

Replace `http://192.168.0.123:2379/dashboard/` with the actual address of the TiDB Dashboard obtained in Step 1.

> **Warning:**
>
> You must retain the `/dashboard/` path in the `proxy_pass` directive to ensure that services **only in this path** are behind reverse proxy; otherwise, security risks might be introduced. See Secure TiDB Dashboard.

If you want that the TiDB Dashboard service is run in the root path (such as `http://example.com:8033/`), use the following configuration:

```
server {
  listen 8033;
  location / {
    proxy_pass http://192.168.0.123:2379/dashboard/;
  }
}
```

Modify the configuration and restart NGINX for the modified configuration to take effect.

```
sudo nginx -s reload
```

9.5.2.2.3 What's next

To learn how to enhance the security of TiDB Dashboard, such as configuring a firewall, see Secure TiDB Dashboard.

9.5.2.3 TiDB Dashboard User Management

TiDB Dashboard uses the same user privilege system and sign-in authentication as TiDB. You can control and manage TiDB SQL users to limit their access to TiDB Dashboard. This document describes the least privileges required for TiDB SQL users to access TiDB Dashboard and exemplifies how to create a least-privileged SQL user and how to authorize via RBAC.

For details about how to control and manage TiDB SQL users, see TiDB User Account Management.

9.5.2.3.1 Required privileges

- To access TiDB Dashboard when Security Enhanced Mode (SEM) is not enabled on the connected TiDB server, the SQL user should have **all** the following privileges:
    - PROCESS
    - SHOW DATABASES
    - CONFIG
    - DASHBOARD_CLIENT
- To access TiDB Dashboard when Security Enhanced Mode (SEM) is enabled on the connected TiDB server, the SQL user should have **all** the following privileges:
    - PROCESS
    - SHOW DATABASES
    - CONFIG
    - DASHBOARD_CLIENT
    - RESTRICTED_TABLES_ADMIN
    - RESTRICTED_STATUS_ADMIN
    - RESTRICTED_VARIABLES_ADMIN
- To modify the configurations on the interface after signing in to TiDB Dashboard, the SQL user must also have the following privilege:
    - SYSTEM_VARIABLES_ADMIN
- To use the Fast Bind Executions Plan feature on the interface after signing in to TiDB Dashboard, the SQL user must also have the following privileges:
    - SYSTEM_VARIABLES_ADMIN
    - SUPER

Note:

Users with high privileges such as `ALL PRIVILEGES` or `SUPER` can sign in to TiDB Dashboard as well. Therefore, to comply with the least privilege principle, it is highly recommended that you create users with the required privileges only to prevent unintended operations. See Privilege Management for more information on these privileges.

If an SQL user does not meet the preceding privilege requirements, the user fails to sign in to TiDB Dashboard, as shown below.

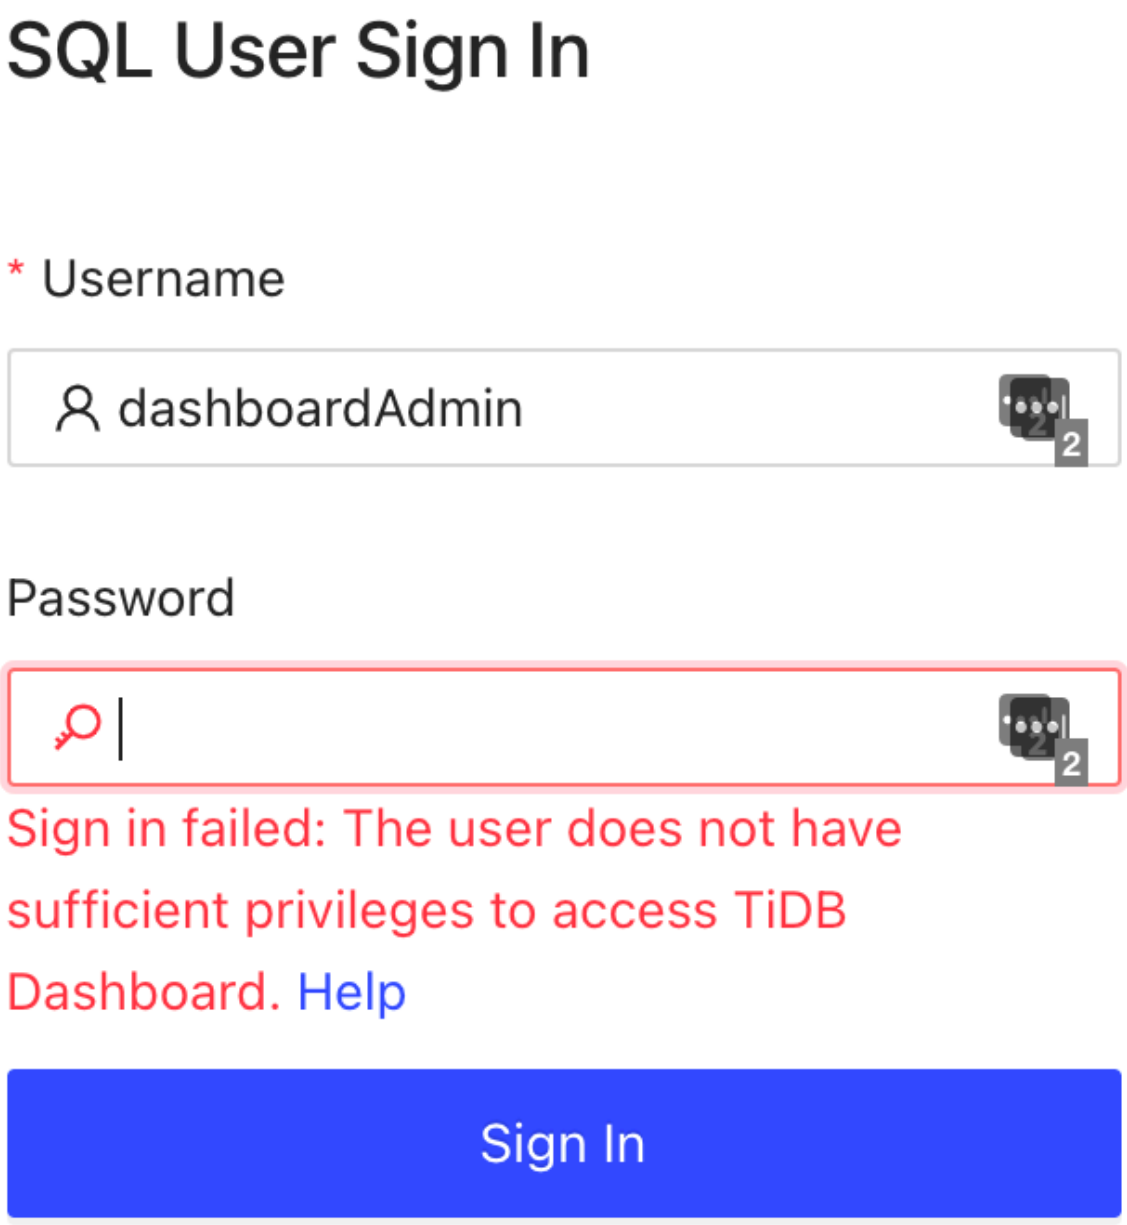

Figure 171: insufficient-privileges

9.5.2.3.2 Example: Create a least-privileged SQL user to access TiDB Dashboard

- When Security Enhanced Mode (SEM) is not enabled on the connected TiDB server, to create an SQL user `dashboardAdmin` that can sign in to TiDB Dashboard, execute the following SQL statements:

```
CREATE USER 'dashboardAdmin'@'%' IDENTIFIED BY '<YOUR_PASSWORD>';
GRANT PROCESS, CONFIG ON *.* TO 'dashboardAdmin'@'%';
GRANT SHOW DATABASES ON *.* TO 'dashboardAdmin'@'%';
GRANT DASHBOARD_CLIENT ON *.* TO 'dashboardAdmin'@'%';

-- To modify the configuration items on the interface after signing
   ↪ in to TiDB Dashboard, the user-defined SQL user must be granted
   ↪  with the following privilege.
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';

-- To use the Fast Bind Executions Plan feature (https://docs.pingcap
   ↪ .com/tidb/dev/dashboard-statement-details#fast-plan-binding) on
   ↪  the interface after signing in to TiDB Dashboard, the user-
   ↪ defined SQL user must be granted with the following privileges.
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';
GRANT SUPER ON *.* TO 'dashboardAdmin'@'%';
```

- When Security Enhanced Mode (SEM) is enabled on the connected TiDB server, disable SEM first and execute the following SQL statements to create an SQL user `dashboardAdmin` that can sign in to TiDB Dashboard. After creating the user, enable SEM again:

```
CREATE USER 'dashboardAdmin'@'%' IDENTIFIED BY '<YOUR_PASSWORD>';
GRANT PROCESS, CONFIG ON *.* TO 'dashboardAdmin'@'%';
GRANT SHOW DATABASES ON *.* TO 'dashboardAdmin'@'%';
GRANT DASHBOARD_CLIENT ON *.* TO 'dashboardAdmin'@'%';
GRANT RESTRICTED_STATUS_ADMIN ON *.* TO 'dashboardAdmin'@'%';
GRANT RESTRICTED_TABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';
GRANT RESTRICTED_VARIABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';

-- To modify the configuration items on the interface after signing
   ↪ in to TiDB Dashboard, the user-defined SQL user must be granted
   ↪  with the following privilege.
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';

-- To use the Fast Bind Executions Plan feature (https://docs.pingcap
   ↪ .com/tidb/dev/dashboard-statement-details#fast-plan-binding) on
   ↪  the interface after signing in to TiDB Dashboard, the user-
   ↪ defined SQL user must be granted with the following privileges.
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO 'dashboardAdmin'@'%';
GRANT SUPER ON *.* TO 'dashboardAdmin'@'%';
```

9.5.2.3.3 Example: Authorize SQL user to access TiDB Dashboard via RBAC

The following example demonstrates how to create a role and a user to access TiDB Dashboard through the role-based access control (RBAC) mechanism.

1. Create a `dashboard_access` role that meets all privilege requirements of TiDB Dashboard:

```
CREATE ROLE 'dashboard_access';
GRANT PROCESS, CONFIG ON *.* TO 'dashboard_access'@'%';
GRANT SHOW DATABASES ON *.* TO 'dashboard_access'@'%';
GRANT DASHBOARD_CLIENT ON *.* TO 'dashboard_access'@'%';
GRANT SYSTEM_VARIABLES_ADMIN ON *.* TO 'dashboard_access'@'%';
GRANT SUPER ON *.* TO 'dashboardAdmin'@'%';
```

2. Grant the `dashboard_access` role to other users and set `dashboard_access` as the default role:

```
CREATE USER 'dashboardAdmin'@'%' IDENTIFIED BY '<YOUR_PASSWORD>';
GRANT 'dashboard_access' TO 'dashboardAdmin'@'%';
-- You need to set dashboard_access as the default role to the user
SET DEFAULT ROLE dashboard_access to 'dashboardAdmin'@'%';
```

After the above steps, you can use the `dashboardAdmin` user to sign in to TiDB Dashboard.

9.5.2.3.4 Sign in to TiDB Dashboard

After creating an SQL user that meets the privilege requirements of TiDB Dashboard, you can use this user to Sign in to TiDB Dashboard.

9.5.2.4 Secure TiDB Dashboard

Although you need to sign into TiDB Dashboard before accessing it, TiDB Dashboard is designed to be accessed by trusted user entities by default. When you want to provide TiDB Dashboard to external network users or untrusted users for access, take the following measures to avoid security vulnerabilities.

9.5.2.4.1 Enhance security of TiDB users

Set a strong password for the TiDB `root` user

The account system of TiDB Dashboard is consistent with that of TiDB SQL users. By default, TiDB's `root` user has no password, so accessing TiDB Dashboard does not require password authentication, which will give the malicious visitor high privileges, including executing privileged SQL statements.

It is recommended that you set a strong password for the TiDB `root` user. See TiDB User Account Management for details. Alternatively, you can disable the TiDB `root` user.

Create a least-privileged user for TiDB Dashboard

The account system of TiDB Dashboard is consistent with that of TiDB SQL. Users accessing TiDB Dashboard are authenticated and authorized based on TiDB SQL user's privileges. Therefore, TiDB Dashboard requires limited privileges, or merely the read-only privilege. You can configure users to access TiDB Dashboard based on the principle of least privilege, thus avoiding access of high-privileged users.

It is recommended that you create a least-privileged SQL user to access and sign in to TiDB Dashboard. This avoids access of high-privileged users and improves security. See TiDB Dashboard User Management for details.

9.5.2.4.2 Use a firewall to block untrusted access

> **Note:**
>
> TiDB v6.5.0 (and later) and TiDB Operator v1.4.0 (and later) support deploying TiDB Dashboard as an independent Pod on Kubernetes. Using TiDB Operator, you can access the IP address of this Pod to start TiDB Dashboard. This port does not communicate with other privileged interfaces of PD and no extra firewall is required if provided externally. For details, see Deploy TiDB Dashboard independently in TiDB Operator.

TiDB Dashboard provides services through the PD client port, which defaults to http://IP:2379/dashboard/. Although TiDB Dashboard requires identity authentication, other privileged interfaces (such as http://IP:2379/pd/api/v1/members) in PD carried on the PD client port do not require identity authentication and can perform privileged operations. Therefore, exposing the PD client port directly to the external network is extremely risky.

It is recommended that you take the following measures:

- Use a firewall to prohibit a component from accessing **any** client port of the PD component via the external network or untrusted network.

> **Note:**
>
> TiDB, TiKV, and other components need to communicate with the PD component through the PD client port, so do not block access to the internal network between components. Otherwise, the cluster will become unavailable.

- See Use TiDB Dashboard behind a Reverse Proxy to learn how to configure the reverse proxy to safely provide the TiDB Dashboard service on another port to the external network.

How to open access to TiDB Dashboard port when deploying multiple PD instances

> **Warning:**
>
> This section describes an unsafe access solution, which is for the test environment only. **DO NOT** use this solution in the production environment.

In the test environment, you might need to configure the firewall to open the TiDB Dashboard port for external access.

When multiple PD instances are deployed, only one of the PD instances actually runs TiDB Dashboard, and browser redirection occurs when you access other PD instances. Therefore, you need to ensure that the firewall is configured with the correct IP address. For details of this mechanism, see Deployment with multiple PD instances.

When using the TiUP deployment tool, you can view the address of the PD instance that actually runs TiDB Dashboard by running the following command (replace `CLUSTER_NAME` with the cluster name):

```
tiup cluster display CLUSTER_NAME --dashboard
```

The output is the actual TiDB Dashboard address.

> **Note:**
>
> This feature is available only in the later version of the `tiup cluster` deployment tool (v1.0.3 or later).
>
> Upgrade TiUP Cluster
>
> ```
> tiup update --self
> tiup update cluster --force
> ```

The following is a sample output:

```
http://192.168.0.123:2379/dashboard/
```

In this example, the firewall needs to be configured with inbound access for the `2379` port of the `192.168.0.123` open IP, and the TiDB Dashboard is accessed via http://192.168.0.123:2379/dashboard/.

9.5.2.4.3 Reverse proxy only for TiDB Dashboard

As mentioned in Use a firewall to block untrusted access, the services provided under the PD client port include not only TiDB Dashboard (located at http://IP:2379/dashboard/), but also other privileged interfaces in PD (such as http://IP:2379/pd/api/v1/members). Therefore, when using a reverse proxy to provide TiDB Dashboard to the external network, ensure that the services **ONLY** with the `/dashboard` prefix are provided (**NOT** all services under the port) to avoid that the external network can access the privileged interface in PD through the reverse proxy.

It is recommended that you see Use TiDB Dashboard behind a Reverse Proxy to learn a safe and recommended reverse proxy configuration.

9.5.2.4.4 Enable TLS for reverse proxy

To further enhance the security of the transport layer, you can enable TLS for reverse proxy, and even introduce mTLS to authenticate user certificates.

See Configuring HTTPS servers and HAProxy SSL Termination for more details.

9.5.2.4.5 Other recommended safety measures

- Enable TLS Authentication and Encrypt the Stored Data
- Enable TLS Between TiDB Clients and Servers

9.5.3 Access TiDB Dashboard

To access TiDB Dashboard, visit http://127.0.0.1:2379/dashboard via your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

> **Note:**
>
> TiDB v6.5.0 (and later) and TiDB Operator v1.4.0 (and later) support deploying TiDB Dashboard as an independent Pod on Kubernetes. Using TiDB Operator, you can access the IP address of this Pod to start TiDB Dashboard. For details, see Deploy TiDB Dashboard independently in TiDB Operator.

9.5.3.1 Access TiDB Dashboard when multiple PD instances are deployed

When multiple PD instances are deployed in your cluster and you can directly access **every** PD instance and port, you can simply replace `127.0.0.1:2379` in the http://127.0.0.1:2379/dashboard/ address with **any** PD instance address and port.

> **Note:**
>
> If a firewall or reverse proxy is configured and you cannot directly access every PD instance, you might not be able to access TiDB Dashboard. Usually, this is because the firewall or reverse proxy is not correctly configured. See Use TiDB Dashboard behind Reverse Proxy and Secure TiDB Dashboard to learn how to correctly configure the firewall or reverse proxy when multiple PD instances are deployed.

9.5.3.2 Browser compatibility

You can use TiDB Dashboard in the following common desktop browsers of a relatively newer version:

- Chrome >= 77
- Firefox >= 68
- Edge >= 17

> **Note:**
>
> If you use the browsers above of earlier versions or other browsers to access TiDB Dashboard, some functions might not work properly.

9.5.3.3 Sign in

After accessing TiDB Dashboard, you will be directed to the user login interface.

- You can sign in to TiDB Dashboard using the TiDB `root` account.
- You can also sign in to TiDB Dashboard via Single Sign-On (SSO). For more information, see Configure SSO for TiDB Dashboard.
- If you have created a User-defined SQL User, you can sign in using this account and the corresponding password.

If one of the following situations exists, the login might fail:

- TiDB `root` user does not exist.
- PD is not started or cannot be accessed.
- TiDB is not started or cannot be accessed.

- Wrong `root` password.

Once you have signed in, the session remains valid within the next 24 hours. To learn how to sign out, refer to the Logout section.

9.5.3.4 Switch language

The following languages are supported in TiDB Dashboard:

- English
- Chinese (simplified)

In the **SQL User Sign In** page, you can click the **Switch Language** drop-down list to switch the interface language.

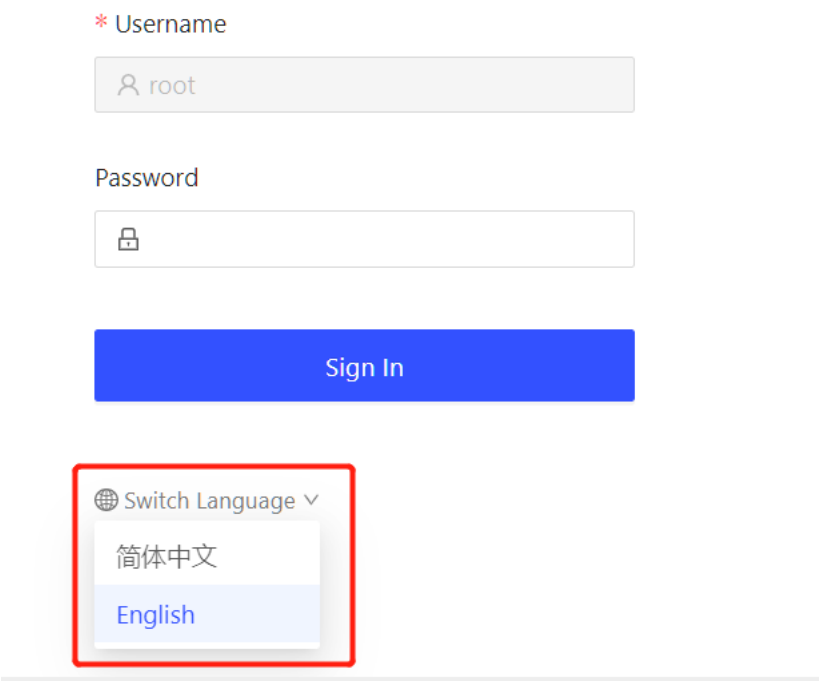

Figure 172: Switch language

9.5.3.5 Logout

Once you have logged in, click the login user name in the left navigation bar to switch to the user page. Click the **Logout** button on the user page to log out the current user. After logging out, you need to re-enter your username and password.

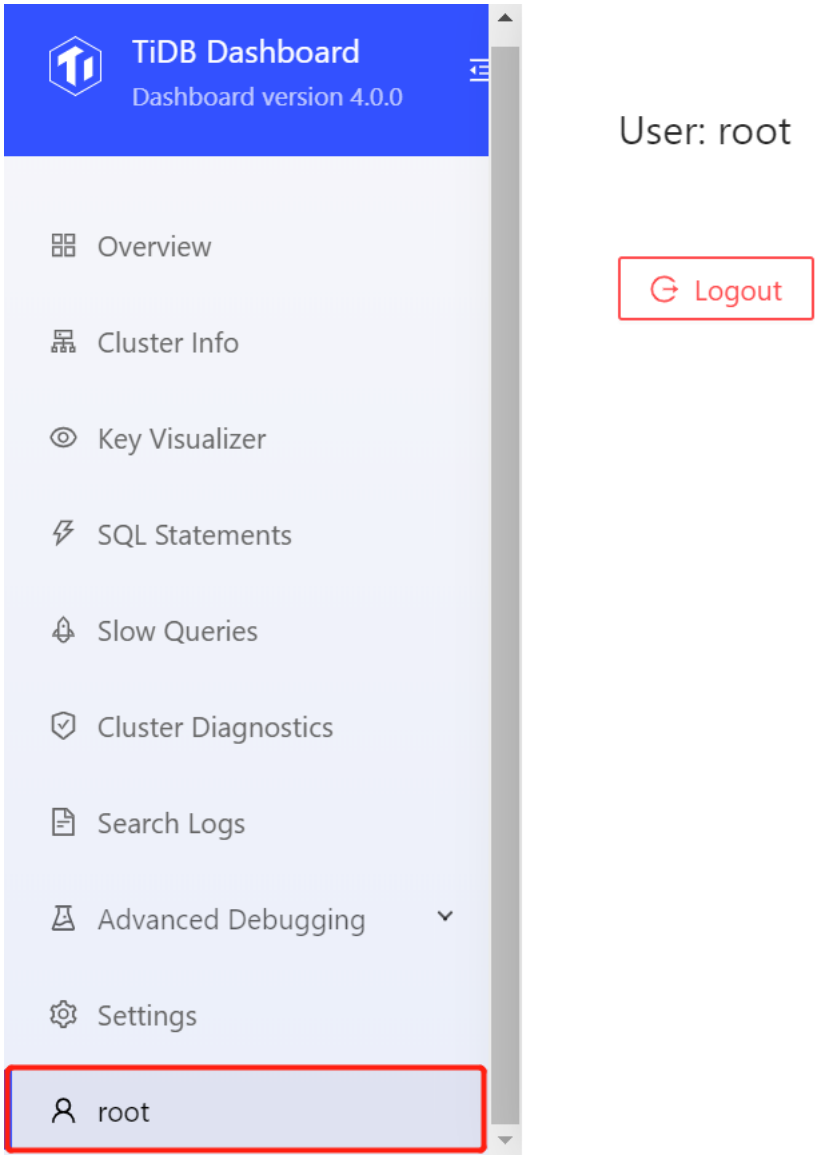

Figure 173: Logout

9.5.4 Overview Page

This page shows the overview of the entire TiDB cluster, including the following information:

- Queries per second (QPS) of the entire cluster.
- The query latency of the entire cluster.
- The SQL statements that have accumulated the longest execution time over the recent period.
- The slow queries whose execution time over the recent period exceeds the threshold.
- The node count and status of each instance.
- Monitor and alert messages.

9.5.4.1 Access the page

After logging in to TiDB Dashboard, the overview page is entered by default, or you can click **Overview** in the left navigation menu to enter this page:

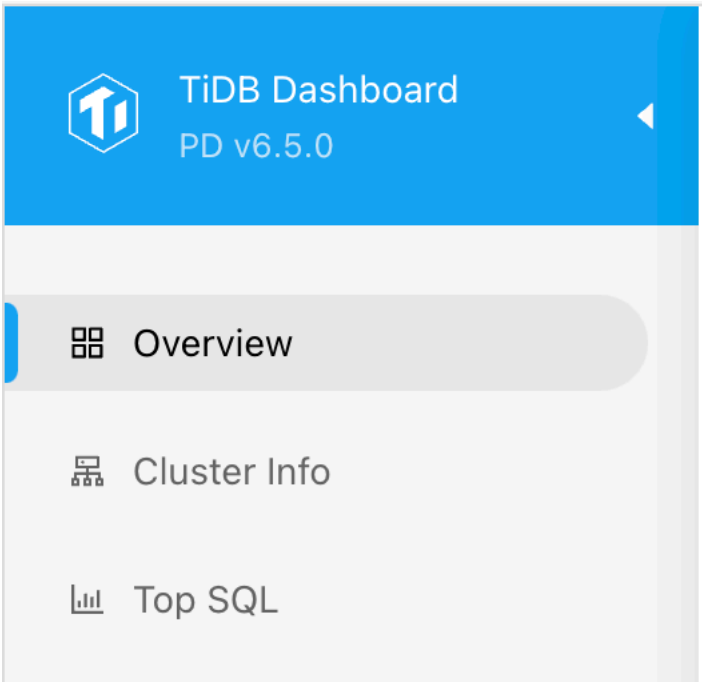

Figure 174: Enter overview page

9.5.4.2 QPS

This area shows the number of successful and failed queries per second for the entire cluster over the recent hour:

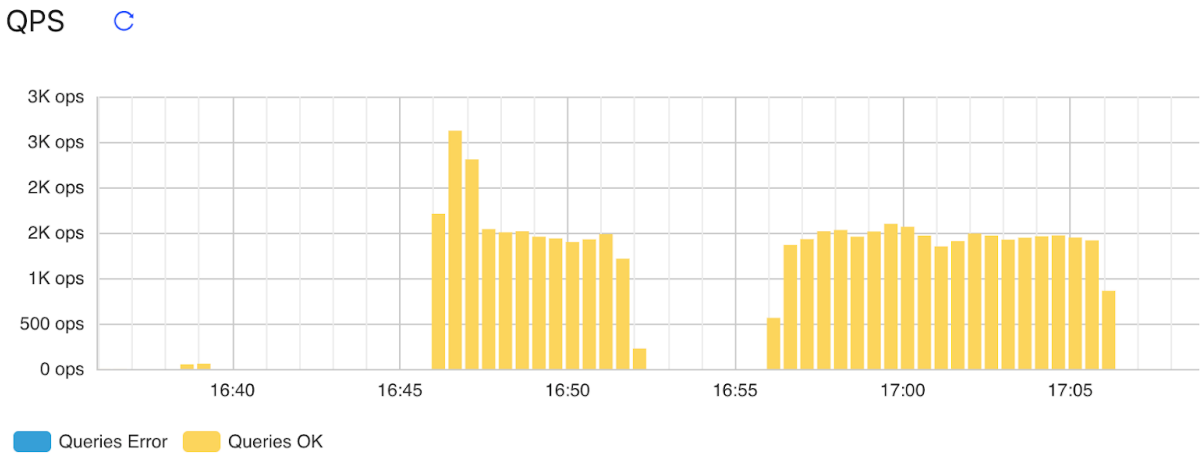

Figure 175: QPS

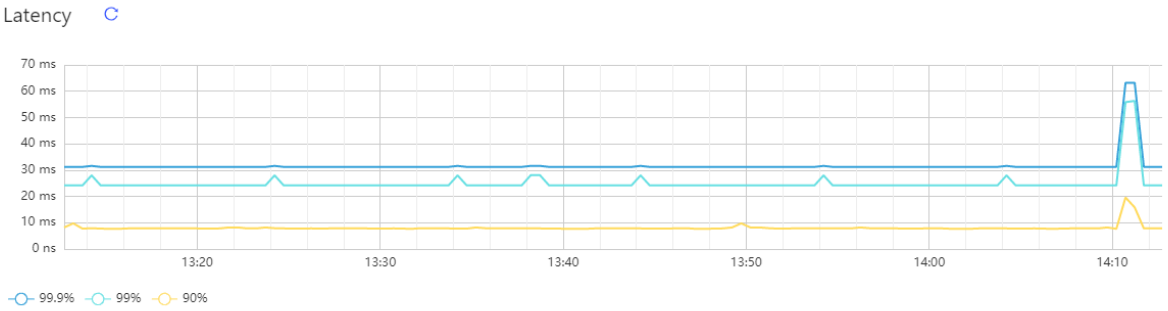
Note:

This feature is available only in the cluster where the Prometheus monitoring component is deployed. If Prometheus is not deployed, an error will be displayed.

9.5.4.3 Latency

This area shows the latency of 99.9%, 99%, and 90% of queries in the entire cluster over the recent one hour:



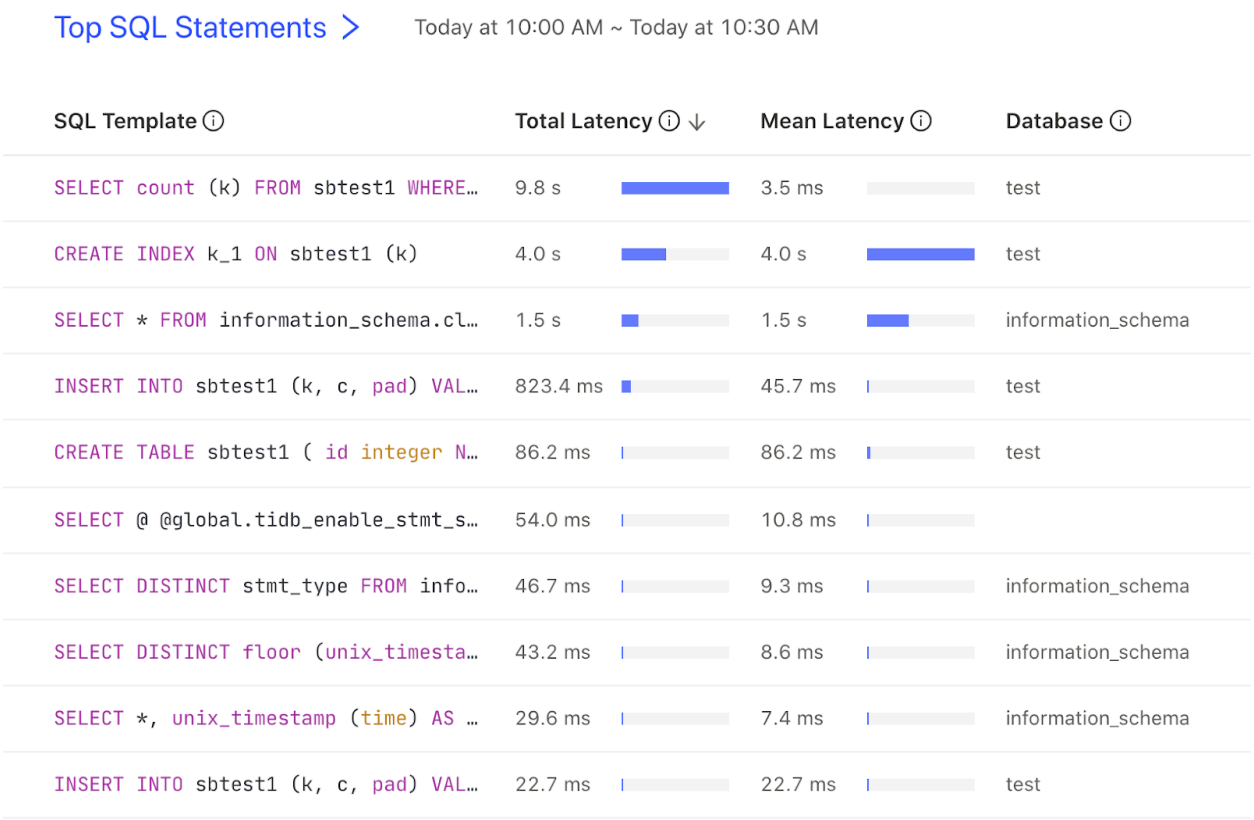


Figure 176: Latency

Note:

This feature is available only on the cluster where the Prometheus monitoring component is deployed. If Prometheus is not deployed, an error will be displayed.

9.5.4.4 Top SQL statements

This area shows the ten types of SQL statements that have accumulated the longest execution time in the entire cluster over the recent period. SQL statements with different query parameters but of the same structure are classified into the same SQL type and displayed in the same row:

Top SQL Statements > Today at 10:00 AM ~ Today at 10:30 AM

SQL Template	Total Latency ↓	Mean Latency	Database
SELECT count (k) FROM sbtest1 WHERE…	9.8 s	3.5 ms	test
CREATE INDEX k_1 ON sbtest1 (k)	4.0 s	4.0 s	test
SELECT * FROM information_schema.cl…	1.5 s	1.5 s	information_schema
INSERT INTO sbtest1 (k, c, pad) VAL…	823.4 ms	45.7 ms	test
CREATE TABLE sbtest1 (id integer N…	86.2 ms	86.2 ms	test
SELECT @ @global.tidb_enable_stmt_s…	54.0 ms	10.8 ms	
SELECT DISTINCT stmt_type FROM info…	46.7 ms	9.3 ms	information_schema
SELECT DISTINCT floor (unix_timesta…	43.2 ms	8.6 ms	information_schema
SELECT *, unix_timestamp (time) AS …	29.6 ms	7.4 ms	information_schema
INSERT INTO sbtest1 (k, c, pad) VAL…	22.7 ms	22.7 ms	test

Figure 177: Top SQL

The information shown in this area is consistent with the more detailed SQL Statements Page. You can click the **Top SQL Statements** heading to view the complete list. For details of the columns in this table, see SQL Statements Page.

> **Note:**
>
> This feature is available only on the cluster where SQL Statements feature is enabled.

9.5.4.5 Recent slow queries

By default, this area shows the latest 10 slow queries in the entire cluster over the recent 30 minutes:

Figure 178: Recent slow queries

By default, the SQL query that is executed longer than 300 milliseconds is counted as a slow query and displayed on the table. You can change this threshold by modifying the tidb_slow_log_threshold variable or the instance.tidb_slow_log_threshold TiDB parameter.

The content displayed in this area is consistent with the more detailed Slow Queries Page. You can click the **Recent Slow Queries** title to view the complete list. For details of the columns in this table, see this Slow Queries Page.

> **Note:**
>
> This feature is available only in the cluster with slow query logs enabled. By default, slow query logs are enabled in the cluster deployed using TiUP.

9.5.4.6 Instances

This area summarizes the total number of instances and abnormal instances of TiDB, TiKV, PD, and TiFlash in the entire cluster:

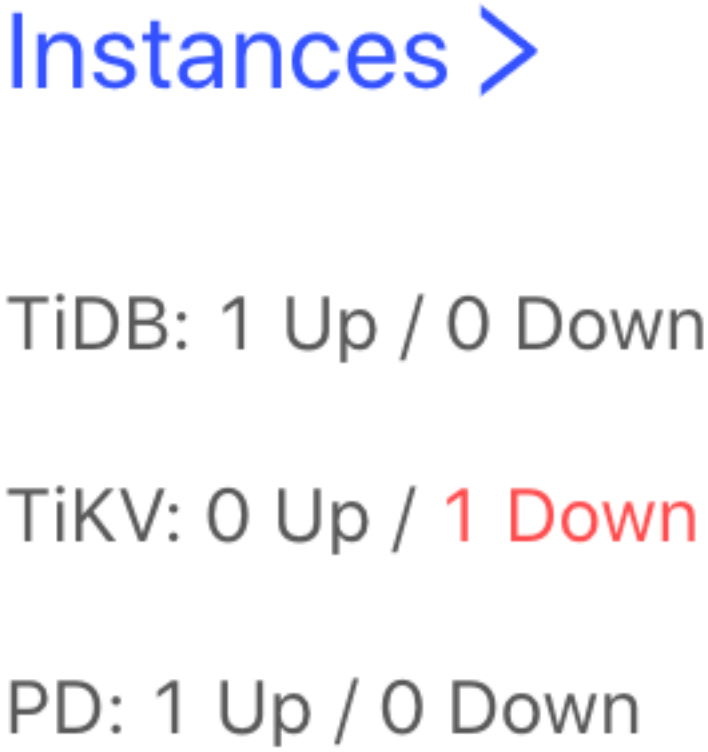

Figure 179: Instances

The statuses in the preceding image are described as follows:

- Up: The instance is running properly (including the offline storage instance).
- Down: The instance is running abnormally, such as network disconnection and process crash.

Click the **Instance** title to enter the Cluster Info Page that shows the detailed running status of each instance.

9.5.4.7 Monitor and alert

This area provides links for you to view detailed monitor and alert:

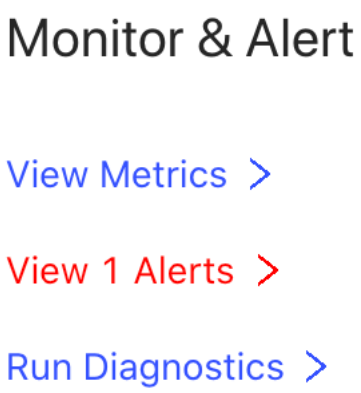

Figure 180: Monitor and alert

- **View Metrics**: Click this link to jump to the Grafana dashboard where you can view detailed monitoring information of the cluster. For details of each monitoring metric in the Grafana dashboard, see monitoring metrics.
- **View Alerts**: Click this link to jump to the AlertManager page where you can view detailed alert information of the cluster. If alerts exist in the cluster, the number of alerts is directly shown in the link text.
- **Run Diagnostics**: Click this link to jump to the more detailed cluster diagnostics page.

> **Note:**
>
> The **View Metrics** link is available only in the cluster where the Grafana node is deployed. The **View Alerts** link is available only in the cluster where the AlertManager node is deployed.

9.5.5 TiDB Dashboard Cluster Information Page

On the cluster information page, you can view the running status of TiDB, TiKV, PD, TiFlash components in the entire cluster and the running status of the host on which these components are located.

9.5.5.1 Access the page

You can use one of the following two methods to access the cluster information page:

- After logging in to TiDB Dashboard, click **Cluster Info** in the left navigation menu.
- Visit http://127.0.0.1:2379/dashboard/#/cluster_info/instance in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

9.5.5.2 Instance list

Click **Instances** to view the list of instances:

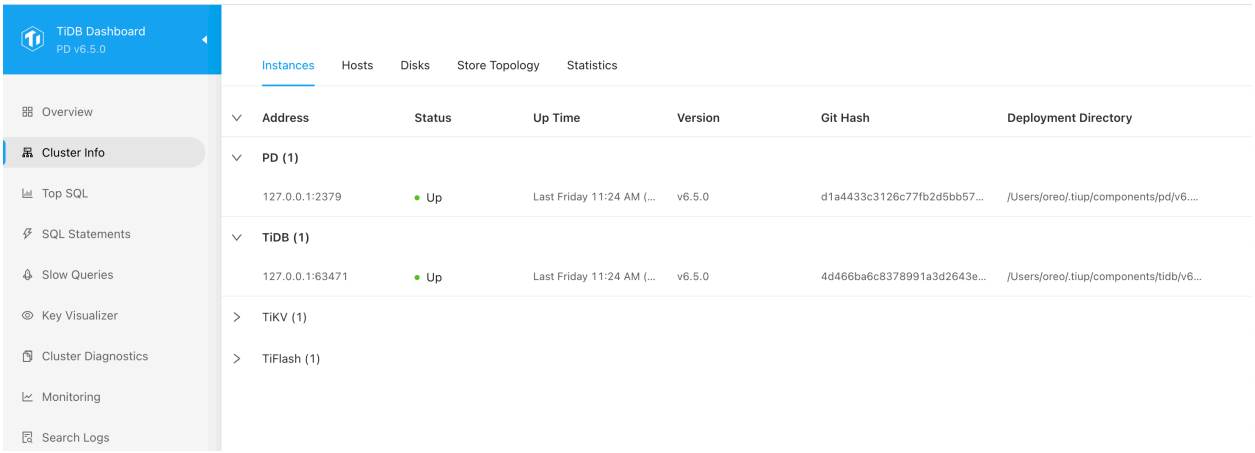

Figure 181: Instance list

This instance list shows the overview information of all instances of TiDB, TiKV, PD, and TiFlash components in the cluster.

The list includes the following information:

- Address: The instance address.
- Status: The running status of the instance.
- Up Time: The start time of the instance.
- Version: The instance version number.
- Git Hash: The Git Hash value corresponding to the instance binary file.
- Deployment directory: The directory in which the instance binary file is located.

9.5.5.2.1 Instance status

An instance can run in one of the following statuses:

- Up: The instance is running normally.
- Down or Unreachable: The instance is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the instance has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash instances.

- Leaving: The data on the instance is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash instances.
- Unknown: The running state of the instance is unknown.

> **Note:**
>
> - `Leaving` in TiDB Dashboard, `Offline` returned by PD API, and `Pending Offline` in TiUP indicate the same status.
> - Some columns in the table can be displayed only when the instance is up.

Instance status derives from the PD scheduling information. For more details, see Information collection.

9.5.5.3 Host list

Click **Hosts** to view the list of hosts:

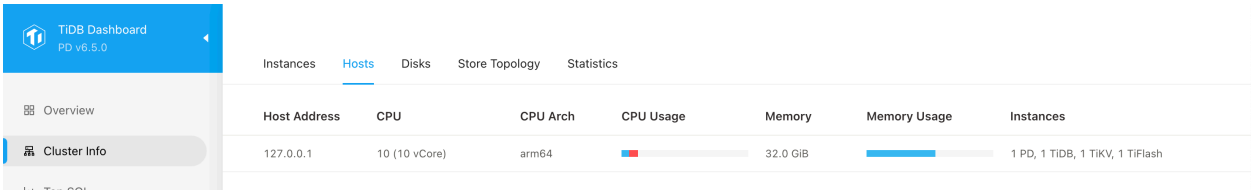

Figure 182: Host list

This host list shows the running status of hosts that correspond to all instances of TiDB, TiKV, PD, and TiFlash components in the cluster.

The list includes the following information:

- Host Address: The Host IP address.
- CPU: The number of logical cores of the host CPU.
- CPU Usage: The user-mode and kernel-mode CPU usage in the current 1 second.
- Memory: The total physical memory size of the host.
- Memory Usage: The current memory usage of the host.

> **Note:**
>
> The host list information is provided by each instance process, so when all instances on the host are down, the host information is not displayed.

9.5.5.4 Disk list

Click **Disks** to view the list of disks:

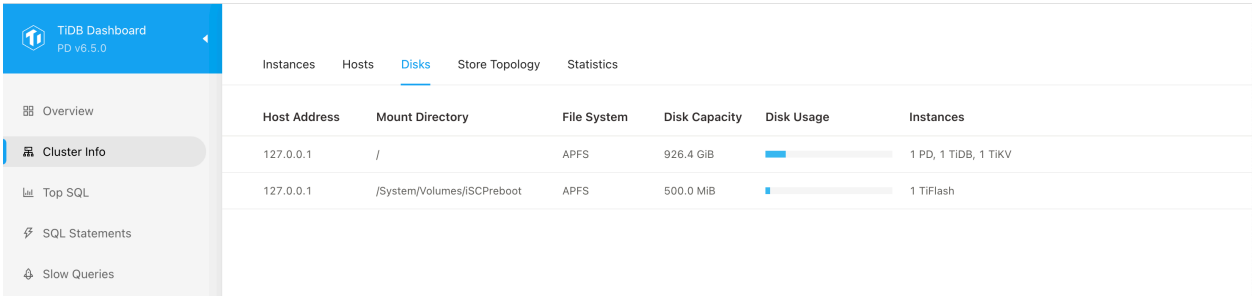

Figure 183: Disk list

This disk list shows the status of disks on which the TiDB, TiKV, PD, and TiFlash instances run.

The list includes the following information:

- Host Address: The Host IP address.
- Mount Directory: The mount path of this disk on the host on which the instance is running.
- File System: The file system type of this disk on the host on which the instance is running.
- Disk Capacity: The total space of the disk on the host on which the instance is running.
- Disk Usage: The space usage of the disk on the host on which the instance is running.
- Instance: The instance running on this host.

9.5.6 TiDB Dashboard Top SQL Page

With Top SQL, you can monitor and visually explore the CPU overhead of each SQL statement in your database in real-time, which helps you optimize and resolve database performance issues. Top SQL continuously collects and stores CPU load data summarized by SQL statements at any seconds from all TiDB and TiKV instances. The collected data can be stored for up to 30 days. Top SQL presents you with visual charts and tables to quickly pinpoint which SQL statements are contributing the high CPU load of a TiDB or TiKV instance over a certain period of time.

Top SQL provides the following features:

- Visualize the top 5 types of SQL statements with the highest CPU overhead through charts and tables.
- Display detailed execution information such as queries per second, average latency, and query plan.
- Collect all SQL statements that are executed, including those that are still running.
- Allow viewing data of a specific TiDB and TiKV instance.

9.5.6.1 Recommended scenarios

Top SQL is suitable for analyzing performance issues. The following are some typical Top SQL scenarios:

- You discovered that an individual TiKV instance in the cluster has a very high CPU usage through the Grafana charts. You want to know which SQL statements cause the CPU hotspots so that you can optimize them and better leverage all of your distributed resources.
- You discovered that the cluster has a very high CPU usage overall and queries are slow. You want to quickly figure out which SQL statements are currently consuming the most CPU resources so that you can optimize them.
- The CPU usage of the cluster has drastically changed and you want to know the major cause.
- Analyze the most resource-intensive SQL statements in the cluster and optimize them to reduce hardware costs.

Top SQL cannot be used in the following scenarios:

- Top SQL cannot be used to pinpoint non-performance issues, such as incorrect data or abnormal crashes.
- Top SQL does not support analyzing database performance issues that are not caused by high CPU load, such as transaction lock conflicts.

9.5.6.2 Access the page

You can access the Top SQL page using either of the following methods:

- After logging in to TiDB Dashboard, click **Top SQL** in the left navigation menu.

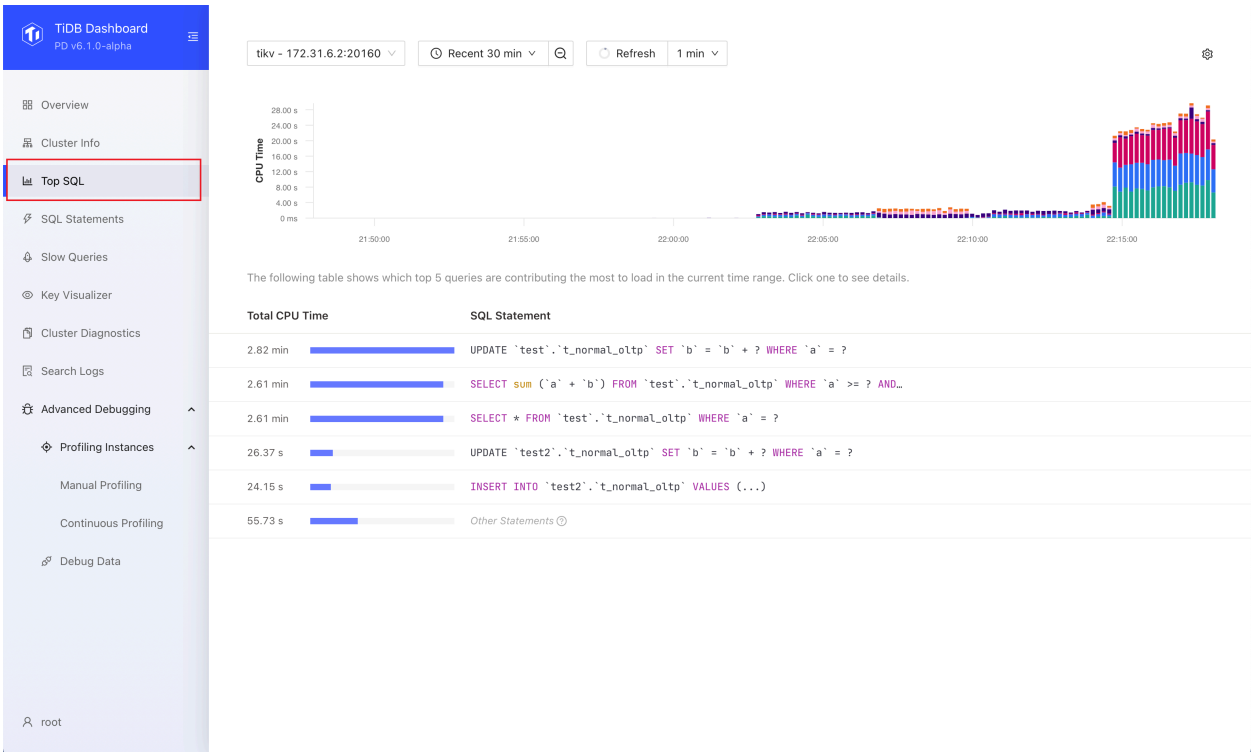

Figure 184: Top SQL

- Visit http://127.0.0.1:2379/dashboard/#/topsql in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

9.5.6.3 Enable Top SQL

> **Note:**
>
> To use Top SQL, your cluster should be deployed or upgraded with a recent version of TiUP (v1.9.0 or above) or TiDB Operator (v1.3.0 or above). If your cluster was upgraded using an earlier version of TiUP or TiDB Operator, see FAQ for instructions.

Top SQL is not enabled by default as it has a slight impact on cluster performance (within 3% on average) when enabled. You can enable Top SQL by the following steps:

1. Visit the Top SQL page.
2. Click **Open Settings**. On the right side of the **Settings** area, switch on **Enable Feature**.

3. Click **Save**.

After enabling the feature, wait up to 1 minute for Top SQL to load the data. Then you can see the CPU load details.

In addition to the UI, you can also enable the Top SQL feature by setting the TiDB system variable `tidb_enable_top_sql`:

```
SET GLOBAL tidb_enable_top_sql = 1;
```

9.5.6.4 Use Top SQL

The following are the common steps to use Top SQL.

1. Visit the Top SQL page.
2. Select a particular TiDB or TiKV instance that you want to observe the load.

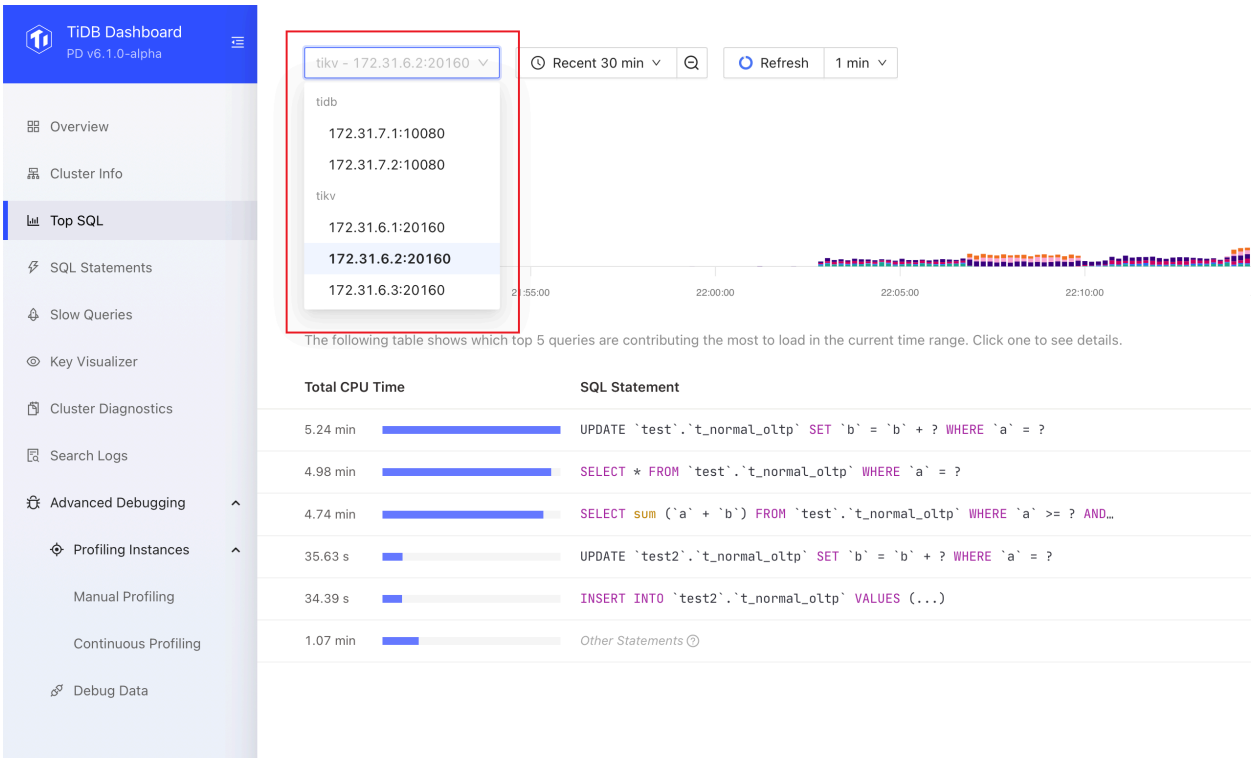

Figure 185: Select Instance

If you are unsure of which TiDB or TiKV instance to observe, you can select an arbitrary instance. Also, when the cluster CPU load is extremely unbalanced, you can first use Grafana charts to determine the specific instance you want to observe.

3. Observe the charts and tables presented by Top SQL.

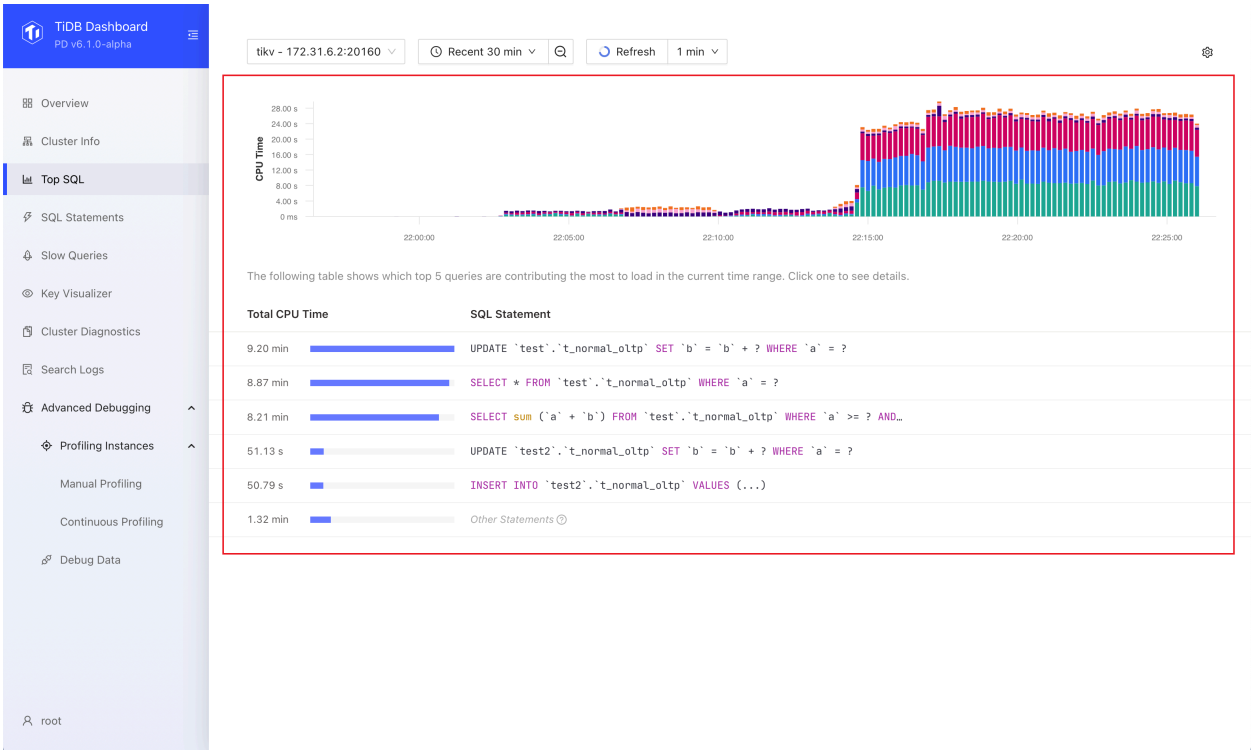

Figure 186: Chart and Table

The size of the bars in the bar chart represents the size of CPU resources consumed by the SQL statement at that moment. Different colors distinguish different types of SQL statements. In most cases, you only need to focus on the SQL statements that have a higher CPU resource overhead in the corresponding time range in the chart.

4. Click a SQL statement in the table to show more information. You can see detailed execution metrics of different plans of that statement, such as Call/sec (average queries per second) and Scan Indexes/sec (average number of index rows scanned per second).

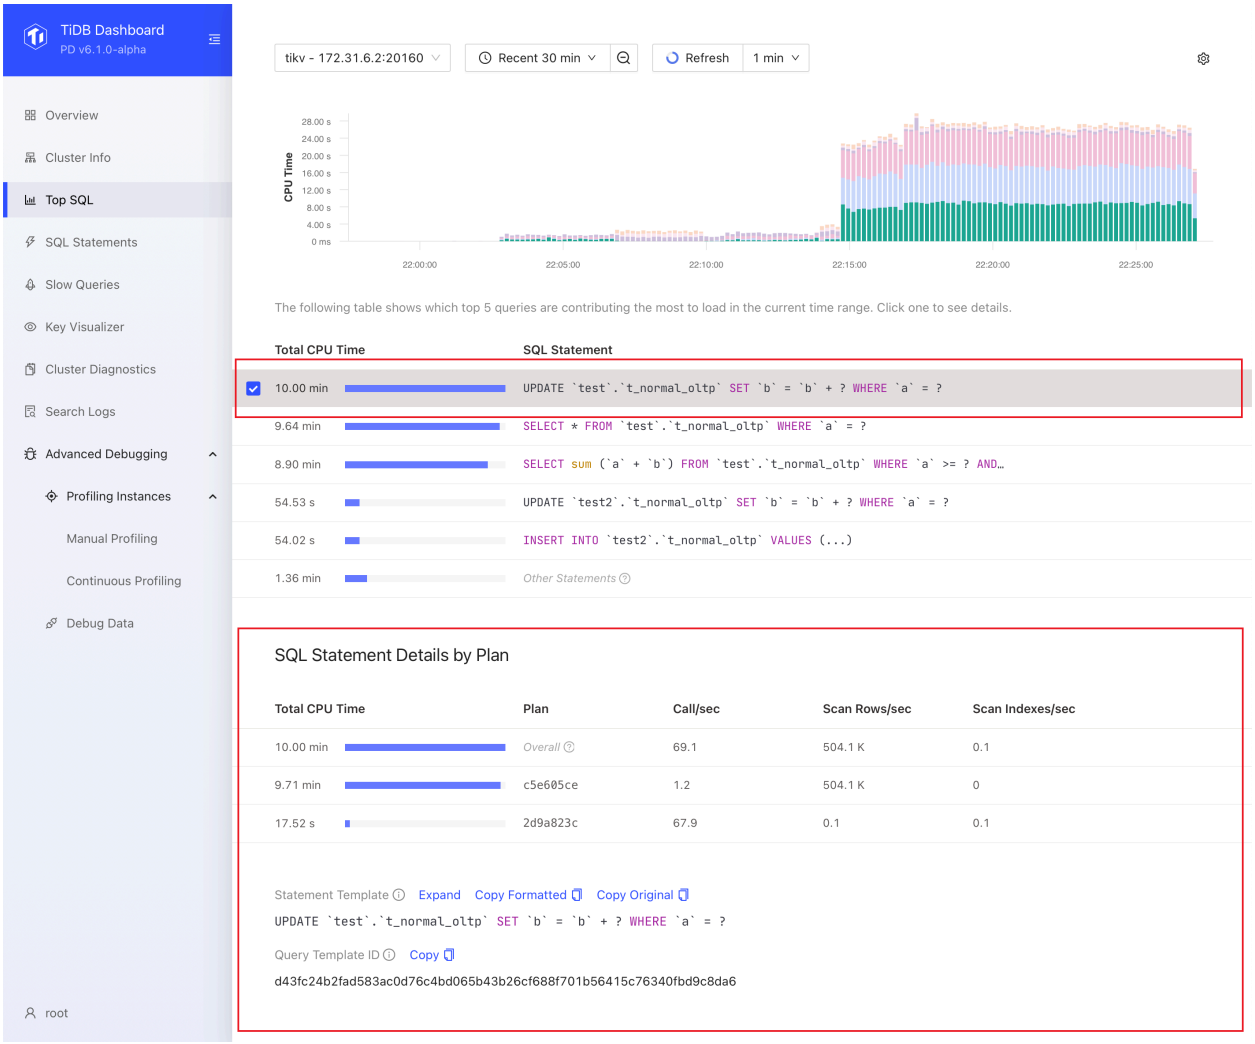

Figure 187: Details

5. Based on these initial clues, you can further explore the SQL Statement or Slow Queries page to find the root cause of high CPU consumption or large data scans of the SQL statement.

   You can adjust the time range in the time picker or select a time range in the chart to get a more precise and detailed look at the problem. A smaller time range can provide more detailed data, with precision of up to 1 second.

Figure 188: Change time range

If the chart is out of date, you can click the **Refresh** button or select Auto Refresh options from the **Refresh** drop-down list.

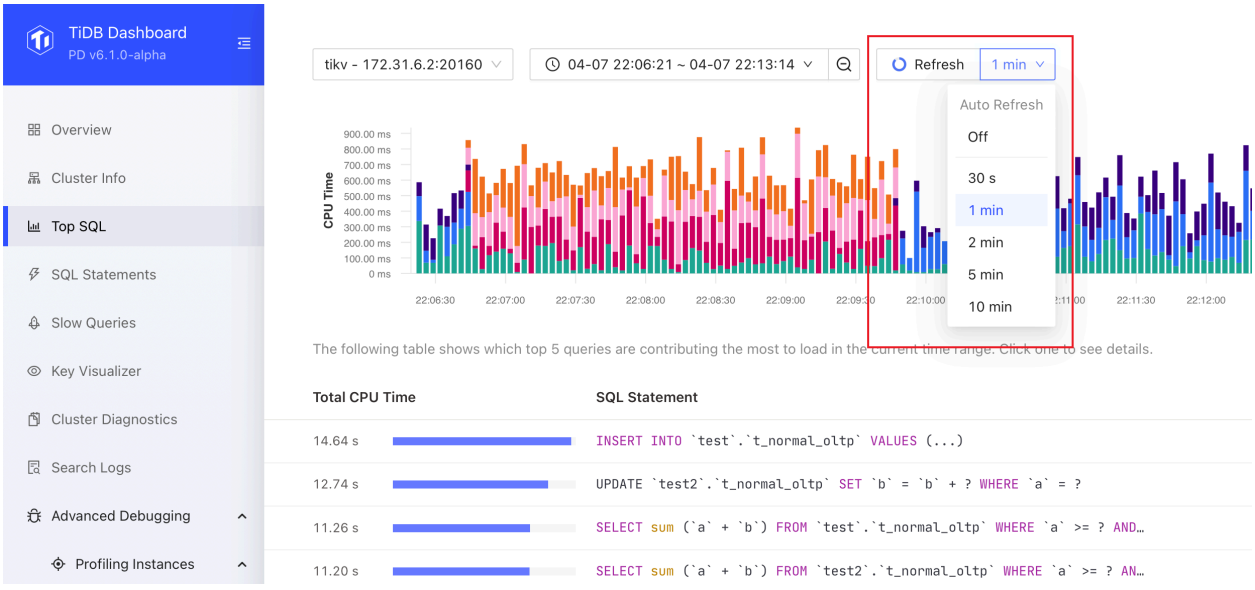

Figure 189: Refresh

6. View the CPU resource usage by table or database level to quickly identify resource

usage at a higher level. Currently, only TiKV instances are supported. Select a TiKV instance, and then select **By TABLE** or **By DB**:

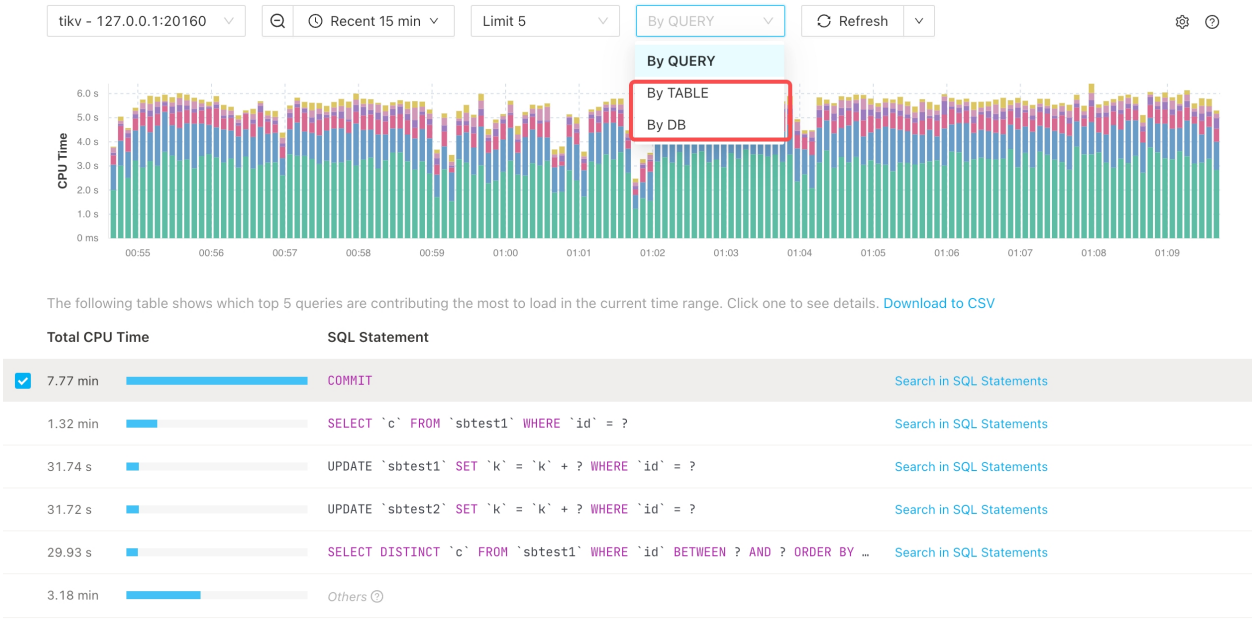

Figure 190: Select aggregation dimension

View the aggregated results at a higher level:

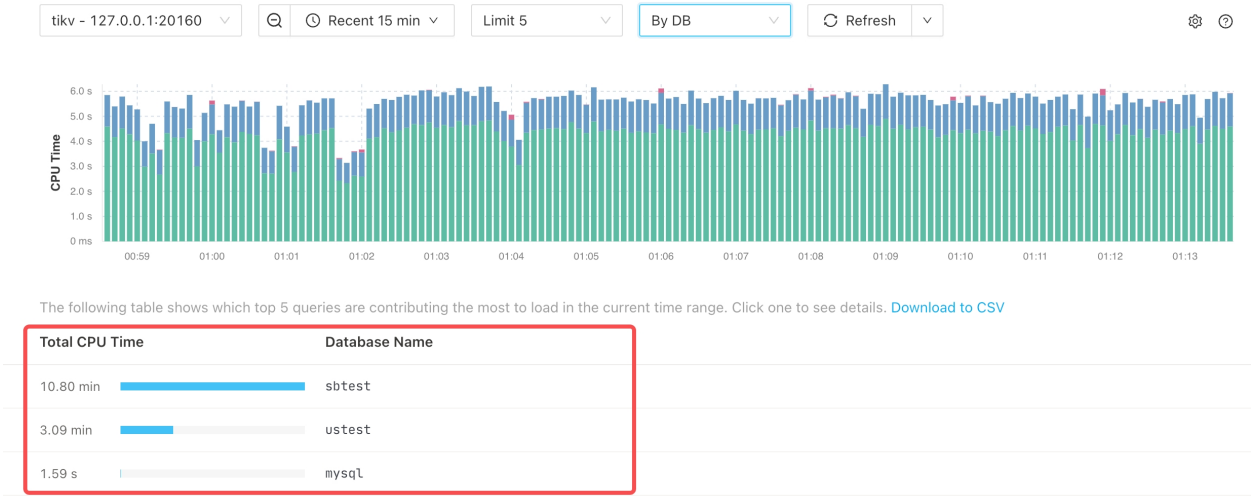

Figure 191: Aggregated results at DB level

9.5.6.5 Disable Top SQL

You can disable this feature by following these steps:

1. Visit Top SQL page.
2. Click the gear icon in the upper right corner to open the settings screen and switch off **Enable Feature**.
3. Click **Save**.
4. In the popped-up dialog box, click **Disable**.

In addition to the UI, you can also disable the Top SQL feature by setting the TiDB system variable `tidb_enable_top_sql`:

```
SET GLOBAL tidb_enable_top_sql = 0;
```

9.5.6.6 Frequently asked questions

1. Top SQL cannot be enabled and the UI displays "required component NgMonitoring is not started".

See TiDB Dashboard FAQ.

2. Will performance be affected after enabling Top SQL?

This feature has a slight impact on cluster performance. According to our benchmark, the average performance impact is usually less than 3% when the feature is enabled.

3. What is the status of this feature?

It is now a generally available (GA) feature and can be used in production environments.

4. What is the meaning of "Other Statements"?

"Other Statement" counts the total CPU overhead of all non-Top 5 statements. With this information, you can learn the CPU overhead contributed by the Top 5 statements compared with the overall.

5. What is the relationship between the CPU overhead displayed by Top SQL and the actual CPU usage of the process?

Their correlation is strong but they are not exactly the same thing. For example, the cost of writing multiple replicas is not counted in the TiKV CPU overhead displayed by Top SQL. In general, SQL statements with higher CPU usage result in higher CPU overhead displayed in Top SQL.

6. What is the meaning of the Y-axis of the Top SQL chart?

It represents the size of CPU resources consumed. The more resources consumed by a SQL statement, the higher the value is. In most cases, you do not need to care about the meaning or unit of the specific value.

7. Does Top SQL collect running (unfinished) SQL statements?

Yes. The bars displayed in the Top SQL chart at each moment indicate the CPU overhead of all running SQL statements at that moment.

9.5.7 Key Visualizer Page

The Key Visualizer page of TiDB Dashboard is used to analyze the usage of TiDB and troubleshoot traffic hotspots. This page visually shows the traffic of the TiDB cluster over a period of time.

9.5.7.1 Access Key Visualizer page

You can use one of the following two methods to access the Key Visualizer page:

- After logging in to TiDB Dashboard, click **Key Visualizer** in the left navigation menu.

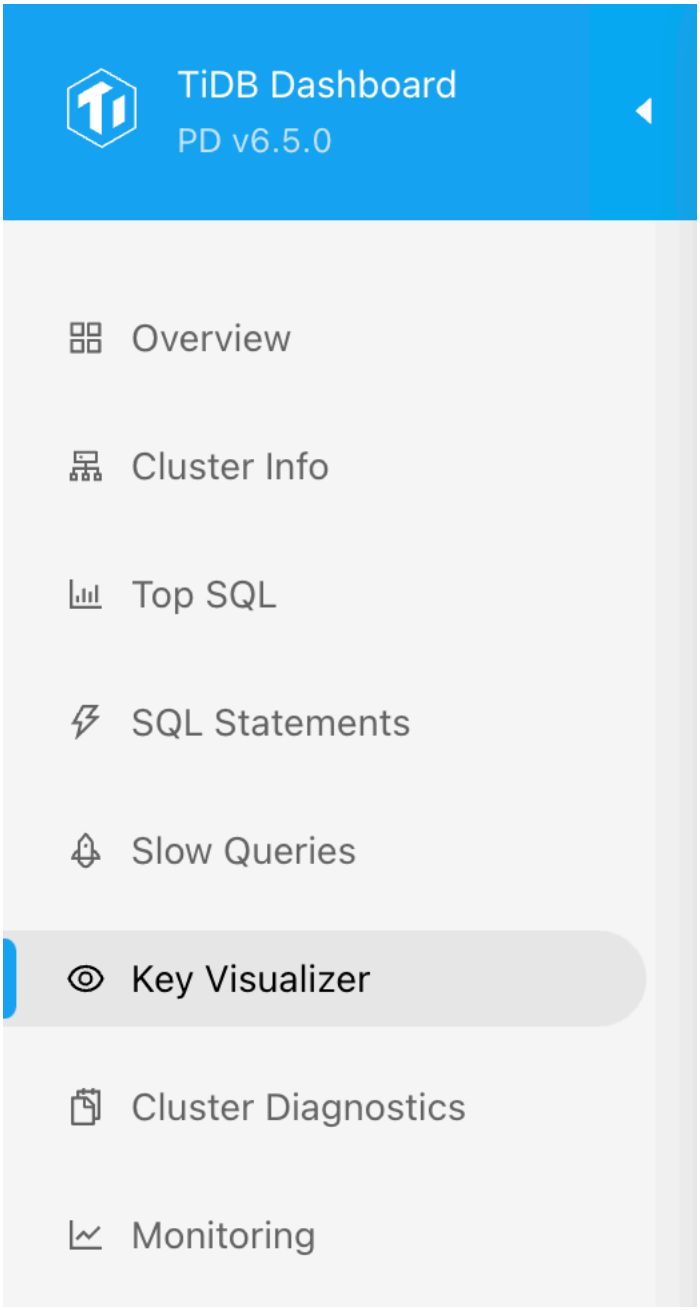

Figure 192: Access Key Visualizer

- Visit http://127.0.0.1:2379/dashboard/#/keyviz in your browser. Replace `127.0.0.1:2379` ↪ with the actual PD instance address and port.

9.5.7.2 Interface demonstration

The following image is a demonstration of the Key Visualizer page:

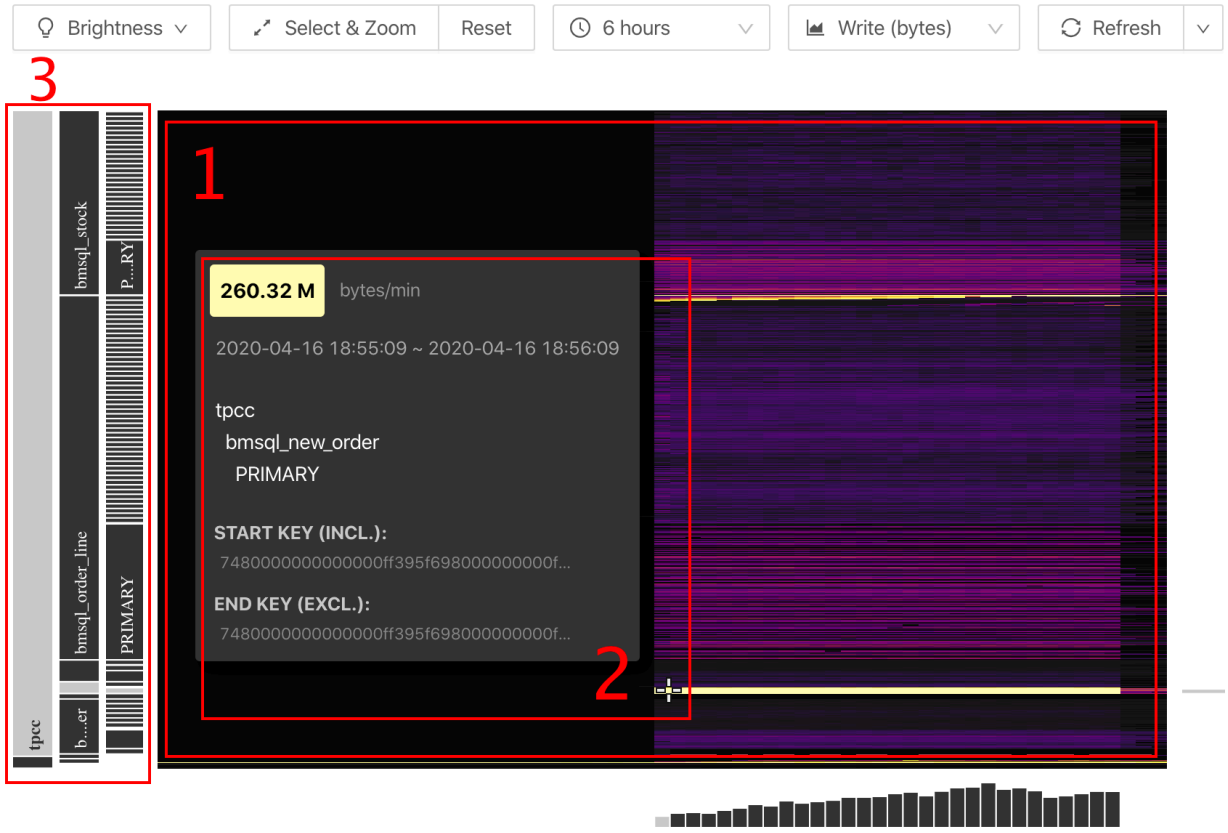

Figure 193: Key Visualizer page

From the preceding interface, you can see the following objects:

- A large heatmap that shows changes of the overall traffic over time.
- The detailed information of a certain coordinate point.
- Information of tables, and indexes (on the left side of the heatmap).

9.5.7.3 Basic concepts

This section introduces the basic concepts that relate to Key Visualizer.

9.5.7.3.1 Region

In a TiDB cluster, the stored data is distributed among TiKV instances. Logically, TiKV is a huge and orderly key-value map. The whole key-value space is divided into many segments and each segment consists of a series of adjacent keys. Such segment is called a `Region`.

For detailed introduction of Region, refer to TiDB Internal (I) - Data Storage.

9.5.7.3.2 Hotspot

When you use the TiDB database, the hotspot issue is typical, where high traffic is concentrated on a small range of data. Because consecutive data ranges are often processed on the same TiKV instance, the TiKV instance on which the hotspot occurs becomes the performance bottleneck of the whole application. The hotspot issue often occurs in the following scenarios:

- Write adjacent data into a table with the `AUTO_INCREMENT` primary key, which causes a hotspot issue on this table.
- Write adjacent time data into the time index of a table, which causes a hotspot issue on the table index.

For more details about hotspot, refer to Highly Concurrent Write Best Practices

9.5.7.3.3 Heatmap

The heatmap is the core part of Key Visualizer, which shows the change of a metric over time. The X-axis of the heatmap indicates the time. The Y-axis of the heatmap indicates the consecutive Regions based on key ranges that cover all schemas and tables of the TiDB cluster.

Colder colors in the heatmap indicate lower read and write traffic of Regions in that period of time. Hotter (brighter) colors indicate higher traffic.

9.5.7.3.4 Region compression

A TiDB cluster might have up to hundreds of thousands of Regions. It is difficult to display so many Regions on screen. Therefore, on each heatmap, these Regions are compressed into 1,500 consecutive ranges, each range called a Bucket. In the heatmap, because hotter instances need more attention, Key Visualizer tends to compress a large number of Regions with lower traffic into one Bucket, and displays the Region with higher traffic also in one Bucket.

9.5.7.4 Use Key Visualizer

This section introduces how to use Key Visualizer.

9.5.7.4.1 Settings

To use the Key Visualizer page for the first time, you need to manually enable this feature on the **Settings** page. Follow the page guide and click **Open Settings** to open the settings page:

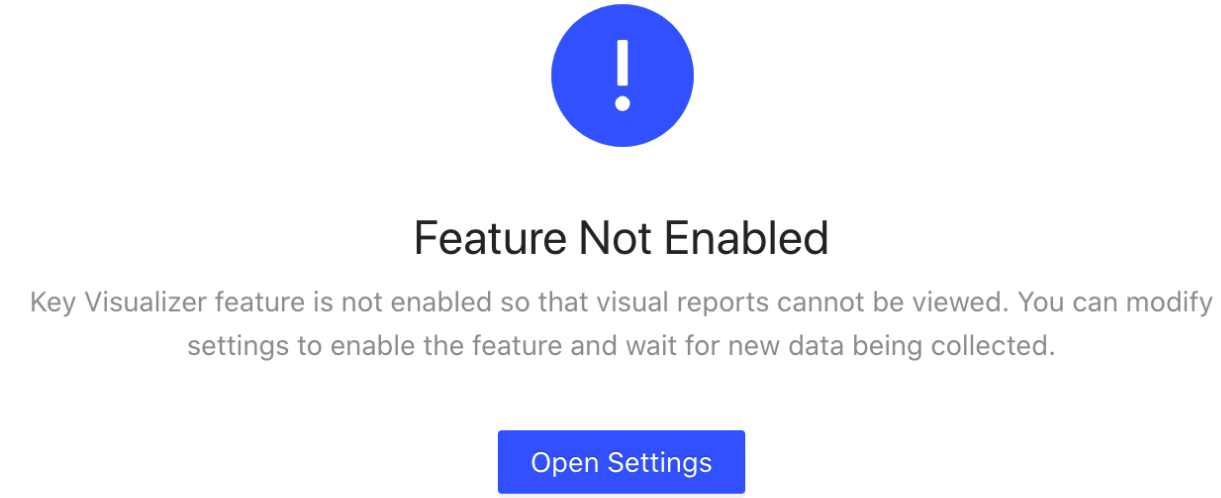

Figure 194: Feature disabled

After this feature is enabled, you can open the settings page by clicking the **Settings** icon in the upper right corner:

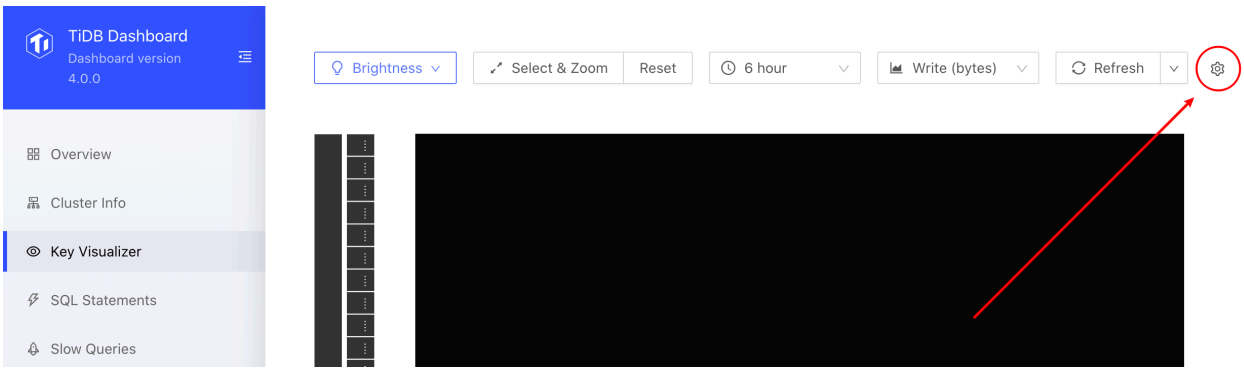

Figure 195: Settings icon

The settings page is shown as follows:

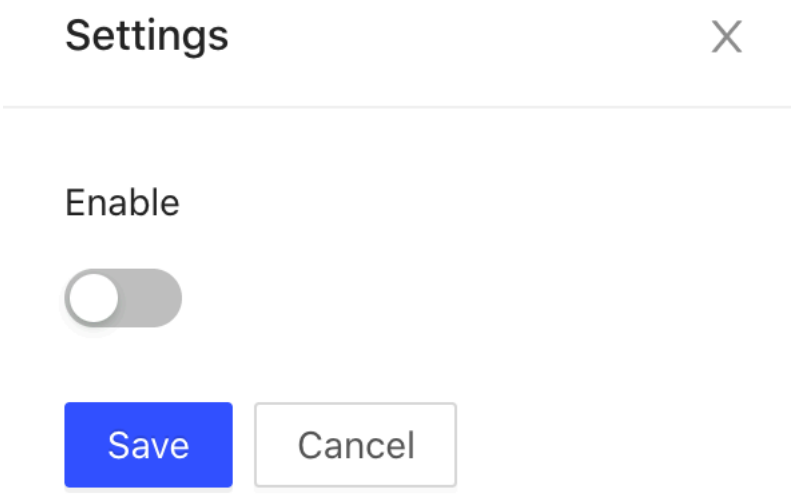

Figure 196: Settings page

Set whether to start data collection through the switch, and click **Save** to take effect. After enabling the feature, you can see that the toolbar is available:

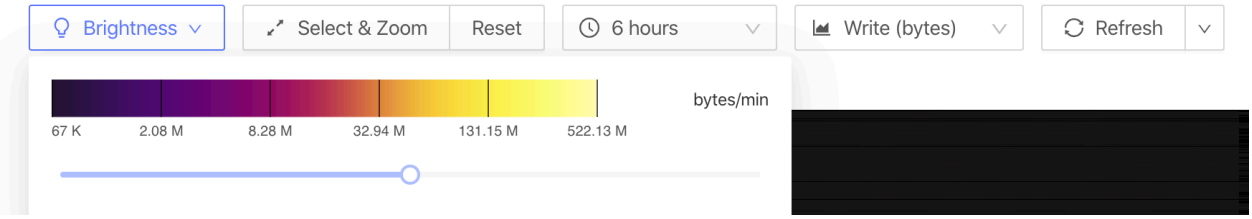

Figure 197: Toolbar

After this feature is enabled, data collection is going on at the backend. You can see the heatmap shortly.

9.5.7.4.2 Observe a certain period of time or Region range

When you open Key Visualizer, the heatmap of the entire database over the recent six hours is displayed by default. In this heatmap, the closer to the right side (current time), the shorter the time interval corresponding to each column of Buckets. If you want to observe a specific time period or a specific Region range, you can zoom in to get more details. The specific instructions are as follows:

1. Scroll up or down in the heatmap.

2. Click and drag one of the following buttons to select the range.

    - Click the **Select & Zoom** button. Then click and drag this button to select the area to zoom in.

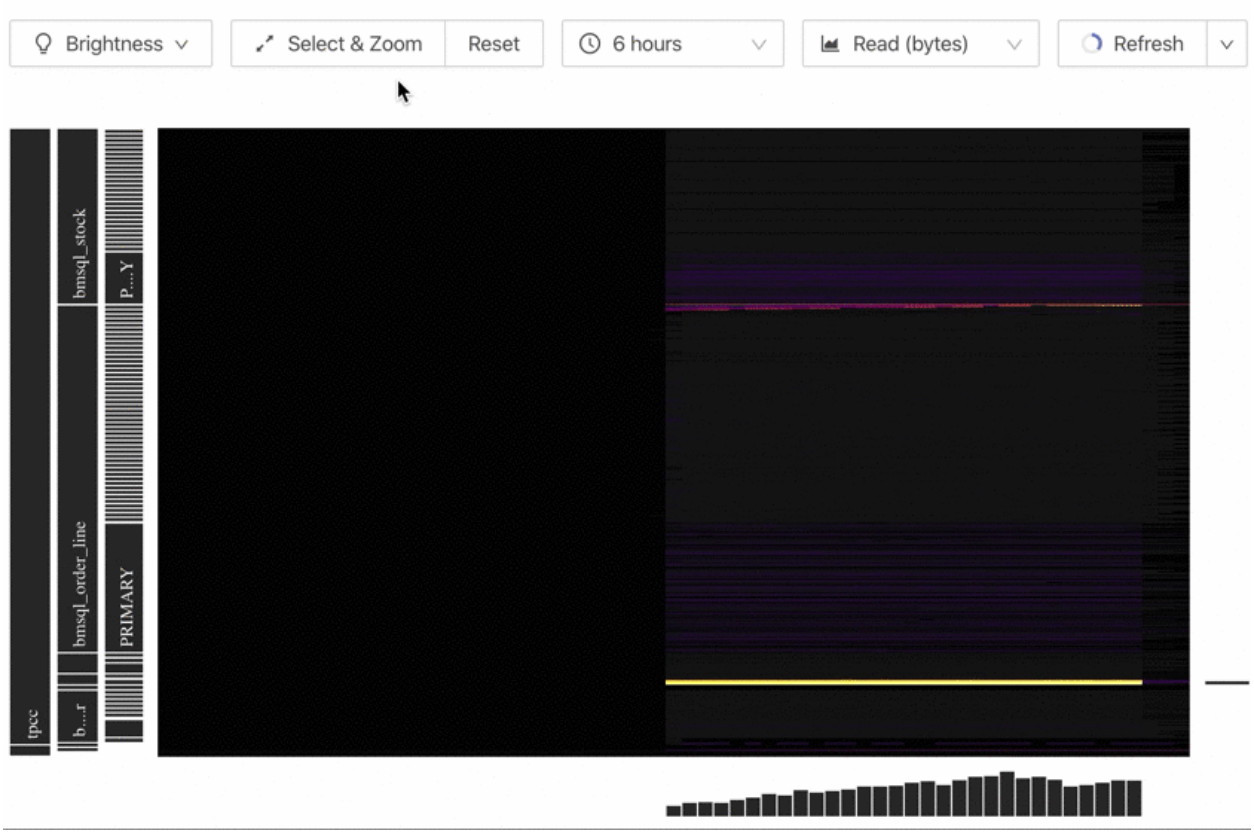

Figure 198: Selection box

- Click the **Reset** button to reset the Region range to the entire database.
- Click the **time selection box** (at the position of `6 hour` on the preceding interface) and select the observation time period again.

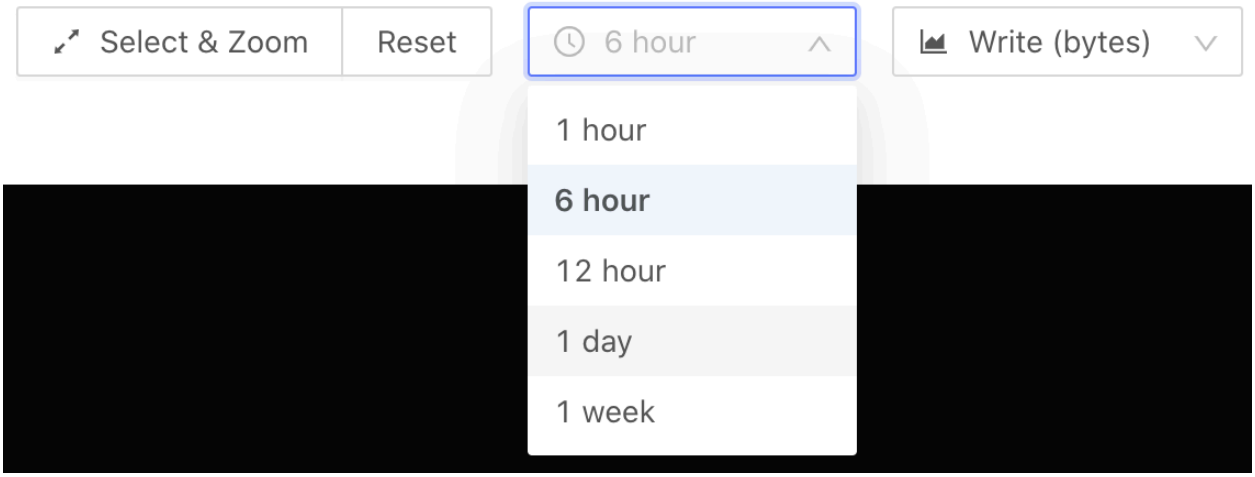

Figure 199: Select time

Note:

If you follow step 2 in the instruction above, the heatmap is redrawn, which might be very different from the original heatmap. This difference is normal because if you observe in more detail, the granularity of the Region compression has changed, or the basis of `hot` in a specific range has changed.

9.5.7.4.3 Adjust brightness

The heatmap uses colors of different brightnesses to indicate the Bucket traffic. Colder colors in the heatmap indicate lower read and write traffic of the Region in that period of time. Hotter (brighter) colors indicate higher traffic. If the color is too cold or too hot, it is difficult to observe in details. In this situation, you can click the **Brightness** button and then use the slider to adjust the brightness of the page.

Note:

When Key Visualizer displays the heatmap of an area, it defines the basis of being cold and hot according to the traffic of this area. When the traffic in the entire area is relatively even, even if the overall traffic is low in value, you might still see a large bright-colored area. Remember to include the value into your analysis.

9.5.7.4.4 Select metrics

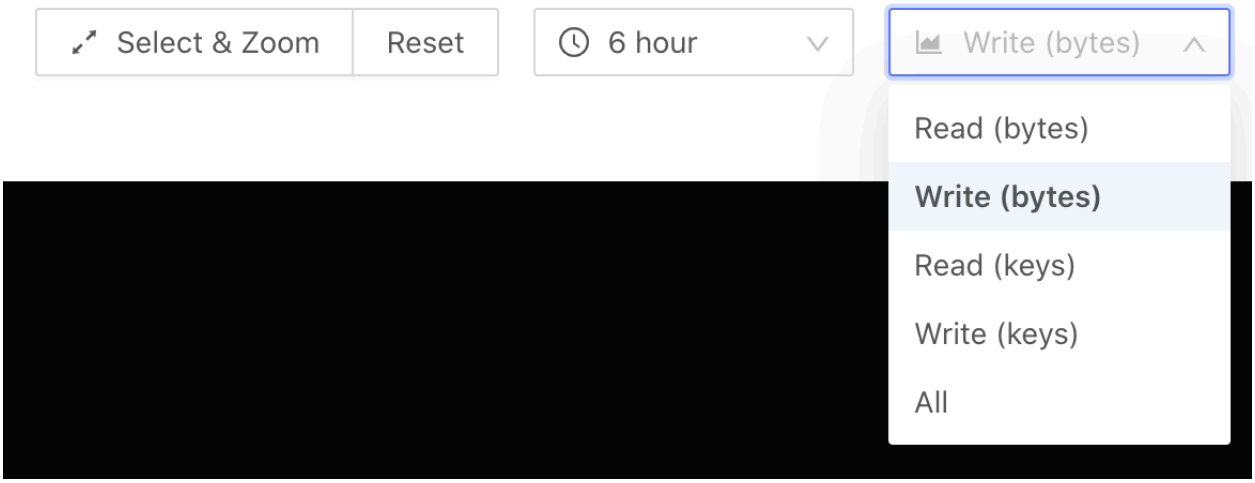

Figure 200: Select metrics

You can view a metric you are interested in by selecting this metric in the **metrics selection box** (at the `Write (bytes)` position in the interface above):

- `Read (bytes)`: Read traffic.
- `Write (bytes)`: Write traffic.
- `Read (keys)`: The number of read rows.
- `Write (keys)`: The number of written rows.
- `All`: The sum of read and write traffic.

9.5.7.4.5 Refresh and automatic refresh

To regain a heatmap based on the current time, click the **Refresh** button. If you need to observe the traffic distribution of the database in real time, click the down arrow on the right side of the **Refresh** button and select a fixed time interval for the heatmap to automatically refresh at this interval.

> **Note:**
>
> If you adjust the time range or Region range, the automatic refresh is disabled.

9.5.7.4.6 See Bucket details

You can hover your mouse over the Bucket you are interested in to view the detailed information of this Region range. The image below is an example of this information:

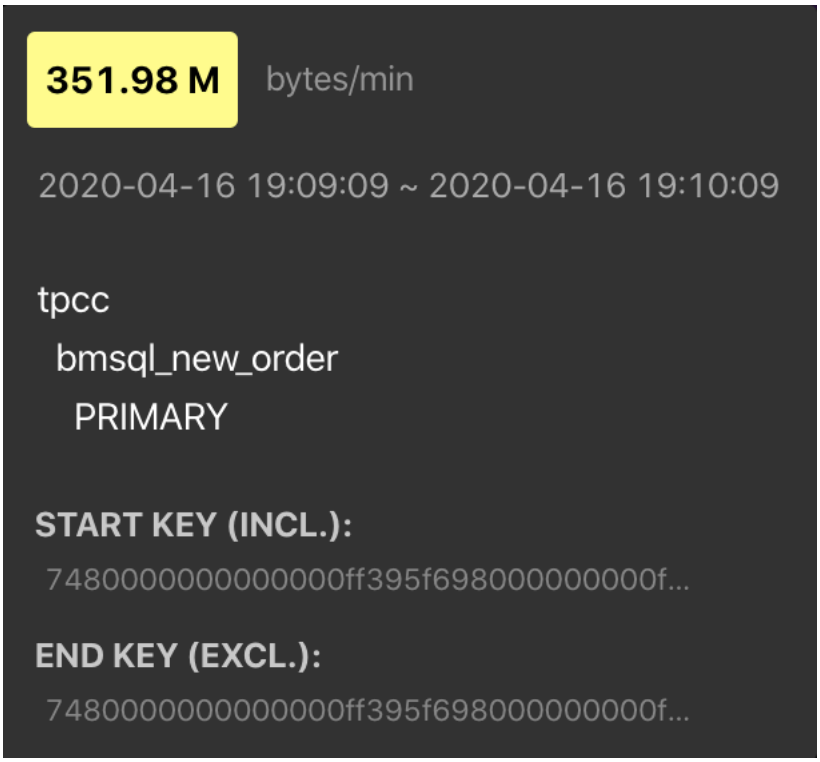

Figure 201: Bucket details

If you want to copy this information, click a Bucket. Then, the page with relevant details is temporarily pinned. Click on the information, and you have copied it to the clipboard.

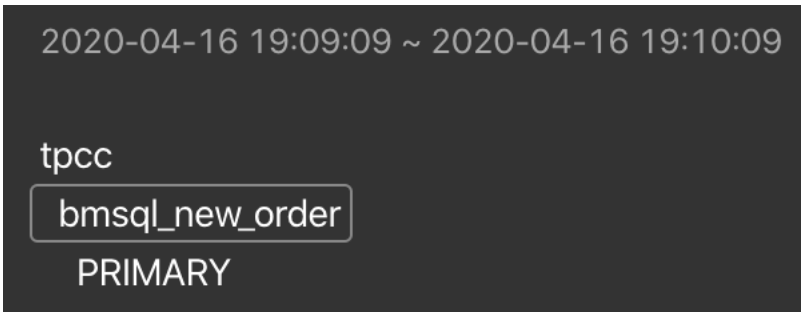

Figure 202: Copy Bucket details

9.5.7.5 Common heatmap types

This section shows and interprets four common types of heatmap in Key Visualizer.

9.5.7.5.1 Evenly distributed workload

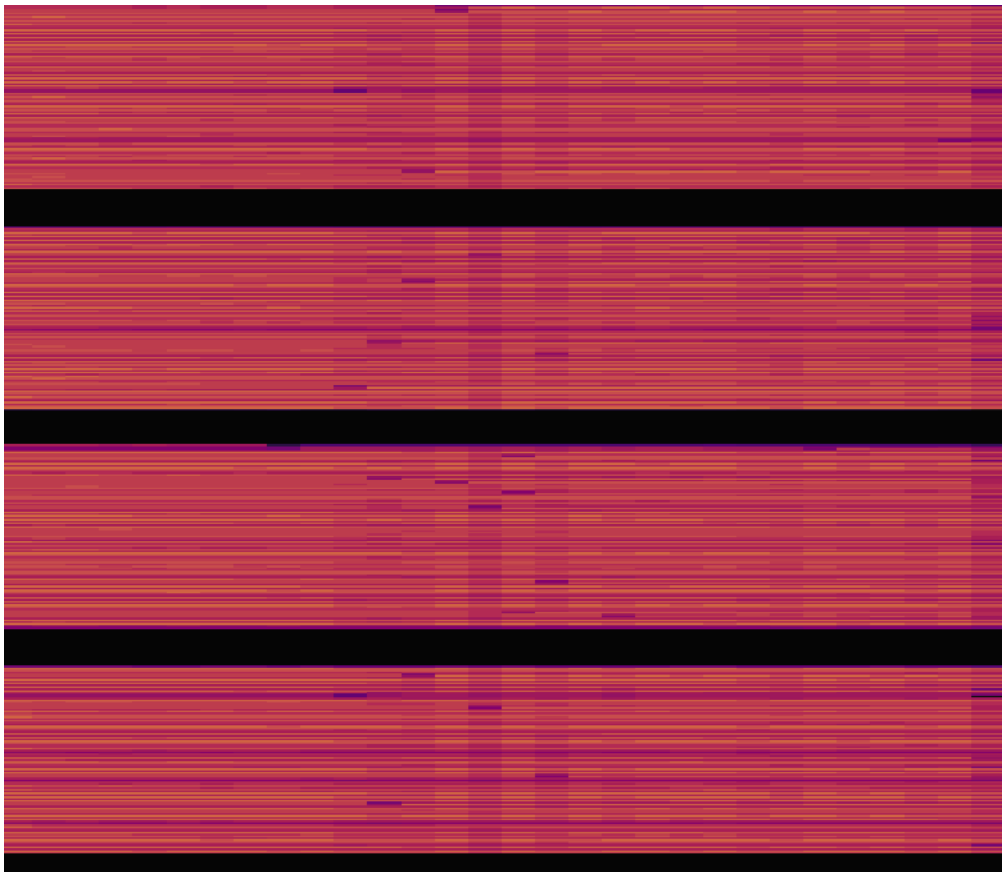

Figure 203: Balanced

In the heatmap above, bright and dark colors are a fine-grained mix. This indicates that reads or writes are evenly distributed over time and among key ranges. The workload is evenly distributed to all nodes, which is ideal for a distributed database.

9.5.7.5.2 Periodically reads and writes

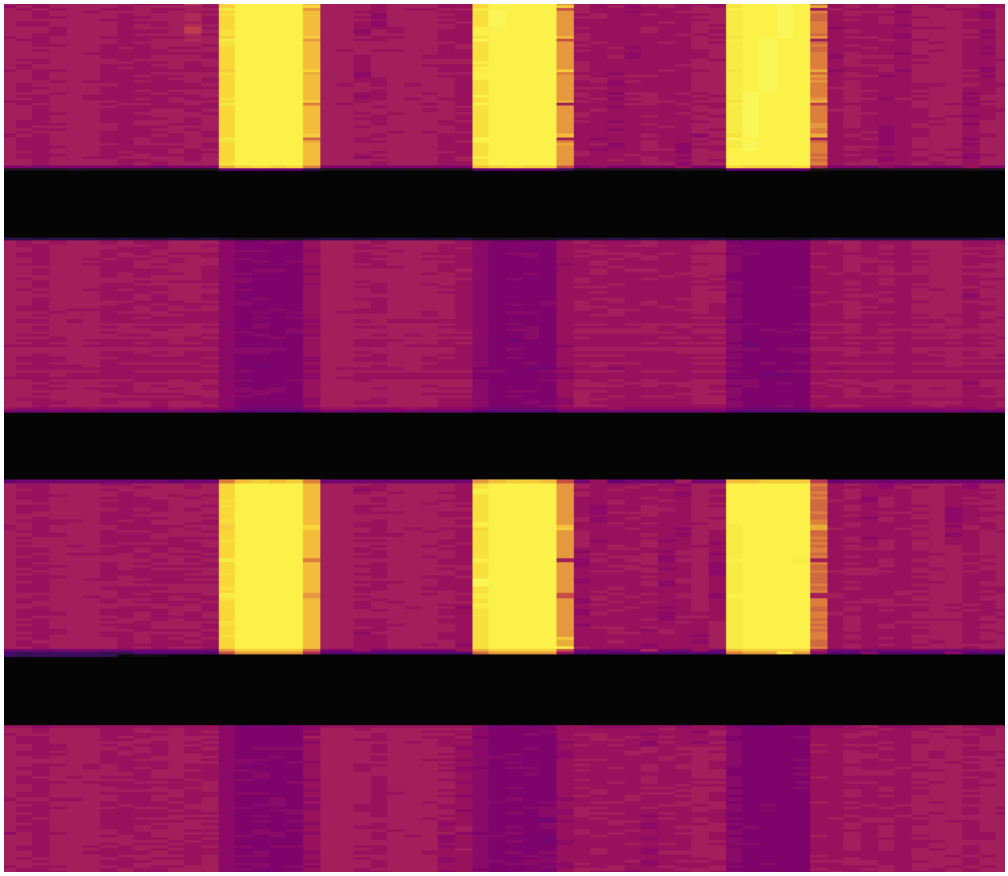

Figure 204: Periodically

In the heatmap above, there is an alternating brightness and darkness along the X-axis (time) but the brightness is relatively even along the Y-axis (Region). This indicates that the reads and writes change periodically, which might occur in scenarios of periodically scheduled tasks. For example, the big data platform periodically extracts data from TiDB every day. In this kind of scenarios, pay attention to whether the resources are sufficient during peak usage.

9.5.7.5.3 Concentrated reads or writes

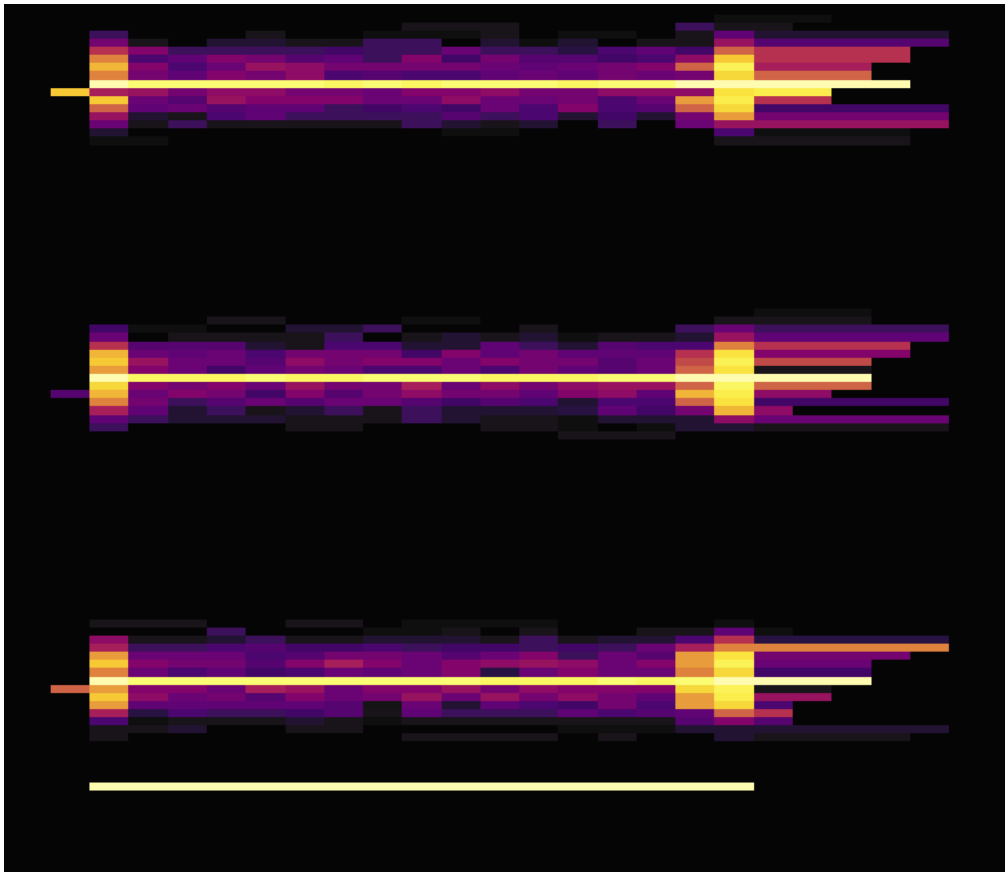

Figure 205: Concentrated

In the heatmap above, you can see several bright lines. Along the Y-axis, the fringes around the bright lines are dark, which indicates that the Regions corresponding to bright lines have high read and write traffic. You can observe whether the traffic distribution is expected by your application. For example, when all services are associated with the user table, the overall traffic of the user table can be high, so it is reasonable to show bright lines in the heatmap.

In addition, the height of the bright lines (the thickness along the Y-axis) is important. Because TiKV has its own Region-based hotspot balancing mechanism, the more Regions involved in the hotspot, the better it is for balancing traffic across all TiKV instances. The thicker and more bright lines indicate that hotspots are more scattered, and TiKV is better used. The thinner and fewer bright lines indicate that hotspots are more concentrated, and the hotspot issue is more obvious in TiKV, which might requires manual intervention.

9.5.7.5.4 Sequential reads or writes

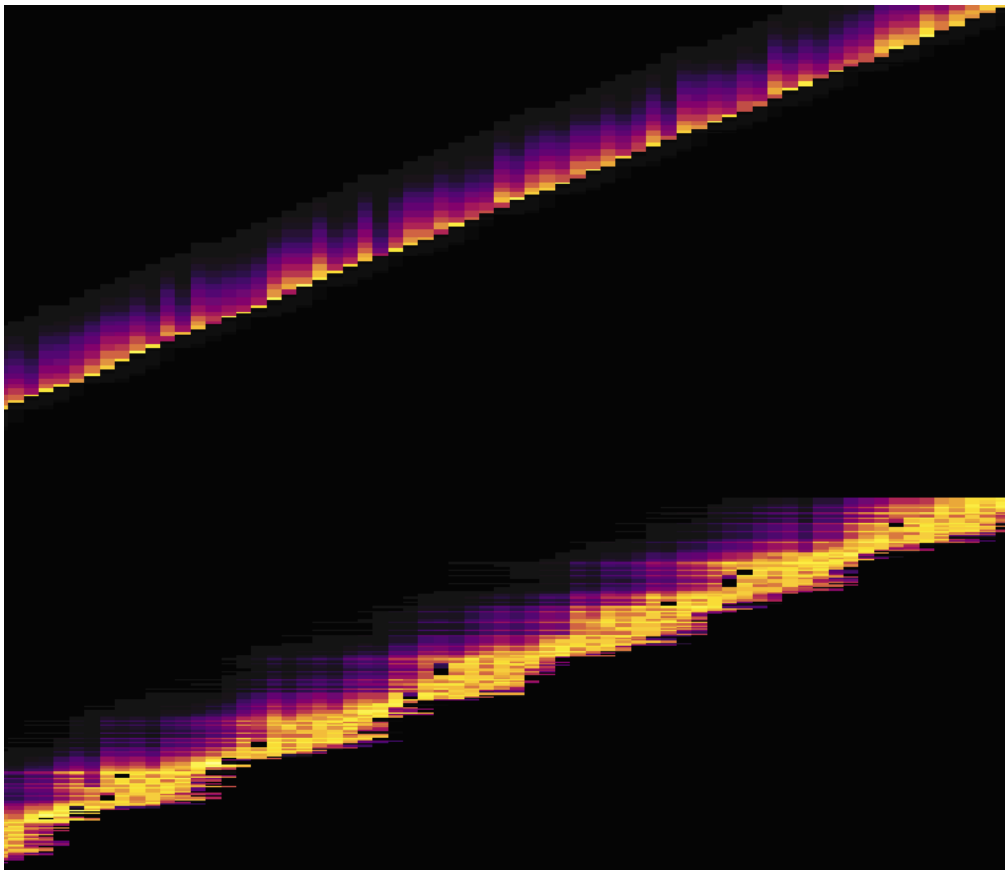

Figure 206: Sequential

In the heatmap above, you can see a bright line. This means that the data reads or writes are sequential. Typical scenarios of sequential data reads or writes are importing data or scanning tables and indexes. For example, you continuously write data to tables with auto-increment IDs.

Regions in the bright areas are the hotspots of read and write traffic, which often become the performance bottleneck of the entire cluster. In this situation, you might need to readjust the primary key for the application. By doing this, you scatter Regions much as possible to spread the pressure across multiple Regions. You can also schedule application tasks during the low-peak period.

Note:

In this section, only the common types of heatmap are shown. Key Visualizer actually displays the heatmap of all schemas and tables in the entire cluster, so you might see different types of heatmap in different areas, or mixed results of multiple heatmap types. Use the heatmap based on the actual situation.

9.5.7.6 Address hotspot issues

TiDB has some built-in features to mitigate the common hotspot issue. Refer to Highly Concurrent Write Best Practices for details.

9.5.8 TiDB Dashboard Metrics Relation Graph

TiDB Dashboard metrics relation graph is a feature introduced in v4.0.7. This feature presents a relation graph of the monitoring data of each internal process's duration in a TiDB cluster. The aim is to help you quickly understand the duration of each process and their relations.

9.5.8.1 Access graph

After logging in to TiDB Dashboard, click **Cluster Diagnostics** in the left navigation menu, and you can see the page of generating the metrics relation graph.

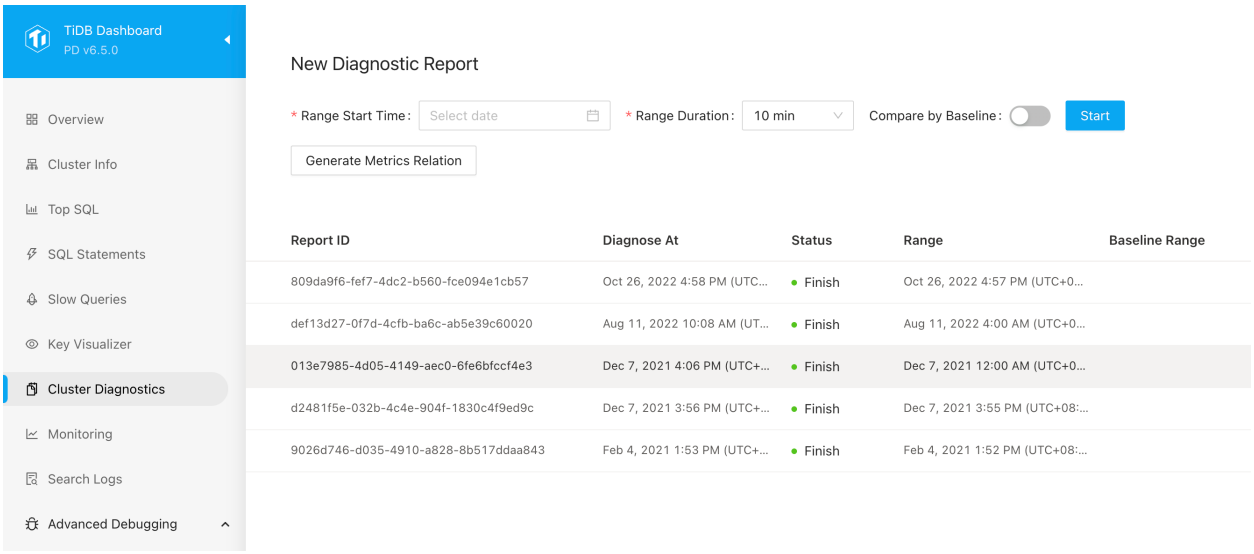

Figure 207: Metrics relation graph homepage

After setting **Range Start Time** and **Range Duration**, click **Generate Metrics Relation** and you will enter the page of metrics relation graph.

9.5.8.2 Understand graph

The following image is an example of the metrics relation graph. This graph illustrates the proportion of each monitoring metric's duration to the total query duration in a TiDB cluster within 5 minutes after 2020-07-29 16:36:00. The graph also illustrates the relations of each monitoring metric.

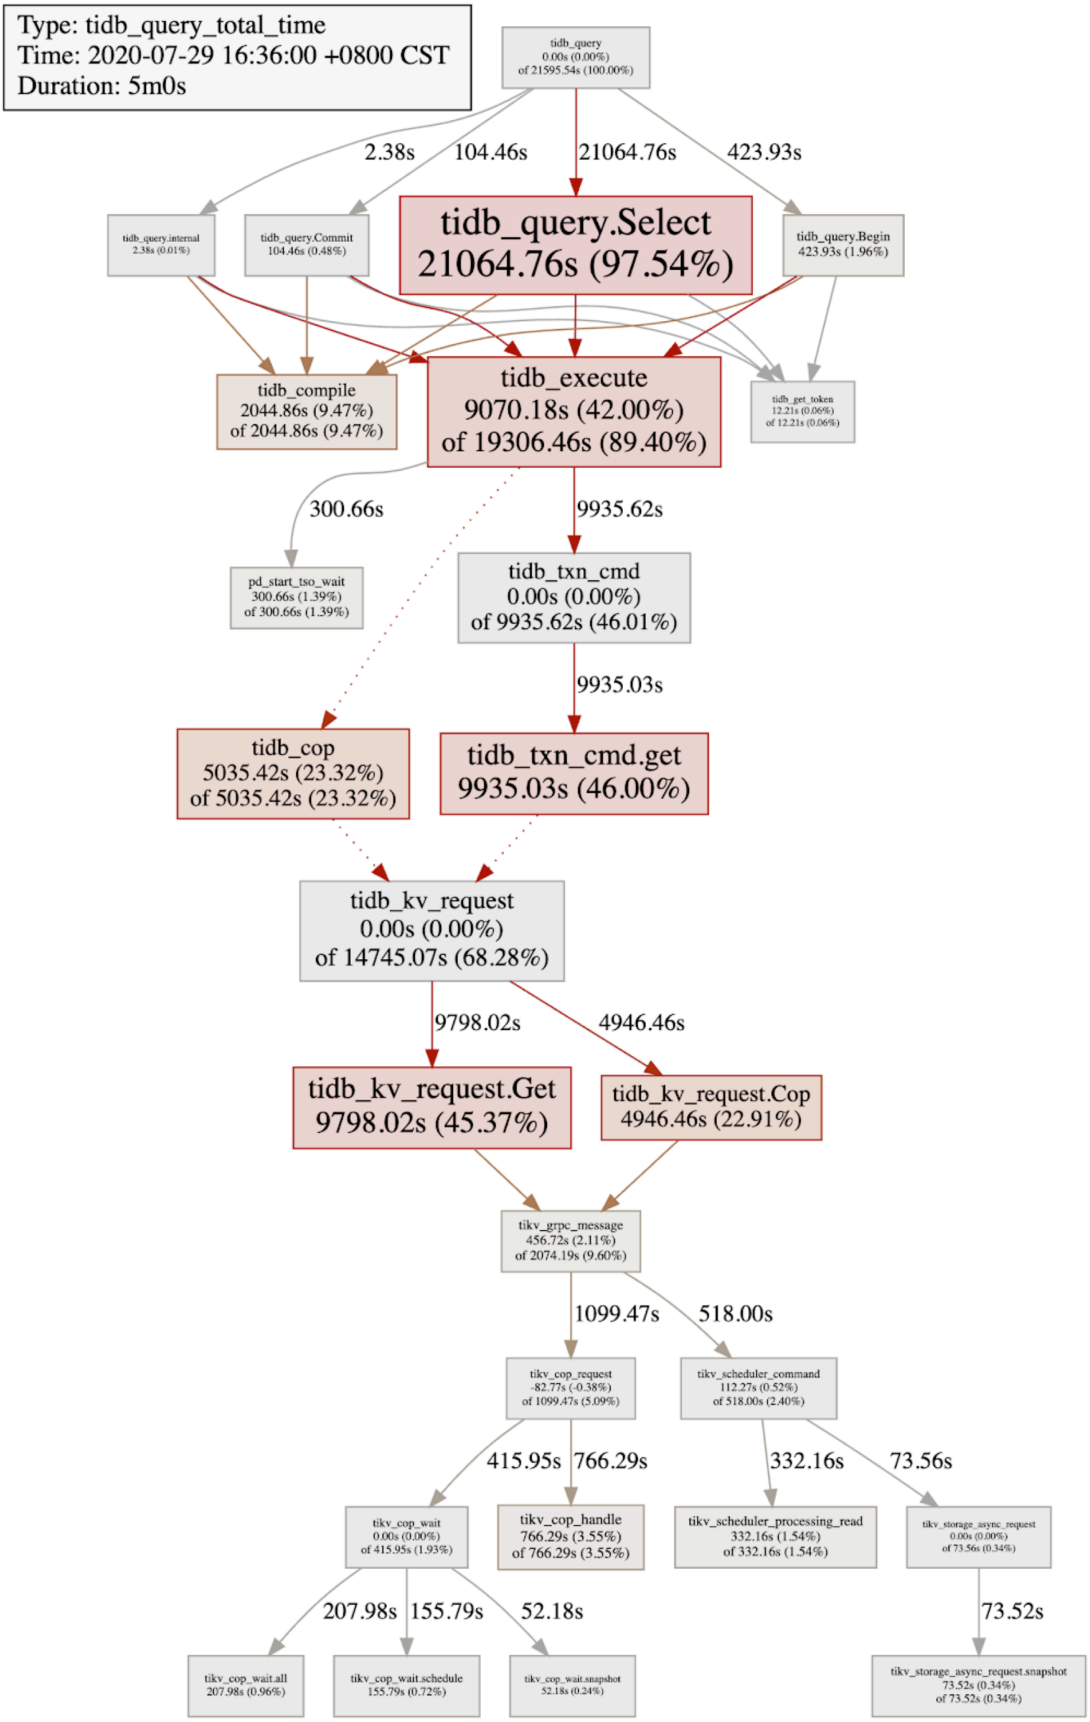

Figure 208: Metrics relation graph example

For example, the node meaning of the `tidb_execute` monitoring metric is as follows:

- The total duration of the `tidb_execute` monitoring metric is 19306.46 seconds, which accounts for 89.4% of the total query duration.
- The duration of the `tidb_execute` node itself is 9070.18 seconds, which accounts for 42% of the total query duration.
- Hover your mouse over the box area, and you can see the detailed information of the metric, including the total duration, the average duration, and the average P99 (99th percentile) duration.

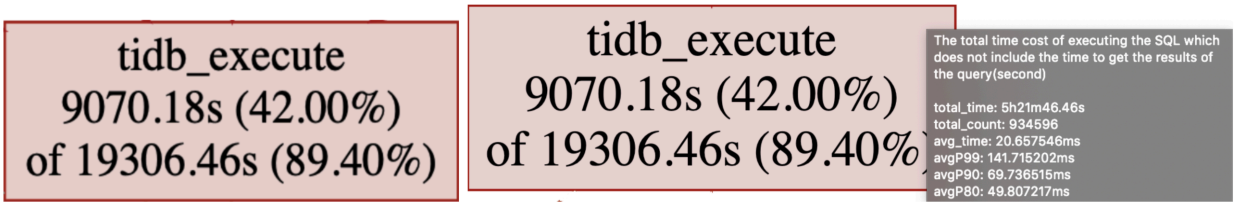

Figure 209: tidb_execute node example

9.5.8.2.1 Node information

Each box area represents a monitoring metric and provides the following information:

- The name of the monitoring metric
- The total duration of the monitoring metric
- The proportion of the metric's total duration to the total query duration

The total duration of the metric node = the duration of the metric node itself + the duration of its child nodes. Therefore, the metric graph of some nodes displays the proportion of the node itself's duration to the total duration, such as the graph of `tidb_execute`.

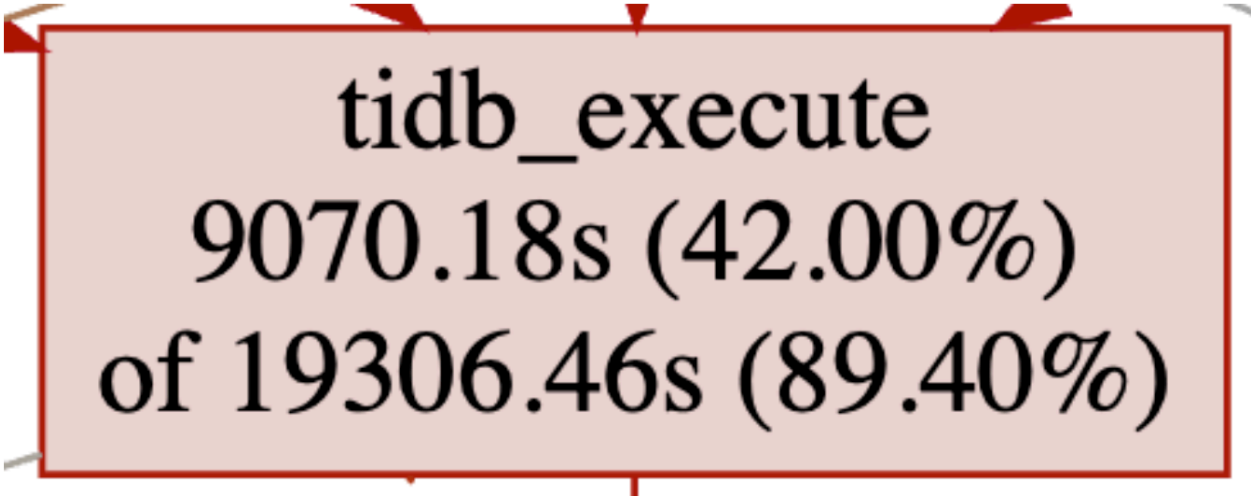

Figure 210: tidb_execute node example1

- `tidb_execute` is the name of the monitoring metric, which represents the execution duration of a SQL query in the TiDB execution engine.
- `19306.46s` represents that total duration of the `tidb_execute` metric is 19306.46 seconds. `89.40%` represents that 19306.46 seconds account for 89.40% of the total time consumed for all SQL queries (including user SQL queries and TiDB's internal SQL queries). The total query duration is the total duration of `tidb_query`.
- `9070.18s` represents that the total execution duration of the `tidb_execute` node itself is 9070.18 seconds, and the rest is the time consumed by its child nodes. `42.00%` represents that 9070.18 seconds account for 42.00% of the total query duration of all queries.

Hover your mouse over the box area and you can see more details of the `tidb_execute` metric node:

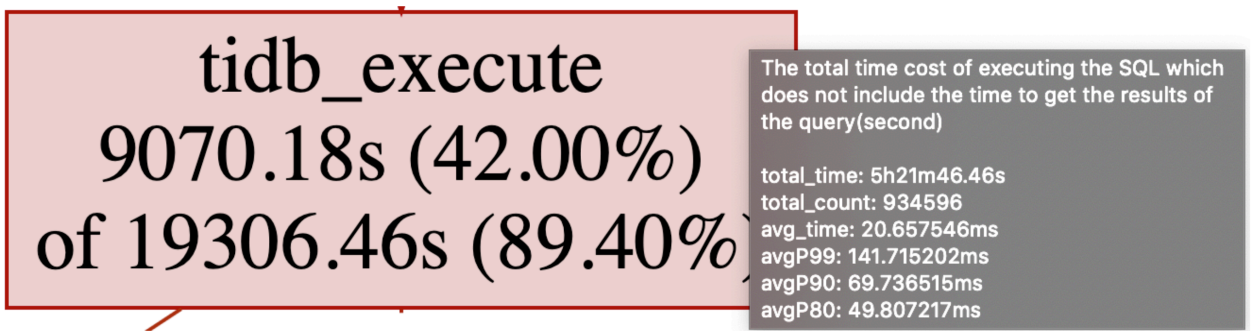

Figure 211: tidb_execute node example2

The text information displayed in the image above is the description of the metric node, including the total duration, the total times, the average duration, and the average duration

P99, P90, and P80.

9.5.8.2.2 The parent-child relations between nodes

Taking the `tidb_execute` metric node as an example, this section introduces a metric's child nodes.

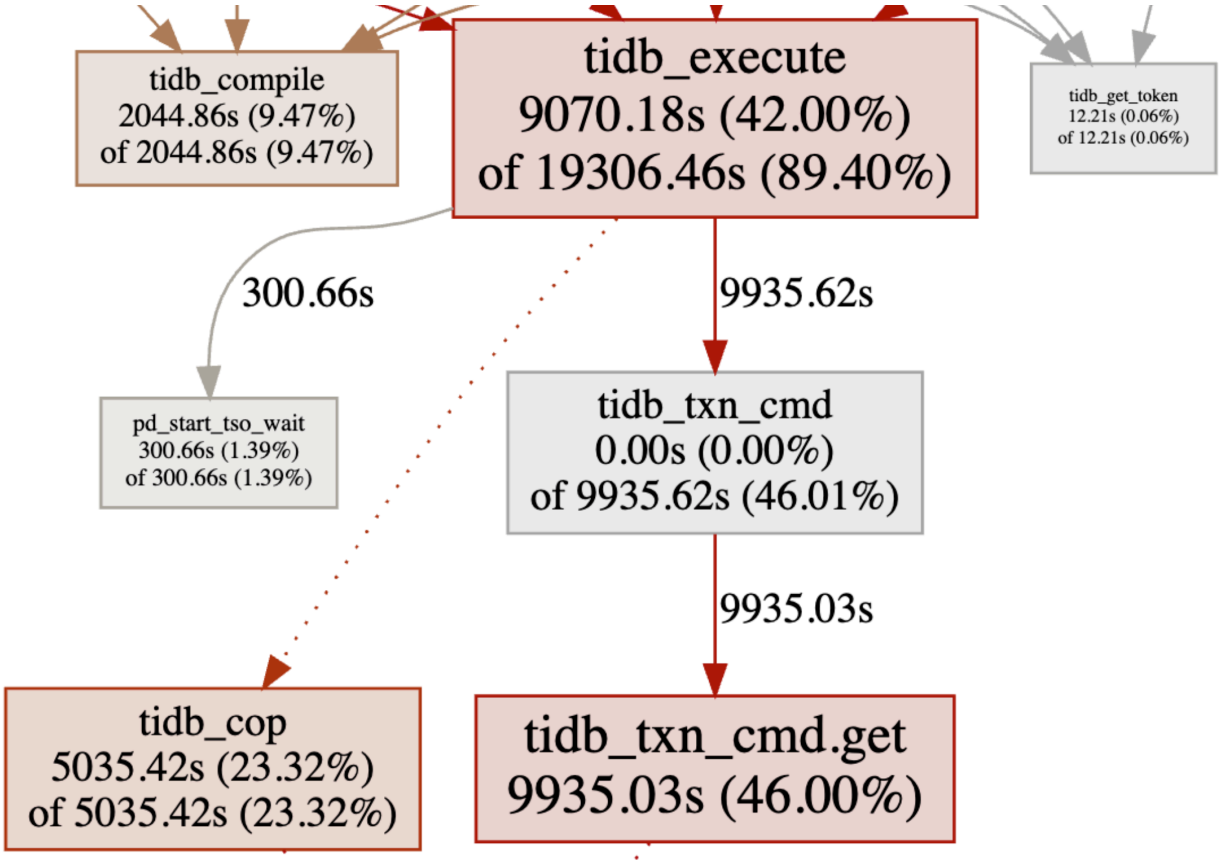

Figure 212: tidb_execute node relation example1

From the graph above, you can see the two child nodes of `tidb_execute`:

- `pd_start_tso_wait`: The total duration of waiting for the transaction's `start_tso`, which is 300.66 seconds.
- `tidb_txn_cmd`: The total duration of TiDB executing the relevant transaction commands, which is 9935.62 seconds.

In addition, `tidb_execute` also has a dotted arrow pointing to the `tidb_cop` box area, which indicates as follows:

`tidb_execute` includes the duration of the `tidb_cop` metric, but `cop` requests might be executed concurrently. For example, the `execute` duration of performing `join` queries

on two tables is 60 seconds, during which table scan requests are concurrently executed on the joined two tables. If the execution durations of `cop` requests are respectively 40 seconds and 30 seconds, the total duration of `cop` requests are 70 seconds. However, the `execute` duration is only 60 seconds. Therefore, if the duration of a parent node does not completely include the duration of a child node, the dotted arrow is used to point to the child node.

Note:

When a node have a dotted arrow pointing to its child node, the duration of this node itself is inaccurate. For example, in the `tidb_execute` node, the duration of the node itself is 9070.18 seconds (`9070.18 = 19306.46 - 300.66 - 9935.62`). In this equation, the duration of the `tidb_cop` child node is not calculated into the duration of `tidb_execute`'s child nodes. But in fact, this is not true. 9070.18 seconds, the duration of `tidb_execute` itself, includes a part of the `tidb_cop` duration, and the duration of this part cannot be determined.

9.5.8.2.3 `tidb_kv_request` and its parent nodes

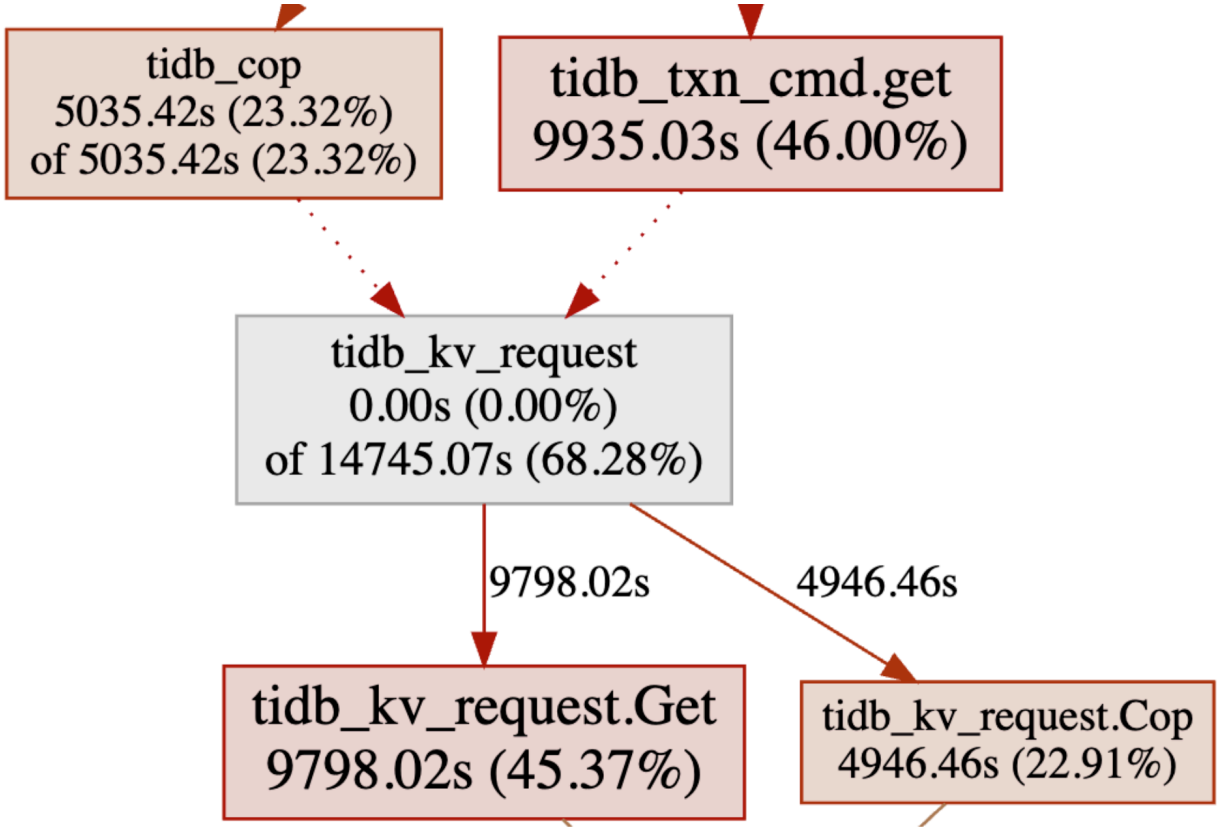

Figure 213: tidb_execute node relation example2

`tidb_cop` and `tidb_txn_cmd.get`, the parent nodes of `tidb_kv_request`, both have dotted arrows pointing to `tidb_kv_request`, which indicates as follows:

- The duration of `tidb_cop` includes a part of `tidb_kv_request`'s duration.
- The duration of `tidb_txn_cmd.get` also includes a part of `tidb_kv_request`'s duration.

However, it is hard to determine how much duration of `tidb_kv_request` is included in `tidb_cop`.

- `tidb_kv_request.Get`: The duration of TiDB sending the `Get` type key-value requests.
- `tidb_kv_request.Cop`: The duration of TiDB sending the `Cop` type key-value requests.

`tidb_kv_request` does not include `tidb_kv_request.Get` and `tidb_kv_request.Cop` nodes as its child nodes, but consists of the latter two nodes. The name prefix of the child node is the name of the parent node plus `.xxx`, which means that the child node is the sub-class of the parent node. You can understand this case in the following way:

The total duration of TiDB sending key-value requests is 14745.07 seconds, during which the key-value requests for the `Get` and `Cop` types respectively consume 9798.02 seconds and 4946.46 seconds.

9.5.9 SQL Statements Analysis

9.5.9.1 SQL Statements Page of TiDB Dashboard

The SQL statements page shows the execution status of all SQL statements in the cluster. This page is often used to analyze the SQL statement whose total or single execution time is long.

On this page, SQL queries with a consistent structure (even if the query parameters are inconsistent) are classified as the same SQL statement. For example, both `SELECT * FROM employee WHERE id IN (1, 2, 3)` and `select * from EMPLOYEE where ID in (4, 5)` are classified as the same `select * from employee where id in (...)` SQL statement.

9.5.9.1.1 Access the page

You can use one of the following two methods to access the SQL statement summary page:

- After logging in to TiDB Dashboard, click **SQL Statements** in the left navigation menu.
- Visit http://127.0.0.1:2379/dashboard/#/statement in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

All the data shown on the SQL statement summary page are from the TiDB statement summary tables. For more details about the tables, see TiDB Statement Summary Tables.

> **Note:**
>
> In the **Mean Latency** column of the SQL statement summary page, the blue bar indicates the average execution time. If there is a yellow line on the blue bar for an SQL statement, the left and right sides of the yellow line respectively represent the minimum and maximum execution time of the SQL statement during the recent data collection cycle.

Change Filters

On the top of the SQL statement summary page, you can modify the time range of SQL executions to be displayed. You can also filter the list by database in which SQL statements are executed, or by SQL types. The following image shows all SQL executions over the recent data collection cycle (recent 30 minutes by default).

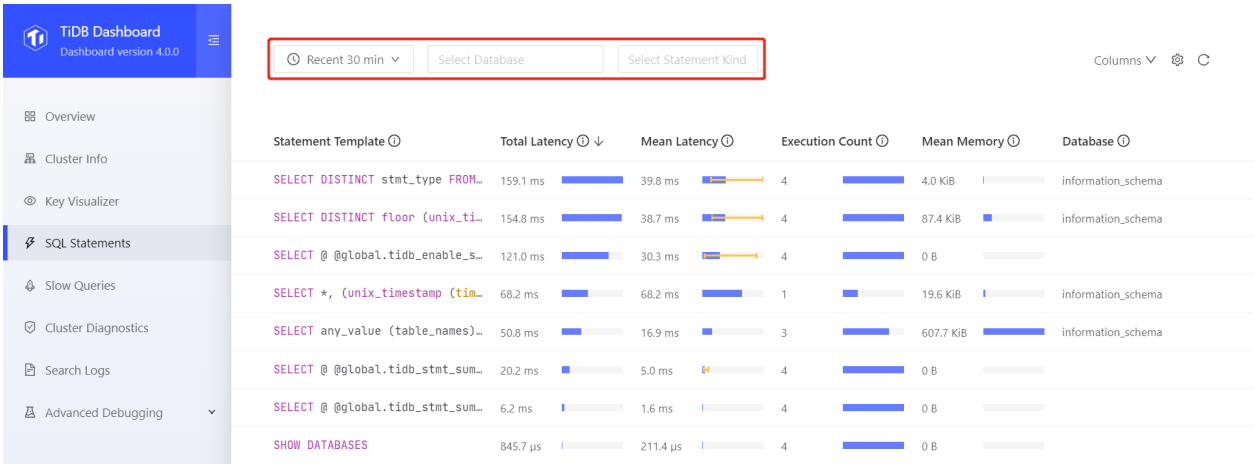

Figure 214: Modify filters

Display More Columns

Click **Columns** on the page and you can choose to see more columns. You can move your mouse to the **(i)** icon at the right side of a column name to view the description of this column:

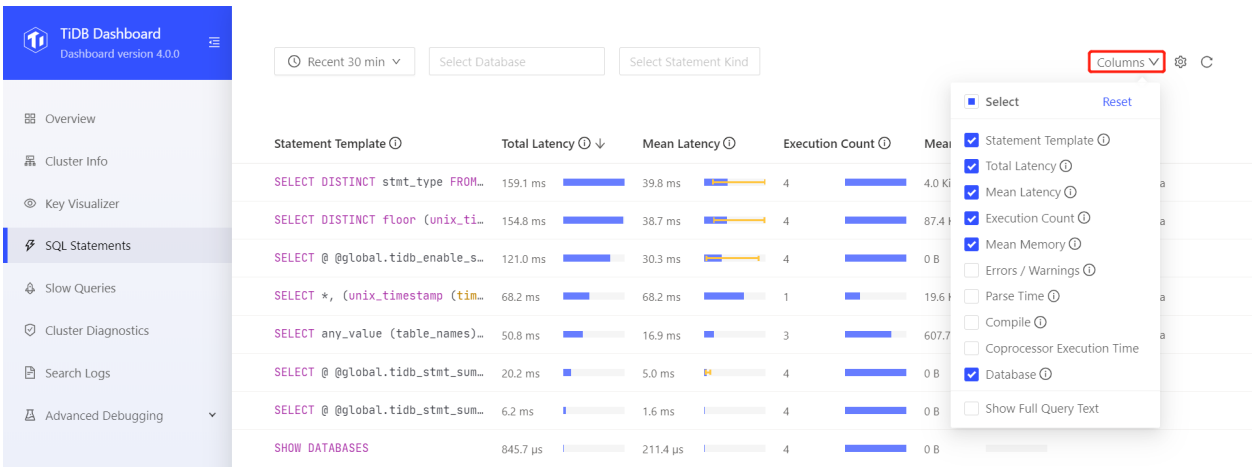

Figure 215: Choose columns

Sort by Column

By default, the list is sorted by **Total Latency** from high to low. Click on different column headings to modify the sorting basis or switch the sorting order:

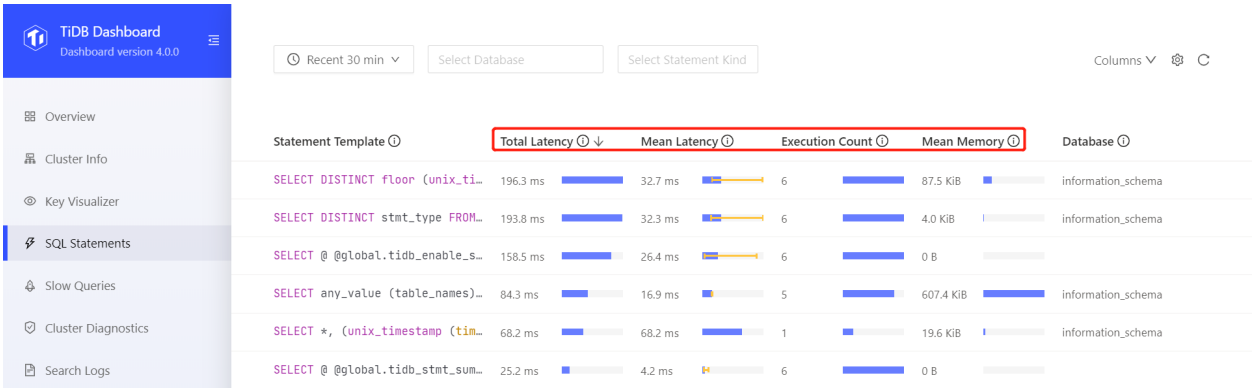

Figure 216: Modify list sorting

Change Settings

On the list page, click the **Settings** button on the top right to change the settings of the SQL statements feature:

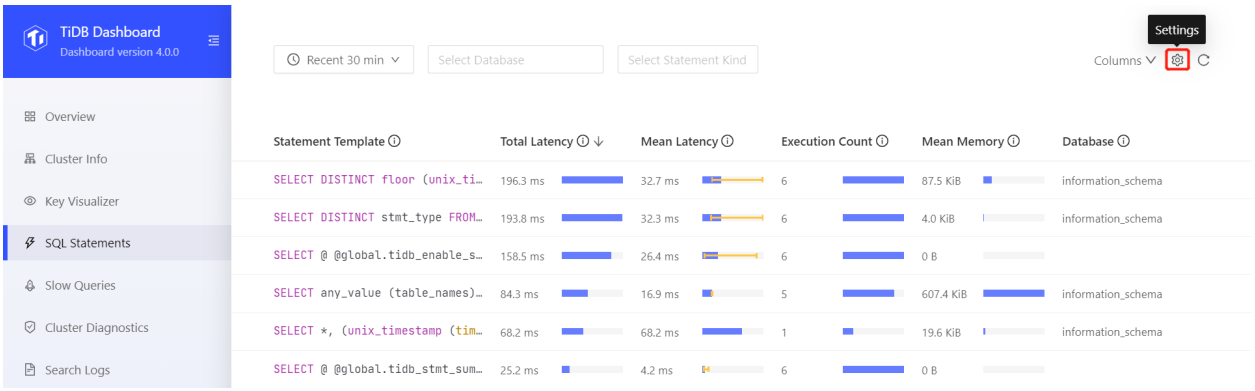

Figure 217: Settings entry

After clicking the **Settings** button, you can see the following setting dialog box:

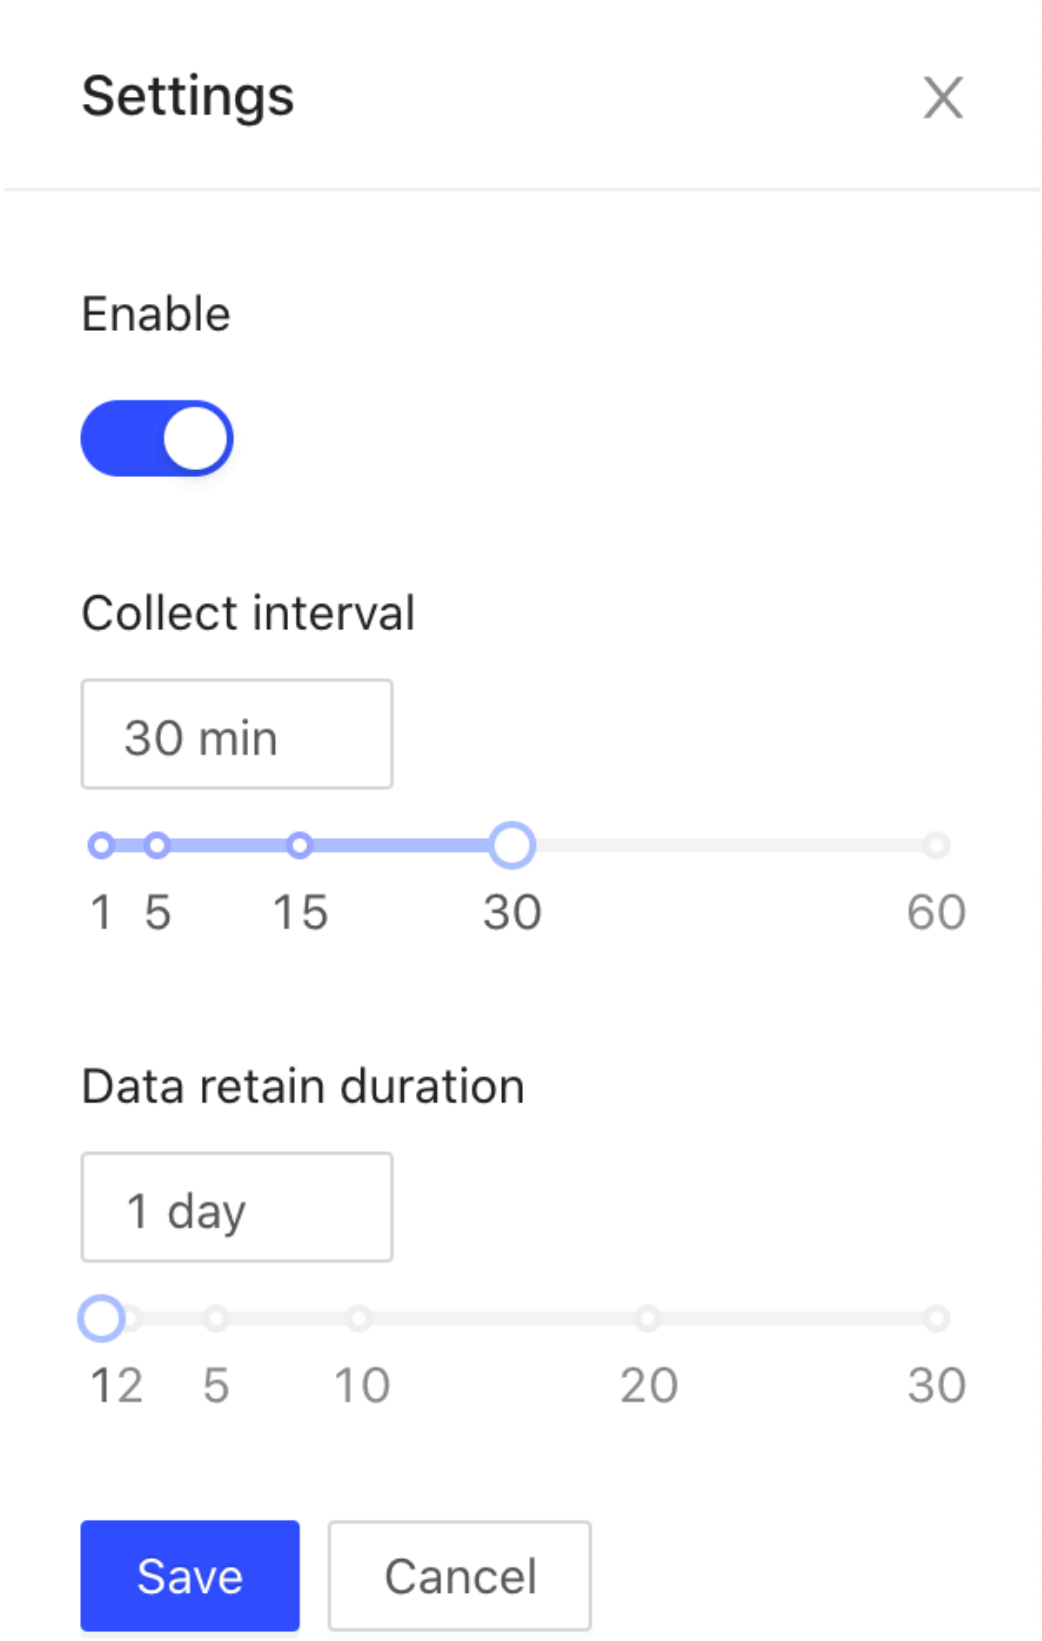

Figure 218: Settings

On the setting page, you can disable or enable the SQL statements feature. When the SQL statements feature is enabled, you can modify the following settings:

- Collect interval: The length of period for each SQL statement analysis, which is 30 minutes by default. The SQL statements feature summarizes and counts all SQL statements within a period of time. If the period is too long, the granularity of the summary is coarse, which is not good for locating problems; if the period is too short, the granularity of the statistics is fine, which is good for locating problems, but this will result in more records and more memory usage within the same data retention duration. Therefore, you need to adjust this value based on the actual situation, and properly lower this value when locating problems.
- Data retain duration: The retention duration of summary information, which is 1 day by default. Data retained longer than this duration will be deleted from system tables.

See Configurations of Statement Summary Tables for details.

Note:

- Because the statement system table is only stored in memory, after the SQL Statements feature is disabled, the data in the system table will be cleared.
- The values of `Collect interval` and `retain duration` affect the memory usage, so it is recommended to adjust these values according to the actual situation. The value of `retain duration` should not be set too large.

Others

`tidb_stmt_summary_max_stmt_count` limits the number of SQL digests that the statements_summary and statements_summary_history tables can store in memory totally. If the limit is exceeded, TiDB clears the SQL statements that recently remain unused. These cleared SQL statements are represented as rows with `DIGEST` set to `NULL`. On the SQL statement page of TiDB Dashboard, the information of these rows is displayed as `Others`.

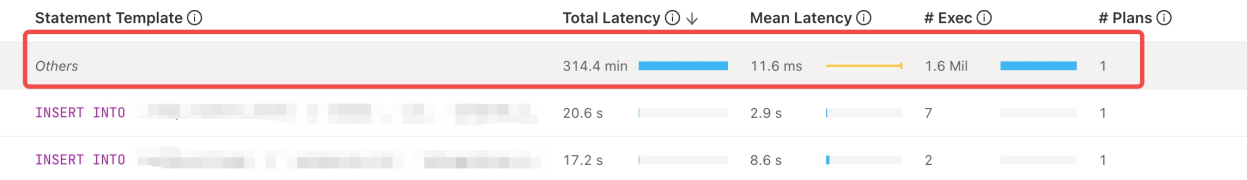

Figure 219: Others

9.5.9.1.2 Next step

For more information about how to view the execution details of SQL statements, see Statement execution details of TiDB Dashboard.

9.5.9.2 Statement Execution Details of TiDB Dashboard

Click any item in the list to enter the detail page of the SQL statement to view more detailed information. This information includes the following parts:

- The overview of SQL statements, which includes the SQL template, the SQL template ID, the current time range of displayed SQL executions, the number of execution plans, the database in which the SQL statement is executed, and the fast plan binding feature (area 1 in the following figure).
- The execution plan list: If a SQL statement has multiple execution plans, this list is displayed. Besides text information of execution plans, TiDB v6.2.0 introduces visual execution plans, through which you can learn each operator of a statement and detailed information more intuitively. You can select different execution plans, and the details of the selected plans are displayed below the list (area 2 in the following figure).
- Execution detail of plans, which displays the detailed information of the selected execution plans. See Execution plan in details (area 3 in the following figure).

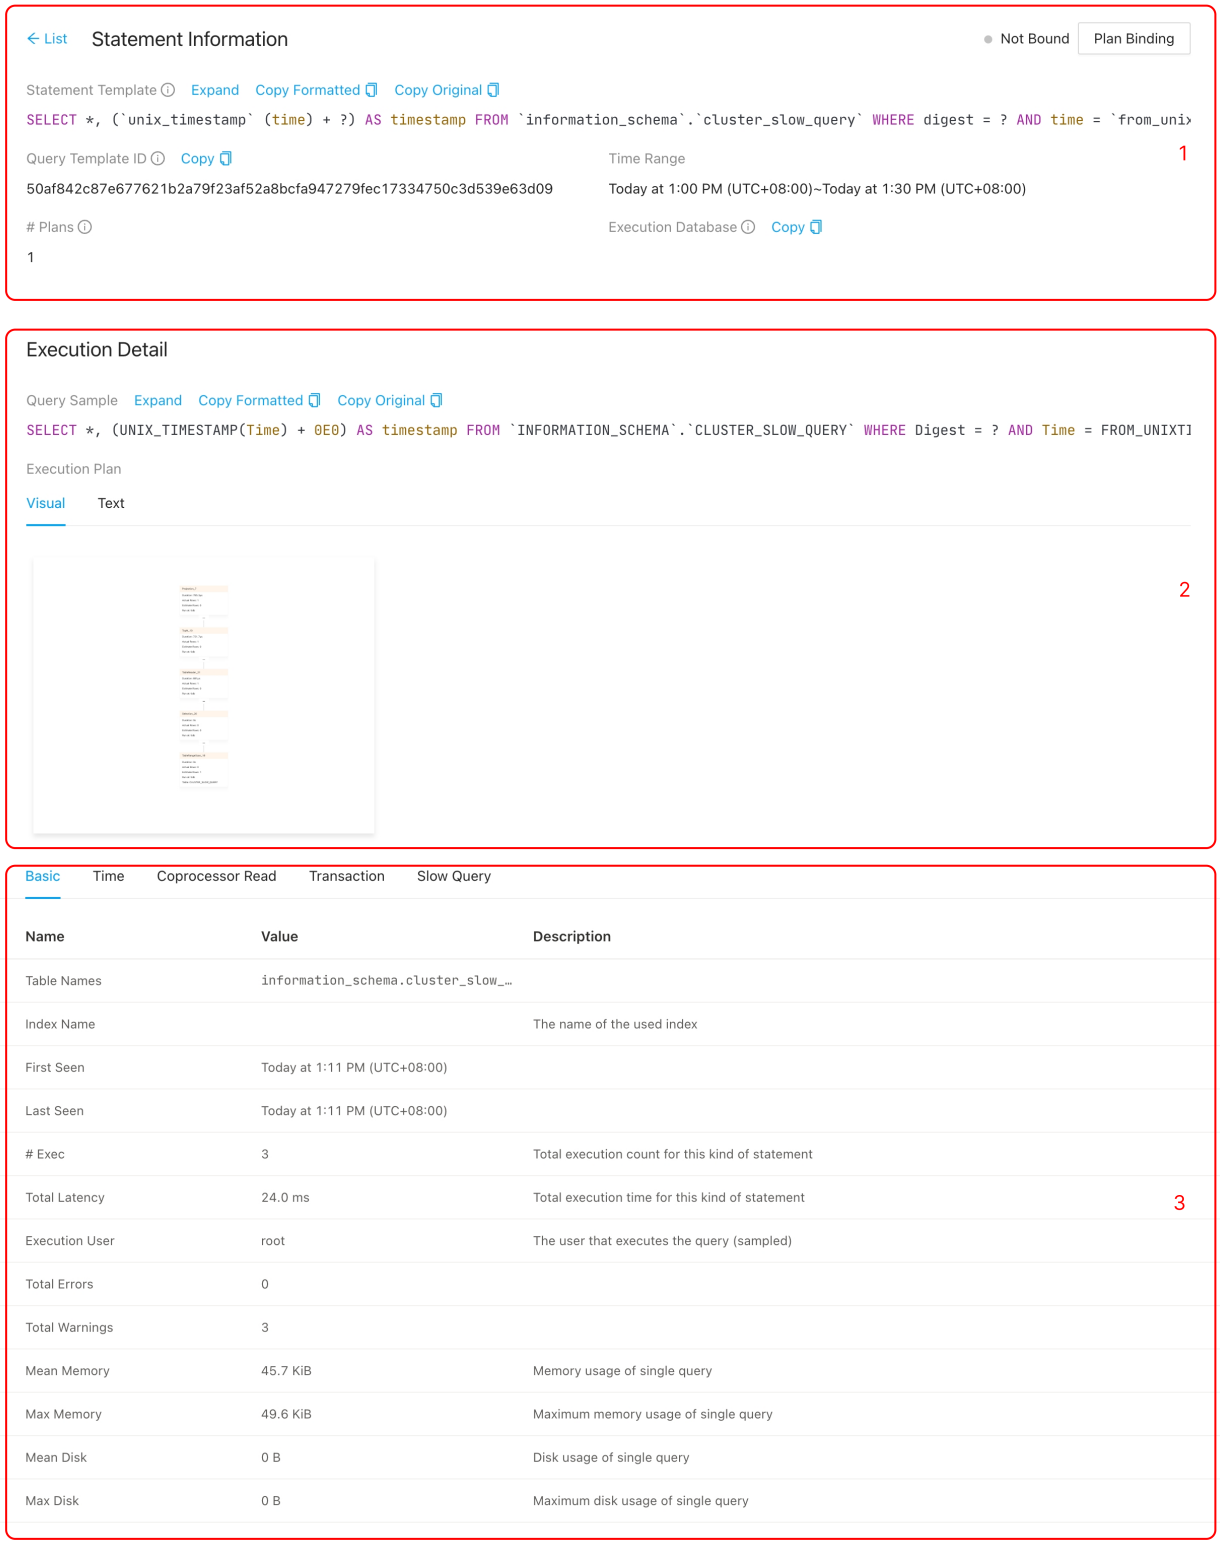

Figure 220: Details

9.5.9.2.1 Fast plan binding

Starting from v6.6.0, TiDB introduces the fast plan binding feature. You can quickly bind a SQL statement to a specific execution plan in TiDB Dashboard.

Usage

Bind an execution plan

1. Click **Plan Binding**. The **Plan Binding** dialog box is displayed.

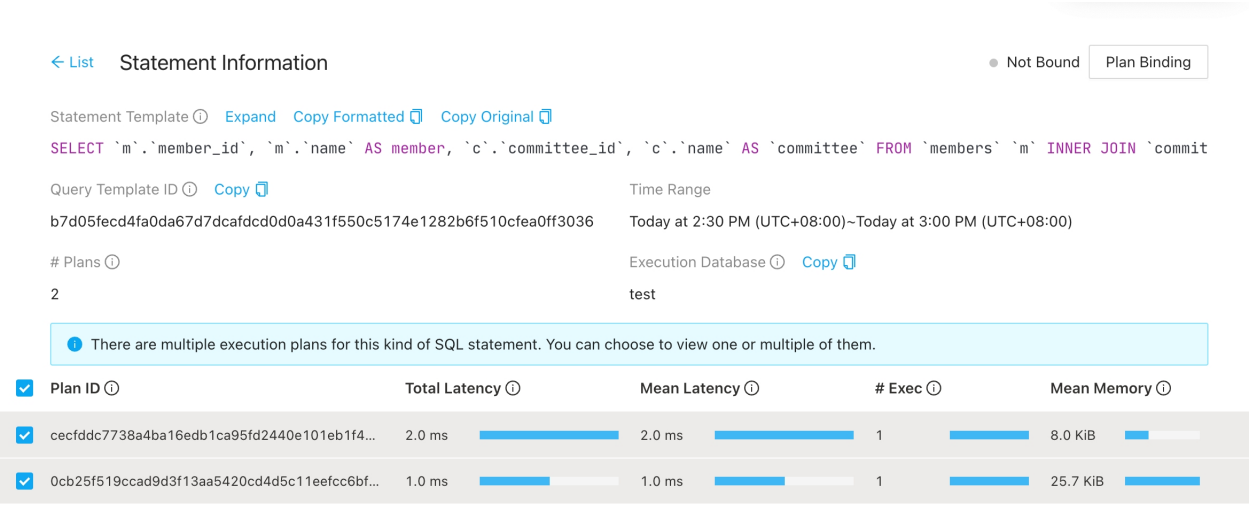

Figure 221: Fast plan binding - not bound - entry

2. Select a plan that you want to bind and click **Bind**.

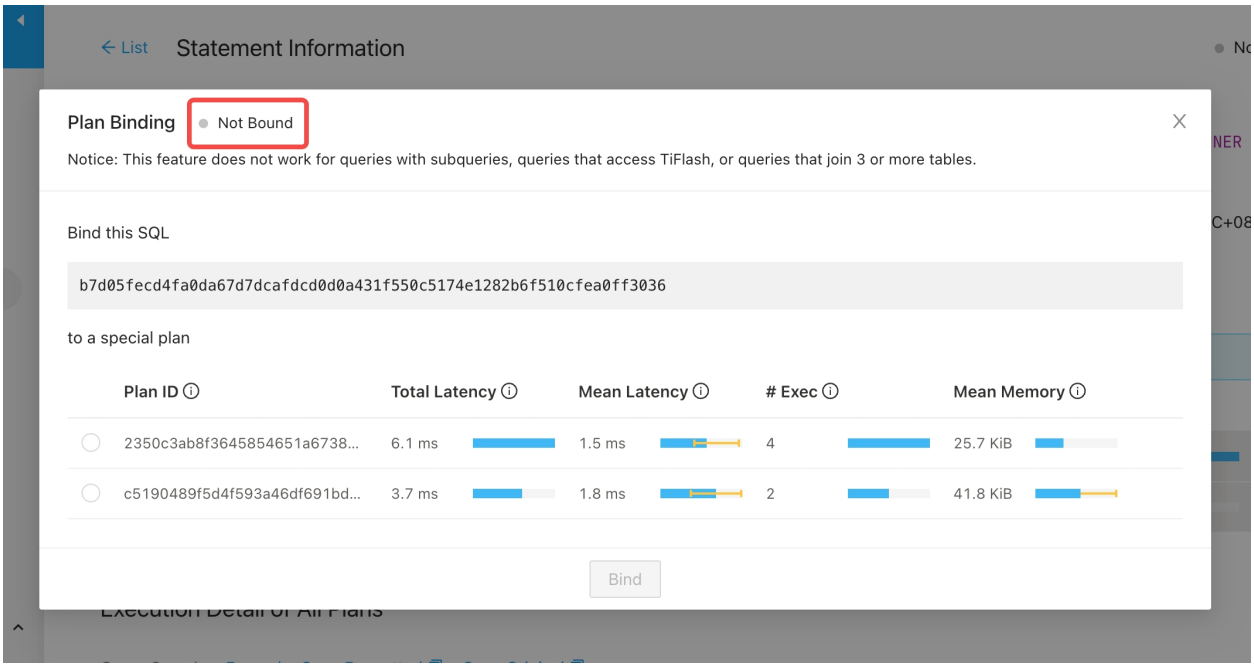

Figure 222: Fast plan binding - popup

3. After the binding is completed, you can see the **Bound** label.

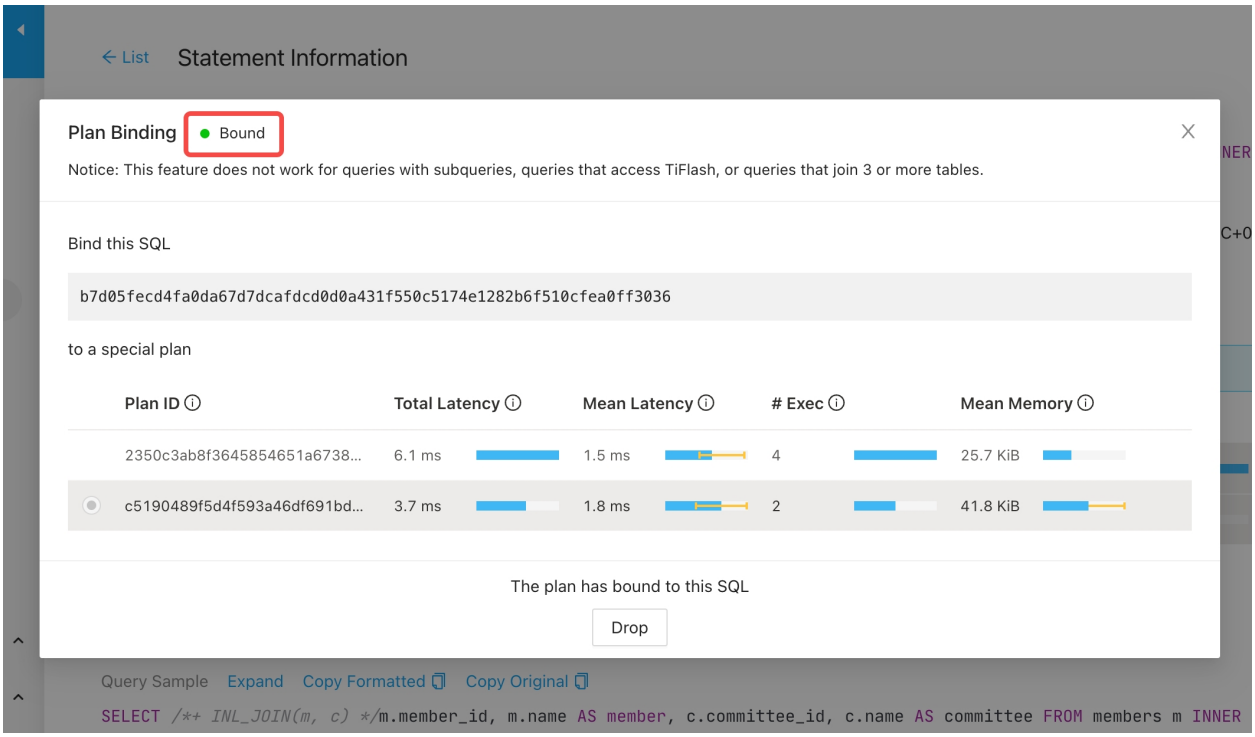

Figure 223: Fast plan binding - popup - binding completed

Drop an existing binding

1. On the page of a SQL statement that has an existing binding, click **Plan Binding**. The **Plan Binding** dialog box is displayed.

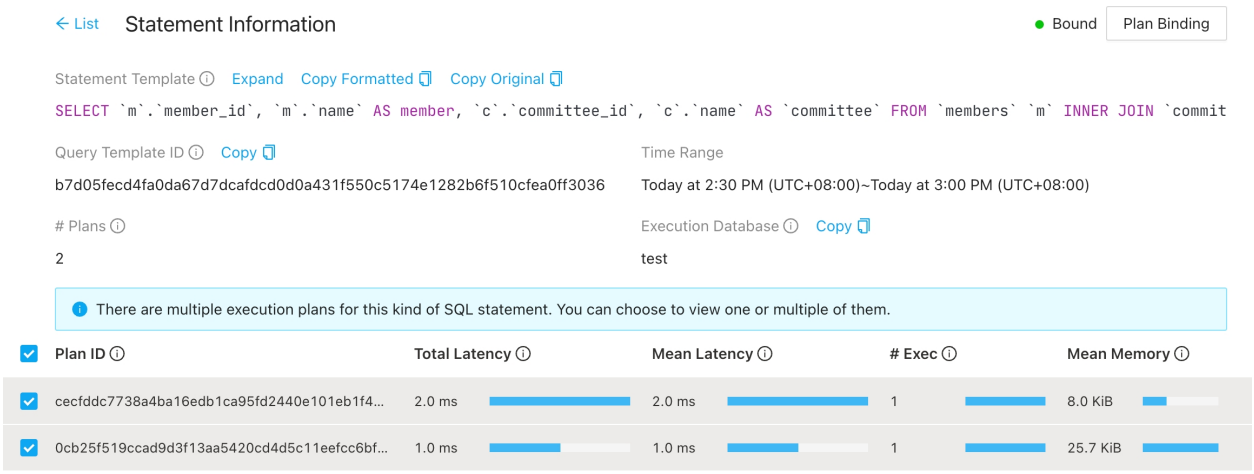

Figure 224: Fast plan binding - bound - entry

2. Click **Drop**.

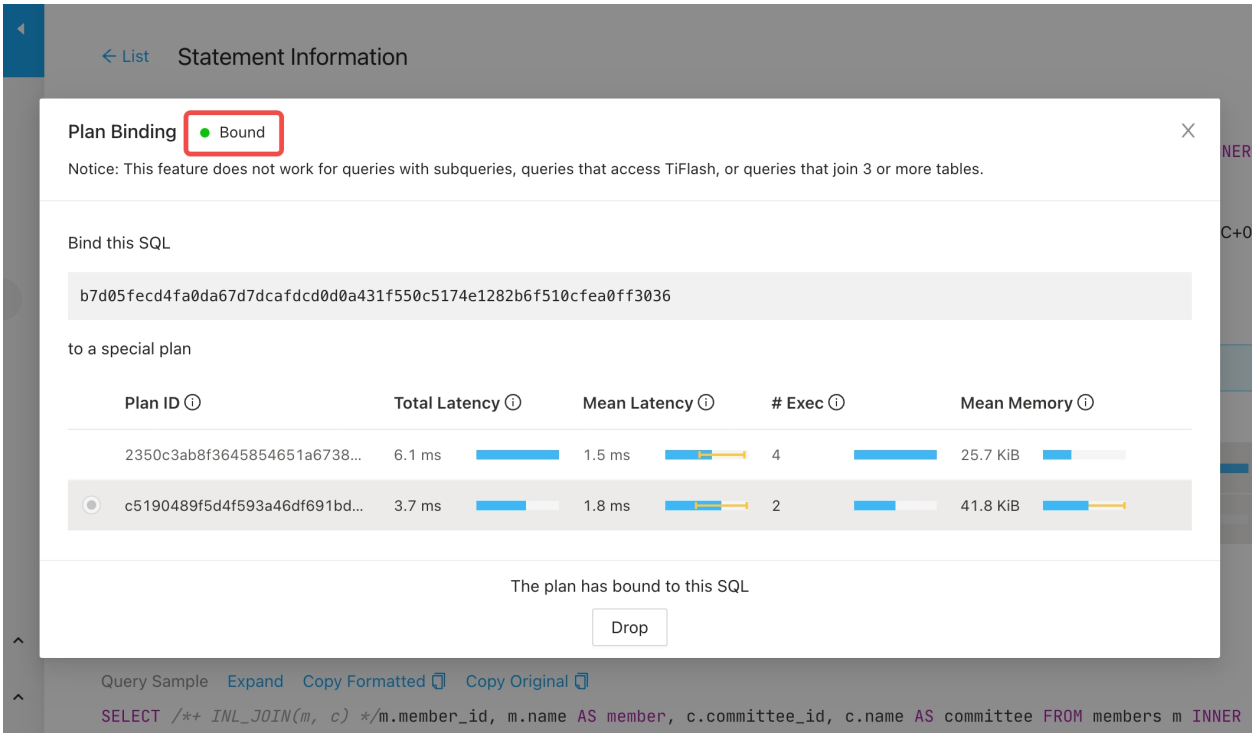

Figure 225: Fast plan binding - popup - bound

3. After the binding is dropped, you can see the **Not bound** label.

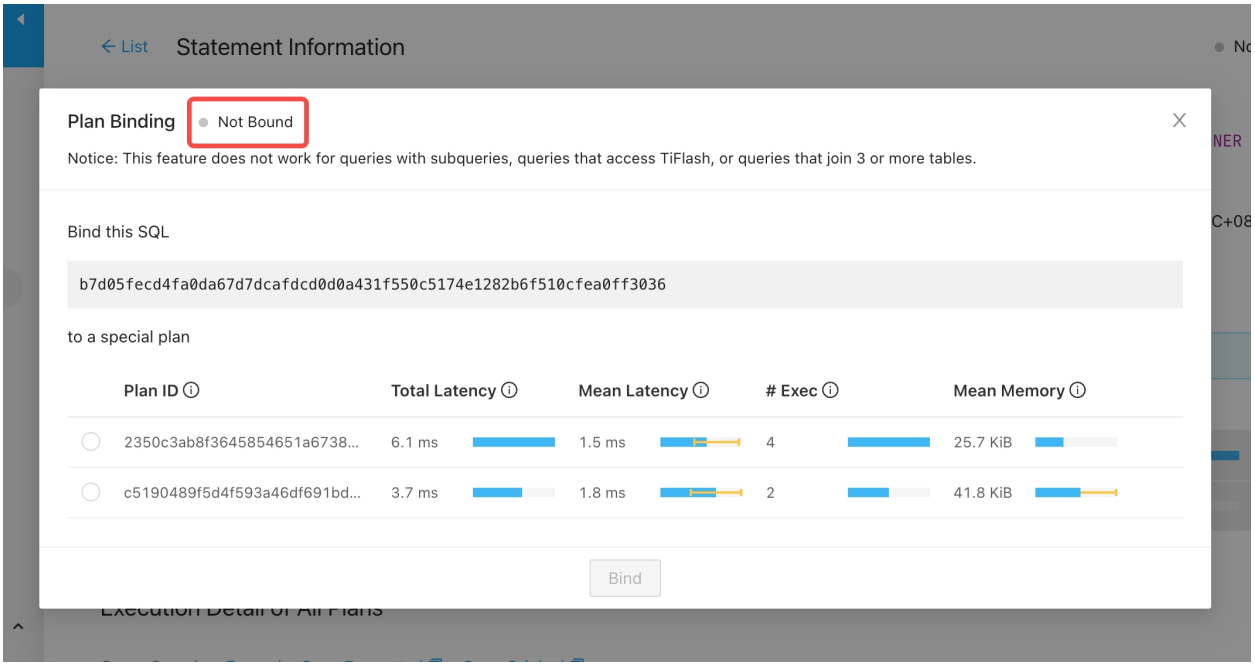

Figure 226: Fast plan binding - popup

Limitation

Currently, the fast plan binding feature does not support the following types of SQL statements:

- Statements that are not `SELECT`, `DELETE`, `UPDATE`, `INSERT`, or `REPLACE`
- Queries with subqueries
- Queries that access TiFlash
- Queries that join three or more tables

To use this feature, you must have the SUPER privilege. If you encounter permission issues while using it, refer to TiDB Dashboard User Management to add the necessary privileges.

9.5.9.2.2 Execution details of plans

The execution detail of plans includes the following information:

- SQL sample: The text of a certain SQL statement that is actually executed corresponding to the plan. Any SQL statement that has been executed within the time range might be used as a SQL sample.
- Execution plan: Complete information about execution plans, displayed in table, graph, and text. For details of the execution plan, see Understand the Query Execution Plan. If multiple execution plans are selected, only (any) one of them is displayed.
- For basic information, execution time, Coprocessor read, transaction, and slow query of the SQL statement, you can click the corresponding tab titles to switch among different information.

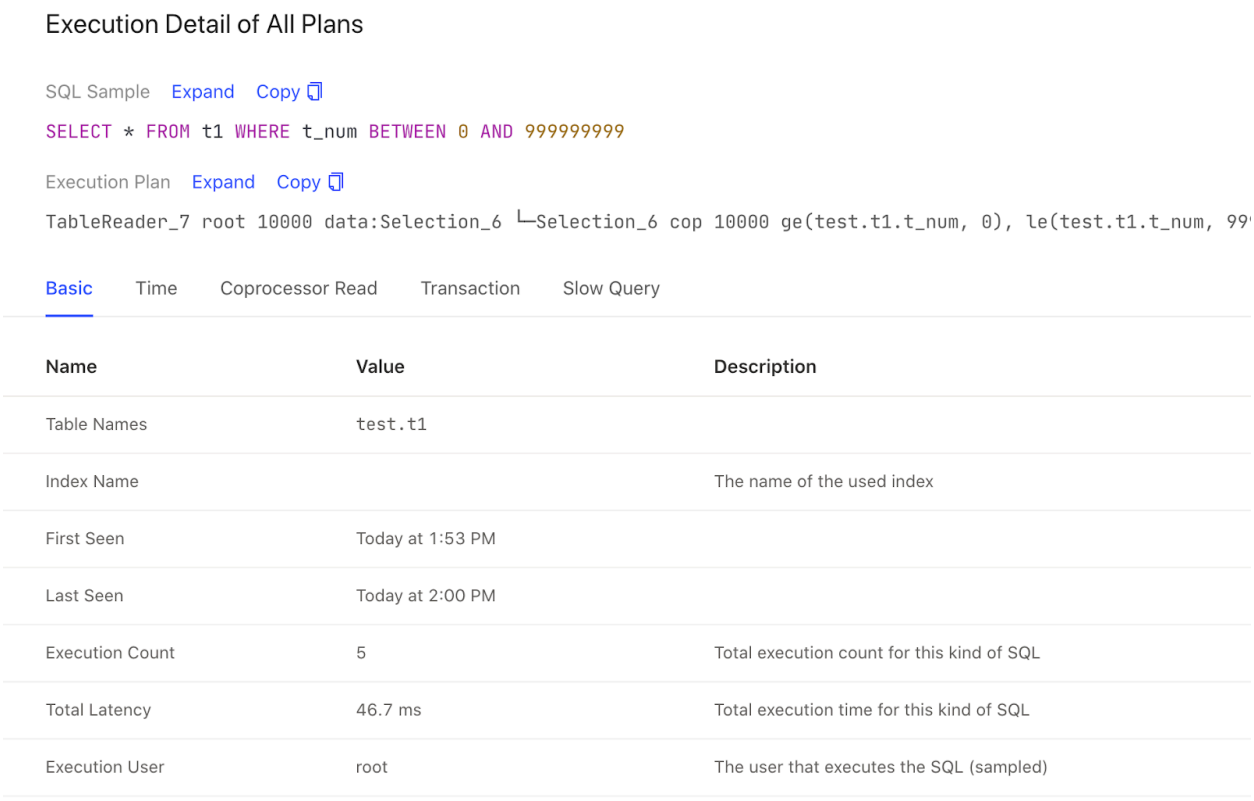

Figure 227: Execution details of plans

SQL sample

To view the detailed information of an item, you can click **Expand**. To copy the detailed information to the clipboard, click **Copy**.

Execution plans

On TiDB Dashboard, you can view execution plans in three ways: table, text, and graph. To learn how to read an execution plan, see Understand the query execution plan.

Execution plan in table format

The table format provides detailed information about the execution plan, which helps you quickly identify abnormal operator metrics and compare the status of different operators. The following figure shows an execution plan in table format:

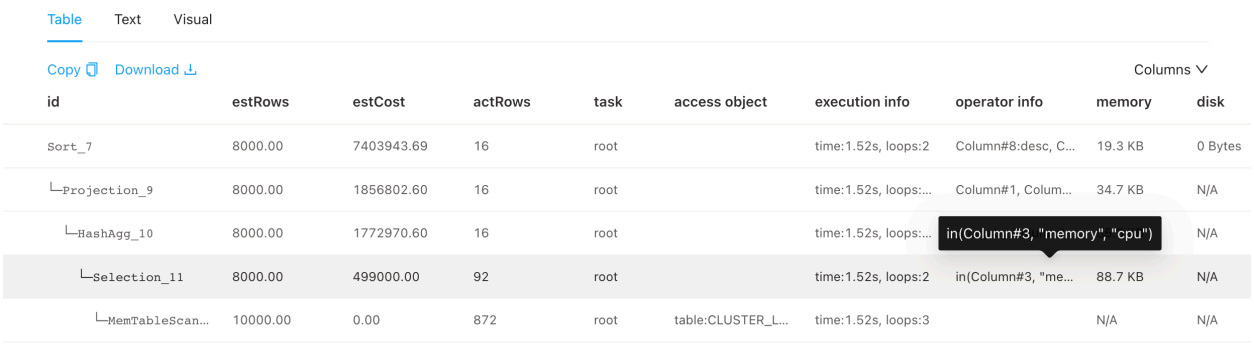

Figure 228: Execution plan in table format

The table format displays similar information to the text format but provides more user-friendly interactions:

- You can adjust the column width freely.
- When content exceeds the column width, it is automatically truncated and a tooltip is shown for the full information.
- If the execution plan is large, you can download it as a text file for local analysis.
- You can hide and manage columns using the column picker.

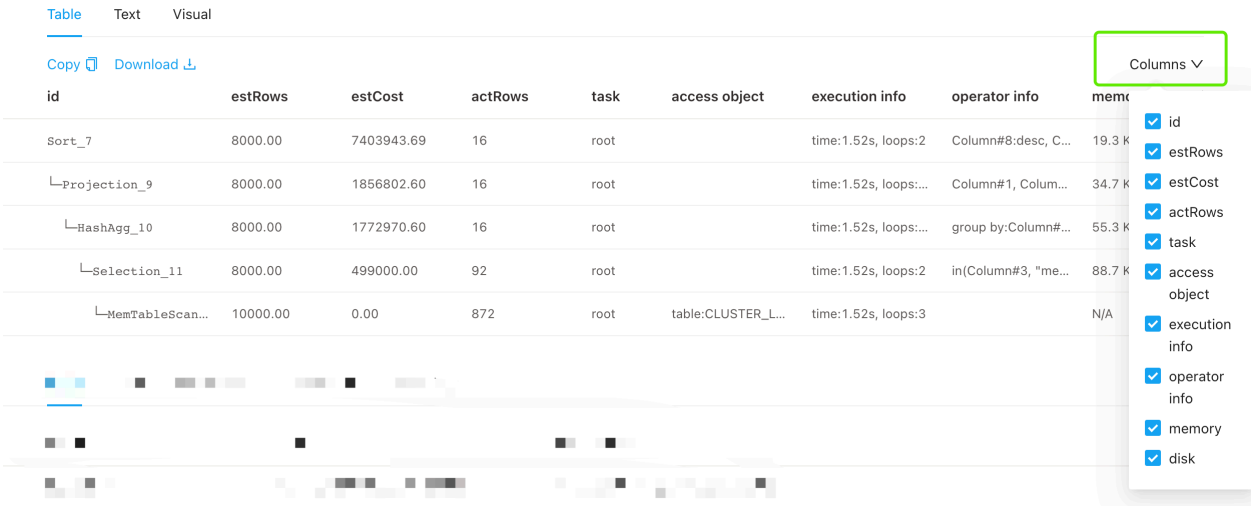

Figure 229: Execution plan in table format - column picker

Execution plan in graph format

The graph format is more suitable for viewing the execution plan tree of a complex SQL statement and understanding each operator and its corresponding content in detail. The following figure shows an execution plan in graph format:

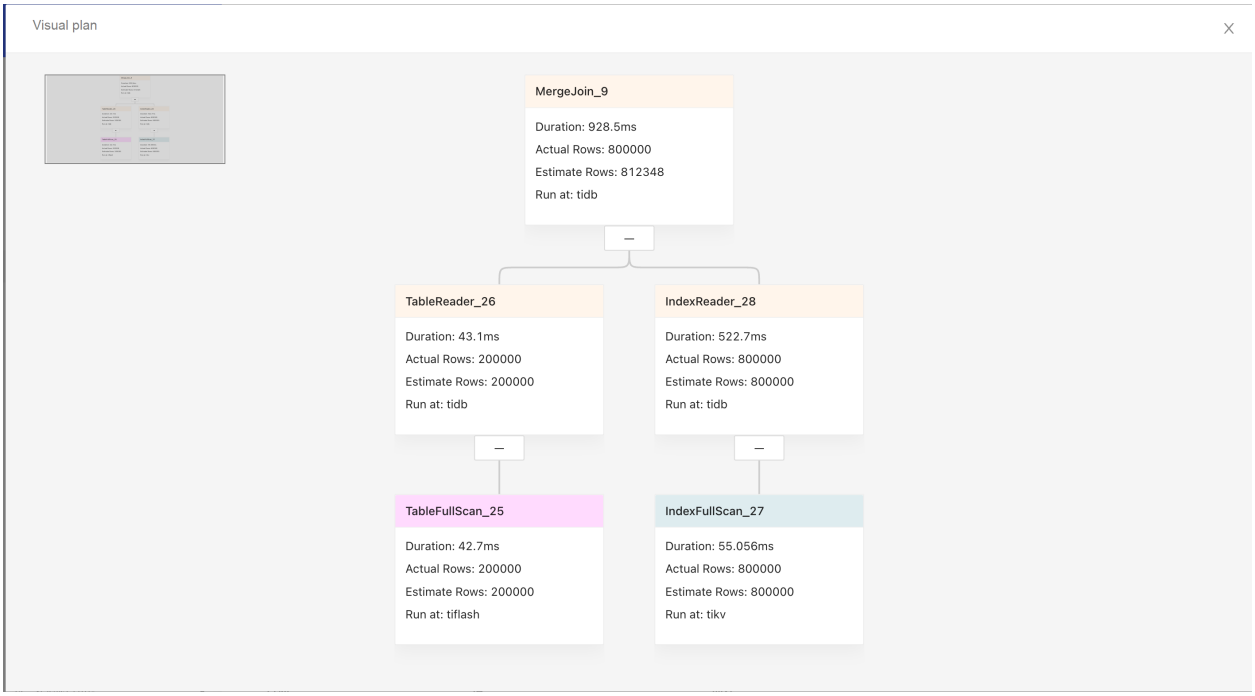

Figure 230: Execution plan in graph format

- The graph shows the execution from left to right, and from top to bottom.
- Upper nodes are parent operators and lower nodes are child operators.
- The color of the title bar indicates the component where the operator is executed: yellow stands for TiDB, blue stands for TiKV, and pink stands for TiFlash.
- The title bar shows the operator name and the text shown below is the basic information of the operator.

Click the node area, and the detailed operator information is displayed on the right sidebar.

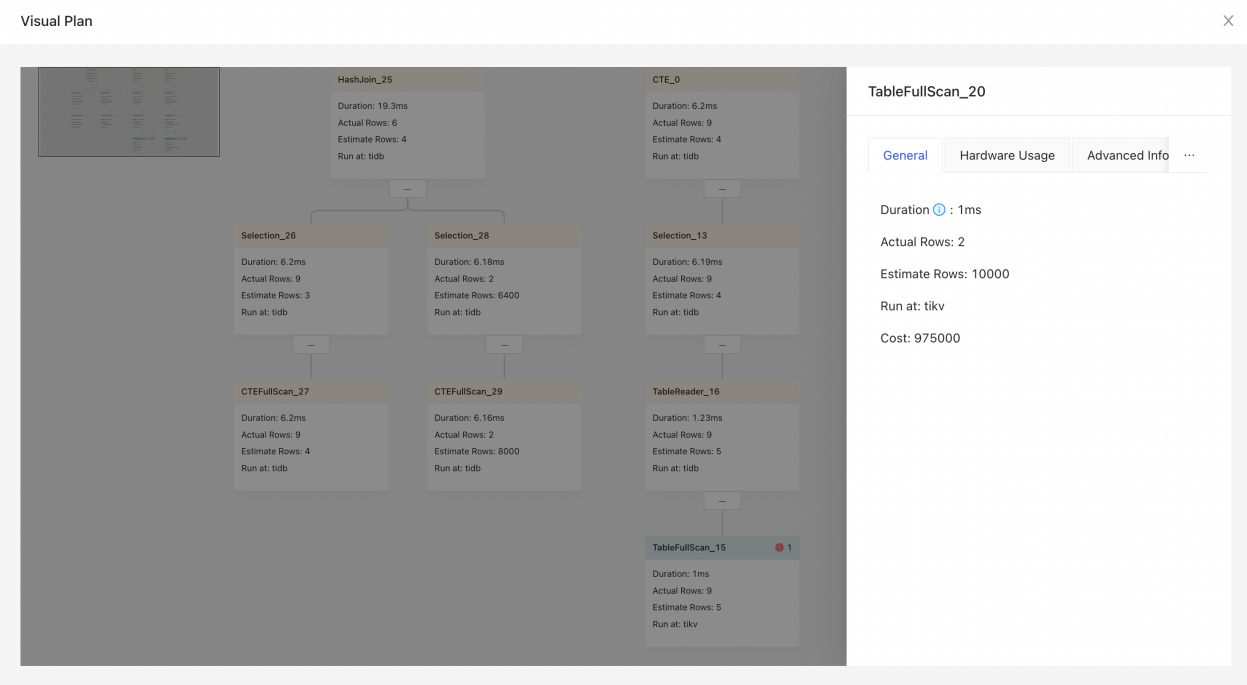

Figure 231: Execution plan in graph format - sidebar

SQL execution details

For basic information, execution time, Coprocessor read, transaction, and slow query of the SQL statement, you can click the corresponding tab titles to switch among different information.

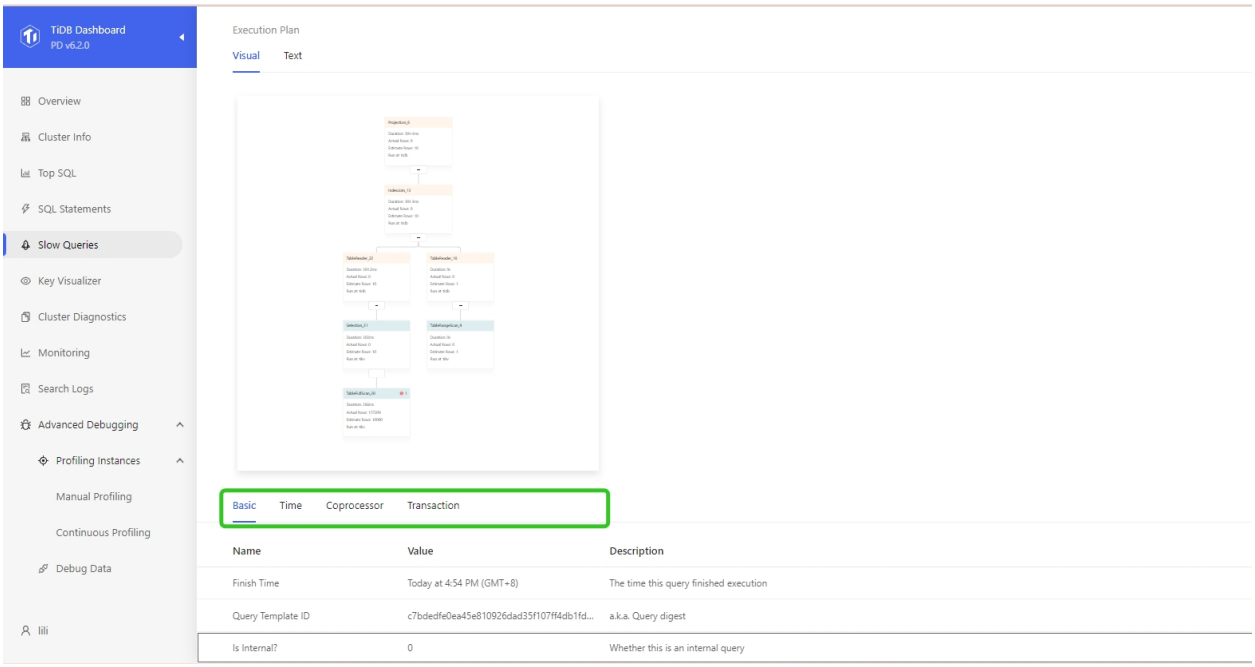

Figure 232: Show different execution information

Basic tab

The basic information of a SQL execution includes the table names, index name, execution count, and total latency. The **Description** column provides detailed description of each field.

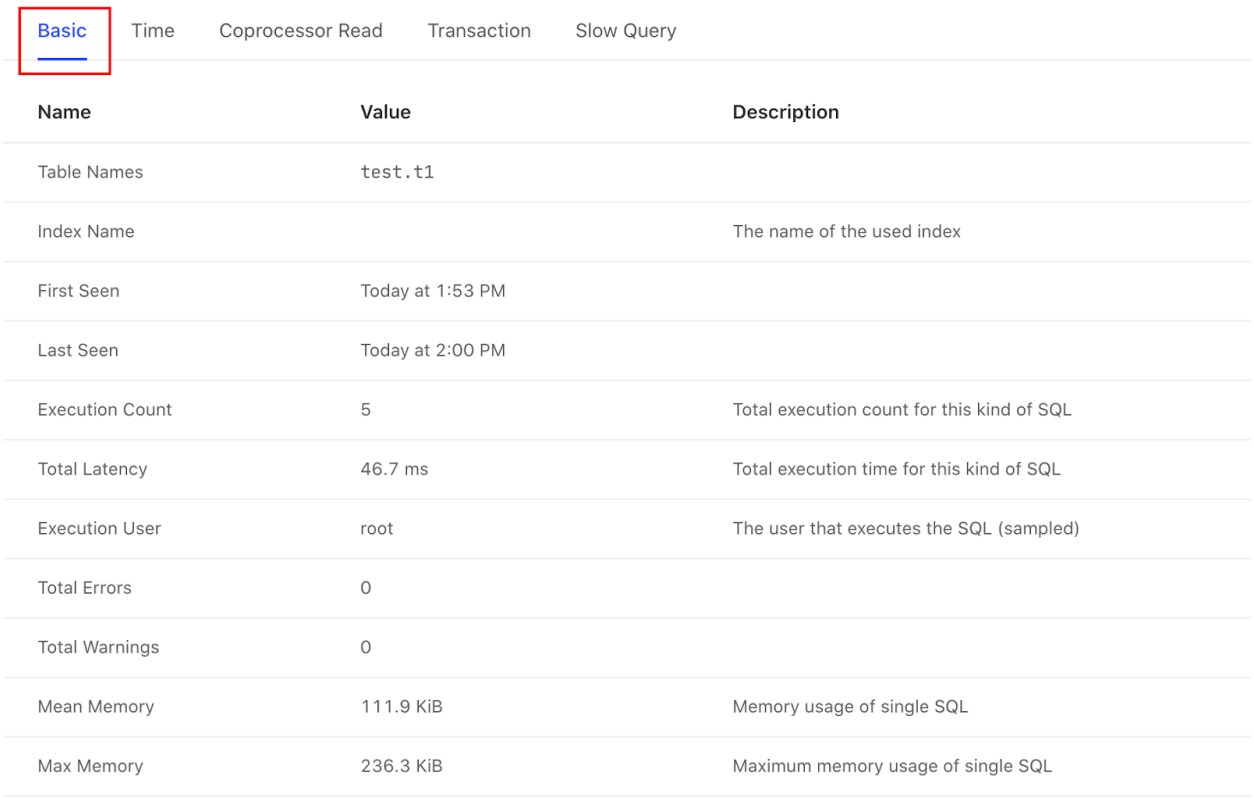

Figure 233: Basic information

Time tab

Click the **Time** tab, and you can see how long each stage of the execution plan lasts.

> **Note:**
>
> Because some operations might be performed in parallel within a single SQL statement, the cumulative duration of each stage might exceed the actual execution time of the SQL statement.

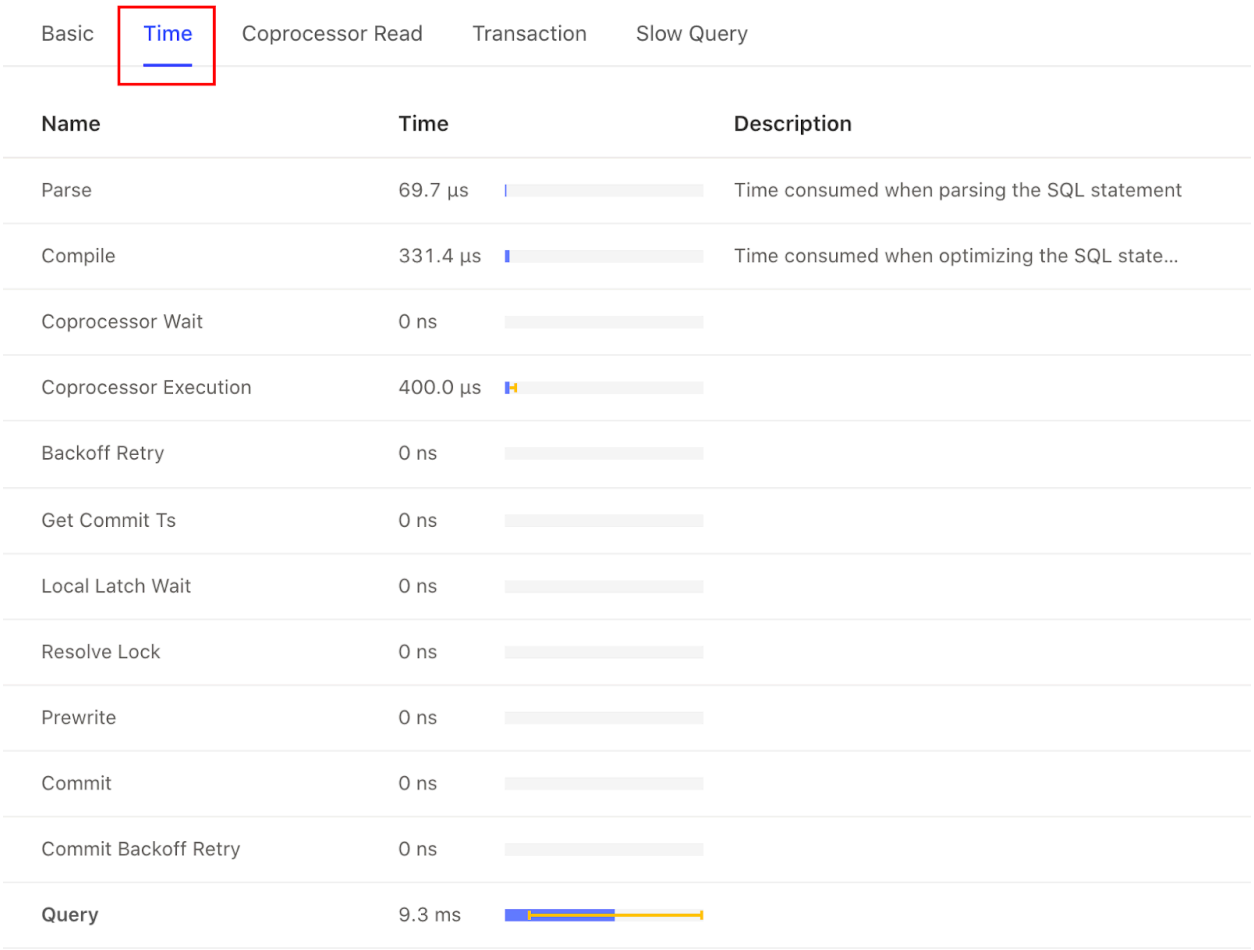

Figure 234: Execution time

Coprocessor Read tab

Click the **Coprocessor Read** tab, and you can see information related to Coprocessor read.

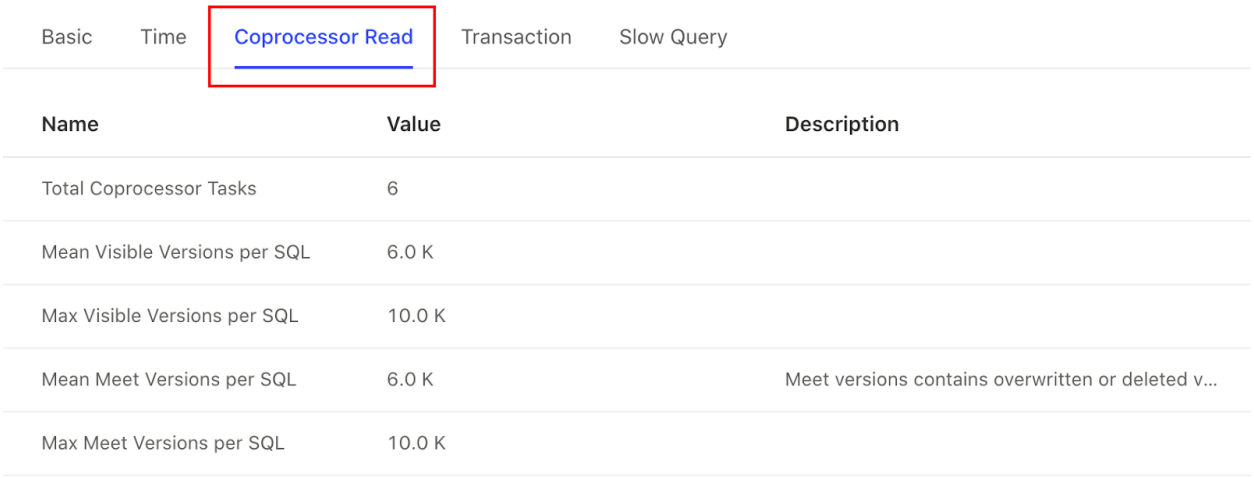

Figure 235: Coprocessor read

Transaction tab

Click the **Transaction** tab, and you can see information related to execution plans and transactions, such as the average number of written keys or the maximum number of written keys.

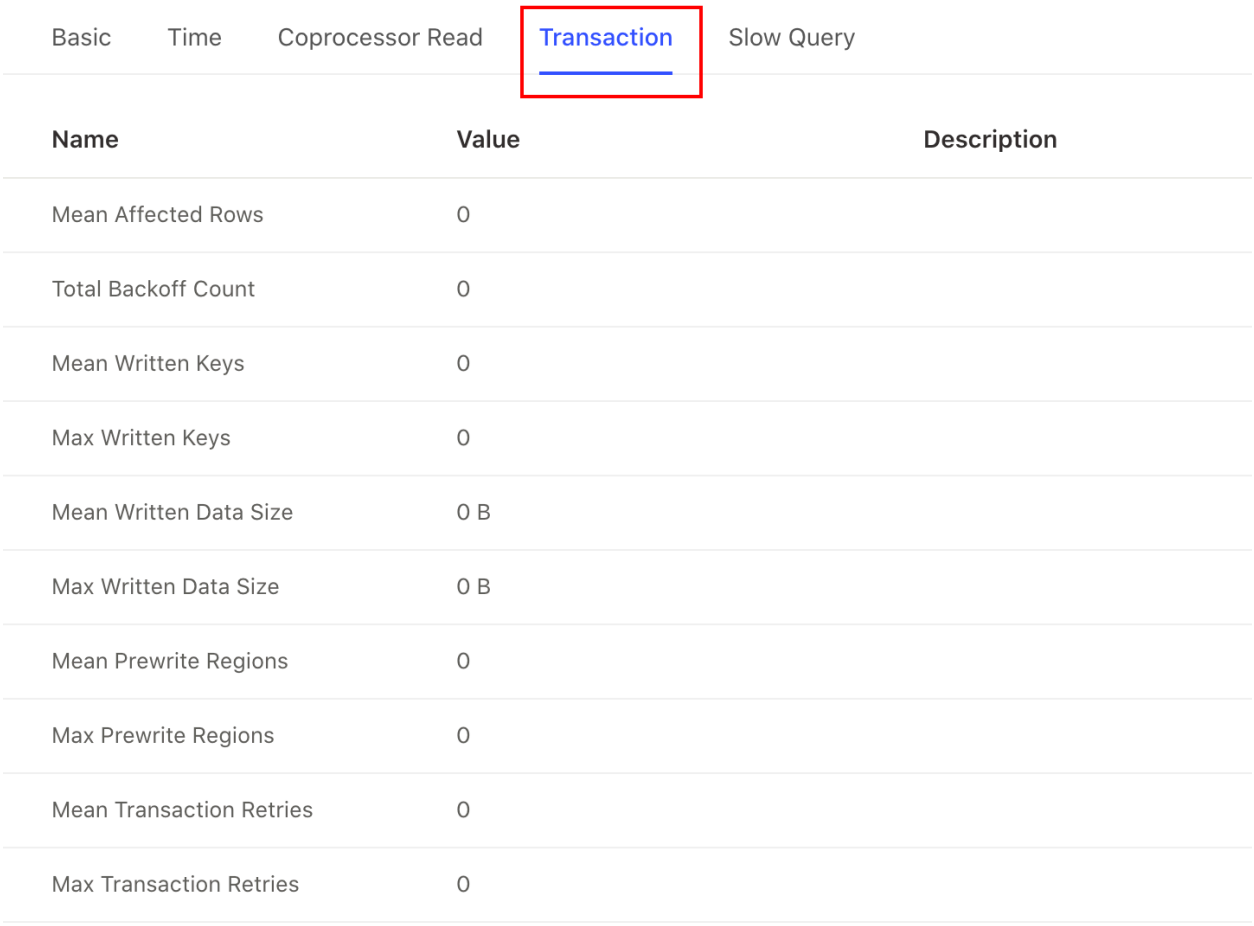

Figure 236: Transaction

Slow Query tab

If an execution plan is executed too slowly, you can see its associated slow query records under the **Slow Query** tab.

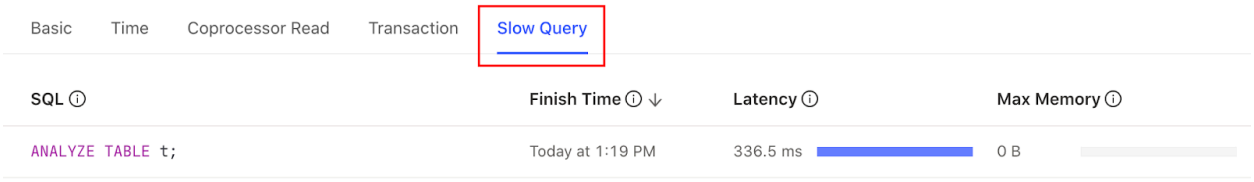

Figure 237: Slow Query

The information displayed in this area has the same structure with the slow query page. See TiDB Dashboard Slow Query Page for details.

9.5.10 Slow Queries Page of TiDB Dashboard

On the Slow Queries page of TiDB Dashboard, you can search and view all slow queries in the cluster.

By default, SQL queries with an execution time of more than 300 milliseconds are considered as slow queries. These queries are recorded in the slow query logs and can be searched via TiDB Dashboard. You can adjust the threshold of slow queries through the `tidb_slow_log_threshold` session variable or the `instance.tidb_slow_log_threshold` TiDB parameter.

> **Note:**
>
> If the slow query log is disabled, this feature will be unavailable. The slow query log is enabled by default, and you can enable or disable it through the system variable `tidb_enable_slow_log`.

9.5.10.1 Access the page

You can use one of the following two methods to access the slow query page:

- After logging in to TiDB Dashboard, click **Slow Queries** in the left navigation menu.
- Visit http://127.0.0.1:2379/dashboard/#/slow_query in your browser. Replace `127.0.0.1:2379` with the actual PD address and port.

All data displayed on the slow query page comes from TiDB slow query system tables and slow query logs. See slow query logs for details.

9.5.10.1.1 Change filters

You can filter slow queries based on the time range, the related database, SQL keywords, SQL types, the number of slow queries to be displayed. In the image below, 100 slow queries over the recent 30 minutes are displayed by default.

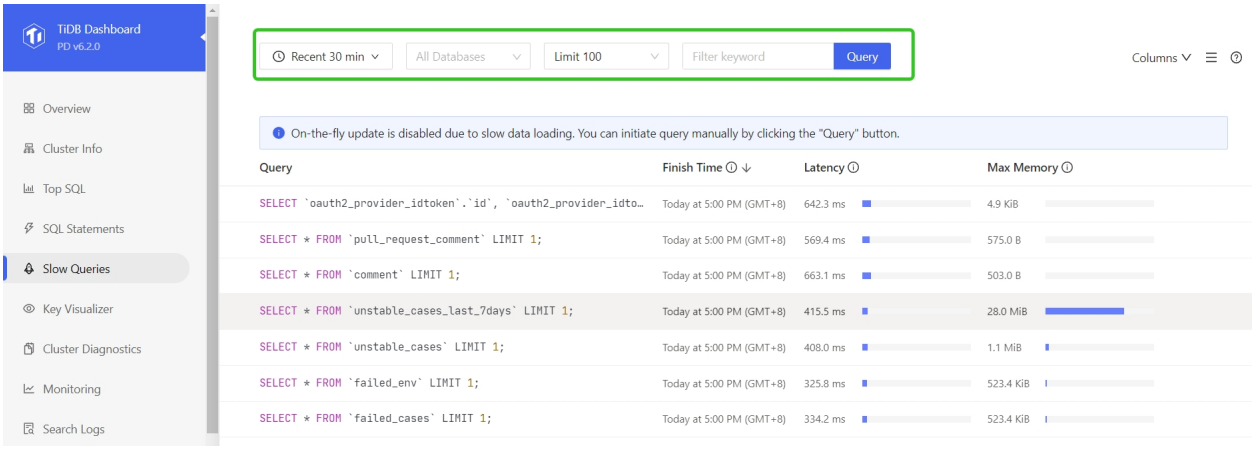

Figure 238: Modify list filters

9.5.10.1.2 Display more columns

Click **Columns** on the page and you can choose to see more columns. You can move your mouse to the **(i)** icon at the right side of a column name to view the description of this column:

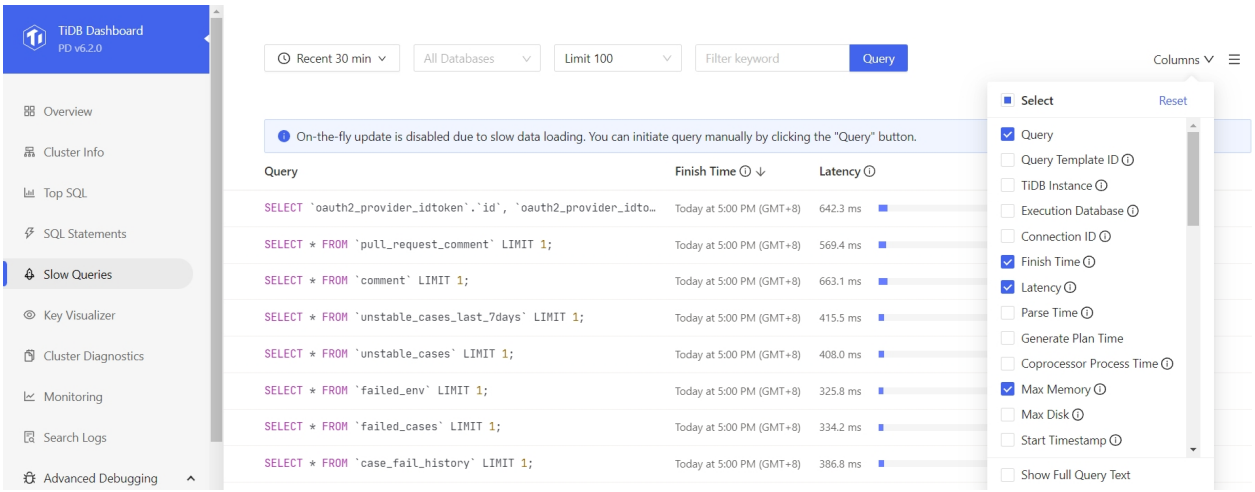

Figure 239: Show more columns

9.5.10.1.3 Export slow queries locally

Click (**More**) in the upper-right corner of the page to display the **Export** option. After you click **Export**, TiDB Dashboard exports slow queries in the current list as a CSV file.

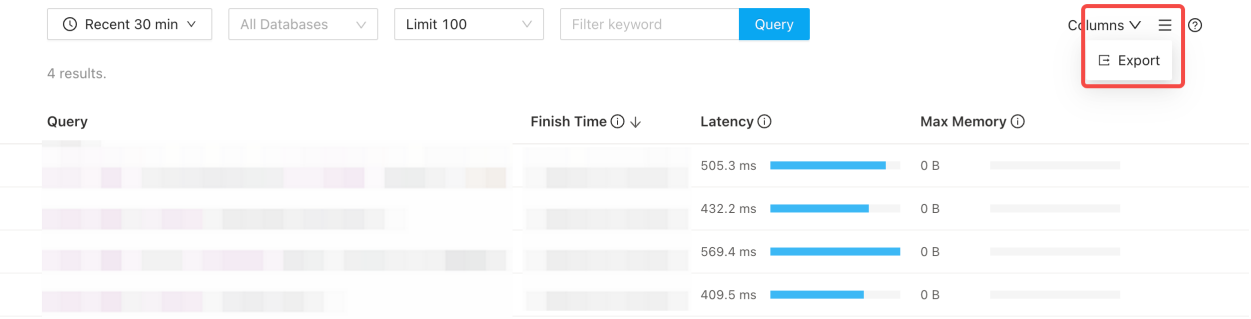

Figure 240: Export slow queries locally

9.5.10.1.4 Sort by column

By default, the list is sorted by **Finish Time** in the descending order. Click column headings to sort by the column or switch the sorting order:

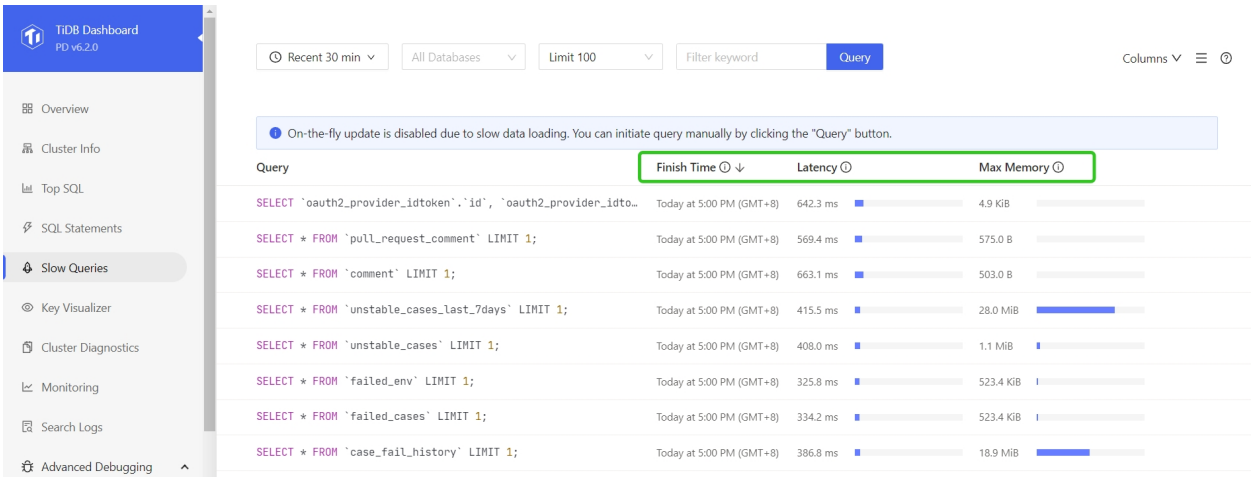

Figure 241: Modify sorting basis

9.5.10.2 View execution details

Click any item in the list to display detailed execution information of the slow query, including:

- Query: The text of the SQL statement (area 1 in the following figure)

- Plan: The execution plan of the slow query (area 2 in the following figure)
- Other sorted SQL execution information (area 3 in the following figure)

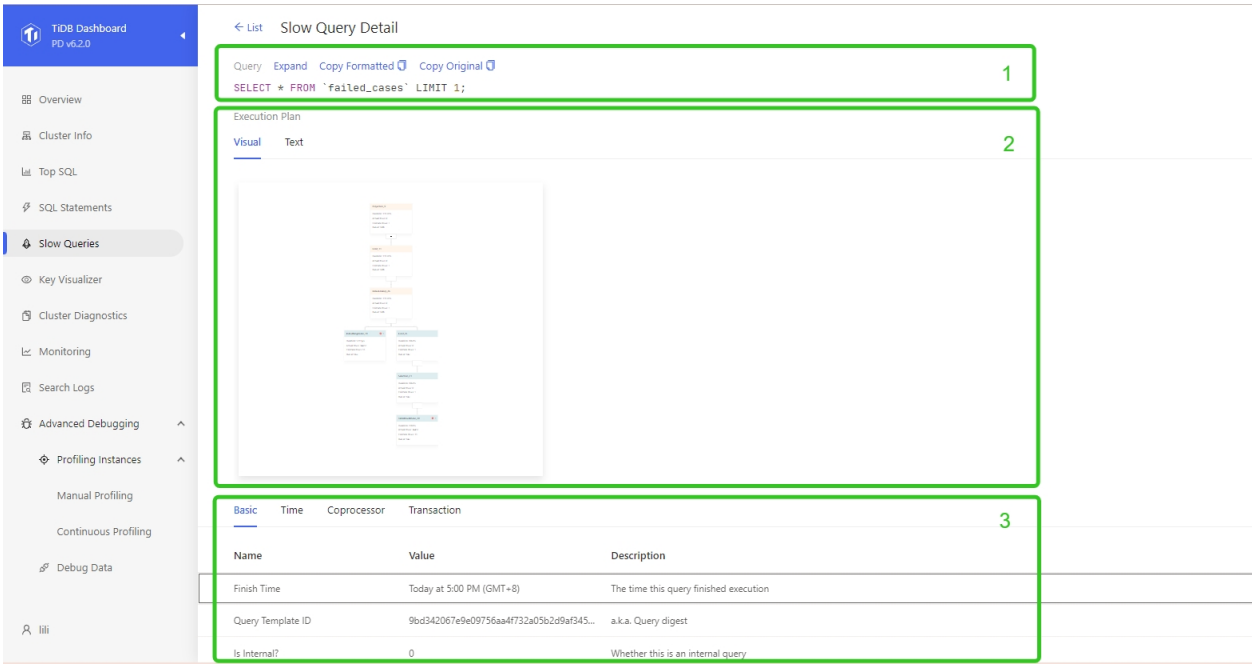

Figure 242: View execution details

9.5.10.2.1 SQL

> **Note:**
>
> The maximum length of the query recorded in the `Query` column is limited by the `tidb_stmt_summary_max_sql_length` system variable.

Click the **Expand** button to view the detailed information of an item. Click the **Copy** button to copy the detailed information to the clipboard.

9.5.10.2.2 Execution plans

On TiDB Dashboard, you can view execution plans in three ways: table, text, and graph. To learn how to read an execution plan, see Understand the query execution plan.

Execution plan in table format

The table format provides detailed information about the execution plan, which helps you quickly identify abnormal operator metrics and compare the status of different operators. The following figure shows an execution plan in table format:

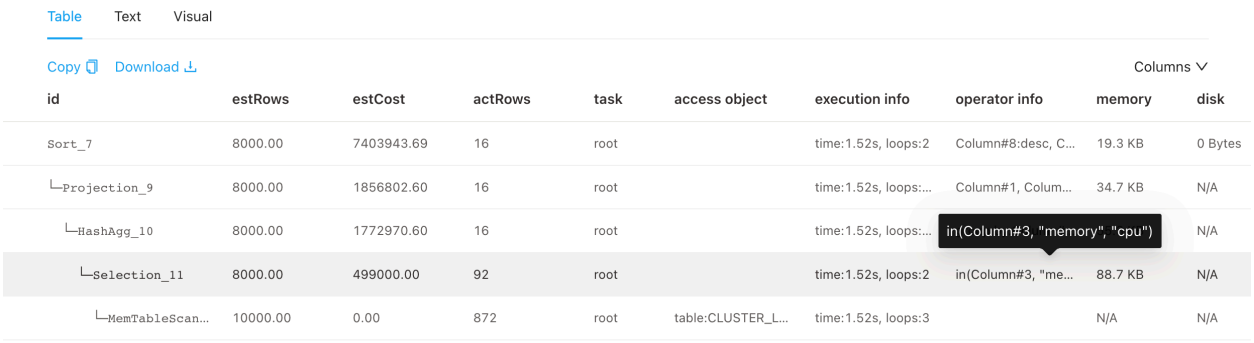

Figure 243: Execution plan in table format

The table format displays similar information to the text format but provides more user-friendly interactions:

- You can adjust the column width freely.
- When content exceeds the column width, it is automatically truncated and a tooltip is shown for the full information.
- If the execution plan is large, you can download it as a text file for local analysis.
- You can hide and manage columns using the column picker.

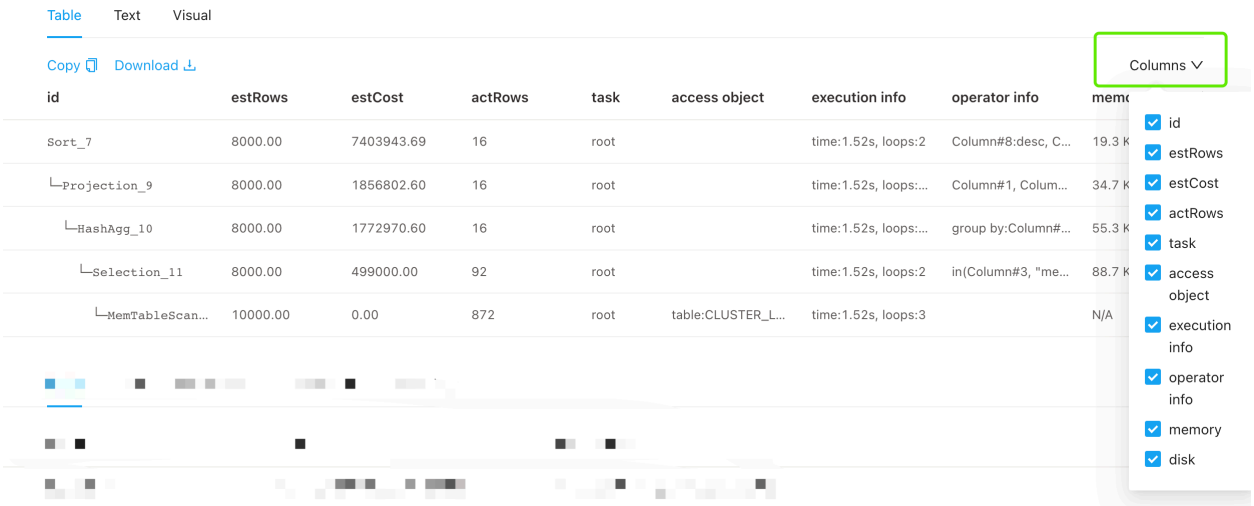

Figure 244: Execution plan in table format - column picker

Execution plan in graph format

The graph format is more suitable for viewing the execution plan tree of a complex SQL statement and understanding each operator and its corresponding content in detail. The following figure shows an execution plan in graph format:

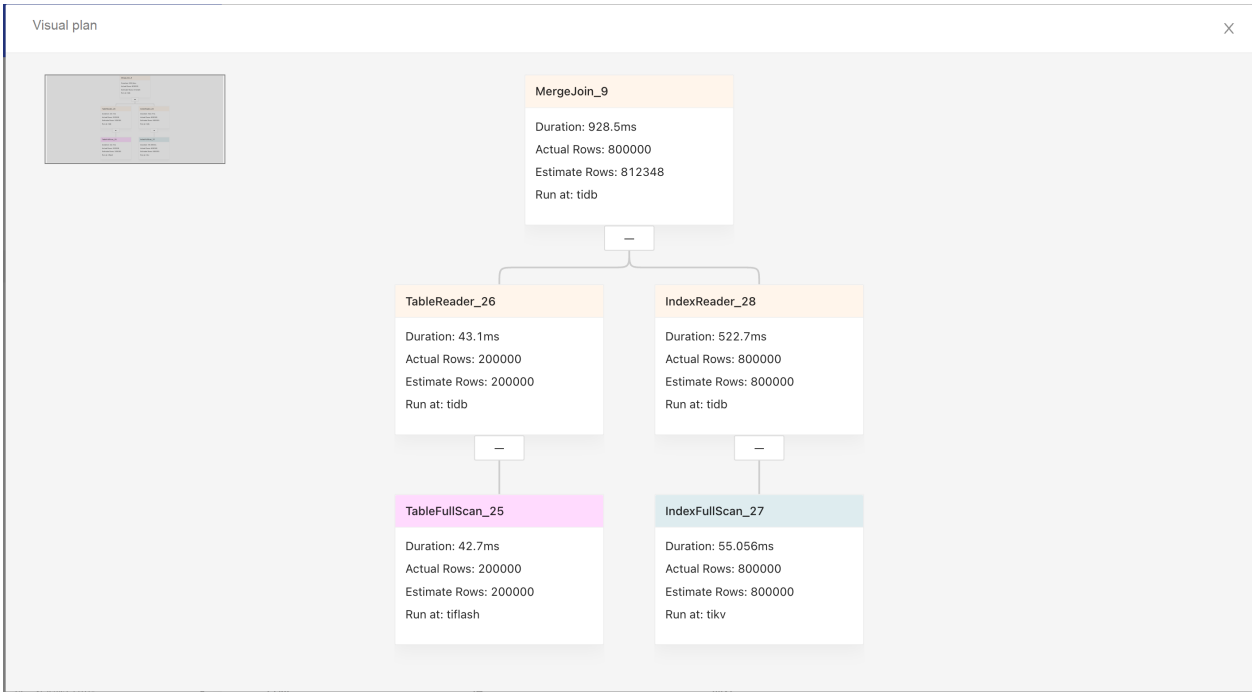

Figure 245: Execution plan in graph format

- The graph shows the execution from left to right, and from top to bottom.
- Upper nodes are parent operators and lower nodes are child operators.
- The color of the title bar indicates the component where the operator is executed: yellow stands for TiDB, blue stands for TiKV, and pink stands for TiFlash.
- The title bar shows the operator name and the text shown below is the basic information of the operator.

Click the node area, and the detailed operator information is displayed on the right sidebar.

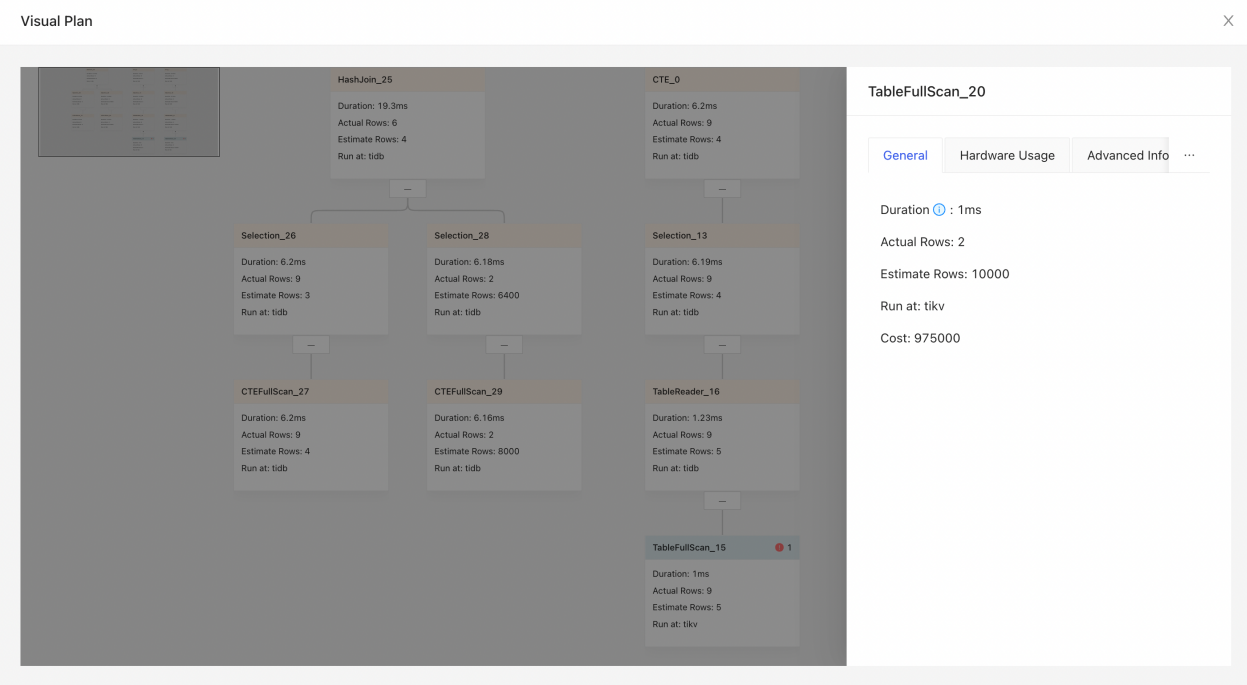

Figure 246: Execution plan in graph format - sidebar

9.5.10.2.3 SQL execution details

For basic information, execution time, Coprocessor read, transaction, and slow query of the SQL statement, you can click the corresponding tab titles to switch among different information.

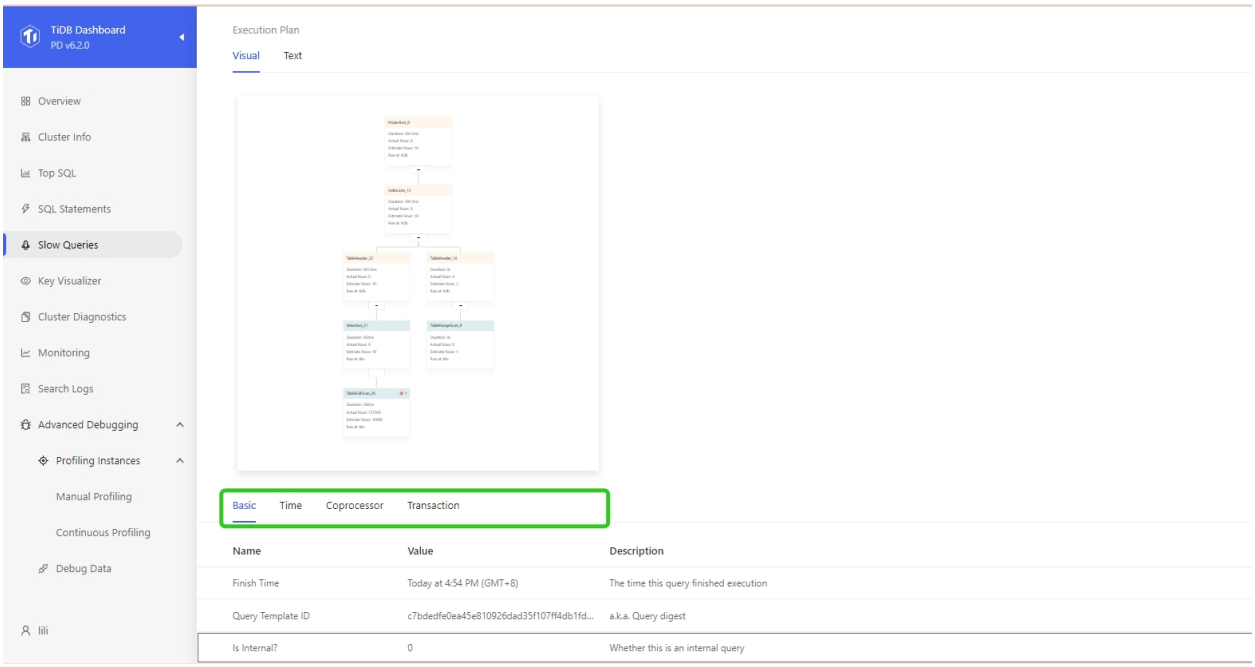

Figure 247: Show different execution information

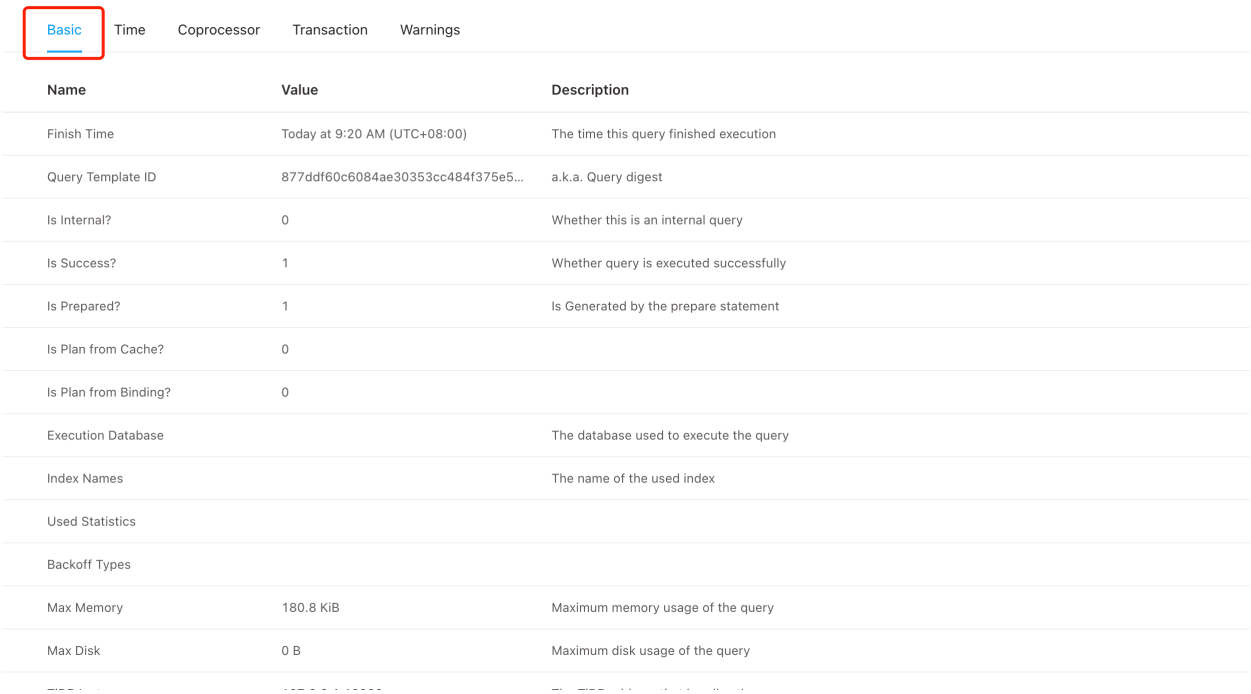
Basic tab

The basic information of a SQL execution includes the table names, index name, execution count, and total latency. The **Description** column provides detailed description of each field.



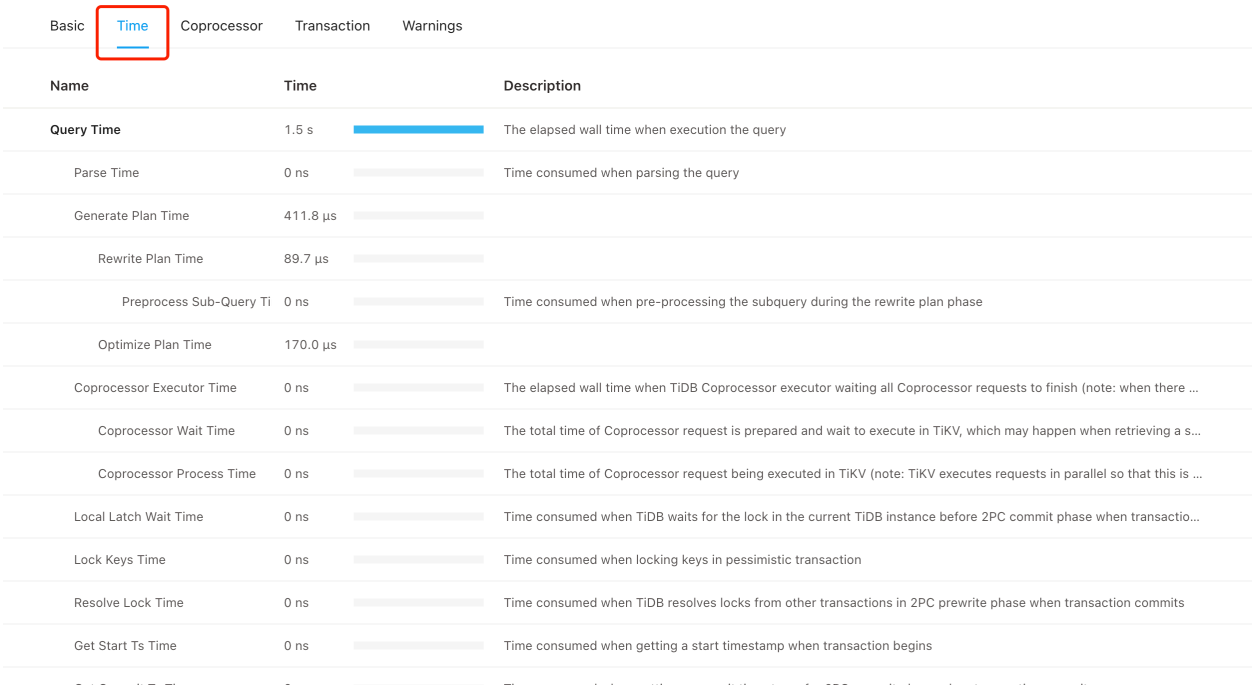


Figure 248: Basic information

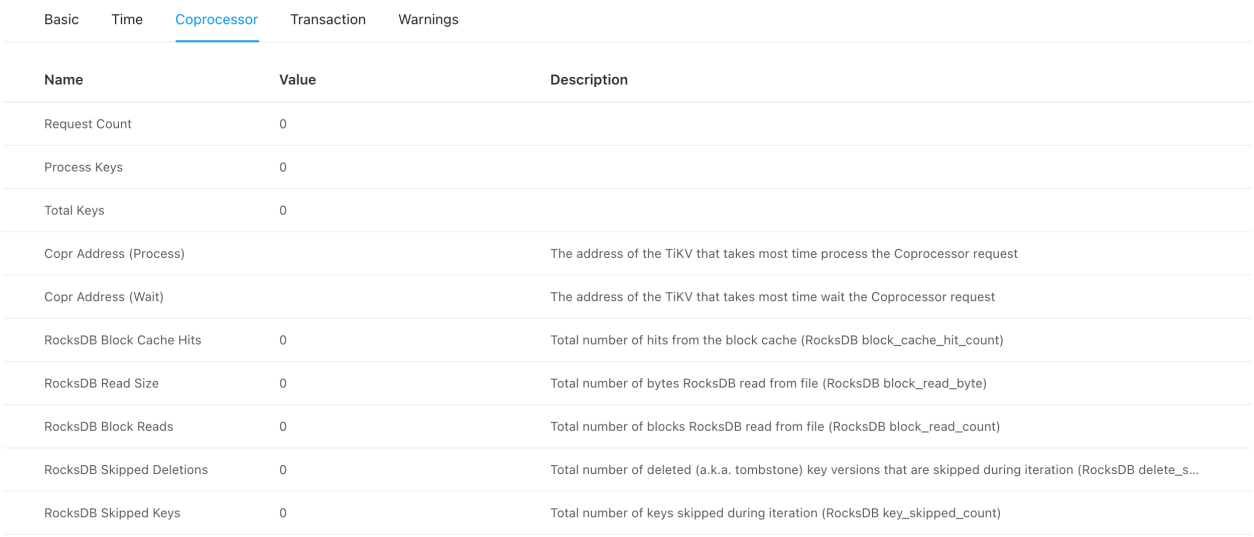
Time tab

Click the **Time** tab, and you can see how long each stage of the execution plan lasts.

> **Note:**
>
> Because some operations might be performed in parallel within a single SQL statement, the cumulative duration of each stage might exceed the actual execution time of the SQL statement.



Basic | Time | Coprocessor | Transaction | Warnings

Name	Time	Description
Query Time	1.5 s	The elapsed wall time when execution the query
Parse Time	0 ns	Time consumed when parsing the query
Generate Plan Time	411.8 µs	
Rewrite Plan Time	89.7 µs	
Preprocess Sub-Query Ti	0 ns	Time consumed when pre-processing the subquery during the rewrite plan phase
Optimize Plan Time	170.0 µs	
Coprocessor Executor Time	0 ns	The elapsed wall time when TiDB Coprocessor executor waiting all Coprocessor requests to finish (note: when there ...
Coprocessor Wait Time	0 ns	The total time of Coprocessor request is prepared and wait to execute in TiKV, which may happen when retrieving a s...
Coprocessor Process Time	0 ns	The total time of Coprocessor request being executed in TiKV (note: TiKV executes requests in parallel so that this is ...
Local Latch Wait Time	0 ns	Time consumed when TiDB waits for the lock in the current TiDB instance before 2PC commit phase when transactio...
Lock Keys Time	0 ns	Time consumed when locking keys in pessimistic transaction
Resolve Lock Time	0 ns	Time consumed when TiDB resolves locks from other transactions in 2PC prewrite phase when transaction commits
Get Start Ts Time	0 ns	Time consumed when getting a start timestamp when transaction begins

Figure 249: Execution time

Coprocessor tab

Click the **Coprocessor** tab, and you can see information related to Coprocessor read.

Basic | Time | Coprocessor | Transaction | Warnings

Name	Value	Description
Request Count	0	
Process Keys	0	
Total Keys	0	
Copr Address (Process)		The address of the TiKV that takes most time process the Coprocessor request
Copr Address (Wait)		The address of the TiKV that takes most time wait the Coprocessor request
RocksDB Block Cache Hits	0	Total number of hits from the block cache (RocksDB block_cache_hit_count)
RocksDB Read Size	0	Total number of bytes RocksDB read from file (RocksDB block_read_byte)
RocksDB Block Reads	0	Total number of blocks RocksDB read from file (RocksDB block_read_count)
RocksDB Skipped Deletions	0	Total number of deleted (a.k.a. tombstone) key versions that are skipped during iteration (RocksDB delete_s...
RocksDB Skipped Keys	0	Total number of keys skipped during iteration (RocksDB key_skipped_count)

Figure 250: Coprocessor read

Transaction tab

Click the **Transaction** tab, and you can see information related to execution plans and transactions, such as the average number of written keys or the maximum number of written keys.

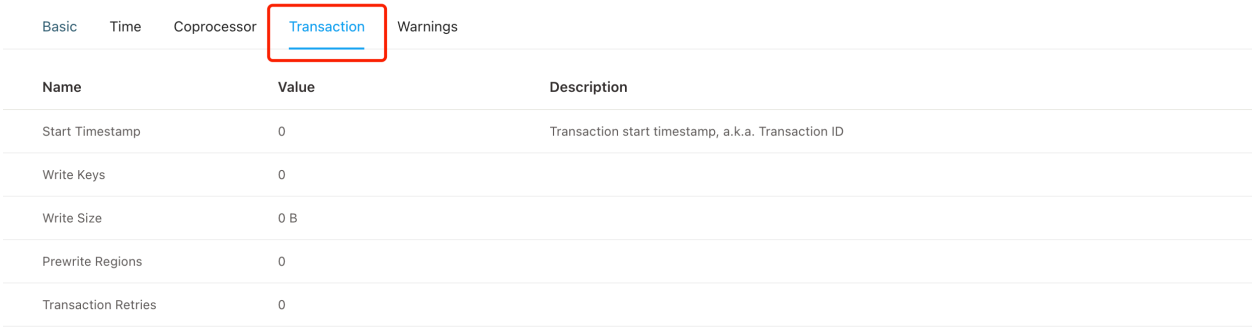


Figure 251: Transaction

9.5.11 Cluster Diagnostics

9.5.11.1 TiDB Dashboard Cluster Diagnostics Page

The cluster diagnostics feature in TiDB Dashboard diagnoses the problems that might exist in a cluster within a specified time range, and summarizes the diagnostic results and the cluster-related load monitoring information into a diagnostic report. This diagnostic report is in the form of a web page. You can browse the page offline and circulate this page link after saving the page from a browser.

> **Note:**
>
> The cluster diagnostics feature depends on Prometheus deployed in the cluster. For details about how to deploy this monitoring component, see the TiUP deployment document. If no monitoring component is deployed in the cluster, the generated diagnostic report will indicate a failure.

9.5.11.1.1 Access the page

You can use one of the following methods to access the cluster diagnostics page:

- After logging in to TiDB Dashboard, click **Cluster Diagnostics** in the left navigation menu.

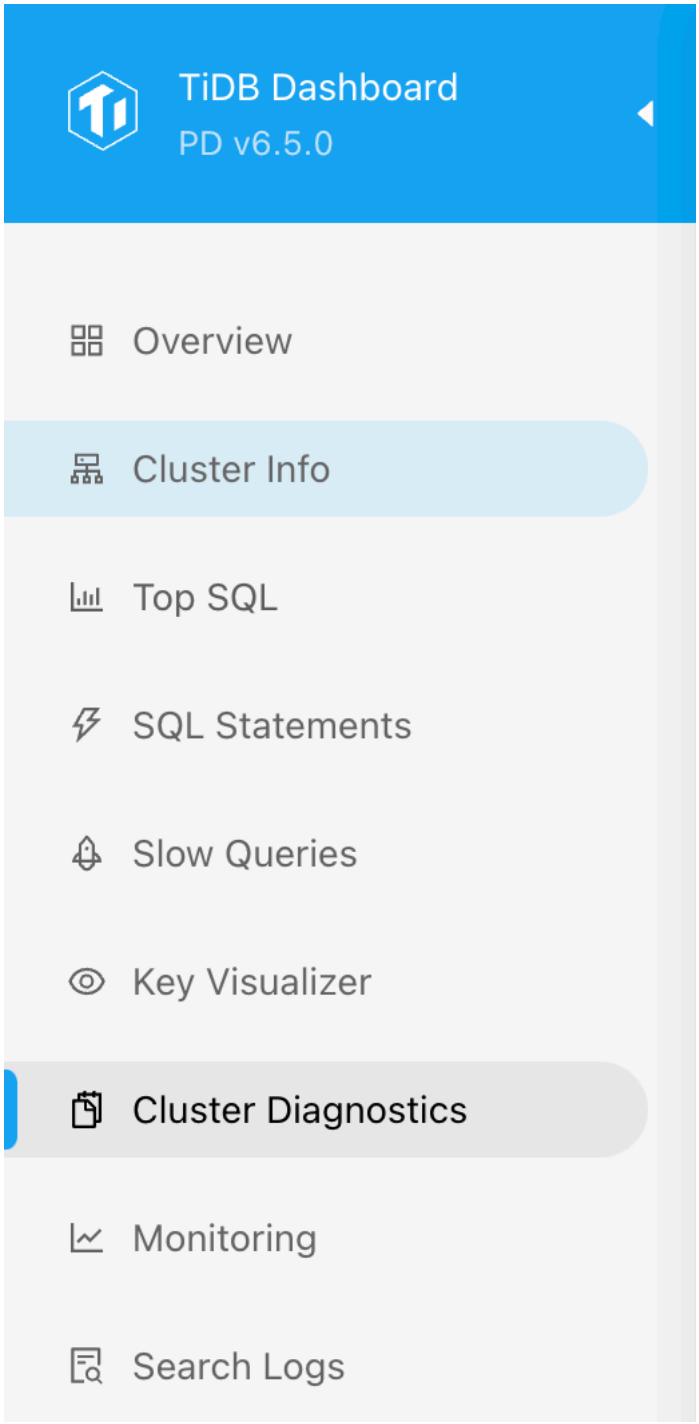

Figure 252: Access Cluster Diagnostics page

- Visit `http://127.0.0.1:2379/dashboard/#/diagnose` in your browser. Replace `127.0.0.1:2379` with the actual PD address and port number.

9.5.11.1.2 Generate diagnostic report

To diagnose a cluster within a specified time range and check the cluster load, you can take the following steps to generate a diagnostic report:

1. Set the **Range Start Time**, such as `2022-05-21 14:40:00`.
2. Set the **Range Duration**, such as `10 min`.
3. Click **Start**.

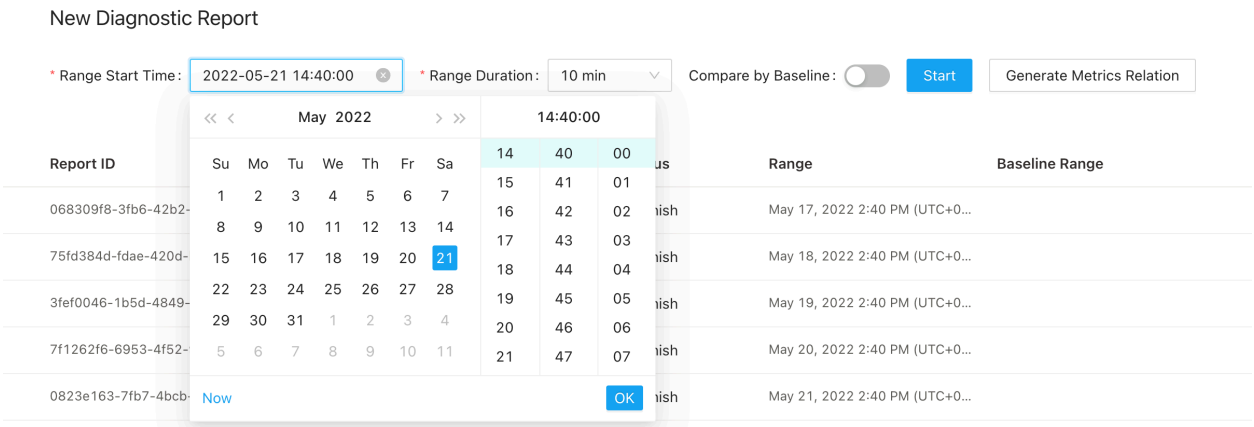

Figure 253: Generate diagnostic report

> **Note:**
>
> It is recommended that the **Range Duration** of the report is between 1 minute and 60 minutes. This **Range Duration** cannot exceed 60 minutes.

The preceding steps generate a diagnostic report for the time range from `2022-05-21 14:40:00` to `2022-05-21 14:50:00`. After clicking **Start**, you can see the interface below. **Progress** is the progress bar of the diagnostic report. After the report is generated, click **View Full Report**.

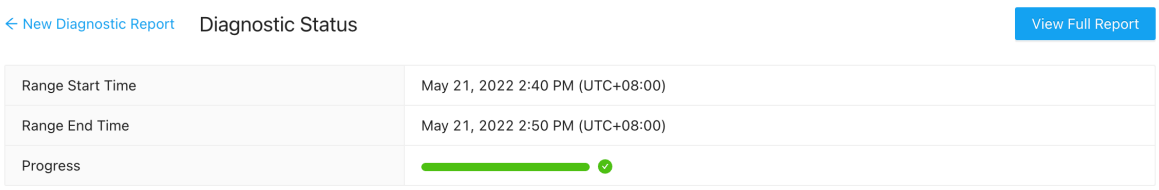

Figure 254: Report progress

9.5.11.1.3 Generate comparison report

If a system exception occurs at a certain point, for example, QPS jitter or higher latency, a diagnostic report can be generated. Particularly, this report compares the system in the abnormal time range with the system in the normal time range. For example:

- Abnormal time range: `2022-05-21 14:40:00-2022-05-21 14:45:00`. Within this time range, the system is abnormal.
- Normal time range: `2022-05-21 14:30:00 - 2022-05-21 14:35:00`. Within this time range, the system is normal.

You can take the following steps to generate a comparison report for the preceding two time ranges:

1. Set the **Range Start Time**, which is the start time of the range in which the system becomes abnormal, such as `2022-05-21 14:40:00`.
2. Set the **Range Duration**. Generally, this duration is the duration of system anomalies, such as 5 minutes.
3. Enable **Compare by Baseline**.
4. Set the **Baseline Range Start Time**, which is the start time of the range (to be compared with) in which the system is normal, such as `2022-05-21 14:30:00`.
5. Click **Start**.

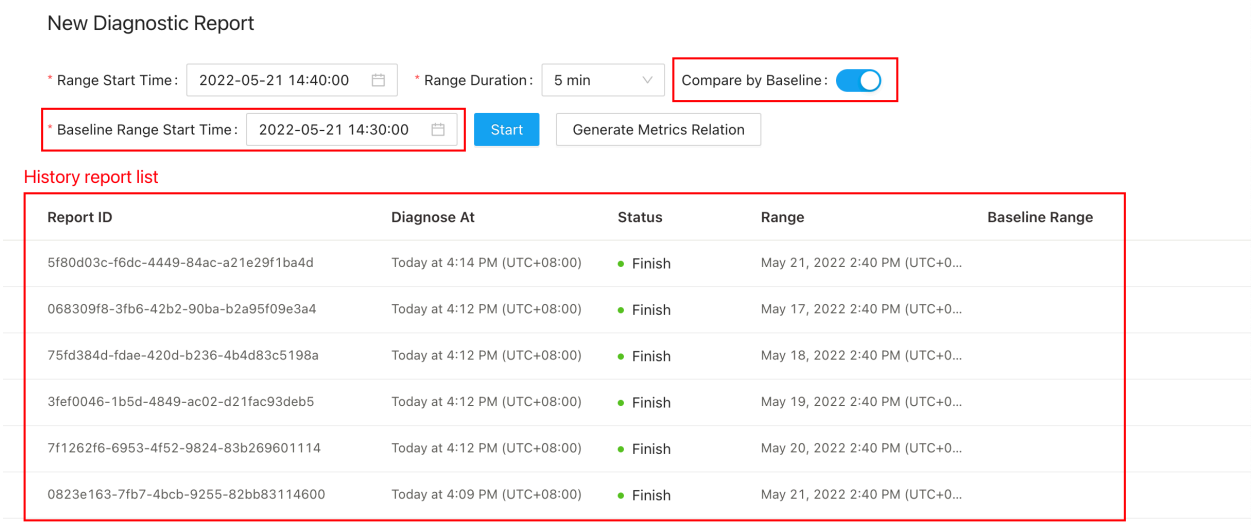

Figure 255: Generate comparison report

Then wait for the report to be generated and click **View Full Report**.

In addition, the historical diagnostic report is displayed in the list on the main page of the diagnostic report. You can click to view these historical reports directly.

9.5.11.2 TiDB Dashboard Diagnostic Report

This document introduces the content of the diagnostic report and viewing tips. To access the cluster diagnostic page and generate reports, see TiDB Dashboard Cluster Diagnostics Page.

9.5.11.2.1 View report

The diagnostic report consists of the following parts:

- Basic information: Includes the time range of the diagnostic report, hardware information of the cluster, the version information of cluster topology.
- Diagnostic information: Shows the results of automatic diagnostics.
- Load information: Includes CPU, memory and other load information of the server, TiDB, PD, or TiKV.
- Overview information: Includes the consumed time and error information of each TiDB, PD, or TiKV module.
- TiDB/PD/TiKV monitoring information: Includes monitoring information of each component.
- Configuration information: Includes configuration information of each component.

An example of the diagnostic report is as follows:

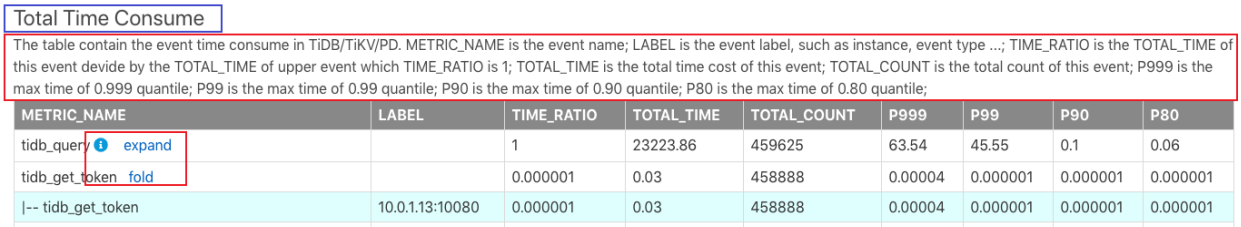

Figure 256: Sample report

In the image above, **Total Time Consume** in the top blue box is the report name. The information in the red box below explains the content of this report and the meaning of each field in the report.

In this report, some small buttons are described as follows:

- **i** icon: You can move your mouse to the **i** icon to see the explanatory note of the row.
- **expand**: Click **expand** to see details about this monitoring metric. For example, the detailed information of `tidb_get_token` in the image above includes the monitoring information of each TiDB instance's latency.
- **collapse**: Contrary to **expand**, the button is used to fold detailed monitoring information.

All monitoring metrics basically correspond to those on the TiDB Grafana monitoring dashboard. After a module is found to be abnormal, you can view more monitoring information on the TiDB Grafana.

In addition, the `TOTAL_TIME` and `TOTAL_COUNT` metrics in this report are monitoring data read from Prometheus, so calculation inaccuracy might exist in their statistics.

Each part of this report is introduced as follows.

Basic information

Diagnostics Time Range

The time range for generating the diagnostics report includes the start time and end time.

Report Time Range

START_TIME	END_TIME
2020-05-21 06:40:00	2020-05-21 06:50:00

Figure 257: Report time range

Cluster Hardware Info

Cluster Hardware Info includes information such as CPU, memory, and disk of each server in the cluster.

Cluster Hardware

HOST	INSTANCE	CPU_CORES	MEMORY (GB)	DISK (GB)	UPTIME (DAY)
10.0.1.14	tiflash*1	20/40	125.64	nvme01: 498.638	2.9132028513567314
10.0.1.11	pd*1	20/40	125.64	sda1: 965.834	2.921851028772416
10.0.1.12	tikv*1	20/40	125.64	nvme0n1: 122.78 sda1: 965.834	2.9197623066052247
10.0.1.13	tidb*1	20/40	125.64	sda1: 498.638	2.917983893669314

Figure 258: Cluster hardware report

The fields in the table above are described as follows:

- `HOST`: The IP address of the server.
- `INSTANCE`: The number of instances deployed on the server. For example, `pd * 1` means that this server has 1 PD instance deployed; `tidb * 2 pd * 1` means that this server has 2 TiDB instances and 1 PD instance deployed.
- `CPU_CORES`: Indicates the number of CPU cores (physical cores or logical cores) of the server.
- `MEMORY`: Indicates the memory size of the server. The unit is GB.
- `DISK`: Indicates the server disk size. The unit is GB.
- `UPTIME`: The uptime of the server. The unit is day.

Cluster Topology Info

The `Cluster Info` table shows the cluster topology information. The information in this table are from TiDB information_schema.cluster_info system table.

Cluster Info

TYPE	INSTANCE	STATUS_ADDRESS	VERSION	GIT_HASH	START_TIME	UPTIME
pd	10.0.1.11:2379	10.0.1.11:2379	4.1.0-alpha	a80b99ef0d70807d106bdc1b7c6e97a118679c7e	2020-05-18T13:47:01Z	65h40m54.520385474s

Figure 259: Cluster info

The fields in the table above are described as follows:

- `TYPE`: The node type.
- `INSTANCE`: The instance address(es), which is a string in the `IP:PORT` format.
- `STATUS_ADDRESS`: The HTTP API service address.
- `VERSION`: The semantic version number of the corresponding node.
- `GIT_HASH`: Git Commit Hash when compiling the node version, which is used to identify whether the two nodes are absolutely the consistent version.
- `START_TIME`: The start time of the corresponding node.
- `UPTIME`: The uptime of the corresponding node.

Diagnostic information

TiDB has built-in automatic diagnostic results. For the description of each field, see information_schema.inspection-result system table.

Load Info

Node Load Info

The `Node Load Info` table shows the load information of the server node, including the average value (AVG), maximum value (MAX), minimum value (MIN) of the following metrics of the server within the time range:

- CPU usage (the maximum value is `100%`)
- Memory usage
- Disk I/O usage
- Disk write latency
- Disk read latency
- Disk read bytes per second
- Disk write bytes per second

- The number of bytes received by the node network per minute
- The number of bytes sent from the node network per minute
- The number of TCP connections in use by the node
- The number of all TCP connections of the node

Node Load Info

METRIC_NAME	instance	AVG	MAX	MIN
node_cpu_usage expand		40.42%	99.6%	6.98%
node_mem_usage expand		66.9%	96.28%	33.65%
node_disk_io_utilization expand		16%	97%	0%
Disk write latency expand		4000 us	50 ms	0 us
Disk read latency expand		2000 us	6000 us	0 us
tikv_disk_read_bytes expand		605.980 KB	15.842 MB	0.000 KB
tikv_disk_write_bytes expand		1.129 MB	12.235 MB	0.000 KB
node_network_in_traffic expand		225.706 KB	1.427 MB	0.000 KB
node_network_out_traffic expand		165.807 KB	1.659 MB	0.000 KB
node_tcp_in_use expand		19	47	5
node_tcp_connections expand		30	61	6

Figure 260: Server Load Info report

Instance CPU Usage

The `Instance CPU Usage` table shows the average value (AVG), maximum value (MAX), and minimum value (MIN) of the CPU usage of each TiDB/PD/TiKV process. The maximum CPU usage of the process is `100% * the number of CPU logical cores`.

INSTANCE	JOB	AVG	MAX	MIN
172.16.5.40:10089	tidb	1891%	1906%	1878%
172.16.5.40:22151	tikv	517%	571%	459%
172.16.5.40:20151	tikv	498%	562%	444%
172.16.5.40:23151	tikv	352%	399%	311%
172.16.5.40:24799	pd	39%	45%	36%

Figure 261: Instance CPU Usage report

Instance Memory Usage

The `Instance Memory Usage` table shows the average value (AVG), maximum value (MAX), and minimum value (MIN) of memory bytes occupied by each TiDB/PD/TiKV process.

INSTANCE	JOB	AVG	MAX	MIN
172.16.5.40:20151	tikv	9.562 GB	9.605 GB	9.523 GB
172.16.5.40:23151	tikv	9.528 GB	9.574 GB	9.496 GB
172.16.5.40:22151	tikv	9.433 GB	9.498 GB	9.345 GB
172.16.5.40:10089	tidb	904.500 MB	911.660 MB	894.336 MB
172.16.5.40:24799	pd	61.089 MB	61.270 MB	60.980 MB

Figure 262: Instance memory usage report

TiKV Thread CPU Usage

The `TiKV Thread CPU Usage` table shows the average value (AVG), maximum value (MAX) and minimum value (MIN) of CPU usage of each module thread in TiKV. The maximum CPU usage of the process is `100% * the thread count of the corresponding configuration`.

TiKV Thread CPU Usage

METRIC_NAME	INSTANCE	AVG	MAX	MIN	CONFIG_KEY	CURRENT_CONFIG_VALUE

Figure 263: TiKV Thread CPU Usage report

In the table above,

- `CONFIG_KEY`: The relevant thread configuration of the corresponding module.
- `CURRENT_CONFIG_VALUE`: The current value of the configuration when the report is generated.

Note:

`CURRENT_CONFIG_VALUE` is the value when the report is generated, not the value within the time range of this report. Currently, some configuration values of historical time cannot be obtained.

`TiDB/PD Goroutines Count`

The `TiDB/PD Goroutines Count` table shows the average value (AVG), maximum value (MAX), and minimum value (MIN) of the number of TiDB or PD goroutines. If the number of goroutines exceeds 2,000, the concurrency of the process is too high, which affects the overall request latency.

INSTANCE	JOB	AVG	MAX	MIN
172.16.5.40:10089	tidb	1434.33	1473	1394
172.16.5.40:24799	pd	157	157	157

Figure 264: TiDB/PD goroutines count report

Overview information

Time Consumed by Each Component

The `Time Consumed by Each Component` table shows the monitored consumed time and the time ratio of TiDB, PD, TiKV modules in the cluster. The default time unit is seconds. You can use this table to quickly locate which modules consume more time.

METRIC_NAME	LABEL	TIME_RATIO	TOTAL_TIME	TOTAL_COUNT	P999	P99	P90	P80

Figure 265: Time Consume report

The fields in columns of the table above are described as follows:

- `METRIC_NAME`: The name of the monitoring metric.
- `Label`: The label information for the monitoring metric. Click **expand** to view more detailed monitoring information of each label for a metric.
- `TIME_RATIO`: The ratio of the total time consumed by this monitoring metric to the total time of the monitoring row where `TIME_RATIO` is `1`. For example, the total

consumed time by `kv_request` is `1.65` (namely, `38325.58/23223.86`) times that of `tidb_query`. Because KV requests are executed concurrently, the total time of all KV requests might exceed the total query (`tidb_query`) execution time.

- `TOTAL_TIME`: The total time consumed by this monitoring metric.
- `TOTAL_COUNT`: The total number of times this monitoring metric is executed.
- `P999`: The maximum P999 time of this monitoring metric.
- `P99`: The maximum P99 time of this monitoring metric.
- `P90`: The maximum P90 time of this monitoring metric.
- `P80`: The maximum P80 time of this monitoring metric.

The following image shows the relationship of time consumption of the related modules in the monitoring metrics above.

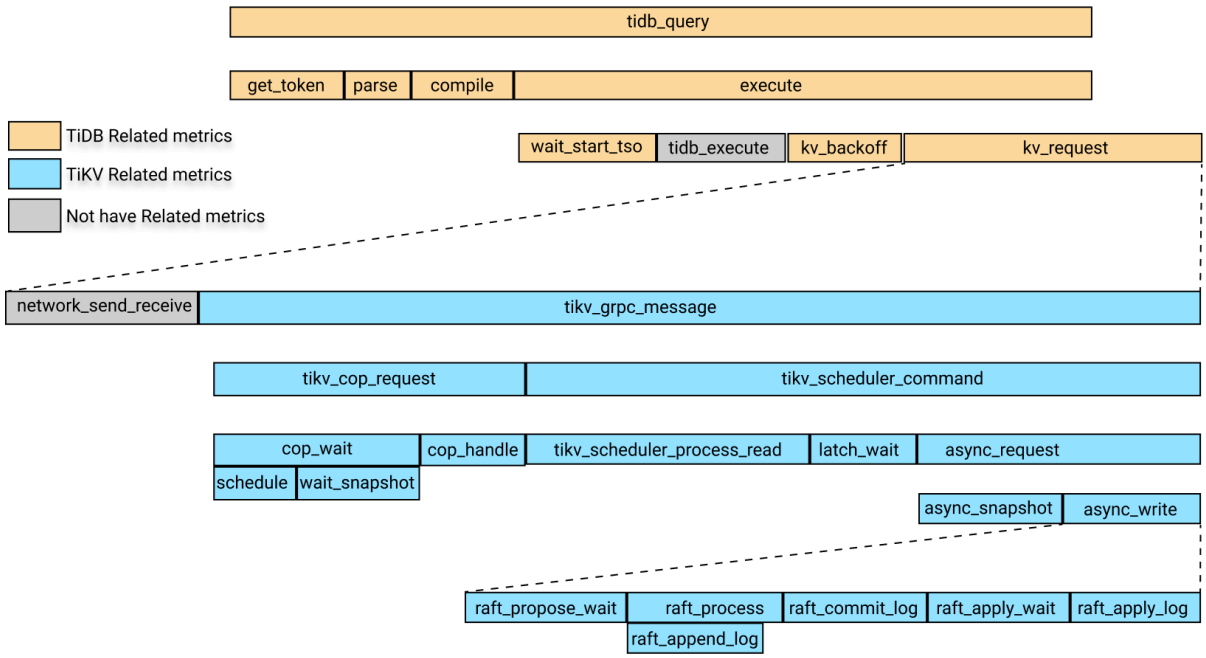

Figure 266: Time-consumption relationship of each module

In the image above, yellow boxes are the TiDB-related monitoring metrics.Blue boxes are TiKV-related monitoring metrics, and gray boxes temporarily do not correspond to specific monitoring metrics.

In the image above, the time consumption of `tidb_query` includes the following four parts:

- `get_token`
- `parse`
- `compile`

- `execute`

The `execute` time includes the following parts:

- `wait_start_tso`
- The execution time at the TiDB layer, which is currently not monitored
- KV request time
- `KV_backoff` time, which is the time for backoff after the KV request fails

Among the parts above, the KV request time includes the following parts:

- The time consumed by the network sending and receiving of requests. Currently, there is no monitoring metric for this item. You can subtract the time of `tikv_grpc_message` from the KV request time to roughly estimate this item.
- `tikv_grpc_message` time consumption.

Among the parts above, `tikv_grpc_message` time consumption includes the following parts:

- Coprocessor request time consumption, which refers to processing the COP type requests. This time consumption includes the following parts:
  - `tikv_cop_wait`: The time consumed by request queue.
  - `Coprocessor handle`: The time consumed to process Coprocessor requests.
- `tikv_scheduler_command` time consumption, which includes the following parts:
  - `tikv_scheduler_processing_read`: The time consumed to process read requests.
  - The time consumed to get snapshot in `tikv_storage_async_request` (snapshot is the label for this monitoring metric).
  - Time consumed to process write requests. This time consumption includes the following parts:
    - `tikv_scheduler_latch_wait`: The time consumed to wait for latch.
    - The time consumption of writes in `tikv_storage_async_request` (write is the label for this monitoring metric).

Among the above metrics, The time consumption of writes in `tikv_storage_async_request` refers to the time consumption of writing Raft KVs, including the following parts:

- `tikv_raft_propose_wait`
- `tikv_raft_process`, which mainly includes `tikv_raft_append_log`
- `tikv_raft_commit_log`

- `tikv_raft_apply_wait`
- `tikv_raft_apply_log`

You can use `TOTAL_TIME`, the P999 time, and the P99 time to determine which modules consume longer time according to the relationship between the time consumptions described above, and then look at the related monitoring metrics.

> **Note:**
>
> Because the Raft KVs writes might be processed in one batch, using `TOTAL_TIME` to measure the time consumed by each module is inapplicable to monitoring metrics related to Raft KV writes, specifically, `tikv_raft_process`, `tikv_raft_append_log`, `tikv_raft_commit_log`, `tikv_raft_apply_wait`, and `tikv_raft_apply_log`. In this situation, it is more reasonable to compare the time consumption of each module with the time of P999 and P99.
>
> The reason is that if there are 10 asynchronous write requests, Raft KVs internally pack 10 requests into a batch execution, and the execution time is 1 second. Therefore, the execution time of each request is 1 second, and the total time of 10 requests is 10 seconds, but the total time for Raft KV processing is 1 second. If you use `TOTAL_TIME` to measure the consumed time, you might not understand where the remaining 9 seconds are spent. You can also see the difference between the monitoring metric of Raft KV and other previous monitoring metrics from the total number of requests (`TOTAL_COUNT`).

Errors Occurred in Each Component

The `Errors Occurred in Each Component` table shows the total number of errors in TiDB and TiKV, such as the failure to write binlog, `tikv server is busy`, `TiKV channel full`, `tikv write stall`. You can see the row comments for the specific meaning of each error.

METRIC_NAME	LABEL	TOTAL_COUNT

Specific TiDB/PD/TiKV monitoring information

This part includes more specific monitoring information of TiDB, PD, or TiKV.

TiDB-related monitoring information

Time Consumed by TiDB Component

This table shows the time consumed by each TiDB module and the ratio of each time consumption, which is similar to the `time consume` table in the overview, but the label information of this table are more detailed.

TiDB Server Connections

This table shows the number of client connections for each TiDB instance.

TiDB Transaction

This table shows transaction-related monitoring metrics.

METRIC_NAME	LABEL	TOTAL_VALUE	TOTAL_COUNT	P999	P99	P90	P80
tidb_transaction_retry_num		0	0	0	0	0	0
tidb_transaction_statement_num expand		6854588	6852371	4	4	3	2
tidb_txn_region_num expand		1070770	706887	3	2	2	2
tidb_txn_kv_write_num expand		513386	181312	234	2	2	2
tidb_txn_kv_write_size expand		266.772 MB	181296	116.913 KB	1.996 KB	1.905 KB	1.805 KB
tidb_load_safepoint_total_num expand		16					
tidb_lock_resolver_total_num expand		420514					

Figure 268: Transaction report

- `TOTAL_VALUE`: The sum of all values (SUM) during the report time range.
- `TOTAL_COUNT`: The total number of occurrences of this monitoring metric.
- `P999`: The maximum P999 value of this monitoring metric.
- `P99`: The maximum P99 value of this monitoring metric.
- `P90`: The maximum P90 value of this monitoring metric.
- `P80`: The maximum P80 value of this monitoring metric.

Example:

In the table above, within the report time range, `tidb_txn_kv_write_size`: a total of about 181,296 transactions of KV writes, and the total KV write size is 266.772 MB, of which the maximum P999, P99, P90, P80 values for a single transaction of KV writes are 116.913 KB, 1.996 KB, 1.905 KB, and 1.805 KB.

DDL Owner

MIN_TIME	DDL OWNER
2020-05-21 14:40:00	10.0.1.13:10080

Figure 269: TiDB DDL Owner Report

The table above shows that from `2020-05-21 14:40:00`, the cluster's `DDL OWNER` is at the `10.0.1.13:10080` node. If the owner changes, multiple rows of data exist in the table above, where the `Min_Time` column indicates the minimum time of the corresponding known owner.

> **Note:**
>
> If the owner information is empty, it does not mean that no owner exists in this period of time. Because in this situation, the DDL owner is determined based on the monitoring information of `ddl_worker`, it might be that `ddl_worker` has not done any DDL job in this period of time, causing the owner information to be empty.

Other monitoring tables in TiDB are as follows:

- Statistics Info: Shows related monitoring metrics of TiDB statistical information.
- Top 10 Slow Query: Shows the Top 10 slow query information in the report time range.
- Top 10 Slow Query Group By Digest: Shows the Top 10 slow query information in the report time range, which is aggregated according to the SQL fingerprint.

- Slow Query With Diff Plan: The SQL statement whose execution plan changes within the report time range.

PD related monitoring information

The tables related to the monitoring information of PD modules are as follows:

- `Time Consumed by PD Component`: The time consumed by the monitoring metrics of related modules in PD.
- `Blance Leader/Region`: The monitoring information of `balance-region` and `balance leader` occurred in the cluster within the report time range, such as the number of leaders that are scheduled out from `tikv_note_1` or the number of leaders that are scheduled in.
- `Cluster Status`: The cluster status information, including total number of TiKV nodes, total cluster storage capacity, the number of Regions, and the number of offline TiKV nodes.
- `Store Status`: Record the status information of each TiKV node, including Region score, leader score, and the number of Regions/leaders.
- `Etcd Status`: etcd related information in PD.

TiKV related monitoring information

The tables related to the monitoring information of TiKV modules are as follows:

- `Time Consumed by TiKV Component`: The time consumed by related modules in TiKV.
- `Time Consumed by RocksDB`: The time consumed by RocksDB in TiKV.
- `TiKV Error`: The error information related to each module in TiKV.
- `TiKV Engine Size`: The size of stored data of column families on each node in TiKV.
- `Coprocessor Info`: Monitoring information related to the Coprocessor module in TiKV.
- `Raft Info`: Monitoring information of the Raft module in TiKV.
- `Snapshot Info`: Snapshot related monitoring information in TiKV.
- `GC Info`: Garbage Collection (GC) related monitoring information in TiKV.
- `Cache Hit`: The hit rate information of each cache of RocksDB in TiKV.

Configuration information

In the configuration information, the configuration values of some modules are shown within the report time range. But the historical values of some other configurations of these modules cannot be obtained, so the shown values of these configurations are the current (when the report is generated) values .

Within the report time range, the following tables include items whose values are configured at the start time of the report time range:

- `Scheduler Initial Config`: The initial value of PD scheduling-related configuration at the report's start time.
- `TiDB GC Initial Config`: The initial value of TiDB GC related-configuration at the report's start time
- `TiKV RocksDB Initial Config`: The initial value of TiKV RocksDB-related configuration at the report's start time
- `TiKV RaftStore Initial Config`: The initial value of TiKV RaftStore-related configuration at the report's start time

Within the report time range, if some configurations have been modified, the following tables include records of some configurations that have been modified:

- `Scheduler Config Change History`
- `TiDB GC Config Change History`
- `TiKV RocksDB Config Change History`
- `TiKV RaftStore Config Change History`

Example:

APPROXIMATE_CHANGE_TIME	CONFIG_ITEM	VALUE
2020-05-22T20:00:00+08:00	leader-schedule-limit	4
2020-05-22T20:07:00+08:00	leader-schedule-limit	8

Figure 270: Scheduler Config Change History report

The table above shows that the `leader-schedule-limit` configuration parameter has been modified within the report time range:

- `2020-05-22T20:00:00+08:00`: At the start time of the report, the configuration value of `leader-schedule-limit` is `4`, which does not mean that the configuration has been modified, but that at the start time in the report time range, its configuration value is `4`.
- `2020-05-22T20:07:00+08:00`: The `leader-schedule-limit` configuration value is `8` ↪ , which indicates that the value of this configuration has been modified around `2020-05-22T20:07:00+08:00`.

The following tables show the current configuration of TiDB, PD, and TiKV at the time when the report is generated:

- `TiDB's Current Config`
- `PD's Current Config`
- `TiKV's Current Config`

9.5.11.2.2 Comparison report

You can generate a comparison report for two time ranges. The report content is the same as the report for a single time range, except that a comparison column is added to show the difference between the two time ranges. The following sections introduce some unique tables in the comparison report and how to view the comparison report.

First, the `Compare Report Time Range` report in the basic information shows the two time ranges for comparison:

Compare Report Time Range

T1.START_TIME	T1.END_TIME	T2.START_TIME	T2.END_TIME
2020-05-21 06:30:00	2020-05-21 06:35:00	2020-05-21 06:40:00	2020-05-21 06:45:00

Figure 271: Compare Report Time Range report

In the table above, `t1` is the normal time range, or the reference time range. `t2` is the abnormal time range.

Tables related to slow queries are shown as follows:

- `Slow Queries In Time Range t2`: Shows slow queries that only appear in `t2` but not during `t1`.
- `Top 10 slow query in time range t1`: The Top 10 slow queries during `t1`.
- `Top 10 slow query in time range t2`: The Top 10 slow queries during `t2`.

DIFF_RATIO introduction

This section introduces `DIFF_RATIO` using the `Instance CPU Usage` table as an example.

Instance CPU Usage

INSTANCE	JOB	t1.AVG	t1.MAX	t1.MIN	t2.AVG	t2.MAX	t2.MIN	AVG_DIFF_RATIO	MAX_DIFF_RATIO	MIN_DIFF_RATIO
172.16.5.40:10089	tidb	410%	410%	410%	1240%	1240%	1240%	2.02	2.02	2.02
172.16.5.40:20151	tikv	221%	221%	221%	617%	617%	617%	1.79	1.79	1.79
172.16.5.40:20379	pd	82%	82%	82%	78%	78%	78%	-0.05	-0.05	-0.05

Figure 272: Compare Instance CPU Usage report

- `t1.AVG`, `t1.MAX`, `t1.Min` are the average value, maximum value, and minimum value of CPU usage in the `t1`.
- `t2.AVG`, `t2.MAX`, and `t2.Min` are the average value, maximum value, and minimum value of CPU usage during `t2`.
- `AVG_DIFF_RATIO` is `DIFF_RATIO` of the average values during `t1` and `t2`.
- `MAX_DIFF_RATIO` is `DIFF_RATIO` of the maximum values during `t1` and `t2`.
- `MIN_DIFF_RATIO` is `DIFF_RATIO` of the minimum values during `t1` and `t2`.

`DIFF_RATIO`: Indicates the difference value between the two time ranges. It has the following values:

- If the monitoring metric has a value only within `t2` and has no value within `t1`, the value of `DIFF_RATIO` is `1`.
- If the monitoring metric has a value only within `t1`, and has no value within `t2` time range, the value of `DIFF_RATIO` is `-1`.
- If the value of `t2` is greater than that of `t1`, then `DIFF_RATIO = (t2.value / t1.value)-1`
- If the value of `t2` is smaller than that of `t1`, then `DIFF_RATIO = 1-(t1.value / t2.value)`

For example, in the table above, the average CPU usage of the `tidb` node in `t2` is 2.02 times higher than that in `t1`, which is `2.02 = 1240/410-1`.

Maximum Different Item table

The `Maximum Different Item` table compares the monitoring metrics of two time ranges, and sorts them according to the difference of the monitoring metrics. Using this table, you can quickly find out which monitoring metric has the biggest difference in the two time ranges. See the following example:

Maximum Different Item

The maximum different metrics between two time ranges.

TABLE	METRIC_NAME	LABEL	MAX_DIFF	t1.VALUE	t2.VALUE	VALUE_TYPE

overview, total_time_consume	Schema load	172.16.5.40:10089	30.25	0.008	0.25	P999

Figure 273: Maximum Different Item table

- `Table`: Indicates this monitoring metric comes from which table in the comparison report. For example, `TiKV, coprocessor_info` indicates the `coprocessor_info` table in the TiKV component.
- `METRIC_NAME`: The monitoring metric name. Click `expand` to view the comparison of different labels of metrics.
- `LABEL`: The label corresponding to the monitoring metric. For example, the monitoring metric of `TiKV Coprocessor scan` has 2 labels, namely `instance`, `req`, `tag`, `sql_type` ↪ , which are the TiKV address, request type, operation type and operation column family.
- `MAX_DIFF`: Difference value, which is the `DIFF_RATIO` calculation of `t1.VALUE` and

`t2.VALUE`.

From the table above, you can see the `t2` time range has much more Coprocessor requests than the `t1` time range, and the SQL parsing time of TiDB in `t2` is much longer.

9.5.11.3 Locate Problems Using Diagnostic Report of TiDB Dashboard

This document introduces how to locate problems using diagnostic report of TiDB Dashboard.

9.5.11.3.1 Comparison diagnostics

This section demonstrates how to use the comparison diagnostic feature to diagnose QPS jitter or latency increase caused by large queries or writes.

Example 1

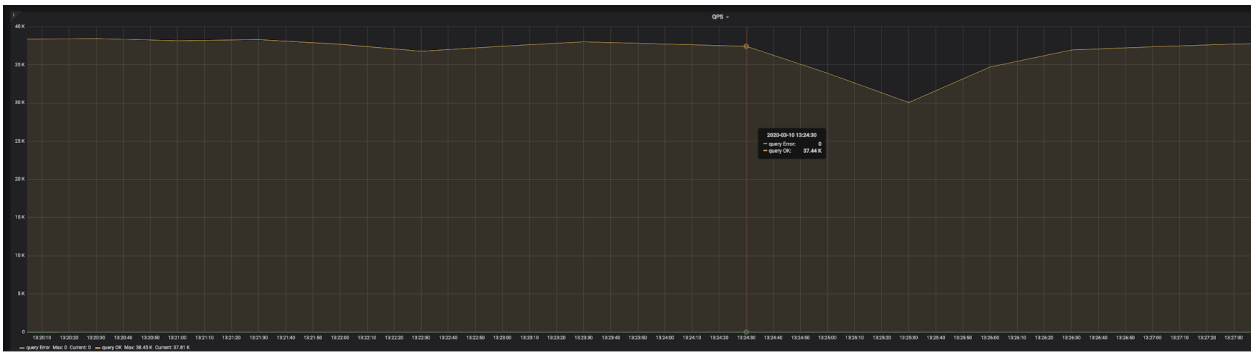

Figure 274: QPS example

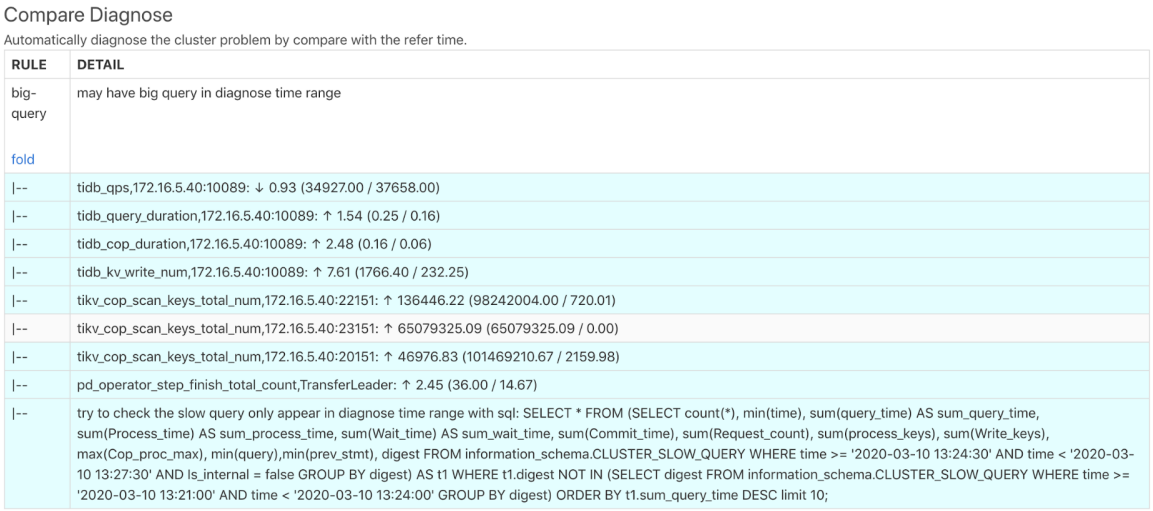
The result of a `go-ycsb` pressure test is shown in the image above. You can see that at `2020-03-10 13:24:30`, QPS suddenly began to decrease. After 3 minutes, QPS began to return to normal. You can use diagnostic report of TiDB Dashboard to find out the cause.



Generate a report that compares the system in the following two time ranges:

T1: `2020-03-10 13:21:00` to `2020-03-10 13:23:00`. In this range, the system is normal, which is called a reference range.

T2: `2020-03-10 13:24:30` to `2020-03-10 13:27:30`. In this range, QPS began to decrease.

Because the impact range of jitter is 3 minutes, the two time ranges above are both 3 minutes. Because some monitored average values are used for comparison during diagnostics, too long a range will cause the difference of average values to be insignificant, and then the problem cannot be accurately located.

After the report is generated, you can view this report on the **Compare Diagnose** page.

Compare Diagnose

Automatically diagnose the cluster problem by compare with the refer time.

RULE	DETAIL
big-query fold	may have big query in diagnose time range
|--	tidb_qps,172.16.5.40:10089: ↓ 0.93 (34927.00 / 37658.00)
|--	tidb_query_duration,172.16.5.40:10089: ↑ 1.54 (0.25 / 0.16)

|--	tikv_cop_scan_keys_total_num,172.16.5.40:23151: ↑ 65079325.09 (65079325.09 / 0.00)
|--	tikv_cop_scan_keys_total_num,172.16.5.40:20151: ↑ 46976.83 (101469210.67 / 2159.98)
|--	pd_operator_step_finish_total_count,TransferLeader: ↑ 2.45 (36.00 / 14.67)
|--	try to check the slow query only appear in diagnose time range with sql: SELECT * FROM (SELECT count(*), min(time), sum(query_time) AS sum_query_time, sum(Process_time) AS sum_process_time, sum(Wait_time) AS sum_wait_time, sum(Commit_time), sum(Request_count), sum(process_keys), sum(Write_keys), max(Cop_proc_max), min(query),min(prev_stmt), digest FROM information_schema.CLUSTER_SLOW_QUERY WHERE time >= '2020-03-10 13:24:30' AND time < '2020-03-10 13:27:30' AND Is_internal = false GROUP BY digest) AS t1 WHERE t1.digest NOT IN (SELECT digest FROM information_schema.CLUSTER_SLOW_QUERY WHERE time >= '2020-03-10 13:21:00' AND time < '2020-03-10 13:24:00' GROUP BY digest) ORDER BY t1.sum_query_time DESC limit 10;

Figure 275: Comparison diagnostics

The diagnostic results above show that big queries might exist during the diagnostic time. Each **DETAIL** in the report above is described as follows:

- `tidb_qps`: QPS decreased by 0.93 times.
- `tidb_query_duration`: P999 query latency increased by 1.54 times.
- `tidb_cop_duration`: The processing latency of P999 coprocessor requests increased by 2.48 times.
- `tidb_kv_write_num`: The number written KVs in the P999 TiDB transaction increased by 7.61 times.
- `tikv_cop_scan_keys_total_nun`: The number of keys/values scanned by the TiKV Coprocessor has greatly improved on 3 TiKV instances.
- In `pd_operator_step_finish_total_count`, the number of transferred leaders increases by 2.45 times, which means that the scheduling in the abnormal time range is higher than that in the normal time range.
- The report indicates that there might be slow queries and indicates that you can use SQL statements to query slow queries. The execution result of the SQL statements are as follows:

```
SELECT * FROM (SELECT count(*), min(time), sum(query_time) AS sum_query_
    ↪ time, sum(Process_time) AS sum_process_time, sum(Wait_time) AS sum_
    ↪ wait_time, sum(Commit_time), sum(Request_count), sum(process_keys),
    ↪ sum(Write_keys), max(Cop_proc_max), min(query),min(prev_stmt), digest
    ↪  FROM information_schema.CLUSTER_SLOW_QUERY WHERE time >= '2020-03-10
    ↪  13:24:30' AND time < '2020-03-10 13:27:30' AND Is_internal = false
    ↪ GROUP BY digest) AS t1 WHERE t1.digest NOT IN (SELECT digest FROM
    ↪ information_schema.CLUSTER_SLOW_QUERY WHERE time >= '2020-03-10
```

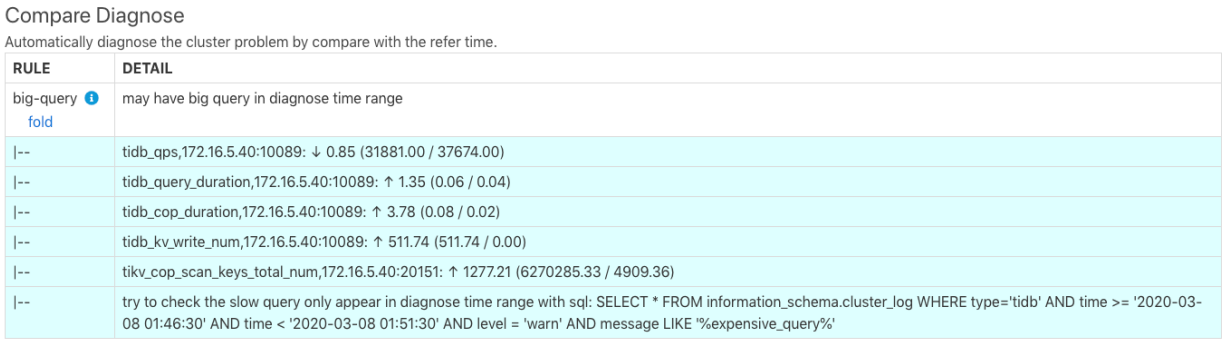
```
    ↪ 13:21:00' AND time < '2020-03-10 13:24:00' GROUP BY digest) ORDER BY
    ↪ t1.sum_query_time DESC limit 10\G
***************************[ 1. row ]***************************
count(*)          | 196
min(time)         | 2020-03-10 13:24:30.204326
sum_query_time    | 46.878509117
sum_process_time | 265.924
sum_wait_time     | 8.308
sum(Commit_time) | 0.926820886
sum(Request_count) | 6035
sum(process_keys) | 201453000
sum(Write_keys)  | 274500
max(Cop_proc_max) | 0.263
min(query)        | delete from test.tcs2 limit 5000;
min(prev_stmt)    |
digest            | 24
    ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df
```

From the result above, you can see that from `13:24:30`, there is a large write of batch deletion, which has been executed 196 times in total, each time deleting 5,000 rows of data, in a total duration of 46.8 seconds.

Example 2

If a large query has not been executed, the query is not recorded in the slow log. In this situation, this large query can still be diagnosed. See the following example:

Figure 276: QPS results



The result of another `go-ycsb` pressure test is shown in the image above. You can see that at `2020-03-08 01:46:30`, QPS suddenly began to drop and did not recover.

Generate a report that compares the system in the following two time ranges:

T1: `2020-03-08 01:36:00` to `2020-03-08 01:41:00`. In this range, the system is normal, which is called a reference range.

T2: `2020-03-08 01:46:30` to `2020-03-08 01:51:30`. In this range, QPS began to decrease.

After the report is generated, you can view this report on the **Compare Diagnose** page.

Compare Diagnose

Automatically diagnose the cluster problem by compare with the refer time.

RULE	DETAIL
big-query fold	may have big query in diagnose time range
|--	tidb_qps,172.16.5.40:10089: ↓ 0.85 (31881.00 / 37674.00)
|--	tidb_query_duration,172.16.5.40:10089: ↑ 1.35 (0.06 / 0.04)
|--	tidb_cop_duration,172.16.5.40:10089: ↑ 3.78 (0.08 / 0.02)

|--	tikv_cop_scan_keys_total_num,172.16.5.40:20151: ↑ 1277.21 (6270285.33 / 4909.36)
|--	try to check the slow query only appear in diagnose time range with sql: SELECT * FROM information_schema.cluster_log WHERE type='tidb' AND time >= '2020-03-08 01:46:30' AND time < '2020-03-08 01:51:30' AND level = 'warn' AND message LIKE '%expensive_query%'

Figure 277: Comparison diagnostics

The diagnostic result is similar to that of example 1. The last row of the image above indicates that there might be slow queries and indicate that you can use SQL statements to query the expensive queries in the TiDB log. The execution result of the SQL statements are as follows.

```
> SELECT * FROM information_schema.cluster_log WHERE type='tidb' AND time
    ↪ >= '2020-03-08 01:46:30' AND time < '2020-03-08 01:51:30' AND level =
    ↪  'warn' AND message LIKE '%expensive_query%'\G
TIME    | 2020/03/08 01:47:35.846
TYPE    | tidb
INSTANCE | 172.16.5.40:4009
LEVEL   | WARN
MESSAGE | [expensivequery.go:167] [expensive_query] [cost_time=60.085949605
    ↪ s] [process_time=2.52s] [wait_time=2.52s] [request_count=9] [total_
    ↪ keys=996009] [process_keys=996000] [num_cop_tasks=9] [process_avg_
    ↪ time=0.28s] [process_p90_time=0.344s] [process_max_time=0.344s] [
    ↪ process_max_addr=172.16.5.40:20150] [wait_avg_time=0.000777777s] [
    ↪ wait_p90_time=0.003s] [wait_max_time=0.003s] [wait_max_addr
    ↪ =172.16.5.40:20150] [stats=t_wide:pseudo] [conn_id=19717] [user=root]
    ↪  [database=test] [table_ids="[80,80]"] [txn_start_ts
    ↪ =415132076148785201] [mem_max="23583169 Bytes (22.490662574768066 MB)
    ↪ "] [sql="select count(*) from t_wide as t1 join t_wide as t2 where t1
    ↪ .c0>t2.c1 and t1.c2>0"]
```

The query result above shows that on this `172.16.5.40:4009` TiDB instance, at `2020/03/08 01:47:35.846` there is an expensive query that has been executed for 60

seconds, but the execution has not yet been finished. This query is a join of Cartesian products.

9.5.11.3.2 Locate problems using comparison diagnostic report

Because the diagnostics might be wrong, using a comparison report might help DBAs locate problems more quickly. See the following example.

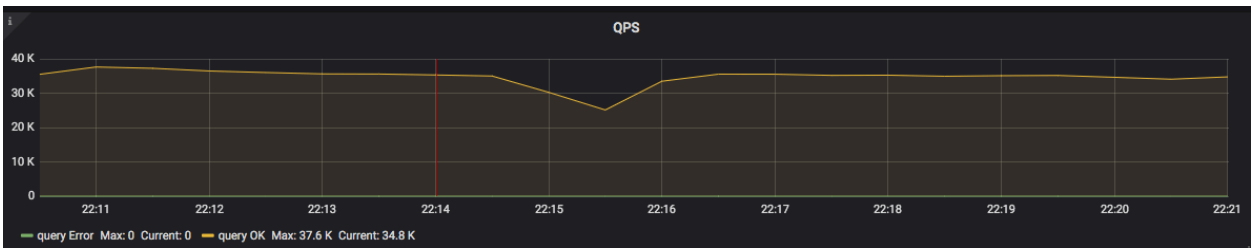

Figure 278: QPS results

The result of a `go-ycsb` pressure test is shown in the image above. You can see that at `2020-05-22 22:14:00`, QPS suddenly began to decrease. After 3 minutes, QPS began to return to normal. You can use the comparison diagnostic report of TiDB Dashboard to find out the cause.

Generate a report that compares the system in the following two time ranges:

T1: `2020-05-22 22:11:00` to `2020-05-22 22:14:00`. In this range, the system is normal, which is called a reference range.

T2: `2020-05-22 22:14:00 2020-05-22 22:17:00`. In this range, QPS began to decrease.

After generating the comparison report, check the **Max diff item** report. This report compares the monitoring items of the two time ranges above and sorts them according to the difference of the monitoring items. The result of this table is as follows:

Maximum Different Item

The maximum different metrics between two time ranges.

TABLE	METRIC_NAME	LABEL	MAX_DIFF	t1.VALUE	t2.VALUE	VALUE_TYPE
TiDB, transaction	Transaction KV write count	172.16.5.40:10089	-21616.00	43234	2	P999

TiDB, transaction	Transaction KV write size	172.16.5.40:10089	-2702.69	5.278 MB	1.999 KB	P999
overview, total_time_consume	Coprocessor handling request	select	2132.50	0.06	128.01	TOTAL_TIME
TiKV, coprocessor_info	TiKV Coprocessor response	172.16.5.40:20151	1535.00	1.792 MB	2.688 GB	TOTAL_VALUE
TiDB, statistics_info	store_query_feedback_total_count	172.16.5.40:10089,ok	1447.00		1447	TOTAL_COUNT
TiKV, scheduler_info Expand	tikv_scheduler_keys_written	172.16.5.40:20151,commit	-860.00	861	1	P99
TiKV, tikv_time_consume	Coprocessor request	172.16.5.40:20151,select	853.87	0.15	128.23	TOTAL_TIME
load, tikv_thread_cpu_usage	unified read pool	172.16.5.40:20151	667.27	0.11%	73.51%	AVG
TiKV, tikv_time_consume	Coprocessor handling request	172.16.5.40:20151,index	444.00	0.002	0.89	P999
TiKV, tikv_time_consume Expand	tikv_grpc_messge	172.16.5.40:20151,coprocessor	419.97	0.33	138.92	TOTAL_TIME
load, node_load_info	tikv_disk_read_bytes	172.16.5.40:19110,sda	-273.41	0.267 KB	0.000 KB	MAX
overview, total_time_consume Expand	KV request	Cop	244.29	0.66	161.89	TOTAL_TIME

Figure 279: Comparison results

From the result above, you can see that the Coprocessor requests in T2 are much more than those in T1. It might be that some large queries appear in T2 that bring more load.

In fact, during the entire time range from T1 to T2, the `go-ycsb` pressure test is running. Then 20 `tpch` queries are running during T2. So it is the `tpch` queries that cause many Coprocessor requests.

If such a large query whose execution time exceeds the threshold of slow log is recorded in the slow log. You can check the `Slow Queries In Time Range t2` report to see whether there is any slow query. However, some queries in T1 might become slow queries in T2, because in T2, other loads cause their executions to slow down.

9.5.12 TiDB Dashboard Monitoring Page

On the monitoring page, you can view the Performance Overview dashboard, a performance analysis and tuning tool introduced in TiDB v6.1.0. With the Performance Overview dashboard, you can analyze performance efficiently, and confirm whether the bottleneck of user response time is in the database. If the bottleneck is in the database, you can identify the bottleneck inside the database, with database time overview, workload profile and SQL latency breakdown. For details, see Performance Analysis and Tuning.

9.5.12.1 Access the page

Log in to TiDB dashboard and click **Monitoring** from the left navigation bar. The Performance Overview dashboard is displayed.

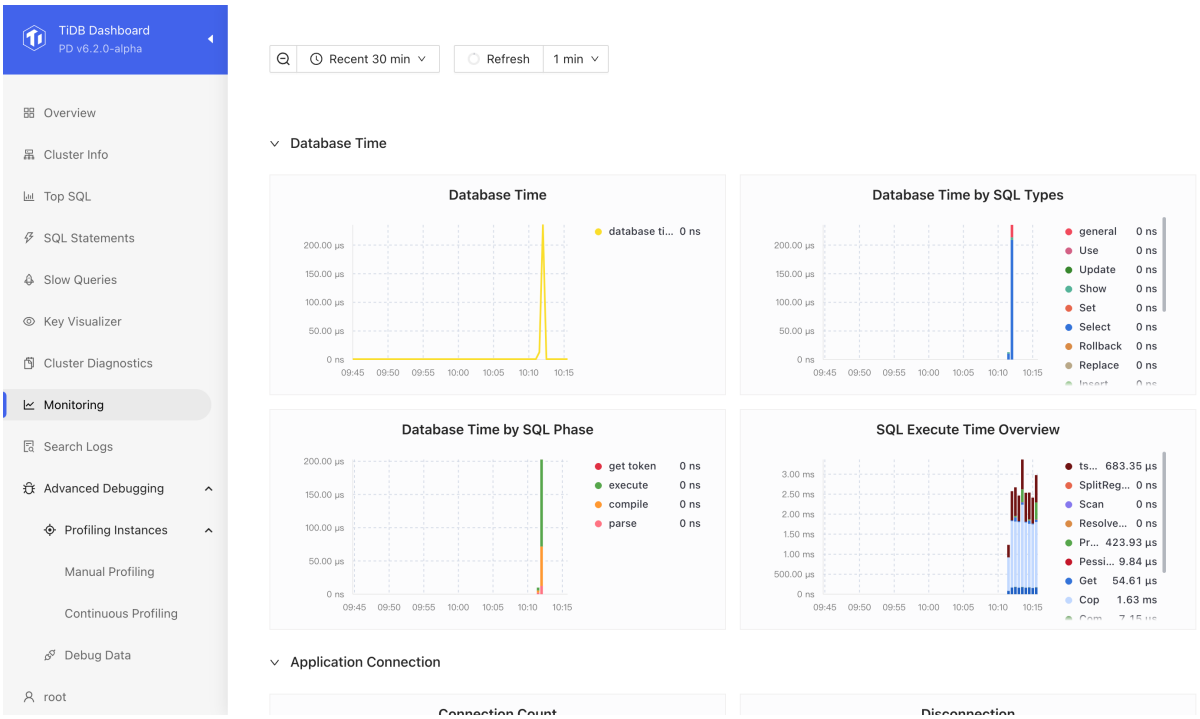

Figure 280: Monitoring page

If the TiDB cluster is deployed using TiUP, you can also view the Performance Overview dashboard on Grafana. In this deployment mode, the monitoring system (Prometheus & Grafana) is deployed at the same time. For more information, see TiDB Monitoring Framework Overview.

Figure 281: performance overview

9.5.12.2 Key Metrics on Performance Overview

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- **Overview**: Database time and SQL execution time summary. By checking different colors in the overview, you can quickly identify the database workload profile and the performance bottleneck.
- **Load profile**: Key metrics and resource usage, including database QPS, connection information, the MySQL command types the application interacts with TiDB, database internal TSO and KV request OPS, and resource usage of the TiKV and TiDB.
- **Top-down latency breakdown**: Query latency versus connection idle time ratio, query latency breakdown, TSO/KV request latency during execution, breakdown of write latency within TiKV.

The following sections illustrate the metrics on the Performance Overview dashboard.

9.5.12.2.1 Database Time by SQL Type

- `database time`: Total database time per second
- `sql_type`: Database time consumed by each type of SQL statements per second

9.5.12.2.2 Database Time by SQL Phase

- `database time`: Total database time per second
- `get token/parse/compile/execute`: Database time consumed in four SQL processing phases

The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required.

9.5.12.2.3 SQL Execute Time Overview

- `execute time`: Database time consumed during SQL execution per second
- `tso_wait`: Concurrent TSO waiting time per second during SQL execution
- `kv request type`: Time waiting for each KV request type per second during SQL execution. The total KV request wait time might exceed SQL execution time, because KV requests are concurrent.

Green metrics stand for common KV write requests (such as prewrite and commit), blue metrics stand for common read requests, and metrics in other colors stand for unexpected situations which you need to pay attention to. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown.

If non-blue or non-green areas are large, it means there is a bottleneck during SQL execution. For example:

- If serious lock conflicts occur, the red area will take a large proportion.
- If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

9.5.12.2.4 QPS

Number of SQL statements executed per second in all TiDB instances, collected by type: such as `SELECT`, `INSERT`, and `UPDATE`

9.5.12.2.5 CPS By Type

Number of commands processed by all TiDB instances per second based on type

9.5.12.2.6 Queries Using Plan Cache OPS

Number of queries using plan cache per second in all TiDB instances

9.5.12.2.7 KV/TSO Request OPS

- kv request total: Total number of KV requests per second in all TiDB instances
- kv request by type: Number of KV requests per second in all TiDB instances based on such types as `Get`, `Prewrite`, and `Commit`
- tso - cmd: Number of gRPC requests per second that TiDB sends to PD in all TiDB instances; each gRPC request contains a batch of TSO requests
- tso - request: Number of TSO requests per second in all TiDB instances

Generally, `tso - request` divided by `tso - cmd` is the average size of TSO request batches per second.

9.5.12.2.8 Connection Count

- `total`: Number of connections to all TiDB instances
- `active connections`: Number of active connections to all TiDB instances
- Number of connections to each TiDB instance

9.5.12.2.9 TiDB CPU/Memory

- `CPU-Avg`: Average CPU utilization across all TiDB instances
- `CPU-Delta`: Maximum CPU utilization of all TiDB instances minus minimum CPU utilization of all TiDB instances
- `CPU-Max`: Maximum CPU utilization across all TiDB instances
- `CPU-Quota`: Number of CPU cores that can be used by TiDB
- `Mem-Max`: Maximum memory utilization across all TiDB instances

9.5.12.2.10 TiKV CPU/Memory

- `CPU-Avg`: Average CPU utilization across all TiKV instances
- `CPU-Delta`: Maximum CPU utilization of all TiKV instances minus minimum CPU utilization of all TiKV instances
- `CPU-Max`: Maximum CPU utilization across all TiKV instances
- `CPU-Quota`: Number of CPU cores that can be used by TiKV
- `Mem-Max`: Maximum memory utilization across all TiKV instances

9.5.12.2.11 PD CPU/Memory

- `CPU-Max`: Maximum CPU utilization across all PD instances
- `CPU-Quota`: Number of CPU cores that can be used by PD
- `Mem-Max`: Maximum memory utilization across all PD instances

9.5.12.2.12 Read Traffic

- `TiDB -> Client`: The outbound traffic statistics from TiDB to the client
- `Rocksdb -> TiKV`: The data flow that TiKV retrieves from RocksDB during read operations within the storage layer

9.5.12.2.13 Write Traffic

- `Client -> TiDB`: The inbound traffic statistics from the client to TiDB
- `TiDB -> TiKV: general`: The rate at which foreground transactions are written from TiDB to TiKV
- `TiDB -> TiKV: internal`: The rate at which internal transactions are written from TiDB to TiKV
- `TiKV -> Rocksdb`: The flow of write operations from TiKV to RocksDB
- `RocksDB Compaction`: The total read and write I/O flow generated by RocksDB compaction operations

9.5.12.2.14 Duration

- `Duration`: Execution time
    - The duration from receiving a request from the client to TiDB till TiDB executing the request and returning the result to the client. In general, client requests are sent in the form of SQL statements; however, this duration can include the execution time of commands such as `COM_PING`, `COM_SLEEP`, `COM_STMT_FETCH`, and `COM_SEND_LONG_DATA`.
    - TiDB supports Multi-Query, which means the client can send multiple SQL statements at one time, such as `select 1; select 1; select 1;`. In this case, the total execution time of this query includes the execution time of all SQL statements.
- `avg`: Average time to execute all requests
- `99`: P99 duration to execute all requests
- `avg by type`: Average time to execute all requests in all TiDB instances, collected by type: `SELECT`, `INSERT`, and `UPDATE`

9.5.12.2.15 Connection Idle Duration

Connection Idle Duration indicates the duration of a connection being idle.

- `avg-in-txn`: Average connection idle duration when the connection is within a transaction
- `avg-not-in-txn`: Average connection idle duration when the connection is not within a transaction
- `99-in-txn`: P99 connection idle duration when the connection is within a transaction
- `99-not-in-txn`: P99 connection idle duration when the connection is not within a transaction

9.5.12.2.16 Parse Duration, Compile Duration, and Execute Duration

- `Parse Duration`: Time consumed in parsing SQL statements
- `Compile Duration`: Time consumed in compiling the parsed SQL AST to execution plans
- `Execution Duration`: Time consumed in executing execution plans of SQL statements

All these three metrics include the average duration and the 99th percentile duration in all TiDB instances.

9.5.12.2.17 Avg TiDB KV Request Duration

Average time consumed in executing KV requests in all TiDB instances based on the type, including `Get`, `Prewrite`, and `Commit`.

9.5.12.2.18 Avg TiKV GRPC Duration

Average time consumed in executing gRPC requests in all TiKV instances based on the type, including `kv_get`, `kv_prewrite`, and `kv_commit`.

9.5.12.2.19 PD TSO Wait/RPC Duration

- `wait - avg`: Average time in waiting for PD to return TSO in all TiDB instances
- `rpc - avg`: Average time from sending TSO requests to PD to receiving TSO in all TiDB instances
- `wait - 99`: P99 time in waiting for PD to return TSO in all TiDB instances
- `rpc - 99`: P99 time from sending TSO requests to PD to receiving TSO in all TiDB instances

9.5.12.2.20 Storage Async Write Duration, Store Duration, and Apply Duration

- `Storage Async Write Duration`: Time consumed in asynchronous write
- `Store Duration`: Time consumed in store loop during asynchronously write
- `Apply Duration`: Time consumed in apply loop during asynchronously write

All these three metrics include the average duration and P99 duration in all TiKV instances.

Average storage async write duration = Average store duration + Average apply duration

9.5.12.2.21 Append Log Duration, Commit Log Duration, and Apply Log Duration

- `Append Log Duration`: Time consumed by Raft to append logs
- `Commit Log Duration`: Time consumed by Raft to commit logs
- `Apply Log Duration`: Time consumed by Raft to apply logs

All these three metrics include the average duration and P99 duration in all TiKV instances.

9.5.13 TiDB Dashboard Log Search Page

On the log search page of TiDB Dashboard, you can search logs of all nodes, preview the search result and download logs.

9.5.13.1 Access the page

After logging in to TiDB Dashboard, you can click **Search Logs** to enter this log search homepage.

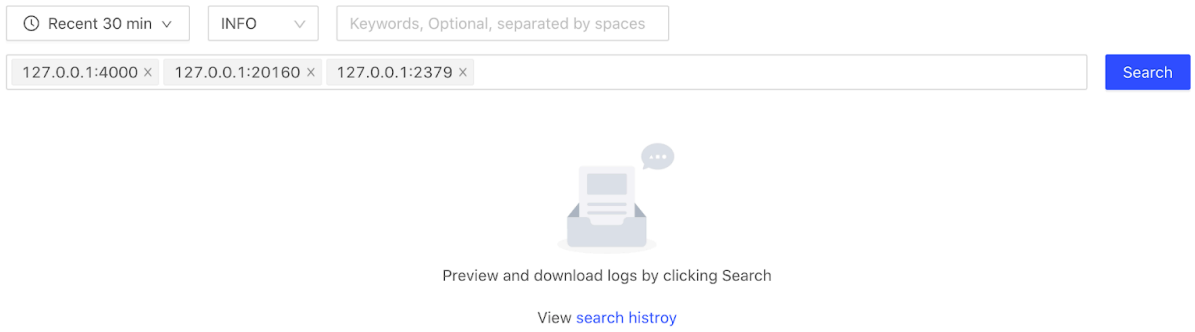

Figure 282: Log Search Page

This page provides the following search parameters:

- Time range: Specifies the time range of logs to search. The default value is the recent 30 minutes.
- Log level: Specifies the minimum log level. All logs above this log level are searched. The default value is the `INFO`.
- Keywords: The parameter is optional and its value can be any legal string. Multiple keywords are separated by a space. Regular expressions are supported (case-insensitive).
- Components: Selects the cluster components to search, which are multi-select and non-empty. By default, all components are selected.

After clicking the **Search** button, you enter the detail page of the search results.

9.5.13.2 Page of search result

The following image shows the page of the search results.

Figure 283: Search result

This page consists of the following three areas:

- Parameter options (area 1 in the image above): These options are the same as the parameter options on the search homepage. You can re-select the parameters in the boxes and start a new search.
- Progress (area 2 in the image above): The current search progress is shown on the right side of this page, including the log search status and statistics of each node.
- Search results (area 3 in the image above):
    - Time: The time at which the log is generated. The time zone is the same as the time zone of the front-end user.
    - Level: log level.
    - Component: Shows the component name and its address.
    - Log: The body part of each log record, excluding the log time and log level. Logs that are too long are automatically truncated. Click a row to expand the full content. The full log can show up to 512 characters.

Note:

At most 500 search results can be previewed on this page. You can get the complete search results by downloading them.

9.5.13.2.1 Search progress

In the search progress area, a search on a node is called a search task. A search task might have the following statuses:

- Running: After starting the search, all tasks enter the **Running** status.
- Success: After the task is completed, it automatically enters the **Success** status. At this time, the logs have been cached in the local disk where the Dashboard backend is located, and can be provided to the frontend to download.
- Failed: When you cancel the search task, or the task exits with an error, the task enters the **Failed** status. When the task fails, the local temporary files are automatically cleaned.

The search progress area has the following three control buttons:

- **Download Selected**: Click this button to download logs of the selected components (only the completed ones can be selected), and you will get a tar file. Unzip this tar file to get one or more zip files (each component corresponds to a zip file). Unzip the zip file(s) to get the log text file.
- **Cancel**: Click this button to cancel all running tasks. You can click this button only when there are running tasks.
- **Retry**: Click this button to retry all failed tasks. You can click this button only when there are failed tasks and no running tasks.

9.5.13.3 Search history list

Click the **View search history** link on the log search homepage to enter page of search history list:

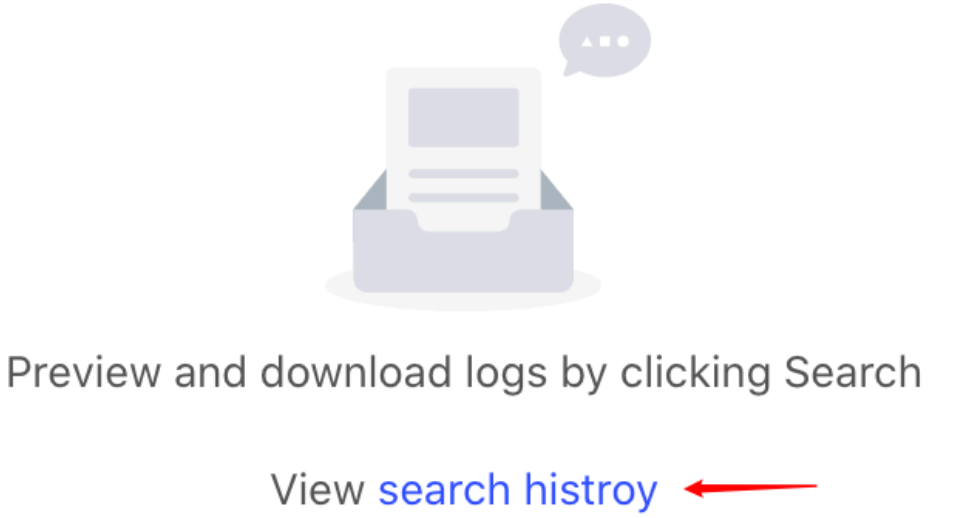

Figure 284: Search history entry

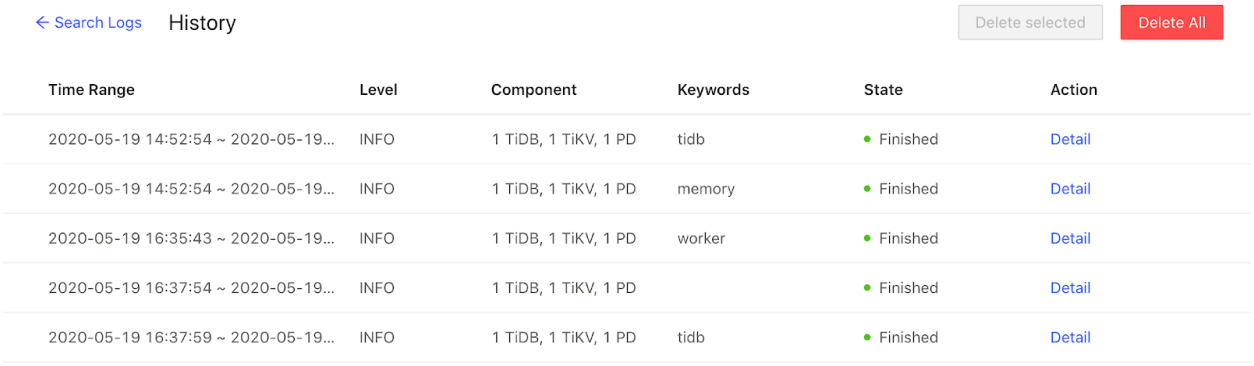

Figure 285: Search history list

The history list shows the time range, log level, components, keywords, and search status of each search log. Click the **Detail** link in the **Action** column to see the search result details:

You can delete the search history that you no longer need. Click **Delete All** in the upper right corner, or select the rows to be deleted and then click **Delete selected** to delete the history:

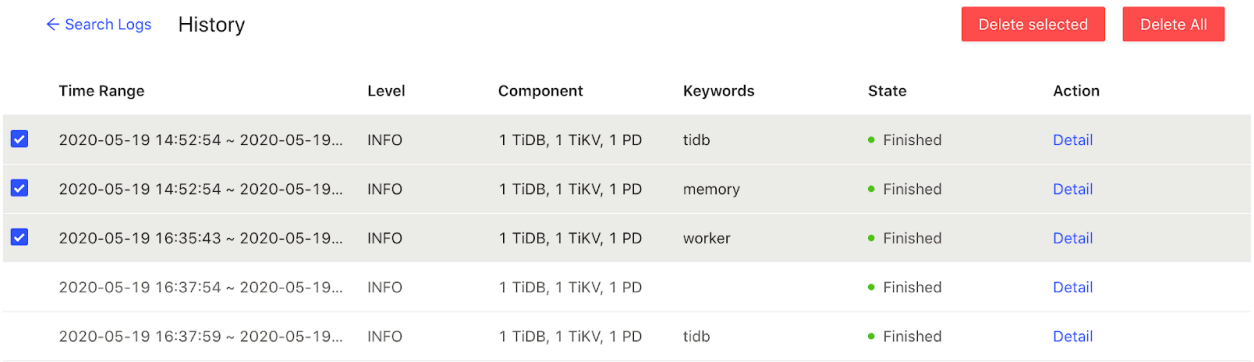

Figure 286: Delete search history

9.5.14 TiDB Dashboard Resource Manager Page

To implement resource isolation using the Resource Control feature, cluster administrators can create resource groups and set quotas for each group. Before resource planning, you need to know the overall capacity of the cluster. This document helps you view the information about resource control, so you can estimate the cluster capacity before resource planning and allocate resources more effectively.

9.5.14.1 Access the page

You can use one of the following two methods to access the Resource Manager page:

- After logging in to TiDB Dashboard, click **Resource Manager** in the left navigation menu.
- Visit http://127.0.0.1:2379/dashboard/#/resource_manager in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

9.5.14.2 Resource Manager page

The following figure shows the Resource Manager details page:

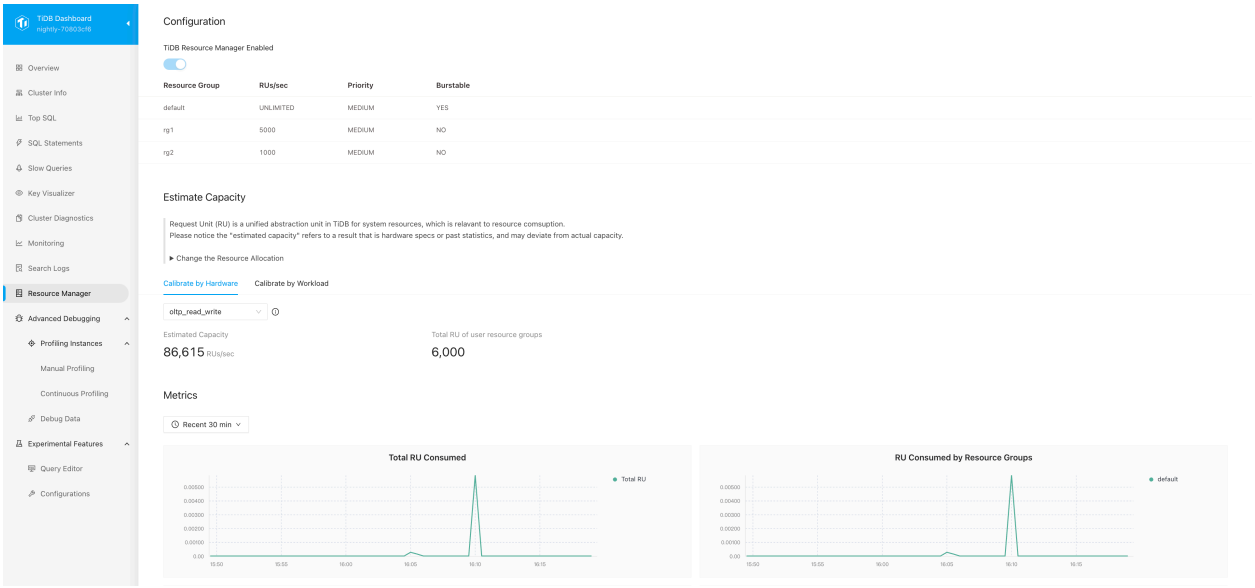

Figure 287: TiDB Dashboard: Resource Manager

The Resource Manager page contains the following three sections:

- Configuration: This section displays the data obtained from the `RESOURCE_GROUPS` ↪ table of TiDB. It contains the information about all resource groups. For more information, see `RESOURCE_GROUPS`.
- Estimate Capacity: Before resource planning, you need to know the overall capacity of the cluster. You can use one of the following methods:
  - Estimate capacity based on actual workload
  - Estimate capacity based on hardware deployment
- Metrics: By observing the metrics on the panels, you can understand the current overall resource consumption status of the cluster.

9.5.14.3 Estimate Capacity

Before resource planning, you need to know the overall capacity of the cluster. TiDB provides two methods to estimate the capacity of Request Unit (RU) in the current cluster:

- Estimate capacity based on hardware deployment

  TiDB accepts the following workload types:

  - `tpcc`: applies to workloads with heavy data write. It is estimated based on a workload model similar to `TPC-C`.

- `oltp_write_only`: applies to workloads with heavy data write. It is estimated based on a workload model similar to `sysbench oltp_write_only`.
- `oltp_read_write`: applies to workloads with even data read and write. It is estimated based on a workload model similar to `sysbench oltp_read_write`.
- `oltp_read_only`: applies to workloads with heavy data read. It is estimated based on a workload model similar to `sysbench oltp_read_only`.

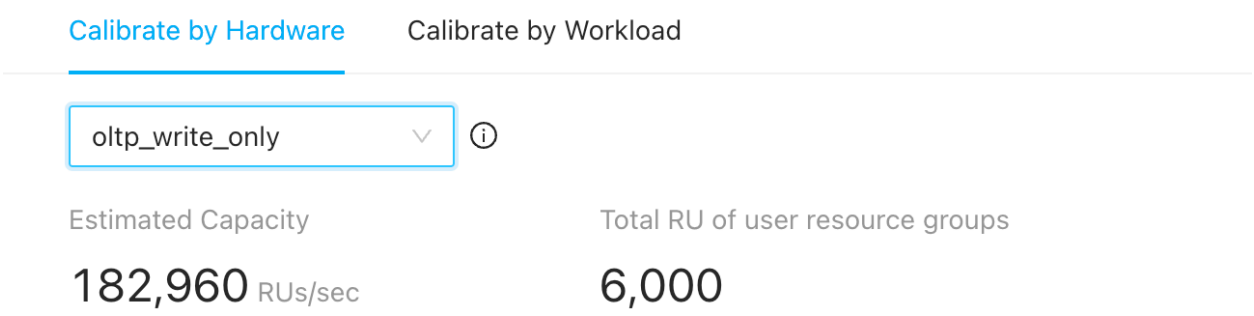

Figure 288: Calibrate by Hardware

```
The **Total RU of user resource groups** represents the total amount of RU
    ↪ for all user resource groups, excluding the `default` resource group.
    ↪  If this value is more than the estimated capacity, the system
    ↪ triggers an alert. By default, the system allocates unlimited usage
    ↪ to the predefined `default` resource group. When all users belong to
    ↪ the `default` resource group, resources are allocated in the same way
    ↪  as when resource control is disabled.
```

- Estimate capacity based on actual workload

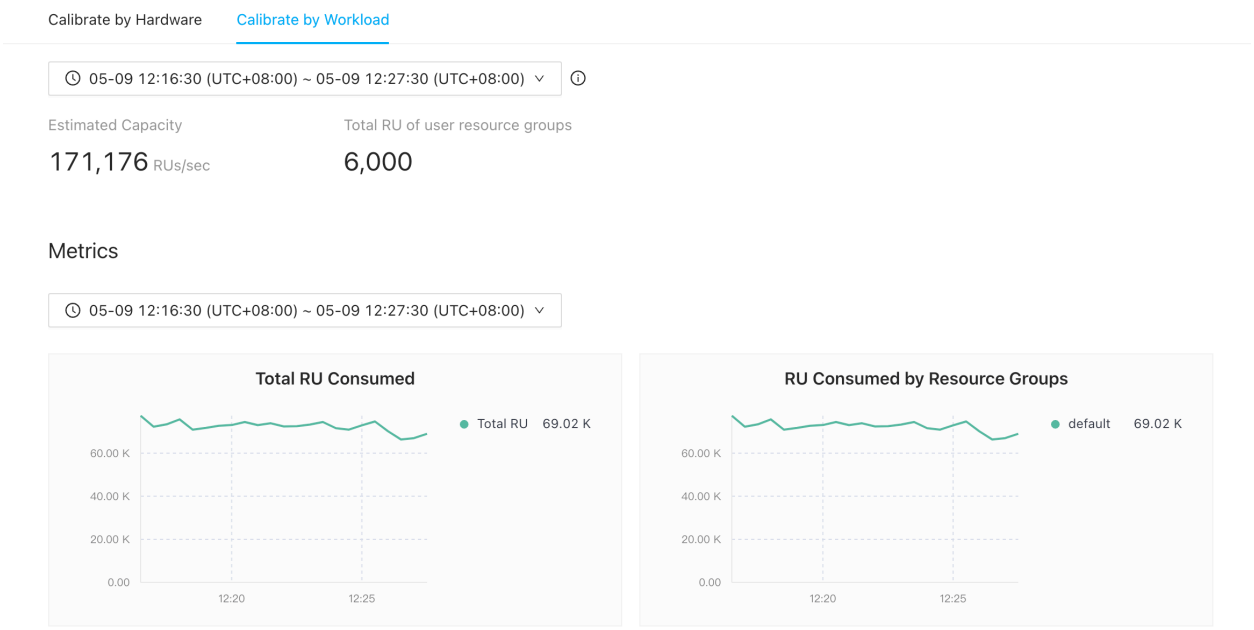

Figure 289: Calibrate by Workload

You can select a time range for estimation within the range of 10 minutes to 24 hours. The time zone used is the same as that of the front-end user.

- When the time window range does not fall between 10 minutes and 24 hours, the following error is displayed `ERROR 1105 (HY000): the duration of calibration is too short, which could lead to inaccurate output. Please make the duration between 10m0s and 24h0m0s`.
- The monitoring metrics for the capacity estimation based on the actual workload feature include `tikv_cpu_quota`, `tidb_server_maxprocs`, `resource_manager_resource_unit`, and `process_cpu_usage`. If the CPU quota monitoring data is empty, there will be an error with the corresponding monitoring metric name, for example, `Error 1105 (HY000): There is no CPU quota metrics, metrics 'tikv_cpu_quota' is empty`.
- If the workload in the time window is too low, or the `resource_manager_resource_unit` and `process_cpu_usage` monitoring data is missing, an error will be reported `Error 1105 (HY000): The workload in selected time window is too low, with which TiDB is unable to reach a capacity estimation; please select another time window with higher workload, or calibrate resource by hardware instead`. In addition, because TiKV does not monitor CPU utilization on macOS, it does not support capacity estimation based on the actual workload, and will also report this error.

You can select an appropriate time range using **CPU Usage** in the Metrics section.

> **Note:**
>
> To use the capacity estimation feature, the current login user must have the `SUPER` or `RESOURCE_GROUP_ADMIN` privilege and the `SELECT` privilege for some system tables. Before using this feature, ensure the current user has these privileges. Otherwise, some features might not work properly. For more information, see `CALIBRATE RESOURCE`.

9.5.14.4 Metrics

By observing the metrics on the panels, you can understand the current overall resource consumption status of the cluster. The monitoring metrics and their meanings are as follows:

- Total RU Consumed: The total consumption of Request Units counted in real time.
- RU Consumed by Resource Groups: The number of Request Units consumed by resource groups in real time.
- TiDB
  - CPU Quota: The maximum CPU usage of TiDB.
  - CPU Usage: The total CPU usage of all TiDB instances.
- TiKV
  - CPU Quota: The maximum CPU usage of TiKV.
  - CPU Usage: The total CPU usage of all TiKV instances.
  - IO MBps: The total I/O throughput of all TiKV instances.

9.5.15 Instance Profiling

9.5.15.1 TiDB Dashboard Instance Profiling - Manual Profiling

> **Note:**
>
> This feature is designed for database experts. For non-expert users, it is recommended to use this feature under the guidance of PingCAP technical supports.

Manual Profiling allows users to collect current performance data **on demand** for each TiDB, TiKV, PD and TiFlash instances with a single click. The collected performance data can be visualized as FlameGraph or DAG.

With these performance data, experts can analyze current resource consumption details like instance's CPU and memory, to help pinpoint sophisticated ongoing performance problems, such as high CPU overhead, high memory usage, and process stalls.

After initiates the profiling, TiDB Dashboard collects current performance data for a period of time (30 seconds by default). Therefore this feature can only be used to analyze ongoing problems that the cluster is facing now and has no significant effect on historical problems. If you want to collect and analyze performance data **at any time**, see Continuous Profiling.

9.5.15.1.1 Supported performance data

The following performance data are currently supported:

- CPU: The CPU overhead of each internal function on TiDB, TiKV, PD and TiFlash instances

> The CPU overhead of TiKV and TiFlash instances is currently not supported in ARM architecture.

- Heap: The memory consumption of each internal function on TiDB, TiKV, and PD instances

> Starting from v7.5, TiDB supports the TiKV Heap Profile. The Perl dependency is required in the running environment of TiDB Dashboard. Otherwise an error will occur.

- Mutex: The mutex contention states on TiDB and PD instances
- Goroutine: The running state and call stack of all goroutines on TiDB and PD instances

9.5.15.1.2 Access the page

You can access the instance profiling page using either of the following methods:

- After logging in to TiDB Dashboard, click **Advanced Debugging** > **Profiling Instances** > **Manual Profiling** in the left navigation menu.

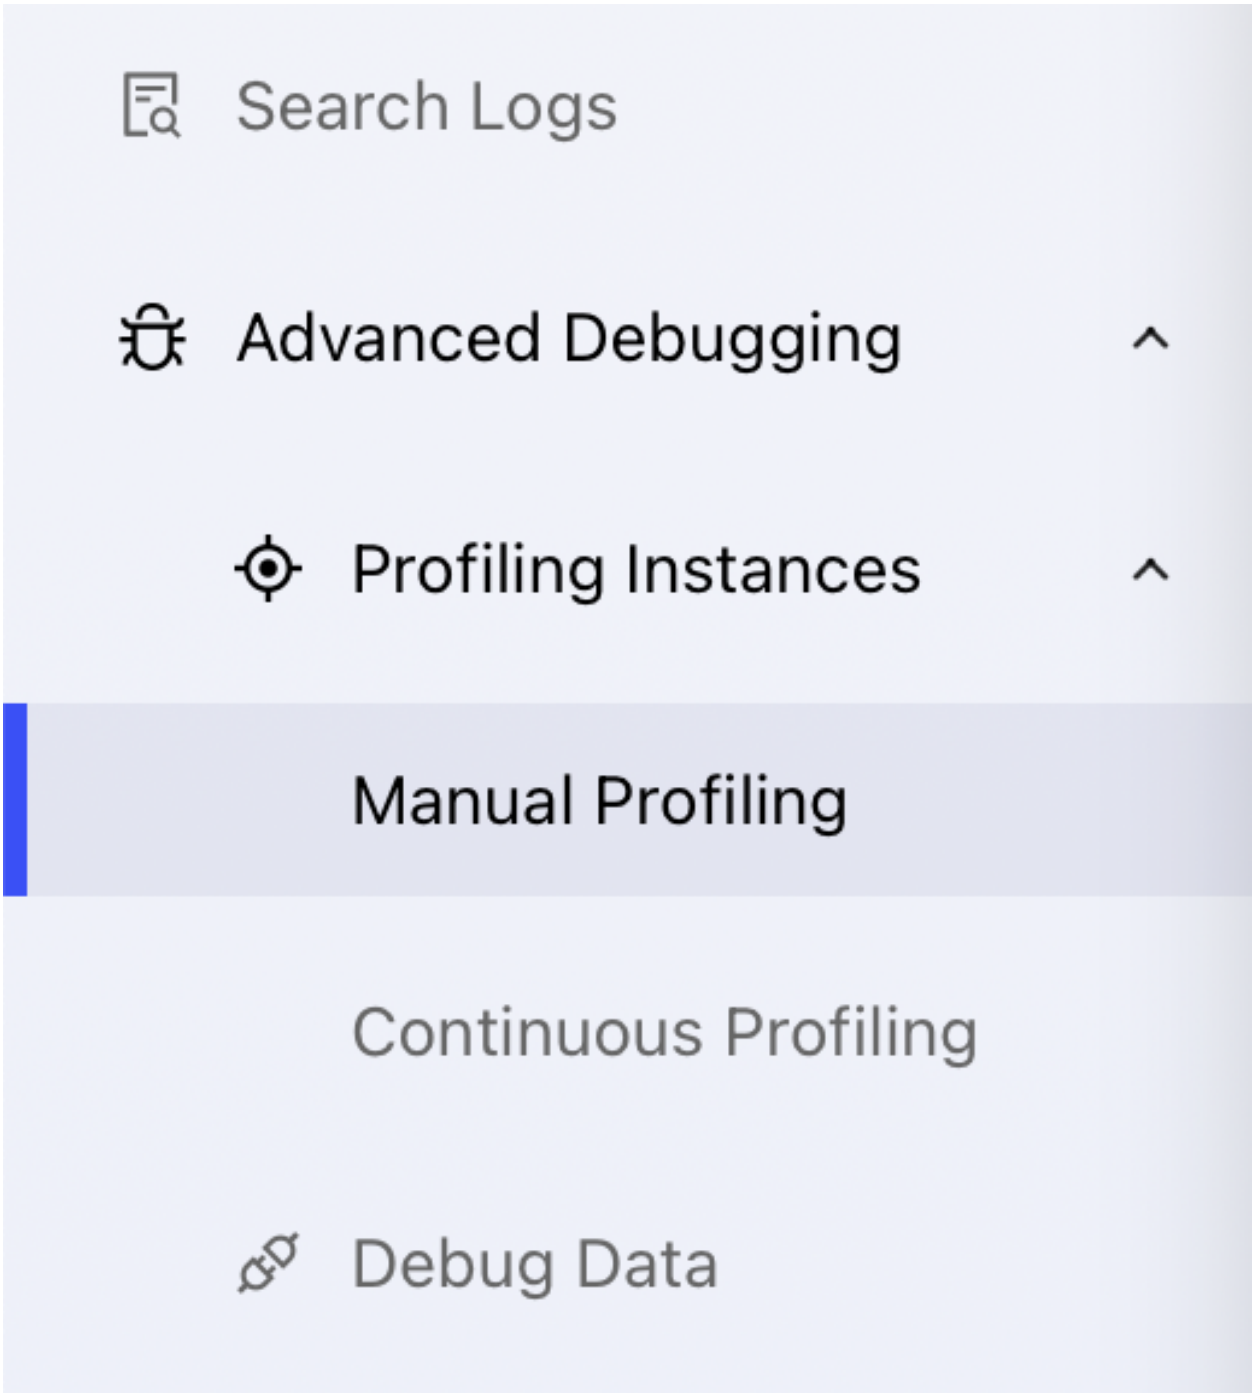

Figure 290: Access instance profiling page

- Visit http://127.0.0.1:2379/dashboard/#/instance_profiling in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

9.5.15.1.3 Start Profiling

In the instance profiling page, choose at least one target instance and click **Start Profiling** to start the instance profiling.

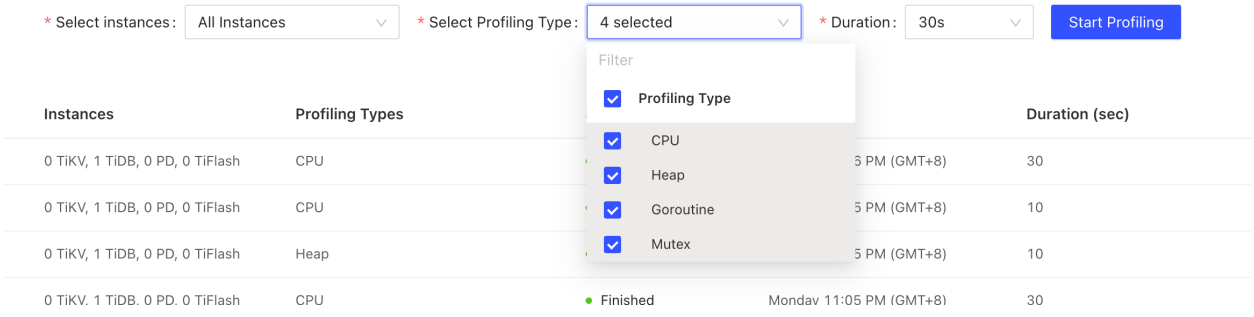

Figure 291: Start instance profiling

You can modify the profiling duration before starting the profiling. This duration is determined by the time needed for the profiling, which is 30 seconds by default. The 30-second duration takes 30 seconds to complete.

Manual Profiling cannot be initiated on clusters that have Continuous Profiling enabled. To view the performance data at the current moment, click on the most recent profiling result in the Continuous Profiling page.

9.5.15.1.4 View profiling status

After a profiling is started, you can view the profiling status and progress in real time.

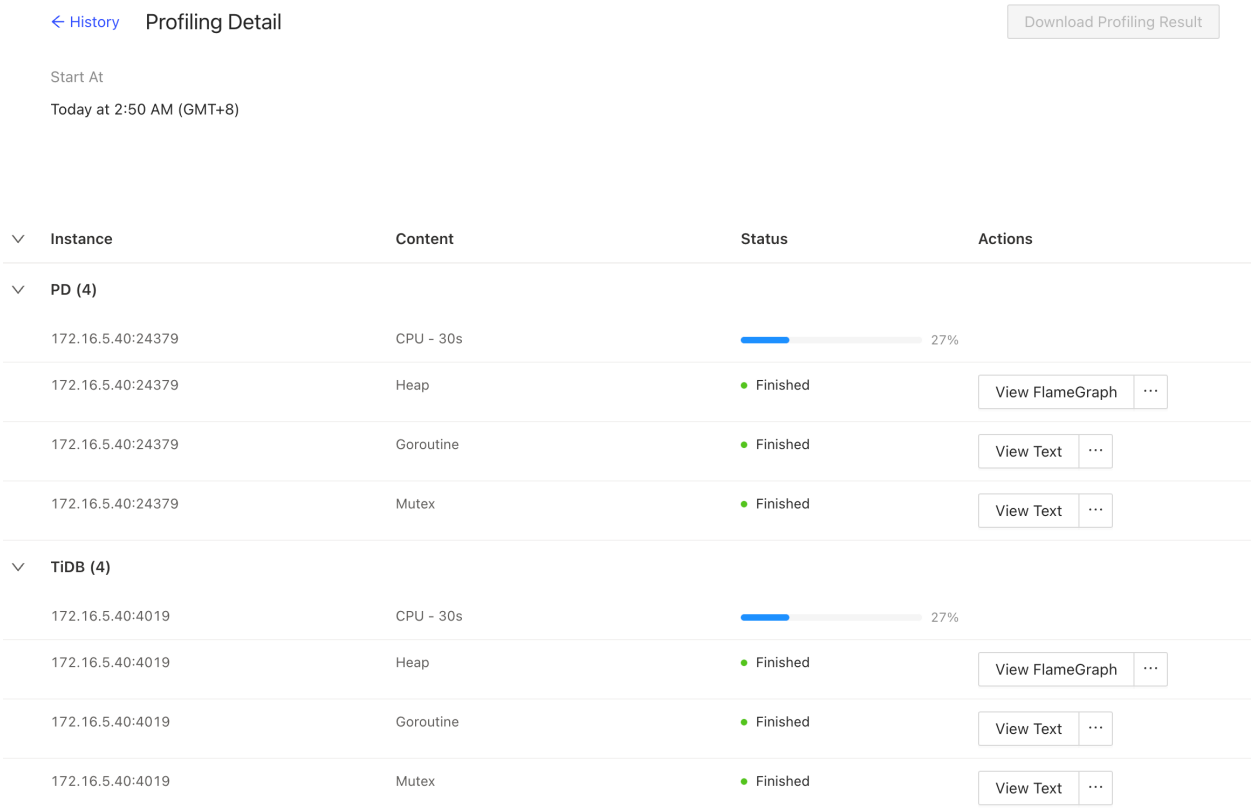

Figure 292: Profiling detail

The profiling runs in the background. Refreshing or exiting the current page does not stop the profiling task that is running.

9.5.15.1.5 Download performance data

After the profiling of all instances is completed, you can click **Download Profiling Result** in the upper right corner to download all performance data.

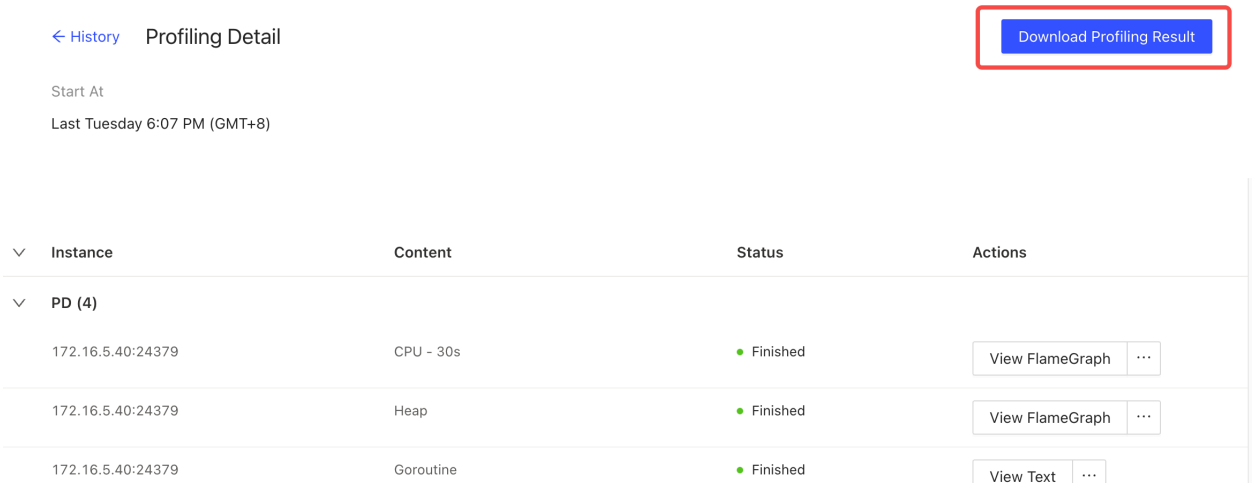

Figure 293: Download profiling result

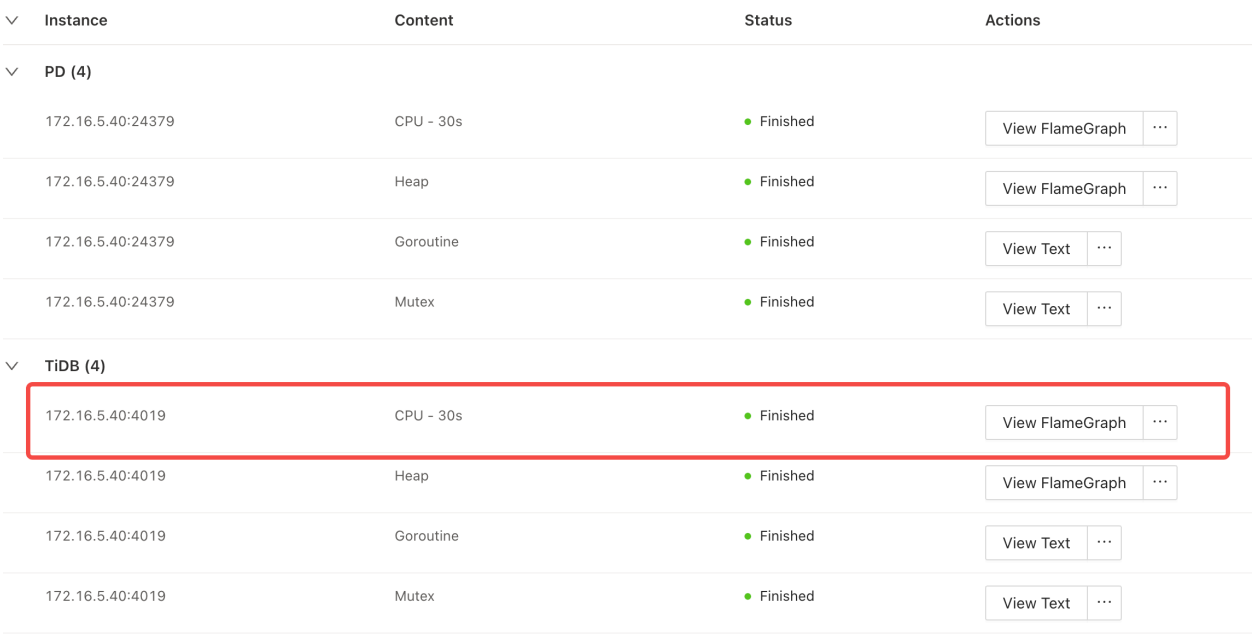
You can also click an individual instance in the table to view its profiling result. Alternatively, you can hover on … to download raw data.



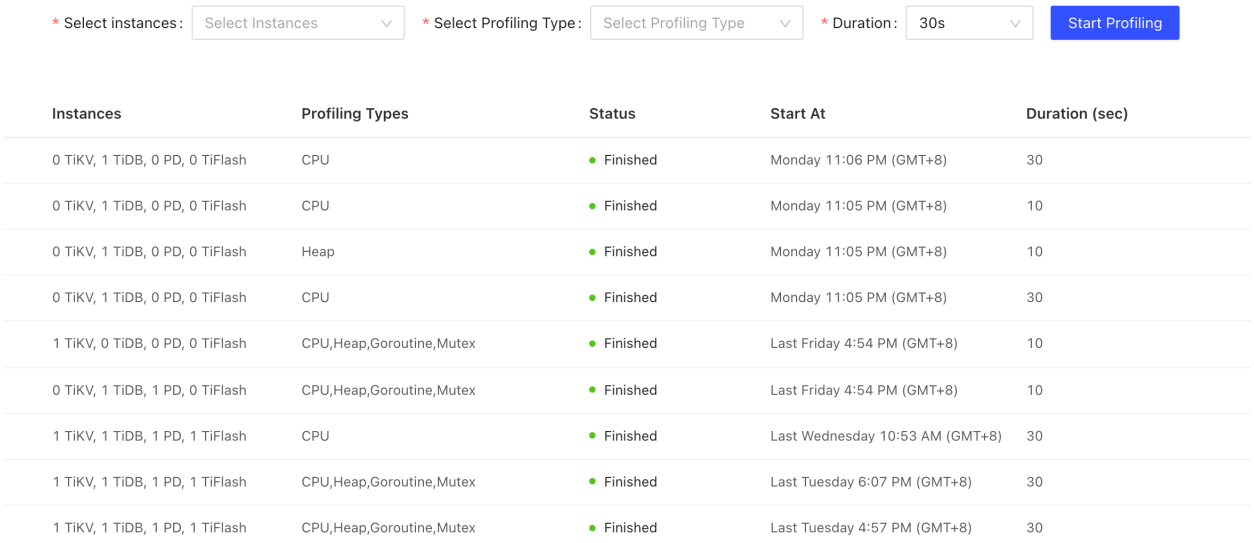


Figure 294: Single instance result

9.5.15.1.6 View profiling history

The on-demand profiling history is listed on the page. Click a row to view details.

Instances	Profiling Types	Status	Start At	Duration (sec)
0 TiKV, 1 TiDB, 0 PD, 0 TiFlash	CPU	Finished	Monday 11:06 PM (GMT+8)	30
0 TiKV, 1 TiDB, 0 PD, 0 TiFlash	CPU	Finished	Monday 11:05 PM (GMT+8)	10
0 TiKV, 1 TiDB, 0 PD, 0 TiFlash	Heap	Finished	Monday 11:05 PM (GMT+8)	10
0 TiKV, 1 TiDB, 0 PD, 0 TiFlash	CPU	Finished	Monday 11:05 PM (GMT+8)	30
1 TiKV, 0 TiDB, 0 PD, 0 TiFlash	CPU,Heap,Goroutine,Mutex	Finished	Last Friday 4:54 PM (GMT+8)	10
0 TiKV, 1 TiDB, 1 PD, 0 TiFlash	CPU,Heap,Goroutine,Mutex	Finished	Last Friday 4:54 PM (GMT+8)	10
1 TiKV, 1 TiDB, 1 PD, 1 TiFlash	CPU	Finished	Last Wednesday 10:53 AM (GMT+8)	30
1 TiKV, 1 TiDB, 1 PD, 1 TiFlash	CPU,Heap,Goroutine,Mutex	Finished	Last Tuesday 6:07 PM (GMT+8)	30
1 TiKV, 1 TiDB, 1 PD, 1 TiFlash	CPU,Heap,Goroutine,Mutex	Finished	Last Tuesday 4:57 PM (GMT+8)	30

Figure 295: View profiling history

For detailed operations on the profiling status page, see View Profiling Status.

9.5.15.2 TiDB Dashboard Instance Profiling - Continuous Profiling

> **Note:**
>
> This feature is designed for database experts. For non-expert users, it is recommended to use this feature under the guidance of PingCAP technical supports.

Continuous Profiling allows collecting performance data **continuously** from each TiDB, TiKV and PD instance. The collected performance data can be visualized as FlameGraph or DAG.

With these performance data, experts can analyze resource consumption details like instance's CPU and memory, to help pinpoint sophisticated performance problems at any time, such as high CPU overhead, high memory usage, process stalls, and so on. Even for problems cannot be reproduced, experts can dig deep into the problem by viewing the historical performance data collected at that moment. In this way, MTTR can be reduced effectively.

9.5.15.2.1 Compare with Manual Profiling

Continuous Profiling is an enhanced feature of Manual Profiling. They can be both used to collect and analyze different kinds of performance data for each instance. Differences between them are as follows:

- Manual Profiling only collects performance data for a short period of time (for example, 30 seconds) at the moment you initiate the profiling, while Continuous Profiling collects data continuously when it is enabled.
- Manual Profiling can only be used to analyze current occurring problems, while Continuous Profiling can be used to analyze both the current and historical problems.
- Manual Profiling allows to collect specific performance data for specific instances, while Continuous Profiling collects all performance data for all instances.
- Continuous Profiling stores more performance data, therefore it takes up more disk space.

9.5.15.2.2 Supported performance data

All performance data in Manual Profiling is collected.

- CPU: The CPU overhead of each internal function on TiDB, TiKV, TiFlash, and PD instances
- Heap: The memory consumption of each internal function on TiDB, TiKV, and PD instances
- Mutex: The mutex contention states on TiDB and PD instances
- Goroutine: The running state and call stack of all goroutines on TiDB and PD instances

9.5.15.2.3 Access the page

You can access the Continuous Profiling page using either of the following methods:

- After logging in to TiDB Dashboard, click **Advanced Debugging** > **Profiling Instances** > **Continuous Profiling** in the left navigation menu.

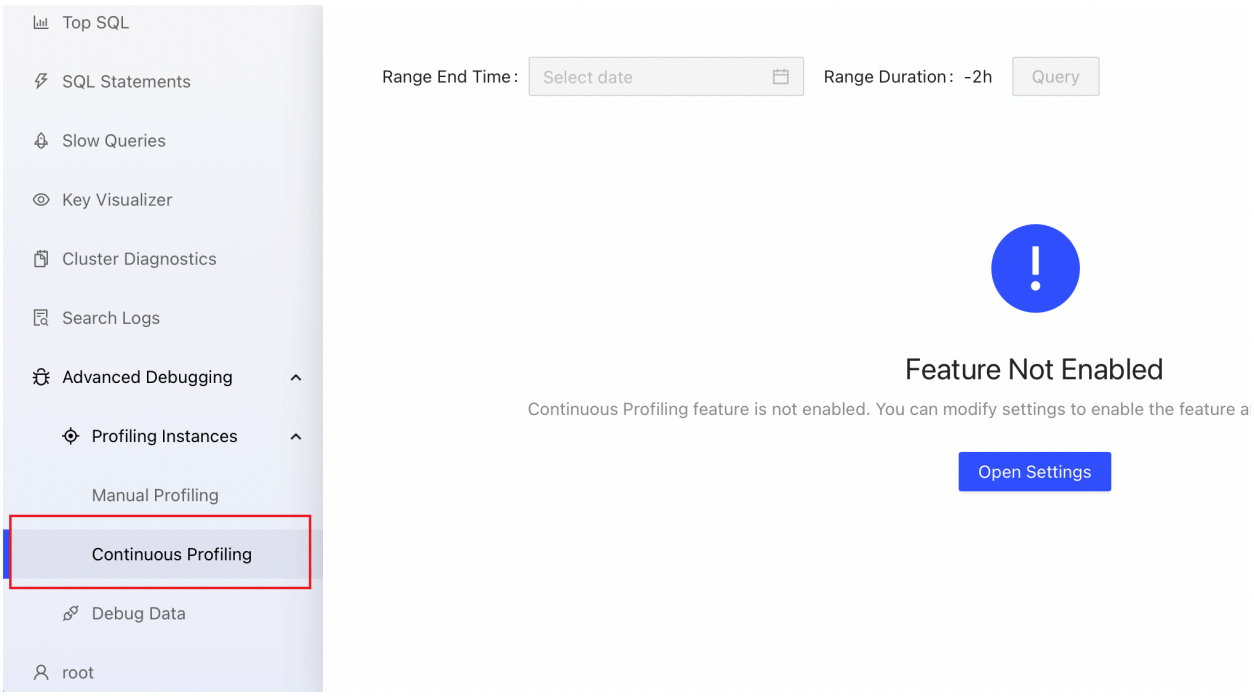

Figure 296: Access page

- Visit http://127.0.0.1:2379/dashboard/#/continuous_profiling in your browser. Replace `127.0.0.1:2379` with the actual PD instance address and port.

9.5.15.2.4 Enable Continuous Profiling

> **Note:**
>
> To use Continuous Profiling, your cluster should be deployed or upgraded with a recent version of TiUP (v1.9.0 or above) or TiDB Operator (v1.3.0 or above). If your cluster was upgraded using an earlier version of TiUP or TiDB Operator, see FAQ for instructions.

After enabling Continuous Profiling, you can have performance data continuously collected in the background without keeping the web pages always active. Data collected can be kept for a certain period of time and expired data is automatically cleared.

To enable this feature:

1. Visit the Continuous Profiling page.

2. Click **Open Settings**. In the **Settings** area on the right, switch **Enable Feature** on, and modify the default value of **Retention Duration** if necessary.
3. Click **Save**.

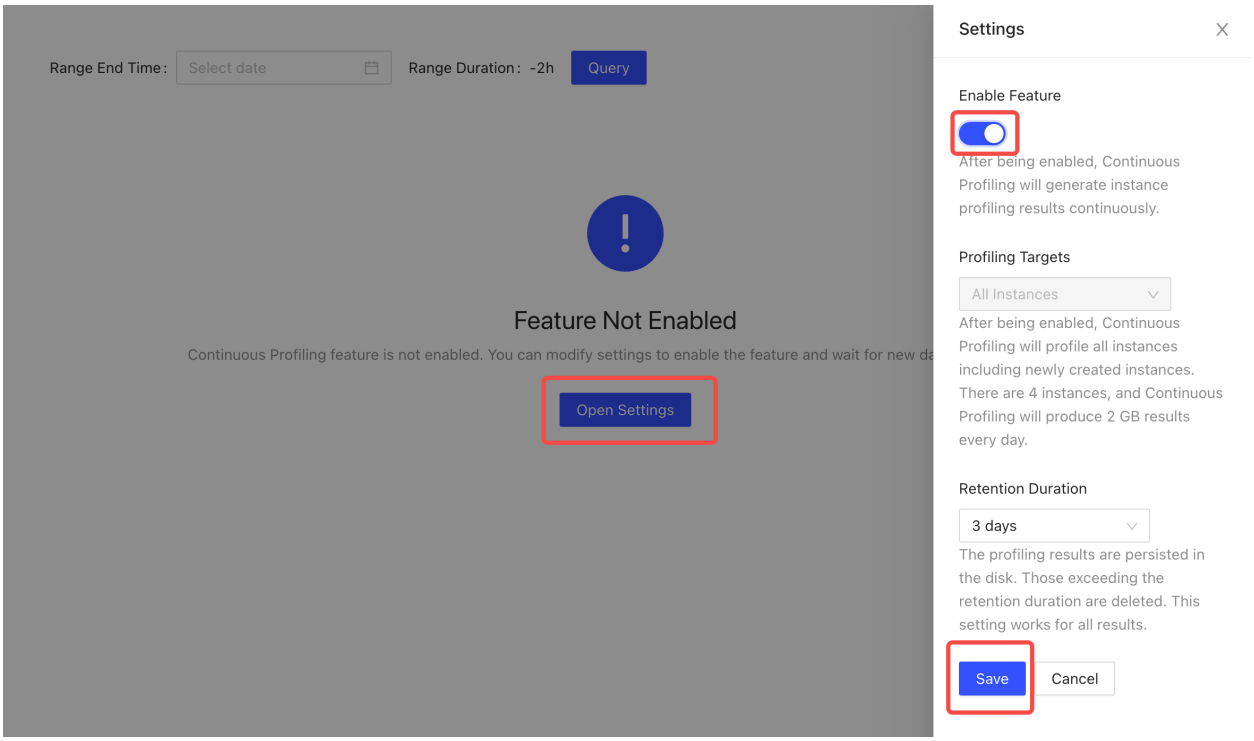

Figure 297: Enable feature

9.5.15.2.5 View current performance data

Manual Profiling cannot be initiated on clusters that have Continuous Profiling enabled. To view the performance data at the current moment, just click on the most recent profiling result.

9.5.15.2.6 View historical performance data

On the list page, you can see all performance data collected since the enabling of this feature.

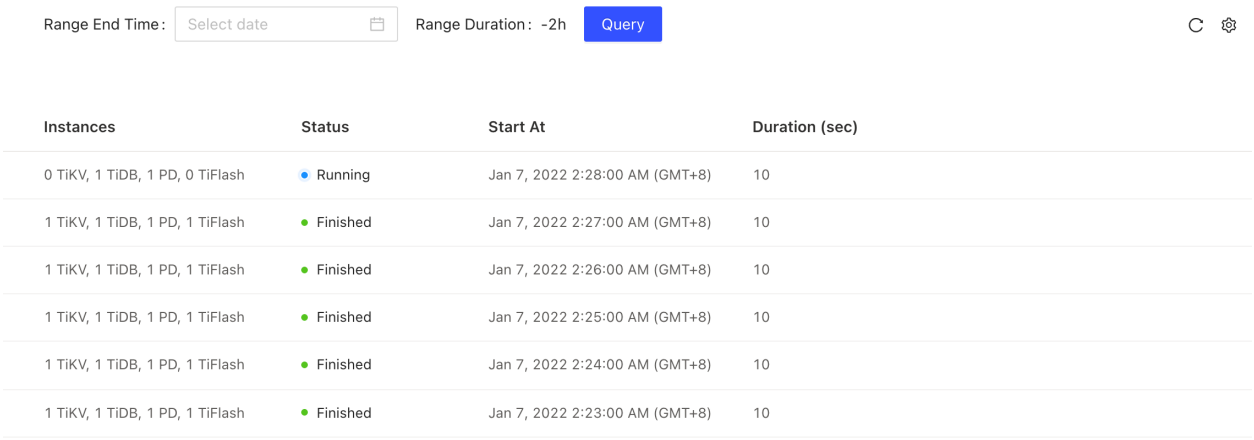

Figure 298: History results

9.5.15.2.7 Download performance data

On the profiling result page, you can click **Download Profiling Result** in the upper-right corner to download all profiling results.

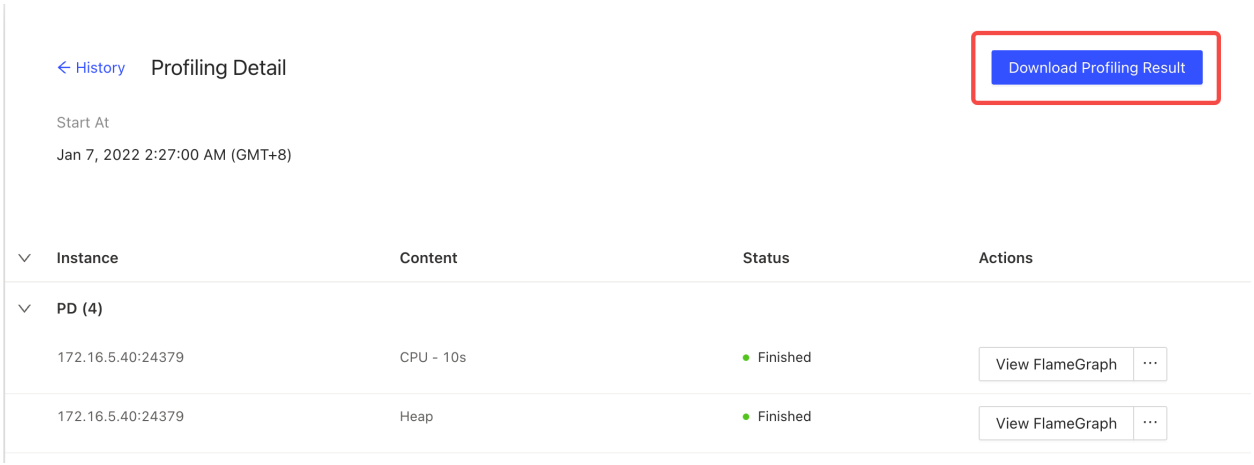

Figure 299: Download profiling result

You can also click an individual instance in the table to view its profiling result. Alternatively, you can hover on … to download raw data.

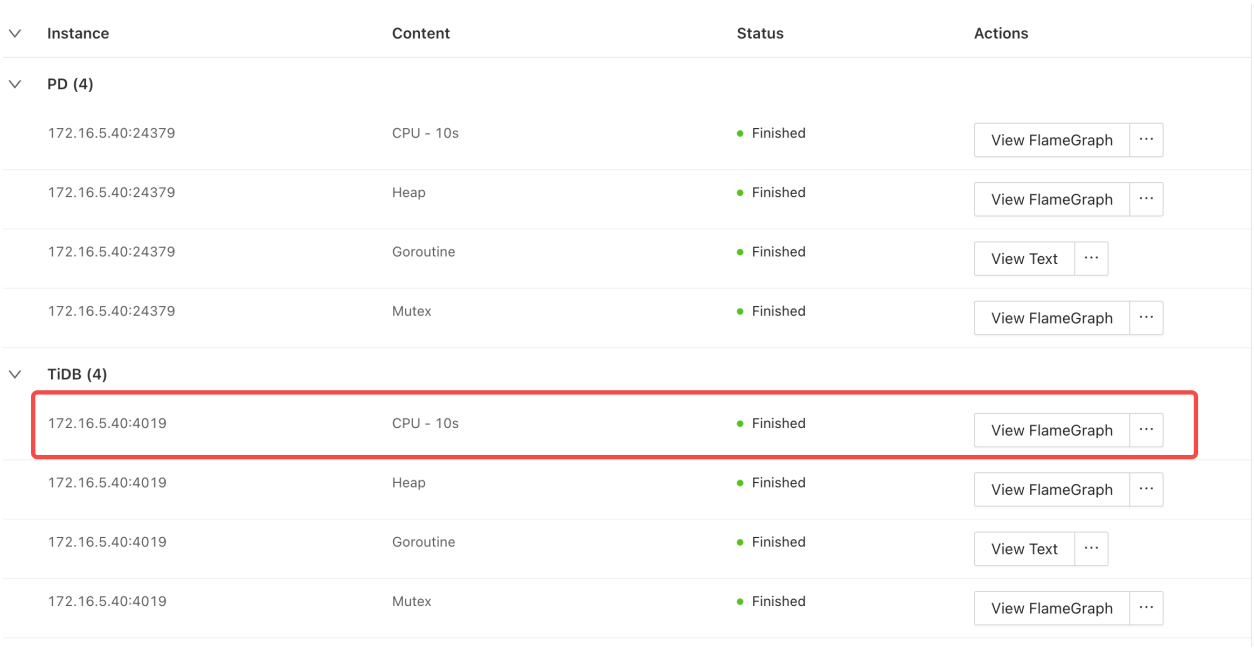

Figure 300: View profiling result

9.5.15.2.8 Disable Continuous Profiling

1. Visit the Continuous Profiling page.
2. Click the gear icon in the upper right corner to open the settings page. Switch **Enable Feature** off.
3. Click **Save**.
4. In the popped-up dialog box, click **Disable**.

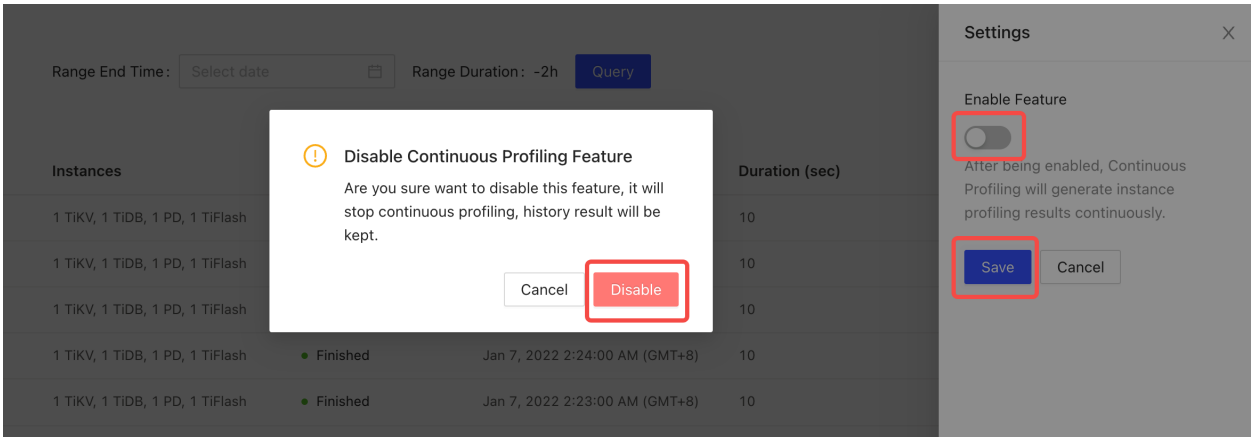

Figure 301: Disable feature

9.5.15.2.9 Frequently asked questions

1. Continuous Profiling cannot be enabled and the UI displays "required component NgMonitoring is not started".

See TiDB Dashboard FAQ.

2. Will performance be affected after enabling Continuous Profiling?

According to our benchmark, the average performance impact is less than 1% when the feature is enabled.

3. What is the status of this feature?

It is now a generally available (GA) feature and can be used in production environments.

9.5.16 Session Management and Configuration

9.5.16.1 Share TiDB Dashboard Sessions

You can share the current session of the TiDB Dashboard to other users so that they can access and operate the TiDB Dashboard without entering the user password.

9.5.16.1.1 Steps for the inviter

1. Sign into TiDB Dashboard.
2. Click the username in the left sidebar to access the configuration page.
3. Click **Share Current Session**.

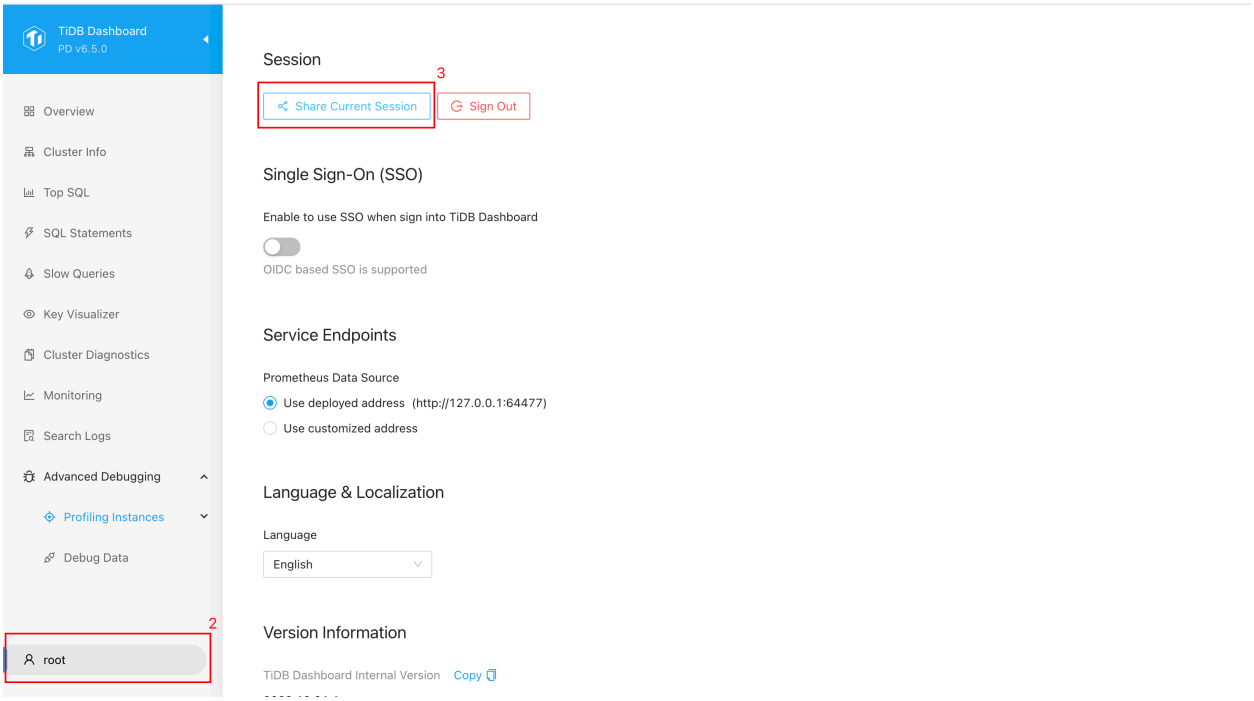

Figure 302: Sample Step

> **Note:**
>
> For security reasons, the shared session cannot be shared again.

4. Adjust sharing settings in the popup dialog:

- Expire in: How long the shared session will be effective. Signing out of the current session does not affect the effective time of the shared session.
- Share as read-only privilege: The shared session only permits read operations but not write operations (such as modifying configurations).

5. Click **Generate Authorization Code**.

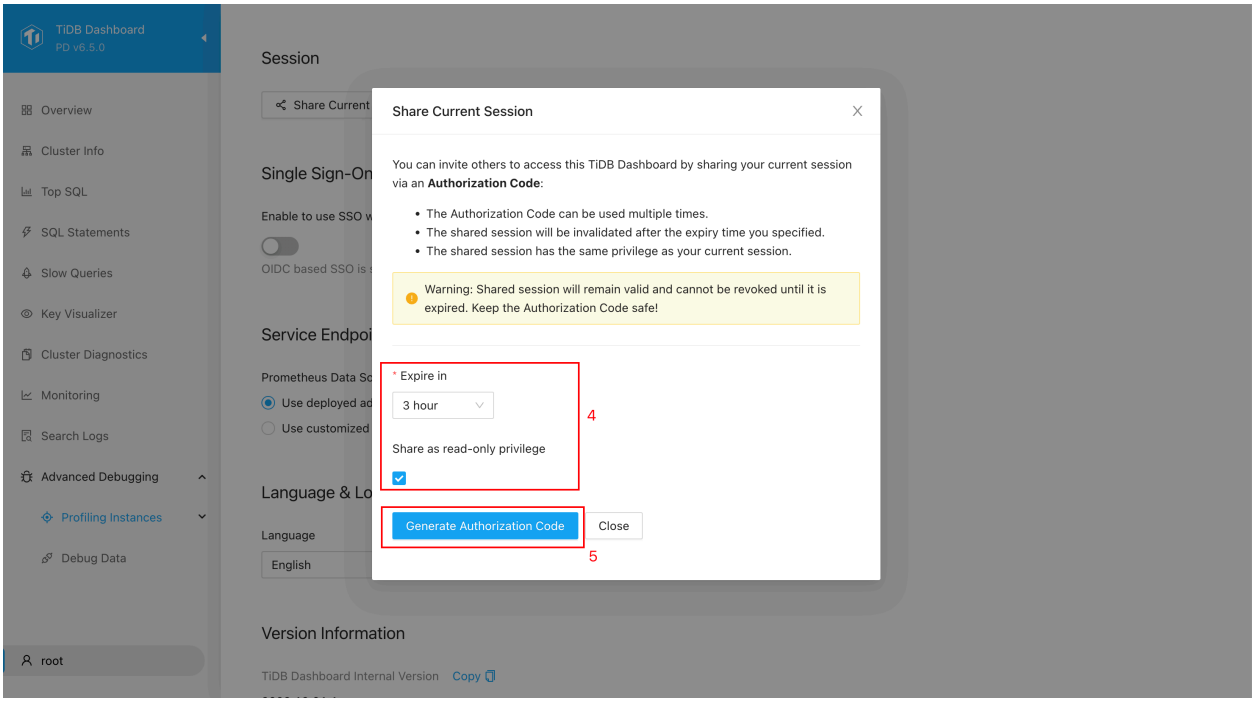

Figure 303: Sample Step

6. Provide the generated **Authorization Code** to the user to whom you want to share the session.

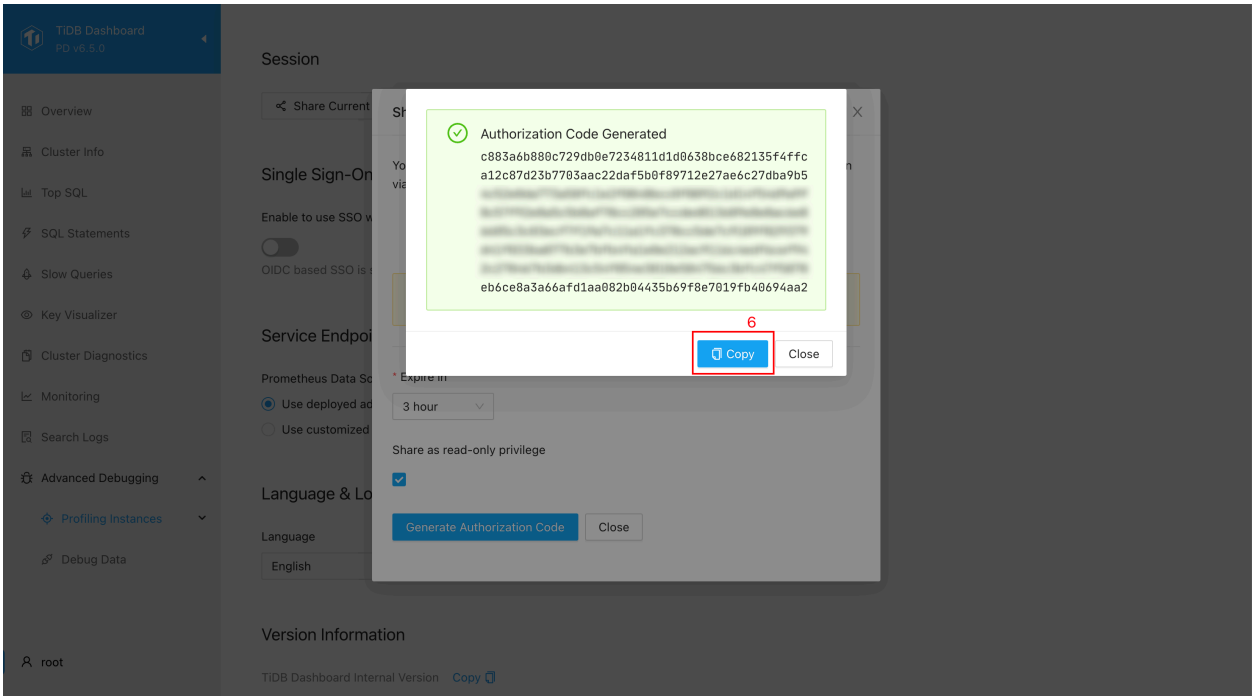

Figure 304: Sample Step

Warning:

Keep your authorization code secure and do not send it to anyone who is untrusted. Otherwise, they will be able to access and operate TiDB Dashboard without your authorization.

9.5.16.1.2 Steps for the invitee

1. On the sign-in page of TiDB Dashboard, click **Use Alternative Authentication**.

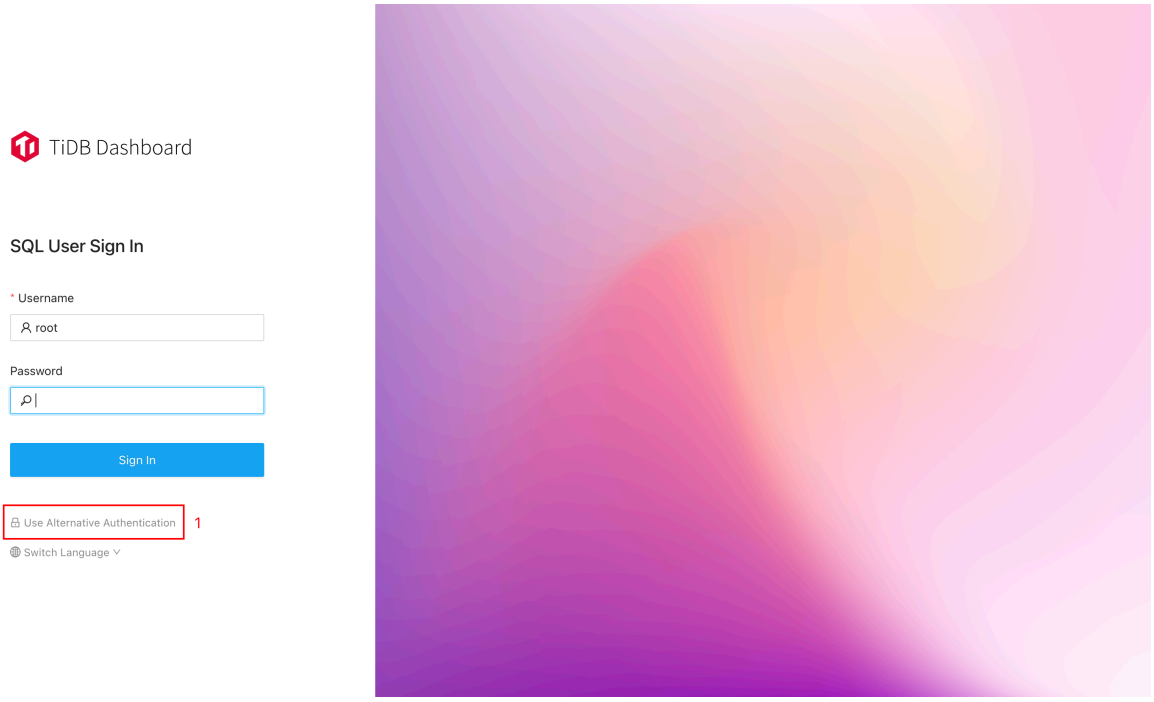

Figure 305: Sample Step

2. Click **Authorization Code** to use it to sign in.

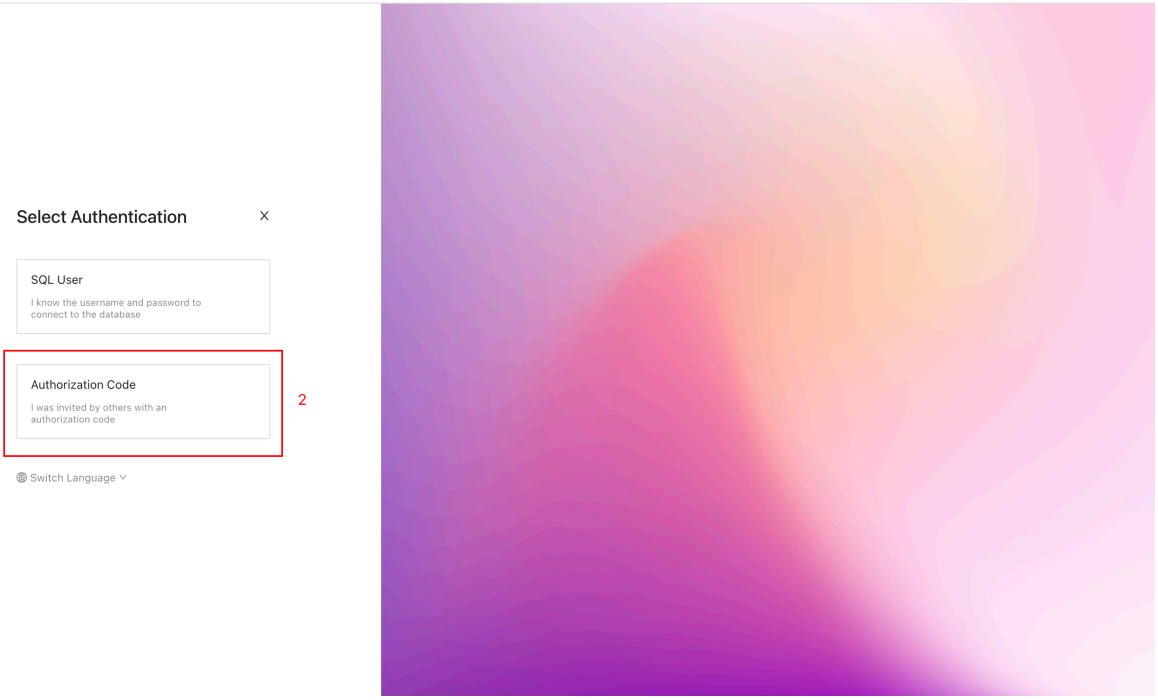

Figure 306: Sample Step

3. Enter the authorization code you have received from the inviter.
4. Click **Sign In**.

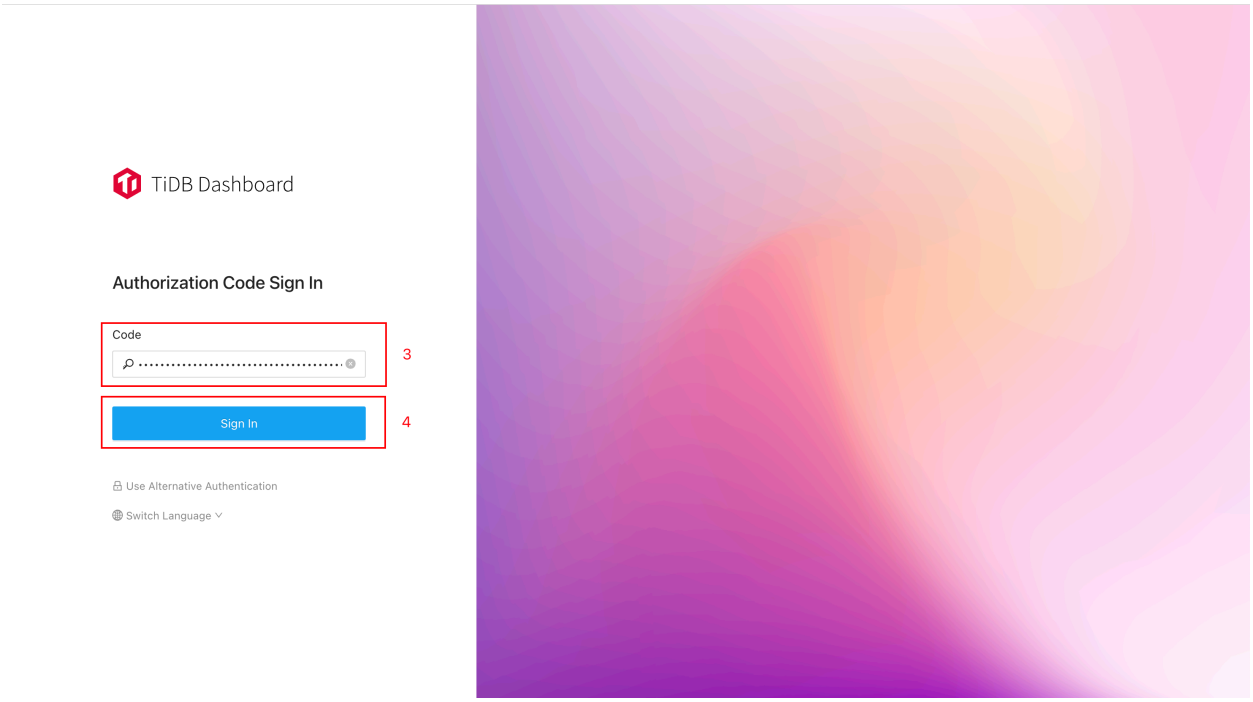

Figure 307: Sample Step

9.5.16.2 Configure SSO for TiDB Dashboard

TiDB Dashboard supports OIDC-based Single Sign-On (SSO). After enabling the SSO feature of TiDB Dashboard, the configured SSO service is used for your sign-in authentication and then you can access TiDB Dashboard without entering the SQL user password.

9.5.16.2.1 Configure OIDC SSO

Enable SSO

1. Sign into TiDB Dashboard.
2. Click the username in the left sidebar to access the configuration page.
3. In the **Single Sign-On** section, select **Enable to use SSO when sign into TiDB Dashboard**.
4. Fill the **OIDC Client ID** and the **OIDC Discovery URL** fields in the form.

   Generally, you can obtain the two fields from the SSO service provider:

- OIDC Client ID is also called OIDC Token Issuer.
- OIDC Discovery URL is also called OIDC Token Audience.

5. Click **Authorize Impersonation** and input the SQL password.

   TiDB Dashboard will store this SQL password and use it to impersonate a normal SQL sign-in after an SSO sign-in is finished.

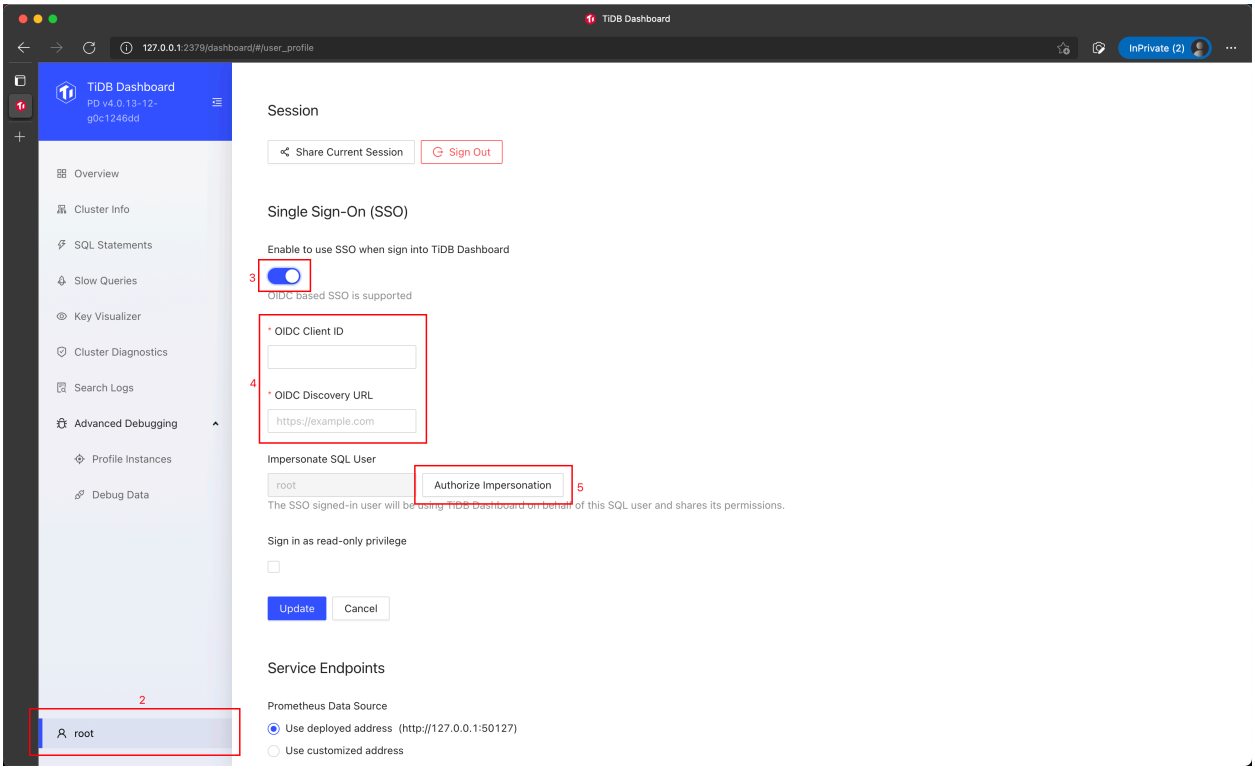

Figure 308: Sample Step

> **Note:**
>
> The password you have entered will be encrypted and stored. The SSO sign-in will fail after the password of the SQL user is changed. In this case, you can re-enter the password to bring SSO back.

6. Click **Authorize and Save**.

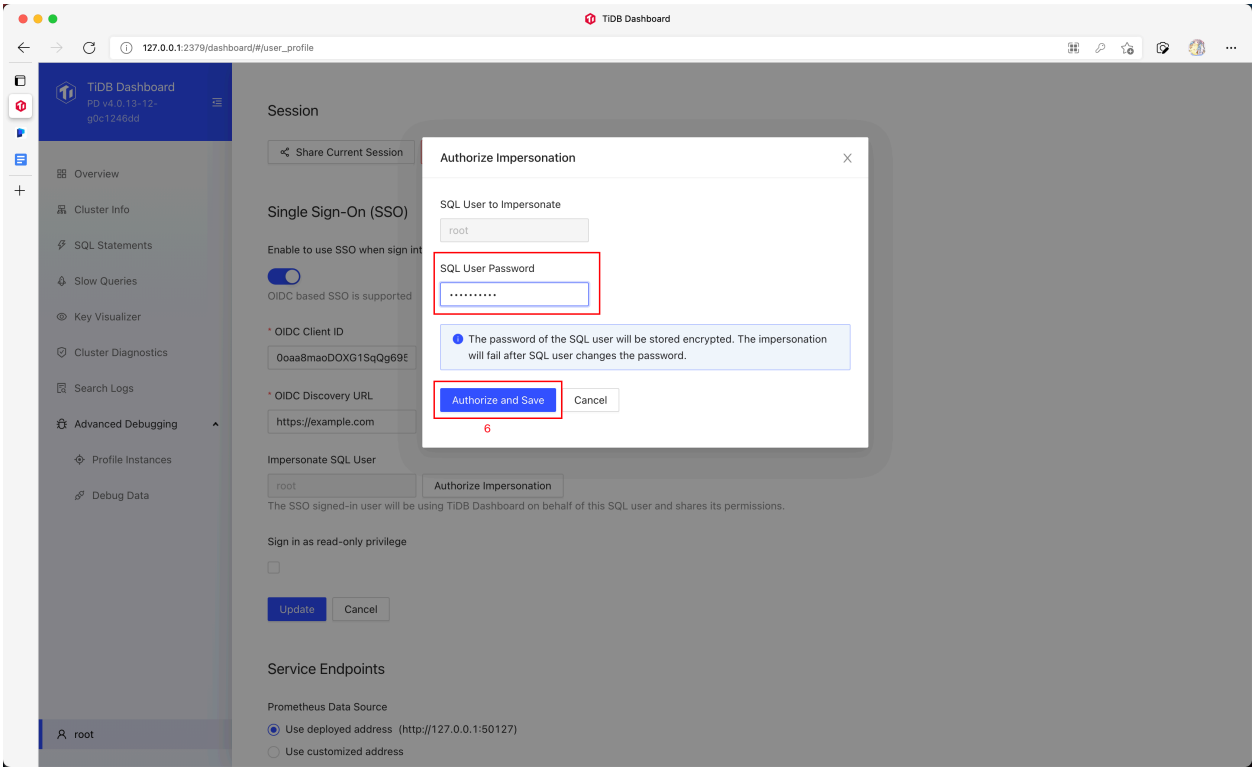

Figure 309: Sample Step

7. Click **Update** (Update) to save the configuration.

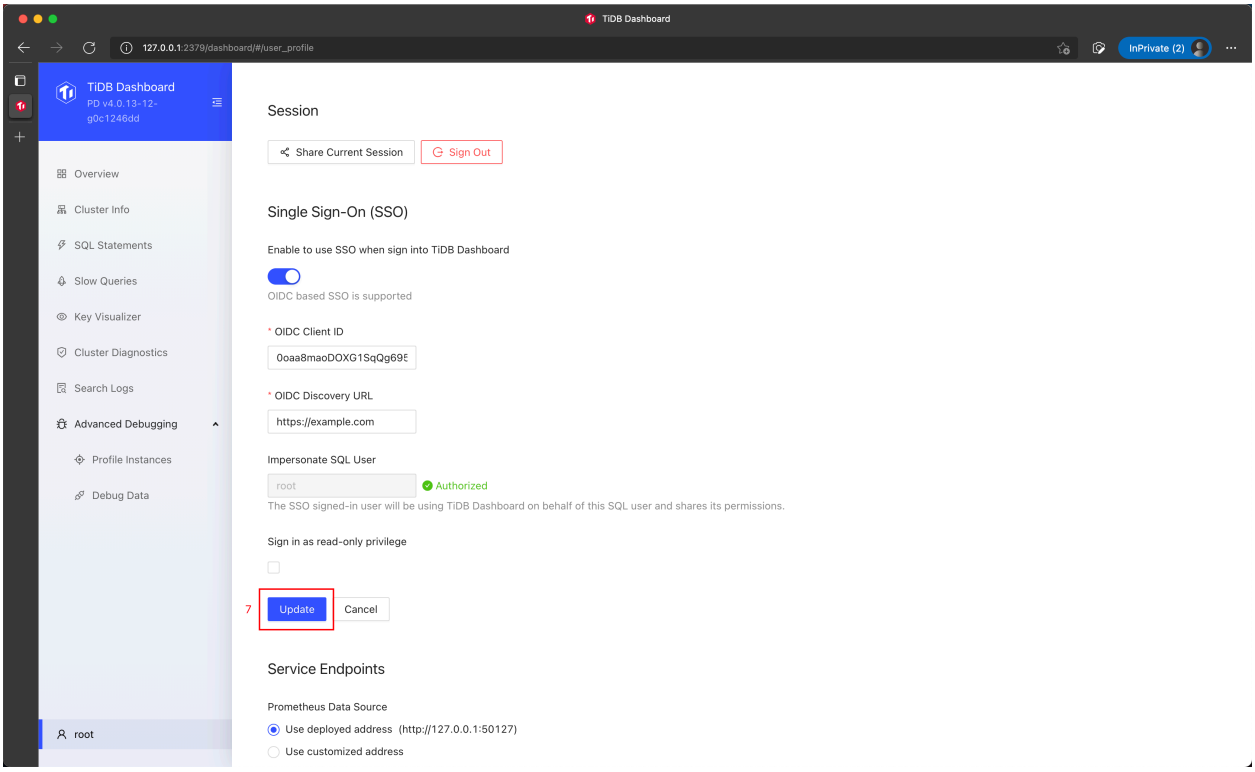

Figure 310: Sample Step

Now SSO sign-in has been enabled for TiDB Dashboard.

> **Note:**
>
> For security reasons, some SSO services require additional configuration for the SSO service, such as the trusted sign-in and sign-out URIs. Refer to the documentation of the SSO service for further information.

Disable SSO

You can disable the SSO, which will completely erase the stored SQL password:

1. Sign into TiDB Dashboard.
2. Click the username in the left sidebar to access the configuration page.
3. In the **Single Sign-On** section, deselect **Enable to use SSO when sign into TiDB Dashboard**.

4. Click **Update** (Update) to save the configuration.

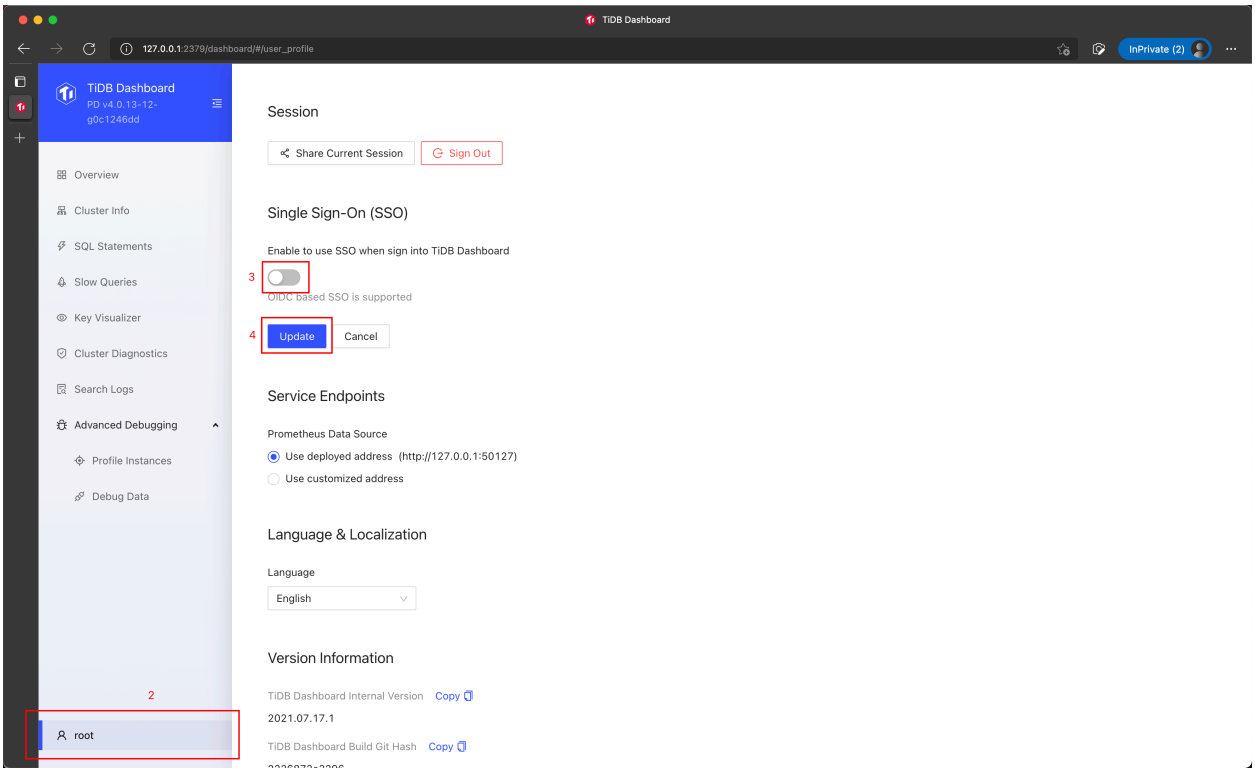

Figure 311: Sample Step

Re-enter the password after a password change

The SSO sign-in will fail once the password of the SQL user is changed. In this case, you can bring back the SSO sign-in by re-entering the SQL password:

1. Sign into TiDB Dashboard.
2. Click the username in the left sidebar to access the configuration page.
3. In the **Single Sign-On** section, Click **Authorize Impersonation** and input the updated SQL password.

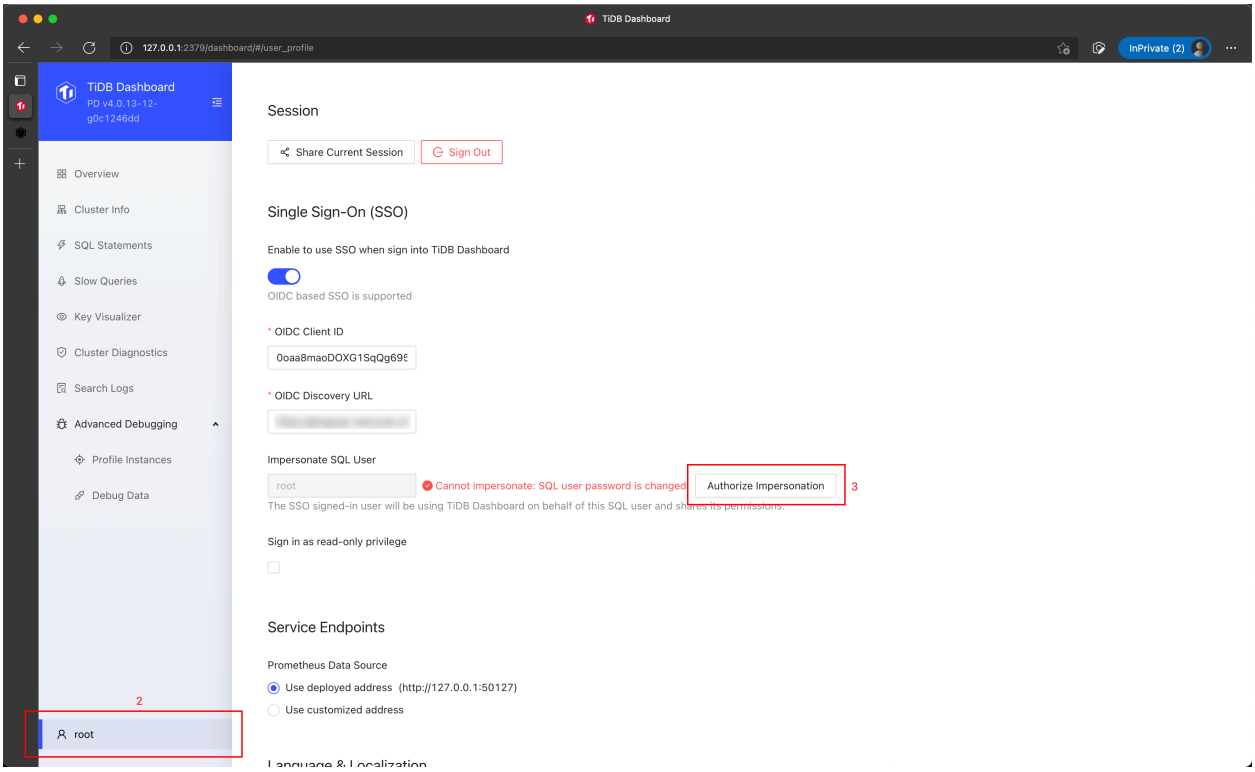

Figure 312: Sample Step

4. Click **Authorize and Save**.

9.5.16.2.2 Sign in via SSO

Once SSO is configured for TiDB Dashboard, you can sign in via SSO by taking following steps:

1. In the sign-in page of TiDB Dashboard, click **Sign in via Company Account**.

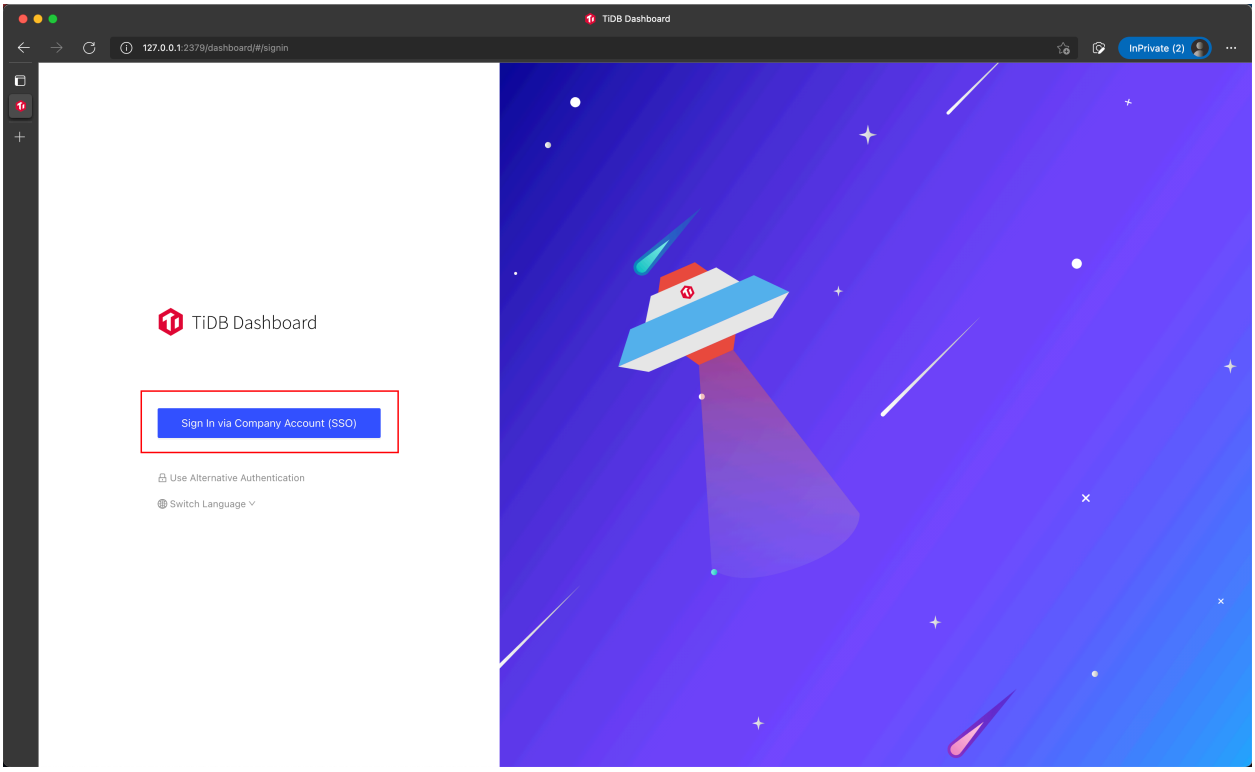

Figure 313: Sample Step

2. Sign into the system with SSO service configured.
3. You are redirected back to TiDB Dashboard to finish the sign-in.

9.5.16.2.3 Example 1: Use Okta for TiDB Dashboard SSO sign-in

Okta is an OIDC SSO identity service, which is compatible with the SSO feature of TiDB Dashboard. The steps below demonstrate how to configure Okta and TiDB Dashboard so that Okta can be used as the TiDB Dashboard SSO provider.

Step 1: Configure Okta

First, create an Okta Application Integration to integrate SSO.

1. Access the Okta administration site.
2. Navigate from the left sidebar **Applications** > **Applications**.
3. Click **Create App Integration**.

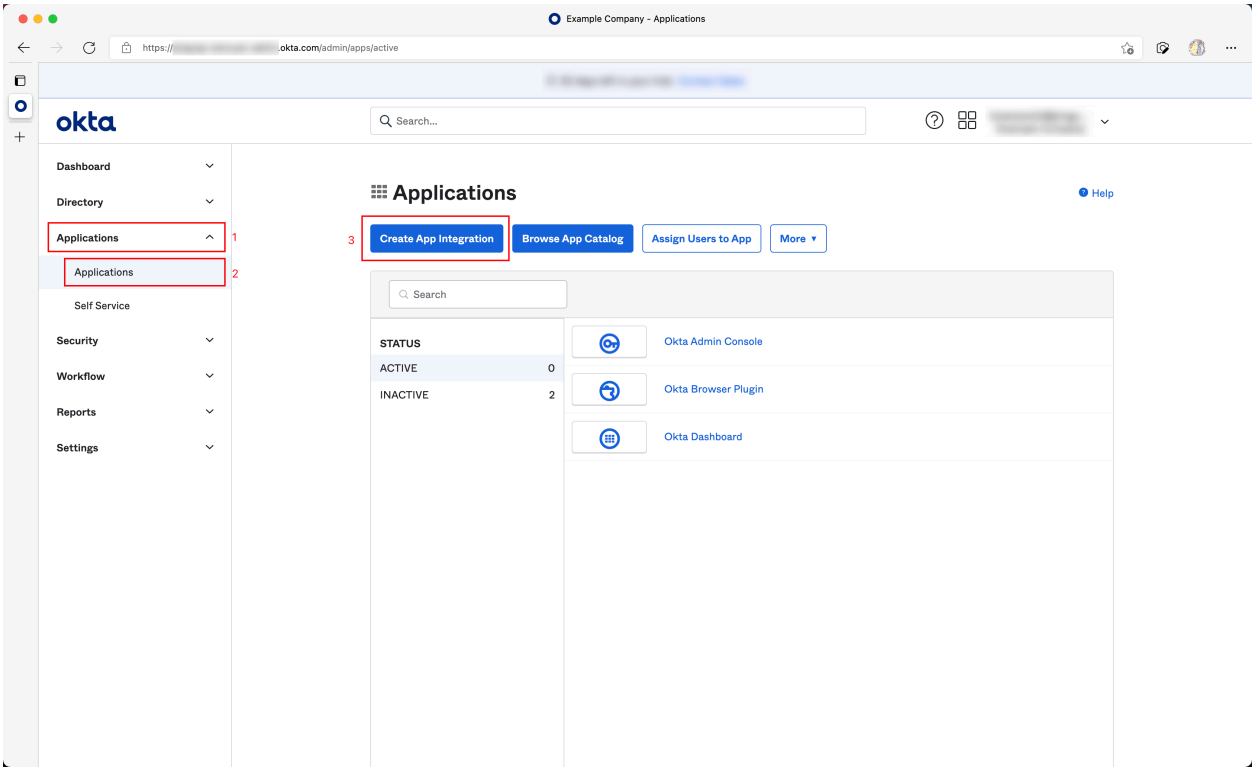

Figure 314: Sample Step

4. In the popped up dialog, choose **OIDC - OpenID Connect** in **Sign-in method**.
5. Choose **Single-Page Application** in **Application Type**.
6. Click the **Next** button.

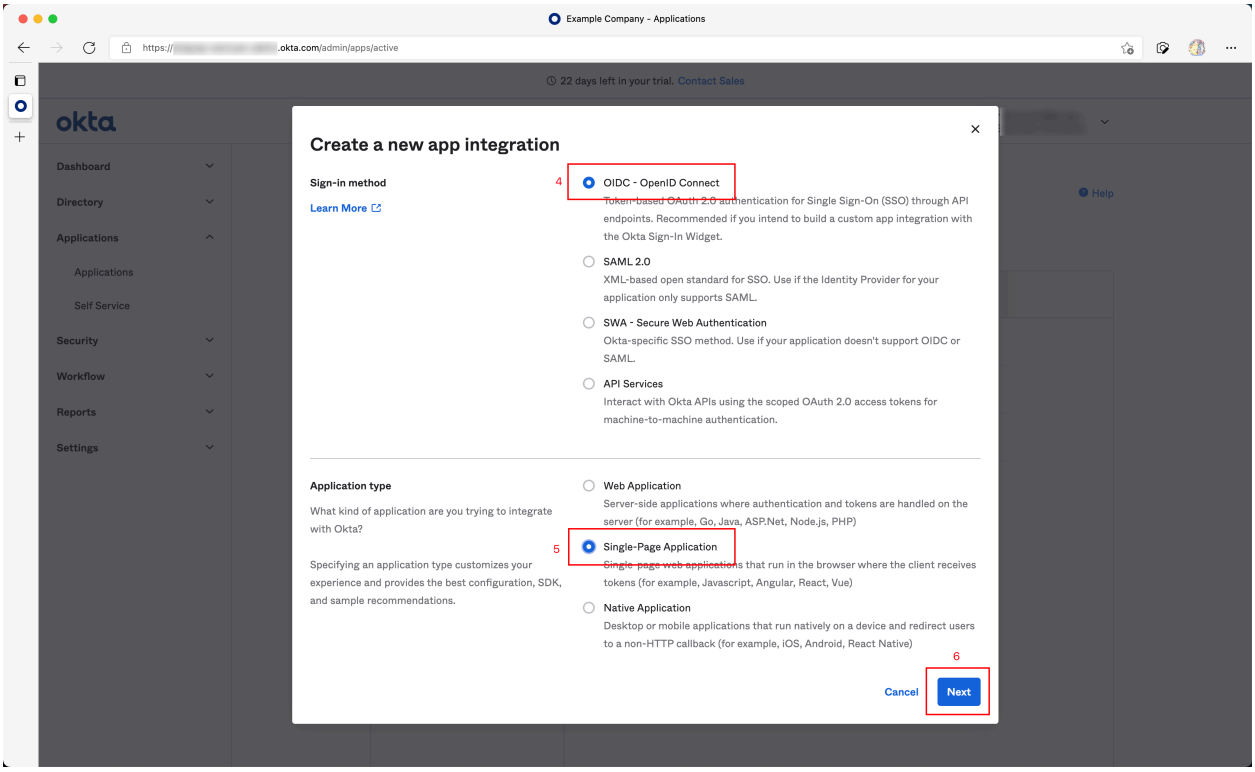

Figure 315: Sample Step

7. Fill **Sign-in redirect URIs** as follows:

```
http://DASHBOARD_IP:PORT/dashboard/?sso_callback=1
```

Substitute `DASHBOARD_IP:PORT` with the actual domain (or IP address) and port that you use to access the TiDB Dashboard in the browser.

8. Fill **Sign-out redirect URIs** as follows:

```
http://DASHBOARD_IP:PORT/dashboard/
```

Similarly, substitute `DASHBOARD_IP:PORT` with the actual domain (or IP address) and port.

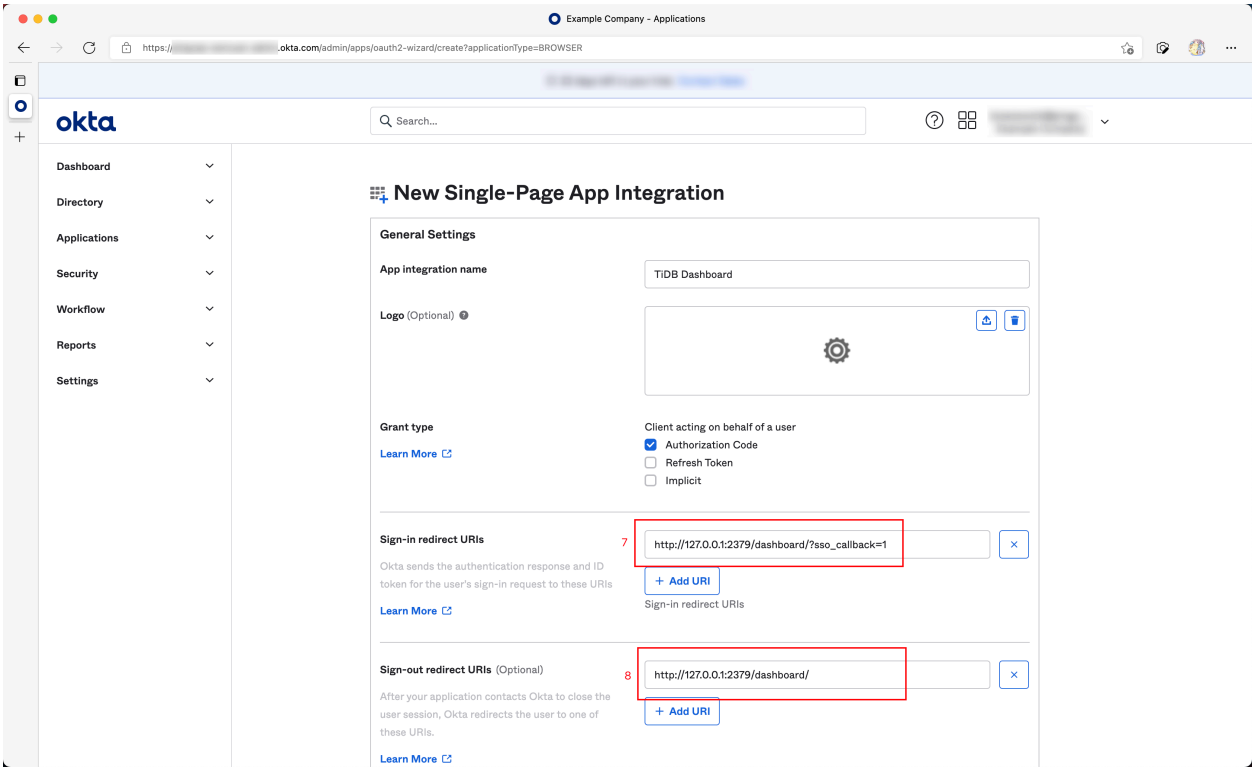

Figure 316: Sample Step

9. Configure what type of users in your organization is allowed for SSO sign-in in the **Assignments** field, and then click **Save** to save the configuration.

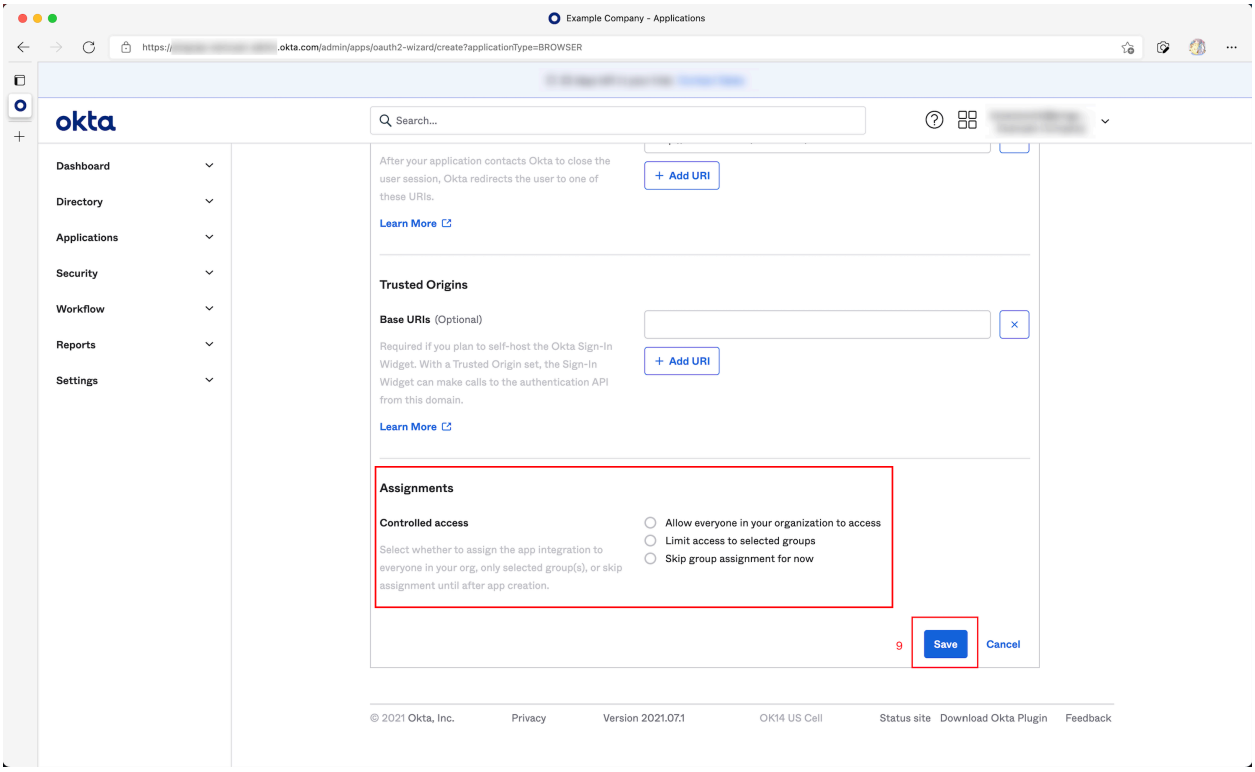

Figure 317: Sample Step

Step 2: Obtain OIDC information and fill in TiDB Dashboard

1. In the Application Integration just created in Okta, click **Sign On**.

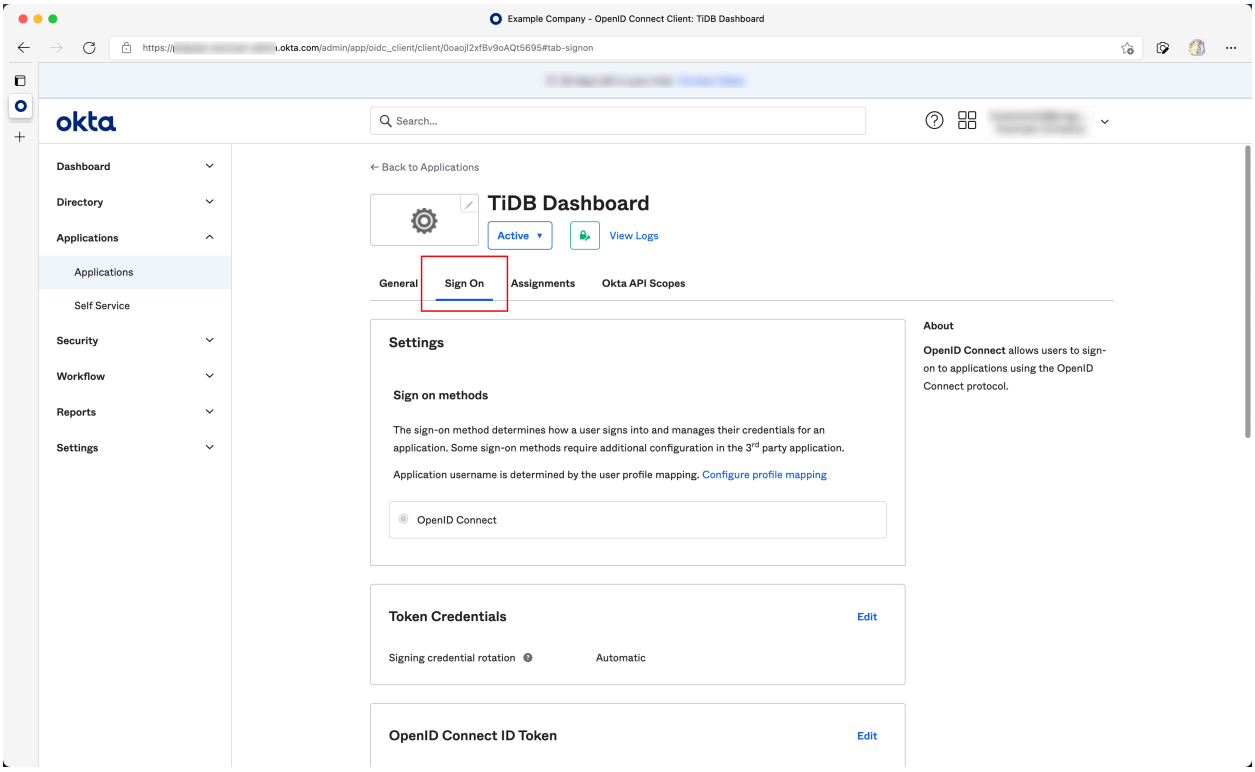

Figure 318: Sample Step 1

2. Copy values of the **Issuer** and **Audience** fields from the **OpenID Connect ID Token** section.

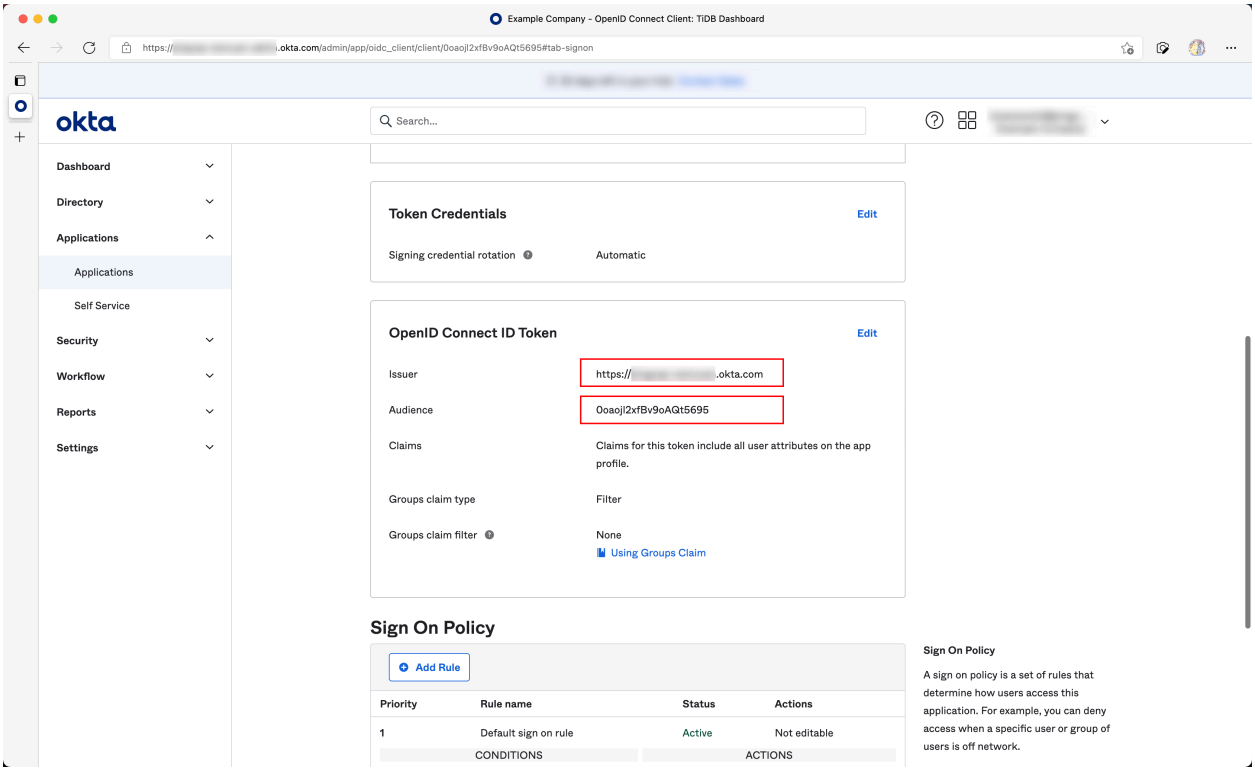

Figure 319: Sample Step 2

3. Open the TiDB Dashboard configuration page, fill **OIDC Client ID** with **Issuer** obtained from the last step and fill **OIDC Discovery URL** with **Audience**. Then finish the authorization and save the configuration. For example:

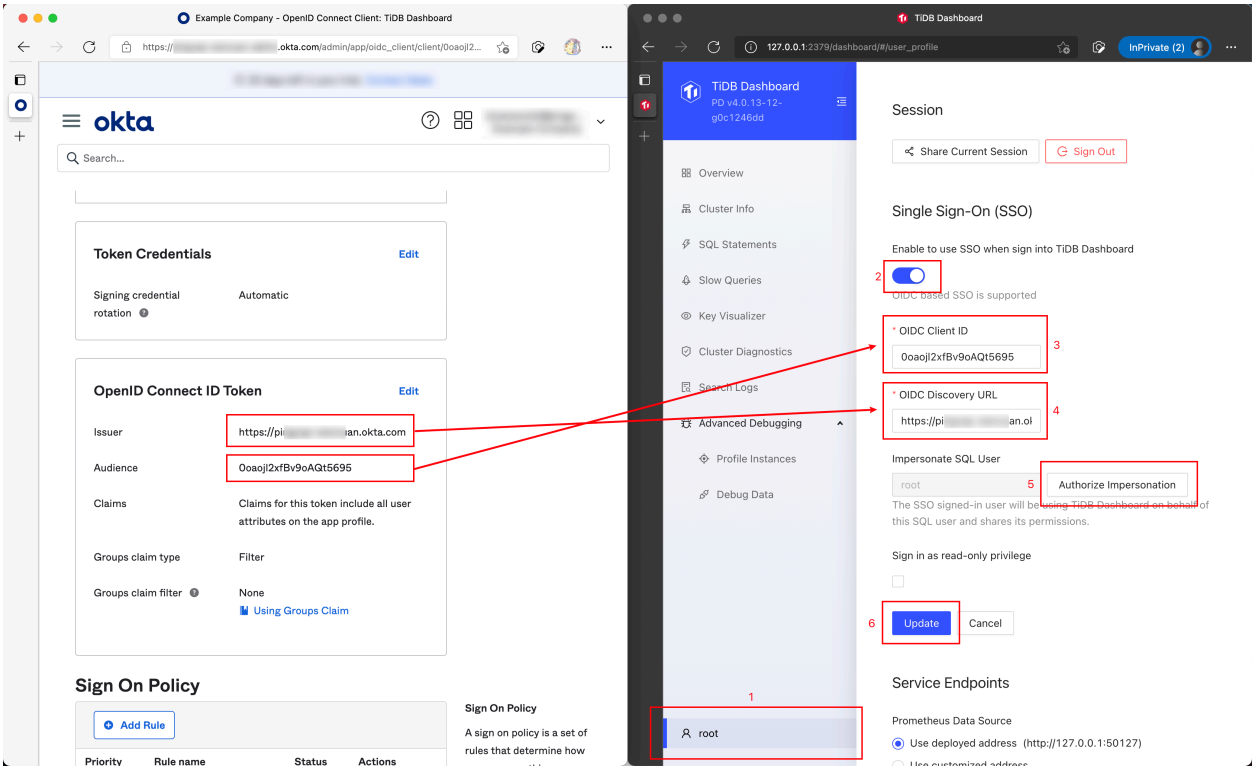

Figure 320: Sample Step 3

Now TiDB Dashboard has been configured to use Okta SSO for sign-in.

9.5.16.2.4 Example 2: Use Auth0 for TiDB Dashboard SSO sign-in

Similar to Okta, Auth0 also provides OIDC SSO identity service. The following steps describe how to configure Auth0 and TiDB Dashboard so that Auth0 can be used as the TiDB Dashboard SSO provider.

Step 1: Configure Auth0

1. Access the Auth0 administration site.
2. Navigate on the left sidebar **Applications** > **Applications**.
3. Click **Create App Integration**.

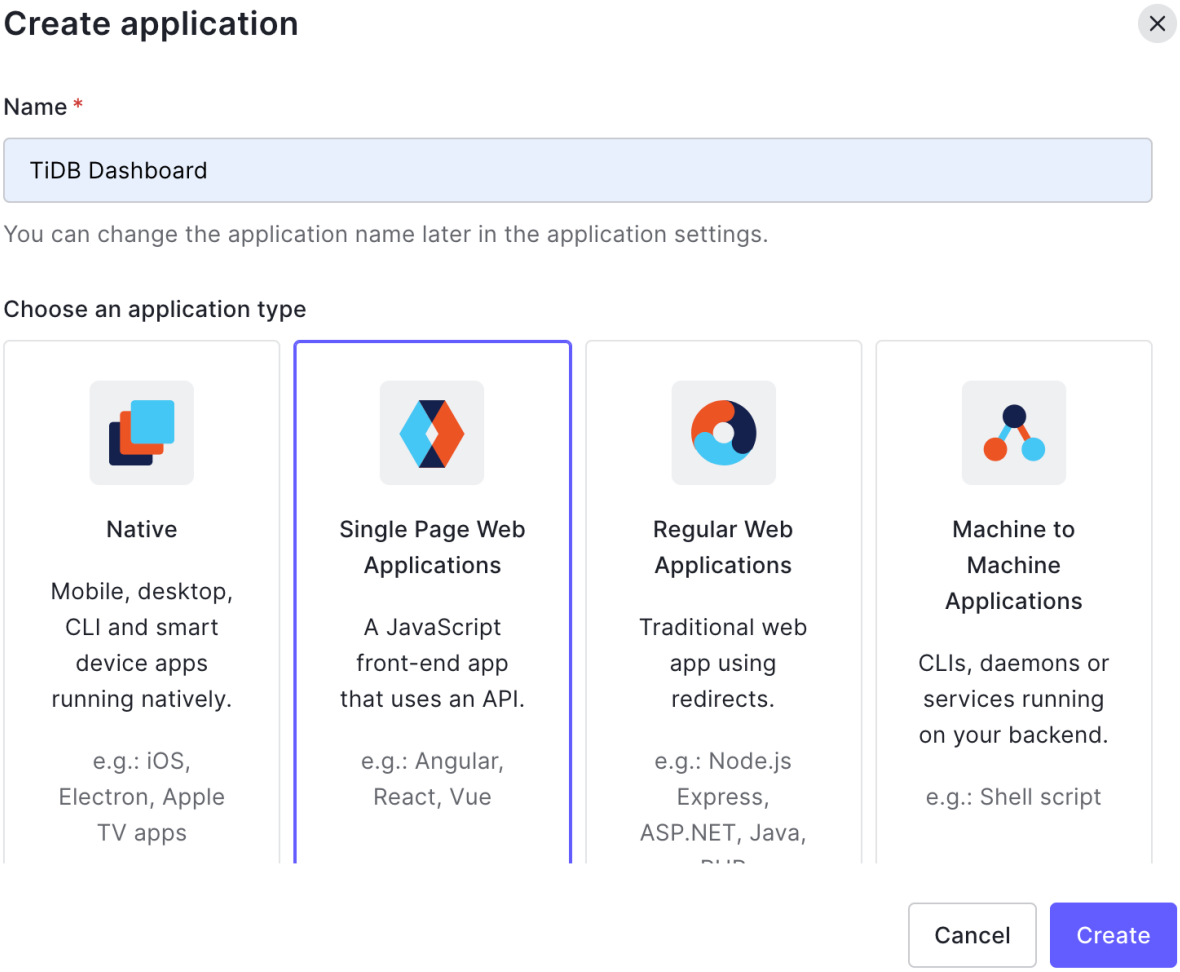

Figure 321: Create Application

In the popped-up dialog, fill **Name**, for example, "TiDB Dashboard". Choose **Single Page Web Applications** in **Choose an application type**. Click **Create**.

4. Click **Settings**.

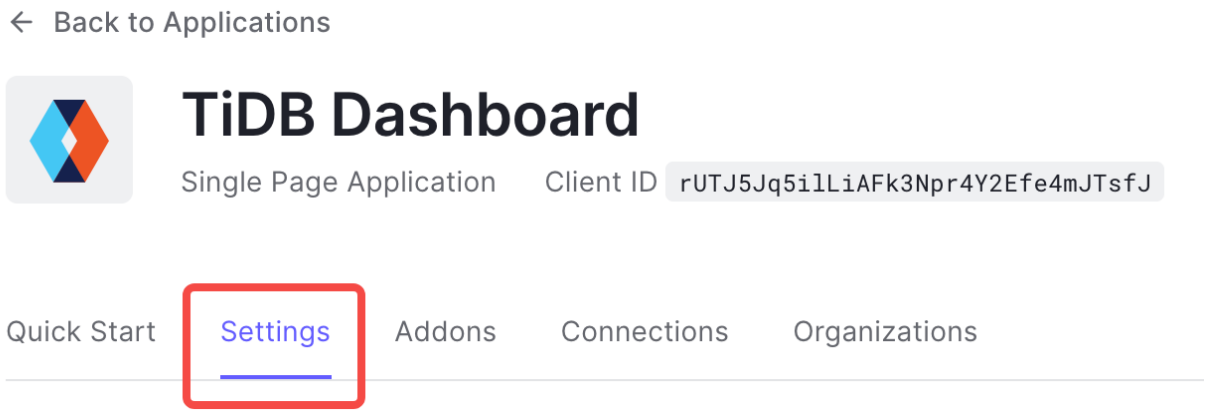

Figure 322: Settings

5. Fill **Allowed Callback URLs** as follows:

```
http://DASHBOARD_IP:PORT/dashboard/?sso_callback=1
```

   Replace `DASHBOARD_IP:PORT` with the actual domain (or IP address) and port that you use to access the TiDB Dashboard in your browser.

6. Fill **Allowed Logout URLs** as follows:

```
http://DASHBOARD_IP:PORT/dashboard/
```

   Similarly, replace `DASHBOARD_IP:PORT` with the actual domain (or IP address) and port.

Allowed Callback URLs

http://localhost:3001/dashboard/?sso_callback=1,
http://127.0.0.1:2379/dashboard/?sso_callback

After the user authenticates we will only call back to any of these URLs. You can specify multiple valid URLs by comma-separating them (typically to handle different environments like QA or testing). Make sure to specify the protocol (`https://`) otherwise the callback may fail in some cases. With the exception of custom URI schemes for native clients, all callbacks should use protocol `https://`. You can use Organization URL parameters in these URLs.

Allowed Logout URLs

http://localhost:3001/dashboard/,
http://127.0.0.1:2379/dashboard/

A set of URLs that are valid to redirect to after logout from Auth0. After a user logs out from Auth0 you can redirect them with the `returnTo` query parameter. The URL that you use in `returnTo` must be listed here. You can specify multiple valid URLs by comma-separating them. You can use the star symbol as a wildcard for subdomains (`*.google.com`). Query strings and hash information are not taken into account when validating these URLs. Read more about this at https://auth0.com/docs/login/logout

Figure 323: Settings

7. Keep the default values for other settings and click **Save Changes**.

Step 2: Obtain OIDC information and fill in TiDB Dashboard

1. Fill **OIDC Client ID** of TiDB Dashboard with **Client ID** in **Basic Information** under the **Settings** tab of Auth0.
2. Fill **OIDC Discovery URL** with the **Domain** field value prefixed with `https://` and suffixed with `/`, for example, `https://example.us.auth0.com/`. Complete

authorization and save the configuration.

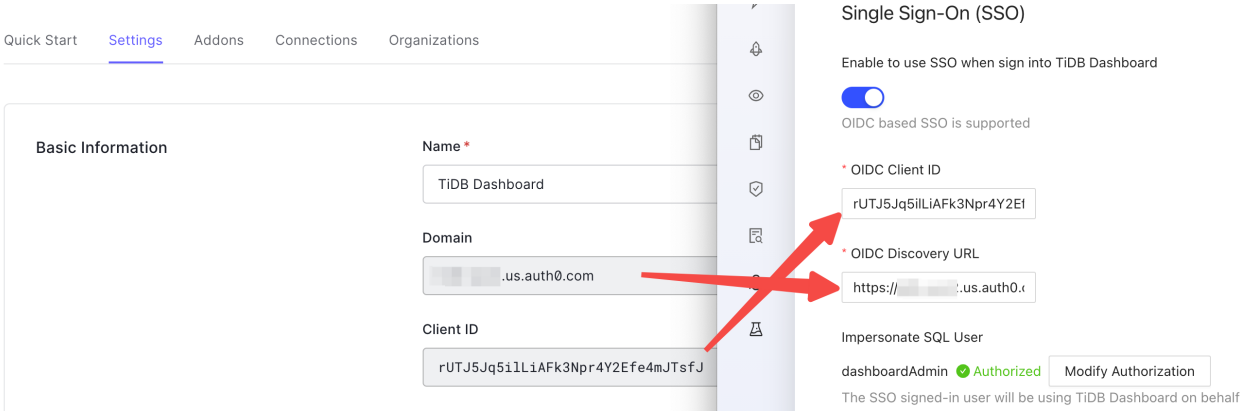

Figure 324: Settings

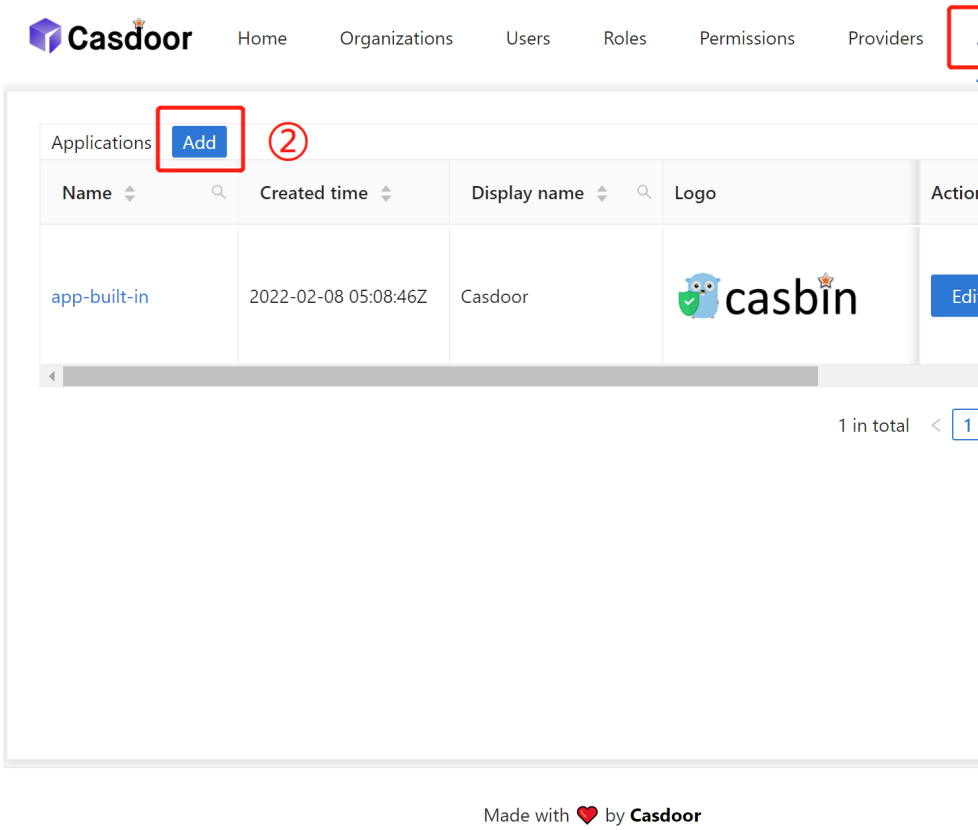

Now TiDB Dashboard has been configured to use Auth0 SSO for sign-in.

9.5.16.2.5 Example 3: Use Casdoor for TiDB Dashboard SSO sign-in

Casdoor is an open-source SSO platform that can be deployed in your own hosts. It is compatible with the SSO feature of TiDB Dashboard. The following steps describe how to configure Casdoor and TiDB Dashboard so that Casdoor can be used as the TiDB Dashboard SSO provider.

Step 1: Configure Casdoor

1. Deploy and access the Casdoor administration site.
2. Navigate from the top sidebar **Applications**.

3. Click **Applications - Add**.
4. Fill **Name** and **Display name**, for example, **TiDB Dashboard**.
5. Add **Redirect URLs** as follows:

```
http://DASHBOARD_IP:PORT/dashboard/?sso_callback=1
```

Replace `DASHBOARD_IP:PORT` with the actual domain (or IP address) and port that you use to access the TiDB Dashboard in your browser.

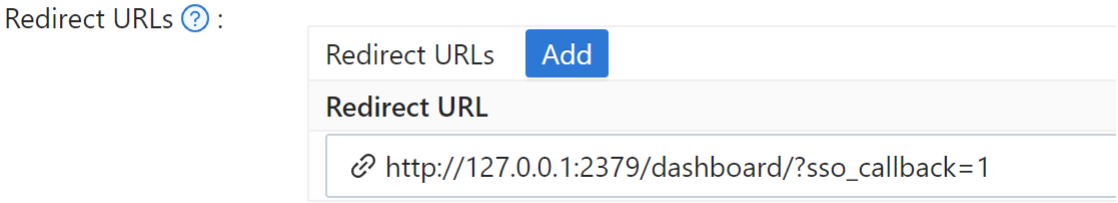

Figure 325: Settings

6. Keep the default values for other settings and click **Save & Exit**.
7. Save the **Client ID** seen on the page.

Step 2: Obtain OIDC information and fill in TiDB Dashboard

1. Fill **OIDC Client ID** of TiDB dashboard with **Client ID** saved in the previous step.
2. Fill **OIDC Discovery URL** with the **Domain** field value prefixed with `https://` ↪ and suffixed with `/`, for example, `https://casdoor.example.com/`. Complete authorization and save the configuration.

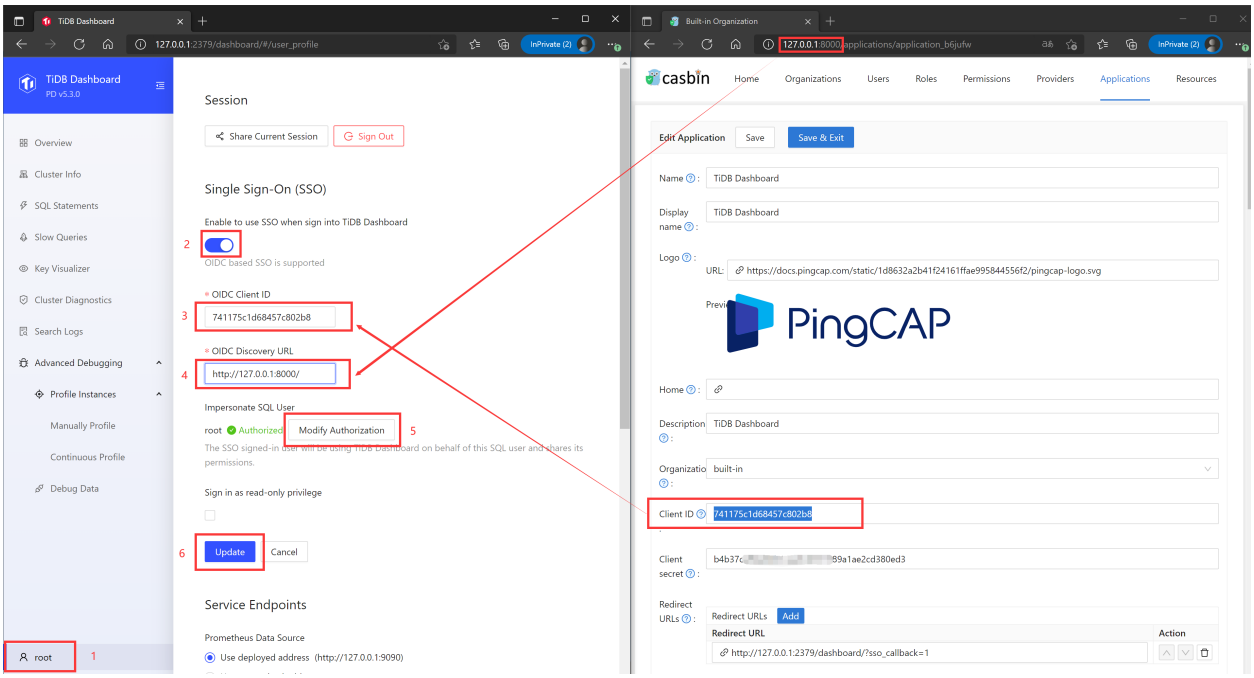

Figure 326: Settings

Now TiDB Dashboard has been configured to use Casdoor SSO for sign-in.

9.5.17 TiDB Dashboard FAQs

This document summarizes the frequently asked questions (FAQs) and answers about TiDB Dashboard. If a problem cannot be located or persists after you perform as instructed, get support from PingCAP or the community.

9.5.17.1 Access-related FAQ

9.5.17.1.1 When the firewall or reverse proxy is configured, I am redirected to an internal address other than TiDB Dashboard

When multiple Placement Driver (PD) instances are deployed in a cluster, only one of the PD instances actually runs the TiDB Dashboard service. If you access other PD

instances instead of this one, your browser redirects you to another address. If the firewall or reverse proxy is not properly configured for accessing TiDB Dashboard, when you visit the Dashboard, you might be redirected to an internal address that is protected by the firewall or reverse proxy.

- See TiDB Dashboard Multi-PD Instance Deployment to learn the working principle of TiDB Dashboard with multiple PD instances.
- See Use TiDB Dashboard through a Reverse Proxy to learn how to correctly configure a reverse proxy.
- See Secure TiDB Dashboard to learn how to correctly configure the firewall.

9.5.17.1.2 When TiDB Dashboard is deployed with dual network interface cards (NICs), TiDB Dashboard cannot be accessed using another NIC

For security reasons, TiDB Dashboard on PD only monitors the IP addresses specified during deployment (that is, it only listens on one NIC), not on `0.0.0.0`. Therefore, when multiple NICs are installed on the host, you cannot access TiDB Dashboard using another NIC.

If you have deployed TiDB using the `tiup cluster` or `tiup playground` command, currently this problem cannot be solved. It is recommended that you use a reverse proxy to safely expose TiDB Dashboard to another NIC. For details, see Use TiDB Dashboard behind a Reverse Proxy.

9.5.17.2 UI-related FAQ

9.5.17.2.1 A `prometheus_not_found` error is shown in QPS and Latency sections on the Overview page

The **QPS** and **Latency** sections on the **Overview** page require a cluster with Prometheus deployed. Otherwise, the error is shown. You can solve this problem by deploying a Prometheus instance in the cluster.

If you still encounter this problem when the Prometheus instance has been deployed, the possible reason is that your deployment tool is out of date (TiUP or TiDB Operator), and your tool does not automatically report metrics addresses, which makes TiDB Dashboard unable to query metrics. You can upgrade your deployment tool to the latest version and try again.

If your deployment tool is TiUP, take the following steps to solve this problem. For other deployment tools, refer to the corresponding documents of those tools.

1. Upgrade TiUP and TiUP Cluster:

```
tiup update --self
tiup update cluster --force
```

2. After the upgrade, when a new cluster is deployed with Prometheus instances, the metrics can be displayed normally.

3. After the upgrade, for an existing cluster, you can restart this cluster to report the metrics addresses. Replace `CLUSTER_NAME` with the actual cluster name:

```
tiup cluster start CLUSTER_NAME
```

Even if the cluster has been started, still execute this command. This command does not affect the normal application in the cluster, but refreshes and reports the metrics addresses, so that the monitoring metrics can be displayed normally in TiDB Dashboard.

9.5.17.2.2 An `invalid connection` error is shown on the Slow Queries page

The possible reason is that you have enabled the Prepared Plan Cache feature of TiDB. As an experimental feature, when enabled, Prepared Plan Cache might not function properly in specific TiDB versions, which could cause this problem in TiDB Dashboard (and other applications). You can disable Prepared Plan Cache by setting the system variable `tidb_enable_prepared_plan_cache = OFF`.

9.5.17.2.3 A `required component NgMonitoring is not started` error is shown

NgMonitoring is an advanced monitoring component built in TiDB clusters of v5.4.0 and later versions to support TiDB Dashboard features such as **Continuous Profiling** and **Top SQL**. NgMonitoring is automatically deployed when you deploy or upgrade a cluster with a newer version of TiUP. For clusters deployed using TiDB Operator, you can deploy NgMonitoring manually by referring to Enable Continuous Profiling.

If the web page shows `required component NgMonitoring is not started`, you can troubleshoot the deployment issue as follows:

Clusters Deployed using TiUP

Step 1. Check versions

1. Check the TiUP cluster version. NgMonitoring is deployed only when TiUP is v1.9.0 or later.

```
tiup cluster --version
```

The command output shows the TiUP version. For example:

```
tiup version 1.9.0 tiup
Go Version: go1.17.2
Git Ref: v1.9.0
```

2. If the TiUP cluster version is earlier than v1.9.0, upgrade TiUP and TiUP cluster to the latest version:

```
tiup update --all
```

Step 2. Add the ng_port configuration item on the control machine by using TiUP. Then reload Prometheus.

1. Open the cluster configuration file in editing mode:

```
tiup cluster edit-config ${cluster-name}
```

2. Under `monitoring_servers`, add the `ng_port:12020` parameter:

```
monitoring_servers:
- host: 172.16.6.6
  ng_port: 12020
```

3. Reload Prometheus:

```
tiup cluster reload ${cluster-name} --role prometheus
```

If the error message is still prompted after performing steps above, get support from PingCAP or the community.

Clusters Deployed using TiDB Operator

Deploy the NgMonitoring component by following instructions in the Enable Continuous Profiling section in TiDB Operator documentation.

Clusters Started using TiUP Playground

When starting the cluster, TiUP Playground (>= v1.8.0) automatically starts the NgMonitoring component. To update TiUP Playground to the latest version, run the following command:

```
tiup update --self
tiup update playground
```

9.5.17.2.4 An `unknown field` error is shown on the Slow Queries page

If the `unknown field` error appears on the **Slow Queries** page after the cluster upgrade, the error is related to a compatibility issue caused by the difference between TiDB Dashboard server fields (which might be updated) and user preferences fields (which are in the browser cache). This issue has been fixed. If your cluster is earlier than v5.0.3 or v4.0.14, perform the following steps to clear your browser cache:

1. Open TiDB Dashboard page.

2. Open Developer Tools. Different browsers have different ways of opening Developer Tools. After clicking the **Menu Bar**:

    - Firefox: **Menu** > **Web Developer** > **Toggle Tools**, or **Tools** > **Web Developer** > **Toggle Tools**.
    - Chrome: **More tools** > **Developer tools**.
    - Safari: **Develop** > **Show Web Inspector**. If you can't see the **Develop** menu, go to **Safari** > **Preferences** > **Advanced**, and check the **Show Develop** menu in menu bar checkbox.

    In the following example, Chrome is used.

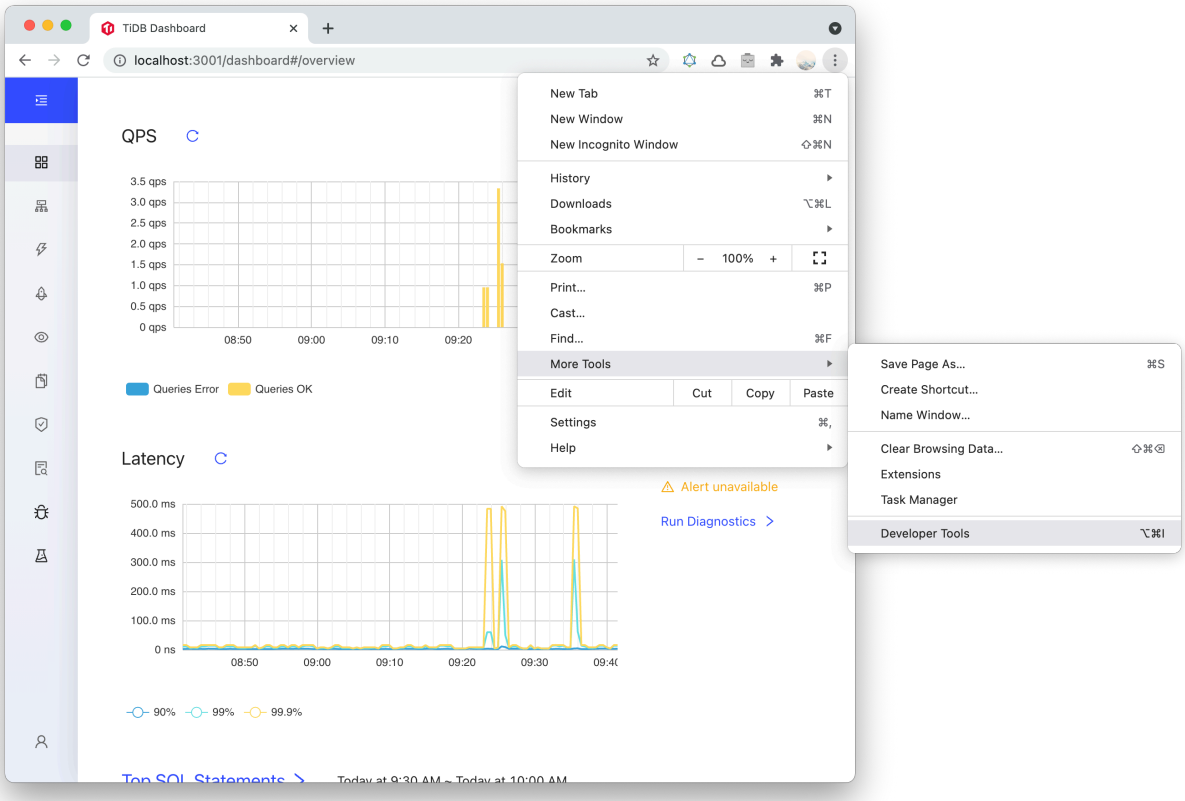

Figure 327: Opening DevTools from Chrome's main menu

3. Select the **Application** panel, expand the **Local Storage** menu and select the **TiDB Dashboard page domain**. Click the **Clear All** button.

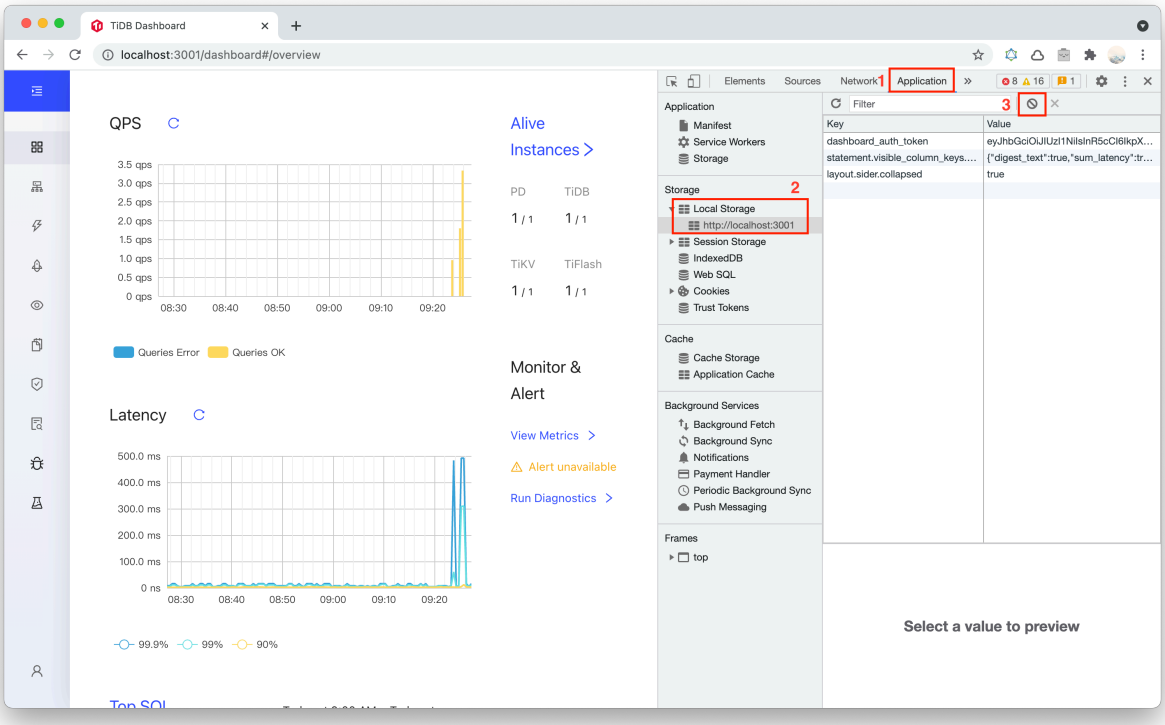

Figure 328: Clear the Local Storage

Warning:

- Since TiDB v6.0.0, PingCAP no longer maintains MetricsTool. Since v6.1.0, PingCAP no longer maintains the MetricsTool document.
- To export monitoring metrics data, use the PingCAP Clinic diagnostic service to get the information required for diagnosing a TiDB cluster, including the monitoring metrics, logs, cluster topology, configuration, and parameters.

9.6 Export Grafana Snapshots

Note:

Currently, MetricsTool can only be used with Grafana v6.x.x.

Metrics data is important in troubleshooting. When you request remote assistance, sometimes the support staff need to view the Grafana dashboards to diagnose problems. MetricsTool can help export snapshots of Grafana dashboards as local files and visualize these snapshots. You can share these snapshots with outsiders and allow them to accurately read out the graphs, without giving out access to other sensitive information on the Grafana server.

9.6.1 Usage

MetricsTool can be accessed from https://metricstool.pingcap.net/. It consists of three sets of tools:

- **Export**: A user script running on the browser's Developer Tool, allowing you to download a snapshot of all visible panels in the current dashboard on any Grafana v6.x.x server.

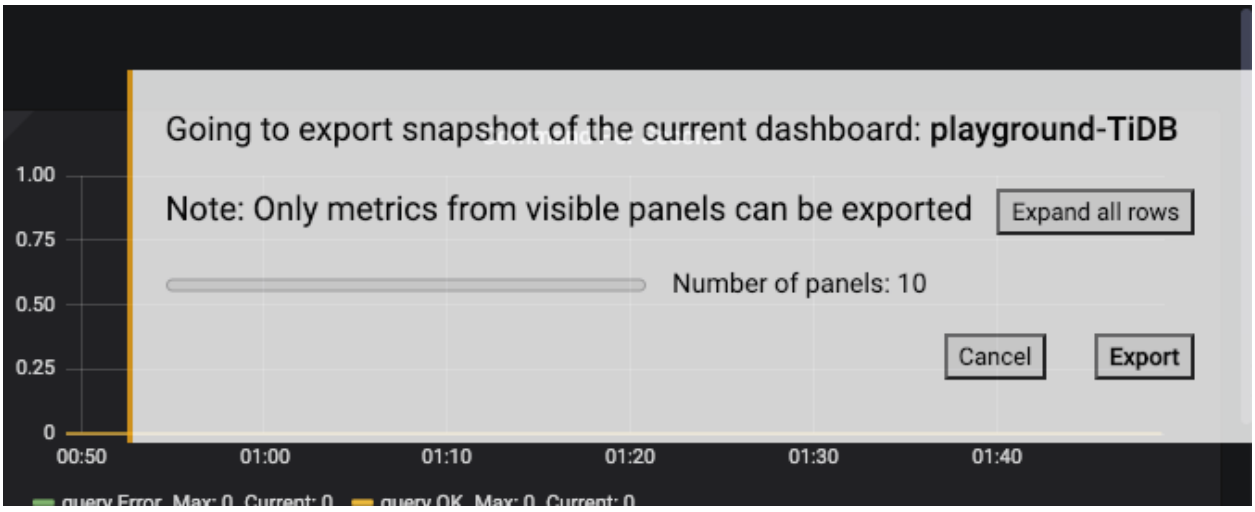

Figure 329: Screenshot of MetricsTool Exporter after running the user script

- **Visualize**: A web page visualizing the exported snapshot files. The visualized snapshots can be operated in the same way as live Grafana dashboards.

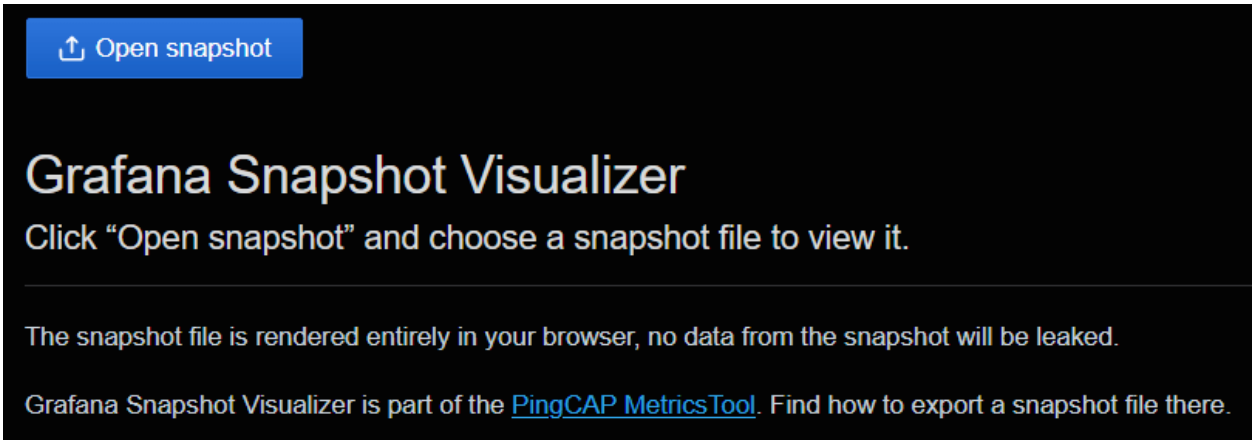

Figure 330: Screenshot of MetricsTool Visualizer

- **Import**: Instructions to import the exported snapshot back into an actual Grafana instance.

9.6.2 FAQs

9.6.2.1 What is the advantage of this tool compared with screenshot or PDF printing?

The snapshot files exported by MetricsTool contain the actual values when they are taken. And the Visualizer allows you to interact with the rendered graphs as if it is a live Grafana dashboard, supporting operations like toggling series, zooming into a smaller time range, and checking the precise value at a given time. This makes MetricsTool much more powerful than images or PDFs.

9.6.2.2 What are included in the snapshot file?

The snapshot file contains the values of all graphs and panels in the selected time range. It does not save the original metrics from the data sources (and thus you cannot edit the query expression in the Visualizer).

9.6.2.3 Will the Visualizer save the uploaded snapshot files in PingCAP's servers?

No, the Visualizer parses the snapshot files entirely inside your browser. Nothing will be sent to PingCAP. You are free to view snapshot files received from sensitive sources, and no need to worry about these leaking to third parties through the Visualizer.

9.6.2.4 Will there be problems to execute the script before all metrics are loaded?

No, the script UI will notify you to wait for all metrics to be loaded. However, you can manually skip waiting and export the snapshot in case of some metrics loading for too long.

9.6.2.5 Can we share a link to a visualized snapshot?

No, but you can share the snapshot file, with instruction on how to use the Visualizer to view it. If you truly need a world-readable URL, you may also try the public `snapshot.raintank.io` service built into Grafana, but make sure all privacy concerns are cleared before doing so.

9.7 TiDB Cluster Alert Rules

This document describes the alert rules for different components in a TiDB cluster, including the rule descriptions and solutions of the alert items in TiDB, TiKV, PD, TiFlash, TiCDC, Node_exporter and Blackbox_exporter.

According to the severity level, alert rules are divided into three categories (from high to low): emergency-level, critical-level, and warning-level. This division of severity levels applies to all alert items of each component below.

Severity level	Description
Emergency-level	The highest severity level at which the service is unavailable. Emergency-level alerts are often caused by a service or node failure. **Manual intervention is required immediately**.

Severity level	Description
Critical-level	Decreased service availability. For the critical-level alerts, a close watch on the abnormal metrics is required.
Warning-level	Warning-level alerts are a reminder for an issue or error.

9.7.1 TiDB alert rules

This section gives the alert rules for the TiDB component.

9.7.1.1 Emergency-level alerts

9.7.1.1.1 `TiDB_schema_error`

- Alert rule:

```
increase(tidb_session_schema_lease_error_total{type="outdated"}[15m])>
↪ 0
```

- Description:

The latest schema information is not reloaded in TiDB within one lease. When TiDB fails to continue providing services, an alert is triggered.

- Solution:

  It is often caused by an unavailable Region or a TiKV timeout. You need to locate the issue by checking the TiKV monitoring items.

9.7.1.1.2 `TiDB_tikvclient_region_err_total`

- Alert rule:

  `increase(tidb_tikvclient_region_err_total[10m])> 6000`

- Description:

  TiDB server accesses the Region leader of TiKV according to its own cache information. If the Region leader has changed or the current TiKV Region information is inconsistent with that in the TiDB cache, a Region cache error occurs. When the error is reported over 6000 times in 10 minutes, an alert is triggered.

- Solution:

  View **TiKV-Details > Cluster** dashboard to see if the leader is balanced.

9.7.1.1.3 `TiDB_domain_load_schema_total`

- Alert rule:

  `increase(tidb_domain_load_schema_total{type="failed"}[10m])> 10`

- Description:

  The total number of failures to reload the latest schema information in TiDB. If the reloading failure occurs over 10 times in 10 minutes, an alert is triggered.

- Solution:

  Same as `TiDB_schema_error`.

9.7.1.2 Critical-level alerts

9.7.1.2.1 `TiDB_server_panic_total`

- Alert rule:

  `increase(tidb_server_panic_total[10m])> 0`

- Description:

  The number of panicked TiDB threads. When a panic occurs, an alert is triggered. The thread is often recovered, otherwise, TiDB will frequently restart.

- Solution:

  Collect the panic logs to locate the issue.

9.7.1.3 Warning-level alerts

9.7.1.3.1 TiDB_memory_abnormal

- Alert rule:

  `go_memstats_heap_inuse_bytes{job="tidb"} > 1e+10`

- Description:

  The monitoring on the TiDB memory usage. If the usage exceeds 10 G, an alert is triggered.

- Solution:

  Use the HTTP API to troubleshoot the goroutine leak issue.

9.7.1.3.2 TiDB_query_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tidb_server_handle_query_duration_
  ↪ seconds_bucket[1m]))BY (le, instance))> 1
  ```

- Description:

  The latency of handling a request in TiDB. The response time for 99% of requests should be within 1 second; otherwise, an alert is triggered.

- Solution:

  View TiDB logs and search for the `SLOW_QUERY` and `TIME_COP_PROCESS` keywords to locate the slow SQL queries.

9.7.1.3.3 TiDB_server_event_error

- Alert rule:

  ```
  increase(tidb_server_event_total{type=~"server_start|server_hang"}[15m
  ↪ ])> 0
  ```

- Description:

  The number of events that happen in the TiDB service. An alert is triggered when the following events happen:

  1. start: The TiDB service starts.
  2. hang: When a critical-level event happens, TiDB enters the `hang` mode and waits to be killed manually.

- Solution:

  Restart TiDB to recover the service.

9.7.1.3.4 `TiDB_tikvclient_backoff_seconds_count`

- Alert rule:

  `increase(tidb_tikvclient_backoff_seconds_count[10m])> 10`

- Description:

  The number of retries when TiDB fails to access TiKV. When the retry times is over 10 in 10 minutes, an alert is triggered.

- Solution:

  View the monitoring status of TiKV.

9.7.1.3.5 `TiDB_monitor_time_jump_back_error`

- Alert rule:

  `increase(tidb_monitor_time_jump_back_total[10m])> 0`

- Description:

  When the time of the machine that holds TiDB rewinds, an alert is triggered.

- Solution:

  Troubleshoot the NTP configurations.

9.7.1.3.6 `TiDB_ddl_waiting_jobs`

- Alert rule:

  `sum(tidb_ddl_waiting_jobs)> 5`

- Description:

  When the number of DDL tasks pending for execution in TiDB exceeds 5, an alert is triggered.

- Solution:

  Check whether there is any time-consuming `add index` operation that is being executed by running `admin show ddl`.

9.7.2 PD alert rules

This section gives the alert rules for the PD component.

9.7.2.1 Emergency-level alerts

9.7.2.1.1 PD_cluster_down_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_down_count"})by (instance)> 0)and (
↪ sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  PD has not received a TiKV/TiFlash heartbeat for a long time (the default configuration is 30 minutes).

- Solution:

  - Check whether the TiKV/TiFlash process is normal, the network is isolated or the load is too high, and recover the service as much as possible.
  - If the TiKV/TiFlash instance cannot be recovered, you can make it offline.

9.7.2.2 Critical-level alerts

9.7.2.2.1 PD_etcd_write_disk_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_disk_wal_fsync_duration_seconds_
↪ bucket[1m]))by (instance, job, le))> 1
```

- Description:

  If the latency of the fsync operation exceeds 1 second, it indicates that etcd writes data to disk at a lower speed than normal. It might lead to PD leader timeout or failure to store TSO on disk in time, which will shut down the service of the entire cluster.

- Solution:

  - Find the cause of slow writes. It might be other services that overload the system. You can check whether PD itself occupies a large amount of CPU or I/O resources.

- Try to restart PD or manually transfer leader to another PD to recover the service.
- If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.7.2.2.2 PD_miss_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="miss-peer-region-count"})by (instance)>
↪ 100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  The number of Region replicas is smaller than the value of `max-replicas`.

- Solution:

  - Find the cause of the issue by checking whether there is any TiKV machine that is down or being made offline.
  - Watch the Region health panel and see whether `miss-peer-region-count` is continuously decreasing.

9.7.2.3 Warning-level alerts

9.7.2.3.1 PD_cluster_lost_connect_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_disconnected_count"})by (instance)>
↪ 0)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  PD does not receive a TiKV/TiFlash heartbeat within 20 seconds. Normally a TiKV/TiFlash heartbeat comes in every 10 seconds.

- Solution:

  - Check whether the TiKV/TiFlash instance is being restarted.
  - Check whether the TiKV/TiFlash process is normal, the network is isolated, and the load is too high, and recover the service as much as possible.
  - If you confirm that the TiKV/TiFlash instance cannot be recovered, you can make it offline.
  - If you confirm that the TiKV/TiFlash instance can be recovered, but not in the short term, you can consider increasing the value of `max-down-time`. It will prevent the TiKV/TiFlash instance from being considered as irrecoverable and the data from being removed from the TiKV/TiFlash.

9.7.2.3.2 PD_cluster_unhealthy_tikv_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_unhealth_count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  Indicates that there are unhealthy stores. If the situation persists for some time (configured by max-store-down-time, defaults to 30m), the store is likely to change to Offline state, which triggers the PD_cluster_down_store_nums alert.

- Solution:

  Check the state of the TiKV stores.

9.7.2.3.3 PD_cluster_low_space

- Alert rule:

```
(sum(pd_cluster_status{type="store_low_space_count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  Indicates that there is no sufficient space on the TiKV/TiFlash node.

- Solution:

  - Check whether the space in the cluster is generally insufficient. If so, increase its capacity.
  - Check whether there is any issue with Region balance scheduling. If so, it will lead to uneven data distribution.
  - Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, and core dump.
  - Lower the Region weight of the node to reduce the data volume.
  - When it is not possible to release the space, consider proactively making the node offline. This prevents insufficient disk space that leads to downtime.

9.7.2.3.4 PD_etcd_network_peer_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_network_peer_round_trip_time_
↪ seconds_bucket[1m]))by (To, instance, job, le))> 1
```

- Description:

  The network latency between PD nodes is high. It might lead to the leader timeout and TSO disk storage timeout, which impacts the service of the cluster.

- Solution:

    - Check the network and system load status.
    - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.7.2.3.5 PD_tidb_handle_requests_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(pd_client_request_handle_requests_
↪ duration_seconds_bucket{type="tso"}[1m]))by (instance, job, le))>
↪ 0.1
```

- Description:

    It takes a longer time for PD to handle the TSO request. It is often caused by a high load.

- Solution:

    - Check the load status of the server.
    - Use pprof to analyze the CPU profile of PD.
    - Manually switch the PD leader.
    - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.7.2.3.6 PD_down_peer_region_nums

- Alert rule:

```
(sum(pd_regions_status{type="down-peer-region-count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

    The number of Regions with an unresponsive peer reported by the Raft leader.

- Solution:

    - Check whether there is any TiKV that is down, or that was just restarted, or that is busy.
    - Watch the Region health panel and see whether `down_peer_region_count` is continuously decreasing.
    - Check the network between TiKV servers.

9.7.2.3.7 PD_pending_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="pending-peer-region-count"})by (instance)>
↪  100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  There are too many Regions that have lagged Raft logs. It is normal that scheduling leads to a small number of pending peers, but if the number remains high, there might be an issue.

- Solution:

  - Watch the Region health panel and see whether `pending_peer_region_count` is continuously decreasing.
  - Check the network between TiKV servers, especially whether there is enough bandwidth.

9.7.2.3.8 PD_leader_change

- Alert rule:

```
count(changes(pd_tso_events{type="save"}[10m])> 0)>= 2
```

- Description:

  The PD leader is recently switched.

- Solution:

  - Exclude the human factors, such as restarting PD, manually transferring leader, and adjusting leader priority.
  - Check the network and system load status.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

9.7.2.3.9 TiKV_space_used_more_than_80%

- Alert rule:

```
sum(pd_cluster_status{type="storage_size"})/ sum(pd_cluster_status{type
↪ ="storage_capacity"})* 100 > 80
```

- Description:

  Over 80% of the cluster space is occupied.

- Solution:

- Check whether it is needed to increase capacity.
- Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, and core dump.

9.7.2.3.10 PD_system_time_slow

- Alert rule:

```
changes(pd_tso_events{type="system_time_slow"}[10m])>= 1
```

- Description:

  The system time rewind might happen.

- Solution:

  Check whether the system time is configured correctly.

9.7.2.3.11 PD_no_store_for_making_replica

- Alert rule:

```
increase(pd_checker_event_count{type="replica_checker", name="no_target
↪ _store"}[1m])> 0
```

- Description:

  There is no appropriate store for additional replicas.

- Solution:

  - Check whether there is enough space in the store.
  - Check whether there is any store for additional replicas according to the label configuration if it is configured.

9.7.2.3.12 PD_cluster_slow_tikv_nums

- Alert rule:

```
sum(pd_cluster_status{type="store_slow_count"})by (instance)> 0)and (
↪ sum(etcd_server_is_leader)by (instance)> 0
```

- Description:

  There is a slow TiKV node. `raftstore.inspect-interval` controls the detection of TiKV slow nodes. For more information, see `raftstore.inspect-interval`.

- Solution:

- Watch the **TiKV-Details > PD** dashboard and view the Store Slow Score metric. Identify the node with a metric value exceeding 80, which is detected as a slow node.
- Watch the **TiKV-Details > Raft IO** dashboard and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk.
- Set the `raftstore.inspect-interval` configuration item to a larger value to increase the timeout limit of latency.
- For further analysis of performance issues of the alerted TiKV node and tuning methods, see Performance analysis and tuning.

9.7.3 TiKV alert rules

This section gives the alert rules for the TiKV component.

9.7.3.1 Emergency-level alerts

9.7.3.1.1 `TiKV_memory_used_too_fast`

- Alert rule:

```
process_resident_memory_bytes{job=~"tikv",instance=~".*"} - (process
↪ _resident_memory_bytes{job=~"tikv",instance=~".*"} offset 5m)>
↪ 5*1024*1024*1024
```

- Description:

  Currently, there are no TiKV monitoring items about memory. You can monitor the memory usage of the machines in the cluster by Node_exporter. The above rule indicates that when the memory usage exceeds 5 GB within 5 minutes (the memory is occupied too fast in TiKV), an alert is triggered.

- Solution:

  Adjust the `block-cache-size` value of both `rocksdb.defaultcf` and `rocksdb.
  ↪ writecf`.

9.7.3.1.2 `TiKV_GC_can_not_work`

- Alert rule:

```
sum(increase(tikv_gcworker_gc_tasks_vec{task="gc"}[1d]))< 1 and (sum(
↪ increase(tikv_gc_compaction_filter_perform[1d]))< 1 and sum(increase
↪ (tikv_engine_event_total{db="kv", cf="write", type="compaction"}[1d
↪ ]))>= 1)
```

- Description:

  GC is not performed successfully on a TiKV instance within 24 hours, which indicates that GC is not working properly. If GC does not run in a short term, it will not cause much trouble; but if GC keeps down, more and more versions are retained, which slows down the query.

- Solution:

  1. Perform `SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME = "tikv_gc_leader_desc"` to locate the `tidb-server` corresponding to the GC leader;
  2. View the log of the `tidb-server`, and grep gc_worker tidb.log;
  3. If you find that the GC worker has been resolving locks (the last log is "start resolve locks") or deleting ranges (the last log is "start delete {number} ranges") during this time, it means the GC process is running normally. Otherwise, get support from PingCAP or the community.

9.7.3.2 Critical-level alerts

9.7.3.2.1 `TiKV_server_report_failure_msg_total`

- Alert rule:

```
sum(rate(tikv_server_report_failure_msg_total{type="unreachable"}[10m]) )BY (store_id)> 10
```

- Description:

  Indicates that the remote TiKV cannot be connected.

- Solution:

  1. Check whether the network is clear.
  2. Check whether the remote TiKV is down.
  3. If the remote TiKV is not down, check whether the pressure is too high. Refer to the solution in `TiKV_channel_full_total`.

9.7.3.2.2 `TiKV_channel_full_total`

- Alert rule:

```
sum(rate(tikv_channel_full_total[10m]))BY (type, instance)> 0
```

- Description:

  This issue is often caused by the stuck Raftstore thread and high pressure on TiKV.

- Solution:

1. Watch the **TiKV-Details > Raft Propose** dashboard, and see whether the alerted TiKV node has a much higher Raft propose than other TiKV nodes. If so, it means that there are one or more hot spots on this TiKV. You need to check whether the hot spot scheduling can work properly.
2. Watch the **TiKV-Details > Raft IO** dashboard, and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk.
3. Watch the **TiKV-Details > Raft process** dashboard, and see whether the `tick duration` is high. If so, you need to set `raftstore.raft-base-tick-interval` to `"2s"`.

9.7.3.2.3 TiKV_write_stall

- Alert rule:

  ```
  delta(tikv_engine_write_stall[10m])> 0
  ```

- Description:

  The write pressure on RocksDB is too high, and a stall occurs.

- Solution:

  1. View the disk monitor, and troubleshoot the disk issues;
  2. Check whether there is any write hot spot on the TiKV;
  3. Set `max-sub-compactions` to a larger value under the `[rocksdb]` and `[raftdb]` configurations.

9.7.3.2.4 TiKV_raft_log_lag

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_raftstore_log_lag_bucket[1m]))by
  ↪  (le, instance))> 5000
  ```

- Description:

  If this value is relatively large, it means Follower has lagged far behind Leader, and Raft cannot be replicated normally. It is possibly because the TiKV machine where Follower is located is stuck or down.

9.7.3.2.5 TiKV_async_request_snapshot_duration_seconds

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_
  ↪ duration_seconds_bucket{type="snapshot"}[1m]))by (le, instance, type
  ↪ ))> 1
  ```

- Description:

  If this value is relatively large, it means the load pressure on Raftstore is too high, and it might be stuck already.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.7.3.2.6 TiKV_async_request_write_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_
↪ duration_seconds_bucket{type="write"}[1m]))by (le, instance, type))>
↪  1
```

- Description:

  If this value is relatively large, it means the Raft write takes a long time.

- Solution:

  1. Watch the **TiKV-Details > Raft propose** dashboard and see whether the **99% Propose wait duration per server** metric of the alerted TiKV node is significantly higher than that of other TiKV nodes. If so, it indicates that hotspots exist on this TiKV node, and you need to check whether the hotspot scheduling works properly.
  2. Watch the **TiKV-Details > Raft IO** dashboard and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk.
  3. For further analysis of performance issues of the alerted TiKV node and tuning methods, see Performance analysis and tuning.

9.7.3.2.7 TiKV_coprocessor_request_wait_seconds

- Alert rule:

```
histogram_quantile(0.9999, sum(rate(tikv_coprocessor_request_wait_
↪ seconds_bucket[1m]))by (le, instance, req))> 10
```

- Description:

  If this value is relatively large, it means the pressure on the Coprocessor worker is high. There might be a slow task that makes the Coprocessor thread stuck.

- Solution:

  1. View the slow query log from the TiDB log to see whether the index or full table scan is used in a query, or see whether it is needed to analyze;

2. Check whether there is a hot spot;
3. View the Coprocessor monitor and see whether `total` and `process` in `coprocessor table/index scan` match. If they differ a lot, it indicates too many invalid queries are performed. You can see whether there is `over seek bound`. If so, there are too many versions that GC does not handle in time. Then you need to increase the number of parallel GC threads.

9.7.3.2.8 TiKV_raftstore_thread_cpu_seconds_total

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"raftstore_.*"}[1m]))by (
↪ instance)> 1.6
```

- Description:

  This rule monitors CPU usage by Raftstore. If the value is high, it indicates pressure on Raftstore threads is heavy.

  The alert threshold is 80% of the `raftstore.store-pool-size` value. `raftstore.store-pool-size` is 2 by default, so the alert threshold is 1.6.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

9.7.3.2.9 TiKV_raft_append_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_append_log_duration_
↪ seconds_bucket[1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of appending Raft log. If it is high, it usually means I/O is too busy.

9.7.3.2.10 TiKV_raft_apply_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_apply_log_duration_
↪ seconds_bucket[1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of applying Raft log. If it is high, it usually means I/O is too busy.

9.7.3.2.11 TiKV_scheduler_latch_wait_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_latch_wait_duration_
↪ seconds_bucket[1m]))by (le, instance, type))> 1
```

- Description:

  The waiting time for the write operations to obtain the memory lock in Scheduler. If it is high, there might be many write conflicts, or that some operations that lead to conflicts take a long time to finish and block other operations that wait for the same lock.

- Solution:

  1. Identify the most time-consuming command by viewing the scheduler command duration in the `Scheduler` and `Scheduler-${cmd}` (`${cmd}` is the write command to query) monitors;
  2. Check the `total` and `process` values in the scheduler scan details of the `Scheduler` and `Scheduler-${cmd}` monitors and see whether `total` and `process` match.
  3. View the storage async snapshot/write duration in the Storage monitor and see whether the Raft operation is performed in time.

9.7.3.2.12 TiKV_thread_apply_worker_cpu_seconds

- Alert rule:

```
max(rate(tikv_thread_cpu_seconds_total{name=~"apply_.*"}[1m]))by (
↪ instance)> 0.9
```

- Description:

  The apply Raft log thread is under great pressure and is approaching or has exceeded its limit. This is often caused by a burst of writes.

9.7.3.3 Warning-level alerts

9.7.3.3.1 TiKV_leader_drops

- Alert rule:

```
delta(tikv_pd_heartbeat_tick_total{type="leader"}[30s])< -10
```

- Description:

  It is often caused by a stuck Raftstore thread.

- Solution:

    1. Refer to TiKV_channel_full_total.
    2. It there is low pressure on TiKV, consider whether the PD scheduling is too frequent. You can view the Operator Create panel on the PD page, and check the types and number of the PD scheduling.

9.7.3.3.2 TiKV_raft_process_ready_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration
↪ _secs_bucket{type='ready'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft ready. If this value is large, it is often caused by the stuck appending log task.

9.7.3.3.3 TiKV_raft_process_tick_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration
↪ _secs_bucket{type='tick'}[1m]))by (le, instance, type))> 2
```

- Description:

    Indicates the time cost of handling Raft tick. If this value is large, it is often caused by too many Regions.

- Solution:

    1. Consider using a higher-level log such as `warn` or `error`.
    2. Add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

9.7.3.3.4 TiKV_scheduler_context_total

- Alert rule:

```
abs(delta( tikv_scheduler_context_total[5m]))> 1000
```

- Description:

    The number of write commands that are being executed by Scheduler. If this value is large, it means the task is not finished timely.

- Solution:

    Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.7.3.3.5 TiKV_scheduler_command_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_command_duration_
↪ seconds_bucket[1m]))by (le, instance, type))> 1
```

- Description:

  Indicates the time cost of executing the Scheduler command.

- Solution:

  Refer to TiKV_scheduler_latch_wait_duration_seconds.

9.7.3.3.6 TiKV_coprocessor_outdated_request_wait_seconds

- Alert rule:

```
delta(tikv_coprocessor_outdated_request_wait_seconds_count[10m])> 0
```

- Description:

  The waiting time of the expired requests by Coprocessor. If this value is large, it means there is high pressure on Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.7.3.3.7 TiKV_coprocessor_pending_request

- Alert rule:

```
delta(tikv_coprocessor_pending_request[10m])> 5000
```

- Description:

  The queuing requests of Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

9.7.3.3.8 TiKV_batch_request_snapshot_nums

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"cop_.*"}[1m]))by (instance
↪ )/ (count(tikv_thread_cpu_seconds_total{name=~"cop_.*"})* 0.9)/
↪ count(count(tikv_thread_cpu_seconds_total)by (instance))> 0
```

- Description:

  The Coprocessor CPU usage of a TiKV machine exceeds 90%.

9.7.3.3.9 TiKV_pending_task

- Alert rule:

  ```
  sum(tikv_worker_pending_task_total)BY (instance,name)> 1000
  ```

- Description:

  The number of pending tasks of TiKV.

- Solution:

  Check which kind of tasks has a higher value from the `Worker pending tasks` metric in the **TiKV-Details > Task** dashboard.

9.7.3.3.10 TiKV_low_space

- Alert rule:

  ```
  sum(tikv_store_size_bytes{type="available"})by (instance)/ sum(tikv_
  ↪ store_size_bytes{type="capacity"})by (instance)< 0.2
  ```

- Description:

  The data volume of TiKV exceeds 80% of the configured node capacity or the disk capacity of the machine.

- Solution:

  - Check the balance condition of node space.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.3.3.11 TiKV_approximate_region_size

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_raftstore_region_size_bucket[1m
  ↪ ]))by (le))> 1073741824
  ```

- Description:

  The maximum Region approximate size that is scanned by the TiKV split checker is continually larger than 1 GB within one minute.

- Solution:

  The speed of splitting Regions is slower than the write speed. To alleviate this issue, you'd better update TiDB to a version that supports batch-split (>= 2.1.0-rc1). If it is not possible to update temporarily, you can use `pd-ctl operator add split-region <region_id> --policy=approximate` to manually split Regions.

9.7.4 TiFlash alert rules

For the detailed descriptions of TiFlash alert rules, see TiFlash Alert Rules.

9.7.5 TiCDC Alert rules

For the detailed descriptions of TiCDC alert rules, see TiCDC Alert Rules.

9.7.6 Node_exporter host alert rules

This section gives the alert rules for the Node_exporter host.

9.7.6.1 Emergency-level alerts

9.7.6.1.1 `NODE_disk_used_more_than_80%`

- Alert rule:

```
node_filesystem_avail_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/boot"}
↪  / node_filesystem_size_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/
↪ boot"} * 100 <= 20
```

- Description:

  The disk space usage of the machine exceeds 80%.

- Solution:

  - Log in to the machine, run the `df -h` command to check the disk space usage.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.6.1.2 `NODE_disk_inode_more_than_80%`

- Alert rule:

```
node_filesystem_files_free{fstype=~"(ext.|xfs)"} / node_filesystem_
↪ files{fstype=~"(ext.|xfs)"} * 100 < 20
```

- Description:

  The inode usage of the filesystem on the machine exceeds 80%.

- Solution:

  - Log in to the machine and run the `df -i` command to view the node usage of the filesystem.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

9.7.6.1.3 NODE_disk_readonly

- Alert rule:

  ```
  node_filesystem_readonly{fstype=~"(ext.|xfs)"} == 1
  ```

- Description:

  The filesystem is read-only and data cannot be written in it. It is often caused by disk failure or filesystem corruption.

- Solution:

  - Log in to the machine and create a file to test whether it is normal.
  - Check whether the disk LED is normal. If not, replace the disk and repair the filesystem of the machine.

9.7.6.2 Critical-level alerts

9.7.6.2.1 NODE_memory_used_more_than_80%

- Alert rule:

  ```
  (((node_memory_MemTotal_bytes-node_memory_MemFree_bytes-node_memory_
  ↪ Cached_bytes)/(node_memory_MemTotal_bytes)*100))>= 80
  ```

- Description:

  The memory usage of the machine exceeds 80%.

- Solution:

  - View the Memory panel of the host in the Grafana Node Exporter dashboard, and see whether Used memory is too high and Available memory is too low.
  - Log in to the machine and run the `free -m` command to view the memory usage. You can run `top` to check whether there is any abnormal process that has an overly high memory usage.

9.7.6.3 Warning-level alerts

9.7.6.3.1 NODE_node_overload

- Alert rule:

  ```
  (node_load5 / count without (cpu, mode)(node_cpu_seconds_total{mode="
  ↪ system"}))> 1
  ```

- Description:

  The CPU load on the machine is relatively high.

- Solution:

  - View the CPU Usage and Load Average of the host in the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the load average and the CPU usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.7.6.3.2 `NODE_cpu_used_more_than_80%`

- Alert rule:

```
avg(irate(node_cpu_seconds_total{mode="idle"}[5m]))by(instance)* 100 <=
↪ 20
```

- Description:

  The CPU usage of the machine exceeds 80%.

- Solution:

  - View the CPU Usage and Load Average of the host on the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the Load Average and the CPU Usage, and see whether there is any abnormal process that has an overly high CPU usage.

9.7.6.3.3 `NODE_tcp_estab_num_more_than_50000`

- Alert rule:

```
node_netstat_Tcp_CurrEstab > 50000
```

- Description:

  There are more than 50,000 TCP links in the "establish" status on the machine.

- Solution:

  - Log in to the machine and run `ss -s` to check the number of TCP links in the "estab" status in the current system.
  - Run `netstat` to check whether there is any abnormal link.

9.7.6.3.4 NODE_disk_read_latency_more_than_32ms

- Alert rule:

```
((rate(node_disk_read_time_seconds_total{device=~".+"}[5m])/ rate(node
↪ _disk_reads_completed_total{device=~".+"}[5m]))or (irate(node_disk_
↪ read_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_reads_
↪ completed_total{device=~".+"}[5m])))* 1000 > 32
```

- Description:

  The read latency of the disk exceeds 32 ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the read latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.7.6.3.5 NODE_disk_write_latency_more_than_16ms

- Alert rule:

```
((rate(node_disk_write_time_seconds_total{device=~".+"}[5m])/ rate(node
↪ _disk_writes_completed_total{device=~".+"}[5m]))or (irate(node_disk_
↪ write_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_writes_
↪ completed_total{device=~".+"}[5m])))> 16
```

- Description:

  The write latency of the disk exceeds 16ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the write latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

9.7.7 Blackbox_exporter TCP, ICMP, and HTTP alert rules

This section gives the alert rules for the Blackbox_exporter TCP, ICMP, and HTTP.

9.7.7.1 Emergency-level alerts

9.7.7.1.1 TiDB_server_is_down

- Alert rule:

  ```
  probe_success{group="tidb"} == 0
  ```

- Description:

  Failure to probe the TiDB service port.

- Solution:

  - Check whether the machine that provides the TiDB service is down.
  - Check whether the TiDB process exists.
  - Check whether the network between the monitoring machine and the TiDB machine is normal.

9.7.7.1.2 TiFlash_server_is_down

- Alert rule:

  ```
  probe_success{group="tiflash"} == 0
  ```

- Description:

  Failure to probe the TiFlash service port.

- Solution:

  - Check whether the machine that provides the TiFlash service is down.
  - Check whether the TiFlash process exists.
  - Check whether the network between the monitoring machine and the TiFlash machine is normal.

9.7.7.1.3 TiKV_server_is_down

- Alert rule:

  ```
  probe_success{group="tikv"} == 0
  ```

- Description:

  Failure to probe the TiKV service port.

- Solution:

  - Check whether the machine that provides the TiKV service is down.
  - Check whether the TiKV process exists.
  - Check whether the network between the monitoring machine and the TiKV machine is normal.

9.7.7.1.4 PD_server_is_down

- Alert rule:

  ```
  probe_success{group="pd"} == 0
  ```

- Description:

  Failure to probe the PD service port.

- Solution:

  - Check whether the machine that provides the PD service is down.
  - Check whether the PD process exists.
  - Check whether the network between the monitoring machine and the PD machine is normal.

9.7.7.1.5 Node_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="node_exporter"} == 0
  ```

- Description:

  Failure to probe the Node_exporter service port.

- Solution:

  - Check whether the machine that provides the Node_exporter service is down.
  - Check whether the Node_exporter process exists.
  - Check whether the network between the monitoring machine and the Node_exporter machine is normal.

9.7.7.1.6 Blackbox_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="blackbox_exporter"} == 0
  ```

- Description:

  Failure to probe the Blackbox_Exporter service port.

- Solution:

  - Check whether the machine that provides the Blackbox_Exporter service is down.
  - Check whether the Blackbox_Exporter process exists.
  - Check whether the network between the monitoring machine and the Blackbox_Exporter machine is normal.

9.7.7.1.7 Grafana_server_is_down

- Alert rule:

  ```
  probe_success{group="grafana"} == 0
  ```

- Description:

  Failure to probe the Grafana service port.

- Solution:

  - Check whether the machine that provides the Grafana service is down.
  - Check whether the Grafana process exists.
  - Check whether the network between the monitoring machine and the Grafana machine is normal.

9.7.7.1.8 Pushgateway_server_is_down

- Alert rule:

  ```
  probe_success{group="pushgateway"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service port.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.7.7.1.9 Kafka_exporter_is_down

- Alert rule:

  ```
  probe_success{group="kafka_exporter"} == 0
  ```

- Description:

  Failure to probe the Kafka_Exporter service port.

- Solution:

  - Check whether the machine that provides the Kafka_Exporter service is down.
  - Check whether the Kafka_Exporter process exists.
  - Check whether the network between the monitoring machine and the Kafka_Exporter machine is normal.

9.7.7.1.10 Pushgateway_metrics_interface

- Alert rule:

  ```
  probe_success{job="blackbox_exporter_http"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service http interface.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

9.7.7.2 Warning-level alerts

9.7.7.2.1 BLACKER_ping_latency_more_than_1s

- Alert rule:

  ```
  max_over_time(probe_duration_seconds{job=~"blackbox_exporter.*_icmp"}[1
  ↪ m])> 1
  ```

- Description:

  The ping latency exceeds 1 second.

- Solution:

  - View the ping latency between the two nodes on the Grafana Blackbox Exporter page to check whether it is too high.
  - Check the TCP panel on the Grafana Node Exporter page to check whether there is any packet loss.

9.8 TiFlash Alert Rules

This document introduces the alert rules of the TiFlash cluster.

9.8.1 TiFlash_schema_error

- Alert rule:

  ```
  increase(tiflash_schema_apply_count{type="failed"}[15m])> 0
  ```

- Description:

  When the schema apply error occurs, an alert is triggered.

- Solution:

  The error might be caused by some wrong logic. Get support from PingCAP or the community.

9.8.2 TiFlash_schema_apply_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_schema_apply_duration_seconds
  ↪ _bucket[1m]))BY (le, instance))> 20
  ```

- Description:

  When the probability that the apply duration exceeds 20 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by the internal problems of the TiFlash storage engine. Get support from PingCAP or the community.

9.8.3 TiFlash_raft_read_index_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_raft_read_index_duration_
  ↪ seconds_bucket[1m]))BY (le, instance))> 3
  ```

- Description:

  When the probability that the read index duration exceeds 3 seconds is over 99%, an alert is triggered.

> **Note:**
>
> `read index` is the kvproto request sent to the TiKV leader. TiKV region retries, busy store, or network problems might lead to long request time of `read index`.

- Solution:

  The frequent retries might be caused by frequent splitting or migration of the TiKV cluster. You can check the TiKV cluster status to identify the retry reason.

9.8.4 `TiFlash_raft_wait_index_duration`

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_wait_index_duration_
↪ seconds_bucket[1m]))BY (le, instance))> 2
```

- Description:

  When the probability that the waiting time for Region Raft Index in TiFlash exceeds 2 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by a communication error between TiKV and the proxy. Get support from PingCAP or the community.

9.9 Customize Configurations of Monitoring Servers

When you deploy a TiDB cluster using TiUP, TiUP also deploys monitoring servers, such as Prometheus, Grafana, and Alertmanager. In the meantime, if you scale out this cluster, TiUP also adds the new nodes into monitoring scope.

To customize the configurations of the monitoring servers mentioned above, you can follow the instructions below to add related configuration items in the topology.yaml of the TiDB cluster.

Note:

- Do not modify the configurations files of the monitoring server directly. Because these modifications will be overwritten by later TiUP operations such as deployment, scaling out, scaling in, and reloading.
- If your monitoring servers are not deployed and managed by TiUP, you can directly modify the configuration files of the monitoring servers instead of referring to this document.
- This feature is supported in TiUP v1.9.0 and above. Therefore, check the TiUP version before using this feature.

9.9.1 Customize Prometheus configurations

Currently, TiUP supports customizing Prometheus rule and scrape configuration files.

9.9.1.1 Customize Prometheus rule configuration

1. Customize the rule configuration file and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `rule_dir` to the directory of the customized rule configuration file.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Prometheus
   ↪ Server.
monitoring_servers:
  # # The ip address of the Monitoring Server.
- host: 127.0.0.1
  rule_dir: /home/tidb/prometheus_rule # prometheus rule dir on TiUP
     ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized rule configurations from `rule_dir` (for example, `/home/tidb/prometheus_rule`) and sends them to the Prometheus Server to replace the default rule configuration.

9.9.1.2 Customize Prometheus scrape configuration

1. Open the topology.yaml file of the TiDB cluster.
2. In the `monitoring_servers` configuration, add the `additional_scrape_conf` field.

   The following is a configuration example of monitoring_servers in the topology.yaml file:

```
monitoring_servers:
- host: xxxxxxx
ssh_port: 22
port: 9090
deploy_dir: /tidb-deploy/prometheus-9090
data_dir: /tidb-data/prometheus-9090
log_dir: /tidb-deploy/prometheus-9090/log
external_alertmanagers: []
arch: amd64
```

```
os: linux
additional_scrape_conf:
  metric_relabel_configs:
    - source_labels: [__name__]
        separator: ;
        regex: tikv_thread_nonvoluntary_context_switches|tikv_thread_
            ↪ voluntary_context_switches|tikv_threads_io_bytes_total
        action: drop
    - source_labels: [__name__,name]
        separator: ;
        regex: tikv_thread_cpu_seconds_total;(tokio|rocksdb).+
        action: drop
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `additional_scrape_conf` field to the corresponding parameters of the Prometheus configuration file.

9.9.2 Customize Grafana configurations

Currently, TiUP supports customizing Grafana Dashboard and other configurations.

9.9.2.1 Customize Grafana Dashboard

1. Customize the configuration file of the Grafana Dashboard and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `dashboard_dir` to the directory of the customized Dashboard configuration file.

   The following is a configuration example of grafana_servers in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
  # # The ip address of the Grafana Server.
 - host: 127.0.0.1
 dashboard_dir: /home/tidb/dashboards # grafana dashboard dir on TiUP
    ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized Dashboard configurations from `dashboard_dir` (for example, `/home/tidb/dashboards`) and sends the configurations to the Grafana Server to replace the default Dashboard configuration.

9.9.2.2 Customize other Grafana configurations

1. Open the topology.yaml file of the TiDB cluster.
2. Add other configuration items in the `grafana_servers` configuration.

   The following is a configuration example of the `[log.file] level` and `smtp` fields in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
   ↪ Servers.
grafana_servers:
# # The ip address of the Grafana Server.
- host: 127.0.0.1
    config:
    log.file.level: warning
    smtp.enabled: true
    smtp.host: {IP}:{port}
    smtp.user: example@pingcap.com
    smtp.password: {password}
    smtp.skip_verify: true
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `config` field to the Grafana configuration file `grafana.ini`.

9.9.3 Customize Alertmanager configurations

Currently, TiUP supports customizing the listening address of Alertmanager.

Alertmanager deployed by TiUP listens to `alertmanager_servers.host` by default. You cannot access Alertmanager if you use a proxy. To address this issue, you can specify the listening address by adding `listen_host` to the cluster configuration file topology.yaml. The recommended value is 0.0.0.0.

The following example sets the `listen_host` field to 0.0.0.0.

```
alertmanager_servers:
  # # The ip address of the Alertmanager Server.
  - host: 172.16.7.147
    listen_host: 0.0.0.0
    # # SSH port of the server.
    ssh_port: 22
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the content of the `listen_host` field to `--web.listen-address` in Alertmanager startup parameters.

9.10 Monitoring and Alert for Backup and Restore

This document describes the monitoring and alert of the backup and restore feature, including how to deploy monitoring components, monitoring metrics, and common alerts.

9.10.1 Snapshot backup and restore monitoring

To view the snapshot backup and restore metrics, go to the **TiKV-Details > Backup & Import** dashboard in Grafana.

9.10.2 Log backup monitoring

Log backup supports using Prometheus to collect monitoring metrics. Currently all monitoring metrics are built into TiKV.

9.10.2.1 Monitoring configuration

- For clusters deployed using TiUP, Prometheus automatically collects monitoring metrics.
- For clusters deployed manually, follow the instructions in TiDB Cluster Monitoring Deployment to add TiKV-related jobs to the `scrape_configs` section of the Prometheus configuration file.

9.10.2.2 Grafana configuration

- For clusters deployed using TiUP, the Grafana dashboard contains the point-in-time recovery (PITR) panel. The **Backup Log** panel in the TiKV-Details dashboard is the PITR panel.
- For clusters deployed manually, refer to Import a Grafana dashboard and upload the tikv_details JSON file to Grafana. Then find the **Backup Log** panel in the TiKV-Details dashboard.

9.10.2.3 Monitoring metrics

Metrics	Type	Description
tikv_log_backup_interval_actor_acting_duration	Histogram	The duration of handling all internal messages and events. `message :: TaskType`
tikv_log_backup_initial_scan_reason	Counter	Statistics of the reasons why initial scan is triggered. The main reason is leader transfer or Region version change. `reason :: {"leader-changed", "region-changed", "retry"}`

Metrics	Type	Description
tikv_log_backup_event_handle_duration_sec	Histogram	The duration of handling KV events. Compared with tikv_log_backup_on_event_duration_seconds, this metric also includes the duration of internal conversion. stage :: {"to_stream_event", "save_to_temp_file ↪ "}
tikv_log_backup_handle_kv_batch	Histogram	Record log-level statistics of the sizes of KV pair batches sent by Raftstore.
tikv_log_backup_initial_scan_disk_read	Counter	The disk IO of data read from the disk during initial scan. In Linux, this information is from procfs, which is the size of data actually read from the block device. The configuration item initial-scan-rate-limit applies to this metric.
tikv_log_backup_incremental_scan_bytes	Histogram	The size of KV pairs actually generated during initial scan. Because of compression and read amplification, this value might be different from that of tikv_log_backup_initial_scan_disk_read.
tikv_log_backup_skip_kv_count	Counter	The number of Raft events being skipped during the log backup because they are not helpful to the backup.
tikv_log_backup_errors	Counter	The errors that can be retried or ignored during the log backup. type :: ErrorType
tikv_log_backup_fatal_errors	Counter	The errors that cannot be retried or ignored during the log backup. When an error of this type occurs, the log backup is paused. type :: ErrorType
tikv_log_backup_heap_memory	Gauge	The memory occupied by events that are unconsumed and found by initial scan during log backup.
tikv_log_backup_on_event_duration_seconds	Histogram	The duration of writing KV events to temporary files. stage :: {"write_to_tempfile", "syscall_write"}
tikv_log_backup_store_checkpoint_ts	Gauge	The store-level checkpoint TS, which is deprecated. It is close to the GC safepoint registered by the current store. task :: string
tidb_log_backup_last_checkpoint	Gauge	The global checkpoint TS. It is a time point till which log data has been backed up. task :: string
tikv_log_backup_flush_duration_sec	Histogram	The duration of moving local temporary files to the external storage. stage :: {"generate_metadata", " ↪ save_files", "clear_temp_files"}
tikv_log_backup_flush_file_size	Histogram	Statistics of the sizes of files generated during the backup.
tikv_log_backup_initial_scan_duration_sec	Histogram	The duration of the overall duration of initial scan.
tikv_log_backup_skip_retry_observe	Counter	Statistics of the errors that can be ignored during log backup, or the reasons why retry is skipped. reason :: {"region-absent", "not-leader", " ↪ stale-command"}

Metrics	Type	Description
tikv_log_backup_initial_scan_operations	Counter	Statistics of RocksDB-related operations during initial scan. `cf :: {"default", "write", "lock"}, op :: RocksDBOP`
tikv_log_backup_enabled	Counter	Whether to enable log backup. If the value is greater than `0`, log backup is enabled.
tikv_log_backup_observed_region	Gauge	The number of Regions being listened to.
tikv_log_backup_task_status	Gauge	The status of the log backup task. `0` means running. `1` means paused. `2` means error. `task :: string`
tikv_log_backup_pending_initial_scan	Gauge	Statistics of pending initial scans. `stage :: {"queuing", "executing"}`

9.10.2.4 Log backup alerts

9.10.2.4.1 Alert configuration

Currently, PITR does not have built-in alert items. This section introduces how to configure alert items in PITR and recommends some items.

To configure alert items in PITR, follow these steps:

1. Create a configuration file (for example, `pitr.rules.yml`) for the alert rules on the node where Prometheus is located. In the file, fill in the alert rules according to the Prometheus documentation, the following recommended alert items, and the configuration sample.
2. In the `rule_files` field of the Prometheus configuration file, add the path of the alert rule file.
3. Send `SIGHUP` signal to the Prometheus process (`kill -HUP pid`) or send an HTTP `POST` request to `http://prometheus-addr/-/reload` (before you send the HTTP request, add the `--web.enable-lifecycle` parameter when starting Prometheus).

The recommended alert items are as follows:

9.10.2.4.2 LogBackupRunningRPOMoreThan10m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (task)/ 60 > 10 and max(tidb_log_backup_last_checkpoint)by (task)> 0 and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: warning
- Description: The log data is not persisted to the storage for more than 10 minutes. This alert item is a reminder. In most cases, it does not affect log backup.

A configuration sample of this alert item is as follows:

```
groups:
- name: PiTR
  rules:
  - alert: LogBackupRunningRPOMoreThan10m
    expr: max(time() - tidb_log_backup_last_checkpoint / 262144000) by (task
       ↪ ) / 60 > 10 and max(tidb_log_backup_last_checkpoint) by (task) > 0
       ↪  and max(tikv_log_backup_task_status) by (task) == 0
    labels:
      severity: warning
    annotations:
      summary: RPO of log backup is high
      message: RPO of the log backup task {{ $labels.task }} is more than 10
         ↪ m
```

9.10.2.4.3 LogBackupRunningRPOMoreThan30m

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (` ↪ `task)/ 60 > 30 and max(tidb_log_backup_last_checkpoint)by (task)> 0` ↪ `and max(tikv_log_backup_task_status)by (task)== 0`
- Alert level: critical
- Description: The log data is not persisted to the storage for more than 30 minutes. This alert often indicates anomalies. You can check the TiKV logs to find the cause.

9.10.2.4.4 LogBackupPausingMoreThan2h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (` ↪ `task)/ 3600 > 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0` ↪ `and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: warning
- Description: The log backup task is paused for more than 2 hours. This alert item is a reminder and you are expected to run `br log resume` as soon as possible.

9.10.2.4.5 LogBackupPausingMoreThan12h

- Alert item: `max(time()- tidb_log_backup_last_checkpoint / 262144000)by (` ↪ `task)/ 3600 > 12 and max(tidb_log_backup_last_checkpoint)by (task)>` ↪ `0 and max(tikv_log_backup_task_status)by (task)== 1`
- Alert level: critical
- Description: The log backup task is paused for more than 12 hours. You are expected to run `br log resume` as soon as possible to resume the task. Log tasks paused for too long have the risk of data loss.

9.10.2.4.6 LogBackupFailed

- Alert item: `max(tikv_log_backup_task_status)by (task)== 2 and max(tidb_log_backup_last_checkpoint)by (task)> 0`
- Alert level: critical
- Description: The log backup task fails. You need to run `br log status` to see the failure reason. If necessary, you need to further check the TiKV logs.

9.10.2.4.7 LogBackupGCSafePointExceedsCheckpoint

- Alert item: `min(tidb_log_backup_last_checkpoint)by (instance)- max(tikv_gcworker_autogc_safe_point)by (instance)< 0`
- Alert level: critical
- Description: Some data has been garbage-collected before the backup. This means that some data has been lost and is very likely to affect your services.

10 Troubleshoot

10.1 Issue Summary

10.1.1 TiDB Troubleshooting Map

This document summarizes common issues in TiDB and other components. You can use this map to diagnose and solve issues when you encounter related problems.

10.1.1.1 1. Service Unavailable

10.1.1.1.1 1.1 The client reports `Region is Unavailable` error

- 1.1.1 The `Region is Unavailable` error is usually because a Region is not available for a period of time. You might encounter `TiKV server is busy`, or the request to TiKV fails due to `not leader` or `epoch not match`, or the request to TiKV time out. In such cases, TiDB performs a `backoff` retry mechanism. When the `backoff` exceeds a threshold (20s by default), the error will be sent to the client. Within the `backoff` threshold, this error is not visible to the client.
- 1.1.2 Multiple TiKV instances are OOM at the same time, which causes no Leader during the OOM period. See case-991 in Chinese.
- 1.1.3 TiKV reports `TiKV server is busy`, and exceeds the `backoff` time. For more details, refer to 4.3. `TiKV server is busy` is a result of the internal flow control mechanism and should not be counted in the `backoff` time. This issue will be fixed.

- 1.1.4 Multiple TiKV instances failed to start, which causes no Leader in a Region. When multiple TiKV instances are deployed in a physical machine, the failure of the physical machine can cause no Leader in a Region if the label is not properly configured. See case-228 in Chinese.
- 1.1.5 When a Follower apply is lagged in a previous epoch, after the Follower becomes a Leader, it rejects the request with `epoch not match`. See case-958 in Chinese (TiKV needs to optimize its mechanism).

10.1.1.1.2 1.2 PD errors cause service unavailable

Refer to 5 PD issues.

10.1.1.2 2. Latency increases significantly

10.1.1.2.1 2.1 Transient increase

- 2.1.1 Wrong TiDB execution plan causes latency increase. Refer to 3.3.
- 2.1.2 PD Leader election issue or OOM. Refer to 5.2 and 5.3.
- 2.1.3 A significant number of Leader drops in some TiKV instances. Refer to 4.4.
- 2.1.4 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.2.2 2.2 Persistent and significant increase

- 2.2.1 TiKV single thread bottleneck
  - Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue. See case-612 in Chinese.
  - For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.
- 2.2.2 CPU load increases.
- 2.2.3 TiKV slow write. Refer to 4.5.
- 2.2.4 TiDB wrong execution plan. Refer to 3.3.
- 2.2.5 For other causes, see Troubleshoot Increased Read and Write Latency.

10.1.1.3 3. TiDB issues

10.1.1.3.1 3.1 DDL

- 3.1.1 An error `ERROR 1105 (HY000): unsupported modify decimal column precision` is reported when you modify the length of the `decimal` field. TiDB does not support changing the length of the `decimal` field.
- 3.1.2 TiDB DDL job hangs or executes slowly (use `admin show ddl jobs` to check DDL progress)
  - Cause 1: TiDB introduces the metadata lock in v6.3.0, and enables it by default in v6.5.0 and later versions. If the table involved in the DDL operation has intersections with the table involved in the uncommitted transaction, the DDL operation is blocked until the transaction is committed or rolled back.
  - Cause 2: Network issue with other components (PD/TiKV).
  - Cause 3: Early versions of TiDB (earlier than v3.0.8) have heavy internal load because of a lot of goroutine at high concurrency.
  - Cause 4: In early versions (v2.1.15 & versions < v3.0.0-rc1), PD instances fail to delete TiDB keys, which causes every DDL change to wait for two leases.
  - For other unknown causes, report a bug.
  - Solution:
    - For cause 1, check the network connection between TiDB and TiKV/PD.
    - For cause 2 and 3, the issues are already fixed in later versions. You can upgrade TiDB to a later version.
    - For other causes, you can use the following solution of migrating the DDL owner.
  - DDL owner migration:
    - If you can connect to the TiDB server, execute the owner election command again: `curl -X POST http://{TiDBIP}:10080/ddl/owner/resign`
    - If you cannot connect to the TiDB server, use `tidb-ctl` to delete the DDL owner from the etcd of the PD cluster to trigger re-election: `tidb-ctl etcd delowner [LeaseID] [flags] + ownerKey`
- 3.1.3 TiDB reports `information schema is changed` error in log
  - For the detailed causes and solution, see Why the `Information schema is changed` error is reported.
  - Background: The increased number of `schema version` is consistent with the number of `schema state` of each DDL change operation. For example, the `create table` operation has 1 version change, and the `add column` operation has 4 version changes. Therefore, too many column change operations might cause `schema version` to increase fast. For details, refer to online schema change.
- 3.1.4 TiDB reports `information schema is out of date` in log

- Cause 1: The TiDB server that is executing the DML statement is stopped by `graceful kill` and prepares to exit. The execution time of the transaction that contains the DML statement exceeds one DDL lease. An error is reported when the transaction is committed.
- Cause 2: The TiDB server cannot connect to PD or TiKV when it is executing the DML statement. As a result, the TiDB server did not load the new schema within one DDL lease (`45s` by default), or the TiDB server disconnects from PD with the `keep alive` setting.
- Cause 3: TiKV has high load or network timed out. Check the node loads in **Grafana** -> **TiDB** and **TiKV**.
- Solution:
  - For cause 1, retry the DML operation when TiDB is started.
  - For cause 2, check the network between the TiDB server and PD/TiKV.
  - For cause 3, investigate why TiKV is busy. Refer to 4 TiKV issues.

10.1.1.3.2 3.2 OOM issues

- 3.2.1 Symptom
  - Client: The client reports the error `ERROR 2013 (HY000): Lost connection to MySQL server during query`.
  - Check the log
    - Execute `dmesg -T | grep tidb-server`. The result shows the OOM-killer log around the time point when the error occurs.
    - Grep the "Welcome to TiDB" log in `tidb.log` around the time point after the error occurs (namely, the time when tidb-server restarts).
    - Grep `fatal error: runtime: out of memory` or `cannot allocate memory` in `tidb_stderr.log`.
    - In v2.1.8 or earlier versions, you can grep `fatal error: stack overflow` in the `tidb_stderr.log`.
  - Monitor: The memory usage of tidb-server instances increases sharply in a short period of time.
- 3.2.2 Locate the SQL statement that causes OOM. (Currently all versions of TiDB cannot locate SQL accurately. You still need to analyze whether OOM is caused by the SQL statement after you locate one.)
  - For versions >= v3.0.0, grep "expensive_query" in `tidb.log`. That log message records SQL queries that timed out or exceed memory quota.
  - For versions < v3.0.0, grep "memory exceeds quota" in `tidb.log` to locate SQL queries that exceed memory quota.

Note:

The default threshold for a single SQL memory usage is `1GB`. You can set this parameter by configuring the system variable `tidb_mem_quota_query`.

- 3.2.3 Mitigate OOM issues
    - By enabling `SWAP`, you can mitigate the OOM issue caused by overuse of memory by large queries. When the memory is insufficient, this method can have impact on the performance of large queries due to the I/O overhead. The degree to which the performance is affected depends on the remaining memory space and the disk I/O speed.
- 3.2.4 Typical reasons for OOM
    - The SQL query has `join`. If you view the SQL statement by using `explain`, you can find that the `join` operation selects the `HashJoin` algorithm and the `inner` table is large.
    - The data volume of a single `UPDATE/DELETE` query is too large. See case-882 in Chinese.
    - The SQL contains multiple sub-queries connected by `Union`. See case-1828 in Chinese.

For more information about troubleshooting OOM, see Troubleshoot TiDB OOM Issues.

10.1.1.3.3 3.3 Wrong execution plan

- 3.3.1 Symptom
    - SQL query execution time is much longer compared with that of previous executions, or the execution plan suddenly changes. If the execution plan is logged in the slow log, you can directly compare the execution plans.
    - SQL query execution time is much longer compared with that of other databases such as MySQL. Compare the execution plan with other databases to see the differences, such as `Join Order`.
    - In slow log, the number of SQL execution time `Scan Keys` is large.
- 3.3.2 Investigate the execution plan

- `explain analyze {SQL}`. When the execution time is acceptable, compare `count` in the result of `explain analyze` and the number of `row` in `execution info`. If a large difference is found in the `TableScan/IndexScan` row, it is likely that the statistics is incorrect. If a large difference is found in other rows, the problem might not be in the statistics.
- `select count(*)`. When the execution plan contains a `join` operation, `explain analyze` might take a long time. You can check whether the problem is in the statistics by executing `select count(*)` for the conditions on `TableScan/IndexScan` and comparing the `row count` information in the `explain` result.

- 3.3.3 Mitigation
  - For v3.0 and later versions, use the `SQL Bind` feature to bind the execution plan.
  - Update the statistics. If you are roughly sure that the problem is caused by the statistics, dump the statistics. If the cause is outdated statistics, such as the `modify count/row count` in `show stats_meta` is greater than a certain value (for example, 0.3), or the table has an index of time column, you can try recovering by using `analyze table`. If `auto analyze` is configured, check whether the `tidb_auto_analyze_ratio` system variable is too large (for example, greater than 0.3), and whether the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.
  - For other situations, report a bug.

10.1.1.3.4 3.4 SQL execution error

- 3.4.1 The client reports the `ERROR 1265(01000)Data Truncated` error. This is because the way TiDB internally calculates the precision of `Decimal` type is incompatible with that of MySQL. This issue has been fixed in v3.0.10 (#14438).
  - Cause:

    In MySQL, if two large-precision `Decimal` are divided and the result exceeds the maximum decimal precision (`30`), only `30` digits are reserved and no error is reported;

    In TiDB, the calculation result is the same as in MySQL, but inside the data structure that represents `Decimal`, a field for decimal precision still retains the actual precision.

    Take `(0.1^30)/ 10` as an example. The results in TiDB and MySQL are both `0`, because the precision is `30` at most. However, in TiDB, the field for decimal precision is still `31`.

    After multiple `Decimal` divisions, even though the result is correct, this precision field could grow larger and larger, and eventually exceeds the threshold in TiDB (`72`), and the `Data Truncated` error is reported.

    The multiplication of `Decimal` does not have this issue, because the out-of-bounds is bypassed, and the precision is set to the maximum precision limit.

- Solution: You can bypass this issue by manually adding `Cast(xx as decimal(a , b))`, in which `a` and `b` are the target precisions.

10.1.1.3.5 3.5 Slow query issues

To identify slow queries, see Identify slow queries. To analyze and handle slow queries, see Analyze slow queries.

10.1.1.3.6 3.6 Hotspot issues

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency. For detailed solutions, see Troubleshoot Hotspot Issues.

10.1.1.3.7 3.7 High disk I/O usage

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck. For how to locate and handle the issue of high I/O usage in TiDB, see Troubleshoot High Disk I/O Usage.

10.1.1.3.8 3.8 Lock conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. To learn how to troubleshoot lock-related issues and how to handle optimistic and pessimistic lock conflicts, see Troubleshoot Lock Conflicts.

10.1.1.3.9 3.9 Inconsistency between data and indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

To learn more about the inconsistency error and how to bypass the check, see Troubleshoot Inconsistency Between Data and Indexes.

10.1.1.4 4. TiKV issues

10.1.1.4.1 4.1 TiKV panics and fails to start

- 4.1.1 If TiKV is deployed on a virtual machine, when the virtual machine is killed or the physical machine is powered off, the `entries[X, Y] is unavailable from storage` error is reported.

  This issue is expected. The `fsync` of virtual machines is not reliable, so you need to restore the Region using `tikv-ctl`.

- 4.1.2 For other unexpected causes, report a bug.

10.1.1.4.2 4.2 TiKV OOM

- 4.2.1 If the `block-cache` configuration is too large, it might cause OOM.

  To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**.

  Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"` ↪ parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- 4.2.2 Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM.

  To verify the cause, you can check whether `response size` exceeds the `network` ↪ `outbound` traffic by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

- 4.2.3 Other components occupy too much memory.

  This issue is unexpected. You can report a bug.

10.1.1.4.3 4.3 The client reports the `server is busy` error

Check the specific cause for busy by viewing the monitor **Grafana** -> **TiKV** -> **errors**. `server is busy` is caused by the flow control mechanism of TiKV, which informs `tidb/ti` ↪ `-client` that TiKV is currently under too much pressure and will retry later.

- 4.3.1 TiKV RocksDB encounters `write stall`.

  A TiKV instance has two RocksDB instances, one in `data/raft` to store the Raft log, and the other in `data/db` to store the real data. You can check the specific cause for the stall by running `grep "Stalling" RocksDB` in the log. The RocksDB log is a file starting with `LOG`, and `LOG` is the current log. `write stall` is a performance degradation mechanism natively built in RocksDB. When `write stall` occurs in RocksDB, the

system performance drops significantly. In versions before v5.2.0, TiDB tries to block all write requests by returning a `ServerIsBusy` error directly to the client when encountering `write stall`, but this could lead to a sharp decrease in QPS performance. Starting from v5.2.0, TiKV introduces a new flow control mechanism that suppresses writes by delaying write requests dynamically in the scheduling layer, which replaces the previous mechanism of returning `server is busy` to clients when `write stall` occurs. The new flow control mechanism is enabled by default, and TiKV automatically disables the `write stall` mechanism for `KvDB` and `RaftDB` (except for memtables). However, when the number of pending requests exceeds a certain threshold, the flow control mechanism still takes effect, beginning to reject some or all write requests and returning a `server is busy` error to clients. For detailed explanations and thresholds, see Flow control configuration.

- If the `server is busy` error is triggered by too many pending compaction bytes, you can alleviate this issue by increasing the values of the `soft-pending-compaction-bytes-limit` and `hard-pending-compaction-bytes-limit` parameters.
    - When pending compaction bytes reach the value of the `soft-pending-compaction-bytes-limit` parameter (`192GiB` by default), the flow control mechanism begins to reject some write requests (by returning `ServerIsBusy` to clients). In this case, you can increase the value of this parameter, for example, `[storage.flow-control] soft-pending-compaction-bytes-limit = "384GiB"`.
    - When pending compaction bytes reach the value of the `hard-pending-compaction-bytes-limit` parameter (`1024GiB` by default), the flow control mechanism begins to reject all write requests (by returning `ServerIsBusy` to clients). This scenario is less likely to occur because the flow control mechanism intervenes to slow down write speed after reaching the threshold of `soft-pending-compaction-bytes-limit`. If it occurs, you can increase the value of this parameter, for example, `[storage.flow-control] hard-pending-compaction-bytes-limit = "2048GiB"`.
    - If the disk I/O capacity fails to keep up with the write for a long time, it is recommended to scale up your disk. If the disk throughput reaches the upper limit and causes write stall (for example, the SATA SSD is much lower than NVME SSD), while the CPU resources is sufficient, you may apply a compression algorithm of higher compression ratio. This way, the CPU resources is traded for disk resources, and the pressure on the disk is eased.
    - If the default CF compaction sees a high pressure, change the `[rocksdb.defaultcf] compression-per-level` parameter from `["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.
- Too many memtables causes stall. This usually occurs when the amount of instant writes is large and the memtables flush to the disk slowly. If the disk write speed cannot be improved, and this issue only occurs during business peaks, you can

mitigate it by increasing the `max-write-buffer-number` of the corresponding CF.

- For example, set `[rocksdb.defaultcf] max-write-buffer-number` to `8` (`5` by default). Note that this might cause more memory usage in the peak, because more memtables might be in the memory.

- 4.3.2 `scheduler too busy`

  - Serious write conflict. `latch wait duration` is high. You can view `latch wait duration` in the monitor **Grafana -> TiKV-details -> scheduler prewrite/scheduler commit**. When the write tasks pile up in the scheduler, the pending write tasks exceed the threshold set in `[storage] scheduler-pending-write-threshold` (100MB). You can verify the cause by viewing the metric corresponding to `MVCC_CONFLICT_COUNTER`.
  - Slow write causes write tasks to pile up. The data being written to TiKV exceeds the threshold set by `[storage] scheduler-pending-write-threshold` (100MB). Refer to 4.5.

- 4.3.3 `raftstore is busy`. The processing of messages is slower than the receiving of messages. The short-term `channel full` status does not affect the service, but if the error persists for a long time, it might cause Leader switch.

  - `append log` encounters stall. Refer to 4.3.1.
  - `append log duration` is high, which causes slow processing of messages. You can refer to 4.5 to analyze why `append log duration` is high.
  - raftstore receives a large batch of messages in an instant (check in the TiKV Raft messages dashboard), and fails to process them. Usually the short-term `channel full` status does not affect the service.

- 4.3.4 TiKV coprocessor is in a queue. The number of piled up tasks exceeds `coprocessor threads * readpool.coprocessor.max-tasks-per-worker-[normal|low|high]`. Too many large queries leads to the tasks piling up in coprocessor. You need to check whether an execution plan change causes a large number of table scan operations. Refer to 3.3.

10.1.1.4.4 4.4 Some TiKV nodes drop Leader frequently

- 4.4.1 Re-election because TiKV is restarted

  - After TiKV panics, it is pulled up by systemd and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
  - TiKV is stopped or killed by a third party and then pulled up by systemd. Check the cause by viewing `dmesg` and the TiKV log.
  - TiKV is OOM, which causes restart. Refer to 4.2.

  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage). See case case-500 in Chinese.

- 4.4.2 TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`. Refer to 4.3.1.

- 4.4.3 Re-election because of network isolation.

10.1.1.4.5 4.5 TiKV write is slow

- 4.5.1 Check whether the TiKV write is slow by viewing the `prewrite/commit/raw-put` duration of TiKV gRPC (only for RawKV clusters). Generally, you can locate the slow phase according to the performance-map. Some common situations are listed as follows.

- 4.5.2 The scheduler CPU is busy (only for transaction kv).

  The `scheduler command duration` of prewrite/commit is longer than the sum of `scheduler latch wait duration` and `storage async write duration`. The scheduler worker has a high CPU demand, such as over 80% of `scheduler-worker-pool-size` * 100%, or the CPU resources of the entire machine are relatively limited. If the write workload is large, check if `[storage] scheduler-worker-pool-size` is set too small.

  For other situations, report a bug.

- 4.5.3 Append log is slow.

  The **Raft IO**/`append log duration` in TiKV Grafana is high, usually because the disk write operation is slow. You can verify the cause by checking the `WAL Sync Duration max` value of RocksDB - raft.

  For other situations, report a bug.

- 4.5.4 The raftstore thread is busy.

  The **Raft Propose**/`propose wait duration` is significantly larger than the append log duration in TiKV Grafana. Take the following methods:

  - Check whether the `[raftstore] store-pool-size` configuration value is too small. It is recommended to set the value between `1` and `5` and not too large.
  - Check whether the CPU resources on the machine are insufficient.

- 4.5.5 Apply is slow.

  The **Raft IO**/`apply log duration` in TiKV Grafana is high, which usually comes with a high **Raft Propose**/`apply wait duration`. The possible causes are as follows:

- `[raftstore] apply-pool-size` is too small (it is recommended to set the value between `1` and `5` and not too large), and the **Thread CPU**/`apply CPU` is large.
- The CPU resources on the machine are insufficient.
- Region write hot spot. A single apply thread has high CPU usage. Currently, we cannot properly address the hot spot problem on a single Region, which is being improved. To view the CPU usage of each thread, modify the Grafana expression and add `by (instance, name)`.
- RocksDB write is slow. **RocksDB kv**/`max write duration` is high. A single Raft log might contain multiple KVs. When writing into RocksDB, 128 KVs are written into RocksDB in a write batch. Therefore, an apply log might be associated with multiple writes in RocksDB.
- For other situations, report a bug.

- 4.5.6 Raft commit log is slow.

  The **Raft IO**/`commit log duration` in TiKV Grafana is high (this metric is only supported in Grafana after v4.x). Every Region corresponds to an independent Raft group. Raft has a flow control mechanism, similar to the sliding window mechanism of TCP. You can control the size of the sliding window by configuring the `[raftstore] raft-max-inflight-msgs = 256` parameter. If there is a write hot spot and the `commit log duration` is high, you can adjust the parameter, such as increasing it to `1024`.

- 4.5.7 For other situations, refer to the write path on performance-map and analyze the cause.

10.1.1.5 5. PD issues

10.1.1.5.1 5.1 PD scheduling

- 5.1.1 Merge

  - Empty Regions across tables cannot be merged. You need to modify the `[coprocessor] split-region-on-table` parameter in TiKV, which is set to `false` in v4.x by default. See case-896 in Chinese.
  - Region merge is slow. You can check whether the merged operator is generated by accessing the monitor dashboard in **Grafana** -> **PD** -> **operator**. To accelerate the merge, increase the value of `merge-schedule-limit`.

- 5.1.2 Add replicas or take replicas online/offline

  - The TiKV disk uses 80% of the capacity, and PD does not add replicas. In this situation, the number of miss peers increases, so TiKV needs to be scaled out. See case-801 in Chinese.

- When a TiKV node is taken offline, some Region cannot be migrated to other nodes. This issue has been fixed in v3.0.4 (#5526). See case-870 in Chinese.

- 5.1.3 Balance

  - The Leader/Region count is not evenly distributed. See case-394 and case-759 in Chinese. The major cause is that the balance performs scheduling based on the size of Region/Leader, so this might result in the uneven distribution of the count. In TiDB 4.0, the `[leader-schedule-policy]` parameter is introduced, which enables you to set the scheduling policy of Leader to be `count`-based or `size`-based.

10.1.1.5.2 5.2 PD election

- 5.2.1 PD switches Leader.

  - Cause 1: Disk. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana -> disk performance -> latency/load**. You can also use the FIO tool to run a check on the disk if necessary. See case-292 in Chinese.
  - Cause 2: Network. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana -> PD -> etcd**. See case-177 in Chinese.
  - Cause 3: High system load. The log shows `server is likely overloaded`. See case-214 in Chinese.

- 5.2.2 PD cannot elect a Leader or the election is slow.

  - PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19. See case-875 in Chinese.
  - The election is slow: The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region -storage` to `true`, which significantly reduce the Region loading duration. See case-429 in Chinese.

- 5.2.3 PD timed out when TiDB executes SQL statements.

  - PD doesn't have a Leader or switches Leader. Refer to 5.2.1 and 5.2.2.
  - Network issue. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> blackbox_exporter -> ping latency**.

- PD panics. Report a bug.
- PD is OOM. Refer to 5.3.
- If the issue has other causes, get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

- 5.2.4 Other issues
  - PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040). For details, see case-947 in Chinese.
  - For other situations, report a bug.

10.1.1.5.3 5.3 PD OOM

- 5.3.1 When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- 5.3.2 PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that TCP InSegs is relatively large. This issue has been fixed in v3.0.6 (#1952).

10.1.1.5.4 5.4 Grafana display

- 5.4.1 The monitor in **Grafana** -> **PD** -> **cluster** -> **role** displays follower. The Grafana expression issue has been fixed in v3.0.8.

10.1.1.6 6. Ecosystem tools

10.1.1.6.1 6.1 Data Migration

- 6.1.1 TiDB Data Migration (DM) is a migration tool that supports data migration from MySQL/MariaDB into TiDB. For details, see DM overview.
- 6.1.2 `Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you run `query status` or check the log.
  - The database related passwords in all the DM configuration files should be encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt the password. Cleartext passwords can be used since v1.0.6.
  - During DM operation, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data replication task.

    - To deploy different versions of DM-worker/DM-master/dmctl in a DM cluster, see the case study on AskTUG in Chinese.

- 6.1.3 A replication task is interrupted with the `driver: bad connection` error returned.

    - The `driver: bad connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure and TiDB restart), and that the data of the current request has not yet been sent to TiDB.
        - For versions earlier than DM 1.0.0 GA, stop the task by running `stop-task` and then restart the task by running `start-task`.
        - For DM 1.0.0 GA or later versions, an automatic retry mechanism for this type of error is added. See #265.

- 6.1.4 A replication task is interrupted with the `invalid connection` error.

    - The `invalid connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, and TiKV busy), and that a part of the data for the current request has been sent to TiDB. Because DM has the feature of concurrently replicating data to the downstream in replication tasks, several errors might occur when a task is interrupted. You can check these errors by running `query-status` or `query-error`.
        - If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
        - If DM does not retry or fails to retry automatically because of version problems (automatic retry is introduced in v1.0.0-rc.1), use `stop-task` to stop the task and then use `start-task` to restart the task.

- 6.1.5 The relay unit reports the error `event from * in * diff from passed-in` ↪ `event *`, or a replication task is interrupted with an error that fails to get or parse binlog, such as `get binlog error ERROR 1236 (HY000)and binlog checksum` ↪ `mismatch, data may be corrupted returned`

    - During the process that DM pulls relay log or the incremental replication, this two errors might occur if the size of the upstream binlog file exceeds 4 GB.
    - Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the binlog file size, and store the replicated binlog positions as checkpoints. However, the official MySQL uses uint32 to store binlog positions, which means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.
    - Solution:
        - For relay processing units, manually recover replication.

    - For binlog replication processing units, manually recover replication.

- 6.1.6 The DM replication is interrupted, and the log returns `ERROR 1236 (HY000) ↪ The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION ↪ = 1, but the master has purged binary logs containing GTIDs that the ↪ slave requires.`

    - Check whether the master binlog is purged.
    - Check the position information recorded in `relay.meta`.
        - `relay.meta` has recorded the empty GTID information. DM-worker saves the GTID information in memory to `relay.meta` when it exits or in every 30s. When DM-worker does not obtain the upstream GTID information, it saves the empty GTID information to `relay.meta`. See case-772 in Chinese.
        - The binlog event recorded in `relay.meta` triggers the incomplete recover process and records the wrong GTID information. This issue is fixed in v1.0.2, and might occur in earlier versions.

- 6.1.7 The DM replication process returns an error `Error 1366: incorrect utf8 ↪ value eda0bdedb29d(\ufffd\ufffd\ufffd\ufffd\ufffd\ufffd)`.

    - This value cannot be successfully written into MySQL 8.0 or TiDB, but can be written into MySQL 5.7. You can skip the data format check by enabling the `tidb_skip_utf8_check` parameter.

10.1.1.6.2 6.2 TiDB Lightning

- 6.2.1 TiDB Lightning is a tool for fast full import of large amounts of data into a TiDB cluster. See TiDB Lightning on GitHub.

- 6.2.2 Import speed is too slow.

    - `region-concurrency` is set too high, which causes thread contention and reduces performance. Three ways to troubleshoot:
        - The setting can be found from the start of the log by searching `region- ↪ concurrency`.
        - If TiDB Lightning shares a server with other services (for example, Importer), you must manually set `region-concurrency` to 75% of the total number of CPU cores on that server.
        - If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning might not be able to read this out. In this case, `region- ↪ concurrency` must also be manually reduced.

- Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Dumpling output. If the indices are negligible, you may first remove them from the schema, and add them back via `CREATE INDEX` after the import is complete.
- The version of TiDB Lightning is old. Try the latest version, which might improve the import speed.

- 6.2.3 `checksum failed: checksum mismatched remote vs local`.
  - Cause 1: The table might already have data. These old data can affect the final checksum.
  - Cause 2: If the checksum of the target database is 0, which means nothing is imported, it is possible that the cluster is too hot and fails to take in any data.
  - Cause 3: If the data source is generated by the machine and not backed up by Dumpling, ensure it respects the constrains of the table. For example:
    - `AUTO_INCREMENT` columns need to be positive, and do not contain the value "0".
    - UNIQUE and PRIMARY KEYs must not have duplicate entries.
  - Solution: See Troubleshooting Solution.

- 6.2.4 `Checkpoint for ··· has invalid status:(error code)`
  - Cause: Checkpoint is enabled, and Lightning/Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed. The error code is an integer less than 25, with possible values as `0, 3, 6, 9, 12, 14, 15, 17, 18, 20 and 21`. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later the exit occurs.
  - Solution: See Troubleshooting Solution.

- 6.2.5 `cannot guess encoding for input file, please convert to UTF-8 manually`
  - Cause: TiDB Lightning only supports the UTF-8 and GB-18030 encodings. This error means the file is not in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical ALTER TABLE executions.
  - Solution: See Troubleshooting Solution.

- 6.2.6 `[sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 0 45 0 0}'`

- Cause: A timestamp type entry has a time value that does not exist. This is either because of DST changes or because the time value has exceeded the supported range (from Jan 1, 1970 to Jan 19, 2038).
- Solution: See Troubleshooting Solution.

10.1.1.7 7. Common log analysis

10.1.1.7.1 7.1 TiDB

- 7.1.1 `GC life time is shorter than transaction duration`.

  The transaction duration exceeds the GC lifetime (10 minutes by default).

  You can increase the GC lifetime by modifying the `tidb_gc_life_time` system variable. Generally, it is not recommended to modify this parameter, because changing it might cause many old versions to pile up if this transaction has a large number of `UPDATE` and `DELETE` statements.

- 7.1.2 `txn takes too much time`.

  This error is returned when you commit a transaction that has not been committed for a long time (over 590 seconds).

  If your application needs to execute a transaction of such a long time, you can increase the `[tikv-client] max-txn-time-use = 590` parameter and the GC lifetime to avoid this issue. It is recommended to check whether your application needs such a long transaction time.

- 7.1.3 `coprocessor.go` reports `request outdated`.

  This error is returned when the coprocessor request sent to TiKV waits in a queue at TiKV for over 60 seconds.

  You need to investigate why the TiKV coprocessor is in a long queue.

- 7.1.4 `region_cache.go` reports a large number of `switch region peer to next due to send request fail`, and the error message is `context deadline exceeded`.

  The request for TiKV timed out and triggers the region cache to switch the request to other nodes. You can continue to run the `grep "<addr> cancelled` command on the `addr` field in the log and take the following steps according to the `grep` results:

  - `send request is cancelled`: The request timed out during the sending phase. You can investigate the monitoring **Grafana** -> **TiDB** -> **Batch Client**/`Pending Request Count by TiKV` and see whether the Pending Request Count is greater than 128:
    - If the value is greater than 128, the sending goes beyond the processing capacity of KV, so the sending piles up.

    - If the value is not greater than 128, check the log to see if the report is caused by the operation and maintenance changes of the corresponding KV; otherwise, this error is unexpected, and you need to report a bug.
  - `wait response is cancelled`: The request timed out after it is sent to TiKV. You need to check the response time of the corresponding TiKV address and the Region logs in PD and KV at that time.

- 7.1.5 `distsql.go` reports `inconsistent index`.

  The data index seems to be inconsistent. Run the `admin check table <TableName>` command on the table where the reported index is. If the check fails, disable garbage collection by running the following command, and report a bug:

```
SET GLOBAL tidb_gc_enable = 0;
```

10.1.1.7.2 7.2 TiKV

- 7.2.1 `key is locked`.

  The read and write have conflict. The read request encounters data that has not been committed and needs to wait until the data is committed.

  A small number of this error has no impact on the business, but a large number of this error indicates that the read-write conflict is severe in your business.

- 7.2.2 `write conflict`.

  This is the write-write conflict in optimistic transactions. If multiple transactions modify the same key, only one transaction succeed and other transactions automatically obtain the timestamp again and retry the operation, with no impact on the business.

  If the conflict is severe, it might cause transaction failure after multiple retries. In this case, it is recommended to use the pessimistic lock. For more details about the error and the solution, see Troubleshoot Write Conflicts in Optimistic Transactions.

- 7.2.3 `TxnLockNotFound`.

  This transaction commit is too slow, causing it to be rolled back by other transactions after Time To Live (TTL). This transaction will automatically retry, so the business is usually not affected. For a transaction with a size of 0.25 MB or smaller, the default TTL is 3 seconds. For more details, see the `LockNotFound` error.

- 7.2.4 `PessimisticLockNotFound`.

  Similar to `TxnLockNotFound`. The pessimistic transaction commit is too slow and thus rolled back by other transactions.

- 7.2.5 `stale_epoch`.

  The request epoch is outdated, so TiDB re-sends the request after updating the routing. The business is not affected. Epoch changes when Region has a split/merge operation or a replica is migrated.

- 7.2.6 `peer is not leader`.

  The request is sent to a replica that is not Leader. If the error response indicates which replica is the latest Leader, TiDB updates the local routing according the error and sends a new request to the latest Leader. Usually, the business is not affected.

  In v3.0 and later versions, TiDB tries other peers if the request to the previous Leader fails, which might lead to frequent `peer is not leader` in TiKV log. You can check the `switch region peer to next due to send request fail` log of the corresponding Region in TiDB to determine the root cause of the sending failure. For details, refer to 7.1.4.

  This error might also be returned if a Region has no Leader due to other reasons. For details, see 4.4.

10.1.2 TiDB Cluster Troubleshooting Guide

You can use this guide to help you diagnose and solve basic problems while using TiDB. If your problem is not resolved, please collect the following information and you can report a bug:

- The exact error message and the operations while the error occurs
- The state of all the components
- The `error/fatal/panic` information in the log of the component that reports the error
- The configuration and deployment topology
- The TiDB component related issue in `dmesg`

For other information, see Frequently Asked Questions (FAQ).

10.1.2.1 Cannot connect to the database

1. Make sure all the services are started, including `tidb-server`, `pd-server`, and `tikv-server`.
2. Use the `ps` command to check if all the processes are running.
   - If a certain process is not running, see the following corresponding sections to diagnose and solve the issue.
   - If all the processes are running, check the `tidb-server` log to see if the following messages are displayed:
     - InformationSchema is out of date: This message is displayed if the `tikv-server` cannot be connected. Check the state and log of `pd-server` and `tikv-server`.
     - panic: This message is displayed if there is an issue with the program. Please provide the detailed panic log and you can report a bug.

3. If the data is cleared and the services are re-deployed, make sure that:

    - All the data in `tikv-server` and `pd-server` are cleared. The specific data is stored in `tikv-server` and the metadata is stored in `pd-server`. If only one of the two servers is cleared, the data will be inconsistent.
    - After the data in `pd-server` and `tikv-server` are cleared and the `pd-server` and `tikv-server` are restarted, the `tidb-server` must be restarted too. The cluster ID is randomly allocated when the `pd-server` is initialized. So when the cluster is re-deployed, the cluster ID changes and you need to restart the `tidb-server` to get the new cluster ID.

10.1.2.2 Cannot start `tidb-server`

See the following for the situations when the `tidb-server` cannot be started:

- Error in the startup parameters.

  See the TiDB configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tidb-server` is not occupied.

- Cannot connect to `pd-server`.

    - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
    - If there is no issue with the network, check the state and log of the `pd-server` process.

10.1.2.3 Cannot start `tikv-server`

See the following for the situations when the `tikv-server` cannot be started:

- Error in the startup parameters: See the TiKV configuration and options.
- The port is occupied: Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tikv-server` is not occupied.
- Cannot connect to `pd-server`.

    - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
    - If there is no issue with the network, check the state and log of the `pd-server` process.

- The file is occupied.

  Do not open two TiKV files on one database file directory.

10.1.2.4 Cannot start `pd-server`

See the following for the situations when the `pd-server` cannot be started:

- Error in the startup parameters.

  See the PD configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `pd-server` is not occupied.

10.1.2.5 The TiDB/TiKV/PD process aborts unexpectedly

- Is the process started on the foreground? The process might exit because the client aborts.
- Is `nohup+&` run in the command line? This might cause the process to abort because it receives the hup signal. It is recommended to write and run the startup command in a script.

10.1.2.6 TiDB panic

Please provide the panic log and you can report a bug.

10.1.2.7 The connection is rejected

Make sure the network parameters of the operating system are correct, including but not limited to:

- The port in the connection string is consistent with the `tidb-server` starting port.
- The firewall is configured correctly.

10.1.2.8 Open too many files

Before starting the process, make sure the result of `ulimit -n` is large enough. It is recommended to set the value to `unlimited` or larger than `1000000`.

10.1.2.9 Database access times out and the system load is too high

First, check the slow query log and see if it is because of some inappropriate SQL statement.

If you failed to solve the problem, provide the following information:

- The deployment topology
    - How many `tidb-server`/`pd-server`/`tikv-server` instances are deployed?
    - How are these instances distributed in the machines?
- The hardware configuration of the machines where these instances are deployed:
    - The number of CPU cores
    - The size of the memory
    - The type of the disk (SSD or Hard Drive Disk)
    - Are they physical machines or virtual machines?
- Are there other services besides the TiDB cluster?
- Are the `pd-server`s and `tikv-server`s deployed separately?
- What is the current operation?
- Check the CPU thread name using the `top -H` command.
- Are there any exceptions in the network or IO monitoring data recently?

10.1.3 Troubleshoot a TiFlash Cluster

This section describes some commonly encountered issues when using TiFlash, the reasons, and the solutions.

10.1.3.1 TiFlash fails to start

The issue might occur due to different reasons. It is recommended that you troubleshoot it following the steps below:

1. Check whether your system is RedHat Enterprise Linux 8.

   RedHat Enterprise Linux 8 does not have the `libnsl.so` system library. You can manually install it via the following command:

   ```
   dnf install libnsl
   ```

2. Check your system's `ulimit` parameter setting.

   ```
   ulimit -n 1000000
   ```

3. Use the PD Control tool to check whether there is any TiFlash instance that failed to go offline on the node (same IP and Port) and force the instance(s) to go offline. For detailed steps, refer to Scale in a TiFlash cluster.

If the above methods cannot resolve your issue, save the TiFlash log files and get support from PingCAP or the community.

10.1.3.2 TiFlash replica is always unavailable

This is because TiFlash is in an abnormal state caused by configuration errors or environment issues. Take the following steps to identify the faulty component:

1. Check whether PD enables the `Placement Rules` feature:

```
echo 'config show replication' | /path/to/pd-ctl -u http://${pd-ip}:${
    ↪ pd-port}
```

   - If `true` is returned, go to the next step.
   - If `false` is returned, enable the Placement Rules feature and go to the next step.

2. Check whether the TiFlash process is working correctly by viewing `UpTime` on the TiFlash-Summary monitoring panel.

3. Check whether the TiFlash proxy status is normal through `pd-ctl`.

```
tiup ctl:nightly pd -u http://${pd-ip}:${pd-port} store
```

   The TiFlash proxy's `store.labels` includes information such as `{"key": "engine ↪ ", "value": "tiflash"}`. You can check this information to confirm a TiFlash proxy.

4. Check whether the number of configured replicas is less than or equal to the number of TiKV nodes in the cluster. If not, PD cannot replicate data to TiFlash.

```
tiup ctl:nightly pd -u http://${pd-ip}:${pd-port} config placement-
    ↪ rules show | grep -C 10 default
```

   Reconfirm the value of `default: count`.

> **Note:**
>
> - When Placement Rules are enabled and multiple rules exist, the previously configured `max-replicas`, `location-labels`, and `isolation-level` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.

- When Placement Rules are enabled and only one default rule exists, TiDB will automatically update this default rule when `max-replicas`, `location-labels`, or `isolation-level` configurations are changed.

5. Check whether the remaining disk space of the machine (where `store` of the TiFlash node is) is sufficient. By default, when the remaining disk space is less than 20% of the `store` capacity (which is controlled by the `low-space-ratio` parameter), PD cannot schedule data to this TiFlash node.

10.1.3.3 Some queries return the `Region Unavailable` error

If the load pressure on TiFlash is too heavy and it causes that TiFlash data replication falls behind, some queries might return the `Region Unavailable` error.

In this case, you can balance the load pressure by adding more TiFlash nodes.

10.1.3.4 Data file corruption

Take the following steps to handle the data file corruption:

1. Refer to Take a TiFlash node down to take the corresponding TiFlash node down.
2. Delete the related data of the TiFlash node.
3. Redeploy the TiFlash node in the cluster.

10.1.3.5 Removing TiFlash nodes is slow

Take the following steps to handle this issue:

1. Check whether any table has more TiFlash replicas than the number of TiFlash nodes available after the cluster scale-in:

```
SELECT * FROM information_schema.tiflash_replica WHERE REPLICA_COUNT >
    ↪  'tobe_left_nodes';
```

`tobe_left_nodes` is the number of TiFlash nodes after the scale-in.

If the query result is not empty, you need to modify the number of TiFlash replicas for the corresponding tables. This is because, when the number of TiFlash replicas exceeds the number of TiFlash nodes after the scale-in, PD will not move Region peers away from the TiFlash nodes to be removed, causing the removal of these TiFlash nodes to fail.

2. In scenarios where all TiFlash nodes need to be removed from a cluster, if the `INFORMATION_SCHEMA.TIFLASH_REPLICA` table shows that there are no TiFlash replicas in the cluster but removing TiFlash nodes still fails, check whether you have recently executed `DROP TABLE <db-name>.<table-name>` or `DROP DATABASE <db-name>` operations.

   For tables or databases with TiFlash replicas, after executing `DROP TABLE <db-name>.<table-name>` or `DROP DATABASE <db-name>`, TiDB does not immediately delete the TiFlash replication rules for the corresponding tables in PD. Instead, it waits until the corresponding tables meet the garbage collection (GC) conditions before deleting these replication rules. After GC is complete, the corresponding TiFlash nodes can be successfully removed.

   To remove data replication rules of TiFlash manually before the GC conditions are met, you can do the following:

> **Note:**
>
> After manually removing TiFlash replication rules for a table, if you perform `RECOVER TABLE`, `FLASHBACK TABLE`, or `FLASHBACK DATABASE` operations on this table, the TiFlash replicas of this table will not be restored.

1. View all data replication rules related to TiFlash in the current PD instance:

```
curl http://<pd_ip>:<pd_port>/pd/api/v1/config/rules/group/tiflash
```

```
[
  {
    "group_id": "tiflash",
    "id": "table-45-r",
    "override": true,
    "start_key": "7480000000000000FF2D5F720000000000FA",
    "end_key": "7480000000000000FF2E00000000000000F8",
    "role": "learner",
    "count": 1,
    "label_constraints": [
      {
        "key": "engine",
        "op": "in",
        "values": [
          "tiflash"
        ]
      }
    ]
  }
]
```

2. Remove all data replication rules related to TiFlash. Take the rule whose `id` is `table-45-r` as an example. Delete it by the following command:

```
curl -v -X DELETE http://<pd_ip>:<pd_port>/pd/api/v1/config/rule/
    ↪ tiflash/table-45-r
```

10.1.3.6 TiFlash analysis is slow

If a statement contains operators or functions not supported in the MPP mode, TiDB does not select the MPP mode. Therefore, the analysis of the statement is slow. In this case, you can execute the `EXPLAIN` statement to check for operators or functions not supported in the MPP mode.

```
create table t(a datetime);
alter table t set tiflash replica 1;
insert into t values('2022-01-13');
set @@session.tidb_enforce_mpp=1;
explain select count(*) from t where subtime(a, '12:00:00') > '2022-01-01'
    ↪ group by a;
show warnings;
```

In this example, the warning message shows that TiDB does not select the MPP mode because TiDB 5.4 and earlier versions do not support the `subtime` function.

```
+---------+------+-----------------------------------------------------------------------
    ↪
> | Level   | Code | Message
    ↪                                                                  |
+---------+------+-----------------------------------------------------------------------
    ↪
| Warning | 1105 | Scalar function 'subtime'(signature: SubDatetimeAndString
    ↪ , return type: datetime) is not supported to push down to tiflash now
    ↪ . |
+---------+------+-----------------------------------------------------------------------
    ↪
```

10.1.3.7 Data is not replicated to TiFlash

After deploying a TiFlash node and starting replication (by performing the ALTER operation), no data is replicated to it. In this case, you can identify and address the problem by following the steps below:

1. Check whether the replication is successful by running the `ALTER table <tbl_name>
    ↪ set tiflash replica <num>` command and check the output.

    - If there is output, go to the next step.

- If there is no output, run the `SELECT * FROM information_schema.tiflash_replica` command to check whether TiFlash replicas have been created. If not, run the `ALTER table ${tbl_name} set tiflash replica ${num}` command again, check whether other statements (for example, `add index`) have been executed, or check whether DDL executions are successful.

2. Check whether TiFlash Region replication runs correctly.

Check whether there is any change in `progress`:

- If yes, TiFlash replication runs correctly.
- If no, TiFlash replication is abnormal. In `tidb.log`, search the log saying `Tiflash replica is not available`. Check whether `progress` of the corresponding table is updated. If not, check the `tiflash log` for further information. For example, search `lag_region_info` in `tiflash log` to find out which Region lags behind.

3. Check whether the Placement Rules function has been enabled by using pd-ctl:

```
echo 'config show replication' | /path/to/pd-ctl -u http://<pd-ip>:<pd-port>
```

- If `true` is returned, go to the next step.
- If `false` is returned, enable the Placement Rules feature and go to the next step.

4. Check whether the `max-replicas` configuration is correct:

- If the value of `max-replicas` does not exceed the number of TiKV nodes in the cluster, go to the next step.
- If the value of `max-replicas` is greater than the number of TiKV nodes in the cluster, the PD does not replicate data to the TiFlash node. To address this issue, change `max-replicas` to an integer fewer than or equal to the number of TiKV nodes in the cluster.

> **Note:**
>
> `max-replicas` is defaulted to 3. In production environments, the value is usually fewer than the number of TiKV nodes. In test environments, the value can be 1.

```
curl -X POST -d '{
    "group_id": "pd",
    "id": "default",
    "start_key": "",
    "end_key": "",
```

```
    "role": "voter",
    "count": 3,
    "location_labels": [
    "host"
    ]
}' <http://172.16.x.xxx:2379/pd/api/v1/config/rule>
```

5. Check whether TiDB has created any placement rule for tables.

   Search the logs of TiDB DDL Owner and check whether TiDB has notified PD to add placement rules. For non-partitioned tables, search `ConfigureTiFlashPDForTable`. For partitioned tables, search `ConfigureTiFlashPDForPartitions`.

   - If the keyword is found, go to the next step.
   - If not, collect logs of the corresponding component for troubleshooting.

6. Check whether PD has configured any placement rule for tables.

   Run the `curl http://<pd-ip>:<pd-port>/pd/api/v1/config/rules/group/tiflash` command to view all TiFlash placement rules on the current PD. If a rule with the ID being `table-<table_id>-r` is found, the PD has configured a placement rule successfully.

7. Check whether the PD schedules properly.

   Search the `pd.log` file for the `table-<table_id>-r` keyword and scheduling behaviors like `add operator`.

   - If the keyword is found, the PD schedules properly.
   - If not, the PD does not schedule properly.

10.1.3.8 Data replication gets stuck

If data replication on TiFlash starts normally but then all or some data fails to be replicated after a period of time, you can confirm or resolve the issue by performing the following steps:

1. Check the disk space.

   Check whether the disk space ratio is higher than the value of `low-space-ratio` (defaulted to 0.8. When the space usage of a node exceeds 80%, the PD stops migrating data to this node to avoid exhaustion of disk space).

   - If the disk usage ratio is greater than or equal to the value of `low-space-ratio`, the disk space is insufficient. To relieve the disk space, remove unnecessary files, such as `space_placeholder_file` (if necessary, set `reserve-space` to 0MB after removing the file) under the `${data}/flash/` folder.

- If the disk usage ratio is less than the value of `low-space-ratio`, the disk space is sufficient. Go to the next step.

2. Check whether there is any `down peer` (a `down peer` might cause the replication to get stuck).

   Run the `pd-ctl region check-down-peer` command to check whether there is any `down peer`. If any, run the `pd-ctl operator add remove-peer <region-id> <tiflash-store-id>` command to remove it.

10.1.3.9 Data replication is slow

The causes may vary. You can address the problem by performing the following steps.

1. Increase `store limit` to accelerate replication.

2. Adjust the load on TiFlash.

   Excessively high load on TiFlash can also result in slow replication. You can check the load of TiFlash indicators on the **TiFlash-Summary** panel on Grafana:

   - `Applying snapshots Count`: `TiFlash-summary` > `raft` > `Applying snapshots Count`
   - `Snapshot Predecode Duration`: `TiFlash-summary` > `raft` > `Snapshot Predecode Duration`
   - `Snapshot Flush Duration`: `TiFlash-summary` > `raft` > `Snapshot Flush Duration`
   - `Write Stall Duration`: `TiFlash-summary` > `Storage Write Stall` > `Write Stall Duration`
   - `generate snapshot CPU`: `TiFlash-Proxy-Details` > `Thread CPU` > `Region task worker pre-handle/generate snapshot CPU`

   Based on your service priorities, adjust the load accordingly to achieve optimal performance.

10.2 Issue Scenarios

10.2.1 Slow Queries

10.2.1.1 Identify Slow Queries

To help users identify slow queries, analyze and improve the performance of SQL execution, TiDB outputs the statements whose execution time exceeds `tidb_slow_log_threshold` (The default value is 300 milliseconds) to slow-query-file (The default value is "tidb-slow.log").

TiDB enables the slow query log by default. You can enable or disable the feature by modifying the system variable `tidb_enable_slow_log`.

10.2.1.1.1 Usage example

```
#### Time: 2019-08-14T09:26:59.487776265+08:00

10.2.1.1.2 Fields description

> **Note:**
>
> The unit of all the following time fields in the slow query log is **"second"**.

Slow query basics:

- `Time`: The print time of log.
- `Query_time`: The execution time of a statement.
- `Parse_time`: The parsing time for the statement.
- `Compile_time`: The duration of the query optimization.
- `Optimize_time`: The time consumed for optimizing the execution plan.
- `Wait_TS`: The waiting time of the statement to get transaction timestamps.
- `Query`: A SQL statement. `Query` is not printed in the slow log, but the corresponding field is called `Query` after the slow log is mapped to the memory table.
- `Digest`: The fingerprint of the SQL statement.
- `Txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `Is_internal`: Whether a SQL statement is TiDB internal. `true` indicates that a SQL statement is executed internally in TiDB and `false` indicates that a SQL statement is executed by the user.
- `Index_names`: The index names used by the statement.
- `Stats`: The health state, internal version, total row count, modified row count, and load state of statistics that are used during this query. `pseudo` indicates that the statistics information is unhealthy. If the optimizer attempts to use some statistics that are not fully loaded, the internal state is also printed. For example, the meaning of `t1:439478225786634241[105000;5000][col1:allEvicted][idx1:allEvicted]` can be understood as follows:
  - `t1`: statistics on table `t1` are used during query optimization.
  - `439478225786634241`: the internal version.
  - `105000`: the total row count in the statistics.
  - `5000`: the number of rows modified since the last statistics collection.
  - `col1:allEvicted`: statistics on the column `col1` are not fully loaded.
  - `idx1:allEvicted`: statistics on the index `idx1` are not fully loaded.

- `Succ`: Whether a statement is executed successfully.
- `Backoff_time`: The waiting time before retry when a statement encounters errors that require a retry. The common errors as such include: `lock occurs`, `Region split`, and `tikv server is busy`.
- `Plan`: The execution plan of a statement. Execute the `SELECT tidb_decode_plan('xxx...')` statement to parse the specific execution plan.
- `Binary_plan`: The execution plan of a binary-encoded statement. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan. The `Plan` and `Binary_plan` fields carry the same information. However, the format of execution plans parsed from the two fields are different.
- `Prepared`: Whether this statement is a `Prepare` or `Execute` request or not.
- `Plan_from_cache`: Whether this statement hits the execution plan cache.
- `Plan_from_binding`: Whether this statement uses the bound execution plans.
- `Has_more_results`: Whether this statement has more results to be fetched by users.
- `Rewrite_time`: The time consumed for rewriting the query of this statement.
- `Preproc_subqueries`: The number of subqueries (in the statement) that are executed in advance. For example, the `where id in (select if from t)` subquery might be executed in advance.
- `Preproc_subqueries_time`: The time consumed for executing the subquery of this statement in advance.
- `Exec_retry_count`: The retry times of this statement. This field is usually for pessimistic transactions in which the statement is retried when the lock is failed.
- `Exec_retry_time`: The execution retry duration of this statement. For example, if a statement has been executed three times in total (failed for the first two times), `Exec_retry_time` means the total duration of the first two executions. The duration of the last execution is `Query_time` minus `Exec_retry_time`.
- `KV_total`: The time spent on all the RPC requests on TiKV or TiFlash by this statement.
- `PD_total`: The time spent on all the RPC requests on PD by this statement.
- `Backoff_total`: The time spent on all the backoff during the execution of this statement.
- `Write_sql_response_total`: The time consumed for sending the results back to the client by this statement.
- `Result_rows`: The row count of the query results.
- `IsExplicitTxn`: Whether this statement is in an explicit transaction. If the value is `false`, the transaction is `autocommit=1` and the statement is automatically committed after execution.
- `Warnings`: The JSON-formatted warnings that are generated during the execution of this statement. These warnings are generally consistent with the output of the `SHOW WARNINGS` statement, but might include extra warnings that provide more diagnostic information. These extra warnings are marked as `IsExtra: true`.

The following fields are related to transaction execution:

- `Prewrite_time`: The duration of the first phase (prewrite) of the two-phase transaction

commit.
- `Commit_time`: The duration of the second phase (commit) of the two-phase transaction commit.
- `Get_commit_ts_time`: The time spent on getting `commit_ts` during the second phase (commit) of the two-phase transaction commit.
- `Local_latch_wait_time`: The time that TiDB spends on waiting for the lock before the second phase (commit) of the two-phase transaction commit.
- `Write_keys`: The count of keys that the transaction writes to the Write CF in TiKV.
- `Write_size`: The total size of the keys or values to be written when the transaction commits.
- `Prewrite_region`: The number of TiKV Regions involved in the first phase (prewrite) of the two-phase transaction commit. Each Region triggers a remote procedure call.
- `Wait_prewrite_binlog_time`: The time used to write binlogs when a transaction is committed. Starting from v8.4.0, TiDB Binlog is removed, and this field has no value.
- `Resolve_lock_time`: The time to resolve or wait for the lock to be expired after a lock is encountered during a transaction commit.

Memory usage fields:

- `Mem_max`: The maximum memory space used during the execution period of a SQL statement (the unit is byte).

Hard disk fields:

- `Disk_max`: The maximum disk space used during the execution period of a SQL statement (the unit is byte).

User fields:

- `User`: The name of the user who executes this statement.
- `Host`: The host name of this statement.
- `Conn_ID`: The Connection ID (session ID). For example, you can use the keyword `con:3` to search for the log whose session ID is `3`.
- `DB`: The current database.

TiKV Coprocessor Task fields:

- `Request_count`: The number of Coprocessor requests that a statement sends.
- `Total_keys`: The number of keys that Coprocessor has scanned.
- `Process_time`: The total processing time of a SQL statement in TiKV. Because data is sent to TiKV concurrently, this value might exceed `Query_time`.

- `Wait_time`: The total waiting time of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `Process_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `Num_cop_tasks`: The number of Coprocessor tasks sent by this statement.
- `Cop_proc_avg`: The average execution time of cop-tasks, including some waiting time that cannot be counted, such as the mutex in RocksDB.
- `Cop_proc_p90`: The P90 execution time of cop-tasks.
- `Cop_proc_max`: The maximum execution time of cop-tasks.
- `Cop_proc_addr`: The address of the cop-task with the longest execution time.
- `Cop_wait_avg`: The average waiting time of cop-tasks, including the time of request queueing and getting snapshots.
- `Cop_wait_p90`: The P90 waiting time of cop-tasks.
- `Cop_wait_max`: The maximum waiting time of cop-tasks.
- `Cop_wait_addr`: The address of the cop-task whose waiting time is the longest.
- `Rocksdb_delete_skipped_count`: The number of deleted (tombstone) keys that RocksDB encounters when scanning data.
- `Rocksdb_key_skipped_count`: The number of all keys that RocksDB encounters when scanning data.
- `Rocksdb_block_cache_hit_count`: The number of times RocksDB reads data from the block cache.
- `Rocksdb_block_read_count`: The number of times RocksDB reads data from the file system.
- `Rocksdb_block_read_byte`: The amount of data RocksDB reads from the file system.
- `Rocksdb_block_read_time`: The time RocksDB takes to read data from the file system.
- `Cop_backoff_{backoff-type}_total_times`: The total times of backoff caused by an error.
- `Cop_backoff_{backoff-type}_total_time`: The total time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_time`: The longest time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_addr`: The address of the cop-task that has the longest backoff time caused by an error.
- `Cop_backoff_{backoff-type}_avg_time`: The average time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_p90_time`: The P90 percentile backoff time caused by an error.

`backoff-type` generally includes the following types:

- `tikvRPC`: The backoff caused by failing to send RPC requests to TiKV.
- `tiflashRPC`: The backoff caused by failing to send RPC requests to TiFlash.
- `pdRPC`: The backoff caused by failing to send RPC requests to PD.
- `txnLock`: The backoff caused by lock conflicts.
- `regionMiss`: The backoff caused by that processing requests fails when the TiDB Region cache information is outdated after Regions are split or merged.
- `regionScheduling`: The backoff caused by that TiDB cannot process requests when Regions are being scheduled and the Leader is not selected.
- `tikvServerBusy`: The backoff caused by that the TiKV load is too high to handle new requests.
- `tiflashServerBusy`: The backoff caused by that the TiFlash load is too high to handle new requests.
- `tikvDiskFull`: The backoff caused by that the TiKV disk is full.
- `txnLockFast`: The backoff caused by that locks are encountered during data reads.

Fields related to Resource Control:

- `Resource_group`: the resource group that the statement is bound to.
- `Request_unit_read`: the total read RUs consumed by the statement.
- `Request_unit_write`: the total write RUs consumed by the statement.
- `Time_queued_by_rc`: the total time that the statement waits for available resources.

10.2.1.1.3 Related system variables

- `tidb_slow_log_threshold`: Sets the threshold for the slow log. The SQL statement whose execution time exceeds this threshold is recorded in the slow log. The default value is 300 (ms).

- `tidb_query_log_max_len`: Sets the maximum length of the SQL statement recorded in the slow log. The default value is 4096 (byte).

- tidb_redact_log: Determines whether to desensitize user data using `?` in the SQL statement recorded in the slow log. The default value is `0`, which means to disable the feature.

- `tidb_enable_collect_execution_info`: Determines whether to record the physical execution information of each operator in the execution plan. The default value is `1`. This feature impacts the performance by approximately 3%. After enabling this feature, you can view the `Plan` information as follows:

```
> select tidb_decode_plan('
    ↪ jAOIMAk1XzE3CTAJMQlmdW5jczpjb3VudChDb2x1bW4jNyktPkMJC/
    ↪ BMNQkxCXRpbWU6MTAuOTMxNTA1bXMsIGxvb3BzOjIJMzcyIEJ5dGVzCU4vQQoxCTMyXzE4CTAJMQl
    ↪ ');
```

    ↪
```

If you are conducting a performance test, you can disable the feature of automatically collecting the execution information of operators:

```
set @@tidb_enable_collect_execution_info=0;
```

The returned result of the `Plan` field has roughly the same format with that of `EXPLAIN` or `EXPLAIN ANALYZE`. For more details of the execution plan, see `EXPLAIN` or `EXPLAIN ANALYZE`.

For more information, see TiDB specific variables and syntax.

10.2.1.1.4 Memory mapping in slow log

You can query the content of the slow query log by querying the `INFORMATION_SCHEMA.` ↪ `SLOW_QUERY` table. Each column name in the table corresponds to one field name in the

slow log. For table structure, see the introduction to the `SLOW_QUERY` table in Information Schema.

> **Note:**
>
> Every time you query the `SLOW_QUERY` table, TiDB reads and parses the current slow query log.

For TiDB 4.0, `SLOW_QUERY` supports querying the slow log of any period of time, including the rotated slow log file. You need to specify the `TIME` range to locate the slow log files that need to be parsed. If you don't specify the `TIME` range, TiDB only parses the current slow log file. For example:

- If you don't specify the time range, TiDB only parses the slow query data that TiDB is writing to the slow log file:

```
select count(*),
     min(time),
     max(time)
from slow_query;
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 122492   | 2020-03-11 23:35:20.908574 | 2020-03-25 19:16:38.229035 |
+----------+----------------------------+----------------------------+
```

- If you specify the time range, for example, from `2020-03-10 00:00:00` to `2020-03-11 00:00:00`, TiDB first locates the slow log files of the specified time range, and then parses the slow query information:

```
select count(*),
     min(time),
     max(time)
from slow_query
where time > '2020-03-10 00:00:00'
  and time < '2020-03-11 00:00:00';
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 2618049  | 2020-03-10 00:00:00.427138 | 2020-03-10 23:00:22.716728 |
+----------+----------------------------+----------------------------+
```

> **Note:**
>
> If the slow log files of the specified time range are removed, or there is no slow query, the query returns NULL.

TiDB 4.0 adds the CLUSTER_SLOW_QUERY system table to query the slow query information of all TiDB nodes. The table schema of the CLUSTER_SLOW_QUERY table differs from that of the SLOW_QUERY table in that an INSTANCE column is added to CLUSTER_SLOW_QUERY. The INSTANCE column represents the TiDB node address of the row information on the slow query. You can use CLUSTER_SLOW_QUERY the way you do with SLOW_QUERY.

When you query the CLUSTER_SLOW_QUERY table, TiDB pushes the computation and the judgment down to other nodes, instead of retrieving all slow query information from other nodes and executing the operations on one TiDB node.

10.2.1.1.5 SLOW_QUERY / CLUSTER_SLOW_QUERY usage examples

Top-N slow queries

Query the Top 2 slow queries of users. Is_internal=false means excluding slow queries inside TiDB and only querying slow queries of users.

```
select query_time, query
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 2;
```

Output example:

```
+-------------+-----------------------------------------------------------------+
   ↪
| query_time | query                                                            |
+-------------+-----------------------------------------------------------------+
   ↪
| 12.77583857 | select * from t_slim, t_wide where t_slim.c0=t_wide.c0; |
|  0.734982725 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=
   ↪ t1.c0; |
+-------------+-----------------------------------------------------------------+
   ↪
```

Query the Top-N slow queries of the test user

In the following example, the slow queries executed by the test user are queried, and the first two results are displayed in reverse order of execution time.

```
select query_time, query, user
from information_schema.slow_query
where is_internal = false
  and user = "test"
order by query_time desc
limit 2;
```

Output example:

```
+------------+-------------------------------------------------------------------------+------
   ↪
| Query_time | query                                                                   |
   ↪ user         |
+------------+-------------------------------------------------------------------------+------
   ↪
| 0.676408014 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1
   ↪ .c1; | test |
+------------+-------------------------------------------------------------------------+------
   ↪
```

Query similar slow queries with the same SQL fingerprints

After querying the Top-N SQL statements, continue to query similar slow queries using the same fingerprints.

1. Acquire Top-N slow queries and the corresponding SQL fingerprints.

```
select query_time, query, digest
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 1;
```

Output example:

```
+-------------+-----------------------------+-----------------------------------
   ↪
| query_time | query                       | digest
   ↪                                                    |
+-------------+-----------------------------+-----------------------------------
   ↪
| 0.302558006 | select * from t1 where a=1; | 4751
   ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa |
+-------------+-----------------------------+-----------------------------------
   ↪
```

2. Query similar slow queries with the fingerprints.

```
select query, query_time
from information_schema.slow_query
where digest = "4751
    ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa";
```

Output example:

```
+-----------------------------+-------------+
| query                       | query_time |
+-----------------------------+-------------+
| select * from t1 where a=1; | 0.302558006 |
| select * from t1 where a=2; | 0.401313532 |
+-----------------------------+-------------+
```

10.2.1.1.6 Query slow queries with pseudo stats

```
select query, query_time, stats
from information_schema.slow_query
where is_internal = false
  and stats like '%pseudo%';
```

Output example:

```
+-----------------------------+-------------+---------------------------------+
    ↪
| query                       | query_time | stats                           |
+-----------------------------+-------------+---------------------------------+
    ↪
| select * from t1 where a=1; | 0.302558006 | t1:pseudo                       |
| select * from t1 where a=2; | 0.401313532 | t1:pseudo                       |
| select * from t1 where a>2; | 0.602011247 | t1:pseudo                       |
| select * from t1 where a>3; | 0.50077719 | t1:pseudo                        |
| select * from t1 join t2; | 0.931260518 | t1:407872303825682445,t2:pseudo
    ↪ |
+-----------------------------+-------------+---------------------------------+
    ↪
```

Query slow queries whose execution plan is changed

When the execution plan of SQL statements of the same category is changed, the execution slows down, because the statistics is outdated, or the statistics is not accurate enough to reflect the real data distribution. You can use the following SQL statement to query SQL statements with different execution plans.

```
select count(distinct plan_digest) as count,
      digest,
      min(query)
from cluster_slow_query
group by digest
having count > 1
limit 3\G
```

Output example:

```
***************************[ 1. row ]***************************
count     | 2
digest    | 17b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94
min(query) | SELECT DISTINCT c FROM sbtest25 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (291638, 291737)];
***************************[ 2. row ]***************************
count     | 2
digest    | 9337865f3e2ee71c1c2e740e773b6dd85f23ad00f8fa1f11a795e62e15fc9b23
min(query) | SELECT DISTINCT c FROM sbtest22 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (215420, 215519)];
***************************[ 3. row ]***************************
count     | 2
digest    | db705c89ca2dfc1d39d10e0f30f285cbbadec7e24da4f15af461b148d8ffb020
min(query) | SELECT DISTINCT c FROM sbtest11 WHERE id BETWEEN ? AND ? ORDER
   ↪ BY c [arguments: (303359, 303458)];
```

Then you can query the different plans using the SQL fingerprint in the query result above:

```
select min(plan),
      plan_digest
from cluster_slow_query
where digest='17
   ↪ b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94'
group by plan_digest\G
```

Output example:

```
*************************** 1. row ***************************
 min(plan):  Sort_6               root   100.00131380758702   sbtest.
    ↪ sbtest25.c:asc
      └─HashAgg_10          root   100.00131380758702   group by:sbtest.
        ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
        ↪ .c
        └─TableReader_15    root   100.00131380758702   data:TableRangeScan
          ↪ _14
```

```
            └─TableScan_14    cop    100.00131380758702   table:sbtest25,
              ↪ range:[502791,502890], keep order:false
plan_digest: 6
   ↪ afbbd21f60ca6c6fdf3d3cd94f7c7a49dd93c00fcf8774646da492e50e204ee
*************************** 2. row ***************************
  min(plan):  Sort_6                root   1                    sbtest.
     ↪ sbtest25.c:asc
        └─HashAgg_12          root   1                    group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          └─TableReader_13    root   1                    data:HashAgg_8
            └─HashAgg_8       cop    1                    group by:sbtest.
              ↪ sbtest25.c,
              └─TableScan_11  cop    1.2440069558121831   table:sbtest25,
                ↪ range:[472745,472844], keep order:false
```

Query the number of slow queries for each TiDB node in a cluster

```
select instance, count(*) from information_schema.cluster_slow_query where
   ↪ time >= "2020-03-06 00:00:00" and time < now() group by instance;
```

Output example:

```
+---------------+----------+
| instance      | count(*) |
+---------------+----------+
| 0.0.0.0:10081 | 124      |
| 0.0.0.0:10080 | 119771   |
+---------------+----------+
```

Query slow logs occurring only in abnormal time period

If you find problems such as decreased QPS or increased latency for the time period from `2020-03-10 13:24:00` to `2020-03-10 13:27:00`, the reason might be that a large query crops up. Run the following SQL statement to query slow logs that occur only in abnormal time period. The time range from `2020-03-10 13:20:00` to `2020-03-10 13:23:00` refers to the normal time period.

```
SELECT * FROM
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ count(*),
        min(time),
        sum(query_time) AS sum_query_time,
        sum(Process_time) AS sum_process_time,
        sum(Wait_time) AS sum_wait_time,
        sum(Commit_time),
        sum(Request_count),
        sum(process_keys),
```

```
        sum(Write_keys),
        max(Cop_proc_max),
        min(query),min(prev_stmt),
        digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:24:00'
           AND time < '2020-03-10 13:27:00'
           AND Is_internal = false
    GROUP BY digest) AS t1
WHERE t1.digest NOT IN
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:20:00'
           AND time < '2020-03-10 13:23:00'
    GROUP BY digest)
ORDER BY t1.sum_query_time DESC limit 10\G
```

Output example:

```
***************************[ 1. row ]***************************
count(*)          | 200
min(time)         | 2020-03-10 13:24:27.216186
sum_query_time    | 50.114126194
sum_process_time | 268.351
sum_wait_time     | 8.476
sum(Commit_time) | 1.044304306
sum(Request_count) | 6077
sum(process_keys) | 202871950
sum(Write_keys)  | 319500
max(Cop_proc_max) | 0.263
min(query)        | delete from test.tcs2 limit 5000;
min(prev_stmt)    |
digest            | 24
    ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df
```

Parse other TiDB slow log files

TiDB uses the session variable `tidb_slow_query_file` to control the files to be read and parsed when querying `INFORMATION_SCHEMA.SLOW_QUERY`. You can query the content of other slow query log files by modifying the value of the session variable.

```
set tidb_slow_query_file = "/path-to-log/tidb-slow.log"
```

Parse TiDB slow logs with `pt-query-digest`

Use `pt-query-digest` to parse TiDB slow logs.

Note:

It is recommended to use `pt-query-digest` 3.0.13 or later versions.

For example:

```
pt-query-digest --report tidb-slow.log
```

Output example:

```
#### 320ms user time, 20ms system time, 27.00M rss, 221.32M vsz
#### Current date: Mon Mar 18 13:18:51 2019

```

10.2.1.1.7 Identify problematic SQL statements

Not all of the `SLOW_QUERY` statements are problematic. Only those whose `process_time` is very large increase the pressure on the entire cluster.

The statements whose `wait_time` is very large and `process_time` is very small are usually not problematic. This is because the statement is blocked by real problematic statements and it has to wait in the execution queue, which leads to a much longer response time.

`ADMIN SHOW SLOW` command

In addition to the TiDB log file, you can identify slow queries by running the `ADMIN SHOW SLOW` command:

```
ADMIN SHOW SLOW recent N
ADMIN SHOW SLOW TOP [internal | all] N
```

`recent N` shows the recent N slow query records, for example:

```
ADMIN SHOW SLOW recent 10
```

`top N` shows the slowest N query records recently (within a few days). If the `internal` option is provided, the returned results would be the inner SQL executed by the system; If the `all` option is provided, the returned results would be the user's SQL combined with inner SQL; Otherwise, this command would only return the slow query records from the user's SQL.

```
ADMIN SHOW SLOW top 3
ADMIN SHOW SLOW top internal 3
ADMIN SHOW SLOW top all 5
```

TiDB stores only a limited number of slow query records because of the limited memory. If the value of `N` in the query command is greater than the records count, the number of returned records is smaller than `N`.

The following table shows output details:

Column name	Description
start	The starting time of the SQL execution
duration	The duration of the SQL execution

Column name	Description
details	The details of the SQL execution
succ	Whether the SQL statement is executed successfully. `1` means success and `0` means failure.
conn_id	The connection ID for the session
transaction_ts	The `start_ts` of the transaction

Column name	Description
user	The user name for the execution of the statement
db	The database involved when the statement is executed
table_ids	The ID of the table involved when the SQL statement is executed

Column name	Description
index_ids	The ID of the index involved when the SQL statement is executed
internal	This is a TiDB internal SQL statement
digest	The fingerprint of the SQL statement
sql	The SQL statement that is being executed or has been executed

10.2.1.2 Analyze Slow Queries

To address the issue of slow queries, you need to take the following two steps:

1. Among many queries, identify which type of queries are slow.
2. Analyze why this type of queries are slow.

You can easily perform step 1 using the slow query log and the statement summary table features. It is recommended to use TiDB Dashboard, which integrates the two features and directly displays the slow queries in your browser.

This document focuses on how to perform step 2 - analyze why this type of queries are slow.

Generally, slow queries have the following major causes:

- Optimizer issues, such as wrong index selected, wrong join type or sequence selected.
- System issues. All issues not caused by the optimizer are system issues. For example, a busy TiKV instance processes requests slowly; outdated Region information causes slow queries.

In actual situations, optimizer issues might cause system issues. For example, for a certain type of queries, the optimizer uses a full table scan instead of the index. As a result, the SQL queries consume many resources, which causes the CPU usage of some TiKV instances to soar. This seems like a system issue, but in essence, it is an optimizer issue.

To identify system issues is relatively simple. To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. Therefore, it is recommended to analyze slow queries by following these procedures:

1. Identify the performance bottleneck of the query, that is, the time-consuming part of the query process.
2. Analyze the system issues: analyze the possible causes according to the query bottleneck and the monitoring/log information of that time.
3. Analyze the optimizer issues: analyze whether there is a better execution plan.

The procedures above are explained in the following sections.

10.2.1.2.1 Identify the performance bottleneck of the query

First, you need to have a general understanding of the query process. The key stages of the query execution process in TiDB are illustrated in TiDB performance map.

You can get the duration information using the following methods:

- Slow log. It is recommended to view the slow log in TiDB Dashboard.

- `EXPLAIN ANALYZE` statement.

The methods above are different in the following aspects:

- The slow log records the duration of almost all stages of a SQL execution, from parsing to returning results, and is relatively comprehensive (you can query and analyze the slow log in TiDB Dashboard in an intuitive way).
- By executing `EXPLAIN ANALYZE`, you can learn the time consumption of each operator in an actual SQL execution. The results have more detailed statistics of the execution duration.

In summary, the slow log and `EXPLAIN ANALYZE` statements help you determine the SQL query is slow in which component (TiDB or TiKV) at which stage of the execution. Therefore, you can accurately identify the performance bottleneck of the query.

In addition, since v4.0.3, the `Plan` field in the slow log also includes the SQL execution information, which is the result of `EXPLAIN ANALYZE`. So you can find all information of SQL duration in the slow log.

10.2.1.2.2 Analyze system issues

System issues can be divided into the following types according to different execution stages of a SQL statement:

1. TiKV is slow in data processing. For example, the TiKV coprocessor processes data slowly.
2. TiDB is slow in execution. For example, a `Join` operator processes data slowly.
3. Other key stages are slow. For example, getting the timestamp takes a long time.

For each slow query, first determine to which type the query belongs, and then analyze it in detail.

TiKV is slow in data processing

If TiKV is slow in data processing, you can easily identify it in the result of `EXPLAIN ANALYZE`. In the following example, `StreamAgg_8` and `TableFullScan_15`, two `tikv-tasks` (as indicated by `cop[tikv]` in the `task` column), take `170ms` to execute. After subtracting `170ms`, the execution time of TiDB operators account for a very small proportion of the total execution time. This indicates that the bottleneck is in TiKV.

```
+--
   ↪ -------------------------+---------+---------+-----------+---------------+-----
   ↪
| id                        | estRows | actRows | task  | access object |
   ↪ execution info                                                          |
   ↪ operator info                | memory   | disk |
```

```
+--
   ↪ ------------------------+---------+---------+-----------+---------------+-----
   ↪
| StreamAgg_16            | 1.00    | 1       | root      |               | time
   ↪ :170.08572ms, loops:2                                                    |
   ↪ funcs:count(Column#5)->Column#3 | 372 Bytes | N/A |
|  ─TableReader_17        | 1.00    | 1       | root      |               | time
   ↪ :170.080369ms, loops:2, rpc num: 1, rpc time:17.023347ms, proc keys
   ↪ :28672 | data:StreamAgg_8  | 202 Bytes | N/A |
|    ─StreamAgg_8         | 1.00    | 1       | cop[tikv] |               | time
   ↪ :170ms, loops:29                                                         |
   ↪ funcs:count(1)->Column#5    | N/A       | N/A |
|      ─TableFullScan_15  | 7.00    | 28672   | cop[tikv] | table:t       | time
   ↪ :170ms, loops:29                                                         |
   ↪ keep order:false, stats:pseudo | N/A    | N/A |
+--
   ↪ ------------------------+---------+---------+-----------+---------------+-----
   ↪
```

In addition, the `Cop_process` and `Cop_wait` fields in the slow log can also help your analysis. In the following example, the total duration of the query is around `180.85ms`, and the largest `coptask` takes `171ms`. This indicates that the bottleneck of this query is on the TiKV side.

For the description of each field in the slow log, see fields description.

```
#### Query_time: 0.18085
...
#### Num_cop_tasks: 1
#### Cop_process: Avg_time: 170ms P90_time: 170ms Max_time: 170ms Max_addr:
   ↪ 10.6.131.78
#### Cop_wait: Avg_time: 1ms P90_time: 1ms Max_time: 1ms Max_Addr:
   ↪ 10.6.131.78
```

After identifying that TiKV is the bottleneck, you can find out the cause as described in the following sections.

TiKV instance is busy

During the execution of a SQL statement, TiDB might fetch data from multiple TiKV instances. If one TiKV instance responds slowly, the overall SQL execution speed is slowed down.

The `Cop_wait` field in the slow log can help you determine this cause.

```
#### Cop_wait: Avg_time: 1ms P90_time: 2ms Max_time: 110ms Max_Addr:
   ↪ 10.6.131.78
```

The log above shows that a `cop-task` sent to the `10.6.131.78` instance waits `110ms` ↪ before being executed. It indicates that this instance is busy. You can check the CPU monitoring of that time to confirm the cause.

Obsolete MVCC versions and excessive keys

If too many obsolete MVCC versions exist on TiKV, or if the retention time of historical MVCC data for GC is long, excessive MVCC versions can accumulate. Handling these unnecessary MVCC versions can affect scan performance.

Check `Total_keys` and `Processed_keys`. If they are greatly different, the TiKV instance has too many keys of the older versions.

```
...
#### Total_keys: 2215187529 Processed_keys: 1108056368
...
```

TiDB v8.5.0 introduces the TiKV MVCC in-memory engine (IME) feature, which can accelerate such slow queries. For more information, see TiKV MVCC In-Memory Engine.

Other key stages are slow

Slow in getting timestamps

You can compare `Wait_TS` and `Query_time` in the slow log. The timestamps are prefetched, so generally `Wait_TS` should be low.

```
#### Query_time: 0.0300000
...
#### Wait_TS: 0.02500000
```

Outdated Region information

Region information on the TiDB side might be outdated. In this situation, TiKV might return the `regionMiss` error. Then TiDB gets the Region information from PD again, which is reflected in the `Cop_backoff` information. Both the failed times and the total duration are recorded.

```
#### Cop_backoff_regionMiss_total_times: 200 Cop_backoff_regionMiss_total_
    ↪ time: 0.2 Cop_backoff_regionMiss_max_time: 0.2 Cop_backoff_regionMiss
    ↪ _max_addr: 127.0.0.1 Cop_backoff_regionMiss_avg_time: 0.2 Cop_backoff
    ↪ _regionMiss_p90_time: 0.2
#### Cop_backoff_rpcPD_total_times: 200 Cop_backoff_rpcPD_total_time: 0.2
    ↪ Cop_backoff_rpcPD_max_time: 0.2 Cop_backoff_rpcPD_max_addr: 127.0.0.1
    ↪  Cop_backoff_rpcPD_avg_time: 0.2 Cop_backoff_rpcPD_p90_time: 0.2
```

Subqueries are executed in advance

For statements with non-correlated subqueries, the subquery part might be executed in advance. For example, in `select * from t1 where a = (select max(a)from t2)`, the `select max(a)from t2` part might be executed in advance in the optimization stage. The result of `EXPLAIN ANALYZE` does not show the duration of this type of subqueries.

```
mysql> explain analyze select count(*) from t where a=(select max(t1.a)
    ↪ from t t1, t t2 where t1.a=t2.a);
+--
    ↪ ---------------------------+---------+---------+----------+---------------+--
    ↪
| id                          | estRows | actRows | task    | access object |
    ↪ execution info      | operator info                 | memory   | disk |
+--
    ↪ ---------------------------+---------+---------+----------+---------------+--
    ↪
| StreamAgg_59                | 1.00    | 1       | root     |               | time
    ↪ :4.69267ms, loops:2 | funcs:count(Column#10)->Column#8 | 372 Bytes |
    ↪ N/A |
| └─TableReader_60            | 1.00    | 1       | root     |               |
    ↪ time:4.690428ms, loops:2 | data:StreamAgg_48          | 141 Bytes | N/A
    ↪  |
|   └─StreamAgg_48            | 1.00    |         | cop[tikv] |               |
    ↪ time:0ns, loops:0     | funcs:count(1)->Column#10    | N/A      | N/A
    ↪ |
|     └─Selection_58          | 16384.00 |        | cop[tikv] |               |
    ↪ time:0ns, loops:0     | eq(test.t.a, 1)              | N/A      | N/A
    ↪ |
|       └─TableFullScan_57    | 16384.00 | -1     | cop[tikv] | table:t     |
    ↪ time:0s, loops:0      | keep order:false             | N/A      | N/A
    ↪ |
+--
    ↪ ---------------------------+---------+---------+----------+---------------+--
    ↪
5 rows in set (7.77 sec)
```

But you can identify this type of subquery execution in the slow log:

```
#### Query_time: 7.770634843
...
#### Rewrite_time: 7.765673663 Preproc_subqueries: 1 Preproc_subqueries_time
    ↪ : 7.765231874
```

From log record above, you can see that a subquery is executed in advance and takes `7.76s`.

TiDB is slow in execution

Assume that the execution plan in TiDB is correct but the execution is slow. To solve this type of issue, you can adjust parameters or use the hint according to the result of `EXPLAIN ANALYZE` for the SQL statement.

If the execution plan is incorrect, see the Analyze optimizer issues section.

Low concurrency

If the bottleneck is in the operator with concurrency, speed up the execution by adjusting the concurrency. For example:

```
mysql> explain analyze select sum(t1.a) from t t1, t t2 where t1.a=t2.a;
+--
   ↪ ------------------------------+-------------+----------+-----------+-------
   ↪
| id                            | estRows     | actRows  | task      | access
   ↪ object | execution info
   ↪                                                                  | operator
   ↪ info                                | memory         | disk   |
+--
   ↪ ------------------------------+-------------+----------+-----------+-------
   ↪
| HashAgg_11                    | 1.00        | 1        | root      |
   ↪             | time:9.666832189s, loops:2, PartialConcurrency:4,
   ↪ FinalConcurrency:4      | funcs:sum(Column#6)->Column#5            |

   ↪                                                               | not(isnull(
   ↪ test.t.a))                      | N/A            | N/A    |
|          ─TableFullScan_19    | 16384.00    | -1       | cop[tikv] | table:
   ↪ t2   | time:0s, loops:0
   ↪                                                                | keep order:
   ↪ false                           | N/A            | N/A    |
|      ─TableReader_18(Probe)   | 16384.00    | 16384    | root      |
   ↪             | time:6.880923ms, loops:17
   ↪                                                  | data:Selection_17
   ↪                         | 33.6318359375 KB | N/A  |
|        ─Selection_17          | 16384.00    |          | cop[tikv] |
   ↪           | time:0ns, loops:0
```

```
    ↪                                                                  | not(isnull(
    ↪ test.t.a))                    | N/A            | N/A    |
|         └─TableFullScan_16    | 16384.00   | -1       | cop[tikv] | table:
    ↪ t1   | time:0s, loops:0
    ↪                                                                   | keep order:
    ↪ false                         | N/A            | N/A    |
+--
    ↪ ------------------------------+------------+----------+-----------+-------
    ↪
9 rows in set (9.67 sec)
```

As shown above, `HashJoin_14` and `Projection_24` consume much of the execution time. Consider increasing their concurrency using SQL variables to speed up execution.

All system variables are documented in system-variables. To increase the concurrency of `HashJoin_14`, you can modify the `tidb_hash_join_concurrency` system variable.

Data is spilled to disk

Another cause of slow execution is disk spill that occurs during execution if the memory limit is reached. You can find out this cause in the execution plan and the slow log:

```
+--
    ↪ ----------------------+----------+---------+----------+--------------+------
    ↪
| id                    | estRows  | actRows | task    | access object |
    ↪ execution info          | operator info     | memory             |
    ↪ disk         |
+--
    ↪ ----------------------+----------+---------+----------+--------------+------
    ↪
| Sort_4                | 462144.00 | 462144 | root    |              | time
    ↪ :2.02848898s, loops:453 | test.t.a       | 149.68795776367188 MB |
    ↪ 219.3203125 MB |
| └─TableReader_8       | 462144.00 | 462144 | root    |              | time
    ↪ :616.211272ms, loops:453 | data:TableFullScan_7 | 197.49601364135742
    ↪ MB | N/A |
|   └─TableFullScan_7   | 462144.00 | -1     | cop[tikv] | table:t    | time:0
    ↪ s, loops:0          | keep order:false  | N/A                | N/A
    ↪           |
+--
    ↪ ----------------------+----------+---------+----------+--------------+------
    ↪
```

```
...
#### Disk_max: 229974016
...
```

Join operations with Cartesian product

Join operations with Cartesian product generate data volume as large as `left child row count * right child row count`. This is inefficient and should be avoided.

This type of join operations is marked `CARTESIAN` in the execution plan. For example:

```
mysql> explain select * from t t1, t t2 where t1.a>t2.a;
+--
   ↪ ---------------------------+------------+----------+--------------+---------
   ↪
| id                          | estRows    | task     | access object | operator
   ↪  info                                  |
+--
   ↪ ---------------------------+------------+----------+--------------+---------
   ↪
| HashJoin_8                  | 99800100.00 | root   |              | CARTESIAN
   ↪ inner join, other cond:gt(test.t.a, test.t.a) |
|  ─TableReader_15(Build)   | 9990.00    | root     |              | data:
   ↪ Selection_14                                 |
|    ─Selection_14          | 9990.00    | cop[tikv] |             | not(
   ↪ isnull(test.t.a))                             |
|      ─TableFullScan_13    | 10000.00   | cop[tikv] | table:t2    | keep
   ↪ order:false, stats:pseudo                     |
|  ─TableReader_12(Probe)   | 9990.00    | root     |              | data:
   ↪ Selection_11                                 |
|    ─Selection_11          | 9990.00    | cop[tikv] |             | not(
   ↪ isnull(test.t.a))                             |
|      ─TableFullScan_10    | 10000.00   | cop[tikv] | table:t1    | keep
   ↪ order:false, stats:pseudo                     |
+--
   ↪ ---------------------------+------------+----------+--------------+---------
   ↪
```

10.2.1.2.3 Analyze optimizer issues

To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. You need to have some understanding of the optimization process and each operator.

For the following examples, assume that the table schema is `create table t (id int , a int, b int, c int, primary key(id), key(a), key(b, c))`.

1. `select * from t`: There is no filter condition and a full table scan is performed. So the `TableFullScan` operator is used to read data.
2. `select a from t where a=2`: There is a filter condition and only the index columns are read, so the `IndexReader` operator is used to read data.

3. `select * from t where a=2`: There is a filter condition for `a` but the `a` index cannot fully cover the data to be read, so the `IndexLookup` operator is used.
4. `select b from t where c=3`: Without the prefix condition, the multi-column index cannot be used. So the `IndexFullScan` is used.
5. …

The examples above are operators used for data reads. For more operators, see Understand TiDB Execution Plan.

In addition, reading SQL Tuning Overview helps you better understand the TiDB optimizer and determine whether the execution plan is reasonable or not.

Most optimizer issues are explained in SQL Tuning Overview. For the solutions, see the following documents:

1. Wrong Index Solution
2. Wrong join order
3. Expressions are not pushed down

10.2.2 Troubleshoot TiDB OOM Issues

This document describes how to troubleshoot TiDB OOM (Out of Memory) issues, including phenomena, causes, solutions, and diagnostic information.

10.2.2.1 Typical OOM phenomena

The following are some typical OOM phenomena:

- The client side reports the following error: `SQL error, errno = 2013, state = '
  ↪ HY000': Lost connection to MySQL server during query`.
- The Grafana dashboard shows:
  - **TiDB** > **Server** > **Memory Usage** shows that the `process/heapInUse` metric keeps rising, and suddenly drops to zero after reaching the threshold.
  - **TiDB** > **Server** > **Uptime** suddenly drops to zero.
  - **TiDB-Runtime** > **Memory Usage** shows that the `estimate-inuse` metric keeps rising.
- Check `tidb.log`, and you can find the following log entries:
  - An alarm about OOM: `[WARN] [memory_usage_alarm.go:139] ["tidb-
    ↪ server has the risk of OOM because of memory usage exceeds alarm
    ↪ ratio. Running SQLs and heap profile will be recorded in record
    ↪ path"]`. For more information, see `memory-usage-alarm-ratio`.
  - A log entry about restart: `[INFO] [printer.go:33] ["Welcome to TiDB."]`.

10.2.2.2 Overall troubleshooting process

When you troubleshoot OOM issues, follow this process:

1. Confirm whether it is an OOM issue.

   Execute the following command to check the operating system logs. If there is an `oom-killer` log near the time when the problem occurs, you can confirm that it is an OOM issue.

   ```
   dmesg -T | grep tidb-server
   ```

   The following is an example of the log that contains `oom-killer`:

   ```
   ......
   Mar 14 16:55:03 localhost kernel: tidb-server invoked oom-killer: gfp_
       ↪ mask=0x201da, order=0, oom_score_adj=0
   Mar 14 16:55:03 localhost kernel: tidb-server cpuset=/ mems_allowed=0
   Mar 14 16:55:03 localhost kernel: CPU: 14 PID: 21966 Comm: tidb-server
       ↪ Kdump: loaded Not tainted 3.10.0-1160.el7.x86_64 #1
   Mar 14 16:55:03 localhost kernel: Hardware name: QEMU Standard PC (
       ↪ i440FX + PIIX, 1996), BIOS rel-1.14.0-0-g155821a1990b-prebuilt.
       ↪ qemu.org 04/01/2014
   ......
   Mar 14 16:55:03 localhost kernel: Out of memory: Kill process 21945 (
       ↪ tidb-server) score 956 or sacrifice child
   Mar 14 16:55:03 localhost kernel: Killed process 21945 (tidb-server),
       ↪ UID 1000, total-vm:33027492kB, anon-rss:31303276kB, file-rss:0kB,
       ↪  shmem-rss:0kB
   Mar 14 16:55:07 localhost systemd: tidb-4000.service: main process
       ↪ exited, code=killed, status=9/KILL
   ......
   ```

2. After confirming that it is an OOM issue, you can further investigate whether the OOM is caused by deployment or the database.

   - If the OOM is caused by a deployment issue, you need to investigate the resource configuration and impact of hybrid deployment.
   - If the OOM is caused by a database issue, the following are some possible causes:
     - TiDB handles large data traffic, such as large queries, large writes, and data import.
     - TiDB is in a high concurrency scenario, where multiple SQL statements consume resources concurrently or operator concurrency is high.
     - TiDB has a memory leak and resources are not released.

   Refer to the following sections for specific troubleshooting methods.

10.2.2.3 Typical causes and solutions

OOM issues are usually caused by the following:

- Deployment issues
- Database issues
- Client side issues

10.2.2.3.1 Deployment issues

The following are some causes of OOM due to improper deployment:

- The memory capacity of the operating system is too small.
- The TiUP configuration `resource_control` is not appropriate.
- In the case of hybrid deployments (meaning that TiDB and other applications are deployed on the same server), TiDB is killed accidentally by `oom-killer` due to lack of resources.

10.2.2.3.2 Database issues

This section describes the causes and solutions for OOM caused by database issues.

> **Note:**
>
> If you have configured `tidb_mem_quota_query`, an error occurs: `ERROR 1105 (HY000): Out Of Memory Quota![conn_id=54]`. It is caused by the memory usage control behavior of the database. It is a normal behavior.

Executing SQL statements consumes too much memory

You can take the following measures to reduce the memory usage of SQL statements, depending on the different causes of OOM issues.

- If the execution plan of SQL is not optimal, for example, due to lack of proper indexes, outdated statistics, or optimizer bugs, a wrong execution plan of SQL might be selected. A huge intermediate result set will then be accumulated in the memory. In this case, consider the following measures:
  - Add appropriate indexes.
  - Use the disk spill feature for execution operators.
  - Adjust the JOIN order between tables.
  - Use hints to optimize SQL statements.

- Some operators and functions are not supported to be pushed down to the storage level, resulting in a huge accumulation of intermediate result sets. In this case, you need to refine the SQL statements or use hints to optimize, and use the functions or operators that support pushing down.
- The execution plan contains the operator HashAgg. HashAgg is executed concurrently by multiple threads, which is faster but consumes more memory. Instead, you can use `STREAM_AGG()`.
- Reduce the number of Regions to be read simultaneously or reduce the concurrency of operators to avoid memory problems caused by high concurrency. The corresponding system variables include:
    - `tidb_distsql_scan_concurrency`
    - `tidb_index_serial_scan_concurrency`
    - `tidb_executor_concurrency`
- The concurrency of sessions is too high near the time point when the problem occurs. In this case, consider scaling out the TiDB cluster by adding more TiDB nodes.

Large transactions or large writes consume too much memory

You need to plan for memory capacity. When a transaction is executed, the memory usage of the TiDB process is scaled up comparing with the transaction size, up to two to three times or more of the transaction size.

You can split a single large transaction to multiple smaller transactions.

The process of collecting and loading statistical information consumes too much memory

A TiDB node needs to load statistics into memory after it starts. TiDB consumes memory when collecting statistical information. You can control memory usage in the following ways:

- Specify a sampling rate, only collect statistics for specific columns, and reduce `ANALYZE` concurrency.
- Since TiDB v6.1.0, you can use the system variable `tidb_stats_cache_mem_quota` to control the memory usage for statistical information.
- Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the maximum memory usage when TiDB updates statistics.

For more information, see Introduction to Statistics.

Prepared statements are overused

The client side keeps creating prepared statements but does not execute `deallocate prepare stmt`, which causes memory consumption to continue to rise and eventually triggers TiDB OOM. The reason is that the memory occupied by a prepared statement is

not released until the session is closed. This is especially important for long-time connection sessions.

To solve the problem, consider the following measures:

- Adjust the session lifecycle.
- Adjust the `wait_timeout` and `max_execution_time` of the connection pool.
- Use the system variable `max_prepared_stmt_count` to control the maximum number of prepared statements in a session.

`tidb_enable_rate_limit_action` is not configured properly

The system variable `tidb_enable_rate_limit_action` controls memory usage effectively when an SQL statement only reads data. When this variable is enabled and computing operations (such as join or aggregation operations) are required, memory usage might not be under the control of `tidb_mem_quota_query`, which increases the risk of OOM.

It is recommended that you disable this system variable. Since TiDB v6.3.0, this system variable is disabled by default.

10.2.2.3.3 Client side issues

If OOM occurs on the client side, investigate the following:

- Check the trend and speed on **Grafana TiDB Details** > **Server** > **Client Data Traffic** to see if there is a network blockage.
- Check whether there is an application OOM caused by wrong JDBC configuration parameters. For example, if the `defaultFetchSize` parameter for streaming read is incorrectly configured, it can cause data to be heavily accumulated on the client side.

10.2.2.4 Diagnostic information to be collected to troubleshoot OOM issues

To locate the root cause of an OOM issue, you need to collect the following information:

- Collect the memory-related configurations of the operating system:
  - TiUP configuration: `resource_control.memory_limit`
  - Operating system configurations:
    - Memory information: `cat /proc/meminfo`
    - Kernel parameters: `vm.overcommit_memory`
  - NUMA information:
    - `numactl --hardware`
    - `numactl --show`
- Collect the version information and the memory-related configurations of the database:

    - TiDB version
    - `tidb_mem_quota_query`
    - `memory-usage-alarm-ratio`
    - `mem-quota-query`
    - `oom-action`
    - `tidb_enable_rate_limit_action`
    - `tidb_server_memory_limit`
    - `oom-use-tmp-storage`
    - `tmp-storage-path`
    - `tmp-storage-quota`
    - `tidb_analyze_version`

- Check the daily usage of TiDB memory on the Grafana dashboard: **TiDB** > **Server** > **Memory Usage**.

- Check the SQL statements that consume more memory.

    - View SQL statement analysis, slow queries, and memory usage on the TiDB Dashboard.
    - Check `SLOW_QUERY` and `CLUSTER_SLOW_QUERY` in `INFORMATION_SCHEMA`.
    - Check `tidb_slow_query.log` on each TiDB node.
    - Run `grep "expensive_query" tidb.log` to check the corresponding log entries.
    - Run `EXPLAIN ANALYZE` to check the memory usage of operators.
    - Run `SELECT * FROM information_schema.processlist;` to check the value of the `MEM` column.

- Run the following command to collect the TiDB Profile information when memory usage is high:

```
curl -G "http://{TiDBIP}:10080/debug/zip?seconds=10" > profile.zip
```

- Run `grep "tidb-server has the risk of OOM" tidb.log` to check the path of the alert file collected by TiDB Server. The following is an example output:

```
["tidb-server has the risk of OOM because of memory usage exceeds alarm
    ↪  ratio. Running SQLs and heap profile will be recorded in record
    ↪ path"] ["is tidb_server_memory_limit set"=false] ["system memory
    ↪ total"=14388137984] ["system memory usage"=11897434112] ["tidb-
    ↪ server memory usage"=11223572312] [memory-usage-alarm-ratio=0.8]
    ↪ ["record path"="/tmp/0_tidb/MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA=/
    ↪ tmp-storage/record"]
```

10.2.3 Troubleshoot Hotspot Issues

This document describes how to locate and resolve the problem of read and write hotspots.

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency.

10.2.3.1 Common hotspots

This section describes TiDB encoding rules, table hotspots, and index hotspots.

10.2.3.1.1 TiDB encoding rules

TiDB assigns a TableID to each table, an IndexID to each index, and a RowID to each row. By default, if the table uses an integer primary key, the value of the primary key is treated as the RowID. Among these IDs, TableID is unique in the entire cluster, while IndexID and RowID are unique in the table. The type of all these IDs is int64.

Each row of data is encoded as a key-value pair according to the following rule:

```
Key: tablePrefix{tableID}_recordPrefixSep{rowID}
Value: [col1, col2, col3, col4]
```

The `tablePrefix` and `recordPrefixSep` of the key are specific string constants, used to distinguish from other data in the KV space.

For Index data, the key-value pair is encoded according to the following rule:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: rowID
```

Index data has two types: the unique index and the non-unique index.

- For unique indexes, you can follow the coding rules above.
- For non-unique indexes, a unique key cannot be constructed through this encoding, because the `tablePrefix{tableID}_indexPrefixSep{indexID}` of the same index is the same and the `ColumnsValue` of multiple rows might be the same. The encoding rule for non-unique indexes is as follows:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue_
    ↪ rowID
Value: null
```

10.2.3.1.2 Table hotspots

According to TiDB coding rules, the data of the same table is in a range prefixed by the beginning of the TableID, and the data is arranged in the order of RowID values. When RowID values are incremented during table inserting, the inserted line can only be appended to the end. The Region will split after it reaches a certain size, and then it still can only be appended to the end of the range. The `INSERT` operation can only be executed on one Region, forming a hotspot.

The common auto-increment primary key is sequentially increasing. When the primary key is of the integer type, the value of the primary key is used as the RowID by default. At this time, the RowID is sequentially increasing, and a write hotspot of the table forms when a large number of `INSERT` operations exist.

Meanwhile, the RowID in TiDB is also sequentially auto-incremental by default. When the primary key is not an integer type, you might also encounter the problem of write hotspots.

In addition, when hotspots occur during the process of data writes (on a newly created table or partition) or data reads (periodic read hotspots in read-only scenarios), you can control the Region merge behavior using table attributes. For details, see Control the Region merge behavior using table attributes.

10.2.3.1.3 Index hotspots

Index hotspots are similar to table hotspots. Common index hotspots appear in fields that are monotonously increasing in time order, or `INSERT` scenarios with a large number of repeated values.

10.2.3.2 Identify hotspot issues

Performance problems are not necessarily caused by hotspots and might be caused by multiple factors. Before troubleshooting issues, confirm whether it is related to hotspots.

- To judge write hotspots, open **Hot Write** in the **TiKV-Trouble-Shooting** monitoring panel to check whether the Raftstore CPU metric value of any TiKV node is significantly higher than that of other nodes.
- To judge read hotspots, open **Thread_CPU** in the **TiKV-Details** monitoring panel to check whether the coprocessor CPU metric value of any TiKV node is particularly high.

10.2.3.2.1 Use TiDB Dashboard to locate hotspot tables

The **Key Visualizer** feature in TiDB Dashboard helps users narrow down hotspot troubleshooting scope to the table level. The following is an example of the thermal diagram shown by **Key Visualizer**. The horizontal axis of the graph is time, and the vertical axis are various tables and indexes. The brighter the color, the greater the load. You can switch the read or write flow in the toolbar.

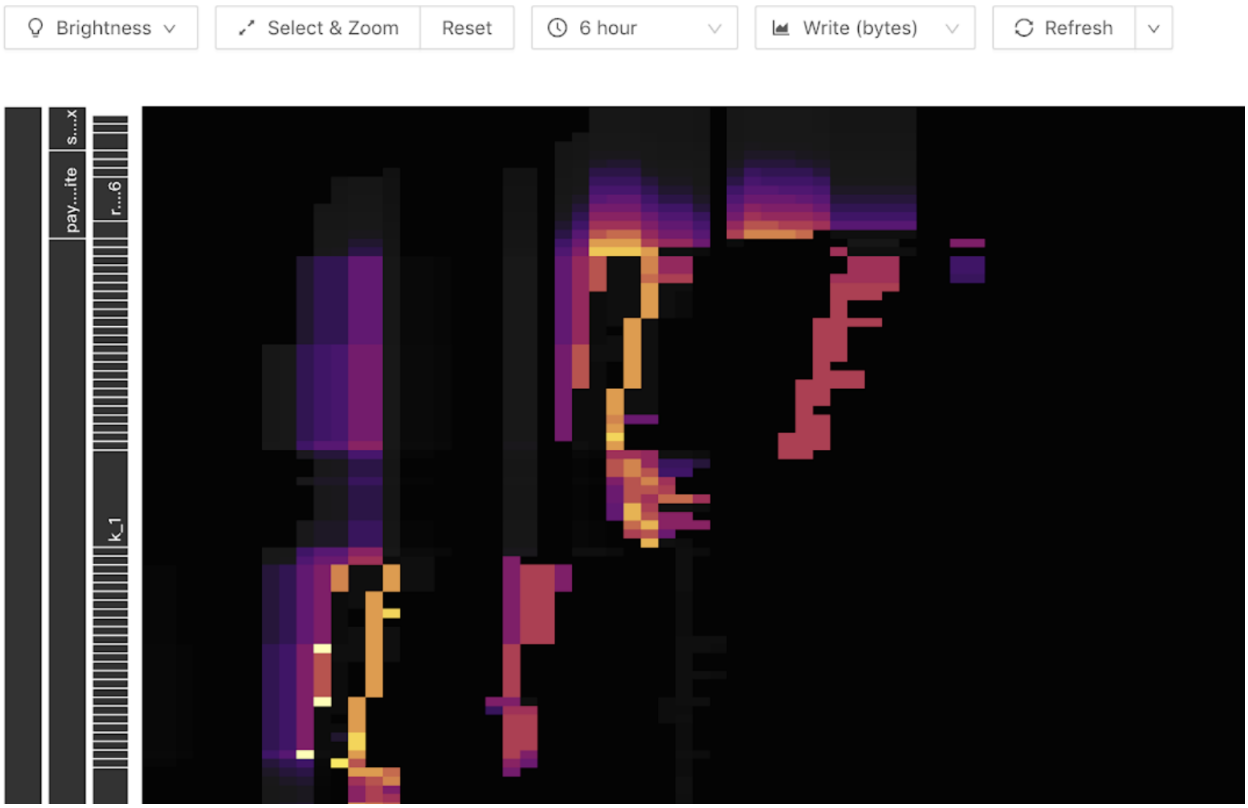

Figure 331: Dashboard Example 1

The following bright diagonal lines (oblique upward or downward) can appear in the write flow graph. Because the write only appears at the end, as the number of table Regions becomes larger, it appears as a ladder. This indicates that a write hotspot shows in this table:

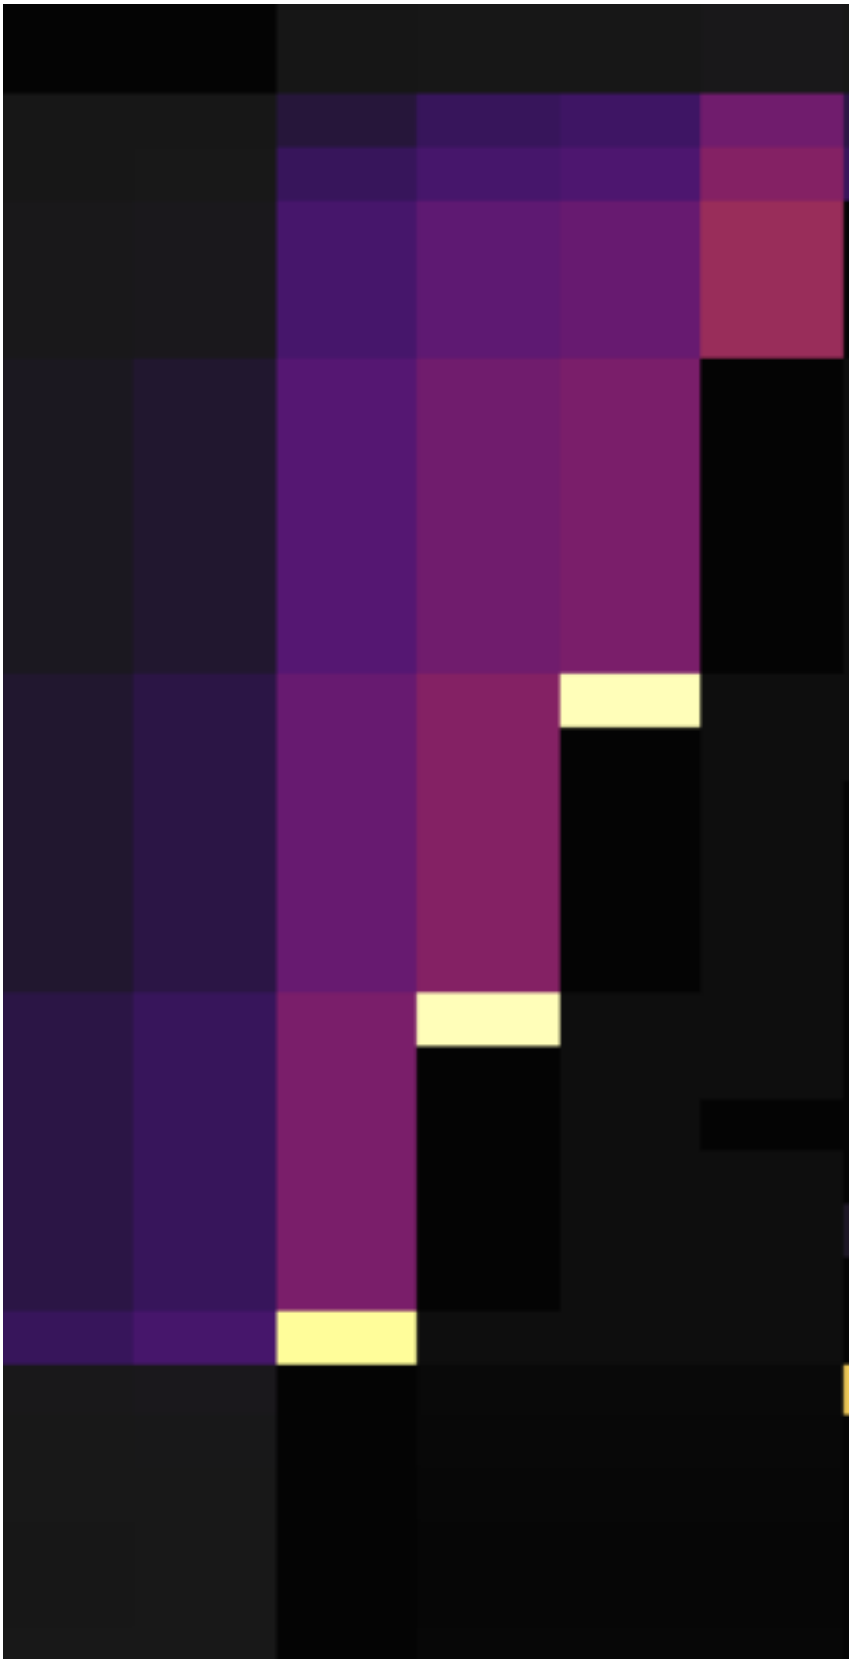

Figure 332: Dashboard Example 2

For read hotspots, a bright horizontal line is generally shown in the thermal diagram. Usually these are caused by small tables with a large number of accesses, shown as follows:

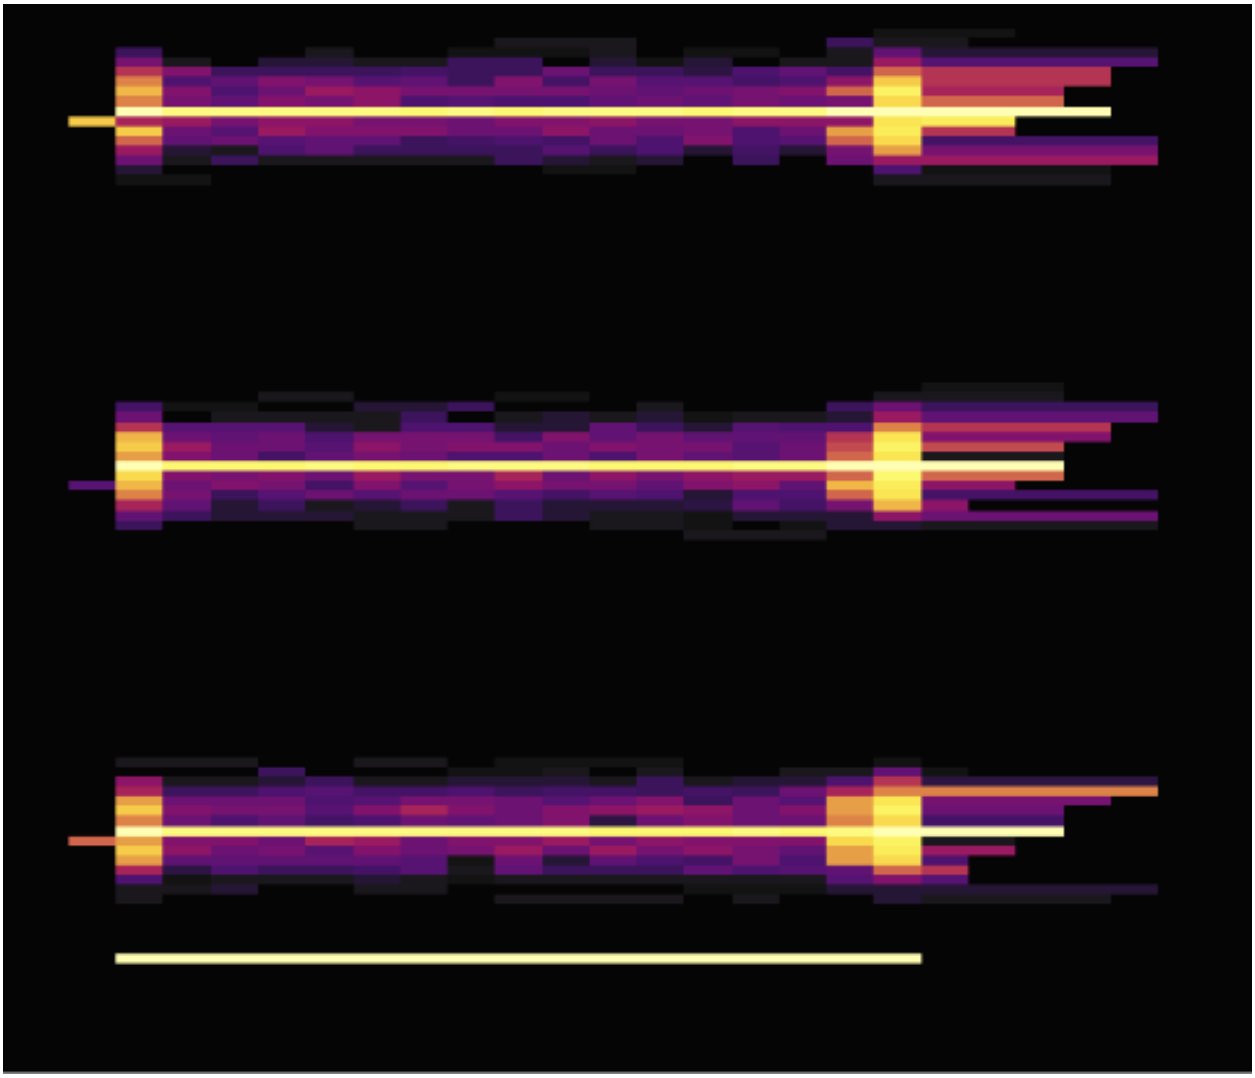

Figure 333: Dashboard Example 3

Hover over the bright block, you can see what table or index has a heavy load. For example:

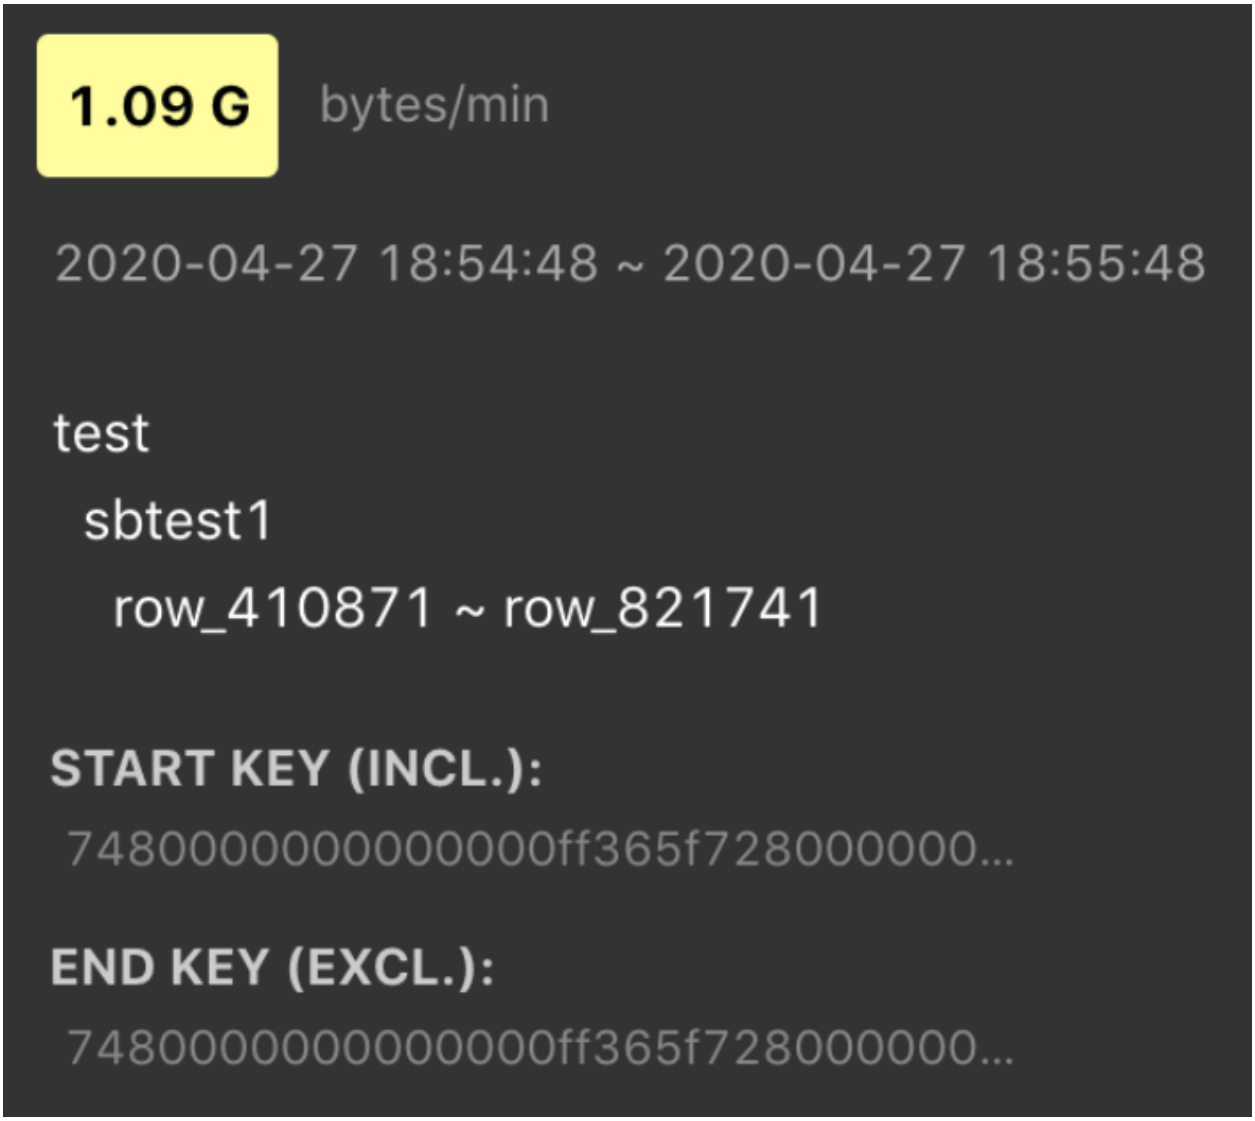

Figure 334: Dashboard Example 4

10.2.3.3 Use `SHARD_ROW_ID_BITS` to process hotspots

For a non-clustered primary key or a table without a primary key, TiDB uses an implicit auto-increment RowID. When a large number of `INSERT` operations exist, the data is written into a single Region, resulting in a write hotspot.

By setting `SHARD_ROW_ID_BITS`, row IDs are scattered and written into multiple Regions, which can alleviate the write hotspot issue.

```
SHARD_ROW_ID_BITS = 4 # Represents 16 shards.
SHARD_ROW_ID_BITS = 6 # Represents 64 shards.
SHARD_ROW_ID_BITS = 0 # Represents the default 1 shard.
```

Statement example:

```
CREATE TABLE: CREATE TABLE t (c int) SHARD_ROW_ID_BITS = 4;
ALTER TABLE: ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

The value of `SHARD_ROW_ID_BITS` can be dynamically modified. The modified value only takes effect for newly written data.

For the table with a primary key of the `CLUSTERED` type, TiDB uses the primary key of the table as the RowID. At this time, the `SHARD_ROW_ID_BITS` option cannot be used because it changes the RowID generation rules. For the table with the primary key of the `NONCLUSTERED` type, TiDB uses an automatically allocated 64-bit integer as the RowID. In this case, you can use the `SHARD_ROW_ID_BITS` feature. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

The following two load diagrams shows the case where two tables without primary keys use `SHARD_ROW_ID_BITS` to scatter hotspots. The first diagram shows the situation before scattering hotspots, while the second one shows the situation after scattering hotspots.

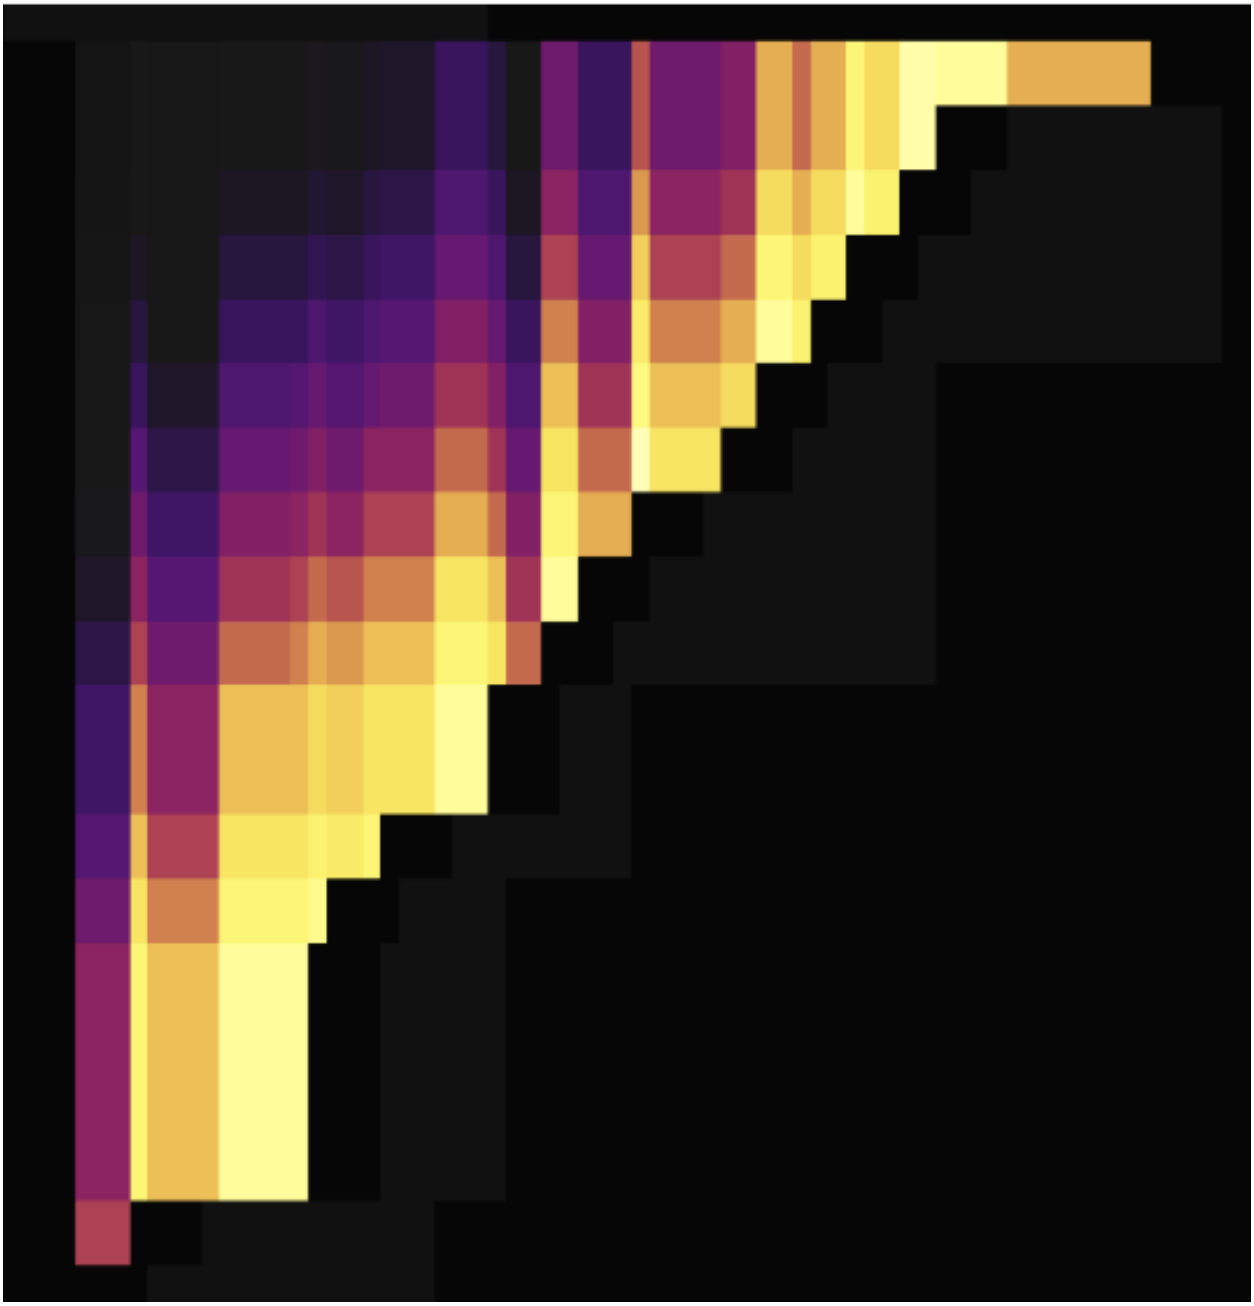

Figure 335: Dashboard Example 5

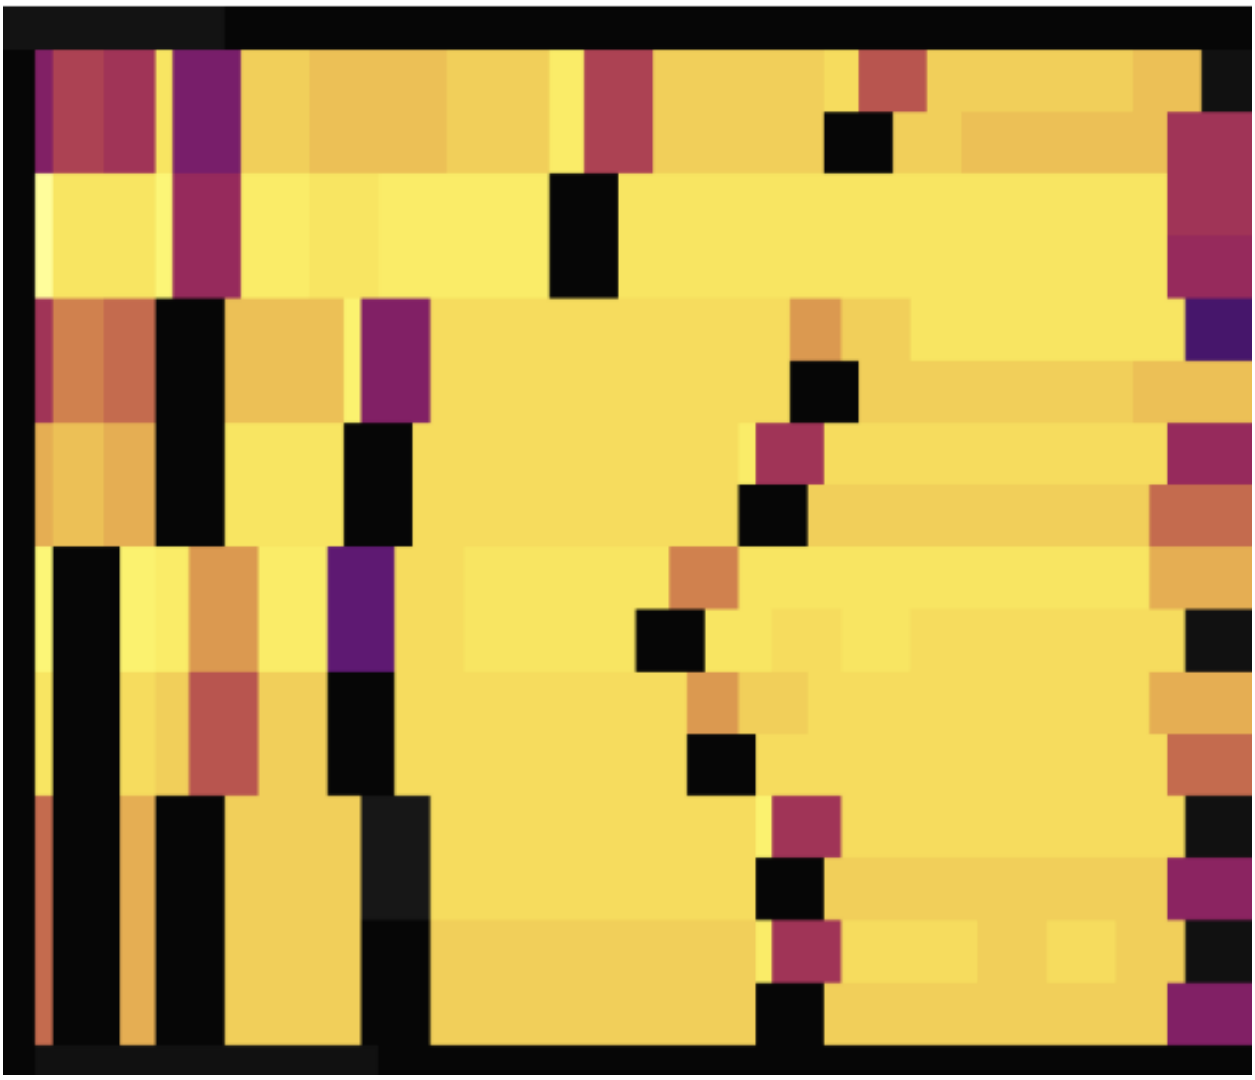

Figure 336: Dashboard Example 6

As shown in the load diagrams above, before setting `SHARD_ROW_ID_BITS`, load hotspots are concentrated on a single Region. After setting `SHARD_ROW_ID_BITS`, load hotspots become scattered.

10.2.3.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM`

To resolve the write hotspots brought by auto-increment primary keys, use `AUTO_RANDOM` to handle hotspot tables that have auto-increment primary keys.

If this feature is enabled, TiDB generates randomly distributed and non-repeated (before the space is used up) primary keys to achieve the purpose of scattering write hotspots.

Note that the primary keys generated by TiDB are no longer auto-increment primary

keys and you can use `LAST_INSERT_ID()` to obtain the primary key value assigned last time.

To use this feature, modify `AUTO_INCREMENT` to `AUTO_RANDOM` in the `CREATE TABLE` statement. This feature is suitable for non-application scenarios where the primary keys only need to guarantee uniqueness.

For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b varchar(255));
INSERT INTO t (b) VALUES ("foo");
SELECT * FROM t;
```

```
+------------+---+
| a          | b |
+------------+---+
| 1073741825 | b |
+------------+---+
```

```
SELECT LAST_INSERT_ID();
```

```
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1073741825       |
+------------------+
```

The following two load diagrams shows the situations both before and after modifying `AUTO_INCREMENT` to `AUTO_RANDOM` to scatter hotspots. The first one uses `AUTO_INCREMENT`, while the second one uses `AUTO_RANDOM`.

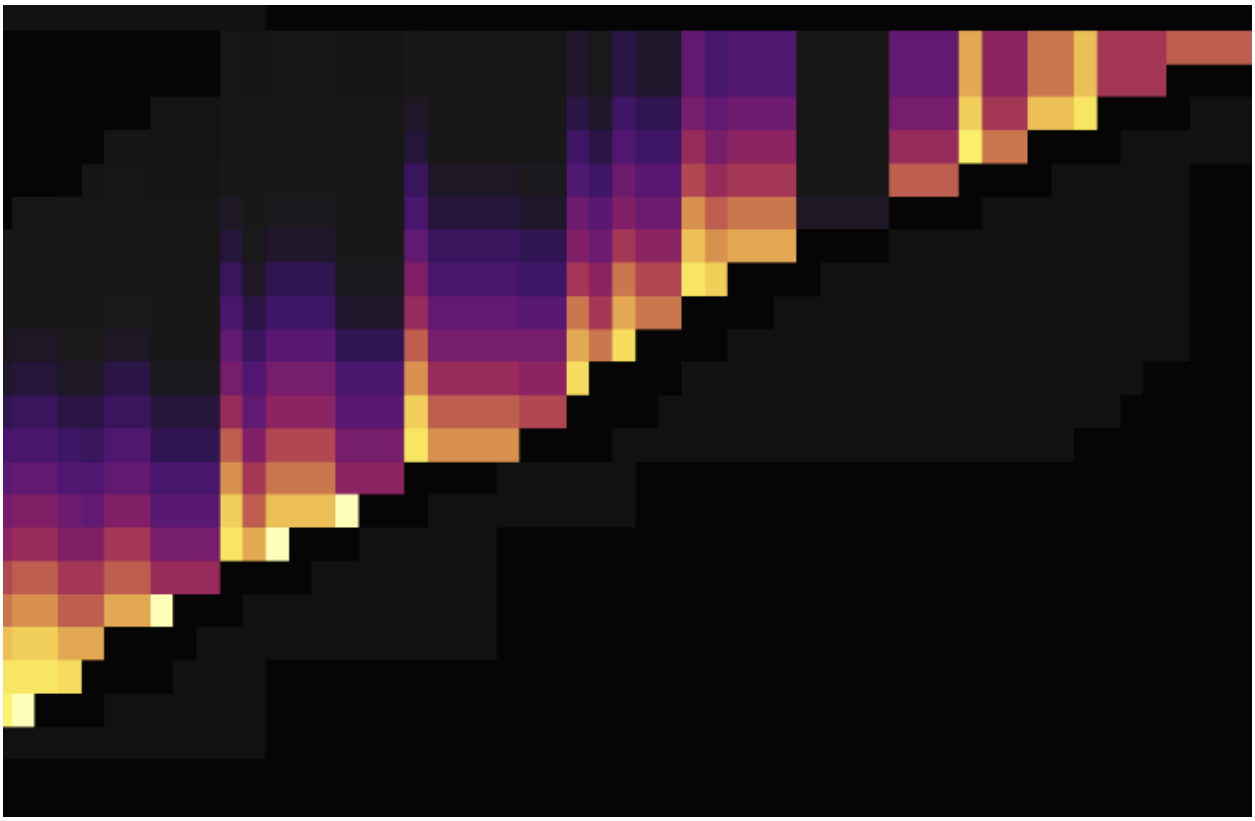

Figure 337: Dashboard Example 7

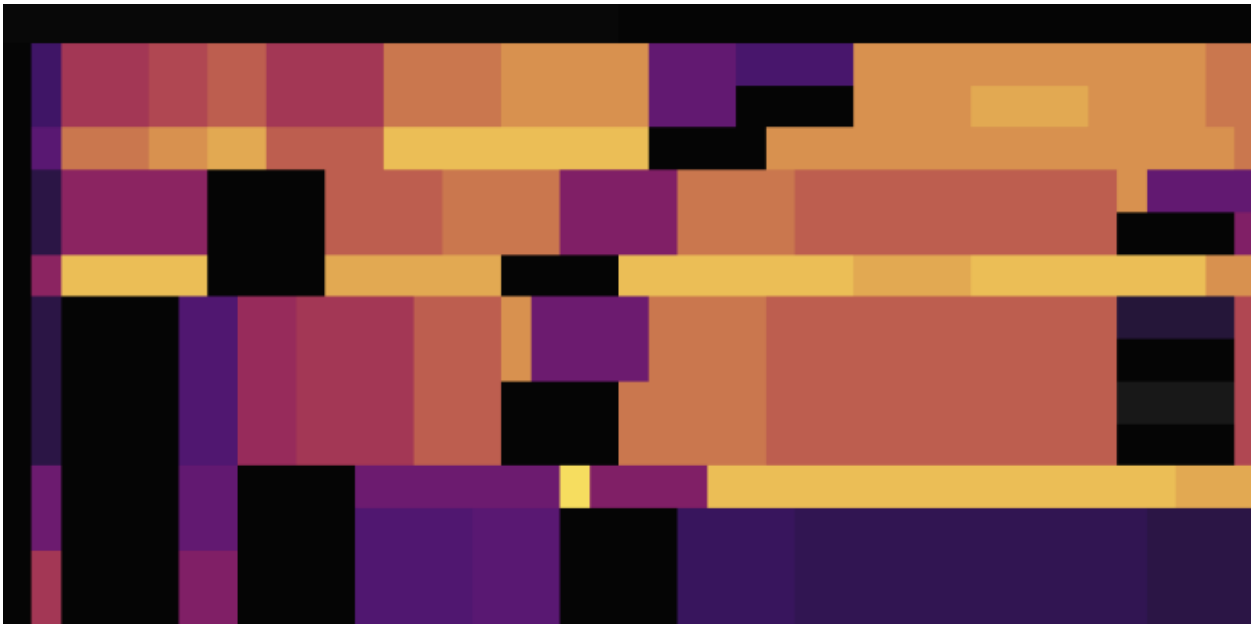

Figure 338: Dashboard Example 8

As shown in the load diagrams above, using `AUTO_RANDOM` to replace `AUTO_INCREMENT` can well scatter hotspots.

For more details, see AUTO_RANDOM.

10.2.3.5 Optimization of small table hotspots

The Coprocessor Cache feature of TiDB supports pushing down computing result caches. After this feature is enabled, TiDB caches the computing results that will be pushed down to TiKV. This feature works well for read hotspots of small tables.

For more details, see Coprocessor Cache.

See also:

- Highly Concurrent Write Best Practices
- Split Region

10.2.3.6 Scatter read hotspots

In a read hotspot scenario, the hotspot TiKV node cannot process read requests in time, resulting in the read requests queuing. However, not all TiKV resources are exhausted at this time. To reduce latency, TiDB v7.1.0 introduces the load-based replica read feature, which allows TiDB to read data from other TiKV nodes without queuing on the hotspot TiKV node. You can control the queue length of read requests using the `tidb_load_based_replica_read_threshold` system variable. When the estimated queue time of the leader node exceeds this threshold, TiDB prioritizes reading data from follower nodes. This feature can improve read throughput by 70% to 200% in a read hotspot scenario compared to not scattering read hotspots.

10.2.3.7 Use TiKV MVCC in-memory engine to mitigate read hotspots caused by high MVCC read amplification

When the retention time of historical MVCC data for GC is too long, or when the records are frequently updated or deleted, read hotspots might occur due to scanning a large number of MVCC versions. To alleviate this type of hotspot, you can enable the TiKV MVCC In-Memory Engine feature.

10.2.4 Troubleshoot Increased Read and Write Latency

This document introduces the possible causes of read and write latency and jitters, and how to troubleshoot these issues.

10.2.4.1 Common causes

10.2.4.1.1 Incorrect TiDB execution plan

The execution plan of queries is unstable and might select the incorrect index, which causes higher latency.

Phenomenon

- If the query execution plan is output in the slow log, you can directly view the plan. Execute the `select tidb_decode_plan('xxx...')` statement to parse the detailed execution plan.
- The number of scanned keys in the monitor abnormally increases; in the slow log, the number of `Scan Keys` are large.
- The SQL execution duration in TiDB is greatly different than that in other databases such as MySQL. You can compare the execution plan of other databases (for example, whether `Join Order` is different).

Possible reason

The statistics is inaccurate.

Troubleshooting methods

- Update the statistical information
  - Execute `analyze table` manually and execute `analyze` periodically with the `crontab` command to keep the statistics accurate.
  - Execute `auto analyze` automatically. Lower the threshold value of `analyze ratio`, increase the frequency of information collection, and set the start and end time of the execution. See the following examples:
    - `set global tidb_auto_analyze_ratio=0.2;`
    - `set global tidb_auto_analyze_start_time='00:00 +0800';`
    - `set global tidb_auto_analyze_end_time='06:00 +0800';`
- Bind the execution plan
  - Modify the application SQL statements and execute `use index` to consistently use the index of the column.
  - In 3.0 versions, you do not need to modify the application SQL statements. Use `create global binding` to create the binding SQL statement of `force index`.
  - In 4.0 versions, SQL Plan Management is supported, which avoids the performance decrease caused by unstable execution plans.

10.2.4.1.2 PD anomalies

Phenomenon

There is an abnormal increase of the `wait duration` metric for the PD TSO. This metric represents the duration of waiting for PD to return requests.

Possible reasons

- Disk issue. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana** -> **disk performance** -> **latency/load**. You can also use the FIO tool to run a check on the disk if necessary.
- Network issues between PD peers. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana** -> **PD** -> **etcd**.
- High server load. The log shows `server is likely overloaded`.
- PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19.
- The leader election is slow. The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region-storage` to `true`, which significantly reduce the Region loading duration.
- The network issue between TiDB and PD. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana** -> **black-box_exporter** -> **ping latency**.
- PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040).
- When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that `TCP InSegs` is relatively large. This issue has been fixed in v3.0.6 (#1952).
- PD panics. Report a bug.
- Other causes. Get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

10.2.4.1.3 TiKV anomalies

Phenomenon

The `KV Cmd Duration` metric in the monitor increases abnormally. This metric represents the duration between the time that TiDB sends a request to TiKV and the time that TiDB receives the response.

Possible reasons

- Check the `gRPC duration` metric. This metric represents the total duration of a gRPC request in TiKV. You can find out the potential network issue by comparing `gRPC duration` of TiKV and `KV duration` of TiDB. For example, the gRPC duration is short but the KV duration of TiDB is long, which indicates that the network latency between TiDB and TiKV might be high, or that the NIC bandwidth between TiDB and TiKV is fully occupied.

- Re-election because TiKV is restarted.

    - After TiKV panics, it is pulled up by `systemd` and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
    - TiKV is stopped or killed by a third party and then pulled up by `systemd`. Check the cause by viewing `dmesg` and the TiKV log.
    - TiKV is OOM, which causes restart.
    - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage).

- Check monitor: TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`.

- Re-election because of network isolation.

- If the `block-cache` configuration is too large, it might cause TiKV OOM. To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**. Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"`parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM. To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

10.2.4.1.4 Bottleneck of a single TiKV thread

There are some single threads in TiKV that might become the bottleneck.

- Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue.

- For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

10.2.4.1.5 CPU load increases

Phenomenon

The usage of CPU resources becomes the bottleneck.

Possible reasons

- Hotspot issue
- High overall load. Check the slow queries and expensive queries of TiDB. Optimize the executing queries by adding indexes or executing queries in batches. Another solution is to scale out the cluster.

10.2.4.2 Other causes

10.2.4.2.1 Cluster maintenance

Most of each online cluster has three or five nodes. If the machine to be maintained has the PD component, you need to determine whether the node is the leader or the follower. Disabling a follower has no impact on the cluster operation. Before disabling a leader, you need to switch the leadership. During the leadership change, performance jitter of about 3 seconds will occur.

10.2.4.2.2 Minority of replicas are offline

By default, each TiDB cluster has three replicas, so each Region has three replicas in the cluster. These Regions elect the leader and replicate data through the Raft protocol. The Raft protocol ensures that TiDB can still provide services without data loss even when the nodes (that are fewer than half of replicas) fail or are isolated. For the cluster with three replicas, the failure of one node might cause performance jitter but the usability and correctness in theory are not affected.

10.2.4.2.3 New indexes

Creating indexes consumes a huge amount of resources when TiDB scans tables and backfills indexes. Index creation might even conflict with the frequently updated fields, which affects the application. Creating indexes on a large table often takes a long time, so you must try to balance the index creation time and the cluster performance (for example, creating indexes at the off-peak time).

Parameter adjustment:

Currently, you can use `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` ↪ to dynamically adjust the speed of index creation. Usually, the smaller the values, the smaller the impact on the system, with longer execution time though.

In general cases, you can first keep their default values (`4` and `256`), observe the resource usage and response speed of the cluster, and then increase the value of `tidb_ddl_reorg_` ↪ `worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor, increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

10.2.4.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

10.2.5 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

10.2.5.1 The reason of write conflicts

TiDB implements its transactions by using the Percolator transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see TiDB Optimistic Transaction Model.

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.
2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts` > `txn.start_ts`), a write conflict occurs.

10.2.5.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

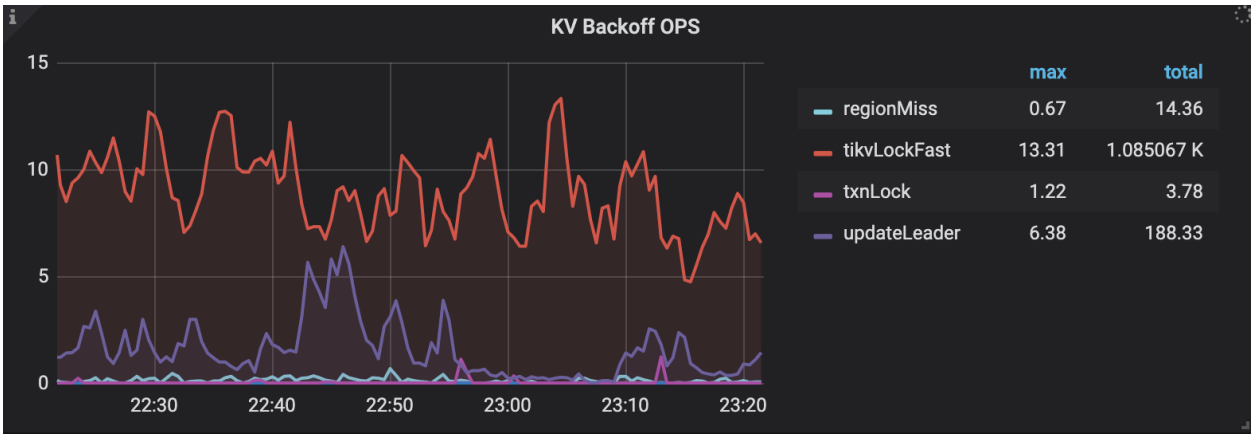

Figure 339: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

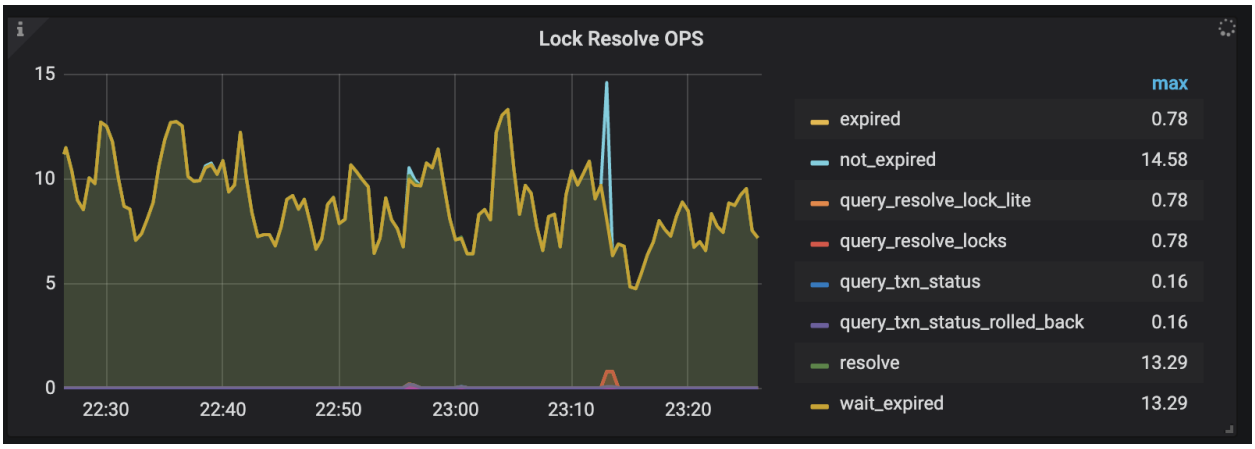

Figure 340: lock-resolve-ops

  - `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
  - `wait_expired` indicates that the transaction needs to wait the lock to expire.
  - `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

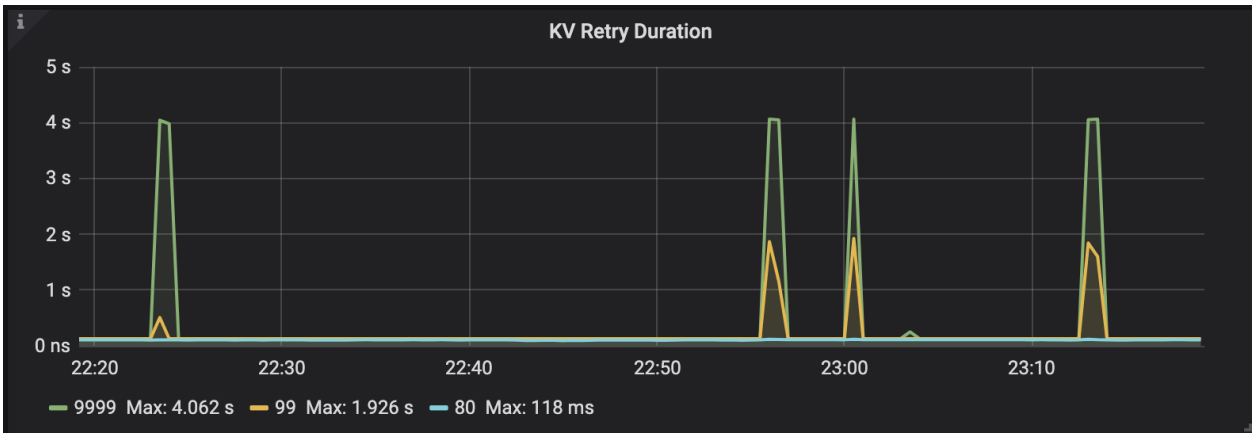

Figure 341: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the keywords to search in the TiDB log. The keywords also indicate the write conflict exists in the cluster.

10.2.5.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts. When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
    ↪ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
    ↪ conflict, txnStartTS=416617006551793665, conflictStartTS
    ↪ =416617018650001409, conflictCommitTS=416617023093080065, key={
    ↪ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
    ↪ indexID=1, indexValues={string, }} [try again later]"]
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.
- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`, indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.
- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
tiup ctl:v<CLUSTER_VERSION> pd -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}
    ↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default mode. The pessimistic transaction mode can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic

transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

10.2.6 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

10.2.6.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

10.2.6.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

The first type of monitoring panels

In **Overview> System Info> IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as `Disk Latency` and `Disk Load` to determine whether any anomaly exists. If necessary, use the fio tool to check the disk.

The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details** > **Raft IO**, you can see the metrics related to disk writes of these two instances:

- `Append log duration`: This metric indicates the response time of writes into RockDB that stores Raft logs. The `.99` response time should be within 50 ms.

- `Apply log duration`: This metric indicates the response time of writes into RockDB that stores real data. The `.99` response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

The third type of monitoring panels

In **TiKV-Details** > **Storage**, there are monitoring metrics related to storage:

- `Storage command total`: Indicates the number of different commands received.
- `Storage async write duration`: Includes monitoring metrics such as `disk sync duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the prewrite/commit/raw-put (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append log`. Otherwise, you might need to report a bug.
- The `raftstore` thread is busy. In TiKV Grafana, `Raft Propose/propose wait duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:
  - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
  - Whether the CPU resource of the machine is insufficient.
- `apply log` is slow. TiKV Grafana's `Raft I/O` and `apply log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose /apply wait duration`. The possible causes are as follows:
  - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU /apply cpu` is also relatively high.
  - Insufficient CPU resources on the machine.
  - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).

- Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply` log might involve multiple RocksDB writes.
- For other causes, report them as bugs.

- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as `1024`.

10.2.6.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

  You can check the monitoring panel (**Grafana** -> **TiKV** -> **errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

  It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

  If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

  For example, when the pressure of `default cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `compression-per-level = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

10.2.6.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- TiKV_write_stall
- TiKV_raft_log_lag
- TiKV_async_request_snapshot_duration_seconds
- TiKV_async_request_write_duration_seconds
- TiKV_raft_append_log_duration_secs
- TiKV_raft_apply_log_duration_secs

10.2.6.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.
- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

10.2.7 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document describes how to use Lock View to troubleshoot lock issues and how to deal with common lock conflict issues in optimistic and pessimistic transactions.

10.2.7.1 Use Lock View to troubleshoot lock issues

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the lock conflicts and lock waitings.

> **Note:**
>
> Currently, the Lock View feature provides conflict and waiting information for pessimistic locks only.

For the detailed introduction of these tables, see the following documents:

- `TIDB_TRX` and `CLUSTER_TIDB_TRX`: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.

- DATA_LOCK_WAITS: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- DEADLOCKS and CLUSTER_DEADLOCKS: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

> **Note:**
>
> The SQL statements shown in the Lock View-related system tables are normalized SQL statements (that is, SQL statements without formats and arguments), which are obtained by internal queries according to SQL digests, so the tables cannot obtain the complete statements that include the format and arguments. For the detailed description of SQL digests and normalized SQL statement, see Statement Summary Tables.

The following sections show the examples of troubleshooting some issues using these tables.

10.2.7.1.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table.

For example, to query the `DEADLOCKS` table, you can execute the following SQL statement:

```
select * from information_schema.deadlocks;
```

The following is an example output:

```
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
| DEADLOCK_ID | OCCUR_TIME                 | RETRYABLE | TRY_LOCK_TRX_ID |
    ↪ CURRENT_SQL_DIGEST                                  | CURRENT_SQL_
    ↪ DIGEST_TEXT            | KEY                           | KEY_INFO
    ↪
    ↪ | TRX_HOLDING_LOCK |
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
```

```
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406216 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000002 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"2"} |
   ↪ 426812829645406217 |
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406217 |
   ↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
   ↪ update `t` set `v` = ? where `id` = ? ; | 7480000000000000355
   ↪ F728000000000000001 | {"db_id":1,"db_name":"test","table_id":53,"
   ↪ table_name":"t","handle_type":"int","handle_value":"1"} |
   ↪ 426812829645406216 |
+--
   ↪ ----------+--------------------------+----------+------------------+------
   ↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the normalized form of the SQL statements currently being executed in each transaction (statements without formats and arguments), the key on which the conflict occurs, and the information of the key.

For example, in the above example, the first row means that the transaction with the ID of `426812829645406216` is executing a statement like `update `t` set `v` =? Where `id ↪ ` =? ;` but is blocked by another transaction with the ID of `426812829645406217`. The transaction with the ID of `426812829645406217` is also executing a statement that is in the form of `update `t` set `v` =? Where `id` =? ;` but is blocked by the transaction with the ID of `426812829645406216`. The two transactions thus form a deadlock.

10.2.7.1.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
   ↪ group by `key` order by `count` desc;
```

The following is an example output:

```
+----------------------------------------+-------+
| key                                    | count |
+----------------------------------------+-------+
| 748000000000000415F728000000000000001 | 2 |
| 748000000000000415F728000000000000002 | 1 |
+----------------------------------------+-------+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

For example, to filter transactions with a long lock-waiting time using the `where` clause, you can execute the following SQL statement:

```
select trx.* from information_schema.data_lock_waits as l left join
    ↪ information_schema.cluster_tidb_trx as trx on l.trx_id = trx.id where
    ↪  l.key = "74800000000000000415F72800000000000000001"\G
```

The following is an example output:

```

10.2.7.1.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select l.key, trx.*, tidb_decode_sql_digests(trx.all_sql_digests) as sqls
   ↪ from information_schema.data_lock_waits as l join information_schema.
   ↪ cluster_tidb_trx as trx on l.current_holding_trx_id = trx.id where l.
   ↪ trx_id = 426831965449355272\G
```

The following is an example output:

```
*************************** 1. row ***************************
                  key: 74800000000000004D5F728000000000000001

                STATE: LockWaiting
    WAITING_START_TIME: 2021-08-06 07:30:16.592763
       MEM_BUFFER_KEYS: 1
      MEM_BUFFER_BYTES: 19
           SESSION_ID: 113
                USER: root
                  DB: test
       ALL_SQL_DIGESTS: ["0
          ↪ fdc781f19da1c6078c9de7eadef8a307889c001e05f107847bee4cfc8f3cdf3
```

```
            ↪ ","
            ↪ a4e28cc182bdd18288e2a34180499b9404cd0ba07e3cc34b6b3be7b7c2de7fe9
            ↪ ","06
            ↪ da614b93e62713bd282d4685fc5b88d688337f36e88fe55871726ce0eb80d7
            ↪ "]
                  sqls: ["begin ;","select * from `t` where `id` = ? for
                     ↪ update ;","update `t` set `v` = `v` + ? where `id` =
                     ↪ ? ;"]
1 row in set (0.01 sec)
```

In the above query, the TIDB_DECODE_SQL_DIGESTS function is used on the ALL_SQL ↪ _DIGESTS column of the CLUSTER_TIDB_TRX table. This function tries to convert this column (the value is a set of SQL digests) to the normalized SQL statements, which improves readability.

If the start_ts of the current transaction is unknown, you can try to find it out from the information in the TIDB_TRX / CLUSTER_TIDB_TRX table or in the PROCESSLIST / CLUSTER_ ↪ PROCESSLIST table.

10.2.7.1.4 Metadata locks

If a session is waiting on a schema change, this can be because of a metadata lock.

See Metadata Lock for more information.

10.2.7.2 Troubleshoot optimistic lock conflicts

This section provides the solutions of common lock conflict issues in the optimistic transaction mode.

10.2.7.2.1 Read-write conflicts

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the start_ts of the current transaction. The transaction needs to read the latest data before start_ts, that is, the target key of the latest commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

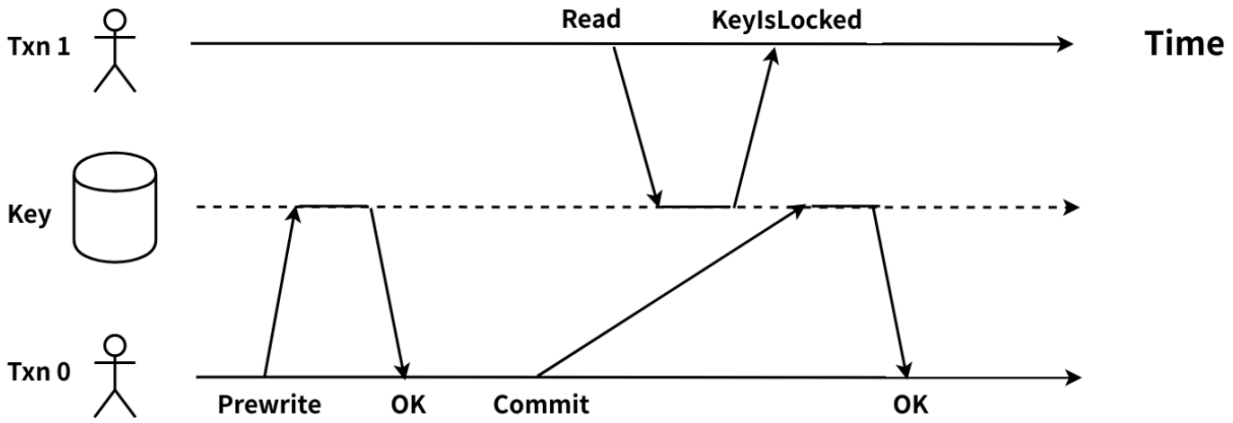

Figure 342: read-write conflict

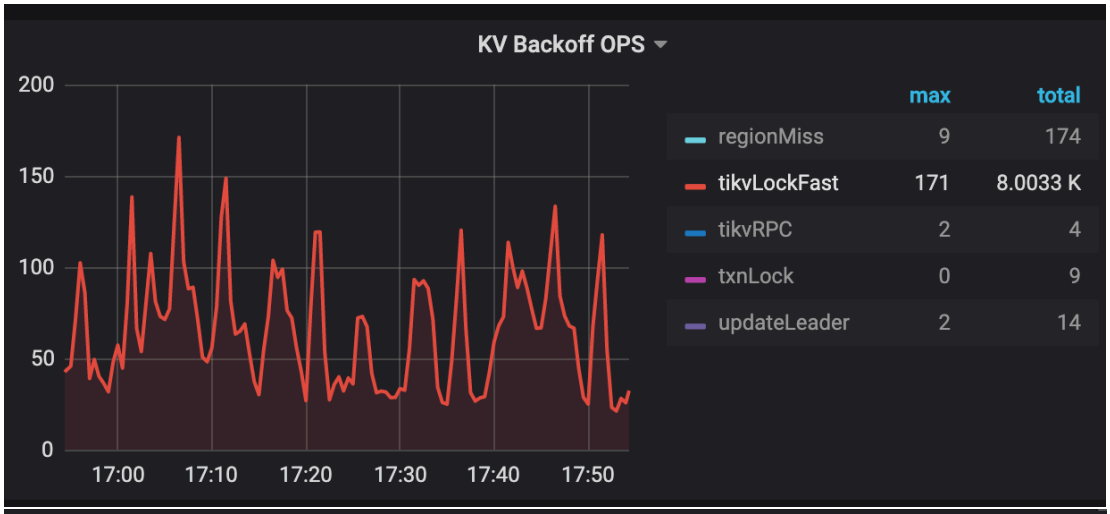
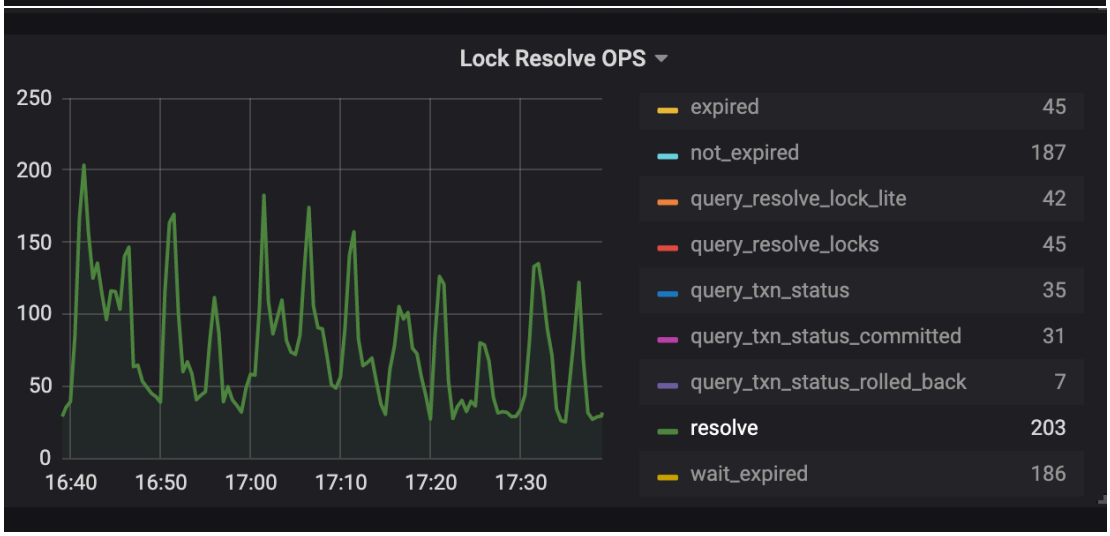


Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.



You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

    - Monitoring data through Grafana

      In the `KV Errors` panel in the TiDB dashboard, `not_expired/resolve` in `Lock Resolve OPS` and `tikvLockFast` in `KV Backoff OPS` are monitoring metrics that can be used to check read-write conflicts in transactions. If the values of all the metrics increase, there might be many read-write conflicts. The `not_expired` item means that the transaction's lock has not timed out. The `resolve` item means that the other transaction tries to clean up the locks. The `tikvLockFast` item means that read-write conflicts occur.

- Logs of the TiDB server

  If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
    ↪ :406.038899ms txnStartTS:416643508703592451 region_id:8297
    ↪ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
    ↪ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
    ↪ :0 scan_processed_write:0 scan_total_data:0 scan_processed_
    ↪ data:0 scan_total_lock:0 scan_processed_lock:0"]
```

  - txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, `416643508703592451` is the start_ts.
  - backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is `TxnLockFast`.
  - backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255 milliseconds in the backoff and retry.

- region_id: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

   If there is any read-write conflict, you can see the following message in the TiKV log:

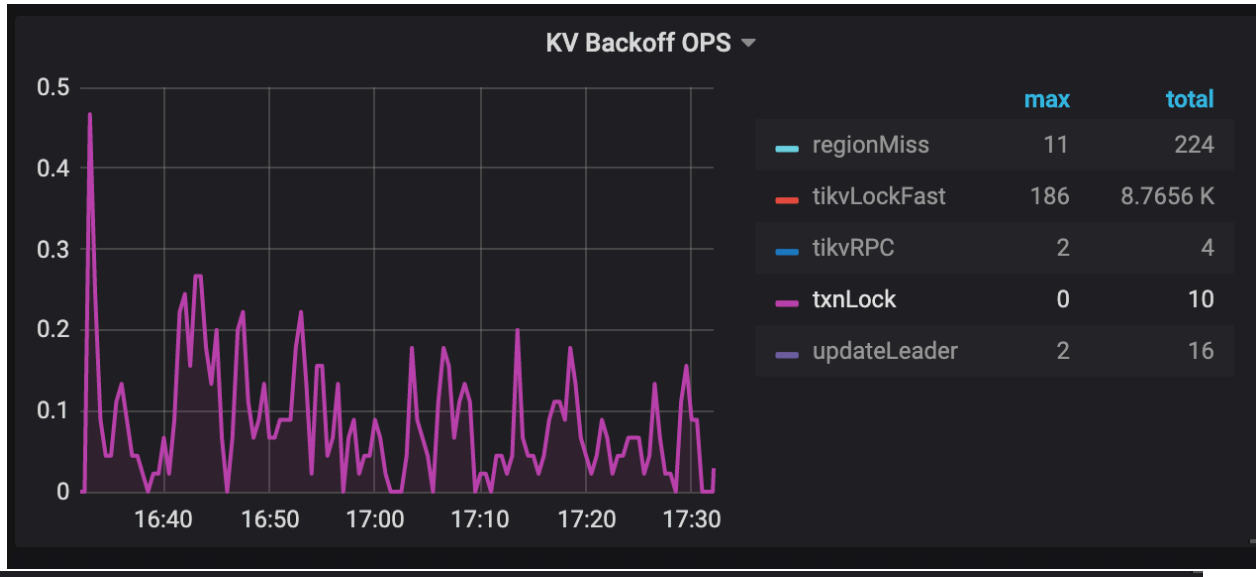
```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
    ↪ :7480000000000004
    ↪ D35F6980000000000000010380000000004C788E0380000000004C0748 lock_
    ↪ version: 411402933858205712 key: 7480000000000004
    ↪ D35F7280000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

   This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

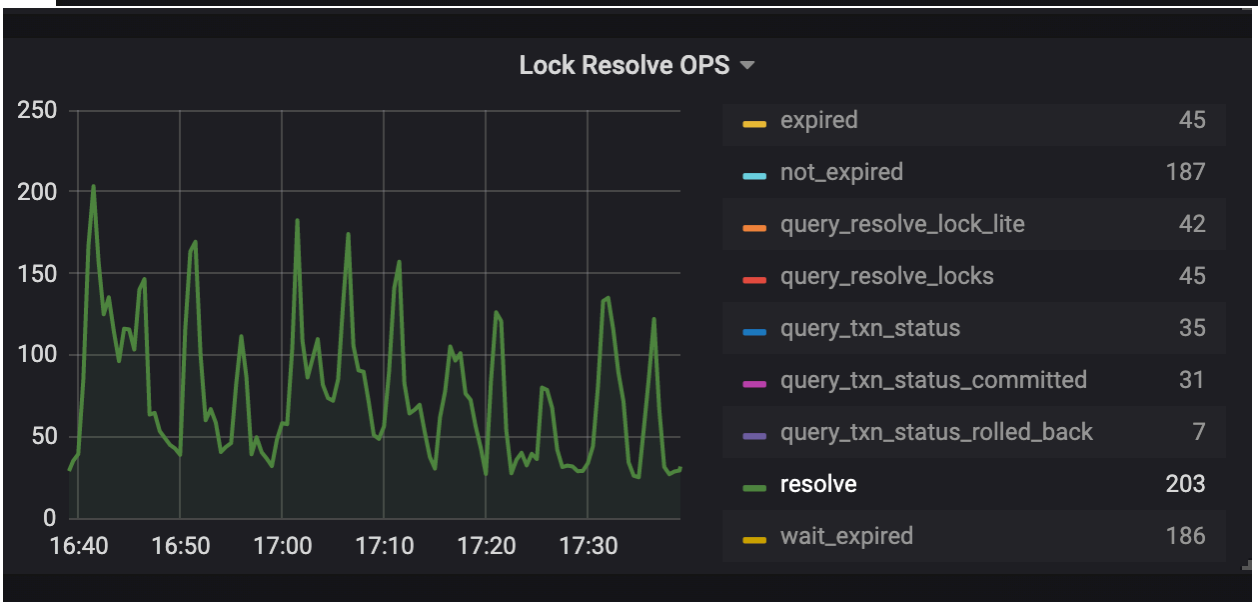
   - primary_lock: Indicates that the target key is locked by the primary lock.
   - lock_version: The start_ts of the transaction that owns the lock.
   - key: The target key that is locked.
   - lock_ttl: The lock's TTL (Time To Live)
   - txn_size: The number of keys that are in the Region of the transaction that owns the lock.

Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 10 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.
- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:



```
./tidb-ctl decoder "t\x00\x00\x00\x00\x00\x00\x1c_r\x00\x00\x00\x00
    ↪ \x00\x00\x00\xfa"
format: table_row
table_id: -9223372036854775780
row_id: -9223372036854775558
```



10.2.7.2.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a "KeyIsLocked" error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when "KeyIsLocked" occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The `KV Errors` panel in the TiDB dashboard has two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under `Lock Resolve OPS` and the `txnLock` item under `KV Backoff OPS` have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.

Solutions:

- If there is a small amount of txnLock in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 100 ms and the maximum time is 3000 ms for a single retry.

- If there are too many "txnLock" operations in the `KV Backoff OPS`, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

10.2.7.2.3 LockNotFound error

The error log of "TxnLockNotFound" means that transaction commit time is longer than the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to tidb_retry_limit. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any "LockNotFound" error in the following ways:

1. View the logs of the TiDB server

   If a "TxnLockNotFound" error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
    ↪ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
    ↪ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
    ↪ 412720515987275779, commit_ts: 412720519984971777, key: [116,
    ↪ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 0, 2]
    ↪ })) [try again later]"]
```

   - start_ts: The start_ts of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the start_ts.
   - commit_ts: The commit_ts of the transaction that outputs the `TxnLockNotFound` ↪ error. In the above log, `412720519984971777` is the commit_ts.

2. View the logs of the TiKV server

   If a "TxnLockNotFound" error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
    ↪ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
    ↪ err=RemoteStoped]
```

   Solutions:

- By checking the time interval between start_ts and commit_ts, you can confirm whether the commit time exceeds the TTL time.

  Checking the time interval using the PD control tool:

```
tiup ctl:v<CLUSTER_VERSION> pd tso [start_ts]
tiup ctl:v<CLUSTER_VERSION> pd tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

10.2.7.3 Troubleshoot pessimistic lock conflicts

This section provides the solutions of common lock conflict issues in the pessimistic transaction mode.

> **Note:**
>
> Even if the pessimistic transaction mode is set, autocommit transactions still try to commit using the optimistic mode first. If a conflict occurs, the transactions will switch to the pessimistic transaction mode during automatic retry.

10.2.7.3.1 Read-write conflicts

The error messages and solutions are the same as Read-write conflict for optimistic lock conflict.

10.2.7.3.2 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by pessimistic-txn.max-retry-count.

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.
- If your business contains high concurrent locking on the same row (the same key) and encounters frequent conflicts, you can try to enable the system variable `tidb_pessimistic_txn_fair_locking`. Note that enabling this variable might bring some cost of throughput reduction (average latency increase) for transactions with lock conflicts. For newly deployed clusters, this variable is enabled (`ON`) by default.

10.2.7.3.3 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the innodb_lock_wait_timeout parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

10.2.7.3.4 TTL manager has timed out

The transaction execution time cannot exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter `performance.max-txn-ttl`.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or
    ↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

10.2.7.3.5 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
    ↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the Deadlock errors section and the `DEADLOCKS` table document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

10.2.8 Troubleshoot Inconsistency Between Data and Indexes

TiDB checks consistency between data and indexes when it executes transactions or the `ADMIN CHECK [TABLE|INDEX]` statement. If the check finds that a record key-value and the corresponding index key-value are inconsistent, that is, a key-value pair storing row data and the corresponding key-value pair storing its index are inconsistent (for example, more indexes or missing indexes), TiDB reports a data inconsistency error and prints the related errors in error logs.

This document describes the meanings of data inconsistency errors and provides some methods to bypass the consistency check. If a data consistency error occurs, you can get support from PingCAP or the community.

10.2.8.1 Error explanation

When inconsistency between data and indexes occurs, you can check TiDB error messages to know which item is inconsistent between row data and index data, or check the related error logs for further investigation.

10.2.8.1.1 Errors reported during transaction execution

This section lists the data inconsistency errors reported when TiDB executes transactions and explains the meanings of these errors with examples.

Error 8133

```
ERROR 8133 (HY000): data inconsistency in table: t, index: k2, index-
↪ count:1 != record-count:0
```

This error indicates that for the `k2` index in table `t`, the number of indexes in the table is 1 and the number of row records is 0. The number is inconsistent.

Error 8138

```
ERROR 8138 (HY000): writing inconsistent data in table: t, expected-
↪ values:{KindString green} != record-values:{KindString GREEN}
```

This error indicates that the transaction was attempting to write an incorrect row value. For the data to be written, the encoded row data does not match the original data before encoding.

Error 8139

```
ERROR 8139 (HY000): writing inconsistent data in table: t, index: i1,
↪ index-handle:4 != record-handle:3, index: tables.mutation{key:kv.Key{0
↪ x74, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x69, 0x80, 0x0, 0
↪ x0, 0x0, 0x0, 0x0, 0x0, 0x1, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0,
↪  0x0, 0xfc, 0x1, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x0, 0x0, 0x0, 0xfc, 0x3,
↪  0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0, 0x4}, flags:0x0, value:[]uint8{0x30
↪ }, indexID:1}, record: tables.mutation{key:kv.Key{0x74, 0x80, 0x0, 0x0,
↪ 0x0, 0x0, 0x0, 0x0, 0x49, 0x5f, 0x72, 0x80, 0x0, 0x0, 0x0, 0x0, 0x0, 0x0
↪ , 0x3}, flags:0xd, value:[]uint8{0x80, 0x0, 0x2, 0x0, 0x0, 0x0, 0x1, 0x2
↪ , 0x5, 0x0, 0xa, 0x0, 0x68, 0x65, 0x6c, 0x6c, 0x6f, 0x68, 0x65, 0x6c, 0
↪ x6c, 0x6f}, indexID:0}
```

This error indicates that the handle (that is, the key of the row data) of the data to be written is inconsistent. For index `i1` in table `t`, the row to be written by the transaction has a handle of 4 in the index key-value pair and a handle of 3 in the row record key-value pair. The data of this row will not be written.

Error 8140

```
ERROR 8140 (HY000): writing inconsistent data in table: t, index: i2,
↪ col: c1, indexed-value:{KindString hellp} != record-value:{KindString
↪ hello}
```

This error indicates that the data in a row to be written by the transaction does not match the data in the index. For index `i2` in table `t`, a row to be written by the transaction has data `hellp` in the index key-value pair and data `hello` in the record key-value pair. The data of this row will not be written.

Error 8141

```
ERROR 8141 (HY000): assertion failed: key: 748000000000000405f7201330000000000000f8
↪ , assertion: NotExist, start_ts: 430590532931813377, existing start ts:
↪ 430590532931551233, existing commit ts: 430590532931551234
```

This error indicates that the assertion failed when a transaction was being committed. Assuming that data and indexes are consistent, TiDB asserted that the key `748000000000000405f7201330000000000000000f8` did not exist. When the transaction was being committed, TiDB found the key did exist, written by the transaction with the `start ts` `430590532931551233`. TiDB will print the Multi-Version Concurrency Control (MVCC) history of this key to logs.

10.2.8.1.2 Errors reported in admin check

This section lists the data inconsistency errors that might occur in TiDB when you execute the `ADMIN CHECK [TABLE|INDEX]` statement, and explains the meanings of these errors with examples.

Error 8003

```
ERROR 8003 (HY000): table count 3 != index(idx)count 2
```

This error indicates that the table on which the `ADMIN CHECK` statement is executed has 3 row key-value pairs but only 2 index key-value pairs.

Error 8134

```
ERROR 8134 (HY000): data inconsistency in table: t, index: c2, col: c2
↪ , handle: "2", index-values:"KindInt64 13" != record-values:"KindInt64
↪ 12", compare err:<nil>
```

This error indicates that for index `c2` in table `t`, the value of column `c2` has the following inconsistency:

- In the index key-value pair of the row whose handle is `2`, the value of column `c2` is `13`.
- In the row record key-value pair, the value of column `c2` is `12`.

Error 8223

```
ERROR 8223 (HY000): data inconsistency in table: t2, index: i1, handle:
↪  {hello, hello}, index-values:"" != record-values:"handle: {hello, hello
↪ }, values: [KindString hello KindString hello]"
```

This error indicates that `index-values` are null and `record-values` are not null, meaning that there is no corresponding index for the row.

10.2.8.2 Solutions

If you encounter a data inconsistency error, get support from PingCAP for troubleshooting immediately instead of dealing with the error by yourself. If your application needs to skip such errors urgently, you can use the following methods to bypass the check.

10.2.8.2.1 Rewrite SQL

If the data inconsistency error occurs in a particular SQL statement only, you can bypass this error by rewriting the SQL statement to another equivalent form using different execution operators.

10.2.8.2.2 Disable error checks

For the following errors reported in transaction execution, you can bypass the corresponding checks:

- To bypass the checks of errors 8138, 8139, and 8140, configure `set @@tidb_enable_mutation_checker=0`.
- To bypass the checks of error 8141, configure `set @@tidb_txn_assertion_level=OFF`.

> **Note:**
>
> Disabling `tidb_enable_mutation_checker` and `tidb_txn_assertion_level` will bypass the corresponding checks of all SQL statements.

For other errors reported in transaction execution and all errors reported during the execution of the `ADMIN CHECK [TABLE|INDEX]` statement, you cannot bypass the corresponding check, because the data is already inconsistent.

10.3 Diagnostic Methods

10.3.1 SQL Diagnostics

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

10.3.1.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table**: The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query this information using SQL statements.

- **Cluster monitoring table**: The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

10.3.1.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.
- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the sysctl information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

10.3.1.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

10.3.1.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

10.3.2 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided statement summary tables in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` in terms of features.

- statements_summary
- statements_summary_history
- cluster_statements_summary
- cluster_statements_summary_history
- statements_summary_evicted

> **Note:**
>
> The preceding tables are not available on TiDB Cloud Serverless clusters.

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

10.3.2.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the resource group, the SQL digest and the plan digest, and provides statistics for each SQL category.

The "SQL digest" here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
    ↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The "plan digest" here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For

example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
  SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
    SUMMARY_END_TIME: 2020-01-02 11:30:00
          STMT_TYPE: Select
        SCHEMA_NAME: test
             DIGEST: 0611
                 ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
                 ↪
        DIGEST_TEXT: select * from employee where id = ?
        TABLE_NAMES: test.employee
        INDEX_NAMES: NULL
        SAMPLE_USER: root
         EXEC_COUNT: 3
        SUM_LATENCY: 1035161
        MAX_LATENCY: 399594
        MIN_LATENCY: 301353
        AVG_LATENCY: 345053
    AVG_PARSE_LATENCY: 57000
    MAX_PARSE_LATENCY: 57000
  AVG_COMPILE_LATENCY: 175458
  MAX_COMPILE_LATENCY: 175458
  ............
              AVG_MEM: 103
              MAX_MEM: 103
              AVG_DISK: 65535
              MAX_DISK: 65535
    AVG_AFFECTED_ROWS: 0
          FIRST_SEEN: 2020-01-02 11:12:54
           LAST_SEEN: 2020-01-02 11:25:24
    QUERY_SAMPLE_TEXT: select * from employee where id=3100
     PREV_SAMPLE_TEXT:
          PLAN_DIGEST:
             ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
             ↪
                PLAN: Point_Get_1   root    1       table:employee, handle:3100
```

Note:

- In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).
- Starting from v7.5.1 and v7.6.0, for clusters with resource control enabled, `statements_summary` will be aggregated by resource group, for example, the same statements executed in different resource groups will be collected as different records.

10.3.2.2 `statements_summary_history`

The table schema of `statements_summary_history` is identical to that of `statements_summary`. `statements_summary_history` saves the history data of a time range. By checking history data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

10.3.2.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` system variable limits the number of SQL digests that the `statements_summary` and `statements_summary_history` tables can store in memory totally. Once this limit is exceeded, TiDB evicts the least recently used SQL digests from both `statements_summary` and `statements_summary_history` tables.

Note:

When `tidb_stmt_summary_enable_persistent` is enabled, data in the `statements_summary_history` table is persisted to the disk. In this case, `tidb_stmt_summary_max_stmt_count` only limits the number of SQL digests that the `statements_summary` table can store in memory, and TiDB evicts the least recently used SQL digests only from the `statements_summary` table when `tidb_stmt_summary_max_stmt_count` is exceeded.

The `statements_summary_evicted` table records the period during which the eviction occurs and the number of SQL digests evicted during that period. This table helps you evaluate whether `tidb_stmt_summary_max_stmt_count` is properly configured for your workload. If this table contains records, it indicates that the number of SQL digests exceeded `tidb_stmt_summary_max_stmt_count` at some time point.

On the SQL statements page of TiDB Dashboard, the information about evicted statements is displayed in the `Others` row.

10.3.2.4 The `cluster` tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` tables only show the statement summary of a single TiDB server. To query the data of the entire cluster, you need to query the `cluster_statements_summary`, `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as those in `statements_summary`, `statements_summary_history`, and `statements_summary_evicted`.

10.3.2.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. `1` represents `enable`, and `0` means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.
- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` table is refreshed. The time unit is second (s). The default value is `1800`.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statements_summary_evicted` table. The default value is `24`.
- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL digests that the `statements_summary` and `statements_summary_history` tables can store in memory totally. The default value is `3000`.

  Once this limit is exceeded, TiDB evicts the least recently used SQL digests from both `statements_summary` and `statements_summary_history` tables. These evicted digests are then counted in the `statements_summary_evicted` table.

Note:

- When a SQL digest is evicted, its related summary data of all time ranges is removed from both the `statements_summary` and `statements_summary_history` tables. As a result, even if the number of SQL digests within a specific time range does not exceed the limit, the number of SQL digests in the `statements_summary_history` table might be less than the actual number of SQL digests. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.
- For TiDB Self-Managed, when `tidb_stmt_summary_enable_persistent` is enabled, data in the `statements_summary_history` table is persisted to the disk. In this case, `tidb_stmt_summary_max_stmt_count` only limits the number of SQL digests that the `statements_summary` table can store in memory, and TiDB evicts the least recently used SQL digests only from the `statements_summary` table when `tidb_stmt_summary_max_stmt_count` is exceeded.

- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is `4096`.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. `1` means to count, and `0` means not to count. The default value is `0`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_stmt_summary_max_stmt_count = 3000;
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the preceding configuration takes effect, the `statements_summary` table is cleared every 30 minutes and the `statements_summary_history` table stores up to 3000 types of SQL statements. For each type, the `statements_summary_history` table stores data for the recent 24 periods. The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` table is updated every 30 minutes.

Note:

- If a SQL type appears every minute, the `statements_summary_history` stores data for the most recent 12 hours. If a SQL type only appears from 00:00 to 00:30 every day, the `statements_summary_history` stores data for the most recent 24 periods, with each period being 1 day. Therefore, the `statements_summary_history` stores the most recent 24 days of data for this SQL type.
- The `tidb_stmt_summary_history_size`, `tidb_stmt_summary_max_stmt_count`, and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs, the SQL size, SQL count, and machine configuration. It is not recommended to set them too large values. You can calculate the memory usage using `tidb_stmt_summary_history_size * tidb_stmt_summary_max_stmt_count * tidb_stmt_summary_max_sql_length * 3`.

10.3.2.5.1 Set a proper size for statement summary

After the system has run for a period of time (depending on the system load), you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----------------------------------------+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----------------------------------------+
| 3000                                    |
+-----------------------------------------+
1 row in set (0.001 sec)

+----------+
| count(*) |
+----------+
|     3001 |
+----------+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+--------------------+--------------------+---------------+
```

```
| BEGIN_TIME          | END_TIME            | EVICTED_COUNT |
+---------------------+---------------------+---------------+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 |     59 |
+---------------------+---------------------+---------------+
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 |     45 |
+---------------------+---------------------+---------------+
2 row in set (0.001 sec)
```

From the preceding result, you can see that a maximum of 59 SQL categories are evicted. In this case, it is recommended that you increase the size of the `statement_summary` table by at least 59 records, which means increasing the size to at least 3059 records.

10.3.2.6 Limitation

By default, statements summary tables are saved in memory. When a TiDB server restarts, all data will be lost.

To address this issue, TiDB v6.6.0 experimentally introduces the statement summary persistence feature, which is disabled by default. After this feature is enabled, the history data is no longer saved in memory, but directly written to disks. In this way, the history data is still available if a TiDB server restarts.

10.3.2.7 Persist statements summary

> **Warning:**
>
> Statements summary persistence is an experimental feature. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

As described in the Limitation section, statements summary tables are saved in memory by default. Once a TiDB server restarts, all the statements summary will be lost. Starting from v6.6.0, TiDB experimentally provides the configuration item `tidb_stmt_summary_enable_persistent` to allow users to enable or disable statements summary persistence.

To enable statements summary persistence, you can add the following configuration items to the TiDB configuration file:

```
[instance]
tidb_stmt_summary_enable_persistent = true
### The following entries use the default values, which can be modified as
    ↪ needed.
### tidb_stmt_summary_filename = "tidb-statements.log"
```

```
### tidb_stmt_summary_file_max_days = 3
### tidb_stmt_summary_file_max_size = 64 # MiB
### tidb_stmt_summary_file_max_backups = 0
```

After statements summary persistence is enabled, the memory keeps only the current real-time data and no history data. Once the real-time data is refreshed as history data, the history data is written to the disk at an interval of `tidb_stmt_summary_refresh_interval` described in the Parameter configuration section. Queries on the `statements_summary_history` or `cluster_statements_summary_history` table will return results combining both in-memory and on-disk data.

Note:

- When statements summary persistence is enabled, the `tidb_stmt_summary_history_size` configuration described in the Parameter configuration section will no longer take effect because the memory does not keep the history data. Instead, the following three configurations will be used to control the retention period and size of history data for persistence: `tidb_stmt_summary_file_max_days`, `tidb_stmt_summary_file_max_size`, and `tidb_stmt_summary_file_max_backups`.
- The smaller the value of `tidb_stmt_summary_refresh_interval`, the more immediate data is written to the disk. However, this also means more redundant data is written to the disk.

10.3.2.8 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

10.3.2.8.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary
    WHERE digest_text LIKE 'select * from employee%';
```

`1ms` and `0.3ms` are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-------------+-----------+-----------------------------------------+
| avg_latency | exec_count | query_sample_text                      |
+-------------+-----------+-----------------------------------------+
|     1042040 |         2 | select * from employee where name='eric' |
|      345053 |         3 | select * from employee where id=3100 |
+-------------+-----------+-----------------------------------------+
2 rows in set (0.00 sec)
```

10.3.2.8.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary_history
    WHERE summary_begin_time='2020-01-02 10:00:00'
    ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
| sum_latency | avg_latency | exec_count | query_sample_text
    ↪                                       |
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
|     7855660 |    1122237 |         7 | select avg(salary) from employee
    ↪ where company_id=2013       |
|     7241960 |    1448392 |         5 | select * from employee join company
    ↪ on employee.company_id=company.id |
|     2084081 |    1042040 |         2 | select * from employee where name='
    ↪ eric'                     |
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
3 rows in set (0.00 sec)
```

10.3.2.9 Fields description

10.3.2.9.1 `statements_summary` fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.
- `INDEX_NAMES`: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- `SAMPLE_USER`: The users who execute SQL statements of this category. Only one user is taken.
- `PLAN_DIGEST`: The digest of the execution plan.
- `PLAN`: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- `BINARY_PLAN`: The original execution plan encoded in binary format. If there are multiple statements, the plan of only one statement is taken. Execute the `SELECT tidb_decode_binary_plan('xxx...')` statement to parse the specific execution plan.
- `PLAN_CACHE_HITS`: The total number of times that SQL statements of this category hit the plan cache.
- `PLAN_IN_CACHE`: Indicates whether the previous execution of SQL statements of this category hit the plan cache.
- `PLAN_CACHE_UNQUALIFIED`: The number of times that the SQL statements of this category fail to hit the plan cache.
- `PLAN_CACHE_UNQUALIFIED_LAST_REASON`: The reason why the SQL statements of this category fail to hit the plan cache last time.

Fields related to execution time:

- `SUMMARY_BEGIN_TIME`: The beginning time of the current summary period.
- `SUMMARY_END_TIME`: The ending time of the current summary period.
- `FIRST_SEEN`: The time when SQL statements of this category are seen for the first time.
- `LAST_SEEN`: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- `EXEC_COUNT`: Total execution times of SQL statements of this category.
- `SUM_ERRORS`: The sum of errors occurred during execution.
- `SUM_WARNINGS`: The sum of warnings occurred during execution.
- `SUM_LATENCY`: The total execution latency of SQL statements of this category.
- `MAX_LATENCY`: The maximum execution latency of SQL statements of this category.
- `MIN_LATENCY`: The minimum execution latency of SQL statements of this category.
- `AVG_LATENCY`: The average execution latency of SQL statements of this category.
- `AVG_PARSE_LATENCY`: The average latency of the parser.
- `MAX_PARSE_LATENCY`: The maximum latency of the parser.
- `AVG_COMPILE_LATENCY`: The average latency of the compiler.
- `MAX_COMPILE_LATENCY`: The maximum latency of the compiler.
- `AVG_MEM`: The average memory (byte) used.
- `MAX_MEM`: The maximum memory (byte) used.
- `AVG_DISK`: The average disk space (byte) used.
- `MAX_DISK`: The maximum disk space (byte) used.
- `AVG_TIDB_CPU_TIME`: The average TiDB server CPU time that SQL statements of this category consume. It shows meaningful values only when the Top SQL feature is enabled. Otherwise the value is always `0`.

Fields related to TiKV Coprocessor task:

- `SUM_COP_TASK_NUM`: The total number of Coprocessor requests sent.
- `MAX_COP_PROCESS_TIME`: The maximum execution time of Coprocessor tasks.
- `MAX_COP_PROCESS_ADDRESS`: The address of the Coprocessor task with the maximum execution time.
- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.
- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.
- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.
- `AVG_TIKV_CPU_TIME`: The average TiKV server CPU time that SQL statements of this category consume.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.
- `AVG_TXN_RETRY`: The average number of transaction retries.
- `MAX_TXN_RETRY`: The maximum number of transaction retries.
- `SUM_BACKOFF_TIMES`: The sum of retries when SQL statements of this category encounter errors that require a retry.
- `BACKOFF_TYPES`: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- `AVG_AFFECTED_ROWS`: The average number of rows affected.
- `PREV_SAMPLE_TEXT`: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

Fields related to Resource Control:

- `AVG_REQUEST_UNIT_WRITE`: the average number of write RUs consumed by SQL statements.
- `MAX_REQUEST_UNIT_WRITE`: the maximum number of write RUs consumed by SQL statements.

- `AVG_REQUEST_UNIT_READ`: the average number of read RUs consumed by SQL statements.
- `MAX_REQUEST_UNIT_READ`: the maximum number of read RUs consumed by SQL statements.
- `AVG_QUEUED_RC_TIME`: the average waiting time for available RU when executing SQL statements.
- `MAX_QUEUED_RC_TIME`: the maximum waiting time for available RU when executing SQL statements.
- `RESOURCE_GROUP`: the resource group bound to SQL statements.

10.3.2.9.2 `statements_summary_evicted` fields description

- `BEGIN_TIME`: Records the starting time.
- `END_TIME`: Records the ending time.
- `EVICTED_COUNT`: The number of SQL categories that are evicted during the record period.

10.3.3 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `tidb_mem_quota_query` (1 GB by default) to the tidb-server log file ("tidb.log" by default).

> **Note:**
>
> The expensive query log differs from the slow query log in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

10.3.3.1 Expensive query log example

```
[expensivequery.go:145] [expensive_query] [cost_time=60.021998785s] [cop_
    ↪ time=0.022540151s] [process_time=28.448316643s] [wait_time
    ↪ =0.045507163s] [request_count=430] [total_keys=3538276] [process_keys
    ↪ =3537846] [num_cop_tasks=430] [process_avg_time=0.066158875s] [
    ↪ process_p90_time=0.140427865s] [process_max_time=0.27903656s] [
    ↪ process_max_addr=tikv-1-peer:20160] [wait_avg_time=0.00010583s] [wait
    ↪ _p90_time=0.000358794s] [wait_max_time=0.001218721s] [wait_max_addr=
```

```
↪ tikv-1-peer:20160] [stats=usertable:451469035823955972] [conn
↪ =1621098504] [user=root] [database=test] [table_ids="[104]"] [txn_
↪ start_ts=451469037501677571] [mem_max="621043469 Bytes (592.3 MB)"] [
↪ sql="insert /*+ SET_VAR(tidb_dml_type=bulk) */ into usertable_2
↪ select * from usertable limit 5000000"] [session_alias=] ["affected
↪ rows"=3505282]]
```

10.3.3.2 Fields description

Basic fields:

- `cost_time`: The execution time of a statement when the log is printed.
- `stats`: The version of statistics used by the tables or indexes involved in a statement. If the value is `pseudo`, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- `table_ids`: The IDs of the tables involved in a statement.
- `txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `sql`: The sql statement.
- `session_alias`: The alias of the current session.
- `affected rows`: The number of rows currently affected by the statement.

Memory usage related fields:

- `mem_max`: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is `60026`.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.

- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

10.3.4 Use PLAN REPLAYER to Save and Restore the On-Site Information of a Cluster

When you locate and troubleshoot the issues of a TiDB cluster, you often need to provide information on the system and the execution plan. To help you get the information and troubleshoot cluster issues in a more convenient and efficient way, the `PLAN REPLAYER` ↪ command is introduced in TiDB v5.3.0. This command enables you to easily save and restore the on-site information of a cluster, improves the efficiency of troubleshooting, and helps you more easily archive the issue for management.

The features of `PLAN REPLAYER` are as follows:

- Exports the information of a TiDB cluster at an on-site troubleshooting to a ZIP-formatted file for storage.
- Imports into a cluster the ZIP-formatted file exported from another TiDB cluster. This file contains the information of the latter TiDB cluster at an on-site troubleshooting.

10.3.4.1 Use `PLAN REPLAYER` to export cluster information

You can use `PLAN REPLAYER` to save the on-site information of a TiDB cluster. The export interface is as follows:

```
PLAN REPLAYER DUMP [WITH STATS AS OF TIMESTAMP expression] EXPLAIN [ANALYZE
    ↪ ] sql-statement;
```

Based on `sql-statement`, TiDB sorts out and exports the following on-site information:

- TiDB version
- TiDB configuration
- TiDB session variables

- TiDB SQL bindings
- The table schema in `sql-statement`
- The statistics of the table in `sql-statement`
- The result of `EXPLAIN [ANALYZE] sql-statement`
- Some internal procedures of query optimization

If historical statistics are enabled, you can specify a time in the `PLAN REPLAYER` statement to get the historical statistics for the corresponding time. You can directly specify a time and date or specify a timestamp. TiDB looks for the historical statistics before the specified time and exports the latest one among them.

If there are no historical statistics before the specified time, TiDB exports the latest statistics, which is consistent with the behavior when no time is specified. In addition, TiDB prints the error messages in the `errors.txt` file within the exported `ZIP` file.

> **Note:**
>
> `PLAN REPLAYER` **DOES NOT** export any table data.

10.3.4.1.1 Examples of exporting cluster information

```
use test;
create table t(a int, b int);
insert into t values(1,1), (2, 2), (3, 3);
analyze table t;

plan replayer dump explain select * from t;
plan replayer dump with stats as of timestamp '2023-07-17 12:00:00' explain
    ↪  select * from t;
plan replayer dump with stats as of timestamp '442012134592479233' explain
    ↪ select * from t;
```

`PLAN REPLAYER DUMP` packages the table information above into a `ZIP` file and returns the file identifier as the execution result.

> **Note:**
>
> The `ZIP` file is stored in a TiDB cluster for at most one hour. After one hour, TiDB will delete it.

```
MySQL [test]> plan replayer dump explain select * from t;
```

```
+-----------------------------------------------------------------+
| Dump_link                                                       |
+-----------------------------------------------------------------+
| replayer_JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip |
+-----------------------------------------------------------------+
1 row in set (0.015 sec)
```

Alternatively, you can use the session variable `tidb_last_plan_replayer_token` to obtain the result of the last `PLAN REPLAYER DUMP` execution.

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_Fdamsm3C7ZiPJ-LQqgVjkA==_1663304195885090000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

When there are multiple SQL statements, you can obtain the result of the `PLAN REPLAYER DUMP` execution using a file. The results of multiple SQL statements are separated by `;` in this file.

```
plan replayer dump explain 'sqls.txt';
```

```
Query OK, 0 rows affected (0.03 sec)
```

```
SELECT @@tidb_last_plan_replayer_token;
```

```
+-----------------------------------------------------------+
| @@tidb_last_plan_replayer_token                           |
+-----------------------------------------------------------+
| replayer_LEDKg8sb-K0u24QesiH8ig==_1663226556509182000.zip |
+-----------------------------------------------------------+
1 row in set (0.00 sec)
```

Because the file cannot be downloaded on MySQL Client, you need to use the TiDB HTTP interface and the file identifier to download the file:

```
http://${tidb-server-ip}:${tidb-server-status-port}/plan_replayer/dump/${
    ↪ file_token}
```

`${tidb-server-ip}:${tidb-server-status-port}` is the address of any TiDB server in the cluster. For example:

```
curl http://127.0.0.1:10080/plan_replayer/dump/replayer_
    ↪ JOGvpu4t7dssySqJfTtS4A==_1635750890568691080.zip > plan_replayer.zip
```

10.3.4.2 Use `PLAN REPLAYER` to import cluster information

> **Warning:**
>
> When you import the on-site information of a TiDB cluster to another cluster, the TiDB session variables, SQL bindings, table schemas and statistics of the latter cluster are modified.

With an existing `ZIP` file exported using `PLAN REPLAYER`, you can use the `PLAN REPLAYER` import interface to restore the on-site information of a cluster to any other TiDB cluster. The syntax is as follows:

```
PLAN REPLAYER LOAD 'file_name';
```

In the statement above, `file_name` is the name of the `ZIP` file to be imported.

For example:

```
PLAN REPLAYER LOAD 'plan_replayer.zip';
```

> **Note:**
>
> You need to disable auto analyze. Otherwise the imported statistics will be overwritten by analyze.

You can disable auto analyze by setting the `tidb_enable_auto_analyze` system variable to `OFF`:

```
set @@global.tidb_enable_auto_analyze = OFF;
```

After the cluster information is imported, the TiDB cluster is loaded with the required table schema, statistics and other information that affects the construction of the execution plan. You can view the execution plan and verify statistics in the following way:

```
mysql> desc t;
+-------+------+------+------+---------+-------+
| Field | Type | Null | Key | Default | Extra |
```

```
+-------+------+------+------+---------+-------+
| a     | int  | YES  |      | NULL    |       |
| b     | int  | YES  |      | NULL    |       |
+-------+------+------+------+---------+-------+
2 rows in set (0.01 sec)

mysql> explain select * from t where a = 1 or b =1;
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| id                     | estRows | task     | access object | operator info
   ↪                    |
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| TableReader_7          | 0.01    | root     |               | data:Selection_6
   ↪                   |
|  ─Selection_6          | 0.01    | cop[tikv] |              | or(eq(test.t.a,
   ↪ 1), eq(test.t.b, 1)) |
|    ─TableFullScan_5    | 6.00    | cop[tikv] | table:t      | keep order:false,
   ↪  stats:pseudo  |
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
3 rows in set (0.00 sec)

mysql> show stats_meta;
+--
   ↪ -------+-----------+---------------+--------------------+-------------+-----
   ↪
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_
   ↪ count |
+--
   ↪ -------+-----------+---------------+--------------------+-------------+-----
   ↪
| test    | t          |               | 2022-08-26 15:52:07 |           3 |
   ↪        6 |
+--
   ↪ -------+-----------+---------------+--------------------+-------------+-----
   ↪
1 row in set (0.04 sec)
```

After the scene is loaded and restored, you can diagnose and improve the execution plan for the cluster.

Note:

If you use the `mysql` command-line client and encounter `ERROR 2068 (HY000): LOAD DATA LOCAL INFILE file request rejected due to restrictions on access.`, you can add `--local-infile=true` in the connection string.

10.3.4.3 Use `PLAN REPLAYER CAPTURE` to capture target plans

When you locate the execution plan of TiDB in some scenarios, the target SQL statement and the target execution plan might only appear occasionally in the query, so you cannot directly capture the statement and the plan using `PLAN REPLAYER`. In such cases, you can use `PLAN REPLAYER CAPTURE` to help you capture the optimizer information of the target SQL statement and the target plan.

`PLAN REPLAYER CAPTURE` has the following main features:

- Registers the target SQL statement and the digest of the target execution plan in the TiDB cluster in advance, and starts matching the target query.
- When the target query is matched successfully, directly captures its optimizer-related information and exports it as a ZIP file.
- For each matched SQL and execution plan, the information is only captured once.
- Displays the ongoing matching tasks and generated files through the system table.
- Periodically cleans up historical files.

10.3.4.3.1 Enable `PLAN REPLAYER CAPTURE`

`PLAN REPLAYER CAPTURE` is controlled by the system variable `tidb_enable_plan_replayer_capture`. To enable `PLAN REPLAYER CAPTURE`, set the value of the system variable to `ON`.

10.3.4.3.2 Use `PLAN REPLAYER CAPTURE`

You can register the digest of the target SQL statement and execution plan in the TiDB cluster using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' 'plan_digest';
```

If the target SQL statement has multiple execution plans and you want to capture all execution plans, you can register all the execution plans at once using the following statement:

```
PLAN REPLAYER CAPTURE 'sql_digest' '*';
```

10.3.4.3.3 View the capture tasks

You can view the ongoing capture tasks of `PLAN REPLAYER CAPTURE` in the TiDB cluster using the following statement:

```
mysql> PLAN REPLAYER CAPTURE 'example_sql' 'example_plan';
Query OK, 1 row affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+-------------+--------------+---------------------+
| sql_digest | plan_digest | update_time     |
+-------------+--------------+---------------------+
| example_sql | example_plan | 2023-01-28 11:58:22 |
+-------------+--------------+---------------------+
1 row in set (0.01 sec)
```

10.3.4.3.4 View the capture results

After `PLAN REPLAYER CAPTURE` successfully captures the result, you can view the token used for file download using the following SQL statement:

```
mysql> SELECT * FROM mysql.plan_replayer_status;
+--
   ↪ ------------------------------------------------------------------+--------------
   ↪
| sql_digest                                                         | plan_digest
   ↪                                                                  | origin_sql | token
   ↪                                                                 | update_time      | fail_
   ↪ reason | instance    |
+--
   ↪ ------------------------------------------------------------------+--------------
   ↪

   ↪ replayer_RZcRHJB7BaCccxFfOIAhWg==_1668746293578282450.zip |
   ↪ 2022-11-18 12:38:13 | NULL | 172.16.4.4:4022 |
+--
   ↪ ------------------------------------------------------------------+--------------
```

```
    ↪
3 rows in set (0.00 sec)
```

The method of downloading the file of `PLAN REPLAYER CAPTURE` is the same as that of `PLAN REPLAYER`. For details, see Examples of exporting cluster information.

> **Note:**
>
> The result file of `PLAN REPLAYER CAPTURE` is kept in the TiDB cluster for up to one week. After one week, TiDB deletes the file.

10.3.4.3.5 Remove the capture tasks

If a capture task is no longer needed, you can remove it using the `PLAN REPLAYER CAPTURE REMOVE` statement. For example:

```
mysql> PLAN REPLAYER CAPTURE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
Query OK, 0 rows affected (0.01 sec)

mysql> SELECT * FROM mysql.plan_replayer_task;
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| sql_digest                                                       | plan_digest
    ↪                                                  | update_time         |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
| 077a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0 | 4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce |
    ↪ 2024-05-21 11:26:10 |
+--
    ↪ ----------------------------------------------------------------+--------------
    ↪
1 row in set (0.01 sec)

mysql> PLAN REPLAYER CAPTURE REMOVE '077
    ↪ a87a576e42360c95530ccdac7a1771c4efba17619e26be50a4cfd967204a0' '4838
    ↪ af52c1e07fc8694761ad193d16a689b2128bc5ced9d13beb31ae27b370ce';
Query OK, 0 rows affected (0.01 sec)
```

```
mysql> SELECT * FROM mysql.plan_replayer_task;
Empty set (0.01 sec)
```

10.3.4.4 Use PLAN REPLAYER CONTINUOUS CAPTURE

After PLAN REPLAYER CONTINUOUS CAPTURE is enabled, TiDB asynchronously records the applications' SQL statements with the PLAN REPLAYER method according to their SQL DIGEST and PLAN DIGEST. For SQL statements and execution plans that share the same DIGEST, PLAN REPLAYER CONTINUOUS CAPTURE does not record them repeatedly.

10.3.4.4.1 Enable PLAN REPLAYER CONTINUOUS CAPTURE

PLAN REPLAYER CONTINUOUS CAPTURE is controlled by the system variable tidb_enable_plan_replayer_continuous_capture. To enable PLAN REPLAYER CONTINUOUS CAPTURE, set the value of the system variable to ON.

10.3.4.4.2 View the capture results

The method of viewing the capture results of PLAN REPLAYER CONTINUOUS CAPTURE is the same as that of Viewing the capture results of PLAN REPLAYER CAPTURE.

10.3.5 Understanding Stale Read and safe-ts in TiKV

In this guide, you can learn about Stale Read and safe-ts in TiKV and how to diagnose common issues related to Stale Read.

10.3.5.1 Overview of Stale Read and safe-ts

Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. In TiKV, Stale Read relies on safe-ts. If a read request on a Region peer has a timestamp (ts) that is less than or equal to the Region's safe-ts, TiDB can safely read the data from the peer. TiKV implements this safety guarantee by ensuring that safe-ts is always less than or equal to resolved-ts.

10.3.5.2 Understand safe-ts and resolved-ts

This section explains the concepts and maintenance of safe-ts and resolved-ts.

10.3.5.2.1 What is safe-ts?

The safe-ts is a timestamp that each peer in a Region maintains. It ensures that all transactions with a timestamp less than this value have been applied locally, which enables local Stale Read.

10.3.5.2.2 What is resolved-ts?

The resolved-ts is a timestamp that guarantees all transactions with a timestamp less than this value have been applied by the leader. Unlike safe-ts, which is a peer concept, resolved-ts is only maintained by the Region leader. Followers might have a smaller apply index than the leader, so resolved-ts cannot be directly treated as safe-ts in followers.

10.3.5.2.3 The maintenance of safe-ts

The `RegionReadProgress` module maintains safe-ts. The Region leader maintains resolved-ts and periodically sends its resolved-ts, the minimum required apply index (which validates this resolved-ts), and the Region itself to the `RegionReadProgerss` modules of all replicas via the CheckLeader RPC.

When a peer applies data, it updates the apply index and checks if any pending resolved-ts can become the new safe-ts.

10.3.5.2.4 The maintenance of resolved-ts

The Region leader uses a resolver to manage resolved-ts. This resolver tracks locks in the LOCK CF (Column Family) by receiving change logs when Raft applies. When initialized, the resolver scans the entire Region to track locks.

10.3.5.3 Diagnose Stale Read issues

This section introduces how to diagnose Stale Read issues using Grafana, `tikv-ctl`, and logs.

10.3.5.3.1 Identify issues

In the Grafana > TiDB dashboard > **KV Request** dashboard, the following panels show the hit rate, OPS, and traffic of Stale Read:

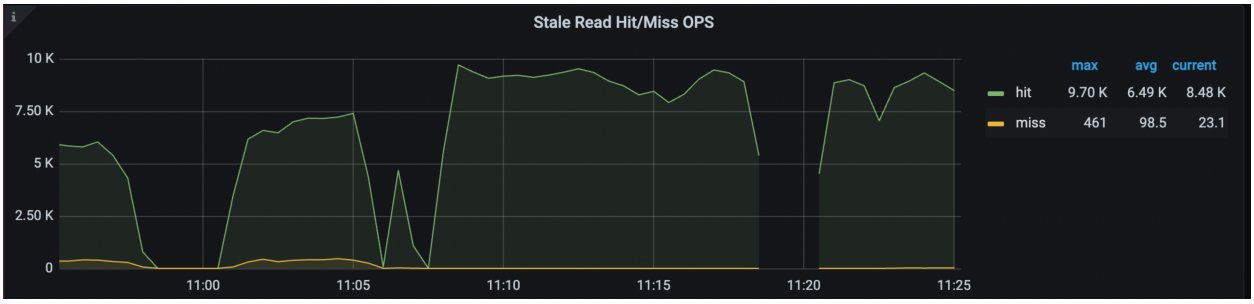

Figure 343: Stale Read Hit/Miss OPS

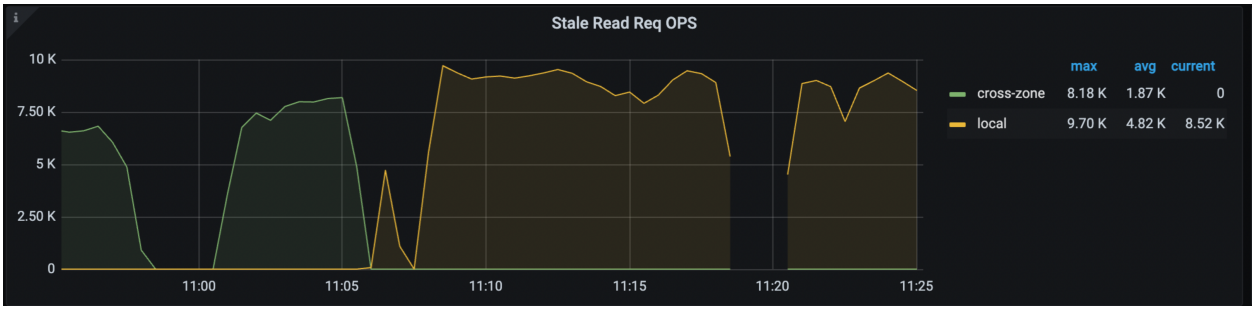

Figure 344: Stale Read Req OPS

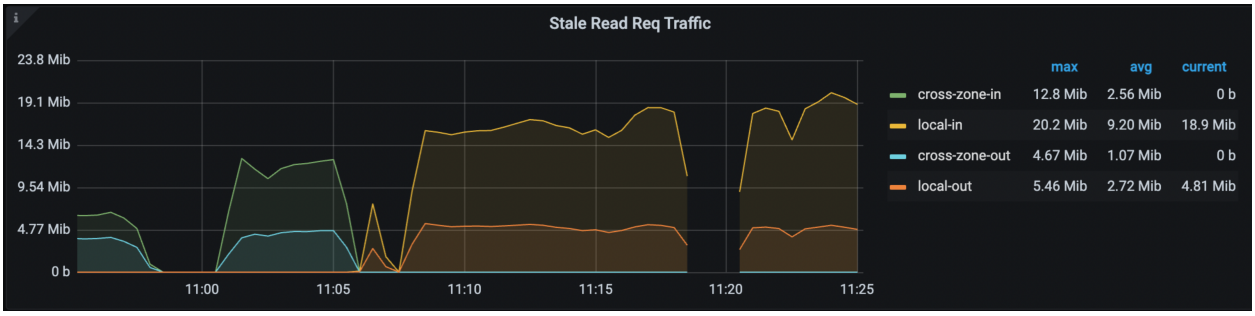

Figure 345: Stale Read Req Traffic

For more information about the preceding metrics, see TiDB monitoring metrics.

When Stale Read issues occur, you might notice changes in the preceding metrics. The most direct indicator is a WARN log from TiDB, which reports `DataIsNotReady` with a Region ID and the `safe-ts` it encounters.

10.3.5.3.2 Common causes

The most common causes that can impact the effectiveness of Stale Read are as follows:

- Transactions that take long time to commit.
- Transactions live too long before they commit.
- Delays in pushing the information of CheckLeader from the leader to the follower.

10.3.5.3.3 Use Grafana to diagnose

In the **TiKV-Details > Resolved-TS** dashboard, you can identify the Region with the smallest resolved-ts and safe-ts for each TiKV. If these timestamps are significantly behind real-time, you need to check the details of these Regions using `tikv-ctl`.

10.3.5.3.4 Use `tikv-ctl` to diagnose

`tikv-ctl` provides up-to-date details of the resolver and `RegionReadProgress`. For more details, see Get the state of a Region's `RegionReadProgress`.

The following is an example:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 14 --log --
    ↪ min-start-ts 0
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 0,
    applied_index: 92,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
    pending back item (latest) applied index: 0,
    paused: false,
Resolver:
    exist: true,
    resolved_ts: 0,
    tracked index: 92,
    number of locks: 0,
    number of transactions: 0,
    stopped: false,
```

The preceding output helps you determine:

- Whether locks are blocking resolved-ts.
- Whether the apply index is too small to update safe-ts.
- Whether the leader is sending a sufficiently updated resolved-ts when a follower peer exists.

10.3.5.3.5 Use logs to diagnose

Every 10 seconds, TiKV checks the following metrics:

- The Region leader whose resolved-ts is the minimal
- The Region follower whose safe-ts is the minimal
- The Region follower whose resolved-ts is the minimal

If any of these timestamps is abnormally small, TiKV prints a log.

These logs are especially useful when you want to diagnose a historical problem that is no longer present.

The following shows an example of the logs:

```
[2023/08/29 16:48:18.118 +08:00] [INFO] [endpoint.rs:505] ["the max gap of

10.3.5.4 Troubleshooting tips

10.3.5.4.1 Handle slow transaction commit

A transaction that takes a long time to commit is often a large transaction. The prewrite phase of this slow transaction leaves some locks, but it takes too long before the commit phase clean the locks. To troubleshoot this issue, you can try to identify the transaction to which the locks belong and try to pinpoint the reason they exist, such as using logs.

The following list some actions you can take:

- Specify the `--log` option in the `tikv-ctl` command and check TiKV logs to find the specific locks with their start_ts.
- Search the start_ts in both TiDB and TiKV logs to identify issues with the transaction.

  If a query takes over 60 seconds, an `expensive_query` log is printed with the SQL statement. You can use the start_ts value to match the log. The following is an example:

```
[2023/07/17 19:32:09.403 +08:00] [WARN] [expensivequery.go:145] [
    ↪ expensive_query] [cost_time=60.025022732s] [cop_time=0.00346666s]
    ↪  [process_time=8.358409508s] [wait_time=0.013582596s] [request_
    ↪ count=278] [total_keys=9943616] [process_keys=9943360] [num_cop_
    ↪ tasks=278] [process_avg_time=0.030066221s] [process_p90_time
    ↪ =0.045296042s] [process_max_time=0.052828934s] [process_max_addr
    ↪ =192.168.31.244:20160] [wait_avg_time=0.000048858s] [wait_p90_
```

```
    ↪ time=0.00006057s] [wait_max_time=0.00040991s] [wait_max_addr
    ↪ =192.168.31.244:20160] [stats=t:4429166669135872O1] [conn
    ↪ =2826881778407440457] [user=root] [database=test] [table_ids
    ↪ ="[100]"] [**txn_start_ts**=442916790435840001] [mem_max
    ↪ ="2514229289 Bytes (2.34 GB)"] [sql="update t set b = b + 1"]
```

- Use the CLUSTER_TIDB_TRX table to find active transactions if you cannot get enough information about the locks from logs.
- Execute SHOW PROCESSLIST to view the current sessions connected to the same TiDB server and their time spent on the current statement. But it does not show start_ts.

If the locks exist due to ongoing large transactions, consider modifying your application logic as these locks can hinder the progress of resolve-ts.

If the locks do not belong to any ongoing transactions, it might be due to a coordinator (TiDB) crashing after it prewrites the locks. In this case, TiDB will automatically resolve the locks. No action is required unless the problem persists.

10.3.5.4.2 Handle long-lived transactions

Transactions that remain active for a long time could possibly block the advance of resolved-ts, even if they eventually commit quickly. This is because it is the start-ts of these long-lived transactions that are used to calculate the resolved-ts.

To address this issue:

- Identify the Transaction: Begin by pinpointing the transaction associated with the locks. It is crucial to understand the reason behind their existence. Leveraging logs can be particularly helpful.
- Examine Application Logic: If the prolonged transaction duration is a result of your application's logic, consider revising it to prevent such occurrences.
- Address Slow Queries: If the transaction's duration is extended due to slow queries, prioritize resolving these queries to alleviate the issue.

10.3.5.4.3 Address CheckLeader issues

To address CheckLeader issues, you can check the network and the **Check Leader Duration** metric in **TiKV-Details > Resolved-TS** dashboard.

10.3.5.5 Example

If you observe an increasing miss rate of **Stale Read OPS** as follows:

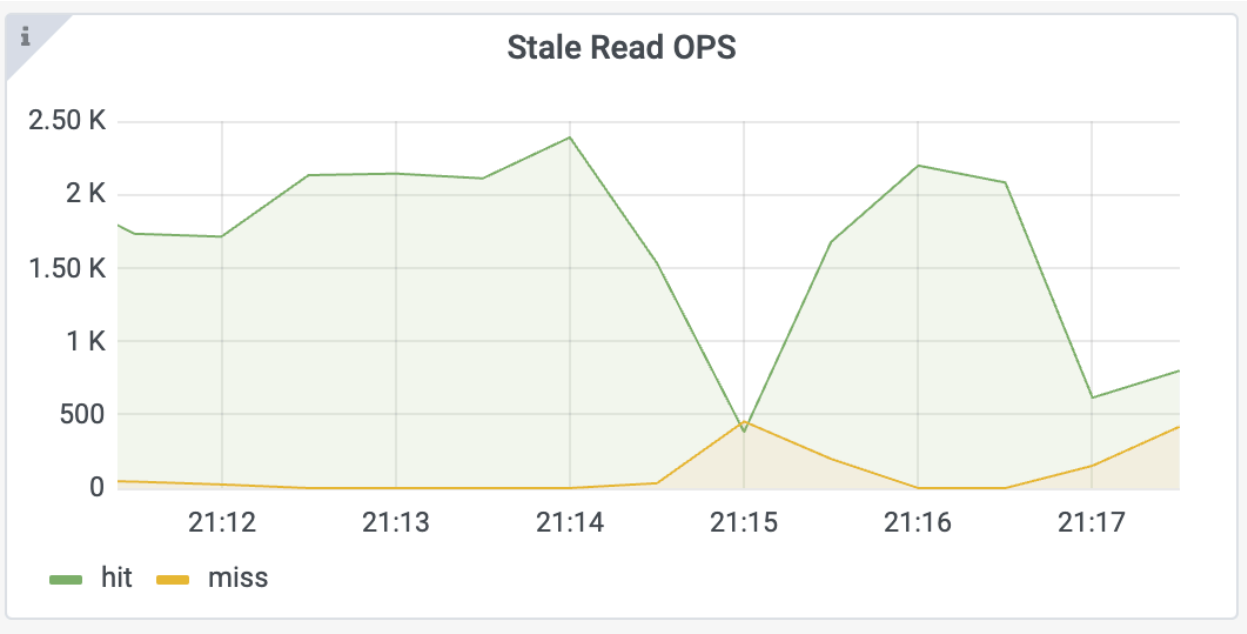

Figure 346: Example: Stale Read OPS

You can first check the **Max Resolved TS gap** and **Min Resolved TS Region** metrics in the **TiKV-Details > Resolved-TS** dashboard:

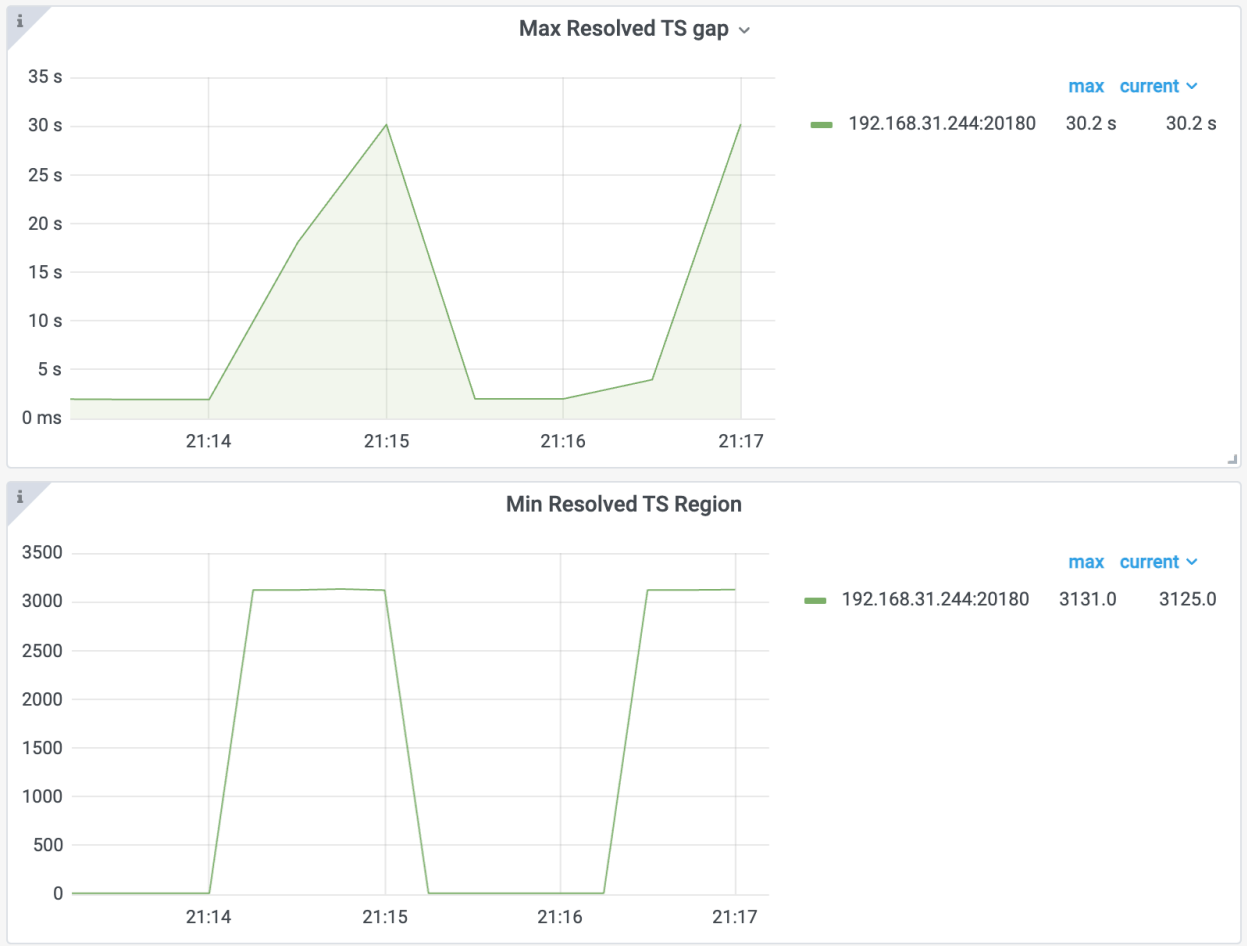

Figure 347: Example: Max Resolved TS gap

From the preceding metrics, you can find that Region `3121` and some other Regions have not updated their resolved-ts in time.

To get more details about the state of Region `3121`, you can run the following command:

```
./tikv-ctl --host 127.0.0.1:20160 get-region-read-progress -r 3121 --log
```

The output is as follows:

```
Region read progress:
    exist: true,
    safe_ts: 442918444145049601,
    applied_index: 2477,
    read_state.ts: 442918444145049601,
    read_state.apply_index: 1532,
    pending front item (oldest) ts: 0,
    pending front item (oldest) applied index: 0,
    pending back item (latest) ts: 0,
```

```
    pending back item (latest) applied index: 0,
    paused: false,
    discarding: false,
Resolver:
    exist: true,
    resolved_ts: 442918444145049601,
    tracked index: 2477,
    number of locks: 480000,
    number of transactions: 1,
    stopped: false,
```

A notable observation here is that the `applied_index` equals to the `tracked index` in resolver. Therefore, the resolver appears to be the root of this issue. You can also see that there is 1 transaction that leaves 480000 locks in this Region, which might be the cause.

To get the exact transaction and the keys of some of the locks, you can check TiKV logs and grep `locks with`. The output is as follows:

```
[2023/07/17 21:16:44.257 +08:00] [INFO] [resolver.rs:213] ["locks with the
    ↪ minimum start_ts in resolver"] [keys="[74800000000000006
    ↪ A5F7280000000000405F6, ... , 748000000000000006A5F72800000000000EFF6,
    ↪ 748000000000000006A5F7280000000000721D9, 74800000000000006
    ↪ A5F72800000000002F691]"] [start_ts=442918429687808001] [region_id
    ↪ =3121]
```

From the TiKV log, you can get the start_ts of the transaction, that is `442918429687808001` ↪ . To get more information about the statement and transaction, you can grep this timestamp in TiDB logs. The output is as follows:

```
[2023/07/17 21:16:18.287 +08:00] [INFO] [2pc.go:685] ["[BIG_TXN]"] [session
    ↪ =2826881778407440457] ["key sample"=74800000000000006
    ↪ a5f728000000000000000] [size=319967171] [keys=10000000] [puts
    ↪ =10000000] [dels=0] [locks=0] [checks=0] [txnStartTS
    ↪ =442918429687808001]

[2023/07/17 21:16:22.703 +08:00] [WARN] [expensivequery.go:145] [expensive_
    ↪ query] [cost_time=60.047172498s] [cop_time=0.004575113s] [process_
    ↪ time=15.356963423s] [wait_time=0.017093811s] [request_count=397] [
    ↪ total_keys=20000398] [process_keys=10000000] [num_cop_tasks=397] [
    ↪ process_avg_time=0.038682527s] [process_p90_time=0.082608262s] [
    ↪ process_max_time=0.116321331s] [process_max_addr
    ↪ =192.168.31.244:20160] [wait_avg_time=0.000043057s] [wait_p90_time
    ↪ =0.00004007s] [wait_max_time=0.00075014s] [wait_max_addr
    ↪ =192.168.31.244:20160] [stats=t:442918428521267201] [conn
    ↪ =2826881778407440457] [user=root] [database=test] [table_ids="[106]"]
    ↪  [txn_start_ts=442918429687808001] [mem_max="2513773983 Bytes (2.34
    ↪ GB)"] [sql="update t set b = b + 1"]
```

Then, you can basically locate the statement that caused the problem. To further check it, you can execute the `SHOW PROCESSLIST` statement. The output is as follows:

```
+--
   ↪ ------------------+------+---------------------+--------+---------+------+-----
   ↪
| Id                 | User | Host                | db     | Command | Time |
   ↪ State   | Info                    |
+--
   ↪ ------------------+------+---------------------+--------+---------+------+-----
   ↪
| 2826881778407440457 | root | 192.168.31.43:58641 | test | Query | 48 |
   ↪ autocommit | update t set b = b + 1 |
| 2826881778407440613 | root | 127.0.0.1:45952 | test | Execute | 0 |
   ↪ autocommit | select * from t where a=? |
| 2826881778407440619 | root | 192.168.31.43:60428 | <null> | Query | 0 |
   ↪ autocommit | show processlist |
+--
   ↪ ------------------+------+---------------------+--------+---------+------+-----
   ↪
```

The output shows that someone is executing an unexpected `UPDATE` statement (`update t set b = b + 1`), which results in a large transaction and hinders Stale Read.

To resolve this issue, you can stop the application that is running this `UPDATE` statement.

10.4 Support Resources

If you encounter a problem when you use TiDB, you can reach out for support from PingCAP or the TiDB community via the following methods:

- Get support from PingCAP for TiDB Enterprise Edition:
  - Submit a request
- Get support from PingCAP for TiDB Cloud:
  - Report an issue directly from the TiDB Cloud console
  - Documentation for TiDB Cloud support
- Seek help from the TiDB community:
  - Discord channels
  - Slack channels: #everyone (English), #tidb-japan (Japanese)

    - Stack Overflow (questions tagged with #tidb)
    - TiDB Forum

- Report a bug

    - Submit an issue on GitHub

- Learn TiDB's implementation and design

    - TiDB development guide
    - Discussions on GitHub

11 Performance Tuning

11.1 Tuning Guide

11.1.1 TiDB Performance Tuning Overview

This document introduces the basic concepts of performance tuning, such as user response time, throughput, and database time, and also provides a general process for performance tuning.

11.1.1.1 User response time and database time

11.1.1.1.1 User response time

User response time indicates how long an application takes to return the results of a request to users. As you can see from the following sequential timing diagram, the time of a typical user request contains the following:

- The network latency between the user and the application
- The processing time of the application
- The network latency during the interaction between the application and the database
- The service time of the database

The user response time is affected by various subsystems on the request chain, such as network latency and bandwidth, number and request types of concurrent users, and resource usage of server CPU and I/O. To optimize the entire system effectively, you need to first identify the bottlenecks in user response time.

To get a total user response time within a specified time range (`ΔT`), you can use the following formula:

Total user response time in `ΔT` = Average TPS (Transactions Per Second) x Average user response time x `ΔT`.

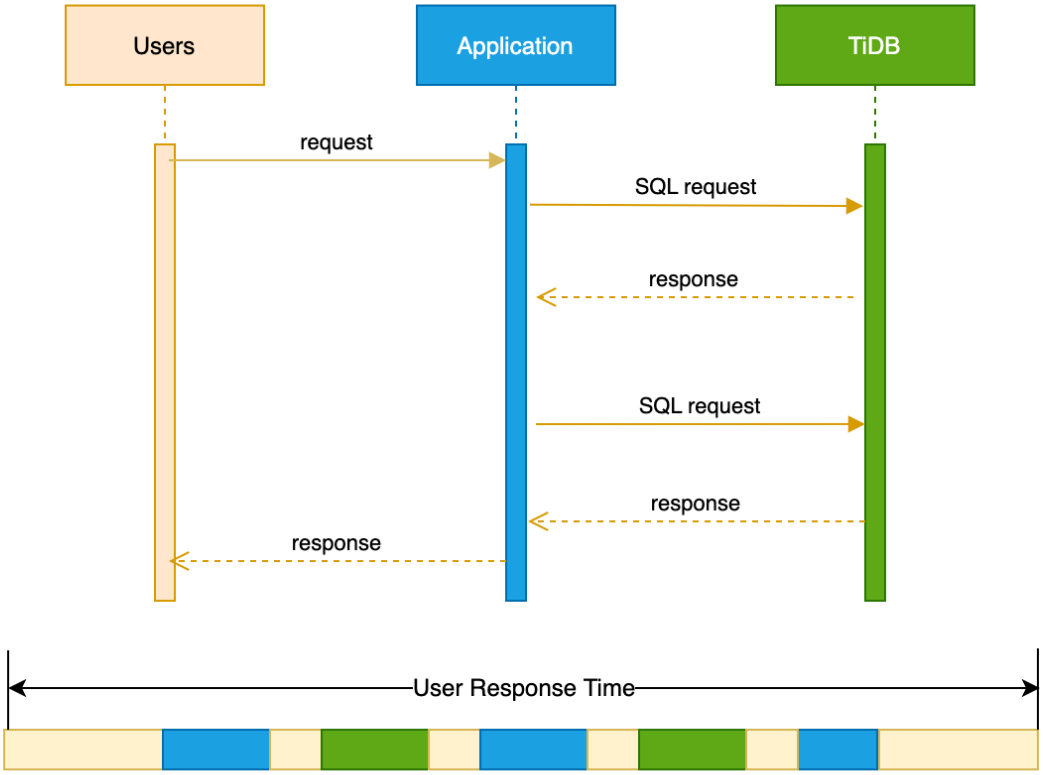

Figure 348: user_response_time

11.1.1.1.2 Database time

Database time indicates the total service time provided by a database. The database time in ΔT is the sum of the time that a database takes to process all application requests concurrently.

To get the database time, you can use any of the following methods:

- Method 1: Multiply the average query latency by QPS and by ΔT, that is, `DB Time in ΔT = QPS × avg latency × ΔT`
- Method 2: Multiply the average number of active sessions by ΔT, that is, `DB Time in ΔT = avg active connections × ΔT`
- Method 3: Calculate the time based on the TiDB internal Prometheus metric `tidb_server_tokens`, that is. `ΔT DB Time = rate(tidb_server_tokens)× ΔT`

11.1.1.2 Relationship between user response time and system throughput

User response time consists of service time, queuing time, and concurrent waiting time to complete a user request.

```
User Response time = Service time + Queuing delay + Coherency delay
```

- Service time: the time a system consumes on certain resources when processing a request, for example, the CPU time that a database consumes to complete a SQL request.
- Queuing delay: the time a system waits in a queue for service of certain resources when processing a request.
- Coherency delay: the time a system communicates and collaborates with other concurrent tasks, so that it can access shared resources when processing a request.

System throughput indicates the number of requests that can be completed by a system per second. User response time and throughput are usually inverse of each other. When the throughput increases, the system resource utilization and the queuing latency for a requested service increase accordingly. Once resource utilization exceeds a certain inflection point, the queuing latency will increase dramatically.

For example, for a database system running OLTP loads, after its CPU utilization exceeds 65%, the CPU queueing scheduling latency increases significantly. This is because concurrent requests of a system are not completely independent, which means that these requests can collaborate and compete for shared resources. For example, requests from different users might perform mutually exclusive locking operations on the same data. When the resource utilization increases, the queuing and scheduling latency increases too, which causes that the shared resources cannot be released in time and in turn prolongs the waiting time for shared resources by other tasks.

11.1.1.3 Performance tuning process

The performance tuning process consists of the following 6 steps:

1. Define a tuning objective.
2. Establish a performance baseline.
3. Identify bottlenecks in user response time.
4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution.
5. Implement tuning solutions.
6. Evaluate tuning results.

To achieve the tuning objective of a performance tuning project, you usually need to repeat Step 2 to Step 6 multiple times.

11.1.1.3.1 Step 1. Define a tuning objective

For different types of systems, tuning objectives are different too. For example, for a financial core OLTP system, the tuning objective might be to reduce the long-tail latency of

transactions; for a financial settlement system, the tuning objective might be to make better use of hardware resources and reduce the time of batch settlement tasks.

A good tuning objective should be easily quantifiable. For example:

- Good tuning objective: The p99 latency for transfer transactions needs to be less than 200 ms during peak business hours of 9 am to 10 am.
- Poor tuning objective: The system is too slow to respond so it needs to be optimized.

Defining a clear tuning objective helps guide the subsequent performance tuning steps.

11.1.1.3.2 Step 2. Establish a performance baseline

To tune performance efficiently, you need to capture the current performance data to establish a performance baseline. The performance data to be captured typically includes the following:

- Mean and long-tail values of user response time, and throughput of your application
- Database performance data such as database time, query latency, and QPS

  TiDB measures and stores performance data thoroughly in different dimensions, such as slow query logs, Top SQL, Continuous Performance Profiling, and traffic visualizer. In addition, you can perform historical backtracking and comparison of the timing metrics data stored in Prometheus.
- Resource utilization, including resources such as CPU, IO, and network
- Configuration information, such as application configurations, database configurations, and operating system configurations

11.1.1.3.3 Step 3. Identify bottlenecks in user response time

Identify or speculate on bottlenecks in user response times based on data from the performance baseline.

Applications usually do not measure and record the full chain of user requests, so you cannot effectively break down user response time from top to bottom through the application.

In contrast, databases have a complete record of performance metrics such as query latency and throughput. Based on database time, you can determine if the bottleneck in user response time is in a database.

- If the bottleneck is not in databases, you need to rely on the resource utilization collected outside databases or profile the application to identify the bottleneck outside databases. Common scenarios include insufficient resources of an application or proxy server, and insufficient usage of hardware resources caused by serial points in an application.

- If bottlenecks are in databases, you can analyze and diagnose the database performances using comprehensive tuning tools. Common scenarios include the presence of slow SQL, unreasonable usage of a database by an application, and the presence of read and write hotspots in databases.

For more information about the analysis and diagnostic methods and tools, see Performance Analysis and Tuning.

11.1.1.3.4 Step 4. Propose tuning solutions, and evaluate the benefits, risks, and costs of each solution

After identifying the bottleneck of a system through performance analysis, you can propose a tuning solution that is cost-effective, has low risks, and provides the maximum benefit based on the actual situation.

According to Amdahl's Law, the maximum gain from performance tuning depends on the percentage of the optimized part in the overall system. Therefore, you need to identify the system bottlenecks and the corresponding percentage based on the performance data, and then predict the gains after the bottleneck is resolved or optimized.

Note that even if a solution can bring the greatest potential benefits by tuning the largest bottleneck, you still need to evaluate the risks and costs of this solution. For example:

- The most straightforward tuning objective solution for a resource-overloaded system is to expand its capacity, but in practice, the expansion solution might be too costly to be adopted.
- When a slow query in a business module causes a slow response of the entire module, upgrading to a new version of the database can solve the slow query issue, but it might also affect modules that did not have this issue. Therefore, this solution might have a potentially high risk. A low-risk solution is to skip the database version upgrade and rewrite the existing slow queries for the current database version.

11.1.1.3.5 Step 5. Implement tuning solutions

Considering the benefits, risks, and costs, choose one or more tuning solutions for implementation. In the implementation process, you need to make thorough preparation for changes to the production system and record the changes in detail.

To mitigate risks and validate the benefits of a tuning solution, it is recommended that you perform validation and complete regression of changes in both test and staging environments. For example, if the selected tuning solution of a slow query is to create a new index to optimize the query access path, you need to ensure that the new index does not introduce any obvious write hotspots to the existing data insertion workload and slows down other modules.

11.1.1.3.6 Step 6. Evaluate tuning results

After applying the tuning solution, you need to evaluate the results:

- If the tuning objective is reached, the entire tuning project is completed successfully.
- If the tuning objective is not reached, you need to repeat Step 2 to Step 6 in this document until the tuning objective is reached.

After reaching your tuning objectives, you might need to further plan your system capacity to meet your business growth.

11.1.2 Configure TiDB for Optimal Performance

This guide describes how to optimize the performance of TiDB, including:

- Best practices for common workloads.
- Strategies for handling challenging performance scenarios.

> **Note:**
>
> The optimization techniques in this guide can help achieve optimal performance in TiDB. However, performance tuning often involves balancing multiple factors, and no single solution addresses all performance needs. Some techniques in this guide use experimental features, which are marked accordingly. Although these optimizations can significantly improve performance, they might not be suitable for production environments and require careful evaluation before implementation.

11.1.3 Overview

Optimizing TiDB for peak performance requires careful tuning of various settings. In many cases, achieving optimal performance involves adjusting configurations beyond their default values.

The default settings prioritize stability over performance. To maximize performance, you might need to use more aggressive configurations and, in some cases, experimental features. These recommendations are based on production deployment experience and performance optimization research.

This guide describes the non-default settings, including their benefits and potential trade-offs. Use this information to optimize TiDB settings for your workload requirements.

11.1.4 Key settings for common workloads

The following settings are commonly used to optimize TiDB performance:

- Enhance execution plan cache, such as SQL Prepared Execution Plan Cache, Non-prepared plan cache, and Instance-level execution plan cache.
- Optimize the behavior of the TiDB optimizer by using Optimizer Fix Controls.
- Use the Titan storage engine more aggressively.

These settings can significantly improve performance for many workloads. However, as with any optimization, thoroughly test them in your environment before deploying to production.

11.1.4.1 System variables

Execute the following SQL commands to apply the recommended settings:

```
SET GLOBAL tidb_enable_instance_plan_cache=on;
SET GLOBAL tidb_instance_plan_cache_max_size=2GiB;
SET GLOBAL tidb_enable_non_prepared_plan_cache=on;
SET GLOBAL tidb_ignore_prepared_cache_close_stmt=on;
SET GLOBAL tidb_analyze_column_options='ALL';
SET GLOBAL tidb_stats_load_sync_wait=2000;
SET GLOBAL tidb_opt_derive_topn=on;
SET GLOBAL tidb_runtime_filter_mode=LOCAL;
SET GLOBAL tidb_opt_enable_mpp_shared_cte_execution=on;
SET GLOBAL tidb_rc_read_check_ts=on;
SET GLOBAL tidb_guarantee_linearizability=off;
SET GLOBAL pd_enable_follower_handle_region=on;
SET GLOBAL tidb_opt_fix_control = '44262:ON,44389:ON,44823:10000,44830:ON
    ↪ ,44855:ON,52869:ON';
```

The following table outlines the impact of specific system variable configurations:

System variable	Description	Note
tidb_enable_instance_plan_cache and tidb_instance_plan_cache_max_size	Use instance-level plan cache instead of session-level caching. This significantly improves performance for workloads with high connection counts or frequent prepared statement usage.	This is an experimental feature. Test in non-production environments first and monitor memory usage as the plan cache size increases.

System variable	Description	Note
tidb_ ↪ enable ↪ _non_ ↪ prepared ↪ _plan ↪ _ ↪ cache	Enable the Non-prepared plan cache feature to reduce compile costs for applications that do not use prepared statements.	N/A

System variable	Description	Note
tidb_ ↪ ignore ↪ _ ↪ prepared ↪ _ ↪ cache ↪ _ ↪ close ↪ _stmt	Cache plans for applications that use prepared statements but close the plan after each execution.	N/A

System variable	Description	Note
tidb_ ↪ analyze ↪ _ ↪ column ↪ _ ↪ options ↪	Collect statistics for all columns to avoid sub-optimal execution plans due to missing column statistics. By default, TiDB only collects statistics for predicate columns.	Setting this variable to 'ALL ↪ ' can cause more resource usage for the ANALYZE ↪ ↪ TABLE ↪ operation compared with the default value ' ↪ PREDICATE ↪ '.

System variable	Description	Note
tidb_ ↪ stats ↪ _load ↪ _sync ↪ _wait	Increase the time-out for syn-chronously load-ing statis-tics from the de-fault 100 mil-lisec-onds to 2 sec-onds. This en-sures TiDB loads the nec-es-sary statis-tics be-fore query com-pila-tion.	Increasing this value leads to a longer syn-chro-niza-tion wait time be-fore query com-pila-tion.

System variable	Description	Note
tidb_opt ↪ _ ↪ derive ↪ _topn	Enable the optimization rule of Deriving TopN or Limit from window functions.	This is limited to the ROW_ ↪ NUMBER ↪ () ↪ window function.
tidb_ ↪ runtime ↪ _ ↪ filter ↪ _mode	Enable Runtime Filter in the local mode to improve hash join efficiency.	The variable is introduced in v7.2.0 and is disabled by default for safety.

System variable	Description	Note
tidb_opt ↪ _ ↪ enable ↪ _mpp_ ↪ shared ↪ _cte_ ↪ execution ↪	Enable non-recursive Common Table Expressions (CTE) push-down to TiFlash.	This is an experimental feature.

System variable	Description	Note
tidb_rc_ ↪ read_ ↪ check ↪ _ts	For the read-committed isolation level, enabling this variable avoids the latency and cost of getting the global timestamp and optimizes transaction-level read latency.	This feature is incompatible with the Repeatable Read isolation level.

System variable	Description	Note
tidb_guarantee_linearizability	Improve performance by skipping the commit timestamp fetch from the PD server.	This sacrifices linearizability in favor of performance. Only causal consistency is guaranteed. It is not suitable for scenarios requiring strict linearizability.

System variable	Description	Note
pd_enable_follower_handle_region	Activate the PD Follower feature, allowing PD followers to process Region requests. This helps distribute load evenly across all PD servers and reduces CPU pressure on the PD leader.	This is an experimental feature. Test in non-production environments.

System variable	Description	Note
tidb_opt ↪ _fix_ ↪ control ↪	Enable advanced query optimization strategies to improve performance through additional optimization rules and heuristics.	Test thoroughly in your environment, as performance improvements vary by workload.

The following describes the optimizer control configurations that enable additional optimizations:

- 44262:ON: Use Dynamic pruning mode to access the partitioned table when the GlobalStats are missing.
- 44389:ON: For filters such as `c = 10 and (a = 'xx' or (a = 'kk' and b = 1))`, build more comprehensive scan ranges for `IndexRangeScan`.
- 44823:10000: To save memory, plan cache does not cache queries with parameters exceeding the specified number of this variable. Increase plan cache parameter limit from 200 to 10000 to make plan cache available for query with long in-lists.
- 44830:ON: Plan cache is allowed to cache execution plans with the `PointGet` operator generated during physical optimization.
- 44855:ON: The optimizer selects `IndexJoin` when the `Probe` side of an `IndexJoin` operator contains a `Selection` operator.
- 52869:ON: The optimizer chooses index merge automatically if the optimizer can choose the single index scan method (other than full table scan) for a query plan.

11.1.4.2 TiKV configurations

Add the following configuration items to the TiKV configuration file:

```
[server]
concurrent-send-snap-limit = 64
concurrent-recv-snap-limit = 64
snap-io-max-bytes-per-sec = "400MiB"

[pessimistic-txn]
in-memory-peer-size-limit = "32MiB"
in-memory-instance-size-limit = "512MiB"

[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"

[storage.flow-control]
l0-files-threshold = 60
```

Configuration item	Description	Note
concurrent ↪ -send ↪ -snap ↪ - ↪ limit ↪ , concurrent ↪ -recv ↪ -snap ↪ - ↪ limit ↪ , and snap-io- ↪ max- ↪ bytes ↪ -per- ↪ sec	Set limits for concurrent snapshot transfer and I/O bandwidth during TiKV scaling operations. Higher limits reduce scaling time by allowing faster data migration.	Adjusting these limits affects the trade-off between scaling and online transaction performance.

Configuration item	Description	Note
in- ↪ memory ↪ -peer ↪ -size ↪ - ↪ limit and in- ↪ memory ↪ - ↪ instance ↪ -size ↪ - ↪ limit	Control the memory allocation for pessimistic lock caching at the Region and TiKV instance levels. Storing locks in memory reduces disk I/O and improves transaction performance.	Monitor memory usage carefully. Higher limits improve performance but increase memory consumption.

Configuration item	Description	Note
rocksdb.titan, defaultcf., titan, min-blob-size, and blob-file-compression	Enable the Titan storage engine to reduce write amplification and alleviate disk I/O bottlenecks. Particularly useful when RocksDB compaction cannot keep up with write workloads, resulting in accumulated	Enable it when write amplification is the primary bottleneck. Trade-offs include: 1. Potential performance impact on primary key range scans. 2. Increased space amplification (up to 2x in the worst case). 3.

Configuration item	Description	Note
storage. ↪ flow- ↪ control ↪ .l0- ↪ files ↪ - ↪ threshold ↪	Control when write flow control is triggered based on the number of kvDB L0 files. Increasing the threshold reduces write stalls during high write workloads.	Higher thresholds might lead to more aggressive compactions when many L0 files exist.

11.1.4.3 TiFlash configurations

Add the following configuration items to the TiFlash configuration file:

```
[raftstore-proxy.server]
snap-io-max-bytes-per-sec = "300MiB"
```

Configuration item	Description	Note
snap-io-max-bytes-per-sec	Control the maximum allowable disk bandwidth for data replication from TiKV to TiFlash. Higher limits accelerate initial data loading and catch-up replication.	Higher bandwidth consumption might impact online transaction performance. Balance between replication speed and system stability.

11.1.5 Benchmark

This section compares performance between default settings (baseline) and optimized settings based on the preceding key settings for common loads.

11.1.5.1 Sysbench workloads on 1000 tables

11.1.5.1.1 Test environment

The test environment is as follows:

- 3 TiDB servers (16 cores, 64 GiB)
- 3 TiKV servers (16 cores, 64 GiB)
- TiDB version: v8.4.0
- Workload: sysbench oltp_read_only

11.1.5.1.2 Performance comparison

The following table compares throughput, latency, and plan cache hit ratio between baseline and optimized settings.

Metric	Baseline	Optimized	Improvement
QPS	89,100	100,128	+12.38%
Average latency (ms)	35.87	31.92	-11.01%
P95 latency (ms)	58.92	51.02	-13.41%
Plan cache hit ratio (%)	56.89%	87.51%	+53.82%
Plan cache memory usage (MiB)	95.3	70.2	-26.34%

11.1.5.1.3 Key benefits

The instance plan cache demonstrates significant performance improvements over the baseline configuration:

- Higher hit ratio: increases by 53.82% (from 56.89% to 87.51%).
- Lower memory usage: decreases by 26.34% (from 95.3 MiB to 70.2 MiB).
- Better performance:
  - QPS increases by 12.38%.
  - Average latency decreases by 11.01%.
  - P95 latency decreases by 13.41%.

11.1.5.1.4 How it works

Instance plan cache improves performance through these mechanisms:

- Cache execution plans for `SELECT` statements in memory.
- Share cached plans across all connections (up to 200) on the same TiDB instance.
- Can effectively store plans for up to 5,000 `SELECT` statements across 1,000 tables.
- Cache misses primarily occur only for `BEGIN` and `COMMIT` statements.

11.1.5.1.5 Real-world benefits

Although the benchmark using simple sysbench `oltp_read_only` queries (14 KB per plan) shows modest improvements, you can expect greater benefits in real-word applications:

- Complex queries can run up to 20 times faster.
- Memory usage is more efficient compared to session-level plan cache.

Instance plan cache is particularly effective for systems with:

- Large tables with many columns.
- Complex SQL queries.
- High concurrent connections.
- Diverse query patterns.

11.1.5.1.6 Memory efficiency

Instance plan cache provides better memory efficiency than session-level plan cache because:

- Plans are shared across all connections
- No need to duplicate plans for each session
- More efficient memory utilization while maintaining higher hit ratios

In scenarios with multiple connections and complex queries, session-level plan cache would require significantly more memory to achieve similar hit ratios, making instance plan cache the more efficient choice.

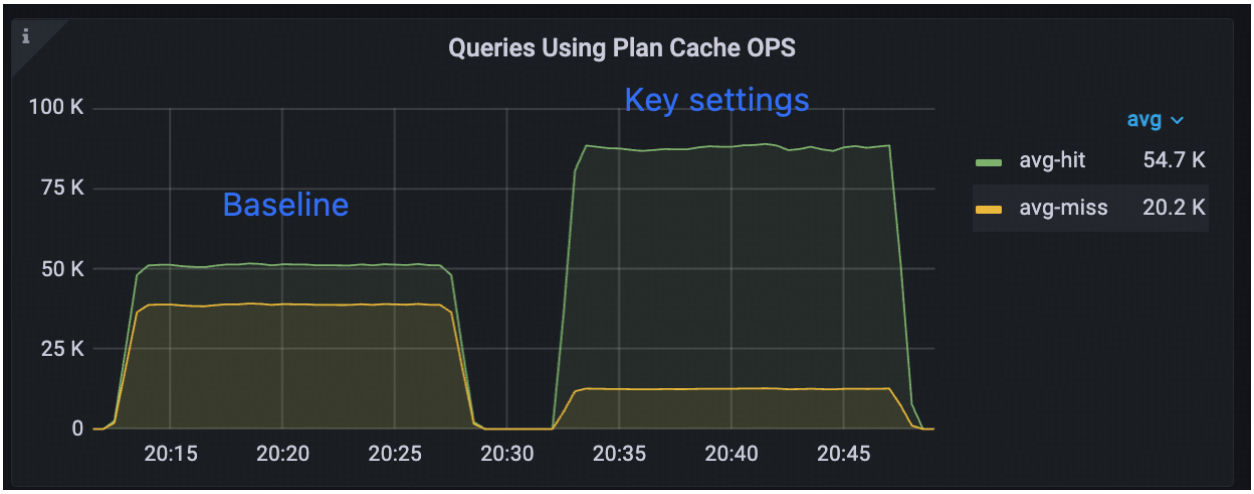

Figure 349: Instance plan cache: Queries Using Plan Cache OPS

11.1.5.1.7 Test workload

The following `sysbench oltp_read_only prepare` command loads data:

```
sysbench oltp_read_only prepare --mysql-host={host} --mysql-port={port} --
    ↪ mysql-user=root --db-driver=mysql --mysql-db=test --threads=100 --
    ↪ time=900 --report-interval=10 --tables=1000 --table-size=10000
```

The following `sysbench oltp_read_only run` command runs workload:

```
sysbench oltp_read_only run --mysql-host={host} --mysql-port={port} --mysql
    ↪ -user=root --db-driver=mysql --mysql-db=test --threads=200 --time=900
    ↪  --report-interval=10 --tables=1000 --table-size=10000
```

For more information, see How to Test TiDB Using Sysbench.

11.1.5.2 YCSB workloads on large record value

11.1.5.2.1 Test environment

The test environment is as follows:

- 3 TiDB servers (16 cores, 64 GiB)
- 3 TiKV servers (16 cores, 64 GiB)
- TiDB version: v8.4.0
- Workload: go-ycsb workloada

11.1.5.2.2 Performance comparison

The following table compares throughput (operations per second) between the baseline and optimized settings.

Item	Baseline (OPS)	Optimized (OPS)	Improvement
load data	2858.5	5074.3	+77.59%
workloada	2243.0	12804.3	+470.86%

11.1.5.2.3 Performance analysis

Titan is enabled by default starting from v7.6.0 and the default `min-blob-size` of Titan in TiDB v8.4.0 is `32KiB`. The baseline configuration uses a record size of `31KiB` to ensure data is stored in RocksDB. In contrast, for the key settings configuration, set `min-blob-size` to `1KiB`, causing data to be stored in Titan.

The performance improvement observed in the key settings is primarily attributed to Titan's ability to reduce RocksDB compactions. As shown in the following figures:

- Baseline: The total throughput of RocksDB compaction exceeds 1 GiB/s, with peaks over 3 GiB/s.
- Key settings: The peak throughput of RocksDB compaction remains below 100 MiB/s.

This significant reduction in compaction overhead contributes to the overall throughput improvement seen in the key settings configuration.

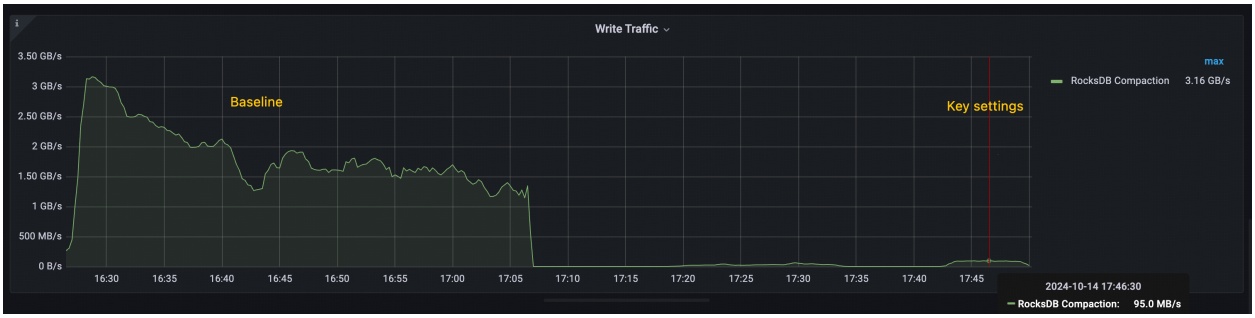

Figure 350: Titan RocksDB compaction:

11.1.5.2.4 Test workload

The following `go-ycsb load` command loads data:

```
go-ycsb load mysql -P /ycsb/workloads/workloada -p {host} -p mysql.port={
    ↪ port} -p threadcount=100 -p recordcount=5000000 -p operationcount
    ↪ =5000000 -p workload=core -p requestdistribution=uniform -pfieldcount
    ↪ =31 -p fieldlength=1024
```

The following `go-ycsb run` command runs workload:

```
go-ycsb run mysql -P /ycsb/workloads/workloada -p {host} -p mysql.port={port
    ↪ } -p mysql.db=test -p threadcount=100 -p recordcount=5000000 -p
    ↪ operationcount=5000000 -p workload=core -prequestdistribution=uniform
    ↪  -p fieldcount=31 -p fieldlength=1024
```

11.1.6 Edge cases and optimizations

This section shows you how to optimize TiDB for specific scenarios that need targeted adjustments beyond basic optimizations. You will learn how to tune TiDB for your particular use cases.

11.1.6.1 Identify edge cases

To identify edge cases, perform the following steps:

1. Analyze query patterns and workload characteristics.
2. Monitor system metrics to identify performance bottlenecks.
3. Gather feedback from application teams about specific issues.

11.1.6.2 Common edge cases

The following lists some common edge cases:

- High TSO wait for high-frequency small queries
- Choose the proper max chunk size for different workloads
- Tune coprocessor cache for read-heavy workloads
- Optimize chunk size for workload characteristics
- Optimize transaction mode and DML type for different workloads
- Optimize `GROUP BY` and `DISTINCT` operations with TiKV pushdown
- Mitigate MVCC version accumulation using in-memory engine
- Optimize statistics collection during batch operations
- Optimize thread pool settings for different instance types

The following sections explain how to handle each of these cases. You need to adjust different parameters or use specific TiDB features for each scenario.

> **Note:**
>
> Apply these optimizations carefully and test thoroughly, as their effectiveness might vary based on your use case and data patterns.

11.1.6.3 High TSO wait for high-frequency small queries

11.1.6.3.1 Troubleshooting

If your workload involves frequent small transactions or queries that frequently request timestamps, TSO (Timestamp Oracle) can become a performance bottleneck. To check if TSO wait time is impacting your system, check the **Performance Overview > SQL Execute Time Overview** panel. If TSO wait time constitutes a large portion of your SQL execution time, consider the following optimizations:

- Use low-precision TSO (enable `tidb_low_resolution_tso`) for read operations that do not need strict consistency. For more information, see Solution 1: use low-precision TSO.
- Combine small transactions into larger ones where possible. For more information, see Solution 2: parallel mode for TSO requests.

11.1.6.3.2 Solution 1: low-precision TSO

You can reduce TSO wait time by enabling the low-precision TSO feature (`tidb_low_resolution_tso`). After this feature is enabled, TiDB uses the cached timestamp to read data, reducing TSO wait time at the expense of potentially stale reads.

This optimization is particularly effective in the following scenarios:

- Read-heavy workloads where slight staleness is acceptable.
- Scenarios where reducing query latency is more important than absolute consistency.
- Applications that can tolerate reads that are a few seconds behind the latest committed state.

Benefits and trade-offs:

- Reduce query latency by enabling stale reads with a cached TSO, eliminating the need to request new timestamps.
- Balance performance against data consistency: this feature is only suitable for scenarios where stale reads are acceptable. It is not recommended to use it when strict data consistency is required.

To enable this optimization:

```
SET GLOBAL tidb_low_resolution_tso=ON;
```

11.1.6.3.3 Solution 2: parallel mode for TSO requests

The `tidb_tso_client_rpc_mode` system variable switches the mode in which TiDB sends TSO RPC requests to PD. The default value is `DEFAULT`. When the following conditions are met, you can consider switching this variable to `PARALLEL` or `PARALLEL-FAST` for potential performance improvements:

- TSO waiting time constitutes a significant portion of the total execution time of SQL queries.
- The TSO allocation in PD has not reached its bottleneck.
- PD and TiDB nodes have sufficient CPU resources.
- The network latency between TiDB and PD is significantly higher than the time PD takes to allocate TSO (that is, network latency accounts for the majority of TSO RPC duration).
    - To get the duration of TSO RPC requests, check the **PD TSO RPC Duration** panel in the PD Client section of the Grafana TiDB dashboard.
    - To get the duration of PD TSO allocation, check the **PD server TSO handle duration** panel in the TiDB section of the Grafana PD dashboard.

- The additional network traffic resulting from more TSO RPC requests between TiDB and PD (twice for `PARALLEL` or four times for `PARALLEL-FAST`) is acceptable.

To switch the parallel mode, execute the following command:

```
-- Use the PARALLEL mode
SET GLOBAL tidb_tso_client_rpc_mode=PARALLEL;

-- Use the PARALLEL-FAST mode
SET GLOBAL tidb_tso_client_rpc_mode=PARALLEL-FAST;
```

11.1.6.4 Tune coprocessor cache for read-heavy workloads

You can improve query performance for read-heavy workloads by optimizing the coprocessor cache. This cache stores the results of coprocessor requests, reducing repeated computations of frequently accessed data. To optimize cache performance, perform the following steps:

1. Monitor the cache hit ratio using the metrics described in Coprocessor Cache.
2. Increase the cache size to improve hit rates for larger working sets.
3. Adjust the admission threshold based on query patterns.

The following lists some recommended settings for a read-heavy workload:

```
[tikv-client.copr-cache]
capacity-mb = 4096
admission-max-ranges = 5000
admission-max-result-mb = 10
admission-min-process-ms = 0
```

11.1.6.5 Optimize chunk size for workload characteristics

The `tidb_max_chunk_size` system variable sets the maximum number of rows in a chunk during the execution process. Adjusting this value based on your workload can improve performance.

- For OLTP workloads with large concurrency and small transactions:
  - Set the value between `128` and `256` rows (the default value is `1024`).
  - This reduces memory usage and makes limit queries faster.
  - Use case: point queries, small range scans.

```
SET GLOBAL tidb_max_chunk_size = 128;
```

- For OLAP or analytical workloads with complex queries and large result sets:
    - Set the value between `1024` and `4096` rows.
    - This increases throughput when scanning large amounts of data.
    - Use case: aggregations, large table scans.

```
SET GLOBAL tidb_max_chunk_size = 4096;
```

11.1.6.6 Optimize transaction mode and DML type for different workloads

TiDB provides different transaction modes and DML execution types to optimize performance for various workload patterns.

11.1.6.6.1 Transaction modes

You can set the transaction mode using the `tidb_txn_mode` system variable.

- Pessimistic transaction mode (default):
    - Suitable for general workloads with potential write conflicts.
    - Provides stronger consistency guarantees.

```
sql  SET SESSION tidb_txn_mode = "pessimistic";
```

- Optimistic transaction mode:
    - Suitable for workloads with minimal write conflicts.
    - Better performance for multi-statement transactions.
    - Example: `BEGIN; INSERT...; INSERT...; COMMIT;`.

```
sql  SET SESSION tidb_txn_mode = "optimistic";
```

11.1.6.6.2 DML types

You can control the execution mode of DML statements using the `tidb_dml_type` system variable, which is introduced in v8.0.0.

To use the bulk DML execution mode, set `tidb_dml_type` to `"bulk"`. This mode optimizes bulk data loading without conflicts and reduces memory usage during large write operations. Before using this mode, ensure that:

- Auto-commit is enabled.
- The `pessimistic-auto-commit` configuration item is set to `false`.

```
SET SESSION tidb_dml_type = "bulk";
```

11.1.6.7 Optimize `GROUP BY` and `DISTINCT` operations with TiKV pushdown

TiDB pushes down aggregation operations to TiKV to reduce data transfer and processing overhead. The performance improvement varies based on your data characteristics.

11.1.6.7.1 Usage scenarios

- **Ideal scenarios** (high performance gain):
  - Columns containing few distinct values (low NDV).
  - Data containing frequent duplicate values.
  - Example: status columns, category codes, date parts.
- **Non-ideal scenarios** (potential performance loss):
  - Columns containing mostly unique values (high NDV).
  - Unique identifiers or timestamps.
  - Example: User IDs, transaction IDs.

11.1.6.7.2 Configuration

Enable pushdown optimizations at the session or global level:

```
-- Enable regular aggregation pushdown
SET GLOBAL tidb_opt_agg_push_down = ON;

-- Enable distinct aggregation pushdown
SET GLOBAL tidb_opt_distinct_agg_push_down = ON;
```

11.1.6.8 Mitigate MVCC version accumulation using in-memory engine

Excessive MVCC versions can cause performance bottlenecks, particularly in high read-/write areas or due to issues with garbage collection and compaction. You can use the in-memory engine introduced in v8.5.0 to mitigate this issue. To enable it, add the following configuration to your TiKV configuration file.

> **Note:**
>
> The in-memory engine helps reduce the impact of excessive MVCC versions but might increase memory usage. Monitor your system after enabling this feature.

```
[in-memory-engine]
enable = true
```

11.1.6.9 Optimize statistics collection during batch operations

You can optimize performance during batch operations while maintaining query optimization by managing statistics collection. This section describes how to manage this process effectively.

11.1.6.9.1 When to disable auto analyze

You can disable auto analyze by setting the `tidb_enable_auto_analyze` system variable to `OFF` in the following scenarios:

- During large data imports.
- During bulk update operations.
- For time-sensitive batch processing.
- When you need full control over the timing of statistics collection.

11.1.6.9.2 Best practices

- Before the batch operation:

```
sql   -- Disable auto analyze SET GLOBAL tidb_enable_auto_analyze = OFF;
```

- After the batch operation:

“‘sql – Manually collect statistics ANALYZE TABLE your_table;

– Re-enable auto analyze SET GLOBAL tidb_enable_auto_analyze = ON; “‘

11.1.6.10 Optimize thread pool settings for different instance types

To improve TiKV performance, configure the thread pools based on your instance's CPU resources. The following guidelines help you optimize these settings:

- For instances with 8 to 16 cores, the default settings are typically sufficient.
- For instances with 32 or more cores, increase the pool sizes for better resource utilization. Adjust the settings as follows:

```
[server]
# Increase gRPC thread pool
grpc-concurrency = 10

[raftstore]
# Optimize for write-intensive workloads
apply-pool-size = 4
store-pool-size = 4
store-io-pool-size = 2
```

11.1.7 A Practical Guide for SQL Tuning

This guide is designed for TiDB SQL tuning beginners. It focuses on the following key principles:

- Low entry barrier: introducing tuning concepts and methods step by step.
- Practice-oriented: providing specific steps and examples for each optimization tip.
- Quick start: prioritizing the most common and effective optimization methods.
- Gentle learning curve: emphasizing practical techniques rather than complex theory.
- Scenario-based: using real-world business cases to demonstrate optimization effects.

11.1.7.1 Introduction to SQL tuning

SQL tuning is crucial for optimizing database performance. It involves systematically improving the efficiency of SQL queries through the following typical steps:

1. Identify high-impact SQL statements:

    - Review the SQL execution history to find statements that consume significant system resources or contribute heavily to the application workload.
    - Use monitoring tools and performance metrics to identify resource-intensive queries.

2. Analyze execution plans:

    - Examine the execution plans generated by the query optimizer for the identified statements.
    - Verify whether these plans are reasonably efficient and use appropriate indexes and join methods.

3. Implement optimizations:

    Implement optimizations to inefficient SQL statements. Optimizations might include rewriting SQL statements, adding or modifying indexes, updating statistics, or adjusting database parameters.

Repeat these steps until:

- The system performance meets target requirements.
- No further improvements can be made to the remaining statements.

SQL tuning is an ongoing process. As your data volume grows and query patterns change, you should:

- Regularly monitor query performance.
- Re-evaluate your optimization strategies.
- Adapt your approach to address new performance challenges.

By consistently applying these practices, you can maintain optimal database performance over time.

11.1.7.2 Goals of SQL tuning

The primary goals of SQL tuning are the following:

- Reduce response time for end users.
- Minimize resource consumption during query execution.

To achieve these goals, you can use the following strategies.

11.1.7.2.1 Optimize query execution

SQL tuning focuses on finding more efficient ways to process the same workload without changing query functionality. You can optimize query execution as follows:

1. Improving execution plans:
    - Analyze and modify query structures for more efficient processing.
    - Use appropriate indexes to reduce data access and processing time.
    - Enable TiFlash for analytical queries on large datasets and leverage the Massively Parallel Processing (MPP) engine for complex aggregations and joins.
2. Enhancing data access methods:
    - Use covering indexes to satisfy queries directly from the index, avoiding full table scans.
    - Implement partitioning strategies to limit data scans to relevant partitions.

Examples:

- Create indexes on frequently queried columns to significantly reduce resource usage, particularly for queries that access small portions of the table.
- Use index-only scans for queries that return a limited number of sorted results to avoid full table scans and sorting operations.

11.1.7.2.2 Balance workload distribution

In a distributed architecture like TiDB, balancing workloads across TiKV nodes is essential for optimal performance. To identify and resolve read and write hotspots, see Troubleshoot hotspot issues.

By implementing these strategies, you can ensure that your TiDB cluster efficiently utilizes all available resources and avoids bottlenecks caused by uneven workload distribution or serialization on individual TiKV nodes.

11.1.7.3 Identify high-load SQL

The most efficient way to identify resource-intensive SQL statements is by using TiDB Dashboard. You can also use other tools, such as views and logs, to identify high-load SQL statements.

11.1.7.3.1 Monitor SQL statements using TiDB Dashboard

SQL Statements page

In TiDB Dashboard, navigate to the **SQL Statements** page to identify the following:

- The SQL statement with the highest total latency, which is the statement that takes the longest time to execute across multiple executions.
- The number of times each SQL statement has been executed, which helps identify statements with the highest execution frequency.
- Execution details of each SQL statement by clicking it to view `EXPLAIN ANALYZE` results.

TiDB normalizes SQL statements into templates by replacing literals and bind variables with `?`. This normalization and sorting process helps you quickly identify the most resource-intensive queries that might require optimization.

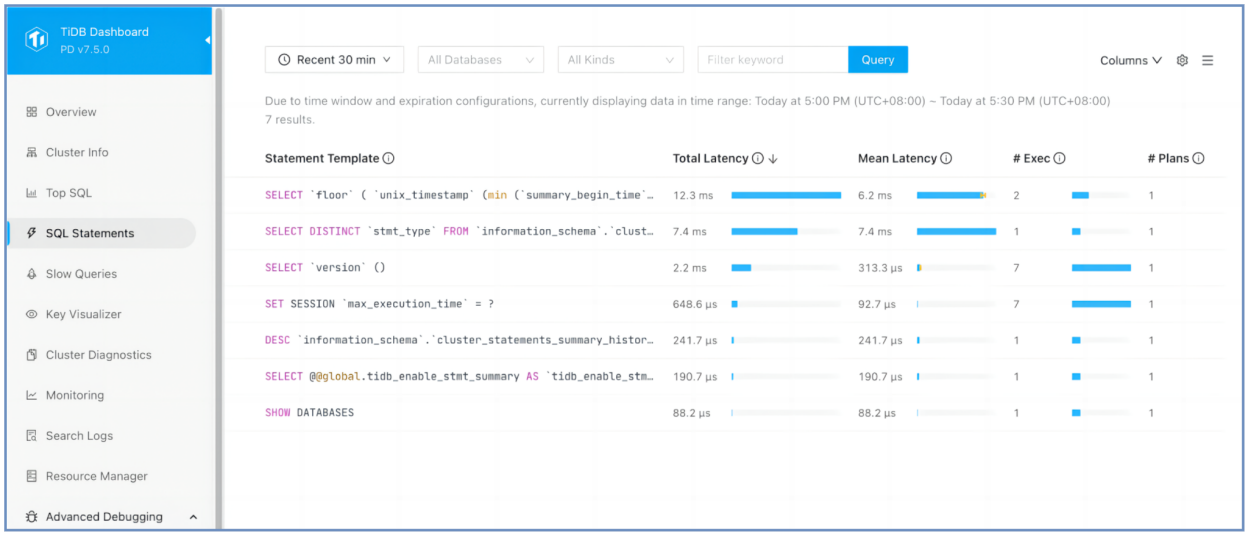

Figure 351: sql-statements-default

Slow Queries page

In TiDB Dashboard, navigate to the **Slow Queries** page to find the following:

- The slowest SQL queries.
- The SQL query that reads the most data from TiKV.
- The `EXPLAIN ANALYZE` output by clicking a query for detailed execution analysis.

The **Slow Queries** page does not display SQL execution frequency. A query appears on this page if its execution time exceeds the `tidb_slow_log_threshold` configuration item for a single instance.

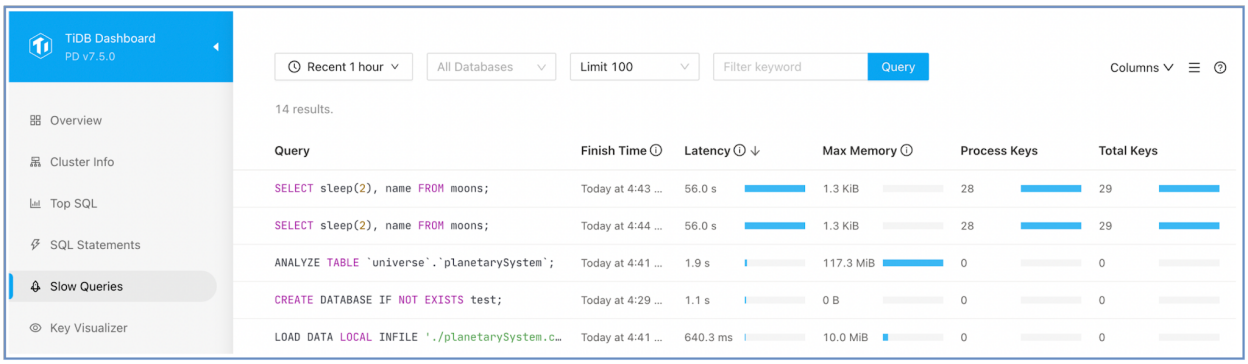

Figure 352: slow-query-default

11.1.7.3.2 Use other tools to identify Top SQL

In addition to TiDB Dashboard, you can use other tools to identify resource-intensive SQL queries. Each tool offers unique insights and can be valuable for different analysis scenarios. Using a combination of these tools helps ensure comprehensive SQL performance monitoring and optimization.

- TiDB Dashboard Top SQL Page
- Logs: slow query log and expensive queries in TiDB log
- Views: `cluster_statements_summary` view and `cluster_processlist` view

11.1.7.3.3 Gather data on identified SQL statements

For the top SQL statements identified, you can use `PLAN REPLAYER` to capture and save SQL execution information from a TiDB cluster. This tool helps recreate the execution environment for further analysis. To export SQL execution information, use the following syntax:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] [WITH STATS AS OF TIMESTAMP expression
    ↪ ] sql-statement;
```

Use `EXPLAIN ANALYZE` whenever possible, as it provides both the execution plan and actual performance metrics for more accurate insights into query performance.

11.1.7.4 SQL tuning guide

This guide provides practical advice for beginners on optimizing SQL queries in TiDB. By following these best practices, you can improve query performance and streamline SQL tuning. This guide covers the following topics:

- Understand query processing
    - Query processing workflow

    - Optimizer fundamentals
    - Statistics management
- Understand execution plans
    - How TiDB builds an execution plan
    - Generate and display execution plans
    - Read execution plans: first child first
    - Identify bottlenecks in execution plans
- Index strategy in TiDB
    - Composite index strategy guidelines
    - The cost of indexing
    - SQL tuning with a covering index
    - SQL tuning with a composite index involving sorting
    - SQL tuning with composite indexes for efficient filtering and sorting
- When to use TiFlash
    - Analytical query
    - SaaS arbitrary filtering workloads

11.1.7.4.1 Understand query processing

This section introduces the query processing workflow, optimizer fundamentals, and statistics management.

Query processing workflow

When a client sends a SQL statement to TiDB, the statement passes through the protocol layer of the TiDB server. This layer manages the connection between the TiDB server and the client, receives SQL statements, and returns data to the client.

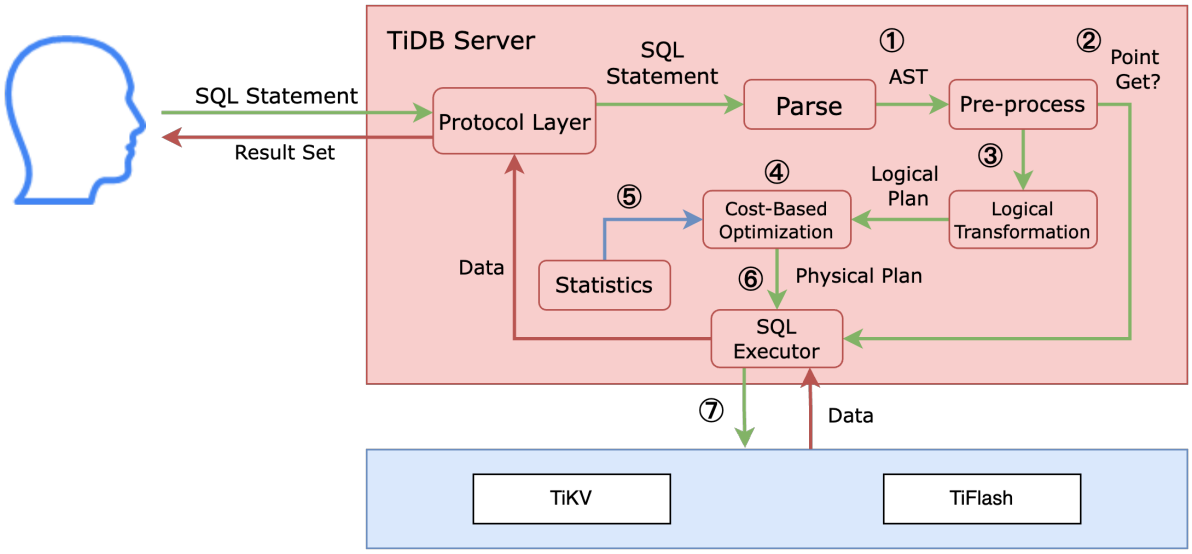

Figure 353: workflow

In the preceding figure, to the right of the protocol layer is the optimizer of the TiDB server, which processes SQL statements as follows:

1. The SQL statement arrives at the SQL optimizer through the protocol layer and is parsed into an abstract syntax tree (AST).
2. TiDB identifies whether it is a Point Get statement, which involves a simple one-table lookup through a primary or unique key, such as `SELECT * FROM t WHERE pk_col = 1` or `SELECT * FROM t WHERE uk_col IN (1,2,3)`. For `Point Get` statements, TiDB skips subsequent optimization steps and proceeds directly to execution in the SQL executor.
3. If the query is not a `Point Get`, the AST undergoes logical transformation, where TiDB rewrites the SQL logically based on specific rules.
4. After logical transformation, TiDB processes the AST through cost-based optimization.
5. During cost-based optimization, the optimizer uses statistics to select appropriate operators and generates a physical execution plan.
6. The generated physical execution plan is sent to the SQL executor of the TiDB node for execution.
7. Unlike traditional single-node databases, TiDB pushes down operators or coprocessors to TiKV and/or TiFlash nodes containing the data. This approach processes parts of the execution plan where the data is stored, efficiently utilizing the distributed architecture, using resources in parallel, and reducing network data transfer. The TiDB node executor then assembles the final result and returns it to the client.

Optimizer fundamentals

TiDB uses a cost-based optimizer (CBO) to determine the most efficient execution plan for a SQL statement. The optimizer evaluates different execution strategies and selects the one with the lowest estimated cost. The cost depends on factors such as:

- The SQL statement
- Schema design
- Statistics, including:
    - Table statistics
    - Index statistics
    - Column statistics

Based on these inputs, the cost model generates an execution plan that details how TiDB will execute the SQL statement, including:

- Access method
- Join method
- Join order

The effectiveness of the optimizer depends on the quality of the information it receives. To achieve optimal performance, ensure that statistics are up to date and indexes are well-designed.

Statistics management

Statistics are essential for the TiDB optimizer. TiDB uses statistics as the input of the optimizer to estimate the number of rows processed in each step of a SQL execution plan.

Statistics are divided into two levels:

- **Table-level statistics**: include the total number of rows in the table and the number of rows modified since the last statistics collection.
- **Index/column-level statistics**: include detailed information such as histograms, Count-Min Sketch, Top-N (values or indexes with the highest occurrences), distribution and quantity of different values, and the number of NULL values.

To check the accuracy and health of your statistics, you can use the following SQL statements:

- `SHOW STATS_META`: shows metadata about table statistics.

```
SHOW STATS_META WHERE table_name='T2'\G;
```

```
*************************** 1. row ***************************
         Db_name: test
      Table_name: T2
   Partition_name:
     Update_time: 2023-05-11 02:16:50
    Modify_count: 10000
       Row_count: 20000
1 row in set (0.03 sec)
```

- SHOW STATS_HEALTHY: shows the health status of table statistics.

```
SHOW STATS_HEALTHY WHERE table_name='T2'\G;
```

```
*************************** 1. row ***************************
      Db_name: test
   Table_name: T2
Partition_name:
      Healthy: 50
1 row in set (0.00 sec)
```

TiDB provides two methods for collecting statistics: automatic and manual collection. In most cases, automatic collection is sufficient. TiDB triggers automatic collection when certain conditions are met. Some common triggering conditions include:

- tidb_auto_analyze_ratio: the healthiness trigger.
- tidb_auto_analyze_start_time and tidb_auto_analyze_end_time: the time window for automatic statistics collection.

```
SHOW VARIABLES LIKE 'tidb\_auto\_analyze%';
```

```
+----------------------------------------+-------------+
| Variable_name                          | Value       |
+----------------------------------------+-------------+
| tidb_auto_analyze_ratio                | 0.5         |
| tidb_auto_analyze_start_time           | 00:00 +0000 |
| tidb_auto_analyze_end_time             | 23:59 +0000 |
+----------------------------------------+-------------+
```

In some cases, automatic collection might not meet your needs. By default, it occurs between 00:00 and 23:59, meaning the analyze job can run at any time. To minimize performance impact on your online business, you can set specific start and end times for statistics collection.

You can manually collect statistics using the `ANALYZE TABLE table_name` statement. This lets you adjust settings such as the sample rate, the number of Top-N values, or collect statistics for specific columns only.

Note that after manual collection, subsequent automatic collection jobs inherit the new settings. This means that any customizations made during manual collection will apply to future automatic analyses.

Locking table statistics is useful in the following scenarios:

- The statistics on the table already represent the data well.
- The table is very large, and statistics collection is time-consuming.
- You want to maintain statistics only during specific time windows.

To lock statistics for a table, you can use the `LOCK STATS table_name` statement.

For more information, see Statistics.

11.1.7.4.2 Understand execution plans

An execution plan details the steps that TiDB will follow to execute a SQL query. This section explains how TiDB builds an execution plan and how to generate, display, and interpret execution plans.

How TiDB builds an execution plan

A SQL statement undergoes three main optimization stages in the TiDB optimizer:

1. Pre-processing
2. Logical transformation
3. Cost-based optimization

1. Pre-processing

During pre-processing, TiDB determines whether the SQL statement can be executed using `Point_Get` or `Batch_Point_Get`. These operations use a primary or unique key to read directly from TiKV through an exact key lookup. If a plan qualifies for `Point_Get` or `Batch_Point_Get`, the optimizer skips the logical transformation and cost-based optimization steps because direct key lookup is the most efficient way to access the row.

The following is an example of a `Point_Get` query:

```
EXPLAIN SELECT id, name FROM emp WHERE id = 901;
```

```
+-------------+---------+------+---------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+---------------+---------------+
| Point_Get_1 | 1.00 | root | table:emp   | handle:901   |
+-------------+---------+------+---------------+---------------+
```

2. Logical transformation

During logical transformation, TiDB optimizes SQL statements based on the `SELECT` list, `WHERE` predicates, and other conditions. It generates a logical execution plan to annotate and rewrite the query. This logical plan is used in the next stage, cost-based optimization. The transformation applies rule-based optimizations such as column pruning, partition pruning, and join reordering. Because this process is rule-based and automatic, manual adjustments are usually unnecessary.

For more information, see SQL Logical Optimization.

3. Cost-based optimization

The TiDB optimizer uses statistics to estimate the number of rows processed in each step of a SQL statement and assigns a cost to each step. During cost-based optimization, the optimizer evaluates all possible plan choices, including index accesses and join methods, and calculates the total cost for each plan. The optimizer then selects the execution plan with the minimal total cost.

The following figure illustrates various data access paths and row set operations considered during cost-based optimization. For data retrieval paths, the optimizer determines the most efficient method between index scans and full table scans, and decides whether to retrieve data from row-based TiKV storage or columnar TiFlash storage.

The optimizer also evaluates operations that manipulate row sets, such as aggregation, join, and sorting. For example, the aggregation operator might use either `HashAgg` or `StreamAgg`, while the join method can select from `HashJoin`, `MergeJoin`, or `IndexJoin`.

Additionally, the physical optimization phase includes pushing down expressions and operators to the physical storage engines. The physical plan is distributed to different components based on the underlying storage engines as follows:

- Root tasks are executed on the TiDB server.
- Cop (Coprocessor) tasks are executed on TiKV.
- MPP tasks are executed on TiFlash.

This distribution enables cross-component collaboration for efficient query processing.

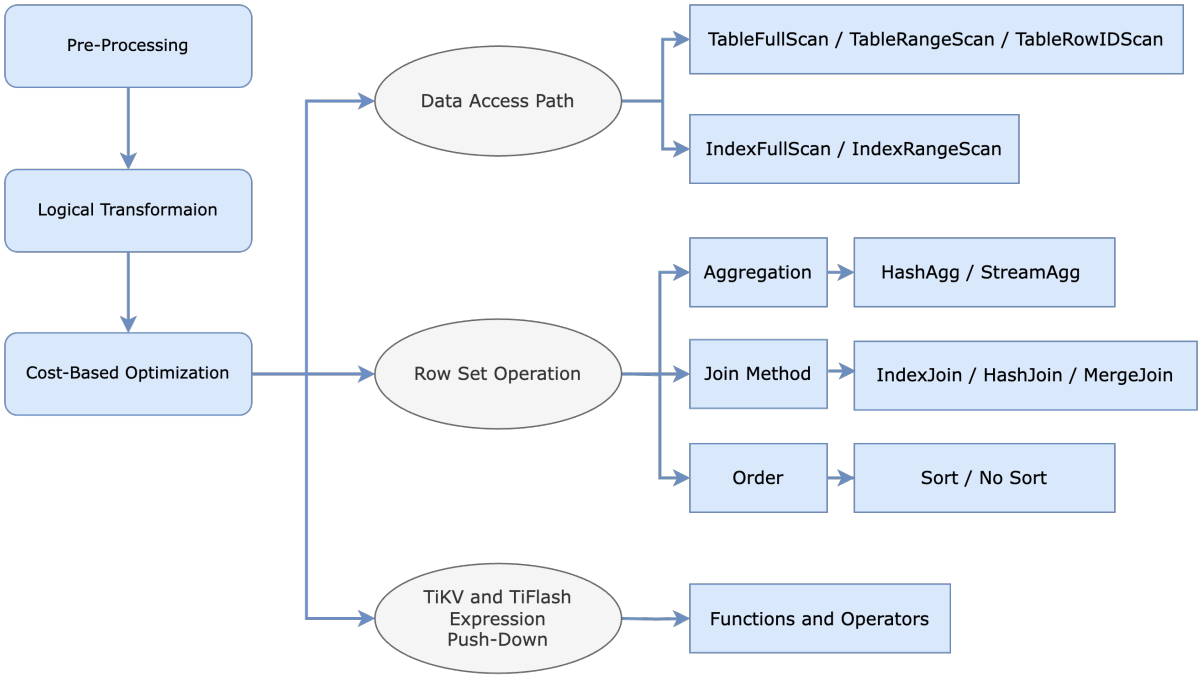

Figure 354: cost-based-optimization

For more information, see SQL Physical Optimization.

Generate and display execution plans

Besides accessing execution plan information through TiDB Dashboard, you can use the `EXPLAIN` statement to display the execution plan for a SQL query. The `EXPLAIN` output includes the following columns:

- `id`: the operator name and a unique identifier of the step.
- `estRows`: the estimated number of rows from the particular step.
- `task`: indicates the layer where the operator is executed. For example, `root` indicates execution on the TiDB server, `cop[tikv]` indicates execution on TiKV, and `mpp[tiflash]` indicates execution on TiFlash.
- `access object`: the object where row sources are located.
- `operator info`: additional details about the operator in the step.

```
EXPLAIN SELECT COUNT(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+-------------------------+------------+-------------+--------------------+-----------
    ↪
```

```
| id                    | estRows    | task         | access object   |
   ↪ operator info
   ↪
   ↪ |
+-------------------------+------------+-------------+-------------------+-----------
   ↪

   ↪ count(Column#13)->Column#11
   ↪                                                          |
|  ─TableReader_21       | 1.00       | root         |                 | data:
   ↪ StreamAgg_9
   ↪
   ↪ |
|    ─StreamAgg_9        | 1.00       | cop[tikv]    |                 | funcs:
   ↪ count(1)->Column#13
   ↪                                                                   |
|      ─Selection_19     | 250.00     | cop[tikv]    |                 | ge(
   ↪ trips.start_date, 2017-07-01 00:00:00.000000), le(trips.start_date,
   ↪ 2017-07-01 23:59:59.000000) |
|        ─TableFullScan_18 | 10000.00 | cop[tikv] | table:trips     | keep
   ↪ order:false, stats:pseudo
   ↪                                                                 |
+-------------------------+------------+-------------+-------------------+-----------
   ↪
5 rows in set (0.00 sec)
```

Different from `EXPLAIN`, `EXPLAIN ANALYZE` executes the corresponding SQL statement, records its runtime information, and returns the runtime information together with the execution plan. This runtime information is crucial for debugging query execution. For more information, see `EXPLAIN ANALYZE`.

The `EXPLAIN ANALYZE` output includes:

- `actRows`: the number of rows output by the operator.
- `execution info`: detailed execution information of the operator. `time` represents the total `wall time`, including the total execution time of all sub-operators. If the operator is called many times by the parent operator, then the time refers to the accumulated time.
- `memory`: the memory used by the operator.
- `disk`: the disk space used by the operator.

The following is an example. Some attributes and table columns are omitted to improve formatting.

```
EXPLAIN ANALYZE
```

```
SELECT SUM(pm.m_count) / COUNT(*)
FROM (
    SELECT COUNT(m.name) m_count
    FROM universe.moons m
    RIGHT JOIN (
        SELECT p.id, p.name
        FROM universe.planet_categories c
        JOIN universe.planets p
            ON c.id = p.category_id
            AND c.name = 'Jovian'
    ) pc ON m.planet_id = pc.id
    GROUP BY pc.name
) pm;
```

Read execution plans: first child first

To diagnose slow SQL queries, you need to understand how to read execution plans. The key principle is **"first child first – recursive descent"**. Each operator in the plan generates a set of rows, and the execution order determines how these rows flow through the plan tree.

The "first child first" rule means that an operator must retrieve rows from all its child operators before producing output. For example, a join operator requires rows from both its child operators to perform the join. The "recursive descent" rule means you analyze the plan from top to bottom, although actual data flows from bottom to top, as each operator depends on its children's output.

Consider these two important concepts when reading execution plans:

- Parent-child interaction: a parent operator calls its child operators sequentially but might cycle through them multiple times. For example, in an index lookup or nested loop join, the parent fetches a batch of rows from the first child, then retrieves zero or more rows from the second child. This process repeats until the first child's result set is fully processed.
- Blocking vs. non-blocking operators: operators can be either blocking or non-blocking:
  - Blocking operators, such as `TopN` and `HashAgg`, must create their entire result set before passing data to their parent.
  - Non-blocking operators, such as `IndexLookup` and `IndexJoin`, produce and pass rows incrementally as needed.

When reading an execution plan, start from the top and work downward. In the following example, the leaf node of the plan tree is `TableFullScan_18`, which performs a full table scan. The rows from this scan are consumed by the `Selection_19` operator, which filters the

data based on `ge(trips.start_date, 2017-07-01 00:00:00.000000)`, `le(trips.start_date, 2017-07-01 23:59:59.000000)`. Then, the group-by operator `StreamAgg_9` performs the final aggregation `COUNT(*)`.

These three operators (`TableFullScan_18`, `Selection_19`, and `StreamAgg_9`) are pushed down to TiKV (marked as `cop[tikv]`), enabling early filtering and aggregation in TiKV to reduce data transfer between TiKV and TiDB. Finally, `TableReader_21` reads the data from `StreamAgg_9`, and `StreamAgg_20` performs the final aggregation `count(*)`.

```
EXPLAIN SELECT COUNT(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```

    ↪ order:false, stats:pseudo
    ↪                                                                      |
+-------------------------+------------+-------------+--------------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In the following example, start by examining `IndexRangeScan_47`, the first leaf node of the plan tree. The optimizer selects only the `name` and `id` columns from the `stars` table, which can be retrieved from the `name(name)` index. As a result, the root reader for `stars` is `IndexReader_48`, not `TableReader`.

The join between `stars` and `planets` is a hash join (`HashJoin_44`). The `planets` table is accessed using a full table scan (`TableFullScan_45`). After the join, `TopN_26` and `TopN_19`

apply the `ORDER BY` and `LIMIT` clauses, respectively. The final operator, `Projection_16`, selects the final column `t5.name`.

```
EXPLAIN
SELECT t5.name
FROM (
    SELECT p.name, p.gravity, p.distance_from_sun
    FROM universe.planets p
    JOIN universe.stars s
        ON s.id = p.sun_id
        AND s.name = 'Sun'
    ORDER BY p.distance_from_sun ASC
    LIMIT 5
) t5
ORDER BY t5.gravity DESC
LIMIT 3;
```

```

   ↪
```

The following figure illustrates the plan tree for the second execution plan:

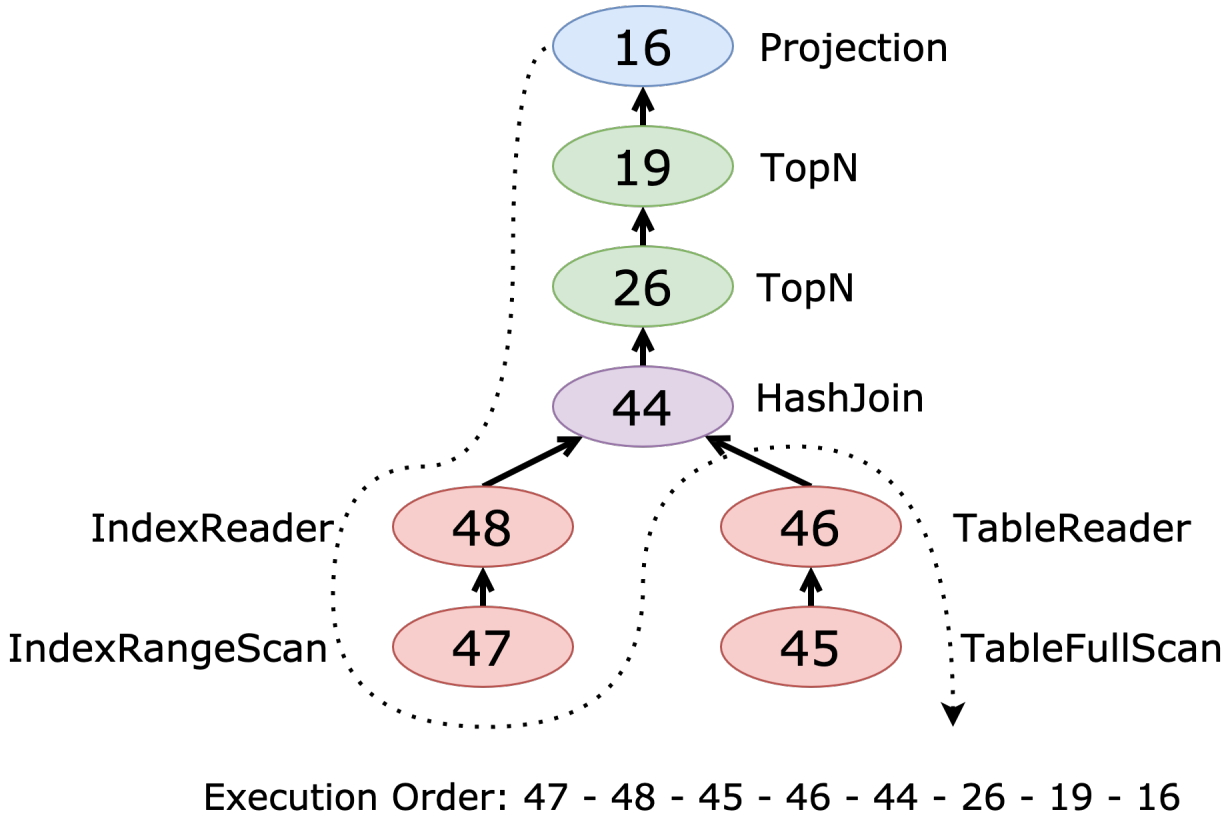

Figure 355: execution-plan-traverse

The execution plan follows a top-to-bottom, first-child-first traversal, corresponding to a postorder traversal (Left, Right, Root) of the plan tree.

You can read this plan in the following order:

1. Start at the top with `Projection_16`.
2. Move to its child, `TopN_19`.
3. Continue to `TopN_26`.
4. Proceed to `HashJoin_44`.
5. For `HashJoin_44`, process its left (Build) child first:
    - `IndexReader_48`
    - `IndexRangeScan_47`
6. For `HashJoin_44`, process its right (Probe) child:
    - `TableReader_46`
    - `TableFullScan_45`

This traversal ensures that each operator's inputs are processed before the operator itself, enabling efficient query execution.

Identify bottlenecks in execution plans

When analyzing execution plans, compare `actRows` (actual rows) with `estRows` (estimated rows) to evaluate the accuracy of the optimizer's estimations. A significant difference between these values might indicate outdated or inaccurate statistics, which can lead to suboptimal query plans.

To identify bottlenecks in a slow query, perform the following steps:

1. Review the `execution info` section from top to bottom, focusing on operators with high execution time.
2. For the first child operator that consumes significant time:
    - Compare `actRows` with `estRows` to assess estimation accuracy.
    - Analyze detailed metrics in `execution info`, such as high execution time or other metrics.
    - Check `memory` and `disk` usage for potential resource constraints.
3. Correlate these factors to determine the root cause of the performance issue. For example, if a `TableFullScan` operation has a high `actRows` count and long execution time in `execution info`, consider creating an index. If a `HashJoin` operation shows high memory usage and execution time, consider optimizing the join order or using an alternative join method.

In the following execution plan, the query runs for 5 minutes and 51 seconds before being canceled. The key issues include:

1. Severe underestimation: The first leaf node `IndexReader_76` reads data from the `index_orders_on_adjustment_id(adjustment_id)` index. The actual number of rows (`actRows`) is 256,811,189, which is significantly higher than the estimated 1 row (`estRows`).
2. Memory overflow: This underestimation causes the hash join operator `HashJoin_69` to build a hash table with far more data than expected, consuming excessive memory (22.6 GB) and disk space (7.65 GB).
3. Query termination: The `actRows` value of `0` for `HashJoin_69` and operators above it indicate either no matching rows or query termination due to resource constraints. In this case, the hash join consumes too much memory, triggering memory control mechanisms to terminate the query.
4. Incorrect join order: The root cause of this inefficient plan is the severe underestimation of `estRows` for `IndexRangeScan_75`, leading the optimizer to choose an incorrect join order.

To address these issues, ensure that table statistics are up to date, particularly for the `orders` table and the `index_orders_on_adjustment_id` index.

```

   ↪ tikv] | table:labels
   ↪                                                                                                  |
   ↪               ...| N/A     | N/A     |
+-------------------------------------------------------------------------------------------------------
   ↪
```

The following execution plan shows the expected results after fixing the incorrect estimation on the `orders` table. The query now takes 1.96 seconds to run, which is a significant improvement from the previous 5 minutes and 51 seconds:

- Accurate estimation: The `estRows` values now closely match the `actRows`, indicating that the statistics are updated and more accurate.
- Efficient join order: The query now starts with a `TableReader` on the `labels` table, followed by an `IndexJoin` with the `rates` table, and another `IndexJoin` with the `orders` table. This join order works more efficiently with the actual data distribution.
- No memory overflow: Unlike the previous plan, this execution shows no signs of excessive memory or disk usage, indicating that the query runs within expected resource limits.

This optimized plan demonstrates the importance of accurate statistics and proper join order in query performance. The execution time reduction (from 351 seconds to 1.96 seconds) shows the impact of addressing estimation errors.

11.1.7.4.3 Index strategy in TiDB

TiDB is a distributed SQL database that separates the SQL layer (TiDB Server) from the storage layer (TiKV). Unlike traditional databases, TiDB does not use a buffer pool to cache data on compute nodes. As a result, SQL query performance and overall cluster performance depend on the number of key-value (KV) RPC requests that need to be processed. Common KV RPC requests include `Point_Get`, `Batch_Point_Get`, and Coprocessor.

To optimize performance in TiDB, it is essential to use indexes effectively, as they can significantly reduce the number of KV RPC requests. Fewer KV RPC requests improve query performance and system efficiency. The following lists some key strategies that help optimize indexing:

- Avoid full table scans.
- Avoid sorting operations.
- Use covering indexes or exclude unnecessary columns to reduce row lookups.

This section explains general indexing strategies and indexing costs. It also provides three practical examples of effective indexing in TiDB, with a focus on composite and covering indexes for SQL tuning.

Composite index strategy guidelines

To create an efficient composite index, order your columns strategically. The column order directly affects how efficiently the index filters and sorts data.

Follow these recommended column order guidelines for a composite index:

1. Start with index prefix columns for direct access:
    - Columns with equivalent conditions
    - Columns with `IS NULL` conditions
    - Columns with `IN` conditions that contain a single value, such as `IN (1)`
2. Add columns for sorting next:
    - Let the index handle sorting operations
    - Enable sort and limit pushdown to TiKV
    - Preserve the sorted order
3. Include additional filtering columns to reduce row lookups:
    - `IN` conditions with multiple values
    - Time range conditions on datetime columns
    - Other non-equivalent conditions, such as `!=`, `<>`, `NOT IN`, and `IS NOT NULL`

4. Add columns from the `SELECT` list or used in aggregation to fully utilize a covering index.

Special consideration: `IN` conditions

When designing composite indexes, you need to handle `IN` conditions carefully.

- Single value: an `IN` clause with a single value (such as `IN (1)`) works similarly to an equality condition and can be placed at the beginning of the index.
- Multiple values: an `IN` clause with multiple values generates multiple ranges. If you place such a column before columns used for sorting, it can break the sorting order. To maintain the sorting order, make sure to place columns used for sorting before columns with multi-value `IN` conditions in the composite index.

The cost of indexing

While indexes can improve query performance, they also introduce costs you should consider:

- Performance impact on writes:
  - A non-clustered index reduces the chance of single-phase commit optimization.
  - Each additional index slows down write operations (such as `INSERT`, `UPDATE`, and `DELETE`).
  - When data is modified, all affected indexes must be updated.
  - The more indexes a table has, the greater the write performance impact.
- Resource consumption:
  - Indexes require additional disk space.
  - More memory is needed to cache frequently accessed indexes.
  - Backup and recovery operations take longer.
- Write hotspot risk:
  - Secondary indexes can create write hotspots. For example, a monotonically increasing datetime index will cause hotspots on table writes.
  - Hotspots can lead to significant performance degradation.

The following lists some best practices:

- Create indexes only when they provide clear performance benefits.
- Regularly review index usage statistics using `TIDB_INDEX_USAGE`.
- Consider the write/read ratio of your workload when designing indexes.

SQL tuning with a covering index

A covering index includes all columns referenced in the `WHERE` and `SELECT` clauses. Using a covering index can eliminate the need for additional index lookups, significantly improving query performance.

The following query requires an index lookup of 2,597,411 rows and takes 46.4 seconds to execute. TiDB dispatches 67 cop tasks for the index range scan on `logs_idx` (`IndexRangeScan_11`) and 301 cop tasks for table access (`TableRowIDScan_12`).

```
SELECT
  SUM(`logs`.`amount`)
FROM
  `logs`
WHERE
  `logs`.`user_id` = 1111
  AND `logs`.`snapshot_id` IS NULL
  AND `logs`.`status` IN ('complete', 'failure')
  AND `logs`.`source_type` != 'online'
  AND (
    `logs`.`source_type` IN ('user', 'payment')
    OR `logs`.`source_type` IN (
      'bank_account',
    )
    AND `logs`.`target_type` IN ('bank_account')
  );
```

The original execution plan is as follows:

```
+------------------------------+-----------+---------+----------+--------------------
   ↪
| id                           | estRows   | actRows | task     | access object
   ↪                                                    | execution info
   ↪                                          |
+------------------------------+-----------+---------+----------+--------------------
   ↪
| HashAgg_18                   | 1.00      | 2571625.22 | 1     | root     |
   ↪                                                     | time:46.4s,
   ↪ loops:2, partial_worker:{wall_time:46.37, ...|
| └─IndexLookUp_19             | 1.00      | 2570096.68 | 301   | root     |
   ↪                                                     | time:46.4s,
   ↪ loops:2, index_task: {total_time: 45.8s, ...|
|   ├─IndexRangeScan_11(Build) | 1309.50 | 317033.98 | 2597411 | cop[tikv]
   ↪ | table:logs, index:logs_idx(snapshot_id, user_id, status) | time:228
   ↪ ms, loops:2547, cop_task: {num: 67, max: 2.17s, ...|
|   └─HashAgg_7(Probe)         | 1.00      | 588434.48 | 301   | cop[tikv] |
   ↪                                                    | time:3m46.7s,
```

```
   ↪ loops:260, cop_task: {num: 301,    ...|
|     └─Selection_13        | 1271.37   | 561549.27 | 2566562 | cop[tikv] |
   ↪                                                          | tikv_task:{proc
   ↪ max:10s, min:0s, avg: 915.3ms,   ...|
|       └─TableRowIDScan_12 | 1309.50   | 430861.31 | 2597411 | cop[tikv] |
   ↪ table:logs                                               | tikv_task:{proc
   ↪ max:10s, min:0s, avg: 908.7ms,   ...|
+-------------------------------+-----------+---------+----------+-------------------
   ↪
```

To improve query performance, you can create a covering index that includes `source_type`, `target_type`, and `amount` columns. This optimization eliminates the need for additional table lookups, reducing execution time to 90 milliseconds, and TiDB only needs to send one cop task to TiKV for data scanning.

After creating the index, execute the `ANALYZE TABLE` statement to collect statistics. In TiDB, index creation does not automatically update statistics, so analyzing the table ensures that the optimizer selects the new index.

```
CREATE INDEX logs_covered ON logs(snapshot_id, user_id, status, source_type
   ↪ , target_type, amount);
ANALYZE TABLE logs INDEX logs_covered;
```

The new execution plan is as follows:

```
+-------------------------------+-----------+---------+----------+-------------------
   ↪
| id                            | estRows   | actRows | task     | access object
   ↪
   ↪ | execution info                          |
+-------------------------------+-----------+---------+----------+-------------------
   ↪
| HashAgg_13                    | 1.00      | 1       | root     |
   ↪
   ↪ | time:90ms, loops:2, RU:158.885311,  ...|
|  └─IndexReader_14             | 1.00      | 1       | root     |
   ↪
   ↪ | time:89.8ms, loops:2, cop_task: {num: 1, ...|
|    └─HashAgg_6                | 1.00      | 1       | cop[tikv] |
   ↪
   ↪ | tikv_task:{time:88ms, loops:52},    ...|
|      └─Selection_12           | 5245632.33 | 52863 | cop[tikv] |
   ↪
   ↪ | tikv_task:{time:80ms, loops:52}     ...|
|        └─IndexRangeScan_11    | 5245632.33 | 52863 | cop[tikv] | table:logs,
   ↪ index:logs_covered(snapshot_id, user_id, status, source_type, target_
   ↪ type, amount)               | tikv_task:{time:60ms, loops:52}     ...|
```

```
+-----------------------------+-----------+--------+----------+--------------------
    ↪
```

SQL tuning with a composite index involving sorting

You can optimize queries with `ORDER BY` clauses by creating composite indexes that include both filtering and sorting columns. This approach helps TiDB access data efficiently while maintaining the desired order.

For example, consider the following query that retrieves data from `test` based on specific conditions:

```
EXPLAIN ANALYZE SELECT
test.*
FROM
  test
WHERE
  test.snapshot_id = 459840
  AND test.id > 998464
ORDER BY
  test.id ASC
LIMIT
  1000
```

The execution plan shows a duration of 170 ms. TiDB uses the `test_index` to perform an `IndexRangeScan_20` with the filter `snapshot_id = 459840`. It then retrieves all columns from the table, returning 5,715 rows to TiDB after `IndexLookUp_23`. TiDB sorts these rows and returns 1,000 rows.

The `id` column is the primary key, which means it is implicitly included in the `test_idx` index. However, `IndexRangeScan_20` does not guarantee order because `test_idx` includes two additional columns (`user_id` and `status`) after the index prefix column `snapshot_id`. As a result, the ordering of `id` is not preserved.

The original plan is as follows:

```
+-----------------------------+---------+---------+-----------+-----------------------
    ↪
| id                          | estRows | actRows | task  | access object
    ↪                                     | execution info
    ↪                           | operator info                          |
+-----------------------------+---------+---------+-----------+-----------------------
    ↪
| id                          | estRows | actRows | task  | access object
    ↪                                     | execution info
    ↪                         ...| test.id, offset:0, count:1000        |
| TopN_10                     | 19.98  | 1000   | root     |
    ↪                                      | time:170.6ms,
    ↪ loops:2                  ...|                                      |
```

```
|  ─IndexLookUp_23          | 19.98  | 5715   | root     |
   ↪                                                    | time:166.6ms,
   ↪ loops:7                  ...|                                    |
|    ─Selection_22(Build)   | 19.98  | 5715   | cop[tikv] |
   ↪                                                  | time:18.6ms, loops
   ↪ :9, cop_task: {num: 3, ...| gt(test.id, 998464)              |
|      ─IndexRangeScan_20   | 433.47 | 7715   | cop[tikv] | table:test,
   ↪ index:test_idx(snapshot_id, user_id, status) | tikv_task:{proc max:4
   ↪ ms, min:4ms, avg: 4ms ...| range:[459840,459840], keep order:false |
|    ─TableRowIDScan_21(Probe) | 19.98 | 5715 | cop[tikv] | table:test
   ↪                                        | time:301.6ms, loops:10, cop_
   ↪ task: {num: 3, ...| keep order:false               |
+-----------------------------+--------+--------+-----------+-----------------------
   ↪
```

To optimize the query, you can create a new index on `(snapshot_id)`. This ensures that `id` is sorted within each `snapshot_id` group. With this index, execution time drops to 96 ms. The `keep order` property becomes `true` for `IndexRangeScan_33`, and `TopN` is replaced with `Limit`. As a result, `IndexLookUp_35` returns only 1,000 rows to TiDB, eliminating the need for additional sorting operations.

The following is the query statement with the optimized index:

```
CREATE INDEX test_new ON test(snapshot_id);
ANALYZE TABLE test INDEX test_new;
```

The new plan is as follows:

```
+---------------------------------+--------+--------+-----------+--------------------
   ↪
| id                              | estRows | actRows | task   | access object
   ↪                              | execution info                          |
   ↪ operator info                                  |
+---------------------------------+--------+--------+-----------+--------------------
   ↪
| Limit_14                        | 17.59  | 1000   | root     |
   ↪                                              | time:96.1ms, loops:2, RU
   ↪ :92.300155     | offset:0, count:1000                          |
|  ─IndexLookUp_35                | 17.59  | 1000   | root     |
   ↪                                              | time:96.1ms, loops:1, index_
   ↪ task:    ...|                                                 |
|    ─IndexRangeScan_33(Build) | 17.59  | 5715   | cop[tikv] | table:test,
   ↪ index:test_new(snapshot_id) | time:7.25ms, loops:8, cop_task: {num:
   ↪ 3, ...| range:(459840 998464,459840 +inf], keep order:true |
|    ─TableRowIDScan_34(Probe) | 17.59  | 5715   | cop[tikv] | table:test
   ↪                               | time:232.9ms, loops:9, cop_task: {num: 3,
   ↪  ...| keep order:false                          |
```

```
+--------------------------------+--------+--------+----------+--------------------
    ↪
```

SQL tuning with composite indexes for efficient filtering and sorting

The following query takes 11 minutes and 9 seconds to execute, which is excessively long for a query that returns only 101 rows. The slow performance is caused by several factors:

- Inefficient index usage: The optimizer selects the index on `created_at`, resulting in a scan of 25,147,450 rows.
- Large intermediate result set: After applying the date range filter, 12,082,311 rows still require processing.
- Late filtering: The most selective predicates `(mode, user_id, and label_id)` are applied after accessing the table, resulting in 16,604 rows.
- Sorting overhead: The final sort operation on 16,604 rows adds additional processing time.

The following is the query statement:

```
SELECT `orders`.*
FROM `orders`
WHERE
    `orders`.`mode` = 'production'
    AND `orders`.`user_id` = 11111
    AND orders.label_id IS NOT NULL
    AND orders.created_at >= '2024-04-07 18:07:52'
    AND orders.created_at <= '2024-05-11 18:07:52'
    AND orders.id >= 1000000000
    AND orders.id < 1500000000
ORDER BY orders.id DESC
LIMIT 101;
```

The following are the existing indexes on `orders`:

```
PRIMARY KEY (`id`),
UNIQUE KEY `index_orders_on_adjustment_id` (`adjustment_id`),
KEY `index_orders_on_user_id` (`user_id`),
KEY `index_orders_on_label_id` (`label_id`),
KEY `index_orders_on_created_at` (`created_at`)
```

```

After creating a composite index `idx_composite` on `orders(user_id, mode, id, created_at, label_id)`, the query performance improves significantly. The execution time drops from 11 minutes and 9 seconds to just 5.3 milliseconds, making the query over 126,000 times faster. This massive improvement results from:

- Efficient index usage: the new index enables an index range scan on `user_id`, `mode`, and `id`, which are the most selective predicates. This reduces the number of scanned

rows from millions to just 224.

- Index-only sort: the `keep order:true` in the execution plan indicates that sorting is performed using the index structure, eliminating the need for a separate sort operation.
- Early filtering: the most selective predicates are applied first, reducing the result set to 224 rows before further filtering.
- Limit push-down: the `LIMIT` clause is pushed down to the index scan, allowing early termination of the scan once 101 rows are found.

This case demonstrates the significant impact of a well-designed index on query performance. By aligning the index structure with the query's predicates, sort order, and required columns, the query achieves a performance improvement of over five orders of magnitude.

```
CREATE INDEX idx_composite ON orders(user_id, mode, id, created_at, label_
    ↪ id);
ANALYZE TABLE orders index idx_composite;
```

The new execution plan is as follows:

```
+--------------------------------+----------+---------+----------+--------------------
    ↪

11.1.7.4.4 When to use TiFlash

This section explains when to use TiFlash in TiDB. TiFlash is optimized for analytical queries that involve complex calculations, aggregations, and large dataset scans. Its columnar storage format and MPP mode significantly improve performance in these scenarios.

Use TiFlash in the following scenarios:

- Large-scale data analysis: TiFlash delivers faster performance for OLAP workloads that require extensive data scans. Its columnar storage and MPP execution mode optimize query efficiency compared to TiKV.
- Complex scans, aggregations, and joins: TiFlash processes queries with heavy aggregations and joins more efficiently by reading only the necessary columns.
- Mixed workloads: in hybrid environments where both transactional (OLTP) and analytical (OLAP) workloads run simultaneously, TiFlash handles analytical queries without affecting TiKV's performance for transactional queries.
- SaaS applications with arbitrary filtering requirements: queries often involve filtering across many columns. Indexing all columns is impractical, especially when queries include a tenant ID as part of the primary key. TiFlash sorts and clusters data by primary key, making it well suited for these workloads. With the late materialization feature, TiFlash enables efficient table range scans, improving query performance without the overhead of maintaining multiple indexes.

Using TiFlash strategically enhances query performance and optimizes resource usage in TiDB for data-intensive analytical queries. The following sections provide examples of TiFlash use cases.

Analytical query

This section compares the execution performance of TPC-H Query 14 on TiKV and TiFlash storage engines.

TPC-H Query 14 involves joining the `order_line` and `item` tables. The query takes **21.1 seconds** on TiKV but only **1.41 seconds** using TiFlash MPP mode, making it 15 times faster.

- TiKV plan: TiDB fetches 3,864,397 rows from the `lineitem` table and 10 million rows from the `part` table. The hash join operation (`HashJoin_21`), along with the subsequent projection (`Projection_38`) and aggregation (`HashAgg_9`) operations, are performed in TiDB.
- TiFlash plan: The optimizer detects TiFlash replicas for both `order_line` and `item` tables. Based on cost estimation, TiDB automatically selects the MPP mode, executing the entire query within the TiFlash columnar storage engine. This includes table scans, hash joins, column projections, and aggregations, significantly improving performance compared to the TiKV plan.

The following is the query:

```
select 100.00 * sum(case when i_data like 'PR%' then ol_amount else 0 end)
    ↪ / (1+sum(ol_amount)) as promo_revenue
from order_line, item
where ol_i_id = i_id and ol_delivery_d >= '2007-01-02 00:00:00.000000' and
    ↪ ol_delivery_d < '2030-01-02 00:00:00.000000';
```

The execution plan on TiKV is as follows:

```
+------------------------------+-------------+----------+----------+----------------

```

SaaS arbitrary filtering workloads

In SaaS applications, tables often use composite primary keys that include tenant identification. The following example demonstrates how TiFlash can significantly improve query performance in these scenarios.

Case study: multi-tenant data access

Consider a table with a composite primary key: `(tenantId, objectTypeId, objectId)`. A typical query pattern for this table involves:

- Retrieving the first N records for a specific tenant and object type while applying random filters across hundreds or thousands of columns. This makes creating indexes for all possible filter combinations impractical. The query might also include a sort operation after filtering.
- Calculating the total count of records that match the filter criteria.

Performance comparison

When running the same query on different storage engines, you can observe significant performance differences:

- TiKV plan: The query takes 2 minutes 38.6 seconds on TiKV. `TableRangeScan` sends 5,121 cop tasks because the data is distributed across 5,121 Regions.
- TiFlash plan: The same query takes only 3.44 seconds on TiFlash MPP engine—nearly 46 times faster. TiFlash stores data sorted by primary key, so queries filtered by the primary key's prefix use `TableRangeScan` instead of a full table scan. TiFlash requires only 2 MPP tasks compared to TiKV's 5,121 tasks.

The following is the query statement:

```
WITH `results` AS (
  SELECT field1, field2, field3, field4
  FROM usertable
  where tenantId = 1234 and objectTypeId = 6789
),
`limited_results` AS (
  SELECT field1, field2, field3, field4
  FROM `results` LIMIT 100
)
SELECT field1, field2, field3, field4
FROM
  (
    SELECT 100 `__total__`, field1, field2, field3, field4
    FROM `limited_results`
    UNION ALL
    SELECT count(*) `__total__`, field1, field2, field3, field4
    FROM `results`
  ) `result_and_count`;
```

The execution plan on TiKV is as follows:

```
+------------------------------+----------+---------+----------+-------------------

Query routing between TiKV and TiFlash

After enabling TiFlash replicas for tables with large amounts of multi-tenant data, the optimizer routes queries to either TiKV or TiFlash based on the row count:

- Small tenants: TiKV is more suitable for tenants with small data size, as it provides high concurrency for small queries with table range scans.
- Large tenants: For tenants with large datasets (such as 10 million rows in this case), TiFlash is more efficient for the following advantages:
    - TiFlash handles dynamic filtering conditions without requiring specific indexes.
    - TiDB can push down `COUNT`, `SORT`, and `LIMIT` operations to TiFlash.
    - TiFlash scans only the required columns using columnar storage.

11.1.8 Tuning by Metrics

11.1.8.1 Performance Analysis and Tuning

This document describes a tuning approach by database time, and illustrates how to use the TiDB Performance Overview dashboard for performance analysis and tuning.

With the methods described in this document, you can analyze user response time and database time from a global and top-down perspective, to confirm whether the bottleneck in user response time is caused by database issues. If the bottleneck is in the database, you can use the database time overview and SQL latency breakdowns to identify the bottleneck and tune performance.

11.1.8.1.1 Performance tuning based on database time

TiDB is constantly measuring and collecting SQL processing paths and database time. Therefore, it is easy to identify database performance bottlenecks in TiDB. Based on database time metrics, you can achieve the following two goals even without data on user response time:

- Determine whether the bottleneck is in TiDB by comparing the average SQL processing latency with the idle time of a TiDB connection in a transaction.
- If the bottleneck is in TiDB, further identify the exact module in the distributed system based on database time overview, color-based performance data, key metrics, resource utilization, and top-down latency breakdowns.

Is TiDB the bottleneck?

- If the average idle time of TiDB connections in transactions is higher than the average SQL processing latency, the database is not to blame for the transaction latency of applications. The database time takes only a small part of the user response time, indicating that the bottleneck is outside the database.

  In this case, check the external components of the database. For example, determine whether there are sufficient hardware resources in the application server, and whether the network latency from the application to the database is excessively high.

- If the average SQL processing latency is higher than the average idle time of TiDB connections in transactions, the bottleneck in transactions is in TiDB, and the database time takes a large percentage of the user response time.

If the bottleneck is in TiDB, how to identify it?

The following figure shows a typical SQL process. You can see that most SQL processing paths are covered in TiDB performance metrics. The database time is broken down into different dimensions, which are colored accordingly. You can quickly understand the workload characteristics and catch the bottlenecks inside the database if any.

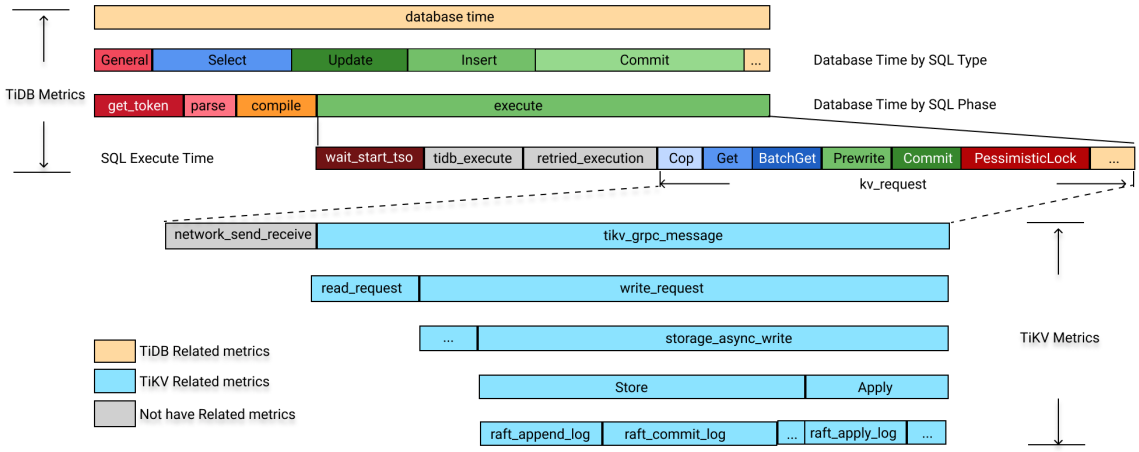

Figure 356: database time decomposition chart

Database time is the sum of all SQL processing time. A breakdown of the database time into the following three dimensions helps you quickly identify bottlenecks in TiDB:

- By SQL processing type: Determine which type of SQL statements consumes the most database time. The formula is:

  ```
  DB Time = Select Time + Insert Time + Update Time + Delete Time +
  ↪ Commit Time + ...
  ```

- By the 4 steps of SQL processing (get_token/parse/compile/execute): Determine which step consumes the most time. The formula is:

  ```
  DB Time = Get Token Time + Parse Time + Compile Time + Execute Time
  ```

- By executor time, TSO wait time, KV request time, and execution retry time: Determine which execution step constitutes the bottleneck. The formula is:

  ```
  Execute Time ~= TiDB Executor Time + KV Request Time + PD TSO Wait Time
  ↪  + Retried execution time
  ```

11.1.8.1.2 Performance analysis and tuning using the Performance Overview dashboard

This section describes how to perform performance analysis and tuning based on database time using the Performance Overview dashboard in Grafana.

The Performance Overview dashboard orchestrates the metrics of TiDB, PD, and TiKV, and presents each of them in the following sections:

- Database time and SQL execution time overview: Color-coded SQL types, database time by SQL execution phase, and database time of different requests help you quickly identify database workload characteristics and performance bottlenecks.
- Key metrics and resource utilization: Contains database QPS, connection information, request command types between the applications and the database, database internal TSO and KV request OPS, and TiDB/TiKV resource usage.
- Top-down latency breakdown: Contains a comparison of query latency and connection idle time, breakdown of query latency, latency of TSO requests and KV requests in SQL execution, and breakdown of TiKV internal write latency.

Database time and SQL execution time overview

The database time metric is the sum of the latency that TiDB processes SQL per second, which is also the total time that TiDB concurrently processes application SQL requests per second (equal to the number of active connections).

The Performance Overview dashboard provides the following three stacked area graphs. They help you understand database workload profile and quickly identify the bottleneck causes in terms of statements, sql phase, and TiKV or PD request type during SQL execution.

- Database Time By SQL Type
- Database Time By SQL Phase
- SQL Execute Time Overview

Tune by color

The diagrams of database time breakdown and execution time overview present both expected and unexpected time consumption intuitively. Therefore, you can quickly identify performance bottleneck and learn the workload profile. Green and blue areas stand for normal time consumption and requests. If non-green or non-blue areas occupy a significant proportion in these two diagrams, the database time distribution is inappropriate.

- Database Time By SQL Type:
  - Blue: `Select` statement
  - Green: `Update`, `Insert`, `Commit` and other DML statements
  - Red: General SQL types, including `StmtPrepare`, `StmtReset`, `StmtFetch`, and `StmtClose`
- Database Time By SQL Phase: The SQL execution phase is in green and other phases are in red on general. If non-green areas are large, it means much database time is consumed in other phases than the execution phase and further cause analysis is required. A common scenario is that the compile phase shown in orange takes a large area due to unavailability of prepared plan cache.

- SQL Execute Time Overview: Green metrics stand for common KV write requests (such as `Prewrite` and `Commit`), blue metrics stand for common KV read requests (such as Cop and Get), purple metrics stand for TiFlash MPP requests, and metrics in other colors stand for unexpected situations which you need to pay attention. For example, pessimistic lock KV requests are marked red and TSO waiting is marked dark brown. If non-blue or non-green areas are large, it means there is bottleneck during SQL execution. For example:
    - If serious lock conflicts occur, the red area will take a large proportion.
    - If excessive time is consumed in waiting TSO, the dark brown area will take a large proportion.

Example 1: TPC-C workload

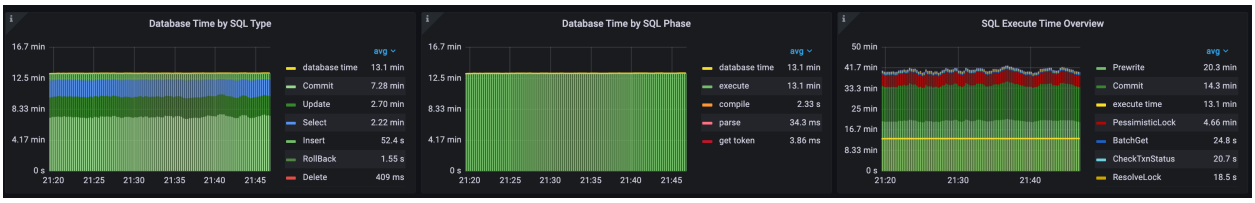

Figure 357: TPC-C

- Database Time by SQL Type: Most time-consuming statements are `commit`, `update`, `select`, and `insert` statements.
- Database Time by SQL Phase: The most time-consuming phase is SQL execution in green.
- SQL Execute Time Overview: The most time-consuming KV requests in SQL execution are `Prewrite` and `Commit` in green.

> **Note:**
> It is normal that the total KV request time is greater than the execute time. Because the TiDB executor may send KV requests to multiple TiKVs concurrently, causing the total KV request wait time to be greater than the execute time. In the preceding TPC-C workload, TiDB sends `Prewrite` and `Commit` requests concurrently to multiple TiKVs when a transaction is committed. Therefore, the total time for `Prewrite`, `Commit` ↪ , and `PessimisticLock` requests in this example is obviously longer than the execute time.
>
> - The `execute` time may also be significantly greater than the total time of the KV request plus the `tso_wait` time. This means that the SQL execution time is spent mostly inside the TiDB executor. Here are two common examples:

```
> - Example 1: After TiDB executor reads a large amount of data from
    ↪ TiKV, it needs to do complex join and aggregation inside TiDB,
    ↪ which consumes a lot of time.
> - Example 2: The application experiences serious write statement lock
    ↪  conflicts. Frequent lock retries result in long `Retried
    ↪ execution time`.
```

Example 2: OLTP read-heavy workload

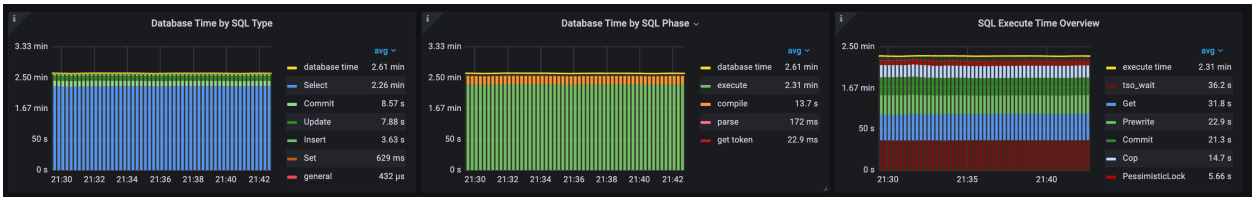

Figure 358: OLTP

- Database Time by SQL Type: Major time-consuming statements are `SELECT`, `COMMIT`, `UPDATE`, and `INSERT`, among which `SELECT` consumes most database time.
- Database Time by SQL Phase: Most time is consumed in the `execute` phase in green.
- SQL Execute Time Overview: In SQL execution phase, `pd tso_wait` in dark brown, `KV Get` in blue, and `Prewrite` and `Commit` in green are time-consuming.

Example 3: Read-only OLTP workload

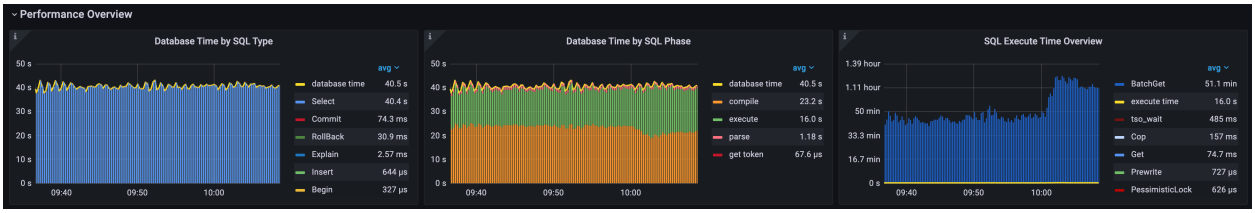

Figure 359: OLTP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Major time-consuming phases are `compile` in orange and `execute` in green. Latency in the `compile` phase is the highest, indicating that TiDB is taking too long to generate execution plans and the root cause needs to be further determined based on the subsequent performance data.
- SQL Execute Time Overview: The KV BatchGet requests in blue consume the most time during SQL execution.

Note:

In example 3, `SELECT` statements need to read thousands of rows concurrently from multiple TiKVs. Therefore, the total time of the `BatchGet` request is much longer than the execution time.

Example 4: Lock contention workload

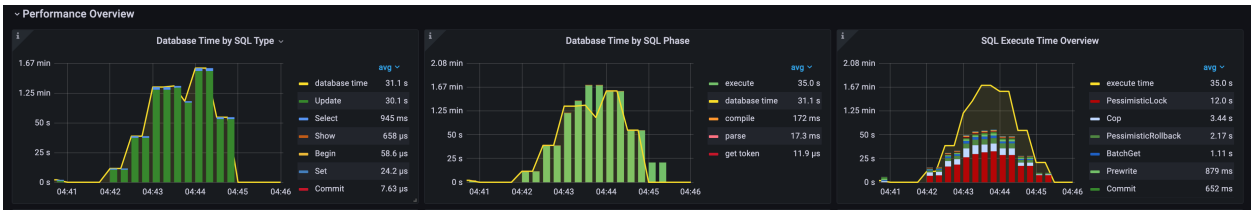

Figure 360: OLTP

- Database Time by SQL Type: Mainly are `UPDATE` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The KV request PessimisticLock shown in red consumes the most time during SQL execution, and the execution time is obviously longer than the total time of KV requests. This is caused by serious lock conflicts in write statements and frequent lock retries prolong `Retried execution time`. Currently, TiDB does not measure `Retried execution time`.

Example 5: HTAP CH-Benchmark workload

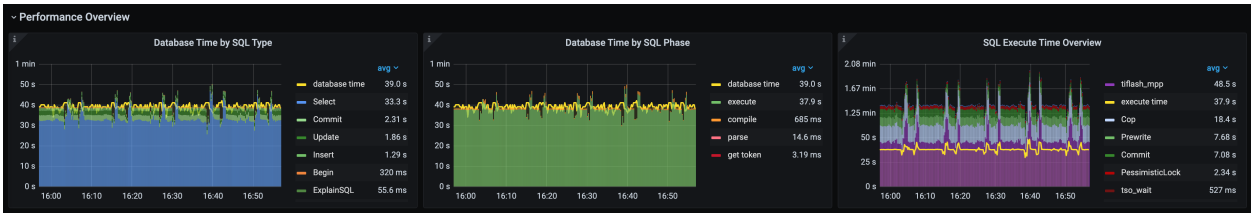

Figure 361: HTAP

- Database Time by SQL Type: Mainly are `SELECT` statements.
- Database Time by SQL Phase: Most time is consumed in the execute phase in green.
- SQL Execute Time Overview: The `tiflash_mpp` requests shown in purple consume the most time during SQL execution, followed by the KV requests, including the `Cop` requests in blue, and the `Prewrite` and `Commit` requests in green.

TiDB key metrics and cluster resource utilization

Query Per Second, Command Per Second, and Prepared-Plan-Cache

By checking the following three panels in Performance Overview, you can learn the application workload type, how the application interacts with TiDB, and whether the application fully utilizes TiDB prepared plan cache.

- QPS: Short for Query Per Second. It shows the count of SQL statements executed by the application.
- CPS By Type: Short for Command Per Second. Command indicates MySQL protocol-specific commands. A query statement can be sent to TiDB either by a query command or a prepared statement.
- Queries Using Plan Cache OPS: `avg-hit` is the number of queries using the execution plan cache per second in a TiDB cluster, and `avg-miss` is the number of queries not using the execution plan cache per second in a TiDB cluster.

  `avg-hit + avg-miss` is equal to `StmtExecute`, which is the number of all queries executed per second. When prepared plan cache is enabled in TiDB, the following three scenarios will occur:

  - No prepared plan cache is hit: `avg-hit` (the number of hits per second) is 0, and `avg-miss` is equal to the number of `StmtExecute` commands per second. The possible reasons include:
    - The application is using the query interface.
    - The cached plans are cleaned up because the application calls the `StmtClose` command after each `StmtExecute` execution.
    - All statements executed by `StmtExecute` do not meet the cache conditions so the execution plan cache cannot be hit.
  - All prepared plan cache is hit: `avg-hit` (the number of hits per second) is equal to the number of `StmtExecute` commands per second, and `avg-miss` (the number without hits per second) is 0.
  - Some prepared plan cache is hit: `avg-hit` (the number of hits per second) is fewer than the number of `StmtExecute` commands per second. Prepared plan cache has known limitations. For example, it does not support subqueries, so SQL statements with subqueries cannot use prepared plan cache.

Example 1: TPC-C workload

The TPC-C workload are mainly `UPDATE`, `SELECT`, and `INSERT` statements. The total QPS is equal to the number of `StmtExecute` commands per second and the latter is almost equal to `avg-hit` on the Queries Using Plan Cache OPS panel. Ideally, the client caches the object of the prepared statement. In this way, the cached statement is called directly when a SQL statement is executed. All SQL executions hit the prepared plan cache, and there is no need to recompile to generate execution plans.

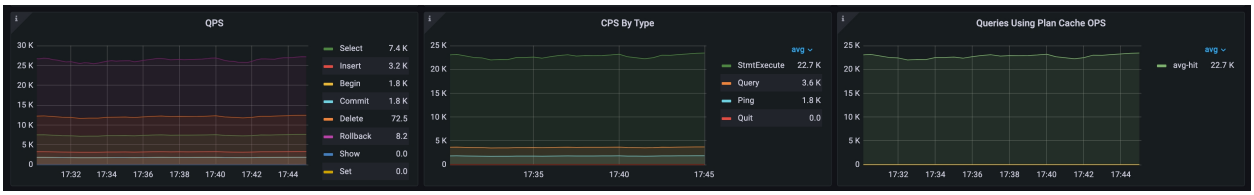

Figure 362: TPC-C

Example 2: Prepared plan cache unavailable for query commands in read-only OLTP workload

In this workload, `Commit QPS` = `Rollback QPS` = `Select QPS`. The application has enabled auto-commit concurrency, and rollback is performed every time a connection is fetched from the connection pool. As a result, these three statements are executed the same number of times.

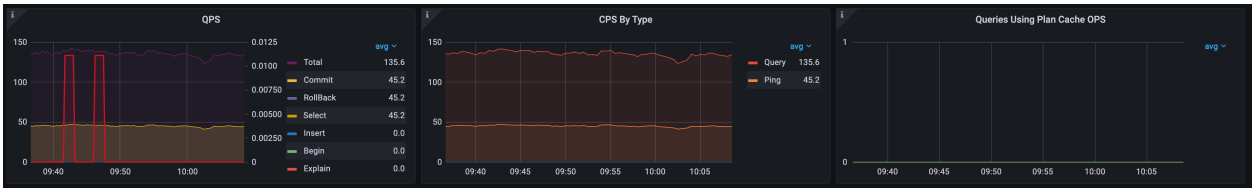

Figure 363: OLTP-Query

- The red bold line in the QPS panel stands for failed queries, and the Y-axis on the right shows the number of failed queries. A value other than 0 means the presence of failed queries.
- The total QPS is equal to the number of queries in the CPS By Type panel, the query command has been used by the application.
- The Queries Using Plan Cache OPS panel has no data, because prepared plan cache is unavailable for query command. This means that TiDB needs to parse and generate an execution plan for every query execution. As a result, the compile time is longer with increasing CPU consumption by TiDB.

Example 3: Prepared plan cache unavailable with prepared statement enabled for OLTP workload

`StmtPrepare` times = `StmtExecute` times = `StmtClose` times ~= `StmtFetch` times. The application uses the prepare > execute > fetch > close loop. To prevent prepared statement object leak, many application frameworks call `close` after the `execute` phase. This creates two problems.

- A SQL execution requires four commands and four network round trips.

- Queries Using Plan Cache OPS is 0, indicating zero hit of prepared plan cache. The `StmtClose` command clears cached execution plans by default and the next `StmtPrepare` command needs to generate the execution plan again.

> **Note:**
>
> Starting from TiDB v6.0.0, you can prevent the `StmtClose` command from clearing cached execution plans via the global variable (`set global tidb ↪ _ignore_prepared_cache_close_stmt=on;`). In this way, subsequent executions can hit the prepared plan cache.

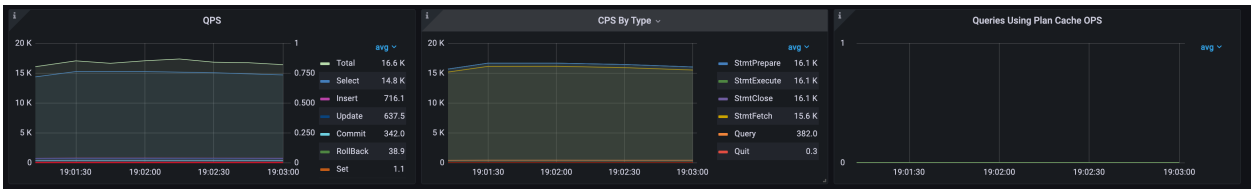

Figure 364: OLTP-Prepared

Example 4: Prepared statements have a resource leak

The number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that the application has an object leak for prepared statements.

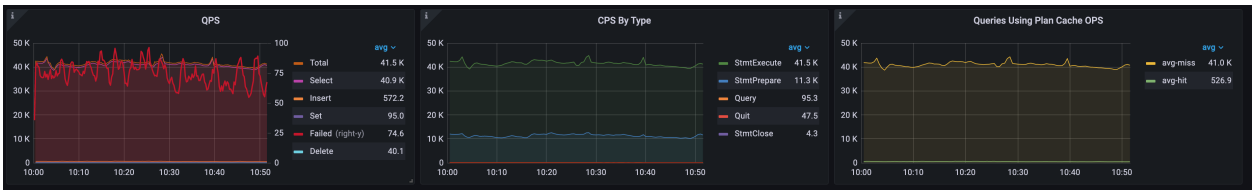

Figure 365: OLTP-Query

- In the QPS panel, the red bold line indicates the number of failed queries, and the Y axis on the right indicates the coordinate value of the number. In this example, the number of failed queries per second is 74.6.
- In the CPS By Type panel, the number of `StmtPrepare` commands per second is much greater than that of `StmtClose` per second, which indicates that an object leak occurs in the application for prepared statements.

- In the Queries Using Plan Cache OPS panel, `avg-miss` is almost equal to `StmtExecute` in the CPS By Type panel, which indicates that almost all SQL executions miss the execution plan cache.

KV/TSO Request OPS and KV Request Time By Source

- In the KV/TSO Request OPS panel, you can view the statistics of KV and TSO requests per second. Among the statistics, `kv request total` represents the sum of all requests from TiDB to TiKV. By observing the types of requests from TiDB to PD and TiKV, you can get an idea of the workload profile within the cluster.
- In the KV Request Time By Source panel, you can view the time ratio of each KV request type and all request sources.
    - kv request total time: The total time of processing KV and TiFlash requests per second.
    - Each KV request and the corresponding request source form a stacked bar chart, in which `external` identifies normal business requests and `internal` identifies internal activity requests (such as DDL and auto analyze requests).

Example 1: Busy workload

Figure 366: TPC-C

In this TPC-C workload:

- The total number of KV requests per second is 79,700. The top request types are `Prewrite`, `Commit`, `PessimisticLock`, and `BatchGet` in order of number of requests.
- Most of the KV processing time is spent on `Commit-external_Commit` and `Prewrite-external_Commit`, which indicates that the most time-consuming KV requests are `Commit` and `Prewrite` from external commit statements.

Example 2: Analyze workload

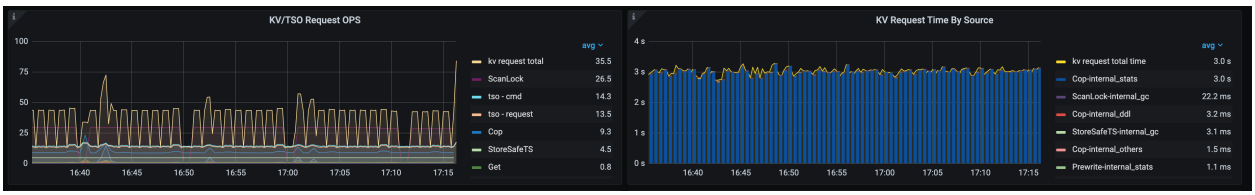

Figure 367: OLTP

In this workload, only `ANALYZE` statements are running in the cluster:

- The total number of KV requests per second is 35.5 and the number of Cop requests per second is 9.3.
- Most of the KV processing time is spent on `Cop-internal_stats`, which indicates that the most time-consuming KV request is `Cop` from internal `ANALYZE` operations.

CPU and memory usage

In the CPU/Memory panels of TiDB, TiKV, and PD, you can monitor their respective logical CPU usage and memory consumption, such as average CPU, maximum CPU, delta CPU (maximum CPU usage minus minimum CPU usage), CPU quota, and maximum memory usage. Based on these metrics, you can determine the overall resource usage of TiDB, TiKV, and PD.

- Based on the `delta` value, you can determine if CPU usage in TiDB or TiKV is unbalanced. For TiDB, a high `delta` usually means unbalanced application connections among the TiDB instances; For TiKV, a high `delta` usually means there are read/write hot spots in the cluster.
- With an overview of TiDB, TiKV, and PD resource usage, you can quickly determine if there are resource bottlenecks in your cluster and whether TiKV, TiDB, or PD needs scale-out or scale-up.

Example 1: High TiKV resource usage

In the following TPC-C workload, each TiDB and TiKV is configured with 16 CPUs. PD is configured with 4 CPUs.

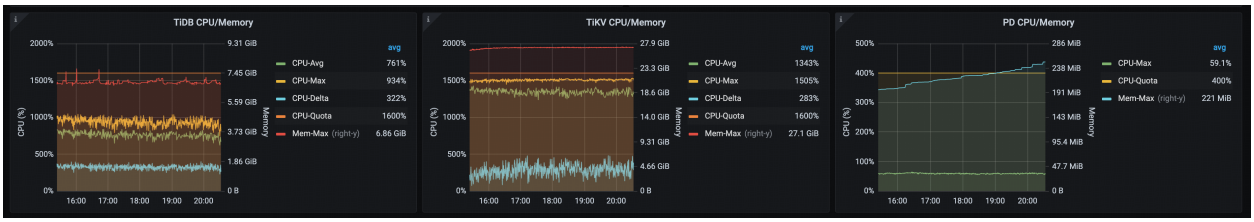

Figure 368: TPC-C

- The average, maximum, and delta CPU usage of TiDB are 761%, 934%, and 322%, respectively. The maximum memory usage is 6.86 GiB.
- The average, maximum, and delta CPU usage of TiKV are 1343%, 1505%, and 283%, respectively. The maximum memory usage is 27.1 GiB.
- The maximum CPU usage of PD is 59.1%. The maximum memory usage is 221 MiB.

Obviously, TiKV consumes more CPU, which is expected because TPC-C is a write-heavy scenario. To improve performance, it is recommended to scale out TiKV.

Data traffic

The read and write traffic panels offer insights into traffic patterns within your TiDB cluster, allowing you to monitor data flow from clients to the database and between internal components comprehensively.

- Read traffic
    - `TiDB -> Client`: the outbound traffic statistics from TiDB to the client
    - `Rocksdb -> TiKV`: the data flow that TiKV retrieves from RocksDB during read operations within the storage layer
- Write traffic
    - `Client -> TiDB`: the inbound traffic statistics from the client to TiDB
    - `TiDB -> TiKV: general`: the rate at which foreground transactions are written from TiDB to TiKV
    - `TiDB -> TiKV: internal`: the rate at which internal transactions are written from TiDB to TiKV
    - `TiKV -> Rocksdb`: the flow of write operations from TiKV to RocksDB
    - `RocksDB Compaction`: the total read and write I/O flow generated by RocksDB compaction operations. If `RocksDB Compaction` is significantly higher than `TiKV -> Rocksdb`, and your average row size is larger than 512 bytes, you can enable Titan to reduce the compaction I/O flow as follows, with min-blob-size set to `"512B"` or `"1KB"` and blob-file-compression set to `"zstd"`.

```
[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"
```

Example 1: Read and write traffic in the TPC-C workload

The following is an example of read and write traffic in the TPC-C workload.

- Read traffic
    - `TiDB -> Client`: 14.2 MB/s
    - `Rocksdb -> TiKV`: 469 MB/s. Note that both read operations (`SELECT` statements) and write operations (`INSERT`, `UPDATE`, and `DELETE` statements) require reading data from RocksDB into TiKV before committing a transaction.

- Write traffic
    - `Client -> TiDB`: 5.05 MB/s
    - `TiDB -> TiKV: general`: 13.1 MB/s
    - `TiDB -> TiKV`: internal: 5.07 KB/s
    - `TiKV -> Rocksdb`: 109 MB/s
    - `RocksDB Compaction`: 567 MB/s

Figure 369: TPC-C

Example 2: Write traffic before and after Titan is enabled

The following example shows the performance changes before and after Titan is enabled. For an insert workload with 6 KB records, Titan significantly reduces write traffic and compaction I/O, enhancing overall performance and resource utilization of TiKV.

- Write traffic before Titan is enabled
    - `Client -> TiDB`: 510 MB/s
    - `TiDB -> TiKV: general`: 187 MB/s
    - `TiDB -> TiKV: internal`: 3.2 KB/s
    - `TiKV -> Rocksdb`: 753 MB/s
    - `RocksDB Compaction`: 10.6 GB/s

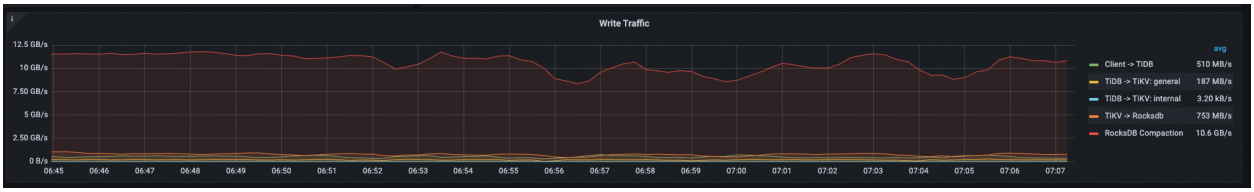

Figure 370: Titan Disable

- Write traffic after Titan is enabled
    - `Client -> TiDB`: 586 MB/s
    - `TiDB -> TiKV: general`: 295 MB/s

- `TiDB -> TiKV: internal`: 3.66 KB/s
- `TiKV -> Rocksdb`: 1.21 GB/s
- `RocksDB Compaction`: 4.68 MB/s

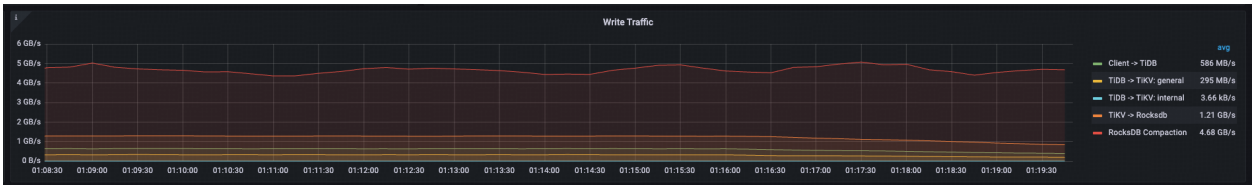

Figure 371: Titan Enable

Query latency breakdown and key latency metrics

The latency panel provides average values and 99th percentile. The average values help identify the overall bottleneck, while the 99th or 999th percentile or 999th helps determine whether there is a significant latency jitter.

Duration, Connection Idle Duration, and Connection Count

The Duration panel contains the average and P99 latency of all statements, and the average latency of each SQL type. The Connection Idle Duration panel contains the average and the P99 connection idle duration. Connection idle duration includes the following two states:

- in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is within a transaction.
- not-in-txn: The interval between processing the previous SQL and receiving the next SQL statement when the connection is not within a transaction.

An applications perform transactions with the same database connection. By comparing the average query latency with the connection idle duration, you can determine if TiDB is the bottleneck for overall system, or if user response time jitter is caused by TiDB.

- If the application workload is not read-only and contains transactions, by comparing the average query latency with `avg-in-txn`, you can determine the proportion in processing transactions inside and outside the database, and identify the bottleneck in user response time.
- If the application workload is read-only or autocommit mode is on, you can compare the average query latency with `avg-not-in-txn`.

In real customer scenarios, it is not rare that the bottleneck is outside the database, for example:

- The client server configuration is too low and the CPU resources are exhausted.
- HAProxy is used as a TiDB cluster proxy, and the HAProxy CPU resource is exhausted.
- HAProxy is used as a TiDB cluster proxy, and the network bandwidth of the HAProxy server is used up under high workload.
- The network latency from the application server to the database is high. For example, the network latency is high because in public-cloud deployments the applications and the TiDB cluster are not in the same region, or the dns workload balancer and the TiDB cluster are not in the same region.
- The bottleneck is in client applications. The application server's CPU cores and Numa resources cannot be fully utilized. For example, only one JVM is used to establish thousands of JDBC connections to TiDB.

In the Connection Count panel, you can check the total number of connections and also the number of connections on each TiDB node, which helps you determine whether the total number of connections is normal and whether the number of connections on each TiDB node is unbalanced. `active connections` indicates the number of active connections, which is equal to the database time per second. The Y axis on the right (`disconnection/s`) indicates the number of disconnections per second in a cluster, which can be used to determine whether the application uses short connections.

Example 1: The number of disconnection/s is too high

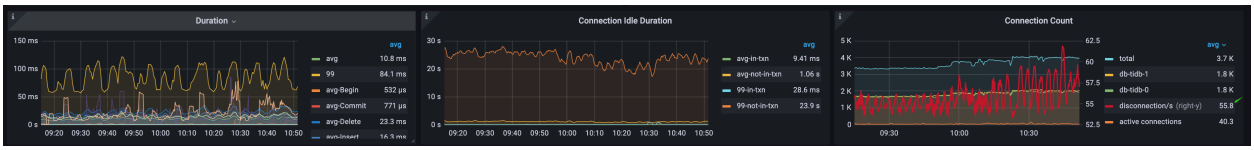

Figure 372: high disconnection/s

In this workload:

- The average latency and P99 latency of all SQL statements are 10.8 ms and 84.1 ms, respectively.
- The average connection idle time in transactions `avg-in-txn` is 9.4 ms.
- The total number of connections to the cluster is 3,700, and the number of connections to each TiDB node is 1,800. The average number of active connections is 40.3, which indicates that most of the connections are idle. The average number of `disconnection /s` is 55.8, which indicates that the application is connecting and disconnecting frequently. The behavior of short connections will have a certain impact on TiDB resources and response time.

Example 2: TiDB is the bottleneck of user response time

Figure 373: TiDB is the Bottleneck

In this TPC-C workload:

- The average latency and P99 latency of all SQL statements are 477 us and 3.13 ms, respectively. The average latencies of the commit statement, insert statement, and query statement are 2.02 ms, 609 us, and 468 us, respectively.
- The average connection idle time in transactions `avg-in-txn` is 171 us.

The average query latency is significantly greater than `avg-in-txn`, which means the main bottleneck in transactions is inside the database.

Example 3: TiDB is not the bottleneck of user response time

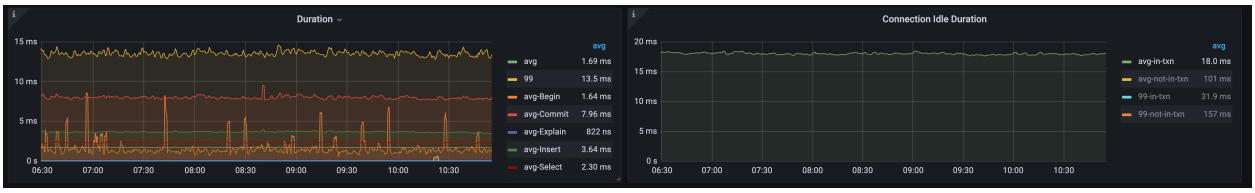

Figure 374: TiDB is not Bottleneck

In this workload, the average query latency is 1.69 ms and `avg-in-txn` is 18 ms, indicating that TiDB spends 1.69 ms on average to process a SQL statement in transactions, and then needs to wait for 18 ms to receive the next statement.

The average query latency is significantly lower than `avg-in-txn`. The bottleneck of user response time is not in TiDB. This example is in a public cloud environment, where high network latency between the application and the database results in extremely high connection idle time, because the application and the database are not in the same region.

Parse, Compile, and Execute Duration

In TiDB, there is a typical processing flow from sending query statements to returning results.

SQL processing in TiDB consists of four phases, `get token`, `parse`, `compile`, and `execute`.

- `get token`: Usually only a few microseconds and can be ignored. The token is limited only when the number of connections to a single TiDB instance reaches the token-limit limit.
- `parse`: The query statements are parsed into abstract syntax tree (AST).
- `compile`: Execution plans are compiled based on the AST from the `parse` phase and statistics. The `compile` phase contains logical optimization and physical optimization. Logical optimization optimizes query plans by rules, such as column pruning based on relational algebra. Physical optimization estimates the cost of the execution plans by statistics by a cost-based optimizer and selects a physical execution plan with the lowest cost.
- `execute`: The time consumption to execute a SQL statement. TiDB first waits for the globally unique timestamp TSO. Then the executor constructs the TiKV API request based on the Key range of the operator in the execution plan and distributes it to TiKV. `execute` time includes the TSO wait time, the KV request time, and the time spent by TiDB executor in processing data.

If an application uses the `query` or `StmtExecute` MySQL command interface only, you can use the following formula to identify the bottleneck in average latency.

```
avg Query Duration = avg Get Token + avg Parse Duration + avg Compile
    ↪ Duration + avg Execute Duration
```

Usually, the `execute` phase accounts for the most of the `query` latency. However, the `parse` and `compile` phases can also take a large part in the following cases:

- Long latency in the `parse` phase: For example, when the `query` statement is long, much CPU will be consumed to parse the SQL text.
- Long latency in the `compile` phase: If the prepared plan cache is not hit, TiDB needs to compile an execution plan for every SQL execution. The latency in the `compile` phase can be several or tens of milliseconds or even higher. If prepared plan cache is not hit, logical and physical optimization are done in the `compile` phase, which consumes a lot of CPU and memory, makes Go Runtime (TiDB is written in Go) under pressure, and affects the performance of other TiDB components. Prepared plan cache is important for efficient processing of OLTP workload in TiDB.

Example 1: Database bottleneck in the `compile` phase

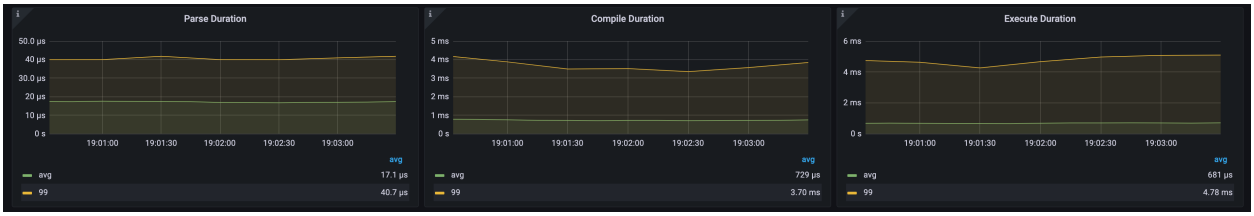

Figure 375: Compile

In the preceding figure, the average time of the `parse`, `compile`, and `execute` phases are 17.1 us, 729 us, and 681 us, respectively. The `compile` latency is high because the application uses the `query` command interface and cannot use prepared plan cache.

Example 2: Database bottleneck in the `execute` phase

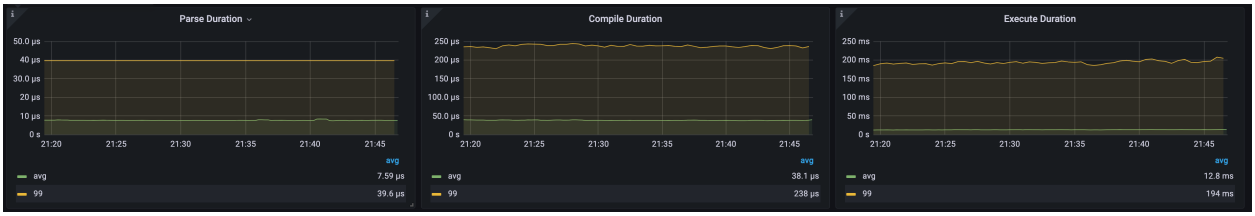

Figure 376: Execute

In this TPC-C workload, the average time of `parse`, `compile` and `execute` phases are 7.39 us, 38.1 us, and 12.8 ms, respectively. The `execute` phase is the bottleneck of the `query` latency.

KV and TSO Request Duration

TiDB interacts with PD and TiKV in the `execute` phase. As shown in the following figure, when processing SQL request, TiDB requests TSOs before entering the `parse` and `compile` phases. The PD Client does not block the caller, but returns a `TSFuture` and asynchronously sends and receives the TSO requests in the background. Once the PD client finishes handling the TSO requests, it returns `TSFuture`. The holder of the `TSFuture` needs to call the Wait method to get the final TSOs. After TiDB finishes the `parse` and `compile` phases, it enters the `execute` phase, where two situations might occur:

- If the TSO request has completed, the Wait method immediately returns an available TSO or an error
- If the TSO request has not yet completed, the Wait method is blocked until a TSO is available or an error appears (the gRPC request has been sent but no result is returned, and the network latency is high)

The TSO wait time is recorded as `TSO WAIT` and the network time of the TSO request is recorded as `TSO RPC`. After the TSO wait is complete, TiDB executor usually sends read or write requests to TiKV.

- Common KV read requests: `Get`, `BatchGet`, and `Cop`
- Common KV write requests: `PessimisticLock`, `Prewrite` and `Commit` for two-phase commits

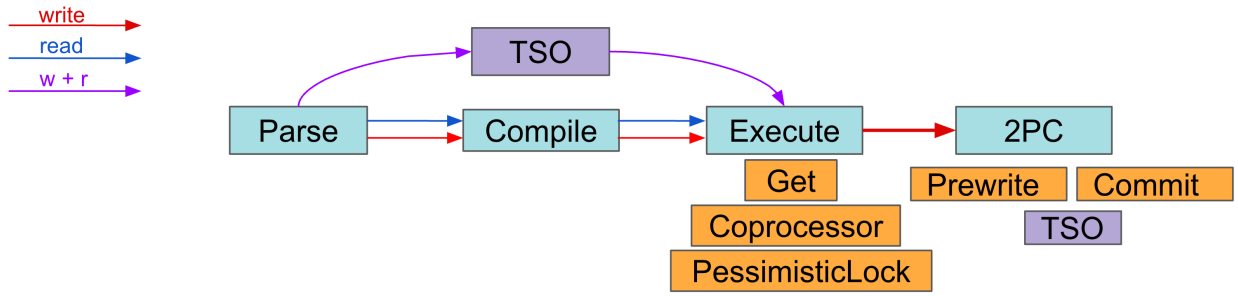

Figure 377: Execute

The indicators in this section correspond to the following three panels.

- Avg TiDB KV Request Duration: The average latency of KV requests measured by TiDB
- Avg TiKV GRPC Duration: The average latency in processing gPRC messages in TiKV
- PD TSO Wait/RPC Duration: TiDB executor TSO wait time and network latency for TSO requests (RPC)

The relationship between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is as follows:

```
Avg TiDB KV Request Duration = Avg TiKV GRPC Duration + Network latency between TiDB and TiKV + TiKV gRPC processing time + TiDB gRPC processing time and scheduling latency
```

The difference between `Avg TiDB KV Request Duration` and `Avg TiKV GRPC Duration` is closely related to the network traffic, network latency, and resource usage by TiDB and TiKV.

- In the same data center: The difference is generally less than 2 ms.
- In different availability zones in the same region: The difference is generally less than 5 ms.

Example 1: Low workload of clusters deployed on the same data center

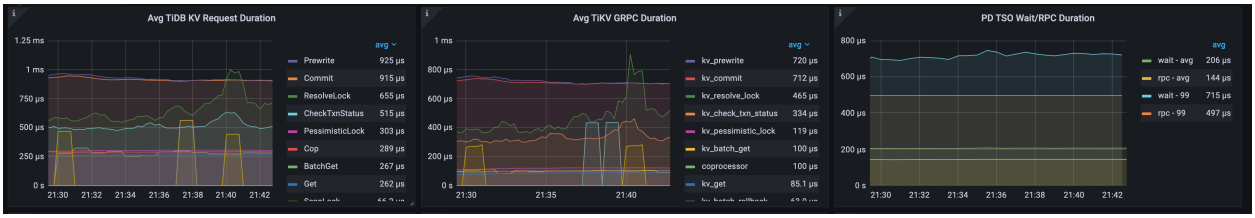

Figure 378: Same Data Center

In this workload, the average `Prewrite` latency on TiDB is 925 us, and the average `kv_prewrite` processing latency inside TiKV is 720 us. The difference is about 200 us, which is normal in the same data center. The average TSO wait latency is 206 us, and the RPC time is 144 us.

Example 2: Normal workload on public cloud clusters

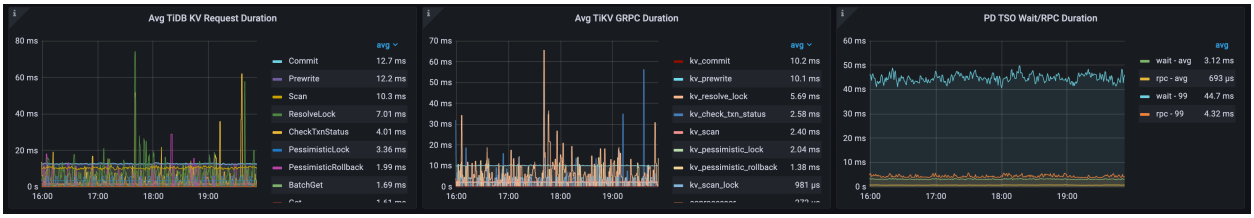

Figure 379: Cloud Env

In this example, TiDB clusters are deployed in different data centers in the same region. The average `commit` latency on TiDB is 12.7 ms, and the average `kv_commit` processing latency inside TiKV is 10.2 ms, a difference of about 2.5 ms. The average TSO wait latency is 3.12 ms, and the RPC time is 693 us.

Example 3: Resource overloaded on public cloud clusters

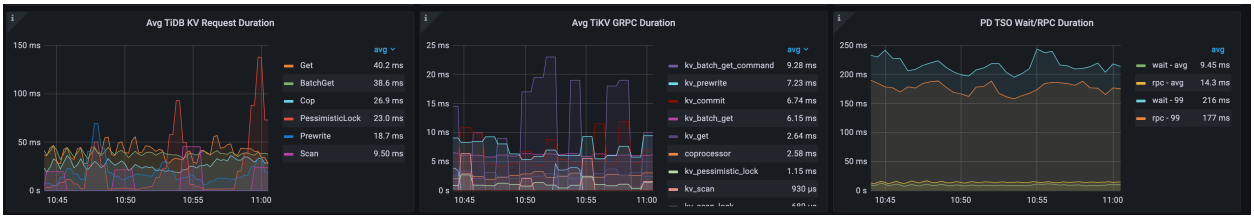

Figure 380: Cloud Env, TiDB Overloaded

In this example, the TiDB clusters are deployed in different data centers in the same region, and TiDB network and CPU resources are severely overloaded. The average `BatchGet` latency on TiDB is 38.6 ms, and the average `kv_batch_get` processing latency inside TiKV is 6.15 ms. The difference is more than 32 ms, which is much higher than the normal value. The average TSO wait latency is 9.45 ms and the RPC time is 14.3 ms.

Storage Async Write Duration, Store Duration, and Apply Duration

TiKV processes a write request in the following procedure:

- `scheduler worker` processes the write request, performs a transaction consistency check, and converts the write request into a key-value pair to be sent to the `raftstore` module.

- The TiKV consensus module `raftstore` applies the Raft consensus algorithm to make the storage layer (composed of multiple TiKVs) fault-tolerant.

  Raftstore consists of a `Store` thread and an `Apply` thread:

  - The `Store` thread processes Raft messages and new `proposals`. When a new `proposals` is received, the `Store` thread of the leader node writes to the local Raft DB and copies the message to multiple follower nodes. When this `proposals` is successfully persisted in most instances, the `proposals` is successfully committed.
  - The `Apply` thread writes the committed `proposals` to the KV DB. When the data is successfully written to the KV DB, the `Apply` thread notifies externally that the write request has completed.

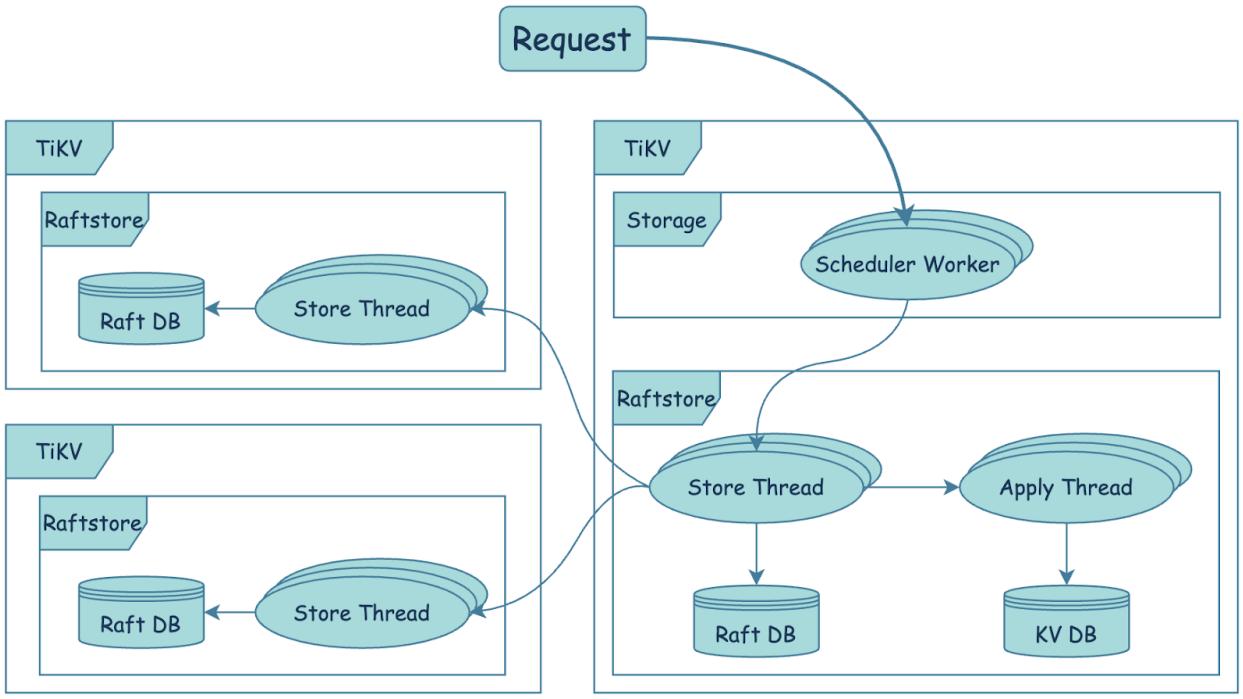

Figure 381: TiKV Write

The `Storage Async Write Duration` metric records the latency after a write request enters raftstore. The data is collected on a basis of per request.

The `Storage Async Write Duration` metric contains two parts, `Store Duration` and `Apply Duration`. You can use the following formula to determine whether the bottleneck for write requests is in the `Store` or `Apply` step.

```
avg Storage Async Write Duration = avg Store Duration + avg Apply Duration
```

> **Note:**
>
> `Store Duration` and `Apply Duration` are supported since v5.3.0.

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

According to the preceding formula, the QPS of a write-heavy OLTP workload in v5.4.0 is 14% higher than that in v5.3.0:

- v5.3.0: 24.4 ms ~= 17.7 ms + 6.59 ms
- v5.4.0: 21.4 ms ~= 14.0 ms + 7.33 ms

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Store Duration` compared with v5.3.0.

v5.3.0:

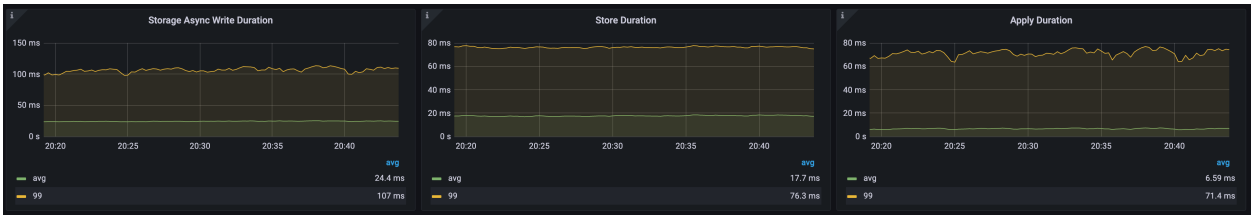

Figure 382: v5.3.0

v5.4.0:

Figure 383: v5.4.0

Example 2: Store Duration is a bottleneck

Apply the preceding formula: 10.1 ms ~= 9.81 ms + 0.304 ms. The result indicates that the latency bottleneck for write requests is in `Store Duration`.

Figure 384: Store

Commit Log Duration, Append Log Duration, and Apply Log Duration

`Commit Log Duration`, `Append Log Duration`, and `Apply Log Duration` are latency metrics for key operations within raftstore. These latencies are captured at the batch operation level, with each operation combining multiple write requests. Therefore, the latencies do not directly correspond to the `Store Duration` and `Apply Duration` mentioned above.

- `Commit Log Duration` and `Append Log Duration` record time of operations performed in the `Store` thread. `Commit Log Duration` includes the time of copying Raft logs to other TiKV nodes (to ensure raft-log persistence). `Commit Log Duration` usually contains two `Append Log Duration` operations, one for the leader and the other for the follower. `Commit Log Duration` is usually significantly higher than `Append Log Duration`, because the former includes the time of copying Raft logs to other TiKV nodes through network.
- `Apply Log Duration` records the latency of `apply` Raft logs by the `Apply` thread.

Common scenarios where `Commit Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.store-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high, resulting in high `Append Log Duration` latency
- The network latency between TiKV nodes is high
- The number of the gRPC threads are too small, CPU usage is uneven among the GRPC threads.

Common scenarios where `Apply Log Duration` is long:

- There is a bottleneck in TiKV CPU resources and the scheduling latency is high
- `raftstore.apply-pool-size` is either excessively small or large (an excessively large value might also cause performance degradation)
- The I/O latency is high

Example 1: Comparison of the same OLTP workload in v5.3.0 and v5.4.0

The QPS of a write-heavy OLTP workload in v5.4.0 is improved by 14% compared with that in v5.3.0. The following table compares the three key latencies.

Avg Duration	v5.3.0 (ms)	v5.4.0 (ms)
Append Log Duration	0.27	0.303
Commit Log Duration	13	8.68
Apply Log Duration	0.457	0.514

In v5.4.0, the gPRC module has been optimized to accelerate Raft log replication, which reduces `Commit Log Duration` and `Store Duration` compared with v5.3.0.

v5.3.0:

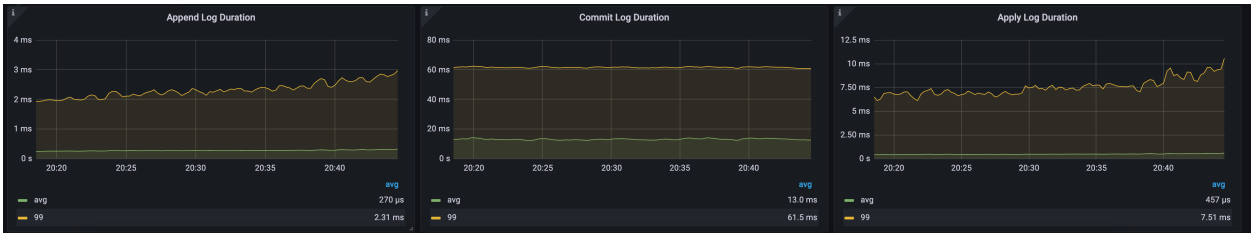

Figure 385: v5.3.0

v5.4.0:

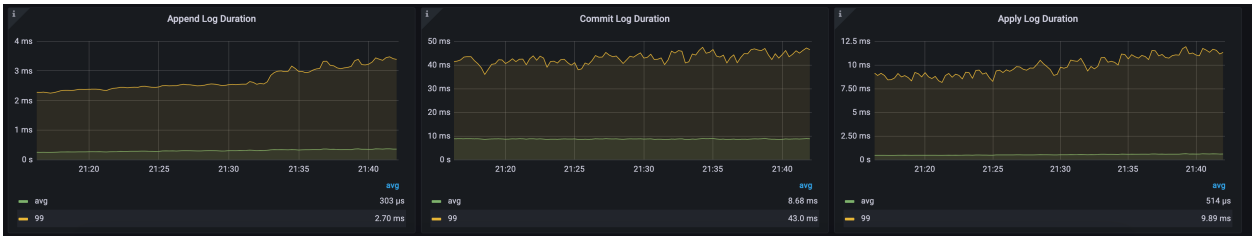

Figure 386: v5.4.0

Example 2: Commit Log Duration is a bottleneck

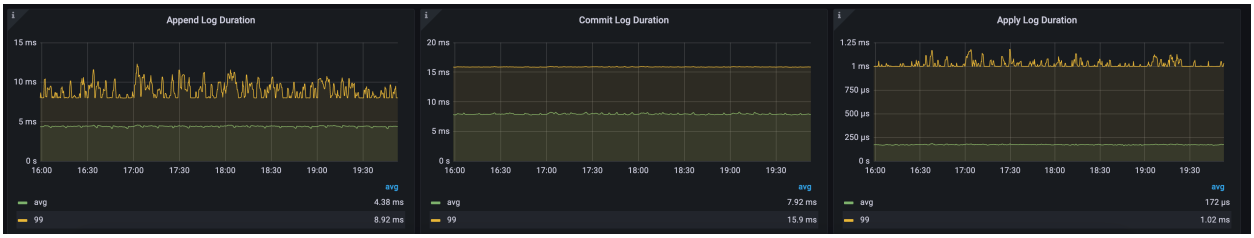

Figure 387: Store

- Average `Append Log Duration` = 4.38 ms
- Average `Commit Log Duration` = 7.92 ms
- Average `Apply Log Duration` = 172 us

For the `Store` thread, `Commit Log Duration` is obviously higher than `Apply Log Duration`. Meanwhile, `Append Log Duration` is significantly higher than `Apply Log Duration`, indicating that the `Store` thread might suffer from bottlenecks in both CPU and I/O. Possible ways to reduce `Commit Log Duration` and `Append Log Duration` are as follows:

- If TiKV CPU resources are sufficient, consider adding `Store` threads by increasing the value of `raftstore.store-pool-size`.
- If TiDB is v5.4.0 or later, consider enabling `Raft Engine` by setting `raft-engine.enable: true`. Raft Engine has a light execution path. This helps reduce I/O writes and long-tail latency of writes in some scenarios.
- If TiKV CPU resources are sufficient and TiDB is v5.3.0 or later, consider enabling `StoreWriter` by setting `raftstore.store-io-pool-size: 1`.

11.1.8.1.3 If my TiDB version is earlier than v6.1.0, what should I do to use the Performance Overview dashboard?

Starting from v6.1.0, Grafana has a built-in Performance Overview dashboard by default. This dashboard is compatible with TiDB v4.x and v5.x versions. If your TiDB is earlier than v6.1.0, you need to manually import `performance_overview.json`, as shown in the following figure:

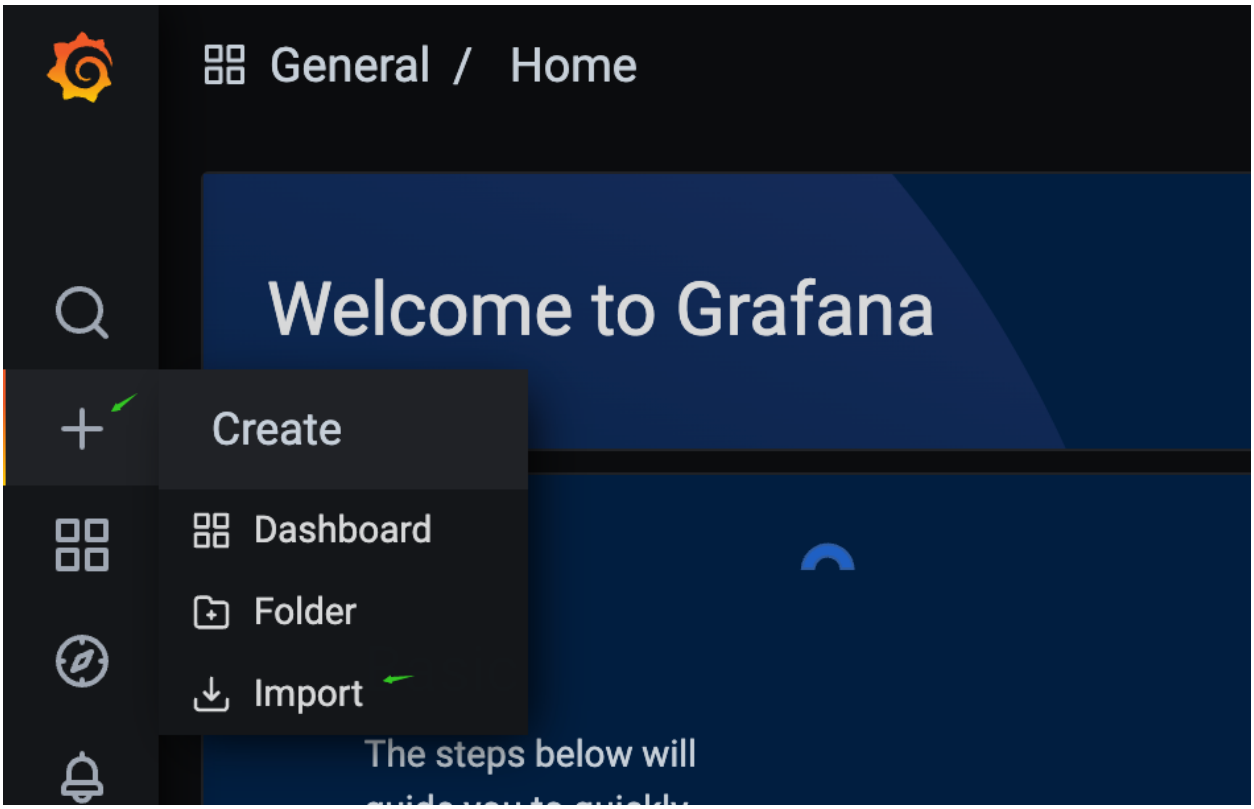

Figure 388: Store

11.1.8.2 Performance Tuning Practices for OLTP Scenarios

TiDB provides comprehensive performance diagnostics and analysis features, such as Top SQL and Continuous Profiling features on the TiDB Dashboard, and TiDB Performance Overview Dashboard.

This document describes how to use these features together to analyze and compare the performance of the same OLTP workload in seven different runtime scenarios, which demonstrates a performance tuning process to help you analyze and tune TiDB performance efficiently.

> **Note:**
>
> Top SQL and Continuous Profiling are not enabled by default. You need to enable them in advance.

By running the same application with different JDBC configurations in these scenarios, this document shows you how the overall system performance is affected by different

interactions between applications and databases, so that you can apply Best Practices for Developing Java Applications with TiDB for better performance.

11.1.8.2.1 Environment description

This document takes a core banking OLTP workload for demonstration. The configurations of the simulation environment are as follows:

- Application development language for the workload: JAVA
- SQL statements used in business: 200 statements in total, 90% of which are SELECT statements. It is a typical read-heavy OLTP workload.
- Tables used in transactions: 60 tables in total. 12 tables involve update operations, and the rest 48 tables are read-only.
- Isolation level used by the application: `read committed`.
- TiDB cluster configuration: 3 TiDB nodes and 3 TiKV nodes, with 16 CPUs allocated to each node.
- Client server configuration: 36 CPUs.

11.1.8.2.2 Scenario 1. Use the Query interface

Application configuration

The application uses the following JDBC configuration to connect to the database through the Query interface.

```
useServerPrepStmts=false
```

Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that the non-business SQL type `SELECT @@session.tx_isolation` consumes the most resources. Although TiDB processes these types of SQL statements quickly, these types of SQL statements have the highest number of executions that result in the highest overall CPU time consumption.

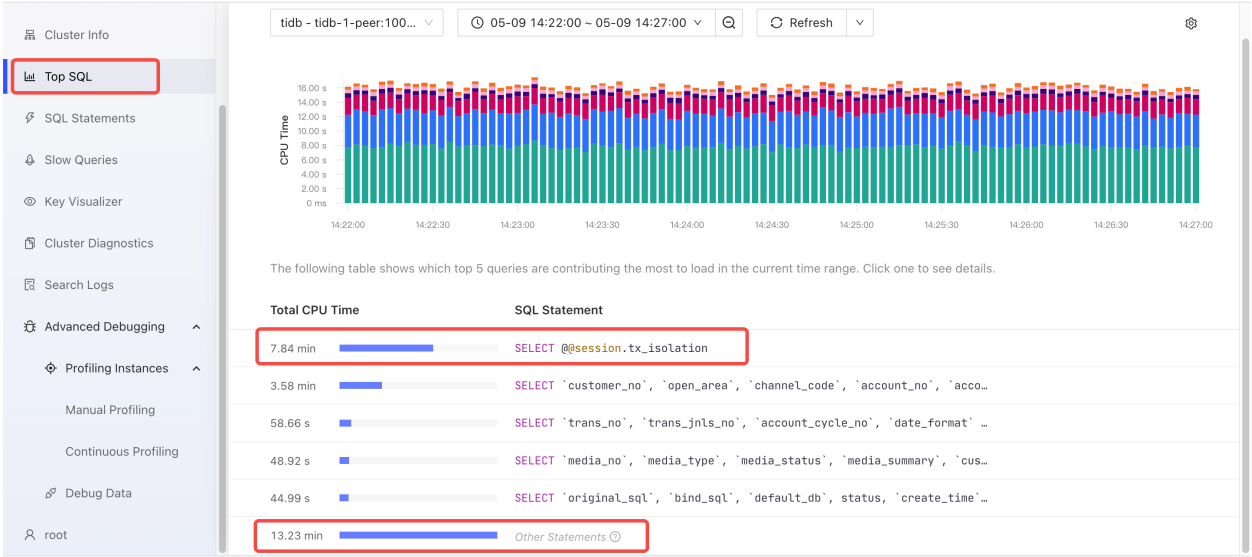

Figure 389: dashboard-for-query-interface

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is significant during the SQL execution. Because the application uses the Query interface, TiDB cannot use the execution plan cache. TiDB needs to compile and generate an execution plan for each SQL statement.

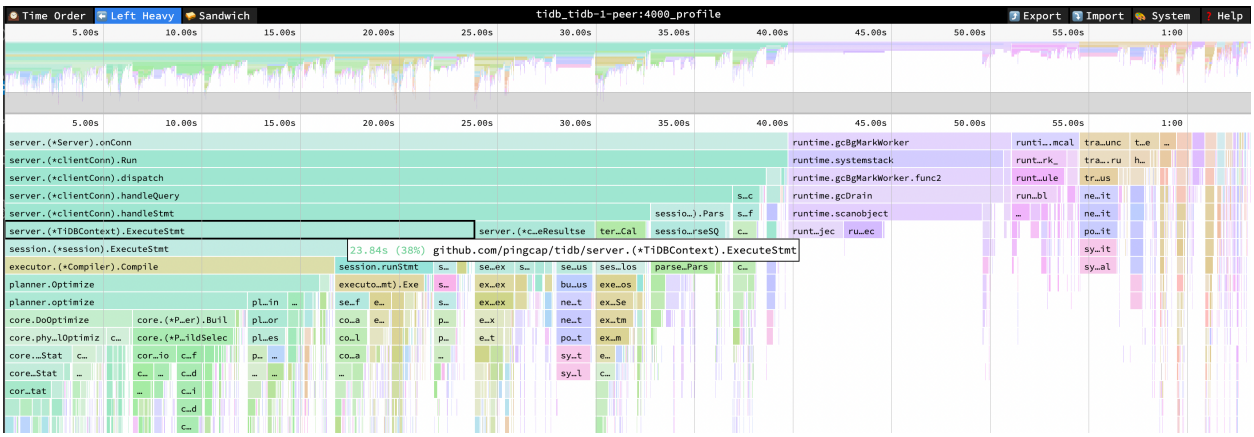

Figure 390: flame-graph-for-query-interface

- ExecuteStmt cpu = 38% cpu time = 23.84s
- Compile cpu = 27% cpu time = 17.17s
- Optimize cpu = 26% cpu time = 16.41s

Performance Overview dashboard

Check the database time overview and QPS in the following Performance Overview dashboard.

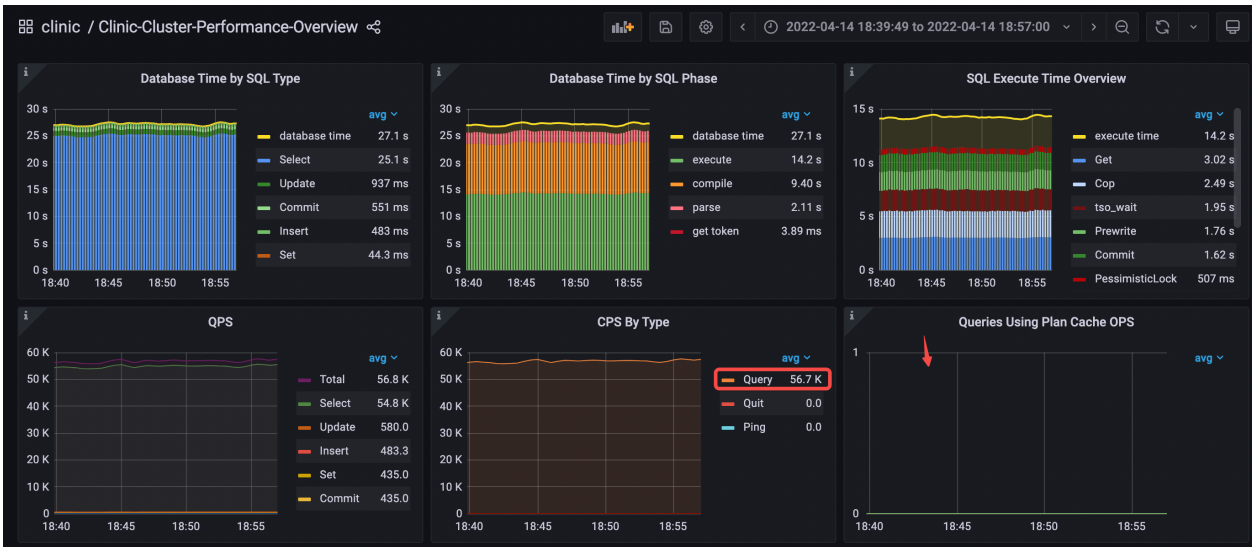

Figure 391: performance-overview-1-for-query-interface

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `tso wait` take most of the time.
- CPS By Type: only the `Query` command is used.
- Queries Using Plan Cache OPS: no data indicates that the execution plan cache is not hit.
- In the query duration, the latency of `execute` and `compile` takes the highest percentage.
- avg QPS = 56.8k

Check the resource consumption of the cluster: the average utilization of TiDB CPU is 925%, the average utilization of TiKV CPU is 201%, and the average throughput of TiKV IO is 18.7 MB/s. The resource consumption of TiDB is significantly higher.

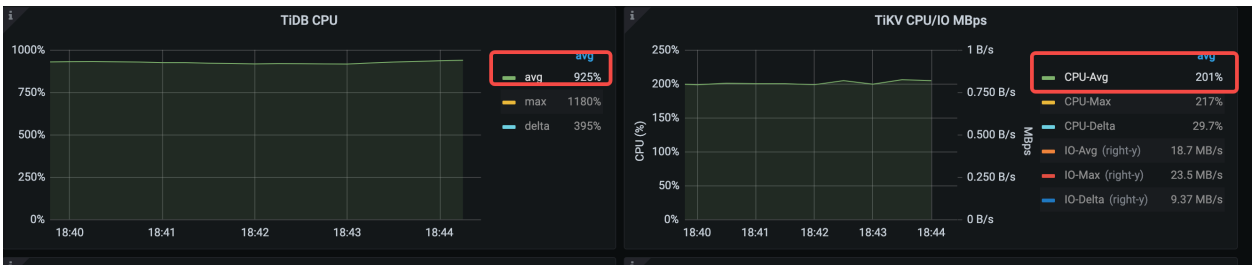

Figure 392: performance-overview-2-for-query-interface

Analysis conclusion

We need to eliminate these useless non-business SQL statements, which have a large number of executions and contribute to the high TiDB CPU usage.

11.1.8.2.3 Scenario 2. Use the maxPerformance configuration

Application configuration

The application adds a new parameter `useConfigs=maxPerformance` to the JDBC connection string in Scenario 1. This parameter can be used to eliminate the SQL statements sent from JDBC to the database (for example, `select @@session.transaction_read_only` ↪). The full configuration is as follows:

```
useServerPrepStmts=false&useConfigs=maxPerformance
```

Performance analysis

TiDB Dashboard

From the Top SQL page in the TiDB Dashboard below, you can see that `SELECT` ↪ `@@session.tx_isolation`, which consumed the most resources, has disappeared.

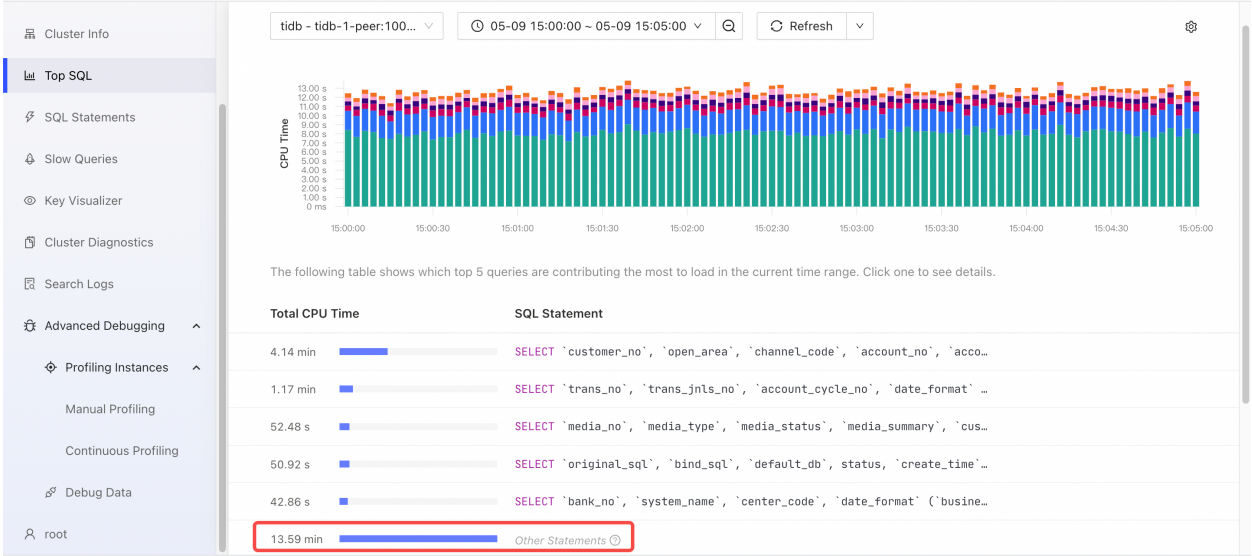

Figure 393: dashboard-for-maxPerformance

From the following flame chart of TiDB, you can see that the CPU consumption of functions such as `Compile` and `Optimize` is still significant during the SQL execution.

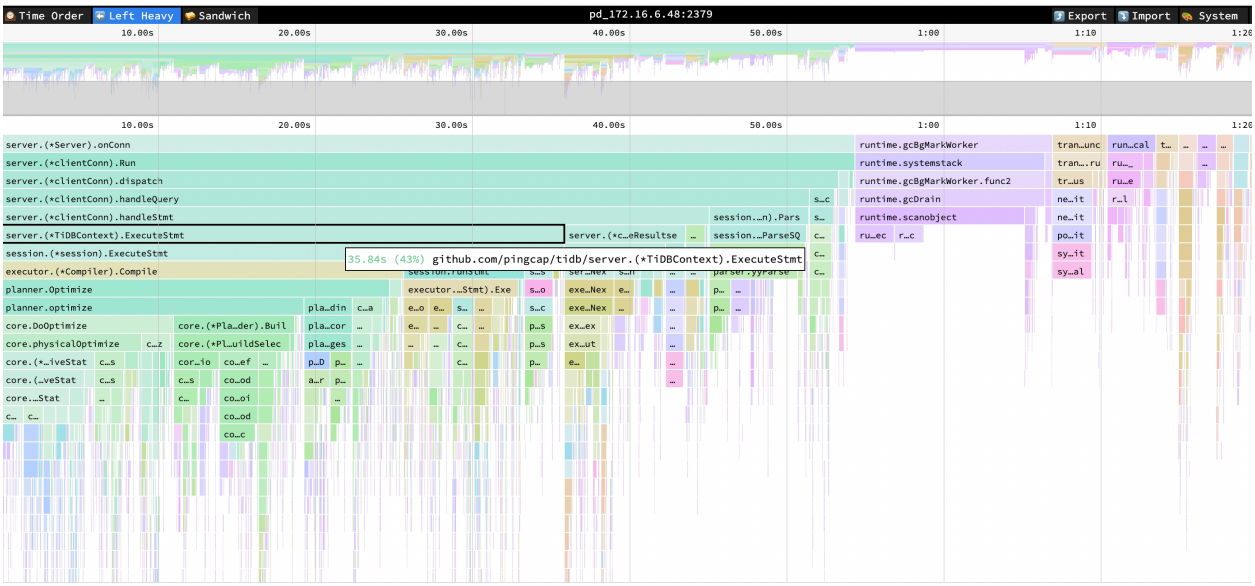

Figure 394: flame-graph-for-maxPerformance

- ExecuteStmt cpu = 43% cpu time =35.84s
- Compile cpu = 31% cpu time =25.61s
- Optimize cpu = 30% cpu time = 24.74s

Performance Overview dashboard

The data of the database time overview and QPS is as follows:

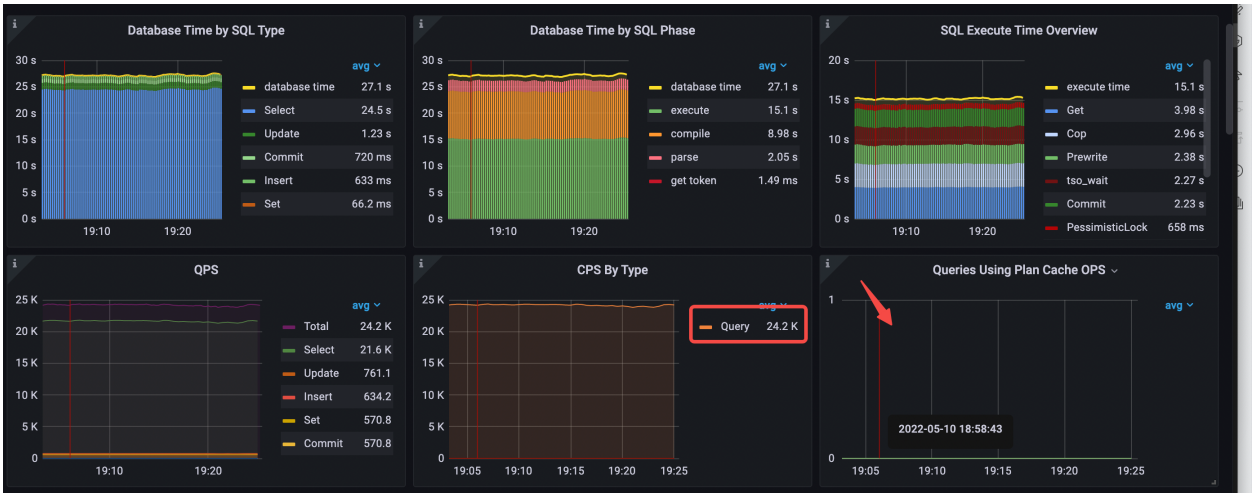

Figure 395: performance-overview-1-for-maxPerformance

- Database Time by SQL Type: the `Select` statement type takes most of the time.

- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- In the database time, the latency of `execute` and `compile` takes the highest percentage.
- CPS By Type: only the `Query` command is used.
- avg QPS = 24.2k (from 56.3k to 24.2k)
- The execution plan cache is not hit.

From Scenario 1 to Scenario 2, the average TiDB CPU utilization drops from 925% to 874%, and the average TiKV CPU utilization increases from 201% to about 250%.

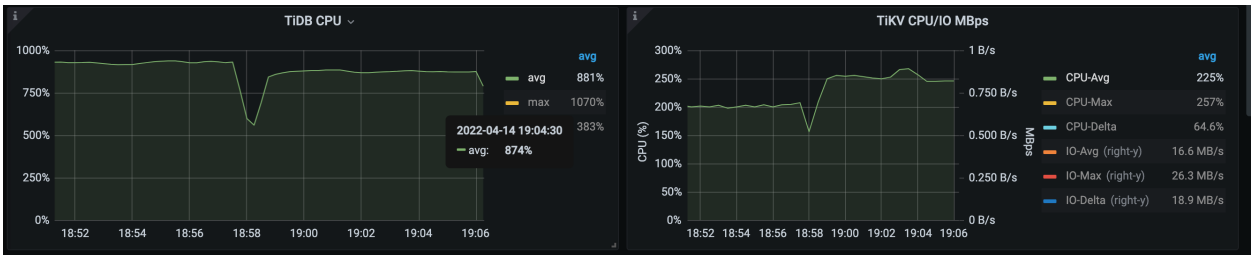

Figure 396: performance-overview-2-for-maxPerformance

The changes in key latency metrics are as follows:

Figure 397: performance-overview-3-for-maxPerformance

- avg query duration = 1.12ms (from 479 s to 1.12ms)
- avg parse duration = 84.7 s (from 37.2 s to 84.7 s)

- avg compile duration = 370 s (from 166 s to 370 s)
- avg execution duration = 626 s (from 251 s to 626 s)

Analysis conclusion

Compared with Scenario 1, the QPS of Scenario 2 has significantly decreased. The average query duration and average `parse`, `compile`, and `execute` durations have significantly increased. This is because SQL statements such as `select @@session.transaction_read_only` in Scenario 1, which are executed many times and have fast processing time, lower the average performance data. After Scenario 2 blocks such statements, only business-related SQL statements remain, so the average duration increases.

When the application uses the Query interface, TiDB cannot use the execution plan cache, which results in TiDB consuming high resources to compile execution plans. In this case, it is recommended that you use the Prepared Statement interface, which uses the execution plan cache of TiDB to reduce the TiDB CPU consumption caused by execution plan compiling and decrease the latency.

11.1.8.2.4 Scenario 3. Use the Prepared Statement interface with execution plan caching not enabled

Application configuration

The application uses the following connection configuration. Compared with Scenario 2, the value of the JDBC parameter `useServerPrepStmts` is modified to `true`, indicating that the Prepared Statement interface is enabled.

```
useServerPrepStmts=true&useConfigs=maxPerformance"
```

Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the CPU consumption of `CompileExecutePreparedStmt` and `Optimize` is still significant after the Prepared Statement interface is enabled.

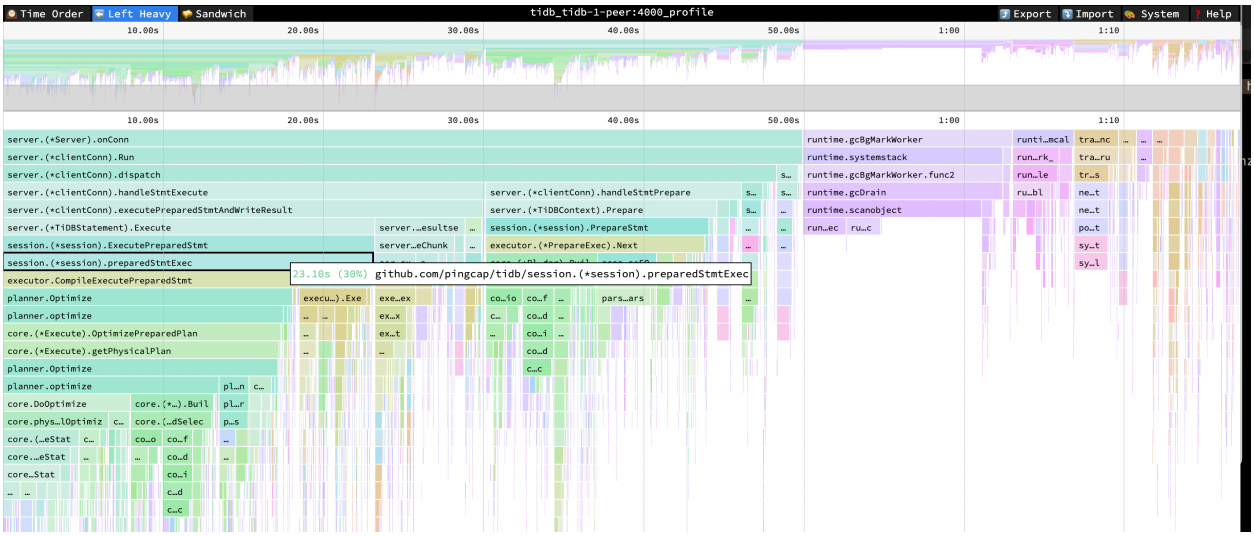

Figure 398: flame-graph-for-PrepStmts

- ExecutePreparedStmt cpu = 31% cpu time = 23.10s
- preparedStmtExec cpu = 30% cpu time = 22.92s
- CompileExecutePreparedStmt cpu = 24% cpu time = 17.83s
- Optimize cpu = 23% cpu time = 17.29s

Performance Overview dashboard

After the Prepared Statement interface is used, the data of database time overview and QPS is as follows:

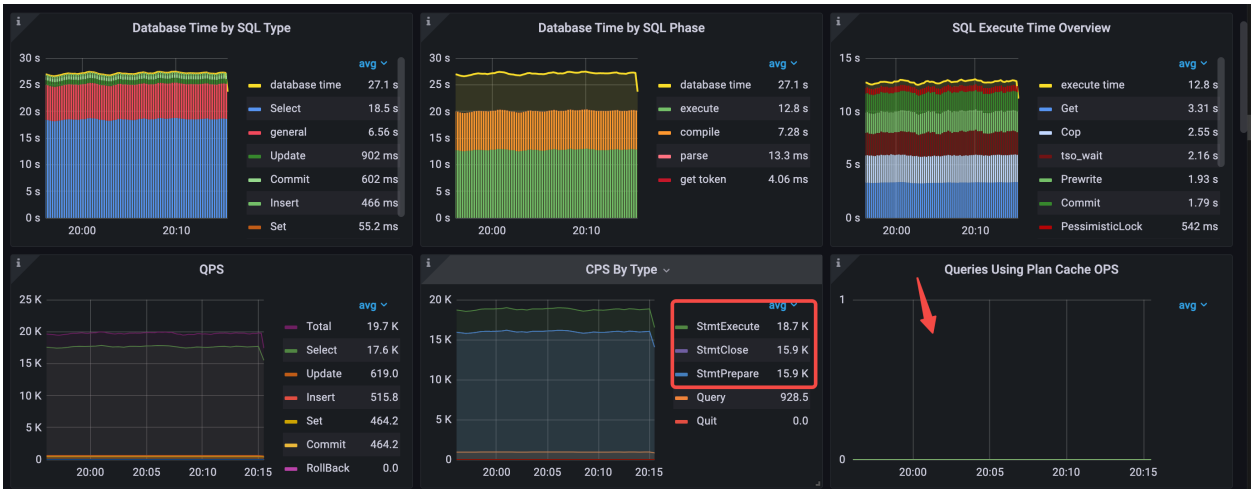

Figure 399: performance-overview-1-for-PrepStmts

The QPS drops from 24.4k to 19.7k. From the Database Time Overview, you can see that the application uses three types of Prepared commands, and the `general` statement

type (which includes the execution time of commands such as `StmtPrepare` and `StmtClose`) takes the second place in Database Time by SQL Type. This indicates that even when the Prepared Statement interface is used, the execution plan cache is not hit. The reason is that, when the `StmtClose` command is executed, TiDB clears the execution plan cache of SQL statements in the internal processing.

- Database Time by SQL Type: the `Select` statement type takes most of the time, followed by `general` statements.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, `Prewrite`, and `tso wait` take most of the time.
- CPS By Type: 3 types of commands (`StmtPrepare`, `StmtExecute`, `StmtClose`) are used.
- avg QPS = 19.7k (from 24.4k to 19.7k)
- The execution plan cache is not hit.

The TiDB average CPU utilization increases from 874% to 936%.

Figure 400: performance-overview-1-for-PrepStmts

The key latency metrics are as follows:

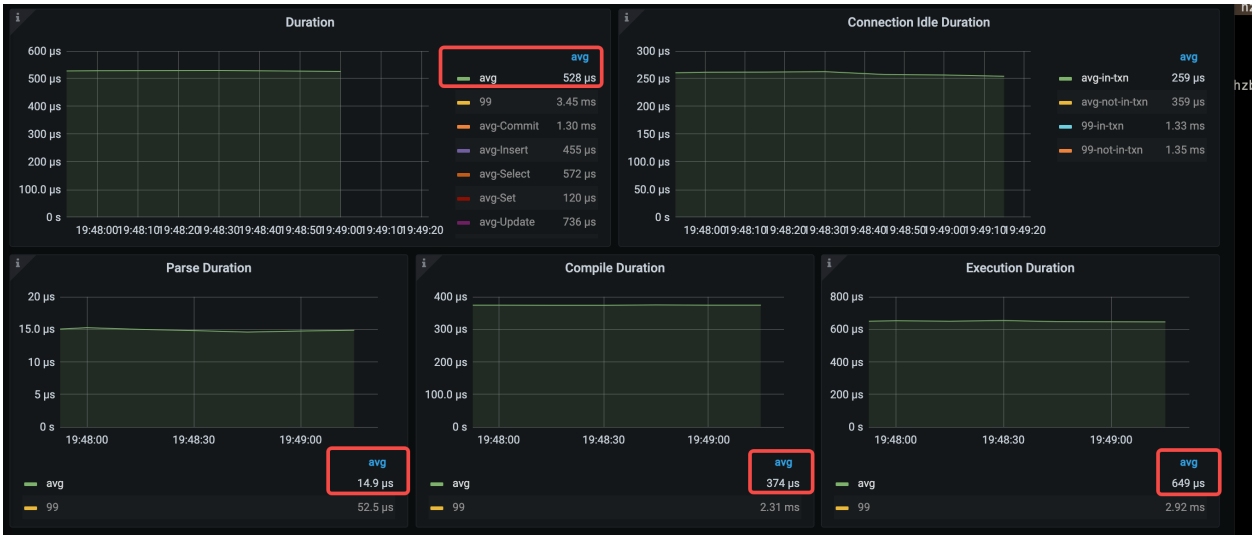

Figure 401: performance-overview-2-for-PrepStmts

- avg query duration = 528 s (from 1.12ms to 528 s)
- avg parse duration = 14.9 s (from 84.7 s to 14.9 s)
- avg compile duration = 374 s (from 370 s to 374 s)
- avg execution duration = 649 s (from 626 s to 649 s)

Analysis conclusion

Unlike Scenario 2, the application in Scenario 3 enables the Prepared Statement interface but still fails to hit the cache. In addition, Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). Compared with Scenario 2, Scenario 3 has two more network round-trip delays.

- Analysis for the decrease in QPS: From the **CPS By Type** pane, you can see that Scenario 2 has only one CPS By Type command type (`Query`), while Scenario 3 has three more command types (`StmtPrepare`, `StmtExecute`, `StmtClose`). `StmtPrepare` and `StmtClose` are non-conventional commands that are not counted by QPS, so QPS is reduced. The non-conventional commands `StmtPrepare` and `StmtClose` are counted in the `general` SQL type, so `general` time is displayed in the database overview of Scenario 3, and it accounts for more than a quarter of the database time.
- Analysis for the significant decrease in average query duration: for the `StmtPrepare` and `StmtClose` command types newly added in Scenario 3, their query duration is calculated separately in the TiDB internal processing. TiDB executes these two types of commands very quickly, so the average query duration is significantly reduced.

Although Scenario 3 uses the Prepared Statement interface, the execution plan cache is still not hit, because many application frameworks call the `StmtClose` method after

`StmtExecute` to prevent memory leaks. Starting from v6.0.0, you can set the global variable `tidb_ignore_prepared_cache_close_stmt=on;`. After that, TiDB will not clear the cached execution plans even if the application calls the `StmtClose` method, so the next SQL execution can reuse the existing execution plan and avoid compiling the execution plan repeatedly.

11.1.8.2.5 Scenario 4. Use the Prepared Statement interface and enable execution plan caching

Application configuration

The application configuration remains the same as that of Scenario 3. To resolve the issue of not hitting the cache even if the application triggers `StmtClose`, the following parameters are configured.

- Set the TiDB global variable `set global tidb_ignore_prepared_cache_close_stmt=on;` (introduced since TiDB v6.0.0, `off` by default).
- Set the TiDB configuration item `prepared-plan-cache: {enabled: true}` to enable the plan cache feature.

Performance analysis

TiDB Dashboard

From the flame chart of the TiDB CPU usage, you can see that `CompileExecutePreparedStmt` and `Optimize` have no significant CPU consumption. 25% of the CPU is consumed by the `Prepare` command, which contains parsing-related functions of Prepare such as `PlanBuilder` and `parseSQL`.

PreparseStmt cpu = 25% cpu time = 12.75s

Figure 402: flame-graph-for-3-commands

Performance Overview dashboard

In the Performance Overview dashboard, the most significant change is the average time of the `compile` phase, which is reduced from 8.95 seconds per second in Scenario 3 to 1.18 seconds per second. The number of queries using the execution plan cache is roughly equal to the value of `StmtExecute`. With the increase in QPS, the database time consumed by `Select` statements per second decreases, and the database time consumed by `general` statements per second type increases.

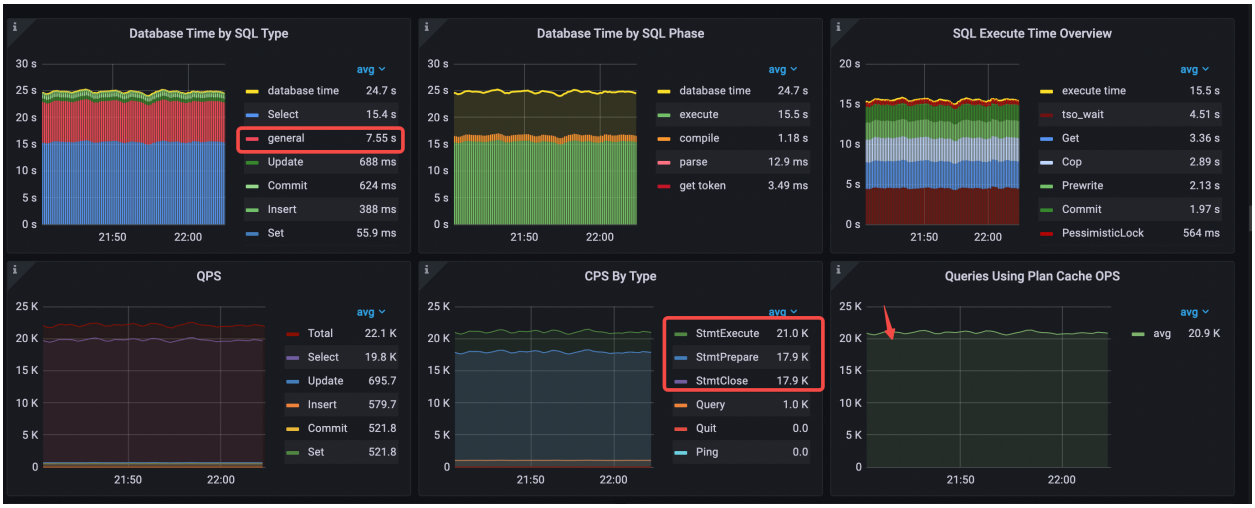

Figure 403: performance-overview-1-for-3-commands

- Database Time by SQL Type: the `Select` statement type takes the most time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: 3 types of commands (same as Scenario 3)
- Compared with scenario 3, the time consumed by `general` statements is longer because the QPS is increased.
- avg QPS = 22.1k (from 19.7k to 22.1k)

The average TiDB CPU utilization drops from 936% to 827%.

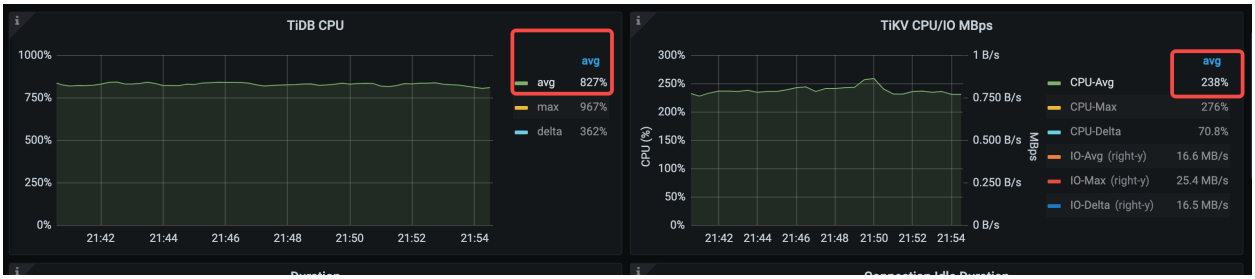

Figure 404: performance-overview-2-for-3-commands

The average `compile` time drops significantly, from 374 us to 53.3 us. Because the QPS increases, the average `execute` time increases too.

Figure 405: performance-overview-3-for-3-commands

- avg query duration = 426 s (from 528 s to 426 s)
- avg parse duration = 12.3 s (from 14.8 s to 12.3 s)
- avg compile duration = 53.3 s (from 374 s to 53.3 s)
- avg execution duration = 699 s (from 649 s to 699us)

Analysis conclusion

Compared with Scenario 3, Scenario 4 also uses 3 command types. The difference is that Scenario 4 hits the execution plan cache, which reduces compile duration greatly, reduces the query duration, and improves QPS.

Because the `StmtPrepare` and `StmtClose` commands consume significant database time and increase the number of interactions between the application and TiDB each time the application executes a SQL statement. The next scenario will further tune the performance by eliminating the calls of these two commands through JDBC configurations.

11.1.8.2.6 Scenario 5. Cache prepared objects on the client side

Application configuration

Compared with Scenario 4, 3 new JDBC parameters `cachePrepStmts=true&prepStmtCacheSize=1000&prepStmtCacheSqlLimit=20480` are configured, as explained below.

- `cachePrepStmts = true`: caches Prepared Statement objects on the client side, which eliminates the calls of StmtPrepare and StmtClose.
- `prepStmtCacheSize`: the value must be greater than 0.
- `prepStmtCacheSqlLimit`: the value must be greater than the length of the SQL text.

In Scenario 5, the complete JDBC configurations are as follows.

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

Performance analysis

TiDB Dashboard

From the following flame chart of TiDB, you can see that the high CPU consumption of the `Prepare` command is no longer present.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

Figure 406: flame-graph-for-1-command

Performance Overview dashboard

In the Performance Overview dashboard, the most notable changes are that the three Stmt command types in the **CPS By Type** pane drop to one type, the `general` statement

type in the **Database Time by SQL Type** pane is disappeared, and the QPS in the **QPS** pane increases to 30.9k.

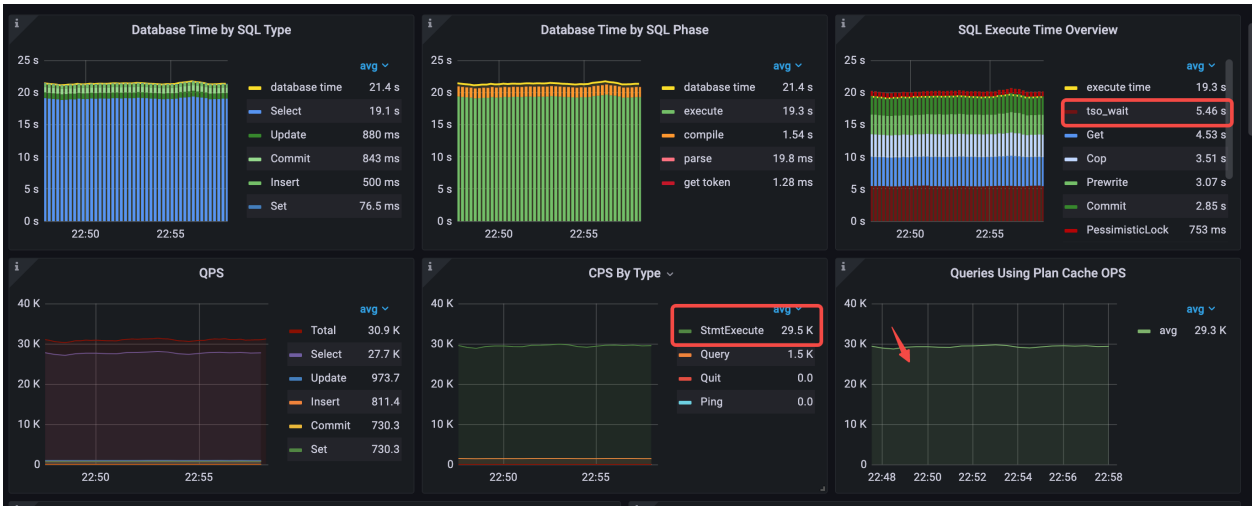

Figure 407: performance-overview-for-1-command

- Database Time by SQL Type: the `Select` statement type takes most of the time and the `general` statement type disappears.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `tso wait`, `Get`, and `Cop` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 30.9k (from 22.1k to 30.9k)

The average TiDB CPU utilization drops from 827% to 577%. As the QPS increases, the average TiKV CPU utilization increases to 313%.

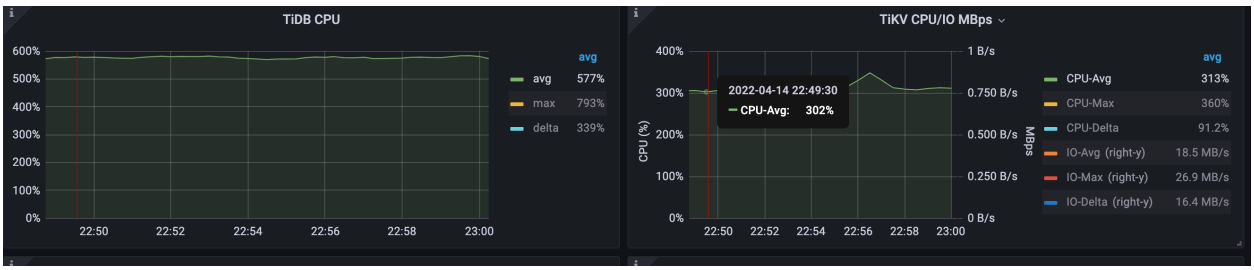

Figure 408: performance-overview-for-2-command

The key latency metrics are as follows:

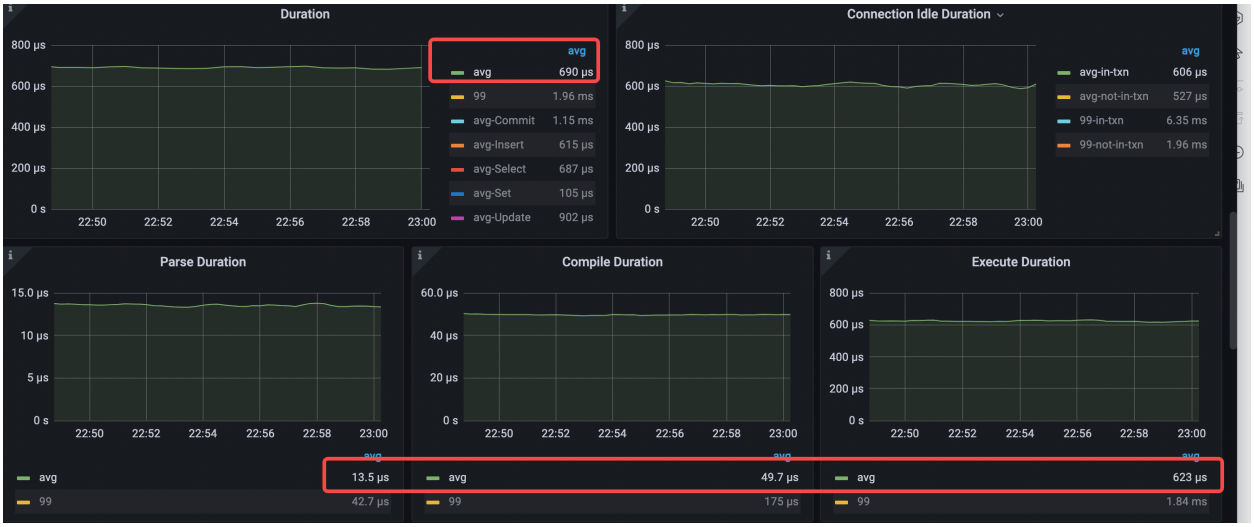

Figure 409: performance-overview-for-3-command

- avg query duration = 690 s (from 426 s to 690 s)
- avg parse duration = 13.5 s (from 12.3 s to 13.5 s)
- avg compile duration = 49.7 s (from 53.3 s to 49.7 s)
- avg execution duration = 623 s (from 699us to 623 s)
- avg pd tso wait duration = 196 s (from 224 s to 196 s)
- connection idle duration avg-in-txn = 608 s (from 250 s to 608 s)

Analysis conclusion

- Compared with Scenario 4, the **CPS By Type** pane in Scenario 5 has the `StmtExecute` command only, which avoids two network round trips and increases the overall system QPS.
- In the case of QPS increase, the latency decreases in terms of parse duration, compile duration, and execution duration, but the query duration increases instead. This is because TiDB processes `StmtPrepare` and `StmtClose` very quickly, and eliminating these two command types increases the average query duration.
- In Database Time by SQL Phase, `execute` takes the most time and is close to the database time. While in SQL Execute Time Overview, `tso wait` takes most of the time, and more than a quarter of `execute` time is taken to wait for TSO.
- The total `tso wait` time per second is 5.46s. The average `tso wait` time is 196 us, and the number of `tso cmd` times per second is 28k, which is very close to the QPS of 30.9k. This is because according to the implementation of the `read committed` isolation level in TiDB, every SQL statement in a transaction needs to request TSO from PD.

TiDB v6.0 provides `rc read`, which optimizes the `read committed` isolation level by reducing `tso cmd`. This feature is controlled by the global variable `set global tidb_rc_read_check_ts=on;`. When this variable is enabled, the default behavior of TiDB acts

the same as the `repeatable-read` isolation level, at which only `start-ts` and `commit-ts` need to be obtained from the PD. The statements in a transaction use the `start-ts` to read data from TiKV first. If the data read from TiKV is earlier than `start-ts`, the data is returned directly. If the data read from TiKV is later than `start-ts`, the data is discarded. TiDB requests TSO from PD, and then retries the read. The `for update ts` of subsequent statements uses the latest PD TSO.

11.1.8.2.7 Scenario 6: Enable the `tidb_rc_read_check_ts` variable to reduce TSO requests

Application configuration

Compared with Scenario 5, the application configuration remains the same. The only difference is that the `set global tidb_rc_read_check_ts=on;` variable is configured to reduce TSO requests.

Performance analysis

Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

- ExecutePreparedStmt cpu = 22% cpu time = 8.4s

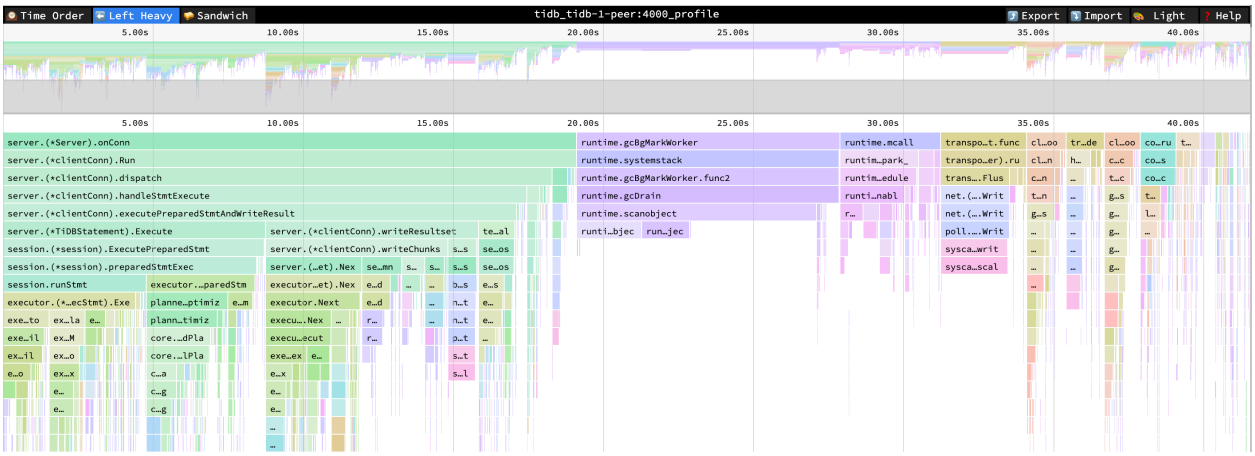

Figure 410: flame-graph-for-rc-read

Performance Overview dashboard

After using RC read, QPS increases from 30.9k to 34.9k, and the `tso wait` time consumed per second decreases from 5.46 s to 456 ms.

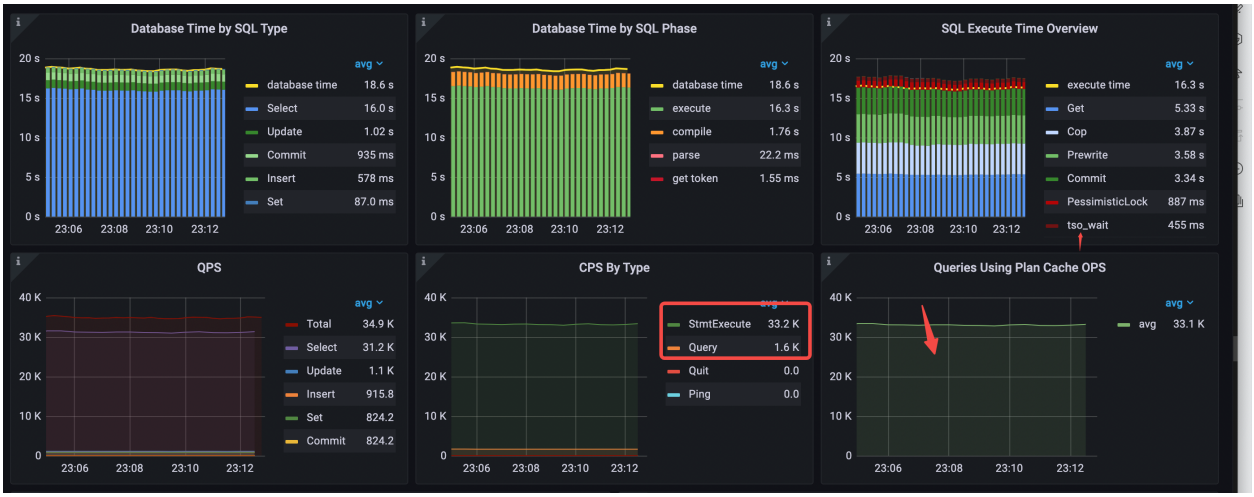

Figure 411: performance-overview-1-for-rc-read

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` phase takes most of the time.
- SQL Execute Time Overview: `Get`, `Cop`, and `Prewrite` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 34.9k (from 30.9k to 34.9k)

The `tso cmd` per second drops from 28.3k to 2.7k.

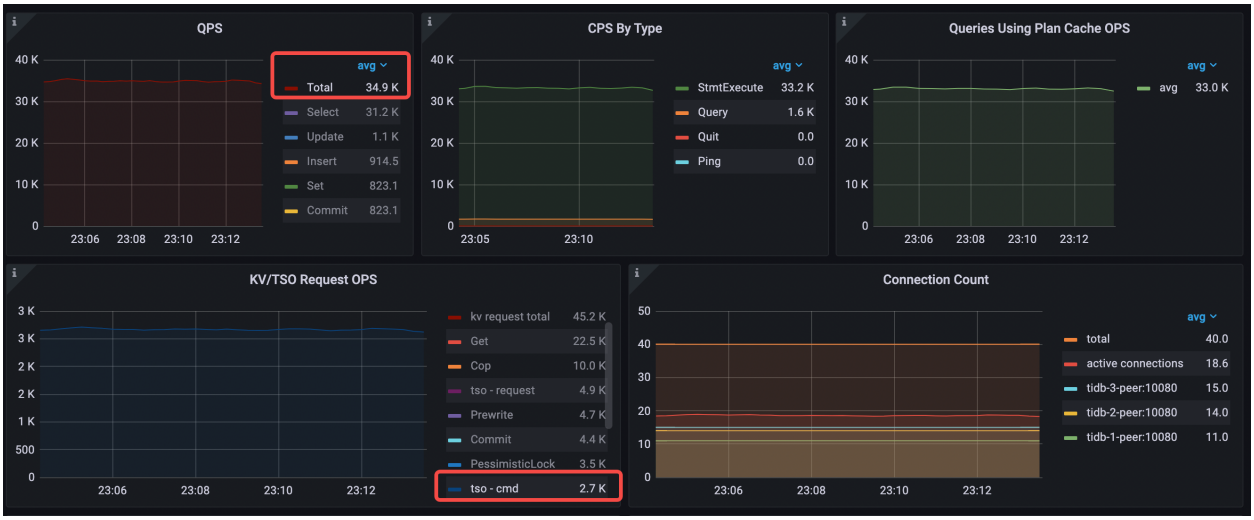

Figure 412: performance-overview-2-for-rc-read

The average TiDB CPU increases to 603% (from 577% to 603%).

Figure 413: performance-overview-3-for-rc-read

The key latency metrics are as follows:

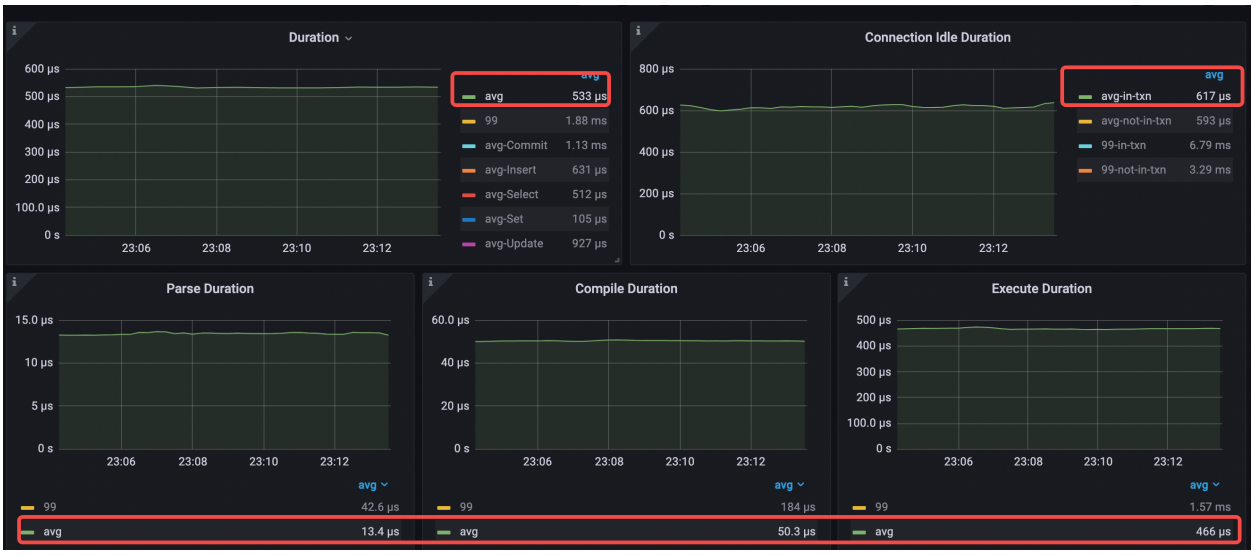

Figure 414: performance-overview-4-for-rc-read

- avg query duration = 533 s (from 690 s to 533 s)
- avg parse duration = 13.4 s (from 13.5 s to 13.4 s)
- avg compile duration = 50.3 s (from 49.7 s to 50.3 s)
- avg execution duration = 466 s (from 623 s to 466 s)
- avg pd tso wait duration = 171 s (from 196 s to 171 s)

Analysis conclusion

After enabling RC Read by `set global tidb_rc_read_check_ts=on;`, RC Read significantly reduces the times of `tso cmd`, thus reducing `tso wait` and average query duration, and improving QPS.

The bottlenecks of both current database time and latency are in the `execute` phase, in which the `Get` and `Cop` read requests take the highest percentage. Most of the tables in this

workload are read-only or rarely modified, so you can use the small table caching feature supported since TiDB v6.0.0 to cache the data of these small tables and reduce the waiting time and resource consumption of KV read requests.

11.1.8.2.8 Scenario 7: Use the small table cache

Application configuration

Compared with Scenario 6, the application configuration remains the same. The only difference is that Scenario 7 uses SQL statements such as `alter table t1 cache;` to cache those read-only tables for the business.

Performance analysis

TiDB Dashboard

The flame chart of the TiDB CPU does not have any significant changes.

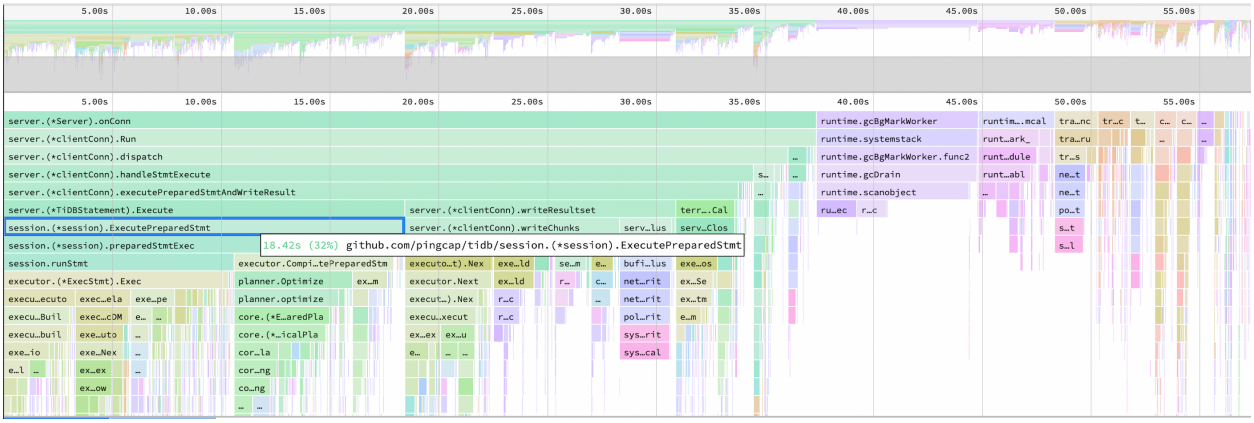

Figure 415: flame-graph-for-table-cache

Performance Overview dashboard

The QPS increases from 34.9k to 40.9k, and the KV request types take the most time in the `execute` phase change to `Prewrite` and `Commit`. The database time consumed by `Get` per second decreases from 5.33 seconds to 1.75 seconds, and the database time consumed by `Cop` per second decreases from 3.87 seconds to 1.09 seconds.

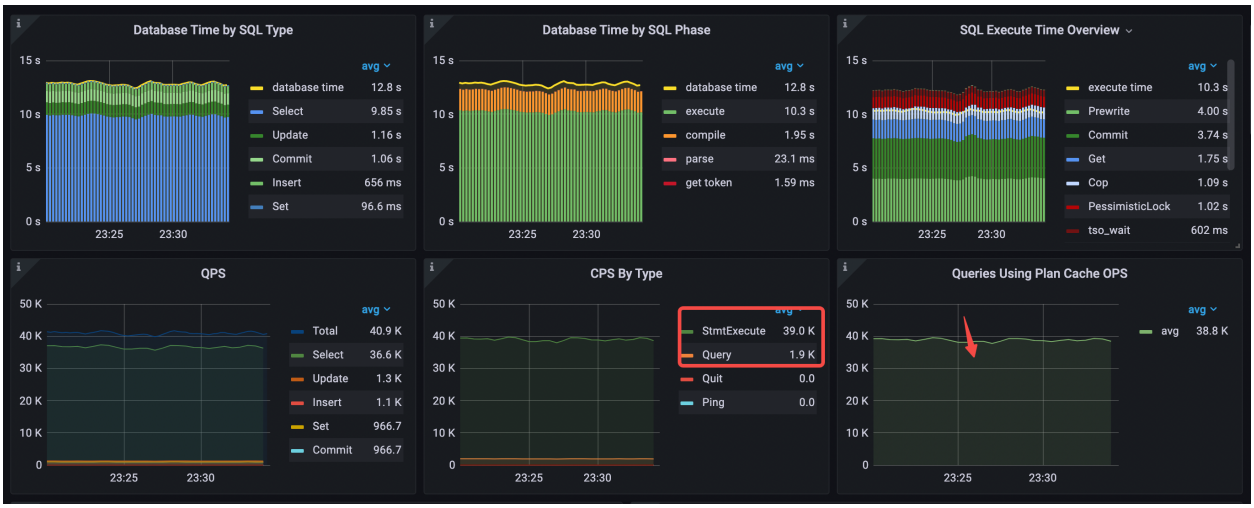

Figure 416: performance-overview-1-for-table-cache

- Database Time by SQL Type: the `Select` statement type takes most of the time.
- Database Time by SQL Phase: the `execute` and `compile` phases take most of the time.
- SQL Execute Time Overview: `Prewrite`, `Commit`, and `Get` take most of the time.
- Execution plan cache is hit. The value of Queries Using Plan Cache OPS roughly equals `StmtExecute` per second.
- CPS By Type: only the `StmtExecute` command is used.
- avg QPS = 40.9k (from 34.9k to 40.9k)

The average TiDB CPU utilization drops from 603% to 478% and the average TiKV CPU utilization drops from 346% to 256%.

Figure 417: performance-overview-2-for-table-cache

The average query latency drops from 533 us to 313 us. The average `execute` latency drops from 466 us to 250 us.

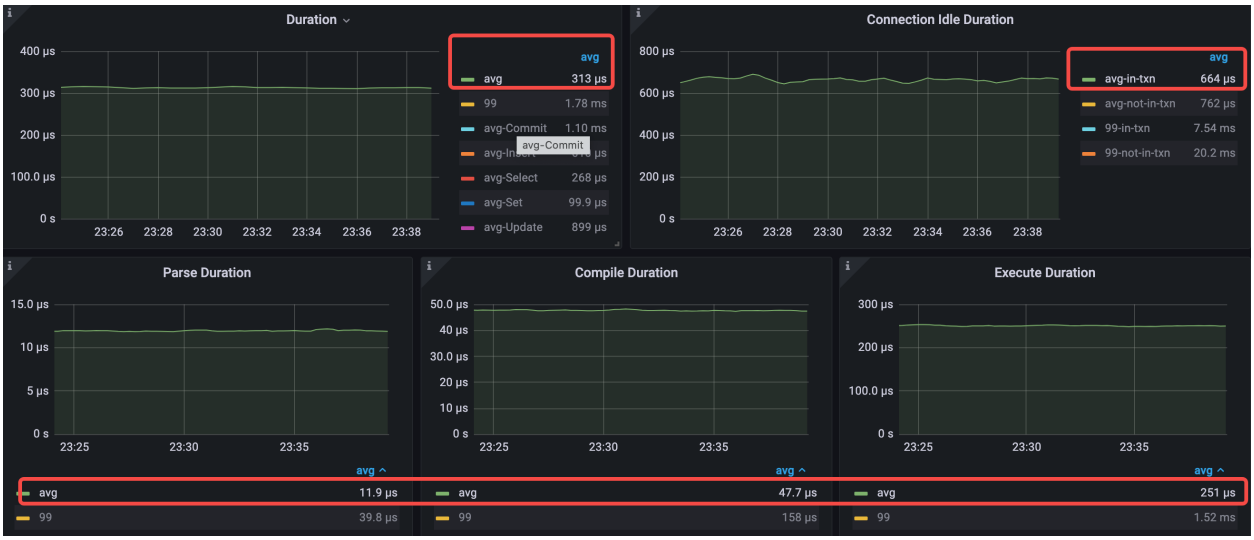

Figure 418: performance-overview-3-for-table-cache

- avg query duration = 313 s (from 533 s to 313 s)
- avg parse duration = 11.9 s (from 13.4 s to 11.9 s)
- avg compile duration = 47.7 s (from 50.3 s to 47.7 s)
- avg execution duration = 251 s (from 466 s to 251 s)

Analysis conclusion

After caching all read-only tables, the `Execute Duration` drops significantly because all read-only tables are cached in TiDB and there is no need to query data in TiKV for those tables, so the query duration drops and the QPS increases.

This is an optimistic result because data of read-only tables in actual business might be too large for TiDB to cache them all. Another limitation is that although the small table caching feature supports write operations, the write operation requires a default wait of 3 seconds to ensure that the cache of all TiDB nodes is invalidated first, which might not be feasible to applications with strict latency requirements.

11.1.8.2.9 Summary

The following table lists the performance of seven different scenarios.

Metrics	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5	Scenario 6	Scenario 7	Comparing Scenario 5 with Scenario 2 (%)	Comparing Scenario 7 with Scenario 3 (%)
query duration	479 s	1120 s	528 s	426 s	690 s	533 s	313 s	-38%	-41%
QPS	56.3k	24.2k	19.7k	22.1k	30.9k	34.9k	40.9k	+28%	+108%

In these scenarios, Scenario 2 is a common scenario where applications use the Query interface, and Scenario 5 is an ideal scenario where applications use the Prepared Statement interface.

- Comparing Scenario 5 with Scenario 2, you can see that by using best practices for Java application development and caching Prepared Statement objects on the client side, each SQL statement requires only one command and database interaction to hit the execution plan cache, which results in a 38% drop in query latency and a 28% increase in QPS, while the average TiDB CPU utilization drops from 936% to 577%.
- Comparing Scenario 7 with Scenario 3, you can see that with the latest TiDB optimization features such as RC Read and small table cache on top of Scenario 5, latency is reduced by 41% and QPS is increased by 108%, while the average TiDB CPU utilization drops from 936% to 478%.

By comparing the performance of each scenario, we can draw the following conclusions:

- The execution plan cache of TiDB plays a critical role in the OLTP performance tuning. The RC Read and small table cache features introduced from v6.0.0 also play an important role in the further performance tuning of this workload.
- TiDB is compatible with different commands of the MySQL protocol. When using the Prepared Statement interface and setting the following JDBC connection parameters, the application can achieve its best performance:

```
useServerPrepStmts=true&cachePrepStmts=true&prepStmtCacheSize=1000&
    ↪ prepStmtCacheSqlLimit=20480&useConfigs=maxPerformance
```

- It is recommended that you use TiDB Dashboard (for example, the Top SQL feature and Continuous Profiling feature) and Performance Overview dashboard for performance analysis and tuning.

- With the Top SQL feature, you can visually monitor and explore the CPU consumption of each SQL statement in your database during execution to troubleshoot database performance issues.
- With Continuous Profiling, you can continuously collect performance data from each instance of TiDB, TiKV, and PD. When applications use different interfaces to interact with TiDB, the difference in the CPU consumption of TiDB is huge.
- With Performance Overview Dashboard, you can get an overview of database time and SQL execution time breakdown information. You can analyze and diagnose performance based on database time to determine whether the performance bottleneck of the entire system is in TiDB or not. If the bottleneck is in TiDB, you can use the database time and latency breakdowns, along with load profile and resource usage, to identify performance bottlenecks within TiDB and tune the performance accordingly.

With a combination usage of these features, you can analyze and tune performance for real-world applications efficiently.

11.1.8.3 TiFlash Performance Analysis and Tuning Methods

This document introduces TiFlash resource utilization and key performance metrics. You can monitor and evaluate the TiFlash cluster performance through the TiFlash panel on the Performance Overview dashboard.

11.1.8.3.1 Resource utilization of a TiFlash cluster

With the following three metrics, you can quickly get the resource utilization of a TiFlash cluster:

- CPU: the CPU utilization per TiFlash instance.
- Memory: the memory usage per TiFlash instance.
- IO utilization: the IO utilization per TiFlash instance.

Example: Resource utilization during CH-benCHmark workload

This TiFlash cluster consists of two nodes, each node configured with 16 cores and 48 GB of memory. During the CH-benCHmark workload, CPU utilization can reach up to 1500%, memory usage can reach up to 20 GB, and IO utilization can reach up to 91%. These metrics indicate that TiFlash node resources are approaching saturation.

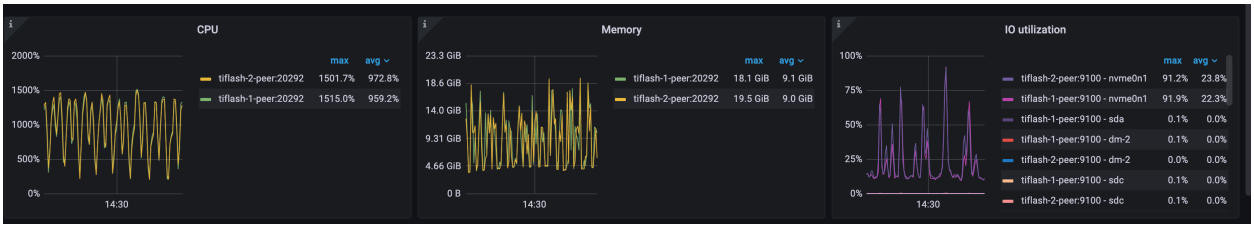

Figure 419: CH-TiFlash-MPP

11.1.8.3.2 Key metrics for TiFlash performance

Throughput metrics

With the following metrics, you can get the throughput of TiFlash:

- MPP Query count: the instant value of MPP query count for each TiFlash instance, reflecting the current number of MPP queries that need to be processed by the TiFlash instance (including those being processed and those awaiting scheduling).
- Request QPS: the number of coprocessor requests received by all TiFlash instances.
  - `run_mpp_task`, `dispatch_mpp_task`, and `mpp_establish_conn` are MPP requests.
  - `batch`: the number of batch requests.
  - `cop`: the number of coprocessor requests that are sent directly via the coprocessor interface.
  - `cop_execution`: the number of coprocessor requests currently being executed.
  - `remote_read`, `remote_read_constructed`, and `remote_read_sent` are remote read-related metrics. An increase in remote reads usually indicates an issue in the system.
- Executor QPS: the number of each type of dag operators in the requests received by all TiFlash instances, where `table_scan` is the table scan operator, `selection` is the selection operator, `aggregation` is the aggregation operator, `top_n` is the TopN operator, `limit` is the limit operator, `join` is a join operator, `exchange_sender` is a data sending operator, and `exchange_receiver` is a data receiving operator.

Latency metrics

With the following metrics, you can get the latency of TiFlash:

- Request Duration Overview: provides a stacked chart of the total processing duration for all request types in all TiFlash instances per second.
  - If the type of a request is `run_mpp_task`, `dispatch_mpp_task`, or `mpp_establish` ↪ `_conn`, it indicates that the SQL statement execution has been partially or fully pushed down to TiFlash, typically involving join and data distribution operations. This is the most common request type in TiFlash.

  - If the type of a request is `cop`, it indicates that the statement related to this request has not been fully pushed down to TiFlash. Typically, TiDB pushes down the table full scan operator to TiFlash for data access and filtering. If `cop` becomes the most common request type in the stacked chart, you need to check if it is reasonable.
    - If the amount of data queried by a SQL statement is large, the optimizer might estimate that TiFlash full table scans are more cost-effective according to the cost model.
    - If the schema of a queried table lacks suitable indexes, the optimizer can only push the query down to TiFlash for a full table scan, even if the amount of data to be queried is small. In this case, it is more efficient to create proper indexes and access the data through TiKV.

- Request Duration: the total processing duration for each MPP and coprocessor request type in all TiFlash instances, which includes the average latency and p99 latency.

- Request Handle Duration: the time from the start of executing the `cop` and `batch cop` ↪ requests to the completion of the execution, excluding waiting time. This metric is only applicable to the `cop` and `batch cop` types of requests, including average and P99 latency.

Example 1: Processing duration overview of TiFlash MPP requests

In the workload of the following diagram, `run_mpp_task` and `mpp_establish_conn` requests constitute the majority of the total processing duration, indicating that most of the requests are MPP tasks that are fully pushed down to TiFlash for execution.

The processing duration of `cop` requests is relatively small, indicating that some of the requests are pushed down to TiFlash for data access and filtering through the coprocessor.

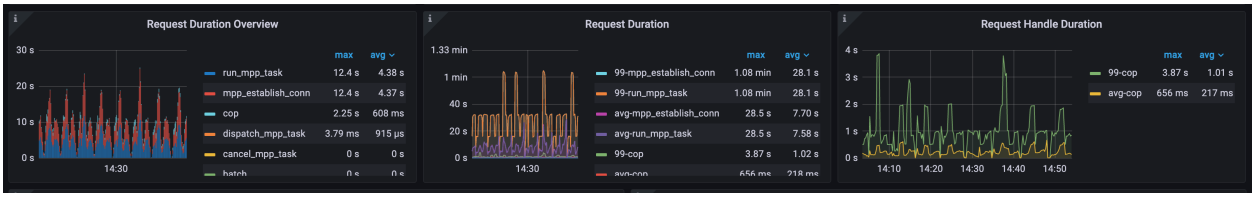

Figure 420: CH-TiFlash-MPP

Example 2: TiFlash `cop` requests constitute the majority of the total processing duration

In the workload of the following diagram, `cop` requests constitute the majority of the total processing duration. In this case, you can check the SQL execution plan to see why these `cop` requests are generated.

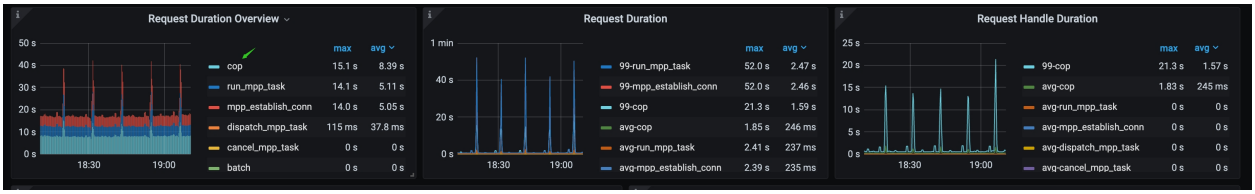

Figure 421: Cop

Raft-related metrics

With the following metrics, you can get the Raft replication status of TiFlash:

- Raft Wait Index Duration: the duration of waiting until the local Region index >= `read_index` for all TiFlash instances, which represents the latency of the `wait_index` operation. If this metric is too high, it indicates that data replication from TiKV to TiFlash has a significant latency. Possible reasons include the following:
    - TiKV resource is overloaded.
    - TiFlash resource is overloaded, especially IO resources.
    - There is a network bottleneck between TiKV and TiFlash.
- Raft Batch Read Index Duration: the latency of `read_index` for all TiFlash instances. If this metric is too high, it indicates that the interaction between TiFlash and TiKV is slow. Possible reasons include the following:
    - TiFlash resource is overloaded.
    - TiKV resource is overloaded.
    - There is a network bottleneck between TiFlash and TiKV.

IO throughput metrics

With the following metrics, you can get the IO throughput of TiFlash:

- Write Throughput By Instance: the throughput of data written by each TiFlash instance. It includes the throughput by applying the Raft data logs and Raft snapshots.
- Write flow: the traffic of disk writes by all TiFlash instances.
    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.
    - Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.
- Read flow: traffic of disk read operations for all TiFlash instances.
    - File Descriptor: the stable layer of the DeltaTree storage engine used by TiFlash.

- Page: refers to Pagestore, the Delta change layer of the DeltaTree storage engine used by TiFlash.

You can calculate the write amplification factor of the entire TiFlash cluster using the `(Read flow + Write flow)÷ total Write Throughput By Instance` formula.

Example 1: Raft and IO metrics of the CH-benCHmark workload in a self-hosted environment

As shown in the following diagram, the `Raft Wait Index Duration` and the 99th percentile of `Raft Batch Read Index Duration` for this TiFlash cluster are relatively high, at 3.24 seconds and 753 milliseconds respectively. This is because the TiFlash workload in this cluster is high and latency occurs in data replication.

In this cluster, there are two TiFlash nodes. The incremental data replication speed from TiKV to TiFlash is approximately 28 MB per second. The maximum write throughput of the stable layer (File Descriptor) is 939 MB/s, and the maximum read throughput is 1.1 GiB/s. Meanwhile, the maximum write throughput of the Delta layer (Page) is 74 MB/s, and the maximum read throughput is 111 MB/s. In this environment, TiFlash uses dedicated NVME disks, which have strong IO throughput capabilities.

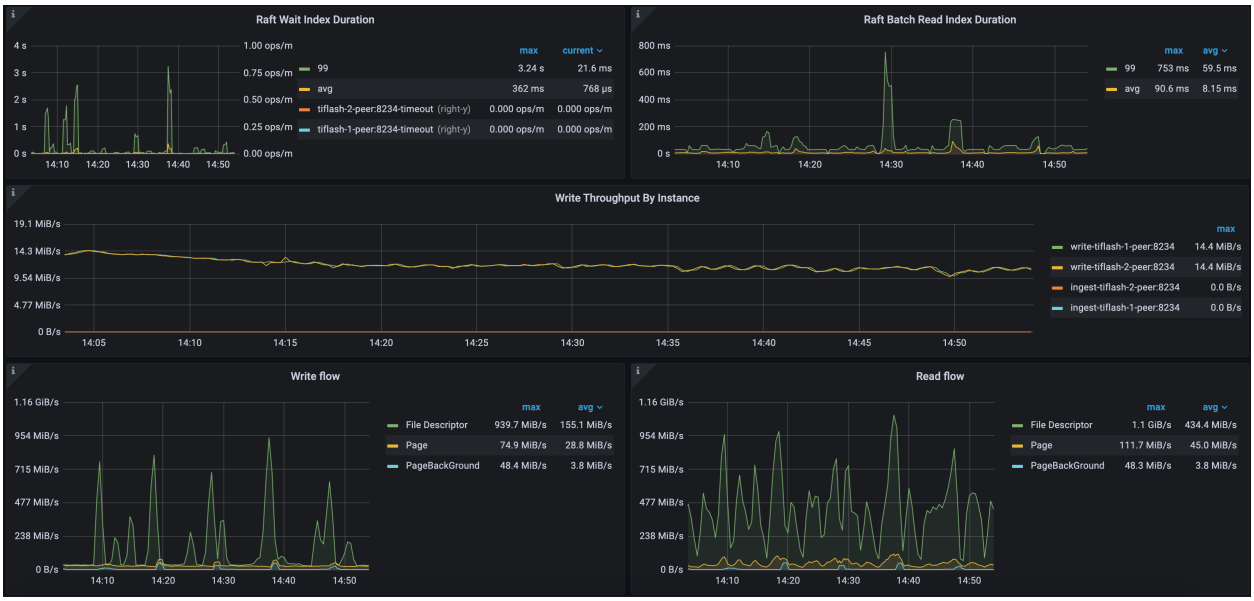

Figure 422: CH-2TiFlash-OP

Example 2: Raft and IO metrics of the CH-benCHmark workload in a public cloud deployment environment

As shown in the following diagram, the 99th percentile of `Raft Wait Index Duration` is up to 438 milliseconds, and 99th percentile of the `Raft Batch Read Index Duration` is up to 125 milliseconds. This cluster has only one TiFlash node. TiKV replicates about 5 MB

of incremental data to TiFlash per second. The maximum write traffic of the stable layer (File Descriptor) is 78 MB/s and the maximum read traffic is 221 MB/s. In the meantime, the maximum write traffic of the Delta layer (Page) is 8 MB/s and the maximum read traffic is 18 MB/s. In this environment, TiFlash uses an AWS EBS cloud disk, which has relatively weak IO throughput.

Figure 423: CH-TiFlash-MPP

11.1.8.4 TiCDC Performance Analysis and Tuning Methods

This document introduces TiCDC resource utilization and key performance metrics. You can monitor and evaluate TiCDC performance on data replication through the CDC panel on the Performance Overview dashboard.

11.1.8.4.1 Resource utilization of a TiCDC cluster

With the following three metrics, you can quickly get the resource utilization of a TiCDC cluster:

- CPU usage: the CPU usage per TiCDC node.
- Memory usage: the memory usage per TiCDC node.
- Goroutine count: the number of goroutines per TiCDC node.

11.1.8.4.2 Key metrics for TiCDC data replication

TiCDC overall metrics

With the following metrics, you can get an overview of TiCDC data replication:

- Changefeed checkpoint lag: the progress lag of data replication between the upstream and the downstream, measured in seconds.

  If the speed at which TiCDC consumes data and writes downstream keeps up with upstream data changes, this metric remains within a small latency range, typically within 10 seconds. Otherwise, this metric will continue to increase.

  When this metric (that is, `Changefeed checkpoint lag`) increases, common reasons are as follows:

  - Insufficient system resources: if the CPU, memory, or disk space of TiCDC is insufficient, it might cause data processing to be too slow, which results in a long checkpoint of the TiCDC changefeed.
  - Network issues: if network interruptions, lags, or insufficient bandwidth occur in TiCDC, it might affect data transfer speed, which results in a long checkpoint of the TiCDC changefeed.
  - High QPS in the upstream: if the data to be processed by TiCDC is excessively large, it might cause data processing timeouts, which results in an increased checkpoint of the TiCDC changefeed. Typically, a single TiCDC node can handle a maximum QPS of around 60K.
  - Database issues:
    - The gap between the `min resolved ts` of the upstream TiKV cluster and the latest PD TSO is significant. This issue usually occurs because TiKV fails to advance the resolved ts in time when the write workload of the upstream is excessively heavy.
    - The write latency in downstream databases is high, blocking TiCDC from replicating data to the downstream timely.

- Changefeed resolved ts lag: the progress lag between the internal replication status of a TiCDC node and the upstream, measured in seconds. If this metric is high, it indicates that the data processing capability of the TiCDC Puller or Sorter module might be insufficient, or there might be network latency or slow disk read/write speed issues. In such cases, to ensure the efficient and stable operation of TiCDC, you need to take appropriate measures, such as increasing the number of TiCDC nodes or optimizing the network configuration.

- The status of changefeeds: for status explanations of changefeeds, see Changefeed state transfer.

Example 1: High checkpoint lag due to high upstream QPS in the case of a single TiCDC node

As shown in the following diagram, because the upstream QPS is excessively high and there is only a single TiCDC node in the cluster, the TiCDC node is overloaded, the CPU usage is high, and both `Changefeed checkpoint lag` and `Changefeed resolved ts lag` keep increasing. The changefeed status intermittently transitions from `0` to `1`, indicating that the changefeed keeps getting errors. You can try resolving this issue by adding more resources as follows:

- Add more TiCDC nodes: scale out the TiCDC cluster to multiple nodes to increase processing capacity.
- Optimize TiCDC node resources: increase CPU and memory configurations of the TiCDC node to improve performance.

Figure 424: TiCDC overview

Data flow throughput metrics and downstream latency

With the following metrics, you can learn the data flow throughput and downstream latency of TiCDC:

- Puller output events/s: the number of rows that the Puller module of TiCDC nodes sends to the Sorter module per second.
- Sorter output events/s: the number of rows that the Sorter module of TiCDC nodes sends to the Mounter module per second.
- Mounter output events/s: the number of rows that the Mounter module of TiCDC nodes sends to the Sink module per second.
- Table sink output events/s: the number of rows that the Table Sorter module of the TiCDC nodes sends to the Sink module per second.
- SinkV2 - Sink flush rows/s: the number of rows that the Sink module in the TiCDC node sends to the downstream per second.
- Transaction Sink Full Flush Duration: the average latency and p999 latency of writing downstream transactions by the MySQL Sink of TiCDC nodes.
- MQ Worker Send Message Duration Percentile: the latency of sending messages by MQ worker when the downstream is Kafka.
- Kafka Outgoing Bytes: the traffic of writing downstream transactions in MQ Workload.

Example 2: Impact of downstream database write speed on TiCDC data replication performance

As shown in the following diagram, both upstream and downstream are TiDB clusters. The TiCDC `Puller output events/s` metric indicates the QPS of the upstream database.

The `Transaction Sink Full Flush Duration` metric indicates the average write latency of the downstream database, which is high during the first workload and low during the second workload.

- During the first workload, because the downstream TiDB cluster writes data slowly, TiCDC consumes data at a speed that falls behind the upstream QPS, leading to a continuous increase in `Changefeed checkpoint lag`. However, `Changefeed resolved ts lag` remains within 300 milliseconds, indicating that replication lag and throughput bottlenecks are not caused by the puller and sorter modules but caused by the downstream sink module.
- During the second workload, because the downstream TiDB cluster writes data faster, TiCDC replicates data at a speed that completely catches up with the upstream, the `Changefeed checkpoint lag` and `Changefeed resolved ts lag` remain within 500 milliseconds, which is a relatively ideal replication speed for TiCDC.

Figure 425: TiCDC overview

Figure 426: data flow and txn latency

11.1.8.5 Latency Breakdown

This document breaks down the latency into metrics and then analyzes it from the user's perspective from the following aspects:

- General SQL layer
- Read queries
- Write queries
- Batch client
- TiKV snapshot
- Async write

These analyses provide you with a deep insight into time cost during TiDB SQL queries. This is a guide to TiDB's critical path diagnosis. Besides, the Diagnosis use cases section introduces how to analyze latency in real use cases.

It's better to read Performance Analysis and Tuning before this document. Note that when breaking down latency into metrics, the average value of duration or latency is calculated instead of some specific slow queries. Many metrics are shown as histogram, which is a distribution of the duration or latency. To calculate the average latency, you need to use the following sum and count counter.

```
avg = ${metric_name}_sum / ${metric_name}_count
```

Metrics described in this document can be read directly from the Prometheus dashboard of TiDB.

11.1.8.5.1 General SQL layer

This general SQL layer latency exists on the top level of TiDB and is shared by all SQL queries. The following is the time cost diagram of general SQL layer operation:

```
Diagram(
    NonTerminal("Token wait duration"),
    Choice(
        0,
        Comment("Prepared statement"),
        NonTerminal("Parse duration"),
    ),
    OneOrMore(
        Sequence(
        Choice(
            0,
            NonTerminal("Optimize prepared plan duration"),
            Sequence(
            Comment("Plan cache miss"),
            NonTerminal("Compile duration"),
            ),
        ),
        NonTerminal("TSO wait duration"),
        NonTerminal("Execution duration"),
        ),
        Comment("Retry"),
    ),
)
```

The general SQL layer latency can be observed as the `e2e duration` metric and is calculated as:

```
e2e duration =
    tidb_server_get_token_duration_seconds +
    tidb_session_parse_duration_seconds +
    tidb_session_compile_duration_seconds +
    tidb_session_execute_duration_seconds{type="general"}
```

- `tidb_server_get_token_duration_seconds` records the duration of Token waiting. This is usually less than 1 millisecond and is small enough to be ignored.
- `tidb_session_parse_duration_seconds` records the duration of parsing SQL queries to an Abstract Syntax Tree (AST), which can be skipped by `PREPARE/EXECUTE` statements.
- `tidb_session_compile_duration_seconds` records the duration of compiling an AST to an execution plan, which can be skipped by SQL prepared execution plan cache.

- `tidb_session_execute_duration_seconds{type="general"}` records the duration of execution, which mixes all types of user queries. This needs to be broken down into fine-grained durations for analyzing performance issues or bottlenecks.

Generally, OLTP (Online Transactional Processing) workload can be divided into read and write queries, which share some critical code. The following sections describe latency in read queries and write queries, which are executed differently.

11.1.8.5.2 Read queries

Read queries have only a single process form.

Point get

The following is the time cost diagram of point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Resolve TSO"),
        Comment("Read by clustered PK in auto-commit-txn mode or snapshot
            ↪ read"),
    ),
    Choice(
        0,
        NonTerminal("Read handle by index key"),
        Comment("Read by clustered PK, encode handle by key"),
    ),
    NonTerminal("Read value by handle"),
)
```

During point get, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handle duration +
    read value duration
```

`pd_client_cmd_handle_cmds_duration_seconds{type="wait"}` records the duration of fetching TSO (Timestamp Oracle) from PD. When reading in an auto-commit transaction mode with a clustered primary index or from a snapshot, the value will be zero.

The `read handle duration` and `read value duration` are calculated as:

```
read handle duration = read value duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="get"} =
    send request duration =
```

```
    tidb_tikvclient_request_seconds{type="Get"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

The `tidb_tikvclient_request_seconds{type="Get"}` records a duration of get requests which are sent directly to TiKV via a batched gRPC wrapper. For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration` ↪ , `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_` ↪ `seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    tikv_engine_seek_micro_seconds{type="seek_average"} +
    read value duration +
    read value duration(non-short value)
```

At this time, requests are in TiKV. TiKV processes get requests by one seek and one or two read actions (short values are encoded in a write column family, and reading it once is enough). TiKV gets a snapshot before processing the read request. For more details about the TiKV snapshot duration, refer to the TiKV snapshot section.

The `read value duration(from disk)` is calculated as:

```
read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="get/
        ↪ batch_get_command"})) / sum(rate(tikv_storage_rocksdb_perf{metric
        ↪ ="block_read_count",req="get/batch_get_command"}))
```

TiKV uses RocksDB as its storage engine. When the required value is missing from the block cache, TiKV needs to load the value from the disk. For `tikv_storage_rocksdb_perf`, the get request can be either `get` or `batch_get_command`.

Batch point get

The following is the time cost diagram of batch point get operations:

```
Diagram(
  NonTerminal("Resolve TSO"),
  Choice(
    0,
    NonTerminal("Read all handles by index keys"),
    Comment("Read by clustered PK, encode handle by keys"),
  ),
  NonTerminal("Read values by handles"),
)
```

During batch point get, the `tidb_session_execute_duration_seconds{type="general"}` is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    read handles duration +
    read values duration
```

The process of batch point get is almost the same as Point get except that batch point get reads multiple values at the same time.

The `read handles duration` and `read values duration` are calculated as:

```
read handles duration = read values duration =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} =
    send request duration =
    tidb_tikvclient_request_seconds{type="BatchGet"} =
    tidb_tikvclient_batch_wait_duration(transaction) +
    tidb_tikvclient_batch_send_latency(transaction) +
    tikv_grpc_msg_duration_seconds{type="kv_batch_get"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration(transaction)`, `tidb_tikvclient_batch_send_latency(transaction)`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}(transaction)`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_batch_get"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_batch_get"} =
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    n * (
        tikv_engine_seek_micro_seconds{type="seek_max"} +
        read value duration +
        read value duration(non-short value)
    )

read value duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="batch_
        get"})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_
        count",req="batch_get"}))
```

After getting a snapshot, TiKV reads multiple values from the same snapshot. The read duration is the same as Point get. When TiKV loads data from disk, the average duration can be calculated by `tikv_storage_rocksdb_perf` with `req="batch_get"`.

Table scan & Index scan

The following is the time cost diagram of table scan and index scan operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related table/index ranges"),
        OneOrMore(
            NonTerminal("Wait for result"),
            Comment("Next loop: drain the result"),
        ),
    ),
)
```

During table scan and index scan, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )
    tidb_distsql_handle_query_duration_seconds{sql_type="general"} <= send
        ↪ request duration
```

Table scan and index scan are processed in the same way. `req_per_copr` is the distributed task count. Because coprocessor execution and data responding to client are in different threads, `tidb_distsql_handle_query_duration_seconds{sql_type="general"}` is the wait time and it is less than the `send request duration`.

The `send request duration` and `req_per_copr` are calculated as:

```
send request duration =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="coprocessor"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tikv_grpc_msg_duration_seconds{type="coprocessor"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} +
    tikv_coprocessor_request_wait_seconds{type="schedule"} +
    tikv_coprocessor_request_handler_build_seconds{type="index/select"} +
    tikv_coprocessor_request_handle_seconds{type="index/select"}

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    ↪ (tidb_distsql_scan_keys_partial_num_count)
```

In TiKV, the table scan type is `select` and the index scan type is `index`. The details of `select` and `index` type duration are the same.

Index look up

The following is the time cost diagram of index look up operations:

```
Diagram(
    Stack(
        NonTerminal("Resolve TSO"),
        NonTerminal("Load region cache for related index ranges"),
        OneOrMore(
            Sequence(
                NonTerminal("Wait for index scan result"),
                NonTerminal("Wait for table scan result"),
            ),
        Comment("Next loop: drain the result"),
        ),
    ),
)
```

During index look up, the `tidb_session_execute_duration_seconds{type="general"}` duration is calculated as:

```
tidb_session_execute_duration_seconds{type="general"} =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"} +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    ) +
    req_per_copr * (
        tidb_distsql_handle_query_duration_seconds{sql_type="general"}
    )

req_per_copr = rate(tidb_distsql_handle_query_duration_seconds_count) / rate
    (tidb_distsql_scan_keys_partial_num_count)
```

An index look up combines index scan and table scan, which are processed in a pipeline.

11.1.8.5.3 Write queries

Write queries are much more complex than read queries. There are some variants of write queries. The following is the time cost diagram of write queries operations:

```
Diagram(
    NonTerminal("Execute write query"),
    Choice(
        0,
        NonTerminal("Pessimistic lock keys"),
        Comment("bypass in optimistic transaction"),
    ),
```

```
    Choice(
        0,
        NonTerminal("Auto Commit Transaction"),
        Comment("bypass in non-auto-commit or explicit transaction"),
    ),
)
```

	Pessimistic transaction	Optimistic transaction
Auto-commit	execute + lock + commit	execute + commit
Non-auto-commit	execute + lock	execute

A write query is divided into the following three phases:

- execute phase: execute and write mutation into the memory of TiDB.
- lock phase: acquire pessimistic locks for the execution result.
- commit phase: commit the transaction via the two-phase commit protocol (2PC).

In the execute phase, TiDB manipulates data in memory and the main latency comes from reading the required data. For update and delete queries, TiDB reads data from TiKV first, and then updates or deletes the row in memory.

The exception is lock-time read operations (`SELECT FOR UPDATE`) with point get and batch point get, which perform read and lock in a single Remote Procedure Call (RPC).

Lock-time point get

The following is the time cost diagram of lock-time point get operations:

```
Diagram(
    Choice(
        0,
        Sequence(
            NonTerminal("Read handle key by index key"),
            NonTerminal("Lock index key"),
        ),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock handle key"),
    NonTerminal("Read value from pessimistic lock cache"),
)
```

During lock-time point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    2 * tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

Lock-time point get locks the key and returns its value. Compared with the lock phase after execution, this saves 1 round trip. The duration of the lock-time point get can be treated the same as Lock duration.

Lock-time batch point get

The following is the time cost diagram of lock-time batch point get operations:

```
Diagram(
    Choice(
        0,
        NonTerminal("Read handle keys by index keys"),
        Comment("Clustered index"),
    ),
    NonTerminal("Lock index and handle keys"),
    NonTerminal("Read values from pessimistic lock cache"),
)
```

During lock-time batch point get, the `execution(clustered PK)` and `execution(non-clustered PK or UK)` duration are calculated as:

```
execution(clustered PK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
execution(non-clustered PK or UK) =
    tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"} +
    tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"}
```

The execution of the lock-time batch point get is similar to the Lock-time point get except that the lock-time batch point get reads multiple values in a single RPC. For more details about the `tidb_tikvclient_txn_cmd_duration_seconds{type="batch_get"}` duration, refer to the Batch point get section.

Lock

This section describes the lock duration.

```
round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_pessimistic_lock
        ↪ "})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_pessimistic_
        ↪ lock"})) /
    committer-concurrency
)
```

```
lock = tidb_tikvclient_txn_cmd_duration_seconds{type="lock_keys"} =
    round * tidb_tikvclient_request_seconds{type="PessimisticLock"}
```

Locks are acquired through the 2PC structure, which has a flow control mechanism. The flow control limits concurrent on-the-fly requests by `committer-concurrency` (default value is 128). For simplicity, the flow control can be treated as an amplification of request latency (`round`).

The `tidb_tikvclient_request_seconds{type="PessimisticLock"}` is calculated as:

```
tidb_tikvclient_request_seconds{type="PessimisticLock"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"}` duration is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_pessimistic_lock"} =
    tikv_scheduler_latch_wait_duration_seconds{type="acquire_pessimistic_
        ↪ lock"} +
    tikv_storage_engine_async_request_duration_seconds{type="snapshot"} +
    (lock in-mem key count + lock on-disk key count) * lock read duration +
    lock on-disk key count / (lock in-mem key count + lock on-disk key count
        ↪ ) *
    lock write duration
```

- Since TiDB v6.0, TiKV uses in-memory pessimistic lock by default. In-memory pessimistic lock bypass the async write process.
- `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` is a snapshot type duration. For more details, refer to the TiKV Snapshot section.
- The `lock in-mem key count` and `lock on-disk key count` are calculated as:

```
lock in-mem key count =
    sum(rate(tikv_in_memory_pessimistic_locking{result="success"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="kv_pessimistic_
        ↪ lock"}))

lock on-disk key count =
```

```
    sum(rate(tikv_in_memory_pessimistic_locking{result="full"})) /
    sum(rate(tikv_grpc_msg_duration_seconds_count{type="kv_pessimistic_
        ↪ lock"}}))
```

The count of in-memory and on-disk locked keys can be calculated by the in-memory lock counter. TiKV reads the keys' values before acquiring locks, and the read duration can be calculated by RocksDB performance context.

```
lock read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        ↪ acquire_pessimistic_lock"})) / sum(rate(tikv_storage_rocksdb_
        ↪ perf{metric="block_read_count",req="acquire_pessimistic_lock
        ↪ "}))
```

- `lock write duration` is the duration of writing on-disk lock. For more details, refer to the Async write section.

Commit

This section describes the commit duration. The following is the time cost diagram of commit operations:

```
Diagram(
    Stack(
        Sequence(
            Choice(
                0,
                Comment("use 2pc or causal consistency"),
                NonTerminal("Get min-commit-ts"),
            ),
            Optional("Async prewrite binlog"),
            NonTerminal("Prewrite mutations"),
            Optional("Wait prewrite binlog result"),
        ),
        Sequence(
            Choice(
                1,
                Comment("1pc"),
                Sequence(
                    Comment("2pc"),
                    NonTerminal("Get commit-ts"),
                    NonTerminal("Check schema"),
                    NonTerminal("Commit PK mutation"),
                ),
                Sequence(
                    Comment("async-commit"),
```

```
                NonTerminal("Commit mutations asynchronously"),
            ),
        ),
        Choice(
            0,
            Comment("committed"),
            NonTerminal("Async cleanup"),
        ),
        Optional("Commit binlog"),
    ),
),
)
```

The duration of the commit phase is calculated as:

```
commit =
    Get_latest_ts_time +
    Prewrite_time +
    Get_commit_ts_time +
    Commit_time

Get_latest_ts_time = Get_commit_ts_time =
    pd_client_cmd_handle_cmds_duration_seconds{type="wait"}

prewrite_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_prewrite"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_prewrite"})) /
    committer-concurrency
)

commit_round = ceil(
    sum(rate(tidb_tikvclient_txn_regions_num_sum{type="2pc_commit"})) /
    sum(rate(tidb_tikvclient_txn_regions_num_count{type="2pc_commit"})) /
    committer-concurrency
)

Prewrite_time =
    prewrite_round * tidb_tikvclient_request_seconds{type="Prewrite"}

Commit_time =
    commit_round * tidb_tikvclient_request_seconds{type="Commit"}
```

The commit duration can be broken down into four metrics:

- `Get_latest_ts_time` records the duration of getting latest TSO in async-commit or single-phase commit (1PC) transaction.

- `Prewrite_time` records the duration of the prewrite phase.
- `Get_commit_ts_time` records the duration of common 2PC transaction.
- `Commit_time` records the duration of the commit phase. Note that an async-commit or 1PC transaction does not have this phase.

Like pessimistic lock, flow control acts as an amplification of latency (`prewrite_round` and `commit_round` in the preceding formula).

The `tidb_tikvclient_request_seconds{type="Prewrite"}` and `tidb_tikvclient_request_seconds{type="Commit"}` duration are calculated as:

```
tidb_tikvclient_request_seconds{type="Prewrite"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_prewrite"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}

tidb_tikvclient_request_seconds{type="Commit"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_commit"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

For more details about the preceding batch client duration, such as `tidb_tikvclient_batch_wait_duration`, `tidb_tikvclient_batch_send_latency`, and `tidb_tikvclient_rpc_net_latency_seconds{store="?"}`, refer to the Batch client section.

The `tikv_grpc_msg_duration_seconds{type="kv_prewrite"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_prewrite"} =
    prewrite key count * prewrite read duration +
    prewrite write duration

prewrite key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="prewrite"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="prewrite"}))

prewrite read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="
        prewrite"})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_
        read_count",req="prewrite"}))
```

Like locks in TiKV, prewrite is processed in read and write phases. The read duration can be calculated from the RocksDB performance context. For more details about the write duration, refer to the Async write section.

The `tikv_grpc_msg_duration_seconds{type="kv_commit"}` is calculated as:

```
tikv_grpc_msg_duration_seconds{type="kv_commit"} =
    commit key count * commit read duration +
    commit write duration

commit key count =
    sum(rate(tikv_scheduler_kv_command_key_write_sum{type="commit"})) /
    sum(rate(tikv_scheduler_kv_command_key_write_count{type="commit"}))

commit read duration(from disk) =
    sum(rate(tikv_storage_rocksdb_perf{metric="block_read_time",req="commit
        ↪ "})) / sum(rate(tikv_storage_rocksdb_perf{metric="block_read_count
        ↪ ",req="commit"})) (storage)
```

The duration of `kv_commit` is almost the same as `kv_prewrite`. For more details about the write duration, refer to the Async write section.

11.1.8.5.4 Batch client

The following is the time cost diagram of the batch client:

```
Diagram(
    NonTerminal("Get conn pool to the target store"),
    Choice(
        0,
        Sequence(
            Comment("Batch enabled"),
                NonTerminal("Push request to channel"),
                NonTerminal("Wait response"),
            ),
            Sequence(
            NonTerminal("Get conn from pool"),
            NonTerminal("Call RPC"),
            Choice(
                0,
                Comment("Unary call"),
                NonTerminal("Recv first"),
            ),
        ),
    ),
)
```

- The overall duration of sending a request is observed as `tidb_tikvclient_request_seconds`.

- RPC client maintains connection pools (named ConnArray) to each store, and each pool has a BatchConn with a batch request (send) channel.
- Batch is enabled when the store is TiKV and batch size is positive, which is true in most cases.
- The size of batch request channel is `tikv-client.max-batch-size` (default is `128`), the duration of enqueue is observed as `tidb_tikvclient_batch_wait_duration`.
- There are three kinds of stream requests: `CmdBatchCop`, `CmdCopStream`, and `CmdMPPConn`, which involve an additional `recv()` call to fetch the first response from the stream.

Though there is still some latency missed observed, the `tidb_tikvclient_request_seconds` can be calculated approximately as:

```
tidb_tikvclient_request_seconds{type="?"} =
    tidb_tikvclient_batch_wait_duration +
    tidb_tikvclient_batch_send_latency +
    tikv_grpc_msg_duration_seconds{type="kv_?"} +
    tidb_tikvclient_rpc_net_latency_seconds{store="?"}
```

- `tidb_tikvclient_batch_wait_duration` records the waiting duration in the batch system.
- `tidb_tikvclient_batch_send_latency` records the encode duration in the batch system.
- `tikv_grpc_msg_duration_seconds{type="kv_?"}` is the TiKV processing duration.
- `tidb_tikvclient_rpc_net_latency_seconds` records the network latency.

11.1.8.5.5 TiKV snapshot

The following is the time cost diagram of TiKV snapshot operations:

```
Diagram(
    Choice(
        0,
        Comment("Local Read"),
        Sequence(
            NonTerminal("Propose Wait"),
            NonTerminal("Read index Read Wait"),
        ),
    ),
    NonTerminal("Fetch A Snapshot From KV Engine"),
)
```

The overall duration of a TiKV snapshot is observed as `tikv_storage_engine_async_request_duration_seconds{type="snapshot"}` and is calculated as:

```
tikv_storage_engine_async_request_duration_seconds{type="snapshot"} =
    tikv_coprocessor_request_wait_seconds{type="snapshot"} =
    tikv_raftstore_request_wait_time_duration_secs +
    tikv_raftstore_commit_log_duration_seconds +
    get snapshot from rocksdb duration
```

When leader lease is expired, TiKV proposes a read index command before getting a snapshot from RocksDB. `tikv_raftstore_request_wait_time_duration_secs` and `tikv_raftstore_commit_log_duration_seconds` are the duration of committing read index command.

Since getting a snapshot from RocksDB is usually a fast operation, the `get snapshot from rocksdb duration` is ignored.

11.1.8.5.6 Async write

Async write is the process that TiKV writes data into the Raft-based replicated state machine asynchronously with a callback.

- The following is the time cost diagram of async write operations when the asynchronous IO is disabled:

```
Diagram(
    NonTerminal("Propose Wait"),
    NonTerminal("Process Command"),
    Choice(
        0,
        Sequence(
            NonTerminal("Wait Current Batch"),
            NonTerminal("Write to Log Engine"),
        ),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

- The following is the time cost diagram of async write operations when the asynchronous IO is enabled:

```
Diagram(
    NonTerminal("Propose Wait"),
```

```
    NonTerminal("Process Command"),
    Choice(
        0,
        NonTerminal("Wait Until Persisted by Write Worker"),
        Sequence(
            NonTerminal("RaftMsg Send Wait"),
            NonTerminal("Commit Log Wait"),
        ),
    ),
    NonTerminal("Apply Wait"),
    NonTerminal("Apply Log"),
)
```

The async write duration is calculated as:

```
async write duration(async io disabled) =
    propose +
    async io disabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds

async write duration(async io enabled) =
    propose +
    async io enabled commit +
    tikv_raftstore_apply_wait_time_duration_secs +
    tikv_raftstore_apply_log_duration_seconds
```

Async write can be broken down into the following three phases:

- Propose
- Commit
- Apply: `tikv_raftstore_apply_wait_time_duration_secs + tikv_raftstore_apply_log_duration_seconds` in the preceding formula

The duration of the propose phase is calculated as:

```
propose =
    propose wait duration +
    propose duration

propose wait duration =
    tikv_raftstore_store_wf_batch_wait_duration_seconds

propose duration =
    tikv_raftstore_store_wf_send_to_queue_duration_seconds -
    tikv_raftstore_store_wf_batch_wait_duration_seconds
```

The Raft process is recorded in a waterfall manner. So the propose duration is calculated from the difference between the two metrics.

The duration of the commit phase is calculated as:

```
async io disabled commit = max(
    persist log locally duration,
    replicate log duration
)

async io enabled commit = max(
    wait by write worker duration,
    replicate log duration
)
```

Since v5.3.0, TiKV supports Async IO Raft (write Raft log by a StoreWriter thread pool). The Async IO Raft is only enabled when the `store-io-pool-size` is set to a positive value, which changes the process of commit. The `persist log locally duration` and `wait by write worker duration` are calculated as:

```
persist log locally duration =
    batch wait duration +
    write to raft db duration

batch wait duration =
    tikv_raftstore_store_wf_before_write_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

write to raft db duration =
    tikv_raftstore_store_wf_write_end_duration_seconds -
    tikv_raftstore_store_wf_before_write_duration_seconds

wait by write worker duration =
    tikv_raftstore_store_wf_persist_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds
```

The difference between with and without Async IO is the duration of persisting logs locally. With Async IO, the duration of persisting log locally can be calculated from the waterfall metrics directly (skip the batch wait duration).

The replicate log duration records the duration of log persisted in quorum peers, which contains an RPC duration and the duration of log persisting in the majority. The `replicate log duration` is calculated as:

```
replicate log duration =
    raftmsg send wait duration +
    commit log wait duration
```

```
raftmsg send wait duration =
    tikv_raftstore_store_wf_send_proposal_duration_seconds -
    tikv_raftstore_store_wf_send_to_queue_duration_seconds

commit log wait duration =
    tikv_raftstore_store_wf_commit_log_duration -
    tikv_raftstore_store_wf_send_proposal_duration_seconds
```

Raft DB

The following is the time cost diagram of Raft DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
    NonTerminal("Write and Sync Log"),
    NonTerminal("Apply Log to Memtable"),
)
```

```
write to raft db duration = raft db write duration
commit log wait duration >= raft db write duration

raft db write duration(raft engine enabled) =
    raft_engine_write_preprocess_duration_seconds +
    raft_engine_write_leader_duration_seconds +
    raft_engine_write_apply_duration_seconds

raft db write duration(raft engine disabled) =
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_thread_
       ↪ wait"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_
       ↪ scheduling_flushes_compactions_time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_wal_
       ↪ time"} +
    tikv_raftstore_store_perf_context_time_duration_secs{type="write_
       ↪ memtable_time"}
```

Because `commit log wait duration` is the longest duration of quorum peers, it might be larger than `raft db write duration`.

Since v6.1.0, TiKV uses Raft Engine as its default log storage engine, which changes the process of writing log.

KV DB

The following is the time cost diagram of KV DB operations:

```
Diagram(
    NonTerminal("Wait for Writer Leader"),
```

```
    NonTerminal("Preprocess"),
    Choice(
        0,
        Comment("No Need to Switch"),
        NonTerminal("Switch WAL or Memtable"),
    ),
    NonTerminal("Write and Sync WAL"),
    NonTerminal("Apply to Memtable"),
)
```

```
tikv_raftstore_apply_log_duration_seconds =
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_thread_
        ↪ wait"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_
        ↪ scheduling_flushes_compactions_time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_wal_
        ↪ time"} +
    tikv_raftstore_apply_perf_context_time_duration_secs{type="write_
        ↪ memtable_time"}
```

In the async write process, committed logs need to be applied to the KV DB. The applying duration can be calculated from the RocksDB performance context.

11.1.8.5.7 Diagnosis use cases

The preceding sections explain the details about time cost metrics during querying. This section introduces common procedures of metrics analysis when you encounter slow read or write queries. All metrics can be checked in the Database Time panel of Performance Overview Dashboard.

Slow read queries

If `SELECT` statements account for a significant portion of the database time, you can assume that TiDB is slow at read queries.

The execution plans of slow queries can be found in the Top SQL statements panel of TiDB Dashboard. To investigate the time costs of slow read queries, you can analyze Point get, Batch point get and some simple coprocessor queries according to the preceding descriptions.

Slow write queries

Before investigating slow writes, you need to troubleshoot the cause of the conflicts by checking `tikv_scheduler_latch_wait_duration_seconds_sum{type="acquire_pessimistic_lock"} by (instance)`:

- If this metric is high in some specific TiKV instances, there might be conflicts in hot Regions.

- If this metric is high across all instances, there might be conflicts in the application.

After confirming the cause of conflicts from the application, you can investigate slow write queries by analyzing the duration of Lock and Commit.

11.1.9 TiDB Best Practices on Public Cloud

Public cloud infrastructure has become an increasingly popular choice for deploying and managing TiDB. However, deploying TiDB on public cloud requires careful consideration of several critical factors, including performance tuning, cost optimization, reliability, and scalability.

This document covers various essential best practices for deploying TiDB on public cloud, such as reducing compaction I/O flow in KV RocksDB, using a dedicated disk for Raft Engine, optimizing costs for cross-AZ traffic, mitigating Google Cloud live migration events, and fine-tuning the PD server in large clusters. By following these best practices, you can maximize the performance, cost efficiency, reliability, and scalability of your TiDB deployment on public cloud.

11.1.9.1 Reduce compaction I/O flow in KV RocksDB

As the storage engine of TiKV, RocksDB is used to store user data. Because the provisioned IO throughput on cloud EBS is usually limited due to cost considerations, RocksDB might exhibit high write amplification, and the disk throughput might become the bottleneck for the workload. As a result, the total number of pending compaction bytes grows over time and triggers flow control, which indicates that TiKV lacks sufficient disk bandwidth to keep up with the foreground write flow.

To alleviate the bottleneck caused by limited disk throughput, you can improve performance by enabling Titan. If your average row size is smaller than 512 bytes, Titan is not applicable. In this case, you can improve performance by increasing all the compression levels.

11.1.9.1.1 Enable Titan

Titan is a high-performance RocksDB plugin for key-value separation, which can reduce write amplification in RocksDB when large values are used.

If your average row size is larger than 512 bytes, you can enable Titan to reduce the compaction I/O flow as follows, with `min-blob-size` set to `"512B"` or `"1KB"` and `blob-file-compression` set to `"zstd"`:

```
[rocksdb.titan]
enabled = true
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
blob-file-compression = "zstd"
```

Note:

When Titan is enabled, there might be a slight performance degradation for range scans on the primary key. For more information, see Impact of `min-blob-size` on performance.

11.1.9.1.2 Increase all the compression levels

If your average row size is smaller than 512 bytes, you can increase all the compression levels of the default column family to `"zstd"` as follows:

```
[rocksdb.defaultcf]
compression-per-level = ["zstd", "zstd", "zstd", "zstd", "zstd", "zstd", "
    ↪ zstd"]
```

11.1.9.2 Use a dedicated disk for Raft Engine

The Raft Engine in TiKV plays a critical role similar to that of a write-ahead log (WAL) in traditional databases. To achieve optimal performance and stability, it is crucial to allocate a dedicated disk for the Raft Engine when you deploy TiDB on public cloud. The following `iostat` shows the I/O characteristics on a TiKV node with a write-heavy workload.

```
Device            r/s     rkB/s       w/s     wkB/s     f/s  aqu-sz %util
sdb          1649.00 209030.67 1293.33 304644.00 13.33   5.09 48.37
sdd          1033.00  4132.00  1141.33 31685.33  571.00   0.94 100.00
```

The device `sdb` is used for KV RocksDB, while `sdd` is used to restore Raft Engine logs. Note that `sdd` has a significantly higher `f/s` value, which represents the number of flush requests completed per second for the device. In Raft Engine, when a write in a batch is marked synchronous, the batch leader will call `fdatasync()` after writing, guaranteeing that buffered data is flushed to the storage. By using a dedicated disk for Raft Engine, TiKV reduces the average queue length of requests, thereby ensuring optimal and stable write latency.

Different cloud providers offer various disk types with different performance characteristics, such as IOPS and MBPS. Therefore, it is important to choose an appropriate cloud provider, disk type, and disk size based on your workload.

11.1.9.2.1 Choose appropriate disks for Raft Engine on public clouds

This section outlines best practices for choosing appropriate disks for Raft Engine on different public clouds. Depending on performance requirements, two types of recommended disks are available.

Middle-range disk

The following are recommended middle-range disks for different public clouds:

- On AWS, gp3 is recommended. The gp3 volume offers a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for the Raft Engine.
- On Google Cloud, pd-ssd is recommended. The IOPS and MBPS vary depending on the allocated disk size. To meet performance requirements, it is recommended to allocate 200 GB for Raft Engine. Although Raft Engine does not require such a large space, it ensures optimal performance.
- On Azure, Premium SSD v2 is recommended. Similar to AWS gp3, Premium SSD v2 provides a free allocation of 3000 IOPS and 125 MB/s throughput, regardless of the volume size, which is usually sufficient for Raft Engine.

High-end disk

If you expect an even lower latency for Raft Engine, consider using high-end disks. The following are recommended high-end disks for different public clouds:

- On AWS, io2 is recommended. Disk size and IOPS can be provisioned according to your specific requirements.
- On Google Cloud, pd-extreme is recommended. Disk size, IOPS, and MBPS can be provisioned, but it is only available on instances with more than 64 CPU cores.
- On Azure, ultra disk is recommended. Disk size, IOPS, and MBPS can be provisioned according to your specific requirements.

11.1.9.2.2 Example 1: Run a social network workload on AWS

AWS offers 3000 IOPS and 125 MBPS/s for a 20 GB gp3 volume.

By using a dedicated 20 GB gp3 Raft Engine disk on AWS for a write-intensive social network application workload, the following improvements are observed but the estimated cost only increases by 0.4%:

- a 17.5% increase in QPS (queries per second)
- an 18.7% decrease in average latency for insert statements
- a 45.6% decrease in p99 latency for insert statements.

Metric	Shared Raft Engine disk	Dedicated Raft Engine disk	Difference (%)
QPS (K/s)	8.0	9.4	17.5
AVG Insert Latency (ms)	11.3	9.2	-18.7
P99 Insert Latency (ms)	29.4	16.0	-45.6

11.1.9.2.3 Example 2: Run TPC-C/Sysbench workload on Azure

By using a dedicated 32 GB ultra disk for Raft Engine on Azure, the following improvements are observed:

- Sysbench `oltp_read_write` workload: a 17.8% increase in QPS and a 15.6% decrease in average latency.
- TPC-C workload: a 27.6% increase in QPS and a 23.1% decrease in average latency.

Metric	Workload	Shared Raft Engine disk	Dedicated Raft Engine disk
QPS (K/s)	Sysbench `oltp_read_write`	60.7	71.5
QPS (K/s)	TPC-C	23.9	30.5
AVG Latency (ms)	Sysbench `oltp_read_write`	4.5	3.8
AVG Latency (ms)	TPC-C	3.9	3.0

11.1.9.2.4 Example 3: Attach a dedicated pd-ssd disk on Google Cloud for Raft Engine on TiKV manifest

The following TiKV configuration example shows how to attach an additional 512 GB pd-ssd disk to a cluster on Google Cloud deployed by TiDB Operator, with `raft-engine.dir` configured to store Raft Engine logs to this specific disk.

```
tikv:
    config: |
      [raft-engine]
        dir = "/var/lib/raft-pv-ssd/raft-engine"
        enable = true
        enable-log-recycle = true
    requests:
      storage: 4Ti
    storageClassName: pd-ssd
    storageVolumes:
    - mountPath: /var/lib/raft-pv-ssd
      name: raft-pv-ssd
      storageSize: 512Gi
```

11.1.9.3 Optimize cost for cross-AZ network traffic

Deploying TiDB across multiple availability zones (AZs) can lead to increased costs due to cross-AZ data transfer fees. To optimize costs, it is important to reduce cross-AZ network traffic.

To reduce cross-AZ read traffic, you can enable the Follower Read feature, which allows TiDB to prioritize selecting replicas in the same availability zone. To enable this feature, set the `tidb_replica_read` variable to `closest-replicas` or `closest-adaptive`.

To reduce cross-AZ write traffic in TiKV instances, you can enable the gRPC compression feature, which compresses data before transmitting it over the network. The following configuration example shows how to enable gzip gRPC compression for TiKV.

```
server_configs:
  tikv:
    server.grpc-compression-type: gzip
```

To reduce network traffic caused by the data shuffle of TiFlash MPP tasks, it is recommended to deploy multiple TiFlash instances in the same availability zones (AZs). Starting from v6.6.0, compression exchange is enabled by default, which reduces the network traffic caused by MPP data shuffle.

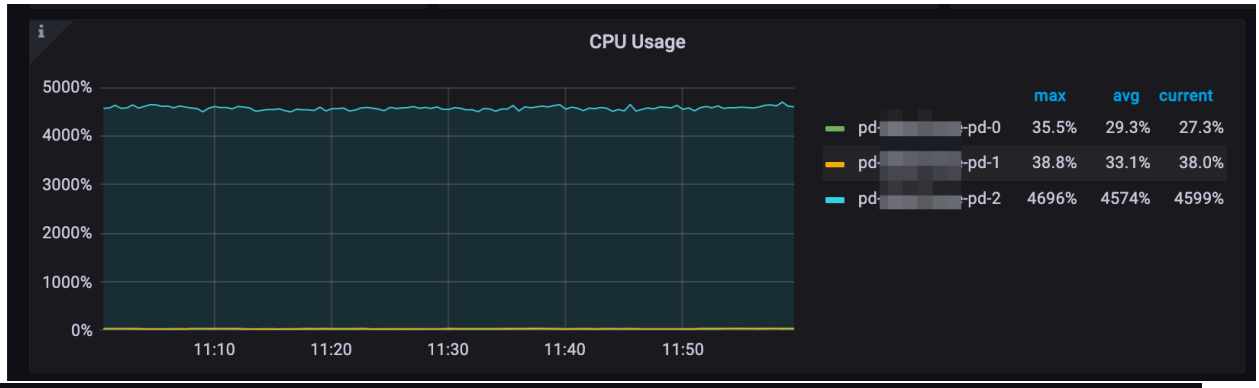
11.1.9.4 Mitigate live migration maintenance events on Google Cloud

The Live Migration feature of Google Cloud enables VMs to be seamlessly migrated between hosts without causing downtime. However, these migration events, although infrequent, can significantly impact the performance of VMs, including those running in a TiDB cluster. During such events, affected VMs might experience reduced performance, leading to longer query processing times in the TiDB cluster.

To detect live migration events initiated by Google Cloud and mitigate the performance impact of these events, TiDB provides a watching script based on Google's metadata example. You can deploy this script on TiDB, TiKV, and PD nodes to detect maintenance events. When a maintenance event is detected, appropriate actions can be taken automatically as follows to minimize disruption and optimize the cluster behavior:

- TiDB: Takes the TiDB node offline by cordoning it and deleting the TiDB pod. This assumes that the node pool of the TiDB instance is set to auto-scale and dedicated to TiDB. Other pods running on the node might experience interruptions, and the cordoned node is expected to be reclaimed by the auto-scaler.
- TiKV: Evicts leaders on the affected TiKV store during maintenance.
- PD: Resigns a leader if the current PD instance is the PD leader.

It is important to note that this watching script is specifically designed for TiDB clusters deployed using TiDB Operator, which offers enhanced management functionalities for TiDB in Kubernetes environments.



By utilizing the watching script and taking necessary actions during maintenance events, TiDB clusters can better handle live migration events on Google Cloud and ensure smoother operations with minimal impact on query processing and response times.

11.1.9.5 Tune PD for a large-scale TiDB cluster with high QPS

In a TiDB cluster, a single active Placement Driver (PD) server is used to handle crucial tasks such as serving the TSO (Timestamp Oracle) and processing requests. However, relying on a single active PD server can limit the scalability of TiDB clusters.

11.1.9.5.1 Symptoms of PD limitation

The following diagrams show the symptoms of a large-scale TiDB cluster consisting of three PD servers, each equipped with 56 CPUs. From these diagrams, it is observed that when the query per second (QPS) exceeds 1 million and the TSO (Timestamp Oracle) requests per second exceed 162,000, the CPU utilization reaches approximately 4,600%. This high CPU utilization indicates that the PD leader is experiencing a significant load and is running out of available CPU resources.

11.1.9.5.2 Tune PD performance

To address the high CPU utilization issue in the PD server, you can make the following tuning adjustments:

Adjust PD configuration

`tso-update-physical-interval`: This parameter controls the interval at which the PD server updates the physical TSO batch. By reducing the interval, the PD server can allocate TSO batches more frequently, thereby reducing the waiting time for the next allocation.

```
tso-update-physical-interval = "10ms" # default: 50ms
```

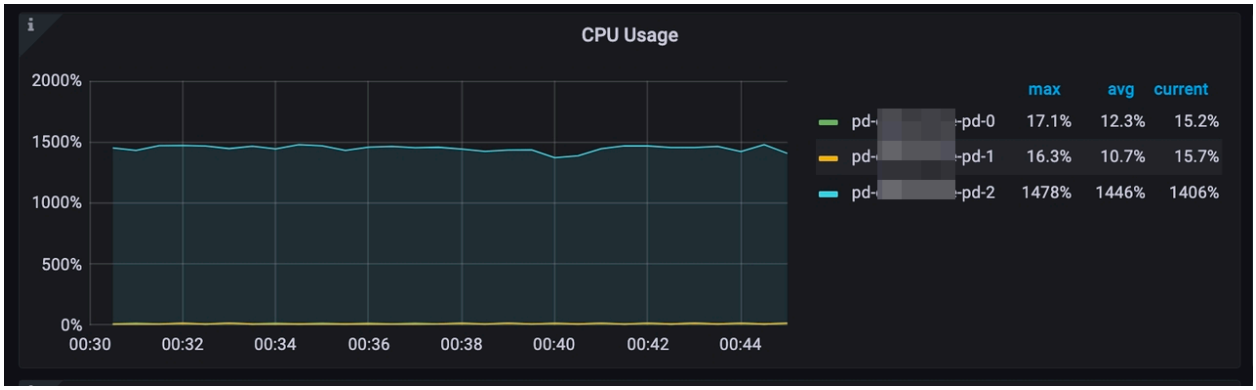
Adjust a TiDB global variable

In addition to the PD configuration, enabling the TSO client batch wait feature can further optimize the TSO client's behavior. To enable this feature, you can set the global variable `tidb_tso_client_batch_max_wait_time` to a non-zero value.

```
set global tidb_tso_client_batch_max_wait_time = 2; # default: 0
```

Adjust TiKV configuration

To reduce the number of Regions and alleviate the heartbeat overhead on the system, you can refer to Adjust Region size to moderately increase the size of the Region in TiKV configuration.



```
[coprocessor]
  region-split-size = "288MiB"
```

11.1.9.5.3 After tuning

After the tuning, the following effects can be observed:

- The TSO requests per second are decreased to 64,800.
- The CPU utilization is significantly reduced from approximately 4,600% to 1,400%.
- The P999 value of `PD server TSO handle time` is decreased from 2ms to 0.5ms.

These improvements indicate that the tuning adjustments have successfully reduced the CPU utilization of the PD server while maintaining stable TSO handling performance.

11.2 Configuration Tuning

11.2.1 Tune Operating System Performance

This document introduces how to tune each subsystem of CentOS 7.

> **Note:**
>
> - The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affect other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
> - Fully test all the changes in the test environment before applying them to the production environment.

11.2.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

11.2.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`
- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

11.2.1.1.2 perf

perf is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see perf Examples.

11.2.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in In 60 seconds. Compared with perf/ftrace, BPF provides programmability and smaller performance overhead. Compared with kprobe, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see BPF Compiler Collection (BCC).

11.2.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

11.2.1.2.1 CPU—frequency scaling

cpufreq is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

11.2.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:

- Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.
- For other devices, check the chip manual to see whether these devices support distributing interrupts.
    - If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
    - If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the kernel document.

11.2.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see tune network.

11.2.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
grubby --update-kernel="$KERNEL" --args='transparent_hugepage=never'
```

11.2.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_background_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

11.2.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to `noop`.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

11.2.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot

catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.

- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see CPU—frequency scaling, CPU—interrupt affinity, and NUMA CPU binding. If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the kernel document.

- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.

- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.

- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.

- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.

- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog`. Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core.netdev_max_backlog` value.

- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is `1000`, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.
- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

11.2.2 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. The system variable `tidb_mem_oom_action` specifies the action to take when a query reaches the memory limit:

- A value of `LOG` means that queries will continue to execute when the `tidb_mem_quota_query` limit is reached, but TiDB will print an entry to the log.
- A value of `CANCEL` means TiDB stops executing the SQL query immediately after the `tidb_mem_quota_query` limit is reached, and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes memory in the SQL execution process.

11.2.2.1 Configure the memory quota of a query

The system variable `tidb_mem_quota_query` sets the limit for a query in bytes. Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:
SET tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:
SET tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:
SET tidb_mem_quota_query = 8 << 10;
```

11.2.2.2 Configure the memory usage threshold of a tidb-server instance

Since v6.5.0, you can use the system variable `tidb_server_memory_limit` to set the threshold for the memory usage of a tidb-server instance.

For example, set the total memory usage of a tidb-server instance to 32 GB:

```
SET GLOBAL tidb_server_memory_limit = "32GB";
```

After you set this variable, when the memory usage of a tidb-server instance reaches 32 GB, TiDB will terminate the SQL operation with the largest memory usage among all running SQL operations in order, until the memory usage of the instance drops below 32 GB. The forcibly terminated SQL operation will return the `Out Of Memory Quota!` error to the client.

Currently, the memory limit set by `tidb_server_memory_limit` **DOES NOT** terminate the following SQL operations:

- DDL operations
- SQL operations that contain window functions and common table expressions

> **Warning:**
>
> - During the startup process, TiDB does not guarantee that the `tidb_server_memory_limit` limit is enforced. If the free memory of the operating system is insufficient, TiDB might still encounter OOM. You need to ensure that the TiDB instance has enough available memory.
> - In the process of memory control, the total memory usage of TiDB might slightly exceed the limit set by `tidb_server_memory_limit`.
> - Since v6.5.0, the configuration item `server-memory-quota` is deprecated. To ensure compatibility, after you upgrade your cluster to v6.5.0 or a later version, `tidb_server_memory_limit` will inherit the value of `server-memory-quota`. If you have not configured `server-memory-quota` before the upgrade, the default value of `tidb_server_memory_limit` is used, which is `80%`.

When the memory usage of a tidb-server instance reaches a certain proportion of the total memory (the proportion is controlled by the system variable `tidb_server_memory_limit_gc_trigger`), tidb-server will try to trigger a Golang GC to relieve memory stress. To avoid frequent GCs that cause performance issues due to the instance memory fluctuating around the threshold, this GC method will trigger GC at most once every minute.

> **Note:**
>
> In a hybrid deployment scenario, `tidb_server_memory_limit` is the memory usage threshold for a single tidb-server instance, instead of the total memory threshold for the whole physical machine.

11.2.2.3 View the memory usage of the current tidb-server instance using the INFORMATION_SCHEMA system table

To view the memory usage of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE`.

To view the memory-related operations and execution basis of the current instance or cluster, you can query the system table `INFORMATION_SCHEMA.(CLUSTER_)MEMORY_USAGE_OPS_HISTORY`. For each instance, this table retains the latest 50 records.

11.2.2.4 Trigger the alarm of excessive memory usage

When the memory usage of a tidb-server instance exceeds its memory threshold (70% of its total memory by default) and any of the following conditions is met, TiDB records the related status files and prints an alarm log.

- It is the first time the memory usage exceeds the memory threshold.
- The memory usage exceeds the memory threshold and it has been more than 60 seconds since the last alarm.
- The memory usage exceeds the memory threshold and `(Current memory usage - Memory usage at the last alarm)/ Total memory > 10%`.

You can control the memory threshold that triggers the alarm by modifying the memory usage ratio via the system variable `tidb_memory_usage_alarm_ratio`.

When the alarm of excessive memory usage is triggered, TiDB takes the following actions:

- TiDB records the following information in the directory where the TiDB log file `filename` is located.
    - The information about the top 10 SQL statements with the highest memory usage and the top 10 SQL statements with the longest running time among all SQL statements currently being executed
    - The goroutine stack information
    - The usage status of heap memory
- TiDB prints an alarm log containing the keyword `tidb-server has the risk of OOM` and the values of the following memory-related system variables.
    - `tidb_mem_oom_action`
    - `tidb_mem_quota_query`
    - `tidb_server_memory_limit`
    - `tidb_analyze_version`
    - `tidb_enable_rate_limit_action`

To avoid accumulating too many status files for alarms, TiDB only retains the status files generated during the recent five alarms by default. You can adjust this number by configuring the system variable tidb_memory_usage_alarm_keep_record_num.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set tidb_memory_usage_alarm_ratio to 0.85:

```
SET GLOBAL tidb_memory_usage_alarm_ratio = 0.85;
```

2. Execute CREATE TABLE t(a int); and insert 1000 rows of data.

3. Execute select * from t t1 join t t2 join t t3 order by t1.a. This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.

4. Check the tidb.log file which records the total system memory, current system memory usage, memory usage of the tidb-server instance, and the directory of status files.

```
[2022/10/11 16:39:02.281 +08:00] [WARN] [memoryusagealarm.go:212] ["
    ↪ tidb-server has the risk of OOM because of memory usage exceeds
    ↪ alarm ratio. Running SQLs and heap profile will be recorded in
    ↪ record path"] ["is tidb_server_memory_limit set"=false] ["system
    ↪ memory total"=33682427904] ["system memory usage"=22120655360] ["
    ↪ tidb-server memory usage"=21468556992] [memory-usage-alarm-ratio
    ↪ =0.85] ["record path"=/tiup/deploy/tidb-4000/log/oom_record]
```

   The fields of the example log file above are described as follows:

   - is tidb_server_memory_limit set indicates whether tidb_server_memory_
     ↪ limit is set.
   - system memory total indicates the total memory of the current system.
   - system memory usage indicates the current system memory usage.
   - tidb-server memory usage indicates the memory usage of the tidb-server instance.
   - memory-usage-alarm-ratio indicates the value of the system variable tidb_
     ↪ memory_usage_alarm_ratio.
   - record path indicates the directory of status files.

5. By checking the directory of status files (In the preceding example, the directory is /tiup/deploy/tidb-4000/log/oom_record), you can see a record directory with the corresponding timestamp (for example, record2022-10-09T17:18:38+08:00). The record directory includes three files: goroutinue, heap, and running_sql. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the content in running_sql, refer to expensive-queries.

11.2.2.5 Reduce the memory usage for write transactions in tidb-server

The transaction model used by TiDB requires that all write operations of transactions are first cached in memory before being committed. When TiDB writes large transactions, memory usage might increase and become a bottleneck. To reduce or avoid high memory usage by large transactions under various constraints, you can adjust the `tidb_dml_type` system variable to `"bulk"` or use Non-transactional DML statements.

11.2.2.6 Other memory control behaviors of tidb-server

11.2.2.6.1 Flow control

- TiDB supports dynamic memory control for the operator that reads data. By default, this operator uses the maximum number of threads that `tidb_distsql_scan_concurrency` allows to read data. When the memory usage of a single SQL execution exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.
- This flow control behavior is controlled by the system variable `tidb_enable_rate_limit_action`.
- When the flow control behavior is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, destroy one token now`.

11.2.2.6.2 Disk spill

TiDB supports disk spill for execution operators. When the memory usage of a SQL execution exceeds the memory quota, tidb-server can spill the intermediate data of execution operators to the disk to relieve memory pressure. Operators supporting disk spill include Sort, MergeJoin, HashJoin, and HashAgg.

- The disk spill behavior is jointly controlled by the following parameters: `tidb_mem_quota_query`, `tidb_enable_tmp_storage_on_oom`, `tmp-storage-path`, and `tmp-storage-quota`.
- When the disk spill is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, spill to disk now` or `memory exceeds quota, set aggregate mode to spill-mode`.
- Disk spill for the Sort, MergeJoin, and HashJoin operators is introduced in v4.0.0. Disk spill for the non-parallel algorithm of the HashAgg operator is introduced in v5.2.0. Disk spill for the parallel algorithm of the HashAgg operator is introduced in v8.0.0 as an experimental feature and becomes generally available (GA) in v8.2.0. Disk spill for the TopN operator is introduced in v8.3.0.
- You can control whether to enable the parallel HashAgg algorithm that supports disk spill using the `tidb_enable_parallel_hashagg_spill` system variable. This variable will be deprecated in a future release.

- When the SQL executions containing Sort, MergeJoin, HashJoin, HashAgg, or TopN cause OOM, TiDB triggers disk spill by default.

> **Note:**
>
> The disk spill for HashAgg does not support SQL executions containing the `DISTINCT` aggregate function. When a SQL execution containing a `DISTINCT` aggregate function uses too much memory, the disk spill does not apply.

The following example uses a memory-consuming SQL statement to demonstrate the disk spill feature for HashAgg:

1. Configure the memory quota of a SQL statement to 1GB (1 GB by default):

```
SET tidb_mem_quota_query = 1 << 30;
```

2. Create a single table `CREATE TABLE t(a int);` and insert 256 rows of different data.

3. Execute the following SQL statement:

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

   Because executing this SQL statement occupies too much memory, the following "Out of Memory Quota" error message is returned:

```
ERROR 1105 (HY000): Out Of Memory Quota![conn_id=3]
```

4. Execute the same SQL statement. You can find that this time, the statement is successfully executed and no error message is returned. From the following detailed execution plan, you can see that HashAgg has used 600 MB of hard disk space.

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
    ↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

```

11.2.2.7 Others

11.2.2.7.1 Mitigate OOM issues by configuring GOMEMLIMIT

GO 1.19 introduces an environment variable GOMEMLIMIT to set the memory limit that triggers GC.

For v6.1.3 <= TiDB < v6.5.0, you can mitigate a typical category of OOM issues by manually setting GOMEMLIMIT. The typical category of OOM issues is: before OOM occurs, the estimated memory in use on Grafana occupies only half of the entire memory (TiDB-Runtime > Memory Usage > estimate-inuse), as shown in the following figure:

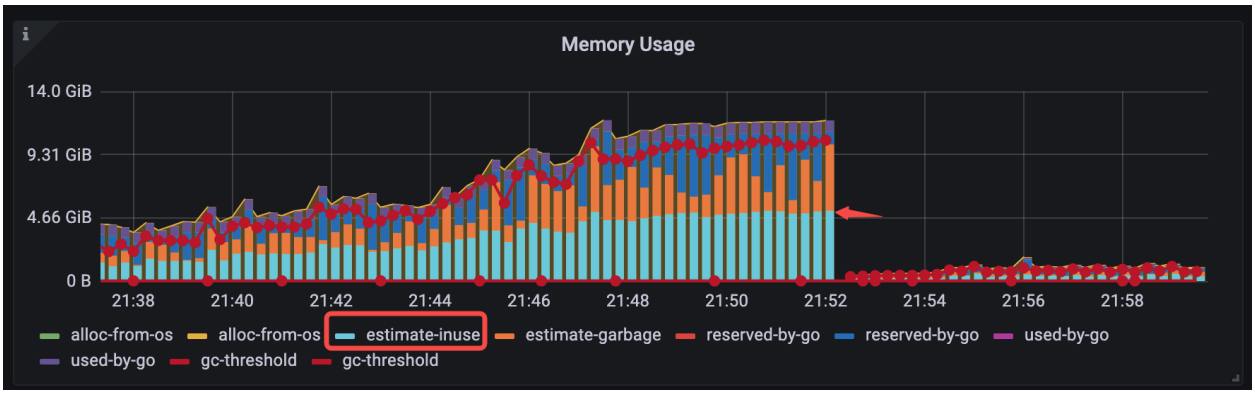

Figure 427: normal OOM case example

To verify the performance of GOMEMLIMIT, a test is performed to compare the specific memory usage with and without GOMEMLIMIT configuration.

- In TiDB v6.1.2, the TiDB server encounters OOM (system memory: about 48 GiB) after the simulated workload runs for several minutes:

Figure 428: v6.1.2 workload oom

- In TiDB v6.1.3, `GOMEMLIMIT` is set to 40000 MiB. It is found that the simulated workload runs stably for a long time, OOM does not occur in the TiDB server, and the maximum memory usage of the process is stable at around 40.8 GiB:

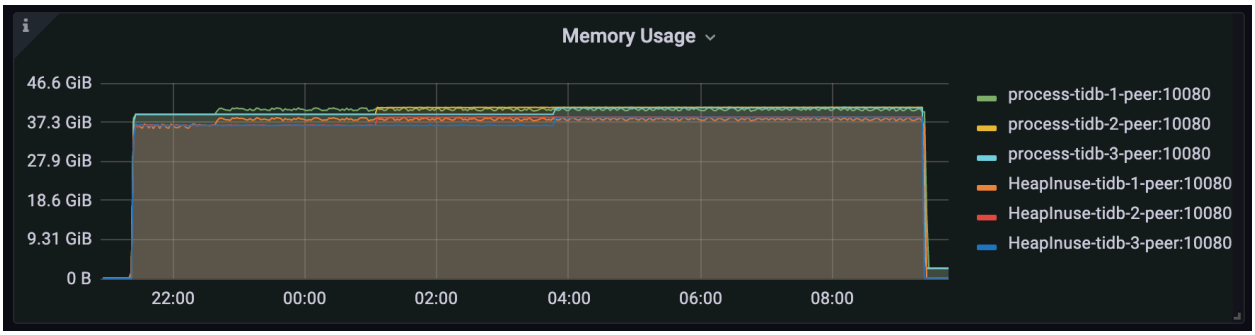

Figure 429: v6.1.3 workload no oom with GOMEMLIMIT

11.2.3 Tune TiKV Thread Pool Performance

This document introduces TiKV internal thread pools and how to tune their performance.

11.2.3.1 Thread pool introduction

The TiKV thread pool is mainly composed of gRPC, Scheduler, UnifyReadPool, Raftstore, StoreWriter, Apply, RocksDB, and some scheduled tasks and detection components that do not consume much CPU. This document mainly introduces a few CPU-intensive thread pools that affect the performance of read and write requests.

- The gRPC thread pool: it handles all network requests and forwards requests of different task types to different thread pools.

- The Scheduler thread pool: it detects write transaction conflicts, converts requests like the two-phase commit, pessimistic locking, and transaction rollbacks into key-value pair arrays, and then sends them to the Raftstore thread for Raft log replication.
- The Raftstore thread pool:
    - It processes all Raft messages and the proposal to add a new log.
    - It writes Raft logs to the disk. If the value of `store-io-pool-size` is `0`, the Raftstore thread writes the logs to the disk; if the value is not `0`, the Raftstore thread sends the logs to the StoreWriter thread.
    - When Raft logs in the majority of replicas are consistent, the Raftstore thread sends the logs to the Apply thread.
- The StoreWriter thread pool: it writes all Raft logs to the disk and returns the result to the Raftstore thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.
- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and `Compact` operation, refer to RocksDB: A Persistent Key-Value Store for Flash and RAM Storage.
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

11.2.3.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage` ↪ `.use-unified-pool` to `true`.

11.2.3.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

  The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is `5`. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

  - If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to `2`.
  - If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` ↪ , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than `80% * server.grpc-concurrency`).

- The Scheduler thread pool.

  When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is `8`; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is `4`.

  This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation**.

  - If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
  - If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

  Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is `8`, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler` ↪ `worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

  The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) of this thread pool is `2`. For the StoreWriter thread pool, the default size (configured by `raftstore.store-io-pool-` ↪ `size`) is `1`.

- When the size of the StoreWriter thread pool is 0, all write requests are written into RocksDB in the way of `fsync` by the Raftstore thread. In this case, it is recommended to tune the performance as follows:
    - Keep the overall CPU usage of the Raftstore thread below 60%. When the number of Raftstore threads is 2, keep the **TiKV-Details**, **Thread CPU**, **Raft store CPU** on Grafana below 120%. Due to I/O requests, the CPU usage of Raftstore threads in theory is always lower than 100%.
    - Do not increase the size of the Raftstore thread pool to improve write performance without careful consideration, because this might increase the disk burden and degrade performance.
- When the size of the StoreWriter thread pool is not 0, all write requests are written into RocksDB in the way of `fsync` by the StoreWriter thread. In this case, it is recommended to tune the performance as follows:
    - Enable the StoreWriter thread pool ONLY when the overall CPU resources are sufficient. When the StoreWriter thread pool is enabled, keep the CPU usage of the StoreWriter thread and the Raftstore thread below 80%.

  Compared with the case that the write requests are processed by the Raftstore thread, in theory, when the write requests are processed by the StoreWriter thread, write latency and the tail latency of data read are significantly reduced. However, as the write speed grows faster, the number of Raft logs increases accordingly. This can cause the CPU overhead of the Raftstore threads, the Apply threads, and the gRPC threads to increase. In this case, insufficient CPU resources might offset the tuning effect, and as a result, the write speed might become slower than before. Therefore, if the CPU resources are not sufficient, it is not recommended to enable the StoreWriter thread. Because the Raftstore thread sends most of the I/O requests to the StoreWriter thread, you need to keep the CPU usage of the Raftstore thread below 80%.
- In most cases, set the size of the StoreWriter thread pool to 1 or 2. This is because the size of the StoreWriter thread pool affects the number of Raft logs, so the value of the thread pool size should not be too large. If the CPU usage is higher than 80%, consider increasing the thread pool size.
- Pay attention to the impact of increasing Raft logs on the CPU overhead of other thread pools. If necessary, you need to increase the number of Raftstore threads, Apply threads, and gRPC threads accordingly.

- The UnifyReadPool thread pool.

  The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified.max-thread-count` to `10`. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

Since v6.3.0, TiKV supports automatically adjusting the UnifyReadPool thread pool size based on the current CPU usage. To enable this feature, you can set the `readpool.unified.auto-adjust-pool-size = true`. It is recommended to automatically adjust the thread pool size for clusters that are reread and whose maximum CPU usage exceeds 80%.

- The RocksDB thread pool.

  The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

  - If the machine has a small number of CPU cores, set both `rocksdb.max-background-jobs` and `raftdb.max-background-jobs` to `4`.
  - If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not `0`.
    - If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to `2` or `3`. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is `3` in TiKV 4.0 and `1` in TiKV 3.0.
    - If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (`5` by default).
    - If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to `64` or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

11.2.4 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance. You can find the default configuration file in etc/config-template.toml. To modify the configuration, you can use TiUP or modify TiKV dynamically for a limited set of configuration items. For the complete configuration, see TiKV configuration file.

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses

two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements `Column Families` (CF) from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.
    - The `default` CF stores the actual data. The corresponding parameters are in `[rocksdb.defaultcf]`.
    - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in `[rocksdb.writecf]`.
    - The `lock` CF stores the lock information. The system uses the default parameters.
- The Raft RocksDB (RaftDB) instance stores Raft logs.
    - The `default` CF stores the Raft log. The corresponding parameters are in `[raftdb.defaultcf]`.

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under `[storage.block-cache]`. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied.

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

11.2.4.1 Parameter specification

```
### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
### Set listening address
### addr = "127.0.0.1:20160"

### Size of thread pool for gRPC
### grpc-concurrency = 4
### The number of gRPC connections between each TiKV instance
### grpc-raft-conn-num = 10

### Most read requests from TiDB are sent to the coprocessor of TiKV. This
   ↪ parameter is used to set the number of threads
```

```
### of the coprocessor. If many read requests exist, add the number of
    ↪ threads and keep the number within that of the
### system CPU cores. For example, for a 32-core machine deployed with TiKV,
    ↪  you can even set this parameter to 30 in
### repeatable read scenarios. If this parameter is not set, TiKV
    ↪ automatically sets it to CPU cores * 0.8.
### end-point-concurrency = 8

### Tag the TiKV instances to schedule replicas.
### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
### The data directory
### data-dir = "/tmp/tikv/store"

### In most cases, you can use the default value. When importing data, it is
    ↪  recommended to set the parameter to 1024000.
### scheduler-concurrency = 102400
### This parameter controls the number of write threads. When write
    ↪ operations occur frequently, set this parameter value
### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker-
    ↪ pool` are busy, set the value of parameter
### `scheduler-worker-pool-size` higher and increase the number of write
    ↪ threads.
### scheduler-worker-pool-size = 4

[storage.block-cache]
#### Whether to create a shared block cache for all RocksDB column families.
#### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
    ↪ block cache can speed up read.
#### It is recommended to turn on shared block cache. Since only the total
    ↪ cache size need to be
#### set, it is easier to configure. In most cases, it should be able to
    ↪ auto-balance cache usage
#### between column families with standard LRU algorithm.
#### ## The rest of config in the storage.block-cache session is effective
    ↪ only when shared block cache
#### is on.
#### Starting from v6.6.0, the `shared` option is always enabled and cannot
    ↪ be disabled.
### shared = true

#### Size of the shared block cache. Normally it should be tuned to 30%-50%
    ↪ of system's total memory.
#### When the config is not set, it is decided by the sum of the following
```

```
   ↪ fields or their default
#### value:
####  * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
####  * rocksdb.writecf.block-cache-size or 15% of system's total memory
####  * rocksdb.lockcf.block-cache-size or 2% of system's total memory
####  * raftdb.defaultcf.block-cache-size or 2% of system's total memory
#### ## To deploy multiple TiKV nodes on a single physical machine,
   ↪ configure this parameter explicitly.
#### Otherwise, the OOM problem might occur in TiKV.
### capacity = "1GiB"

[pd]
### PD address
### endpoints = ["127.0.0.1:2379","127.0.0.2:2379","127.0.0.3:2379"]

[metric]
### The interval of pushing metrics to Prometheus Pushgateway
interval = "15s"
### Prometheus Pushgateway address
address = ""
job = "tikv"

[raftstore]
### Raft RocksDB directory. The default value is Raft subdirectory of [
   ↪ storage.data-dir].
### If there are multiple disks on the machine, store the data of Raft
   ↪ RocksDB on different disks to improve TiKV performance.
### raftdb-path = "/tmp/tikv/store/raft"

### When the data size change in a Region is larger than the threshold value
   ↪ , TiKV checks whether this Region needs split.
### To reduce the costs of scanning data in the checking process, set the
   ↪ value to 32 MiB during the data import process. In the normal
   ↪ operation status, set it to the default value.
region-split-check-diff = "32MiB"

[coprocessor]
#### If the size of a Region with the range of [a,e) is larger than the
   ↪ value of `region_max_size`, TiKV tries to split the Region to several
   ↪  Regions, for example, the Regions with the ranges of [a,b), [b,c), [
   ↪ c,d), and [d,e).
#### After the Region split, the size of the split Regions is equal to the
   ↪ value of `region_split_size` (or slightly larger than the value of `
   ↪ region_split_size`).
### region-max-size = "144MiB"
```

```
### region-split-size = "96MiB"

[rocksdb]
### The maximum number of threads of RocksDB background tasks. The
   ↪ background tasks include compaction and flush.
### For detailed information why RocksDB needs to implement compaction, see
   ↪ RocksDB-related materials. When write
### traffic (like the importing data size) is big, it is recommended to
   ↪ enable more threads. But set the number of the enabled
### threads smaller than that of CPU cores. For example, when importing data
   ↪ , for a machine with a 32-core CPU,
### set the value to 28.
### max-background-jobs = 8

### The maximum number of file handles RocksDB can open
### max-open-files = 40960

### The file size limit of RocksDB MANIFEST. For more details, see https://
   ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MiB"

### The directory of RocksDB write-ahead logs. If there are two disks on the
   ↪  machine, store the RocksDB data and WAL logs
### on different disks to improve TiKV performance.
### wal-dir = "/tmp/tikv/store"

### Use the following two parameters to deal with RocksDB archiving WAL.
### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
   ↪ persist-in-memory-RocksDB-database%3F
### wal-ttl-seconds = 0
### wal-size-limit = 0

### In most cases, set the maximum total size of RocksDB WAL logs to the
   ↪ default value.
### max-total-wal-size = "4GiB"

### Use this parameter to enable the readahead feature during RocksDB
   ↪ compaction. If you are using mechanical disks, it is recommended to
   ↪ set the value to 2MiB at least.
### compaction-readahead-size = "2MiB"

[rocksdb.defaultcf]
### The data block size. RocksDB compresses data based on the unit of block.
### Similar to page in other databases, block is the smallest unit cached in
   ↪  block-cache.
```

```
block-size = "64KB"

### The compaction mode of each layer of RocksDB data. The optional values
    ↪ include no, snappy, zlib,
### bzip2, lz4, lz4hc, and zstd. Note that the Snappy compressed file must
    ↪ be in the [official Snappy format](https://github.com/google/snappy).
    ↪  Other variants of Snappy compression are not supported.
### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of level0
    ↪  and level1; lz4 compaction algorithm is used
### from level2 to level4; zstd compaction algorithm is used from level5 to
    ↪ level6.
### "no" means no compaction. "lz4" is a compaction algorithm with moderate
    ↪ speed and compaction ratio. The
### compaction ratio of zlib is high. It is friendly to the storage space,
    ↪ but its compaction speed is slow. This
### compaction occupies many CPU resources. Different machines deploy
    ↪ compaction modes according to CPU and I/O resources.
### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
    ↪ zstd" and find much I/O pressure of the
### system (run the iostat command to find %util lasts 100%, or run the top
    ↪ command to find many iowaits) when writing
### (importing) a lot of data while the CPU resources are adequate, you can
    ↪ compress level0 and level1 and exchange CPU
### resources for I/O resources. If you use the compaction mode of "no:no:
    ↪ lz4:lz4:lz4:zstd:zstd" and you find the I/O
### pressure of the system is not big when writing a lot of data, but CPU
    ↪ resources are inadequate. Then run the top
### command and choose the -H option. If you find a lot of bg threads (
    ↪ namely the compaction thread of RocksDB) are
### running, you can exchange I/O resources for CPU resources and change the
    ↪  compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
### In a word, it aims at making full use of the existing resources of the
    ↪ system and improving TiKV performance
### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### The RocksDB memtable size
write-buffer-size = "128MiB"

### The maximum number of the memtables. The data written into RocksDB is
    ↪ first recorded in the WAL log, and then inserted
### into memtables. When the memtable reaches the size limit of `write-
    ↪ buffer-size`, it turns into read only and generates
### a new memtable receiving new write operations. The flush threads of
    ↪ RocksDB will flush the read only memtable to the
```

```
### disks to become an sst file of level0. `max-background-flushes` controls
    ↪  the maximum number of flush threads. When the
### flush threads are busy, resulting in the number of the memtables waiting
    ↪  to be flushed to the disks reaching the limit
### of `max-write-buffer-number`, RocksDB stalls the new operation.
### "Stall" is a flow control mechanism of RocksDB. When importing data, you
    ↪  can set the `max-write-buffer-number` value
### higher, like 10.
max-write-buffer-number = 5

### When the number of sst files of level0 reaches the limit of `level0-
    ↪ slowdown-writes-trigger`, RocksDB
### tries to slow down the write operation, because too many sst files of
    ↪ level0 can cause higher read pressure of
### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
    ↪ trigger` are for the flow control of RocksDB.
### When the number of sst files of level0 reaches 4 (the default value),
    ↪ the sst files of level0 and the sst files
### of level1 which overlap those of level0 implement compaction to relieve
    ↪ the read pressure.
level0-slowdown-writes-trigger = 20

### When the number of sst files of level0 reaches the limit of `level0-stop
    ↪ -writes-trigger`, RocksDB stalls the new
### write operation.
level0-stop-writes-trigger = 36

### When the level1 data size reaches the limit value of `max-bytes-for-
    ↪ level-base`, the sst files of level1
### and their overlap sst files of level2 implement compaction. The golden
    ↪ rule: the first reference principle
### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
    ↪ bytes-for-level-base` value is roughly equal to the
### data volume of level0. Thus unnecessary compaction is reduced. For
    ↪ example, if the compaction mode is
### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
    ↪ write-buffer-size * 4, because there is no
### compaction of level0 and level1 and the trigger condition of compaction
    ↪ for level0 is that the number of the
### sst files reaches 4 (the default value). When both level0 and level1
    ↪ adopt compaction, it is necessary to analyze
### RocksDB logs to know the size of an sst file compressed from an mentable
    ↪ . For example, if the file size is 32MB,
### the proposed value of `max-bytes-for-level-base` is 32MiB * 4 = 128MiB.
max-bytes-for-level-base = "512MiB"
```

```
### The sst file size. The sst file size of level0 is influenced by the
    ↪ compaction algorithm of `write-buffer-size`
### and level0. `target-file-size-base` is used to control the size of a
    ↪ single sst file of level1-level6.
target-file-size-base = "32MiB"

[rocksdb.writecf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MiB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MiB"
target-file-size-base = "32MiB"

[raftdb]
### The maximum number of the file handles RaftDB can open
### max-open-files = 40960

### Enable the readahead feature in RaftDB compaction. If you are using
    ↪ mechanical disks, it is recommended to set
### this value to 2MB at least.
### compaction-readahead-size = "2MiB"

[raftdb.defaultcf]
### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MiB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MiB"
target-file-size-base = "32MiB"
```

11.2.4.2 TiKV memory usage

Besides `block cache` and `write buffer` which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.
- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

11.2.4.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GiB.
- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

11.2.5 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

11.2.5.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

> **Note:**
>
> To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

11.2.5.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` variable as follows:

```
set [session | global] tidb_replica_read = '<target value>';
```

Scope: SESSION | GLOBAL

Default: leader

This variable is used to set the expected data read mode.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its default behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations. In this mode, read requests are load balanced between the leader and follower.
- When the value of `tidb_replica_read` is set to `prefer-leader`, TiDB prefers to select the leader replica to perform read operations. If the leader replica is obviously slow in processing read operations (such as caused by disk or network performance jitter), TiDB will select other available follower replicas to perform read operations.
- When the value of `tidb_replica_read` is set to `closest-replicas`, TiDB prefers to select a replica in the same availability zone to perform read operations, which can be a leader or a follower. If there is no replica in the same availability zone, TiDB reads from the leader replica.
- When the value of `tidb_replica_read` is set to `closest-adaptive`:
    - If the estimated result of a read request is greater than or equal to the value of `tidb_adaptive_closest_read_threshold`, TiDB prefers to select a replica in the same availability zone for read operations. To avoid unbalanced distribution of read traffic across availability zones, TiDB dynamically detects the distribution of availability zones for all online TiDB and TiKV nodes. In each availability zone, the number of TiDB nodes whose `closest-adaptive` configuration takes effect is limited, which is always the same as the number of TiDB nodes in the availability zone with the fewest TiDB nodes, and the other TiDB nodes automatically read from the leader replica. For example, if TiDB nodes are distributed across 3 availability zones (A, B, and C), where A and B each contains 3 TiDB nodes and C contains only 2 TiDB nodes, the number of TiDB nodes whose `closest-adaptive` configuration takes effect in each availability zone is 2, and the other TiDB node in each of the A and B availability zones automatically selects the leader replica for read operations.

- If the estimated result of a read request is less than the value of `tidb_adaptive_closest_read_threshold`, TiDB can only select the leader replica for read operations.

- When the value of `tidb_replica_read` is set to `learner`, TiDB reads data from the learner replica. If there is no learner replica in the Region, TiDB returns an error.

> **Note:**
>
> When the value of `tidb_replica_read` is set to `closest-replicas` or `closest-adaptive`, you need to configure the cluster to ensure that replicas are distributed across availability zones according to the specified configuration. To configure `location-labels` for PD and set the correct `labels` for TiDB and TiKV, refer to Schedule replicas by topology labels. TiDB depends on the `zone` label to match TiKV nodes in the same availability zone, so you need to make sure that the `zone` label is included in the `location-labels` of PD and `zone` is included in the configuration of each TiDB and TiKV node. If your cluster is deployed using TiDB Operator, refer to High availability of data.

11.2.5.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

11.2.5.3.1 Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

11.2.5.3.2 Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted. If a transaction contains both point queries and coprocessor requests, the two types of requests are scheduled for reading separately according to the preceding scheduling policy. In this case, even if a coprocessor request and a point query are for the same Region, TiDB processes them as independent events.

11.2.6 TiKV MVCC In-Memory Engine

TiKV MVCC In-Memory Engine (IME) is primarily used to accelerate queries that need to scan a large number of MVCC historical versions, that is, the total number of versions scanned (`total_keys`) is much greater than the number of versions processed (`processed_keys`).

TiKV MVCC in-memory engine is suitable for the following scenarios:

- The application that requires querying records that are frequently updated or deleted.
- The application that requires adjusting `tidb_gc_life_time` to retain historical versions in TiDB for a longer period (for example, 24 hours).

11.2.6.1 Implementation principles

The TiKV MVCC in-memory engine caches the latest written MVCC versions in memory, and implements an MVCC GC mechanism independent of TiDB. This allows it to quickly perform GC on MVCC versions in memory, reducing the number of versions scanned during queries, thereby lowering request latency and reducing CPU overhead.

The following diagram illustrates how TiKV organizes MVCC versions:

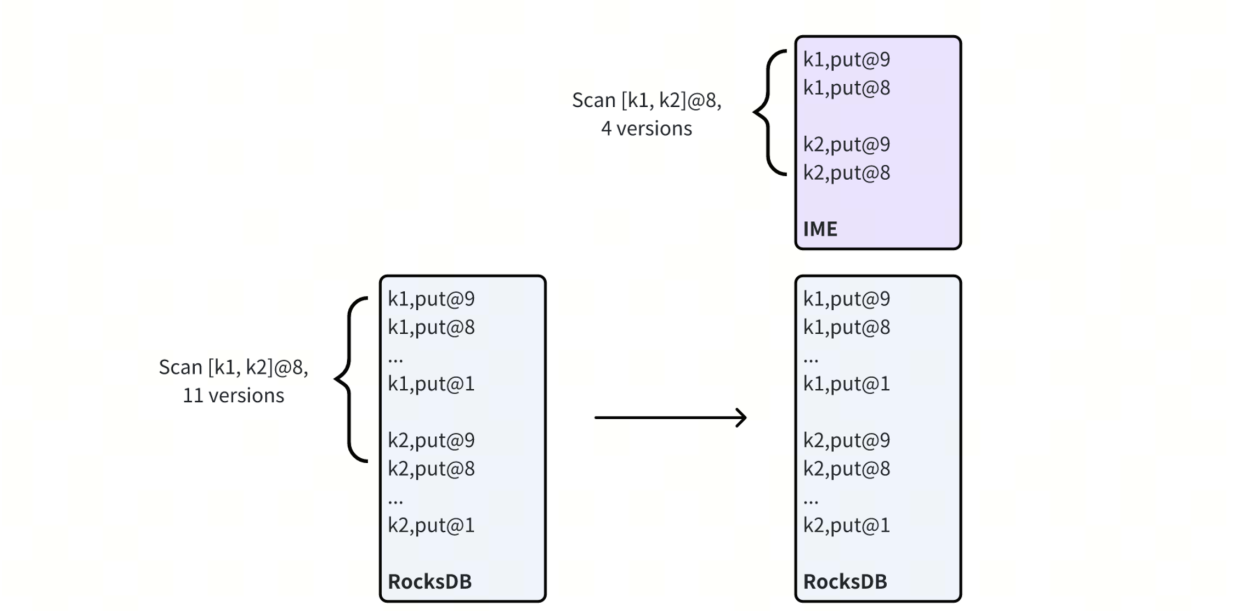

Figure 430: IME caches recent versions to reduce CPU overhead

The preceding diagram shows two rows of records, each with 9 MVCC versions. The behavior comparison between enabling and not enabling the in-memory engine is as follows:

- On the left (in-memory engine disabled): the table records are stored in RocksDB in ascending order by the primary key, with all MVCC versions of the same row adjacent to each other.
- On the right (in-memory engine enabled): the data in RocksDB is the same as that on the left, but the in-memory engine caches the two latest MVCC versions for each of the two rows.
- When TiKV processes a scan request with a range of `[k1, k2]` and a start timestamp of `8`:
  - Without the in-memory engine (left), it needs to process 11 MVCC versions.
  - With the in-memory engine (right), it only processes 4 MVCC versions, reducing request latency and CPU consumption.
- When TiKV processes a scan request with a range of `[k1, k2]` and a start timestamp of `7`:
  - Because the required historical versions are missing in the in-memory engine (right), the cache becomes invalid, and TiKV falls back to reading data from RocksDB.

11.2.6.2 Usage

To enable the TiKV MVCC in-memory engine (IME), you need to adjust the TiKV configuration and restart TiKV. The configuration details are as follows:

```
[in-memory-engine]
### This parameter is the switch for the in-memory engine feature, which is
    ↪ disabled by default. You can set it to true to enable it.
### It is recommended to configure at least 8 GiB of memory for the TiKV
    ↪ node, with 32 GiB or more for optimal performance.
### If the available memory for the TiKV node is insufficient, the in-memory
    ↪  engine will not be enabled even if this configuration item is set to
    ↪  true. In such cases, check the TiKV log file for messages containing
    ↪  "in-memory engine is disabled because" to learn why the in-memory
    ↪ engine is not enabled.
enable = false

### This parameter controls the memory size available to the in-memory
    ↪ engine.
### The default value is 10% of the system memory, and the maximum value is
    ↪ 5 GiB.
### You can manually adjust this configuration to allocate more memory.
### Note: When the in-memory engine is enabled, block-cache.capacity
    ↪ automatically decreases by 10%.
capacity = "5GiB"

### This parameter controls the time interval for the in-memory engine to GC
    ↪  the cached MVCC versions.
### The default value is 3 minutes, representing that GC is performed every
    ↪ 3 minutes on the cached MVCC versions.
### Decreasing the value of this parameter can increase the GC frequency,
    ↪ reduce the number of MVCC versions, but will increase CPU consumption
    ↪  for GC and increase the probability of in-memory engine cache miss.
gc-run-interval = "3m"

### This parameter controls the threshold for the in-memory engine to select
    ↪  and load Regions based on MVCC read amplification.
### The default value is 10, indicating that if reading a single row in a
    ↪ Region requires processing more than 10 MVCC versions, this Region
    ↪ might be loaded into the in-memory engine.
mvcc-amplification-threshold = 10
```

Note:

- The in-memory engine is disabled by default. After you enable it, you need to restart TiKV.

- Except for `enable`, all the other configuration items can be dynamically adjusted.

11.2.6.2.1 Automatic loading

After you enable the in-memory engine, TiKV automatically selects the Regions to load based on the read traffic and MVCC amplification of the Region. The specific process is as follows:

1. Regions are sorted based on the number of recent `next` (RocksDB Iterator next API) and `prev` (RocksDB Iterator prev API) calls.
2. Regions are filtered using the `mvcc-amplification-threshold` configuration parameter. The default value is `10`. MVCC amplification measures read amplification, calculated as (`next` + `prev`) / `processed_keys`.
3. The top N Regions with severe MVCC amplification are loaded, where N is determined based on memory estimation.

The in-memory engine also periodically evicts Regions. The process is as follows:

1. The in-memory engine evicts Regions with low read traffic or low MVCC amplification.
2. If memory usage reaches 90% of `capacity` and new Regions need to be loaded, then the in-memory engine selects and evicts Regions based on read traffic.

11.2.6.3 Compatibility

- BR: the in-memory engine can be used alongside BR. However, during a BR restore, the Regions involved in the restore process are evicted from the in-memory engine. After the BR restore is complete, if the corresponding Regions remain hotspots, they will be automatically loaded by the in-memory engine.
- TiDB Lightning: the in-memory engine can be used alongside TiDB Lightning. However, when TiDB Lightning operates in physical import mode, it evicts the Regions involved in the restore process from the in-memory engine. Once the physical import is complete, if the corresponding Regions remain hotspots, they will be automatically loaded by the in-memory engine.
- Follower Read and Stale Read: the in-memory engine can be used alongside these two features. However, the in-memory engine can only accelerate coprocessor requests on the Leader, and cannot accelerate Follower Read and Stale Read operations.
- `FLASHBACK CLUSTER`: the in-memory engine can be used alongside Flashback. However, Flashback invalidates the in-memory engine cache. After the Flashback process is complete, the in-memory engine will automatically load hotspot Regions.

11.2.6.4 FAQ

11.2.6.4.1 Can the in-memory engine reduce write latency and increase write throughput?

No. The in-memory engine can only accelerate read requests that scan a large number of MVCC versions.

11.2.6.4.2 How to determine if the in-memory engine can improve my scenario?

You can execute the following SQL statement to check if there are slow queries with `Total_keys` much greater than `Process_keys`:

```
SELECT
    Time,
    DB,
    Index_names,
    Process_keys,
    Total_keys,
    CONCAT(
        LEFT(REGEXP_REPLACE(Query, '\\s+', ' '), 20),
        '...',
        RIGHT(REGEXP_REPLACE(Query, '\\s+', ' '), 10)
    ) as Query,
    Query_time,
    Cop_time,
    Process_time
FROM
    INFORMATION_SCHEMA.SLOW_QUERY
WHERE
    Is_internal = 0
    AND Cop_time > 1
    AND Process_keys > 0
    AND Total_keys / Process_keys >= 10
    AND Time >= NOW() - INTERVAL 10 MINUTE
ORDER BY Total_keys DESC
LIMIT 5;
```

Example:

The following result shows that queries with severe MVCC amplification exist on the `db1.tbl1` table. TiKV processes 1358517 MVCC versions and only returns 2 versions.

```

11.2.6.4.3 How can I check whether the TiKV MVCC in-memory engine is enabled?

You can check the TiKV configuration using the `SHOW CONFIG` statement. If the value of `in-memory-engine.enable` is `true`, it means that TiKV MVCC in-memory engine is enabled.

```
SHOW CONFIG WHERE Type='tikv' AND Name LIKE 'in-memory-engine\.%';
```

```
+------+----------------+-------------------------------------------------+---------+
   ↪
| Type | Instance     | Name                                            | Value   |
+------+----------------+-------------------------------------------------+---------+
   ↪
| tikv | 127.0.0.1:20160 | in-memory-engine.capacity                     | 5GiB    |

11.2.6.4.4 How can I monitor the TiKV MVCC in-memory engine?

You can check the **In Memory Engine** section on the **TiKV-Details** dashboard in Grafana.

11.2.7 Tune Region Performance

This document introduces how to tune Region performance by adjusting the Region size and how to use bucket to optimize concurrent queries when the Region size is large. In addition, this document introduces how to enhance the ability of PD to provide Region information to TiDB nodes by enabling the Active PD Follower feature.

11.2.7.1 Overview

TiKV automatically shards bottom-layered data. Data is split into multiple Regions based on the key ranges. When the size of a Region exceeds a threshold, TiKV splits it into two or more Regions.

In scenarios involving large datasets, if the Region size is relatively small, TiKV might have too many Regions, which causes more resource consumption and performance regression.

> **Note:**
>
> - In v6.1.0, TiDB supports customizing Region size as an experimental feature.
> - Starting from v6.5.0, this feature becomes generally available (GA).
> - Starting from v8.4.0, the default size of the Region is resized from 96 MiB to 256 MiB. Increasing the Region size can reduce the number of Regions.

To reduce the performance overhead of many Regions, you can also enable Hibernate Region or `Region Merge`.

11.2.7.2 Use `region-split-size` to adjust Region size

> **Note:**
>
> The recommended range for the Region size is [48 MiB, 256 MiB]. Commonly used sizes include 96 MiB, 128 MiB, and 256 MiB. It is NOT recommended to set the Region size beyond 1 GiB. Avoid setting the size to more than 10 GiB. An excessively large Region size might result in the following side effects:
>
> - Performance jitters
> - Decreased query performance, especially for queries that deal with a large range of data
> - Slower Region scheduling

To adjust the Region size, you can use the `coprocessor.region-split-size` configuration item. When TiFlash or the Dumpling tool is used, the Region size should not exceed 1 GiB. After increasing the Region size, you need to reduce the concurrency if the Dumpling tool is used; otherwise, TiDB might run out of memory.

11.2.7.3 Use bucket to increase concurrency

> **Warning:**
>
> Currently, this is an experimental feature introduced in TiDB v6.1.0. It is not recommended that you use it in production environments.

After Regions are set to a larger size, if you want to further improve the query concurrency, you can set `coprocessor.enable-region-bucket` to `true`. When you use this configuration, Regions are divided into buckets. Buckets are smaller ranges within a Region and are used as the unit of concurrent query to improve the scan concurrency. You can control the bucket size using `coprocessor.region-bucket-size`.

11.2.7.4 Use the Active PD Follower feature to enhance the scalability of PD's Region information query service

In a TiDB cluster with a large number of Regions, the PD leader might experience high CPU load due to the increased overhead of handling heartbeats and scheduling tasks. If the cluster has many TiDB instances, and there is a high concurrency of requests for Region information, the CPU pressure on the PD leader increases further and might cause PD services to become unavailable.

To ensure high availability, the PD leader synchronizes Region information with its followers in real time. PD followers maintain and store Region information in memory, enabling them to process Region information requests. You can enable the Active PD Follower feature by setting the system variable `pd_enable_follower_handle_region` to `ON`. After this feature is enabled, TiDB evenly distributes Region information requests to all PD servers, and PD followers can also directly handle Region requests, thereby reducing the CPU pressure on the PD leader.

PD ensures that the Region information in TiDB is always up-to-date by maintaining the status of Region synchronization streams and using the fallback mechanism of TiKV client-go.

- When the network between the PD leader and a follower is unstable or a follower is unavailable, the Region synchronization stream is disconnected, and the PD follower rejects Region information requests. In this case, TiDB automatically retries the request to the PD leader and temporarily marks the follower as unavailable.
- When the network is stable, because there might be a delay in the synchronization between the leader and the follower, some Region information obtained from the follower might be outdated. In this case, if the KV request corresponding to the Region fails, TiDB automatically re-requests the latest Region information from the PD leader and sends the KV request to TiKV again.

11.2.8 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash by properly planning machine resources and tuning TiDB parameters. By following these methods, your TiFlash cluster can achieve optimal performance.

11.2.8.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

11.2.8.2 Tune TiDB parameters

This section describes how to improve TiFlash performance by tuning TiDB parameters, including:

- Forcibly enable the MPP mode
- Push down aggregate functions to a position before `Join` or `Union`
- Enable `Distinct` optimization
- Compact data using the `ALTER TABLE ... COMPACT` statement
- Replace Shuffled Hash Join with Broadcast Hash Join
- Set a greater execution concurrency
- Configure `tiflash_fine_grained_shuffle_stream_count`

11.2.8.2.1 Forcibly enable the MPP mode

MPP execution plans can fully utilize distributed computing resources, thereby significantly improving the efficiency of batch data queries. When the optimizer does not generate an MPP execution plan for a query, you can forcibly enable the MPP mode:

The variable `tidb_enforce_mpp` controls whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution. To enable MPP mode forcibly, run the following command:

```
set @@tidb_enforce_mpp = ON;
```

The following example shows the query result before and after `tidb_enforce_mpp` is enabled. Before this variable is enabled, TiDB needs to read data from TiKV and execute `Join` and `Aggregation` in TiDB. After `tidb_enforce_mpp` is enabled, `Join` and `Aggregation` are pushed down to TiFlash. In addition, because the optimizer does not necessarily generate MPP execution plans, by enabling `tidb_enforce_mpp`, you can force the optimizer to generate MPP execution plans.

Before MPP mode is enabled:

```

11.2.8.2.2 Push down aggregate functions to a position before Join or Union

By pushing down aggregate operations to the position before `Join` or `Union`, you can reduce the data to be processed in the `Join` or `Union` operation, thereby improving performance.

The variable `tidb_opt_agg_push_down` controls whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before `Join` or `Union`. When the aggregate operations are quite slow in the query, you can set this variable to `ON`.

```
set @@tidb_opt_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_agg_push_down` variable is enabled. Before this variable is enabled, the `HashAgg_58` operation

is executed following the `HashJoin_41` operation. After this variable is enabled, newly generated `HashAgg_21` and `HashAgg_32` operations are executed before the `HashJoin_76` operation. This significantly reduces the data to be processed by the `Join` operation.

Before `tidb_opt_agg_push_down` is enabled:

```
mysql> explain analyze select count(*) from t1 join t2 where t1.a = t2.b
    ↪ group by t1.a;

11.2.8.2.3 Enable `Distinct` optimization

TiFlash does not support some aggregate functions that accept the `Distinct` column, such as `Sum`. By default, the entire aggregate function is calculated in TiDB. By enabling the `Distinct` optimization, some operations can be pushed down to TiFlash, thereby improving query performance.

If the aggregate function with the `distinct` operation is slow in a query, you can enable the optimization operation of pushing down the aggregate function with `Distinct` (such as `select sum(distinct a)from t`) to Coprocessor by setting the value of the `tidb_opt_distinct_agg_push_down` variable to `ON`.

```
set @@tidb_opt_distinct_agg_push_down = ON;
```

The following example shows the query result before and after the `tidb_opt_distinct_agg_push_down` variable is enabled. Before this variable is enabled, TiDB needs to read all data from TiFlash and execute `distinct` in TiDB. After this variable is enabled, `distinct a` is pushed down to TiFlash, and a new `group by` column `test.t.a` is added in `HashAgg_6`. The two warnings in the query result indicate that the aggregate function cannot be fully pushed down to TiFlash.

Before `tidb_opt_distinct_agg_push_down` is enabled:

```

11.2.8.2.4 Compact data using the `ALTER TABLE ... COMPACT` statement

Executing the `ALTER TABLE ... COMPACT` statement can initiate compaction for a specific table or partition on a TiFlash node. During the compaction, the physical data on the node is rewritten, including cleaning up deleted rows and merging multiple versions of data caused by updates. This helps enhance access performance and reduce disk usage. The following are examples:

```
ALTER TABLE employees COMPACT TIFLASH REPLICA;
```

```
ALTER TABLE employees COMPACT PARTITION pNorth, pEast TIFLASH REPLICA;
```

11.2.8.2.5 Replace Shuffled Hash Join with Broadcast Hash Join

For `Join` operations with small tables, the Broadcast Hash Join algorithm can avoid transferring large tables, thereby improving the computing performance.

- The `tidb_broadcast_join_threshold_size` variable controls whether to use the Broadcast Hash Join algorithm. If the table size (unit: byte) is smaller than the value

of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

```
set @@tidb_broadcast_join_threshold_size = 2000000;
```

- The tidb_broadcast_join_threshold_count variable also controls whether to use the Broadcast Hash Join algorithm. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set. In this situation, the size is determined by the number of rows in the result set. If the estimated number of rows for the subquery is fewer than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

```
set @@tidb_broadcast_join_threshold_count = 100000;
```

The following example shows the query result before and after `tidb_broadcast_join_threshold_size` is re-configured. Before the re-configuration, the `ExchangeType` of `ExchangeSender_29` is `HashPartition`. After the value of this variable changes to `10000000`, the `ExchangeType` of `ExchangeSender_29` changes to `Broadcast`.

Before `tidb_broadcast_join_threshold_size` is re-configured:

```

```

TiFlash to execute a request. The unit is threads.

```
set @@tidb_max_tiflash_threads = 20;
```

The following example shows the query result before and after `tidb_max_tiflash_threads` is re-configured. Before `tidb_max_tiflash_threads` is set, the concurrency of request execution for a single TiFlash instance is 8 threads. Since the cluster has a total of 3 TiFlash instances, the total number of threads for request execution on all TiFlash instances is 24 (8 × 3). After `tidb_max_tiflash_threads` is set to 20, the total number of threads for request execution on all TiFlash instances is 60 (20 × 3).

Before `tidb_max_tiflash_threads` is re-configured:

```

11.2.8.2.7 Configure `tiflash_fine_grained_shuffle_stream_count`

You can increase the concurrency for executing window functions by configuring `tiflash_fine_grained_shuffle_stream_count` of the Fine Grained Shuffle feature. In this way, the execution of window functions can occupy more system resources, which improves query performance.

When a window function is pushed down to TiFlash for execution, you can use this variable to control the concurrency level of the window function execution. The unit is threads.

```
set @@tiflash_fine_grained_shuffle_stream_count = 20;
```

The following example shows the query result before and after the `tiflash_fine_grained_shuffle_stream_count` variable is re-configured. Before the re-configuration, the `stream_count` of `[ExchangeSender_11, ExchangeReceiver_12, Sort_13, Window_22]` is 8. After the re-configuration, the `stream_count` becomes 20.

Before `tiflash_fine_grained_shuffle_stream_count` is re-configured:

```
mysql> explain analyze select *, row_number() over (partition by a) from t;
+--

11.2.9 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

11.2.9.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see TiDB Configuration File.

11.2.9.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.
- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.

- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
    - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.

      In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
    - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
    - The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

      In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

11.2.9.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

11.2.9.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in Operators for accessing tables by using the `EXPLAIN ANALYZE` statement. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);
+--
   ↪ ----------------------------+----------+---------+-----------+---------------
   ↪
| id                          | estRows  | actRows | task    | access object
   ↪       | execution info
   ↪
   ↪ | operator info              | memory             | disk |
+--
   ↪ ----------------------------+----------+---------+-----------+---------------
   ↪
| IndexLookUp_6               | 262400.00 | 262400 | root    |
   ↪                       | time:620.513742ms, loops:258, cop_task: {num:
   ↪ 4, max: 5.530817ms, min: 1.51829ms, avg: 2.70883ms, p95: 5.530817ms,
```

```
    ↪ max_proc_keys: 2480, p95_proc_keys: 2480, tot_proc: 1ms, tot_wait: 1
    ↪ ms, rpc_num: 4, rpc_time: 10.816328ms, copr_cache_hit_rate: 0.75} | |
    ↪  6.685169219970703 MB | N/A |
|  ─IndexFullScan_4(Build)   | 262400.00 | 262400 | cop[tikv] | table:t,
    ↪ index:a(a, c) | proc max:93ms, min:1ms, p80:93ms, p95:93ms, iters
    ↪ :275, tasks:4
    ↪
    ↪ | keep order:false, stats:pseudo | 1.7549400329589844 MB | N/A |
|  ─TableRowIDScan_5(Probe)  | 262400.00 | 0     | cop[tikv] | table:t
    ↪            | time:0ns, loops:0
    ↪
    ↪ | keep order:false, stats:pseudo | N/A             | N/A |
+--
    ↪ ----------------------------+----------+---------+----------+----------------
    ↪
3 rows in set (0.62 sec)
```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The `0.75` in the above example means that the hit rate is about 75%.

11.2.9.3.2 View the Grafana monitoring panel

In Grafana, you can see the **copr-cache** panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

11.2.10 Garbage Collection (GC)

11.2.10.1 GC Overview

TiDB uses MVCC to control transaction concurrency. When you update the data, the original data is not deleted immediately but is kept together with the new data, with a timestamp to distinguish the version. The goal of Garbage Collection (GC) is to clear the obsolete data.

11.2.10.1.1 GC process

Each TiDB cluster contains a TiDB instance that is selected as the GC leader, which controls the GC process.

GC runs periodically on TiDB. For each GC, TiDB firstly calculates a timestamp called "safe point". Then, TiDB clears the obsolete data under the premise that all the snapshots after the safe point retain the integrity of the data. Specifically, there are three steps involved in each GC process:

1. Resolve Locks. During this step, TiDB scans locks before the safe point on all Regions and clears these locks.
2. Delete Ranges. During this step, the obsolete data of the entire range generated from the `DROP TABLE/DROP INDEX` operation is quickly cleared.
3. Do GC. During this step, each TiKV node scans data on it and deletes unneeded old versions of each key.

In the default configuration, GC is triggered every 10 minutes. Each GC retains data of the recent 10 minutes, which means that the GC life time is 10 minutes by default (safe point = the current time - GC life time). If one round of GC has been running for too long, before this round of GC is completed, the next round of GC will not start even if it is time to trigger the next GC. In addition, for long-duration transactions to run properly after exceeding the GC life time, the safe point does not exceed the start time (start_ts) of the ongoing transactions.

11.2.10.1.2 Implementation details

Resolve Locks

The TiDB transaction model is implemented based on Google's Percolator. It's mainly a two-phase commit protocol with some practical optimizations. When the first phase is finished, all the related keys are locked. Among these locks, one is the primary lock and the others are secondary locks which contain a pointer to the primary lock; in the second phase, the key with the primary lock gets a write record and its lock is removed. The write record indicates the write or delete operation in the history or the transactional rollback record of this key. The type of write record that replaces the primary lock indicates whether the corresponding transaction is committed successfully. Then all the secondary locks are replaced successively. If, for some reason such as failure, these secondary locks are retained and not replaced, you can still find the primary key based on the information in the secondary locks and determines whether the entire transaction is committed based on whether the primary key is committed. However, if the primary key information is cleared by GC and this transaction has uncommitted secondary locks, you will never learn whether these locks can be committed. As a result, data integrity cannot be guaranteed.

The Resolve Locks step clears the locks before the safe point. This means that if the primary key of a lock is committed, this lock needs to be committed; otherwise, it needs to be rolled back. If the primary key is still locked (not committed or rolled back), this transaction is seen as timing out and rolled back.

The Resolve Locks step is implemented in either of the following two ways, which can be configured using the system variable `tidb_gc_scan_lock_mode`:

> **Warning:**
>
> Currently, `PHYSICAL` (Green GC) is an experimental feature. It is not recommended that you use it in the production environment.

- `LEGACY` (default): The GC leader sends requests to all Regions to scan obsolete locks, checks the primary key statuses of scanned locks, and sends requests to commit or roll back the corresponding transaction.
- `PHYSICAL`: TiDB bypasses the Raft layer and directly scans data on each TiKV node.

Delete Ranges

A great amount of data with consecutive keys is removed during operations such as `DROP TABLE/INDEX`. Removing each key and performing GC later for them can result in low execution efficiency on storage reclaiming. In such scenarios, TiDB actually does not delete each key. Instead, it only records the range to be removed and the timestamp of the deletion. Then the Delete Ranges step performs a fast physical deletion on the ranges whose timestamp is before the safe point.

Do GC

The Do GC step clears the outdated versions for all keys. To guarantee that all timestamps after the safe point have consistent snapshots, this step deletes the data committed before the safe point, but retains the last write for each key before the safe point as long as it is not a deletion.

In this step, TiDB only needs to send the safe point to PD, and then the whole round of GC is completed. TiKV automatically detects the change of safe point and performs GC for all Region leaders on the current node. At the same time, the GC leader can continue to trigger the next round of GC.

> **Note:**
>
> Starting with TiDB 5.0, the Do GC step will always use the `DISTRIBUTED` gc mode. This replaces the earlier `CENTRAL` gc mode, which was implemented by TiDB servers sending GC requests to each Region.

11.2.10.2 Garbage Collection Configuration

You can configure garbage collection (GC) using the following system variables:

- `tidb_gc_enable`: controls whether to enable garbage collection for TiKV.
- `tidb_gc_run_interval`: specifies the GC interval.
- `tidb_gc_life_time`: specifies the time limit during which data is retained for each GC.
- `tidb_gc_concurrency`: specifies the number of threads in the Resolve Locks step of GC.
- `tidb_gc_scan_lock_mode`: specifies the way of scanning locks in the Resolve Locks step of GC.

- `tidb_gc_max_wait_time`: specifies the maximum time that active transactions block the GC safe point.

For more information about how to modify the value of a system variable, see System variables.

11.2.10.2.1 GC I/O limit

TiKV supports the GC I/O limit. You can configure `gc.max-write-bytes-per-sec` to limit writes of a GC worker per second, and thus to reduce the impact on normal requests.

`0` indicates disabling this feature.

You can dynamically modify this configuration using tikv-ctl:

```
tikv-ctl --host=ip:port modify-tikv-config -n gc.max-write-bytes-per-sec -v
    ↪ 10MB
```

11.2.10.2.2 Changes in TiDB 5.0

In previous releases of TiDB, garbage collection was configured via the `mysql.tidb` system table. While changes to this table continue to be supported, it is recommended to use the system variables provided. This helps ensure that any changes to configuration can be validated, and prevent unexpected behavior (#20655).

The `CENTRAL` garbage collection mode is no longer supported. The `DISTRIBUTED` GC mode (which has been the default since TiDB 3.0) will automatically be used in its place. This mode is more efficient, since TiDB no longer needs to send requests to each TiKV region to trigger garbage collection.

For information on changes in previous releases, refer to earlier versions of this document using the *TIDB version selector* in the left hand menu.

11.2.10.2.3 Changes in TiDB 6.1.0

Before TiDB v6.1.0, the transaction in TiDB does not affect the GC safe point. Starting from v6.1.0, TiDB considers the startTS of the transaction when calculating the GC safe point, to resolve the problem that the data to be accessed has been cleared. If the transaction is too long, the safe point will be blocked for a long time, which affects the application performance.

In TiDB v6.1.0, the system variable `tidb_gc_max_wait_time` is introduced to control the maximum time that active transactions block the GC safe point. After the value is exceeded, the GC safe point is forwarded forcefully.

GC in Compaction Filter

Based on the `DISTRIBUTED` GC mode, the mechanism of GC in Compaction Filter uses the compaction process of RocksDB, instead of a separate GC worker thread, to run GC.

This new GC mechanism helps to avoid extra disk read caused by GC. Also, after clearing the obsolete data, it avoids a large number of left tombstone marks which degrade the sequential scan performance.

The following example shows how to enable the mechanism in the TiKV configuration file:

```
[gc]
enable-compaction-filter = true
```

You can also enable this GC mechanism by modifying the configuration dynamically. See the following example:

```
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | false |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | false |
+------+------------------+-----------------------------+-------+
```

```
set config tikv gc.enable-compaction-filter = true;
show config where type = 'tikv' and name like '%enable-compaction-filter%';
```

```
+------+------------------+-----------------------------+-------+
| Type | Instance         | Name                        | Value |
+------+------------------+-----------------------------+-------+
| tikv | 172.16.5.37:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.36:20163 | gc.enable-compaction-filter | true |
| tikv | 172.16.5.35:20163 | gc.enable-compaction-filter | true |
+------+------------------+-----------------------------+-------+
```

11.3 SQL Tuning

11.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various

statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- Understanding the Query Execution Plan introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- SQL Optimization Process introduces what optimizations TiDB is capable of using to improve query execution performance.
- Control Execution Plans introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.
- Index Advisor introduces how to let TiDB recommend indexes for you automatically based on your workload.

11.3.2 Understanding the Query Execution Plan

11.3.2.1 TiDB Query Execution Plan Overview

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow → button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
    ↪ pad1 VARCHAR(255), INDEX(a));
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)

Query OK, 2 rows affected (0.02 sec)
Records: 2 Duplicates: 0 Warnings: 0

+--
   ↪ ----------------------------+---------+-----------+--------------------+------
   ↪
| id                          | estRows | task    | access object     |
   ↪ operator info                           |
+--
   ↪ ----------------------------+---------+-----------+--------------------+------
   ↪
| IndexLookUp_10              | 10.00   | root      |                    |
   ↪                                         |
|  ─IndexRangeScan_8(Build)  | 10.00   | cop[tikv] | table:t, index:a(a) |
   ↪ range:[1,1], keep order:false, stats:pseudo |
|  ─TableRowIDScan_9(Probe)  | 10.00   | cop[tikv] | table:t          | keep
   ↪ order:false, stats:pseudo         |
+--
   ↪ ----------------------------+---------+-----------+--------------------+------
   ↪
3 rows in set (0.00 sec)
```

`EXPLAIN` does not execute the actual query. `EXPLAIN ANALYZE` can be used to execute the query and show `EXPLAIN` information. This can be useful in diagnosing cases where the execution plan selected is suboptimal. For additional examples of using `EXPLAIN`, see the following documents:

- Indexes
- Joins
- Subqueries
- Aggregation
- Views
- Partitions

11.3.2.1.1 Understand EXPLAIN output

The following describes the output of the `EXPLAIN` statement above:

- `id` describes the name of an operator, or sub-task that is required to execute the SQL statement. See Operator overview for additional details.
- `estRows` shows an estimate of the number of rows TiDB expects to process. This number might be based on dictionary information, such as when the access method is

based on a primary or unique key, or it could be based on statistics such as a CMSketch or histogram.

- `task` shows where an operator is performing the work. See Task overview for additional details.
- `access object` shows the table, partition and index that is being accessed. The parts of the index are also shown, as in the case above that the column `a` from the index was used. This can be useful in cases where you have composite indexes.
- `operator info` shows additional details about the access. See Operator info overview for additional details.

Note:

In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0.

Before v6.4.0, `estRows` means the number of estimated rows to be processed by the probe side operators for each row from the build side operators. Since v6.4.0, `estRows` means the **total number** of estimated rows to be processed by the probe side operators. The actual number of rows displayed (indicated by the `actRows` column) in the result of `EXPLAIN ANALYZE` means the total row count, so since v6.4.0 the meanings of `estRows` and `actRows` for the probe side child nodes of `IndexJoin` and `Apply` operators are consistent.

For example:

```
CREATE TABLE t1(a INT, b INT);
CREATE TABLE t2(a INT, b INT, INDEX ia(a));
EXPLAIN SELECT /*+ INL_JOIN(t2) */ * FROM t1 JOIN t2 ON t1.a =
    ↪  t2.a;
EXPLAIN SELECT (SELECT a FROM t2 WHERE t2.a = t1.b LIMIT 1)
    ↪ FROM t1;
```

```

Operator overview

An operator is a particular step that is executed as part of returning query results. The operators that perform table scans (of the disk or the TiKV Block Cache) are listed as follows:

- **TableFullScan**: Full table scan

- **TableRangeScan**: Table scans with the specified range
- **TableRowIDScan**: Scans the table data based on the RowID. Usually follows an index read operation to retrieve the matching data rows.
- **IndexFullScan**: Similar to a "full table scan", except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.
- **IndexLookUp**: First aggregates the RowID (in TiKV) scanned by the `Build` side. Then at the `Probe` side, accurately reads the data from TiKV based on these RowIDs. At the `Build` side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the `Probe` side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookUp`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many `Build`s and one `Probe`. The execution process of `IndexMerge` the same as that of `IndexLookUp`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism, so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `└─IndexRangeScan_8(Build)` operator finds the internal `RowID` for rows that match the `a(a)` index. The `└─TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE/HAVING/ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column)< 1992` cannot use an index, but `date_column < '1992-01-01` can.

- It is recommended to compare data of the same type and character set and collation. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index `(a, b, c)`:
  - When `a` is an equivalent query, continue to figure out the query range of `b`; when `b` is also an equivalent query, continue to figure out the query range of `c`.
  - Otherwise, if `a` is a non-equivalent query, you can only figure out the range of `a`.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see Optimizer Hints.

11.3.2.2 `EXPLAIN` Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the `EXPLAIN` statement to learn the current execution plan.

The following statement from the bikeshare example database counts how many trips were taken on July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```

    ↪
5 rows in set (0.00 sec)
```

From the child operator `└─TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` operator. Approximately `250` rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `└─TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV (`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.
4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is `1`, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see `EXPLAIN ANALYZE`.
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `└─TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

> **Note:**
>
> For a general view of the Regions that a table contains, execute `SHOW TABLE REGIONS`.

11.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ---------------------------+----------+----------+-----------+---------------+-
    ↪
```

+--
    ↪ ----------------------------+---------+---------+----------+---------------+-
    ↪
5 rows in set (1.03 sec)
```

The example query above takes `1.03` seconds to execute, which is not ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the `operator info` (`stats:pseudo`) of `-TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
Query OK, 0 rows affected (10.22 sec)

5 rows in set (0.93 sec)
```

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `└─ ↪ TableFullScan_18` operator is accurate and the estimate for `└─Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a background operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```
+----------+------------+----------------+---------+
| Db_name  | Table_name | Partition_name | Healthy |
+----------+------------+----------------+---------+
| bikeshare | trips   |                |     100 |
+----------+------------+----------------+---------+
1 row in set (0.00 sec)
```

11.3.2.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.

- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
*************************** 1. row ***************************
       Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint NOT NULL AUTO_INCREMENT,
  `duration` int NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
    ↪ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

> **Note:**
>
> You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL JOBS` command. The defaults in TiDB are carefully chosen so that adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of `10240` and worker count of `32` can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in `EXPLAIN`. In the following output, you can see that a new execution plan is chosen, and the `TableFullScan` and `Selection` operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
| id                        | estRows | task    | access object
    ↪                         | operator info
    ↪                                                |
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
| StreamAgg_17              | 1.00    | root      |
    ↪                                               | funcs:count(Column#13)->Column
    ↪ #11                           |
|  ─IndexReader_18          | 1.00    | root      |
    ↪                                               | index:StreamAgg_9
    ↪                                                 |
|    ─StreamAgg_9           | 1.00    | cop[tikv] |
    ↪                                                   | funcs:count(1)->Column#13
    ↪                                     |
|      ─IndexRangeScan_16   | 8471.88 | cop[tikv] | table:trips, index:start
    ↪ _date(start_date) | range:[2017-07-01 00:00:00,2017-07-01 23:59:59],
    ↪ keep order:false |
+--
    ↪ -------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```

   ↪                                       | time:4.516728ms, loops:2
   ↪
   ↪ | funcs:count(Column#13)->Column#11                          | 372
   ↪ Bytes | N/A |
|  ─IndexReader_18          | 1.00    | 1       | root     |
   ↪                                       | time:4.514278ms, loops:2, cop_
   ↪ task: {num: 1, max:4.462288ms, proc_keys: 11409, rpc_num: 1, rpc_time
   ↪ : 4.457148ms} | index:StreamAgg_9                          | 238 Bytes
   ↪  | N/A |
|    ─StreamAgg_9           | 1.00    | 1       | cop[tikv] |
   ↪                                     | time:4ms, loops:12
   ↪
   ↪ | funcs:count(1)->Column#13                                  | N/A
   ↪      | N/A |
|      ─IndexRangeScan_16   | 8471.88 | 11409 | cop[tikv] | table:trips,
   ↪ index:start_date(start_date) | time:4ms, loops:12
   ↪
   ↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
   ↪  N/A | N/A |
+--
   ↪ -------------------------+---------+---------+----------+-------------------
   ↪
4 rows in set (0.00 sec)
```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

> **Note:**
>
> Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the coprocessor cache. When it is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive `TableFullScan` and `Selection` operators.

11.3.2.2.3 Disable the early execution of subqueries

During query optimization, TiDB pre-executes subqueries that can be directly calculated. For example:

```
CREATE TABLE t1(a int);
INSERT INTO t1 VALUES(1);
CREATE TABLE t2(a int);
EXPLAIN SELECT * FROM t2 WHERE a = (SELECT a FROM t1);
```

```
+--
   ↪ ----------------------+---------+----------+--------------+---------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+---------------
   ↪
| TableReader_14        | 10.00   | root     |               | data:Selection_
   ↪ 13          |
| └─Selection_13         | 10.00   | cop[tikv] |               | eq(test.t2.a,
   ↪ 1)           |
|   └─TableFullScan_12   | 10000.00 | cop[tikv] | table:t2 | keep order:
   ↪ false, stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+---------------
   ↪
3 rows in set (0.00 sec)
```

In the preceding example, the `a = (SELECT a FROM t1)` subquery is calculated during optimization and rewritten as `t2.a=1`. This allows more optimizations such as constant propagation and folding during optimization. However, it affects the execution time of the `EXPLAIN` statement. When the subquery itself takes a long time to execute, the `EXPLAIN` statement might not be completed, which could affect online troubleshooting.

Starting from v7.3.0, TiDB introduces the `tidb_opt_enable_non_eval_scalar_subquery` system variable, which controls whether to disable the pre-execution of such subqueries in `EXPLAIN`. The default value of this variable is `OFF`, which means that the subquery is pre-calculated. You can set this variable to `ON` to disable the pre-execution of subqueries:

```
SET @@tidb_opt_enable_non_eval_scalar_subquery = ON;
EXPLAIN SELECT * FROM t2 WHERE a = (SELECT a FROM t1);
```

```
+--
   ↪ ----------------------+---------+----------+--------------+---------------
   ↪
| id                     | estRows | task     | access object | operator info
   ↪              |
```

```

   ↪ false, stats:pseudo |
+--
   ↪ ------------------------+---------+----------+--------------+---------------
   ↪
7 rows in set (0.00 sec)
```

As you can see, the scalar subquery is not expanded during the execution, which makes it easier to understand the specific execution process of such SQL.

> **Note:**
>
> `tidb_opt_enable_non_eval_scalar_subquery` only affects the behavior of the `EXPLAIN` statement, and the `EXPLAIN ANALYZE` statement still pre-executes the subquery in advance.

11.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- `IndexLookup`
- `IndexReader`
- `Point_Get` and `Batch_Point_Get`
- `IndexFullScan`

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 intkey INT NOT NULL,
 pad1 VARBINARY(1024),
 INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
    ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

11.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

|  ─IndexRangeScan_8(Build)  | 6.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[99,103], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 6.00    | cop[tikv] | table:t1
   ↪                  | keep order:false              |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator has two child nodes:

- The `─IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal `RowID` (for this table, the primary key).
- The `─TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on statistics in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪      |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7         | 898.50 | root     |               | data:Selection_6
   ↪     |
|  ─Selection_6         | 898.50 | cop[tikv] |              | gt(test.t1.intkey
   ↪ , 100) |
|    ─TableFullScan_5   | 1010.00 | cop[tikv] | table:t1 | keep order:false
   ↪     |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

The IndexLookup operator can also be used to efficiently optimize LIMIT on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| id                           | estRows | task     | access object
   ↪              | operator info                    |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| IndexLookUp_21               | 10.00  | root     |
   ↪                              | limit embedded(offset:0, count:10) |
|  ─Limit_20(Build)            | 10.00  | cop[tikv] |
   ↪                              | offset:0, count:10             |
|    ─IndexFullScan_18         | 10.00  | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true, desc    |
|  ─TableRowIDScan_19(Probe)  | 10.00  | cop[tikv] | table:t1
   ↪                  | keep order:false, stats:pseudo |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
```

```
4 rows in set (0.00 sec)
```

In the above example, the last 10 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

11.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task     | access object
   ↪              | operator info                  |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| IndexLookUp_10              | 1.00    | root     |
   ↪                               |                                |
|  ─IndexRangeScan_8(Build)  | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 1.00    | cop[tikv] | table:t1
   ↪                  | keep order:false               |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)

+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| id                     | estRows | task     | access object               |
   ↪ operator info                  |
+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| Projection_4           | 1.00    | root     |                             |
   ↪ test.t1.id                     |
|  ─IndexReader_6        | 1.00    | root     |                              |
   ↪ index:IndexRangeScan_5         |
```

```
|   └─IndexRangeScan_5   | 1.00   | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | range:[123,123], keep order:false |
+--
    ↪ ----------------------+---------+-----------+-----------------------------+
    ↪
3 rows in set (0.00 sec)
```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `└─IndexRangeScan_5`, the value of the `RowID` can be returned directly.

11.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```
EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);
```

```
+-------------+---------+------+--------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+--------------+---------------+

    ↪ ----------------+---------+------+-------------------------------------+----
    ↪
1 row in set (0.00 sec)
```

11.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪

+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| StreamAgg_12                | 1.00    | root     |
   ↪ | funcs:max(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
   ↪                               | offset:0, count:1                |
|    ─IndexReader_29          | 1.00    | root     |
   ↪                               | index:Limit_28                   |
|      ─Limit_28              | 1.00    | cop[tikv] |
   ↪                              | offset:0, count:1                |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true, desc     |
```

```
+--
    ↪ ---------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)
```

In the above statements, an `IndexFullScan` task is performed on each TiKV Region. Despite the name `FullScan`, only the first row needs to be read (`-Limit_28`). Each TiKV Region returns its `MIN` or `MAX` value to TiDB, which then performs Stream Aggregation to filter for a single row. Stream Aggregation with the aggregation function `MAX` or `MIN` also ensures that `NULL` is returned if the table is empty.

By contrast, executing the `MIN` function on an unindexed value will result in `TableFullScan`. The query will require all rows to be scanned in TiKV, but a `TopN` calculation is performed to ensure each TiKV Region only returns one row to TiDB. Although `TopN` prevents excessive rows from being transferred between TiKV and TiDB, this statement is still considered far less efficient than the above example where `MIN` is able to make use of an index.

```
EXPLAIN SELECT MIN(pad1) FROM t1;
```

```
+--

   ↪ Column#8 |
|      ─IndexFullScan_19    | 1010.00 | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:false                                      |
+--
```

```
    ↪ ------------------------+---------+----------+-------------------------------
    ↪
4 rows in set (0.00 sec)
```

In the above examples, `IndexFullScan` is more efficient than `TableFullScan` because the width of the value in the `(intkey + RowID)` index is less than the width of the full row.

The following statement does not support using an `IndexFullScan` operator because additional columns are required from the table:

```
EXPLAIN SELECT AVG(intkey), ANY_VALUE(pad1) FROM t1;
```

```

11.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
```

```
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
SELECT SLEEP(1);
ANALYZE TABLE t1, t2;
```

11.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `TableReader_29(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

> **Note:**
>
> In the returned execution plan, for all probe-side child nodes of `IndexJoin` and `Apply` operators, the meaning of `estRows` since v6.4.0 is different from that before v6.4.0. For more details, see TiDB Query Execution Plan Overview.

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
    ↪ t2.t1_id;
```

```

   ↪                 | keep order:false
   ↪
   ↪ |
+--
   ↪ ------------------------------+----------+-----------+-------------------------
   ↪
```

Index join is efficient in memory usage, but might be slower to execute than other join methods when a large number of probe operations are required. Consider also the following query:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id=t2.t1_id WHERE t1.pad1 = 'value'
   ↪ and t2.pad1='value';
```

In an inner join operation, TiDB implements join reordering and might access either `t1` or `t2` first. Assume that TiDB selects `t1` as the first table to apply the `build` step, and then TiDB is able to filter on the predicate `t1.pad1 = 'value'` before probing the table `t2`. The filter for the predicate `t2.pad1='value'` will be applied on each probe of table `t2`, which might be less efficient than other join methods.

Index join is effective if the build side is small and the probe side is pre-indexed and large. Consider the following query where an index join performs worse than a hash join and is not chosen by the SQL Optimizer:

```
-- DROP previously added index
ALTER TABLE t2 DROP INDEX t1_id;

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
```

```
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```

```

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from `0.3 sec` to `0.06 sec`, as the following result shows:

```
-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

Note:

In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an NP-complete problem, and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use SQL Plan Management to bind a hint to a

query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint `INL_JOIN` creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on the outer table using the hint `INL_HASH_JOIN`. Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- `tidb_index_join_batch_size` (default value: `25000`) - the batch size of `index lookup join` operations.
- `tidb_index_lookup_join_concurrency` (default value: `4`) - the number of concurrent index lookup tasks.

11.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the `Build` side of the join in a hash table, and then reads the data on the `Probe` side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```

   ↪
5 rows in set (0.00 sec)
```

For the execution process of `HashJoin_27`, TiDB performs the following operations in order:

1. Cache the data of the `Build` side in memory.
2. Construct a Hash Table on the `Build` side based on the cached data.
3. Read the data at the `Probe` side.
4. Use the data of the `Probe` side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1 GB) is exceeded, and the `tidb_enable_tmp` ↪ `_storage_on_oom` value is `ON` (default), TiDB will attempt to use temporary storage, and might create the `Build` operator (used as part of the hash join) on disk. Runtime statistics such as memory usage are recorded in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1 GB (default) and a 500 MB quota for `tidb_mem_quota_query`. At 500 MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
   ↪  t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
   ↪  t2.id;
```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the `Build` operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: `5`) - the number of concurrent hash join tasks.

Related optimizations

TiDB provides the Runtime Filter feature, which optimizes the performance of hash join and greatly improves its execution speed. For specific optimization usage, see Runtime Filter.

11.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the `Build` and the `Probe` sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--
   ↪ -------------------------+----------+----------+--------------+-----------
   ↪
| id                        | estRows  | task     | access object | operator
   ↪ info                                  |
+--
   ↪ -------------------------+----------+----------+--------------+-----------
   ↪
| MergeJoin_7               | 142020.00 | root    |               | inner join,
   ↪ left key:test.t1.id, right key:test.t2.id |
|  ─TableReader_12(Build)  | 180000.00 | root    |               | data:

|    ─TableFullScan_11     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ true                                      |
|  ─TableReader_10(Probe)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_9                           |
|    ─TableFullScan_9      | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ true                                      |
+--
   ↪ -------------------------+----------+----------+--------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the `Build` side into the memory.
2. Read the data of the `Probe` side.
3. Compare whether each row of data on the `Probe` side matches a complete Join Group on the `Build` side. Apart from equivalent conditions, there are non-equivalent conditions. Here "match" mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

11.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the MPP mode to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on TiFlash.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id int, value int);
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;
SET tidb_allow_mpp = 1;
```

11.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

11.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSender`are two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--

|        ─ExchangeReceiver_29       | 2.00    | batchCop[tiflash] |           |
   ↪                                               |
|          ─ExchangeSender_28       | 2.00    | batchCop[tiflash] |           |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
|            ─HashAgg_9            | 2.00    | batchCop[tiflash] |           |
   ↪ group by:test.t1.id, funcs:count(1)->Column#7 |
|              ─TableFullScan_25    | 3.00    | batchCop[tiflash] | table:t1  |
   ↪ keep order:false                              |
+--
   ↪ ---------------------------------+---------+------------------+-------------
   ↪
```

The above execution plan contains two query fragments:

- The first is `[TableFullScan_25, HashAgg_9, ExchangeSender_28]`, which is mainly responsible for the first-stage aggregation.
- The second is `[ExchangeReceiver_29, HashAgg_27, Projection_26, ExchangeSender ↪ _30]`, which is mainly responsible for the second-stage aggregation.

The `operator info` column of the `ExchangeSender` operator shows the exchange type information. Currently, there are three exchange types. See the following:

- HashPartition: The `ExchangeSender` operator firstly partitions data according to the Hash values and then distributes data to the `ExchangeReceiver` operator of upstream MPP tasks. This exchange type is often used for Hash Aggregation and Shuffle Hash Join algorithms.
- Broadcast: The `ExchangeSender` operator distributes data to upstream MPP tasks through broadcast. This exchange type is often used for Broadcast Join.

- PassThrough: The `ExchangeSender` operator sends data to the only upstream MPP task, which is different from the Broadcast type. This exchange type is often used when returning data to TiDB.

In the example execution plan, the exchange type of the operator `ExchangeSender_28` is HashPartition, meaning that it performs the Hash Aggregation algorithm. The exchange type of the operator `ExchangeSender_30` is PassThrough, meaning that it is used to return data to TiDB.

MPP is also often applied to join operations. The MPP mode in TiDB supports the following two join algorithms:

- Shuffle Hash Join: Shuffle the data input from the join operation using the HashPartition exchange type. Then, upstream MPP tasks join data within the same partition.
- Broadcast Join: Broadcast data of the small table in the join operation to each node, after which each node joins the data separately.

The following is a typical execution plan for Shuffle Hash Join:

```
SET tidb_broadcast_join_threshold_count=0;
SET tidb_broadcast_join_threshold_size=0;
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

+--
   ↪ ------------------------------------+--------+--------------+---------------+
   ↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment `[TableFullScan_20, Selection_21, ExchangeSender_22]` reads data from table b and shuffles data to upstream MPP tasks.
- The query fragment `[TableFullScan_16, Selection_17, ExchangeSender_18]` reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment `[ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_ ↪ 44, ExchangeSender_47]` joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

   ↪ ------------------------------------+--------+-------------+---------------+
   ↪
```

In the above execution plan:

- The query fragment `[TableFullScan_17, Selection_18, ExchangeSender_19]` reads data from the small table (table a) and broadcasts the data to each node that contains data from the large table (table b).
- The query fragment `[TableFullScan_21, Selection_22, ExchangeReceiver_20, ↪ HashJoin_43, ExchangeSender_46]` joins all data and returns it to TiDB.

11.3.2.5.3 `EXPLAIN ANALYZE` statements in the MPP mode

The `EXPLAIN ANALYZE` statement is similar to `EXPLAIN`, but it also outputs some runtime information.

The following is the output of a simple `EXPLAIN ANALYZE` example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ---------------------------------+---------+---------+-------------------+-----

   ↪                             | N/A    | N/A |
+--
   ↪ ---------------------------------+---------+---------+-----------------+-----
   ↪
```

Compared to the output of `EXPLAIN`, the `operator info` column of the operator `ExchangeSender` also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

11.3.2.5.4 MPP version and exchange data compression

Starting from v6.6.0, the new fields `MPPVersion` and `Compression` are added to the MPP execution plan.

- `MppVersion`: The version number of the MPP execution plan, which can be set through the system variable `mpp_version`.
- `Compression`: The data compression mode of the `Exchange` operator, which can be set through the system variable `mpp_exchange_compression_mode`. If data compression is not enabled, this field is not displayed in the execution plan.

See the following example:

```
mysql > EXPLAIN SELECT COUNT(*) AS count_order FROM lineitem GROUP BY l_
    ↪ returnflag, l_linestatus ORDER BY l_returnflag, l_linestatus;

+--
    ↪ ------------------------------------+--------------+--------------+----------
    ↪
```

In the preceding execution plan result, TiDB uses an MPP execution plan of version 1 to build `TableReader`. The `ExchangeSender` operator of the `HashPartition` type uses the `FAST` data compression mode. Data compression is not enabled for the `ExchangeSender` operator of the `PassThrough` type.

11.3.2.6 Explain Statements That Use Subqueries

TiDB performs several optimizations to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of `EXPLAIN`.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
```

```
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 t1_id INT NOT NULL,
 UNIQUE (t1_id)
);

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
```

```
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
ANALYZE TABLE t1, t2, t3;
```

11.3.2.6.1 Inner join (non-unique subquery)

In the following example, the `IN` subquery searches for a list of IDs from the table `t2` ↪ . For semantic correctness, TiDB needs to guarantee that the column `t1_id` is unique. Using `EXPLAIN`, you can see the execution plan used to remove duplicates and perform an `INNER JOIN` operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```
+--
    ↪ ------------------------------+---------+-----------+-----------------------
    ↪

    ↪                             | group by:test.t2.t1_id, funcs:firstrow(
    ↪ test.t2.t1_id)->test.t2.t1_id                                          |
|    ─IndexReader_45           | 21.11   | root      |
    ↪                             | index:StreamAgg_34
    ↪
    ↪ |
|      ─StreamAgg_34           | 21.11   | cop[tikv] |
    ↪                             | group by:test.t2.t1_id,
    ↪
    ↪ |
```

```
|       └─IndexFullScan_26     | 90000.00 | cop[tikv] | table:t2, index:t1_id
    ↪ (t1_id) | keep order:true
    ↪
    ↪ |
|  └─TableReader_12(Probe)     | 21.11    | root      |
    ↪                            | data:TableRangeScan_11
    ↪
    ↪ |
|    └─TableRangeScan_11       | 21.11    | cop[tikv] | table:t1
    ↪                 | range: decided by [test.t2.t1_id], keep order:false
    ↪                                                    |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
```

From the query results above, you can see that TiDB uses the index join operation `IndexJoin_15` to join and transform the subquery. In the execution plan, the execution process is as follows:

1. The index scanning operator `└─IndexFullScan_26` at the TiKV side reads the values of the `t2.t1_id` column.
2. Some tasks of the `└─StreamAgg_34` operator deduplicate the values of `t1_id` in TiKV.
3. Some tasks of the `└─StreamAgg_44(Build)` operator deduplicate the values of `t1_id` in TiDB. The deduplication is performed by the aggregate function `firstrow(test.t2.t1_id)`.
4. The operation results are joined with the primary key of the `t1` table. The join condition is `eq(test.t1.id, test.t2.t1_id)`.

11.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

11.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `StreamAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
   ↪ t1.int_col);
```

```

   ↪
   ↪ |
+--
   ↪ --------------------------+----------+-----------+-----------------------------
   ↪
```

From the result above, you can see that TiDB uses a `Semi Join` algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the subquery decorrelation optimization has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `─Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

11.3.2.6.4 Anti semi join (`NOT IN` subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```
EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE int_
   ↪ col < 100);
```

```

   ↪ -------------------------+---------+----------+--------------+-----------
   ↪
```

This query starts by reading the table `t3` and then probes the table `t1` based on the `PRIMARY KEY`. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (`NOT IN`) and semi-join because only the first row needs to match before the join is rejected.

11.3.2.6.5 Null-aware semi join (`IN` and `= ANY` subqueries)

The value of the `IN` or `= ANY` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the

NULL on both sides of the join key and process it in a special way.

Subqueries containing IN and = ANY operators are converted to semi join and left outer semi join respectively. In the preceding example of Semi join, since columns test.t1.id ↪ and test.t2.t1_id on both sides of the join key are not NULL, the semi join does not need to be considered as null-aware (NULL is not processed specially). TiDB processes the null-aware semi join based on the Cartesian product and filter without special optimization. The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a,b) IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a,b) IN (SELECT * FROM s);
```

```

    ↪
8 rows in set (0.01 sec)
```

In the first query statement `EXPLAIN SELECT (a,b)IN (SELECT * FROM s)FROM t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by the `IN` subquery is null-aware. Specifically, the Cartesian product is calculated first, then the column connected by `IN` or `= ANY` is put into other conditions as a normal equality query for filtering.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a,b)IN (SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the `IN` subquery

should have been converted to a null-aware semi join. But TiDB optimizes it by converting semi join to inner join and aggregate. This is because `NULL` and `false` are equivalent in `IN` subqueries for non-scalar output. The `NULL` rows in the push-down filter results in the negative semantics of the `WHERE` clause. Therefore, these rows can be ignored beforehand.

> **Note:**
>
> The `Exists` operator is also converted to semi join, but it is not null-aware.

11.3.2.6.6 Null-aware anti semi join (`NOT IN` and `!= ALL` subqueries)

The value of the `NOT IN` or `!= ALL` set operator is three-valued (`true`, `false`, and `NULL`). For the join type converted from either of the two operators, TiDB needs to be aware of the `NULL` on both sides of the join key and process it in a special way.

Subqueries containing `NOT IN` and `! = ALL` operators are converted to anti semi join and anti left outer semi join respectively. In the preceding example of Anti semi join, since columns `test.t3.t1_id` and `test.t1.id` on both sides of the join key are `not NULL`, the anti semi join does not need to be considered as null-aware (`NULL` is not processed specially).

TiDB v6.3.0 optimizes null-aware anti join (NAAJ) as follows:

- Build hash join using the null-aware equality condition (NA-EQ)

  Set operators introduce the equality condition, which requires a special process for the `NULL` value of operators on both sides of the condition. The equality condition that requires null-aware is called NA-EQ. Different from earlier versions, TiDB v6.3.0 no longer processes NA-EQ as before, but places it in other conditions after join, and then determines the legitimacy of the result set after matching the Cartesian product.

  Since TiDB v6.3.0, NA-EQ, a weakened equality condition, is still used to build hash join. This reduces the matching amount of data that needs to be traversed and speeds up the matching process. The acceleration is more significant when the percentage of total `DISTINCT()` values of the build table is almost 100%.

- Speed up the return of matching results using the special property of `NULL`

  Since anti semi join is a conjunctive normal form (CNF), a `NULL` on either side of the join leads to a definite result. This property can be used to speed up the return of the entire matching process.

The following is an example:

```
CREATE TABLE t(a INT, b INT);
CREATE TABLE s(a INT, b INT);
EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;
EXPLAIN SELECT * FROM t WHERE (a, b) NOT IN (SELECT * FROM s);
```

```
tidb> EXPLAIN SELECT (a, b) NOT IN (SELECT * FROM s) FROM t;

    ↪
5 rows in set (0.00 sec)
```

In the first query statement `EXPLAIN SELECT (a, b)NOT IN (SELECT * FROM s)FROM ↪ t;`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the left outer semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

In the second query statement `EXPLAIN SELECT * FROM t WHERE (a, b)NOT IN ( ↪ SELECT * FROM s);`, since columns `a` and `b` of tables `t` and `s` are NULLABLE, the anti semi join converted by `NOT IN` subquery is null-aware. The difference is that NAAJ optimization also uses the NA-EQ as the hash join condition, which greatly speeds up the join calculation.

Currently, TiDB can only be null-aware of anti semi join and anti left outer semi join. Only the hash join type is supported and its build table should be fixed to the right table.

> **Note:**
>
> The `Not Exists` operator is also converted to the anti semi join, but it is not null-aware.

11.3.2.6.7 Explain statements using other types of subqueries

- Explain Statements Using Index Merge

11.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB);
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_
    ↪ BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

From the output of SHOW TABLE REGIONS, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```
+--
    ↪ ---------+-------------+-------------+----------+----------------+-------+--
    ↪

    ↪ 63211 |
+--
    ↪ ---------+-------------+-------------+----------+----------------+-------+--
    ↪
4 rows in set (0.00 sec)
```

Using EXPLAIN with the following aggregation statement, you can see that −StreamAgg ↪ _8 is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in StreamAgg_16:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ ------------------------+----------+----------+-------------+-----------
    ↪
| id                        | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ ------------------------+----------+----------+-------------+-----------
    ↪
| StreamAgg_16              | 1.00     | root     |               | funcs:count(
    ↪ Column#7)->Column#5 |
|  −TableReader_17          | 1.00     | root     |               | data:
    ↪ StreamAgg_8             |
```

```
|   └─StreamAgg_8          | 1.00     | cop[tikv] |            | funcs:count
    ↪ (1)->Column#7    |
|     └─TableFullScan_15   | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ ------------------------+----------+----------+-------------+-----------
    ↪
4 rows in set (0.00 sec)
```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ ------------------------+----------+--------+----------+---------------+---
    ↪

```

11.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the `HashAgg` operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
    ↪ ------------------------+----------+----------+---------------+-------------
    ↪
| id                    | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ ------------------------+----------+----------+---------------+-------------
    ↪
| HashAgg_9             | 1.00     | root     |               | funcs:count(
    ↪ Column#6)->Column#5 |
|  ─TableReader_10      | 1.00     | root     |               | data:HashAgg_
    ↪ 5              |
|    ─HashAgg_5         | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#6    |
|      ─TableFullScan_8 | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ ------------------------+----------+----------+---------------+-------------
    ↪
4 rows in set (0.00 sec)
```

The `operator info` shows that the hashing function used to aggregate the data is `funcs
↪ :count(1)->Column#6`.

11.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
```

```
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

+--
    ↪ ---------------------------+----------+----------+---------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪ |
+--
    ↪ ---------------------------+----------+----------+---------------+-----------
    ↪
| Projection_4                | 8000.00 | root     |               | test.t2.col1
    ↪ , Column#3                                                                    |
|  ─StreamAgg_8               | 8000.00 | root     |               | group by:
    ↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
    ↪ ->test.t2.col1 |
|    ─Sort_13                 | 10000.00 | root    |               | test.t2.
    ↪ col1
    ↪                                                                               |
|      ─TableReader_12        | 10000.00 | root    |               | data:
    ↪ TableFullScan_11
    ↪                                                                 |
|        ─TableFullScan_11    | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo
    ↪ |
+--
    ↪ ---------------------------+----------+----------+---------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In this example, the `─Sort_13` operator can be eliminated by adding an index on `col1` ↪ . Once the index is added, the data can be read in order and the `─Sort_13` operator is eliminated:

```
ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.28 sec)
```

```

+--
   ↪ ---------------------------+---------+----------+--------------------------
   ↪
5 rows in set (0.00 sec)
```

11.3.2.7.3 Multidimensional data aggregation with ROLLUP

Starting from v7.4.0, the `GROUP BY` clause of TiDB supports the `WITH ROLLUP` modifier.

In the `GROUP BY` clause, you can specify one or more columns as a group list and append the `WITH ROLLUP` modifier after the list. Then, TiDB will conduct multidimensional descending grouping based on the columns in the group list and provide you with summary results for each group in the output.

> **Note:**
>
> Currently, TiDB does not support the Cube syntax.

```
explain SELECT year, month, grouping(year), grouping(month), SUM(profit) AS
    ↪  profit FROM bank GROUP BY year, month WITH ROLLUP;
+--
    ↪ ------------------------------------+--------+-------------+---------------+

    ↪
    ↪
    ↪ |
|                └─TableFullScan_17  | 3.00   | mpp[tiflash] | table:bank |
    ↪ keep order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ------------------------------------+--------+--------------+---------------+
    ↪
10 rows in set (0.05 sec)
```

According to the `GROUP BY year, month WITH ROLLUP` syntax in the preceding statement, the SQL aggregation results for this statement can be calculated and concatenated in three groups: `{year, month}`, `{year}`, and `{}` respectively.

For more information, see GROUP BY modifiers.

11.3.2.8 EXPLAIN Statements Using Views

`EXPLAIN` displays the tables and indexes that a view references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves. The definition of the view and the rest of the statement are merged together during SQL optimization.

From the bikeshare example database, you can see that the following two queries are executed in a similar manner:

```
ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
    ↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;
```

```
Query OK, 0 rows affected (2 min 10.11 sec)

Query OK, 0 rows affected (0.13 sec)

+--

   ↪ ----------------------------+----------+----------+----------------------
   ↪
3 rows in set (0.00 sec)
```

Similarly, predicates from the view are pushed down to the base table:

```
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```

+--
    ↪ ----------------------+-------------+-----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself. Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
```

```
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
Query OK, 0 rows affected (2 min 31.20 sec)

    ↪                                                  |
    ↪                                               |
|  ─IndexRangeScan_8(Build)  | 19117.64 | cop[tikv] | table:trips, index:
    ↪ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
    ↪ order:false |
|  ─TableRowIDScan_9(Probe)  | 19117.64 | cop[tikv] | table:trips
    ↪                                       | keep order:false
    ↪                           |
```

```
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement, TiDB is able to use both parts of the composite index `(bike_number, duration)`. In the second statement, only the first part which is `bike_number` of the index `(bike_number, duration)` is used.

11.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to execute a query. Because of partition pruning, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
 ('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
```

```
 ('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

SELECT SLEEP(1);
ANALYZE TABLE t1;
```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```
+--

|       └─TableFullScan_19    | 8870.00 | cop[tikv] | table:t1, partition:
   ↪ p2017 | keep order:false              |
+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪
5 rows in set (0.01 sec)
```

Starting from the inner-most (`└─TableFullScan_19`) operator and working back towards the root operator (`StreamAgg_21`):

- TiDB successfully identified that only one partition (p2017) needed to be accessed. This is noted under `access object`.
- The partition itself was scanned in the operator `─TableFullScan_19` and then `─Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `─Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `─TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

   ↪ partition:pmax | keep order:false      |
+--
   ↪ ---------------------------------+----------+-----------+----------------------
   ↪
27 rows in set (0.00 sec)
```

From the output above:

- TiDB believes that it needs to access all of the partitions (`p2016..pMax`). This is because the predicate `YEAR(d)= 2017` is considered non-sargable. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.

- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `-PartitionUnion_21` unions the results from accessing each partition.

11.3.2.10 Explain Statements Using Index Merge

Index merge is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

Index merge in TiDB has two types: the intersection type and the union type. The former applies to the `AND` expression, while the latter applies to the `OR` expression. The union-type index merge is introduced in TiDB v4.0 as an experimental feature and has become GA in v5.4.0. The intersection type is introduced in TiDB v6.5.0, and can be used only when the `USE_INDEX_MERGE` hint is specified.

11.3.2.10.1 Enable index merge

In v5.4.0 or a later TiDB version, index merge is enabled by default. In other situations, if index merge is not enabled, you need to set the variable `tidb_enable_index_merge` to `ON` to enable this feature.

```
SET session tidb_enable_index_merge = ON;
```

11.3.2.10.2 Examples

```
CREATE TABLE t(a int, b int, c int, d int, INDEX idx_a(a), INDEX idx_b(b),
    ↪ INDEX idx_c(c), INDEX idx_d(d));
```

```
EXPLAIN SELECT /*+ NO_INDEX_MERGE() */ * FROM t WHERE a = 1 OR b = 1;

```

In the preceding query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without index merge, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, index merge is introduced in TiDB to access tables.

For the preceding query, the optimizer chooses the union-type index merge to access the table. Index merge allows the optimizer to use multiple indexes per table, to merge the results returned by each index, and to generate the latter execution plan in the preceding output.

In the output, the `type: union` information in `operator info` of the `IndexMerge_8` ↪ operator indicates that this operator is a union-type index merge. It has three child nodes. `IndexRangeScan_5` and `IndexRangeScan_6` scan the `RowID`s that meet the condition according to the range, and then the `TableRowIDScan_7` operator accurately reads all the data that meets the condition according to these `RowID`s.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan`/`TableRangeScan`, the `operator info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan` ↪ /`TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_5` operator indicates that the operator scans the data from 1 to positive infinity.

```

```
↪
```

From the preceding example, you can see that the filter condition is a `WHERE` clause that uses `AND` as the connector. Before index merge is enabled, the optimizer can only choose one of the three indexes (`idx_a`, `idx_b`, or `idx_c`).

If one of the filter conditions has a low selectivity, the optimizer directly chooses the corresponding index to achieve the ideal execution efficiency. However, if the data distribution meets all of the following three conditions, you can consider using the intersection-type index merge:

- The data size of the whole table is large, and directly reading the whole table is inefficient.
- For each one of the three filter conditions, the respective selectivity is very high, so the execution efficiency of `IndexLookUp` using a single index is not ideal.
- The overall selectivity of the three filter conditions is low.

When using the intersection-type index merge to access tables, the optimizer can choose to use multiple indexes on a table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the preceding example output. The `type: intersection` information in the `operator info` of the `IndexMerge_9` operator indicates that this operator is an intersection-type index merge. The other parts of the execution plan are similar to the preceding union-type index merge example.

Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is `ON`.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge`. To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.
- If the optimizer can choose the single index scan method (other than full table scan) for a query plan, the optimizer will not automatically use index merge. For the optimizer to use index merge, you need to use the optimizer hint. Starting from v8.1.0, you can remove this limitation by setting Optimizer Fix Control 52869. Removing this limitation enables the optimizer to choose index merge automatically in more queries, but might cause the optimizer to ignore the optimal execution plans. Therefore, it is recommended to conduct sufficient tests on actual use cases before removing this limitation to make sure that it will not cause performance regressions.

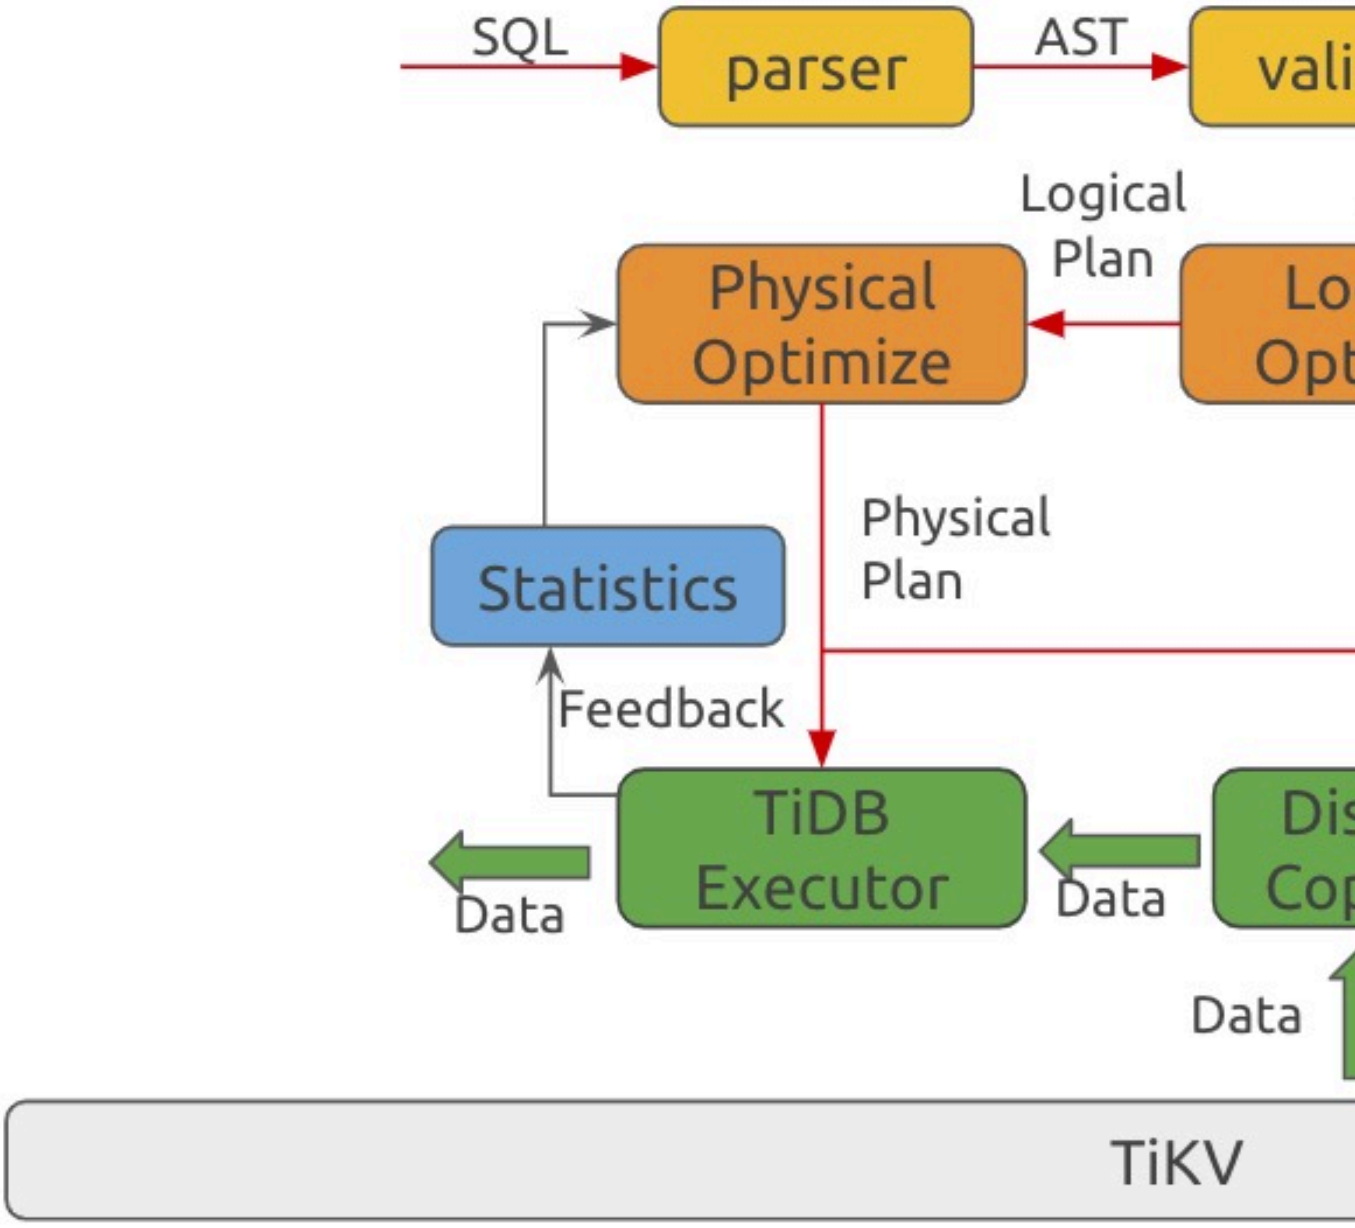

Figure 431: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see SQL Logical Optimization.

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see SQL Physical Optimization.

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see Execution Plan Cache.

11.3.3.2 Logic Optimization

11.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- Subquery Related Optimizations
- Column Pruning
- Decorrelation of Correlated Subquery
- Eliminate Max/Min
- Predicates Push Down
- Partition Pruning
- TopN and Limit Operator Push Down
- Join Reorder
- Derive TopN or Limit from Window Functions

11.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ..)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a "correlated subquery", and the externally introduced column is called a "correlated column". For optimizations about correlated subquery, see Decorrelation of correlated subquery. This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in Understanding TiDB Execution Plan as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

`... < ALL (SELECT ... FROM ...)` or `... > ANY (SELECT ... FROM ...)`

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is NULL. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id)and if(sum(s.id is null)!= 0, null, true)`
- `t.id > any (select s.id from s)` is rewritten as `t.id > max(s.id)or if(sum(s.id is null)!= 0, null, false)`

`... != ANY (SELECT ... FROM ...)`

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s)where (t.id != s.id or cnt_distinct > 1)`

`... = ALL (SELECT ... FROM ...)`

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s )where (t.id = s.id and cnt_distinct <= 1)`

`... IN (SELECT ... FROM ...)`

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2.The form of a`. The `DISTINCT` attribute here can be eliminated automatically if `t2.a` has the `UNIQUE` attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```

   ↪ --------------------------+---------+----------+----------------------+----
   ↪
```

This rewrite gets better performance when the `IN` subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable tidb_opt_insubq_to_join_and_agg is used to control this optimization. When this optimization is not suitable, you can manually disable it.

`EXISTS` subquery and `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the `EXISTS` subquery is evaluated to `TRUE` in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```

   ↪ --------------------+----------+-----------+--------------+------------------
   ↪
```

In the preceding optimization, the optimizer automatically optimizes the statement execution. In addition, you can also add the SEMI_JOIN_REWRITE hint to further rewrite the statement.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

11.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b> 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called "Column Pruning", corresponding to the `columnPruner` rule. If you want to disable this rule, refer to The Blocklist of Optimization Rules and Expression Pushdown.

11.3.3.2.4 Decorrelation of Correlated Subquery

Subquery related optimizations describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into `JOIN`.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, which might bring better execution performance. In this case, you can disable this optimization by using the `NO_DECORRELATE` optimizer hint or by disabling the "subquery decorrelation" optimization rule in the blocklist of optimization rules and expression pushdown. In most cases, it is recommended to use the optimizer hint along with SQL Plan Management to disable the decorrelation.

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

   ↪ isnull(test.t2.b))
   ↪                                                          |
|          ─TableFullScan_21    | 10000.00 | cop[tikv] | table:t2 | keep
   ↪ order:false, stats:pseudo
   ↪                                                  |
|  ─TableReader_15(Probe)       | 9990.00 | root     |              | data:
   ↪ Selection_14
   ↪                                                               |
|    ─Selection_14              | 9990.00 | cop[tikv] |             | not(
   ↪ isnull(test.t1.b))
   ↪                                                          |
|      ─TableFullScan_13        | 10000.00 | cop[tikv] | table:t1 | keep
   ↪ order:false, stats:pseudo
   ↪                                                  |
+--
   ↪ ------------------------------+---------+----------+--------------+-------
   ↪
```

The above is an example where the optimization takes effect. `HashJoin_11` is a normal `inner join`.

Then, you can use the `NO_DECORRELATE` optimizer hint to tell the optimizer not to perform decorrelation for the subquery:

```
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

```

    ↪                                                     |
|        ─Projection_45                 | 100000.00 | root    |
    ↪                       | cast(test.t2.a, decimal(10,0) BINARY)->Column
    ↪ #14                             |
|          ─IndexLookUp_44              | 100000.00 | root    |
    ↪                       |
    ↪
    ↪ |
```

```
|           └─IndexRangeScan_42(Build)  | 100000.00 | cop[tikv] | table:t2,
    ↪ index:idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep
    ↪ order:false, stats:pseudo |
|           └─TableRowIDScan_43(Probe)  | 100000.00 | cop[tikv] | table:t2
    ↪           | keep order:false, stats:pseudo
    ↪                                                |
+--
    ↪ ----------------------------------------+----------+----------+--------------
    ↪
```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(` ↪ `test.t2.b, test.t1.b)]` in `operator info` of `IndexRangeScan_42(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

11.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert the `max/min` aggregate functions to the TopN operator by applying the `max/min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max/min` functions in the `select` statement:

- The statement with only one `max/min` function
- The statement with multiple `max/min` functions

One `max/min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
    ↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
| id                        | estRows | task    | access object         |
   ↪ operator info                    |
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
| StreamAgg_13              | 1.00    | root     |                       |
   ↪ funcs:max(test.t.a)->Column#4  |
|  ─Limit_17                 | 1.00    | root     |                        |
   ↪ offset:0, count:1                |
|    ─IndexReader_27         | 1.00    | root     |                        |
   ↪ index:Limit_26                   |
|      ─Limit_26             | 1.00    | cop[tikv] |                       |
   ↪ offset:0, count:1                |
|        ─IndexFullScan_25   | 1.00    | cop[tikv] | table:t, index:idx_a(a) |
   ↪  keep order:true, desc, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
5 rows in set (0.00 sec)
```

Multiple `max`/`min` functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max`/`min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
    (select max(a) as max_a from t) t1,
    (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max` ↪ `/min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
    (select max(a) as max_a from (select a from t where a is not null order
       ↪  by a desc limit 1) t) t1,
    (select min(a) as min_a from (select a from t where a is not null order
       ↪  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+--
   ↪ ----------------------------------+---------+-----------+-------------------
   ↪
| id                                  | estRows | task      | access object       |
   ↪  operator info                        |
+--
   ↪ ----------------------------------+---------+-----------+-------------------
   ↪

    ↪
12 rows in set (0.01 sec)
```

11.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```
create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪           |
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
    ↪           |
|  └─Selection_6        | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
    ↪            |
|    └─TableFullScan_5  | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
```

```
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪            |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
   ↪           |
|  ─Selection_6         | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
   ↪            |
|    ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
   ↪ ---------------------------+----------+-----------+---------------+-----------
   ↪
| id                          | estRows | task    | access object | operator
   ↪ info                          |
+--
   ↪ ---------------------------+----------+-----------+---------------+-----------
   ↪
| HashJoin_8                  | 4154.17 | root    |               | inner join,
   ↪ equal:[eq(test.t.a, test.s.a)] |
```

```
|  └─TableReader_15(Build)   | 3323.33 | root    |             | data:
   ↪ Selection_14                      |
|    └─Selection_14          | 3323.33 | cop[tikv] |           | lt(test.s.a
   ↪ , 1)                        |
|      └─TableFullScan_13    | 10000.00 | cop[tikv] | table:s  | keep order:
   ↪ false, stats:pseudo         |
|  └─TableReader_12(Probe)   | 3323.33 | root    |             | data:
   ↪ Selection_11                      |
|    └─Selection_11          | 3323.33 | cop[tikv] |           | lt(test.t.a
   ↪ , 1)                        |
|      └─TableFullScan_10    | 10000.00 | cop[tikv] | table:t  | keep order:
   ↪ false, stats:pseudo         |
+--
   ↪ --------------------------+---------+----------+-------------+-----------
   ↪
7 rows in set (0.00 sec)
```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the `ON` condition is `t.a = s.a`. The predicate `s.a <1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```
create table t(id int primary key, a varchar(10) not null);
desc select * from t where truncate(a, " ") = '1';
+--
   ↪ ----------------------+---------+----------+-------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪                          |
+--
   ↪ ----------------------+---------+----------+-------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |             | eq(truncate(cast(
   ↪ test.t.a, double BINARY), 0), 1) |
|  └─TableReader_7       | 10000.00 | root    |              | data:
   ↪ TableFullScan_6                        |
|    └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t  | keep order:false
   ↪ , stats:pseudo              |
+--
   ↪ ----------------------+---------+----------+-------------+----------------
   ↪
```

In this query, there is a predicate `truncate(a, " ")= '1'`.

From the `explain` results, you can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `truncate`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
| id                          | estRows | task    | access object | operator
   ↪ info                           |
+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪

+--
   ↪ ----------------------------+----------+-----------+---------------+-----------
   ↪
6 rows in set (0.00 sec)
```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with `NULL` values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```
create table t(id int primary key, a char);
set @a = 1;
```

```
explain select * from t where a < @a;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |               | lt(test.t.a,
   ↪ getvar("a"))  |
| └─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6       |
|   └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with `1`, and does not push down it to TiKV.

An example to help you understand is as follows:

```
create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+----+------+----------+
| id | a    | @a:=@a+1 |
+----+------+----------+
|  1 |    1 | 2        |
|  2 |    2 | 3        |
+----+------+----------+
2 rows in set (0.00 sec)
```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

11.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--

+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
5 rows in set (0.00 sec)
```

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
| id                    | estRows | task     | access object       | operator
   ↪ info               |
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
| TableReader_8         | 10.00   | root     |                      | data:
   ↪ Selection_7            |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
   ↪ .x, 1)              |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+----------------------+--------
   ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value `1` can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that `partition pruning` takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
   ↪ ---------------------------+---------+----------+---------------------+---
   ↪
| id                          | estRows | task     | access object       |
   ↪ operator info               |
+--
   ↪ ---------------------------+---------+----------+---------------------+---
   ↪
| Union_10                    | 13333.33 | root    |                     |
   ↪                             |
|  ─TableReader_13            | 3333.33 | root     |                     | data
   ↪ :Selection_12             |
|    ─Selection_12            | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_11      | 10000.00 | cop[tikv] | table:t, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_16            | 3333.33 | root     |                     | data
   ↪ :Selection_15             |
|    ─Selection_15            | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_14      | 10000.00 | cop[tikv] | table:t, partition:p1
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_19            | 3333.33 | root     |                     | data
   ↪ :Selection_18             |
|    ─Selection_18            | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_17      | 10000.00 | cop[tikv] | table:t, partition:p2
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_22            | 3333.33 | root     |                     | data
   ↪ :Selection_21             |
|    ─Selection_21            | 3333.33 | cop[tikv] |                    | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_20      | 10000.00 | cop[tikv] | table:t, partition:p3
   ↪ | keep order:false, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+---------------------+---
   ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the `x > 2` condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
    ↪ t2.x < 2);
```

```
+--
    ↪ ------------------------------------+---------+----------+-------------------
    ↪
| id                                | estRows | task     | access object
    ↪       | operator info                                 |
+--
    ↪ ------------------------------------+---------+----------+-------------------
    ↪

|          ─TableReader_24          | 2.00    | root     |
    ↪                     | data:Selection_23                             |
|            ─Selection_23          | 2.00    | cop[tikv] |
    ↪                   | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_22    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p0 | keep order:false, stats:pseudo    |
|          ─TableReader_27          | 2.00    | root     |
    ↪                     | data:Selection_26                             |
|            ─Selection_26          | 2.00    | cop[tikv] |
    ↪                   | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
|              ─TableFullScan_25    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p1 | keep order:false, stats:pseudo    |
+--
```

```
    ↪ ----------------------------------+---------+----------+--------------------
    ↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x = 3;
```

```
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7           |
|  ─Selection_7         | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 3)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x in(1,13);
```

```
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
| id                        | estRows | task     | access object      |
    ↪ operator info               |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
| Union_8                   | 40.00   | root     |                    |
    ↪                             |
|  ─TableReader_11          | 20.00   | root     |                    | data:
    ↪ Selection_10            |
|    ─Selection_10          | 20.00   | cop[tikv] |                   | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_9     | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14          | 20.00   | root     |                    | data:
    ↪ Selection_13            |
|    ─Selection_13          | 20.00   | cop[tikv] |                   | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_12    | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
```

```
    partition p2 values less than (15)
    );
explain select * from t where x between 7 and 14;
```

```
+--

    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of `fn(col)`, the query condition is one of `>`, `<`, `=`, `>=`, and `<=`, and the `fn` function is monotonous.

If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn` ↪ `(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

- `UNIX_TIMESTAMP()`
- `TO_DAYS()`
- `EXTRACT(<time unit> FROM <DATETIME/DATE/TIME column>)`. For `DATE` and `DATETIME` columns, `YEAR` and `YEAR_MONTH` time units are considered monotonous func-

tions. For the `TIME` column, `HOUR`, `HOUR_MINUTE`, `HOUR_SECOND` and `HOUR_MICROSECOND` are considered monotonous functions. Note that `WEEK` is not supported as time unit in `EXTRACT` for partition pruning.

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
   partition p0 values less than (to_days('2020-04-01')),
   partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```
+--
   ↪ ----------------------+----------+-----------+----------------------+---------
   ↪
| id                    | estRows | task    | access object      | operator
   ↪ info                          |
+--
   ↪ ----------------------+----------+-----------+----------------------+---------
   ↪
| TableReader_8         | 3333.33 | root    |                      | data:
   ↪ Selection_7                     |
|  ─Selection_7         | 3333.33 | cop[tikv] |                    | gt(test.t
   ↪ .id, 2020-04-18 00:00:00.000000) |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+----------+-----------+----------------------+---------
   ↪
```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
   ↪ t2.x < 2);
```

```
+--
   ↪ ----------------------------------+----------+-----------+-------------------
   ↪
```

```
| id                                | estRows | task     | access object
   ↪       | operator info                                          |
+--
   ↪ ----------------------------------+---------+----------+-------------------
   ↪

   ↪                     | not(isnull(test.t1.x))
   ↪                                 |
|      ─MaxOneRow_20                 | 1.00     | root     |
   ↪                     |
   ↪                                                  |
|        ─Union_21                   | 2.00     | root     |
   ↪                     |
   ↪                                                    |
|          ─TableReader_24           | 2.00     | root     |
   ↪                     | data:Selection_23
   ↪                                       |
|            ─Selection_23           | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|              ─TableFullScan_22     | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p0 | keep order:false, stats:pseudo                 |
|          ─TableReader_27           | 2.00     | root     |
   ↪                     | data:Selection_26
   ↪                                       |
|            ─Selection_26           | 2.00     | cop[tikv] |
   ↪                     | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|              ─TableFullScan_25     | 2.50     | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo                 |
+--
```

```
    ↪ ----------------------------------+---------+-----------+--------------------
    ↪
14 rows in set (0.00 sec)
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the `t1.x> val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

11.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to Optimization Rules and Blocklist for Expression Pushdown.

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+---------------------------+----------+-----------+---------------+--------------------
    ↪
| id                        | estRows | task     | access object | operator
    ↪ info            |
+---------------------------+----------+-----------+---------------+--------------------
    ↪
| TopN_7                    | 10.00   | root     |               | test.t.a,
    ↪ offset:0, count:10 |
|  ─TableReader_15          | 10.00   | root     |               | data:TopN_14
    ↪                 |
|    ─TopN_14               | 10.00   | cop[tikv] |              | test.t.a,
    ↪ offset:0, count:10 |
|      ─TableFullScan_13    | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
```

```
+--------------------------+---------+----------+--------------+--------------------
    ↪
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+---------------------------------+---------+----------+--------------+------------
    ↪
| id                            | estRows | task     | access object |
    ↪ operator info                              |
+---------------------------------+---------+----------+--------------+------------
    ↪
| TopN_12                       | 10.00   | root     |              | test.t.a,
    ↪  offset:0, count:10                 |
|  ─HashJoin_17                 | 12.50   | root     |              | left
    ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    ─TopN_18(Build)            | 10.00   | root     |              | test.t.a
    ↪ , offset:0, count:10                |
|      ─TableReader_26          | 10.00   | root     |              | data:
    ↪ TopN_25                               |
|        ─TopN_25               | 10.00   | cop[tikv] |             | test.t.a
    ↪ , offset:0, count:10                |
|          ─TableFullScan_24    | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo             |
|    ─TableReader_30(Probe)     | 10000.00 | root     |              | data:
    ↪ TableFullScan_29                      |
|      ─TableFullScan_29        | 10000.00 | cop[tikv] | table:s   | keep
    ↪ order:false, stats:pseudo             |
+---------------------------------+---------+----------+--------------+------------
    ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+------------------------------+---------+----------+--------------+---------------
   ↪
| id                           | estRows | task     | access object | operator
   ↪ info                       |
+------------------------------+---------+----------+--------------+---------------
   ↪
| TopN_12                      | 10.00   | root     |              | test.t.id,
   ↪ offset:0, count:10         |
|  ─HashJoin_16                | 12500.00 | root    |              | inner join,
   ↪  equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_21(Build)    | 10000.00 | root    |              | data:
   ↪ TableFullScan_20                |
|      ─TableFullScan_20       | 10000.00 | cop[tikv] | table:s    | keep order:
   ↪ false, stats:pseudo        |
|    ─TableReader_19(Probe)    | 10000.00 | root    |              | data:
   ↪ TableFullScan_18                |
|      ─TableFullScan_18       | 10000.00 | cop[tikv] | table:t    | keep order:
   ↪ false, stats:pseudo        |
+------------------------------+---------+----------+--------------+---------------
   ↪
6 rows in set (0.00 sec)
```

TopN cannot be pushed down before `Inner Join`. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;
```

```
+--------------------------------+---------+----------+--------------+------------
   ↪
| id                             | estRows | task     | access object |
   ↪ operator info                          |
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                       | 10.00    | root      |               | test.t.id
   ↪ , offset:0, count:10              |
|  ─HashJoin_17                 | 12.50    | root      |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    ─Limit_21(Build)           | 10.00    | root      |               | offset
   ↪ :0, count:10                          |
|      ─TableReader_31          | 10.00    | root      |               | data:
   ↪ Limit_30                              |
|        ─Limit_30              | 10.00    | cop[tikv] |               | offset
   ↪ :0, count:10                          |
|          ─TableFullScan_29    | 10.00    | cop[tikv] | table:t       | keep
   ↪ order:true, stats:pseudo              |
|    ─TableReader_35(Probe)     | 10000.00 | root      |               | data:
   ↪ TableFullScan_34                      |
|      ─TableFullScan_34        | 10000.00 | cop[tikv] | table:s       | keep
   ↪ order:false, stats:pseudo             |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
8 rows in set (0.00 sec)
```

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t ↪ .id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

11.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, the following two Join Reorder algorithms are used in TiDB:

- The greedy algorithm: among all nodes participating in the join, TiDB selects the table with the least rows to estimate its join result with each of the other tables respectively, and then selects the pair with the smallest join result. After that, TiDB continues the similar process to select and join other nodes for the next round, until all the nodes have completed the join.
- The dynamic programming algorithm: among all nodes participating in the join, TiDB enumerates all possible join orders and selects the optimal join order.

Example: the greedy algorithm of Join Reorder

Take the preceding three tables (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

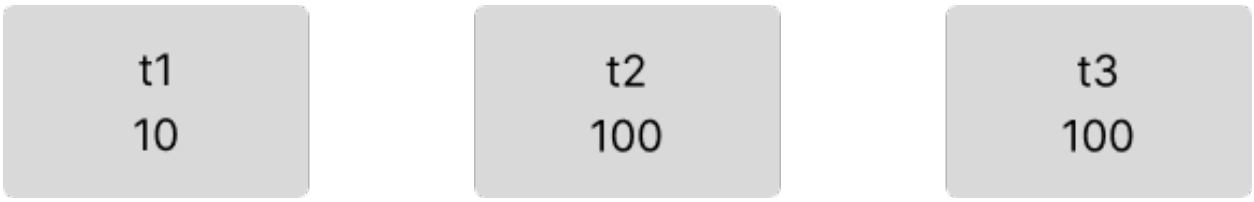

Figure 432: join-reorder-1

After that, the table with the least rows is selected and joined with other two tables respectively. By comparing the sizes of the output result sets, TiDB selects the pair with a smaller result set.

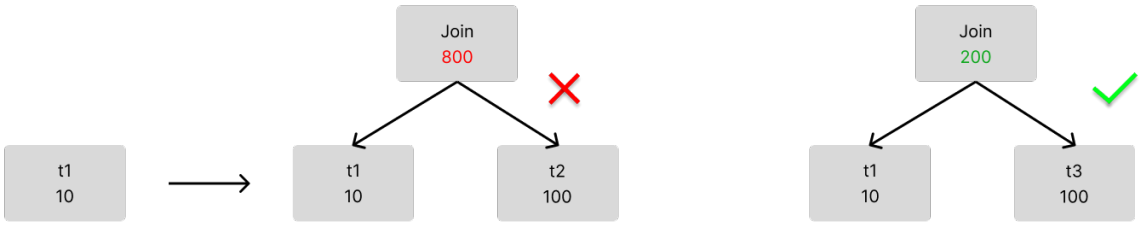

Figure 433: join-reorder-2

Then TiDB enters the next round of selection. If you try to join four tables, TiDB continues to compare the sizes of the output result sets and selects the pair with a smaller result set.

In this case only three tables are joined, so TiDB gets the final join result.

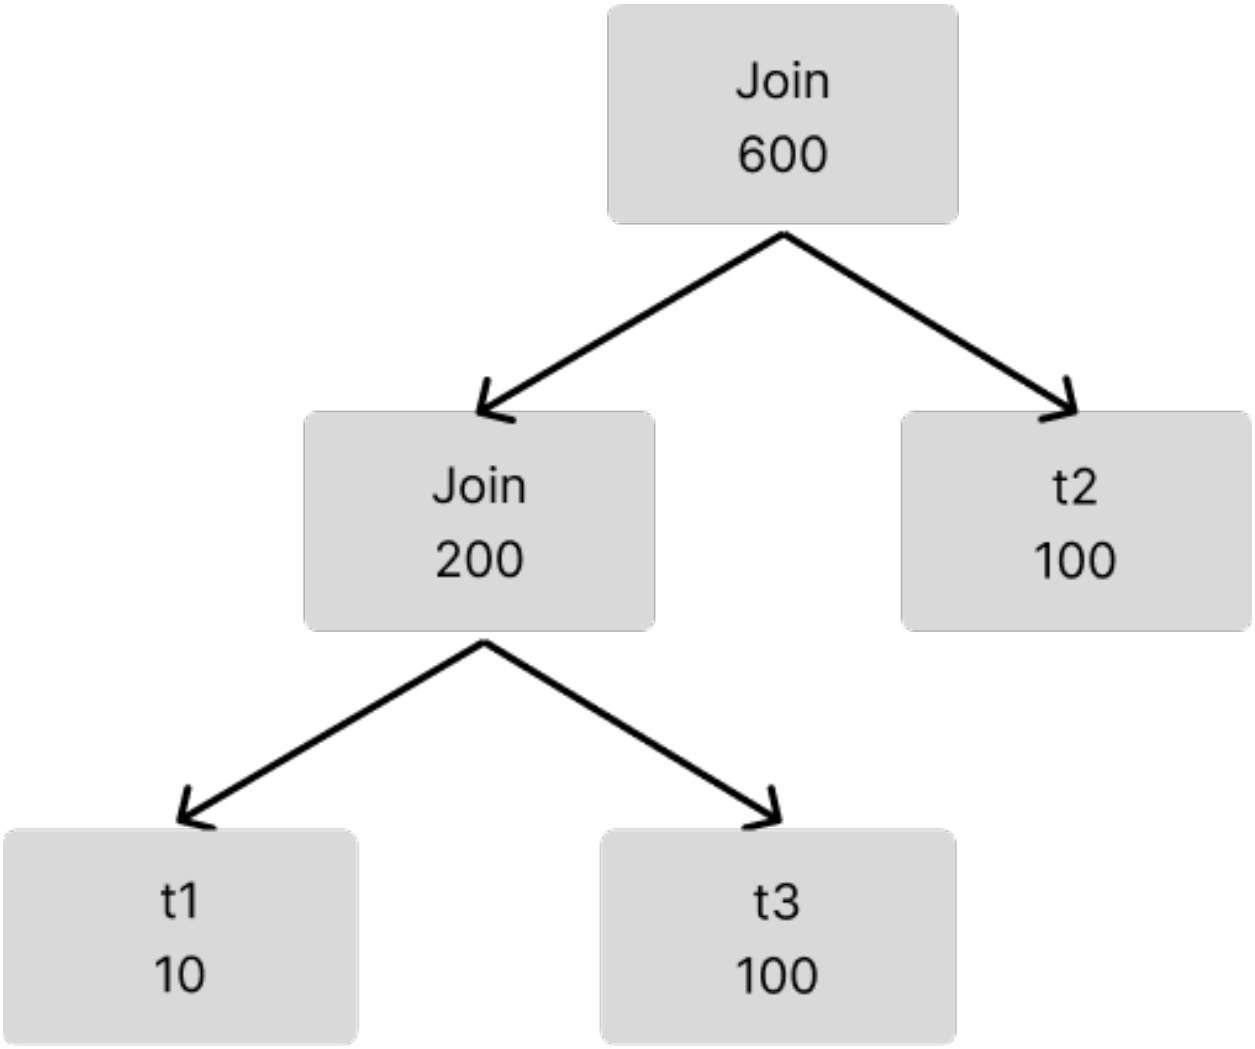

Figure 434: join-reorder-3

Example: the dynamic programming algorithm of Join Reorder

Taking the preceding three tables (t1, t2, and t3) as an example again, the dynamic programming algorithm can enumerate all possibilities. Therefore, comparing with the greedy algorithm, which must start with the `t1` table (the table with the least rows), the dynamic programming algorithm can enumerate a join order as follows:

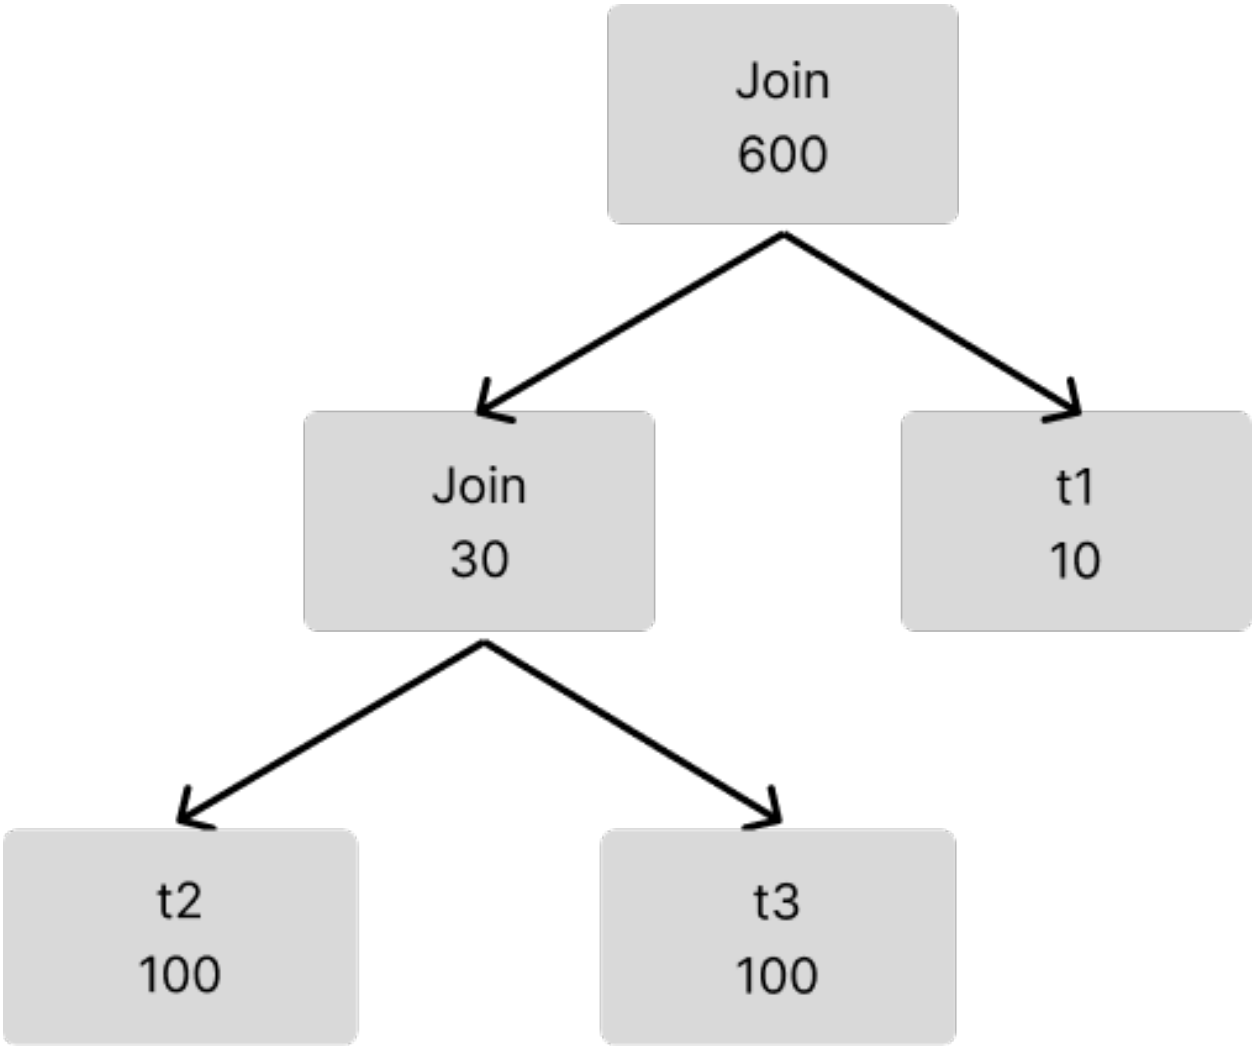

Figure 435: join-reorder-4

When this choice is better than the greedy algorithm, the dynamic programming algorithm can choose a better join order.

Because all possibilities are enumerated, the dynamic programming algorithm consumes more time and is more susceptible to statistics.

Selection of the Join Reorder algorithms

The selection of the TiDB Join Reorder algorithms is controlled by the `tidb_opt_join_reorder_threshold` variable. If the number of nodes participating in Join Reorder is greater than this threshold, TiDB uses the greedy algorithm. Otherwise, TiDB uses the dynamic programming algorithm.

Limitations of Join Reorder algorithms

The current Join Reorder algorithms have the following limitations:

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.
- The Join Reorder algorithm's support for Outer Join is controlled by the `tidb_enable_outer_join_reorder` system variable.
- Currently, the dynamic programming algorithm cannot perform Join Reorder for outer join.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to Description of the syntax elements.

11.3.3.2.10 Derive TopN or Limit from Window Functions

Window Functions are a common type of SQL function. When you use a window function for row numbering, such as `ROW_NUMBER()` or `RANK()`, it is common to filter the results after the window function is evaluated. For example:

```
SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t)
    ↪ dt WHERE rownumber <= 3
```

In a typical SQL execution process, TiDB first sorts all data in the table `t`, then calculates the `ROW_NUMBER()` result for each row, and finally filters with `rownumber <= 3`.

Starting from v7.0.0, TiDB supports deriving the TopN or Limit operator from window functions. With this optimization rule, TiDB can rewrite the original SQL into an equivalent form as follows:

```
WITH t_topN AS (SELECT a FROM t1 ORDER BY a LIMIT 3) SELECT * FROM (SELECT
    ↪ ROW_NUMBER() OVER (ORDER BY a) AS rownumber FROM t_topN) dt WHERE
    ↪ rownumber <= 3
```

After rewriting, TiDB can derive a TopN operator from the window function and the subsequent filter condition. Compared with the Sort operator in the original SQL (`ORDER BY` ↪), the TopN operator has a much higher execution efficiency. In addition, both TiKV and TiFlash support pushing down the TopN operator, which further improves the performance of the rewritten SQL.

Deriving TopN or Limit from window functions is disabled by default. To enable this feature, you can set the session variable tidb_opt_derive_topn to `ON`.

After enabling this feature, you can disable it by performing one of the following operations:

- Set the session variable tidb_opt_derive_topn to `OFF`.
- Follow the steps described in The blocklist of optimization rules and expression pushdown.

Limitations

- Only the `ROW_NUMBER()` window function is supported for SQL rewriting.
- TiDB can only rewrite SQL when filtering on the `ROW_NUMBER()` results and the filter condition is `<` or `<=`.

Usage examples

The following examples demonstrate how to use the optimization rule.

Window functions without PARTITION BY

Example 1: window functions without ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER () AS rownumber FROM t) dt
    ↪ WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| id                              | estRows | task      | access object | operator
    ↪  info                                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
| Projection_9                    | 2.40    | root      |               | Column#5
    ↪                                                    |
|  ─Selection_10                   | 2.40    | root      |               | le(Column
    ↪ #5, 3)                                             |
|    ─Window_11                    | 3.00    | root      |               | row_
    ↪ number()->Column#5 over(rows between current row and current row) |
|      ─Limit_15                   | 3.00    | root      |               | offset:0,
    ↪  count:3                                           |
|        ─TableReader_26           | 3.00    | root      |               | data:
    ↪ Limit_25                                                 |
|          ─Limit_25               | 3.00    | cop[tikv] |               | offset:0,
    ↪  count:3                                           |
|            ─TableFullScan_24     | 3.00    | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo                                |
+---------------------------------+---------+-----------+---------------+--------------
    ↪
```

In this query, the optimizer derives the Limit operator from the window function and pushes it down to TiKV.

Example 2: window functions with ORDER BY

```
CREATE TABLE t(id int, value int);
SET tidb_opt_derive_topn=on;
```

```
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (ORDER BY value) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| id                              | estRows | task      | access object |
    ↪ operator info
    ↪                                                                    |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| Projection_10                   | 2.40     | root      |               | Column#5
    ↪
    ↪ |
|  └Selection_11                  | 2.40     | root      |               | le(
    ↪ Column#5, 3)
    ↪                                                                      |
|    └Window_12                   | 3.00     | root      |               | row_
    ↪ number()->Column#5 over(order by test.t.value rows between current
    ↪ row and current row) |
|      └TopN_13                   | 3.00     | root      |               | test.t.
    ↪ value, offset:0, count:3
    ↪                                                        |
|        └TableReader_25          | 3.00     | root      |               | data:
    ↪ TopN_24
    ↪                                                                          |
|          └TopN_24               | 3.00     | cop[tikv] |               | test.t.
    ↪ value, offset:0, count:3
    ↪                                                      |
|            └TableFullScan_23    | 10000.00 | cop[tikv] | table:t       | keep
    ↪ order:false, stats:pseudo
    ↪                                                       |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
```

In this query, the optimizer derives the TopN operator from the window function and pushes it down to TiKV.

Window functions with PARTITION BY

> **Note:**
>
> For a window function containing `PARTITION BY`, the optimization rule only takes effect when the partition column is a prefix of the primary key and the

primary key is a clustered index.

Example 3: window functions without ORDER BY

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-----------------------------------+---------+----------+---------------+-----------
    ↪
| id                                | estRows | task     | access object |
    ↪ operator info
    ↪                                                                                |
+-----------------------------------+---------+----------+---------------+-----------
    ↪
| Projection_10                     | 2.40    | root     |               | Column#6
    ↪
    ↪
    ↪ |
| └─Selection_11                    | 2.40    | root     |               | le(
    ↪ Column#6, 3)
    ↪                                                                                  |
|   └─Shuffle_26                    | 3.00    | root     |               |
    ↪ execution info: concurrency:2, data sources:[TableReader_24]
    ↪                         |
|     └─Window_12                   | 3.00    | root     |               | row_
    ↪ number()->Column#6 over(partition by test.t.id1 rows between current
    ↪ row and current row) |
|       └─Sort_25                   | 3.00    | root     |               | test.t.
    ↪ id1
    ↪
    ↪ |
|         └─TableReader_24          | 3.00    | root     |               | data:
    ↪ Limit_23
    ↪                                                                                  |
|           └─Limit_23              | 3.00    | cop[tikv] |              |
    ↪ partition by test.t.id1, offset:0, count:3
    ↪                                          |
|             └─TableFullScan_22    | 3.00    | cop[tikv] | table:t      | keep
    ↪ order:false, stats:pseudo
```

```
    ↪                                                                    |
+-----------------------------------+---------+----------+---------------+-----------
    ↪
```

In this query, the optimizer derives the Limit operator from the window function and pushes it down to TiKV. Note that this Limit is actually a partition Limit, which means that the Limit will be applied to each group of data with the same `id1` value.

Example 4: window functions with ORDER BY

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1 ORDER BY
    ↪ value1) AS rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+-----------------------------------+----------+----------+---------------+-----------
    ↪
| id                                | estRows | task     | access object |
    ↪ operator info
    ↪
    ↪ |
+-----------------------------------+----------+----------+---------------+-----------
    ↪
| Projection_10                     | 2.40     | root     |               | Column
    ↪ #6
    ↪
    ↪ |
|  ─Selection_11                    | 2.40     | root     |               | le(
    ↪ Column#6, 3)
    ↪
    ↪ |
|    ─Shuffle_23                    | 3.00     | root     |               |
    ↪ execution info: concurrency:3, data sources:[TableReader_21]
    ↪                                                    |
|      ─Window_12                   | 3.00     | root     |               | row_
    ↪ number()->Column#6 over(partition by test.t.id1 order by test.t.
    ↪ value1 rows between current row and current row) |
|        ─Sort_22                   | 3.00     | root     |               | test.t
    ↪ .id1, test.t.value1
    ↪
    ↪ |
|          ─TableReader_21          | 3.00     | root     |               | data:
    ↪ TopN_19
```

```
    ↪
    ↪ |
|           └─TopN_19              | 3.00    | cop[tikv] |            |
    ↪ partition by test.t.id1 order by test.t.value1, offset:0, count:3
    ↪                                          |
|             └─TableFullScan_18   | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
+----------------------------------+----------+-----------+---------------+-----------
    ↪
```

In this query, the optimizer derives the TopN operator from the window function and pushes it down to TiKV. Note that this TopN is actually a partition TopN, which means that the TopN will be applied to each group of data with the same `id1` value.

Example 5: PARTITION BY column is not a prefix of the primary key

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) clustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY value1) AS
    ↪ rownumber FROM t) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+----------------------------------+----------+-----------+---------------+------------
    ↪
| id                               | estRows | task     | access object |
    ↪ operator info
    ↪                                                                    |
+----------------------------------+----------+-----------+---------------+------------
    ↪
| Projection_9                     | 8000.00 | root     |               | Column#6
    ↪
    ↪ |
|  └─Selection_10                   | 8000.00 | root     |               | le(
    ↪ Column#6, 3)
    ↪                                                                    |
|    └─Shuffle_15                   | 10000.00 | root    |               |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                                |
|      └─Window_11                  | 10000.00 | root    |               | row_
    ↪ number()->Column#6 over(partition by test.t.value1 rows between
    ↪ current row and current row) |
|        └─Sort_14                  | 10000.00 | root    |               | test.t.
    ↪ value1
```

```
    ↪
    ↪ |
|         └─TableReader_13       | 10000.00 | root    |               | data:
    ↪ TableFullScan_12
    ↪                                                                    |
|           └─TableFullScan_12   | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪                                                          |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
```

In this query, the SQL is not rewritten because the `PARTITION BY` column is not a prefix of the primary key.

Example 6: PARTITION BY column is a prefix of the primary key but not a clustered index

```
CREATE TABLE t(id1 int, id2 int, value1 int, value2 int, primary key(id1,
    ↪ id2) nonclustered);
SET tidb_opt_derive_topn=on;
EXPLAIN SELECT * FROM (SELECT ROW_NUMBER() OVER (PARTITION BY id1) AS
    ↪ rownumber FROM t use index()) dt WHERE rownumber <= 3;
```

The result is as follows:

```
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| id                              | estRows | task     | access object |
    ↪ operator info
    ↪                                                                   |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
| Projection_9                    | 8000.00 | root     |               | Column#7
    ↪
    ↪ |
|  └─Selection_10                 | 8000.00 | root     |               | le(
    ↪ Column#7, 3)
    ↪                                                                       |
|    └─Shuffle_15                 | 10000.00 | root    |               |
    ↪ execution info: concurrency:5, data sources:[TableReader_13]
    ↪                          |
|      └─Window_11                | 10000.00 | root    |               | row_
    ↪ number()->Column#7 over(partition by test.t.id1 rows between current
    ↪ row and current row) |
|        └─Sort_14                | 10000.00 | root    |               | test.t.
    ↪ id1
```

```
    ↪
    ↪ |
|         └─TableReader_13       | 10000.00 | root    |               | data:
    ↪ TableFullScan_12
    ↪                                                                  |
|           └─TableFullScan_12   | 10000.00 | cop[tikv] | table:t   | keep
    ↪ order:false, stats:pseudo
    ↪                                                    |
+---------------------------------+----------+-----------+---------------+-------------
    ↪
```

In this query, although the `PARTITION BY` column is a prefix of the primary key, the SQL is not rewritten because the primary key is not a clustered index.

11.3.3.3 Physical Optimization

11.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

Understand the Query Execution Plan has introduced some physical operators. This chapter focuses on the following aspects:

- In Index Selection, you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In Introduction to Statistics, you will learn what statistics TiDB collects to obtain the data distribution of a table.
- Wrong Index Solution introduces how to use the right index when you find the index is selected wrongly.
- Distinct Optimization introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.
- Cost Model introduces how to choose a optimal execution plan based on the cost model during physical optimization.

11.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and

different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / BatchPointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	This TableReader operator is for TiKV. It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the `_tidb_rowid` column, or if there are no

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	This TableReader operator is for TiFlash. TiFlash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookupReader	A table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the index does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexMerge	A table has multiple indexes or a multi-valued index.	When a multi-valued index or multiple indexes are used.	To use the operator, you can specify the optimizer hints, or let the optimizer to automatically select this operator based on cost estimation. For details, see Explain Statements Using Index Merge.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection of an operator for accessing tables.

Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

Rule-based selection

Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies "unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)", TiDB directly selects this index.
- Rule 2: If an index satisfies "unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexLookupReader operator)", TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies "ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold", TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The "index with full match" in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition "unique index with full match + the need to retrieve rows from a table" in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b
    ↪ ));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;
+--

```

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following dimensions are needed:

- How many access conditions are covered by the indexed columns. An "access condition" is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.

- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or IndexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.
- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.
- Whether the index is a global index. In partitioned tables, global indexes can effectively reduce the number of cop tasks for a SQL compared to normal indexes, thus improving overall performance.

For these preceding dimensions, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
    ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT * FROM t WHERE b = 2 AND c > 4;

Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

   This is usually due to stale or inaccurate statistics. You can re-execute the `ANALYZE TABLE` statement or modify the parameters of the `ANALYZE TABLE` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

   At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

   In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through Optimizer Hints.

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes. `FORCE_INDEX` and `USE_INDEX` have the same effect.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

Use multi-valued indexes

Multi-valued indexes are different from normal indexes. TiDB currently only uses IndexMerge to access multi-valued indexes. Therefore, to use multi-valued indexes for data access, make sure that the value of the system variable `tidb_enable_index_merge` is set to `ON`.

For the limitations of multi-valued indexes, refer to `CREATE INDEX`.

Supported scenarios

Currently, TiDB supports accessing multi-valued indexes using IndexMerge that is automatically converted from `json_member_of`, `json_contains`, and `json_overlaps` conditions. You can either rely on the optimizer to automatically select IndexMerge based on cost, or specify the selection of multi-valued indexes through the optimizer hint `use_index_merge` or `use_index`. See the following examples:

```
mysql> CREATE TABLE t1 (j JSON, INDEX idx((CAST(j->'$.path' AS SIGNED ARRAY
    ↪ ))));  -- Uses '$.path' as the path to create a multi-valued index
Query OK, 0 rows affected (0.04 sec)

mysql> EXPLAIN SELECT /*+ use_index_merge(t1, idx) */ * FROM t1 WHERE (1
    ↪ MEMBER OF (j->'$.path'));

- When both `OR` and `AND` are used to connect conditions (essentially nested `OR`

and AND), the conditions that constitute an IndexMerge must either all match the semantics of OR or all match the semantics of AND, not partially match the semantics of OR and partially match the semantics of AND. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE 1 member of (j->'$.a') AND (2 member of (j->'$.b') OR
    ↪ 3 member of (j->'$.a'));
EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4
    ↪ WHERE 1 member of (j->'$.a') OR (2 member of (j->'$.b') AND
    ↪ 3 member of (j->'$.a'));
```

```
-- Only 2 member of (j->'$.b') and 3 member of (j->'$.a') that
    ↪ match the semantics of OR constitute the IndexMerge. 1
    ↪ member of (j->'$.a') that matches the semantics of AND is
    ↪ not included.
> EXPLAIN SELECT /*+ use_index_merge(t4, mvi1, mvi2) */ * FROM t4

```

If conditions contain nested `OR`/`AND`, or if conditions correspond to only indexed columns after transformations, such as expansion, TiDB might not be able to use IndexMerge or make full use of all conditions. It is recommended to verify the behavior of each specific case.

The following are some examples:

```
CREATE TABLE t5 (a INT, j JSON, b INT, k JSON, INDEX idx(a, (CAST(j AS
    ↪ SIGNED ARRAY))), INDEX idx2(b, (CAST(k as SIGNED ARRAY))));
CREATE TABLE t6 (a INT, j JSON, b INT, k JSON, INDEX idx(a, (CAST(j AS
    ↪ SIGNED ARRAY)), b), INDEX idx2(a, (CAST(k as SIGNED ARRAY)), b));
```

If `AND` is nested in conditions connected by `OR` and subconditions connected by `AND` correspond to the exact columns of a multi-column index, TiDB can usually make full use of the conditions. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t5, idx, idx2) */ * FROM t5 WHERE (a=1
    ↪ AND 1 member of (j)) OR (b=2 AND 2 member of (k));
```

```
> EXPLAIN SELECT /*+ use_index_merge(t5, idx, idx2) */ * FROM t5 WHERE (a=1
    ↪  AND 1 member of (j)) OR (b=2 AND 2 member of (k));

   ↪
```

If a single `OR` is nested in conditions connected by `AND` and subconditions connected by `OR` correspond to the indexed columns after expansion, TiDB can usually make full use of the conditions. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t6, idx, idx2) */ * FROM t6 WHERE a=1
   ↪ AND (1 member of (j) OR 2 member of (k));
```

```

    ↪
    ↪ |
+--
    ↪ ----------------------------+---------+----------+-------------------------
    ↪
```

If multiple `OR` are nested in conditions connected by `AND` and subconditions connected by `OR` need expansion to correspond to the index columns, TiDB might not be able to make full use of all conditions. For example:

```
EXPLAIN SELECT /*+ use_index_merge(t6, idx, idx2) */ * FROM t6 WHERE a=1
    ↪ AND (1 member of (j) OR 2 member of (k)) and (b = 1 OR b = 2);
EXPLAIN SELECT /*+ use_index_merge(t6, idx, idx2) */ * FROM t6 WHERE a=1
    ↪ AND ((1 member of (j) AND b = 1) OR (1 member of (j) AND b = 2) OR (2
    ↪  member of (k) AND b = 1) OR (2 member of (k) AND b = 2));
```

```
-- Due to current implementation limitations, (b = 1 or b = 2) does not
    ↪ constitute the IndexMerge, but becomes a Selection operator
> EXPLAIN SELECT /*+ use_index_merge(t6, idx, idx2) */ * FROM t6 WHERE a=1
    ↪ AND (1 member of (j) OR 2 member of (k)) AND (b = 1 OR b = 2);
+--

Multi-valued indexes and plan cache

A query plan that uses `member of` to choose multi-valued indexes can be cached. A query plan that uses the `JSON_CONTAINS()` or `JSON_OVERLAPS()` function to choose multi-valued indexes cannot be cached.

The following are some examples that query plans can be cached:

```
mysql> CREATE TABLE t5 (j1 JSON, j2 JSON, INDEX idx1((CAST(j1 AS SIGNED
    ↪ ARRAY))));
Query OK, 0 rows affected (0.04 sec)

mysql> PREPARE st FROM 'SELECT /*+ use_index(t5, idx1) */ * FROM t5 WHERE
    ↪ (? member of (j1))';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @a=1;
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE st USING @a;
Empty set (0.01 sec)

mysql> EXECUTE st USING @a;
Empty set (0.00 sec)
```

```
mysql> SELECT @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)

mysql> PREPARE st FROM 'SELECT /*+ use_index(t5, idx1) */ * FROM t5 WHERE
    ↪ (? member of (j1)) AND JSON_CONTAINS(j2, ?)';
Query OK, 0 rows affected (0.00 sec)

mysql> SET @a=1, @b='[1,2]';
Query OK, 0 rows affected (0.00 sec)

mysql> EXECUTE st USING @a, @b;
Empty set (0.00 sec)

mysql> EXECUTE st USING @a, @b;
Empty set (0.00 sec)

mysql> SELECT @@LAST_PLAN_FROM_CACHE; -- can hit plan cache if the JSON_
    ↪ CONTAINS doesn't impact index selection

11.3.3.3.3 Introduction to Statistics

TiDB uses statistics as input to the optimizer to estimate the number of rows processed in each plan step for a SQL statement. The optimizer estimates the cost of each available plan choice, including index accesses and the sequence of table joins, and produces a cost for each available plan. The optimizer then picks the execution plan with the lowest overall cost.

Collect statistics

This section describes two ways of collecting statistics: automatic update and manual collection.

Automatic update

For the `INSERT`, `DELETE`, or `UPDATE` statements, TiDB automatically updates the number of rows and modified rows in statistics.

TiDB persists the update information regularly and the update cycle is 20 * `stats-lease`. The default value of `stats-lease` is `3s`. If you specify the value as `0`, TiDB stops updating statistics automatically.

Based upon the number of changes to a table, TiDB will automatically schedule `ANALYZE` to collect statistics on those tables. This is controlled by the following system variables.

System Variable	Default Value	Description
tidb_auto_analyze_concurrency	1	The concurrency for auto-analyze operations within a TiDB cluster.
tidb_auto_analyze_end_time	23:59 +0000	The end time in a day when TiDB can perform automatic updates.

System Variable	Default Value	Description
tidb_auto_analyze_partition_batch_size	8192	The number of partitions that TiDB automatically analyzes when analyzing a partitioned table (that is, when automatically updating statistics on a partitioned table).

System Variable	Default Value	Description
tidb_auto_analyze_ratio	0.5	The threshold value of automatic update.
tidb_auto_analyze_start_time	00:00 +0000	The start time in a day when TiDB can perform automatic update.
tidb_enable_auto_analyze	ON	Controls whether TiDB automatically executes ANALYZE.

System Variable	Default Value	Description
tidb_enable_auto_analyze_priority_queue	ON	Controls whether to enable the priority queue to schedule the tasks of automatically collecting statistics. When this variable is enabled, TiDB prioritizes collecting statistics for tables that

System Variable	Default Value	Description
tidb_enable_stats_owner	ON	Controls whether the corresponding TiDB instance can run automatic statistics update tasks.
tidb_max_auto_analyze_time	43200 (12 hours)	The maximum execution time of automatic ANALYZE tasks. The unit is second.

When the ratio of the number of modified rows to the total number of rows of `tbl` in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, modifications do not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

> **Note:**
>
> Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Manual collection

Currently, TiDB collects statistics as a full collection. You can execute the `ANALYZE TABLE` statement to collect statistics.

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
    ↪ CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated `TOPN`s.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

See Histograms, Top-N and CMSketch (Count-Min Sketch) for detailed explanations. For `SAMPLES/SAMPLERATE`, see Improve collection performance.

For information on persisting the options for easier reuse, see Persist `ANALYZE` configurations.

Types of statistics

This section describes three types of statistics: histogram, Count-Min Sketch, and Top-N.

Histogram

Histogram statistics are used by the optimizer to estimate selectivity of an interval or range predicate, and might also be used to determine the number of distinct values within a column for estimation of equal/IN predicates in Version 2 of statistics (refer to Versions of Statistics).

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here "equal-depth" means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

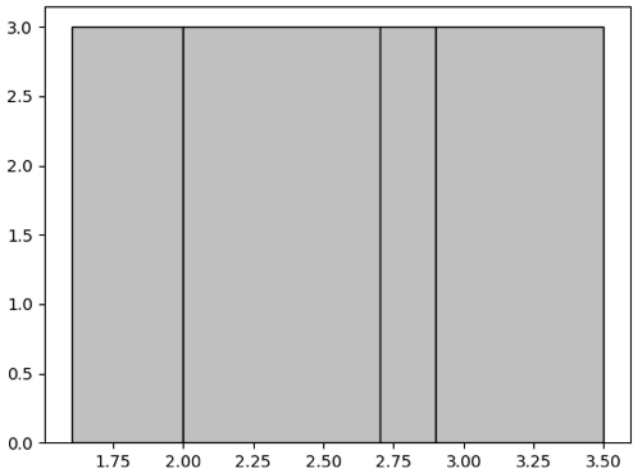

Figure 436: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to Manual Collection. When the number of buckets is larger, the

accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

> **Note:**
>
> Count-Min Sketch is used in statistics Version 1 only for equal/IN predicate selectivity estimation. In Version 2, Histogram statistics are used instead due to challenges in managing Count-Min sketch to avoid collisions as discussed below.

Count-Min Sketch is a hash structure. When processing an equivalence query such as `a = 1` or an `IN` query (for example, `a IN (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see Manual collection.
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see Manual collection.

Top-N

Top-N values are values with the top N occurrences in a column or index. Top-N statistics are often referred to as frequency statistics or data skew.

TiDB records the values and occurrences of Top-N values. Here `N` is controlled by the `WITH NUM TOPN` parameter. The default value is 20, meaning the top 20 most frequent values are collected. The maximum value is 1024. For details about the parameter, see Manual collection.

Selective statistics collection

This section describes how to collect statistics selectively.

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName` ↪ .

> **Note:**
>
> To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is `2`, this syntax collects statistics on the indexed columns and all indexes.

Collect statistics on some columns

When TiDB executes SQL statements, the optimizer uses statistics for only a subset of columns in most cases. For example, columns that appear in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` clauses. These columns are referred to as predicate columns.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics for only specific columns (that you choose) or `PREDICATE COLUMNS` to be used by the optimizer. To persist the column list of any subset of columns for reuse in future, see Persist column configurations.

> **Note:**
>
> - Collecting statistics on predicate columns is only applicable for `tidb_` ↪ `analyze_version = 2`.
> - Starting from TiDB v7.2.0, TiDB also introduces the `tidb_analyze` ↪ `_skip_column_types` system variable, indicating which types of columns are skipped for statistics collection when executing the `ANALYZE` command to collect statistics. The system variable is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

  In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

- To collect statistics on `PREDICATE COLUMNS`, use the following syntax:

```
ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM
    ↪ SAMPLERATE];
```

  TiDB always writes the `PREDICATE COLUMNS` information to the `mysql.column_stats_usage` system table every 100 * `stats-lease`.

  In addition to collecting statistics on `PREDICATE COLUMNS` in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

> **Note:**
>
> - If the `mysql.column_stats_usage` system table does not contain any `PREDICATE COLUMNS` recorded for that table, the preceding syntax collects statistics on indexed columns and all indexes in that table.
> - Any columns excluded from collection (either by manually listing columns or using `PREDICATE COLUMNS`) will not have their statistics overwritten. When executing a new type of SQL query, the optimizer will use the old statistics for such columns if it exists, or pseudo column statistics if columns never had statistics collected. The next ANALYZE using `PREDICATE COLUMNS` will collect the statistics on those columns.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
    ↪ DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
    ↪ ];
```

Collect statistics on partitions

- To collect statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH]|[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to collect statistics on some columns of some partitions in a table, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
    ↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH]|[WITH NUM SAMPLES|WITH
    ↪ FLOATNUM SAMPLERATE];
```

Collect statistics of partitioned tables in dynamic pruning mode

When accessing partitioned tables in dynamic pruning mode (which is the default since v6.3.0), TiDB collects table-level statistics, meaning global statistics of partitioned tables. Currently, global statistics are aggregated from statistics of all partitions. In dynamic pruning mode, an update to the statistics in any partition of a table can trigger an update to the global statistics for that table.

If the statistics of some partitions are empty, or statistics of some columns are missing in some partitions, then the collection behavior is controlled by the `tidb_skip_missing_partition_stats` variable:

- When an update to the global statistics is triggered and `tidb_skip_missing_partition_stats` is `OFF`:
    - If some partitions have no statistics (such as a new partition that has never been analyzed), global statistics generation is interrupted and a warning message is displayed saying that no statistics are available on partitions.
    - If statistics of some columns are absent in specific partitions (different columns are specified for analyzing in these partitions), global statistics generation is interrupted when statistics of these columns are aggregated, and a warning message is displayed saying that statistics of some columns are absent in specific partitions.
- When an update to the global statistics is triggered and `tidb_skip_missing_partition_stats` is `ON`:

- If statistics of all or some columns are missing for some partitions, TiDB skips these missing partition statistics when generating global statistics so the generation of global statistics is not affected.

In dynamic pruning mode, the `ANALYZE` configurations of partitions and tables should be the same. Therefore, if you specify the `COLUMNS` configuration following the `ANALYZE TABLE TableName PARTITION PartitionNameList` statement or the `OPTIONS` configuration following `WITH`, TiDB will ignore them and return a warning.

Improve collection performance

Note:

- The execution time of `ANALYZE TABLE` in TiDB might be longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while by default in TiDB a comprehensive set of statistics are completely rebuilt.

TiDB provides two options to improve the performance of statistics collection:

- Collecting statistics on a subset of the columns. See Collecting statistics on some columns.
- Sampling.

Statistics sampling

Sampling is available via two separate options of the `ANALYZE` statement - with each corresponding to a different collection algorithm:

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.
- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range `(0, 1]`, this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics

by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the sum of all the values in the `APPROXIMATE_KEYS` column in the results of `SHOW TABLE REGIONS` of the table as another reference to calculate the sampling rate.

> **Note:**
>
> Normally, `STATS_META` is more credible than `APPROXIMATE_KEYS`. However, when the result of `STATS_META` is much smaller than the result of `APPROXIMATE_KEYS`, it is recommended that you use `APPROXIMATE_KEYS` to calculate the sampling rate.

The memory quota for collecting statistics

> **Warning:**
>
> Currently, the `ANALYZE` memory quota is an experimental feature, and the memory statistics might be inaccurate in production environments.

Since TiDB v6.1.0, you can use the system variable `tidb_mem_quota_analyze` to control the memory quota for collecting statistics in TiDB.

To set a proper value of `tidb_mem_quota_analyze`, consider the data size of the cluster. When the default sampling rate is used, the main considerations are the number of columns, the size of column values, and the memory configuration of TiDB. Consider the following suggestions when you configure the maximum and minimum values:

> **Note:**
>
> The following suggestions are for reference only. You need to configure the values based on the real scenario.

- Minimum value: should be greater than the maximum memory usage when TiDB collects statistics from the table with the most columns. An approximate reference: when

TiDB collects statistics from a table with 20 columns using the default configuration, the maximum memory usage is about 800 MiB; when TiDB collects statistics from a table with 160 columns using the default configuration, the maximum memory usage is about 5 GiB.

- Maximum value: should be less than the available memory when TiDB is not collecting statistics.

Persist ANALYZE configurations

Since v5.4.0, TiDB supports persisting some `ANALYZE` configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the `ANALYZE` configurations that support persistence:

Configurations	Corresponding ANALYZE syntax
The number of histogram buckets	`WITH NUM BUCKETS`
The number of Top-N	`WITH NUM TOPN`
The number of samples	`WITH NUM SAMPLES`
The sampling rate	`WITH FLOATNUM SAMPLERATE`

Configurations	Corresponding ANALYZE syntax
The `ANALYZE` ↪ column type	AnalyzeColumnOp ::= ('ALL COLUMNS' | 'PREDICATE COLUMNS' | 'COLUMNS' ColumnNameList)
The `ANALYZE` ↪ column	ColumnNameList ::= Identifier (',' Identifier)*

Enable ANALYZE configuration persistence

The `ANALYZE` configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is `2` and `tidb_persist_analyze_options` is `ON` by default).

You can use this feature to record the persistence configurations specified in the `ANALYZE` ↪ statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

To query the configuration persisted on a specific table used for auto analyze operations, you can use the following SQL statement:

```
SELECT sample_num, sample_rate, buckets, topn, column_choice, column_ids
    ↪ FROM mysql.analyze_options opt JOIN information_schema.tables tbl ON
```

```
    ↪ opt.table_id = tbl.tidb_table_id WHERE tbl.table_schema = '{db_name}'
    ↪  AND tbl.table_name = '{table_name}';
```

TiDB will overwrite the previously recorded persistent configuration using the new configurations specified by the latest `ANALYZE` statement. For example, if you run `ANALYZE TABLE t WITH 200 TOPN;`, it will set the top 200 values in the `ANALYZE` statement. Subsequently, executing `ANALYZE TABLE t WITH 0.1 SAMPLERATE;` will set both the top 200 values and a sampling rate of 0.1 for auto `ANALYZE` statements, similar to `ANALYZE TABLE t WITH 200 TOPN, 0.1 SAMPLERATE;`.

Disable ANALYZE configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

> **Note:**
>
> When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

Persist column configurations

If you want to persist the column configuration in the `ANALYZE` statement (including `COLUMNS ColumnNameList`, `PREDICATE COLUMNS`, and `ALL COLUMNS`), set the value of the `tidb_persist_analyze_options` system variable to `ON` to enable the ANALYZE configuration persistence feature. After enabling the ANALYZE configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the `ANALYZE` statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the `ANALYZE` statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest `ANALYZE` statement.

To locate `PREDICATE COLUMNS` and columns on which statistics have been collected, use the `SHOW COLUMN_STATS_USAGE` statement.

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns `b`, `c`, and `d`, where column `b` is a `PREDICATE COLUMN` and columns `c` and `d` are index columns.

```
CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
   ↪  collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
   ↪ collected by TiDB.
SHOW COLUMN_STATS_USAGE
WHERE db_name = 'test' AND table_name = 't' AND last_used_at IS NOT NULL;
+--
   ↪ -------+-----------+---------------+------------+-------------------+------
   ↪

```

Versions of statistics

The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`.

- For TiDB Self-Managed, the default value of this variable changes from `1` to `2` starting from v5.3.0.
- For TiDB Cloud, the default value of this variable changes from `1` to `2` starting from v6.5.0.
- If your cluster is upgraded from an earlier version, the default value of `tidb_analyze_version` does not change after the upgrade.

Version 2 is preferred, and will continue to be enhanced to ultimately replace Version 1 completely. Compared to Version 1, Version 2 improves the accuracy of many of the statistics collected for larger data volumes. Version 2 also improves collection performance by removing the need to collect Count-Min sketch statistics for predicate selectivity estimation, and also supporting automated collection only on selected columns (see Collecting statistics on some columns).

The following table lists the information collected by each version for usage in the optimizer estimates:

Information	Version 1	Version 2
The total number of rows in the table		
Equal/IN predicate estimation	(Column/Index Top-N & Count-Min Sketch)	(Column/Index Top-N & Histogram)
Range predicate estimation	(Column/Index Top-N & Histogram)	(Column/Index Top-N & Histogram)
`NULL` ↪ predicate estimation		

Information	Version 1	Version 2
The average length of columns		
The average length of indexes		

Switch between statistics versions

It is recommended to ensure that all tables/indexes (and partitions) utilize statistics collection from the same version. Version 2 is recommended, however, it is not recommended to switch from one version to another without a justifiable reason such as an issue experienced with the version in use. A switch between versions might take a period of time when no statistics are available until all tables have been analyzed with the new version, which might negatively affect the optimizer plan choices if statistics are not available.

Examples of justifications to switch might include - with Version 1, there could be inaccuracies in equal/IN predicate estimation due to hash collisions when collecting Count-Min sketch statistics. Solutions are listed in the Count-Min Sketch section. Alternatively, setting `tidb_analyze_version = 2` and rerunning `ANALYZE` on all objects is also a solution. In the early release of Version 2, there was a risk of memory overflow after `ANALYZE`. This issue is resolved, but initially, one solution was to set `tidb_analyze_version = 1` and rerun `ANALYZE` on all objects.

To prepare `ANALYZE` for switching between versions:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema, '.', table_name
    ↪ , ';'))
FROM information_schema.tables JOIN mysql.stats_histograms
ON table_id = tidb_table_id
WHERE stats_ver = 2;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
SELECT DISTINCT(CONCAT('DROP STATS ', table_schema, '.', table_name, '
    ↪ ;'))
FROM information_schema.tables JOIN mysql.stats_histograms
ON table_id = tidb_table_id
WHERE stats_ver = 2;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt';
mysql -h ${TiDB_IP} -u user -P ${TIDB_PORT} ... < '/tmp/sql.txt'
```

View statistics

You can view the `ANALYZE` status and statistics information using the following statements.

`ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using `SHOW ANALYZE STATUS`.

Starting from TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement supports showing cluster-level tasks. Even after a TiDB restart, you can still view task records before the restart using this statement. Before TiDB v6.1.0, the `SHOW ANALYZE STATUS` statement can only show instance-level tasks, and task records are cleared after a TiDB restart.

`SHOW ANALYZE STATUS` shows the most recent task records only. Starting from TiDB v6.1.0, you can view the history tasks within the last 7 days through the system table `mysql.analyze_jobs`.

When `tidb_mem_quota_analyze` is set and an automatic `ANALYZE` task running in the TiDB background uses more memory than this threshold, the task will be retried. You can see failed and retried tasks in the output of the `SHOW ANALYZE STATUS` statement.

When `tidb_max_auto_analyze_time` is greater than 0 and an automatic `ANALYZE` task running in the TiDB background takes more time than this threshold, the task will be terminated.

```
mysql> SHOW ANALYZE STATUS [ShowLikeOrWhere];
+--
    ↪ ------------+------------+----------------+-------------------------------------
    ↪
| Table_schema | Table_name | Partition_name | Job_info
    ↪                                                                  |
    ↪ Processed_rows | Start_time     | End_time          | State   | Fail_
    ↪ reason                                                           |
```

```
+--
    ↪ -----------+-----------+---------------+----------------------------------
    ↪
| test       | sbtest1   |               | retry auto analyze table all
    ↪ columns with 100 topn, 0.055 samplerate          |       2000000 |
    ↪ 2022-05-07 16:41:09 | 2022-05-07 16:41:20 | finished | NULL
    ↪                                                              |
| test       | sbtest1   |               | auto analyze table all columns
    ↪ with 100 topn, 0.5 samplerate                    |            0 |
    ↪ 2022-05-07 16:40:50 | 2022-05-07 16:41:09 | failed | analyze panic
    ↪ due to memory quota exceeds, please try with smaller samplerate |
```

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count >= row_count`, the health state is 0; when `modify_count < row_count`, the health state is (1 - `modify_count` ↪ `/row_count`) * 100.

Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

Load statistics

> **Note:**
>
> Loading statistics is not available on TiDB Cloud Serverless clusters.

By default, depending on the size of column statistics, TiDB loads statistics differently as follows:

- For statistics that consume small amounts of memory (such as count, distinctCount, and nullCount), as long as the column data is updated, TiDB automatically loads the corresponding statistics into memory for use in the SQL optimization stage.
- For statistics that consume large amounts of memory (such as histograms, TopN, and Count-Min Sketch), to ensure the performance of SQL execution, TiDB loads the statistics asynchronously on demand. Take histograms as an example. TiDB loads histogram statistics on a column into memory only when the optimizer uses the histogram statistics on that column. On-demand asynchronous statistics loading does not affect the performance of SQL execution but might provide incomplete statistics for SQL optimization.

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, TopN, and Count-Min Sketch statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

To enable this feature, set the value of the `tidb_stats_load_sync_wait` system variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. The default value of this variable is `100`, indicating that the feature is enabled.

After enabling the synchronously loading statistics feature, you can further configure the feature as follows:

- To control how TiDB behaves when the waiting time of SQL optimization reaches the timeout, modify the value of the `tidb_stats_load_pseudo_timeout` system variable. The default value of this variable is `ON`, indicating that after the timeout, the SQL optimization process does not use any histogram, TopN, or CMSketch statistics on any columns. If this variable is set to `OFF`, after the timeout, SQL execution fails.
- To specify the maximum number of columns that the synchronously loading statistics feature can process concurrently, modify the value of the `stats-load-concurrency` ↪ option in the TiDB configuration file. Starting from v8.2.0, the default value of this option is `0`, indicating that TiDB automatically adjusts concurrency based on the server configuration.
- To specify the maximum number of column requests that the synchronously loading statistics feature can cache, modify the value of the `stats-load-queue-size` option in the TiDB configuration file. The default value is `1000`.

During TiDB startup, SQL statements executed before the initial statistics are fully loaded might have suboptimal execution plans, thus causing performance issues. To avoid such issues, TiDB v7.1.0 introduces the configuration parameter `force-init-stats`. With this option, you can control whether TiDB provides services only after statistics initialization has been finished during startup. Starting from v7.2.0, this parameter is enabled by default.

Starting from v7.1.0, TiDB introduces `lite-init-stats` for lightweight statistics initialization.

- When the value of `lite-init-stats` is `true`, statistics initialization does not load any histogram, TopN, or Count-Min Sketch of indexes or columns into memory.
- When the value of `lite-init-stats` is `false`, statistics initialization loads histograms, TopN, and Count-Min Sketch of indexes and primary keys into memory but does not load any histogram, TopN, or Count-Min Sketch of non-primary key columns into memory. When the optimizer needs the histogram, TopN, and Count-Min Sketch of a specific index or column, the necessary statistics are loaded into memory synchronously or asynchronously.

The default value of `lite-init-stats` is `true`, which means to enable lightweight statistics initialization. Setting `lite-init-stats` to `true` speeds up statistics initialization and reduces TiDB memory usage by avoiding unnecessary statistics loading.

Export and import statistics

This section describes how to export and import statistics.

Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_
    ↪ name}/${table_name}
```

For example:

```
curl -s http://127.0.0.1:10080/stats/dump/test/t1 -o /tmp/t1.json
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_
    ↪ name}/${table_name}/${yyyyMMddHHmmss}
```

Import statistics

Note:

When you start the MySQL client, use the `--local-infile=1` option.

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Loading statistics can be done with the `LOAD STATS` statement.

For example:

```
LOAD STATS 'file_name';
```

`file_name` is the file name of the statistics to be imported.

Lock statistics

Starting from v6.5.0, TiDB supports locking statistics. After the statistics of a table or a partition are locked, the statistics of the table cannot be modified and the `ANALYZE` statement cannot be executed on the table. For example:

Create table `t`, and insert data into it. When the statistics of table `t` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT);
Query OK, 0 rows affected (0.03 sec)

mysql> INSERT INTO t VALUES (1,2), (3,4), (5,6), (7,8);
Query OK, 4 rows affected (0.00 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.02 sec)

mysql> SHOW WARNINGS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t, reason to use this rate is "Row count in stats_meta is much
    ↪ smaller compared with the row count got by PD, use min(1, 15000/4) as
    ↪  the sample-rate=1" |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Lock the statistics of table `t` and execute `ANALYZE`. The warning message shows that the `ANALYZE` statement has skipped table `t`.

```
mysql> LOCK STATS t;
Query OK, 0 rows affected (0.00 sec)

mysql> SHOW STATS_LOCKED;
+---------+------------+----------------+--------+
| Db_name | Table_name | Partition_name | Status |
+---------+------------+----------------+--------+
| test    | t          |                | locked |
+---------+------------+----------------+--------+
1 row in set (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 2 warnings (0.00 sec)

mysql> SHOW WARNINGS;
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
| Note    | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
   ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
   ↪ sample-rate=1" |
| Warning | 1105 | skip analyze locked table: test.t
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------------------
   ↪
2 rows in set (0.00 sec)
```

Unlock the statistics of table `t` and `ANALYZE` can be successfully executed again.

```
mysql> UNLOCK STATS t;
Query OK, 0 rows affected (0.01 sec)

mysql> ANALYZE TABLE t;
Query OK, 0 rows affected, 1 warning (0.03 sec)
```

```
mysql> SHOW WARNINGS;
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Level | Code | Message
    ↪
    ↪ |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
| Note | 1105 | Analyze use auto adjusted sample rate 1.000000 for table
    ↪ test.t, reason to use this rate is "use min(1, 110000/8) as the
    ↪ sample-rate=1" |
+--
    ↪ -----+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In addition, you can also lock the statistics of a partition using `LOCK STATS`. For example:

Create a partition table `t`, and insert data into it. When the statistics of partition `p1` are not locked, the `ANALYZE` statement can be successfully executed.

```
mysql> CREATE TABLE t(a INT, b INT) PARTITION BY RANGE (a) (PARTITION p0

Behaviors of locking statistics

- If you lock the statistics on a partitioned table, the statistics of all partitions on the partitioned table are locked.

- If you truncate a table or partition, the statistics lock on the table or partition will be released.

The following table describes the behaviors of locking statistics:

	Delete the whole table	Truncate the whole table	Truncate a partition	Create a new partition	Delete a partition	Reorganize a partition	Exchange a partition
A non-partitioned table is locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	/	/	/	/	/
A partitioned table and the whole table is locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	The old partition lock information is invalid, and the new partition is automatically locked	The new partition is automatically locked	The lock information of the deleted partition is cleared, and the lock of the whole table continues to take effect	The lock information of the deleted partition is cleared, and the new partition is automatically locked	The lock information is transferred to the exchanged table, and the new partition is automatically locked

	Delete the whole table	Truncate the whole table	Truncate a partition	Create a new partition	Delete a partition	Reorganize a partition	Exchange a partition
A partitioned table and only some partitions are locked	The lock is invalid	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	The lock is invalid because TiDB deletes the old table, so the lock information is also deleted	/	The deleted partition lock information is cleared	The deleted partition lock information is cleared	The lock information is transferred to the exchanged table

Manage `ANALYZE` tasks and concurrency

This section describes how to terminate background `ANALYZE` tasks and control the `ANALYZE` concurrency.

Terminate background `ANALYZE` tasks

Since TiDB v6.0, TiDB supports using the `KILL` statement to terminate an `ANALYZE` task running in the background. If you find that an `ANALYZE` task running in the background consumes a lot of resources and affects your application, you can terminate the `ANALYZE` task by taking the following steps:

1. Execute the following SQL statement:

   ```
   SHOW ANALYZE STATUS
   ```

   By checking the `instance` column and the `process_id` column in the result, you can get the TiDB instance address and the task `ID` of the background `ANALYZE` task.

2. Terminate the `ANALYZE` task that is running in the background.

   - If `enable-global-kill` is `true` (`true` by default), you can execute the `KILL TIDB ${id};` statement directly, where `${id}` is the `ID` of the background `ANALYZE` task obtained from the previous step.
   - If `enable-global-kill` is `false`, you need to use a client to connect to the TiDB instance that is executing the backend `ANALYZE` task, and then execute the `KILL TIDB ${id};` statement. If you use a client to connect to another TiDB instance, or if there is a proxy between the client and the TiDB cluster, the `KILL` statement cannot terminate the background `ANALYZE` task.

For more information on the `KILL` statement, see KILL.

Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using system variables, to control its effect on the system.

The relationships of the relevant system variables are shown below:

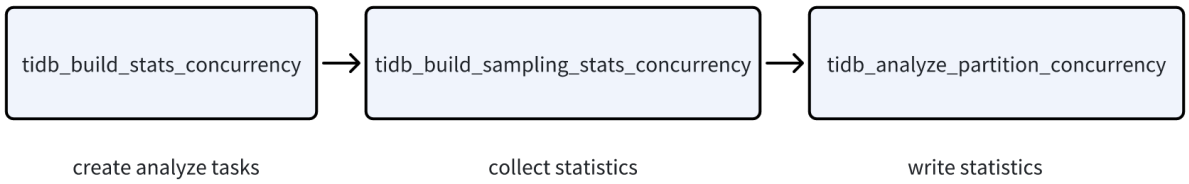

Figure 437: analyze_concurrency

`tidb_build_stats_concurrency`, `tidb_build_sampling_stats_concurrency`, and `tidb_analyze_partition_concurrency` are in an upstream-downstream relationship, as shown in the preceding diagram. The actual total concurrency is: `tidb_build_stats_concurrency` * (`tidb_build_sampling_stats_concurrency` + `tidb_analyze_partition_concurrency`). When modifying these variables, you need to consider their respective values at the same time. It is recommended to adjust them one by one in the order of `tidb_analyze_partition_concurrency`, `tidb_build_sampling_stats_concurrency`, `tidb_build_stats_concurrency`, and observe the impact on the system. The larger the values of these three variables, the greater the resource overhead on the system.

`tidb_build_stats_concurrency`

When you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on statistics of one column or index. You can use the `tidb_build_stats_concurrency` variable to control the number of simultaneous small tasks. The default value is 2. The default value is 4 for v7.4.0 and earlier versions.

`tidb_build_sampling_stats_concurrency`

When analyzing ordinary columns, you can use `tidb_build_sampling_stats_concurrency` to control the concurrency of executing sampling tasks. The default value is 2.

`tidb_analyze_partition_concurrency`

When running the `ANALYZE` statement, you can use `tidb_analyze_partition_concurrency` to control the concurrency of reading and writing statistics for a partitioned table. The default value is 2. The default value is 1 for v7.4.0 and earlier versions.

`tidb_distsql_scan_concurrency`

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` variable to control the number of Regions to be read at one time. The default value is `15`. Note that changing the value will affect query performance. Adjust the value carefully.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency` variable to control the number of Regions to be read at one time. The default value is `1`. Note that changing the value will affect query performance. Adjust the value carefully.

11.3.3.3.4 Introduction to Extended Statistics

TiDB can collect the following two types of statistics. This document describes how to use extended statistics to guide the optimizer. Before reading this document, it is recommended that you read Introduction to Statistics first.

- Basic statistics: statistics such as histograms and Count-Min Sketch, which primarily focus on individual columns. They are essential for the optimizer to estimate the query cost. See Introduction to Statistics for details.
- Extended statistics: statistics that focus on data correlations between specified columns, which guide the optimizer to estimate the query cost more precisely when the queried columns are correlated.

When the `ANALYZE` statement is executed manually or automatically, TiDB by default only collects the basic statistics and does not collect the extended statistics. This is because the extended statistics are only used for optimizer estimates in specific scenarios, and collecting them requires additional overhead.

Extended statistics are disabled by default. To collect extended statistics, you need to first enable extended statistics, and then create your desired extended statistics objects one by one. After the object creation, the next time the `ANALYZE` statement is executed, TiDB collects both the basic statistics and the corresponding extended statistics of the created objects.

> **Warning:**
>
> This feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.

Limitations

Extended statistics are not collected in the following scenarios:

- Statistics collection on indexes only
- Statistics collection using the `ANALYZE INCREMENTAL` command
- Statistics collection when the value of the system variable `tidb_enable_fast_analyze` is set to `true`

Common operations

Enable extended statistics

To enable extended statistics, set the system variable `tidb_enable_extended_stats` to `ON`:

```
SET GLOBAL tidb_enable_extended_stats = ON;
```

The default value of this variable is `OFF`. The setting of this system variable applies to all extended statistics objects.

Create extended statistics objects

The creation of extended statistics objects is not a one-time task. You need to repeat the creation for each extended statistics object.

To create an extended statistics object, use the SQL statement `ALTER TABLE ADD STATS_EXTENDED`. The syntax is as follows:

```
ALTER TABLE table_name ADD STATS_EXTENDED IF NOT EXISTS stats_name stats_type(column_name, column_name...);
```

In the syntax, you can specify the table name, statistics name, statistics type, and column name of the extended statistics object to be collected.

- `table_name` specifies the name of the table from which the extended statistics are collected.
- `stats_name` specifies the name of the statistics object, which must be unique for each table.
- `stats_type` specifies the type of the statistics. Currently, only the correlation type is supported.

- `column_name` specifies the column group, which might have multiple columns. Currently, you can only specify two column names.

How it works

To improve access performance, each TiDB node maintains a cache in the system table `mysql.stats_extended` for extended statistics. After you create the extended statistics objects, the next time the `ANALYZE` statement is executed, TiDB will collect the extended statistics if the system table `mysql.stats_extended` has the corresponding objects.

Each row in the `mysql.stats_extended` table has a `version` column. Once a row is updated, the value of `version` is increased. In this way, TiDB loads the table into memory incrementally, instead of fully.

TiDB loads `mysql.stats_extended` periodically to ensure that the cache is kept the same as the data in the table.

Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can execute the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

Delete extended statistics objects

To delete an extended statistics object, use the following statement:

```
ALTER TABLE table_name DROP STATS_EXTENDED stats_name;
```

How it works

After you execute the statement, TiDB marks the value of the corresponding object in `mysql.stats_extended`'s column `status` to `2`, instead of deleting the object directly.

Other TiDB nodes will read this change and delete the object in their memory cache. The background garbage collection will delete the object eventually.

Warning:

It is **NOT RECOMMENDED** to directly operate on the `mysql.stats_extended` system table. Otherwise, inconsistent caches occur on different TiDB nodes.

If you have mistakenly operated on the table, you can use the following statement on each TiDB node. Then the current cache will be cleared and the `mysql.stats_extended` table will be fully reloaded:

```
ADMIN RELOAD STATS_EXTENDED;
```

Export and import extended statistics

The way of exporting or importing extended statistics is the same as exporting or importing basic statistics. See Introduction to Statistics - Import and export statistics for details.

Usage examples for correlation-type extended statistics

Currently, TiDB only supports the correlation-type extended statistics. This type is used to estimate the number of rows in the range query and improve index selection. The following example shows how the correlation-type extended statistics are used to estimate the number of rows in a range query.

Step 1. Define the table

Define a table `t` as follows:

```
CREATE TABLE t(col1 INT, col2 INT, KEY(col1), KEY(col2));
```

Suppose that `col1` and `col2` of table `t` both obey monotonically increasing constraints in row order. This means that the values of `col1` and `col2` are strictly correlated in order, and the correlation factor is `1`.

Step 2. Execute an example query without extended statistics

Execute the following query without using extended statistics:

```
SELECT * FROM t WHERE col1 > 1 ORDER BY col2 LIMIT 1;
```

For the execution of the preceding query, the TiDB optimizer has the following options to access table `t`:

- Uses the index on `col1` to access table `t` and then sorts the result by `col2` to calculate `Top-1`.
- Uses the index on `col2` to meet the first row that satisfies `col1 > 1`. The cost of this access method mainly depends on how many rows are filtered out when TiDB scans the table in `col2`'s order.

Without extended statistics, the TiDB optimizer only supposes that `col1` and `col2` are independent, which **leads to a significant estimation error**.

Step 3. Enable extended statistics

Set `tidb_enable_extended_stats` to `ON`, and create the extended statistics object for `col1` and `col2`:

```
ALTER TABLE t ADD STATS_EXTENDED s1 correlation(col1, col2);
```

When you execute `ANALYZE` after the object creation, TiDB calculates the Pearson correlation coefficient of `col1` and `col2` of table `t`, and writes the object into the `mysql.stats_extended` table.

Step 4. See how extended statistics make a difference

After TiDB has the extended statistics for correlation, the optimizer can estimate how many rows to be scanned more precisely.

At this time, for the query in Stage 2. Execute an example query without extended statistics, `col1` and `col2` are strictly correlated in order. If TiDB accesses table `t` by using the index on `col2` to meet the first row that satisfies `col1 > 1`, the TiDB optimizer will equivalently translate the row count estimation into the following query:

```
SELECT * FROM t WHERE col1 <= 1 OR col1 IS NULL;
```

The preceding query result plus one will be the final estimation for the row count. In this way, you do not need to use the independent assumption and **the significant estimation error is avoided**.

If the correlation factor (`1` in this example) is less than the value of the system variable `tidb_opt_correlation_threshold`, the optimizer will use the independent assumption, but it will also increase the estimation heuristically. The larger the value of `tidb_opt_correlation_exp_factor`, the larger the estimation result. The larger the absolute value of the correlation factor, the larger the estimation result.

11.3.3.3.5 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

There are multiple reasons why the optimizer might choose an unexpected index:

- **Outdated statistics**: the optimizer relies on statistics to estimate query costs. If the statistics are outdated, the optimizer might make suboptimal choices.
- **Statistics mismatch**: even if statistics are current, they might not accurately reflect the data distribution, leading to incorrect cost estimations.
- **Incorrect cost calculation**: the optimizer might miscalculate the cost of using an index due to complex query structures or data distribution.

- **Inappropriate engine selection**: in some cases, the optimizer might select a storage engine that is not optimal for the query.
- **Function pushdown limitations**: certain functions or operations might not be pushed down to storage engines, potentially affecting query performance.

Statistics health

You can first view the health state of tables in the statistics, and then solve this issue according to the different health states.

Low health state

The low health state means TiDB has not performed the`ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be Count-Min Sketch. You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimizer hint (see USE_INDEX for details). Also, you can change the query behavior by using SQL Plan Management in a non-intrusive way.

Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

Statistics mismatch

When data distribution is highly skewed, the statistics might not accurately reflect the actual data. In such cases, try configuring the options of the `ANALYZE TABLE` statement. It might help improve the accuracy of statistics and better match the index.

For example, suppose you have an `orders` table with an index on the `customer_id` column, and more than 50% of the orders share the same `customer_id`. In this case, the statistics might not represent the data distribution well, affecting query performance.

Cost information

To view detailed information on execution costs, you can execute the `EXPLAIN` and `EXPLAIN ANALYZE` statements with the `FORMAT=verbose` option. According to the information, you can see cost differences between different execution paths.

Engine selection

By default, TiDB chooses TiKV or TiFlash for table access based on cost estimation. You can experiment with different engines for the same query by applying engine isolation.

For more information, see Engine isolation.

Function pushdown

To enhance query performance, TiDB can push down certain functions to the TiKV or TiFlash storage engine for execution. However, some functions do not support pushdown, which might limit available execution plans and potentially affect query performance.

For expressions that support pushdown, see TiKV supported pushdown calculations and TiFlash supported pushdown calculations.

Note that you can also disable the pushdown of specific expressions. For more information, see Blocklist of optimization rules and expression pushdown.

11.3.3.3.6 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                               |
+--
   ↪ ----------------------+---------+-----------+--------------+-----------------
   ↪
| HashAgg_6             | 2.40    | root      |               | group by:test.t.a
   ↪ , funcs:firstrow(test.t.a)->test.t.a |
| └─TableReader_11      | 3.00    | root      |               | data:
   ↪ TableFullScan_10                          |
|   └─TableFullScan_10  | 3.00    | cop[tikv] | table:t       | keep order:false
   ↪ , stats:pseudo                |
```

```
+--
    ↪ ----------------------+---------+-----------+--------------+----------------
    ↪
3 rows in set (0.00 sec)
```

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The `tidb_opt_distinct_agg_push_down` system variable or the `distinct-agg-push ↪ -down` configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV or TiFlash Coprocessor.

Take the following queries as an example of this optimization. `tidb_opt_distinct_agg ↪ _push_down` is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to `1`, the `distinct ↪ a` part of `count(distinct a)` is pushed to TiKV or TiFlash Coprocessor: there is a HashAgg_5 to remove the duplicated values on column a in the TiKV Coprocessor. It might reduce the computation overhead of `HashAgg_8` in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+--
    ↪ ----------------------+---------+-----------+--------------+----------------
    ↪
| id                    | estRows | task      | access object | operator info
    ↪                     |
+--
    ↪ ----------------------+---------+-----------+--------------+----------------
    ↪
| StreamAgg_6           | 1.00    | root      |               | funcs:count(
    ↪ distinct test.t.a)->Column#4 |
| └─TableReader_10      | 10000.00 | root     |               | data:
    ↪ TableFullScan_9                |
|   └─TableFullScan_9   | 10000.00 | cop[tikv] | table:t       | keep order:false
    ↪ , stats:pseudo      |
+--
    ↪ ----------------------+---------+-----------+--------------+----------------
    ↪
3 rows in set (0.01 sec)

mysql> set session tidb_opt_distinct_agg_push_down = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> desc select count(distinct a) from test.t;
+--
    ↪ ----------------------+---------+-----------+--------------+----------------
```

```
    ↪
| id                    | estRows | task     | access object | operator info
    ↪                     |
+--
    ↪ ----------------------+---------+----------+---------------+--------------
    ↪
| HashAgg_8             | 1.00    | root     |               | funcs:count(
    ↪ distinct test.t.a)->Column#3 |
| ─TableReader_9        | 1.00    | root     |               | data:HashAgg_5
    ↪                       |
|   ─HashAgg_5          | 1.00    | cop[tikv] |              | group by:test.
    ↪ t.a,                  |
|     ─TableFullScan_7  | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo     |
+--
    ↪ ----------------------+---------+----------+---------------+--------------
    ↪
4 rows in set (0.00 sec)
```

11.3.3.3.7 Cost Model

TiDB uses a cost model to choose an index and operator during physical optimization. The process is illustrated in the following diagram:

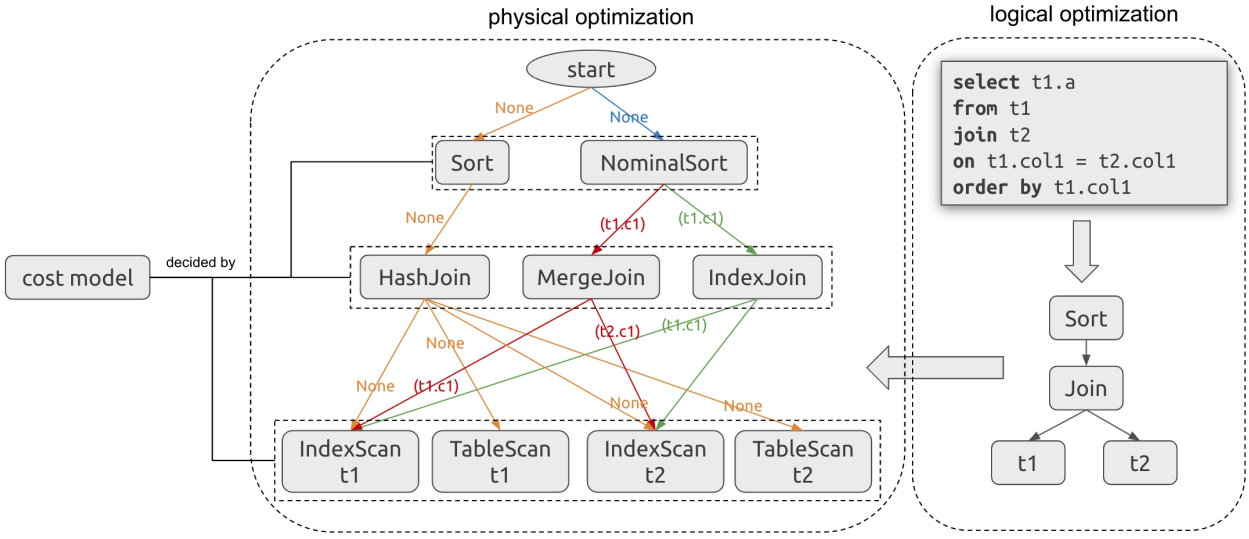

Figure 438: CostModel

TiDB calculates the access cost of each index and the execution cost of each physical operator in plans (such as HashJoin and IndexJoin) and chooses the minimum cost plan.

The following is a simplified example to explain how the cost model works. Suppose that there is a table `t`:

```
mysql> SHOW CREATE TABLE t;
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| Table | Create Table
    ↪
    ↪ |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
| t     | CREATE TABLE `t` (
  `a` int DEFAULT NULL,
  `b` int DEFAULT NULL,
  `c` int DEFAULT NULL,
  KEY `b` (`b`),
  KEY `c` (`c`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

When executing the `SELECT * FROM t WHERE b < 100 and c < 100` statement, suppose that TiDB estimates 20 rows meet the `b < 100` condition and 500 rows meet `c < 100`, and the length of `INT` type indexes is 8. Then TiDB calculates the cost for two indexes:

- The cost of index `b` = row count of `b < 100` * length of index `b` = 20 * 8 = 160
- The cost of index `c` = row count of `c < 100` * length of index `c` = 500 * 8 = 4000

Because the cost of index `b` is lower, TiDB chooses `b` as the index.

The preceding example is simplified and only used to explain the basic principle. In real SQL executions, the TiDB cost model is more complex.

Cost Model Version 2

TiDB v6.2.0 introduces Cost Model Version 2, a new cost model.

Cost Model Version 2 provides a more accurate regression calibration of the cost formula, adjusts some of the cost formulas, and is more accurate than the previous version of the cost formula.

To switch the version of cost model, you can set the `tidb_cost_model_version` variable.

Note:

Switching the version of the cost model might cause changes to query plans.

11.3.3.3.8 Runtime Filter

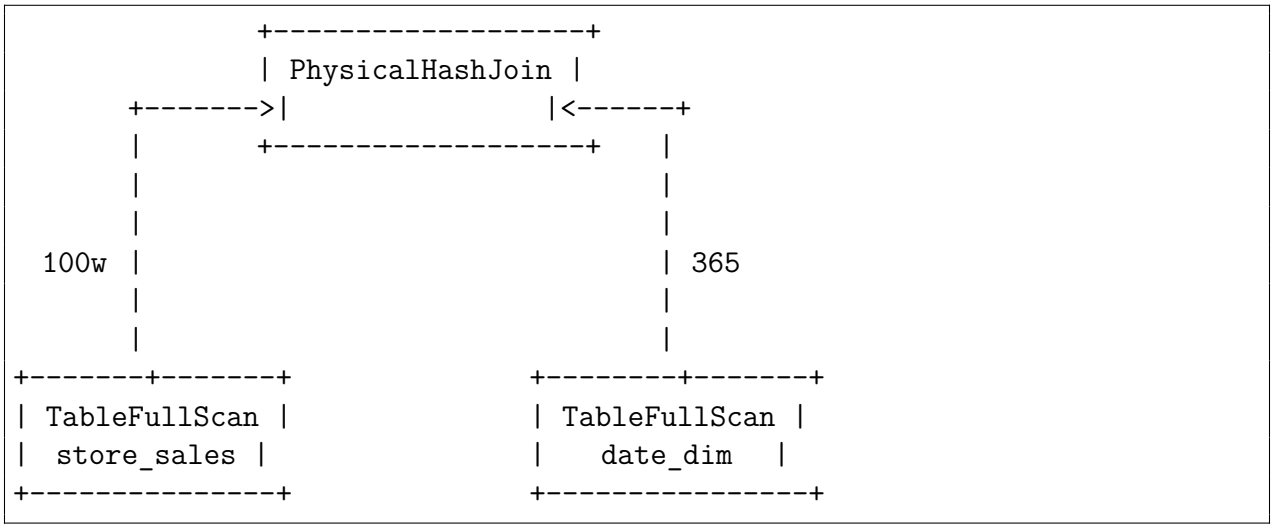
Runtime Filter is a new feature introduced in TiDB v7.3, which aims to improve the performance of hash join in MPP scenarios. By generating filters dynamically to filter the data of hash join in advance, TiDB can reduce the amount of data scanning and the amount of calculation of hash join at runtime, ultimately improving the query performance.

Concepts

- Hash join: a way to implement the join relational algebra. It gets the result of Join by building a hash table on one side and continuously matching the hash table on the other side.
- Build side: one side of hash join used to build a hash table. In this document, the right table of hash join is called the build side by default.
- Probe side: one side of hash join used to continuously match the hash table. In this document, the left table of hash join is called the probe side by default.
- Filter: also known as predicate, which refers to the filter condition in this document.

Working principles of Runtime Filter

Hash join performs the join operation by building a hash table based on the right table and continuously probing the hash table using the left table. If some join key values cannot hit the hash table during the probing process, it means that the data does not exist in the right table and will not appear in the final join result. Therefore, if TiDB can **filter out the join key data in advance** during scanning, it will reduce the scanning time and network overhead, thereby greatly improving the join efficiency.

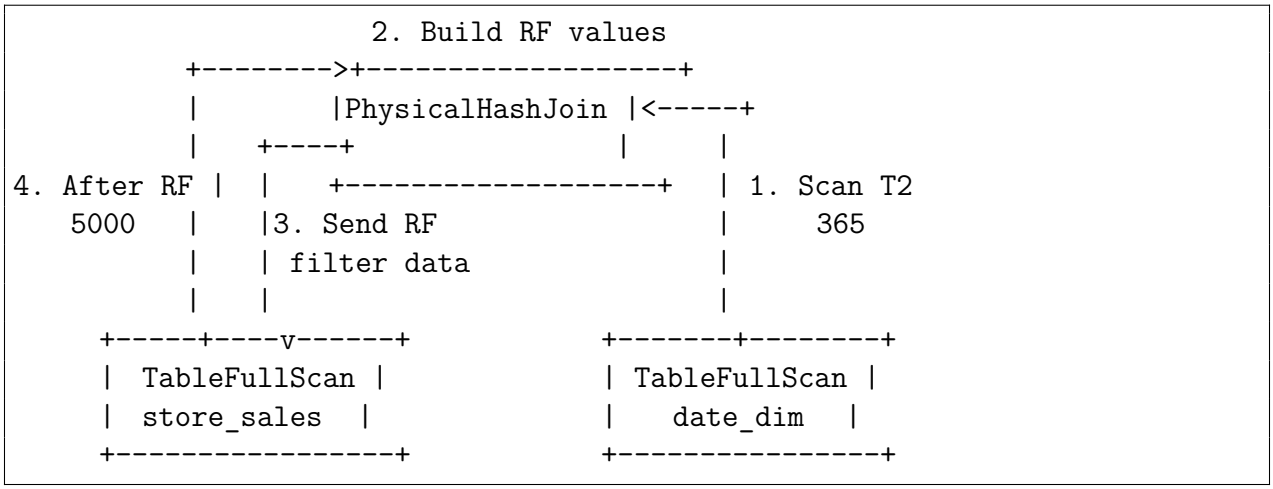


Runtime Filter is a **dynamic predicate** generated during the query planning phase. This predicate has the same function as other predicates in the TiDB Selection operator. These predicates are all applied to the Table Scan operation to filter out rows that do not match the predicate. The only difference is that the parameter values in Runtime Filter come from the results generated during the hash join build process.

Example

Assume that there is a join query between the `store_sales` table and the `date_dim` table, and the join method is hash join. `store_sales` is a fact table that mainly stores the sales data of stores, and the number of rows is 1 million. `date_dim` is a time dimension table that mainly stores date information. You want to query the sales data of the year 2001, so 365 rows of the `date_dim` table are involved in the join operation.

```
SELECT * FROM store_sales, date_dim
WHERE ss_date_sk = d_date_sk
    AND d_year = 2001;
```



The execution plan of hash join is usually as follows:

(The above figure omits the exchange node and other nodes.)

The execution process of Runtime Filter is as follows:

1. Scan the data of the `date_dim` table.
2. `PhysicalHashJoin` calculates a filter condition based on the data of the build side, such as `date_dim in (2001/01/01~2001/12/31)`.
3. Send the filter condition to the `TableFullScan` operator that is waiting to scan `store_sales`.
4. The filter condition is applied to `store_sales`, and the filtered data is passed to `PhysicalHashJoin`, thereby reducing the amount of data scanned by the probe side and the amount of calculation of matching the hash table.

(RF is short for Runtime Filter)

From the above two figures, you can see that the amount of data scanned by `store_sales` is reduced from 1 million to 5000. By reducing the amount of data scanned by `TableFullScan`, Runtime Filter can reduce the number of times to match the hash table, avoiding unnecessary I/O and network transmission, thus significantly improving the efficiency of the join operation.

Use Runtime Filter

To use Runtime Filter, you need to create a table with TiFlash replicas and set `tidb_runtime_filter_mode` to `LOCAL`.

Taking the TPC-DS dataset as an example, this section uses the `catalog_sales` table and the `date_dim` table for join operations to illustrate how Runtime Filter improves query efficiency.

Step 1. Create TiFlash replicas for tables to be joined

Add a TiFlash replica to each of the `catalog_sales` table and the `date_dim` table.

```
ALTER TABLE catalog_sales SET tiflash REPLICA 1;
ALTER TABLE date_dim SET tiflash REPLICA 1;
```

Wait until the TiFlash replicas of the two tables are ready, that is, the `AVAILABLE` and `PROGRESS` fields of the replicas are both `1`.

```
SELECT * FROM INFORMATION_SCHEMA.TIFLASH_REPLICA WHERE TABLE_NAME='catalog_
    ↪ sales';
+--
    ↪ ------------+---------------+----------+---------------+----------------+------
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--
    ↪ ------------+---------------+----------+---------------+----------------+------
    ↪
| tpcds50    | catalog_sales |  1055 |             1 |                |
    ↪ 1 |        1 |
+--
    ↪ ------------+---------------+----------+---------------+----------------+------
    ↪

SELECT * FROM INFORMATION_SCHEMA.TIFLASH_REPLICA WHERE TABLE_NAME='date_dim
    ↪ ';
+--
    ↪ ------------+------------+----------+---------------+----------------+---------
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
```

```
+--
    ↪ -----------+-----------+---------+--------------+----------------+--------
    ↪
| tpcds50    | date_dim |    1015 |           1 |                |        1 |
    ↪        1 |
+--
    ↪ -----------+-----------+---------+--------------+----------------+--------
    ↪
```

Step 2. Enable Runtime Filter

To enable Runtime Filter, set the value of the system variable `tidb_runtime_filter_mode` to `LOCAL`.

```
SET tidb_runtime_filter_mode="LOCAL";
```

Check whether the change is successful:

```
SHOW VARIABLES LIKE "tidb_runtime_filter_mode";
+--------------------------+-------+
| Variable_name            | Value |
+--------------------------+-------+
| tidb_runtime_filter_mode | LOCAL |
+--------------------------+-------+
```

If the value of the system variable is `LOCAL`, Runtime Filter is enabled.

Step 3. Execute the query

Before executing the query, use the `EXPLAIN` statement to show the execution plan and check whether Runtime Filter has taken effect.

```
EXPLAIN SELECT cs_ship_date_sk FROM catalog_sales, date_dim
WHERE d_date = '2002-2-01' AND
    cs_ship_date_sk = d_date_sk;
```

When Runtime Filter takes effect, the corresponding Runtime Filter is mounted on the `HashJoin` node and the `TableScan` node, indicating that Runtime Filter is applied successfully.

```
TableFullScan: runtime filter:0[IN] -> tpcds50.catalog_sales.cs_ship_date_sk
HashJoin: runtime filter:0[IN] <- tpcds50.date_dim.d_date_sk |
```

The complete query execution plan is as follows:

```
+-----------------------------------------+------------+-------------+-----------------
    ↪
```

```
| id                                  | estRows    | task       | access
   ↪ object    | operator info
   ↪
   ↪ |
+-------------------------------------+------------+-------------+----------------
   ↪
| TableReader_53                      | 37343.19   | root       |
   ↪                   | MppVersion: 1, data:ExchangeSender_52
   ↪
   ↪ |
|  ─ExchangeSender_52                 | 37343.19   | mpp[tiflash] |
   ↪                 | ExchangeType: PassThrough
   ↪
   ↪ |
|    ─Projection_51                   | 37343.19   | mpp[tiflash] |
   ↪                 | tpcds50.catalog_sales.cs_ship_date_sk
   ↪
   ↪ |
|      ─HashJoin_48                   | 37343.19   | mpp[tiflash] |
   ↪                 | inner join, equal:[eq(tpcds50.date_dim.d_date_sk,
   ↪ tpcds50.catalog_sales.cs_ship_date_sk)], runtime filter:0[IN] <-
   ↪ tpcds50.date_dim.d_date_sk |
|        ─ExchangeReceiver_29(Build) | 1.00       | mpp[tiflash] |
   ↪                 |
   ↪
   ↪ |
|          ─ExchangeSender_28         | 1.00       | mpp[tiflash] |
   ↪                 | ExchangeType: Broadcast, Compression: FAST
   ↪
   ↪ |
|            ─TableFullScan_26        | 1.00       | mpp[tiflash] | table:date
   ↪ _dim  | pushed down filter:eq(tpcds50.date_dim.d_date, 2002-02-01
   ↪ 00:00:00.000000), keep order:false                                  |
|        ─Selection_31(Probe)         | 71638034.00 | mpp[tiflash] |
   ↪                | not(isnull(tpcds50.catalog_sales.cs_ship_date_sk))
   ↪
   ↪ |
|          ─TableFullScan_30          | 71997669.00 | mpp[tiflash] | table:
   ↪ catalog_sales | pushed down filter:empty, keep order:false, runtime
   ↪ filter:0[IN] -> tpcds50.catalog_sales.cs_ship_date_sk             |
+-------------------------------------+------------+-------------+----------------
   ↪
9 rows in set (0.01 sec)
```

Now, execute the SQL query, and Runtime Filter is applied.

```
SELECT cs_ship_date_sk FROM catalog_sales, date_dim
WHERE d_date = '2002-2-01' AND
    cs_ship_date_sk = d_date_sk;
```

Step 4. Performance comparison

This example uses the 50 GB TPC-DS data. After Runtime Filter is enabled, the query time is reduced from 0.38 seconds to 0.17 seconds, and efficiency is improved by 50%. You can use the `ANALYZE` statement to view the execution time of each operator after Runtime Filter takes effect.

The following is the execution information of the query when Runtime Filter is not enabled:

```
EXPLAIN ANALYZE SELECT cs_ship_date_sk FROM catalog_sales, date_dim WHERE d
    ↪ _date = '2002-2-01' AND cs_ship_date_sk = d_date_sk;
+--
    ↪ ------------------------------------+------------+---------+--------------+-
    ↪
| id                                | estRows    | actRows | task       |
    ↪ access object    | execution info
    ↪
    ↪ | operator info
    ↪                                                                          |
    ↪ memory | disk |
+--
    ↪ ------------------------------------+------------+---------+--------------+-
    ↪
| TableReader_53                    | 37343.19   | 59574   | root       |
    ↪                   | time:379.7ms, loops:83, RU:0.000000, cop_task: {
    ↪ num: 48, max: 0s, min: 0s, avg: 0s, p95: 0s, copr_cache_hit_ratio:
    ↪ 0.00}
    ↪
    ↪ | MppVersion: 1, data:ExchangeSender_52
    ↪                                                 | 12.0 KB | N/A |

9 rows in set (0.17 sec)
```

By comparing the execution information of the two queries, you can find the following improvements:

- IO reduction: by comparing the `total_scanned_rows` of the TableFullScan operator, you can see that the scan volume of `TableFullScan` is reduced by 2/3 after Runtime Filter is enabled.
- Hash join performance improvement: the execution duration of the `HashJoin` operator is reduced from 376.1 ms to 157.6 ms.

Best practices

Runtime Filter is applicable to the scenario where a large table and a small table are joined, such as a join query of a fact table and a dimension table. When the dimension table has a small amount of hit data, it means that the filter has fewer values, so the fact table can filter out the data that does not meet the conditions more effectively. Compared with the default scenario where the entire fact table is scanned, this significantly improves the query performance.

The join operation of the `Sales` table and the `date_dim` table in TPC-DS is a typical example.

Configure Runtime Filter

When using Runtime Filter, you can configure the mode and predicate type of Runtime Filter.

Runtime Filter mode

The mode of Runtime Filter is the relationship between the **Filter Sender operator** and **Filter Receiver operator**. There are three modes: `OFF`, `LOCAL`, and `GLOBAL`. In v7.3.0, only `OFF` and `LOCAL` modes are supported. The Runtime Filter mode is controlled by the system variable `tidb_runtime_filter_mode`.

- `OFF`: Runtime Filter is disabled. After it is disabled, the query behavior is the same as in previous versions.
- `LOCAL`: Runtime Filter is enabled in the local mode. In the local mode, the **Filter Sender operator** and **Filter Receiver operator** are in the same MPP task. In other words, Runtime Filter can be applied to the scenario where the HashJoin operator and TableScan operator are in the same task. Currently, Runtime Filter only supports the local mode. To enable this mode, set it to `LOCAL`.
- `GLOBAL`: currently, the global mode is not supported. You cannot set Runtime Filter to this mode.

Runtime Filter type

The type of Runtime Filter is the type of the predicate used by the generated Filter operator. Currently, only one type is supported: `IN`, which means that the generated predicated is similar to `k1 in (xxx)`. The Runtime Filter type is controlled by the system variable `tidb_runtime_filter_type`.

- `IN`: the default type. It means that the generated Runtime Filter uses the `IN` type predicate.

Limitations

- Runtime Filter is an optimization in the MPP architecture and can only be applied to queries pushed down to TiFlash.
- Join type: Left outer, Full outer, and Anti join (when the left table is the probe side) do not support Runtime Filter. Because Runtime Filter filters the data involved in the join in advance, the preceding types of join do not discard the unmatched data, so Runtime Filter cannot be used.
- Equal join expression: When the probe column in the equal join expression is a complex expression, or when the probe column type is JSON, Blob, Array, or other complex data types, Runtime Filter is not generated. The main reason is that the preceding types of columns are rarely used as the join column. Even if the Filter is generated, the filtering rate is usually low.

For the preceding limitations, if you need to confirm whether Runtime Filter is generated correctly, you can use the `EXPLAIN` statement to verify the execution plan.

11.3.3.4 SQL Prepared Execution Plan Cache

TiDB supports execution plan caching for `Prepare` and `Execute` queries. This includes both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the

cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

TiDB also supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare`/`Execute` statements. For more details, refer to Non-prepared plan cache.

In the current version of TiDB, if a `Prepare` statement meets any of the following conditions, the query or the plan is not cached:

- The query contains SQL statements other than `SELECT`, `UPDATE`, `INSERT`, `DELETE`, `Union`, `Intersect`, and `Except`.
- The query accesses temporary tables, or a table that contains generated columns, or uses static mode (that is, `tidb_partition_prune_mode` is set to `static`) to access partitioning tables.
- The query contains non-correlated sub-queries, such as `SELECT * FROM t1 WHERE t1 ↪ .a > (SELECT 1 FROM t2 WHERE t2.b < 1)`.
- The query contains correlated sub-queries with `PhysicalApply` operators in the execution plan, such as `SELECT * FROM t1 WHERE t1.a > (SELECT a FROM t2 WHERE ↪ t1.b > t2.b)`.
- The query contains the `ignore_plan_cache` or `set_var` hint, such as `SELECT /*+ ↪ ignore_plan_cache()*/ * FROM t` or `SELECT /*+ set_var(max_execution_ ↪ time=1)*/ * FROM t`.
- The query contains variables other than `?` (including system variables or user-defined variables), such as `select * from t where a>? and b>@x`.
- The query contains the functions that cannot be cached: `database()`, `current_user ↪ , current_role`, `user`, `connection_id`, `last_insert_id`, `row_count`, `version`, and `like`.
- The query uses a variable as the `LIMIT` parameter (such as `LIMIT ?` and `LIMIT 10, ?`) and the variable value is greater than 10000.
- The query contains `?` after `Order By`, such as `Order By ?`. Such queries sort data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Order By a+?`, it is cached.
- The query contains `?` after `Group By`, such as `Group By?`. Such queries group data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Group By a+?`, it is cached.
- The query contains `?` in the definition of the `Window Frame` window function, such as `(partition by year order by sale rows ? preceding)`. If `?` appears elsewhere in the window function, the query is cached.
- The query contains parameters for comparing `int` and `string`, such as `c_int >= ? ↪ or c_int in (?, ?)`, in which `?` indicates the string type, such as `set @x='123'`. To ensure that the query result is compatible with MySQL, parameters need to be adjusted in each query, so such queries are not cached.
- The plan attempts to access `TiFlash`.

- In most cases, the plan that contains `TableDual` is not cached, unless the current `Prepare` statement does not have parameters.
- The query accesses TiDB system views, such as `information_schema.columns`. It is not recommended to use `Prepare` and `Execute` statements to access system views.

TiDB has a limitation on the number of `?` in a query. If a query contains more than 65535 `?`, an error `Prepared statement contains too many placeholders` is reported.

The LRU linked list is designed as a session-level cache because `Prepare`/`Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword
- The current schema version, which is updated after every successfully executed DDL statement
- The SQL mode when executing `Execute`
- The current time zone, which is the value of the `time_zone` system variable
- The value of the `sql_select_limit` system variable

Any change in the preceding information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode/`time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are several points worth noting about execution plan caching and query performance:

- No matter an execution plan is cached or not, it is affected by SQL bindings. For execution plans that have not been cached (the first `Execute`), these plans are affected by existing SQL bindings. For execution plans that have been cached, if new SQL Bindings are created, these plans become invalid.
- Cached plans are not affected by changes in statistics, optimization rules, and blocklist pushdown by expressions.
- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not

be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are `2` and `1` respectively. Considering that these two parameters maybe be `1` and `2` in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;

- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also results in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is `1`, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes `10000`, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Starting from v6.1.0, the execution plan cache is enabled by default. You can control prepared plan cache via the system variable `tidb_enable_prepared_plan_cache`.

> **Note:**
>
> The `tidb_enable_prepared_plan_cache` system variable controls the execution plan cache only for `Prepare`/`Execute` queries, not for normal queries. For the execution plan cache for normal queries, see SQL Non-Prepared Execution Plan Cache.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous `Execute` statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
   ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
```

```
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)

-- The second execution hits the cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 1                      |
+------------------------+
1 row in set (0.00 sec)
```

If you find that a certain set of `Prepare`/`Execute` has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the preceding statement as an example:

```
MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
    ↪  where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
```

11.3.3.4.1 Diagnostics of Prepared Plan Cache

Use `SHOW WARNINGS` to diagnose

Some queries or plans cannot be cached. You can use the `SHOW WARNINGS` statement to check whether the query or plan is cached. If it is not cached, you can check the reason for the failure in the result. For example:

```
mysql> PREPARE st FROM 'SELECT * FROM t WHERE a > (SELECT MAX(a) FROM t)';
    ↪ -- The query contains a subquery and cannot be cached.

Query OK, 0 rows affected, 1 warning (0.01 sec)

mysql> SHOW WARNINGS; -- Checks the reason why the query plan cannot be
    ↪ cached.

+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1105 | skip plan-cache: sub-queries are un-cacheable |
+---------+------+-----------------------------------------------+
1 row in set (0.00 sec)

mysql> prepare st from 'select * from t where a<?';

Query OK, 0 rows affected (0.00 sec)

mysql> set @a='1';

Query OK, 0 rows affected (0.00 sec)

mysql> execute st using @a; -- The optimization converts a non-INT type to
    ↪  an INT type, and the execution plan might change with the change of
    ↪  the parameter, so TiDB does not cache the plan.

Empty set, 1 warning (0.01 sec)

mysql> SHOW WARNINGS;

+---------+------+-----------------------------------------------+
| Level   | Code | Message                                       |
+---------+------+-----------------------------------------------+
| Warning | 1105 | skip plan-cache: '1' may be converted to INT  |
+---------+------+-----------------------------------------------+
1 row in set (0.00 sec)
```

Use `Statements Summary` to diagnose

The `Statements Summary` table contains two fields, `plan_cache_unqualified` and `plan_cache_unqualified_last_reason`, which respectively indicate the number of times and the reason why the corresponding query is unable to use the plan cache. You can use these two fields for diagnostic purposes:

```
mysql> SELECT digest_text, plan_cache_unqualified, plan_cache_unqualified_last_reason FROM information_schema.statements_summary WHERE plan_cache_unqualified > 0 ORDER BY plan_cache_unqualified DESC
LIMIT 10;

+------------------------------+------------------------+------------------------------+
| digest_text                  | plan_cache_unqualified | plan_cache_unqualified_last_reason |
+------------------------------+------------------------+------------------------------+
| select * from `t` where `a` < ? |                     10 | '1' may be converted to INT      |
| select * from `t` order by ? |                      4 | query has 'order by ?' is un-cacheable |
| select database ( ) from `t` |                      2 | query has 'database()' is un-cacheable |
...
+------------------------------+------------------------+------------------------------+
10 row in set (0.01 sec)
```

11.3.3.4.2 Memory management of Prepared Plan Cache

Using Prepared Plan Cache incurs memory overhead. To view the total memory consumption by the cached execution plans of all sessions in each TiDB instance, you can use the **Plan Cache Memory Usage** monitoring panel in Grafana.

> **Note:**
>
> Because of the memory reclaim mechanism of Golang and some uncounted memory structures, the memory displayed in Grafana is not equal to the actual heap memory usage. It is tested that there is a deviation of about ±20% between the memory displayed in Grafana and the actual heap memory usage.

To view the total number of execution plans cached in each TiDB instance, you can use the **Plan Cache Plan Num** panel in Grafana.

The following is an example of the **Plan Cache Memory Usage** and **Plan Cache Plan Num** panels in Grafana:

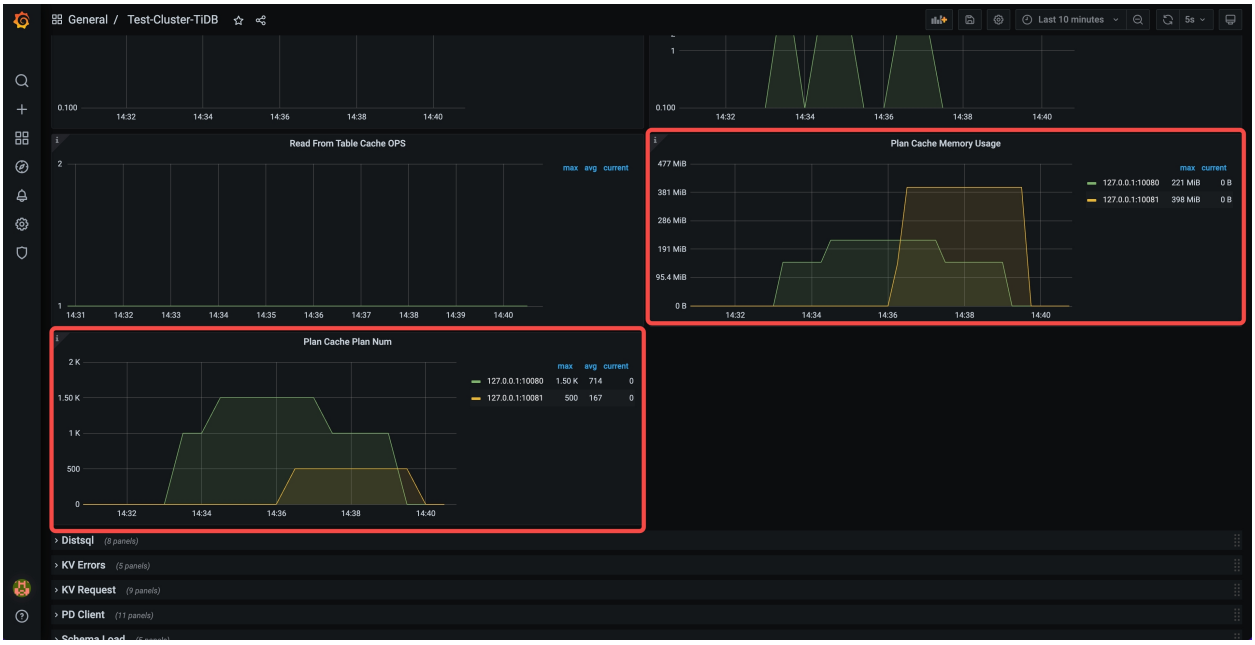

Figure 439: grafana_panels

Starting from v7.1.0, you can control the maximum number of plans that can be cached in each session by configuring the system variable `tidb_session_plan_cache_size`. For different environments, the recommended value is as follows and you can adjust it according to the monitoring panels:

- When the memory threshold of the TiDB server instance is <= 64 GiB, set `tidb_session_plan_cache_size` to `50`.
- When the memory threshold of the TiDB server instance is > 64 GiB, set `tidb_session_plan_cache_size` to `100`.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

When the unused memory of the TiDB server is less than a certain threshold, the memory protection mechanism of plan cache is triggered, through which some cached plans will be evicted.

You can control the threshold by configuring the system variable `tidb_prepared_plan_cache_memory_guard_ratio`. The threshold is 0.1 by default, which means when the

unused memory of the TiDB server is less than 10% of the total memory (90% of the memory is used), the memory protection mechanism is triggered.

Due to memory limit, plan cache might be missed sometimes. You can check the status by viewing the `Plan Cache Miss OPS` metric in the Grafana dashboard.

11.3.3.4.3 Clear execution plan cache

You can clear execution plan cache by executing the `ADMIN FLUSH [SESSION | INSTANCE] PLAN_CACHE` statement.

In this statement, `[SESSION | INSTANCE]` specifies whether the plan cache is cleared for the current session or the whole TiDB instance. If the scope is not specified, the preceding statement applies to the `SESSION` cache by default.

The following is an example of clearing the `SESSION` execution plan cache:

```
MySQL [test]> create table t (a int);
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> prepare stmt from 'select * from t';
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- Select the cached plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)

MySQL [test]> admin flush session plan_cache; -- Clear the cached plan of
    ↪ the current session
Query OK, 0 rows affected (0.00 sec)

MySQL [test]> execute stmt;
Empty set (0.00 sec)

MySQL [test]> select @@last_plan_from_cache; -- The cached plan cannot be
    ↪ selected again, because it has been cleared
+------------------------+
```

```
| @@last_plan_from_cache |
+------------------------+
|                      0 |
+------------------------+
1 row in set (0.00 sec)
```

Currently, TiDB does not support clearing `GLOBAL` execution plan cache. That means you cannot clear the cached plan of the whole TiDB cluster. The following error is reported if you try to clear the `GLOBAL` execution plan cache:

```
MySQL [test]> admin flush global plan_cache;
ERROR 1105 (HY000): Do not support the 'admin flush global scope.'
```

11.3.3.4.4 Ignore the `COM_STMT_CLOSE` command and the `DEALLOCATE PREPARE` statement

To reduce the syntax parsing cost of SQL statements, it is recommended that you run `prepare stmt` once, then `execute stmt` multiple times before running `deallocate prepare`:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...; -- Execute once
MySQL [test]> ...
MySQL [test]> execute stmt using ...; -- Execute multiple times
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In real practice, you may be used to running `deallocate prepare` each time after running `execute stmt`, as shown below:

```
MySQL [test]> prepare stmt from '...'; -- Prepare once
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
MySQL [test]> prepare stmt from '...'; -- Prepare twice
MySQL [test]> execute stmt using ...;
MySQL [test]> deallocate prepare stmt; -- Release the prepared statement
```

In such practice, the plan obtained by the first executed statement cannot be reused by the second executed statement.

To address the problem, you can set the system variable `tidb_ignore_prepared_cache_close_stmt` to `ON` so TiDB ignores commands to close `prepare stmt`:

```
mysql> set @@tidb_ignore_prepared_cache_close_stmt=1; -- Enable the
    ↪ variable
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare once
```

```
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                    -- Execute once
Empty set (0.00 sec)

mysql> deallocate prepare stmt;         -- Release after the first execute
Query OK, 0 rows affected (0.00 sec)

mysql> prepare stmt from 'select * from t'; -- Prepare twice
Query OK, 0 rows affected (0.00 sec)

mysql> execute stmt;                    -- Execute twice
Empty set (0.00 sec)

mysql> select @@last_plan_from_cache;  -- Reuse the last plan
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

Monitoring

In the Grafana dashboard on the TiDB page in the **Executor** section, there are the "Queries Using Plan Cache OPS" and "Plan Cache Miss OPS" graphs. These graphs can be used to check if both TiDB and the application are configured correctly to allow the SQL Plan Cache to work correctly. The **Server** section on the same page provides the "Prepared Statement Count" graph. This graph shows a non-zero value if the application uses prepared statements, which is required for the SQL Plan Cache to function correctly.

Figure 440: `sql_plan_cache`

11.3.3.5 SQL Non-Prepared Execution Plan Cache

TiDB supports execution plan caching for some non-`PREPARE` statements, similar to the `Prepare`/`Execute` statements. This feature allows these statements to skip the optimization phase and improve performance.

Enabling the non-prepared plan cache might incur additional memory and CPU overhead and might not be suitable for all situations. To determine whether to enable this feature in your scenario, refer to the Performance benefits and Memory monitoring sections.

11.3.3.5.1 Principle

The non-prepared plan cache is a session-level feature that shares a cache with the prepared plan cache. The basic principle of the non-prepared plan cache is as follows:

1. After you enable the non-prepared plan cache, TiDB first parameterizes the query based on the abstract syntax tree (AST). For example, `SELECT * FROM t WHERE b < 10 AND a = 1` is parameterized as `SELECT * FROM t WHERE b < ? and a = ?`.
2. Then, TiDB uses the parameterized query to search the plan cache.
3. If a reusable plan is found, it is directly used and the optimization phase is skipped.
4. Otherwise, the optimizer generates a new plan and adds it back into the cache for reuse in the subsequent query.

11.3.3.5.2 Usage

To enable or disable the non-prepared plan cache, you can set the `tidb_enable_non_prepared_plan_cache` system variable. You can also control the size of the non-prepared plan cache using the `tidb_session_plan_cache_size` system variable. When the number of cached plans exceeds `tidb_session_plan_cache_size`, TiDB evicts plans using the least recently used (LRU) strategy.

Starting from v7.1.0, you can control the maximum size of a plan that can be cached using the system variable `tidb_plan_cache_max_plan_size`. The default value is 2 MB. If the size of a plan exceeds this value, the plan will not be cached.

> **Note:**
>
> The memory specified by `tidb_session_plan_cache_size` is shared between the prepared and non-prepared plan cache. If you have enabled the prepared plan cache for the current cluster, enabling the non-prepared plan cache might reduce the hit rate of the original prepared plan cache.

11.3.3.5.3 Example

The following example shows how to use the non-prepared plan cache:

1. Create a table `t` for testing:

```
CREATE TABLE t (a INT, b INT, KEY(b));
```

2. Enable the non-prepared plan cache:

```
SET tidb_enable_non_prepared_plan_cache = ON;
```

3. Execute the following two queries:

```
SELECT * FROM t WHERE b < 10 AND a = 1;
SELECT * FROM t WHERE b < 5 AND a = 2;
```

4. Check whether the second query hits the cache:

```
SELECT @@last_plan_from_cache;
```

   If the value of `last_plan_from_cache` in the output is `1`, it means that the execution plan of the second query comes from the cache:

```
+------------------------+
| @@last_plan_from_cache |
+------------------------+
|                      1 |
+------------------------+
1 row in set (0.00 sec)
```

11.3.3.5.4 Restrictions

Cache suboptimal plans

TiDB only caches one plan for a parameterized query. For example, the queries `SELECT * FROM t WHERE a < 1` and `SELECT * FROM t WHERE a < 100000` share the same parameterized form, `SELECT * FROM t WHERE a < ?`, and thus share the same plan.

If this causes performance issues, you can use the `ignore_plan_cache()` hint to ignore plans in the cache, so that the optimizer generates a new execution plan for the SQL every time. If the SQL cannot be modified, you can create a binding to solve the problem. For example, `CREATE BINDING FOR SELECT ... USING SELECT /*+ ignore_plan_cache()*/ ...`.

Usage restrictions

Due to the preceding risks and the fact that the execution plan cache only provides significant benefits for simple queries (if a query is complex and takes a long time to execute, using the execution plan cache might not be very helpful), TiDB has strict restrictions on the scope of non-prepared plan cache. The restrictions are as follows:

- Queries or plans that are not supported by the Prepared plan cache are also not supported by the non-prepared plan cache.
- Queries that contain complex operators such as `Window` or `Having` are not supported.
- Queries that contain three or more `Join` tables or subqueries are not supported.
- Queries that contain numbers or expressions directly after `ORDER BY` or `GROUP BY` are not supported, such as `ORDER BY 1` and `GROUP BY a+1`. Only `ORDER BY column_name` and `GROUP BY column_name` are supported.
- Queries that filter on columns of `JSON`, `ENUM`, `SET`, or `BIT` type are not supported, such as `SELECT * FROM t WHERE json_col = '{}'`.
- Queries that filter on `NULL` values are not supported, such as `SELECT * FROM t WHERE a is NULL`.
- Queries with more than 200 parameters after parameterization are not supported by default, such as `SELECT * FROM t WHERE a in (1, 2, 3, ... 201)`. Starting from v7.3.0, you can modify this limit by setting the 44823 fix in the `tidb_opt_fix_control` system variable.
- Queries that access virtual columns, temporary tables, views, or memory tables are not supported, such as `SELECT * FROM INFORMATION_SCHEMA.COLUMNS`, where `COLUMNS` is a TiDB memory table.
- Queries with hints or bindings are not supported.
- DML statements or `SELECT` statements with the `FOR UPDATE` clause are not supported by default. To remove this restriction, you can execute `SET tidb_enable_non_prepared_plan_cache_for_dml = ON`.

After you enable this feature, the optimizer quickly evaluates the query. If it does not meet the support conditions for non-prepared plan cache, the query falls back to the regular optimization process.

11.3.3.5.5 Performance benefits

In internal tests, enabling the non-prepared plan cache feature can achieve significant performance benefits in most TP scenarios. For example, a performance improvement of about 4% in TPC-C tests, over 10% in some banking workloads, and 15% in Sysbench RangeScan.

However, this feature also introduces some additional memory and CPU overhead, including determining whether the query is supported, parameterizing the query, and searching for a plan in the cache. If the cache cannot hit the majority of queries in your workload, enabling it might actually adversely affect performance.

In this case, you need to observe the `non-prepared` metric in the **Queries Using Plan Cache OPS** panel and the `non-prepared-unsupported` metric in the **Plan Cache Miss OPS** panel on Grafana. If most queries are not supported and only a few can hit the plan cache, you can disable this feature.

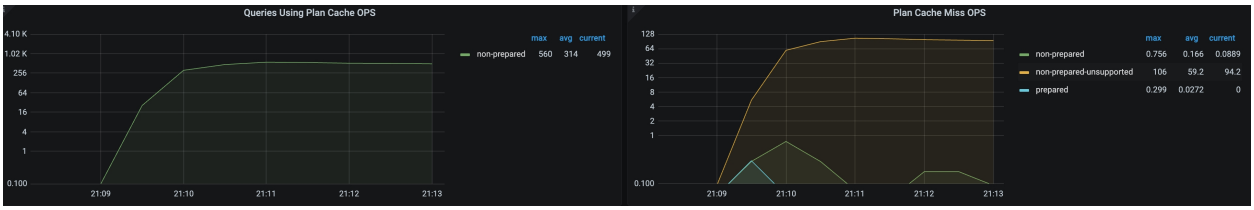

Figure 441: non-prepared-unsupported

11.3.3.5.6 Diagnostics

After enabling the non-prepared plan cache, you can execute the `EXPLAIN FORMAT='plan_cache' SELECT ...` statement to verify whether the query can hit the cache. For queries that cannot hit the cache, the system returns the reason in a warning.

Note that if you do not add `FORMAT='plan_cache'`, the `EXPLAIN` statement will never hit the cache.

To verify whether the query hits the cache, execute the following `EXPLAIN FORMAT='plan_cache'` statement:

```
EXPLAIN FORMAT='plan_cache' SELECT * FROM (SELECT a+1 FROM t) t;
```

The output is as follows:

```
3 rows in set, 1 warning (0.00 sec)
```

To view the queries that cannot hit the cache, execute `SHOW warnings;`:

```
SHOW warnings;
```

The output is as follows:

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                 |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | skip non-prepared plan-cache: queries that have sub-
    ↪ queries are not supported |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

In the preceding example, the query cannot hit the cache because the non-prepared plan cache does not support the + operation.

11.3.3.5.7 Monitoring

After enabling the non-prepared plan cache, you can monitor the memory usage, number of plans in the cache, and cache hit rate in the following panes:

Figure 442: non-prepare-plan-cache

You can also monitor the cache hit rate in the `statements_summary` table and slow query log. The following shows how to view the cache hit rate in the `statements_summary` table:

1. Create a table `t`:

```
CREATE TABLE t (a int);
```

2. Enable the non-prepared plan cache:

```
SET @@tidb_enable_non_prepared_plan_cache=ON;
```

3. Execute the following three queries:

```
SELECT * FROM t WHERE a<1;
SELECT * FROM t WHERE a<2;
SELECT * FROM t WHERE a<3;
```

4. Query the `statements_summary` table to view the cache hit rate:

```
SELECT digest_text, query_sample_text, exec_count, plan_in_cache, plan
    ↪ _cache_hits FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE
    ↪ query_sample_text LIKE '%SELECT * FROM %';
```

The output is as follows:

```
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
| digest_text                   | query_sample_text                     |
    ↪ exec_count | plan_in_cache | plan_cache_hits |
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
| SELECT * FROM `t` WHERE `a` < ? | SELECT * FROM t WHERE a<1      |
    ↪         3 |             1 |              2 |
+--
    ↪ ------------------------------+-------------------------------------+
    ↪
1 row in set (0.01 sec)
```

From the output, you can see that the query was executed three times and hit the cache twice.

11.3.4 Control Execution Plans

11.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB's execution plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In Optimizer Hints, you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In SQL Plan Management, you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background. This method helps address issues such as execution plan instability caused by version upgrades and cluster performance degradation.
- Finally, you will learn how to use the blocklist in Blocklist of Optimization Rules and Expression Pushdown.

Besides the preceding methods, the execution plan is also affected by some system variables. By modifying these variables at the system level or session level, you can control the generation of the execution plan. Starting from v6.5.3 and v7.1.0, TiDB introduces a relatively special variable `tidb_opt_fix_control`. This variable can accept multiple control items to control the behavior of the optimizer in a more fine-grained way, to prevent performance regression caused by behavior changes in the optimizer after cluster upgrade. Refer to Optimizer Fix Controls for a more detailed introduction.

11.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

If you encounter a situation where hints do not take effect, see Troubleshoot common issues that hints do not take effect.

11.3.4.2.1 Syntax

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `INSERT`, `UPDATE` or `DELETE` keyword in a SQL statement.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```
SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM t t1, t t2 WHERE t1.a = t2.b;
```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

> **Note:**
>
> If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to

the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

11.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
    ↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.
- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

> **Note:**
>
> You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

QB_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
    ↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

> **Note:**
>
> In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

MERGE_JOIN(t1_name [, tl_name ...])

The `MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_SMJ` is the alias for `MERGE_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_SMJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_SMJ` and `MERGE_JOIN` are both valid names for the hint, but `MERGE_JOIN` is recommended.

NO_MERGE_JOIN(t1_name [, tl_name ...])

The `NO_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the sort-merge join algorithm for the given table(s). For example:

```
SELECT /*+ NO_MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_JOIN(t1_name [, tl_name ...])

Note:

In some cases, the `INL_JOIN` hint might not take effect. For more information, see `INL_JOIN` hint does not take effect.

The `INL_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the `WHERE` condition, it is recommended to use this hint. For example:

```
SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id AND t2
    ↪ .id = t3.id;
```

In the preceding SQL statement, the `INL_JOIN(t1, t2)` hint tells the optimizer to use the index nested loop join algorithm for `t1` and `t2`. Note that this does not mean that the index nested loop join algorithm is used between `t1` and `t2`. Instead, the hint indicates that `t1` and `t2` each use the index nested loop join algorithm with another table (`t3`).

The parameter(s) given in `INL_JOIN()` is the candidate table for the inner table when you create the query plan. For example, `INL_JOIN(t1)` means that TiDB only considers using `t1` as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in `INL_JOIN()`; if it does not have an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/ * from t t1, t t2 where t1.a = t2.b;` query, you must use the `t` table's alias `t1` or `t2` rather than `t` as `INL_JOIN()`'s parameter.

Note:

`TIDB_INLJ` is the alias for `INL_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_INLJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_INLJ` and `INL_JOIN` are both valid names for the hint, but `INL_JOIN` is recommended.

NO_INDEX_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop join algorithm for the given table(s). For example:

```
SELECT /*+ NO_INDEX_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

INL_HASH_JOIN

The `INL_HASH_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that `INL_JOIN` creates a hash table on the joined inner table, but `INL_HASH_JOIN` creates a hash table on the joined outer table. `INL_HASH_JOIN` has a fixed limit on memory usage, while the memory used by `INL_JOIN` depends on the number of rows matched in the inner table.

NO_INDEX_HASH_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop hash join algorithm for the given table(s).

INL_MERGE_JOIN

The `INL_MERGE_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop merge join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm.

NO_INDEX_MERGE_JOIN(t1_name [, tl_name ...])

The `NO_INDEX_MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the index nested loop merge join algorithm for the given table(s).

HASH_JOIN(t1_name [, tl_name ...])

The `HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

NO_HASH_JOIN(t1_name [, tl_name ...])

The `NO_HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer not to use the hash join algorithm for the given table(s). For example:

```
SELECT /*+ NO_HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_BUILD(t1_name [, tl_name ...])

The `HASH_JOIN_BUILD(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the build side. In this way, you can build hash tables using specific tables. For example:

```
SELECT /*+ HASH_JOIN_BUILD(t1) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

HASH_JOIN_PROBE(t1_name [, tl_name ...])

The `HASH_JOIN_PROBE(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm on specified tables with these tables working as the probe side. In this way, you can execute the hash join algorithm with specific tables as the probe side. For example:

```
SELECT /*+ HASH_JOIN_PROBE(t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

SEMI_JOIN_REWRITE()

The `SEMI_JOIN_REWRITE()` hint tells the optimizer to rewrite the semi-join query to an ordinary join query. Currently, this hint only works for `EXISTS` subqueries.

If this hint is not used to rewrite the query, when the hash join is selected in the execution plan, the semi-join query can only use the subquery to build a hash table. In this case, when the result of the subquery is bigger than that of the outer query, the execution speed might be slower than expected.

Similarly, when the index join is selected in the execution plan, the semi-join query can only use the outer query as the driving table. In this case, when the result of the subquery is smaller than that of the outer query, the execution speed might be slower than expected.

When `SEMI_JOIN_REWRITE()` is used to rewrite the query, the optimizer can extend the selection range to select a better execution plan.

```
-- Does not use SEMI_JOIN_REWRITE() to rewrite the query.
EXPLAIN SELECT * FROM t WHERE EXISTS (SELECT 1 FROM t1 WHERE t1.a = t.a);
```

```

    ↪ pseudo                  |
+--
    ↪ ---------------------------+---------+-----------+----------------------+----
    ↪
```

From the preceding example, you can see that when using the `SEMI_JOIN_REWRITE()` hint, TiDB can select the execution method of IndexJoin based on the driving table `t1`.

SHUFFLE_JOIN(t1_name [, tl_name ...])

The `SHUFFLE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Shuffle Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ SHUFFLE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.
- This hint can be used in combination with the `HASH_JOIN_BUILD` hint and `HASH_JOIN_PROBE` hint to control the Build side and Probe side of the Shuffle Join algorithm.

BROADCAST_JOIN(t1_name [, tl_name ...])

`BROADCAST_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the Broadcast Join algorithm on specified tables. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ BROADCAST_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

Note:

- Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

- This hint can be used in combination with the HASH_JOIN_BUILD hint and HASH_JOIN_PROBE hint to control the Build side and Probe side of the Broadcast Join algorithm.

NO_DECORRELATE()

The NO_DECORRELATE() hint tells the optimizer not to try to perform decorrelation for the correlated subquery in the specified query block. This hint is applicable to the EXISTS, IN, ANY, ALL, SOME subqueries and scalar subqueries that contain correlated columns (that is, correlated subqueries).

When this hint is used in a query block, the optimizer will not try to perform decorrelation for the correlated columns between the subquery and its outer query block, but always use the Apply operator to execute the query.

By default, TiDB tries to perform decorrelation for correlated subqueries to achieve higher execution efficiency. However, in some scenarios, decorrelation might actually reduce the execution efficiency. In this case, you can use this hint to manually tell the optimizer not to perform decorrelation. For example:

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
```

```
-- Not using NO_DECORRELATE().
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

+--
    ↪ ---------------------------------+---------+----------+--------------+--------
    ↪
```

From the preceding execution plan, you can see that the optimizer has automatically performed decorrelation. The decorrelated execution plan does not have the Apply operator. Instead, the plan has join operations between the subquery and the outer query block. The original filter condition (`t2.b = t1.b`) with the correlated column becomes a regular join condition.

```
-- Using NO_DECORRELATE().
explain select * from t1 where t1.a < (select /*+ NO_DECORRELATE() */ sum(
    ↪ t2.a) from t2 where t2.b = t1.b);
```

   ↪          | keep order:false, stats:pseudo
   ↪                                               |
+--
   ↪ ---------------------------------------+----------+----------+--------------
   ↪
```

From the preceding execution plan, you can see that the optimizer does not perform decorrelation. The execution plan still contains the Apply operator. The filter condition (`t2.b = t1.b`) with the correlated column is still the filter condition when accessing the `t2` table.

HASH_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.
    ↪ id;
```

STREAM_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1
    ↪ .id;
```

MPP_1PHASE_AGG()

`MPP_1PHASE_AGG()` tells the optimizer to use the one-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_1PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

Note:

Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

MPP_2PHASE_AGG()

`MPP_2PHASE_AGG()` tells the optimizer to use the two-phase aggregation algorithm for all aggregate functions in the specified query block. This hint only takes effect in the MPP mode. For example:

```
SELECT /*+ MPP_2PHASE_AGG() */ COUNT(*) FROM t1, t2 WHERE t1.a > 10 GROUP
    ↪ BY t1.id;
```

Note:

Before using this hint, make sure that the current TiDB cluster can support using TiFlash MPP mode in the query. For details, refer to Use TiFlash MPP Mode.

USE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, idx2);` statement.

```
SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;
```

Note:

If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es).

The usage and effect of `FORCE_INDEX(t1_name, idx1_name [, idx2_name ...])` are the same as the usage and effect of `USE_INDEX(t1_name, idx1_name [, idx2_name ...])`.

The following 4 queries have the same effect:

```
SELECT /*+ USE_INDEX(t, idx1) */ * FROM t;
SELECT /*+ FORCE_INDEX(t, idx1) */ * FROM t;
SELECT * FROM t use index(idx1);
SELECT * FROM t force index(idx1);
```

IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to ignore the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and read the specified index in order.

> **Warning:**
>
> This hint might cause SQL statements to fail. It is recommended to test it first. If an error occurs during the test, remove the hint. If the test runs normally, you can continue using it.

This hint is usually applied in the following scenario:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
| id                        | estRows | task    | access object     | operator
   ↪ info              |
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
| Limit_10                  | 10.00   | root      |                    | offset:0,
   ↪ count:10         |
|  ─IndexReader_14          | 10.00   | root      |                    | index:
   ↪ Limit_13             |
|    ─Limit_13              | 10.00   | cop[tikv] |                    | offset:0,
   ↪  count:10         |
|      ─IndexFullScan_12    | 10.00   | cop[tikv] | table:t, index:a(a) | keep
   ↪  order:true, stats:pseudo |
+--
   ↪ -------------------------+---------+-----------+--------------------+---------
   ↪
```

The optimizer generates two types of plan for this query: `Limit + IndexScan(keep ↪ order: true)` and `TopN + IndexScan(keep order: false)`. When the `ORDER_INDEX` hint is used, the optimizer chooses the first plan that reads the index in order.

> **Note:**

- If the query itself does not need to read the index in order (that is, without a hint, the optimizer does not generate a plan that reads the index in order in any situation), when the `ORDER_INDEX` hint is used, the error `Can't find a proper physical plan for this query` occurs. In this case, you need to remove the corresponding `ORDER_INDEX` hint.
- The index on a partitioned table cannot be read in order, so do not use the `ORDER_INDEX` hint on the partitioned table and its related indexes.

NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])

The `NO_ORDER_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index for a specified table and not to read the specified index in order. This hint is usually applied in the following scenario.

The following example shows that the effect of the query statement is equivalent to `SELECT * FROM t t1 use index(idx1, idx2);`:

```
CREATE TABLE t(a INT, b INT, key(a), key(b));
EXPLAIN SELECT /*+ NO_ORDER_INDEX(t, a) */ a FROM t ORDER BY a LIMIT 10;
```

```
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| id                        | estRows | task     | access object     | operator
   ↪ info               |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
| TopN_7                    | 10.00   | root     |                   | test.t.a,
   ↪  offset:0, count:10 |
| ─IndexReader_14           | 10.00   | root     |                   | index:
   ↪ TopN_13                |
|   ─TopN_13                | 10.00   | cop[tikv] |                   | test.t.a
   ↪ , offset:0, count:10 |
|     ─IndexFullScan_12     | 10000.00 | cop[tikv] | table:t, index:a(a) |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ -------------------------+----------+-----------+-------------------+--------
   ↪
```

The same as the example of `ORDER_INDEX` hint, the optimizer generates two types of plans for this query: `Limit + IndexScan(keep order: true)` and `TopN + IndexScan(` ↪ `keep order: false)`. When the `NO_ORDER_INDEX` hint is used, the optimizer will choose the latter plan to read the index out of order.

AGG_TO_COP()

The `AGG_TO_COP()` hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

LIMIT_TO_COP()

The `LIMIT_TO_COP()` hint tells the optimizer to push down the `Limit` and `TopN` operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c
    ↪ LIMIT 1;
```

READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])

The `READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])` hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - `TIKV` and `TIFLASH`. If a table has an alias, use the alias as the parameter of `READ_FROM_STORAGE()`; if the table does not have an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
    ↪ t2 where t1.a = t2.a;
```

USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. Index merge has two types: intersection type and union type. For details, see Explain Statements Using Index Merge.

If you explicitly specify the list of indexes, TiDB selects indexes from the list to build index merge; if you do not specify the list of indexes, TiDB selects indexes from all available indexes to build index merge.

For the intersection-type index merge, the given list of indexes is a required parameter in the hint. For the union-type index merge, the given list of indexes is an optional parameter in the hint. See the following example.

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
    ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

> **Note:**
>
> The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

LEADING(t1_name [, tl_name ...])

The `LEADING(t1_name [, tl_name ...])` hint reminds the optimizer that, when generating the execution plan, to determine the order of multi-table joins according to the order of table names specified in the hint. For example:

```
SELECT /*+ LEADING(t1, t2) */ * FROM t1, t2, t3 WHERE t1.id = t2.id and t2.
    ↪ id = t3.id;
```

In the above query with multi-table joins, the order of joins is determined by the order of table names specified in the `LEADING()` hint. The optimizer will first join `t1` and `t2` and then join the result with `t3`. This hint is more general than `STRAIGHT_JOIN`.

The `LEADING` hint does not take effect in the following situations:

- Multiple `LEADING` hints are specified.
- The table name specified in the `LEADING` hint does not exist.
- A duplicated table name is specified in the `LEADING` hint.
- The optimizer cannot perform join operations according to the order as specified by the `LEADING` hint.
- The `straight_join()` hint already exists.
- The query contains an outer join together with the Cartesian product.

In the preceding situations, a warning is generated.

```
-- Multiple `LEADING` hints are specified.
SELECT /*+ LEADING(t1, t2) LEADING(t3) */ * FROM t1, t2, t3 WHERE t1.id =
    ↪ t2.id and t2.id = t3.id;

-- To learn why the `LEADING` hint fails to take effect, execute `show
    ↪ warnings`.
SHOW WARNINGS;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | We can only use one leading hint at most, when multiple
    ↪ leading hints are used, all leading hints will be invalid |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
```

Note:

If the query statement includes an outer join, in the hint you can specify only the tables whose join order can be swapped. If there is a table in the hint whose join order cannot be swapped, the hint will be invalid. For example, in `SELECT * FROM t1 LEFT JOIN (t2 JOIN t3 JOIN t4)ON t1.a = t2.a;`, if you want to control the join order of `t2`, `t3`, and `t4` tables, you cannot specify `t1` in the `LEADING` hint.

MERGE()

Using the `MERGE()` hint in queries with common table expressions (CTE) can disable the materialization of the subqueries and expand the subquery inlines into CTE. This hint is only applicable to non-recursive CTE. In some scenarios, using `MERGE()` brings higher execution efficiency than the default behavior of allocating a temporary space. For example, pushing down query conditions or in nesting CTE queries:

```
-- Uses the hint to push down the predicate of the outer query.
WITH CTE AS (SELECT /*+ MERGE() */ * FROM tc WHERE tc.a < 60) SELECT * FROM
    ↪  CTE WHERE CTE.a < 18;

-- Uses the hint in a nested CTE query to expand a CTE inline into the
    ↪ outer query.
WITH CTE1 AS (SELECT * FROM t1), CTE2 AS (WITH CTE3 AS (SELECT /*+ MERGE()
    ↪ */ * FROM t2), CTE4 AS (SELECT * FROM t3) SELECT * FROM CTE3, CTE4)
    ↪ SELECT * FROM CTE1, CTE2;
```

Note:

`MERGE()` is only applicable to simple CTE queries. It is not applicable in the following situations:

- Recursive CTE
- Subqueries with inlines that cannot be expanded, such as aggregate operators, window functions, and `DISTINCT`.

When the number of CTE references is too high, the query performance might be lower than the default materialization behavior.

11.3.4.2.3 Hints that take effect globally

The global hint works in views. When specified as a global hint, the hint defined in a query can take effect inside the view. To specify a global hint, first use the `QB_NAME` hint to define a query block name, and then add the target hints in the form of `ViewName@QueryBlockName`.

Step 1: Define the query block name of the view using the `QB_NAME` hint

Use the `QB_NAME` hint to define a new name for each query block of the view. The definition of the `QB_NAME` hint for views is the same as that for query blocks, but the syntax is extended from `QB_NAME(QB)` to `QB_NAME(QB, ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...])`.

Note:

There is a white space between `@QueryBlockName` and the immediately following `.ViewName@QueryBlockName`. Otherwise, the `.ViewName@QueryBlockName` will be treated as a part of the `QueryBlockName`. For example, `QB_NAME(v2_1, v2@SEL_1 .@SEL_1)` is valid, while `QB_NAME(v2_1, v2@SEL_1.@SEL_1)` cannot be parsed correctly.

- For a simple statement with a single view and no subqueries, the following example specifies the first query block name of view `v`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪ @SEL_1 */ * FROM v;
```

For view `v`, the first view name in the list (`ViewName@QueryBlockName [. ViewName@QueryBlockName .ViewName@QueryBlockName ...]`) starting from the query statement is `v@SEL_1`. The first query block of the view `v` can be declared as `QB_NAME(v_1, v@SEL_1 .@SEL_1)`, or simply written as `QB_NAME(v_1, v)`, omitting `@SEL_1`:

```
CREATE VIEW v AS SELECT /* Comment: The name of the current query
    ↪ block is the default @SEL_1 */ * FROM t;

-- Specifies the global hint
SELECT /*+ QB_NAME(v_1, v) USE_INDEX(t@v_1, idx) */ * FROM v;
```

- For a complex statement with nested views and subqueries, the following example specifies the names for each of two query blocks of the view `v1` and `v2`:

```
SELECT /* Comment: The name of the current query block is the default
    ↪  @SEL_1 */ * FROM v2 JOIN (
    SELECT /* Comment: The name of the current query block is the
        ↪ default @SEL_2 */ * FROM v2) vv;
```

For the first view `v2`, the first view name in the list starting from the first query statement is `v2@SEL_1`. For the second view `v2`, the first view name is `v2@SEL_2`. The following example only considers the first view `v2`.

The first query block of view `v2` can be declared as `QB_NAME(v2_1, v2@SEL_1 .@SEL ↪ _1)`, and the second query block of the view `v2` can be declared as `QB_NAME(v2_2, ↪  v2@SEL_1 .@SEL_2)`:

```
CREATE VIEW v2 AS
    SELECT * FROM t JOIN /* Comment: For view v2, the name of the
        ↪ current query block is the default @SEL_1. So, the current
        ↪ query block view list is v2@SEL_1 .@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN v1 /* Comment: For view v2, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .@SEL_
            ↪ 2 */
    ) tt;
```

For view `v1`, the first view name in the list starting from the preceding statement is `v2@SEL_1 .v1@SEL_2`. The first query block in view `v1` can be declared as `QB_NAME ↪ (v1_1, v2@SEL_1 .v1@SEL_2 .@SEL_1)`, and the second query block in view `v1` can be declared as `QB_NAME(v1_2, v2@SEL_1 .v1@SEL_2 .@SEL_2)`:

```
CREATE VIEW v1 AS SELECT * FROM t JOIN /* Comment: For view `v1`, the
    ↪ name of the current query block is the default @SEL_1. So, the
    ↪ current query block view list is v2@SEL_1 .@SEL_2 .v1@SEL_1 */
    (
        SELECT COUNT(*) FROM t1 JOIN t2 /* Comment: For view `v1`, the
            ↪ name of the current query block is the default @SEL_2.
            ↪ So, the current query block view list is v2@SEL_1 .@SEL_
            ↪ 2 .v1@SEL_2 */
```

```
) tt;
```

Note:

- To use global hints with views, you must define the corresponding `QB_NAME` hints in the view. Otherwise, the global hints will not take effect.
- When using a hint to specify multiple table names in a view, you need to ensure that the table names appearing in the same hint are in the same query block of the same view.
- When you define the `QB_NAME` hint in a view for the outermost query block:
  - For the first item of the view list in the `QB_NAME`, if the `@SEL_` is not explicitly declared, the default is consistent with the query block position where the `QB_NAME` is defined. That is, the query `SELECT /*+ QB_NAME(qb1, v2)*/ * FROM v2 JOIN (SELECT /*+ QB_NAME(qb2, v2)*/ * FROM v2)vv;` is equivalent to `SELECT /*+ QB_NAME(qb1, v2@SEL_1)*/ * FROM v2 JOIN (SELECT /*+ QB_NAME(qb2, v2@SEL_2)*/ * FROM v2)vv;`.
  - For items other than the first item of the view list in the `QB_NAME`, only `@SEL_1` can be omitted. That is, if `@SEL_1` is declared in the first query block of the current view, `@SEL_1` can be omitted. Otherwise, `@SEL_` cannot be omitted. For the preceding example:
    - The first query block of the view `v2` can be declared as `QB_NAME(v2_1, v2)`.
    - The second query block of the view `v2` can be declared as `QB_NAME(v2_2, v2.@SEL_2)`.
    - The first query block of the view `v1` can be declared as `QB_NAME(v1_1, v2.v1@SEL_2)`.
    - The second query block of the view `v1` can be declared as `QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2)`.

Step 2: Add the target hints

After defining the `QB_NAME` hint for query blocks of the view, you can add required hints that take effect in query blocks in the form of `ViewName@QueryBlockName` to make them effective inside the view. For example:

- Specify the `MERGE_JOIN()` hint for the first query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_1, v2) merge_join(t@v2_1) */ * FROM v2;
```

- Specify the `MERGE_JOIN()` and `STREAM_AGG()` hints for the second query block of the view `v2`:

```
SELECT /*+ QB_NAME(v2_2, v2.@SEL_2) merge_join(t1@v2_2) stream_agg(
    ↪ @v2_2) */ * FROM v2;
```

- Specify the `HASH_JOIN()` hint for the first query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_1, v2.v1@SEL_2) hash_join(t@v1_1) */ * FROM v2;
```

- Specify the `HASH_JOIN()` and `HASH_AGG()` hints for the second query block of the view `v1`:

```
SELECT /*+ QB_NAME(v1_2, v2.v1@SEL_2 .@SEL_2) hash_join(t1@v1_2) hash
    ↪ _agg(@v1_2) */ * FROM v2;
```

11.3.4.2.4 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

> **Note:**
>
> This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

NO_INDEX_MERGE()

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

> **Note:**

- `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.
- For a subquery, `NO_INDEX_MERGE` only takes effect when it is placed at the outermost level of the subquery.

USE_TOJA(boolean_value)

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a
    ↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

MAX_EXECUTION_TIME(N)

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id
    ↪  = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

MEMORY_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

READ_CONSISTENT_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to `'follower'` or `'leader'` also controls whether to enable this feature.

IGNORE_PLAN_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when prepare-plan-cache is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id = ?';
```

SET_VAR(VAR_NAME=VAR_VALUE)

You can temporarily modify the value of system variables during statement execution by using the `SET_VAR(VAR_NAME=VAR_VALUE)` hint. After the statement is executed, the value of the system variable in the current session is automatically restored to the original value. This hint can be used to modify some system variables related to the optimizer and executor. For a list of system variables that can be modified using this hint, refer to System Variables.

Warning:

- It is strongly recommended not to modify variables that are not explicitly supported, as this might cause unpredictable behavior.
- Do not write `SET_VAR` in subqueries. Otherwise it might not take effect. For more information, see `SET_VAR` does not take effect when written in subqueries.

The following is an example:

```
SELECT /*+ SET_VAR(MAX_EXECUTION_TIME=1234) */ @@MAX_EXECUTION_TIME;
SELECT @@MAX_EXECUTION_TIME;
```

After executing the preceding SQL statements, the first query returns the value `1234` set in the hint, instead of the default value of `MAX_EXECUTION_TIME`. The second query returns the default value of the variable.

```
+----------------------+
| @@MAX_EXECUTION_TIME |
+----------------------+
|                 1234 |
+----------------------+
1 row in set (0.00 sec)
+----------------------+
| @@MAX_EXECUTION_TIME |
+----------------------+
|                    0 |
+----------------------+
1 row in set (0.00 sec)
```

STRAIGHT_JOIN()

The `STRAIGHT_JOIN()` hint reminds the optimizer to join tables in the order of table names in the `FROM` clause when generating the join plan.

```
SELECT /*+ STRAIGHT_JOIN() */ * FROM t t1, t t2 WHERE t1.a = t2.a;
```

Note:

- `STRAIGHT_JOIN` has higher priority over `LEADING`. When both hints are used, `LEADING` does not take effect.
- It is recommended to use the `LEADING` hint, which is more general than the `STRAIGHT_JOIN` hint.

NTH_PLAN(N)

The `NTH_PLAN(N)` hint reminds the optimizer to select the `N`th physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

> **Note:**
>
> `NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

RESOURCE_GROUP(resource_group_name)

`RESOURCE_GROUP(resource_group_name)` is used for Resource Control to isolate resources. This hint temporarily executes the current statement using the specified resource group. If the specified resource group does not exist, this hint will be ignored.

Example:

```
SELECT /*+ RESOURCE_GROUP(rg1) */ * FROM t limit 10;
```

> **Note:**
>
> Starting from v8.2.0, TiDB introduces privilege control for this hint. When the system variable `tidb_resource_control_strict_mode` is set to `ON`, you need to have the `SUPER` or `RESOURCE_GROUP_ADMIN` or `RESOURCE_GROUP_USER` privilege to use this hint. If you do not have the required privilege, this hint is ignored, and TiDB returns a warning. You can view the details by executing `SHOW WARNINGS;` after the query.

11.3.4.2.5 Troubleshoot common issues that hints do not take effect

Hints do not take effect because your MySQL command-line client strips hints

MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the Hint syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

Hints do not take effect because the database name is not specified

If you do not specify the database name when creating a connection, hints might not take effect. For example:

When connecting to TiDB, you use the `mysql -h127.0.0.1 -P4000 -uroot` command without the `-D` option, and then execute the following SQL statements:

```
SELECT /*+ use_index(t, a) */ a FROM test.t;
SHOW WARNINGS;
```

Because TiDB cannot identify the database for table `t`, the `use_index(t, a)` hint does not take effect.

```
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Warning | 1815 | use_index(.t, a) is inapplicable, check whether the
    ↪ table(.t) exists |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

Hints do not take effect because the database name is not explicitly specified in cross-table queries

When executing cross-table queries, you need to explicitly specify database names. Otherwise, hints might not take effect. For example:

```
USE test1;
CREATE TABLE t1(a INT, KEY(a));
USE test2;
CREATE TABLE t2(a INT, KEY(a));
SELECT /*+ use_index(t1, a) */ * FROM test1.t1, t2;
SHOW WARNINGS;
```

In the preceding statements, because table `t1` is not in the current `test2` database, the `use_index(t1, a)` hint does not take effect.

```
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
| Warning | 1815 | use_index(test2.t1, a) is inapplicable, check whether
    ↪ the table(test2.t1) exists |
+--
    ↪ -------+------+-----------------------------------------------------------
    ↪
```

```
1 row in set (0.00 sec)
```

In this case, you need to specify the database name explicitly by using `use_index(test1.t1, a)` instead of `use_index(t1, a)`.

Hints do not take effect because they are placed in wrong locations

Hints cannot take effect if they are not placed directly after the specific keywords. For example:

```
SELECT * /*+ use_index(t, a) */ FROM t;
SHOW WARNINGS;
```

The warning is as follows:

```
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
| Warning | 1064 | You have an error in your SQL syntax; check the manual
   ↪ that corresponds to your TiDB version for the right syntax to use [
   ↪ parser:8066]Optimizer hint can only be followed by certain keywords
   ↪ like SELECT, INSERT, etc. |
+--
   ↪ -------+------+-----------------------------------------------------------------
   ↪
1 row in set (0.01 sec)
```

In this case, you need to place the hint directly after the `SELECT` keyword. For more details, see the Syntax section.

`INL_JOIN` hint does not take effect

`INL_JOIN` hint does not take effect when built-in functions are used on columns for joining tables

In some cases, if you use a built-in function on a column that joins tables, the optimizer might fail to choose the `IndexJoin` plan, resulting in the `INL_JOIN` hint not taking effect either.

For example, the following query uses the built-in function `substr` on the column `tname` that joins tables:

```
CREATE TABLE t1 (id varchar(10) primary key, tname varchar(10));
CREATE TABLE t2 (id varchar(10) primary key, tname varchar(10));
```

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id=t2.id and
    ↪ SUBSTR(t1.tname,1,2)=SUBSTR(t2.tname,1,2);
```

The execution plan is as follows:

```
+--
    ↪ ----------------------------+---------+----------+--------------+-----------
    ↪
| id                          | estRows | task     | access object | operator
    ↪ info                                                |
+--
    ↪ ----------------------------+---------+----------+--------------+-----------
    ↪

```
+---------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                |
+---------+------+-----------------------------------------------------------------
    ↪
| Warning | 1815 | Optimizer Hint /*+ INL_JOIN(t1, t2) */ or /*+ TIDB_INLJ(
    ↪ t1, t2) */ is inapplicable |
+---------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

As you can see from the preceding example, the `INL_JOIN` hint does not take effect. This is due to a limitation of the optimizer that prevents using the `Projection` or `Selection` operator as the probe side of `IndexJoin`.

Starting from TiDB v8.0.0, you can avoid this issue by setting `tidb_enable_inl_join_inner_multi_pattern` to `ON`.

```
SET @@tidb_enable_inl_join_inner_multi_pattern=ON;
Query OK, 0 rows affected (0.00 sec)

EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id=t2.id AND
    ↪ SUBSTR(t1.tname,1,2)=SUBSTR(t2.tname,1,2);
+--
    ↪ ---------------------------+-------------+----------+--------------+--------

    ↪ pseudo                                                          |
```

```
+--
    ↪ --------------------------+-------------+----------+--------------+-------
    ↪
7 rows in set (0.00 sec)
```

`INL_JOIN`, `INL_HASH_JOIN`, and `INL_MERGE_JOIN` hints do not take effect due to collation incompatibility

When the collation of the join key is incompatible between two tables, the `IndexJoin` operator cannot be utilized to execute the query. In this case, the `INL_JOIN`, `INL_HASH_JOIN`, and `INL_MERGE_JOIN` hints do not take effect. For example:

```
CREATE TABLE t1 (k varchar(8), key(k)) COLLATE=utf8mb4_general_ci;
CREATE TABLE t2 (k varchar(8), key(k)) COLLATE=utf8mb4_bin;
EXPLAIN SELECT /*+ tidb_inlj(t1) */ * FROM t1, t2 WHERE t1.k=t2.k;
```

The execution plan is as follows:

```
+--
    ↪ --------------------------+---------+----------+--------------------+------
    ↪
| id                        | estRows | task     | access object      |
    ↪ operator info                              |
+--
    ↪ --------------------------+---------+----------+--------------------+------
    ↪
| HashJoin_19               | 12487.50 | root    |                    | inner
    ↪ join, equal:[eq(test.t1.k, test.t2.k)] |
| ─IndexReader_24(Build)  | 9990.00 | root     |                     | index:
    ↪ IndexFullScan_23                  |
|   ─IndexFullScan_23     | 9990.00 | cop[tikv] | table:t2, index:k(k) |
    ↪ keep order:false, stats:pseudo    |
| ─IndexReader_22(Probe)  | 9990.00 | root     |                     | index:
    ↪ IndexFullScan_21                  |
|   ─IndexFullScan_21     | 9990.00 | cop[tikv] | table:t1, index:k(k) |
    ↪ keep order:false, stats:pseudo    |
+--
    ↪ --------------------------+---------+----------+--------------------+------
    ↪
5 rows in set, 1 warning (0.00 sec)
```

In the preceding statements, the collations of `t1.k` and `t2.k` are incompatible (`utf8mb4_` ↪ `general_ci` and `utf8mb4_bin` respectively), which prevents the `INL_JOIN` or `TIDB_INLJ` hint from taking effect.

```
SHOW WARNINGS;
```

```
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪                                                                 |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪

    ↪ */ is inapplicable |
+--
    ↪ -------+------+-------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

`INL_JOIN` hint does not take effect due to join order

The `INL_JOIN(t1, t2)` or `TIDB_INLJ(t1, t2)` hint semantically instructs `t1` and `t2` to act as inner tables in an `IndexJoin` operator to join with other tables, rather than directly joining them using an `IndexJoin` operator. For example:

```
EXPLAIN SELECT /*+ inl_join(t1, t3) */ * FROM t1, t2, t3 WHERE t1.id = t2.
    ↪ id AND t2.id = t3.id AND t1.id = t3.id;
+--
    ↪ ------------------------------+----------+-----------+--------------+--------
    ↪

```

In the preceding example, `t1` and `t3` are not directly joined together by an `IndexJoin`.

To perform a direct `IndexJoin` between `t1` and `t3`, you can first use `LEADING(t1, t3)` hint to specify the join order of `t1` and `t3`, and then use the `INL_JOIN` hint to specify the join algorithm. For example:

```
EXPLAIN SELECT /*+ leading(t1, t3), inl_join(t3) */ * FROM t1, t2, t3 WHERE
    ↪  t1.id = t2.id AND t2.id = t3.id AND t1.id = t3.id;

Using hints causes the `Can't find a proper physical plan for this query` error

The `Can't find a proper physical plan for this query` error might occur in the following scenarios:

- A query itself does not require reading indexes in order. That is, for this query, the optimizer does not generate a plan to read indexes in order in any case without using hints. In this case, if the `ORDER_INDEX` hint is specified, this error occurs. To resolve this issue, remove the corresponding `ORDER_INDEX` hint.
- A query excludes all possible join methods by using the `NO_JOIN` related hints.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
```

```
EXPLAIN SELECT /*+ NO_HASH_JOIN(t1), NO_MERGE_JOIN(t1) */ * FROM t1, t2
    ↪ WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

- The system variable `tidb_opt_enable_hash_join` is set to `OFF`, and all other join types are also excluded.

```
CREATE TABLE t1 (a INT);
CREATE TABLE t2 (a INT);
set tidb_opt_enable_hash_join=off;
EXPLAIN SELECT /*+ NO_MERGE_JOIN(t1) */ * FROM t1, t2 WHERE t1.a=t2.a;
ERROR 1815 (HY000): Internal : Can't find a proper physical plan for this
    ↪ query
```

`SET_VAR` does not take effect when written in subqueries

`SET_VAR` is used to modify the value of system variables for the current statement. Do not write it in subqueries. If you write it in a subquery, `SET_VAR` might not take effect due to the special handling of subqueries.

In the following example, `SET_VAR` is written in the subquery, so it does not take effect.

```
mysql> SELECT @@MAX_EXECUTION_TIME, a FROM (SELECT /*+ SET_VAR(MAX_
    ↪ EXECUTION_TIME=123) */ 1 as a) t;
+----------------------+---+
| @@MAX_EXECUTION_TIME | a |
+----------------------+---+
|                    0 | 1 |
+----------------------+---+
1 row in set (0.00 sec)
```

In the following example, `SET_VAR` is not written in a subquery, so it takes effect.

```
mysql> SELECT /*+ SET_VAR(MAX_EXECUTION_TIME=123) */ @@MAX_EXECUTION_TIME,
    ↪ a FROM (SELECT 1 as a) t;
+----------------------+---+
| @@MAX_EXECUTION_TIME | a |
+----------------------+---+
|                  123 | 1 |
+----------------------+---+
1 row in set (0.00 sec)
```

11.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

11.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The Optimizer Hints document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

> **Note:**
>
> To use SQL bindings, you need to have the `SUPER` privilege. If TiDB prompts that you do not have sufficient privileges, see Privilege Management to add the required privileges.

Create a binding

You can create a binding for a SQL statement according to a SQL statement or a historical execution plan.

Create a binding according to a SQL statement

```
CREATE [GLOBAL | SESSION] BINDING [FOR BindableStmt] USING BindableStmt;
```

This statement binds SQL execution plans at the GLOBAL or SESSION level. Currently, supported bindable SQL statements (BindableStmt) in TiDB include `SELECT`, `DELETE`, `UPDATE`, and `INSERT` / `REPLACE` with `SELECT` subqueries. The following is an example:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(orders, orders_book_id_
    ↪ idx) */ * FROM orders;
CREATE GLOBAL BINDING FOR SELECT * FROM orders USING SELECT /*+ use_index(
    ↪ orders, orders_book_id_idx) */ * FROM orders;
```

> **Note:**
>
> Bindings have higher priority over manually added hints. Therefore, when you execute a statement containing a hint while a corresponding binding is present, the hint controlling the behavior of the optimizer does not take effect. However, other types of hints are still effective.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. A syntax error will be reported during binding creation. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `JOIN`
    ↪  keyword and not specifying the associated columns with the `USING`
    ↪ keyword.
CREATE GLOBAL BINDING for
    SELECT * FROM orders o1 JOIN orders o2
USING
    SELECT * FROM orders o1 JOIN orders o2;

-- Type two: `DELETE` statements that contain the `USING` keyword.
CREATE GLOBAL BINDING for
    DELETE FROM users USING users JOIN orders ON users.id = orders.user_id
USING
    DELETE FROM users USING users JOIN orders ON users.id = orders.user_id;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- Rewrite of type one statements: Delete the `JOIN` keyword. Replace it
    ↪ with a comma.
CREATE GLOBAL BINDING for
    SELECT * FROM orders o1, orders o2
USING
    SELECT * FROM orders o1, orders o2;

-- Rewrite of type two statements: Remove the `USING` keyword from the `
    ↪ DELETE` statement.
CREATE GLOBAL BINDING for
    DELETE users FROM users JOIN orders ON users.id = orders.user_id
USING
    DELETE users FROM users JOIN orders ON users.id = orders.user_id;
```

> **Note:**
>
> When creating execution plan bindings for `INSERT` / `REPLACE` statements with `SELECT` subqueries, you need to specify the optimizer hints you want to bind in the `SELECT` subquery, not after the `INSERT` / `REPLACE` keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO orders SELECT * FROM pre_orders WHERE status = 'VALID' AND
        ↪ created <= (NOW() - INTERVAL 1 HOUR)
USING
    INSERT INTO orders SELECT /*+ use_index(@sel_1 pre_orders, idx_created)
        ↪  */ * FROM pre_orders WHERE status = 'VALID' AND created <= (NOW
        ↪ () - INTERVAL 1 HOUR);

-- The hint cannot take effect in the following statement.
CREATE GLOBAL BINDING for
    INSERT INTO orders SELECT * FROM pre_orders WHERE status = 'VALID' AND
        ↪ created <= (NOW() - INTERVAL 1 HOUR)
USING
    INSERT /*+ use_index(@sel_1 pre_orders, idx_created) */ INTO orders
        ↪ SELECT * FROM pre_orders WHERE status = 'VALID' AND created <= (
        ↪ NOW() - INTERVAL 1 HOUR);
```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

`Normalization` is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```
SELECT * FROM users WHERE balance > 100
-- After normalization, the above statement is as follows:
SELECT * FROM bookshop . users WHERE balance > ?
```

Note:

In the normalization process, `?` in the `IN` predicate is normalized as `...`.

For example:

```
SELECT * FROM books WHERE type IN ('Novel')
SELECT * FROM books WHERE type IN ('Novel','Life','Education')
-- After normalization, the above statements are as follows:
```

```
SELECT * FROM bookshop . books WHERE type IN ( ... )
SELECT * FROM bookshop . books WHERE type IN ( ... )
```

After normalization, `IN` predicates of different lengths are recognized as the same statement, so you only need to create one binding that applies to all these predicates.

For example:

```
CREATE TABLE t (a INT, KEY(a));
CREATE BINDING FOR SELECT * FROM t WHERE a IN (?) USING SELECT
    ↪  /*+ use_index(t, idx_a) */ * FROM t WHERE a in (?);

SELECT * FROM t WHERE a IN (1);
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
+--------------------------+

SELECT * FROM t WHERE a IN (1, 2, 3);
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
+--------------------------+
```

Bindings created in TiDB clusters earlier than v7.4.0 might contain `IN (?)`. After the upgrade to v7.4.0 or a later version, these bindings will be modified to `IN (...)`.

For example:

```
-- Create a binding on v7.3.0
mysql> CREATE GLOBAL BINDING FOR SELECT * FROM t WHERE a IN (1)
    ↪  USING SELECT /*+ use_index(t, idx_a) */ * FROM t WHERE
    ↪ a IN (1);
mysql> SHOW GLOBAL BINDINGS;

+--
    ↪ ----------------------------------------------+-------------------------
    ↪
```

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```
-- Creates a GLOBAL binding and specifies using `sort merge join` in this
   ↪ binding.
CREATE GLOBAL BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ merge_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
   ↪ specified in the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
   ↪  binding.
CREATE BINDING for
    SELECT * FROM t1, t2 WHERE t1.id = t2.id
USING
    SELECT /*+ hash_join(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
   ↪ SESSION binding is used, instead of `sort merge join` specified in
   ↪ the GLOBAL binding.
explain SELECT * FROM t1, t2 WHERE t1.id = t2.id;
```

When the first `SELECT` statement is being executed, the optimizer adds the `sm_join(` ↪ `t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is MergeJoin. When the second `SELECT` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is HashJoin.

Each standardized SQL statement can have only one binding created using `CREATE` ↪ `BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use ${` ↪ `database}` is executed.

The original SQL statement and the bound statement must have the same text after

normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `SELECT * FROM test . t WHERE a > ?`

```
CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t
    ↪ use index (idx) WHERE a > 2
```

- This binding will fail because the original SQL statement is processed as `SELECT * ↪ FROM test . t WHERE a > ?`, while the bound SQL statement is processed differently as `SELECT * FROM test . t WHERE b > ?`.

```
CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM t
    ↪ use index(idx) WHERE b > 2
```

> **Note:**
>
> For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

Create a binding according to a historical execution plan

To make the execution plan of a SQL statement fixed to a historical execution plan, you can use Plan Digest to bind that historical execution plan to the SQL statement, which is more convenient than binding it according to a SQL statement. In addition, you can bind the execution plan for multiple SQL statements at once. For more details and examples, see `CREATE [GLOBAL|SESSION] BINDING`.

When using this feature, note the following:

- The feature generates hints according to historical execution plans and uses the generated hints for binding. Because historical execution plans are stored in Statement Summary Tables, before using this feature, you need to enable the `tidb_enable_stmt ↪ _summary` system variable first.
- For TiFlash queries, Join queries with three or more tables, and queries that contain subqueries, the auto-generated hints are not adequate, which might result in the plan not being fully bound. In such cases, a warning will occur when creating a binding.
- If a historical execution plan is for a SQL statement with hints, the hints will be added to the binding. For example, after executing `SELECT /*+ max_execution_ ↪ time(1000)*/ * FROM t`, the binding created with its Plan Digest will include `max_execution_time(1000)`.

The SQL statement of this binding method is as follows:

```
CREATE [GLOBAL | SESSION] BINDING FROM HISTORY USING PLAN DIGEST
    ↪ StringLiteralOrUserVariableList;
```

The preceding statement binds an execution plan to a SQL statement using Plan Digest. The default scope is SESSION. The applicable SQL statements, priorities, scopes, and effective conditions of the created bindings are the same as that of bindings created according to SQL statements.

To use this binding method, you need to first get the Plan Digest corresponding to the target historical execution plan in `statements_summary`, and then create a binding using the Plan Digest. The detailed steps are as follows:

1. Get the Plan Digest corresponding to the target execution plan in `statements_summary`.

   For example:

   ```
   CREATE TABLE t(id INT PRIMARY KEY , a INT, KEY idx_a(a));
   SELECT /*+ IGNORE_INDEX(t, idx_a) */ * FROM t WHERE a = 1;
   SELECT * FROM INFORMATION_SCHEMA.STATEMENTS_SUMMARY WHERE QUERY_SAMPLE
       ↪ _TEXT = 'SELECT /*+ IGNORE_INDEX(t, idx_a) */ * FROM t WHERE a =
       ↪ 1'\G
   ```

   The following is a part of the example query result of `statements_summary`:

   ```
   SUMMARY_BEGIN_TIME: 2022-12-01 19:00:00
   ...........
        DIGEST_TEXT: select * from `t` where `a` = ?
   ...........
        PLAN_DIGEST: 4

       ↪ ////CQMEAXgJCBD///8
       ↪ BIQFzCDhVQw19BAAkBX0QUg9lcSgBfCAudC5hLCAxKWrmYQAYHOi0gc6hBB1hJAFAAVIQZGF
       ↪ ////////////8BGAE=
```

In this example, you can see that the execution plan corresponding to Plan Digest is `4e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb`.

2. Use Plan Digest to create a binding:

```
CREATE BINDING FROM HISTORY USING PLAN DIGEST '4
   ↪ e3159169cc63c14b139a4e7d72eae1759875c9a9581f94bb2079aae961189cb';
```

To verify whether the created binding takes effect, you can view bindings:

```
SHOW BINDINGS\G
```

```
*************************** 1. row ***************************
Original_sql: select * from `test` . `t` where `a` = ?
    Bind_sql: SELECT /*+ use_index(@`sel_1` `test`.`t` ) ignore_index(`t` `
       ↪ idx_a`)*/ * FROM `test`.`t` WHERE `a` = 1
       ..........
  Sql_digest: 6909
     ↪ a1bbce5f64ade0a532d7058dd77b6ad5d5068aee22a531304280de48349f
 Plan_digest:
1 row in set (0.01 sec)

ERROR:

```

Remove a binding

You can remove a binding according to a SQL statement or SQL Digest.

Remove a binding according to a SQL statement

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in create binding in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.
drop session binding for SELECT * FROM t1, t2 WHERE t1.id = t2.id;

-- Views the SQL execution plan again.
explain SELECT * FROM t1,t2 WHERE t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

Remove a binding according to SQL Digest

In addition to removing a binding according to a SQL statement, you can also remove a binding according to SQL Digest. For more details and examples, see DROP [GLOBAL| ↪ SESSION] BINDING.

```
DROP [GLOBAL | SESSION] BINDING FOR SQL DIGEST
    ↪ StringLiteralOrUserVariableList;
```

This statement removes an execution plan binding corresponding to SQL Digest at the GLOBAL or SESSION level. The default scope is SESSION. You can get the SQL Digest by viewing bindings.

Note:

Executing `DROP GLOBAL BINDING` drops the binding in the current tidb-server instance cache and changes the status of the corresponding row in the system table to 'deleted'. This statement does not directly delete the records in the system table, because other tidb-server instances need to read the 'deleted' status to drop the corresponding binding in their cache. For the records in these system tables with the status of 'deleted', at every 100 `bind-info-lease` (the default value is `3s`, and `300s` in total) interval, the background thread triggers an operation of reclaiming and clearing on the bindings of `update_time` before 10 `bind-info-lease` (to ensure that all tidb-server instances have read the 'deleted' status and updated the cache).

Change binding status

Change binding status according to a SQL statement

```
SET BINDING [ENABLED | DISABLED] FOR BindableStmt;
```

You can execute this statement to change the status of a binding. The default status is ENABLED. The effective scope is GLOBAL by default and cannot be modified.

When executing this statement, you can only change the status of a binding from `Disabled` to `Enabled` or from `Enabled` to `Disabled`. If no binding is available for status changes, a warning message is returned, saying `There are no bindings can be set the status. Please check the SQL text`. Note that a binding in `Disabled` status is not used by any query.

Change binding status according to `sql_digest`

In addition to changing the binding status according to a SQL statement, you can also change the binding status according to `sql_digest`:

```
SET BINDING [ENABLED | DISABLED] FOR SQL DIGEST 'sql_digest';
```

The binding status that can be changed by `sql_digest` and the effect is the same as those changed according to a SQL statement. If no binding is available for status changes, a warning message `can't find any binding for 'sql_digest'` is returned.

View bindings

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the GLOBAL or SESSION level according to the order of binding update time from the latest to earliest. The default scope is SESSION. Currently `SHOW BINDINGS` outputs 11 columns, as shown below:

Column Name	Note
original_sql	Original SQL statement after parameterization
bind_sql	Bound SQL statement with hints
default_db	Default database
status	Status including `enabled` (replacing the `using` status from v6.0), `disabled`, `deleted`, `invalid`, `rejected`, and `pending verify`
create_time	Creating time
update_time	Updating time
charset	Character set
collation	Ordering rule

Column Name	Note
source	The way in which a binding is created, including `manual` (created according to a SQL statement), `history` (created according to a historical execution plan), `capture` (captured automatically by TiDB), and `evolve` (evolved automatically by TiDB)
sql_digest	Digest of a normalized SQL statement
plan_digest	Digest of an execution plan

Troubleshoot a binding

You can use either of the following methods to troubleshoot a binding:

- Use the system variable `last_plan_from_binding` to show whether the execution plan used by the last executed statement is from the binding.

```
-- Create a global binding
CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

SELECT * FROM t;
SELECT @@[SESSION.]last_plan_from_binding;
```

```
+--------------------------+
| @@last_plan_from_binding |
+--------------------------+
|                        1 |
+--------------------------+
1 row in set (0.00 sec)
```

- Use the `explain format = 'verbose'` statement to view the query plan of a SQL statement. If the SQL statement uses a binding, you can run `show warnings` to check which binding is used in the SQL statement.

```
-- Create a global binding

CREATE GLOBAL BINDING for
    SELECT * FROM t
USING
    SELECT /*+ USE_INDEX(t, idx_a) */ * FROM t;

-- Use explain format = 'verbose' to view the execution plan of a SQL
    ↪  statement

explain format = 'verbose' SELECT * FROM t;

-- Run `show warnings` to view the binding used in the query.

show warnings;
```

```
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Level | Code | Message
    ↪                                                                 |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
| Note | 1105 | Using the bindSQL: SELECT /*+ USE_INDEX(`t` `idx_a`)*/
    ↪  * FROM `test`.`t` |
+--
    ↪ -----+------+-----------------------------------------------------------
    ↪
1 row in set (0.01 sec)
```

Cache bindings

Each TiDB instance has a least recently used (LRU) cache for bindings. The cache capacity is controlled by the system variable `tidb_mem_quota_binding_cache`. You can view bindings that are cached in the TiDB instance.

To view the cache status of bindings, run the `SHOW binding_cache status` statement. In this statement, the effective scope is GLOBAL by default and cannot be modified. This statement returns the number of available bindings in the cache, the total number of available bindings in the system, memory usage of all cached bindings, and the total memory for the cache.

```
SHOW binding_cache status;
```

```
+------------------+------------------+-------------+-------------+
| bindings_in_cache | bindings_in_table | memory_usage | memory_quota |
+------------------+------------------+-------------+-------------+
|                1 |                1 | 159 Bytes   | 64 MB       |
+------------------+------------------+-------------+-------------+
1 row in set (0.00 sec)
```

11.3.4.3.2 Utilize the statement summary table to obtain queries that need to be bound

Statement summary records recent SQL execution information, such as latency, execution times, and corresponding query plans. You can query statement summary tables to get qualified `plan_digest`, and then create bindings according to these historical execution plans.

The following example queries `SELECT` statements that have been executed more than 10 times in the past two weeks, and have multiple execution plans without SQL binding. It sorts the queries by the execution times, and binds the top 100 queries to their fastest plans.

```
WITH stmts AS (                                          -- Gets all
    ↪ information
  SELECT * FROM INFORMATION_SCHEMA.CLUSTER_STATEMENTS_SUMMARY
  UNION ALL
  SELECT * FROM INFORMATION_SCHEMA.CLUSTER_STATEMENTS_SUMMARY_HISTORY
),
best_plans AS (
  SELECT plan_digest, `digest`, avg_latency,
  CONCAT('create global binding from history using plan digest "', plan_
     ↪ digest, '"') as binding_stmt
  FROM stmts t1
  WHERE avg_latency = (SELECT min(avg_latency) FROM stmts t2 -- The plan
     ↪ with the lowest query latency
                       WHERE t2.`digest` = t1.`digest`)
)
```

```
SELECT any_value(digest_text) as query,
      SUM(exec_count) as exec_count,
      plan_hint, binding_stmt
FROM stmts, best_plans
WHERE stmts.`digest` = best_plans.`digest`
  AND summary_begin_time > DATE_SUB(NOW(), interval 14 day) -- Executed in
     ↪ the past 2 weeks
  AND stmt_type = 'Select'                                  -- Only consider
     ↪ select statements
  AND schema_name NOT IN ('INFORMATION_SCHEMA', 'mysql') -- Not an internal
     ↪  query
  AND plan_in_binding = 0                                   -- No binding yet
GROUP BY stmts.`digest`
  HAVING COUNT(DISTINCT(stmts.plan_digest)) > 1         -- This query is
     ↪ unstable. It has more than 1 plan.
        AND SUM(exec_count) > 10                            -- High-frequency,
           ↪ and has been executed more than 10 times.
ORDER BY SUM(exec_count) DESC LIMIT 100;                -- Top 100 high-
   ↪ frequency queries.
```

By applying certain filtering conditions to obtain queries that meet the criteria, you can then directly execute the statements in the corresponding `binding_stmt` column to create bindings.

```
+-----------------------------------------------+------------+-----------------------------
   ↪
| query                                         | exec_count | plan_hint
   ↪                                                                  | binding_stmt
   ↪
   ↪ |
+-----------------------------------------------+------------+-----------------------------
   ↪
| select * from `t` where `a` = ? and `b` = ? | 401 | use_index(@`sel_1` `
   ↪ test`.`t` `a`), no_order_index(@`sel_1` `test`.`t` `a`) | create
   ↪ global binding from history using plan digest "0

   ↪ test`.`t` `b`), no_order_index(@`sel_1` `test`.`t` `b`) | create
   ↪ global binding from history using plan digest "80
   ↪ c2aa0aa7e6d3205755823aa8c6165092c8521fb74c06a9204b8d35fc037dd9" |
+-----------------------------------------------+------------+-----------------------------
   ↪
```

11.3.4.4.3.3 Cross-database binding

Starting from v7.6.0, you can create cross-database bindings in TiDB by using the wildcard * to represent a database name in the binding creation syntax. Before creating cross-database bindings, you need to first enable the tidb_opt_enable_fuzzy_binding system variable.

You can use cross-database bindings to simplify the process of fixing execution plans in scenarios where data is categorized and stored across different databases, and each database maintains identical object definitions and executes similar application logic. The following are some common use cases:

- When you run SaaS or PaaS services on TiDB, where the data of each tenant is stored in separate databases for easier data maintenance and management
- When you performed database sharding in a single instance and retained the original database schema after migrating to TiDB, that is, the data in the original instance is categorized and stored by database

In these scenarios, cross-database binding can effectively mitigate SQL performance issues caused by uneven distribution and rapid changes in user data and workload. SaaS providers can use cross-database bindings to fix execution plans validated by applications with large data volumes, thereby avoiding potential performance issues due to the rapid growth of applications with small data volumes.

To create a cross-database binding, you only need to use * to represent the database name when creating a binding. For example:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t, idx_a) */ * FROM t; --
    ↪  Create a GLOBAL scope standard binding.
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t, idx_a) */ * FROM *.t;
    ↪ -- Create a GLOBAL scope cross-database binding.
SHOW GLOBAL BINDINGS;
```

The output is as follows:

```
+--
    ↪ -------------------------+-------------------------------------------------+-
    ↪
| Original_sql            | Bind_sql                                          |
    ↪ Default_db | Status | Create_time        | Update_time         |
    ↪ Charset | Collation    | Source | Sql_digest
    ↪                                              | Plan_digest |
+--
    ↪ -------------------------+-------------------------------------------------+-
    ↪
| select * from `test` . `t` | SELECT /*+ use_index(`t` `idx_a`)*/ * FROM `
    ↪ test`.`t` | test | enabled | 2023-12-29 14:19:01.332 | 2023-12-29
    ↪ 14:19:01.332 | utf8 | utf8_general_ci | manual | 8
    ↪ b193b00413fdb910d39073e0d494c96ebf24d1e30b131ecdd553883d0e29b42 | |
```

```
| select * from `*` . `t` | SELECT /*+ use_index(`t` `idx_a`)*/ * FROM
    ↪ `*`.`t` |     | enabled | 2023-12-29 14:19:02.232 | 2023-12-29
    ↪ 14:19:02.232 | utf8 | utf8_general_ci | manual | 8
    ↪ b193b00413fdb910d39073e0d494c96ebf24d1e30b131ecdd553883d0e29b42 | |
+--
    ↪ -------------------------+-----------------------------------------------+-
    ↪
```

In the `SHOW GLOBAL BINDINGS` output, the `Default_db` field value of a cross-database binding is empty, and the database name in the `Original_sql` and `Bind_sql` fields is represented as `*`. This binding applies to `select * from t` queries in all databases, not just in a specific database.

For the same query, both cross-database and standard bindings can coexist. TiDB matches bindings in the following order: SESSION scope standard bindings > SESSION scope cross-database bindings > GLOBAL scope standard bindings > GLOBAL scope cross-database bindings.

Apart from the creation syntax, cross-database bindings share the same deletion and status change syntax as standard bindings. The following is a detailed usage example.

1. Create databases `db1` and `db2`, and create two tables in each database:

```
CREATE DATABASE db1;
CREATE TABLE db1.t1 (a INT, KEY(a));
CREATE TABLE db1.t2 (a INT, KEY(a));
CREATE DATABASE db2;
CREATE TABLE db2.t1 (a INT, KEY(a));
CREATE TABLE db2.t2 (a INT, KEY(a));
```

2. Enable the cross-database binding feature:

```
SET tidb_opt_enable_fuzzy_binding=1;
```

3. Create a cross-database binding:

```
CREATE GLOBAL BINDING USING SELECT /*+ use_index(t1, idx_a), use_index
    ↪ (t2, idx_a) */ * FROM *.t1, *.t2;
```

4. Execute queries and verify whether the binding is used:

```
SELECT * FROM db1.t1, db1.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+--------------------------+
| @@LAST_PLAN_FROM_BINDING |
+--------------------------+
|                        1 |
```

```
+-------------------------+

SELECT * FROM db2.t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+

SELECT * FROM db1.t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+

USE db1;
SELECT * FROM t1, db2.t2;
SELECT @@LAST_PLAN_FROM_BINDING;
+-------------------------+
| @@LAST_PLAN_FROM_BINDING |
+-------------------------+
|                       1 |
+-------------------------+
```

5. View the binding:

```
SHOW GLOBAL BINDINGS;
+--
   ↪ ----------------------------------------+----------------------------
   ↪
| Original_sql                              | Bind_sql
   ↪
   ↪ | Default_db | Status | Create_time        | Update_time
   ↪          | Charset | Collation      | Source | Sql_digest
   ↪                                                | Plan_digest |
+--
   ↪ ----------------------------------------+----------------------------
   ↪
| select * from ( `*` . `t1` ) join `*` . `t2` | SELECT /*+ use_index
   ↪ (`t1` `idx_a`) use_index(`t2` `idx_a`)*/ * FROM (`*` . `t1`)
   ↪ JOIN `*` . `t2` | | enabled | 2023-12-29 14:22:28.144 |
   ↪ 2023-12-29 14:22:28.144 | utf8 | utf8_general_ci | manual |
```

```
    ↪ ea8720583e80644b58877663eafb3579700e5f918a748be222c5b741a696daf4
    ↪ | |
+--
    ↪ ----------------------------------------+-------------------------
    ↪
```

6. Delete the cross-database binding:

```
DROP GLOBAL BINDING FOR SQL DIGEST '
    ↪ ea8720583e80644b58877663eafb3579700e5f918a748be222c5b741a696daf4'
    ↪ ;
SHOW GLOBAL BINDINGS;
Empty set (0.00 sec)
```

11.3.4.3.4 Baseline capturing

Used for preventing regression of execution plans during an upgrade, this feature captures queries that meet capturing conditions and creates bindings for these queries.

A plan baseline refers to a collection of accepted plans that the optimizer can use for executing a SQL statement. Generally, TiDB adds a plan into the plan baseline only after confirming that the plan performs well. A plan in this context encompasses all the necessary plan-related details (such as SQL plan identifier, hint set, bind values, and optimizer environment) that the optimizer requires to reproduce an execution plan.

Enable capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

> **Note:**
>
> Because the automatic binding creation function relies on Statement Summary, make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.
- Statements that contain `Enabled` or `Disabled` bindings.
- Statements that are filtered out by capturing conditions.

> **Note:**
>
> Currently, a binding generates a group of hints to fix an execution plan generated by a query statement. In this way, for the same query, the execution plan does not change. For most OLTP queries, including queries using the same index or Join algorithm (such as HashJoin and IndexJoin), TiDB guarantees plan consistency before and after the binding. However, due to the limitations of hints, TiDB cannot guarantee plan consistency for some complex queries, such as Join of more than two tables, MPP queries, and complex OLAP queries.

For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

> **Note:**
>
> Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

Filter out bindings

This feature allows you to configure a blocklist to filter out queries whose bindings you do not want to capture. A blocklist has three dimensions, table name, frequency, and user name.

Usage

Insert filtering conditions into the system table `mysql.capture_plan_baselines_blacklist`. Then the filtering conditions take effect in the entire cluster immediately.

```
-- Filter by table name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'test.t');
```

```
-- Filter by database name and table name through wildcards
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'test.table_*');
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('table', 'db_*.table_*');

-- Filter by frequency
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('frequency', '2');

-- Filter by user name
INSERT INTO mysql.capture_plan_baselines_blacklist(filter_type, filter_
    ↪ value) VALUES('user', 'user1');
```

Dimension name	Description	Remarks
table	Filter by table name. Each filtering rule is in the `db.table` format. The supported filtering syntax includes Plain table names and Wildcards.	Case insensitive. If a table name contains illegal characters, the log returns a warning message `[sql-bind] failed to load mysql .capture_plan_baselines_ blacklist`.
frequency	Filter by frequency. SQL statements executed more than once are captured by default. You can set a high frequency to capture statements that are frequently executed.	Setting frequency to a value smaller than 1 is considered illegal, and the log returns a warning message `[sql-bind] frequency threshold is less than 1, ignore it`. If multiple frequency filter rules are inserted, the value with the highest frequency prevails.
user	Filter by user name. Statements executed by blocklisted users are not captured.	If multiple users execute the same statement and their user names are all in the blocklist, this statement is not captured.

Note:

- Modifying a blocklist requires the super privilege.
- If a blocklist contains illegal filters, TiDB returns the warning message `[sql-bind] unknown capture filter type, ignore it` in the log.

Prevent regression of execution plans during an upgrade

Before upgrading a TiDB cluster, you can use baseline capturing to prevent regression of execution plans by performing the following steps:

1. Enable baseline capturing and keep it working.

> **Note:**
> Test data shows that long-term working of baseline capturing has a slight impact on the performance of the cluster load. Therefore, it is recommended to enable baseline capturing as long as possible so that important plans (appear twice or above) are captured.

2. Upgrade the TiDB cluster. After the upgrade, TiDB uses those captured bindings to ensure execution plan consistency.
3. After the upgrade, delete bindings as required.

    - Check the binding source by running the `SHOW GLOBAL BINDINGS` statement.

      In the output, check the `Source` field to see whether a binding is captured (`capture`) or manually created (`manual`).
    - Determine whether to retain the captured bindings:

```
-- View the plan with the binding enabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = true;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;

-- View the plan with the binding disabled
SET @@SESSION.TIDB_USE_PLAN_BASELINES = false;
EXPLAIN FORMAT='VERBOSE' SELECT * FROM t1 WHERE ...;
```

        - If the execution plan is consistent, you can delete the binding safely.
        - If the execution plan is inconsistent, you need to identify the cause, for example, by checking statistics. In this case, you need to retain the binding to ensure plan consistency.

11.3.4.3.5 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
SET GLOBAL tidb_evolve_plan_baselines = ON;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

Warning:

- Baseline evolution is an experimental feature. Unknown risks might exist. It is **NOT** recommended that you use it in the production environment.
- This variable is forcibly set to `off` until the baseline evolution feature becomes generally available (GA). If you try to enable this feature, an error is returned. If you have already used this feature in a production environment, disable it as soon as possible. If you find that the binding status is not as expected, get support from PingCAP or the community.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is `3s`) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than 2/3 that of the binding execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
CREATE TABLE t(a INT, b INT, KEY(a), KEY(b));
```

Perform the following query on table `t`:

```
SELECT * FROM t WHERE a < 100 AND b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
CREATE GLOBAL BINDING for SELECT * FROM t WHERE a < 100 AND b < 100 USING
    ↪ SELECT * FROM t use index(a) WHERE a < 100 AND b < 100;
```

When the query above is executed again, the optimizer selects index `a` (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table `t`, an increasing number of rows meet the `a < 100` condition and a decreasing number of rows meet the `b < 100` condition. At this time, using index `a` under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index `b`. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index `a`, index `b` is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index `b` and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is `600s`. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (`00:00 +0000` by default) and `tidb_` ↪ `evolve_plan_task_end_time` (`23:59 +0000` by default) to limit the time window.

Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.
- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
`memory_quota`	The maximum memory that can be used for a query.
`use_toja`	Whether the optimizer transforms sub-queries to Join.
`use_cascades`	Whether to use the cascades optimizer.
`no_index_merge`	Whether the optimizer uses Index Merge as an option for reading tables.
`read_consistent_replica`	Whether to forcibly enable Follower Read when reading tables.
`max_execution_time`	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads, when the isolation condition changes, this hint has a great influence on the evolved execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

11.3.4.3.6 Upgrade checklist

During cluster upgrade, SQL Plan Management (SPM) might cause compatibility issues and make the upgrade fail. To ensure a successful upgrade, you need to include the following list for upgrade precheck:

- When you upgrade from a version earlier than v5.2.0 (that is, v4.0, v5.0, and v5.1) to the current version, make sure that `tidb_evolve_plan_baselines` is disabled before the upgrade. To disable this variable, perform the following steps.

```
-- Check whether `tidb_evolve_plan_baselines` is disabled in the
   ↪ earlier version.
```

```
SELECT @@global.tidb_evolve_plan_baselines;

-- If `tidb_evolve_plan_baselines` is still enabled, disable it.

SET GLOBAL tidb_evolve_plan_baselines = OFF;
```

- Before you upgrade from v4.0 to the current version, you need to check whether the syntax of all queries corresponding to the available SQL bindings is correct in the new version. If any syntax errors exist, delete the corresponding SQL binding. To do that, perform the following steps.

```
-- Check the query corresponding to the available SQL binding in the
   ↪ version to be upgraded.

SELECT bind_sql FROM mysql.bind_info WHERE status = 'using';

-- Verify the result from the above SQL query in the test environment
   ↪  of the new version.

bind_sql_0;
bind_sql_1;
...

-- In the case of a syntax error (ERROR 1064 (42000): You have an
   ↪ error in your SQL syntax), delete the corresponding binding.
-- For any other errors (for example, tables are not found), it means
   ↪  that the syntax is compatible. No other operation is needed.
```

11.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

11.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Rule Name	Description
Column pruning	column_prune	One operator will prune the column if it is not needed by the upper executor.
Decorrelate subquery	decorrelate	Tries to rewrite the correlated subquery to non-correlated join or aggregation.

Optimization Rule	Rule Name	Description
Aggregation elimination	aggregation_eliminate	Tries to remove unnecessary aggregation operators from the execution plan.
Projection elimination	projection_eliminate	Removes unnecessary projection operators from the execution plan.

Optimization Rule	Rule Name	Description
Max/Min elimination	max_min_eliminate	Rewrites some max/min functions in aggregation to the `order by` + `limit 1` form.
Predicate push-down	predicate_push_down	Tries to push predicates down to the operator that is closer to the data source.

Optimization Rule	Rule Name	Description
Outer join elimination	outer_join_eliminate	Tries to remove the unnecessary left join or right join from the execution plan.

Optimization Rule	Rule Name	Description
Partition pruning	partition_processor	Prunes partitions which are rejected by the predicates and rewrite partitioned table query to the `UnionAll` ↪ ↪ `+` ↪ ↪ `Partition` ↪ ↪ `Datasource` ↪ form.
Aggregation push-down	aggregation_push_down	Tries to push aggregations down to their children.

Optimization Rule	Rule Name	Description
TopN push-down	topn_push_down	Tries to push the TopN operator to the place closer to the data source.
Join reorder	join_reorder	Decides the order of multi-table joins.
Derive TopN or Limit from window functions	derive_topn_from_window	Derives the TopN or Limit operator from window functions.

Disable optimization rules

You can use the blocklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

Note:

All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table Important Optimization Rules.

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("topn_
    ↪ push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

Note:

`admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
    ↪ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

11.3.4.4.2 The blocklist of expression pushdown

The blocklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions that are supported to be pushed down

For more information about the expressions that are supported to be pushed down, see Supported expressions for pushdown to TiKV.

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blocklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```
+------------+-------------+------+------+-------------------+-------+
| Field      | Type        | Null | Key | Default           | Extra |
+------------+-------------+------+------+-------------------+-------+
| name       | char(100)   | NO   |     | NULL              |       |
| store_type | char(100)  | NO   |     | tikv,tiflash,tidb |     |
| reason     | varchar(200) | YES |     | NULL              |       |
+------------+-------------+------+------+-------------------+-------+
3 rows in set (0.00 sec)
```

Here is the description of each field above:

- `name`: The name of the function that is disabled to be pushed down.
- `store_type`: To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.
    - When `store_type` is `tidb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
    - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
    - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- `reason`: To record the reason why this function is added to the blocklist.

Usage

This section describes how to use the blocklist of expression pushdown.

Add to the blocklist

To add one or more expressions (functions or operators) to the blocklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.

2. Execute `admin reload expr_pushdown_blacklist`.

Remove from the blocklist

To remove one or more expressions from the blocklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

> **Note:**
>
> `admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

11.3.4.4.3 Expression blocklist usage example

In the following example, the `<` and `>` operators are added to the blocklist, and then the `>` operator is removed from the blocklist.

To judge whether the blocklist takes effect, observe the results of `EXPLAIN` (See TiDB Query Execution Plan Overview).

1. The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| id                    | estRows | task    | access object | operator
   ↪ info                |
+--
   ↪ ----------------------+----------+-----------+---------------+-----------
   ↪
| TableReader_7         | 0.00    | root    |               | data:
   ↪ Selection_6                |
| └─Selection_6         | 0.00    | cop[tikv] |               | gt(ssb_1.t.
   ↪ a, 2), lt(ssb_1.t.a, 2) |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo |
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

2. Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
    ↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

3. Observe the execution plan again and you will find that both the `<` and `>` operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| id                    | estRows | task     | access object | operator
    ↪ info                |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| Selection_7           | 10000.00 | root    |               | gt(ssb_1.t.a
    ↪ , 2), lt(ssb_1.t.a, 2) |
| └─TableReader_6       | 10000.00 | root    |               | data:
    ↪ TableFullScan_5           |
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

4. Remove one expression (here is `>`) from the blocklist and execute `admin reload expr_pushdown_blacklist`.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

5. Observe the execution plan again and you will find that < is not pushed down while > is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| id                        | estRows | task      | access object | operator
   ↪  info            |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
| Selection_8               | 0.00     | root      |               | lt(ssb_1.t
   ↪ .a, 2)           |
| └─TableReader_7           | 0.00     | root      |               | data:
   ↪ Selection_6           |
|   └─Selection_6           | 0.00     | cop[tikv] |               | gt(ssb_1.
   ↪ t.a, 2)           |
|     └─TableFullScan_5     | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo |
+--
   ↪ ------------------------+----------+-----------+---------------+----------
   ↪
4 rows in set (0.00 sec)
```

11.3.4.5 Optimizer Fix Controls

As the product evolves iteratively, the behavior of the TiDB optimizer changes, which in turn generates more reasonable execution plans. However, in some particular scenarios, the new behavior might lead to unexpected results. For example:

- The effect of some behaviors relies on a specific scenario. Changes that bring improvements to most scenarios might cause regressions to others.

- Sometimes, the relationship between changes in the behavior details and their consequences is very complicated. An improvement in a certain behavior might cause overall regression.

Therefore, TiDB provides the Optimizer Fix Controls feature that allows you to make fine-grained control of TiDB optimizer behaviors by setting values for a group of fixes. This document describes the Optimizer Fix Controls feature and how to use them, and lists all the fixes that TiDB currently supports for Optimizer Fix Controls.

11.3.4.5.1 Introduction to `tidb_opt_fix_control`

Starting from v6.5.3 and v7.1.0, TiDB provides the `tidb_opt_fix_control` system variable to control the behavior of the optimizer in a more fine-grained way.

Each fix is a control item used to adjust the behavior in the TiDB optimizer for one particular purpose. It is denoted by a number that corresponds to a GitHub Issue that contains the technical details of the behavior change. For example, for fix `44262`, you can review what it controls in Issue 44262.

The `tidb_opt_fix_control` system variable accepts multiple fixes as one value, separated by commas (`,`). The format is `"<#issue1>:<value1>,<#issue2>:<value2>,...,<#issueN>:<valueN>"`, where `<#issueN>` is the fix number. For example:

```
SET SESSION tidb_opt_fix_control = '44262:ON,44389:ON';
```

11.3.4.5.2 Optimizer Fix Controls reference

33031 New in v8.0.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to allow plan cache for partitioned tables. If it is set to `ON`, neither Prepared statement plan cache nor Non-prepared statement plan cache will be enabled for partitioned tables.

44262 New in v6.5.3 and v7.2.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to allow the use of Dynamic pruning mode to access a partitioned table when the global statistics of that table are missing.

44389 New in v6.5.3 and v7.2.0

- Default value: `OFF`

- Possible values: `ON`, `OFF`
- For filters such as `c = 10 and (a = 'xx' or (a = 'kk' and b = 1))`, this variable controls whether to try to build more comprehensive scan ranges for `IndexRangeScan`.

44823 New in v7.3.0

- Default value: `200`
- Possible values: `[0, 2147483647]`
- To save memory, Plan Cache does not cache queries with parameters exceeding the specified number of this variable. `0` means no limit.

44830 New in v6.5.7 and v7.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether Plan Cache is allowed to cache execution plans with the `PointGet` operator generated during physical optimization.

44855 New in v6.5.4 and v7.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- In some scenarios, when the `Probe` side of an `IndexJoin` operator contains a `Selection` operator, TiDB severely overestimates the row count of `IndexScan`. This might cause suboptimal query plans to be selected instead of `IndexJoin`.
- To mitigate this issue, TiDB has introduced an improvement. However, due to potential query plan fallback risks, this improvement is disabled by default.
- This variable controls whether to enable the preceding improvement.

45132 New in v7.4.0

- Default value: `1000`
- Possible values: `[0, 2147483647]`
- This variable sets the threshold for the optimizer's heuristic strategy to select access paths. If the estimated rows for an access path (such as `Index_A`) is much smaller than that of other access paths (default `1000` times), the optimizer skips the cost comparison and directly selects `Index_A`.
- `0` means to disable this heuristic strategy.

45798 New in v7.5.0

- Default value: `ON`

- Possible values: `ON`, `OFF`
- This variable controls whether Plan Cache is allowed to cache execution plans that access generated columns.

46177 New in v6.5.6, v7.1.3 and v7.5.0

- Default value: `ON`. Before v8.5.0, the default value is `OFF`.
- Possible values: `ON`, `OFF`
- This variable controls whether the optimizer explores enforced plans during query optimization after finding an unenforced plan.

47400 New in v8.4.0

- Default value: `ON`
- Possible values: `ON`, `OFF`
- Due to challenges in accurately estimating the number of qualified rows for each plan step in a query plan, the optimizer might estimate a smaller value for `estRows`. This variable controls whether to limit the minimum value of `estRows`.
- `ON`: limits the minimum value of `estRows` to 1, which is the new behavior introduced in v8.4.0 and is consistent with other databases, such as Oracle and Db2.
- `OFF`: disables the minimum row estimate limit, which maintains the behavior consistent with versions before v8.4.0. In this case, `estRows` might be zero.

52592 New in v8.4.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- This variable controls whether to disable the `Point Get` and `Batch Point Get` operators for query execution. The default value `OFF` means that `Point Get` and `Batch Point Get` can be used for query execution. If set to `ON`, the optimizer disables `Point Get` and `Batch Point Get`, forcing the selection of Coprocessor for query execution.
- `Point Get` and `Batch Point Get` do not support column projection (that is, they cannot return only a subset of the columns), so in some scenarios, their execution efficiency might be lower than that of the Coprocessor, and setting this variable to `ON` can improve query performance. The following are recommended scenarios for setting this variable to `ON`:
    - Wide tables with many columns, where only a few columns are queried.
    - Tables with large JSON values, where the JSON column is not queried, or only a small portion of the JSON column is queried.

52869 New in v8.1.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- As stated in the **Note** of Explain Statements Using Index Merge, if the optimizer can choose the single index scan method (other than full table scan) for a query plan, the optimizer will not automatically use index merge.
- You can remove this limitation by enabling this fix control. Removing this limitation enables the optimizer to choose index merge automatically in more queries, but might cause the optimizer to ignore the optimal execution plans. Therefore, it is recommended to conduct sufficient tests on actual use cases before removing this limitation to make sure that it will not cause performance regressions.

54337 New in v8.3.0

- Default value: `OFF`
- Possible values: `ON`, `OFF`
- Currently, the TiDB optimizer has limitations in deriving index ranges for complex conjunctive conditions where each conjunct comprises a list of ranges. This can be addressed by applying general range intersection.
- You can remove this limitation by enabling this fix control, allowing the optimizer to handle complex range intersections. However, for conditions with a large number of conjuncts (more than 10), there is a slight risk of increased optimization time.

11.3.5 Index Advisor

In v8.5.0, TiDB introduces the Index Advisor feature, which helps optimize your workload by recommending indexes that improve query performance. Using the new SQL statement, `RECOMMEND INDEX`, you can generate index recommendations for a single query or an entire workload. To avoid the resource-intensive process of physically creating indexes for evaluation, TiDB supports hypothetical indexes, which are logical indexes that are not materialized.

The Index Advisor analyzes queries to identify indexable columns from clauses such as `WHERE`, `GROUP BY`, and `ORDER BY`. Then, it generates index candidates and estimates their performance benefits using hypothetical indexes. TiDB uses a genetic search algorithm to select the optimal set of indexes starting with single-column indexes and iteratively exploring multi-column indexes, leveraging a "What-If" analysis to evaluate potential indexes based on their impact on optimizer plan costs. The advisor recommends indexes when they reduce the overall cost compared to executing queries without them.

In addition to recommending new indexes, the Index Advisor also suggests removing inactive indexes to ensure efficient index management.

11.3.5.1 Recommend indexes using the `RECOMMEND INDEX` statement

TiDB introduces the `RECOMMEND INDEX` SQL statement for index advisor tasks. The `RUN` subcommand analyzes historical workloads and saves recommendations in system tables. With the `FOR` option, you can target a specific SQL statement, even if it was not executed previously. You can also use additional options for advanced control. The syntax is as follows:

```
RECOMMEND INDEX RUN [ FOR <SQL> ] [<Options>]
```

11.3.5.1.1 Recommend indexes for a single query

The following example shows how to generate an index recommendation for a query on table `t`, which contains 5,000 rows. For brevity, the `INSERT` statements are omitted.

```
CREATE TABLE t (a INT, b INT, c INT);
RECOMMEND INDEX RUN for "SELECT a, b FROM t WHERE a = 1 AND b = 1"\G
*************************** 1. row ***************************
            database: test
               table: t
          index_name: idx_a_b
       index_columns: a,b
       est_index_size: 0
              reason: Column [a b] appear in Equal or Range Predicate
                 ↪ clause(s) in query: select `a` , `b` from `test` . `t`
                 ↪ where `a` = ? and `b` = ?
   top_impacted_query: [{"Query":"SELECT `a`,`b` FROM `test`.`t` WHERE `a`
      ↪ = 1 AND `b` = 1","Improvement":0.999994}]
create_index_statement: CREATE INDEX idx_a_b ON t(a,b);
```

The Index Advisor evaluates single-column indexes on `a` and `b` separately and ultimately combines them into a single index for optimal performance.

The following `EXPLAIN` results compare the query execution without indexes and with the recommended two-column hypothetical index. The Index Advisor internally evaluates both cases and selects the option with the minimum cost. The Index Advisor also considers single-column hypothetical indexes on `a` and `b`, but these do not provide better performance than the combined two-column index. For brevity, the execution plans are omitted.

```
EXPLAIN FORMAT='VERBOSE' SELECT a, b FROM t WHERE a=1 AND b=1;

+--

```

11.3.5.1.2 Recommend indexes for a workload

The following example shows how to generate index recommendations for an entire workload. Assume tables `t1` and `t2` each contain 5,000 rows:

```
CREATE TABLE t1 (a INT, b INT, c INT, d INT);
CREATE TABLE t2 (a INT, b INT, c INT, d INT);

-- Run some queries in this workload.
SELECT a, b FROM t1 WHERE a=1 AND b<=5;
SELECT d FROM t1 ORDER BY d LIMIT 10;
SELECT * FROM t1, t2 WHERE t1.a=1 AND t1.d=t2.d;

RECOMMEND INDEX RUN;
```

```
+--
   ↪ --------+-------+-----------+--------------+-----------+--------------------
   ↪
| database | table | index_name | index_columns | est_index_size | reason
   ↪
   ↪ | top_impacted_query
   ↪
   ↪ | create_index_statement      |
+--
   ↪ --------+-------+-----------+--------------+-----------+--------------------
   ↪
| test    | t1    | idx_a_b   | a,b          | 19872     | Column [a b] appear
   ↪ in Equal or Range Predicate clause(s) in query: select `a` , `b` from
   ↪  `test` . `t1` where `a` = ? and `b` <= ?              | [{"Query":"
   ↪ SELECT `a`,`b` FROM `test`.`t1` WHERE `a` = 1 AND `b` \u003c= 5","
   ↪ Improvement":0.998214},{"Query":"SELECT * FROM (`test`.`t1`) JOIN `
   ↪ test`.`t2` WHERE `t1`.`a` = 1 AND `t1`.`d` = `t2`.`d`","Improvement"
   ↪ :0.336837}] | CREATE INDEX idx_a_b ON t1(a,b); |
| test    | t1    | idx_d     | d            | 9936      | Column [d] appear in
   ↪  Equal or Range Predicate clause(s) in query: select `d` from `test`
   ↪ . `t1` order by `d` limit ?                            | [{"Query":"
   ↪ SELECT `d` FROM `test`.`t1` ORDER BY `d` LIMIT 10","Improvement"
   ↪ :0.999433}]
   ↪
   ↪ | CREATE INDEX idx_d ON t1(d); |
| test    | t2    | idx_d     | d            | 9936      | Column [d] appear in
   ↪  Equal or Range Predicate clause(s) in query: select * from ( `test`
   ↪ . `t1` ) join `test` . `t2` where `t1` . `a` = ? and `t1` . `d` = `t2
   ↪ ` . `d` | [{"Query":"SELECT * FROM (`test`.`t1`) JOIN `test`.`t2`
   ↪ WHERE `t1`.`a` = 1 AND `t1`.`d` = `t2`.`d`","Improvement":0.638567}]
   ↪                                                    | CREATE INDEX idx_d
   ↪  ON t2(d); |
+--
   ↪ --------+-------+-----------+--------------+-----------+--------------------
   ↪
```

In this case, the Index Advisor identifies optimal indexes for the entire workload rather than a single query. The workload queries are sourced from the TiDB system table `INFORMATION_SCHEMA.STATEMENTS_SUMMARY`.

This table can contain tens of thousands to hundreds of thousands of queries, which might affect the performance of the Index Advisor. To address this issue, the Index Advisor prioritizes the most frequently executed queries, as these queries have a greater impact on overall workload performance. By default, the Index Advisor selects the top 1,000 queries. You can adjust this value using the `max_num_query` parameter.

The results of the `RECOMMEND INDEX` statements are stored in the `mysql.index_advisor_results` table. You can query this table to view the recommended indexes. The following example shows the contents of this system table after the previous two `RECOMMEND INDEX` statements are executed:

```
SELECT * FROM mysql.index_advisor_results;
+--
   ↪ --+---------------------+---------------------+------------+-----------+------
   ↪
| id | created_at          | updated_at          | schema_name | table_name |
   ↪ index_name | index_columns | index_details
   ↪
   ↪ | top_impacted_queries
   ↪
   ↪ | workload_impact                | extra |
+--
   ↪ --+---------------------+---------------------+------------+-----------+------
   ↪
|  1 | 2024-12-10 11:44:45 | 2024-12-10 11:44:45 | test | t1       | idx_a_b
   ↪   | a,b          | {"IndexSize": 0, "Reason": "Column [a b] appear in

   ↪ test` . `t1` where `a` = ? and `b` <= ?"}           | [{"Improvement"
   ↪ : 0.998214, "Query": "SELECT `a`,`b` FROM `test`.`t1` WHERE `a` = 1
   ↪ AND `b` <= 5"}, {"Improvement": 0.337273, "Query": "SELECT * FROM (`
   ↪ test`.`t1`) JOIN `test`.`t2` WHERE `t1`.`a` = 1 AND `t1`.`d` = `t2`.`
   ↪ d`"}] | {"WorkloadImprovement": 0.395235} | NULL |
|  2 | 2024-12-10 11:44:45 | 2024-12-10 11:44:45 | test | t1       | idx_d
   ↪    | d            | {"IndexSize": 0, "Reason": "Column [d] appear in
   ↪ Equal or Range Predicate clause(s) in query: select `d` from `test` .
   ↪  `t1` order by `d` limit ?"}                         | [{"Improvement
   ↪ ": 0.999715, "Query": "SELECT `d` FROM `test`.`t1` ORDER BY `d` LIMIT
   ↪  10"}]
   ↪
   ↪ | {"WorkloadImprovement": 0.225116} | NULL |
|  3 | 2024-12-10 11:44:45 | 2024-12-10 11:44:45 | test | t2       | idx_d
   ↪    | d            | {"IndexSize": 0, "Reason": "Column [d] appear in
   ↪ Equal or Range Predicate clause(s) in query: select * from ( `test` .
   ↪  `t1` ) join `test` . `t2` where `t1` . `a` = ? and `t1` . `d` = `t2`
   ↪  . `d`"} | [{"Improvement": 0.639393, "Query": "SELECT * FROM (`test
   ↪ `.`t1`) JOIN `test`.`t2` WHERE `t1`.`a` = 1 AND `t1`.`d` = `t2`.`d`"
   ↪ }]                                                | {"
   ↪ WorkloadImprovement": 0.365871} | NULL |
+--
   ↪ --+---------------------+---------------------+------------+-----------+------
   ↪
```

11.3.5.1.3 `RECOMMEND INDEX` options

You can configure and view options for the `RECOMMEND INDEX` statement to fine-tune its behavior for your workloads as follows:

```
RECOMMEND INDEX SET <option> = <value>;
RECOMMEND INDEX SHOW OPTION;
```

The following options are available:

- `timeout`: specifies the maximum time allowed for running the `RECOMMEND INDEX` command.
- `max_num_index`: specifies the maximum number of indexes to include in the result of `RECOMMEND INDEX`.
- `max_index_columns`: specifies the maximum number of columns allowed in multi-column indexes in the result.
- `max_num_query`: specifies the maximum number of queries to select from the statement summary workload.

To check your current option settings, execute the `RECOMMEND INDEX SHOW OPTION` statement:

```
RECOMMEND INDEX SHOW OPTION;
+--
   ↪ -----------------+-------+-----------------------------------------------------
   ↪
| option          | value | description
   ↪ |
+--
   ↪ -----------------+-------+-----------------------------------------------------
   ↪
| max_num_index   | 5     | The maximum number of indexes to recommend.
   ↪ |
| max_index_columns | 3   | The maximum number of columns in an index.
   ↪ |
| max_num_query   | 1000  | The maximum number of queries to recommend
   ↪ indexes. |
| timeout         | 30s   | The timeout of index advisor.
   ↪ |
+--
   ↪ -----------------+-------+-----------------------------------------------------
   ↪
4 rows in set (0.00 sec)
```

To modify an option, use the `RECOMMEND INDEX SET` statement. For example, to change the `timeout` option:

```
RECOMMEND INDEX SET timeout='20s';
Query OK, 1 row affected (0.00 sec)
```

11.3.5.1.4 Limitations

The index recommendation feature has the following limitations:

- Currently, it does not support prepared statements. The `RECOMMEND INDEX RUN` statement cannot recommend indexes for queries executed through the `Prepare` and `Execute` protocol.
- Currently, it does not provide recommendations for deleting indexes.
- Currently, a user interface (UI) for the Index Advisor is not yet available.

11.3.5.2 Remove unused indexes

For v8.0.0 or later versions, you can identify inactive indexes in your workload using `schema_unused_indexes` and `INFORMATION_SCHEMA.CLUSTER_TIDB_INDEX_USAGE`. Removing these indexes can save storage space and reduce overhead. For production environments, it is highly recommended to make the target indexes invisible first and observe the impact for one complete business cycle before permanently removing them.

11.3.5.2.1 Use `sys.schema_unused_indexes`

The `sys.schema_unused_indexes` view identifies indexes that have not been used since the last startup of all TiDB instances. This view, based on system tables containing schema, table, and column information, provides the full specification for each index, including schema, table, and index names. You can query this view to decide which indexes to make invisible or delete.

Warning:

Because the `sys.schema_unused_indexes` view shows unused indexes since the last startup of all TiDB instances, ensure that the TiDB instances have been running long enough. Otherwise, the view might show false candidates if certain workloads have not yet run. Use the following SQL query to identify the uptime of all TiDB instances.

```
SELECT START_TIME,UPTIME FROM INFORMATION_SCHEMA.CLUSTER_INFO
    ↪ WHERE TYPE='tidb';
```

11.3.5.2.2 Use `INFORMATION_SCHEMA.CLUSTER_TIDB_INDEX_USAGE`

The `INFORMATION_SCHEMA.CLUSTER_TIDB_INDEX_USAGE` table provides metrics such as selectivity buckets, last access time, and rows accessed. The following examples show queries to identify unused or inefficient indexes based on this table:

```
-- Find indexes that have not been accessed in the last 30 days.
SELECT table_schema, table_name, index_name, last_access_time
FROM information_schema.cluster_tidb_index_usage
WHERE last_access_time IS NULL
  OR last_access_time < NOW() - INTERVAL 30 DAY;

-- Find indexes that are consistently scanned with over 50% of total
   ↪ records.
SELECT table_schema, table_name, index_name,
      query_total, rows_access_total,
      percentage_access_0 as full_table_scans
FROM information_schema.cluster_tidb_index_usage
WHERE last_access_time IS NOT NULL AND percentage_access_0 + percentage_
   ↪ access_0_1 + percentage_access_1_10 + percentage_access_10_20 +
   ↪ percentage_access_20_50 = 0;
```

> **Note:**
>
> The data in `INFORMATION_SCHEMA.CLUSTER_TIDB_INDEX_USAGE` might be delayed by up to five minutes, and the usage data is reset whenever a TiDB node restarts. Additionally, index usage is only recorded if the table has valid statistics.

11.3.5.3 Hypothetical indexes

Hypothetical indexes (Hypo Indexes) are created using SQL comments, similar to query hints, rather than through the `CREATE INDEX` statement. This approach enables lightweight experimentation with indexes without the overhead of physically materializing them.

For example, the `/*+ HYPO_INDEX(t, idx_ab, a, b)*/` comment instructs the query planner to create a hypothetical index named `idx_ab` on table `t` for columns `a` and `b`. The planner generates the index's metadata but does not physically materialize it. If applicable, the planner considers this hypothetical index during query optimization without incurring the costs associated with index creation.

The `RECOMMEND INDEX` advisor uses hypothetical indexes for "What-If" analysis to evaluate potential benefits of different indexes. You can also use hypothetical indexes directly to experiment with index designs before proceeding to create them.

The following example shows a query using a hypothetical index:

```
CREATE TABLE t(a INT, b INT, c INT);
Query OK, 0 rows affected (0.02 sec)

EXPLAIN FORMAT='verbose' SELECT a, b FROM t WHERE a=1 AND b=1;
+--
   ↪ ----------------------+---------+-----------+----------+---------------+----
   ↪
| id                    | estRows | estCost   | task     | access object |
   ↪ operator info              |
+--
   ↪ ----------------------+---------+-----------+----------+---------------+----
   ↪
| TableReader_7         | 0.01    | 392133.42 | root     |               | data:
   ↪ Selection_6             |
|  ─Selection_6         | 0.01    | 5882000.00 | cop[tikv] |           | eq(
   ↪ test.t.a, 1), eq(test.t.b, 1) |
|    ─TableFullScan_5   | 10000.00 | 4884000.00 | cop[tikv] | table:t | keep
   ↪  order:false, stats:pseudo |
+--
   ↪ ----------------------+---------+-----------+----------+---------------+----
   ↪

EXPLAIN FORMAT='verbose' SELECT /*+ HYPO_INDEX(t, idx_ab, a, b) */ a, b
   ↪ FROM t WHERE a=1 AND b=1;
+--
   ↪ ----------------------+---------+---------+----------+-----------------------
   ↪
| id                    | estRows | estCost | task   | access object
   ↪           | operator info                                |
+--
   ↪ ----------------------+---------+---------+----------+-----------------------
   ↪
| IndexReader_6         | 0.10    | 2.20    | root     |
   ↪                           | index:IndexRangeScan_5                       |
|  ─IndexRangeScan_5    | 0.10    | 20.35   | cop[tikv] | table:t, index:idx_ab
   ↪ (a, b) | range:[1 1,1 1], keep order:false, stats:pseudo |
+--
   ↪ ----------------------+---------+---------+----------+-----------------------
   ↪
```

In this example, the `HYPO_INDEX` comment specifies a hypothetical index. Using this index reduces the estimated cost from `392133.42` to `2.20` by enabling an index range scan (`IndexRangeScan`) instead of a full table scan (`TableFullScan`).

Based on queries in your workload, TiDB can automatically generate index candidates that could benefit your workload. It uses hypothetical indexes to estimate their potential benefits and recommend the most effective ones.

12 Tutorials

12.1 Multiple Availability Zones in One Region Deployment

As a distributed SQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across availability zones (AZs). This document introduces the deployment of multiple AZs in one region.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is implemented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three AZs in case one AZ fails.
- Deploy TiDB in at least three regions in case data safety issue occurs in one region.

The native Raft protocol does not have good support for an even number of replicas. Considering the impact of cross-region network latency, three AZs in the same region might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

12.1.2 Three AZs in one region deployment

TiDB clusters can be deployed in three AZs in the same region. In this solution, data replication across the three AZs is implemented using the Raft protocol within the cluster. These three AZs can provide read and write services at the same time. Data consistency is not affected even if one AZ fails.

12.1.2.1 Simple architecture

TiDB, TiKV, and PD are distributed among three AZs, which is the most common deployment with the highest availability.

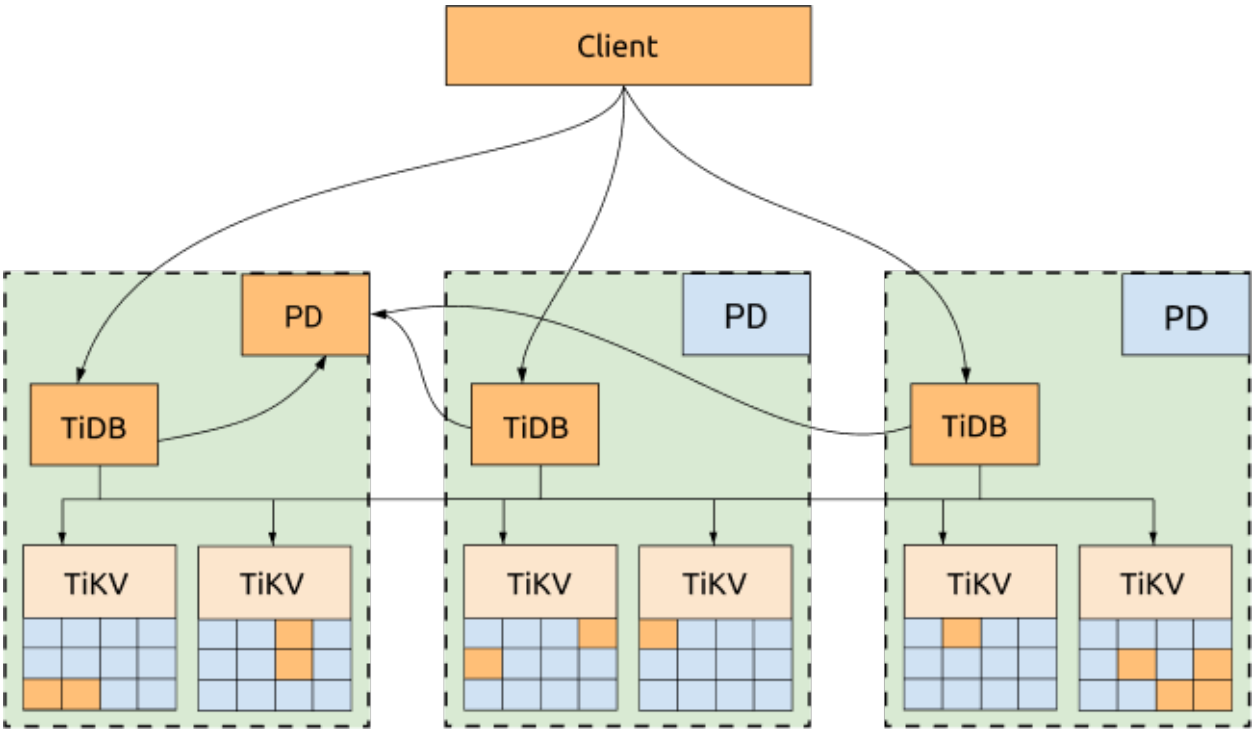

Figure 443: 3-AZ Deployment Architecture

Advantages:

- All replicas are distributed among three AZs, with high availability and disaster recovery capability.
- No data will be lost if one AZ is down (RPO = 0).
- Even if one AZ is down, the other two AZs will automatically start leader election and automatically resume services within a certain period (within 20 seconds in most cases). See the following diagram for more information:

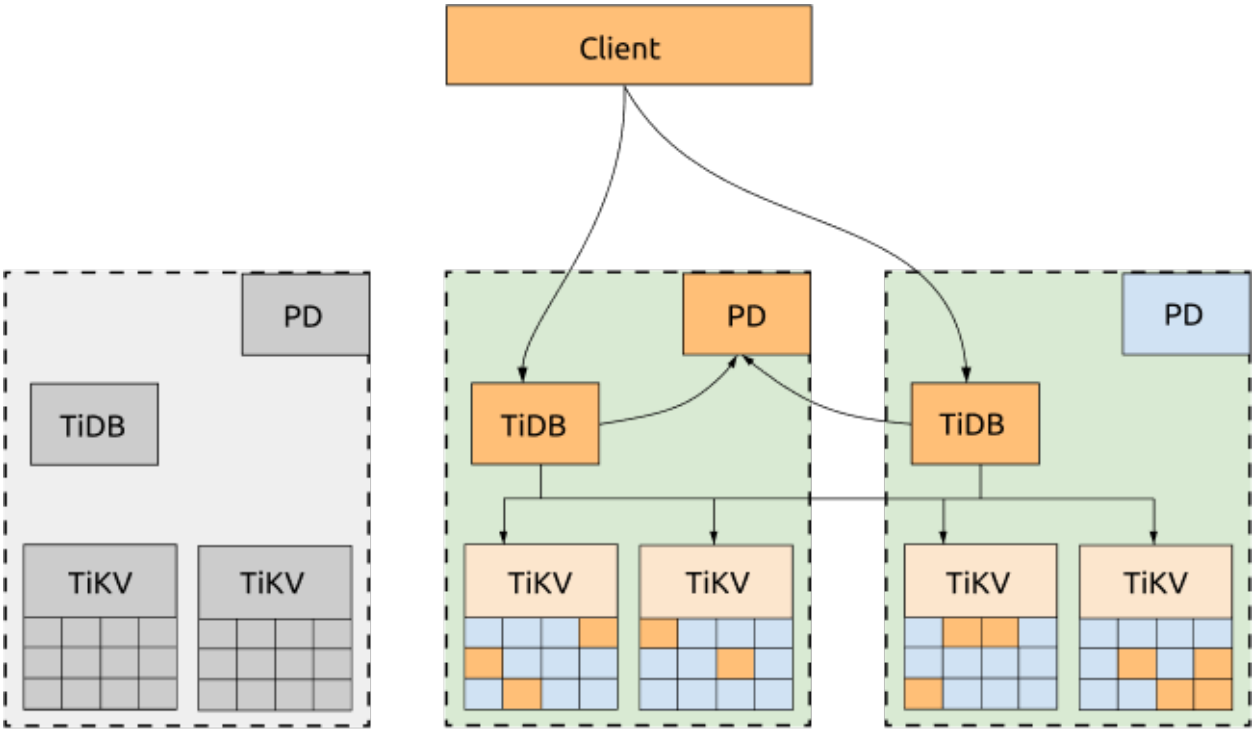

Figure 444: Disaster Recovery for 3-AZ Deployment

Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least two AZs. Because TiDB uses a two-phase commit for writes, the write latency is at least twice the latency of the network between two AZs.
- The read performance will also be affected by the network latency if the leader is not in the same AZ with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same AZ, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

12.1.2.2 Optimized architecture

If not all of the three AZs need to provide services to the applications, you can dispatch all the requests to one AZ and configure the scheduling policy to migrate the TiKV Region leader and PD leader to the same AZ. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across AZs. If this AZ is down, the PD leader and TiKV Region leader will be automatically elected in other surviving AZs, and you just need to switch the requests to the AZs that are still alive.

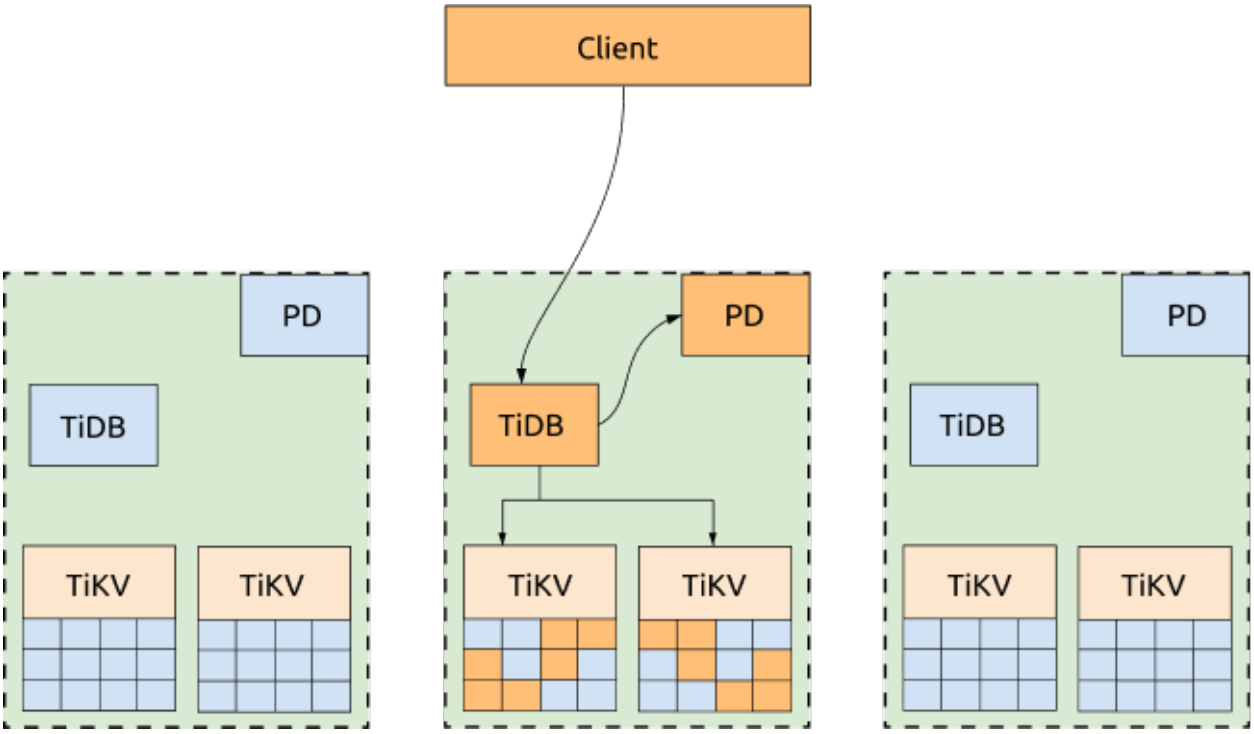

Figure 445: Read Performance Optimized 3-AZ Deployment

Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other AZs to the AZ that provides services to the
   ↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

Note:

Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

Disadvantages:

- Write scenarios are still affected by network latency across AZs. This is because Raft follows the majority protocol and all written data must be replicated to at least two AZs.
- The TiDB server that provides services is only in one AZ.
- All application traffic is processed by one AZ and the performance is limited by the network bandwidth pressure of that AZ.
- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the AZ that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

12.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

12.1.2.3.1 Topology example

The following example assumes that three AZs (AZ1, AZ2, and AZ3) are located in one region; each AZ has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three AZs in one region is as follows:

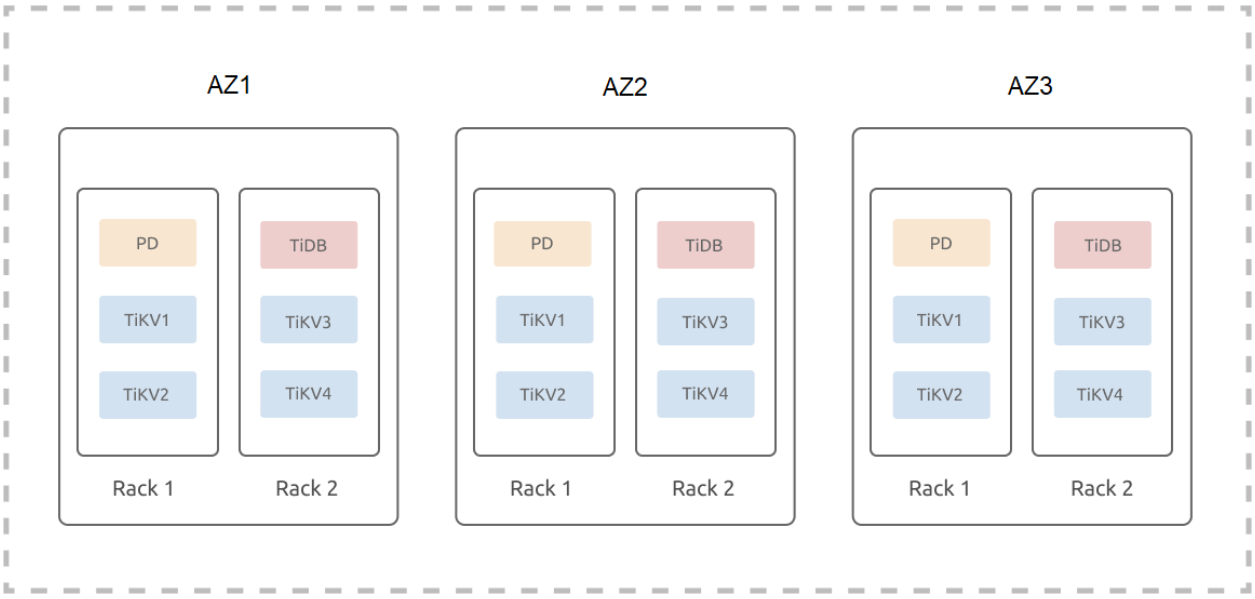

Figure 446: 3-AZ in One Region

12.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the preceding limitation, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

12.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to edit the cluster initialization configuration file according to the planned topology:

```
server_configs:
  pd:
    replication.location-labels: ["zone","az","rack","host"]

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r1", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { zone: "z1", az: "az1", rack: "r2", host: "32" }
  - host: 10.63.10.33
    config:
```

```
    server.labels: { zone: "z1", az: "az1", rack: "r2", host: "33" }

- host: 10.63.10.34
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "34" }
- host: 10.63.10.35
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r1", host: "35" }
- host: 10.63.10.36
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "36" }
- host: 10.63.10.37
  config:
    server.labels: { zone: "z2", az: "az2", rack: "r2", host: "37" }

- host: 10.63.10.38
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "38" }
- host: 10.63.10.39
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r1", host: "39" }
- host: 10.63.10.40
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "40" }
- host: 10.63.10.41
  config:
    server.labels: { zone: "z3", az: "az3", rack: "r2", host: "41" }
```

In the preceding example, `zone` is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the AZs might be scaled out in the future, the three-layer label structure (`az`, `rack`, and `host`) is not directly adopted. Assuming that `AZ2`, `AZ3`, and `AZ4` are to be scaled out, you only need to scale out the AZs in the corresponding availability zone and scale out the racks in the corresponding AZ.

If this three-layer label structure is directly adopted, after scaling out an AZ, you might need to apply new labels and the data in TiKV needs to be rebalanced.

12.1.2.4 High availability and disaster recovery analysis

The multiple AZs in one region deployment can guarantee that if one AZ fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when a failure occurs, these policies prioritize availability over performance.

12.2 Three Availability Zones in Two Regions Deployment

This document introduces the architecture and configuration of the three availability zones (AZs) in two regions deployment.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.2.1 Overview

The architecture of three AZs in two regions is a highly available and disaster tolerant deployment solution that provides a production data AZ, a disaster recovery AZ in the same region, and a disaster recovery AZ in another region. In this mode, the three AZs in two regions are interconnected. If one AZ fails or suffers from a disaster, other AZs can still operate well and take over the key applications or all applications. Compared with the multi-AZ in one region deployment, this solution has the advantage of cross-region high availability and can survive region-level natural disasters.

The distributed database TiDB natively supports the three-AZ-in-two-region architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across AZs in the same region is relatively low, the application traffic can be dispatched to two AZs in the same region, and the traffic load can be shared by these two AZs by controlling the distribution of TiKV Region leaders and PD leaders.

12.2.2 Deployment architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three AZs in two regions for the distributed database of TiDB.

In this example, two AZs (AZ1 and AZ2) are located in Seattle and another AZ (AZ3) is located in San Francisco. The network latency between AZ1 and AZ2 is lower than 3 milliseconds. The network latency between AZ3 and AZ1/AZ2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three AZs in two regions: AZ1 in Seattle, AZ2 in Seattle, and AZ3 in San Francisco.
- The cluster has five replicas, two in AZ1, two in AZ2, and one in AZ3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

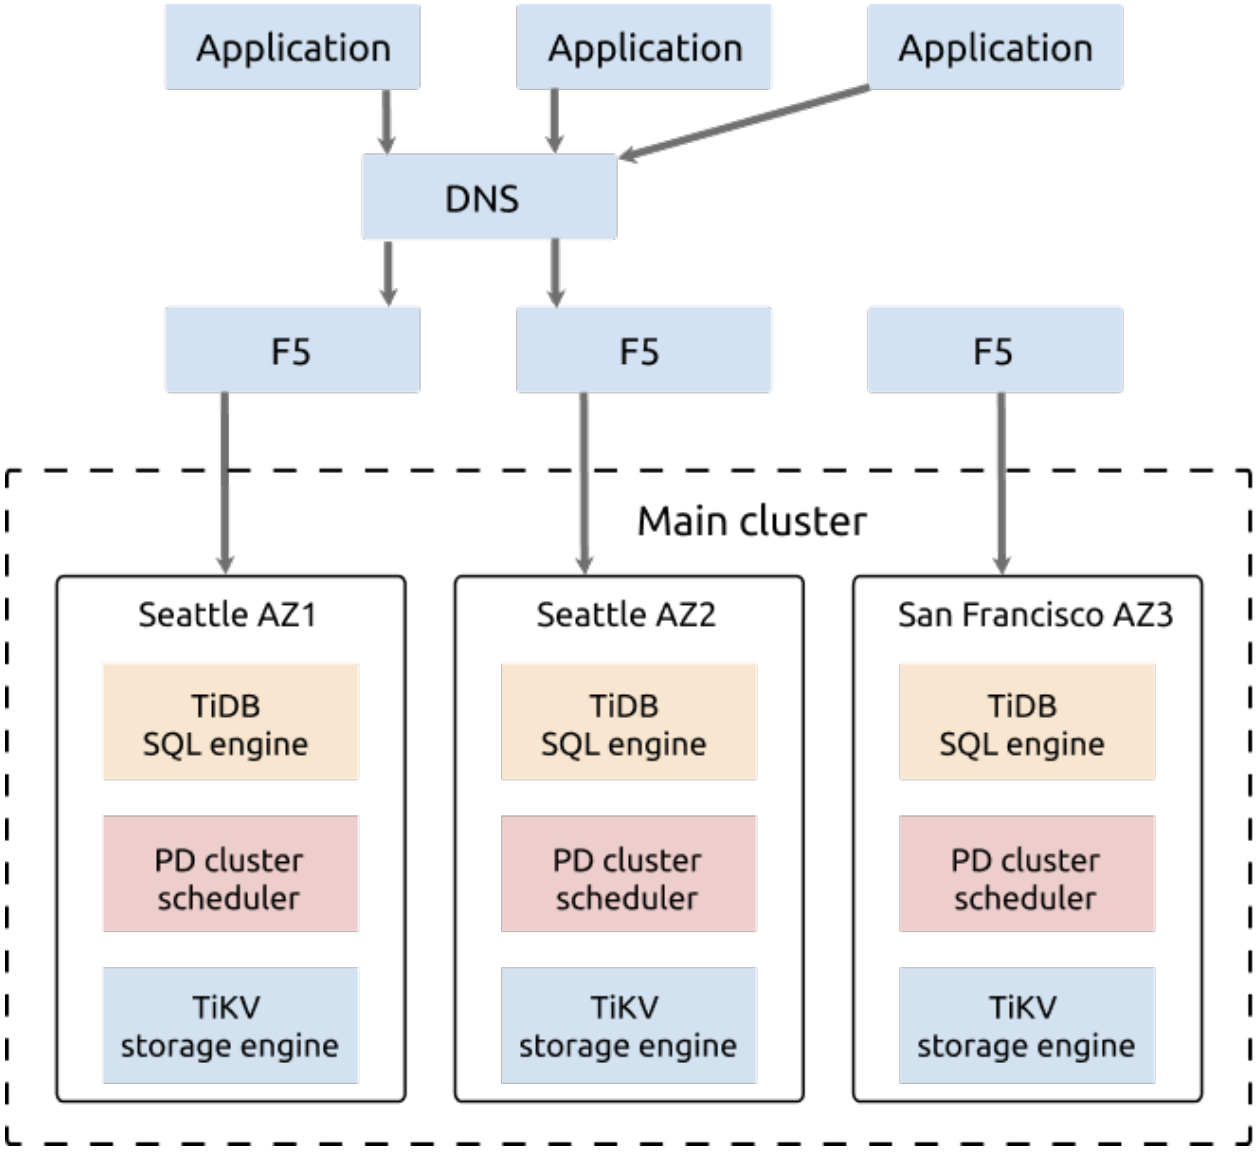

Figure 447: 3-AZ-in-2-region architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two AZs (AZ1 and AZ2) that are in the same region (Seattle). Compared with the three-AZ solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**
    - Region leaders are in AZs of the same region with low latency, so the write is faster.
    - The two AZs can provide services at the same time, so the resource usage rate is higher.

- If one AZ fails, services are still available and data safety is ensured.

- **Disadvantages**

  - Because the data consistency is achieved by the Raft algorithm, when two AZs in the same region fail at the same time, only one surviving replica remains in the disaster recovery AZ in another region (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
  - Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
  - Five replicas are configured in three AZs in two regions, data redundancy increases, which brings a higher storage cost.

12.2.2.1 Deployment details

The configuration of the three AZs in two regions (Seattle and San Francisco) deployment plan is illustrated as follows:

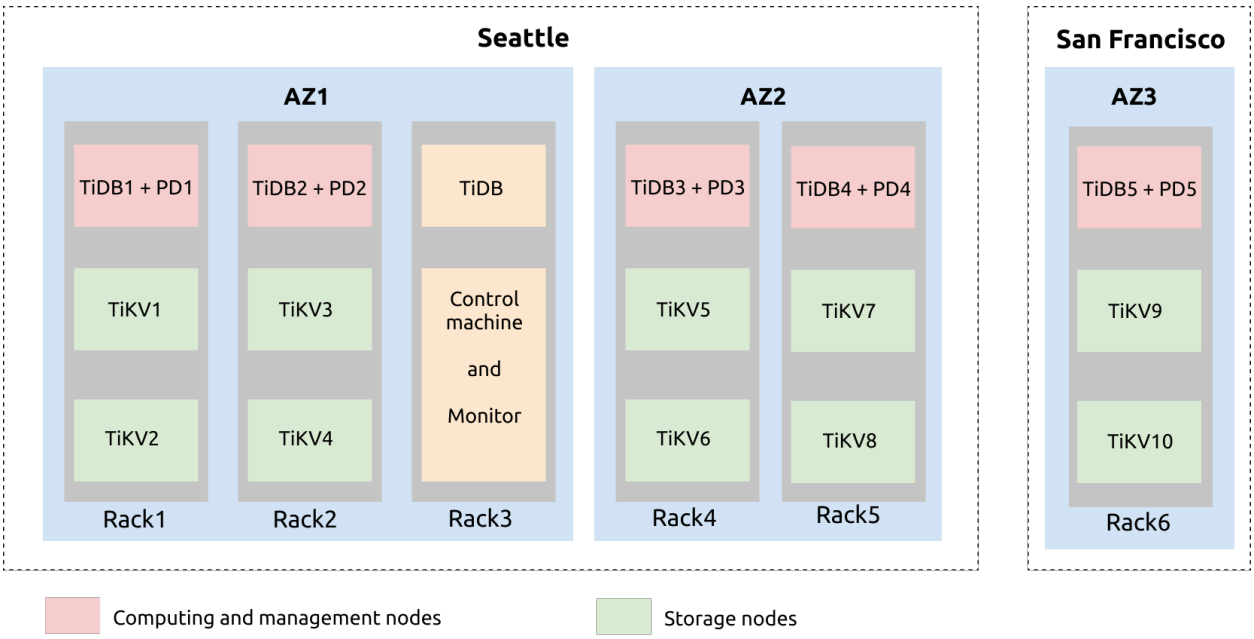

Figure 448: 3-AZ-2-region

From the preceding illustration, you can see that Seattle has two AZs: AZ1 and AZ2. AZ1 has three sets of racks: rac1, rac2, and rac3. AZ2 has two racks: rac4 and rac5. The AZ3 in San Francisco has the rac6 rack.

In the rac1 of AZ1, one server is deployed with TiDB and PD services, and the other two servers are deployed with TiKV services. Each TiKV server is deployed with two TiKV instances (tikv-server). This is similar to rac2, rac4, rac5, and rac6.

The TiDB server, the control machine, and the monitoring server are on rac3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.

12.2.3 Configuration

12.2.3.1 Example

See the following `tiup topology.yaml` yaml file for example:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]

pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
  - host: 10.63.10.13
    name: "pd-13"
  - host: 10.63.10.14
    name: "pd-14"

tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
  - host: 10.63.10.13
```

```
  - host: 10.63.10.14

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
    config:
      server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
          ↪ }
      raftstore.raft-min-election-timeout-ticks: 50
      raftstore.raft-max-election-timeout-ticks: 60

monitoring_servers:
  - host: 10.63.10.60

grafana_servers:
  - host: 10.63.10.60

alertmanager_servers:
  - host: 10.63.10.60
```

12.2.3.2 Labels design

In the deployment of three AZs in two regions, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`az`, `replication zone`, `rack`, and `host`) based on the physical structure of the deployment.

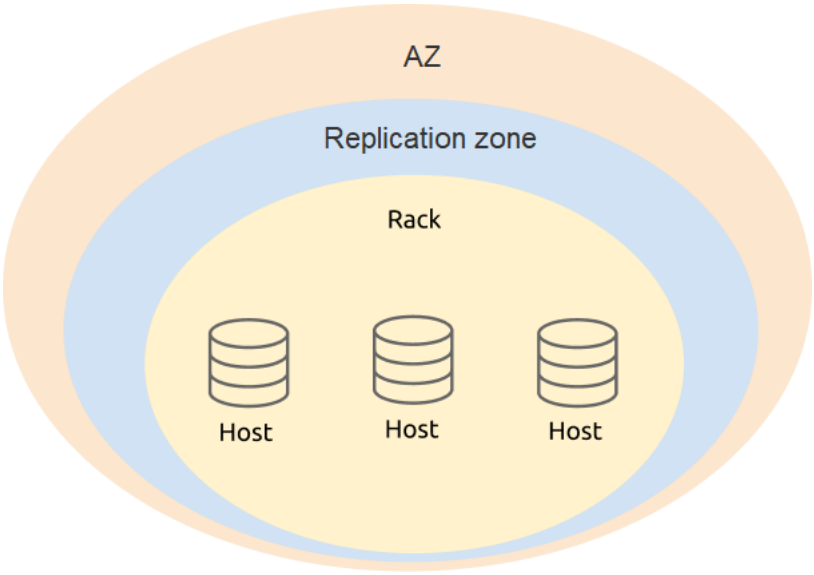

Figure 449: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
  pd:
    replication.location-labels: ["az","replication zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { az: "1", replication zone: "1", rack: "1", host: "30"
          ↪ }
  - host: 10.63.10.31
    config:
      server.labels: { az: "1", replication zone: "2", rack: "2", host: "31"
          ↪ }
  - host: 10.63.10.32
    config:
      server.labels: { az: "2", replication zone: "3", rack: "3", host: "32"
          ↪ }
  - host: 10.63.10.33
    config:
      server.labels: { az: "2", replication zone: "4", rack: "4", host: "33"
          ↪ }
  - host: 10.63.10.34
```

```
config:
  server.labels: { az: "3", replication zone: "5", rack: "5", host: "34"
    ↪ }
```

12.2.3.3 Optimize parameter configuration

In the deployment of three AZs in two regions, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another region (San Francisco). Modify the following TiKV parameters for AZ3 in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 50
raftstore.raft-max-election-timeout-ticks: 60
```

> **Note:**
>
> Using `raftstore.raft-min-election-timeout-ticks` and `raftstore.` ↪ `raft-max-election-timeout-ticks` to configure larger election timeout ticks for a TiKV node can significantly decrease the likelihood of Regions on that node becoming Leaders. However, in a disaster scenario where some TiKV nodes are offline and the remaining active TiKV nodes lag behind in Raft logs, only Regions on this TiKV node with large election timeout ticks can become Leaders. Because Regions on this TiKV node must wait for at least the duration set by `raftstore.raft-min-election-timeout-ticks` before initiating an election, it is recommended to avoid setting these values excessively large to prevent potential impact on the cluster availability in such scenarios.

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:v{CLUSTER_` ↪ `VERSION} pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to AZ3. Scheduling the Raft leader to another region (AZ3) causes unnecessary network overhead between AZ1/AZ2 in Seattle and AZ3 in San Francisco. The network bandwidth and latency also affect the performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

> **Note:**
>
> Starting from TiDB v5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

- Configure the priority of PD. To avoid the situation where the PD leader is in another region (AZ3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another region (San Francisco). The larger the number, the higher the priority. In all available PD nodes, the node with the highest priority number becomes the leader.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

12.3 Two Availability Zones in One Region Deployment

This document introduces the deployment mode of two availability zones (AZs) in one region, including the architecture, configuration, how to enable this deployment mode, and how to use replicas in this mode.

The term "region" in this document refers to a geographic area, while the capitalized "Region" refers to a basic unit of data storage in TiKV. "AZ" refers to an isolated location within a region, and each region has multiple AZs. The solution described in this document also applies to the scenario where multiple data centers are located in a single city.

12.3.1 Introduction

TiDB usually adopts the multi-AZ deployment solution to ensure high availability and disaster recovery capability. The multi-AZ deployment solution includes multiple deployment modes, such as multiple AZs in one region and multiple AZs in two regions. This document introduces the deployment mode of two AZs in one region. Deployed in this mode, TiDB can

also meet the requirements of high availability and disaster recovery, with a lower cost. This deployment solution adopts Data Replication Auto Synchronous mode, or the DR Auto-Sync mode.

Under the mode of two AZs in one region, the two AZs are less than 50 kilometers apart. They are usually located in the same region or in two adjacent regions. The network latency between the two AZs is lower than 1.5 milliseconds and the bandwidth is higher than 10 Gbps.

12.3.2 Deployment architecture

This section takes the example of a region where two availability zones AZ1 and AZ2 are located respectively in the east and west. AZ1 is the primary AZ and AZ2 is the disaster recovery (DR) AZ.

The architecture of the cluster deployment is as follows:

- The cluster has six replicas: three Voter replicas in AZ1, and two Voter replicas along with one Learner replica in AZ2. For the TiKV component, each rack has a proper label.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

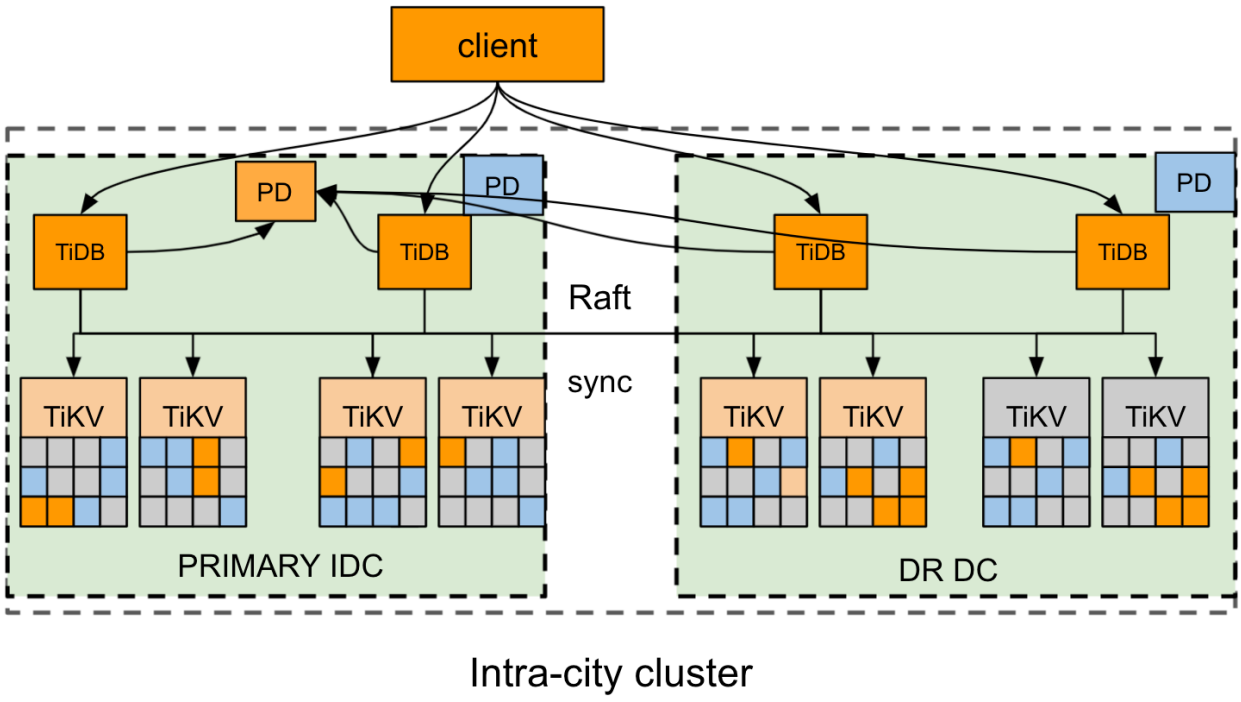

Figure 450: 2-AZ-in-1-region architecture

This deployment solution defines three statuses to control and identify the replication status of the cluster, which restricts the replication mode of TiKV. The replication mode of the cluster can automatically and adaptively switch between the three statuses. For details, see the Status switch section.

- **sync**: Synchronous replication mode. In this mode, at least one replica in the disaster recovery AZ synchronizes with the primary AZ. The Raft algorithm ensures that each log is replicated to the DR based on the label.
- **async**: Asynchronous replication mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. The Raft algorithm follows the majority protocol to replicate logs.
- **sync-recover**: Synchronous recovery mode. In this mode, the disaster recovery AZ is not fully synchronized with the primary AZ. Raft gradually switches to the label replication mode and then reports the label information to PD.

12.3.3 Configuration

12.3.3.1 Example

The following `tiup topology.yaml` example file is a typical topology configuration for the two availability zones in one region deployment mode:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"
server_configs:
  pd:
    replication.location-labels: ["az","rack","host"]
pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
tikv_servers:
  - host: 10.63.10.30
```

```
    config:
      server.labels: { az: "east", rack: "east-1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { az: "east", rack: "east-2", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { az: "east", rack: "east-3", host: "32" }
  - host: 10.63.10.33
    config:
      server.labels: { az: "west", rack: "west-1", host: "33" }
  - host: 10.63.10.34
    config:
      server.labels: { az: "west", rack: "west-2", host: "34" }
  - host: 10.63.10.35
    config:
      server.labels: { az: "west", rack: "west-3", host: "35" }
monitoring_servers:
  - host: 10.63.10.60
grafana_servers:
  - host: 10.63.10.60
alertmanager_servers:
  - host: 10.63.10.60
```

12.3.3.2 Placement Rules

To deploy a cluster based on the planned topology, you need to use Placement Rules to determine the locations of the cluster replicas. Taking the deployment of four replicas (two Voter replicas are at the primary AZ, one Voter replica, and one Learner replica are at the disaster recovery AZ) as an example, you can use the Placement Rules to configure the replicas as follows:

```
cat rule.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "az-east",
        "start_key": "",
        "end_key": "",
        "role": "voter",
```

```
    "count": 3,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "east"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-1",
    "start_key": "",
    "end_key": "",
    "role": "follower",
    "count": 2,
    "label_constraints": [
      {
        "key": "az",
        "op": "in",
        "values": [
          "west"
        ]
      }
    ],
    "location_labels": [
      "az",
      "rack",
      "host"
    ]
  },
  {
    "group_id": "pd",
    "id": "az-west-2",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
```

```
      "label_constraints": [
        {
          "key": "az",
          "op": "in",
          "values": [
            "west"
          ]
        }
      ],
      "location_labels": [
        "az",
        "rack",
        "host"
      ]
    }
  ]
 }
]
```

To use the configurations in `rule.json`, run the following command to back up the existing configuration to the `default.json` file and overwrite the existing configuration with `rule.json`:

```
pd-ctl config placement-rules rule-bundle load --out="default.json"
pd-ctl config placement-rules rule-bundle save --in="rule.json"
```

If you need to roll back to the previous configuration, you can restore the backup file `default.json` or write the following JSON file manually and overwrite the current configuration with this JSON file:

```
cat default.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "default",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 5
      }
    ]
```

```
  }
]
```

12.3.3.3 Enable the DR Auto-Sync mode

The replication mode is controlled by PD. You can configure the replication mode in the PD configuration file using one of the following methods:

- Method 1: Configure the PD configuration file, and then deploy a cluster.

```
[replication-mode]
replication-mode = "dr-auto-sync"
[replication-mode.dr-auto-sync]
label-key = "az"
primary = "east"
dr = "west"
primary-replicas = 3
dr-replicas = 2
wait-store-timeout = "1m"
wait-recover-timeout = "0s"
pause-region-split = false
```

- Method 2: If you have deployed a cluster, use pd-ctl commands to modify the configurations of PD.

```
config set replication-mode dr-auto-sync
config set replication-mode dr-auto-sync label-key az
config set replication-mode dr-auto-sync primary east
config set replication-mode dr-auto-sync dr west
config set replication-mode dr-auto-sync primary-replicas 3
config set replication-mode dr-auto-sync dr-replicas 2
```

Descriptions of configuration items:

- `replication-mode` is the replication mode to be enabled. In the preceding example, it is set to `dr-auto-sync`. By default, the majority protocol is used.
- `label-key` is used to distinguish different AZs and needs to match Placement Rules. In this example, the primary AZ is "east" and the disaster recovery AZ is "west".
- `primary-replicas` is the number of Voter replicas in the primary AZ.
- `dr-replicas` is the number of Voter replicas in the disaster recovery (DR) AZ.
- `wait-store-timeout` is the waiting time for switching to asynchronous replication mode when network isolation or failure occurs. If the time of network failure exceeds the waiting time, asynchronous replication mode is enabled. The default waiting time is 60 seconds.

- `wait-recover-timeout` is the waiting time for switching back to the `sync-recover` status after the network recovers. The default value is 0 seconds.
- `pause-region-split` controls whether to pause Region split operations in the `async_wait` and `async` statuses. Pausing Region split can prevent temporary partial data loss in the DR AZ when synchronizing data in the `sync-recover` status. The default value is `false`.

To check the current replication status of the cluster, use the following API:

```
curl http://pd_ip:pd_port/pd/api/v1/replication_mode/status
```

```
{
  "mode": "dr-auto-sync",
  "dr-auto-sync": {
    "label-key": "az",
    "state": "sync"
  }
}
```

12.3.3.3.1 Status switch

The replication mode of a cluster can automatically and adaptively switch between three statuses:

- When the cluster is normal, the synchronous replication mode is enabled to maximize the data integrity of the disaster recovery AZ.
- When the network connection between the two AZs fails or the disaster recovery AZ breaks down, after a pre-set protective interval, the cluster enables the asynchronous replication mode to ensure the availability of the application.
- When the network reconnects or the disaster recovery AZ recovers, the TiKV node joins the cluster again and gradually replicates the data. Finally, the cluster switches to the synchronous replication mode.

The details for the status switch are as follows:

1. **Initialization**: At the initialization stage, the cluster is in the synchronous replication mode. PD sends the status information to TiKV, and all TiKV nodes strictly follow the synchronous replication mode to work.
2. **Switch from sync to async**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node fails or is disconnected. If the number of failed nodes exceeds the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can no longer serve the data replication and it is necessary to switch the status. When the failure or

disconnect time exceeds the time set by `wait-store-timeout`, PD switches the status of the cluster to the async mode. Then PD sends the status of async to all TiKV nodes, and the replication mode for TiKV switches from two-availability-zone replication to the native Raft majority.

3. **Switch from async to sync**: PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node is reconnected. If the number of failed nodes is less than the number of replicas of the primary AZ (`primary-replicas`) and the disaster recovery AZ (`dr-replicas`), the synchronous replication mode can be enabled again. PD first switches the status of the cluster to sync-recover and sends the status information to all TiKV nodes. All Regions of TiKV gradually switch to the two-availability-zone synchronous replication mode and then report the heartbeat information to PD. PD records the status of TiKV Regions and calculates the recovery progress. When all TiKV Regions finish the switching, PD switches the replication mode to sync.

12.3.3.4 Disaster recovery

This section introduces the disaster recovery solution of the two AZs in one region deployment.

When a disaster occurs to a cluster in the synchronous replication mode, you can perform data recovery with `RPO = 0`:

- If the primary AZ fails and most of the Voter replicas are lost, but complete data exists in the disaster recovery AZ, the lost data can be recovered from the disaster recovery AZ. At this time, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.
- If the disaster recovery AZ fails and a few Voter replicas are lost, the cluster automatically switches to the asynchronous replication mode.

When a disaster occurs to a cluster that is not in the synchronous replication mode and you cannot perform data recovery with `RPO = 0`:

- If most of the Voter replicas are lost, manual intervention is required with professional tools. You can get support from PingCAP or the community for a recovery solution.

12.4 Read Historical Data

12.4.1 Use Stale Read (Recommended)

12.4.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism,

you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

12.4.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `Readindex` from different data centers for verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see Local Read under Three Data Centers Deployment.

12.4.1.1.2 Usages

TiDB provides the methods of performing Stale Read at the statement level, the session level and the global level as follows:

- Statement level
  - Specifying an exact point in time (**recommended**): If you need TiDB to read data that is globally consistent from a specific point in time without violating the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see `AS OF TIMESTAMP` clause.
  - Specifying a time range: If you need TiDB to read the data as new as possible within a time range without violating the isolation level, you can specify the time range in the query statement. Within the specified time range, TiDB selects a suitable timestamp to read the corresponding data. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed

replica and the read operations are not blocked. For detailed usage, refer to the introduction of the AS OF TIMESTAMP Clause and the TIDB_BOUNDED_STALENESS function.

- Session level
    - Specifying a time range: In a session, if you need TiDB to read the data as new as possible within a time range in subsequent queries without violating the isolation level, you can specify the time range by setting the `tidb_read_staleness` system variable. For detailed usage, refer to `tidb_read_staleness`.

Besides, TiDB provides a way to specify an exact point in time at the session or global level by setting the `tidb_external_ts` and `tidb_enable_external_ts_read` system variables. For detailed usage, refer to Perform Stale Read Using `tidb_external_ts`.

Reduce Stale Read latency

The Stale Read feature periodically advances the Resolved TS timestamp of the TiDB cluster, which ensures that TiDB reads data that meets transaction consistency. If the timestamp used by Stale Read (for example, `AS OF TIMESTAMP '2016-10-08 16:45:26'`) is greater than the Resolved TS, Stale Read will trigger TiDB to advance the Resolved TS first and wait for the advance to complete before reading the data, leading to an increase in latency.

To reduce the Stale Read latency, you can modify the following TiKV configuration item to make TiDB advance the Resolved TS timestamp more frequently:

```
[resolved-ts]
advance-ts-interval = "20s" # The default value is "20s". You can set it to
    ↪ a smaller value such as "1s" to advance the Resolved TS timestamp
    ↪ more frequently.
```

Note:

Decreasing the preceding TiKV configuration item will lead to an increase in TiKV CPU usage and traffic between nodes.

For more information about the internals of Resolved TS and diagnostic techniques, see Understanding Stale Read and safe-ts in TiKV.

12.4.1.1.3 Restrictions

When a Stale Read query for a table is pushed down to TiFlash, the query will return an error if this table has newer DDL operations executed after the read timestamp specified

by the query. This is because TiFlash only supports reading data from the tables with the latest schemas.

Take the following table as an example:

```
create table t1(id int);
alter table t1 set tiflash replica 1;
```

Execute the following DDL operation after one minute:

```
alter table t1 add column c1 int not null;
```

Then, use Stale Read to query the data from one minute ago:

```
set @@session.tidb_enforce_mpp=1;
select * from t1 as of timestamp NOW() - INTERVAL 1 minute;
```

TiFlash will report an error as follows:

```
ERROR 1105 (HY000): other error for mpp stream: From MPP<query:<query_ts
    ↪ :1673950975508472943, local_query_id:18, server_id:111947, start_ts
    ↪ :438816196526080000>,task_id:1>: Code: 0, e.displayText() = DB::
    ↪ TiFlashException: Table 323 schema version 104 newer than query
    ↪ schema version 100, e.what() = DB::TiFlashException,
```

To avoid this error, you can change the read timestamp specified by Stale Read to the time after the DDL operation.

12.4.1.2 Read Historical Data Using the `AS OF TIMESTAMP` Clause

This document describes how to perform the Stale Read feature using the `AS OF TIMESTAMP` clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

TiDB supports reading historical data through a standard SQL interface, which is the `AS OF TIMESTAMP` SQL clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

> **Note:**
>
> When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.1.2.1 Syntax

You can use the `AS OF TIMESTAMP` clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the `AS OF TIMESTAMP` clause. The format of datetime is like "2016-10-08 16:45:26.999", with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as "2016-10-08 16:45:26". You can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW()- INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()- INTERVAL 20 SECOND, NOW())`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

> **Note:**
>
> In addition to specifying a timestamp, the most common use of the `AS OF TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.

You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.

To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.2.2 Usage examples

This section describes different ways to use the `AS OF TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to use `AS OF TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+---------------------+
| now()               |
+---------------------+
| 2021-05-26 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Read historical data using the `SELECT` statement

You can use the `SELECT ... FROM ... AS OF TIMESTAMP` statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Note:

When reading multiple tables using one `SELECT` statement, you need to make sure that the format of TIMESTAMP EXPRESSIONs is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, c as of timestamp NOW()- INTERVAL 2 SECOND;`. In addition, you must specify the `AS OF` information for the relevant table in the `SELECT` statement; otherwise, the `SELECT` statement reads the latest data by default.

Read historical data using the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
```

```
|   3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `START TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `SET TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

12.4.1.3 Read Historical Data Using the `tidb_read_staleness` System Variable

To support reading the historical data, in v5.4, TiDB introduces a new system variable `tidb_read_staleness`. This document describes how to read historical data through this system variable, including detailed operating procedures.

12.4.1.3.1 Feature description

The `tidb_read_staleness` system variable is used to set the time range of historical data that TiDB can read in the current session. The data type of this variable is int type, and the scope of it is `SESSION`. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

After enabling `tidb_read_staleness`, you still can perform the following operations:

- Insert, modify, delete data or perform DML operations in the current session. These statements are not affected by `tidb_read_staleness`.
- Start an interactive transaction in the current session. Queries within this transaction still read the latest data.

After reading the historical data, you can read the latest data in the following two ways:

- Start a new session.

- Set the value of the `tidb_read_staleness` variable to `""` using the `SET` statement.

> **Note:**
>
> To reduce the latency and improve the timeliness of the Stale Read data, you can modify the TiKV `advance-ts-interval` configuration item. See Reduce Stale Read latency for details.

12.4.1.3.2 Usage examples

This section describes how to use `tidb_read_staleness` with examples.

1. Create a table, and insert a few rows of data into the table:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. Check out the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

4. Confirm that the data has been updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

5. Set the `tidb_read_staleness` system variable.

   The scope of this variable is `SESSION`. After setting its value, TiDB reads the latest version data before the time set by the value.

   The following setting indicates that TiDB selects a timestamp as new as possible within the time range from 5 seconds ago to now and uses it as the timestamp for reading historical data:

```
set @@tidb_read_staleness="-5";
```

```
Query OK, 0 rows affected (0.00 sec)
```

Note:

- Use `@@` instead of `@` before `tidb_read_staleness`. `@@` means system variables, and `@` means user variables.
- You need to set the historical time range (the value of `tidb_read_staleness`) according to the total time that you spent in step 3 and step 4. Otherwise, the latest data will be displayed in the query results, not the historical data. Therefore, you need to adjust this time range according to the time you spent on operations. For example, in this example, since the set time range is 5 seconds, you need to complete step 3 and step 4 within 5 seconds.

The data read here is the data before the update, that is, the historical data:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
```

```
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. After un-setting this variable as follows, TiDB can read the latest data:

```
set @@tidb_read_staleness="";
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

12.4.1.4 Read Historical Data Using the `tidb_external_ts` Variable

To support reading the historical data, TiDB v6.4.0 introduces a system variable `tidb_external_ts`. This document describes how to read historical data through this system variable, including detailed usage examples.

12.4.1.4.1 Scenarios

Read historical data from a specified point in time is very useful for data replication tools such as TiCDC. After the data replication tool completes the data replication before a certain point in time, you can set the `tidb_external_ts` system variable of the downstream TiDB to read the data before that point in time. This prevents the data inconsistency caused by data replication.

12.4.1.4.2 Feature description

The system variable `tidb_external_ts` specifies the timestamp of the historical data to be read when `tidb_enable_external_ts_read` is enabled.

The system variable `tidb_enable_external_ts_read` controls whether to read historical data in the current session or globally. The default value is `OFF`, which means the feature of reading historical data is disabled, and the `tidb_external_ts` value is ignored. When `tidb_enable_external_ts_read` is set to `ON` globally, all queries read historical data before

the time specified by `tidb_external_ts`. If `tidb_enable_external_ts_read` is set to `ON` only for a certain session, only queries in that session read historical data.

When the `tidb_enable_external_ts_read` is enabled, TiDB becomes read-only. All write queries will fail with an error like `ERROR 1836 (HY000): Running in read-only mode`.

12.4.1.4.3 Usage examples

This section describes how to use the `tidb_external_ts` variable to read historical data with examples.

1. Create a table and insert some rows into the table:

```
CREATE TABLE t (c INT);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
INSERT INTO t VALUES (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. Set `tidb_external_ts` to `@@tidb_current_ts`:

```
START TRANSACTION;
SET GLOBAL tidb_external_ts=@@tidb_current_ts;
COMMIT;
```

4. Insert a new row and confirm that it is inserted:

```
INSERT INTO t VALUES (4);
```

```
Query OK, 1 row affected (0.001 sec)
```

```
SELECT * FROM t;
```

```
+------+
| id   |
+------+
|    1 |
|    2 |
|    3 |
|    4 |
+------+
4 rows in set (0.00 sec)
```

5. Set `tidb_enable_external_ts_read` to `ON` and then view data in the table:

```
SET tidb_enable_external_ts_read=ON;
SELECT * FROM t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Because `tidb_external_ts` is set to the timestamp before the new row is inserted, the newly inserted row is not returned after the `tidb_enable_external_ts_read` is enabled.

12.4.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

> **Note:**
>
> You can also use the Stale Read feature to read historical data, which is more recommended.

12.4.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

> **Note:**
>
> - Even when data is updated or removed, its history versions can be read using the SQL interface.
> - When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

12.4.2.2 How TiDB reads data from history versions

The `tidb_snapshot` system variable is introduced to support reading history data. About the `tidb_snapshot` variable:

- The variable is valid in the `SESSION` scope.
- Its value can be modified using the `SET` statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is "2016-10-08 16:45:26.999". Generally, the datetime can be set using second precision, for example "2016-10-08 16:45:26".
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the `SELECT` operations will read data from this Snapshot.

> **Note:**
>
> Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the `tidb_snapshot` variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the `SET` statement to set the value of the `tidb_snapshot` variable to "" (empty string).

12.4.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see TiDB Garbage Collection (GC)

Pay special attention to the following:

- `tidb_gc_life_time`: This system variable is used to configure the retention time of earlier modifications (default: `10m0s`).
- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point'`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

12.4.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+---------------------+
| now()               |
```

```
+---------------------+
| 2016-10-08 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

> **Note:**
> In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

Result: The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

7. Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

12.4.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

Note:

Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO OUTFILE` and then use `LOAD DATA` to import the data later on.
- Use Dumpling to export a historical snapshot. Dumpling performs well in exporting larger sets of data.

12.5 Best Practices

12.5.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- TiDB Internal (I) - Data Storage
- TiDB Internal (II) - Computing
- TiDB Internal (III) - Scheduling

12.5.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

12.5.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to PingCAP blog posts.

12.5.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

12.5.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of Google Percolator. This document introduces the following features:

- Optimistic transaction model

  TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

  Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction mode

  In TiDB, the pessimistic transaction mode has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

  However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

  As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

  - A transaction is limited to 5,000 SQL statements (by default)
  - Each Key-Value entry is no more than 6 MB (by default)
  - The total size of Key-Value entries is no more than 10 GB.

  You can find similar limits in Google Cloud Spanner.

12.5.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval, `[StartKey, EndKey ↪ )`. When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

12.5.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

12.5.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see TiDB Internal (II) - Computing.

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

12.5.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

  Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index, there will be one more Key-Value when inserting a row. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

  In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

  As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

  - For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
  - If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

  For example, if a commonly used query is `select * from t where c1 = 10 and c2 = 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

  TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

  If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

  The following two conditions do not have the problem of two accesses:

  - Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where c > 10;`. At this time, all needed data can be obtained if you access the index. This situation is called `Covering Index`. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10;` as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.
  - The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

  As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

  - `tidb_distsql_scan_concurrency`:

    The concurrency of scanning data, including scanning the table and index data.
  - `tidb_index_lookup_size`:

    If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.
  - `tidb_index_lookup_concurrency`:

If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

  You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

  TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

12.5.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

12.5.1.3.1 Deployment

Before deployment, read TiDB Software and Hardware Requirements.

It is recommended to deploy the TiDB cluster using TiUP. This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

12.5.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in Tune TiKV Memory Parameter Performance.

12.5.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

> **Note:**
>
> When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are `INSERT`, `UPDATE` or `DELETE` statements.

When deleting a large amount of data, it is recommended to use `Delete from t where xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following `DELETE` statement. If possible, it is recommended to refine the `WHERE` condition. Assume that you need to delete all data on `2017-05-26`, you can use the following statements:

```
for i from 0 to 23:
    while affected_rows > 0:
        delete from t where insert_time >= i:00:00 and insert_time < (i+1)
            ↪ :00:00 limit 5000;
        affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier `Delete` statements do not affect the later ones.

12.5.1.3.4 Query

For query requirements and specific statements, refer to System Variables.

You can control the concurrency of SQL execution through the `SET` statement and the selection of the `Join` operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index hint`.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

12.5.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses Grafana + Prometheus to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate `overview` panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, tidb-server, tikv-server, and pd-server, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides TiDB Dashboard UI to improve usability. You can access TiDB Dashboard by visiting http://$%7BPD_IP%7D:$%7BPD_PORT%7D/dashboard in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

12.5.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from FAQ and TiDB Cluster Troubleshooting Guide. You can also search the issue list or create an issue in TiDB repository on GitHub.

TiDB also has many useful migration tools. See Migration Tool Overview for details.

For more articles on the technical details of TiDB, see the PingCAP official blog site.

12.5.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot

- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

12.5.2 Best Practices for Optimizing Multi-Column Indexes

In today's data-driven world, efficiently handling complex queries on large datasets is critical to keeping applications responsive and performant. For TiDB, a distributed SQL database designed to manage high-scale and high-demand environments, optimizing data access paths is essential to delivering smooth and efficient queries.

Indexes are a powerful tool for improving query performance by avoiding the need to scan all rows in a table. TiDB's query optimizer leverages multi-column indexes to intelligently filter data, handling complex query conditions that traditional databases such as MySQL cannot process as effectively.

This document walks you through how multi-column indexes function, why they are crucial, and how TiDB's optimization transforms intricate query conditions into efficient access paths. After optimization, you can achieve faster responses, minimized table scans, and streamlined performance, even at massive scale.

Without these optimizations, query performance in large TiDB databases can degrade quickly. Full table scans and inadequate filtering can turn milliseconds into minutes. Additionally, excessive memory use can lead to out-of-memory (OOM) errors, especially in constrained environments. TiDB's targeted approach ensures only relevant data is accessed. This keeps latency low and memory usage efficient, even for the most complex queries.

12.5.2.1 Prerequisites

- The multi-column index feature is available in TiDB v8.3 and later versions.
- Before using this feature, you must set the value of the optimizer fix control **54337** to `ON`.

12.5.2.2 Background: multi-column indexes

This document takes an example of a rental listings table defined as follows. In this example, each listing contains a unique ID, city, number of bedrooms, rent price, and availability date:

```
CREATE TABLE listings (
    listing_id INT PRIMARY KEY AUTO_INCREMENT,
    city VARCHAR(100) NOT NULL,
    bedrooms INT NOT NULL,
    price DECIMAL(10, 2) NOT NULL,
    availability_date DATE NOT NULL
);
```

Suppose this table has 20 million listings across the United States. If you want to find all listings with a price under $2,000, you can add an index on the price column. This index allows the optimizer to filter out rows, scanning only the range `[-inf, 2000.00)`. This helps reduce the search to about 14 million rows (assuming 70% of rentals are priced above `$2,000`). In the query execution plan, TiDB performs an index range scan on price. This limits the need for a full table scan and improves efficiency.

```
-- Query 1: Find listings with price < 2000
EXPLAIN FORMAT = "brief" SELECT * FROM listings WHERE price < 2000;
```

```
+-----------------------------+---------+-----------------------------------------------+
   ↪
| id                          | task    | access object
   ↪                              | operator info          |
+-----------------------------+---------+-----------------------------------------------+
   ↪
| IndexLookUp                 | root    |
   ↪                                                 |                               |
|  ─IndexRangeScan(Build)  | root    | table: listings, index: price_idx(
   ↪ price) | range: [-inf, 2000.00) |
|  ─TableRowIDScan(Probe)  | root    | table: listings
   ↪                              |                          |
+-----------------------------+---------+-----------------------------------------------+
   ↪
```

While this filter improves performance, it might still return a large number of rows. This is not ideal for a user looking for more specific listings. Adding filters, such as specifying the city, number of bedrooms, and a maximum price, narrows the results significantly. For example, a query to find two-bedroom listings in San Francisco under `$2,000` is more useful, likely returning only a few dozen rows.

To optimize this query, you can create a multi-column index on `city`, `bedrooms`, and `price` as follows:

```
CREATE INDEX idx_city_bedrooms_price ON listings (city, bedrooms, price);
```

Multi-column indexes in SQL are ordered lexicographically. In the case of an index on `(city, bedrooms, price)`, the data is first sorted by `city`, then by `bedrooms` within each city, and finally by `price` within each `(city, bedrooms)` combination. This ordering lets TiDB efficiently access rows based on each condition:

1. Filter by `city`, which is the primary filter.
2. Optionally filter by `bedrooms` within that city.
3. Optionally filter by `price` within the city-bedroom grouping.

12.5.2.3 Sample data

The following table shows a sample dataset that illustrates how multi-column indexing refines search results:

City	Bedrooms	Price
San Diego	1	1000
San Diego	1	1500
San Diego	2	1000
San Diego	2	2500
San Diego	3	1000
San Diego	3	2500
San Francisco	1	1000
San Francisco	1	1500
San Francisco	2	1000
San Francisco	2	1500
San Francisco	3	2500
San Francisco	3	3000

12.5.2.4 Optimized queries and results

Using the multi-column index, TiDB can efficiently narrow the scan range to find listings in San Francisco with two bedrooms and a price under $2,000:

```
-- Query 2: Find two-bedroom listings in San Francisco under $2,000
EXPLAIN FORMAT = "brief"
    SELECT * FROM listings
    WHERE city = 'San Francisco' AND bedrooms = 2 AND price < 2000;
```

```
+-----------------------+------+-----------------------------------------------------------
   ↪
| id                    | task | access object
   ↪                                                                  |
   ↪ operator info               |
+-----------------------+------+-----------------------------------------------------------
   ↪
| IndexLookUp           | root |
   ↪
   ↪ |                               |
|  ─IndexRangeScan(Build)| root |table:listings,index:idx_city_bedrooms_
   ↪ price ["San Francisco" 2 -inf,(city, bedrooms, price)]|range:["San
   ↪ Francisco" 2 2000.00)|
|  ─TableRowIDScan(Probe)| root |table:listings
   ↪                                                                 |
   ↪                               |
```

```
+----------------------+------+-------------------------------------------------------------
    ↪
```

This query returns the following filtered results from the sample data:

City	Bedrooms	Price
San Francisco	2	1000
San Francisco	2	1500

By using a multi-column index, TiDB avoids unnecessary row scanning and significantly boosts query performance.

12.5.2.5 Index range derivation

The TiDB optimizer includes a powerful range derivation component. It is designed to take a query's conditions and relevant index columns and generate efficient index ranges for table access. This derived range then feeds into TiDB's table access component, which determines the most resource-efficient way to access the table.

For each table in a query, the table access component evaluates all applicable indexes to identify the optimal access method—whether through a full table scan or an index scan. It calculates the range for each relevant index, assesses the access cost, and selects the path with the lowest cost. This process combines range derivation with a cost assessment subsystem to find the most efficient way to retrieve data, balancing performance and resource usage.

The diagram below illustrates how the range derivation and cost assessment work together within TiDB's table access logic to achieve optimal data retrieval.

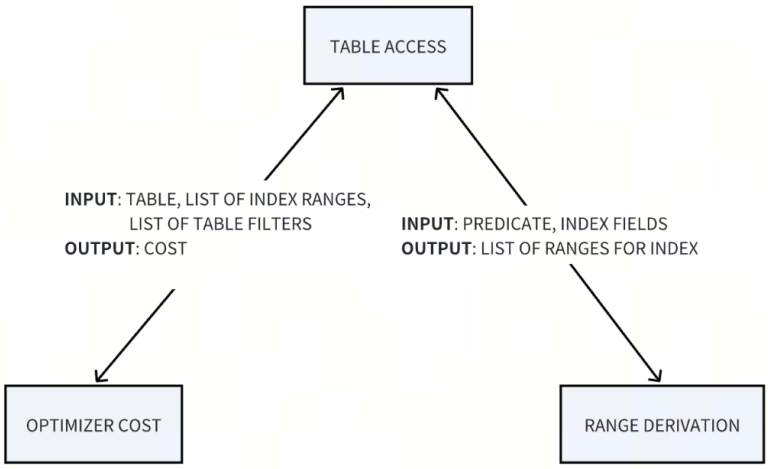

Figure 451: Table Access Path Selection

Multi-column filters are often more complex than the basic examples discussed earlier. They might include **AND** conditions, **OR** conditions, or a combination of both. TiDB's range derivation subsystem is designed to handle these cases efficiently, generating the most selective (and therefore, most effective) index ranges.

In general, the subsystem applies a **UNION** operation for ranges generated from **OR** conditions and an **INTERSECT** operation for ranges derived from **AND** conditions. This approach ensures that TiDB can filter data as precisely as possible, even with complex filtering logic.

12.5.2.6 Disjunctive conditions (`OR` conditions) in multi-column indexes

When there are `OR` conditions in a query (known as "disjunctive predicates"), the optimizer handles each condition separately, creating a range for each part of the `OR` condition. If any of these ranges overlap, the optimizer merges them into one continuous range. If they do not overlap, they remain as separate ranges, both of which can still be used for an index scan.

12.5.2.6.1 Example 1: overlapping ranges

Consider a query that looks for listings in New York with two bedrooms, where the price falls into one of two overlapping ranges:

- Price between `$1,000` and `$2,000`
- Price between `$1,500` and `$2,500`

In this case, the two ranges overlap, so the optimizer combines them into a single range from `$1,000` to `$2,500`. Here is the query and its execution plan:

```
-- Query 3: Overlapping price ranges
EXPLAIN FORMAT = "brief"
    SELECT * FROM listings
    WHERE (city = 'New York' AND bedrooms = 2 AND price >= 1000 AND price <
        ↪ 2000)
       OR (city = 'New York' AND bedrooms = 2 AND price >= 1500 AND price <
          ↪ 2500);
```

```
+------------------------+------+-------------------------------------------------------------
   ↪
| id                     | task | access object
   ↪                                                | operator info
   ↪                                 |
+------------------------+------+-------------------------------------------------------------
   ↪
| IndexLookUp            | root |
   ↪                                                                    |
   ↪                                                 |
```

```
|  └─IndexRangeScan(Build) | root | table:listings,index:idx_city_bedrooms_
   ↪ price(city, bedrooms, price) | range:["New York" 2 1000.00,"New York"
   ↪  2 2500.00)|
|  └─TableRowIDScan(Probe) | root | table:listings
   ↪                                                |
   ↪                                                 |
+------------------------+------+--------------------------------------------------
   ↪
```

12.5.2.6.2 Example 2: non-overlapping ranges

In a different scenario, imagine a query that looks for affordable single-bedroom listings in either San Francisco or San Diego. Here, the `OR` condition specifies two distinct ranges for different cities:

- Listings in San Francisco, 1 bedroom, priced between `$1,500` and `$2,500`
- Listings in San Diego, 1 bedroom, priced between `$1,000` and `$1,500`

Because the index ranges do not overlap, they remain separate in the execution plan, with each city having its own index range:

```
-- Query 4: Non-overlapping ranges for different cities

EXPLAIN FORMAT = "brief"
    SELECT * FROM listings
    WHERE
        (city = 'San Francisco' AND bedrooms = 1 AND price >= 1500 AND price
           ↪  < 2500)
     OR (city = 'San Diego' AND bedrooms = 1 AND price >= 1000 AND price <
        ↪ 1500);
```

```
+------------------------+------+--------------------------------------------------
   ↪
| id                     | task | access object
   ↪                                              | operator info
   ↪                                         |
+------------------------+------+--------------------------------------------------
   ↪
| IndexLookUp            | root |
   ↪                                                              |
   ↪                                                        |
|  └─IndexRangeScan(Build) | root | table:listings,index:idx_city_bedrooms_
   ↪ price(city, bedrooms, price)| range:["San Francisco" 1 1500.00,"San
   ↪ Francisco" 1 2500.00)|
```

```
|  └─TableRowIDScan(Probe) | root | table:listings
   ↪                                                |      ["San Diego" 1
   ↪ 1000.00,"San Diego" 1 1500.00) |
+------------------------+------+-------------------------------------------------
   ↪
```

By creating either merged or distinct ranges based on overlap, the optimizer can efficiently use indexes for `OR` conditions, avoiding unnecessary scans and improving query performance.

12.5.2.7 Conjunctive conditions (`AND` conditions) in multi-column indexes

For queries with **AND** conditions (also known as conjunctive conditions), the TiDB optimizer creates a range for each condition. It then finds the overlap (intersection) of these ranges to get a precise result for index access. If each condition has only one range, this is straightforward, but it becomes more complex if any condition contains multiple ranges. In such cases, TiDB combines these ranges to produce the most selective, efficient result.

12.5.2.7.1 Example 1: table setup

Consider a table `t1` that is defined as follows:

```
CREATE TABLE t1 (
    a1 INT,
    b1 INT,
    c1 INT,
    KEY iab (a1,b1)
);
```

Suppose you have a query with the following conditions:

```
(a1, b1) > (1, 10) AND (a1, b1) < (10, 20)
```

This query involves comparing multiple columns, and requires the TiDB optimizer to process it in the following two steps:

1. Translate the expressions.

   The TiDB optimizer breaks down these complex conditions into simpler parts.

   - `(a1, b1)> (1, 10)` translates to `(a1 > 1)OR (a1 = 1 AND b1 > 10)`, meaning it includes all cases where `a1` is greater than `1` or where `a1` is exactly `1` and `b1` is greater than `10`.
   - `(a1, b1)< (10, 20)` translates to `(a1 < 10)OR (a1 = 10 AND b1 < 20)`, covering cases where `a1` is less than `10` or where `a1` is exactly `10` and `b1` is less than `20`.

These expressions are then combined using `AND`:

```
((a1 > 1) OR (a1 = 1 AND b1 > 10)) AND ((a1 < 10) OR (a1 = 10 AND b1 <
    ↪ 20))
```

2. Derive and combine ranges.

   After breaking down the conditions, the TiDB optimizer calculates ranges for each part and combines them. For this example, it derives:

   - For `(a1, b1)> (1, 10)`: it creates ranges such as `(1, +inf]` for cases where `a1 > 1` and `(1, 10, 1, +inf]` for cases where `a1 = 1` and `b1 > 10`.
   - For `(a1, b1)< (10, 20)`: it creates ranges `[-inf, 10)` for cases where `a1 < 10` and `[10, -inf, 10, 20)` for cases where `a1 = 10` and `b1 < 20`.

   The final result combines these to get a refined range: `(1, 10, 1, +inf] UNION (1, ↪ 10)UNION [10, -inf, 10, 20)`.

12.5.2.7.2 Example 2: query plan

The following query plan shows the derived ranges:

```
-- Query 5: Conjunctive conditions on (a1, b1)
EXPLAIN FORMAT = "brief"
    SELECT * FROM t1
    WHERE (a1, b1) > (1, 10) AND (a1, b1) < (10, 20);
```

```
+------------------------+------+----------------------------+------------------------
    ↪
| id                     | task | access object          | operator info
    ↪                        |
+------------------------+------+----------------------------+------------------------
    ↪
| IndexLookUp            | root |                            |
    ↪                                        |
|  ─IndexRangeScan(Build) | root | table:t1,index:iab(a1, b1) | range:(1
    ↪ 10,1 +inf],(1,10)[10 -inf,10 20) |
|  ─TableRowIDScan(Probe) | root | table:t1                    |
    ↪                                        |
+------------------------+------+----------------------------+------------------------
    ↪
```

In this example, the table has about 500 million rows. However, this optimization allows TiDB to narrow down the access to only around 4,000 rows, just 0.0008% of the total data. This refinement drastically reduces query latency to a few milliseconds, as opposed to over two minutes without optimization.

Unlike MySQL, which requires a full table scan for such conditions, the TiDB optimizer can handle complex row expressions efficiently by leveraging these derived ranges.

12.5.2.8 Conclusion

The TiDB optimizer uses multi-column indexes and advanced range derivation to significantly lower data access costs for complex SQL queries. By effectively managing both conjunctive (`AND`) and disjunctive (`OR`) conditions, TiDB converts row-based expressions into optimal access paths, reducing query times and enhancing performance. Unlike MySQL, TiDB supports union and intersection operations on multi-column indexes, allowing efficient processing of intricate filters. In practical use, this optimization enables TiDB to complete queries in just a few milliseconds—compared to over two minutes without it, demonstrating a substantial reduction in latency.

Check out the comparison white paper to discover even more differences between MySQL and TiDB's architecture, and why this matters for scalability, reliability, and hybrid transactional and analytical workloads.

12.5.3 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

12.5.3.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard MySQL protocol.
- JDBC API and JDBC drivers: Java applications usually use the standard JDBC (Java Database Connectivity) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include MySQL Connector/J and MariaDB Connector/J.
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC DataSource defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as MyBatis and Hibernate to further simplify and manage the database access operations.
- Application implementation: The application logic controls when to send what commands to the database. Some applications use Spring Transaction aspects to manage transactions' start and commit logics.

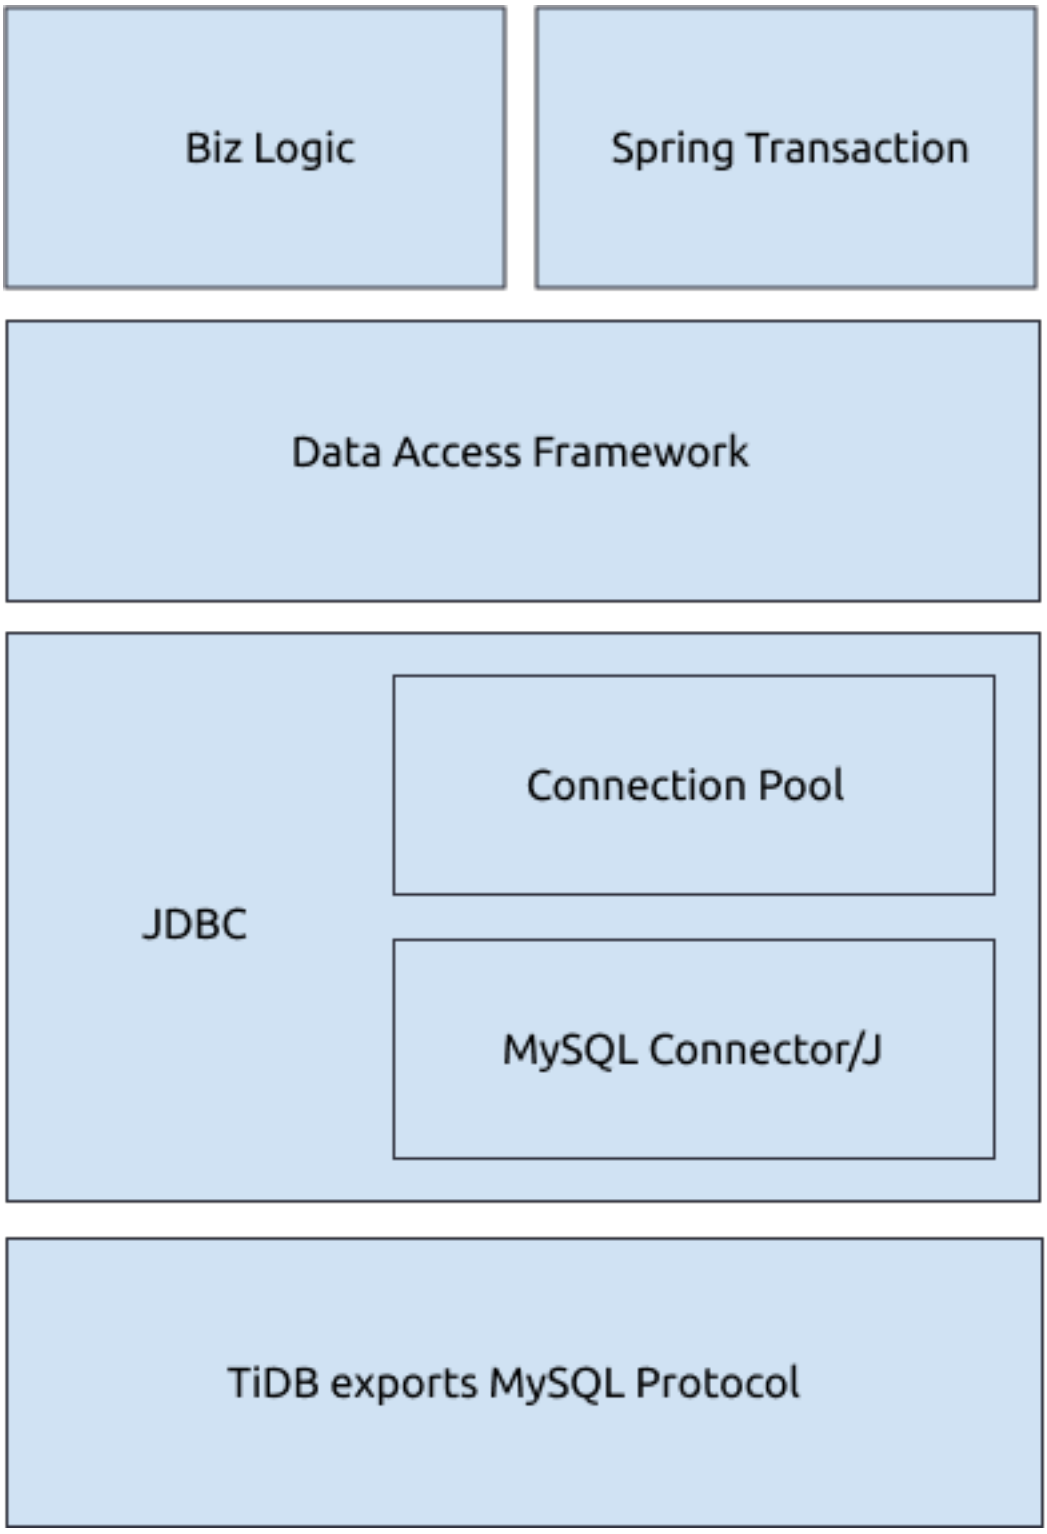

Figure 452: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

12.5.3.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

12.5.3.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

Note:

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

The following two processing methods are usually used in JDBC:

- The first method: Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

  When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection. Ensure that you have called .close()on any active streaming result sets before attempting more queries.` is returned.

  To avoid such an error in queries before the client finishes reading or closes `resultset`, you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- The second method: Use Cursor Fetch by first setting `FetchSize` as a positive integer and then configuring `useCursorFetch = true` in the JDBC URL.

TiDB supports both methods, but it is recommended that you use the first method that sets `FetchSize` to `Integer.MIN_VALUE`, because it is a simpler implementation and has better execution efficiency.

For the second method, TiDB first loads all data to the TiDB node, and then returns data to the client according to the `FetchSize`. Therefore, it usually consumes more memory

than the first method. If `tidb_enable_tmp_storage_on_oom` is set to `ON`, TiDB might temporarily write the result to the hard disk.

If the `tidb_enable_lazy_cursor_fetch` system variable is set to `ON`, TiDB tries to read part of the data only when the client fetches it, which uses less memory. For more details and limitations, read the complete descriptions for the `tidb_enable_lazy_cursor_fetch` system variable.

12.5.3.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

`useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

`cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

`prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

`prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > CPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements =true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("insert into t (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
    ↪ values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
    ↪ t set a = 12 where id = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements` `↪ =true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless

for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively.

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

> **Note:**
>
> Enabling `useConfigs=maxPerformance` requires MySQL Connector/J version 8.0.33 or later. For more details, see MySQL JDBC Bug.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters that controls the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. The default value of both parameters is `0`, which by default allows the connection to be infinitely idle and infinitely busy (an infinite duration for one SQL statement to execute).

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

Typical JDBC connection string parameters

Combining the preceding parameter values, the JDBC connection string configuration is as follows:

```
jdbc:mysql://<IP_ADDRESS>:<PORT_NUMBER>/<DATABASE_NAME>?characterEncoding=
    ↪ UTF-8&useSSL=false&useServerPrepStmts=true&cachePrepStmts=true&
    ↪ prepStmtCacheSqlLimit=10000&prepStmtCacheSize=1000&useConfigs=
    ↪ maxPerformance&rewriteBatchedStatements=true
```

> **Note:**

If you are connecting over a public network, you need to set `useSSL=true` and enable TLS between TiDB clients and servers.

12.5.3.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

TiDB supports the following Java connection pools:

- HikariCP
- tomcat-jdbc
- druid
- c3p0
- dbcp

In practice, some connection pools might persistently use specific active sessions. Although the total number of connections appears evenly distributed across TiDB compute nodes, uneven distribution of active connections can lead to actual load imbalance. In distributed scenarios, it is recommended to use HikariCP, which manages connection lifecycles effectively and helps prevent active connections from being fixed on certain nodes, achieving balanced load distribution.

12.5.3.3.1 Typical connection pool configuration

The following is an example configuration for HikariCP:

```
hikari:
  maximumPoolSize: 20
  poolName: hikariCP
  connectionTimeout: 30000
  maxLifetime: 1200000
  keepaliveTime: 120000
```

The parameter explanations are as follows. For more details, refer to the official HikariCP documentation.

- `maximumPoolSize`: the maximum number of connections in the pool. The default value is `10`. In containerized environments, it is recommended to set this to 4–10 times the number of CPU cores available to the Java application. Setting this value too high can lead to resource wastage, while setting it too low can slow down connection acquisition. See About Pool Sizing for more details.

- `minimumIdle`: HikariCP recommends not setting this parameter. The default value is equal to the value of `maximumPoolSize`, which disables connection pool scaling. This ensures that connections are readily available during traffic spikes and avoids delays caused by connection creation.
- `connectionTimeout`: the maximum time (in milliseconds) that an application waits to acquire a connection from the pool. The default value is `30000` milliseconds (30 seconds). If no available connection is obtained within this time, a `SQLException` exception occurs.
- `maxLifetime`: the maximum lifetime (in milliseconds) of a connection in the pool. The default value is `1800000` milliseconds (30 minutes). Connections in use are not affected. After the connection is closed, it will be removed according to this setting. Setting this value too low can cause frequent reconnections. If you are using `graceful-wait-before-shutdown`, ensure this value is less than the wait time.
- `keepaliveTime`: the interval (in milliseconds) between keepalive operations on connections in the pool. This setting helps prevent disconnections caused by database or network idle timeouts. The default value is `120000` milliseconds (2 minutes). The pool prefers using the JDBC4 `isValid()` method to keep idle connections alive.

12.5.3.3.2 Probe configuration

The connection pool maintains persistent connections from clients to TiDB as follows:

- Before v5.4, TiDB does not proactively close client connections by default (unless an error is reported).
- Starting from v5.4, TiDB automatically closes client connections after `28800` seconds (this is, `8` hours) of inactivity by default. You can control this timeout setting using the TiDB and MySQL compatible `wait_timeout` variable. For more information, see JDBC Query Timeout.

Moreover, there might be network proxies such as LVS or HAProxy between clients and TiDB. These proxies typically proactively clean up connections after a specific idle period (determined by the proxy's idle configuration). In addition to monitoring the proxy's idle configuration, connection pools also need to maintain or probe connections for keep-alive.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual

solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

12.5.3.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

12.5.3.4.1 MyBatis

MyBatis is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t where id =?` as a Prepared Statement and be "prepared", and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.
- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for "preparing" the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

Dynamic SQL Batch

Dynamic SQL - foreach

To support the automatic rewriting of multiple `INSERT` statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements=true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
  insert into test
   (id, v1, v2)
  values
  <foreach item="item" index="index" collection="list" separator=",">
  (
   #{item.id}, #{item.v1}, #{item.v2}
  )
  </foreach>
  on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of `(?,?,?)` following "values" is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

Streaming result

A previous section introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping's `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
  select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer .MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

12.5.3.4.2 `ExecutorType`

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`
- Batch: Each update operation (`INSERT`/`DELETE`/`UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

12.5.3.5 Spring Transaction

In the real world, applications might use Spring Transaction and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the Propagation configuration.

12.5.3.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

12.5.3.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

jstack

jstack is similar to pprof/goroutine in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using jstack multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using Batch ExecutorType in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or Java swiss knife are common methods to view the thread ID. Also, to locate the issue of "a thread occupies a lot of CPU resources and I don't know what it is executing", do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the jstack output to find the stack information of the corresponding thread.

jmap & mat

Unlike pprof/heap in Go, jmap dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool mat.

Through mat, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use mat to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that mat only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust mat configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

trace

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using btrace or arthas trace is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see Java Flame Graphs Introduction: Fire For Everyone!.

12.5.3.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

12.5.4 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of HAProxy in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

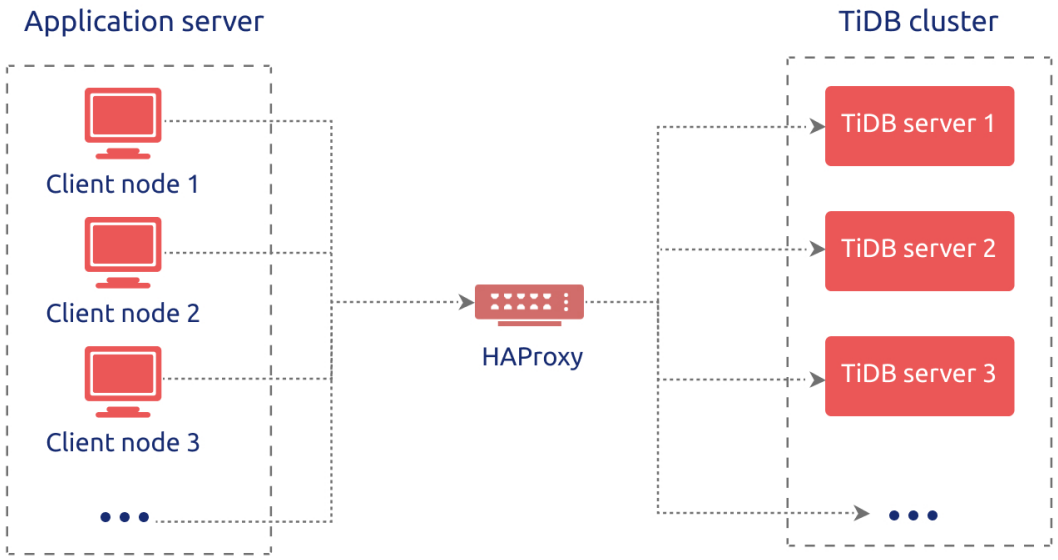

Figure 453: HAProxy Best Practices in TiDB

> **Note:**
>
> The minimum version of HAProxy that works with all versions of TiDB is v1.5. Between v1.5 and v2.1, you need to set the `post-41` option in `mysql-check`. It is recommended to use HAProxy v2.2 or newer.

12.5.4.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its

fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. In this guide, HAProxy 2.6 is used. It is recommended to use the latest stable version. See the released version of HAProxy for details.

12.5.4.2 Basic features

- High Availability: HAProxy provides high availability with support for a graceful shutdown and a seamless switchover;
- Load Balancing: Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- Health Check: HAProxy periodically checks the status of HTTP or TCP mode of the server;
- Sticky Session: HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- SSL: HTTPS communication and resolution are supported;
- Monitoring and Statistics: Through the web page, you can monitor the service state and traffic flow in real time.

12.5.4.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

12.5.4.3.1 Hardware requirements

According to the HAProxy documentation, the minimum hardware configuration for HAProxy is shown in the following table. Under the Sysbench `oltp_read_write` workload, the maximum QPS for this configuration is about 50K. You can increase the server configuration according to your load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	4 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

12.5.4.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Linux distribution	Version
Red Hat Enterprise Linux	7 or 8
CentOS	7 or 8
Oracle Enterprise Linux	7 or 8
Ubuntu LTS	18.04 or later versions

Note:

- For more information about other supported operating systems, see HAProxy documentation.

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

12.5.4.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the configuration file based on your actual scenario.

12.5.4.4.1 Install HAProxy

1. Download the package of the HAProxy 2.6.21 source code:

   ```
   wget https://www.haproxy.org/download/2.6/src/haproxy-2.6.21.tar.gz
   ```

2. Extract the package:

```
tar zxf haproxy-2.6.21.tar.gz
```

3. Compile the application from the source code:

```
cd haproxy-2.6.21
make clean
make -j 8 TARGET=linux-glibc USE_THREAD=1
make PREFIX=${/app/haproxy} SBINDIR=${/app/haproxy/bin} install # Replace `${/app/haproxy}` and `${/app/haproxy/bin}` with your custom directories.
```

4. Reconfigure the profile:

```
echo 'export PATH=/app/haproxy/bin:$PATH' >> /etc/profile
. /etc/profile
```

5. Check whether the installation is successful:

```
which haproxy
```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
-v	Reports the version and build date.
-vv	Displays the version, build options, libraries versions and usable pollers.
-d	Enables debug mode.

Option	Description
`-db`	Disables background mode and multi-process mode.
`-dM [< ↪ byte ↪ >]`	Forces memory poisoning, which means that each and every memory region allocated with malloc() or pool_alloc2() will be filled with `<byte>` before being passed to the caller.
`-V`	Enables verbose mode (disables quiet mode).
`-D`	Starts as a daemon.
`-C <dir>`	Changes to directory `<dir>` before loading configuration files.

Option	Description
`-W`	Master-worker mode.
`-q`	Sets “quiet” mode: This disables some messages during the configuration parsing and during startup.
`-c`	Only performs a check of the configuration files and exits before trying to bind.
`-n <limit>`	Limits the per-process connection limit to `<limit>`.
`-m <limit>`	Limits the total allocatable memory to `<limit>` megabytes across all processes.

Option	Description
`-N <limit>`	Sets the default per-proxy maxconn to `<limit>` instead of the builtin default value (usually 2000).
`-L <name>`	Changes the local peer name to `<name>`, which defaults to the local hostname.
`-p <file>`	Writes all processes' PIDs into `<file>` during startup.
`-de`	Disables the use of epoll(7). epoll(7) is available only on Linux 2.6 and some custom Linux 2.4 systems.
`-dp`	Disables the use of poll(2). select(2) might be used instead.

Option	Description
`-dS`	Disables the use of splice(2), which is broken on older kernels.
`-dR`	Disables SO_REUSEPORT usage.
`-dr`	Ignores server address resolution failures.
`-dV`	Disables SSL verify on the server side.

Option	Description
`-sf <pidlist>`	Sends the “finish” signal to the PIDs in pidlist after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
`-st <` `↪ pidlist` `↪ >`	Sends the “terminate” signal to the PIDs in pidlist after startup. The processes which receive this signal terminate immedi- ately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
`-x <unix_socket>`	Connects to the specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
`-S <bind>[,<bind_options>...]`	In master-worker mode, creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to Management Guide of HAProxy and General Commands Manual of HAProxy.

12.5.4.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global                                  # Global configuration.
   log         127.0.0.1 local2         # Global syslog servers (up to two).
   chroot      /var/lib/haproxy         # Changes the current directory and
      ↪ sets superuser privileges for the startup process to improve
      ↪ security.
   pidfile     /var/run/haproxy.pid     # Writes the PIDs of HAProxy processes
      ↪  into this file.
   maxconn     4096                     # The maximum number of concurrent
      ↪ connections for a single HAProxy process. It is equivalent to the
      ↪ command-line argument "-n".
   nbthread    48                       # The maximum number of threads. (The
      ↪ upper limit is equal to the number of CPUs)
   user        haproxy                  # Same with the UID parameter.
   group       haproxy                  # Same with the GID parameter. A
      ↪ dedicated user group is recommended.
   daemon                               # Makes the process fork into
      ↪ background. It is equivalent to the command line "-D" argument. It
      ↪ can be disabled by the command line "-db" argument.
   stats socket /var/lib/haproxy/stats # The directory where statistics
      ↪ output is saved.

defaults                                # Default configuration.
   log global                           # Inherits the settings of the global
      ↪ configuration.
   retries 2                            # The maximum number of retries to
      ↪ connect to an upstream server. If the number of connection attempts
      ↪  exceeds the value, the backend server is considered unavailable.
   timeout connect 2s                   # The maximum time to wait for a
      ↪ connection attempt to a backend server to succeed. It should be set
      ↪  to a shorter time if the server is located on the same LAN as
      ↪ HAProxy.
   timeout client 30000s                # The maximum inactivity time on the
      ↪ client side.
   timeout server 30000s                # The maximum inactivity time on the
      ↪ server side.

listen admin_stats                      # The name of the Stats page reporting
   ↪  information from frontend and backend. You can customize the name
   ↪ according to your needs.
   bind 0.0.0.0:8080                    # The listening port.
   mode http                            # The monitoring mode.
   option httplog                       # Enables HTTP logging.
   maxconn 10                           # The maximum number of concurrent
      ↪ connections.
```

```
  stats refresh 30s                   # Automatically refreshes the Stats
     ↪ page every 30 seconds.
  stats uri /haproxy                  # The URL of the Stats page.
  stats realm HAProxy                 # The authentication realm of the
     ↪ Stats page.
  stats auth admin:pingcap123         # User name and password in the Stats
     ↪ page. You can have multiple user names.
  stats hide-version                  # Hides the version information of
     ↪ HAProxy on the Stats page.
  stats admin if TRUE                 # Manually enables or disables the
     ↪ backend server (supported in HAProxy 1.4.9 or later versions).

listen tidb-cluster                   # Database load balancing.
  bind 0.0.0.0:3390                   # The Floating IP address and
     ↪ listening port.
  mode tcp                            # HAProxy uses layer 4, the transport
     ↪ layer.
  balance leastconn                   # The server with the smallest number
     ↪ of connections receives the connection. "leastconn" is recommended
     ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
     ↪  than protocols using short sessions, such as HTTP. The algorithm
     ↪ is dynamic, which means that server weights might be adjusted on
     ↪ the fly for slow starts for instance.
  server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
     ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
     ↪ detected as successful twice, the server is considered available;
     ↪ if it is detected as failed three times, the server is considered
     ↪ unavailable.
  server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

To check the source IP address using `SHOW PROCESSLIST`, you need to configure the PROXY protocol to connect to TiDB.

```
  server tidb-1 10.9.18.229:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-2 10.9.39.208:4000 send-proxy check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 send-proxy check inter 2000 rise 2 fall 3
```

Note:

Before using the PROXY protocol, you need to configure `proxy-protocol.networks` in the configuration file of the TiDB server.

12.5.4.4.3 Start HAProxy

To start HAProxy, run `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

12.5.4.4.4 Stop HAProxy

To stop HAProxy, use the `kill -9` command.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

12.5.5 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

12.5.5.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and TiDB Best Practices:

- Data Storage
- Computing
- Scheduling

12.5.5.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing and settlement. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

12.5.5.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to Scheduling for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports Follower-Read) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

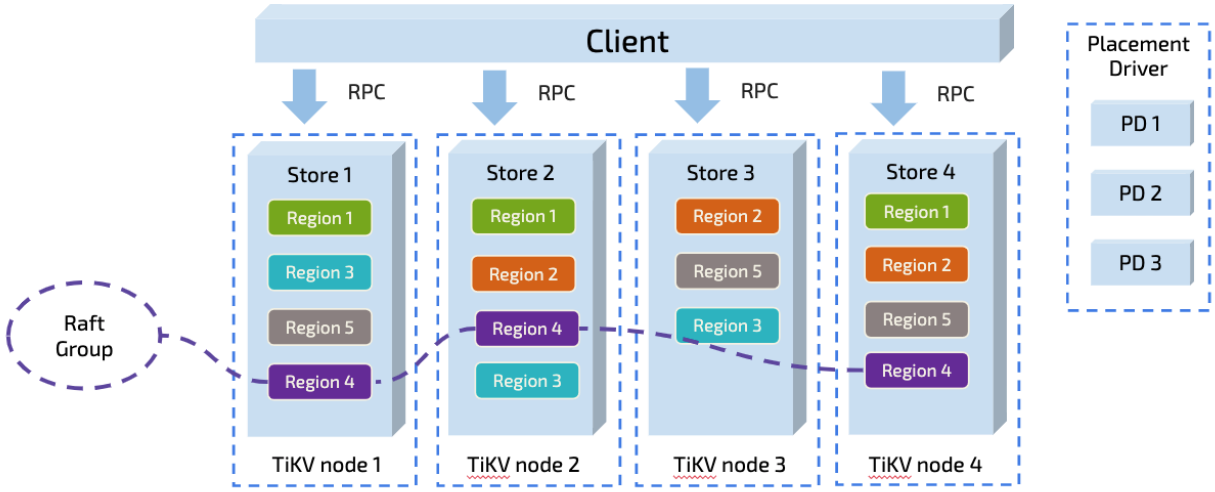

Figure 454: TiDB Data Overview

In theory, if an application has no write hotspot, TiDB, by the virtue of its architecture, can not only linearly scale its read and write capacities, but also make full use of the distributed resources. From this point of view, TiDB is especially suitable for the high-concurrent and write-intensive scenario.

However, the actual situation often differs from the theoretical assumption.

> **Note:**
>
> No write hotspot in an application means the write scenario does not have any `AUTO_INCREMENT` primary key or monotonically increasing index.

12.5.5.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(
     id        BIGINT PRIMARY KEY,
     age       INT,
     user_name VARCHAR(32),
     email     VARCHAR(128)
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
SET SESSION cte_max_recursion_depth = 1000000;
INSERT INTO TEST_HOTSPOT
SELECT
  n,                                    -- ID
  RAND()*80,                            -- Number between 0 and 80
  CONCAT('user-',n),
  CONCAT(
    CHAR(65 + (RAND() * 25) USING ascii), -- Number between 65 and 65+25,
       ↪ converted to a character, A-Z
    '-user-',
    n,
    '@example.com'
  )
FROM
  (WITH RECURSIVE nr(n) AS
    (SELECT 1                           -- Start CTE at 1
      UNION ALL SELECT n + 1            -- increase n with 1 every loop
      FROM nr WHERE n < 1000000         -- stop loop at 1_000_000
    ) SELECT n FROM nr
  ) a;
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

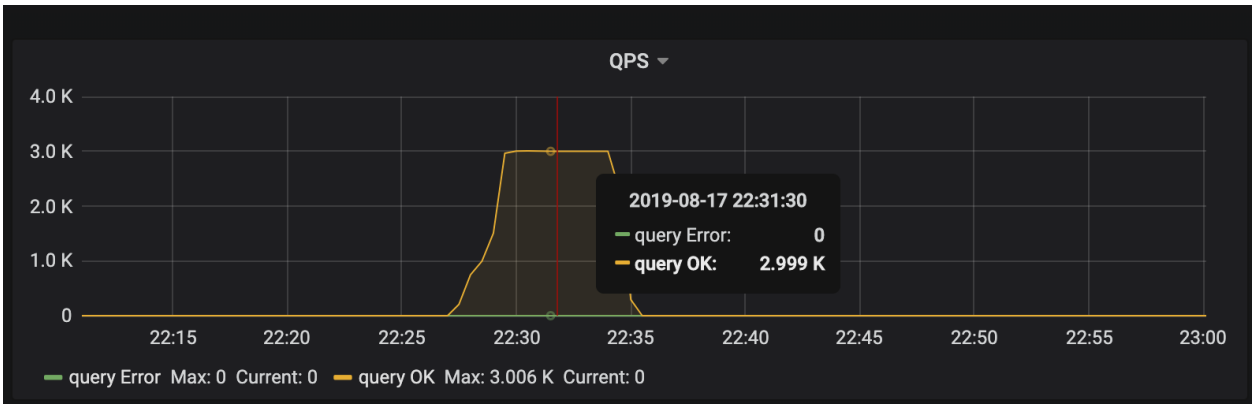

Figure 455: QPS1

The client starts "intensive" write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

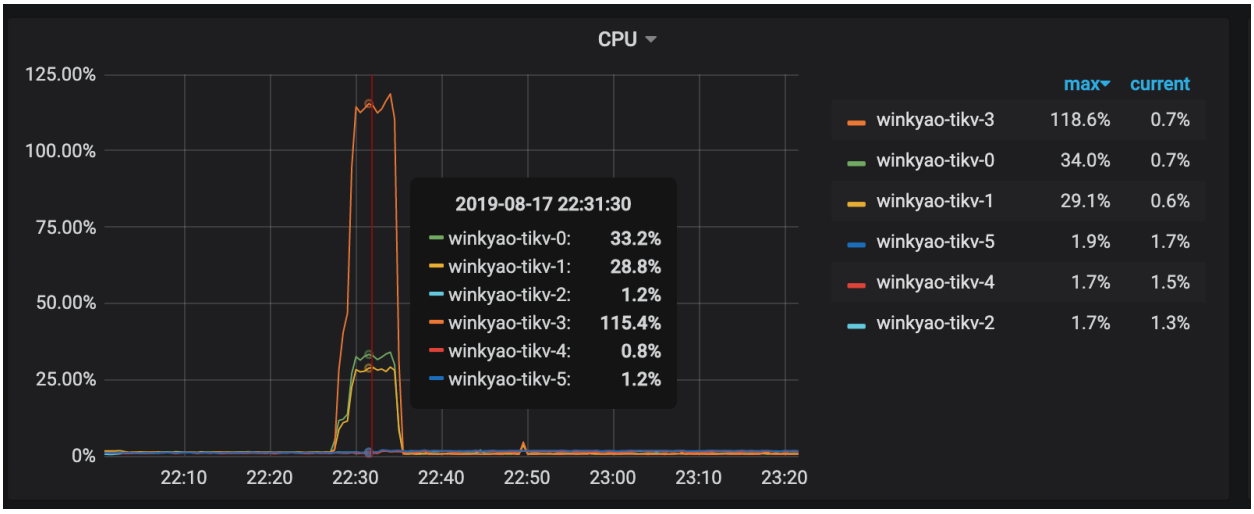

Figure 456: QPS2

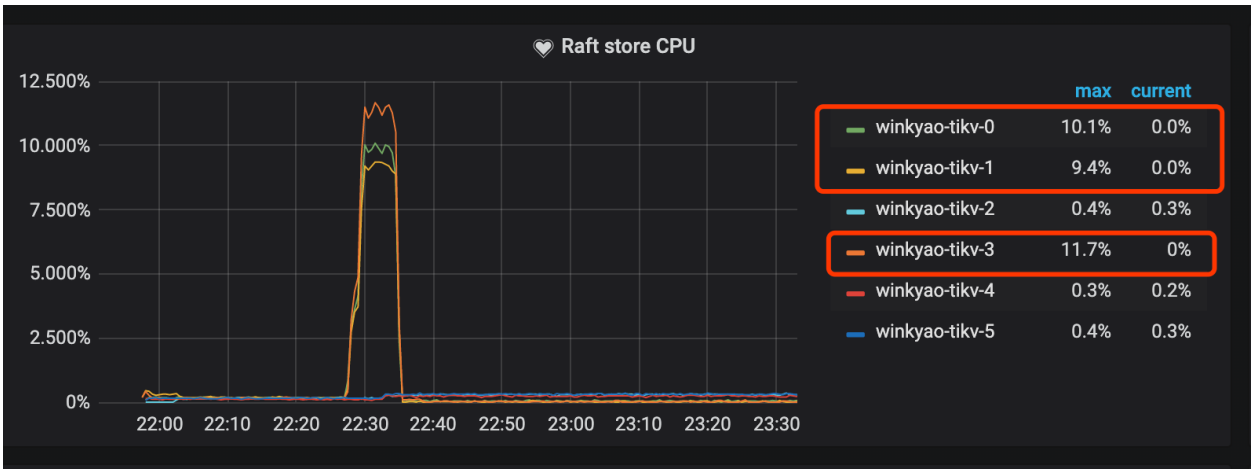

Figure 457: QPS3

Raft store CPU is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

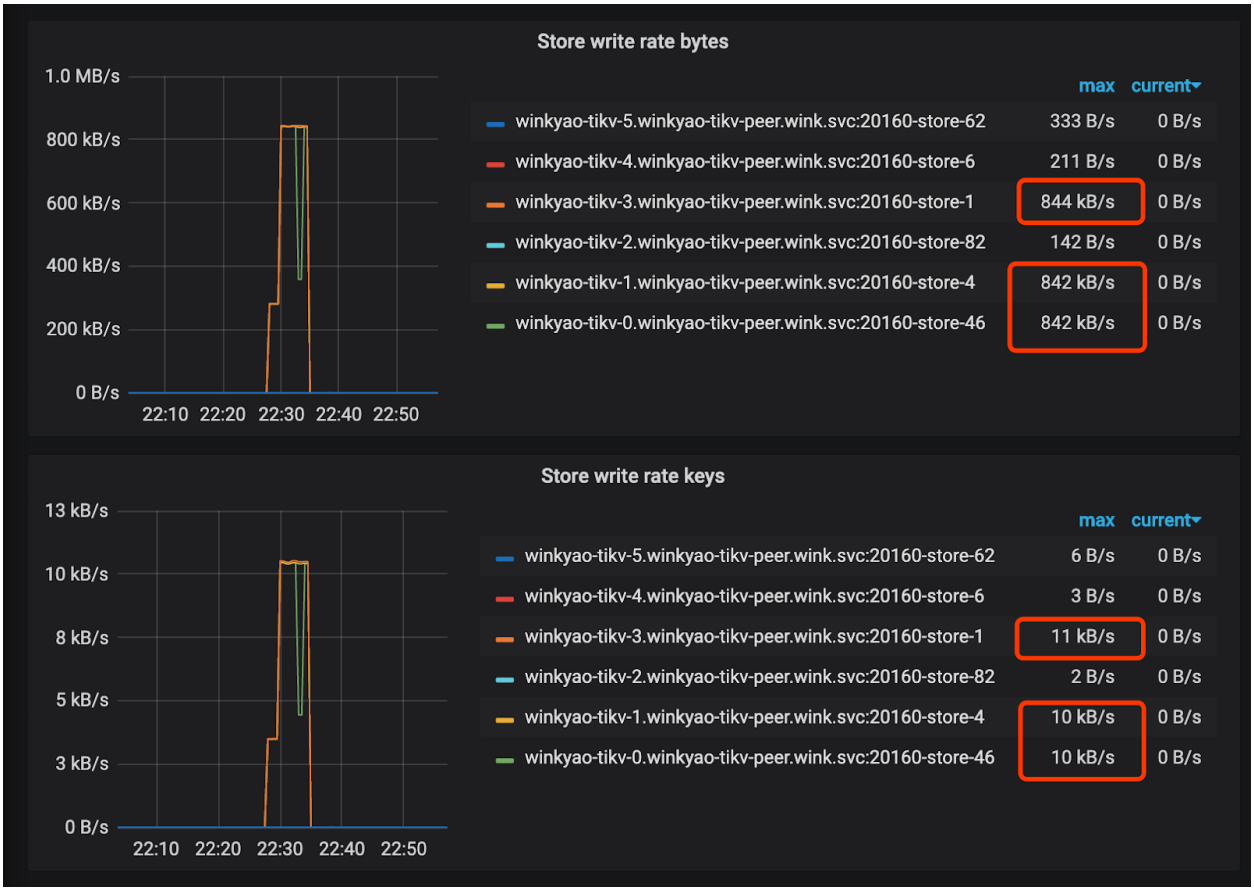

Figure 458: QPS4

12.5.5.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

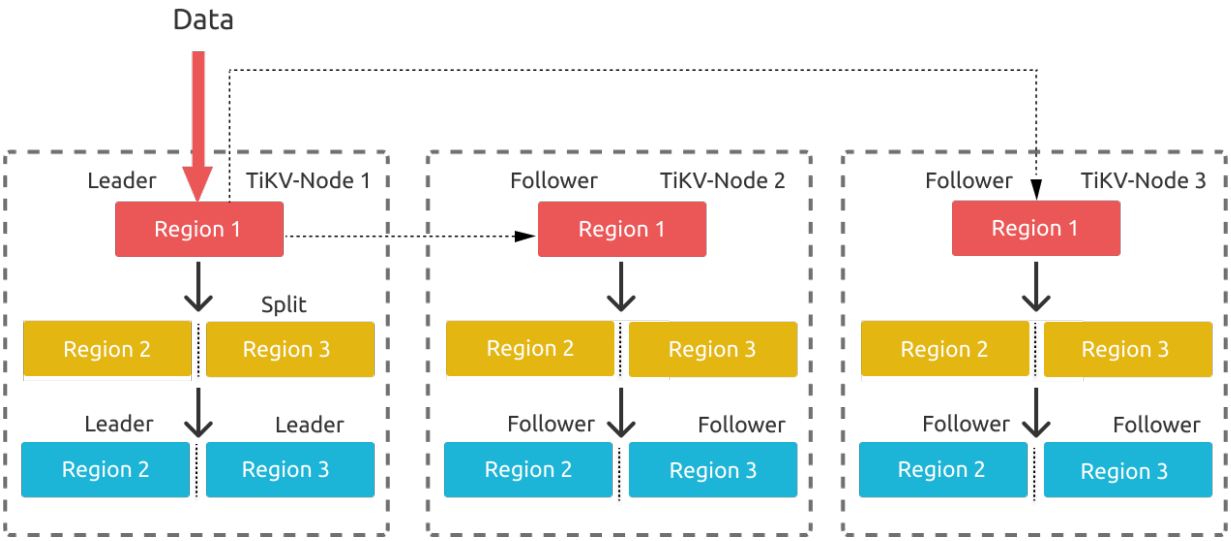

Figure 459: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

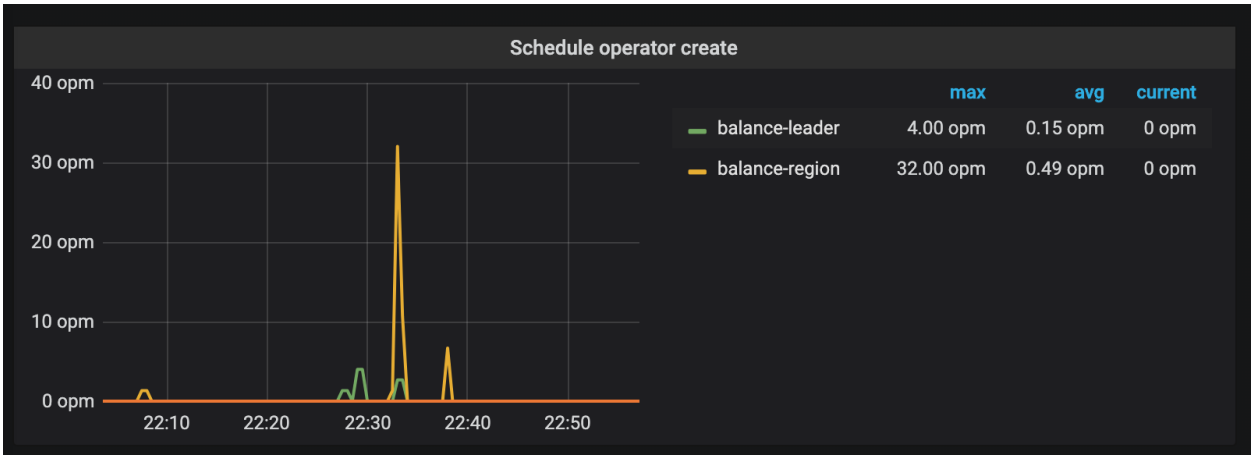

Figure 460: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

12.5.5.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called Split Region. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (upper_
    ↪ value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

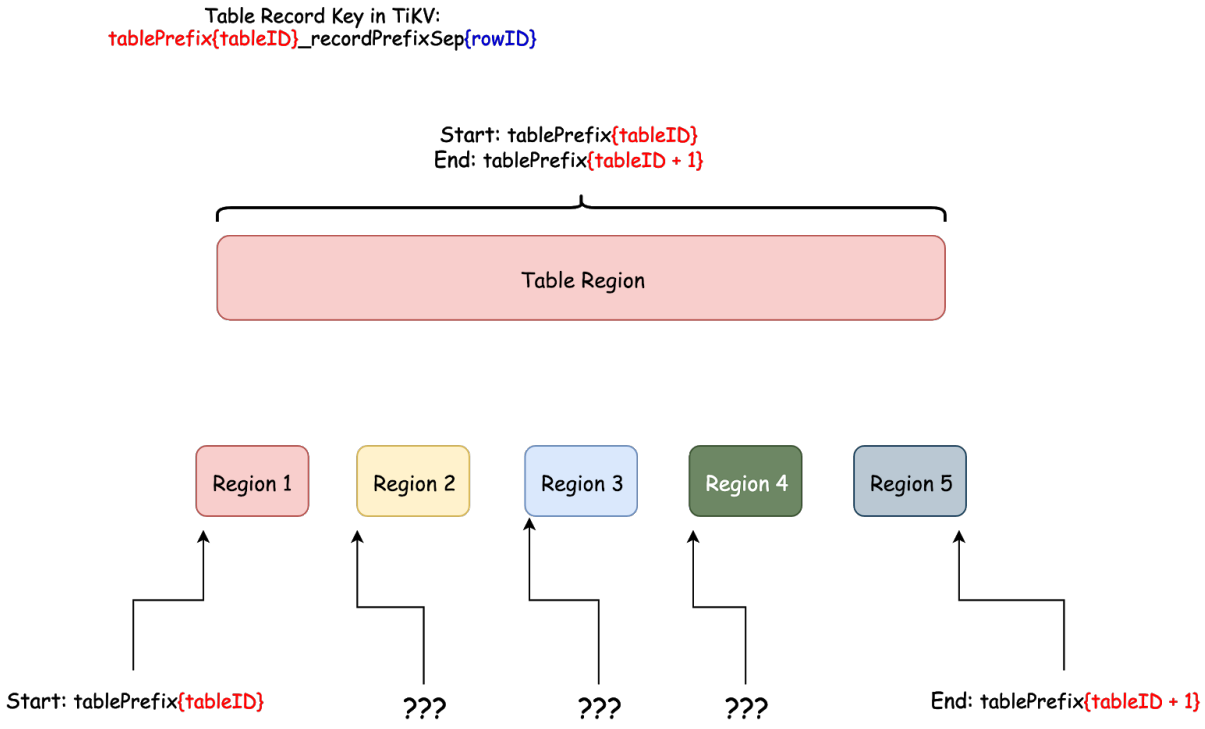

Figure 461: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all `0`, the scheduling is successful.

You can also check the Region leader distribution using the following SQL statement. You need to replace `table_name` with the actual table name.

```
SELECT
    p.STORE_ID,
    COUNT(s.REGION_ID) PEER_COUNT
FROM
    INFORMATION_SCHEMA.TIKV_REGION_STATUS s
    JOIN INFORMATION_SCHEMA.TIKV_REGION_PEERS p ON s.REGION_ID = p.REGION_ID
WHERE
    TABLE_NAME = 'table_name'
    AND p.is_leader = 1
GROUP BY
    p.STORE_ID
ORDER BY
    PEER_COUNT DESC;
```

Then operate the write load again:

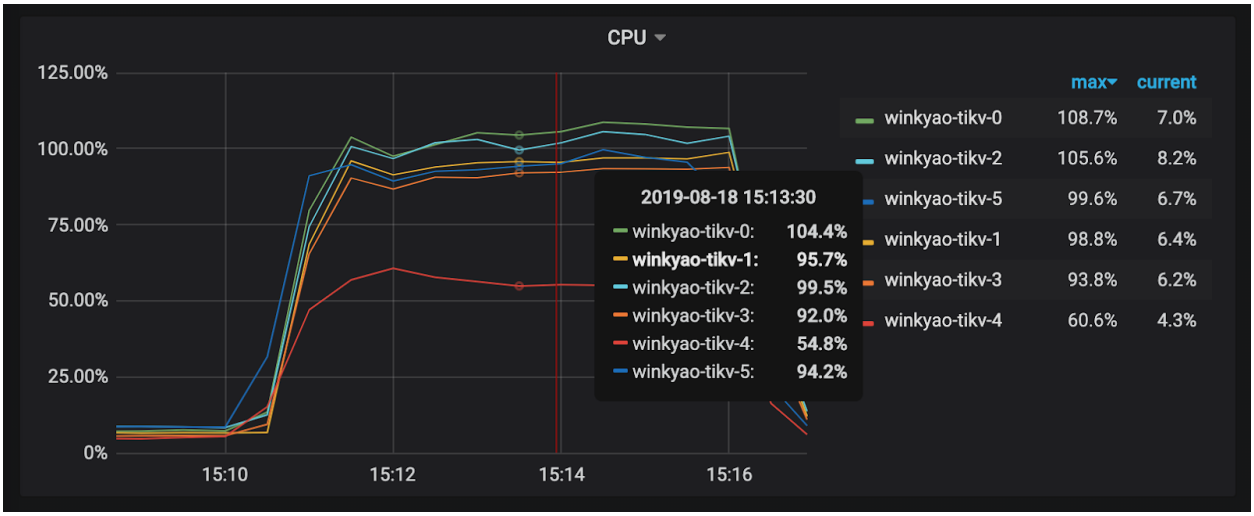

Figure 462: QPS6

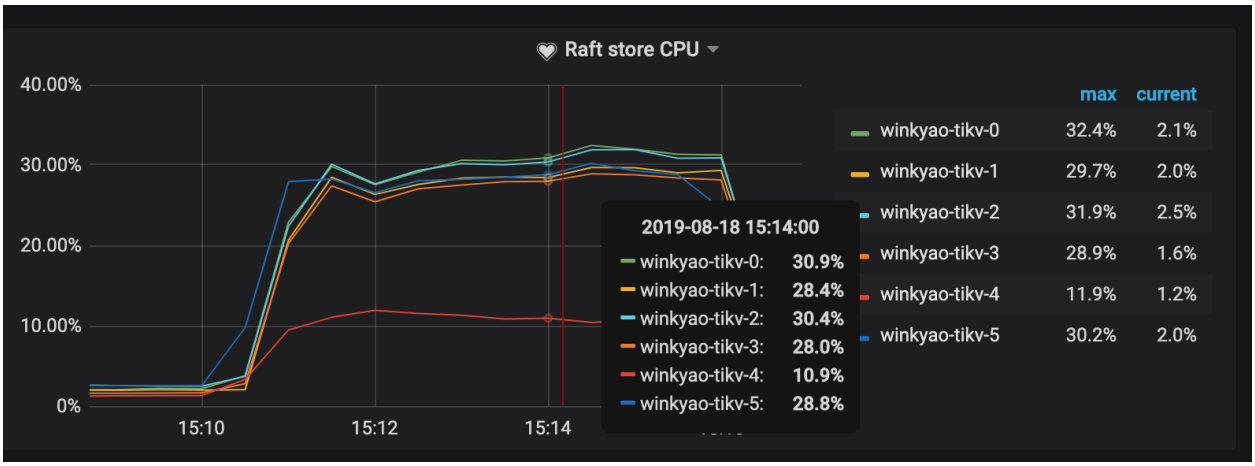

Figure 463: QPS7

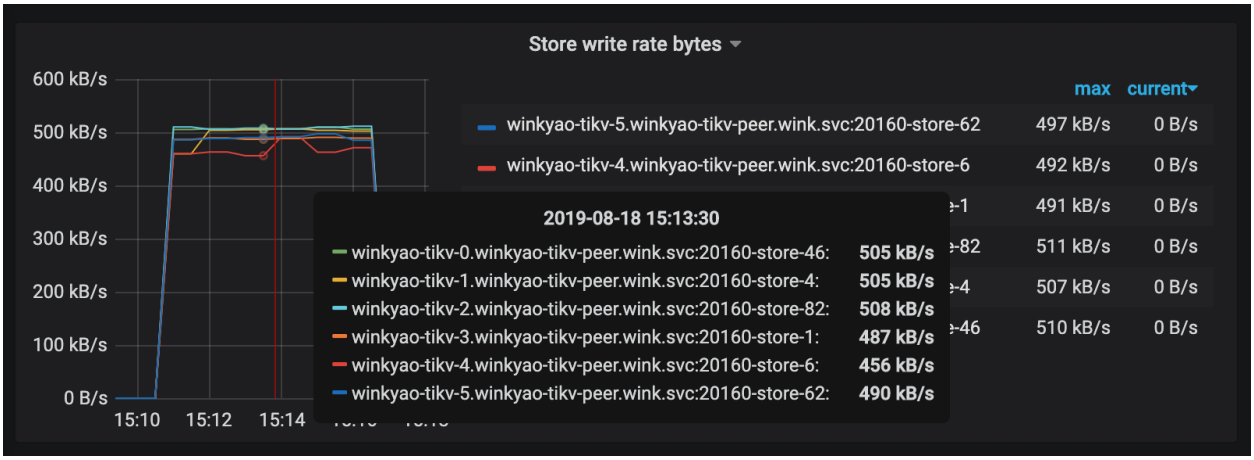

Figure 464: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to Split Region.

12.5.5.7 Complex hotspot problems

Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to `SHARD_ROW_ID_BITS` for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to Pre-split Regions.

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

> **Note:**
>
> The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 (16=2^4) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 (2^3) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

> **Note:**
>
> The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.
>
> This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to `global`, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

12.5.5.8 Parameter configuration

In v2.1, the latch mechanism is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

12.5.6 Best Practices for Monitoring TiDB Using Grafana

When you deploy a TiDB cluster using TiUP and have added Grafana and Prometheus in the topology configuration, a set of Grafana + Prometheus monitoring platform is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

12.5.6.1 Monitoring architecture

Prometheus is a time series database with a multi-dimensional data model and a flexible query language. Grafana is an open source monitoring system for analyzing and visualizing metrics.

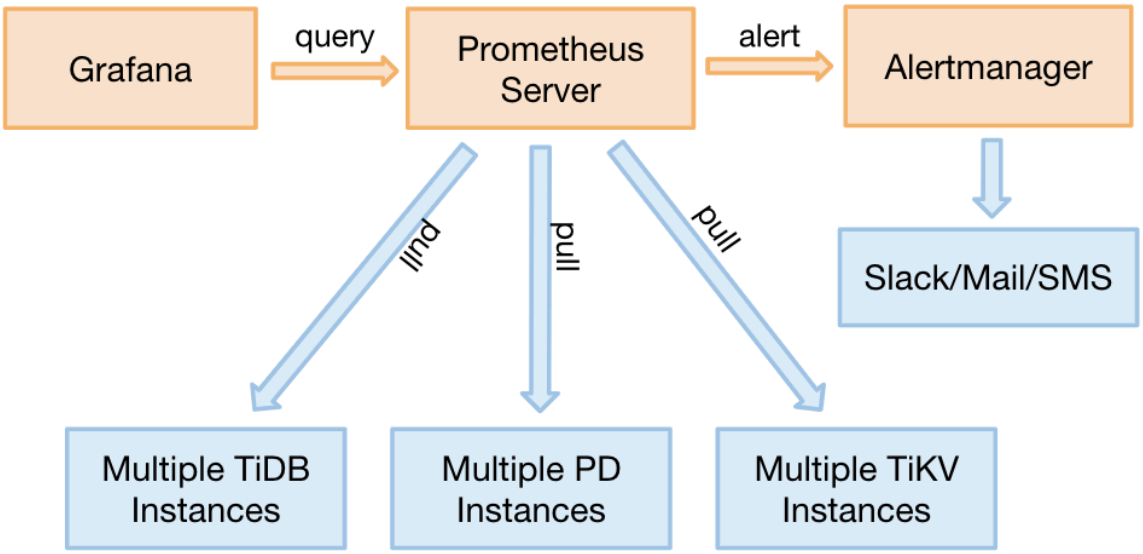

Figure 465: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

12.5.6.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the default ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20180
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
### Check the real-time QPS of different types of SQL statements. The
    ↪ numbers below are the cumulative values of counter type (scientific
    ↪ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

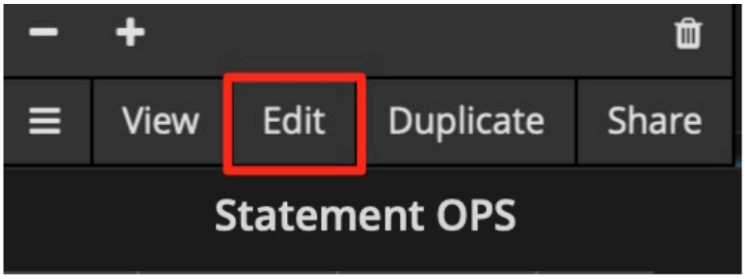

Figure 466: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_total` metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- `rate[1m]`: The growth rate in one minute. It can only be used for the data of counter type.
- `sum`: The sum of values.
- `by type`: The summed data is grouped by type in the original metric value.
- `Legend format`: The format of the metric name.
- `Resolution`: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 467: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to Prometheus official website.

12.5.6.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

12.5.6.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the source and display of monitoring data section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the `Legend format` field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (`instance`, `job` and `type`):

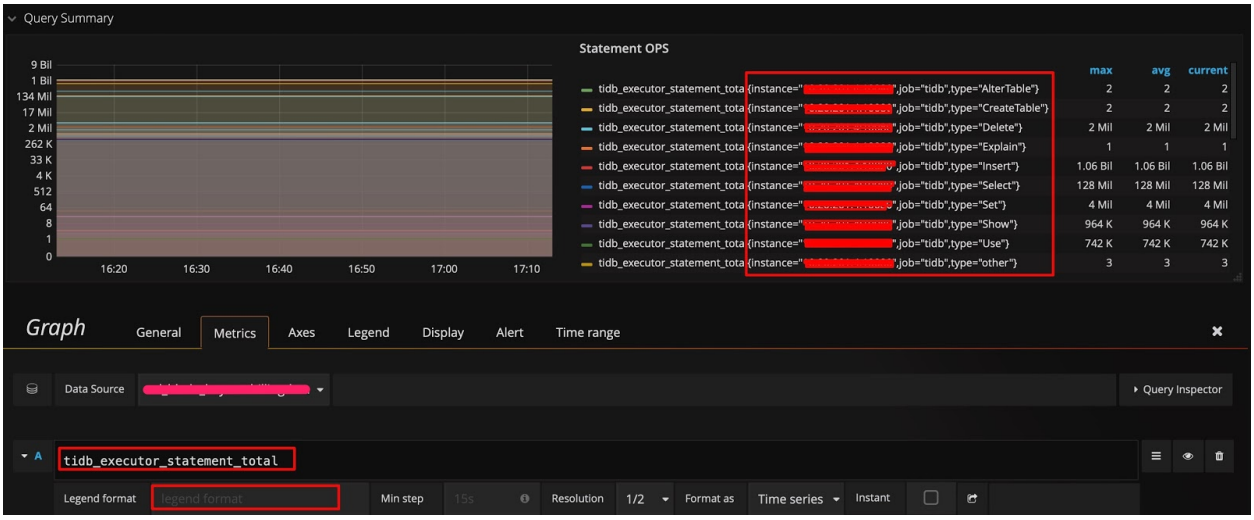

Figure 468: Edit query expression and check all dimensions

Then you can modify the query expression by adding the `instance` dimension after `type`, and adding `{{instance}}` to the `Legend format` field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

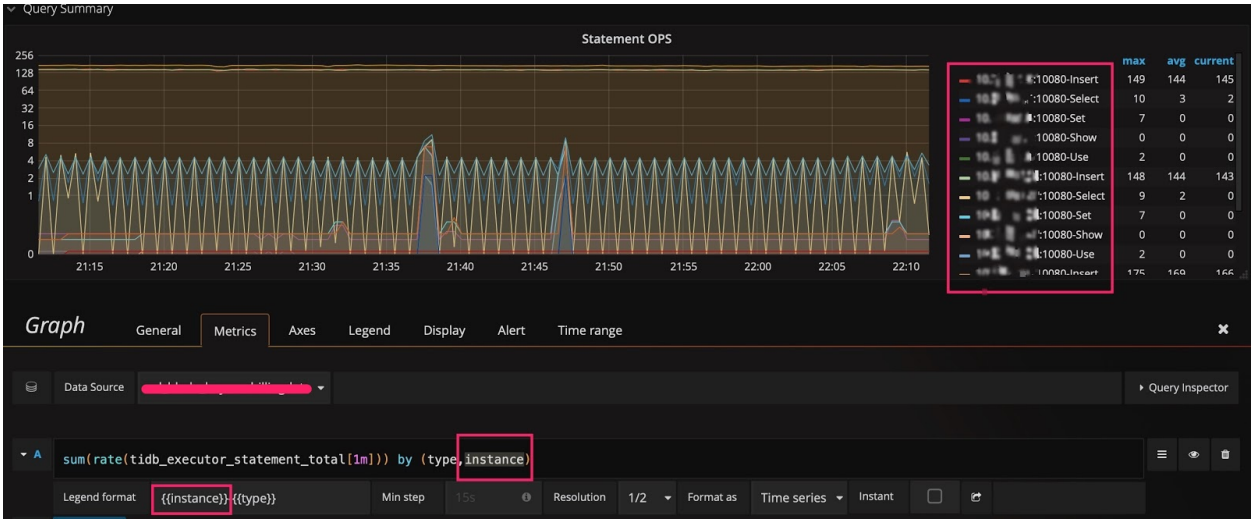

Figure 469: Add an instance dimension to the query expression

12.5.6.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale (log2n), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

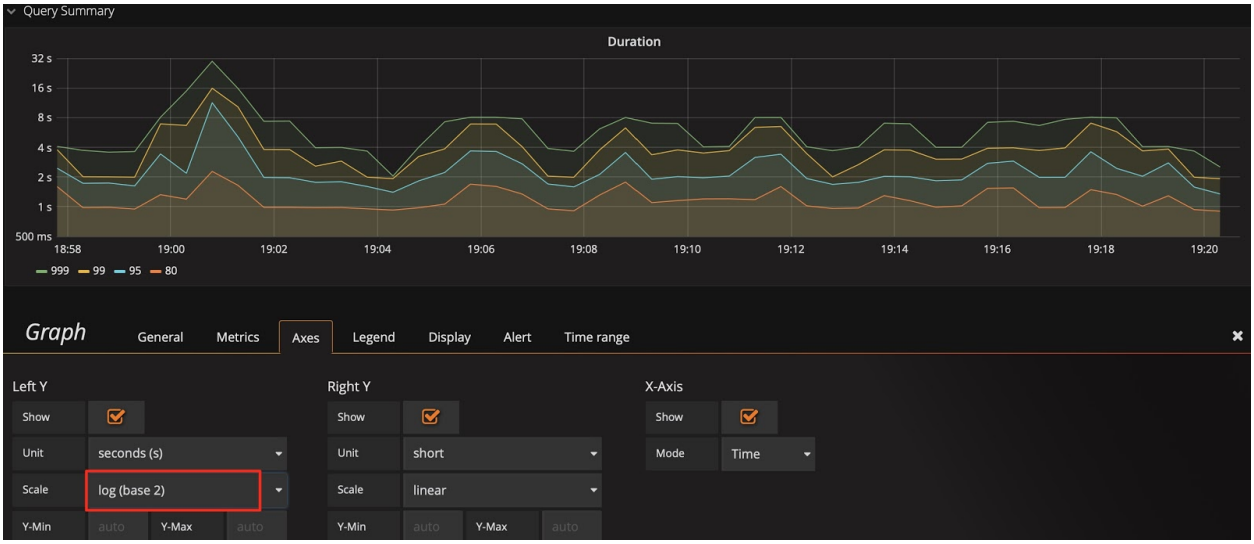

Figure 470: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

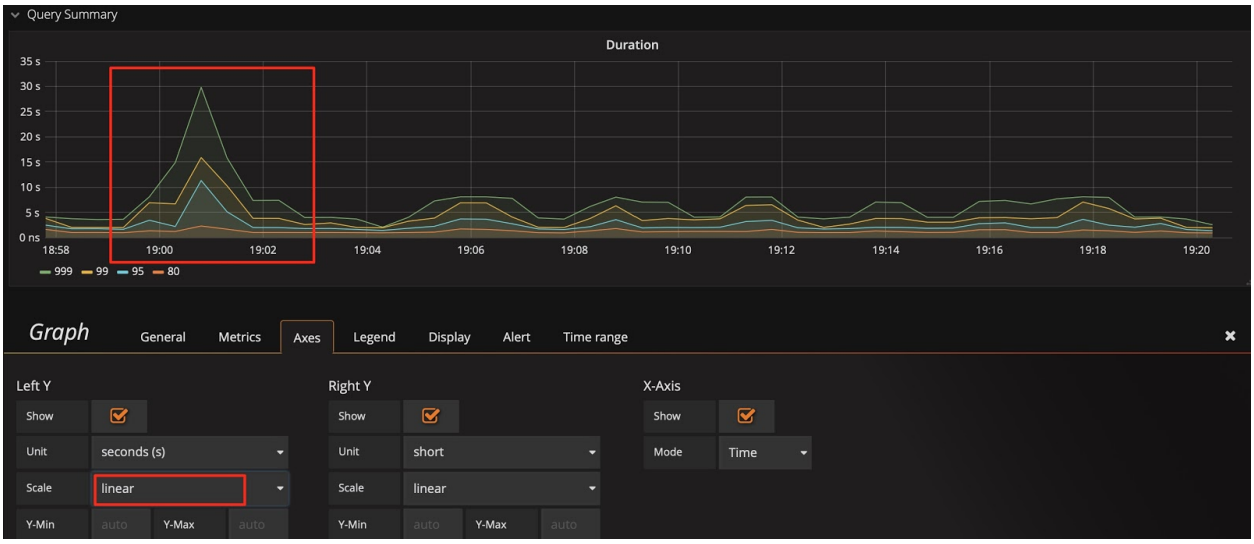

Figure 471: Switch to a linear scale

Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

12.5.6.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from `0` to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to `0`:

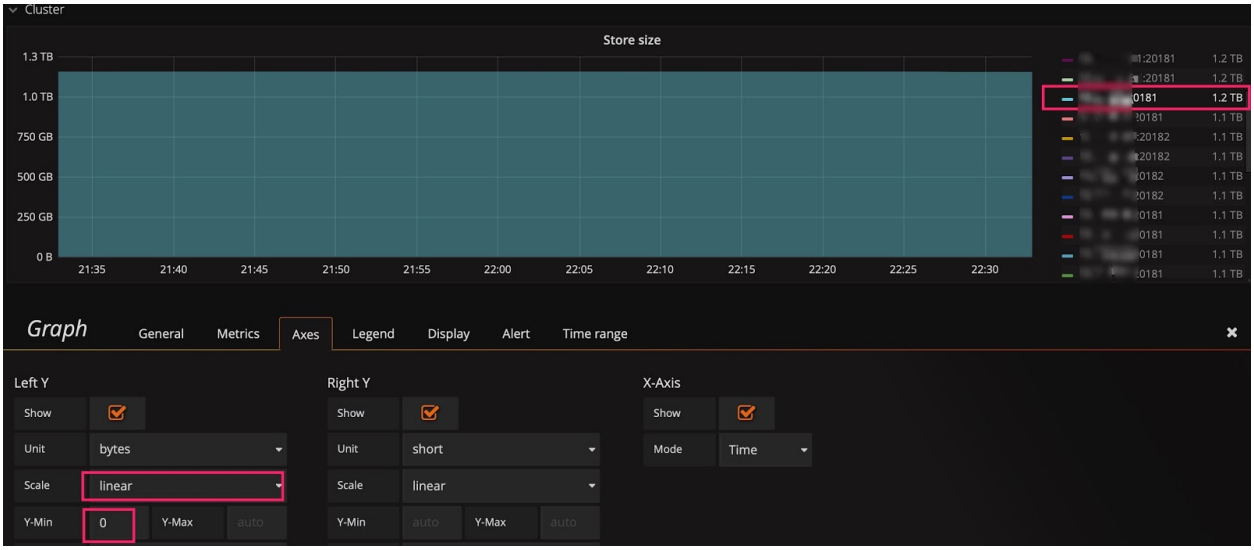

Figure 472: Baseline defaults to 0

Change the baseline to `auto`:

Figure 473: Change the baseline to auto

12.5.6.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

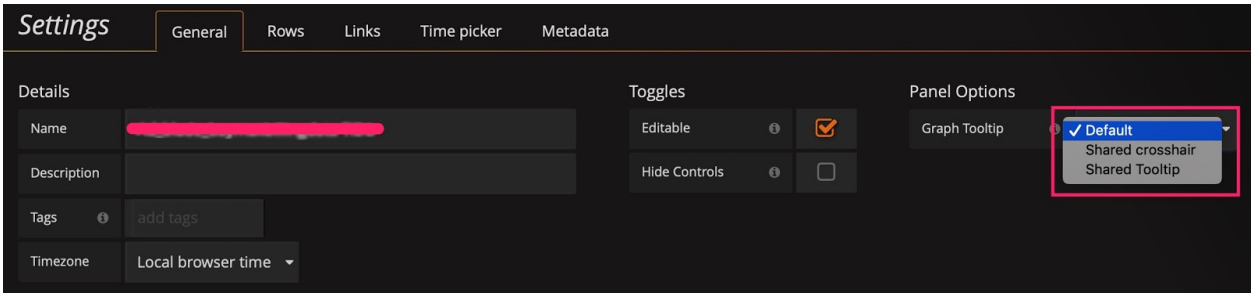

Figure 474: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

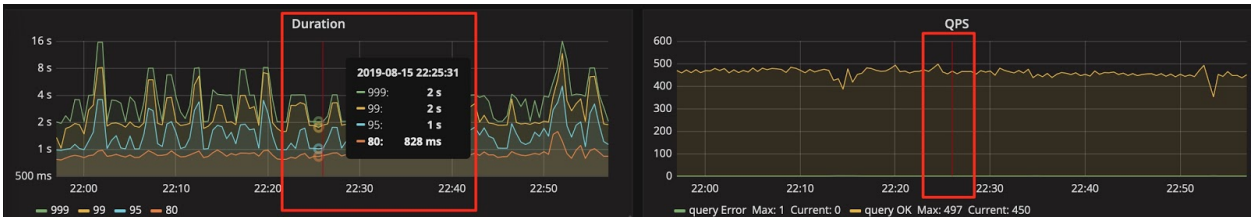

Figure 475: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

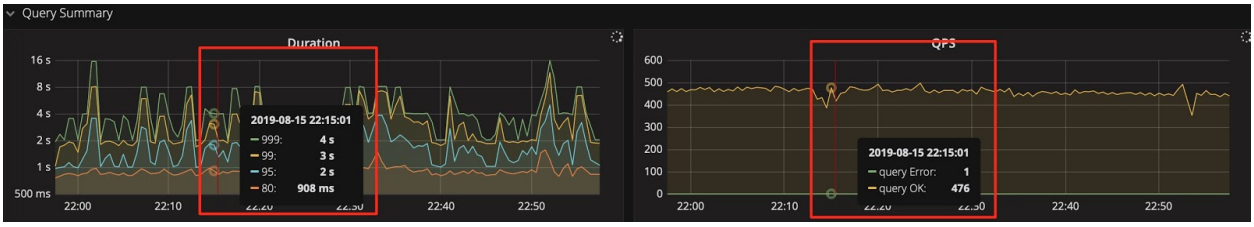

Figure 476: Set the graphic presentation tool to Shared Tooltip

12.5.6.3.5 Tip 5: Enter `IP address:port number` to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the `instance` field, you can manually enter `IP address:2379` to check the data of the leader.

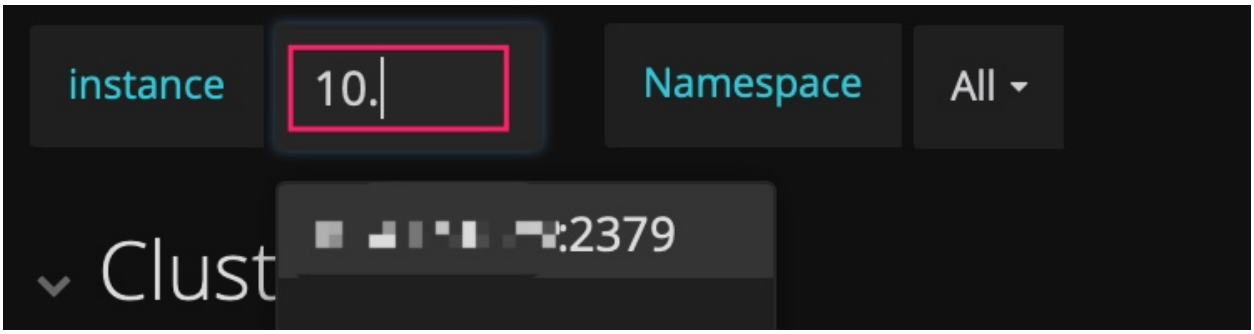

Figure 477: Check the metrics in history

12.5.6.3.6 Tip 6: Use the `Avg` function

Generally, only `Max` and `Current` functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the `Avg` function to the legend to check the overall trend for the duration of time.

Add summary functions such as the `Avg` function:

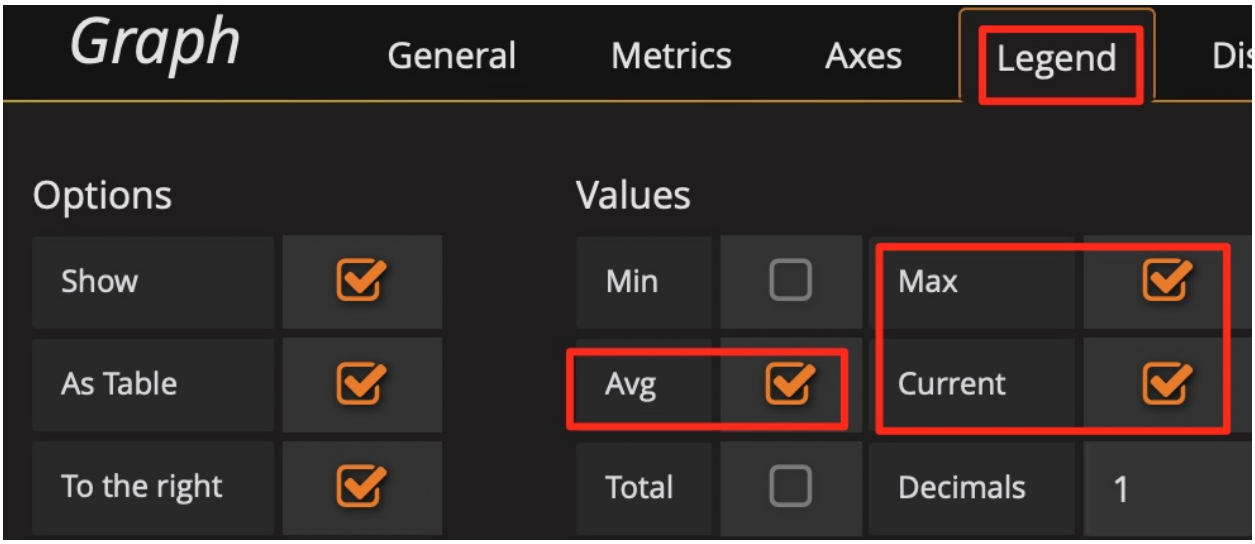

Figure 478: Add summary functions such as Avg

Then check the overall trend:

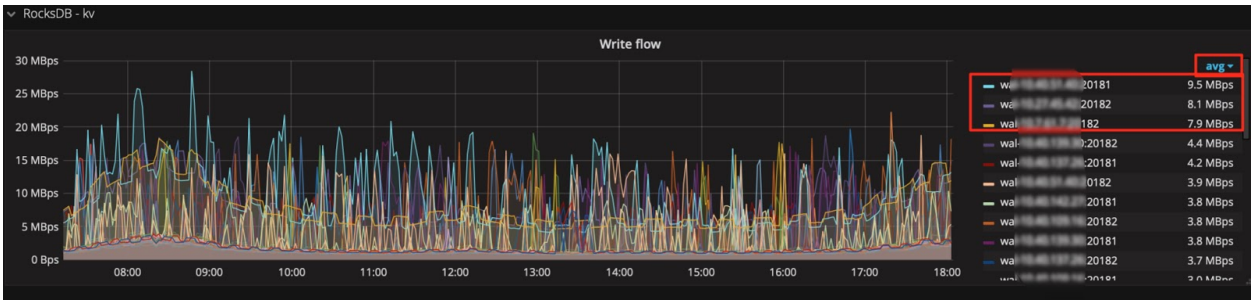

Figure 479: Add Avg function to check the overall trend

12.5.6.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

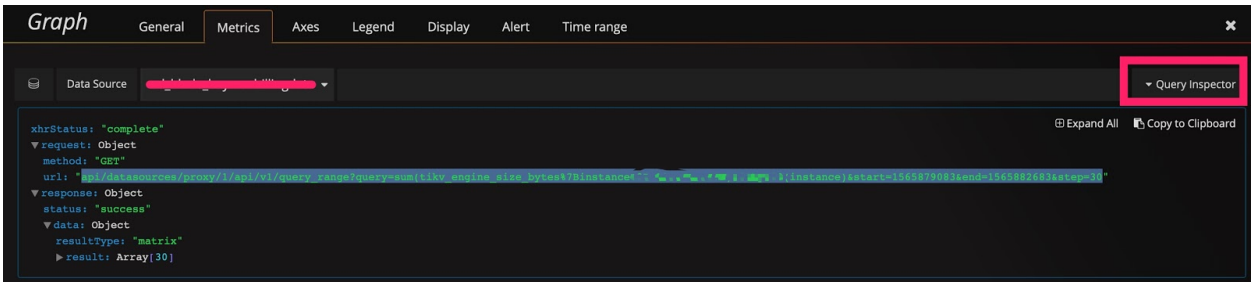

Figure 480: The API of Prometheus

```
curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
    ↪ /query_range?query=sum(tikv_engine_size_bytes%7
    ↪ Binstancexxxxxxxxx20180%22%7D)%20by%20(instance)&start=1565879269&end
    ↪ =1565882869&step=30' |python -m json.tool
```

```
{
    "data": {
```

```
        "result": [
            {
                "metric": {
                    "instance": "xxxxxxxxxx:20180"
                },
                "values": [
                    [
                        1565879269,
                        "1006046235280"
                    ],
                    [
                        1565879299,
                        "1006057877794"
                    ],
                    [
                        1565879329,
                        "1006021550039"
                    ],
                    [
                        1565879359,
                        "1006021550039"
                    ],
                    [
                        1565882869,
                        "1006132630123"
                    ]
                ]
            }
        ],
        "resultType": "matrix"
    },
    "status": "success"
}
```

12.5.6.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

12.5.7 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

> **Note:**
>
> This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

12.5.7.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

12.5.7.1.1 Scheduling process

The scheduling process generally has three steps:

1. Collect information

   Each TiKV node periodically reports two types of heartbeats to PD:

   - `StoreHeartbeat`: Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
   - `RegionHeartbeat`: Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

   PD collects and restores this information for scheduling decisions.

2. Generate operators

   Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

3. Execute operators

   To execute the operators, the general procedure is:

   1. The generated operator first joins a queue managed by `OperatorController`.
   2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
   3. The operator is marked as "finish" or "timeout" and removed from the queue.

12.5.7.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively ("1" by default for both). For example, when the `leader-weight` of a store is set to "2", the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to "0.5", the number of leaders on the node is about half as many as that of other nodes.

12.5.7.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

12.5.7.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient.

12.5.7.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as "offline" using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker` ↪ finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

12.5.7.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (`1h` by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size`. Starting from v8.4.0, the default value is changed from 20 MiB to 54 MiB. The new default value is automatically applied only to newly created clusters. Existing clusters are not affected.
- The number of keys in this Region is smaller than the value of `max-merge-region-keys`. Starting from v8.4.0, the default value is changed from 200000 to 540000. The new default value is automatically applied only to newly created clusters. Existing clusters are not affected.

12.5.7.2 Query scheduling status

You can check the status of scheduling system through metrics, pd-ctl and logs. This section briefly introduces the methods of metrics and pd-ctl. Refer to PD Monitoring Metrics and PD Control for details.

12.5.7.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using pd-ctl with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

12.5.7.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of pd-ctl to query balance status of each store.

12.5.7.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using pd-ctl with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

12.5.7.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using pd-ctl with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

12.5.7.3 Control scheduling strategy

You can use pd-ctl to adjust the scheduling strategy from the following three aspects. Refer to PD Control for more details.

12.5.7.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through pd-ctl. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

12.5.7.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through pd-ctl. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

12.5.7.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in pd-ctl, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

12.5.7.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

12.5.7.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on hot regions scheduling.
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a region merge scheduling.
- Hardware and software environment varies among stores. To control the distribution of leader/region, you can refer to Load balancing and adjust the values of `leader-weight` and `region-weight`.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
    - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
    - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
    - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
    - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit it set to "0".

- Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
- Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

12.5.7.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger values. Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in Leaders/regions are not evenly distributed.
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to "0".
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

12.5.7.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to Leaders/regions are not evenly distributed for troubleshooting.

12.5.7.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

  Solution: adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

  Solutions: Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to TiDB HTTP API for more details.

12.5.7.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to `10ms` (the default value of this configuration item is `10ms` in v5.3.0 and later versions of TiDB). This makes region scanning faster at the cost of more CPU consumption.

- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:

  - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
  - PD: Use PD Control to set the parameters required by your cluster situation.

- Suppose that your cluster has no TiDB instance, and the value of `key-type` is set to `raw` or `txn`. In this case, PD can merge Regions across tables, regardless of the value of `enable-cross-table-merge setting`. You can modify the `key-type` parameter dynamically.

```
config set key-type txn
```

- Suppose that your cluster has a TiDB instance, and the value of `key-type` is set to `table`. In this case, PD can merge Regions across tables only if the value of `enable-cross-table-merge` is set to `true`. You can modify the `key-type` parameter dynamically.

```
config set enable-cross-table-merge true
```

If the modification does not take effect, refer to FAQ - Why the modified `toml` configuration for TiKV/PD does not take effect?.

> **Note:**
> After enabling Placement Rules, properly switch the value of `key-type` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

12.5.7.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

In TiDB v5.2.0, TiKV introduces the mechanism of slow TiKV node detection. By sampling the requests in TiKV, this mechanism works out a score ranging from 1 to 100. A TiKV node with a score higher than or equal to 80 is marked as slow. You can add `evict-slow-store-scheduler` to detect and schedule slow nodes. If only one TiKV is detected as slow, and the slow score reaches the limit (80 by default), the Leader in this node will be evicted (similar to the effect of `evict-leader-scheduler`).

Note:

Leader eviction is accomplished by PD sending scheduling requests to TiKV slow nodes and then TiKV executing the received scheduling requests sequentially. Due to factors such as **slow I/O**, slow nodes might experience request accumulation, causing some Leaders to wait until the delayed requests are processed before handling **Leader eviction** requests. This results in an overall extended time for **Leader eviction**. Therefore, when you enable `evict-slow-store-scheduler`, it is recommended to enable `store-io-pool-size` as well to mitigate this situation.

12.5.8 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of Regions might be created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

12.5.8.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

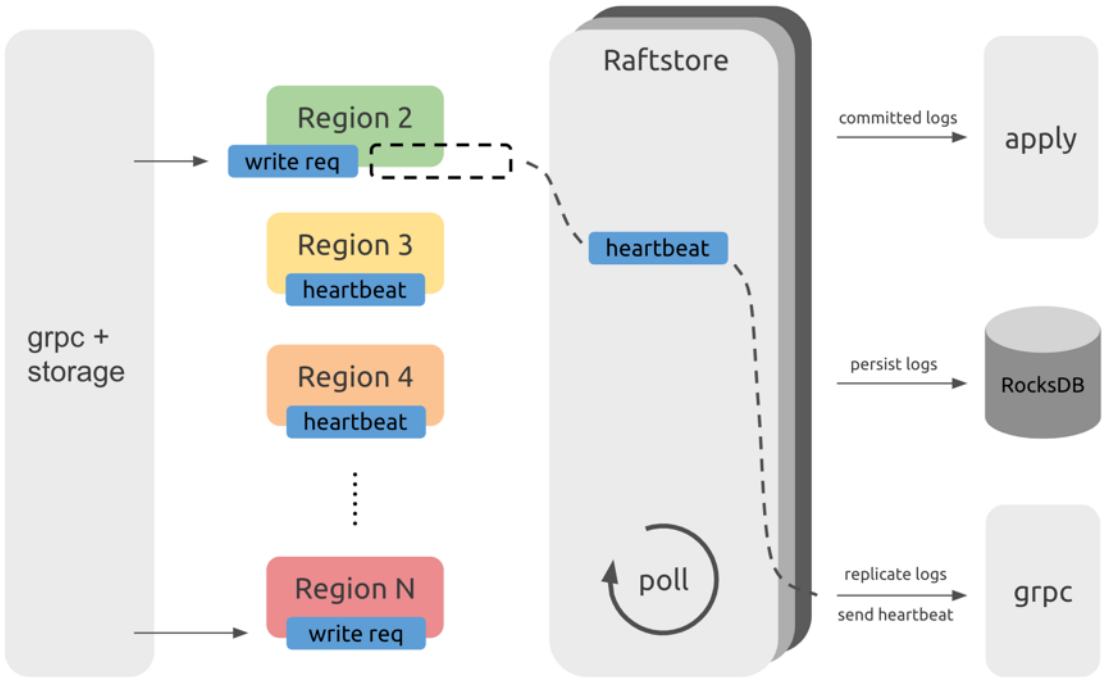

Figure 481: Raftstore Workflow

> **Note:**
>
> This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

12.5.8.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the

Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, `propose wait duration` can be as high as hundreds of milliseconds.

Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

12.5.8.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- `Raft store CPU` in the **Thread-CPU** panel

  Reference value: lower than `raftstore.store-pool-size * 85%`.

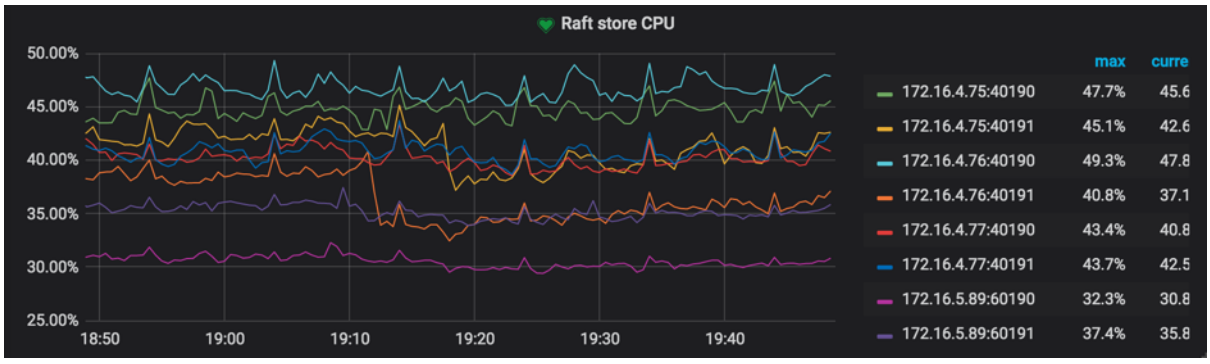

Figure 482: Check Raftstore CPU

- `Propose wait duration` in the **Raft Propose** panel

  `Propose wait duration` is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

  Reference value: lower than 50~100 ms according to the cluster size

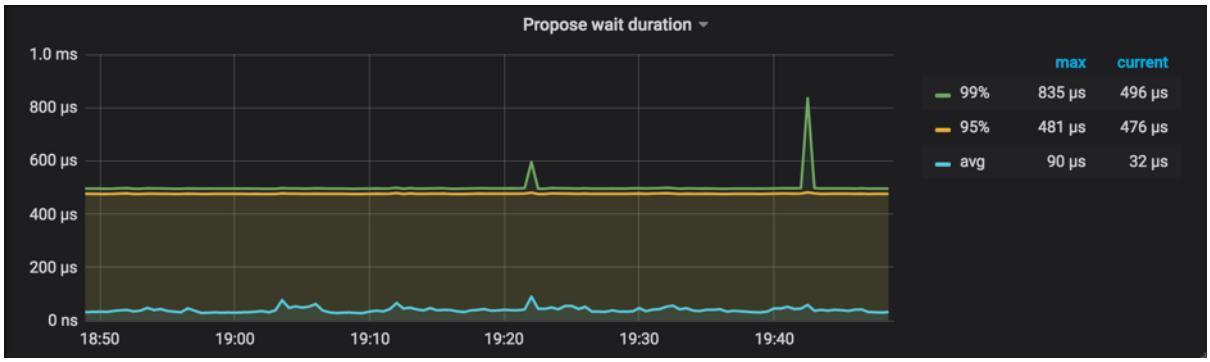

Figure 483: Check Propose wait duration

- `Commit log duration` in the **Raft IO** panel

  `Commit log duration` is the time Raftstore takes to commit Raft logs to the majority of members in the respective Region. The possible reasons for a high value of this metric with significant fluctuations include the following:

  - The workload on Raftstore is heavy.
  - The append log operation is slow.
  - Raft logs cannot be committed timely due to network congestion.

Reference value: lower than 200-500 ms.

```

```

12.5.8.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

12.5.8.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to `2` in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

12.5.8.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore doesn't send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in TiKV master. You can configure this feature according to your needs. For details, refer to Configure Hibernate Region.

12.5.8.3.3 Method 3: Enable `Region Merge`

> **Note:**
>
> `Region Merge` is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling `Region Merge`. Contrary to `Region Split`, `Region Merge` is the process of merging adjacent small Regions through scheduling. After dropping data or executing the `Drop Table` or `Truncate Table` statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable `Region Merge` by configuring the following parameters:

```
config set max-merge-region-size 54
config set max-merge-region-keys 540000
config set merge-schedule-limit 8
```

Refer to Region Merge and the following three configuration parameters in the PD configuration file for more details:

- `max-merge-region-size`
- `max-merge-region-keys`
- `merge-schedule-limit`

The default configuration of the `Region Merge` parameters is rather conservative. You can speed up the `Region Merge` process by referring to the method provided in PD Scheduling Best Practices.

12.5.8.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

12.5.8.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between `election timeout` and `heartbeat`. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
    ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

12.5.8.3.6 Method 6: Adjust Region size

The default size of a Region is 256 MiB, and you can reduce the number of Regions by setting Regions to a larger size. For more information, see Tune Region Performance.

> **Note:**
>
> Starting from v8.4.0, the default Region size is increased from 96 MiB to 256 MiB. If you have not modified the Region size manually, when you upgrade a TiKV cluster to v8.4.0 or later, the TiKV cluster's default Region size will automatically be updated to 256 MiB.

> **Note:**

> Customized Region size is an experimental feature before TiDB v6.5.0. If you need to resize the Region size, it is recommended that you upgrade to v6.5.0 or a later version.

12.5.8.3.7 Method 7: Increase the maximum number of connections for Raft communication

By default, the maximum number of connections used for Raft communication between TiKV nodes is 1. Increasing this number can help alleviate blockage issues caused by heavy communication workloads of a large number of Regions. For detailed instructions, see `grpc-raft-conn-num`.

> **Note:**
>
> To reduce unnecessary thread switching overhead and mitigate potential negative impacts from batch processing, it is recommended to set the number within the range of `[1, 4]`.
