2 About TiDB Self-Managed **42**

2.1 What is TiDB Self-Managed · · · · · 42

2.1.1 Key features · · · · · 42

2.1.2 Use cases · · · · · 43

2.1.3 See also · · · · · 44

2.2 TiDB 8.5.0 Release Notes · · · · · 44

2.2.1 Feature details · · · · · 49

2.2.2 Compatibility changes · · · · · 52

2.2.3 Removed features · · · · · 63

2.2.4 Deprecated features · · · · · 63

2.2.5 Improvements · · · · · 64

2.2.6 Bug fixes · · · · · 65

2.2.7 Performance test · · · · · 70

2.2.8 Contributors · · · · · 70

2.3 TiDB Features · · · · · 70

2.3.1 Data types, functions, and operators · · · · · 71

2.3.2 Indexing and constraints · · · · · 71

2.3.3 SQL statements · · · · · 72

2.3.4 Advanced SQL features · · · · · 73

2.3.5 Data definition language (DDL) 73
2.3.6 Transactions 74
2.3.7 Partitioning 74
2.3.8 Statistics 75
2.3.9 Security 77
2.3.10 Data import and export 77
2.3.11 Management, observability, and tools 80
2.4 MySQL Compatibility 87
2.4.1 Unsupported features 88
2.4.2 Differences from MySQL 88
2.4.3 Differences on pessimistic transaction (lock) with MySQL InnoDB 95
2.5 TiDB Limitations 95
2.5.1 Limitations on identifier length 95
2.5.2 Limitations on the total number of databases, tables, views, and connections 96
2.5.3 Limitations on a single database 96
2.5.4 Limitations on a single table 96
2.5.5 Limitation on a single row 96
2.5.6 Limitations on indexes 96
2.5.7 Limitations on data types 97
2.5.8 Limitations on SQL statements 97
2.5.9 Limitations on TiKV version 97
2.6 Credits 97
2.6.1 TiDB developers 97
2.6.2 Writers and translators for TiDB documentation 98
2.7 Roadmap 98

3 Get Started **98**

3.1 Quick Start with TiDB Self-Managed 98
3.1.1 Deploy a local test cluster 99
3.1.2 Simulate production deployment on a single machine 104
3.1.3 What's next 109

3.2 Quick Start with TiDB HTAP 110
3.2.1 Basic concepts 110
3.2.2 Steps 110
3.2.3 What's next 115
3.3 Explore SQL with TiDB 115
3.3.1 Category 115
3.3.2 Show, create and drop a database 116
3.3.3 Create, show, and drop a table 116
3.3.4 Create, show, and drop an index 117
3.3.5 Insert, update, and delete data 118
3.3.6 Query data 118
3.3.7 Create, authorize, and delete a user 119
3.4 Explore HTAP 119
3.4.1 Use cases 119
3.4.2 Architecture 121
3.4.3 Environment preparation 121
3.4.4 Data preparation 122
3.4.5 Data processing 122
3.4.6 Performance monitoring 122
3.4.7 Troubleshooting 123
3.4.8 What's next 123
3.5 Import Example Database 123
3.5.1 Download all data files 123
3.5.2 Load data into TiDB 124

4 Develop **125**

4.1 Developer Guide Overview 125
4.1.1 TiDB basics 125
4.1.2 TiDB transaction mechanisms 125
4.1.3 The way applications interact with TiDB 126
4.1.4 Read more 126
4.1.5 Need help? 126

4.2 Quick Start · · · · · 126
4.2.1 Build a TiDB Cloud Serverless Cluster · · · · · 126
4.2.2 CRUD SQL in TiDB · · · · · 129
4.3 Example Applications · · · · · 131
4.3.1 Java · · · · · 131
4.3.2 Go · · · · · 156
4.3.3 Python · · · · · 167
4.3.4 Node.js · · · · · 203
4.3.5 Ruby · · · · · 252
4.3.6 C · · · · · 264
4.4 Connect to TiDB · · · · · 267
4.4.1 GUI Database Tools · · · · · 267
4.4.2 Choose Driver or ORM · · · · · 327
4.4.3 Connect to TiDB · · · · · 333
4.4.4 Connection Pools and Connection Parameters · · · · · 336
4.5 Design Database Schema · · · · · 345
4.5.1 TiDB Database Schema Design Overview · · · · · 345
4.5.2 Create a Database · · · · · 347
4.5.3 Create a Table · · · · · 349
4.5.4 Create a Secondary Index · · · · · 361
4.6 Write Data · · · · · 365
4.6.1 Insert Data · · · · · 365
4.6.2 Update Data · · · · · 372
4.6.3 Delete Data · · · · · 383
4.6.4 Periodically Delete Expired Data Using TTL (Time to Live) · · · · · 391
4.6.5 Prepared Statements · · · · · 408
4.7 Read Data · · · · · 413
4.7.1 Query Data from a Single Table · · · · · 413
4.7.2 Multi-table Join Queries · · · · · 420
4.7.3 Subquery · · · · · 427
4.7.4 Paginate Results · · · · · 430
4.7.5 Views · · · · · 437

4.7.6 Temporary Tables · · · · · 440
4.7.7 Common Table Expression · · · · · 446
4.7.8 Read Replica Data · · · · · 451
4.7.9 HTAP Queries · · · · · 465
4.8 Vector Search · · · · · 472
4.8.1 Vector Search Overview · · · · · 472
4.8.2 Get Started · · · · · 475
4.8.3 Integrations · · · · · 484
4.8.4 Improve Vector Search Performance · · · · · 529
4.8.5 Vector Search Limitations · · · · · 530
4.9 Transaction · · · · · 531
4.9.1 Transaction overview · · · · · 531
4.9.2 Optimistic Transactions and Pessimistic Transactions · · · · · 535
4.9.3 Transaction Restraints · · · · · 566
4.9.4 Handle Transaction Errors · · · · · 586
4.10 Optimize · · · · · 589
4.10.1 Overview of Optimizing SQL Performance · · · · · 589
4.10.2 SQL Performance Tuning · · · · · 590
4.10.3 Performance Tuning Best Practices · · · · · 597
4.10.4 Best Practices for Indexing · · · · · 600
4.10.5 Other Optimization Methods · · · · · 603
4.11 Troubleshoot · · · · · 607
4.11.1 SQL or Transaction Issues · · · · · 607
4.11.2 Unstable Result Set · · · · · 608
4.11.3 Timeouts in TiDB · · · · · 614
4.12 Reference · · · · · 617
4.12.1 Bookshop Example Application · · · · · 617
4.12.2 Guidelines · · · · · 623
4.13 Cloud Native Development Environment · · · · · 626
4.13.1 Gitpod · · · · · 626

4.14 Third-Party Support · · · · · 633
4.14.1 Third-Party Tools Supported by TiDB · · · · · 633
4.14.2 Known Incompatibility Issues with Third-Party Tools · · · · · 638
4.14.3 Integrate TiDB with ProxySQL · · · · · 644
4.14.4 Integrate TiDB with Amazon AppFlow · · · · · 663

5 Deploy **681**
5.1 TiDB Software and Hardware Requirements · · · · · 681
5.1.1 OS and platform requirements · · · · · 682
5.1.2 Software requirements · · · · · 685
5.1.3 Server requirements · · · · · 685
5.1.4 Network requirements · · · · · 688
5.1.5 Disk space requirements · · · · · 694
5.1.6 Web browser requirements · · · · · 695
5.1.7 Hardware and software requirements for TiFlash disaggregated storage and compute architecture · · · · · 695
5.2 TiDB Environment and System Configuration Check · · · · · 698
5.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV · · · · · 698
5.2.2 Check and disable system swap · · · · · 700
5.2.3 Set temporary spaces for TiDB instances (Recommended) · · · · · 700
5.2.4 Check the firewall service of target machines · · · · · 701
5.2.5 Check and install the NTP service · · · · · 704
5.2.6 Check and configure the optimal parameters of the operating system · · 706
5.2.7 Manually configure the SSH mutual trust and sudo without password · 713
5.2.8 Install the `numactl` tool · · · · · 714
5.2.9 Disable SELinux · · · · · 715
5.3 Plan Cluster Topology · · · · · 715
5.3.1 Minimal Deployment Topology · · · · · 715
5.3.2 TiFlash Deployment Topology · · · · · 718
5.3.3 PD Microservice Deployment Topology · · · · · 721
5.3.4 TiProxy Deployment Topology · · · · · 724
5.3.5 TiCDC Deployment Topology · · · · · 726

5.3.6 TiSpark Deployment Topology · · · · · 729
5.3.7 Geo-Distributed Deployment Topology · · · · · 733
5.3.8 Hybrid Deployment Topology · · · · · 737
5.4 Deploy a TiDB Cluster Using TiUP · · · · · 742
5.4.1 Step 1. Prerequisites and prechecks · · · · · 742
5.4.2 Step 2. Deploy TiUP on the control machine · · · · · 743
5.4.3 Step 3. Initialize the cluster topology file · · · · · 747
5.4.4 Step 4. Run the deployment command · · · · · 754
5.4.5 Step 5. Check the clusters managed by TiUP · · · · · 756
5.4.6 Step 6. Check the status of the deployed TiDB cluster · · · · · 756
5.4.7 Step 7. Start a TiDB cluster · · · · · 756
5.4.8 Step 8. Verify the running status of the TiDB cluster · · · · · 757
5.4.9 See also · · · · · 757
5.5 Deploy a TiDB Cluster on Kubernetes · · · · · 758
5.6 Check Cluster Status · · · · · 758
5.6.1 Check the TiDB cluster status · · · · · 758
5.6.2 Log in to the database and perform simple operations · · · · · 761
5.7 Test Cluster Performance · · · · · 763
5.7.1 How to Test TiDB Using Sysbench · · · · · 763
5.7.2 How to Run TPC-C Test on TiDB · · · · · 768
5.7.3 How to Run CH-benCHmark Test on TiDB · · · · · 770

6 Migrate **775**

6.1 Data Migration Overview · · · · · 775
6.1.1 Migrate data from Aurora MySQL to TiDB · · · · · 776
6.1.2 Migrate data from MySQL to TiDB · · · · · 776
6.1.3 Migrate and merge MySQL shards into TiDB · · · · · 776
6.1.4 Migrate data from Vitess to TiDB · · · · · 776
6.1.5 Migrate data from files to TiDB · · · · · 776
6.1.6 Incremental replication between TiDB clusters · · · · · 777
6.1.7 More advanced migration solutions · · · · · 777

6.2 TiDB Migration Tools Overview · · · · · 777
6.2.1 TiDB Data Migration (DM) · · · · · 777
6.2.2 TiDB Lightning · · · · · 777
6.2.3 Dumpling · · · · · 778
6.2.4 TiCDC · · · · · 778
6.2.5 Backup & Restore (BR) · · · · · 779
6.2.6 sync-diff-inspector · · · · · 779
6.2.7 Install tools using TiUP · · · · · 779
6.2.8 See also · · · · · 781
6.3 Best Practices for Importing 50 TiB Data · · · · · 781
6.3.1 Key factors · · · · · 782
6.3.2 Prepare source files · · · · · 783
6.3.3 Estimate storage space · · · · · 784
6.3.4 Change configuration parameters · · · · · 784
6.3.5 Resolve the “checksum mismatch” error · · · · · 785
6.3.6 Enable checkpoint · · · · · 785
6.3.7 Best practices for importing a large single table · · · · · 785
6.3.8 Troubleshooting · · · · · 786
6.4 Migration Scenarios · · · · · 787
6.4.1 Migrate Data from Amazon Aurora to TiDB · · · · · 787
6.4.2 Migrate Small Datasets from MySQL to TiDB · · · · · 797
6.4.3 Migrate Large Datasets from MySQL to TiDB · · · · · 802
6.4.4 Migrate and Merge MySQL Shards of Small Datasets to TiDB · · · · · 815
6.4.5 Migrate and Merge MySQL Shards of Large Datasets to TiDB · · · · · 823
6.4.6 Migrate Data from Vitess to TiDB · · · · · 841
6.4.7 Migrate Data from MariaDB to TiDB · · · · · 845
6.4.8 Migrate Data from CSV Files to TiDB · · · · · 854
6.4.9 Migrate Data from SQL Files to TiDB · · · · · 859
6.4.10 Migrate Data from Parquet Files to TiDB · · · · · 861
6.4.11 Migrate from One TiDB Cluster to Another TiDB Cluster · · · · · 865
6.4.12 Migrate Data from TiDB to MySQL-compatible Databases · · · · · 872

6.5 Advanced Migration · · · · · 877
6.5.1 Continuous Replication from Databases that Use gh-ost or pt-osc · · · · · 877
6.5.2 Migrate Data to a Downstream TiDB Table with More Columns · · · · · 879
6.5.3 Filter Binlog Events · · · · · 886
6.5.4 Filter DML Events Using SQL Expressions · · · · · 889

7 Stream Data 891

7.1 TiCDC Overview · · · · · 891
7.1.1 Usage scenarios · · · · · 891
7.1.2 Major features · · · · · 892
7.1.3 TiCDC architecture · · · · · 893
7.1.4 Valid index · · · · · 894
7.1.5 Best practices · · · · · 895
7.1.6 Implementation of processing data changes · · · · · 895
7.1.7 Unsupported scenarios · · · · · 897
7.2 Deploy and Maintain TiCDC · · · · · 897
7.2.1 Software and hardware recommendations · · · · · 898
7.2.2 Deploy a new TiDB cluster that includes TiCDC using TiUP · · · · · 898
7.2.3 Add or scale out TiCDC to an existing TiDB cluster using TiUP · · · · · 899
7.2.4 Delete or scale in TiCDC from an existing TiDB cluster using TiUP · · 900
7.2.5 Upgrade TiCDC using TiUP · · · · · 900
7.2.6 Modify TiCDC cluster configurations using TiUP · · · · · 901
7.2.7 Stop and start TiCDC using TiUP · · · · · 901
7.2.8 Enable TLS for TiCDC · · · · · 901
7.2.9 View TiCDC status using the command-line tool · · · · · 901
7.3 Changefeed · · · · · 902
7.3.1 Changefeed Overview · · · · · 902
7.3.2 Create Changefeeds · · · · · 905
7.3.3 Manage Changefeeds · · · · · 949
7.3.4 Changefeed Log Filters · · · · · 957
7.3.5 Changefeed DDL Replication · · · · · 962
7.3.6 Bidirectional Replication · · · · · 987

7.4 Monitor and Alert · · · · · 992
7.4.1 TiCDC Monitoring Metrics Summary · · · · · 992
7.4.2 TiCDC Monitoring Metrics Details · · · · · 998
7.4.3 TiCDC Alert Rules · · · · · 1005
7.5 Integration Scenarios · · · · · 1009
7.5.1 Data Integration Overview · · · · · 1009
7.5.2 Integrate Data with Confluent Cloud and Snowflake · · · · · 1009
7.5.3 Integrate Data with Apache Kafka and Apache Flink · · · · · 1024
7.5.4 Architecture and Principles of TiCDC · · · · · 1029
7.5.5 TiCDC Data Replication Capabilities · · · · · 1037
7.5.6 TiCDC Server Configurations · · · · · 1038
7.5.7 CLI and Configuration Parameters of TiCDC Changefeeds · · · · · 1044
7.5.8 TiCDC Client Authentication · · · · · 1060
7.5.9 TiCDC Data Integrity Validation for Single-Row Data · · · · · 1063
7.5.10 Upstream and Downstream Clusters Data Validation and Snapshot Read · · · · · 1066
7.5.11 TiCDC Behavior in Splitting UPDATE Events · · · · · 1070
7.5.12 Output Protocols · · · · · 1078
7.5.13 TiCDC OpenAPI v2 · · · · · 1136
7.5.14 TiCDC OpenAPI v1 · · · · · 1165
7.5.15 TiCDC Data Consumption · · · · · 1178
7.5.16 TiCDC Compatibility · · · · · 1195
7.6 Troubleshoot TiCDC · · · · · 1203
7.6.1 TiCDC replication interruptions · · · · · 1203
7.6.2 How do I handle the `Error 1298: Unknown or incorrect time zone: 'UTC'` error when creating the replication task or replicating data to MySQL? · · · · · 1205
7.6.3 How do I handle the incompatibility issue of configuration files caused by TiCDC upgrade? · · · · · 1205
7.6.4 The `start-ts` timestamp of the TiCDC task is quite different from the current time. During the execution of this task, replication is interrupted and an error `[CDC:ErrBufferReachLimit]` occurs. What should I do? · · · · · 1206

7.6.5 When the downstream of a changefeed is a database similar to MySQL and TiCDC executes a time-consuming DDL statement, all other changefeeds are blocked. What should I do? · · · · · 1206

7.6.6 The `[tikv:9006]GC life time is shorter than transaction duration, transaction starts at xx, GC safe point is yy` error is reported when I use TiCDC to create a changefeed. What should I do? · · · · · 1206

7.6.7 When I use TiCDC to replicate messages to Kafka, Kafka returns the `Message was too large` error. Why? · · · · · 1206

7.6.8 How can I find out whether a DDL statement fails to execute in downstream during TiCDC replication? How to resume the replication? · · · · 1207

7.6.9 The `Kafka: client has run out of available brokers to talk to: EOF` error is reported when I use TiCDC to replicate messages to Kafka. What should I do? · · · · · 1208

7.7 TiCDC FAQs · · · · · 1208

7.7.1 How do I choose `start-ts` when creating a task in TiCDC? · · · · · 1208

7.7.2 Why can't some tables be replicated when I create a task in TiCDC? · 1209

7.7.3 How do I view the state of TiCDC replication tasks? · · · · · 1209

7.7.4 How to verify if TiCDC has replicated all updates after upstream stops updating? · · · · · 1210

7.7.5 What is `gc-ttl` in TiCDC? · · · · · 1212

7.7.6 What is the complete behavior of TiCDC garbage collection (GC) safepoint? · · · · · 1213

7.7.7 How to recover a replication task after it fails? · · · · · 1213

7.7.8 How to understand the relationship between the TiCDC time zone and the time zones of the upstream/downstream databases? · · · · · 1213

7.7.9 What is the default behavior of TiCDC if I create a replication task without specifying the configuration file in `--config`? · · · · · 1216

7.7.10 Does TiCDC support outputting data changes in the Canal protocol? · 1216

7.7.11 Why does the latency from TiCDC to Kafka become higher and higher? 1217

7.7.12 When TiCDC replicates data to Kafka, can I control the maximum size of a single message in TiDB? · · · · · 1217

7.7.13 If I modify a row multiple times in a transaction, will TiCDC output multiple row change events? · · · · · 1217

7.7.14 When TiCDC replicates data to Kafka, does a message contain multiple types of data changes? · · · · · 1217

7.7.15 When TiCDC replicates data to Kafka, how do I view the timestamp, table name, and schema name in the output of TiCDC Open Protocol? 1217

7.7.16 When TiCDC replicates data to Kafka, how do I know the timestamp of the data changes in a message? 1218

7.7.17 How does TiCDC Open Protocol represent `null`? 1218

7.7.18 How can I tell if a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event? 1218

7.7.19 How much PD storage does TiCDC use? 1218

7.7.20 Does TiCDC support replicating large transactions? Is there any risk? 1219

7.7.21 Does TiCDC replicate data changes caused by lossy DDL operations to the downstream? 1220

7.7.22 The default value of the time type field is inconsistent when replicating a DDL statement to the downstream MySQL 5.7. What can I do? 1220

7.7.23 Why do `INSERT/UPDATE` statements from the upstream become `REPLACE INTO` after being replicated to the downstream if I set `safe-mode` to `true` when I create a TiCDC replication task? 1221

7.7.24 Why does TiCDC use disks? When does TiCDC write to disks? Does TiCDC use memory buffer to improve replication performance? 1221

7.7.25 Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning physical import mode and BR from upstream? 1222

7.7.26 After a changefeed resumes from pause, its replication latency gets higher and higher and returns to normal only after a few minutes. Why? 1222

7.7.27 How should I deploy TiCDC to replicate data between two TiDB cluster located in different regions? 1222

7.7.28 What is the order of executing DML and DDL statements? 1223

7.7.29 How should I check whether the upstream and downstream data is consistent? 1223

7.7.30 Replication of a single table can only be run on a single TiCDC node. Will it be possible to use multiple TiCDC nodes to replicate data of multiple tables? 1223

7.7.31 Does TiCDC replication get stuck if the upstream has long-running uncommitted transactions? 1223

7.7.32 Why can't I use the `cdc cli` command to operate a TiCDC cluster deployed by TiDB Operator? 1223

7.7.33 Does TiCDC replicate generated columns of DML operations? 1224

7.7.34 How do I resolve frequent `CDC:ErrMySQLDuplicateEntryCDC` errors? 1225

7.8 TiCDC Glossary · · · · · 1225
7.8.1 C · · · · · 1226
7.8.2 O · · · · · 1226
7.8.3 P · · · · · 1226

8 Maintain 1226
8.1 Security · · · · · 1226
8.1.1 Best Practices for TiDB Security Configuration · · · · · 1226
8.1.2 Enable TLS between TiDB Clients and Servers · · · · · 1232
8.1.3 Enable TLS Between TiDB Components · · · · · 1237
8.1.4 Generate Self-Signed Certificates · · · · · 1242
8.1.5 Encryption at Rest · · · · · 1245
8.1.6 Enable Encryption for Disk Spill · · · · · 1259
8.1.7 Log Redaction · · · · · 1259
8.2 Upgrade · · · · · 1261
8.2.1 Upgrade TiDB Using TiUP · · · · · 1261
8.2.2 Use TiDB Operator · · · · · 1271
8.2.3 TiDB Smooth Upgrade · · · · · 1271
8.2.4 Migrate and Upgrade a TiDB Cluster · · · · · 1275
8.2.5 TiFlash Upgrade Guide · · · · · 1284
8.3 Scale · · · · · 1287
8.3.1 Scale a TiDB Cluster Using TiUP · · · · · 1287
8.3.2 Use TiDB Operator · · · · · 1298
8.4 Backup and Restore · · · · · 1298
8.4.1 TiDB Backup & Restore Overview · · · · · 1298
8.4.2 Architecture · · · · · 1313
8.4.3 Use BR · · · · · 1327
8.4.4 BR CLI Manuals · · · · · 1353
8.4.5 References · · · · · 1375
8.5 Cluster Disaster Recovery (DR) · · · · · 1392
8.5.1 Overview of TiDB Disaster Recovery Solutions · · · · · 1392
8.5.2 DR Solution Based on Primary and Secondary Clusters · · · · · 1403
8.5.3 DR Solution Based on Multiple Replicas in a Single Cluster · · · · · 1416
8.5.4 DR Solution Based on BR · · · · · 1421

8.6 Resource Manager · · · · · 1423
8.6.1 Use Resource Control to Achieve Resource Group Limitation and Flow Control · · · · · 1423
8.6.2 Manage Queries That Consume More Resources Than Expected (Runaway Queries) · · · · · 1434
8.6.3 Use Resource Control to Manage Background Tasks · · · · · 1439
8.7 Time Zone Support · · · · · 1442
8.7.1 View time zone settings · · · · · 1442
8.7.2 Set the time zone · · · · · 1442
8.7.3 Functions and data types affected by time zone settings · · · · · 1443
8.7.4 Important considerations for time zone settings · · · · · 1444
8.7.5 See also · · · · · 1444
8.8 Daily Check · · · · · 1444
8.8.1 Key indicators of TiDB Dashboard · · · · · 1445
8.9 Maintain a TiFlash Cluster · · · · · 1451
8.9.1 Check the TiFlash version · · · · · 1451
8.9.2 TiFlash critical logs · · · · · 1451
8.9.3 TiFlash system table · · · · · 1452
8.10 TiUP Common Operations · · · · · 1453
8.10.1 View the cluster list · · · · · 1453
8.10.2 Start the cluster · · · · · 1453
8.10.3 View the cluster status · · · · · 1454
8.10.4 Modify the configuration · · · · · 1454
8.10.5 Replace with a hotfix package · · · · · 1455
8.10.6 Rename the cluster · · · · · 1456
8.10.7 Stop the cluster · · · · · 1457
8.10.8 Clean up cluster data · · · · · 1457
8.10.9 Destroy the cluster · · · · · 1458
8.10.10 Switch from Prometheus to VictoriaMetrics · · · · · 1458
8.11 Modify Configuration Dynamically · · · · · 1461
8.11.1 Common Operations · · · · · 1461

8.12 Online Unsafe Recovery 1559
8.12.1 Feature description 1559
8.12.2 User scenarios 1560
8.12.3 Usage 1560
8.13 Replicate Data Between Primary and Secondary Clusters 1565
8.13.1 Step 1. Set up the environment 1566
8.13.2 Step 2. Migrate full data 1567
8.13.3 Step 3. Migrate incremental data 1570
8.13.4 Step 4. Simulate a disaster in the upstream cluster 1572
8.13.5 Step 5. Use redo log to ensure data consistency 1572
8.13.6 Step 6. Recover the primary cluster and its services 1572

9 Monitor and Alert 1573
9.1 TiDB Monitoring Framework Overview 1573
9.1.1 About Prometheus in TiDB 1573
9.1.2 About Grafana in TiDB 1574
9.1.3 TiDB Dashboard 1576
9.2 TiDB Monitoring API 1576
9.2.1 Use the status interface 1576
9.2.2 Use the metrics interface 1578
9.3 Deploy Monitoring Services for the TiDB Cluster 1578
9.3.1 Deploy Prometheus and Grafana 1579
9.3.2 Configure Grafana 1582
9.3.3 View component metrics 1584
9.4 Upgrade TiDB Cluster Monitoring Services 1585
9.4.1 Upgrade Prometheus 1585
9.4.2 Upgrade Grafana 1587
9.4.3 Upgrade Alertmanager 1588
9.5 TiDB Dashboard 1589
9.5.1 TiDB Dashboard Introduction 1589
9.5.2 Maintain 1592
9.5.3 Access TiDB Dashboard 1609

9.5.14 TiDB Dashboard Resource Manager Page · · · · · 1719
9.5.15 Instance Profiling · · · · · 1723
9.5.16 Session Management and Configuration · · · · · 1735
9.5.17 TiDB Dashboard FAQs · · · · · 1759
9.6 Export Grafana Snapshots · · · · · 1764
9.6.1 Usage · · · · · 1765
9.6.2 FAQs · · · · · 1766
9.7 TiDB Cluster Alert Rules · · · · · 1767
9.7.1 TiDB alert rules · · · · · 1769
9.7.2 PD alert rules · · · · · 1773
9.7.3 TiKV alert rules · · · · · 1779
9.7.4 TiFlash alert rules · · · · · 1788
9.7.5 TiCDC Alert rules · · · · · 1788
9.7.6 Node_exporter host alert rules · · · · · 1788
9.7.7 Blackbox_exporter TCP, ICMP, and HTTP alert rules · · · · · 1791
9.8 TiFlash Alert Rules · · · · · 1795
9.8.1 `TiFlash_schema_error` · · · · · 1796
9.8.2 `TiFlash_schema_apply_duration` · · · · · 1796
9.8.3 `TiFlash_raft_read_index_duration` · · · · · 1796
9.8.4 `TiFlash_raft_wait_index_duration` · · · · · 1797

9.9 Customize Configurations of Monitoring Servers · · · · · 1797
9.9.1 Customize Prometheus configurations · · · · · 1798
9.9.2 Customize Grafana configurations · · · · · 1799
9.9.3 Customize Alertmanager configurations · · · · · 1800
9.10 Monitoring and Alert for Backup and Restore · · · · · 1801
9.10.1 Snapshot backup and restore monitoring · · · · · 1801
9.10.2 Log backup monitoring · · · · · 1801

10 Troubleshoot **1805**
10.1 Issue Summary · · · · · 1805
10.1.1 TiDB Troubleshooting Map · · · · · 1805
10.1.2 TiDB Cluster Troubleshooting Guide · · · · · 1824
10.1.3 Troubleshoot a TiFlash Cluster · · · · · 1827
10.2 Issue Scenarios · · · · · 1834
10.2.1 Slow Queries · · · · · 1834
10.2.2 Troubleshoot TiDB OOM Issues · · · · · 1862
10.2.3 Troubleshoot Hotspot Issues · · · · · 1868
10.2.4 Troubleshoot Increased Read and Write Latency · · · · · 1879
10.2.5 Troubleshoot Write Conflicts in Optimistic Transactions · · · · · 1884
10.2.6 Troubleshoot High Disk I/O Usage in TiDB · · · · · 1888
10.2.7 Troubleshoot Lock Conflicts · · · · · 1891
10.2.8 Troubleshoot Inconsistency Between Data and Indexes · · · · · 1904
10.3 Diagnostic Methods · · · · · 1907
10.3.1 SQL Diagnostics · · · · · 1907
10.3.2 Statement Summary Tables · · · · · 1909
10.3.3 Identify Expensive Queries · · · · · 1922
10.3.4 Use PLAN REPLAYER to Save and Restore the On-Site Information of a Cluster · · · · · 1924
10.3.5 Understanding Stale Read and safe-ts in TiKV · · · · · 1932
10.4 Support Resources · · · · · 1941

11 Performance Tuning **1942**

11.1 Tuning Guide · · · · · 1942

11.1.1 TiDB Performance Tuning Overview · · · · · 1942

11.1.2 Configure TiDB for Optimal Performance · · · · · 1947

11.1.3 Overview · · · · · 1947

11.1.4 Key settings for common workloads · · · · · 1948

11.1.5 Benchmark · · · · · 1965

11.1.6 Edge cases and optimizations · · · · · 1969

11.1.7 A Practical Guide for SQL Tuning · · · · · 1976

11.1.8 Tuning by Metrics · · · · · 2011

11.1.9 TiDB Best Practices on Public Cloud · · · · · 2090

11.2 Configuration Tuning · · · · · 2097

11.2.1 Tune Operating System Performance · · · · · 2097

11.2.2 TiDB Memory Control · · · · · 2102

11.2.3 Tune TiKV Thread Pool Performance · · · · · 2110

11.2.4 Tune TiKV Memory Parameter Performance · · · · · 2114

11.2.5 Follower Read · · · · · 2122

11.2.6 TiKV MVCC In-Memory Engine · · · · · 2125

11.2.7 Tune Region Performance · · · · · 2131

11.2.8 Tune TiFlash Performance · · · · · 2133

11.2.9 Coprocessor Cache · · · · · 2162

11.2.10 Garbage Collection (GC) · · · · · 2164

11.3 SQL Tuning · · · · · 2168

11.3.1 SQL Tuning Overview · · · · · 2168

11.3.2 Understanding the Query Execution Plan · · · · · 2169

11.3.3 SQL Optimization Process · · · · · 2253

11.3.4 Control Execution Plans · · · · · 2402

11.3.5 Index Advisor · · · · · 2479

12 Tutorials **2488**

12.1 Multiple Availability Zones in One Region Deployment · · · · · 2488

12.1.1 Raft protocol · · · · · 2488

12.1.2 Three AZs in one region deployment · · · · · 2489

12.2 Three Availability Zones in Two Regions Deployment 2495
12.2.1 Overview 2495
12.2.2 Deployment architecture 2495
12.2.3 Configuration 2498
12.3 Two Availability Zones in One Region Deployment 2502
12.3.1 Introduction 2502
12.3.2 Deployment architecture 2503
12.3.3 Configuration 2504
12.4 Read Historical Data 2510
12.4.1 Use Stale Read (Recommended) 2510
12.4.2 Read Historical Data Using the System Variable `tidb_snapshot` 2524
12.5 Best Practices 2529
12.5.1 TiDB Best Practices 2529
12.5.2 Best Practices for Optimizing Multi-Column Indexes 2537
12.5.3 Best Practices for Developing Java Applications with TiDB 2545
12.5.4 Best Practices for Using HAProxy in TiDB 2559
12.5.5 Highly Concurrent Write Best Practices 2572
12.5.6 Best Practices for Monitoring TiDB Using Grafana 2584
12.5.7 PD Scheduling Best Practices 2595
12.5.8 Best Practices for TiKV Performance Tuning with Massive Regions 2605
12.5.9 Best Practices for Three-Node Hybrid Deployment 2612
12.5.10 Local Read under Three Data Centers Deployment 2618
12.5.11 UUID Best Practices 2619
12.5.12 Best Practices for Read-Only Storage Nodes 2621
12.5.13 Best Practices for Handling Millions of Tables in SaaS Multi-Tenant Scenarios 2624
12.6 Placement Rules 2627
12.6.1 Rule system 2628
12.6.2 Configure rules 2630
12.6.3 Typical usage scenarios 2635

12.7 Load Base Split 2638
12.7.1 Scenarios 2638
12.7.2 Implementation principles 2639
12.7.3 Usage 2639
12.8 Store Limit 2640
12.8.1 Implementation principles 2641
12.8.2 Usage 2641
12.9 Execution Principles and Best Practices of DDL Statements 2643
12.9.1 DDL execution principles 2643
12.9.2 Best practices 2648
12.9.3 DDL-related commands 2649
12.9.4 DDL-related tables 2650
12.9.5 Common questions 2650
12.10 Batch Processing 2650
12.10.1 Data import 2651
12.10.2 Data inserts, updates, and deletions 2651
12.11 Use PD Microservices 2653
12.11.1 PD Microservices 2653
12.11.2 Scale PD Microservices Nodes Using TiUP 2656
12.11.3 TSO Configuration File 2663
12.11.4 TSO Configuration Flags 2666
12.11.5 Scheduling Configuration File 2668
12.11.6 Scheduling Configuration Flags 2672

13 TiDB Tools 2674

13.1 TiDB Tools Overview 2674
13.1.1 Deployment and operation Tools 2674
13.1.2 Data management tools 2675
13.1.3 OLAP Query tool - TiSpark 2678

13.2 TiDB Tools Use Cases · · · · · 2678
13.2.1 Deploy and operate TiDB on physical or virtual machines · · · · · 2678
13.2.2 Deploy and operate TiDB on Kubernetes · · · · · 2678
13.2.3 Import data from CSV to TiDB · · · · · 2678
13.2.4 Import full data from MySQL/Aurora · · · · · 2678
13.2.5 Migrate data from MySQL/Aurora · · · · · 2678
13.2.6 Back up and restore TiDB cluster · · · · · 2679
13.2.7 Migrate data to TiDB · · · · · 2679
13.2.8 TiDB incremental data subscription · · · · · 2679
13.3 Download TiDB Tools · · · · · 2679
13.3.1 Environment requirements · · · · · 2679
13.3.2 Download link · · · · · 2680

15 FAQs **5478**
15.1 TiDB FAQ Summary · · · · · 5478
15.2 TiDB Architecture FAQs · · · · · 5479
15.2.1 TiDB introduction and architecture · · · · · 5479
15.2.2 TiDB techniques · · · · · 5482
15.3 SQL FAQs · · · · · 5483
15.3.1 Does TiDB support the secondary key? · · · · · 5483
15.3.2 How does TiDB perform when executing DDL operations on a large table? · · · · · 5483
15.3.3 How to choose the right query plan? Do I need to use hints? Or can I use hints? · · · · · 5483
15.3.4 How to prevent the execution of a particular SQL statement? · · · · · 5484
15.3.5 What are the MySQL variables that TiDB is compatible with? · · · · · 5484
15.3.6 The order of results is different from MySQL when `ORDER BY` is omitted 5484
15.3.7 Does TiDB support `SELECT FOR UPDATE`? · · · · · 5486
15.3.8 Can the codec of TiDB guarantee that the UTF-8 string is memcomparable? Is there any coding suggestion if our key needs to support UTF-8? · · · · · 5486
15.3.9 What is the maximum number of statements in a transaction? · · · · · 5486
15.3.10 Why does the auto-increment ID of the later inserted data is smaller than that of the earlier inserted data in TiDB? · · · · · 5486
15.3.11 How do I modify the `sql_mode` in TiDB? · · · · · 5487
15.3.12 Error: `java.sql.BatchUpdateException:statement count 5001 exceeds the transaction limitation` while using Sqoop to write data into TiDB in batches · · · · · 5487

15.3.13 Does TiDB have a function like the Flashback Query in Oracle? Does it support DDL? · · · 5487
15.3.14 Does TiDB release space immediately after deleting data? · · · 5488
15.3.15 Why does the query speed get slow after data is deleted? · · · 5488
15.3.16 What should I do if it is slow to reclaim storage space after deleting data? · · · 5488
15.3.17 Does `SHOW PROCESSLIST` display the system process ID? · · · 5488
15.3.18 How to control or change the execution priority of SQL commits? · · · 5488
15.3.19 What's the trigger strategy for `auto analyze` in TiDB? · · · 5489
15.3.20 Can I use optimizer hints to override the optimizer behavior? · · · 5490
15.3.21 DDL Execution · · · 5490
15.3.22 Collation used in JDBC connections · · · 5495
15.3.23 SQL optimization · · · 5497
15.3.24 Database optimization · · · 5499
15.4 TiDB Deployment FAQs · · · 5499
15.4.1 Software and hardware requirements · · · 5500
15.4.2 Installation and deployment · · · 5500
15.4.3 What public cloud vendors are currently supported by TiDB? · · · 5502
15.5 Migration FAQs · · · 5502
15.5.1 Full data export and import · · · 5503
15.5.2 Migrate the data online · · · 5505
15.5.3 Migrate the traffic · · · 5505
15.6 Upgrade and After Upgrade FAQs · · · 5507
15.6.1 Upgrade FAQs · · · 5508
15.6.2 After upgrade FAQs · · · 5508
15.7 TiDB Monitoring FAQs · · · 5514
15.7.1 Is there a better way of monitoring the key metrics? · · · 5514
15.7.2 The Prometheus monitoring data is deleted every 15 days by default. Could I set it to two months or delete the monitoring data manually? · 5514
15.7.3 Region Health monitor · · · 5515
15.7.4 What is the meaning of `selectsimplefull` in Statement Count monitor? · · · 5515
15.7.5 What is the difference between `QPS` and `Statement OPS` in the monitor? 5515

15.8 TiDB Cluster Management FAQs · · · · · 5515
15.8.1 Daily management · · · · · 5515
15.8.2 PD management · · · · · 5519
15.8.3 TiDB server management · · · · · 5521
15.8.4 TiKV server management · · · · · 5524
15.8.5 TiDB testing · · · · · 5529
15.8.6 Backup and restoration · · · · · 5530
15.9 High Availability FAQs · · · · · 5531
15.9.1 How is TiDB strongly consistent? · · · · · 5531
15.9.2 What's the recommended solution for the deployment of three geo-distributed data centers? · · · · · 5531
15.10 High Reliability FAQs · · · · · 5531
15.10.1 Does TiDB support data encryption? · · · · · 5531
15.10.2 Does TiDB support modifying the MySQL version string of the server to a specific one that is required by the security vulnerability scanning tool? · · · · · 5531
15.10.3 What authentication protocols does TiDB support? What's the process? · · · · · 5532
15.10.4 How to modify the user password and privilege? · · · · · 5532
15.11 Backup & Restore FAQs · · · · · 5532
15.11.1 What should I do to quickly recover data after mistakenly deleting or updating data? · · · · · 5532
15.11.2 In TiDB v5.4.0 and later versions, when backup tasks are performed on the cluster under a heavy workload, why does the speed of backup tasks become slow? · · · · · 5533
15.11.3 PITR issues · · · · · 5533
15.11.4 After restoring a downstream cluster using the `br restore point` command, data cannot be accessed from TiFlash. What should I do? · 5534
15.11.5 Feature compatibility issues · · · · · 5536
15.11.6 Data restore issues · · · · · 5537
15.11.7 Other things you may want to know about backup and restore · · · · · 5541
15.11.8 If the recovery process is interrupted, is it necessary to delete the already recovered data and start the recovery again? · · · · · 5542
15.11.9 After the recovery is complete, can I delete a specific table and then recover it again? · · · · · 5543

2 About TiDB Self-Managed

2.1 What is TiDB Self-Managed

TiDB (/'ta di bi:/, "Ti" stands for Titanium) is an open-source distributed SQL database that supports Hybrid Transactional and Analytical Processing (HTAP) workloads. It is MySQL compatible and features horizontal scalability, strong consistency, and high availability. The goal of TiDB is to provide users with a one-stop database solution that covers OLTP (Online Transactional Processing), OLAP (Online Analytical Processing), and HTAP services. TiDB is suitable for various use cases that require high availability and strong consistency with large-scale data.

TiDB Self-Managed is a product option of TiDB, where users or organizations can deploy and manage TiDB on their own infrastructure with complete flexibility. With TiDB Self-Managed, you can enjoy the power of open source, distributed SQL while retaining full control over your environment.

The following video introduces key features of TiDB.

2.1.1 Key features

- **Easy horizontal scaling**

  The TiDB architecture design separates computing from storage, letting you scale out or scale in the computing or storage capacity online as needed. The scaling process is transparent to application operations and maintenance staff.

- **Financial-grade high availability**

  Data is stored in multiple replicas, and the Multi-Raft protocol is used to obtain the transaction log. A transaction can only be committed when data has been successfully written into the majority of replicas. This guarantees strong consistency and availability when a minority of replicas go down. You can configure the geographic location and number of replicas as needed to meet different disaster tolerance levels.

- **Real-time HTAP**

  TiDB provides two storage engines: TiKV, a row-based storage engine, and TiFlash, a columnar storage engine. TiFlash uses the Multi-Raft Learner protocol to replicate data from TiKV in real time, ensuring consistent data between the TiKV row-based storage engine and the TiFlash columnar storage engine. TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.

- **Cloud-native distributed database**

TiDB is a distributed database designed for the cloud, providing flexible scalability, reliability, and security on the cloud platform. Users can elastically scale TiDB to meet the requirements of their changing workloads. In TiDB, each piece of data has at least 3 replicas, which can be scheduled in different cloud availability zones to tolerate the outage of a whole data center. TiDB Operator helps manage TiDB on Kubernetes and automates tasks related to operating the TiDB cluster, making TiDB easier to deploy on any cloud that provides managed Kubernetes. TiDB Cloud, the fully-managed TiDB service, is the easiest, most economical, and most resilient way to unlock the full power of TiDB in the cloud, allowing you to deploy and run TiDB clusters with just a few clicks.

- **Compatible with the MySQL protocol and MySQL ecosystem**

  TiDB is compatible with the MySQL protocol, common features of MySQL, and the MySQL ecosystem. To migrate applications to TiDB, you do not need to change a single line of code in many cases, or only need to modify a small amount of code. In addition, TiDB provides a series of data migration tools to help easily migrate application data into TiDB.

2.1.2 Use cases

- **Financial industry scenarios**

  TiDB is ideal for financial industry scenarios with high requirements for data consistency, reliability, availability, scalability, and disaster tolerance. Traditional solutions are costly and inefficient, with low resource utilization and high maintenance costs. TiDB uses multiple replicas and the Multi-Raft protocol to schedule data to different data centers, racks, and machines, ensuring system RTO 30 seconds and RPO = 0.

- **Massive data and high concurrency scenarios**

  Traditional standalone databases cannot meet the data capacity requirements of rapidly growing applications. TiDB is a cost-effective solution that adopts a separate computing and storage architecture, enabling easy scaling of computing or storage capacity separately. The computing layer supports a maximum of 512 nodes, each node supports a maximum of 1,000 concurrencies, and the maximum cluster capacity is at the PB (petabytes) level.

- **Real-time HTAP scenarios**

  TiDB is ideal for scenarios with massive data and high concurrency that require real-time processing. TiDB introduces the TiFlash columnar storage engine in v4.0, which combines with the TiKV row-based storage engine to build TiDB as a true HTAP database. With a small amount of extra storage cost, you can handle both online transactional processing and real-time data analysis in the same system, which greatly saves cost.

- **Data aggregation and secondary processing scenarios**

TiDB is suitable for companies that need to aggregate scattered data into the same system and execute secondary processing to generate a T+0 or T+1 report. Compared with Hadoop, TiDB is much simpler. You can replicate data into TiDB using ETL (Extract, Transform, Load) tools or data migration tools provided by TiDB. Reports can be directly generated using SQL statements.

2.2 TiDB 8.5.0 Release Notes

Release date: December 19, 2024

TiDB version: 8.5.0

Quick access: Quick start | Production deployment

TiDB 8.5.0 is a Long-Term Support Release (LTS).

Compared with the previous LTS 8.1.0, 8.5.0 includes new features, improvements, and bug fixes released in 8.2.0-DMR, 8.3.0-DMR, and 8.4.0-DMR. When you upgrade from 8.1.x to 8.5.0, you can download the TiDB Release Notes PDF to view all release notes between the two LTS versions. The following table lists some highlights from 8.1.0 to 8.5.0:

```
<th>Category</th>
<th>Feature/Enhancement</th>
<th>Description</th>
```

```
<td rowspan="7">Scalability and Performance</td>
<td>Reduce data processing latency in multiple dimensions</td>
<td>TiDB continuously refines data processing to improve performance,
   ↪ effectively meeting the low-latency SQL processing requirements in
   ↪ financial scenarios. Key updates include:
<li>Support <a href="https://docs.pingcap.com/tidb/v8.5/system-variables#
   ↪ tidb_executor_concurrency-new-in-v50">parallel sorting</a> (
   ↪ introduced in v8.2.0) </li>
<li>Optimize <a href="https://docs.pingcap.com/tidb/v8.5/tidb-configuration-
   ↪ file#batch-policy-new-in-v830">batch processing strategy for KV (key-
   ↪ value) requests </a> (introduced in v8.3.0) </li>
<li>Support <a href="https://docs.pingcap.com/tidb/v8.5/system-variables#
   ↪ tidb_tso_client_rpc_mode-new-in-v840">parallel mode for TSO requests
   ↪ </a> (introduced in v8.4.0) </li>
```

```
<li>Reduce the resource overhead of <a href="https://docs.pingcap.com/tidb/
    ↪ v8.5/sql-statement-delete">DELETE</a> operations (introduced in v8
    ↪ .4.0) </li>
<li>Improve query performance for <a href="https://docs.pingcap.com/tidb/v8
    ↪ .5/cached-tables">cached tables</a> (introduced in v8.4.0) </li>
<li>Introduce <a href="https://docs.pingcap.com/tidb/v8.5/system-variables#
    ↪ tidb_hash_join_version-new-in-v840">an optimized version of Hash Join
    ↪ </a> (experimental, introduced in v8.4.0) </li>
</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/tikv-in-memory-engine">TiKV
    ↪ MVCC In-Memory Engine (IME)</a> (introduced in v8.5.0)</td>
<td>The TiKV MVCC in-memory engine caches the most recent MVCC versions of
    ↪ data in memory, helping TiKV quickly skip older versions and retrieve
    ↪  the latest data. This feature can significantly improve data scan
    ↪ performance in scenarios where data records are frequently updated or
    ↪  historical versions are retained for a longer period.</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/tune-region-performance#use-
    ↪ the-active-pd-follower-feature-to-enhance-the-scalability-of-pds-
    ↪ region-information-query-service">Use Active PD Followers to enhance
    ↪ PD's Region information query service</a> (GA in v8.5.0)</td>
<td>TiDB v7.6.0 introduces an experimental feature "Active PD Follower",
    ↪ which allows PD followers to provide Region information query
    ↪ services. This feature improves the capability of the PD cluster to
    ↪ handle <code>GetRegion</code> and <code>ScanRegions</code> requests
    ↪ in clusters with a large number of TiDB nodes and Regions, thereby
    ↪ reducing the CPU pressure on PD leaders. In v8.5.0, this feature
    ↪ becomes generally available (GA).</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/system-variables#tidb_enable
    ↪ _instance_plan_cache-new-in-v840">Instance-level execution plan cache
    ↪ </a> (experimental, introduced in v8.4.0) </td>
<td>Instance-level plan cache allows all sessions within the same TiDB
    ↪ instance to share the plan cache. Compared with session-level plan
    ↪ cache, this feature reduces SQL compilation time by caching more
    ↪ execution plans in memory, decreasing overall SQL execution time. It
    ↪ improves OLTP performance and throughput while providing better
    ↪ control over memory usage and enhancing database stability.</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/partitioned-table#global-
    ↪ indexes">Global indexes for partitioned tables</a> (GA in v8.4.0)</td
    ↪ >
<td>Global indexes can effectively improve the efficiency of retrieving non-
    ↪ partitioned columns, and remove the restriction that a unique key
```

```
    ↪ must contain the partition key. This feature extends the usage
    ↪ scenarios of TiDB partitioned tables, improves the performance of
    ↪ partitioned tables, and reduces resource consumption in certain query
    ↪  scenarios.</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/system-variables#tidb_opt_
    ↪ projection_push_down-new-in-v610">Default pushdown of the <code>
    ↪ Projection</code> operator to the storage engine</a> (introduced in
    ↪ v8.3.0) </td>
<td>Pushing the <code>Projection</code> operator down to the storage engine
    ↪ can distribute the load across storage nodes while reducing data
    ↪ transfer between nodes. This optimization helps to reduce the
    ↪ execution time for certain SQL queries and improves the overall
    ↪ database performance.</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/statistics#collect-
    ↪ statistics-on-some-columns">Ignoring unnecessary columns when
    ↪ collecting statistics</a> (introduced in v8.3.0) </td>
<td>Under the premise of ensuring that the optimizer can obtain the
    ↪ necessary information, TiDB speeds up statistics collection, improves
    ↪  the timeliness of statistics, and thus ensures that the optimal
    ↪ execution plan is selected, improving the performance of the cluster.
    ↪  Meanwhile, TiDB also reduces the system overhead and improves the
    ↪ resource utilization.</td>
```

```
<td rowspan="5">Reliability and availability</td>
<td>Improve the stability of large-scale clusters</td>
<td>Companies that use TiDB to run multi-tenant or SaaS applications often
    ↪ need to store a large number of tables. In v8.5.0, TiDB significantly
    ↪  enhances the stability of large-scale clusters.
<li><a href="https://docs.pingcap.com/tidb/v8.5/schema-cache">Schema cache
    ↪ control</a> and <a href="https://docs.pingcap.com/tidb/v8.5/system-
    ↪ variables#tidb_stats_cache_mem_quota-new-in-v610">setting the memory
    ↪ quota for the TiDB statistics cache</a> are generally available (GA),
    ↪  reducing stability issues caused by excessive memory consumption. </
    ↪ li>
<li>PD introduces <a href="https://docs.pingcap.com/tidb/v8.5/tune-region-
    ↪ performance#use-the-active-pd-follower-feature-to-enhance-the-
    ↪ scalability-of-pds-region-information-query-service">Active Follower
    ↪ </a> to handle the pressure brought by numerous Regions, gradually <a
    ↪  href="https://docs.pingcap.com/tidb/v8.5/pd-microservices">decouples
    ↪  the services handled by PD</a> for independent deployment. </li>
<li>PD improves the performance of Region heartbeat processing and supports
    ↪ tens of millions of Regions for a single cluster.</li>
```

```
<li>You can <a href="https://docs.pingcap.com/tidb/v8.5/system-variables#
    ↪ tidb_auto_analyze_concurrency-new-in-v840">increase concurrency</a>
    ↪ and <a href="https://docs.pingcap.com/tidb/v8.5/statistics#collect-
    ↪ statistics-on-some-columns">reduce the number of collected objects</a
    ↪ > to improve the efficiency of statistics collection and loading,
    ↪ ensuring the stability of execution plans in large clusters.</li>
</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/tidb-resource-control-
    ↪ runaway-queries#query_limit-parameters">Support more triggers for
    ↪ runaway queries, and support switching resource groups</a> (
    ↪ introduced in v8.4.0) </td>
<td>Runaway Queries offer an effective way to mitigate the impact of
    ↪ unexpected SQL performance issues on systems. TiDB v8.4.0 introduces
    ↪ the number of keys processed by the Coprocessor (<code>PROCESSED_KEYS
    ↪ </code>) and request units (<code>RU</code>) as identifying
    ↪ conditions, and puts identified queries into the specified resource
    ↪ group for more precise identification and control of runaway queries
    ↪ .</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/tidb-resource-control-
    ↪ background-tasks#background-parameters">Support setting the maximum
    ↪ limit on resource usage for background tasks of resource control</a>
    ↪ (experimental, introduced in v8.4.0) </td>
<td>By setting a maximum percentage limit on background tasks of resource
    ↪ control, you can control their resource consumption based on the
    ↪ needs of different application systems. This keeps background task
    ↪ consumption at a low level and ensures the quality of online services
    ↪ .</td>
```

```
<td>Enhance and expand TiProxy use cases</td>
<td>As a crucial component of the high availability of TiDB, <a href="https
    ↪ ://docs.pingcap.com/tidb/v8.5/tiproxy-overview">TiProxy</a> extends
    ↪ its capabilities beyond SQL traffic access and forwarding to support
    ↪ cluster change evaluation. Key features include:
<li><a href="https://docs.pingcap.com/tidb/v8.5/tiproxy-traffic-replay">
    ↪ TiProxy supports traffic capture and replay</a> (experimental,
    ↪ introduced in v8.4.0)</li>
<li><a href="https://docs.pingcap.com/tidb/v8.5/tiproxy-overview">TiProxy
    ↪ supports built-in virtual IP management</a> (introduced in v8.3.0)</
    ↪ li>
<li><a href="https://docs.pingcap.com/tidb/v8.5/tiproxy-load-balance">
    ↪ TiProxy supports multiple load balancing policies</a> (introduced in
    ↪ v8.2.0)</li>
</td>
```

```
<td><a href="https://docs.pingcap.com/tidb/v8.5/system-variables#tidb_enable
   ↪ _parallel_hashagg_spill-new-in-v800">The parallel HashAgg algorithm
   ↪ of TiDB supports disk spill</a> (GA in v8.2.0) </td>
<td>HashAgg is a widely used aggregation operator in TiDB for efficiently
   ↪ aggregating rows with the same field values. TiDB v8.0.0 introduces
   ↪ parallel HashAgg as an experimental feature to further enhance
   ↪ processing speed. When memory resources are insufficient, parallel
   ↪ HashAgg spills temporary sorted data to disk, avoiding potential OOM
   ↪ risks caused by excessive memory usage. This improves query
   ↪ performance while maintaining node stability. In v8.2.0, this feature
   ↪  becomes generally available (GA) and is enabled by default, enabling
   ↪  you to safely configure the concurrency of parallel HashAgg using <
   ↪ code>tidb_executor_concurrency</code>.</td>
```

```
<td rowspan="2"> SQL </td>
<td><a href="https://docs.pingcap.com/tidb/v8.5/foreign-key">Foreign key</a>
   ↪  (GA in v8.5.0)</td>
<td>Foreign keys are constraints in a database that establish relationships
   ↪ between tables, ensuring data consistency and integrity. They ensure
   ↪ that the data referenced in a child table exist in the parent table,
   ↪ preventing the insertion of invalid data. Foreign keys also support
   ↪ cascading operations (such as automatic synchronization during
   ↪ deletion or update), simplifying business logic implementation and
   ↪ reducing the complexity of manually maintaining data relationships.</
   ↪ td>
```

```

2.2.1 Feature details

2.2.1.1 Scalability

- Setting the memory limit for schema cache is now generally available (GA). When the number of tables reaches hundreds of thousands or even millions, this feature significantly reduces the memory usage of schema metadata #50959 @tiancaiamao @wjhuang2016 @gmhdbjd @tangenta

  In some SaaS scenarios, where the number of tables reaches hundreds of thousands or even millions, schema metadata can consume a significant amount of memory. With this feature enabled, TiDB uses the Least Recently Used (LRU) algorithm to cache and evict the corresponding schema metadata, effectively reducing memory usage.

Starting from v8.4.0, this feature is enabled by default with a default value of `536870912` (that is, 512 MiB). You can adjust it as needed using the variable `tidb_schema_cache_size`.

For more information, see documentation.

- Provide the Active PD Follower feature to enhance the scalability of PD's Region information query service (GA) #7431 @okJiang

  In a TiDB cluster with a large number of Regions, the PD leader might experience high CPU load due to the increased overhead of handling heartbeats and scheduling tasks. If the cluster has many TiDB instances, and there is a high concurrency of requests for Region information, the CPU pressure on the PD leader increases further and might cause PD services to become unavailable.

  To ensure high availability, TiDB v7.6.0 introduces Active PD Follower as an experimental feature to enhance the scalability of PD's Region information query service. In v8.5.0, this feature becomes generally available (GA). You can enable the Active PD Follower feature by setting the system variable `pd_enable_follower_handle_region` ↪ to `ON`. After this feature is enabled, TiDB evenly distributes Region information requests to all PD servers, and PD followers can also handle Region requests, thereby reducing the CPU pressure on the PD leader.

  For more information, see documentation.

2.2.1.2 Performance

- TiDB accelerated table creation becomes generally available (GA), significantly reducing data migration and cluster initialization time #50052 @D3Hunter @gmhdbjd

  TiDB v7.6.0 introduces accelerated table creation as an experimental feature, controlled by the system variable `tidb_ddl_version`. Staring from v8.0.0, this system variable is renamed to `tidb_enable_fast_create_table`.

  In v8.5.0, TiDB accelerated table creation becomes generally available (GA) and is enabled by default. During data migration and cluster initialization, this feature supports rapid creation of millions of tables, significantly reducing operation time.

  For more information, see documentation.

- TiKV supports the MVCC in-memory engine (IME), which accelerates queries involving scans of extensive MVCC historical versions #16141 @SpadeA-Tang @glorv @overvenus

  When records are frequently updated, or TiDB is required to retain historical versions for extended periods (for example, 24 hours), the accumulation of MVCC versions can degrade scan performance. The TiKV MVCC in-memory engine improves scan performance by caching the latest MVCC versions in memory, and using a rapid GC mechanism to remove historical versions from memory.

Starting from v8.5.0, TiKV introduces MVCC in-memory engine. If the accumulation of MVCC versions in the TiKV cluster leads to degraded scan performance, you can enable the TiKV MVCC in-memory engine to improve scan performance by setting the TiKV configuration parameter `in-memory-engine.enable`.

For more information, see documentation.

2.2.1.3 Reliability

- Support limiting the maximum rate and concurrency of requests processed by PD #5739 @rleungx

  When a sudden influx of requests is sent to PD, it can lead to high workloads and potentially affect PD performance. Starting from v8.5.0, you can use `pd-ctl` to limit the maximum rate and concurrency of requests processed by PD, improving its stability.

  For more information, see documentation.

2.2.1.4 SQL

- Support foreign keys (GA) #36982 @YangKeao @crazycs520

  The foreign key feature becomes generally available (GA) in v8.5.0. Foreign key constraints help ensure data consistency and integrity. You can easily establish foreign key relationships between tables, with support for cascading updates and deletions, simplifying data management. This feature enhances support for applications with complex data relationships.

  For more information, see documentation.

- Introduce the `ADMIN ALTER DDL JOBS` statement to support modifying the DDL jobs online #57229 @fzzf678 @tangenta

  Starting from v8.3.0, you can set the variables `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` at the session level. As a result, setting these two variables globally no longer affects all running DDL jobs. To modify the values of these variables, you need to cancel the DDL job first, adjust the variables, and then resubmit the job.

  TiDB v8.5.0 introduces the `ADMIN ALTER DDL JOBS` statement, letting you adjust the variable values of specific DDL jobs online. This enables flexible balancing of resource consumption and performance. The changes are limited to individual jobs, making the impact more controllable. For example:

  - `ADMIN ALTER DDL JOBS job_id THREAD = 8;`: adjusts the `tidb_ddl_reorg_worker_cnt` of the specified DDL job online.
  - `ADMIN ALTER DDL JOBS job_id BATCH_SIZE = 256;`: adjusts the `tidb_ddl_reorg_batch_size` of the specified job online.

- `ADMIN ALTER DDL JOBS job_id MAX_WRITE_SPEED = '200MiB';`: adjusts the write traffic of index data to each TiKV node online.

For more information, see documentation.

2.2.1.5 Security

- BR supports client-side encryption of both full backup data and log backup data (GA) #28640 #56433 @joccau @Tristan1900
  - Client-side encryption of full backup data (introduced as experimental in TiDB v5.3.0) enables you to encrypt backup data on the client side using a custom fixed key.
  - Client-side encryption of log backup data (introduced as experimental in TiDB v8.4.0) enables you to encrypt log backup data on the client side using one of the following methods:
    - Encrypt using a custom fixed key
    - Encrypt using a master key stored on a local disk
    - Encrypt using a master key managed by a Key Management Service (KMS)

Starting from v8.5.0, both encryption features become generally available (GA), offering enhanced client-side data security.

```
For more information, see [Encrypt the backup data](#encrypt-the-backup-data
    ↪ ) and [Encrypt the log backup data](#encrypt-the-log-backup-data).
```

- TiKV encryption at rest supports Google Cloud Key Management Service (Google Cloud KMS) (GA) #8906 @glorv

  TiKV ensures data security by using the encryption at rest technique to encrypt stored data. The core aspect of this technique is proper key management. In v8.0.0, TiKV encryption at rest experimentally supports using Google Cloud KMS for master key management.

  Starting from v8.5.0, encryption at rest using Google Cloud KMS becomes generally available (GA). To use this feature, first create a key on Google Cloud, and then configure the `[security.encryption.master-key]` section in the TiKV configuration file.

  For more information, see documentation.

2.2.2 Compatibility changes

Note:

This section provides compatibility changes you need to know when you upgrade from v8.4.0 to the current version (v8.5.0). If you are upgrading from v8.3.0 or earlier versions to the current version, you might also need to check the compatibility changes introduced in intermediate versions.

2.2.2.1 Behavior changes

- In non-strict mode (`sql_mode = ''`), inserting `NULL` values into non-`NULL` columns now returns an error for MySQL compatibility. #55457 @joechenrh
- The `ALTER TABLE ... DROP FOREIGN KEY IF EXISTS ...` statement is no longer supported. #56703 @YangKeao

2.2.2.2 System variables

Variable name	Change type	Description
tidb_ ↪ enable ↪ _ ↪ fast ↪ _ ↪ create ↪ _ ↪ table ↪	Modified	Changes the default value from `OFF` to `ON` after further tests, meaning that the accelerated table creation feature is enabled by default.

Variable name	Change type	Description
tidb_ ↪ ddl_ ↪ reorg ↪ _max ↪ _ ↪ write ↪ _ ↪ speed ↪	Newly added	Limits the write bandwidth for each TiKV node and only takes effect when index creation acceleration is enabled (controlled by the tidb_ ↪ ddl ↪ _ ↪ enable ↪ _ ↪ fast ↪ _ ↪ reorg ↪ variable). For example, setting the variable to 200MiB limits the maximum write

Variable name	Change type	Description

2.2.2.3 Configuration parameters

Configuration file or component	Configuration parameter	Change type	Description
TiDB	`deprecate-integer-display-length`	Modified	Starting from v8.5.0, the integer display width feature is deprecated. The default value of this configuration item is changed from `false` to `true`.
TiKV	`raft-client-queue-size`	Modified	Changes the default value from `8192` to `16384`.

Configuration file or component	Configuration parameter	Change type	Description
TiKV	`in-memory-engine.capacity`	Newly added	Controls the maximum memory size that the TiKV MVCC in-memory engine can use. The default value is 10% of the system memory. The maximum value is 5 GiB.

Configuration file or component	Configuration parameter	Change type	Description
TiKV	`in-memory-engine.enable`	Newly added	Controls whether to enable the TiKV MVCC in-memory engine to accelerate multi-version queries. The default value is `false`, which means that the in-memory engine is disabled.

Configuration file or component	Configuration parameter	Change type	Description
TiKV	`in-memory-engine.gc-run-interval`	Newly added	Controls the time interval at which the in-memory engine performs garbage collection (GC) on cached MVCC versions. The default value is `"3m"`.

Configuration file or component	Configuration parameter	Change type	Description
TiKV	`in-memory-engine.mvcc-amplification-threshold`	Newly added	Controls the threshold for MVCC read amplification when the in-memory engine selects and loads Regions. The default value is `10`, indicating that if reading a single row in a Region requires processing more than 10 MVCC versions, this Region might be loaded into the in-memory engine.

Configuration file or component	Configuration parameter	Change type	Description
PD	patrol-region-worker-count	Newly added	Controls the number of concurrent operators created by the checker when inspecting the health state of a Region.

Configuration file or component	Configuration parameter	Change type	Description
BR	`--checksum`	Modified	Changes the default value from `true` to `false`, meaning that BR does not calculate the table-level checksum during full backups by default, to improve backup performance.

2.2.2.4 Operating system and platform requirement changes

Before upgrading TiDB, ensure that your operating system version meets the OS and platform requirements.

- According to CentOS Linux EOL, the upstream support for CentOS Linux 7 ended on June 30, 2024. Therefore, TiDB drops the support of CentOS 7 in v8.4.0 and v8.5.0. It is recommended to use Rocky Linux 9.1 or a later version. Upgrading a TiDB cluster on CentOS 7 to v8.4.0 or v8.5.0 will cause the risk of cluster unavailability. To assist users still using CentOS Linux 7, TiDB v8.5.1 resumes testing of CentOS Linux 7 and is compatible with it. For more information, see TiDB v8.5.1 Release Notes.
- According to Red Hat Enterprise Linux Life Cycle, the maintenance support for Red Hat Enterprise Linux 7 ended on June 30, 2024. TiDB ends the support for Red Hat

Enterprise Linux 7 starting from v8.4.0. It is recommended to use Rocky Linux 9.1 or a later version. Upgrading a TiDB cluster on Red Hat Enterprise Linux 7 to v8.4.0 or later will cause the cluster to become unavailable.

2.2.3 Removed features

- The following feature has been removed:
    - In v8.4.0, TiDB Binlog is removed. Starting from v8.3.0, TiDB Binlog is fully deprecated. For incremental data replication, use TiCDC instead. For point-in-time recovery (PITR), use PITR. Before you upgrade your TiDB cluster to v8.4.0 or later versions, be sure to switch to TiCDC and PITR.
- The following features are planned for removal in future versions:
    - Starting from v8.0.0, TiDB Lightning deprecates the old version of conflict detection strategy for the physical import mode, and enables you to control the conflict detection strategy for both logical and physical import modes via the `conflict.strategy` parameter. The `duplicate-resolution` parameter for the old version of conflict detection will be removed in a future release.

2.2.4 Deprecated features

The following features are planned for deprecation in future versions:

- In v8.0.0, TiDB introduces the `tidb_enable_auto_analyze_priority_queue` system variable to control whether priority queues are enabled to optimize the ordering of tasks that automatically collect statistics. In future releases, the priority queue will be the only way to order tasks for automatically collecting statistics, so this system variable will be deprecated.
- In v7.5.0, TiDB introduces the `tidb_enable_async_merge_global_stats` system variable. You can use it to set TiDB to use asynchronous merging of partition statistics to avoid OOM issues. In future releases, partition statistics will be merged asynchronously, so this system variable will be deprecated.
- It is planned to redesign the automatic evolution of execution plan bindings in subsequent releases, and the related variables and behavior will change.
- In v8.0.0, TiDB introduces the `tidb_enable_parallel_hashagg_spill` system variable to control whether TiDB supports disk spill for the concurrent HashAgg algorithm. In future versions, this system variable will be deprecated.
- In v5.1, TiDB introduces the `tidb_partition_prune_mode` system variable to control whether to enable the dynamic pruning mode for partitioned tables. Starting from v8.5.0, a warning is returned when you set this variable to `static` or `static-only`. In future versions, this system variable will be deprecated.

- The TiDB Lightning parameter `conflict.max-record-rows` is planned for deprecation in a future release and will be subsequently removed. This parameter will be replaced by `conflict.threshold`, which means that the maximum number of conflicting records is consistent with the maximum number of conflicting records that can be tolerated in a single import task.
- Starting from v6.3.0, partitioned tables use dynamic pruning mode by default. Compared with static pruning mode, dynamic pruning mode supports features such as IndexJoin and plan cache with better performance. Therefore, static pruning mode will be deprecated.

2.2.5 Improvements

- TiDB
    - Improve the response speed of job cancellation for the `ADD INDEX` acceleration feature when disabling the Distributed eXecution Framework (DXF) #56017 @lance6716
    - Improve the speed of adding indexes to small tables #54230 @tangenta
    - Add a new system variable `tidb_ddl_reorg_max_write_speed` to limit the maximum speed of the ingest phase when adding indexes #57156 @CbcWestwolf
    - Improve the performance of querying `information_schema.tables` in some cases #57295 @tangenta
    - Support dynamically adjusting more DDL job parameters #57526 @fzzf678
    - Support global indexes that contain all columns from a partition expression #56230 @Defined2014
    - Support partition pruning for list partitioned tables in range query scenarios #56673 @Defined2014
    - Enable FixControl#46177 by default to fix the issue that a full table scan is incorrectly selected instead of an index range scan in some cases #46177 @terry1purcell
    - Improve the internal estimation logic to better utilize statistics of multi-column and multi-value indexes, enhancing estimation accuracy for certain queries involving multi-value indexes #56915 @time-and-fate
    - Improve the cost estimation for full table scans in specific scenarios, reducing the probability of incorrectly choosing a full table scan #57085 @terry1purcell
    - Optimize the amount of data required for synchronous loading of statistics to improve loading performance #56812 @winoros
    - Optimize the execution plan in specific cases where an `OUTER JOIN` involves a unique index and an `ORDER BY ... LIMIT` clause, improving execution efficiency #56321 @winoros
- TiKV
    - Use a separate thread to clean up replicas, ensuring stable latency for critical paths of Raft reads and writes #16001 @hbisheng

    - Improve the performance of the vector distance function by supporting SIMD #17290 @EricZequan

- PD

    - Support dynamic switching of the `tso` service between microservice and non-microservice modes #8477 @rleungx
    - Optimize the case format of certain fields in the `pd-ctl config` output #8694 @lhy1024
    - Store limit v2 becomes generally available (GA) #8865 @lhy1024
    - Support configuring Region inspection concurrency (experimental) #8866 @lhy1024

- TiFlash

    - Improve the garbage collection speed of outdated data in the background for tables with clustered indexes #9529 @JaySon-Huang
    - Improve query performance of vector search in data update scenarios #9599 @Lloyd-Pottiger
    - Add monitoring metrics for CPU usage during vector index building #9032 @JaySon-Huang
    - Improve the execution efficiency of logical operators #9146 @windtalker

- Tools

    - Backup & Restore (BR)

        - Reduce unnecessary log printing during backup #55902 @Leavrth
        - Optimize the error message for the encryption key `--crypter.key` #56388 @Tristan1900
        - Increase concurrency in BR when creating databases to improve data restore performance #56866 @Leavrth
        - Disable the table-level checksum calculation during full backups by default (`--checksum=false`) to improve backup performance #56373 @Tristan1900
        - Add a mechanism to independently track and reset the connection timeout for each storage node, enhancing the handling of slow nodes and preventing backup operations from hanging #57666 @3pointer

    - TiDB Data Migration (DM)

        - Add retries for DM-worker to connect to DM-master during DM cluster startup #4287 @GMHDBJD

2.2.6 Bug fixes

- TiDB

- Fix the issue that TiDB does not automatically retry requests when the Region metadata returned from PD lacks Leader information, potentially causing execution errors #56757 @cfzjywxk
- Fix the issue that TTL tasks cannot be canceled when there is a write conflict #56422 @YangKeao
- Fix the issue that when canceling a TTL task, the corresponding SQL is not killed forcibly #56511 @lcwangchao
- Fix the issue that existing TTL tasks are executed unexpectedly frequently in a cluster that is upgraded from v6.5 to v7.5 or later #56539 @lcwangchao
- Fix the issue that the `INSERT ... ON DUPLICATE KEY` statement is not compatible with `mysql_insert_id` #55965 @tiancaiamao
- Fix the issue that TTL might fail if TiKV is not selected as the storage engine #56402 @YangKeao
- Fix the issue that the `AUTO_INCREMENT` field is not correctly set after importing data using the `IMPORT INTO` statement #56476 @D3Hunter
- Fix the issue that TiDB does not check the index length limitation when executing `ADD INDEX` #56930 @fzzf678
- Fix the issue that executing `RECOVER TABLE BY JOB JOB_ID;` might cause TiDB to panic #55113 @crazycs520
- Fix the issue that stale read does not strictly verify the timestamp of the read operation, resulting in a small probability of affecting the consistency of the transaction when an offset exists between the TSO and the real physical time #56809 @MyonKeminta
- Fix the issue that TiDB could not resume Reorg DDL tasks from the previous progress after the DDL owner node is switched #56506 @tangenta
- Fix the issue that some metrics in the monitoring panel of Distributed eXecution Framework (DXF) are inaccurate #57172 @fzzf678 #56942 @fzzf678
- Fix the issue that `REORGANIZE PARTITION` fails to return error reasons in certain cases #56634 @mjonss
- Fix the issue that querying `INFORMATION_SCHEMA.TABLES` returns incorrect results due to case sensitivity #56987 @joechenrh
- Fix the issue of illegal memory access that might occur when a Common Table Expression (CTE) has multiple data consumers and one consumer exits without reading any data #55881 @windtalker
- Fix the issue that `INDEX_HASH_JOIN` might hang during an abnormal exit #54055 @wshwsh12
- Fix the issue that the `TRUNCATE` statement returns incorrect results when handling `NULL` values #53546 @tuziemon
- Fix the issue that the `CAST AS CHAR` function returns incorrect results due to type inference errors #56640 @zimulala
- Fix the issue of truncated strings in the output of some functions due to type inference errors #56587 @joechenrh
- Fix the issue that the `ADDTIME()` and `SUBTIME()` functions returns incorrect results when their first argument is a date type #57569 @xzhangxian1008
- Fix the issue that invalid `NULL` values can be inserted in non-strict mode (`sql_`

↪ `mode = ''`) #56381 @joechenrh

- Fix the issue that the `UPDATE` statement incorrectly updates values of the `ENUM` type #56832 @xhebox
- Fix the issue that enabling the `tidb_low_resolution_tso` variable causes resource leaks during the execution of `SELECT FOR UPDATE` statements #55468 @tiancaiamao
- Fix the issue that the `JSON_TYPE()` function does not validate the parameter type, causing no errors returned when a non-JSON data type is passed #54029 @YangKeao
- Fix the issue that using JSON functions in `PREPARE` statements might cause execution failures #54044 @YangKeao
- Fix the issue that converting data from the `BIT` type to the `CHAR` type might cause TiKV panics #56494 @lcwangchao
- Fix the issue that using variables or parameters in the `CREATE VIEW` statement does not report errors #53176 @mjonss
- Fix the issue that the `JSON_VALID()` function returns incorrect results #56293 @YangKeao
- Fix the issue that TTL tasks are not canceled after the `tidb_ttl_job_enable` variable is disabled #57404 @YangKeao
- Fix the issue that using the `RANGE COLUMNS` partition function and the `utf8mb4_0900_ai_ci` collation at the same time could result in incorrect query results #57261 @Defined2014
- Fix the runtime error caused by executing a prepared statement that begins with a newline character, resulting in an array out of bounds #54283 @Defined2014
- Fix the precision issue in the `UTC_TIMESTAMP()` function, such as setting the precision too high #56451 @chagelo
- Fix the issue that foreign key errors are not omitted in `UPDATE`, `INSERT`, and `DELETE IGNORE` statements #56678 @YangKeao
- Fix the issue that when querying the `information_schema.cluster_slow_query` table, if the time filter is not added, only the latest slow log file is queried #56100 @crazycs520
- Fix the issue of memory leaks in TTL tables #56934 @lcwangchao
- Fix the issue that foreign key constraints do not take effect for tables in `write_only` status, preventing using tables in `non-public` status #55813 @YangKeao
- Fix the issue that using subqueries after the `NATURAL JOIN` or `USING` clause might result in errors #53766 @dash12653
- Fix the issue that if a CTE contains the `ORDER BY`, `LIMIT`, or `SELECT DISTINCT` clause and is referenced by the recursive part of another CTE, it might be incorrectly inlined and result in an execution error #56603 @elsa0520
- Fix the issue that the CTE defined in `VIEW` is incorrectly inlined #56582 @elsa0520
- Fix the issue that Plan Replayer might report an error when importing a table structure containing foreign keys #56456 @hawkingrei
- Fix the issue that Plan Replayer might report an error when importing a table structure containing Placement Rules #54961 @hawkingrei

- Fix the issue that when using `ANALYZE` to collect statistics for a table, if the table contains expression indexes of virtually generated columns, the execution reports an error #57079 @hawkingrei
- Fix the issue that the `DROP DATABASE` statement does not correctly trigger the corresponding update in statistics #57227 @Rustin170506
- Fix the issue that when parsing a database name in CTE, it returns a wrong database name #54582 @hawkingrei
- Fix the issue that the upper bound and lower bound of the histogram are corrupted when `DUMP STATS` is transforming statistics into JSON #56083 @hawkingrei
- Fix the issue that `EXISTS` subquery results, when further involved in algebraic operations, could differ from the results in MySQL #56641 @windtalker
- Fix the issue that execution plan bindings cannot be created for the multi-table `DELETE` statement with aliases #56726 @hawkingrei
- Fix the issue that the optimizer does not take into account the character set and collations when simplifying complex predicates, resulting in possible execution errors #56479 @dash12653
- Fix the issue that the data in the **Stats Healthy Distribution** panel of Grafana might be incorrect #57176 @hawkingrei
- Fix the issue that vector search might return incorrect results when querying tables with clustered indexes #57627 @winoros

- TiKV

    - Fix the panic issue that occurs when read threads access outdated indexes in the MemTable of the Raft Engine #17383 @LykxSassinator
    - Fix the issue that when a large number of transactions are queuing for lock release on the same key and the key is frequently updated, excessive pressure on deadlock detection might cause TiKV OOM issues #17394 @MyonKeminta
    - Fix the issue that CPU usage for background tasks of resource control is counted twice #17603 @glorv
    - Fix the issue that TiKV OOM might occur due to the accumulation of CDC internal tasks #17696 @3AceShowHand
    - Fix the issue that large batch writes cause performance jitter when `raft-entry-max-size` is set too high #17701 @SpadeA-Tang
    - Fix the issue that the leader could not be quickly elected after Region split #17602 @LykxSassinator
    - Fix the issue that TiKV might panic when executing queries containing `RADIANS()` or `DEGREES()` functions #17852 @gengliqi
    - Fix the issue that write jitter might occur when all hibernated Regions are awakened #17101 @hhwyt

- PD

    - Fix the memory leak issue in hotspot cache #8698 @lhy1024
    - Fix the issue that the resource group selector does not take effect on any panel #56572 @glorv

- Fix the issue that deleted resource groups still appear in the monitoring panel #8716 @AndreMouche
- Fix unclear log descriptions during the Region syncer loading process #8717 @lhy1024
- Fix the memory leak issue in label statistics #8700 @lhy1024
- Fix the issue that configuring `tidb_enable_tso_follower_proxy` to `0` or `OFF` fails to disable the TSO Follower Proxy feature #8709 @JmPotato

- TiFlash

  - Fix the issue that the `SUBSTRING()` function does not support the `pos` and `len` arguments for certain integer types, causing query errors #9473 @gengliqi
  - Fix the issue that vector search performance might degrade after scaling out TiFlash write nodes in the disaggregated storage and compute architecture #9637 @kolafish
  - Fix the issue that the `SUBSTRING()` function returns incorrect results when the second parameter is negative #9604 @guo-shaoge
  - Fix the issue that the `REPLACE()` function returns an error when the first parameter is a constant #9522 @guo-shaoge
  - Fix the issue that `LPAD()` and `RPAD()` functions return incorrect results in some cases #9465 @guo-shaoge
  - Fix the issue that after creating a vector index, if the internal task for building the vector index is unexpectedly interrupted, it could result in TiFlash writing corrupted data and being unable to restart #9714 @JaySon-Huang

- Tools

  - Backup & Restore (BR)

    - Fix the OOM issue during backups when there are too many uncompleted range gaps, reducing the amount of pre-allocated memory #53529 @Leavrth
    - Fix the issue that global indexes cannot be backed up #57469 @Defined2014
    - Fix the issue that logs might print out encrypted information #57585 @kennytm
    - Fix the issue that the advancer cannot handle lock conflicts #57134 @3pointer
    - Fix potential security vulnerabilities by upgrading the `k8s.io/api` library version #57790 @BornChanger
    - Fix the issue that PITR tasks might return the `Information schema is out of date` error when there are a large number of tables in the cluster but the actual data size is small #57743 @Tristan1900
    - Fix the issue that log backup might unexpectedly enter a paused state when the advancer owner switches #58031 @3pointer
    - Fix the issue that the `tiup br restore` command omits checking whether the target cluster table already exists during database or table restoration, which might overwrite existing tables #58168 @RidRisR

  - TiCDC

- Fix the issue that the Kafka messages lack Key fields when using the Debezium protocol #1799 @wk989898
- Fix the issue that the redo module fails to properly report errors #11744 @CharlesCheung96
- Fix the issue that TiCDC mistakenly discards DDL tasks when the schema versions of DDL tasks become non-incremental during TiDB DDL owner changes #11714 @wlwilliamx

- TiDB Lightning
  - Fix the issue that TiDB Lightning fails to receive oversized messages sent from TiKV #56114 @fishiu
  - Fix the issue that the `AUTO_INCREMENT` value is set too high after importing data using the physical import mode #56814 @D3Hunter

2.2.7 Performance test

To learn about the performance of TiDB v8.5.0, you can refer to the performance test reports of the TiDB Cloud Dedicated cluster.

2.2.8 Contributors

We would like to thank the following contributors from the TiDB community:

- dash12653 (First-time contributor)
- chagelo (First-time contributor)
- LindaSummer
- songzhibin97
- Hexilee

2.3 TiDB Features

This document lists the features supported in different TiDB versions, including Long-Term Support (LTS) versions and Development Milestone Release (DMR) versions after the latest LTS version.

You can try out TiDB features on TiDB Playground.

> **Note:**
>
> PingCAP does not provide patch releases for DMR versions. Any bugs will be fixed in future releases. For general purposes, it is recommended to use the latest LTS version.
>
> The abbreviations in the table below have the following meanings:

- Y: the feature is generally available (GA) and can be used in production environments. Note that even if a feature is GA in a DMR version, it is recommended to use the feature in production environments in a later LTS version.
- N: the feature is not supported.
- E: the feature is not GA yet (experimental) and you need to be aware of the usage limitations. Experimental features are subject to change or removal without prior notice. The syntax and implementation might be modified before the general availability. If you encounter any problems, you can report an issue on GitHub.

2.3.1 Data types, functions, and operators

Data types, functions, and operators	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.1
Numeric types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Date and time types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
String types	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
JSON type	Y	Y	Y	Y	Y	E	E	E	E	E
Vector types	E	N	N	N	N	N	N	N	N	N
Control flow functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
String functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Numeric functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Date and time functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Bit functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Cast functions and operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Encryption and compression functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Vector functions and operators	E	N	N	N	N	N	N	N	N	N
Information functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
JSON functions	Y	Y	Y	Y	Y	E	E	E	E	E
Aggregation functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Window functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Miscellaneous functions	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Operators	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Character sets and collations [1]	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
User-level lock	Y	Y	Y	Y	Y	Y	N	N	N	N

2.3.2 Indexing and constraints

[1]The explanation of KNN search is adapted from the Approximate Nearest Neighbor Search Indexes document authored by rschu1ze in ClickHouse documentation, licensed under the Apache License 2.0.

Indexing and constraints	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.
Expression indexes [2]	Y	Y	Y	Y	Y	E	E	E	E	E
Columnar storage (TiFlash)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Use FastScan to accelerate queries in OLAP scenarios	Y	Y	Y	Y	E	N	N	N	N	N
RocksDB engine	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Titan plugin	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Titan Level Merge	E	E	E	E	E	E	E	E	E	E
Use buckets to improve scan concurrency	E	E	E	E	E	E	N	N	N	N
Invisible indexes	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Composite `PRIMARY KEY`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
`CHECK` constraints	Y	Y	Y	N	N	N	N	N	N	N
Unique indexes	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Clustered index on integer `PRIMARY KEY`	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Clustered index on composite or non-integer key	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Multi-valued indexes	Y	Y	Y	Y	N	N	N	N	N	N
Foreign key	Y	E	E	E	N	N	N	N	N	N
TiFlash late materialization	Y	Y	Y	Y	N	N	N	N	N	N
Global index	Y	N	N	N	N	N	N	N	N	N
Vector index	E	N	N	N	N	N	N	N	N	N

2.3.3 SQL statements

SQL statements [3]	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3
Basic `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REPLACE`	Y	Y	Y	Y	Y	Y	Y	Y
`INSERT ON DUPLICATE KEY UPDATE`	Y	Y	Y	Y	Y	Y	Y	Y
`LOAD DATA INFILE`	Y	Y	Y	Y	Y	Y	Y	Y
`SELECT INTO OUTFILE`	Y	Y	Y	Y	Y	Y	Y	Y
`INNER JOIN`, LEFT|RIGHT [OUTER] JOIN	Y	Y	Y	Y	Y	Y	Y	Y
`UNION`, `UNION ALL`	Y	Y	Y	Y	Y	Y	Y	Y
`EXCEPT` and `INTERSECT` operators	Y	Y	Y	Y	Y	Y	Y	Y
`GROUP BY`, `ORDER BY`	Y	Y	Y	Y	Y	Y	Y	Y
`GROUP BY` modifier	Y	Y	Y	N	N	N	N	N
Window Functions	Y	Y	Y	Y	Y	Y	Y	Y
Common Table Expressions (CTE)	Y	Y	Y	Y	Y	Y	Y	Y
`START TRANSACTION`, `COMMIT`, `ROLLBACK`	Y	Y	Y	Y	Y	Y	Y	Y
`EXPLAIN`	Y	Y	Y	Y	Y	Y	Y	Y
`EXPLAIN ANALYZE`	Y	Y	Y	Y	Y	Y	Y	Y

[2] Starting from v6.5.0, the expression indexes created on the functions listed by the `tidb_allow_function_for_expression_index` system variable have been tested and can be used in production environments, and more functions will be supported in the future releases. For functions not listed by this variable, the corresponding expression indexes are not recommended for use in production environments. See expression indexes for details.

SQL statements [3]	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3
User-defined variables	E	E	E	E	E	E	E	E
`BATCH [ON COLUMN] LIMIT INTEGER DELETE`	Y	Y	Y	Y	Y	Y	N	N
`BATCH [ON COLUMN] LIMIT INTEGER INSERT/UPDATE/REPLACE`	Y	Y	Y	Y	Y	N	N	N
`ALTER TABLE ... COMPACT`	Y	Y	Y	Y	Y	E	N	N
Table Lock	E	E	E	E	E	E	E	E
TiFlash Query Result Materialization	Y	Y	Y	Y	E	N	N	N

2.3.4 Advanced SQL features

Advanced SQL features	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5
Vector search	E	N	N	N	N	N	N	N	N

2.3.10 Data import and export

Data import and export	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.1
Fast import using TiDB Lightning	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

Data import and export	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.1
Fast import using the `IMPORT INTO` statement	Y	Y	Y	N	N	N	N	N	N	N
mydumper logical dumper	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated
Dumpling logical dumper	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Transactional `LOAD DATA` [5]	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Database migration toolkit (DM)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y

[5] Starting from TiDB v7.0.0, the new parameter `FIELDS DEFINED NULL BY` and support for importing data from S3 and GCS are experimental features. Starting from v7.6.0, TiDB processes `LOAD DATA` in transactions in the same way as MySQL. The `LOAD DATA` statement in a transaction no longer automatically commits the current transaction or starts a new transaction. Moreover, you can explicitly commit or roll back the `LOAD DATA` statement in a transaction. Additionally, the `LOAD DATA` statement is affected by the TiDB transaction mode setting (optimistic or pessimistic transaction).

Data import and export	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.1
TiDB Binlog [6]	Removed	Y	Y	Y	Y	Y	Y	Y	Y	Y
Change data capture (CDC)	Y	Y	Y	Y	Y	Y	Y	Y	Y	Y
Stream data to Amazon S3, GCS, Azure Blob Storage, and NFS through TiCDC	Y	Y	Y	Y	E	N	N	N	N	N

[6] Starting from v7.5.0, TiDB Binlog replication is deprecated. Starting from v8.3.0, TiDB Binlog is fully deprecated. Starting from v8.4.0, TiDB Binlog is removed. For incremental data replication, use TiCDC instead. For point-in-time recovery (PITR), use PITR. Before you upgrade your TiDB cluster to v8.4.0 or later versions, be sure to switch to TiCDC and PITR.

Data import and export	8.5	8.1	7.5	7.1	6.5	6.1	5.4	5.3	5.2	5.1
TiCDC supports bidirectional replication between two TiDB clusters	Y	Y	Y	Y	Y	N	N	N	N	N
TiCDC OpenAPI v2	Y	Y	Y	Y	N	N	N	N	N	N
DM supports migrating MySQL 8.0	Y	Y	E	E	E	E	N	N	N	N

2.3.11 Management, observability, and tools

Schema cache	Y	N	N	N	N	N	N	N	N	N

2.4 MySQL Compatibility

TiDB is highly compatible with the MySQL protocol and the common features and syntax of MySQL 5.7 and MySQL 8.0. The ecosystem tools for MySQL (PHPMyAdmin, Navicat, MySQL Workbench, DBeaver and more) and the MySQL client can be used for TiDB.

However, some features of MySQL are not supported in TiDB. This could be because there is now a better way to solve the problem (such as the use of JSON instead of XML functions) or a lack of current demand versus effort required (such as stored procedures and functions). Additionally, some features might be difficult to implement in a distributed system.

It's important to note that TiDB does not support the MySQL replication protocol. Instead, specific tools are provided to replicate data with MySQL:

- Replicate data from MySQL: TiDB Data Migration (DM) is a tool that supports full data migration and incremental data replication from MySQL or MariaDB into TiDB.
- Replicate data to MySQL: TiCDC is a tool for replicating the incremental data of TiDB by pulling TiKV change logs. TiCDC uses the MySQL sink to replicate the incremental data of TiDB to MySQL.

Note:

This page describes general differences between MySQL and TiDB. For more information on compatibility with MySQL in the areas of security, see Security Compatibility with MySQL.

You can try out TiDB features on TiDB Playground.

2.4.1 Unsupported features

- Stored procedures and functions
- Triggers
- Events
- User-defined functions
- `FULLTEXT` syntax and indexes #1793
- `SPATIAL` (also known as `GIS/GEOMETRY`) functions, data types and indexes #6347
- Character sets other than `ascii`, `latin1`, `binary`, `utf8`, `utf8mb4`, and `gbk`.
- Optimizer trace
- XML Functions
- X-Protocol #1109
- Column-level privileges #9766
- `XA` syntax (TiDB uses a two-phase commit internally, but this is not exposed via an SQL interface)
- `CREATE TABLE tblName AS SELECT stmt` syntax #4754
- `CHECK TABLE` syntax #4673
- `CHECKSUM TABLE` syntax #1895
- `REPAIR TABLE` syntax
- `OPTIMIZE TABLE` syntax
- `HANDLER` statement
- `CREATE TABLESPACE` statement
- "Session Tracker: Add GTIDs context to the OK packet"
- Descending Index #2519
- `SKIP LOCKED` syntax #18207
- Lateral derived tables #40328
- JOIN ON subquery #11414

2.4.2 Differences from MySQL

2.4.2.1 Auto-increment ID

- In TiDB, the auto-incremental column values (IDs) are globally unique and incremental within a single TiDB server. To make the IDs incremental among multiple TiDB

servers, you can use the AUTO_INCREMENT MySQL compatibility mode. However, the IDs are not necessarily allocated sequentially, so it is recommended that you avoid mixing default and custom values to prevent encountering the `Duplicated Error` message.

- You can use the `tidb_allow_remove_auto_inc` system variable to allow or forbid removing the `AUTO_INCREMENT` column attribute. To remove the column attribute, use the `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE` syntax.
- TiDB does not support adding the `AUTO_INCREMENT` column attribute, and once removed, it cannot be recovered.
- For TiDB v6.6.0 and earlier versions, auto-increment columns in TiDB behave the same as in MySQL InnoDB, requiring them to be primary keys or index prefixes. Starting from v7.0.0, TiDB removes this restriction, allowing for more flexible table primary key definitions. #40580

For more details, see AUTO_INCREMENT.

Note:

- If you do not specify a primary key when creating a table, TiDB uses `_tidb_rowid` to identify the row. The allocation of this value shares an allocator with the auto-increment column (if such a column exists). If you specify an auto-increment column as the primary key, TiDB uses this column to identify the row. In this situation, the following situation might occur:

```
mysql> CREATE TABLE t(id INT UNIQUE KEY AUTO_INCREMENT);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES();
Query OK, 1 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES();
Query OK, 1 rows affected (0.00 sec)

mysql> INSERT INTO t VALUES();
Query OK, 1 rows affected (0.00 sec)

mysql> SELECT _tidb_rowid, id FROM t;
+-------------+------+
| _tidb_rowid | id |
```

```
+-------------+------+
|           2 |    1 |
|           4 |    3 |
|           6 |    5 |
+-------------+------+
3 rows in set (0.01 sec)
```

As shown, because of the shared allocator, the `id` increments by 2 each time. This behavior changes in MySQL compatibility mode, where there is no shared allocator and therefore no skipping of numbers.

> **Note:**
>
> The `AUTO_INCREMENT` attribute might cause hotspot in production environments. See Troubleshoot HotSpot Issues for details. It is recommended to use `AUTO_RANDOM` instead.

2.4.2.2 Performance schema

TiDB utilizes a combination of Prometheus and Grafana for storing and querying performance monitoring metrics. In TiDB, most performance schema tables do not return any results.

2.4.2.3 Query Execution Plan

The output format, content, and privilege settings of Query Execution Plan (`EXPLAIN` ↪ `/EXPLAIN FOR`) in TiDB differ significantly from those in MySQL.

In TiDB, the MySQL system variable `optimizer_switch` is read-only and has no effect on query plans. Although optimizer hints can be used in similar syntax to MySQL, the available hints and their implementation might differ.

For more information, refer to Understand the Query Execution Plan.

2.4.2.4 Built-in functions

TiDB supports most of the built-in functions in MySQL, but not all. You can use the statement `SHOW BUILTINS` to get a list of the available functions.

2.4.2.5 DDL operations

In TiDB, all supported DDL changes can be performed online. However, there are some major restrictions on DDL operations in TiDB compared to MySQL:

- When using a single `ALTER TABLE` statement to alter multiple schema objects (such as columns or indexes) of a table, specifying the same object in multiple changes is not supported. For example, if you execute the `ALTER TABLE t1 MODIFY COLUMN c1 INT, DROP COLUMN c1` command, the `Unsupported operate same column/index` error is output.
- It is not supported to modify multiple TiDB-specific schema objects using a single `ALTER TABLE` statement, such as `TIFLASH REPLICA`, `SHARD_ROW_ID_BITS`, and `AUTO_ID_CACHE`.
- TiDB does not support the changes of some data types using `ALTER TABLE`. For example, TiDB does not support the change from the `DECIMAL` type to the `DATE` type. If a data type change is unsupported, TiDB reports the `Unsupported modify column: type %d not match origin %d` error. Refer to `ALTER TABLE` for more details.
- The `ALGORITHM={INSTANT,INPLACE,COPY}` syntax functions only as an assertion in TiDB, and does not modify the `ALTER` algorithm. See `ALTER TABLE` for further details.
- Adding/Dropping the primary key of the `CLUSTERED` type is unsupported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.
- Different types of indexes (`HASH|BTREE|RTREE|FULLTEXT`) are not supported, and will be parsed and ignored when specified.
- TiDB supports `HASH`, `RANGE`, `LIST`, and `KEY` partitioning types. For an unsupported partition type, TiDB returns `Warning: Unsupported partition type %s, treat as normal table`, where `%s` is the specific unsupported partition type.
- Range, Range COLUMNS, List, and List COLUMNS partitioned tables support `ADD`, `DROP`, `TRUNCATE`, and `REORGANIZE` operations. Other partition operations are ignored.
- Hash and Key partitioned tables support `ADD`, `COALESCE`, and `TRUNCATE` operations. Other partition operations are ignored.
- The following syntaxes are not supported for partitioned tables:
    - `SUBPARTITION`
    - `{CHECK|OPTIMIZE|REPAIR|IMPORT|DISCARD|REBUILD} PARTITION`

  For more details on partitioning, see Partitioning.

2.4.2.6 Analyzing tables

In TiDB, Statistics Collection differs from MySQL in that it completely rebuilds the statistics for a table, making it a more resource-intensive operation that takes longer to complete. In contrast, MySQL/InnoDB performs a relatively lightweight and short-lived operation.

For more information, refer to `ANALYZE TABLE`.

2.4.2.7 Limitations of `SELECT` syntax

TiDB does not support the following `SELECT` syntax:

- `SELECT ... INTO @variable`
- `SELECT .. GROUP BY expr` does not imply `GROUP BY expr ORDER BY expr` as it does in MySQL 5.7.

For more details, see the `SELECT` statement reference.

2.4.2.8 `UPDATE` statement

See the `UPDATE` statement reference.

2.4.2.9 Views

Views in TiDB are not updatable and do not support write operations such as `UPDATE`, `INSERT`, and `DELETE`.

2.4.2.10 Temporary tables

For more information, see Compatibility between TiDB local temporary tables and MySQL temporary tables.

2.4.2.11 Character sets and collations

- To learn about the character sets and collations supported by TiDB, see Character Set and Collation Overview.
- For information on the MySQL compatibility of the GBK character set, refer to GBK compatibility .
- TiDB inherits the character set used in the table as the national character set.

2.4.2.12 Storage engines

TiDB allows for tables to be created with alternative storage engines. Despite this, the metadata as described by TiDB is for the InnoDB storage engine as a way to ensure compatibility.

To specify a storage engine using the `--store` option, it is necessary to start the TiDB server. This storage engine abstraction feature is similar to MySQL.

2.4.2.13 SQL modes

TiDB supports most SQL modes:

- The compatibility modes, such as `Oracle` and `PostgreSQL` are parsed but ignored. Compatibility modes are deprecated in MySQL 5.7 and removed in MySQL 8.0.
- The `ONLY_FULL_GROUP_BY` mode has minor semantic differences from MySQL 5.7.
- The `NO_DIR_IN_CREATE` and `NO_ENGINE_SUBSTITUTION` SQL modes in MySQL are accepted for compatibility, but are not applicable to TiDB.

2.4.2.14 Default differences

TiDB has default differences when compared with MySQL 5.7 and MySQL 8.0:

- Default character set:
  - TiDB's default value is `utf8mb4`.
  - MySQL 5.7's default value is `latin1`.
  - MySQL 8.0's default value is `utf8mb4`.
- Default collation:
  - TiDB's default collation is `utf8mb4_bin`.
  - MySQL 5.7's default collation is `utf8mb4_general_ci`.
  - MySQL 8.0's default collation is `utf8mb4_0900_ai_ci`.
- Default SQL mode:
  - TiDB's default SQL mode includes these modes: `ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`.
  - MySQL's default SQL mode:
    - The default SQL mode in MySQL 5.7 is the same as TiDB.
    - The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_ENGINE_SUBSTITUTION`.
- Default value of `lower_case_table_names`:
  - The default value in TiDB is `2`, and only `2` is currently supported.
  - MySQL defaults to the following values:
    - On Linux: `0`. It means that table and database names are stored on disk according to the letter case specified in the `CREATE TABLE` or `CREATE DATABASE` statement. Name comparisons are case-sensitive.
    - On Windows: `1`. It means table names are stored in lowercase on disk, and name comparisons are not case-sensitive. MySQL converts all table names to lowercase on storage and lookup. This behavior also applies to database names and table aliases.

    - On macOS: `2`. It means table and database names are stored on disk according to the letter case specified in the `CREATE TABLE` or `CREATE DATABASE` statement, but MySQL converts them to lowercase on lookup. Name comparisons are not case-sensitive.

- Default value of `explicit_defaults_for_timestamp`:
    - The default value in TiDB is `ON`, and only `ON` is currently supported.
    - MySQL defaults to the following values:
        - For MySQL 5.7: `OFF`.
        - For MySQL 8.0: `ON`.

2.4.2.15 Date and Time

TiDB supports named timezones with the following considerations:

- TiDB uses all the timezone rules presently installed in the system for calculation, typically the `tzdata` package. This makes it possible to use all timezone names without needing to import timezone table data. Importing timezone table data will not change the calculation rules.
- Currently, MySQL uses the local timezone by default, then relies on the current timezone rules built into the system (for example, when daylight savings time begins) for calculation. Without importing timezone table data, MySQL cannot specify the timezone by name.

2.4.2.16 Type system differences

The following column types are supported by MySQL but **not** by TiDB:

- `SQL_TSI_*` (includes SQL_TSI_MONTH, SQL_TSI_WEEK, SQL_TSI_DAY, SQL_TSI_HOUR, SQL_TSI_MINUTE, and SQL_TSI_SECOND, but excludes SQL_TSI_YEAR)

2.4.2.17 Regular expressions

For information about TiDB regular expression compatibility with MySQL, including `REGEXP_INSTR()`, `REGEXP_LIKE()`, `REGEXP_REPLACE()`, and `REGEXP_SUBSTR()`, see Regular expression compatibility with MySQL.

2.4.2.18 Incompatibility due to deprecated features

TiDB does not implement specific features deprecated in MySQL, including:

- Specifying precision for floating-point types. MySQL 8.0 deprecates this feature, and it is recommended to use the `DECIMAL` type instead.
- The `ZEROFILL` attribute. MySQL 8.0 deprecates this feature, and it is recommended to pad numeric values in your application instead.

2.4.2.19 `CREATE RESOURCE GROUP`, `DROP RESOURCE GROUP`, and `ALTER RESOURCE GROUP` statements

The following statements for creating, modifying, and dropping resource groups have different supported parameters than MySQL. For details, see the following documents:

- `CREATE RESOURCE GROUP`
- `DROP RESOURCE GROUP`
- `ALTER RESOURCE GROUP`

2.4.3 Differences on pessimistic transaction (lock) with MySQL InnoDB

For differences on pessimistic transaction (lock) between TiDB and MySQL InnoDB, see Differences from MySQL InnoDB.

2.5 TiDB Limitations

This document describes the common usage limitations of TiDB, including the maximum identifier length and the maximum number of supported databases, tables, indexes, partitioned tables, and sequences.

> **Note:**
>
> TiDB offers high compatibility with the MySQL protocol and syntax, including many MySQL limitations. For example, a single index can include a maximum of 16 columns. For more information, see MySQL Compatibility and the official MySQL documentation.

2.5.1 Limitations on identifier length

Identifier type	Maximum length (number of characters allowed)
Database	64
Table	64
Column	64
Index	64
View	64
Sequence	64

2.5.2 Limitations on the total number of databases, tables, views, and connections

Type	Maximum number
Databases	unlimited
Tables	unlimited
Views	unlimited
Connections	unlimited

2.5.3 Limitations on a single database

Type	Upper limit
Tables	unlimited

2.5.4 Limitations on a single table

Type	Upper limit (default value)
Columns	Defaults to 1017 and can be adjusted up to 4096
Indexes	Defaults to 64 and can be adjusted up to 512
Rows	unlimited
Size	unlimited
Partitions	8192

- The upper limit of `Columns` can be modified via `table-column-count-limit`.
- The upper limit of `Indexes` can be modified via `index-limit`.

2.5.5 Limitation on a single row

Type	Upper limit (default value)
Size	Defaults to 6 MiB and can be adjusted to 120 MiB

You can adjust the size limit via the `txn-entry-size-limit` configuration item.

2.5.6 Limitations on indexes

The maximum index length is 3072 bytes, equivalent to 768 characters using 4-byte UTF-8 encoding. The maximum number of columns in a single index is limited to 16.

You can adjust this limit using the `max-index-length` configuration item.

2.5.7 Limitations on data types

Type	Upper limit
CHAR	255 characters
BINARY	255 characters
VARBINARY	65535 characters
VARCHAR	16383 characters
TEXT	Defaults to 6 MiB and can be adjusted to 120 MiB
BLOB	Defaults to 6 MiB and can be adjusted to 120 MiB

2.5.8 Limitations on SQL statements

Type	Upper limit
The maximum number of SQL statements in a single transaction	When the optimistic transaction is used and the transaction retry is enabled, the upper limit is 5000.

You can modify the limit via the `stmt-count-limit` configuration item.

2.5.9 Limitations on TiKV version

In your cluster, if the version of the TiDB component is v6.2.0 or later, the version of TiKV must be v6.2.0 or later.

2.6 Credits

Each contributor has played an important role in promoting the robust development of TiDB. We sincerely appreciate all contributors who have submitted code, written and translated documents for TiDB.

2.6.1 TiDB developers

TiDB developers contribute to new feature development, performance improvement, stability guarantee, and bug fixes. The following is the list of contributors in TiDB related

repos:

- pingcap/tidb
- tikv/tikv
- tikv/pd
- pingcap/tiflash
- pingcap/tidb-operator
- pingcap/tiup
- pingcap/tidb-dashboard
- pingcap/tiflow
- pingcap/tidb-tools
- pingcap/tispark
- tikv/client-java
- tidb-incubator/TiBigData
- ti-community-infra

2.6.2 Writers and translators for TiDB documentation

Writers and translators write and translate documents for TiDB and the related projects. The following is the list of contributors in TiDB documentation related repos:

- pingcap/docs-cn
- pingcap/docs
- pingcap/docs-tidb-operator
- tikv/website

2.7 Roadmap

3 Get Started

3.1 Quick Start with TiDB Self-Managed

This guide provides the quickest way to get started with TiDB Self-Managed. For non-production environments, you can deploy your TiDB database using either of the following methods:

- Deploy a local test cluster (for macOS and Linux)
- Simulate production deployment on a single machine (for Linux only)

In addition, you can try out TiDB features on TiDB Playground.

Note:

The deployment method provided in this guide is **ONLY FOR** quick start, **NOT FOR** production or comprehensive functionality and stability testing.

- To deploy a self-hosted production cluster, see the production installation guide.
- To deploy TiDB on Kubernetes, see Get Started with TiDB on Kubernetes.
- To manage TiDB in the cloud, see TiDB Cloud Quick Start.

3.1.1 Deploy a local test cluster

This section describes how to quickly deploy a local TiDB cluster for testing on a single macOS or Linux server. By deploying such a cluster, you can learn the basic architecture of the TiDB database and the operation of its components, such as TiDB, TiKV, PD, and the monitoring components.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly set up a test cluster by following these steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

If the following message is displayed, you have successfully installed TiUP:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com
Detected shell: zsh
Shell profile: /Users/user/.zshrc
/Users/user/.zshrc has been modified to add tiup to PATH
open a new terminal or source /Users/user/.zshrc to use it
Installed path: /Users/user/.tiup/bin/tiup
===============================================
Have a try:   tiup playground
===============================================
```

Note the Shell profile path in the output above. You need to use the path in the next step.

Note:

Starting from v5.2.0, TiDB supports running `tiup playground` on the machine that uses the Apple silicon chip.

2. Declare the global environment variable:

Note:

After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path. In this case, `${your_shell_profile}` is `/Users/user/.zshrc` from the output of Step 1.

```
source ${your_shell_profile}
```

3. Start the cluster in the current session:

Note:

- For the playground operated in the following way, after the deployment and testing are finished, TiUP will automatically clean up the cluster data. You will get a new cluster after re-running the command.
- If you want to persist data on storage, then add the `--tag` flag when you start the cluster. For details, see Specify a tag when starting the TiDB cluster to store the data.

```
tiup playground --tag ${tag_name}
```

- To start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

```
tiup playground
```

If this is the first time you run the command, TiUP will download the latest version of TiDB and start the cluster.

The output displays a list of endpoints of the cluster:

```
 TiDB Playground Cluster is started, enjoy!
```

```
Connect TiDB:  mysql --comments --host 127.0.0.1 --port 4000 -u
    ↪ root
TiDB Dashboard: http://127.0.0.1:2379/dashboard
Grafana:       http://127.0.0.1:3000
```

- To specify the TiDB version and the number of instances of each component, run a command like this:

```
tiup playground v8.5.1 --db 2 --pd 3 --kv 3
```

It is recommended to run this command on a machine with at least 10 GiB of memory and 4 CPU cores. Insufficient resources might cause the system to crash. To view all available versions, run `tiup list tidb`.

4. Start a new session to access the TiDB cluster endpoints:

- Connect to the TiDB database:
  - Use the TiUP client to connect to TiDB.

```
tiup client
```

  - Alternatively, you can use the MySQL client to connect to TiDB.

```
mysql --host 127.0.0.1 --port 4000 -u root
```

- Prometheus: http://127.0.0.1:9090.
- TiDB Dashboard: http://127.0.0.1:2379/dashboard. The default username is `root`, and the password is empty.
- Grafana: http://127.0.0.1:3000. Both the default username and password are `admin`.

5. (Optional) Load data to TiFlash for analysis.

6. Clean up the cluster after testing:

1. Stop the above TiDB service by pressing Control+C.
2. Run the following command after the service is stopped:

```
tiup clean --all
```

Note:

TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly set up a test cluster by following these steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

   If the following message is displayed, you have successfully installed TiUP:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com
Detected shell: bash
Shell profile: /home/user/.bashrc
/home/user/.bashrc has been modified to add tiup to PATH
open a new terminal or source /home/user/.bashrc to use it
Installed path: /home/user/.tiup/bin/tiup
==============================================
Have a try:   tiup playground
==============================================
```

   Note the Shell profile path in the output above. You need to use the path in the next step.

2. Declare the global environment variable:

> **Note:**
> After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path.

```
source ${your_shell_profile}
```

3. Start the cluster in the current session:

> **Note:**
>
> - For the playground operated in the following way, after the deployment and testing are finished, TiUP will automatically clean up the cluster data. You will get a new cluster after re-running the command.
> - If you want to persist data on storage, then add the `--tag` flag when you start the cluster. For details, see Specify a tag when starting the TiDB cluster to store the data.

```
tiup playground --tag ${tag_name}
```

- To start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

  ```
  tiup playground
  ```

  If this is the first time you run the command, TiUP will download the latest version of TiDB and start the cluster.

  The output displays a list of endpoints of the cluster:

  ```
  □ TiDB Playground Cluster is started, enjoy!

  Connect TiDB:  mysql --comments --host 127.0.0.1 --port 4000 -u
     ↪ root
  TiDB Dashboard: http://127.0.0.1:2379/dashboard
  Grafana:       http://127.0.0.1:3000
  ```

- To specify the TiDB version and the number of instances of each component, run a command like this:

  ```
  tiup playground v8.5.1 --db 2 --pd 3 --kv 3
  ```

  To view all available versions, run `tiup list tidb`.

4. Start a new session to access the TiDB cluster endpoints:

   - Connect to the TiDB database:
     - Use the TiUP client to connect to TiDB.

       ```
       tiup client
       ```

     - Alternatively, you can use the MySQL client to connect to TiDB.

       ```
       mysql --host 127.0.0.1 --port 4000 -u root
       ```

   - Prometheus: http://127.0.0.1:9090.
   - TiDB Dashboard: http://127.0.0.1:2379/dashboard. The default username is `root`, and the password is empty.
   - Grafana: http://127.0.0.1:3000. Both the default username and password are `admin`.

5. (Optional) Load data to TiFlash for analysis.

6. Clean up the cluster after testing:

1. Stop the process by pressing Control+C.
2. Run the following command after the service is stopped:

```
tiup clean --all
```

Note:

TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

3.1.2 Simulate production deployment on a single machine

This section describes how to set up the smallest TiDB cluster with a full topology, and simulate production deployment steps on a single Linux server.

The following describes how to deploy a TiDB cluster using a YAML file of the smallest topology in TiUP.

3.1.2.1 Prepare

Before deploying the TiDB cluster, ensure that the target machine meets the following requirements:

- CentOS 7.3 or a later version is installed.
- The Linux OS has access to the internet, which is required to download TiDB and related software installation packages.

The smallest TiDB cluster topology consists of the following instances:

Instance	Count	IP	Configuration
TiKV	3	10.0.1.1	Use incremental port numbers to avoid conflicts
TiDB	1	10.0.1.1	Use default port and other configurations
PD	1	10.0.1.1	Use default port and other configurations
TiFlash	1	10.0.1.1	Use default port and other configurations
Monitor	1	10.0.1.1	Use default port and other configurations

> **Note:**
>
> The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

Other requirements for the target machine include:

- The `root` user and its password are required.
- Stop the firewall service of the target machine, or open the ports needed by the TiDB cluster nodes.
- Currently, the TiUP cluster supports deploying TiDB on the x86_64 (AMD64) and ARM architectures:
  - It is recommended to use CentOS 7.3 or later versions on AMD64 architecture.
  - It is recommended to use CentOS 7.6 (1810) on ARM architecture.

3.1.2.2 Deploy

> **Note:**
>
> You can log in to the target machine as a regular user or the `root` user. The following steps use the `root` user as an example.

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Declare the global environment variable.

> **Note:**
>
> After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path.

```
source ${your_shell_profile}
```

3. Install the cluster component of TiUP:

```
tiup cluster
```

4. If the TiUP cluster is already installed on the machine, update the software version:

```
tiup update --self && tiup update cluster
```

5. Increase the connection limit of the `sshd` service using the root user privilege. This is because TiUP needs to simulate deployment on multiple machines.

    1. Modify `/etc/ssh/sshd_config`, and set `MaxSessions` to 20.
    2. Restart the `sshd` service:

    ```
    service sshd restart
    ```

6. Create and start the cluster:

    Create and edit the topology configuration file according to the following template, and name it as `topo.yaml`:

```
# # Global variables are applied to all deployments and used as the
    ↪ default value of
# # the deployments if a specific deployment value is missing.
global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/tidb-deploy"
 data_dir: "/tidb-data"

# # Monitored variables are applied to all the machines.
monitored:
 node_exporter_port: 9100
 blackbox_exporter_port: 9115

server_configs:
 tidb:
   instance.tidb_slow_log_threshold: 300
 tikv:
   readpool.storage.use-unified-pool: false
   readpool.coprocessor.use-unified-pool: true
 pd:
   replication.enable-placement-rules: true
```

```
  replication.location-labels: ["host"]
 tiflash:
  logger.level: "info"

pd_servers:
 - host: 10.0.1.1

tidb_servers:
 - host: 10.0.1.1

tikv_servers:
 - host: 10.0.1.1
  port: 20160
  status_port: 20180
  config:
   server.labels: { host: "logic-host-1" }

 - host: 10.0.1.1
  port: 20161
  status_port: 20181
  config:
   server.labels: { host: "logic-host-2" }

 - host: 10.0.1.1
  port: 20162
  status_port: 20182
  config:
   server.labels: { host: "logic-host-3" }

tiflash_servers:
 - host: 10.0.1.1

monitoring_servers:
 - host: 10.0.1.1

grafana_servers:
 - host: 10.0.1.1
```

- `user: "tidb"`: Use the `tidb` system user (automatically created during deployment) to perform the internal management of the cluster. By default, use port 22 to log in to the target machine via SSH.
- `replication.enable-placement-rules`: This PD parameter is set to ensure that TiFlash runs normally.
- `host`: The IP of the target machine.

7. Execute the cluster deployment command:

```
tiup cluster deploy <cluster-name> <version> ./topo.yaml --user root -p
```

- `<cluster-name>`: sets the cluster name.
- `<version>`: sets the TiDB cluster version, such as `v8.5.1`. You can see all the supported TiDB versions by running the `tiup list tidb` command.
- `--user`: specifies the user to initialize the environment.
- `-p`: specifies the password used to connect to the target machine.

> **Note:**
> If you use secret keys, you can specify the path of the keys through `-i`. Do not use `-i` and `-p` at the same time.

Enter "y" and the `root` user's password to complete the deployment:

```
Do you want to continue? [y/N]: y
Input SSH password:
```

8. Start the cluster:

```
tiup cluster start <cluster-name>
```

9. Access the cluster endpoints:

- Install the MySQL client. If it is already installed, skip this step.

```
yum -y install mysql
```

- Connect to the TiDB database using the MySQL client. The password is empty:

```
mysql -h 10.0.1.1 -P 4000 -u root
```

- Grafana: http://%7Bgrafana-ip%7D:3000. The default username and password are both `admin`.
- TiDB Dashboard: http://%7Bpd-ip%7D:2379/dashboard. The default username is `root`, and the password is empty.

10. (Optional) View the cluster list and topology.

- To view the cluster list:

```
tiup cluster list
```

- To view the cluster topology and status:

```
tiup cluster display <cluster-name>
```

To learn more about the `tiup cluster` commands, see TiUP Cluster Commands.

11. Clean up the cluster after testing:

    1. Stop the above TiDB service by pressing Control+C.
    2. Run the following command after the service is stopped:

```
tiup clean --all
```

3.1.3 What's next

If you have just deployed a TiDB cluster for the local test environment, here are the next steps:

- Learn about basic SQL operations in TiDB by referring to Basic SQL operations in TiDB.
- You can also migrate data to TiDB by referring to Migrate data to TiDB.
- Learn more about using TiUP to manage TiDB clusters by referring to TiUP Overview.

If you are ready to deploy a TiDB cluster for the production environment, here are the next steps:

- Deploy TiDB using TiUP
- Alternatively, you can deploy TiDB on Cloud using TiDB Operator by referring to the TiDB on Kubernetes documentation.

If you are an application developer and want to quickly build an application using TiDB, here are the next steps:

- Developer Guide Overview
- Build a TiDB Cloud Serverless Cluster
- Example Applications

If you are looking for an analytics solution with TiFlash, here are the next steps:

- TiFlash Overview
- Use TiFlash

3.2 Quick Start with TiDB HTAP

This guide walks you through the quickest way to get started with TiDB's one-stop solution of Hybrid Transactional and Analytical Processing (HTAP).

> **Note:**
>
> The steps provided in this guide is ONLY for quick start in the test environment. For production environments, explore HTAP is recommended.

3.2.1 Basic concepts

Before using TiDB HTAP, you need to have some basic knowledge about TiKV, a row-based storage engine for TiDB Online Transactional Processing (OLTP), and TiFlash, a columnar storage engine for TiDB Online Analytical Processing (OLAP).

- Storage engines of HTAP: The row-based storage engine and the columnar storage engine co-exist for HTAP. Both storage engines can replicate data automatically and keep strong consistency. The row-based storage engine optimizes OLTP performance, and the columnar storage engine optimizes OLAP performance.
- Data consistency of HTAP: As a distributed and transactional key-value database, TiKV provides transactional interfaces with ACID compliance, and guarantees data consistency between multiple replicas and high availability with the implementation of the Raft consensus algorithm. As a columnar storage extension of TiKV, TiFlash replicates data from TiKV in real time according to the Raft Learner consensus algorithm, which ensures that data is strongly consistent between TiKV and TiFlash.
- Data isolation of HTAP: TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.
- MPP computing engine: MPP is a distributed computing framework provided by the TiFlash engine since TiDB 5.0, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. In the MPP mode, the run time of the analytic queries can be significantly reduced.

3.2.2 Steps

In this document, you can experience the convenience and high performance of TiDB HTAP by querying an example table in a TPC-H dataset. TPC-H is a popular decision support benchmark that consists of a suite of business oriented ad-hoc queries with large volumes of data and a high degree of complexity. To experience 22 complete SQL queries using TPC-H, visit tidb-bench repo or TPC-H for instructions on how to generate query statements and data.

3.2.2.1 Step 1. Deploy a local test environment

Before using TiDB HTAP, follow the steps in the Quick Start with TiDB Self-Managed to prepare a local test environment, and run the following command to deploy a TiDB cluster:

```
tiup playground
```

> **Note:**
>
> `tiup playground` command is ONLY for quick start, NOT for production.

3.2.2.2 Step 2. Prepare test data

In the following steps, you can create a TPC-H dataset as the test data to use TiDB HTAP. If you are interested in TPC-H, see General Implementation Guidelines.

> **Note:**
>
> If you want to use your existing data for analytic queries, you can migrate your data to TiDB. If you want to design and create your own test data, you can create it by executing SQL statements or using related tools.

1. Install the test data generation tool by running the following command:

   ```
   tiup install bench
   ```

2. Generate the test data by running the following command:

   ```
   tiup bench tpch --sf=1 prepare
   ```

   If the output of this command shows `Finished`, it indicates that the data is created.

3. Execute the following SQL statement to view the generated data:

   ```
   SELECT
     CONCAT(table_schema,'.',table_name) AS 'Table Name',
     table_rows AS 'Number of Rows',
     FORMAT_BYTES(data_length) AS 'Data Size',
     FORMAT_BYTES(index_length) AS 'Index Size',
     FORMAT_BYTES(data_length+index_length) AS'Total'
   FROM
   ```

```
  information_schema.TABLES
WHERE
  table_schema='test';
```

As you can see from the output, eight tables are created in total, and the largest table has 6.5 million rows (the number of rows created by the tool depends on the actual SQL query result because the data is randomly generated).

```
+--
    ↪ ------------+---------------+----------+----------+----------+
    ↪
|  Table Name  | Number of Rows | Data Size | Index Size | Total |
+--
    ↪ ------------+---------------+----------+----------+----------+
    ↪
| test.nation |            25 | 2.44 KiB | 0 bytes  | 2.44 KiB |
| test.region |             5 | 416 bytes | 0 bytes | 416 bytes |
| test.part   |        200000 | 25.07 MiB | 0 bytes | 25.07 MiB |
| test.supplier |       10000 | 1.45 MiB | 0 bytes | 1.45 MiB |
| test.partsupp |      800000 | 120.17 MiB| 12.21 MiB | 132.38 MiB|
| test.customer |      150000 | 24.77 MiB | 0 bytes | 24.77 MiB |
| test.orders |       1527648 | 174.40 MiB| 0 bytes | 174.40 MiB|
| test.lineitem |     6491711 | 849.07 MiB| 99.06 MiB | 948.13 MiB|
+--
    ↪ ------------+---------------+----------+----------+----------+
    ↪
8 rows in set (0.06 sec)
```

This is a database of a commercial ordering system. In which, the `test.nation` table indicates the information about countries, the `test.region` table indicates the information about regions, the `test.part` table indicates the information about parts, the `test.supplier` table indicates the information about suppliers, the `test.partsupp` ↪ table indicates the information about parts of suppliers, the `test.customer` table indicates the information about customers, the `test.customer` table indicates the information about orders, and the `test.lineitem` table indicates the information about online items.

3.2.2.3 Step 3. Query data with the row-based storage engine

To know the performance of TiDB with only the row-based storage engine, execute the following SQL statements:

```
USE test;
SELECT
    l_orderkey,
    SUM(
```

```
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    o_orderdate,
    o_shippriority
FROM
    customer,
    orders,
    lineitem
WHERE
    c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
    l_orderkey,
    o_orderdate,
    o_shippriority
ORDER BY
    revenue DESC,
    o_orderdate
limit 10;
```

This is a shipping priority query, which provides the priority and potential revenue of the highest-revenue order that has not been shipped before a specified date. The potential revenue is defined as the sum of `l_extendedprice * (1-l_discount)`. The orders are listed in the descending order of revenue. In this example, this query lists the unshipped orders with potential query revenue in the top 10.

3.2.2.4 Step 4. Replicate the test data to the columnar storage engine

After TiFlash is deployed, TiKV does not replicate data to TiFlash immediately. You need to execute the following DDL statements in a MySQL client of TiDB to specify which tables need to be replicated. After that, TiDB will create the specified replicas in TiFlash accordingly.

```
ALTER TABLE test.customer SET TIFLASH REPLICA 1;
ALTER TABLE test.orders SET TIFLASH REPLICA 1;
ALTER TABLE test.lineitem SET TIFLASH REPLICA 1;
```

To check the replication status of the specific tables, execute the following statements:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'customer';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'orders';
```

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
    ↪ ' and TABLE_NAME = 'lineitem';
```

In the result of the above statements:

- `AVAILABLE` indicates whether the TiFlash replica of a specific table is available or not. `1` means available and `0` means unavailable. Once the `AVAILABLE` field becomes `1`, this status does not change anymore.
- `PROGRESS` means the progress of the replication. The value is between 0.0 and 1.0. 1 means that the replication progress of the TiFlash replica is complete.

3.2.2.5 Step 5. Analyze data faster using HTAP

Execute the SQL statements in Step 3 again, and you can see the performance of TiDB HTAP.

For tables with TiFlash replicas, the TiDB optimizer automatically determines whether to use TiFlash replicas based on the cost estimation. To check whether or not a TiFlash replica is selected, you can use the `desc` or `explain analyze` statement. For example:

```
USE test;
EXPLAIN ANALYZE SELECT
    l_orderkey,
    SUM(
        l_extendedprice * (1 - l_discount)
    ) AS revenue,
    o_orderdate,
    o_shippriority
FROM
    customer,
    orders,
    lineitem
WHERE
    c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
    l_orderkey,
    o_orderdate,
    o_shippriority
ORDER BY
    revenue DESC,
    o_orderdate
limit 10;
```

If the result of the `EXPLAIN` statement shows `ExchangeSender` and `ExchangeReceiver` operators, it indicates that the MPP mode has taken effect.

In addition, you can specify that each part of the entire query is computed using only the TiFlash engine. For detailed information, see Use TiDB to read TiFlash replicas.

You can compare query results and query performance of these two methods.

3.2.3 What's next

- Architecture of TiDB HTAP
- Explore HTAP
- Use TiFlash

3.3 Explore SQL with TiDB

TiDB is compatible with MySQL, you can use MySQL statements directly in most of the cases. For unsupported features, see Compatibility with MySQL.

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can try TiDB Playground. You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML and CRUD operations. For a complete list of TiDB statements, see SQL Statement Overview.

3.3.1 Category

SQL is divided into the following 4 types according to their functions:

- DDL (Data Definition Language): It is used to define database objects, including databases, tables, views, and indexes.
- DML (Data Manipulation Language): It is used to manipulate application related records.
- DQL (Data Query Language): It is used to query the records after conditional filtering.
- DCL (Data Control Language): It is used to define access privileges and security levels.

Common DDL features are creating, modifying, and deleting objects (such as tables and indexes). The corresponding commands are `CREATE`, `ALTER`, and `DROP`.

3.3.2 Show, create and drop a database

A database in TiDB can be considered as a collection of objects such as tables and indexes.

To show the list of databases, use the `SHOW DATABASES` statement:

```
SHOW DATABASES;
```

To use the database named `mysql`, use the following statement:

```
USE mysql;
```

To show all the tables in a database, use the `SHOW TABLES` statement:

```
SHOW TABLES FROM mysql;
```

To create a database, use the `CREATE DATABASE` statement:

```
CREATE DATABASE db_name [options];
```

To create a database named `samp_db`, use the following statement:

```
CREATE DATABASE IF NOT EXISTS samp_db;
```

Add `IF NOT EXISTS` to prevent an error if the database exists.

To delete a database, use the `DROP DATABASE` statement:

```
DROP DATABASE samp_db;
```

3.3.3 Create, show, and drop a table

To create a table, use the `CREATE TABLE` statement:

```
CREATE TABLE table_name column_name data_type constraint;
```

For example, to create a table named `person` which includes fields such as number, name, and birthday, use the following statement:

```
CREATE TABLE person (
    id INT,
    name VARCHAR(255),
    birthday DATE
    );
```

To view the statement that creates the table (DDL), use the `SHOW CREATE` statement:

```
SHOW CREATE table person;
```

To delete a table, use the `DROP TABLE` statement:

```
DROP TABLE person;
```

3.3.4 Create, show, and drop an index

Indexes are used to speed up queries on indexed columns. To create an index for the column whose value is not unique, use the `CREATE INDEX` statement:

```
CREATE INDEX person_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD INDEX person_id (id);
```

To create a unique index for the column whose value is unique, use the `CREATE UNIQUE INDEX` statement:

```
CREATE UNIQUE INDEX person_unique_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD UNIQUE person_unique_id (id);
```

To show all the indexes in a table, use the `SHOW INDEX` statement:

```
SHOW INDEX FROM person;
```

To delete an index, use the `DROP INDEX` or `ALTER TABLE` statement. `DROP INDEX` can be nested in `ALTER TABLE`:

```
DROP INDEX person_id ON person;
```

```
ALTER TABLE person DROP INDEX person_unique_id;
```

> **Note:**
>
> DDL operations are not transactions. You don't need to run a `COMMIT` statement when executing DDL operations.

3.3.5 Insert, update, and delete data

Common DML features are adding, modifying, and deleting table records. The corresponding commands are `INSERT`, `UPDATE`, and `DELETE`.

To insert data into a table, use the `INSERT` statement:

```
INSERT INTO person VALUES(1,'tom','20170912');
```

To insert a record containing data of some fields into a table, use the `INSERT` statement:

```
INSERT INTO person(id,name) VALUES('2','bob');
```

To update some fields of a record in a table, use the `UPDATE` statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

> **Note:**
>
> The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

3.3.6 Query data

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
```

```
+------+
| name |
+------+
| tom |
+------+
1 rows in set (0.00 sec)
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person where id<5;
```

3.3.7 Create, authorize, and delete a user

DCL are usually used to create or delete users, and manage user privileges.

To create a user, use the `CREATE USER` statement. The following example creates a user named `tiuser` with the password `123456`:

```
CREATE USER 'tiuser'@'localhost' IDENTIFIED BY '123456';
```

To grant `tiuser` the privilege to retrieve the tables in the `samp_db` database:

```
GRANT SELECT ON samp_db.* TO 'tiuser'@'localhost';
```

To check the privileges of `tiuser`:

```
SHOW GRANTS for tiuser@localhost;
```

To delete `tiuser`:

```
DROP USER 'tiuser'@'localhost';
```

3.4 Explore HTAP

This guide describes how to explore and use the features of TiDB Hybrid Transactional and Analytical Processing (HTAP).

> **Note:**
>
> If you are new to TiDB HTAP and want to start using it quickly, see Quick Start with TiDB HTAP.

3.4.1 Use cases

TiDB HTAP can handle the massive data that increases rapidly, reduce the cost of DevOps, and be deployed in either self-hosted or cloud environments easily, which brings the value of data assets in real time.

The following are the typical use cases of HTAP:

- Hybrid workload

  When using TiDB for real-time Online Analytical Processing (OLAP) in hybrid load scenarios, you only need to provide an entry point of TiDB to your data. TiDB automatically selects different processing engines based on the specific business.

- Real-time stream processing

  When using TiDB in real-time stream processing scenarios, TiDB ensures that all the data flowed in constantly can be queried in real time. At the same time, TiDB also can handle highly concurrent data workloads and Business Intelligence (BI) queries.

- Data hub

  When using TiDB as a data hub, TiDB can meet specific business needs by seamlessly connecting the data for the application and the data warehouse.

For more information about use cases of TiDB HTAP, see blogs about HTAP on the PingCAP website.

To enhance the overall performance of TiDB, it is recommended to use HTAP in the following technical scenarios:

- Improve analytical processing performance

  If your application involves complex analytical queries, such as aggregation and join operations, and these queries are performed on a large amount of data (more than 10 million rows), the row-based storage engine TiKV might not meet your performance requirements if the tables in these queries cannot effectively use indexes or have low index selectivity.

- Hybrid workload isolation

While dealing with high-concurrency Online Transactional Processing (OLTP) workloads, your system might also need to handle some OLAP workloads. To ensure the overall system stability, you expect to avoid the impact of OLAP queries on OLTP performance.

- Simplify the ETL technology stack

  When the amount of data to be processed is of medium scale (less than 100 TB), the data processing and scheduling processes are relatively simple, and the concurrency is not high (less than 10), you might want to simplify the technology stack of your system. By replacing multiple different technology stacks used in OLTP, ETL, and OLAP systems with a single database, you can meet the requirements of both transactional systems and analytical systems. This reduces technical complexity and the need for maintenance personnel.

- Strongly consistent analysis

  To achieve real-time, strongly consistent data analysis and calculation, and ensure the analysis results to be completely consistent with the transactional data, you need to avoid data latency and inconsistency issues.

3.4.2 Architecture

In TiDB, a row-based storage engine TiKV for Online Transactional Processing (OLTP) and a columnar storage engine TiFlash for Online Analytical Processing (OLAP) co-exist, replicate data automatically, and keep strong consistency.

For more information about the architecture, see architecture of TiDB HTAP.

3.4.3 Environment preparation

Before exploring the features of TiDB HTAP, you need to deploy TiDB and the corresponding storage engines according to the data volume. If the data volume is large (for example, 100 T), it is recommended to use TiFlash Massively Parallel Processing (MPP) as the primary solution and TiSpark as the supplementary solution.

- TiFlash
    - If you have deployed a TiDB cluster with no TiFlash node, add the TiFlash nodes in the current TiDB cluster. For detailed information, see Scale out a TiFlash cluster.
    - If you have not deployed a TiDB cluster, see Deploy a TiDB Cluster Using TiUP. Based on the minimal TiDB topology, you also need to deploy the topology of TiFlash.
    - When deciding how to choose the number of TiFlash nodes, consider the following scenarios:
        - If your use case requires OLTP with small-scale analytical processing and Ad-Hoc queries, deploy one or several TiFlash nodes. They can dramatically increase the speed of analytic queries.
        - If the OLTP throughput does not cause significant pressure to I/O usage rate of the TiFlash nodes, each TiFlash node uses more resources for computation, and thus the TiFlash cluster can have near-linear scalability. The number of TiFlash nodes should be tuned based on expected performance and response time.
        - If the OLTP throughput is relatively high (for example, the write or update throughput is higher than 10 million lines/hours), due to the limited write capacity of network and physical disks, the I/O between TiKV and TiFlash becomes a bottleneck and is also prone to read and write hotspots. In this case, the number of TiFlash nodes has a complex non-linear relationship with the computation volume of analytical processing, so you need to tune the number of TiFlash nodes based on the actual status of the system.
- TiSpark
    - If your data needs to be analyzed with Spark, deploy TiSpark. For specific process, see TiSpark User Guide.

3.4.4 Data preparation

After TiFlash is deployed, TiKV does not replicate data to TiFlash automatically. You need to manually specify which tables need to be replicated to TiFlash. After that, TiDB creates the corresponding TiFlash replicas.

- If there is no data in the TiDB Cluster, migrate the data to TiDB first. For detailed information, see data migration.
- If the TiDB cluster already has the replicated data from upstream, after TiFlash is deployed, data replication does not automatically begin. You need to manually specify the tables to be replicated to TiFlash. For detailed information, see Use TiFlash.

3.4.5 Data processing

With TiDB, you can simply enter SQL statements for query or write requests. For the tables with TiFlash replicas, TiDB uses the front-end optimizer to automatically choose the optimal execution plan.

Note:

The MPP mode of TiFlash is enabled by default. When an SQL statement is executed, TiDB automatically determines whether to run in the MPP mode through the optimizer.

- To disable the MPP mode of TiFlash, set the value of the tidb_allow_mpp system variable to `OFF`.
- To forcibly enable MPP mode of TiFlash for query execution, set the values of tidb_allow_mpp and tidb_enforce_mpp to `ON`.
- To check whether TiDB chooses the MPP mode to execute a specific query, see Explain Statements in the MPP Mode. If the output of `EXPLAIN` statement includes the `ExchangeSender` and `ExchangeReceiver` operators, the MPP mode is in use.

3.4.6 Performance monitoring

When using TiDB, you can monitor the TiDB cluster status and performance metrics in either of the following ways:

- TiDB Dashboard: you can see the overall running status of the TiDB cluster, analyse distribution and trends of read and write traffic, and learn the detailed execution information of slow queries.

- Monitoring system (Prometheus & Grafana): you can see the monitoring parameters of TiDB cluster-related components including PD, TiDB, TiKV, TiFlash, TiCDC, and Node_exporter.

To see the alert rules of TiDB cluster and TiFlash cluster, see TiDB cluster alert rules and TiFlash alert rules.

3.4.7 Troubleshooting

If any issue occurs during using TiDB, refer to the following documents:

- Analyze slow queries
- Identify expensive queries
- Troubleshoot hotspot issues
- TiDB cluster troubleshooting guide
- Troubleshoot a TiFlash Cluster

You are also welcome to create GitHub Issues or submit your questions on AskTUG.

3.4.8 What's next

- To check the TiFlash version, critical logs, system tables, see Maintain a TiFlash cluster.
- To remove a specific TiFlash node, see Scale out a TiFlash cluster.

3.5 Import Example Database

Examples used in the TiDB manual use System Data from Capital Bikeshare, released under the Capital Bikeshare Data License Agreement.

3.5.1 Download all data files

The system data is available for download in .zip files organized per year. Downloading and extracting all files requires approximately 3GB of disk space. To download all files for years 2010-2017 using a bash script:

```
mkdir -p bikeshare-data && cd bikeshare-data

curl -L --remote-name-all https://s3.amazonaws.com/capitalbikeshare-data
    ↪ /{2010..2017}-capitalbikeshare-tripdata.zip
unzip \*-tripdata.zip
```

3.5.2 Load data into TiDB

You can import the system data into TiDB using the following method.

1. Rename the CSV files.

```
i=1; for csv in *csv; do mv $csv bikeshare.trips.$(printf "%03d" $i).
    ↪ csv; i=$((i+1)); done
```

2. Create the database and table.

```
CREATE SCHEMA bikeshare;
USE bikeshare;
CREATE TABLE trips (
  `trip_id` BIGINT NOT NULL PRIMARY KEY AUTO_RANDOM,
  `duration` INT NOT NULL,
  `start date` DATETIME,
  `end date` DATETIME,
  `start station number` INT,
  `start station` VARCHAR(255),
  `end station number` INT,
  `end station` VARCHAR(255),
  `bike number` VARCHAR(255),
  `member type` VARCHAR(255)
);
```

3. Create a `tidb-lightning.toml` file as follows:

```
[tikv-importer]
backend = "tidb"

[mydumper]
no-schema = true
data-source-dir = "~/bikeshare-data"

[mydumper.csv]
header = true

[tidb]
host = "127.0.0.1"
port = 4000
user = "root"
password = "very_secret"
```

4. Run the following command.

```
tiup tidb-lightning -c tidb-lightning.toml
```

4 Develop

4.1 Developer Guide Overview

This guide is written for application developers, but if you are interested in the inner workings of TiDB or want to get involved in TiDB development, read the TiDB Kernel Development Guide for more information about TiDB.

This tutorial shows how to quickly build an application using TiDB, the possible use cases of TiDB and how to handle common problems.

Before reading this page, it is recommended that you read the Quick Start with TiDB Self-Managed.

4.1.1 TiDB basics

Before you start working with TiDB, you need to understand some important mechanisms of how TiDB works:

- Read the TiDB Transaction Overview to understand how transactions work in TiDB, or check out the Transaction Notes for Application Developers to learn about transaction knowledge required for application development.
- Understand the way applications interact with TiDB.
- To learn core components and concepts of building up the distributed database TiDB and TiDB Cloud, refer to the free online course Introduction to TiDB.

4.1.2 TiDB transaction mechanisms

TiDB supports distributed transactions and offers both optimistic transaction and pessimistic transaction modes. The current version of TiDB uses the **pessimistic transaction** mode by default, which allows you to transact with TiDB as you would with a traditional monolithic database (for example, MySQL).

You can start a transaction using `BEGIN`, explicitly specify a **pessimistic transaction** using `BEGIN PESSIMISTIC`, or explicitly specify an **optimistic transaction** using `BEGIN OPTIMISTIC`. After that, you can either commit (`COMMIT`) or roll back (`ROLLBACK`) the transaction.

TiDB guarantees atomicity for all statements between the start of `BEGIN` and the end of `COMMIT` or `ROLLBACK`, that is, all statements that are executed during this period either succeed or fail as a whole. This is used to ensure data consistency you need for application development.

If you are not sure what an **optimistic transaction** is, do ***NOT*** use it yet. Because **optimistic transactions** require that the application can correctly handle all errors returned by the `COMMIT` statement. If you are not sure how your application handles them, use a **pessimistic transaction** instead.

4.1.3 The way applications interact with TiDB

TiDB is highly compatible with the MySQL protocol and supports most MySQL syntax and features, so most MySQL connection libraries are compatible with TiDB. If your application framework or language does not have an official adaptation from PingCAP, it is recommended that you use MySQL's client libraries. More and more third-party libraries are actively supporting TiDB's different features.

Since TiDB is compatible with the MySQL protocol and MySQL syntax, most of the ORMs that support MySQL are also compatible with TiDB.

4.1.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.2 Quick Start

4.2.1 Build a TiDB Cloud Serverless Cluster

This document walks you through the quickest way to get started with TiDB. You will use TiDB Cloud to create a TiDB Cloud Serverless cluster, connect to it, and run a sample application on it.

If you need to run TiDB on your local machine, see Starting TiDB Locally.

4.2.1.1 Step 1. Create a TiDB Cloud Serverless cluster

1. If you do not have a TiDB Cloud account, click here to sign up for an account.
2. Log in to your TiDB Cloud account.
3. On the **Clusters** page, click **Create Cluster**.

4. On the **Create Cluster** page, **Serverless** is selected by default. Update the default cluster name if necessary, and then select the region where you want to create your cluster.

5. Click **Create** to create a TiDB Cloud Serverless cluster.

   Your TiDB Cloud cluster will be created in approximately 30 seconds.

6. After your TiDB Cloud cluster is created, click your cluster name to go to the cluster overview page, and then click **Connect** in the upper-right corner. A connection dialog box is displayed.

7. In the dialog, select your preferred connection method and operating system to get the corresponding connection string. This document uses MySQL client as an example.

8. Click **Generate Password** to generate a random password. The generated password will not show again, so save your password in a secure location. If you do not set a root password, you cannot connect to the cluster.

> **Note:**
>
> For TiDB Cloud Serverless clusters, when you connect to your cluster, you must include the prefix for your cluster in the user name and wrap the name with quotation marks. For more information, see User name prefix.

4.2.1.2 Step 2. Connect to a cluster

1. If the MySQL client is not installed, select your operating system and follow the steps below to install it.

For macOS, install Homebrew if you do not have it, and then run the following command to install the MySQL client:

```
brew install mysql-client
```

The output is as follows:

```
mysql-client is keg-only, which means it was not symlinked into /opt/
    ↪ homebrew,
because it conflicts with mysql (which contains client libraries).

If you need to have mysql-client first in your PATH, run:
  echo 'export PATH="/opt/homebrew/opt/mysql-client/bin:$PATH"' >> ~/.zshrc
```

```
For compilers to find mysql-client you may need to set:
  export LDFLAGS="-L/opt/homebrew/opt/mysql-client/lib"
  export CPPFLAGS="-I/opt/homebrew/opt/mysql-client/include"
```

To add the MySQL client to your PATH, locate the following command in the above output (if your output is inconsistent with the above output in the document, use the corresponding command in your output instead) and run it:

```
echo 'export PATH="/opt/homebrew/opt/mysql-client/bin:$PATH"' >> ~/.zshrc
```

Then, declare the global environment variable by the `source` command and verify that the MySQL client is installed successfully:

```
source ~/.zshrc
mysql --version
```

An example of the expected output:

```
mysql Ver 8.0.28 for macos12.0 on arm64 (Homebrew)
```

For Linux, the following takes Ubuntu as an example:

```
apt-get install mysql-client
```

Then, verify that the MySQL client is installed successfully:

```
mysql --version
```

An example of the expected output:

```
mysql Ver 15.1 Distrib 5.5.68-MariaDB, for Linux (x86_64) using readline
    ↪ 5.1
```

2. Run the connection string obtained in Step 1.

    ```
    mysql --connect-timeout 15 -u '<prefix>.root' -h <host> -P 4000 -D test
        ↪  --ssl-mode=VERIFY_IDENTITY --ssl-ca=/etc/ssl/cert.pem -p
    ```

    Note:

    - When you connect to a TiDB Cloud Serverless cluster, you must use the TLS connection.
    - If you encounter problems when connecting to a TiDB Cloud Serverless cluster, you can read Secure Connections to TiDB Cloud Serverless Clusters for more information.

3. Fill in the password to sign in.

4.2.1.3 Step 3. Execute a SQL statement

Let's try to execute your first SQL statement on TiDB Cloud.

```
SELECT 'Hello TiDB Cloud!';
```

Expected output:

```
+--------------------+
| Hello TiDB Cloud! |
+--------------------+
| Hello TiDB Cloud! |
+--------------------+
```

If your actual output is similar to the expected output, congratulations, you have successfully executed a SQL statement on TiDB Cloud.

4.2.1.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.2.2 CRUD SQL in TiDB

This document briefly introduces how to use TiDB's CRUD SQL.

4.2.2.1 Before you start

Please make sure you are connected to a TiDB cluster. If not, refer to Build a TiDB Cloud Serverless Cluster to create a TiDB Cloud Serverless cluster.

4.2.2.2 Explore SQL with TiDB

> **Note:**
>
> This document references and simplifies Explore SQL with TiDB. For more details, see Explore SQL with TiDB.

TiDB is compatible with MySQL, you can use MySQL statements directly in most cases. For unsupported features, see Compatibility with MySQL.

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can try TiDB Playground. You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML, and CRUD operations. For a complete list of TiDB statements, see SQL Statement Overview.

4.2.2.3 Category

SQL is divided into the following 4 types according to their functions:

- **DDL (Data Definition Language)**: It is used to define database objects, including databases, tables, views, and indexes.
- **DML (Data Manipulation Language)**: It is used to manipulate application related records.
- **DQL (Data Query Language)**: It is used to query the records after conditional filtering.
- **DCL (Data Control Language)**: It is used to define access privileges and security levels.

The following mainly introduces DML and DQL. For more information about DDL and DCL, see Explore SQL with TiDB or SQL Statement Overview.

4.2.2.4 Data Manipulation Language

Common DML features are adding, modifying, and deleting table records. The corresponding commands are `INSERT`, `UPDATE`, and `DELETE`.

To insert data into a table, use the `INSERT` statement:

```
INSERT INTO person VALUES(1,'tom','20170912');
```

To insert a record containing data of some fields into a table, use the `INSERT` statement:

```
INSERT INTO person(id,name) VALUES('2','bob');
```

To update some fields of a record in a table, use the `UPDATE` statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

> **Note:**
>
> The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

4.2.2.5 Data Query Language

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
```

The result is as follows:

```
+------+
| name |
+------+
| tom |
+------+
1 rows in set (0.00 sec)
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person WHERE id < 5;
```

4.2.2.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.3 Example Applications

4.3.1 Java

4.3.1.1 Connect to TiDB with JDBC

TiDB is a MySQL-compatible database, and JDBC (Java Database Connectivity) is the data access API for Java. MySQL Connector/J is MySQL's implementation of JDBC.

In this tutorial, you can learn how to use TiDB and JDBC to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using JDBC.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

Note:

- This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.
- Starting from TiDB v7.4, if `connectionCollation` is not configured, and `characterEncoding` is either not configured or set to `UTF-8` in the JDBC URL, the collation used in a JDBC connection depends on the JDBC driver version. For more information, see Collation used in JDBC connections.

4.3.1.1.1 Prerequisites

To complete this tutorial, you need:

- **Java Development Kit (JDK) 17** or higher. You can choose OpenJDK or Oracle JDK based on your business and personal requirements.
- Maven **3.8** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.1.1.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-java-jdbc-quickstart.git
cd tidb-java-jdbc-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

6. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.
    ↪ tidbcloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. xxxxxx.root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='true'
```

    Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

    TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `env.sh` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

5. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `env.sh` file.

1. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

2. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}'
export TIDB_PORT='4000'
export TIDB_USER='root'
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `env.sh` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.1.1.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-java-jdbc-quickstart repository.

Connect to TiDB

```
public MysqlDataSource getMysqlDataSource() throws SQLException {
    MysqlDataSource mysqlDataSource = new MysqlDataSource();

    mysqlDataSource.setServerName(${tidb_host});
    mysqlDataSource.setPortNumber(${tidb_port});
    mysqlDataSource.setUser(${tidb_user});
    mysqlDataSource.setPassword(${tidb_password});
    mysqlDataSource.setDatabaseName(${tidb_db_name});
    if (${tidb_use_ssl}) {
        mysqlDataSource.setSslMode(PropertyDefinitions.SslMode.VERIFY_
            ↪ IDENTITY.name());
        mysqlDataSource.setEnabledTLSProtocols("TLSv1.2,TLSv1.3");
    }

    return mysqlDataSource;
}
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, and `${tidb_db_name}` with the actual values of your TiDB cluster.

Insert data

```
public void createPlayer(PlayerBean player) throws SQLException {
    MysqlDataSource mysqlDataSource = getMysqlDataSource();
    try (Connection connection = mysqlDataSource.getConnection()) {
        PreparedStatement preparedStatement = connection.prepareStatement("
            ↪ INSERT INTO player (id, coins, goods) VALUES (?, ?, ?)");
        preparedStatement.setString(1, player.getId());
        preparedStatement.setInt(2, player.getCoins());
        preparedStatement.setInt(3, player.getGoods());

        preparedStatement.execute();
    }
}
```

For more information, refer to Insert data.

Query data

```
public void getPlayer(String id) throws SQLException {
    MysqlDataSource mysqlDataSource = getMysqlDataSourceByEnv();
    try (Connection connection = mysqlDataSource.getConnection()) {
        PreparedStatement preparedStatement = connection.prepareStatement("
            ↪ SELECT * FROM player WHERE id = ?");
        preparedStatement.setString(1, id);
        preparedStatement.execute();

        ResultSet res = preparedStatement.executeQuery();
        if(res.next()) {
            PlayerBean player = new PlayerBean(res.getString("id"), res.
                ↪ getInt("coins"), res.getInt("goods"));
            System.out.println(player);
        }
    }
}
```

For more information, refer to Query data.

Update data

```
public void updatePlayer(String id, int amount, int price) throws
    ↪ SQLException {
    MysqlDataSource mysqlDataSource = getMysqlDataSourceByEnv();
    try (Connection connection = mysqlDataSource.getConnection()) {
        PreparedStatement transfer = connection.prepareStatement("UPDATE
            ↪ player SET goods = goods + ?, coins = coins + ? WHERE id=?");
        transfer.setInt(1, -amount);
        transfer.setInt(2, price);
```

```
        transfer.setString(3, id);
        transfer.execute();
    }
}
```

For more information, refer to Update data.

Delete data

```
public void deletePlayer(String id) throws SQLException {
    MysqlDataSource mysqlDataSource = getMysqlDataSourceByEnv();
    try (Connection connection = mysqlDataSource.getConnection()) {
        PreparedStatement deleteStatement = connection.prepareStatement("
            ↪ DELETE FROM player WHERE id=?");
        deleteStatement.setString(1, id);
        deleteStatement.execute();
    }
}
```

For more information, refer to Delete data.

4.3.1.1.4 Useful notes

Using driver or ORM framework?

The Java driver provides low-level access to the database, but it requires the developers to:

- Manually establish and release database connections.
- Manually manage database transactions.
- Manually map data rows to data objects.

Unless you need to write complex SQL statements, it is recommended to use ORM framework for development, such as Hibernate, MyBatis, or Spring Data JPA. It can help you:

- Reduce boilerplate code for managing connections and transactions.
- Manipulate data with data objects instead of a number of SQL statements.

4.3.1.1.5 Next steps

- Learn more usage of MySQL Connector/J from the documentation of MySQL Connector/J.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.

- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.
- Learn through the course for Java developers: Working with TiDB from Java.

4.3.1.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.1.2 Connect to TiDB with MyBatis

TiDB is a MySQL-compatible database, and MyBatis is a popular open-source Java ORM.

In this tutorial, you can learn how to use TiDB and MyBatis to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using MyBatis.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.1.2.1 Prerequisites

To complete this tutorial, you need:

- **Java Development Kit (JDK) 17** or higher. You can choose OpenJDK or Oracle JDK based on your business and personal requirements.
- Maven **3.8** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.1.2.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-java-mybatis-quickstart.git
cd tidb-java-mybatis-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

    ```
    cp env.sh.example env.sh
    ```

6. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.
    ↪ tidbcloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. xxxxxx.root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='true'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `env.sh` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

5. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `env.sh` file.

1. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

2. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}'
export TIDB_PORT='4000'
export TIDB_USER='root'
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `env.sh` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.1.2.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-java-mybatis-quickstart repository.

Connect to TiDB

Edit the MyBatis configuration file `mybatis-config.xml`:

```
<?xml version="1.0" encoding="UTF-8" ?>
<!DOCTYPE configuration
        PUBLIC "-//mybatis.org//DTD Config 3.0//EN"
        "http://mybatis.org/dtd/mybatis-3-config.dtd">
<configuration>
    <settings>
```

```
        <setting name="cacheEnabled" value="true"/>
        <setting name="lazyLoadingEnabled" value="false"/>
        <setting name="aggressiveLazyLoading" value="true"/>
        <setting name="logImpl" value="LOG4J"/>
    </settings>

    <environments default="development">
        <environment id="development">
            <!-- JDBC transaction manager -->
            <transactionManager type="JDBC"/>
            <!-- Database pool -->
            <dataSource type="POOLED">
                <property name="driver" value="com.mysql.cj.jdbc.Driver"/>
                <property name="url" value="${tidb_jdbc_url}"/>
                <property name="username" value="${tidb_user}"/>
                <property name="password" value="${tidb_password}"/>
            </dataSource>
        </environment>
    </environments>
    <mappers>
        <mapper resource="${mapper_location}.xml"/>
    </mappers>
</configuration>
```

Be sure to replace `${tidb_jdbc_url}`, `${tidb_user}`, and `${tidb_password}` with the actual values of your TiDB cluster. Also, replace `${mapper_location}` with the path of your mapper XML configuration file. For multiple mapper XML configuration files, you need to add a `<mapper/>` tag for each. Then, define the following function:

```
public SqlSessionFactory getSessionFactory() {
    InputStream inputStream = Resources.getResourceAsStream("mybatis-config.
        ↪ xml");
    SqlSessionFactory sessionFactory = new SqlSessionFactoryBuilder().build(
        ↪ inputStream);
}
```

Insert data

Add a node in the mapper XML and add a function with the same name in the interface class configured in the `mapper.namespace` attribute of the XML configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
<mapper namespace="com.pingcap.model.PlayerMapper">
    <insert id="insert" parameterType="com.pingcap.model.Player">
```

```
    insert into player (id, coins, goods)
    values (#{id,jdbcType=VARCHAR}, #{coins,jdbcType=INTEGER}, #{goods,
        ↪ jdbcType=INTEGER})
    </insert>
</mapper>
```

For more information, refer to Insert data.

Query data

Add a node in the mapper XML and add a function with the same name in the interface class configured in the `mapper.namespace` attribute of the XML configuration file. Specifically, if you use `resultMap` as the return type for MyBatis query functions, make sure that the `<resultMap/>` node is configured correctly.

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
<mapper namespace="com.pingcap.model.PlayerMapper">
    <resultMap id="BaseResultMap" type="com.pingcap.model.Player">
        <constructor>
            <idArg column="id" javaType="java.lang.String" jdbcType="VARCHAR"
                ↪  />
            <arg column="coins" javaType="java.lang.Integer" jdbcType="
                ↪ INTEGER" />
            <arg column="goods" javaType="java.lang.Integer" jdbcType="
                ↪ INTEGER" />
        </constructor>
    </resultMap>

    <select id="selectByPrimaryKey" parameterType="java.lang.String"
        ↪ resultMap="BaseResultMap">
    select id, coins, goods
    from player
    where id = #{id,jdbcType=VARCHAR}
    </select>
</mapper>
```

For more information, refer to Query data.

Update data

Add a node in the mapper XML and add a function with the same name in the interface class configured in the `mapper.namespace` attribute of the XML configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
```

```
<mapper namespace="com.pingcap.model.PlayerMapper">
    <update id="updateByPrimaryKey" parameterType="com.pingcap.model.Player"
        ↪ >
    update player
    set coins = #{coins,jdbcType=INTEGER},
      goods = #{goods,jdbcType=INTEGER}
    where id = #{id,jdbcType=VARCHAR}
    </update>
</mapper>
```

For more information, refer to Update data.

Delete data

Add a node in the mapper XML and add a function with the same name in the interface class configured in the `mapper.namespace` attribute of the XML configuration file:

```
<?xml version="1.0" encoding="UTF-8"?>
<!DOCTYPE mapper PUBLIC "-//mybatis.org//DTD Mapper 3.0//EN" "http://
    ↪ mybatis.org/dtd/mybatis-3-mapper.dtd">
<mapper namespace="com.pingcap.model.PlayerMapper">
    <delete id="deleteByPrimaryKey" parameterType="java.lang.String">
    delete from player
    where id = #{id,jdbcType=VARCHAR}
    </delete>
</mapper>
```

For more information, refer to Delete data.

4.3.1.2.4 Next steps

- Learn more usage of MyBatis from the documentation of MyBatis.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.
- Learn through the course for Java developers: Working with TiDB from Java.

4.3.1.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.1.3 Connect to TiDB with Hibernate

TiDB is a MySQL-compatible database, and Hibernate is a popular open-source Java ORM. Starting from version `6.0.0.Beta2`, Hibernate supports TiDB dialect, which fits TiDB features well.

In this tutorial, you can learn how to use TiDB and Hibernate to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Hibernate.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.1.3.1 Prerequisites

To complete this tutorial, you need:

- **Java Development Kit (JDK) 17** or higher. You can choose OpenJDK or Oracle JDK based on your business and personal requirements.
- Maven **3.8** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.1.3.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-java-hibernate-quickstart.git
cd tidb-java-hibernate-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

6. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.
    ↪ tidbcloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. xxxxxx.root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='true'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `env.sh` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

5. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `env.sh` file.

1. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

2. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}'
export TIDB_PORT='4000'
export TIDB_USER='root'
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `env.sh` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.1.3.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-java-hibernate-quickstart repository.

Connect to TiDB

Edit the Hibernate configuration file `hibernate.cfg.xml`:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>

        <!-- Database connection settings -->
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">${tidb_jdbc_url}</property>
```

```
        <property name="hibernate.connection.username">${tidb_user}</property
            ↪ >
        <property name="hibernate.connection.password">${tidb_password}</
            ↪ property>
        <property name="hibernate.connection.autocommit">false</property>

        <!-- Required so a table can be created from the 'PlayerDAO' class
            ↪ -->
        <property name="hibernate.hbm2ddl.auto">create-drop</property>

        <!-- Optional: Show SQL output for debugging -->
        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

Be sure to replace `${tidb_jdbc_url}`, `${tidb_user}`, and `${tidb_password}` with the actual values of your TiDB cluster. Then, define the following function:

```
public SessionFactory getSessionFactory() {
    return new Configuration()
            .configure("hibernate.cfg.xml")
            .addAnnotatedClass(${your_entity_class})
            .buildSessionFactory();
}
```

When using this function, you need to replace `${your_entity_class}` with your own data entity class. For multiple entity classes, you need to add a `.addAnnotatedClass(${your_entity_class})` statement for each. The preceding function is just one way to configure Hibernate. If you encounter any issues in the configuration or want to learn more about Hibernate, refer to the Hibernate official documentation.

Insert or update data

```
try (Session session = sessionFactory.openSession()) {
    session.persist(new PlayerBean("id", 1, 1));
}
```

For more information, refer to Insert data and Update data.

Query data

```
try (Session session = sessionFactory.openSession()) {
    PlayerBean player = session.get(PlayerBean.class, "id");
    System.out.println(player);
}
```

For more information, refer to Query data.

Delete data

```
try (Session session = sessionFactory.openSession()) {
    session.remove(new PlayerBean("id", 1, 1));
}
```

For more information, refer to Delete data.

4.3.1.3.4 Next steps

- Learn more usage of Hibernate from the documentation of Hibernate.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.
- Learn through the course for Java developers: Working with TiDB from Java.

4.3.1.3.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.1.4 Connect to TiDB with Spring Boot

TiDB is a MySQL-compatible database, and Spring is a popular open-source container framework for Java. This document uses Spring Boot as the way to use Spring.

In this tutorial, you can learn how to use TiDB along with Spring Data JPA and Hibernate as the JPA provider to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Hibernate and Spring Data JPA.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.1.4.1 Prerequisites

To complete this tutorial, you need:

- **Java Development Kit (JDK) 17** or higher. You can choose OpenJDK or Oracle JDK based on your business and personal requirements.
- Maven **3.8** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.1.4.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-java-springboot-jpa-
    ↪ quickstart.git
cd tidb-java-springboot-jpa-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

6. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.
    ↪ tidbcloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. xxxxxx.root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='true'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

   TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `env.sh` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

5. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
export TIDB_PORT='4000'
export TIDB_USER='{user}' # e.g. root
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `env.sh` file.

1. Run the following command to copy `env.sh.example` and rename it to `env.sh`:

```
cp env.sh.example env.sh
```

2. Copy and paste the corresponding connection string into the `env.sh` file. The example result is as follows:

```
export TIDB_HOST='{host}'
export TIDB_PORT='4000'
export TIDB_USER='root'
export TIDB_PASSWORD='{password}'
export TIDB_DB_NAME='test'
export USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `env.sh` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Run the request script in another terminal session:

```
make request
```

3. Check the Expected-Output.txt to see if the output matches.

4.3.1.4.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-java-springboot-jpa-quickstart repository.

Connect to TiDB

Edit the configuration file `application.yml`:

```
spring:
  datasource:
    url: ${TIDB_JDBC_URL:jdbc:mysql://localhost:4000/test}
    username: ${TIDB_USER:root}
    password: ${TIDB_PASSWORD:}
    driver-class-name: com.mysql.cj.jdbc.Driver
  jpa:
    show-sql: true
    database-platform: org.hibernate.dialect.TiDBDialect
    hibernate:
      ddl-auto: create-drop
```

After configuration, set the environment variables `TIDB_JDBC_URL`, `TIDB_USER`, and `TIDB_PASSWORD` to the actual values of your TiDB cluster. The configuration file provides default settings for these environment variables. If you do not configure the environment variables, the default values are as follows:

- `TIDB_JDBC_URL`: `"jdbc:mysql://localhost:4000/test"`
- `TIDB_USER`: `"root"`
- `TIDB_PASSWORD`: `""`

Data management: `@Repository`

Spring Data JPA manages data through the `@Repository` interface. To use the CRUD operations provided by `JpaRepository`, you need to extend the `JpaRepository` interface:

```
@Repository
public interface PlayerRepository extends JpaRepository<PlayerBean, Long> {
}
```

Then, you can use `@Autowired` for automatic dependency injection in any class that requires the `PlayerRepository`. This enables you to directly use CRUD functions. The following is an example:

```
@Autowired
private PlayerRepository playerRepository;
```

Insert or update data

```
playerRepository.save(player);
```

For more information, refer to Insert data and Update data.

Query data

```
PlayerBean player = playerRepository.findById(id).orElse(null);
```

For more information, refer to Query data.

Delete data

```
playerRepository.deleteById(id);
```

For more information, refer to Delete data.

4.3.1.4.4 Next steps

- Learn more usage about the third-party libraries and frameworks used in this document, refer to their official documentation:
    - The documentation of Spring Framework
    - The documentation of Spring Boot
    - The documentation of Spring Data JPA
    - The documentation of Hibernate
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.
- Learn through the course for Java developers: Working with TiDB from Java.

4.3.1.4.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.2 Go

4.3.2.1 Connect to TiDB with Go-MySQL-Driver

TiDB is a MySQL-compatible database, and Go-MySQL-Driver is a MySQL implementation for the database/sql interface.

In this tutorial, you can learn how to use TiDB and Go-MySQL-Driver to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Go-MySQL-Driver.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.2.1.1 Prerequisites

To complete this tutorial, you need:

- Go **1.20** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.2.1.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-golang-sql-driver-quickstart.
    ↪ git
cd tidb-golang-sql-driver-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

    ```
    cp .env.example .env
    ```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='true'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='false'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.2.1.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-golang-sql-driver-quickstart repository.

Connect to TiDB

```
func openDB(driverName string, runnable func(db *sql.DB)) {
    dsn := fmt.Sprintf("%s:%s@tcp(%s:%s)/%s?charset=utf8mb4&tls=%s",
        ${tidb_user}, ${tidb_password}, ${tidb_host}, ${tidb_port}, ${tidb_db
            ↪ _name}, ${use_ssl})
    db, err := sql.Open(driverName, dsn)
    if err != nil {
        panic(err)
```

```
    }
    defer db.Close()

    runnable(db)
}
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, and `${tidb_db_name}` with the actual values of your TiDB cluster. TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `${use_ssl}` to `true`.

Insert data

```
openDB("mysql", func(db *sql.DB) {
    insertSQL = "INSERT INTO player (id, coins, goods) VALUES (?, ?, ?)"
    _, err := db.Exec(insertSQL, "id", 1, 1)

    if err != nil {
        panic(err)
    }
})
```

For more information, refer to Insert data.

Query data

```
openDB("mysql", func(db *sql.DB) {
    selectSQL = "SELECT id, coins, goods FROM player WHERE id = ?"
    rows, err := db.Query(selectSQL, "id")
    if err != nil {
        panic(err)
    }

    // This line is extremely important!
    defer rows.Close()

    id, coins, goods := "", 0, 0
    if rows.Next() {
        err = rows.Scan(&id, &coins, &goods)
        if err == nil {
            fmt.Printf("player id: %s, coins: %d, goods: %d\n", id, coins,
                ↪ goods)
        }
    }
})
```

For more information, refer to Query data.

Update data

```
openDB("mysql", func(db *sql.DB) {
    updateSQL = "UPDATE player set goods = goods + ?, coins = coins + ?
        ↪ WHERE id = ?"
    _, err := db.Exec(updateSQL, 1, -1, "id")

    if err != nil {
        panic(err)
    }
})
```

For more information, refer to Update data.

Delete data

```
openDB("mysql", func(db *sql.DB) {
    deleteSQL = "DELETE FROM player WHERE id=?"
    _, err := db.Exec(deleteSQL, "id")

    if err != nil {
        panic(err)
    }
})
```

For more information, refer to Delete data.

4.3.2.1.4 Useful notes

Using driver or ORM framework?

The Golang driver provides low-level access to the database, but it requires the developers to:

- Manually establish and release database connections.
- Manually manage database transactions.
- Manually map data rows to data objects.

Unless you need to write complex SQL statements, it is recommended to use ORM framework for development, such as GORM. It can help you:

- Reduce boilerplate code for managing connections and transactions.
- Manipulate data with data objects instead of a number of SQL statements.

4.3.2.1.5 Next steps

- Learn more usage of Go-MySQL-Driver from the documentation of Go-MySQL-Driver.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.2.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.2.2 Connect to TiDB with GORM

TiDB is a MySQL-compatible database, and GORM is a popular open-source ORM framework for Golang. GORM adapts to TiDB features such as `AUTO_RANDOM` and supports TiDB as a default database option.

In this tutorial, you can learn how to use TiDB and GORM to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using GORM.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.2.2.1 Prerequisites

To complete this tutorial, you need:

- Go **1.20** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.2.2.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-golang-gorm-quickstart.git
cd tidb-golang-gorm-quickstart
```

Step 2: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='true'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

   TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `USE_SSL` to `true`.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
USE_SSL='false'
```

Be sure to replace the placeholders `{}` with the connection parameters, and set `USE_SSL` to `false`. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 3: Run the code and check the result

1. Execute the following command to run the sample code:

```
make
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.2.2.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-golang-gorm-quickstart repository.

Connect to TiDB

```
func createDB() *gorm.DB {
    dsn := fmt.Sprintf("%s:%s@tcp(%s:%s)/%s?charset=utf8mb4&tls=%s",
        ${tidb_user}, ${tidb_password}, ${tidb_host}, ${tidb_port}, ${tidb_db
            ↪ _name}, ${use_ssl})
```

```
    db, err := gorm.Open(mysql.Open(dsn), &gorm.Config{
        Logger: logger.Default.LogMode(logger.Info),
    })
    if err != nil {
        panic(err)
    }

    return db
}
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, and `${tidb_db_name}` with the actual values of your TiDB cluster. TiDB Cloud Serverless requires a secure connection. Therefore, you need to set the value of `${use_ssl}` to `true`.

Insert data

```
db.Create(&Player{ID: "id", Coins: 1, Goods: 1})
```

For more information, refer to Insert data.

Query data

```
var queryPlayer Player
db.Find(&queryPlayer, "id = ?", "id")
```

For more information, refer to Query data.

Update data

```
db.Save(&Player{ID: "id", Coins: 100, Goods: 1})
```

For more information, refer to Update data.

Delete data

```
db.Delete(&Player{ID: "id"})
```

For more information, refer to Delete data.

4.3.2.2.4 Next steps

- Learn more usage of GORM from the documentation of GORM and the TiDB section in the documentation of GORM.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.2.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3 Python

4.3.3.1 Connect to TiDB with mysqlclient

TiDB is a MySQL-compatible database, and mysqlclient is a popular open-source driver for Python.

In this tutorial, you can learn how to use TiDB and mysqlclient to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using mysqlclient.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.3.1.1 Prerequisites

To complete this tutorial, you need:

- Python **3.10** or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.1.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-mysqlclient-quickstart
    ↪ .git
cd tidb-python-mysqlclient-quickstart;
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysqlclient`) for the sample app:

```
pip install -r requirements.txt
```

If you encounter installation issues, refer to the mysqlclient official documentation.

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{gateway-region}.aws.tidbcloud.com'
TIDB_PORT='4000'
TIDB_USER='{prefix}.root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH=''
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

   TiDB Cloud Serverless requires a secure connection. Since the `ssl_mode` of mysqlclient defaults to `PREFERRED`, you don't need to manually specify `CA_PATH`. Just leave it empty. But if you have a special reason to specify `CA_PATH` manually, you can refer to the TLS connections to TiDB Cloud Serverless to get the certificate paths for different operating systems.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}.clusters.tidb-cloud.com'
TIDB_PORT='4000'
TIDB_USER='{username}'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Execute the following command to run the sample code:

```
python mysqlclient_example.py
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.3.1.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-mysqlclient-quickstart repository.

Connect to TiDB

```
def get_mysqlclient_connection(autocommit:bool=True) -> MySQLdb.Connection:
    db_conf = {
        "host": ${tidb_host},
        "port": ${tidb_port},
        "user": ${tidb_user},
        "password": ${tidb_password},
        "database": ${tidb_db_name},
        "autocommit": autocommit
    }

    if ${ca_path}:
        db_conf["ssl_mode"] = "VERIFY_IDENTITY"
        db_conf["ssl"] = {"ca": ${ca_path}}

    return MySQLdb.connect(**db_conf)
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}` and `${ca_path}` with the actual values of your TiDB cluster.

Insert data

```
with get_mysqlclient_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player = ("1", 1, 1)
        cursor.execute("INSERT INTO players (id, coins, goods) VALUES (%s, %s
            ↪ , %s)", player)
```

For more information, refer to Insert data.

Query data

```
with get_mysqlclient_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        cur.execute("SELECT count(*) FROM players")
        print(cur.fetchone()[0])
```

For more information, refer to Query data.

Update data

```
with get_mysqlclient_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id, amount, price="1", 10, 500
        cursor.execute(
            "UPDATE players SET goods = goods + %s, coins = coins + %s WHERE
                ↪ id = %s",
            (-amount, price, player_id),
        )
```

For more information, refer to Update data.

Delete data

```
with get_mysqlclient_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id = "1"
        cursor.execute("DELETE FROM players WHERE id = %s", (player_id,))
```

For more information, refer to Delete data.

4.3.3.1.4 Useful notes

Using driver or ORM framework?

The Python driver provides low-level access to the database, but it requires the developers to:

- Manually establish and release database connections.
- Manually manage database transactions.
- Manually map data rows (represented as tuples in `mysqlclient`) to data objects.

Unless you need to write complex SQL statements, it is recommended to use ORM framework for development, such as SQLAlchemy, Peewee, and Django ORM. It can help you:

- Reduce boilerplate code for managing connections and transactions.
- Manipulate data with data objects instead of a number of SQL statements.

4.3.3.1.5 Next steps

- Learn more usage of `mysqlclient` from the documentation of mysqlclient.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3.2 Connect to TiDB with MySQL Connector/Python

TiDB is a MySQL-compatible database, and MySQL Connector/Python is the official MySQL driver for Python.

In this tutorial, you can learn how to use TiDB and MySQL Connector/Python to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using MySQL Connector/Python.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed clusters.

4.3.3.2.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.2.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-mysqlconnector-
    ↪ quickstart.git
cd tidb-python-mysqlconnector-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including mysql-connector-python) for the sample app:

```
pip install -r requirements.txt
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

    ```
    cp .env.example .env
    ```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{ssl_ca}' # e.g. /etc/ssl/certs/ca-certificates.crt (Debian /
    ↪ Ubuntu / Arch)
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Execute the following command to run the sample code:

```
python mysql_connector_example.py
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.3.2.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-mysqlconnector-quickstart repository.

Connect to TiDB

```
def get_connection(autocommit: bool = True) -> MySQLConnection:
    config = Config()
    db_conf = {
        "host": ${tidb_host},
        "port": ${tidb_port},
        "user": ${tidb_user},
        "password": ${tidb_password},
        "database": ${tidb_db_name},
        "autocommit": autocommit,
        "use_pure": True,
    }
```

```
    if ${ca_path}:
        db_conf["ssl_verify_cert"] = True
        db_conf["ssl_verify_identity"] = True
        db_conf["ssl_ca"] = ${ca_path}
    return mysql.connector.connect(**db_conf)
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}` and `${ca_path}` with the actual values of your TiDB cluster.

Insert data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player = ("1", 1, 1)
        cursor.execute("INSERT INTO players (id, coins, goods) VALUES (%s, %s
            ↪ , %s)", player)
```

For more information, refer to Insert data.

Query data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        cur.execute("SELECT count(*) FROM players")
        print(cur.fetchone()[0])
```

For more information, refer to Query data.

Update data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id, amount, price="1", 10, 500
        cursor.execute(
            "UPDATE players SET goods = goods + %s, coins = coins + %s WHERE
                ↪ id = %s",
            (-amount, price, player_id),
        )
```

For more information, refer to Update data.

Delete data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id = "1"
        cursor.execute("DELETE FROM players WHERE id = %s", (player_id,))
```

For more information, refer to Delete data.

4.3.3.2.4 Useful notes

Using driver or ORM framework?

The Python driver provides low-level access to the database, but it requires the developers to:

- Manually establish and release database connections.
- Manually manage database transactions.
- Manually map data rows (represented as a tuple or dict in `mysql-connector-python`) to data objects.

Unless you need to write complex SQL statements, it is recommended to use ORM framework for development, such as SQLAlchemy, Peewee, and Django ORM. It can help you:

- Reduce boilerplate code for managing connections and transactions.
- Manipulate data with data objects instead of a number of SQL statements.

4.3.3.2.5 Next steps

- Learn more usage of mysql-connector-python from the documentation of MySQL Connector/Python.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.2.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3.3 Connect to TiDB with PyMySQL

TiDB is a MySQL-compatible database, and PyMySQL is a popular open-source driver for Python.

In this tutorial, you can learn how to use TiDB and PyMySQL to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using PyMySQL.

- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed clusters.

4.3.3.3.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.3.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-pymysql-quickstart.git
cd tidb-python-pymysql-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including PyMySQL) for the sample app:

```
pip install -r requirements.txt
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{ssl_ca}' # e.g. /etc/ssl/certs/ca-certificates.crt (Debian /
    ↪ Ubuntu / Arch)
```

    Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Execute the following command to run the sample code:

```
python pymysql_example.py
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.3.3.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-pymysql-quickstart repository.

Connect to TiDB

```
from pymysql import Connection
from pymysql.cursors import DictCursor

def get_connection(autocommit: bool = True) -> Connection:
    config = Config()
    db_conf = {
        "host": ${tidb_host},
        "port": ${tidb_port},
        "user": ${tidb_user},
        "password": ${tidb_password},
        "database": ${tidb_db_name},
        "autocommit": autocommit,
        "cursorclass": DictCursor,
    }

    if ${ca_path}:
        db_conf["ssl_verify_cert"] = True
        db_conf["ssl_verify_identity"] = True
        db_conf["ssl_ca"] = ${ca_path}

    return pymysql.connect(**db_conf)
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}` and `${ca_path}` with the actual values of your TiDB cluster.

Insert data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player = ("1", 1, 1)
        cursor.execute("INSERT INTO players (id, coins, goods) VALUES (%s, %s
            ↪ , %s)", player)
```

For more information, refer to Insert data.

Query data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        cur.execute("SELECT count(*) FROM players")
        print(cursor.fetchone()["count(*)"])
```

For more information, refer to Query data.

Update data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id, amount, price="1", 10, 500
        cursor.execute(
            "UPDATE players SET goods = goods + %s, coins = coins + %s WHERE
                ↪ id = %s",
            (-amount, price, player_id),
        )
```

For more information, refer to Update data.

Delete data

```
with get_connection(autocommit=True) as conn:
    with conn.cursor() as cur:
        player_id = "1"
        cursor.execute("DELETE FROM players WHERE id = %s", (player_id,))
```

For more information, refer to Delete data.

4.3.3.3.4 Useful notes

Using driver or ORM framework?

The Python driver provides low-level access to the database, but it requires the developers to:

- Manually establish and release database connections.
- Manually manage database transactions.
- Manually map data rows (represented as a tuple or dict in `pymysql`) to data objects.

Unless you need to write complex SQL statements, it is recommended to use ORM framework for development, such as SQLAlchemy, Peewee, and Django ORM. It can help you:

- Reduce boilerplate code for managing connections and transactions.
- Manipulate data with data objects instead of a number of SQL statements.

4.3.3.3.5 Next steps

- Learn more usage of PyMySQL from the documentation of PyMySQL.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.3.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3.4 Connect to TiDB with SQLAlchemy

TiDB is a MySQL-compatible database, and SQLAlchemy is a popular Python SQL toolkit and Object Relational Mapper (ORM).

In this tutorial, you can learn how to use TiDB and SQLAlchemy to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using SQLAlchemy.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed clusters.

4.3.3.4.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.4.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-sqlalchemy-quickstart.
    ↪ git
cd tidb-python-sqlalchemy-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including SQLAlchemy and PyMySQL) for the sample app:

```
pip install -r requirements.txt
```

Why use PyMySQL?

SQLAlchemy is an ORM library that works with multiple databases. It provides a high-level abstraction of the database, which helps developers write SQL statements in a more object-oriented way. However, SQLAlchemy does not include a database driver. To connect to a database, you need to install a database driver. This sample application uses PyMySQL as the database driver, which is a pure Python MySQL client library that is compatible with TiDB and can be installed on all platforms.

You can also use other database drivers, such as mysqlclient and mysql-connector-python. But they are not pure Python libraries and require the corresponding C/C++ compiler and MySQL client for compiling. For more information, refer to SQLAlchemy official documentation.

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

> **Note:**
>
> Currently, TiDB Cloud Serverless clusters have a limitation: if there are no active connections for 5 minutes, they will shut down, which closes all connections. Therefore, when using SQLAlchemy with TiDB Cloud Serverless clusters, pooled connections might encounter `OperationalError` such as `Lost connection to MySQL server during query` or `MySQL Connection not available`. To avoid this error, you can set the `pool_recycle` parameter to `300`. For more information, see Dealing with Disconnects in SQLAlchemy documentation.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{ssl_ca}' # e.g. /etc/ssl/certs/ca-certificates.crt (Debian /
    ↪ Ubuntu / Arch)
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Execute the following command to run the sample code:

```
python sqlalchemy_example.py
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.3.4.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-sqlalchemy-quickstart repository.

Connect to TiDB

```
from sqlalchemy import create_engine, URL
from sqlalchemy.orm import sessionmaker

def get_db_engine():
    connect_args = {}
    if ${ca_path}:
        connect_args = {
            "ssl_verify_cert": True,
            "ssl_verify_identity": True,
            "ssl_ca": ${ca_path},
        }
```

```
    return create_engine(
        URL.create(
            drivername="mysql+pymysql",
            username=${tidb_user},
            password=${tidb_password},
            host=${tidb_host},
            port=${tidb_port},
            database=${tidb_db_name},
        ),
        connect_args=connect_args,
    )

engine = get_db_engine()
Session = sessionmaker(bind=engine)
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}` and `${ca_path}` with the actual values of your TiDB cluster.

Define a table

```
from sqlalchemy import Column, Integer, String
from sqlalchemy.orm import declarative_base

Base = declarative_base()

class Player(Base):
    id = Column(Integer, primary_key=True)
    name = Column(String(32), unique=True)
    coins = Column(Integer)
    goods = Column(Integer)

    __tablename__ = "players"
```

For more information, refer to SQLAlchemy documentation: Mapping classes with declarative.

Insert data

```
with Session() as session:
    player = Player(name="test", coins=100, goods=100)
    session.add(player)
    session.commit()
```

For more information, refer to Insert data.

Query data

```
with Session() as session:
    player = session.query(Player).filter_by(name == "test").one()
    print(player)
```

For more information, refer to Query data.

Update data

```
with Session() as session:
    player = session.query(Player).filter_by(name == "test").one()
    player.coins = 200
    session.commit()
```

For more information, refer to Update data.

Delete data

```
with Session() as session:
    player = session.query(Player).filter_by(name == "test").one()
    session.delete(player)
    session.commit()
```

For more information, refer to Delete data.

4.3.3.4.4 Next steps

- Learn more usage of SQLAlchemy from the documentation of SQLAlchemy.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.4.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3.5 Connect to TiDB with peewee

TiDB is a MySQL-compatible database, and peewee is a popular Object Relational Mapper (ORM) for Python.

In this tutorial, you can learn how to use TiDB and peewee to accomplish the following tasks:

- Set up your environment.

- Connect to your TiDB cluster using peewee.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed clusters.

4.3.3.5.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.5.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-peewee-quickstart.git
cd tidb-python-peewee-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including peewee and PyMySQL) for the sample app:

```
pip install -r requirements.txt
```

Why use PyMySQL?

peewee is an ORM library that works with multiple databases. It provides a high-level abstraction of the database, which helps developers write SQL statements in a more object-oriented way. However, peewee does not include a database driver. To connect to a database, you need to install a database driver. This sample application uses PyMySQL as the database driver, which is a pure Python MySQL client library that is compatible with TiDB and can be installed on all platforms. For more information, refer to peewee official documentation.

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{ssl_ca}' # e.g. /etc/ssl/certs/ca-certificates.crt (Debian /
    ↪ Ubuntu / Arch)
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

   Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Execute the following command to run the sample code:

```
python peewee_example.py
```

2. Check the Expected-Output.txt to see if the output matches.

4.3.3.5.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-peewee-quickstart repository.

Connect to TiDB

```
from peewee import MySQLDatabase

def get_db_engine():
    config = Config()
    connect_params = {}
    if ${ca_path}:
        connect_params = {
            "ssl_verify_cert": True,
            "ssl_verify_identity": True,
            "ssl_ca": ${ca_path},
        }
```

```
    return MySQLDatabase(
        ${tidb_db_name},
        host=${tidb_host},
        port=${tidb_port},
        user=${tidb_user},
        password=${tidb_password},
        **connect_params,
    )
```

When using this function, you need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}` and `${ca_path}` with the actual values of your TiDB cluster.

Define a table

```
from peewee import Model, CharField, IntegerField

db = get_db_engine()

class BaseModel(Model):
    class Meta:
        database = db

class Player(BaseModel):
    name = CharField(max_length=32, unique=True)
    coins = IntegerField(default=0)
    goods = IntegerField(default=0)

    class Meta:
        table_name = "players"
```

For more information, refer to peewee documentation: Models and Fields.

Insert data

```
#### Insert a single record
Player.create(name="test", coins=100, goods=100)

#### Insert multiple records
Player.insert_many(
    [
        {"name": "test1", "coins": 100, "goods": 100},
        {"name": "test2", "coins": 100, "goods": 100},
    ]
).execute()
```

For more information, refer to Insert data.

Query data

```
#### Query all records
players = Player.select()

#### Query a single record
player = Player.get(Player.name == "test")

#### Query multiple records
players = Player.select().where(Player.coins == 100)
```

For more information, refer to Query data.

Update data

```
#### Update a single record
player = Player.get(Player.name == "test")
player.coins = 200
player.save()

#### Update multiple records
Player.update(coins=200).where(Player.coins == 100).execute()
```

For more information, refer to Update data.

Delete data

```
#### Delete a single record
player = Player.get(Player.name == "test")
player.delete_instance()

#### Delete multiple records
Player.delete().where(Player.coins == 100).execute()
```

For more information, refer to Delete data.

4.3.3.5.4 Next steps

- Learn more usage of peewee from the documentation of peewee.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.5.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.3.6 Connect to TiDB with Django

TiDB is a MySQL-compatible database, and Django is a popular web framework for Python, which includes a powerful Object Relational Mapper (ORM) library.

In this tutorial, you can learn how to use TiDB and Django to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Django.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed clusters.

4.3.3.6.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.3.6.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-python-django-quickstart.git
cd tidb-python-django-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including Django, django-tidb, and mysqlclient) for the sample app:

```
pip install -r requirements.txt
```

If you encounter installation issues with mysqlclient, refer to the mysqlclient official documentation.

What is `django-tidb`?

`django-tidb` is a TiDB dialect for Django that resolves compatibility issues between TiDB and Django.

To install `django-tidb`, choose a version that matches your Django version. For example, if you are using `django==4.2.*`, install `django-tidb==4.2.*`. The minor version does not need to be the same. It is recommended to use the latest minor version.

For more information, refer to django-tidb repository.

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click **Generate Password** to create a random password.

> **Tip:**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. gateway01.ap-northeast-1.prod.aws.tidbcloud.
    ↪ com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. xxxxxx.root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{ssl_ca}' # e.g. /etc/ssl/certs/ca-certificates.crt (Debian /
    ↪ Ubuntu / Arch)
```

   Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog.

   TiDB Cloud Serverless requires a secure connection. Since the `ssl_mode` of mysqlclient defaults to `PREFERRED`, you don't need to manually specify `CA_PATH`. Just leave it empty. But if you have a special reason to specify `CA_PATH` manually, you can refer to the TLS connections to TiDB Cloud Serverless to get the certificate paths for different operating systems.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{host}' # e.g. tidb.xxxx.clusters.tidb-cloud.com
TIDB_PORT='4000'
TIDB_USER='{user}' # e.g. root
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
CA_PATH='{your-downloaded-ca-path}'
```

Be sure to replace the placeholders `{}` with the connection parameters obtained from the connection dialog, and configure `CA_PATH` with the certificate path downloaded in the previous step.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

Be sure to replace the placeholders `{}` with the connection parameters, and remove the `CA_PATH` line. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Initialize the database

In the root directory of the project, run the following command to initialize the database:

```
python manage.py migrate
```

Step 5: Run the sample application

1. Run the application in the development mode:

```
python manage.py runserver
```

The application runs on port `8000` by default. To use a different port, you can append the port number to the command. The following is an example:

```
python manage.py runserver 8080
```

2. To access the application, open your browser and go to `http://localhost:8000/`. In the sample application, you can:

    - Create a new player.
    - Bulk create players.
    - View all players.
    - Update a player.
    - Delete a player.
    - Trade goods between two players.

4.3.3.6.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-python-django-quickstart repository.

Connect to TiDB

In the file `sample_project/settings.py`, add the following configurations:

```
DATABASES = {
    "default": {
        "ENGINE": "django_tidb",
        "HOST": ${tidb_host},
        "PORT": ${tidb_port},
        "USER": ${tidb_user},
        "PASSWORD": ${tidb_password},
        "NAME": ${tidb_db_name},
        "OPTIONS": {
            "charset": "utf8mb4",
        },
    }
}

TIDB_CA_PATH = ${ca_path}
if TIDB_CA_PATH:
    DATABASES["default"]["OPTIONS"]["ssl_mode"] = "VERIFY_IDENTITY"
    DATABASES["default"]["OPTIONS"]["ssl"] = {
        "ca": TIDB_CA_PATH,
    }
```

You need to replace `${tidb_host}`, `${tidb_port}`, `${tidb_user}`, `${tidb_password}`, `${tidb_db_name}`, and `${ca_path}` with the actual values of your TiDB cluster.

Define the data model

```
from django.db import models

class Player(models.Model):
    name = models.CharField(max_length=32, blank=False, null=False)
    coins = models.IntegerField(default=100)
    goods = models.IntegerField(default=1)
    created_at = models.DateTimeField(auto_now_add=True)
    updated_at = models.DateTimeField(auto_now=True)
```

For more information, refer to Django models.

Insert data

```
#### insert a single object
player = Player.objects.create(name="player1", coins=100, goods=1)

#### bulk insert multiple objects
Player.objects.bulk_create([
    Player(name="player1", coins=100, goods=1),
    Player(name="player2", coins=200, goods=2),
    Player(name="player3", coins=300, goods=3),
])
```

For more information, refer to Insert data.

Query data

```
#### get a single object
player = Player.objects.get(name="player1")

#### get multiple objects
filtered_players = Player.objects.filter(name="player1")

#### get all objects
all_players = Player.objects.all()
```

For more information, refer to Query data.

Update data

```
#### update a single object
player = Player.objects.get(name="player1")
player.coins = 200
player.save()

#### update multiple objects
Player.objects.filter(coins=100).update(coins=200)
```

For more information, refer to Update data.

Delete data

```
#### delete a single object
player = Player.objects.get(name="player1")
player.delete()

#### delete multiple objects
Player.objects.filter(coins=100).delete()
```

For more information, refer to Delete data.

4.3.3.6.4 Next steps

- Learn more usage of Django from the documentation of Django.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.3.6.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4 Node.js

4.3.4.1 Connect to TiDB with node-mysql2

TiDB is a MySQL-compatible database, and node-mysql2 is a fast mysqljs/mysql compatible MySQL driver for Node.js.

In this tutorial, you can learn how to use TiDB and node-mysql2 to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using node-mysql2.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.4.1.1 Prerequisites

To complete this tutorial, you need:

- Node.js >= 16.x installed on your machine.
- Git installed on your machine.
- A TiDB cluster running.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.1.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-nodejs-mysql2-quickstart.git
cd tidb-nodejs-mysql2-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql2` and `dotenv`) for the sample app:

```
npm install
```

Install dependencies to existing project

For your existing project, run the following command to install the packages:

```
npm install mysql2 dotenv --save
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

- **Connection Type** is set to `Public`.
- **Branch** is set to `main`.
- **Connect With** is set to `General`.
- **Operating System** matches the operating system where you run the application.

4. If you have not set a password yet, click **Generate Password** to generate a random password.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER={user}
TIDB_PASSWORD={password}
TIDB_DATABASE=test
TIDB_ENABLE_SSL=true
```

> **Note**
>
> For TiDB Cloud Serverless, TLS connection **MUST** be enabled via `TIDB_ENABLE_SSL` when using public endpoint.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER={user}
TIDB_PASSWORD={password}
TIDB_DATABASE=test
TIDB_ENABLE_SSL=true
TIDB_CA_PATH={downloaded_ssl_ca_path}
```

> **Note**
>
> It is recommended to enable TLS connection when using the public endpoint to connect to TiDB Cloud Dedicated.
>
> To enable TLS connection, modify `TIDB_ENABLE_SSL` to `true` and using `TIDB_CA_PATH` to specify the file path of CA certificate downloaded from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER=root
TIDB_PASSWORD={password}
TIDB_DATABASE=test
```

If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

Run the following command to execute the sample code:

```
npm start
```

If the connection is successful, the console will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
 Loading sample game data...
  Loaded sample game data.

  Created a new player with ID 12.
  Got Player 12: Player { id: 12, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 12, updated 1 row.
 Deleted 1 player data.
```

4.3.4.1.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-nodejs-mysql2-quickstart repository.

Connect with connection options

The following code establishes a connection to TiDB with options defined in the environment variables:

```
// Step 1. Import the 'mysql' and 'dotenv' packages.
import { createConnection } from "mysql2/promise";
import dotenv from "dotenv";
import * as fs from "fs";

// Step 2. Load environment variables from .env file to process.env.
dotenv.config();

async function main() {
  // Step 3. Create a connection to the TiDB cluster.
  const options = {
    host: process.env.TIDB_HOST || '127.0.0.1',
    port: process.env.TIDB_PORT || 4000,
    user: process.env.TIDB_USER || 'root',
    password: process.env.TIDB_PASSWORD || '',
    database: process.env.TIDB_DATABASE || 'test',
    ssl: process.env.TIDB_ENABLE_SSL === 'true' ? {
      minVersion: 'TLSv1.2',
      ca: process.env.TIDB_CA_PATH ? fs.readFileSync(process.env.TIDB_CA_
        ↪ PATH) : undefined
    } : null,
  }
```

```
    const conn = await createConnection(options);

    // Step 4. Perform some SQL operations...

    // Step 5. Close the connection.
    await conn.end();
}

void main();
```

> **Note**
>
> For TiDB Cloud Serverless, you **MUST** enable TLS connection via `TIDB_ENABLE_SSL` when using public endpoint. However, you **don't** have to specify an SSL CA certificate via `TIDB_CA_PATH`, because Node.js uses the built-in Mozilla CA certificate by default, which is trusted by TiDB Cloud Serverless.

Insert data

The following query creates a single `Player` record and returns a `ResultSetHeader` object:

```
const [rsh] = await conn.query('INSERT INTO players (coins, goods) VALUES (?, ?);', [100, 100]);
console.log(rsh.insertId);
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` record by ID `1`:

```
const [rows] = await conn.query('SELECT id, coins, goods FROM players WHERE id = ?;', [1]);
console.log(rows[0]);
```

For more information, refer to Query data.

Update data

The following query adds `50` coins and `50` goods to the `Player` with ID `1`:

```
const [rsh] = await conn.query(
    'UPDATE players SET coins = coins + ?, goods = goods + ? WHERE id = ?;',
    [50, 50, 1]
```

```
);
console.log(rsh.affectedRows);
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` record with ID `1`:

```
const [rsh] = await conn.query('DELETE FROM players WHERE id = ?;', [1]);
console.log(rsh.affectedRows);
```

For more information, refer to Delete data.

4.3.4.1.4 Useful notes

- Using connection pools to manage database connections can reduce the performance overhead caused by frequently establishing and destroying connections.
- To avoid SQL injection, it is recommended to use prepared statements.
- In scenarios where there are not many complex SQL statements involved, using ORM frameworks like Sequelize, TypeORM, or Prisma can greatly improve development efficiency.
- It is recommended to enable the `supportBigNumbers: true` option when dealing with big numbers (`BIGINT` and `DECIMAL` columns) in the database.
- It is recommended to enable the `enableKeepAlive: true` option to avoid socket error `read ECONNRESET` due to network problems. (Related issue: sidorares/node-mysql2#683)

4.3.4.1.5 Next steps

- Learn more usage of node-mysql2 driver from the documentation of node-mysql2.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.2 Connect to TiDB with mysql.js

TiDB is a MySQL-compatible database, and mysql.js driver is a pure Node.js JavaScript client implementing the MySQL protocol.

In this tutorial, you can learn how to use TiDB and mysql.js driver to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using mysql.js driver.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.4.2.1 Prerequisites

To complete this tutorial, you need:

- Node.js >= 16.x installed on your machine.
- Git installed on your machine.
- A TiDB cluster running.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.2.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-nodejs-mysqljs-quickstart.git
cd tidb-nodejs-mysqljs-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql` and `dotenv` ↪) for the sample app:

```
npm install
```

Install dependencies to existing project

For your existing project, run the following command to install the packages:

```
npm install mysql dotenv --save
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `General`.
    - **Operating System** matches the operating system where you run the application.
4. If you have not set a password yet, click **Generate Password** to generate a random password.
5. Run the following command to copy `.env.example` and rename it to `.env`:

    ```
    cp .env.example .env
    ```

6. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

    ```
    TIDB_HOST={host}
    TIDB_PORT=4000
    TIDB_USER={user}
    TIDB_PASSWORD={password}
    TIDB_DATABASE=test
    TIDB_ENABLE_SSL=true
    ```

> **Note**
>
> For TiDB Cloud Serverless, TLS connection **MUST** be enabled via `TIDB_ENABLE_SSL` when using public endpoint.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER={user}
TIDB_PASSWORD={password}
TIDB_DATABASE=test
TIDB_ENABLE_SSL=true
TIDB_CA_PATH={downloaded_ssl_ca_path}
```

> **Note**
>
> It is recommended to enable TLS connection when using the public endpoint to connect to TiDB Cloud Dedicated.
>
> To enable TLS connection, modify `TIDB_ENABLE_SSL` to `true` and using `TIDB_CA_PATH` to specify the file path of CA certificate downloaded from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, replace the corresponding placeholders `{}` with connection parameters of your cluster. The example configuration is as follows:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER=root
TIDB_PASSWORD={password}
TIDB_DATABASE=test
```

If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

Run the following command to execute the sample code:

```
npm start
```

If the connection is successful, the console will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
 Loading sample game data...
  Loaded sample game data.

  Created a new player with ID 12.
  Got Player 12: Player { id: 12, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 12, updated 1 row.
 Deleted 1 player data.
```

4.3.4.2.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-nodejs-mysqljs-quickstart repository.

Connect with connection options

The following code establishes a connection to TiDB with options defined in the environment variables:

```
// Step 1. Import the 'mysql' and 'dotenv' packages.
import { createConnection } from "mysql";
import dotenv from "dotenv";
import * as fs from "fs";

// Step 2. Load environment variables from .env file to process.env.
```

```
dotenv.config();

// Step 3. Create a connection to the TiDB cluster.
const options = {
    host: process.env.TIDB_HOST || '127.0.0.1',
    port: process.env.TIDB_PORT || 4000,
    user: process.env.TIDB_USER || 'root',
    password: process.env.TIDB_PASSWORD || '',
    database: process.env.TIDB_DATABASE || 'test',
    ssl: process.env.TIDB_ENABLE_SSL === 'true' ? {
        minVersion: 'TLSv1.2',
        ca: process.env.TIDB_CA_PATH ? fs.readFileSync(process.env.TIDB_CA_
            ↪ PATH) : undefined
    } : null,
}
const conn = createConnection(options);

// Step 4. Perform some SQL operations...

// Step 5. Close the connection.
conn.end();
```

> **Note**
>
> For TiDB Cloud Serverless, you **MUST** enable TLS connection via `TIDB_ENABLE_SSL` when using public endpoint. However, you **don't** have to specify an SSL CA certificate via `TIDB_CA_PATH`, because Node.js uses the built-in Mozilla CA certificate by default, which is trusted by TiDB Cloud Serverless.

Insert data

The following query creates a single `Player` record and returns the ID of the newly created record:

```
conn.query('INSERT INTO players (coins, goods) VALUES (?, ?);', [100, 100],
    ↪ (err, ok) => {
   if (err) {
       console.error(err);
   } else {
       console.log(ok.insertId);
   }
});
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` record by ID `1`:

```
conn.query('SELECT id, coins, goods FROM players WHERE id = ?;', [1], (err,
    ↪ rows) => {
   if (err) {
      console.error(err);
   } else {
      console.log(rows[0]);
   }
});
```

For more information, refer to Query data.

Update data

The following query adds `50` coins and `50` goods to the `Player` with ID `1`:

```
conn.query(
   'UPDATE players SET coins = coins + ?, goods = goods + ? WHERE id = ?;',
   [50, 50, 1],
   (err, ok) => {
      if (err) {
         console.error(err);
      } else {
          console.log(ok.affectedRows);
      }
   }
);
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` record with ID `1`:

```
conn.query('DELETE FROM players WHERE id = ?;', [1], (err, ok) => {
    if (err) {
        reject(err);
    } else {
        resolve(ok.affectedRows);
    }
});
```

For more information, refer to Delete data.

4.3.4.2.4 Useful notes

- Using connection pools to manage database connections can reduce the performance overhead caused by frequently establishing and destroying connections.
- To avoid SQL injection attacks, it is recommended to use Escaping query values before executing SQL.

> **Note**
>
> The `mysqljs/mysql` package does not yet support prepared statements, it only escapes values on the client side (related issue: mysqljs/mysql#274).
>
> If you want to use this feature to avoid SQL injection or improve efficiency of batch insert/update, it is recommended to use mysql2 package instead.

- Using ORM frameworks to improve development efficiency in scenarios without a number of complex SQL statements, such as: Sequelize, TypeORM, and Prisma.
- It is recommended to enable the `supportBigNumbers: true` option when dealing with big numbers (`BIGINT` and `DECIMAL` columns) in the database.

4.3.4.2.5 Next steps

- Learn more usage of mysql.js driver from the documentation of mysql.js.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.2.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.3 Connect to TiDB with Prisma

TiDB is a MySQL-compatible database, and Prisma is a popular open-source ORM framework for Node.js.

In this tutorial, you can learn how to use TiDB and Prisma to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Prisma.

- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.4.4.3.1 Prerequisites

To complete this tutorial, you need:

- Node.js >= 16.x installed on your machine.
- Git installed on your machine.
- A TiDB cluster running.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.4.3.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-nodejs-prisma-quickstart.git
cd tidb-nodejs-prisma-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `prisma`) for the sample app:

```
npm install
```

Install dependencies to existing project

For your existing project, run the following command to install the packages:

```
npm install prisma typescript ts-node @types/node --save-dev
```

Step 3: Provide connection Parameters

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `Prisma`.
    - **Operating System** matches the operating system where you run the application.
4. If you have not set a password yet, click **Generate Password** to generate a random password.
5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Edit the `.env` file, set up the environment variable `DATABASE_URL` as follows, and replace the corresponding placeholders `{}` with the connection string in the connection dialog:

```
DATABASE_URL='{connection_string}'
```

> **Note**
>
> For TiDB Cloud Serverless, you **MUST** enable TLS connection by setting `sslaccept=strict` when using public endpoint.

7. Save the `.env` file.
8. In the `prisma/schema.prisma`, set up `mysql` as the connection provider and `env("` ↪ `DATABASE_URL")` as the connection URL:

```
datasource db {
  provider = "mysql"
  url      = env("DATABASE_URL")
}
```

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variable `DATABASE_URL` as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
DATABASE_URL='mysql://{user}:{password}@{host}:4000/test?sslaccept=
    ↪ strict&sslcert={downloaded_ssl_ca_path}'
```

> **Note**
>
> For TiDB Cloud Serverless, It is **RECOMMENDED** to enable TLS connection by setting `sslaccept=strict` when using public endpoint. When you set up `sslaccept=strict` to enable TLS connection, you **MUST** specify the file path of the CA certificate downloaded from connection dialog via `sslcert=/path/to/ca.pem`.

6. Save the `.env` file.

7. In the `prisma/schema.prisma`, set up `mysql` as the connection provider and `env("
   ↪ DATABASE_URL")` as the connection URL:

```
datasource db {
  provider = "mysql"
  url      = env("DATABASE_URL")
}
```

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the environment variable `DATABASE_URL` as follows, replace the corresponding placeholders `{}` with connection parameters of your TiDB cluster:

```
DATABASE_URL='mysql://{user}:{password}@{host}:4000/test'
```

If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

4. In the `prisma/schema.prisma`, set up `mysql` as the connection provider and `env("DATABASE_URL")` as the connection URL:

```
datasource db {
  provider = "mysql"
  url      = env("DATABASE_URL")
}
```

Step 4. Initialize the database schema

Run following command to invoke Prisma Migrate to initialize the database with the data models defined in `prisma/prisma.schema`.

```
npx prisma migrate dev
```

Data models defined in `prisma.schema`:

```
// Define a Player model, which represents the `players` table.
model Player {
  id       Int     @id @default(autoincrement())
  name     String  @unique(map: "uk_player_on_name") @db.VarChar(50)
  coins    Decimal @default(0)
  goods    Int     @default(0)
  createdAt DateTime @default(now()) @map("created_at")
  profile  Profile?

  @@map("players")
}

// Define a Profile model, which represents the `profiles` table.
model Profile {
  playerId Int   @id @map("player_id")
  biography String @db.Text

  // Define a 1:1 relation between the `Player` and `Profile` models with
     ↪ foreign key.
```

```
  player   Player @relation(fields: [playerId], references: [id], onDelete:
     ↪ Cascade, map: "fk_profile_on_player_id")

  @@map("profiles")
}
```

To learn how to define data models in Prisma, please check the Data model documentation.

Expected execution output:

```
Your database is now in sync with your schema.

  Generated Prisma Client (5.1.1 | library) to ./node_modules/@prisma/client
    ↪  in 54ms
```

This command will also generate Prisma Client for TiDB database accessing based on the `prisma/prisma.schema`.

Step 5: Run the code

Run the following command to execute the sample code:

```
npm start
```

Main logic in the sample code:

```
// Step 1. Import the auto-generated `@prisma/client` package.
import {Player, PrismaClient} from '@prisma/client';

async function main(): Promise<void> {
  // Step 2. Create a new `PrismaClient` instance.
  const prisma = new PrismaClient();
  try {

    // Step 3. Perform some CRUD operations with Prisma Client ...

  } finally {
    // Step 4. Disconnect Prisma Client.
    await prisma.$disconnect();
  }
}

void main();
```

Expected execution output:

If the connection is successful, the terminal will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
  Created a new player with ID 1.
  Got Player 1: Player { id: 1, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 1, now player 1 has 150 coins and
    ↪ 150 goods.
 Player 1 has been deleted.
```

4.3.4.3.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-nodejs-prisma-quickstart repository.

Insert data

The following query creates a single `Player` record, and returns the created `Player` object, which contains the `id` field generated by TiDB:

```
const player: Player = await prisma.player.create({
   data: {
      name: 'Alice',
      coins: 100,
      goods: 200,
      createdAt: new Date(),
   }
});
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` object with ID `101` or `null` if no record is found:

```
const player: Player | null = prisma.player.findUnique({
   where: {
      id: 101,
   }
});
```

For more information, refer to Query data.

Update data

The following query adds `50` coins and `50` goods to the `Player` with ID `101`:

```
await prisma.player.update({
   where: {
      id: 101,
   },
   data: {
      coins: {
         increment: 50,
      },
      goods: {
         increment: 50,
      },
   }
});
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` with ID `101`:

```
await prisma.player.delete({
   where: {
      id: 101,
   }
});
```

For more information, refer to Delete data.

4.3.4.3.4 Useful notes

Foreign key constraints vs Prisma relation mode

To check referential integrity, you can use foreign key constraints or Prisma relation mode:

- Foreign key is a feature supported starting from TiDB v6.6.0, and generally available starting from v8.5.0. Foreign keys allow cross-table references of related data, while foreign key constraints ensure the consistency of related data.

> **Warning:**
> **Foreign keys are suitable for small and medium-volumes data scenarios.** Using foreign keys in large data volumes might lead to serious performance issues and could have unpredictable effects on the system. If you plan to use foreign keys, conduct thorough validation first and use them with caution.

- Prisma relation mode is the emulation of referential integrity in Prisma Client side. However, it should be noted that there are performance implications, as it requires additional database queries to maintain referential integrity.

4.3.4.4.3.5 Next steps

- Learn more usage of the ORM framework Prisma driver from the documentation of Prisma.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.4.3.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.4 Connect to TiDB with Sequelize

TiDB is a MySQL-compatible database, and Sequelize is a popular ORM framework for Node.js.

In this tutorial, you can learn how to use TiDB and Sequelize to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Sequelize.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.4.4.1 Prerequisites

To complete this tutorial, you need:

- Node.js **18** or later.
- Git.

- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.4.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

> **Note**
>
> For complete code snippets and running instructions, refer to the tidb-samples/tidb-nodejs-sequelize-quickstart GitHub repository.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone git@github.com:tidb-samples/tidb-nodejs-sequelize-quickstart.git
cd tidb-nodejs-sequelize-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `sequelize`) for the sample app:

```
npm install
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`

- **Branch** is set to `main`
- **Connect With** is set to `General`
- **Operating System** matches your environment.

> **Note**
>
> In Node.js applications, you don't have to provide an SSL CA certificate, because Node.js uses the built-in Mozilla CA certificate by default when establishing the TLS (SSL) connection.

4. Click **Generate Password** to create a random password.

> **Tip**
>
> If you have generated a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST='{host}'
TIDB_PORT='4000'
TIDB_USER='{user}'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
TIDB_ENABLE_SSL='true'
```

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST='{host}'
TIDB_PORT='4000'
TIDB_USER='{user}'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
TIDB_ENABLE_SSL='true'
TIDB_CA_PATH='{path/to/ca}'
```

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST='{host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

   If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the sample app

Run the following command to execute the sample code:

```
npm start
```

Expected output(partial):

```
INFO (app/10117): Getting sequelize instance...
Executing (default): SELECT 1+1 AS result
Executing (default): DROP TABLE IF EXISTS `players`;
```

```
Executing (default): CREATE TABLE IF NOT EXISTS `players` (`id` INTEGER NOT
    ↪ NULL auto_increment COMMENT 'The unique ID of the player.', `coins`
    ↪ INTEGER NOT NULL COMMENT 'The number of coins that the player had.',
    ↪ `goods` INTEGER NOT NULL COMMENT 'The number of goods that the player
    ↪  had.', `createdAt` DATETIME NOT NULL, `updatedAt` DATETIME NOT NULL,
    ↪  PRIMARY KEY (`id`)) ENGINE=InnoDB;
Executing (default): SHOW INDEX FROM `players`
Executing (default): INSERT INTO `players` (`id`,`coins`,`goods`,`createdAt
    ↪ `,`updatedAt`) VALUES (1,100,100,'2023-08-31 09:10:11','2023-08-31
    ↪ 09:10:11'),(2,200,200,'2023-08-31 09:10:11','2023-08-31 09:10:11')
    ↪ ,(3,300,300,'2023-08-31 09:10:11','2023-08-31 09:10:11')
    ↪ ,(4,400,400,'2023-08-31 09:10:11','2023-08-31 09:10:11')
    ↪ ,(5,500,500,'2023-08-31 09:10:11','2023-08-31 09:10:11');
Executing (default): SELECT `id`, `coins`, `goods`, `createdAt`, `updatedAt`
    ↪  FROM `players` AS `players` WHERE `players`.`coins` > 300;
Executing (default): UPDATE `players` SET `coins`=?,`goods`=?,`updatedAt`=?
    ↪ WHERE `id` = ?
Executing (default): DELETE FROM `players` WHERE `id` = 6
```

4.3.4.4.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-nodejs-sequelize-quickstart repository.

Connect to TiDB

The following code establish a connection to TiDB with options defined in the environment variables:

```
// src/lib/tidb.ts
import { Sequelize } from 'sequelize';

export function initSequelize() {
  return new Sequelize({
    dialect: 'mysql',
    host: process.env.TIDB_HOST || 'localhost', // TiDB host, for example: {
       ↪ gateway-region}.aws.tidbcloud.com
    port: Number(process.env.TIDB_PORT) || 4000, // TiDB port, default: 4000
    username: process.env.TIDB_USER || 'root', // TiDB user, for example: {
       ↪ prefix}.root
    password: process.env.TIDB_PASSWORD || 'root', // TiDB password
    database: process.env.TIDB_DB_NAME || 'test', // TiDB database name,
       ↪ default: test
    dialectOptions: {
```

```
    ssl:
      process.env?.TIDB_ENABLE_SSL === 'true' // (Optional) Enable SSL
        ? {
            minVersion: 'TLSv1.2',
            rejectUnauthorized: true,
            ca: process.env.TIDB_CA_PATH     // (Optional) Path to the
               ↪ custom CA certificate
              ? readFileSync(process.env.TIDB_CA_PATH)
              : undefined,
          }
        : null,
  },
}

export async function getSequelize() {
  if (!sequelize) {
    sequelize = initSequelize();
    try {
      await sequelize.authenticate();
      logger.info('Connection has been established successfully.');
    } catch (error) {
      logger.error('Unable to connect to the database:');
      logger.error(error);
      throw error;
    }
  }
  return sequelize;
}
```

Insert data

The following query creates a single `Players` record and returns a `Players` object:

```
logger.info('Creating a new player...');
const newPlayer = await playersModel.create({
  id: 6,
  coins: 600,
  goods: 600,
});
logger.info('Created a new player.');
logger.info(newPlayer.toJSON());
```

For more information, refer to Insert data.

Query data

The following query returns a single `Players` record those coins are greater than 300:

```
logger.info('Reading all players with coins > 300...');
const allPlayersWithCoinsGreaterThan300 = await playersModel.findAll({
  where: {
    coins: {
      [Op.gt]: 300,
    },
  },
});
logger.info('Read all players with coins > 300.');
logger.info(allPlayersWithCoinsGreaterThan300.map((p) => p.toJSON()));
```

For more information, refer to Query data.

Update data

The following query set `700` coins and `700` goods to the `Players` with ID `6` that was created in the Insert data section:

```
logger.info('Updating the new player...');
await newPlayer.update({ coins: 700, goods: 700 });
logger.info('Updated the new player.');
logger.info(newPlayer.toJSON());
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` record with ID `6` that was created in the Insert data section:

```
logger.info('Deleting the new player...');
await newPlayer.destroy();
const deletedNewPlayer = await playersModel.findByPk(6);
logger.info('Deleted the new player.');
logger.info(deletedNewPlayer?.toJSON());
```

For more information, refer to Delete data.

4.3.4.4.4 Next steps

- Learn more usage of the ORM framework Sequelize driver from the documentation of Sequelize.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.4.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.5 Connect to TiDB with TypeORM

TiDB is a MySQL-compatible database, and TypeORM is a popular open-source ORM framework for Node.js.

In this tutorial, you can learn how to use TiDB and TypeORM to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using TypeORM.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.4.5.1 Prerequisites

To complete this tutorial, you need:

- Node.js >= 16.x installed on your machine.
- Git installed on your machine.
- A TiDB cluster running.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.5.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-nodejs-typeorm-quickstart.git
cd tidb-nodejs-typeorm-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `typeorm` and `mysql2`) for the sample app:

```
npm install
```

Install dependencies to an existing project

For your existing project, run the following command to install the packages:

- `typeorm`: the ORM framework for Node.js.
- `mysql2`: the MySQL driver for Node.js. You can also use the `mysql` driver.
- `dotenv`: loads environment variables from the `.env` file.
- `typescript`: compiles TypeScript code to JavaScript.
- `ts-node`: runs TypeScript code directly without compiling.
- `@types/node`: provides TypeScript type definitions for Node.js.

```
npm install typeorm mysql2 dotenv --save
npm install @types/node ts-node typescript --save-dev
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `General`.
    - **Operating System** matches the operating system where you run the application.
4. If you have not set a password yet, click **Generate Password** to generate a random password.
5. Run the following command to copy `.env.example` and rename it to `.env`:

    ```
    cp .env.example .env
    ```

6. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER={user}
TIDB_PASSWORD={password}
TIDB_DATABASE=test
TIDB_ENABLE_SSL=true
```

> **Note**
>
> For TiDB Cloud Serverless, you **MUST** enable TLS connection via `TIDB_ENABLE_SSL` when using public endpoint.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.
4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters on the connection dialog:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER={user}
TIDB_PASSWORD={password}
TIDB_DATABASE=test
TIDB_ENABLE_SSL=true
TIDB_CA_PATH={downloaded_ssl_ca_path}
```

> **Note**
>
> For TiDB Cloud Dedicated, it is **RECOMMENDED** to enable TLS connection via `TIDB_ENABLE_SSL` when using public endpoint. When you set up `TIDB_ENABLE_SSL=true`, you **MUST** specify the path of the CA certificate downloaded from connection dialog via `TIDB_CA_PATH=/path/to/ca.pem`.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the environment variables as follows, replace the corresponding placeholders `{}` with connection parameters of your TiDB cluster:

```
TIDB_HOST={host}
TIDB_PORT=4000
TIDB_USER=root
TIDB_PASSWORD={password}
TIDB_DATABASE=test
```

   If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Initialize the database schema

Run the following command to invoke TypeORM CLI to initialize the database with the SQL statements written in the migration files in the `src/migrations` folder:

```
npm run migration:run
```

Expected execution output

The following SQL statements create a `players` table and a `profiles` table, and the two tables are associated through foreign keys.

```
query: SELECT VERSION() AS `version`
query: SELECT * FROM `INFORMATION_SCHEMA`.`COLUMNS` WHERE `TABLE_SCHEMA` =
    ↪ 'test' AND `TABLE_NAME` = 'migrations'
query: CREATE TABLE `migrations` (`id` int NOT NULL AUTO_INCREMENT, `
    ↪ timestamp` bigint NOT NULL, `name` varchar(255) NOT NULL, PRIMARY
    ↪ KEY (`id`)) ENGINE=InnoDB
```

```
query: SELECT * FROM `test`.`migrations` `migrations` ORDER BY `id` DESC
0 migrations are already loaded in the database.
1 migrations were found in the source code.
1 migrations are new migrations must be executed.
query: START TRANSACTION
query: CREATE TABLE `profiles` (`player_id` int NOT NULL, `biography` text
    ↪ NOT NULL, PRIMARY KEY (`player_id`)) ENGINE=InnoDB
query: CREATE TABLE `players` (`id` int NOT NULL AUTO_INCREMENT, `name`
    ↪ varchar(50) NOT NULL, `coins` decimal NOT NULL, `goods` int NOT NULL,
    ↪  `created_at` datetime NOT NULL, `profilePlayerId` int NULL, UNIQUE
    ↪ INDEX `uk_players_on_name` (`name`), UNIQUE INDEX `REL_
    ↪ b9666644b90ccc5065993425ef` (`profilePlayerId`), PRIMARY KEY (`id`))
    ↪ ENGINE=InnoDB
query: ALTER TABLE `players` ADD CONSTRAINT `fk_profiles_on_player_id`
    ↪ FOREIGN KEY (`profilePlayerId`) REFERENCES `profiles`(`player_id`) ON
    ↪  DELETE NO ACTION ON UPDATE NO ACTION
query: INSERT INTO `test`.`migrations`(`timestamp`, `name`) VALUES (?, ?)
    ↪ -- PARAMETERS: [1693814724825,"Init1693814724825"]
Migration Init1693814724825 has been executed successfully.
query: COMMIT
```

Migration files are generated from the entities defined in the `src/entities` folder. To learn how to define entities in TypeORM, refer to TypeORM: Entities.

Step 5: Run the code and check the result

Run the following command to execute the sample code:

```
npm start
```

Expected execution output:

If the connection is successful, the terminal will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
  Created a new player with ID 2.
  Got Player 2: Player { id: 2, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 2, now player 2 has 100 coins and
    ↪ 150 goods.
 Deleted 1 player data.
```

4.3.4.5.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-nodejs-typeorm-quickstart repository.

Connect with connection options

The following code establishes a connection to TiDB with options defined in the environment variables:

```
// src/dataSource.ts

// Load environment variables from .env file to process.env.
require('dotenv').config();

export const AppDataSource = new DataSource({
  type: "mysql",
  host: process.env.TIDB_HOST || '127.0.0.1',
  port: process.env.TIDB_PORT ? Number(process.env.TIDB_PORT) : 4000,
  username: process.env.TIDB_USER || 'root',
  password: process.env.TIDB_PASSWORD || '',
  database: process.env.TIDB_DATABASE || 'test',
  ssl: process.env.TIDB_ENABLE_SSL === 'true' ? {
    minVersion: 'TLSv1.2',
    ca: process.env.TIDB_CA_PATH ? fs.readFileSync(process.env.TIDB_CA_PATH)
      ↪  : undefined
  } : null,
  synchronize: process.env.NODE_ENV === 'development',
  logging: false,
  entities: [Player, Profile],
  migrations: [__dirname + "/migrations/**/*{.ts,.js}"],
});
```

> **Note**
>
> For TiDB Cloud Serverless, you MUST enable TLS connection when using public endpoint. In this sample code, please set up the environment variable `TIDB_ENABLE_SSL` in the `.env` file to `true`.
>
> However, you **don't** have to specify an SSL CA certificate via `TIDB_CA_PATH`, because Node.js uses the built-in Mozilla CA certificate by default, which is trusted by TiDB Cloud Serverless.

Insert data

The following query creates a single `Player` record, and returns the created `Player` object, which contains the `id` field generated by TiDB:

```
const player = new Player('Alice', 100, 100);
await this.dataSource.manager.save(player);
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` object with ID 101 or `null` if no record is found:

```
const player: Player | null = await this.dataSource.manager.findOneBy(Player
    ↪ , {
  id: id
});
```

For more information, refer to Query data.

Update data

The following query adds `50` goods to the `Player` with ID `101`:

```
const player = await this.dataSource.manager.findOneBy(Player, {
  id: 101
});
player.goods += 50;
await this.dataSource.manager.save(player);
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` with ID `101`:

```
await this.dataSource.manager.delete(Player, {
  id: 101
});
```

For more information, refer to Delete data.

Execute raw SQL queries

The following query executes a raw SQL statement (`SELECT VERSION()AS tidb_ ↪ version;`) and returns the version of the TiDB cluster:

```
const rows = await dataSource.query('SELECT VERSION() AS tidb_version;');
console.log(rows[0]['tidb_version']);
```

For more information, refer to TypeORM: DataSource API.

4.3.4.5.4 Useful notes

Foreign key constraints

Using foreign key constraints ensures the referential integrity of data by adding checks on the database side. However, this might lead to serious performance issues in scenarios with large data volumes.

You can control whether foreign key constraints are created when constructing relationships between entities by using the `createForeignKeyConstraints` option (default value is `true`).

```
@Entity()
export class ActionLog {
    @PrimaryColumn()
    id: number

    @ManyToOne((type) => Person, {
        createForeignKeyConstraints: false,
    })
    person: Person
}
```

For more information, refer to the TypeORM FAQ and Foreign key constraints.

4.3.4.5.5 Next steps

- Learn more usage of TypeORM from the documentation of TypeORM.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.5.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.6 Connect to TiDB with mysql2 in Next.js

TiDB is a MySQL-compatible database, and mysql2 is a popular open-source driver for Node.js.

In this tutorial, you can learn how to use TiDB and mysql2 in Next.js to accomplish the following tasks:

- Set up your environment.

- Connect to your TiDB cluster using mysql2.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note**
>
> This tutorial works with TiDB Cloud Serverless and TiDB Self-Managed.

4.3.4.6.1 Prerequisites

To complete this tutorial, you need:

- Node.js **18** or later.
- Git.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.4.6.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

> **Note**
>
> For complete code snippets and running instructions, refer to the tidb-nextjs-vercel-quickstart GitHub repository.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone git@github.com:tidb-samples/tidb-nextjs-vercel-quickstart.git
cd tidb-nextjs-vercel-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql2`) for the sample app:

```
npm install
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Note**
>
> In Node.js applications, you do not have to provide an SSL CA certificate, because Node.js uses the built-in Mozilla CA certificate by default when establishing the TLS (SSL) connection.

4. Click **Generate Password** to create a random password.

> **Tip**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
# Linux
cp .env.example .env
```

```
# Windows
Copy-Item ".env.example" -Destination ".env"
```

6. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{gateway-region}.aws.tidbcloud.com'
TIDB_PORT='4000'
TIDB_USER='{prefix}.root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

Replace the placeholders in `{}` with the values obtained in the connection dialog.

7. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
# Linux
cp .env.example .env
```

```
# Windows
Copy-Item ".env.example" -Destination ".env"
```

2. Copy and paste the corresponding connection string into the `.env` file. The example result is as follows:

```
TIDB_HOST='{tidb_server_host}'
TIDB_PORT='4000'
TIDB_USER='root'
TIDB_PASSWORD='{password}'
TIDB_DB_NAME='test'
```

Replace the placeholders in `{}` with the values obtained in the **Connect** window. If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Start the application:

```
bash   npm run dev
```

2. Open your browser and visit `http://localhost:3000`. (Check your terminal for the actual port number, and the default is `3000`.)

3. Click **RUN SQL** to execute the sample code.

4. Check the output in the terminal. If the output is similar to the following, the connection is successful:

```
json   {     "results": [     {         "Hello World": "Hello World"    }
↪      ]    }
```

4.3.4.6.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-nextjs-vercel-quickstart repository.

Connect to TiDB

The following code establish a connection to TiDB with options defined in the environment variables:

```
// src/lib/tidb.js
import mysql from 'mysql2';

let pool = null;

export function connect() {
  return mysql.createPool({
    host: process.env.TIDB_HOST, // TiDB host, for example: {gateway-region
       ↪ }.aws.tidbcloud.com
    port: process.env.TIDB_PORT || 4000, // TiDB port, default: 4000
    user: process.env.TIDB_USER, // TiDB user, for example: {prefix}.root
    password: process.env.TIDB_PASSWORD, // The password of TiDB user.
    database: process.env.TIDB_DATABASE || 'test', // TiDB database name,
       ↪ default: test
    ssl: {
      minVersion: 'TLSv1.2',
      rejectUnauthorized: true,
    },
    connectionLimit: 1, // Setting connectionLimit to "1" in a serverless
       ↪ function environment optimizes resource usage, reduces costs,
       ↪ ensures connection stability, and enables seamless scalability.
    maxIdle: 1, // max idle connections, the default value is the same as `
       ↪ connectionLimit`
    enableKeepAlive: true,
  });
}

export function getPool() {
  if (!pool) {
    pool = createPool();
  }
  return pool;
}
```

Insert data

The following query creates a single `Player` record and returns a `ResultSetHeader` object:

```
const [rsh] = await pool.query('INSERT INTO players (coins, goods) VALUES
    ↪ (?, ?);', [100, 100]);
console.log(rsh.insertId);
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` record by ID `1`:

```
const [rows] = await pool.query('SELECT id, coins, goods FROM players WHERE
    ↪ id = ?;', [1]);
console.log(rows[0]);
```

For more information, refer to Query data.

Update data

The following query adds `50` coins and `50` goods to the `Player` with ID `1`:

```
const [rsh] = await pool.query(
    'UPDATE players SET coins = coins + ?, goods = goods + ? WHERE id = ?;',
    [50, 50, 1]
);
console.log(rsh.affectedRows);
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` record with ID `1`:

```
const [rsh] = await pool.query('DELETE FROM players WHERE id = ?;', [1]);
console.log(rsh.affectedRows);
```

For more information, refer to Delete data.

4.3.4.6.4 Useful notes

- Using connection pools to manage database connections can reduce the performance overhead caused by frequently establishing and destroying connections.
- To avoid SQL injection, it is recommended to use prepared statements.
- In scenarios where there are not many complex SQL statements involved, using ORM frameworks like Sequelize, TypeORM, or Prisma can greatly improve development efficiency.

4.3.4.6.5 Next steps

- For more details on how to build a complex application with ORM and Next.js, see our Bookshop Demo.
- Learn more usage of node-mysql2 driver from the documentation of node-mysql2.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.6.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.4.7 Connect to TiDB with mysql2 in AWS Lambda Function

TiDB is a MySQL-compatible database, AWS Lambda Function is a compute service, and mysql2 is a popular open-source driver for Node.js.

In this tutorial, you can learn how to use TiDB and mysql2 in AWS Lambda Function to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using mysql2.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.
- Deploy your AWS Lambda Function.

> **Note**
>
> This tutorial works with TiDB Cloud Serverless and TiDB Self-Managed.

4.3.4.7.1 Prerequisites

To complete this tutorial, you need:

- Node.js **18** or later.
- Git.
- A TiDB cluster.
- An AWS user with administrator permissions.
- AWS CLI

- AWS SAM CLI

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

If you don't have an AWS account or a user, you can create them by following the steps in the Getting Started with Lambda guide.

4.3.4.7.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

> **Note**
>
> For complete code snippets and running instructions, refer to the tidb-samples/tidb-aws-lambda-quickstart GitHub repository.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone git@github.com:tidb-samples/tidb-aws-lambda-quickstart.git
cd tidb-aws-lambda-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql2`) for the sample app:

```
npm install
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper right corner. A connection dialog is displayed.

3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Note**
>
> In Node.js applications, you don't have to provide an SSL CA certificate, because Node.js uses the built-in Mozilla CA certificate by default when establishing the TLS (SSL) connection.

4. Click **Generate Password** to create a random password.

> **Tip**
>
> If you have generated a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Copy and paste the corresponding connection string into `env.json`. The following is an example:

```
{
  "Parameters": {
    "TIDB_HOST": "{gateway-region}.aws.tidbcloud.com",
    "TIDB_PORT": "4000",
    "TIDB_USER": "{prefix}.root",
    "TIDB_PASSWORD": "{password}"
  }
}
```

    Replace the placeholders in `{}` with the values obtained in the connection dialog.

Copy and paste the corresponding connection string into `env.json`. The following is an example:

```
{
  "Parameters": {
    "TIDB_HOST": "{tidb_server_host}",
    "TIDB_PORT": "4000",
    "TIDB_USER": "root",
    "TIDB_PASSWORD": "{password}"
  }
}
```

Replace the placeholders in `{}` with the values obtained in the **Connect** window.

Step 4: Run the code and check the result

1. (Prerequisite) Install the AWS SAM CLI.
2. Build the bundle:

```
npm run build
```

3. Invoke the sample Lambda function:

```
sam local invoke --env-vars env.json -e events/event.json "
    ↪ tidbHelloWorldFunction"
```

4. Check the output in the terminal. If the output is similar to the following, the connection is successful:

```
{"statusCode":200,"body":"{\"results\":[{\"Hello World\":\"Hello World\
    ↪ "}]}"}
```

After you confirm that the connection is successful, you can follow the next section to deploy the AWS Lambda Function.

4.3.4.7.3 Deploy the AWS Lambda Function

You can deploy the AWS Lambda Function using either the SAM CLI or the AWS Lambda console.

SAM CLI deployment (Recommended)

1. (Prerequisite) Install the AWS SAM CLI.
2. Build the bundle:

```
npm run build
```

3. Update the environment variables in `template.yml`:

```
Environment:
  Variables:
    TIDB_HOST: {tidb_server_host}
    TIDB_PORT: 4000
    TIDB_USER: {prefix}.root
    TIDB_PASSWORD: {password}
```

4. Set AWS environment variables (refer to Short-term credentials):

```
export AWS_ACCESS_KEY_ID={your_access_key_id}
export AWS_SECRET_ACCESS_KEY={your_secret_access_key}
export AWS_SESSION_TOKEN={your_session_token}
```

5. Deploy the AWS Lambda Function:

```
sam deploy --guided

# Example:

# Configuring SAM deploy
# ======================

#       Looking for config file [samconfig.toml] : Not found

#       Setting default arguments for 'sam deploy'
#       =========================================
#       Stack Name [sam-app]: tidb-aws-lambda-quickstart
#       AWS Region [us-east-1]:
#       #Shows you resources changes to be deployed and require a 'Y'
    ↪ to initiate deploy
#       Confirm changes before deploy [y/N]:
#       #SAM needs permission to be able to create roles to connect to
    ↪  the resources in your template
#       Allow SAM CLI IAM role creation [Y/n]:
#       #Preserves the state of previously provisioned resources when
    ↪ an operation fails
#       Disable rollback [y/N]:
#       tidbHelloWorldFunction may not have authorization defined, Is
    ↪ this okay? [y/N]: y
#       tidbHelloWorldFunction may not have authorization defined, Is
    ↪ this okay? [y/N]: y
#       tidbHelloWorldFunction may not have authorization defined, Is
    ↪ this okay? [y/N]: y
#       tidbHelloWorldFunction may not have authorization defined, Is
    ↪ this okay? [y/N]: y
#       Save arguments to configuration file [Y/n]:
#       SAM configuration file [samconfig.toml]:
#       SAM configuration environment [default]:

#       Looking for resources needed for deployment:
#       Creating the required resources...
#       Successfully created!
```

Web console deployment

1. Build the bundle:

```
npm run build

# Bundle for AWS Lambda
# =====================
# dist/index.zip
```

2. Visit the AWS Lambda console.
3. Follow the steps in Creating a Lambda function to create a Node.js Lambda function.
4. Follow the steps in Lambda deployment packages and upload the `dist/index.zip` file.
5. Copy and configure the corresponding connection string in Lambda Function.
    1. In the Functions page of the Lambda console, select the **Configuration** tab, and then choose **Environment variables**.
    2. Choose **Edit**.
    3. To add your database access credentials, do the following:
        - Choose **Add environment variable**, then for **Key** enter `TIDB_HOST` and for **Value** enter the host name.
        - Choose **Add environment variable**, then for **Key** enter `TIDB_PORT` and for **Value** enter the port (4000 is default).
        - Choose **Add environment variable**, then for **Key** enter `TIDB_USER` and for **Value** enter the user name.
        - Choose **Add environment variable**, then for **Key** enter `TIDB_PASSWORD` and for **Value** enter the password you chose when you created your database.
        - Choose **Save**.

4.3.4.7.4 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-aws-lambda-quickstart repository.

Connect to TiDB

The following code establish a connection to TiDB with options defined in the environment variables:

```
// lib/tidb.ts
import mysql from 'mysql2';
```

```
let pool: mysql.Pool | null = null;

function connect() {
  return mysql.createPool({
    host: process.env.TIDB_HOST, // TiDB host, for example: {gateway-region
       ↪ }.aws.tidbcloud.com
    port: process.env.TIDB_PORT ? Number(process.env.TIDB_PORT) : 4000, //
       ↪ TiDB port, default: 4000
    user: process.env.TIDB_USER, // TiDB user, for example: {prefix}.root
    password: process.env.TIDB_PASSWORD, // TiDB password
    database: process.env.TIDB_DATABASE || 'test', // TiDB database name,
       ↪ default: test
    ssl: {
      minVersion: 'TLSv1.2',
      rejectUnauthorized: true,
    },
    connectionLimit: 1, // Setting connectionLimit to "1" in a serverless
       ↪ function environment optimizes resource usage, reduces costs,
       ↪ ensures connection stability, and enables seamless scalability.
    maxIdle: 1, // max idle connections, the default value is the same as `
       ↪ connectionLimit`
    enableKeepAlive: true,
  });
}

export function getPool(): mysql.Pool {
  if (!pool) {
    pool = connect();
  }
  return pool;
}
```

Insert data

The following query creates a single `Player` record and returns a `ResultSetHeader` object:

```
const [rsh] = await pool.query('INSERT INTO players (coins, goods) VALUES
   ↪ (?, ?);', [100, 100]);
console.log(rsh.insertId);
```

For more information, refer to Insert data.

Query data

The following query returns a single `Player` record by ID `1`:

```
const [rows] = await pool.query('SELECT id, coins, goods FROM players WHERE
    ↪ id = ?;', [1]);
console.log(rows[0]);
```

For more information, refer to Query data.

Update data

The following query adds `50` coins and `50` goods to the `Player` with ID `1`:

```
const [rsh] = await pool.query(
    'UPDATE players SET coins = coins + ?, goods = goods + ? WHERE id = ?;',
    [50, 50, 1]
);
console.log(rsh.affectedRows);
```

For more information, refer to Update data.

Delete data

The following query deletes the `Player` record with ID `1`:

```
const [rsh] = await pool.query('DELETE FROM players WHERE id = ?;', [1]);
console.log(rsh.affectedRows);
```

For more information, refer to Delete data.

4.3.4.7.5 Useful notes

- Using connection pools to manage database connections can reduce the performance overhead caused by frequently establishing and destroying connections.
- To avoid SQL injection, it is recommended to use prepared statements.
- In scenarios where there are not many complex SQL statements involved, using ORM frameworks like Sequelize, TypeORM, or Prisma can greatly improve development efficiency.
- For building a RESTful API for your application, it is recommended to use AWS Lambda with API Gateway.
- For designing high-performance applications using TiDB Cloud Serverless and AWS Lambda, refer to this blog.

4.3.4.7.6 Next steps

- For more details on how to use TiDB in AWS Lambda Function, see our TiDB-Lambda-integration/aws-lambda-bookstore Demo. You can also use AWS API Gateway to build a RESTful API for your application.
- Learn more usage of `mysql2` from the documentation of `mysql2`.
- Learn more usage of AWS Lambda from the AWS developer guide of `Lambda`.

- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.4.7.7 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.3.5 Ruby

4.3.5.1 Connect to TiDB with mysql2

TiDB is a MySQL-compatible database, and mysql2 is one of the most popular MySQL drivers for Ruby.

In this tutorial, you can learn how to use TiDB and mysql2 to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using mysql2.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.5.1.1 Prerequisites

To complete this tutorial, you need:

- Ruby >= 3.0 installed on your machine
- Bundler installed on your machine
- Git installed on your machine
- A TiDB cluster running

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.5.1.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-ruby-mysql2-quickstart.git
cd tidb-ruby-mysql2-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql2` and `dotenv`) for the sample app:

```
bundle install
```

Install dependencies for existing projects

For your existing project, run the following command to install the packages:

```
bundle add mysql2 dotenv
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

- **Connection Type** is set to `Public`.
- **Branch** is set to `main`.
- **Connect With** is set to `General`.
- **Operating System** matches the operating system where you run the application.

4. If you have not set a password yet, click **Generate Password** to generate a random password.
5. Run the following command to copy `.env.example` and rename it to `.env`:

   ```
   cp .env.example .env
   ```

6. Edit the `.env` file, set up the environment variables as follows, and replace the corresponding placeholders `{}` with connection parameters in the connection dialog:

```
DATABASE_HOST={host}
DATABASE_PORT=4000
DATABASE_USER={user}
DATABASE_PASSWORD={password}
DATABASE_NAME=test
DATABASE_ENABLE_SSL=true
```

Note

For TiDB Cloud Serverless, TLS connection **MUST** be enabled via `DATABASE_ENABLE_SSL` when using public endpoint.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.
4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the environment variables as follows, and replace the corresponding placeholders `{}` with connection parameters in the connection dialog:

```
DATABASE_HOST={host}
DATABASE_PORT=4000
DATABASE_USER={user}
DATABASE_PASSWORD={password}
DATABASE_NAME=test
DATABASE_ENABLE_SSL=true
DATABASE_SSL_CA={downloaded_ssl_ca_path}
```

Note

It is recommended to enable TLS connection when using the public endpoint to connect to a TiDB Cloud Dedicated cluster.

To enable TLS connection, modify `DATABASE_ENABLE_SSL` to `true` and use `DATABASE_SSL_CA` to specify the file path of CA certificate downloaded from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the environment variables as follows, and replace the corresponding placeholders `{}` with your own TiDB connection information:

```
DATABASE_HOST={host}
DATABASE_PORT=4000
DATABASE_USER={user}
DATABASE_PASSWORD={password}
DATABASE_NAME=test
```

If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

Run the following command to execute the sample code:

```
ruby app.rb
```

If the connection is successful, the console will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
 Loading sample game data...
  Loaded sample game data.

  Created a new player with ID 12.
  Got Player 12: Player { id: 12, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 12, updated 1 row.
 Deleted 1 player data.
```

4.3.5.1.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-ruby-mysql2-quickstart repository.

Connect to TiDB with connection options

The following code establishes a connection to TiDB with options defined in the environment variables:

```
require 'dotenv/load'
require 'mysql2'
Dotenv.load # Load the environment variables from the .env file

options = {
  host: ENV['DATABASE_HOST'] || '127.0.0.1',
  port: ENV['DATABASE_PORT'] || 4000,
  username: ENV['DATABASE_USER'] || 'root',
  password: ENV['DATABASE_PASSWORD'] || '',
  database: ENV['DATABASE_NAME'] || 'test'
}
options.merge(ssl_mode: :verify_identity) unless ENV['DATABASE_ENABLE_SSL']
    ↪  == 'false'
options.merge(sslca: ENV['DATABASE_SSL_CA']) if ENV['DATABASE_SSL_CA']
client = Mysql2::Client.new(options)
```

> **Note**
>
> For TiDB Cloud Serverless, TLS connection **MUST** be enabled via `DATABASE_ENABLE_SSL` when using public endpoint, but you **don't** have to specify an SSL CA certificate via `DATABASE_SSL_CA`, because mysql2 gem will search for existing CA certificates in a particular order until a file is discovered.

Insert data

The following query creates a single player with two fields and returns the `last_insert_id`:

```
def create_player(client, coins, goods)
  result = client.query(
    "INSERT INTO players (coins, goods) VALUES (#{coins}, #{goods});"
  )
```

```
  client.last_id
end
```

For more information, refer to Insert data.

Query data

The following query returns the record of a specific player by ID:

```
def get_player_by_id(client, id)
  result = client.query(
    "SELECT id, coins, goods FROM players WHERE id = #{id};"
  )
  result.first
end
```

For more information, refer to Query data.

Update data

The following query updated the record of a specific player by ID:

```
def update_player(client, player_id, inc_coins, inc_goods)
  result = client.query(
    "UPDATE players SET coins = coins + #{inc_coins}, goods = goods + #{inc_
      ↪ goods} WHERE id = #{player_id};"
  )
  client.affected_rows
end
```

For more information, refer to Update data.

Delete data

The following query deletes the record of a specific player:

```
def delete_player_by_id(client, id)
  result = client.query(
    "DELETE FROM players WHERE id = #{id};"
  )
  client.affected_rows
end
```

For more information, refer to Delete data.

4.3.5.1.4 Best practices

By default, the mysql2 gem can search for existing CA certificates in a particular order until a file is discovered.

1. `/etc/ssl/certs/ca-certificates.crt` for Debian, Ubuntu, Gentoo, Arch, or Slackware
2. `/etc/pki/tls/certs/ca-bundle.crt` for RedHat, Fedora, CentOS, Mageia, Vercel, or Netlify
3. `/etc/ssl/ca-bundle.pem` for OpenSUSE
4. `/etc/ssl/cert.pem` for macOS or Alpine (docker container)

While it is possible to specify the CA certificate path manually, doing so might cause significant inconvenience in multi-environment deployment scenarios, because different machines and environments might store the CA certificate in different locations. Therefore, setting `sslca` to `nil` is recommended for flexibility and ease of deployment across different environments.

4.3.5.1.5 Next steps

- Learn more usage of mysql2 driver from the documentation of mysql2.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.5.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.3.5.2 Connect to TiDB with Rails Framework and ActiveRecord ORM

TiDB is a MySQL-compatible database, Rails is a popular web application framework written in Ruby, and ActiveRecord ORM is the object-relational mapping in Rails.

In this tutorial, you can learn how to use TiDB and Rails to accomplish the following tasks:

- Set up your environment.
- Connect to your TiDB cluster using Rails.
- Build and run your application. Optionally, you can find sample code snippets for basic CRUD operations using ActiveRecord ORM.

> **Note:**
>
> This tutorial works with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.3.5.2.1 Prerequisites

To complete this tutorial, you need:

- Ruby >= 3.0 installed on your machine
- Bundler installed on your machine
- Git installed on your machine
- A TiDB cluster running

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.3.5.2.2 Run the sample app to connect to TiDB

This section demonstrates how to run the sample application code and connect to TiDB.

Step 1: Clone the sample app repository

Run the following commands in your terminal window to clone the sample code repository:

```
git clone https://github.com/tidb-samples/tidb-ruby-rails-quickstart.git
cd tidb-ruby-rails-quickstart
```

Step 2: Install dependencies

Run the following command to install the required packages (including `mysql2` and `dotenv`) for the sample app:

```
bundle install
```

Install dependencies for existing projects

For your existing project, run the following command to install the packages:

```
bundle add mysql2 dotenv
```

Step 3: Configure connection information

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select `Rails` from the **Connect With** drop-down list and keep the default setting of the **Connection Type** as `Public`.

4. If you have not set a password yet, click **Generate Password** to generate a random password.

5. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

6. Edit the `.env` file, set up the `DATABASE_URL` environment variable as follows, and copy the connection string from the connection dialog as the variable value.

```
DATABASE_URL='mysql2://{user}:{password}@{host}:{port}/{database_name}?
    ↪ ssl_mode=verify_identity'
```

> **Note**
>
> For TiDB Cloud Serverless, TLS connection **MUST** be enabled with the `ssl_mode=verify_identity` query parameter when using public endpoint.

7. Save the `.env` file.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

5. Edit the `.env` file, set up the `DATABASE_URL` environment variable as follows, copy the connection string from the connection dialog as the variable value, and set the `sslca` query parameter to the file path of the CA certificate downloaded from the connection dialog:

```
DATABASE_URL='mysql2://{user}:{password}@{host}:{port}/{database}?ssl_
    ↪ mode=verify_identity&sslca=/path/to/ca.pem'
```

Note

It is recommended to enable TLS connection when using the public endpoint to connect to TiDB Cloud Dedicated.

To enable TLS connection, modify the value of the `ssl_mode` query parameter to `verify_identity` and the value of `sslca` to the file path of CA certificate downloaded from the connection dialog.

6. Save the `.env` file.

1. Run the following command to copy `.env.example` and rename it to `.env`:

```
cp .env.example .env
```

2. Edit the `.env` file, set up the `DATABASE_URL` environment variable as follows, and replace the `{user}`, `{password}`, `{host}`, `{port}`, and `{database}` with your own TiDB connection information:

```
DATABASE_URL='mysql2://{user}:{password}@{host}:{port}/{database}'
```

If you are running TiDB locally, the default host address is `127.0.0.1`, and the password is empty.

3. Save the `.env` file.

Step 4: Run the code and check the result

1. Create the database and table:

```
bundle exec rails db:create
bundle exec rails db:migrate
```

2. Seed the sample data:

```
bundle exec rails db:seed
```

3. Run the following command to execute the sample code:

```
bundle exec rails runner ./quickstart.rb
```

If the connection is successful, the console will output the version of the TiDB cluster as follows:

```
 Connected to TiDB cluster! (TiDB version: 8.0.11-TiDB-v8.5.1)
 Loading sample game data...
  Loaded sample game data.

  Created a new player with ID 12.
  Got Player 12: Player { id: 12, coins: 100, goods: 100 }
  Added 50 coins and 50 goods to player 12, updated 1 row.
 Deleted 1 player data.
```

4.3.5.2.3 Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

For complete sample code and how to run it, check out the tidb-samples/tidb-ruby-rails-quickstart repository.

Connect to TiDB with connection options

The following code in `config/database.yml` establishes a connection to TiDB with options defined in the environment variables:

```
default: &default
  adapter: mysql2
  encoding: utf8mb4
  pool: <%= ENV.fetch("RAILS_MAX_THREADS") { 5 } %>
  url: <%= ENV["DATABASE_URL"] %>

development:
  <<: *default

test:
  <<: *default
  database: quickstart_test

production:
  <<: *default
```

> **Note**
>
> For TiDB Cloud Serverless, TLS connection **MUST** be enabled via setting the `ssl_mode` query parameter to `verify_identity` in `DATABASE_URL` when using public endpoint, but you **don't** have to specify an SSL CA certificate via `DATABASE_URL`, because mysql2 gem will search for existing CA certificates in a particular order until a file is discovered.

Insert data

The following query creates a single Player with two fields and returns the created `Player` object:

```
new_player = Player.create!(coins: 100, goods: 100)
```

For more information, refer to Insert data.

Query data

The following query returns the record of a specific player by ID:

```
player = Player.find_by(id: new_player.id)
```

For more information, refer to Query data.

Update data

The following query updates a `Player` object:

```
player.update(coins: 50, goods: 50)
```

For more information, refer to Update data.

Delete data

The following query deletes a `Player` object:

```
player.destroy
```

For more information, refer to Delete data.

4.3.5.2.4 Best practices

By default, the mysql2 gem (used by ActiveRecord ORM to connect TiDB) will search for existing CA certificates in a particular order until a file is discovered.

1. /etc/ssl/certs/ca-certificates.crt # Debian / Ubuntu / Gentoo / Arch / Slackware

2. /etc/pki/tls/certs/ca-bundle.crt # RedHat / Fedora / CentOS / Mageia / Vercel / Netlify
3. /etc/ssl/ca-bundle.pem # OpenSUSE
4. /etc/ssl/cert.pem # MacOS / Alpine (docker container)

While it is possible to specify the CA certificate path manually, this approach may cause significant inconvenience in multi-environment deployment scenarios, as different machines and environments may store the CA certificate in varying locations. Therefore, setting `sslca` to `nil` is recommended for flexibility and ease of deployment across different environments.

4.3.5.2.5 Next steps

- Learn more usage of ActiveRecord ORM from the documentation of ActiveRecord.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as: Insert data, Update data, Delete data, Query data, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.3.5.2.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.3.6 C

4.3.6.1 Connect to TiDB with C#

C# (pronounced "C-Sharp") is one of the programming languages in the .NET family, developed by Microsoft. Other .NET languages include VB.NET and F#. In this tutorial, you will use C# along with MySQL Connector/NET to connect a C# application to TiDB using the MySQL protocol. This works because TiDB is highly compatible with MySQL.

While .NET is commonly used on Windows, it is also available for macOS and Linux. Across all platforms, the commands and code are largely the same, with only minor differences in prompts and file paths.

4.3.6.1.1 Prerequisites

- Download the .NET 9.0 SDK.
- This tutorial uses the `dotnet` command-line tool. Alternatively, you can use the Visual Studio Code IDE to work with C# code.
- To complete this tutorial, you need access to a TiDB instance. You can use a TiDB Cloud Serverless or TiDB Cloud Dedicated cluster on TiDB Cloud, or a TiDB Self-Managed cluster, such as one started using `tiup playground`.

4.3.6.1.2 Step 1. Set up a console project

Create a new project using the `console` template. This will generate a new directory named `tidb_cs`. Before running the following command, either navigate to the location where you want this directory to be created, or specify a full path.

```
$ dotnet new console -o tidb_cs
The template "Console App" was created successfully.

Processing post-creation actions...
Restoring /home/dvaneeden/tidb_cs/tidb_cs.csproj:
Restore succeeded.
```

4.3.6.1.3 Step 2. Add the MySql.Data package

The package manager for .NET is called NuGet. The NuGet package name for MySQL Connector/NET is MySql.Data, which provides support for the MySQL protocol in .NET applications. If you do not specify a version, NuGet installs the latest stable version (for example, version 9.3.0).

```
$ cd tidb_cs
$ dotnet add package MySql.Data

Build succeeded in 1.0s
info : X.509 certificate chain validation will use the system certificate
    ↪ bundle at '/etc/pki/ca-trust/extracted/pem/objsign-ca-bundle.pem'.
info : X.509 certificate chain validation will use the fallback certificate
    ↪ bundle at '/usr/lib64/dotnet/sdk/9.0.106/trustedroots/timestampctl.

```

4.3.6.1.4 Step 3. Update the code

Replace the "Hello World" example in `Program.cs` with the following code.

```
using System;
using MySql.Data.MySqlClient;
public class Tutorial1
{
    public static void Main()
    {
        // For production, always use strong, unique passwords.
        string connStr = "server=127.0.0.1;user=root;database=test;port=4000;
            ↪ AllowUserVariables=true";
        MySqlConnection conn = new MySqlConnection(connStr);
        try
        {
            Console.WriteLine("Connecting to TiDB...\n");
            conn.Open();
        }
        catch (Exception ex)
        {
            Console.WriteLine(ex.ToString());
            Environment.Exit(1);
        }

        Console.WriteLine("Connected to: " + conn.ServerVersion);

        MySqlCommand cmd = new MySqlCommand("SELECT TIDB_VERSION()", conn);

        MySqlDataReader rdr = cmd.ExecuteReader();

        rdr.Read();
        Console.WriteLine("\nVersion details:\n" + rdr[0]);
        rdr.Close();
```

```
        conn.Close();
        Console.WriteLine("Done.");
    }
}
```

This connects to a TiDB instance on the specified IP and port. If you use TiDB Cloud, replace connection string parameters (such as hostname, port, user, and password) with the details provided in the TiDB Cloud console.

The code connects to the database, prints its version, then executes a SQL query using `TIDB_VERSION()` to retrieve more detailed version information, and finally prints this result.

4.3.6.1.5 Step 4. Run the program

```
$ dotnet run
Connecting to TiDB...

Connected to: 8.0.11-TiDB-v8.5.2

Version details:
Release Version: v8.5.2
Edition: Community
Git Commit Hash: f43a13324440f92209e2a9f04c0bbe9cf763978d
Git Branch: HEAD
UTC Build Time: 2025-05-29 03:30:55
GoVersion: go1.23.8
Race Enabled: false
Check Table Before Drop: false
Store: tikv
Done.
```

4.4 Connect to TiDB

4.4.1 GUI Database Tools

4.4.1.1 Connect to TiDB with JetBrains DataGrip

TiDB is a MySQL-compatible database, and JetBrains DataGrip is a powerful integrated development environment (IDE) for database and SQL. This tutorial walks you through the process of connecting to your TiDB cluster using DataGrip.

Note:

This tutorial is compatible with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

You can use DataGrip in two ways:

- As the DataGrip IDE standalone tool.
- As the Database Tools and SQL plugin in JetBrains IDEs, such as IntelliJ, PhpStorm, and PyCharm.

This tutorial mainly focuses on the standalone DataGrip IDE. The steps of connecting to TiDB using the JetBrains Database Tools and SQL plugin in JetBrains IDEs are similar. You can also follow the steps in this document for reference when connecting to TiDB from any JetBrains IDE.

4.4.1.1.1 Prerequisites

To complete this tutorial, you need:

- DataGrip **2023.2.1** or later or a non-community edition JetBrains IDE.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.4.1.1.2 Connect to TiDB

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`

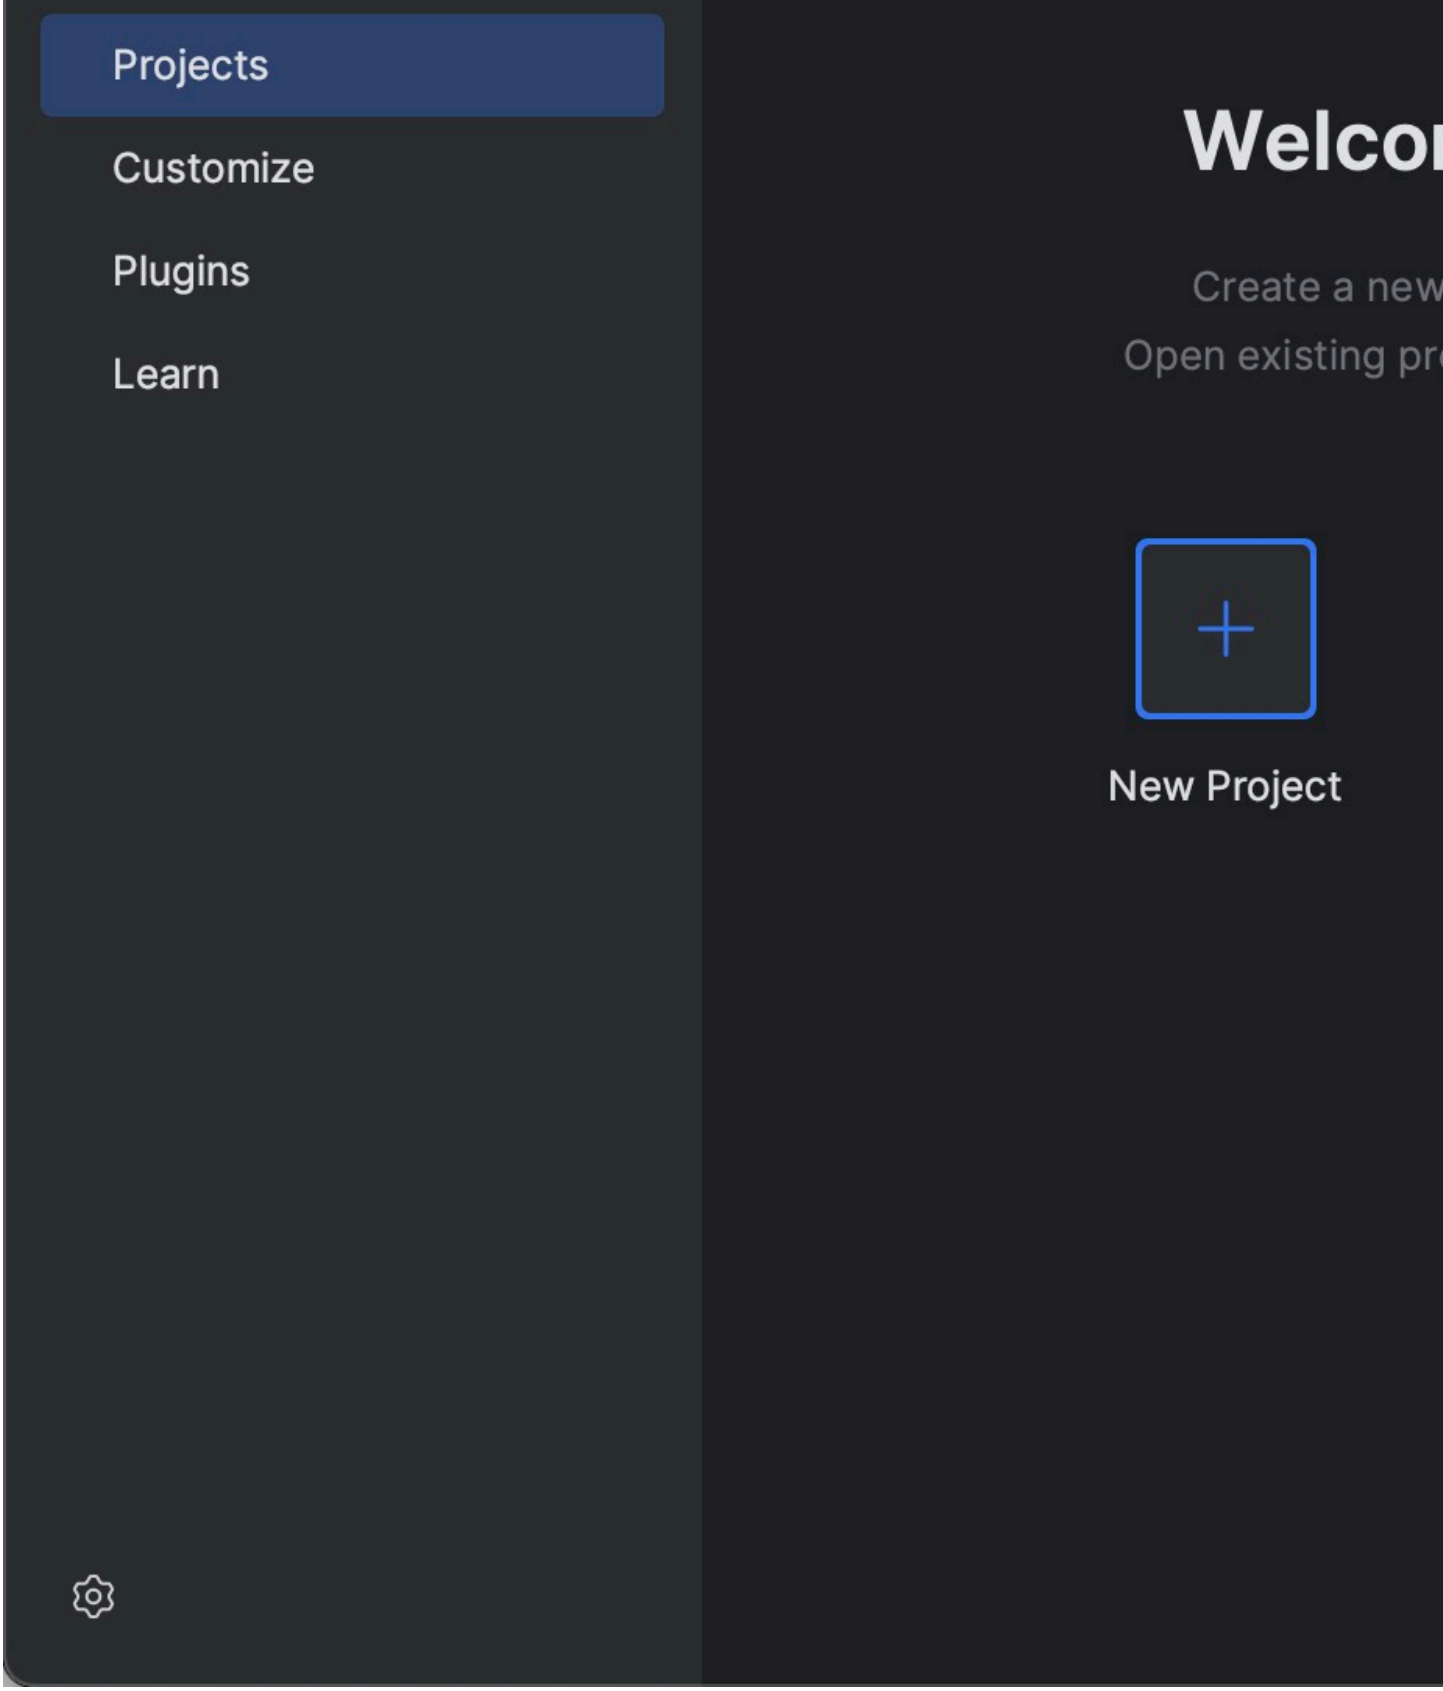

Figure 1: Create a project in DataGrip

6. In the newly created project, click + in the upper-left corner of the **Database Explorer** panel, and select **Data Source** > **Other** > **TiDB**.

Figure 2: Select a data source in DataGrip

7. Copy the connection string from the TiDB Cloud connection dialog. Then, paste it into the **URL** field, and the remaining parameters will be auto-populated. An example result is as follows:

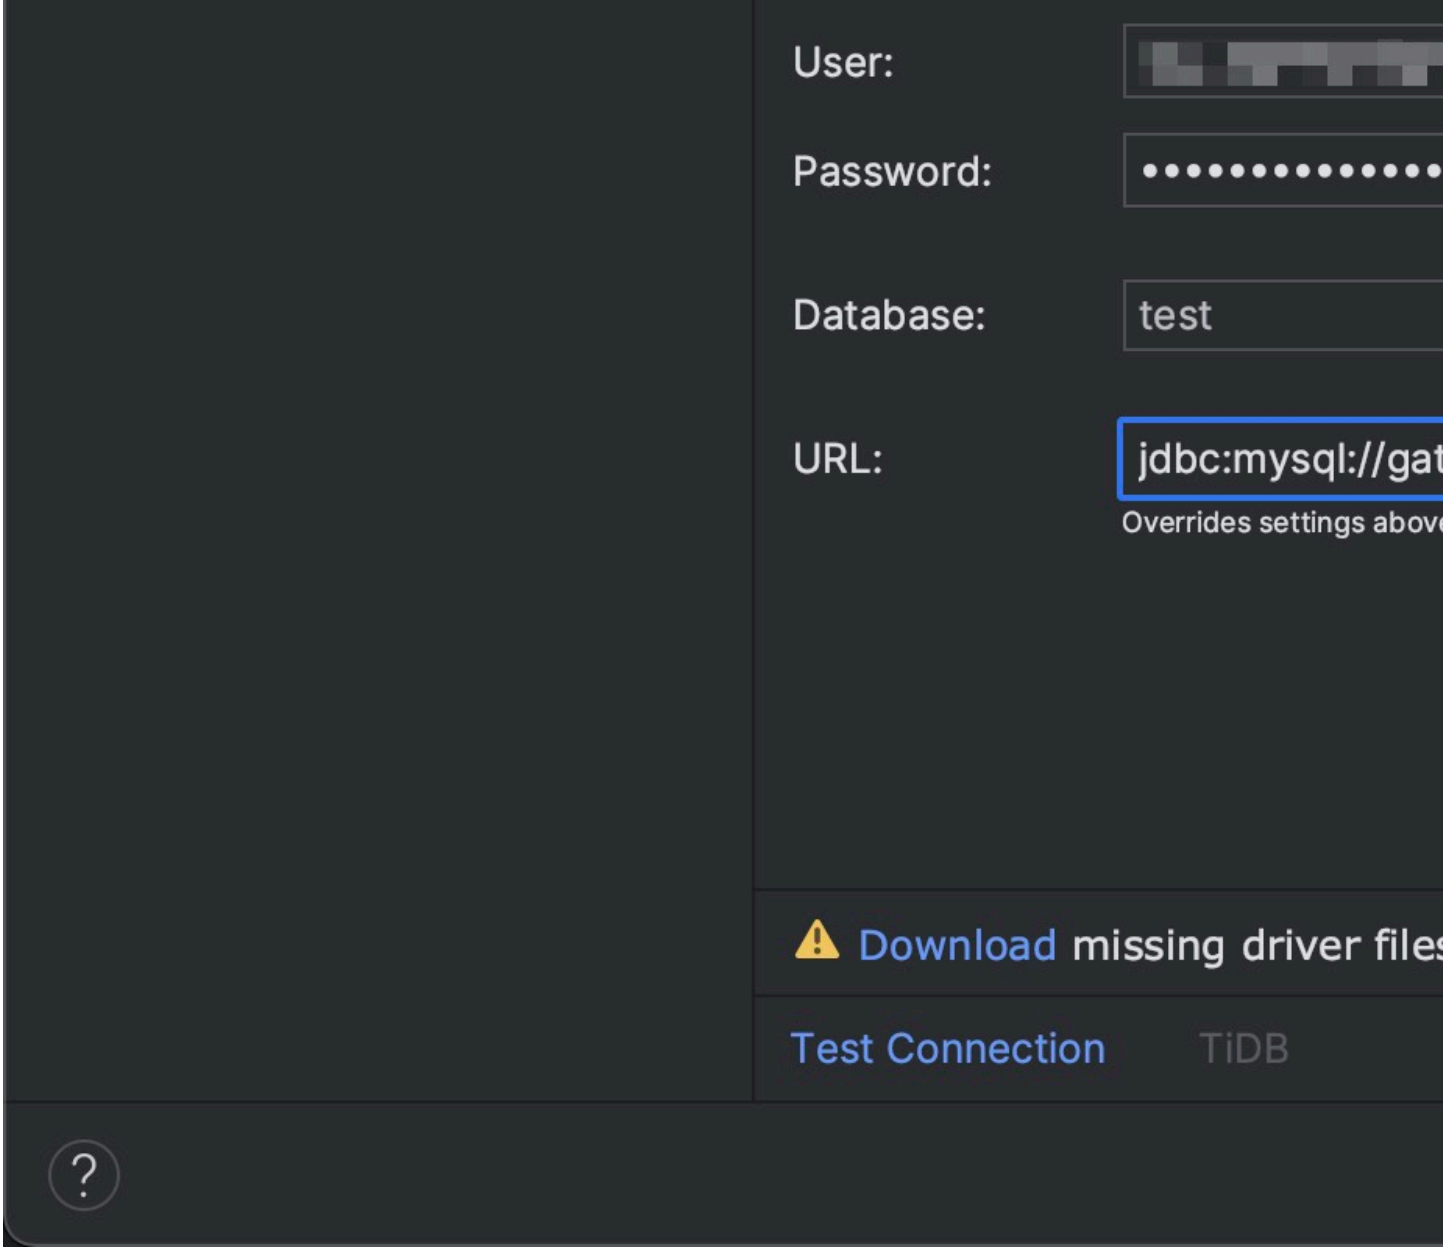

Figure 3: Configure the URL field for TiDB Cloud Serverless

If a **Download missing driver files** warning displays, click **Download** to acquire the driver files.

8. Click **Test Connection** to validate the connection to the TiDB Cloud Serverless cluster.

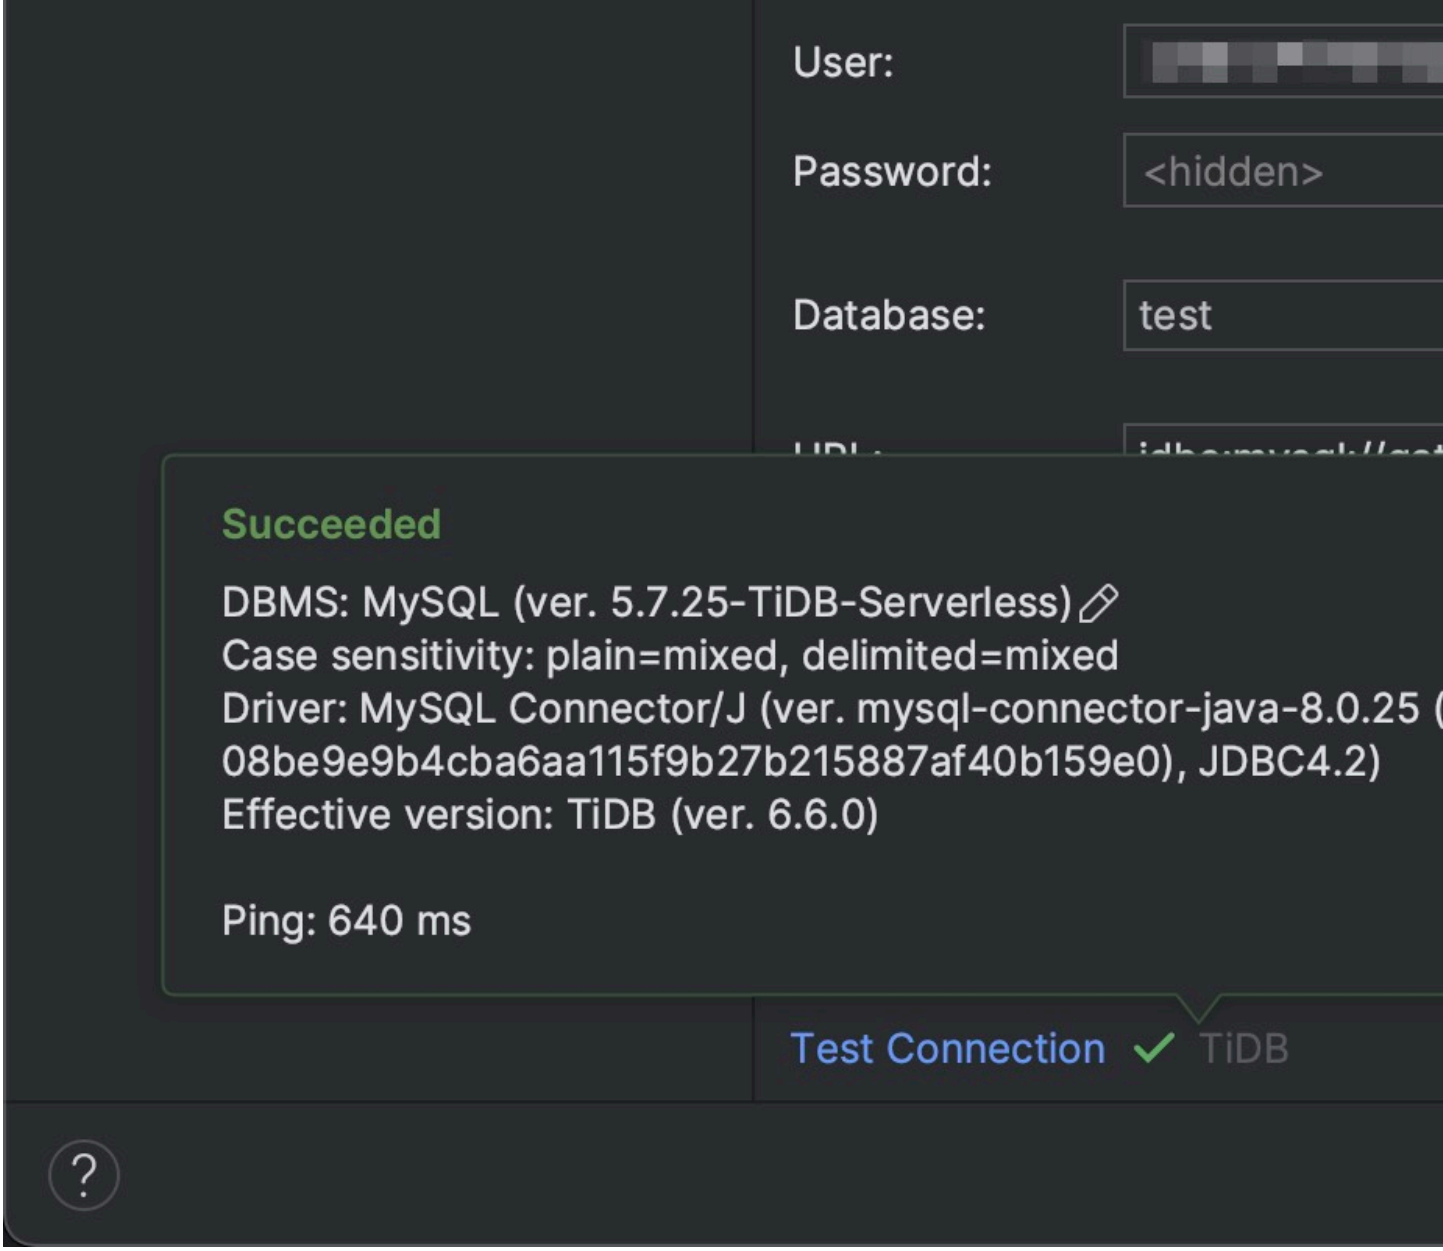

Figure 4: Test the connection to a TiDB Cloud Serverless cluster

9. Click **OK** to save the connection configuration.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

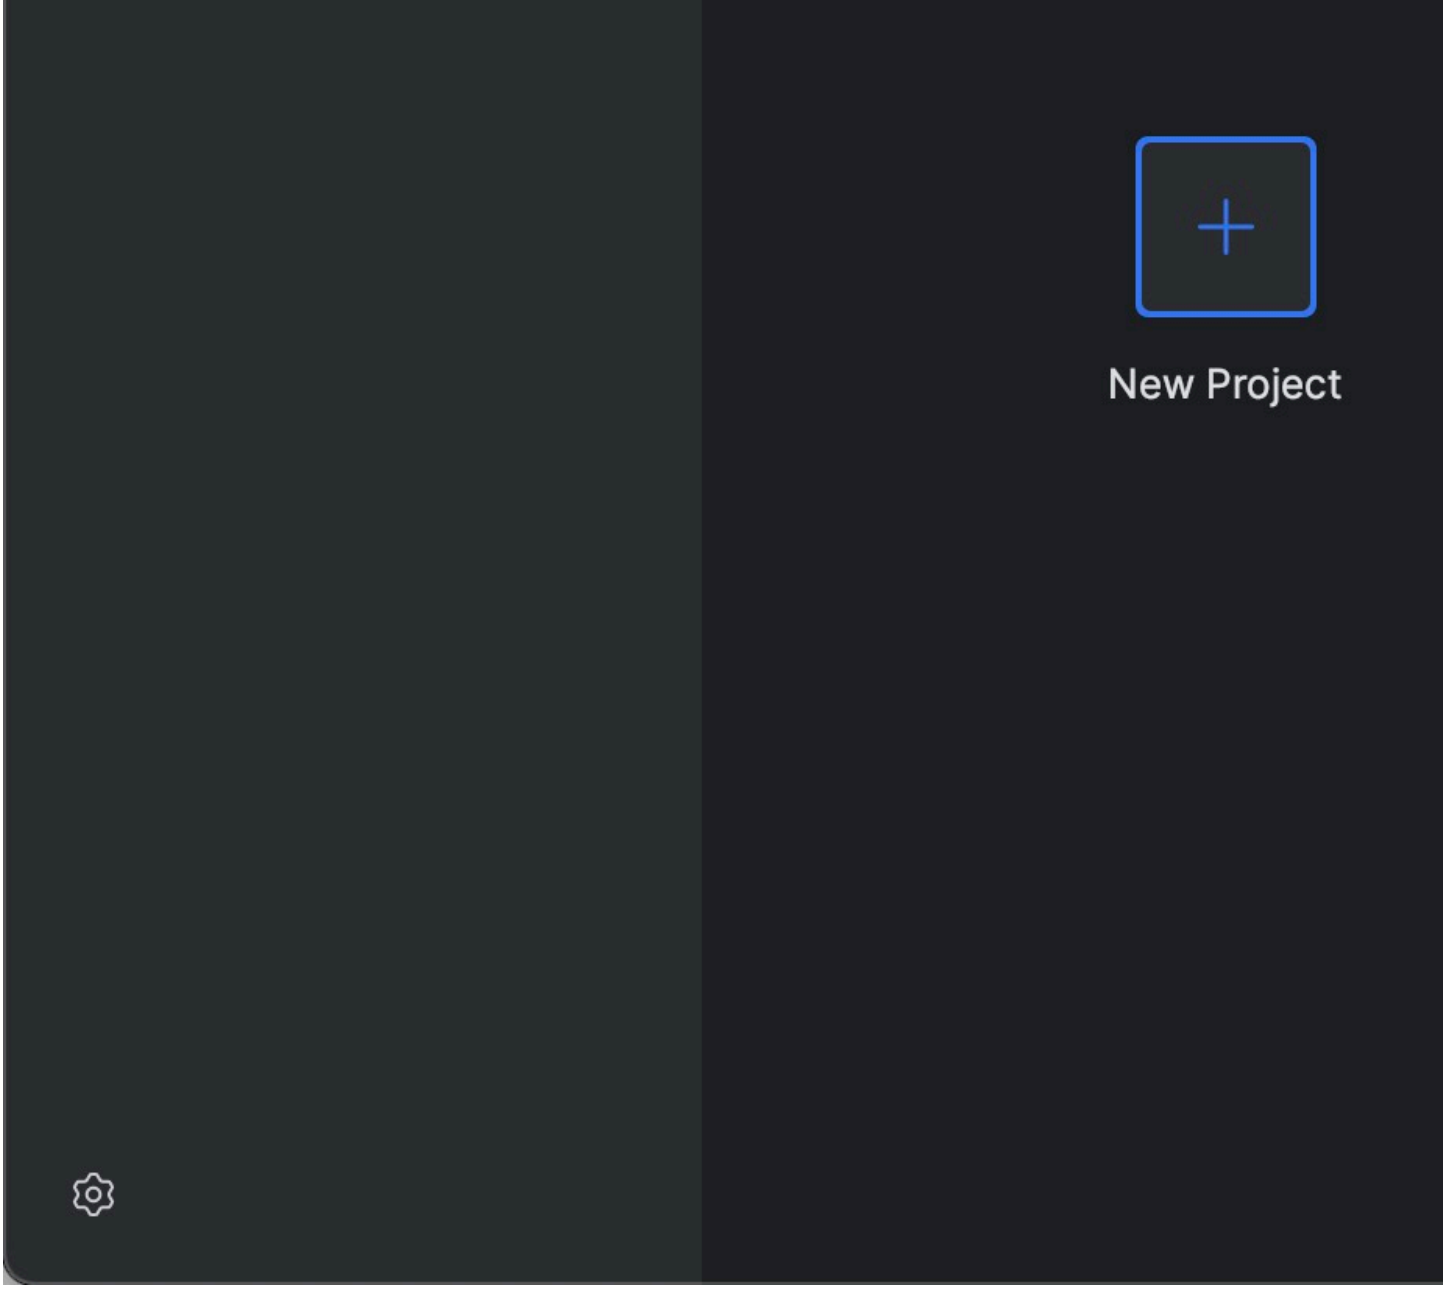

Figure 5: Create a project in DataGrip

5. In the newly created project, click + in the upper-left corner of the **Database Explorer** panel, and select **Data Source** > **Other** > **TiDB**.

Figure 6: Select a data source in DataGrip

6. Copy and paste the appropriate connection string into the **Data Source and Drivers** window in DataGrip. The mappings between DataGrip fields and TiDB Cloud Dedicated connection string are as follows:

DataGrip field	TiDB Cloud Dedicated connection string
Host	`{host}`
Port	`{port}`
User	`{user}`
Password	`{password}`

An example is as follows:

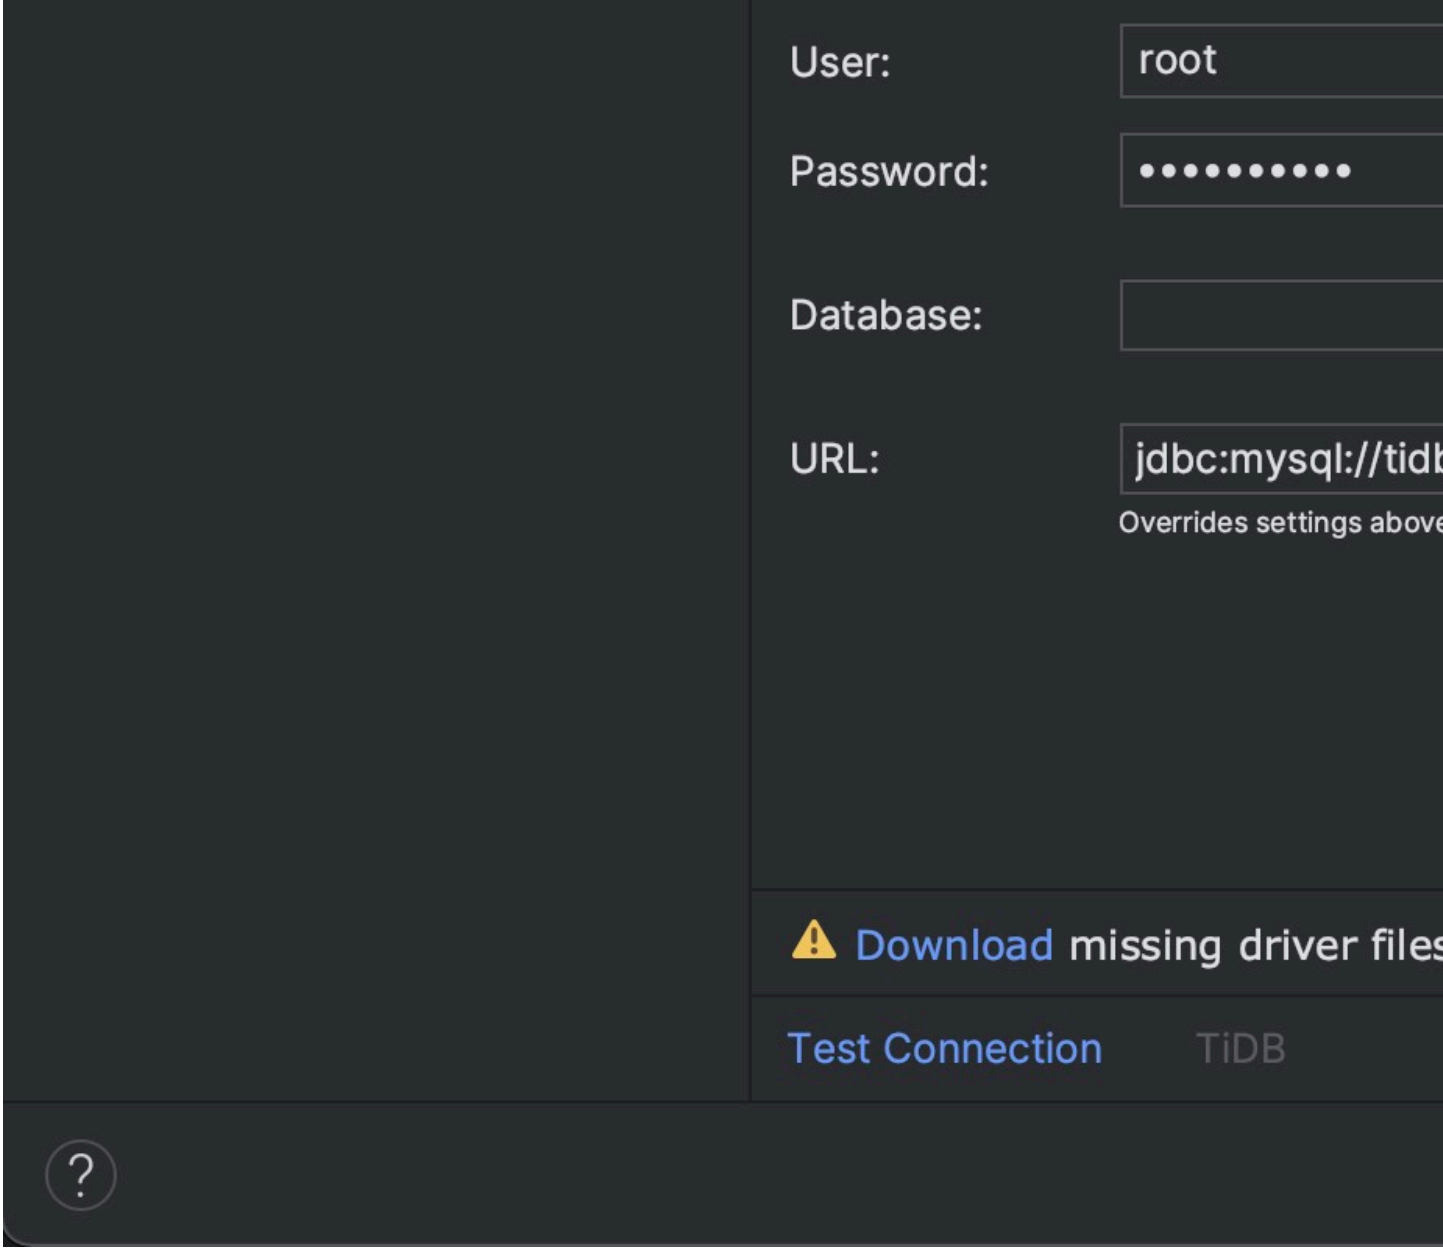

Figure 7: Configure the connection parameters for TiDB Cloud Dedicated

7. Click the **SSH/SSL** tab, select the **Use SSL** checkbox, and input the CA certificate path into the **CA file** field.

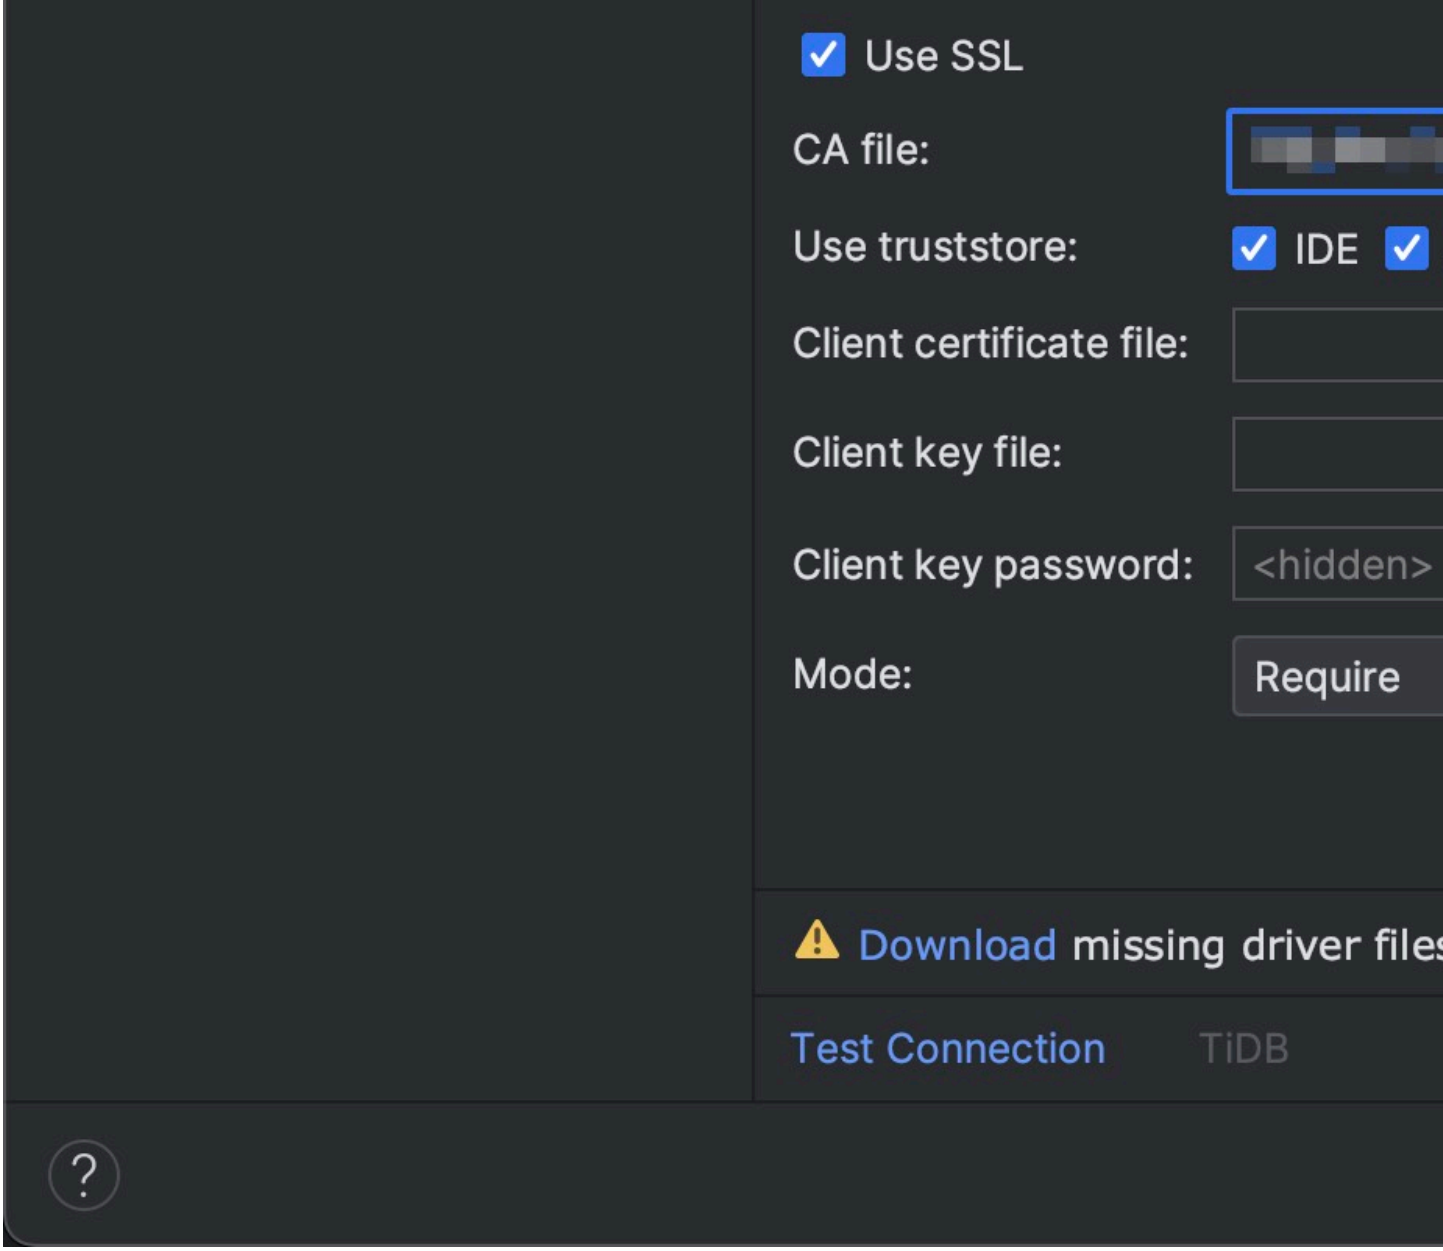

Figure 8: Configure the CA for TiDB Cloud Dedicated

If a **Download missing driver files** warning displays, click **Download** to acquire the driver files.

8. Click the **Advanced** tab, scroll to find the **enabledTLSProtocols** parameter, and set its value to `TLSv1.2,TLSv1.3`.

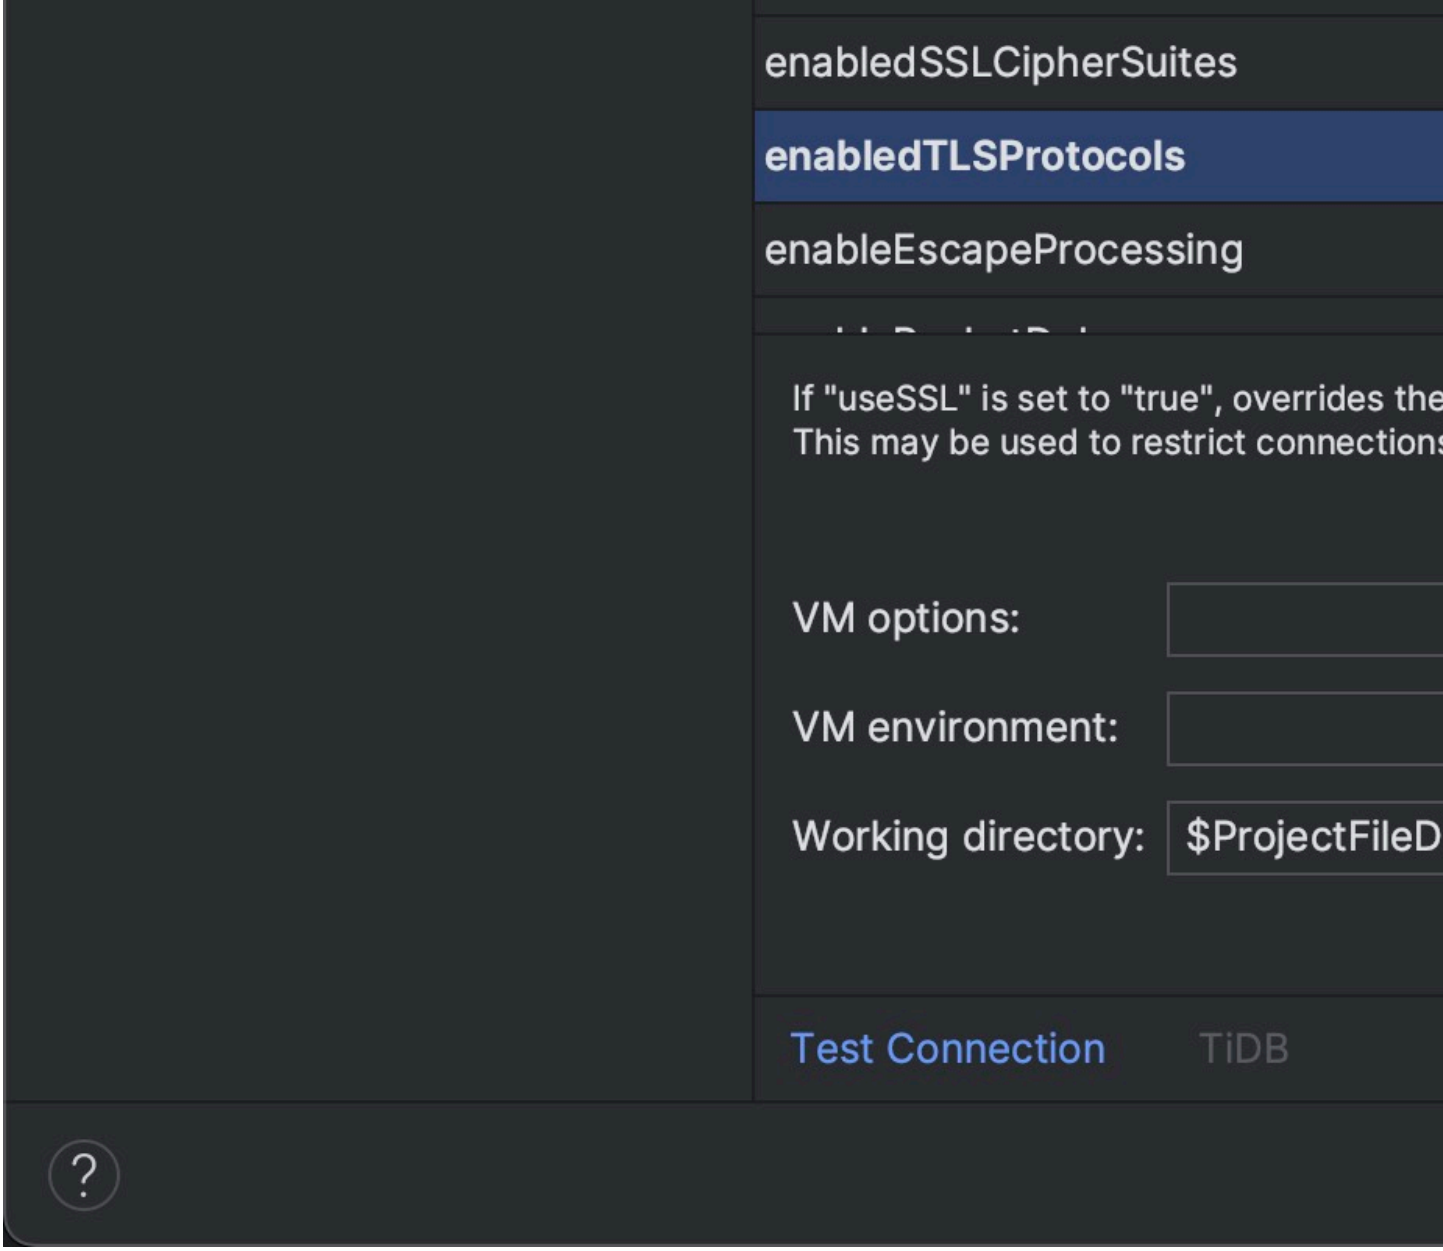

Figure 9: Configure the TLS for TiDB Cloud Dedicated

9. Click **Test Connection** to validate the connection to the TiDB Cloud Dedicated cluster.

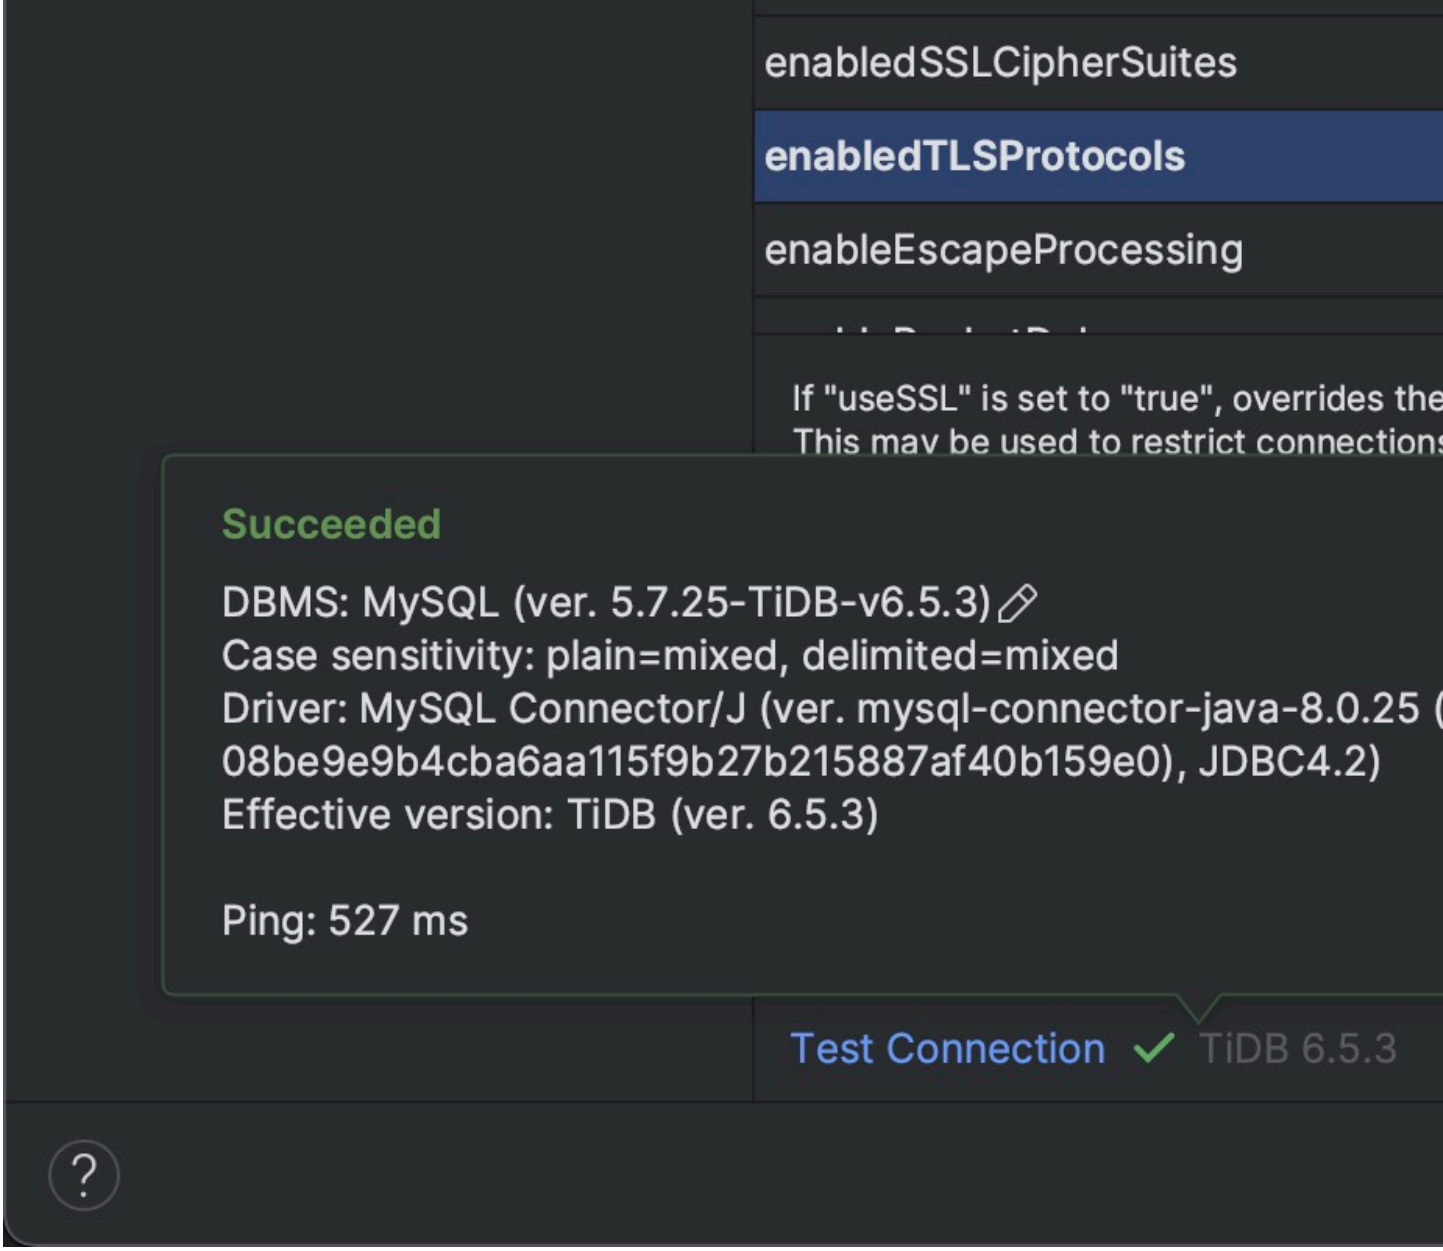

Figure 10: Test the connection to a TiDB Cloud Dedicated cluster

10. Click **OK** to save the connection configuration.

1. Launch DataGrip and create a project to manage your connections.

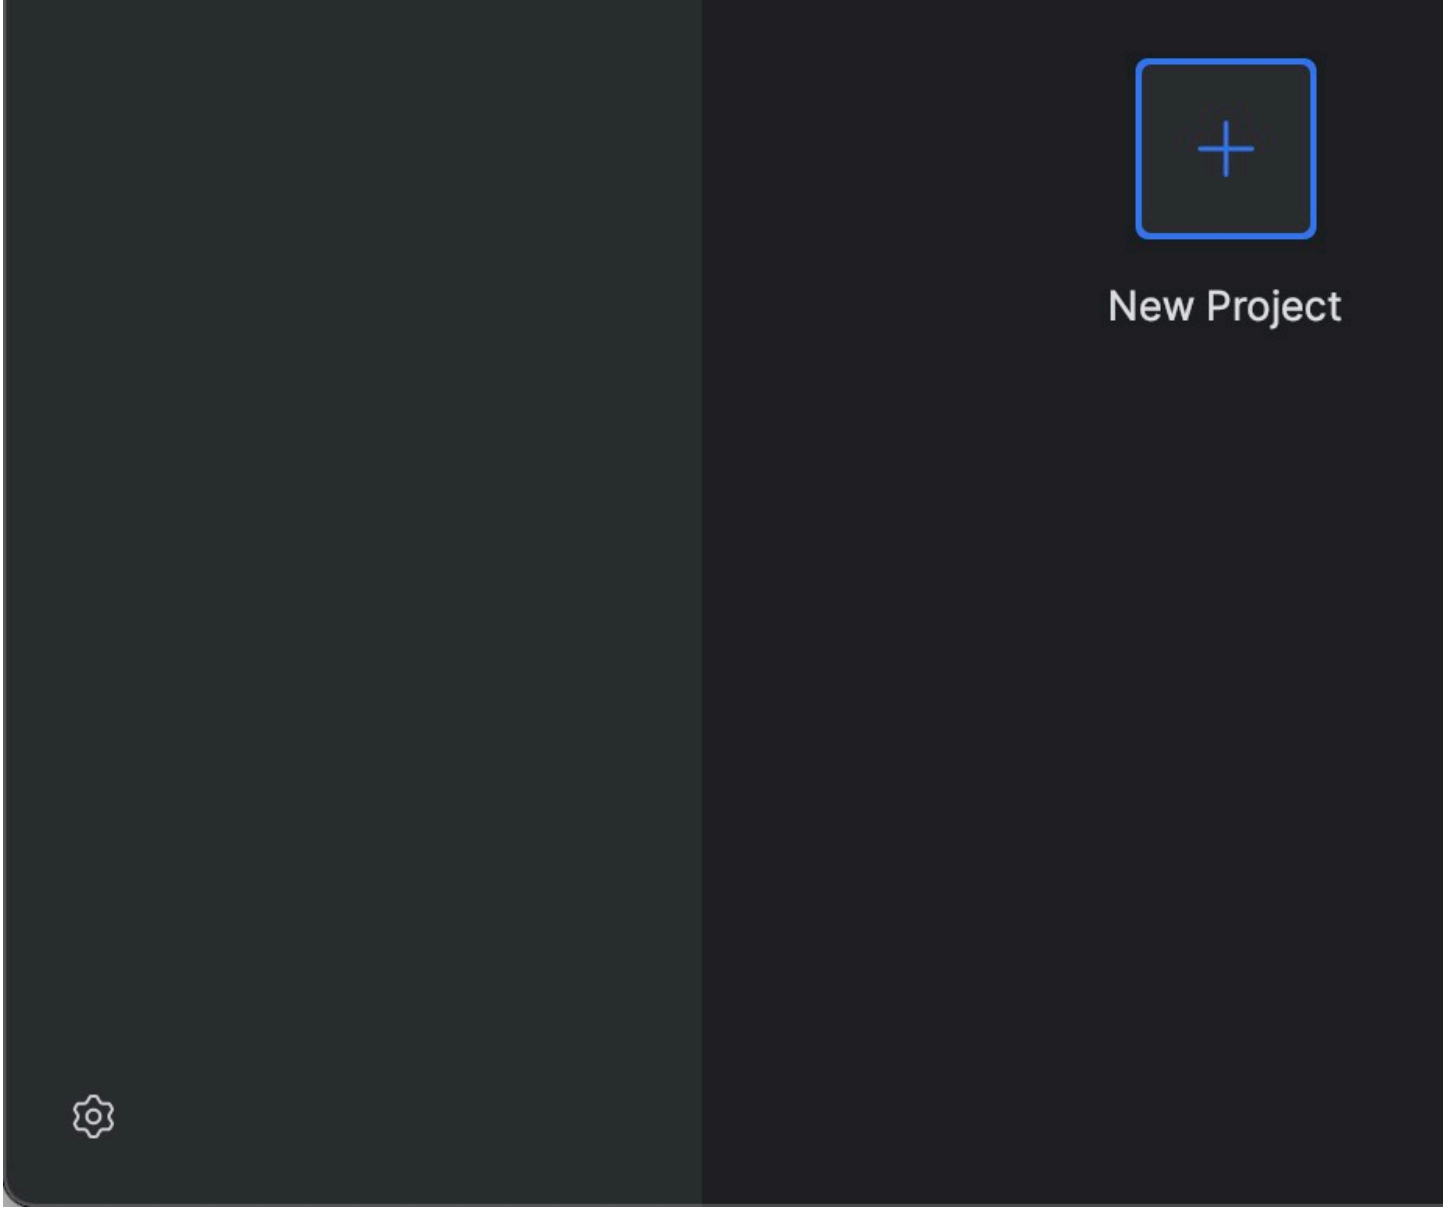

Figure 11: Create a project in DataGrip

2. In the newly created project, click + in the upper-left corner of the **Database Explorer** panel, and select **Data Source** > **Other** > **TiDB**.

Figure 12: Select a data source in DataGrip

3. Configure the following connection parameters:

    - **Host**: The IP address or domain name of your TiDB Self-Managed cluster.
    - **Port**: The port number of your TiDB Self-Managed cluster.
    - **User**: The username to use to connect to your TiDB Self-Managed cluster.
    - **Password**: The password of the username.

    An example is as follows:

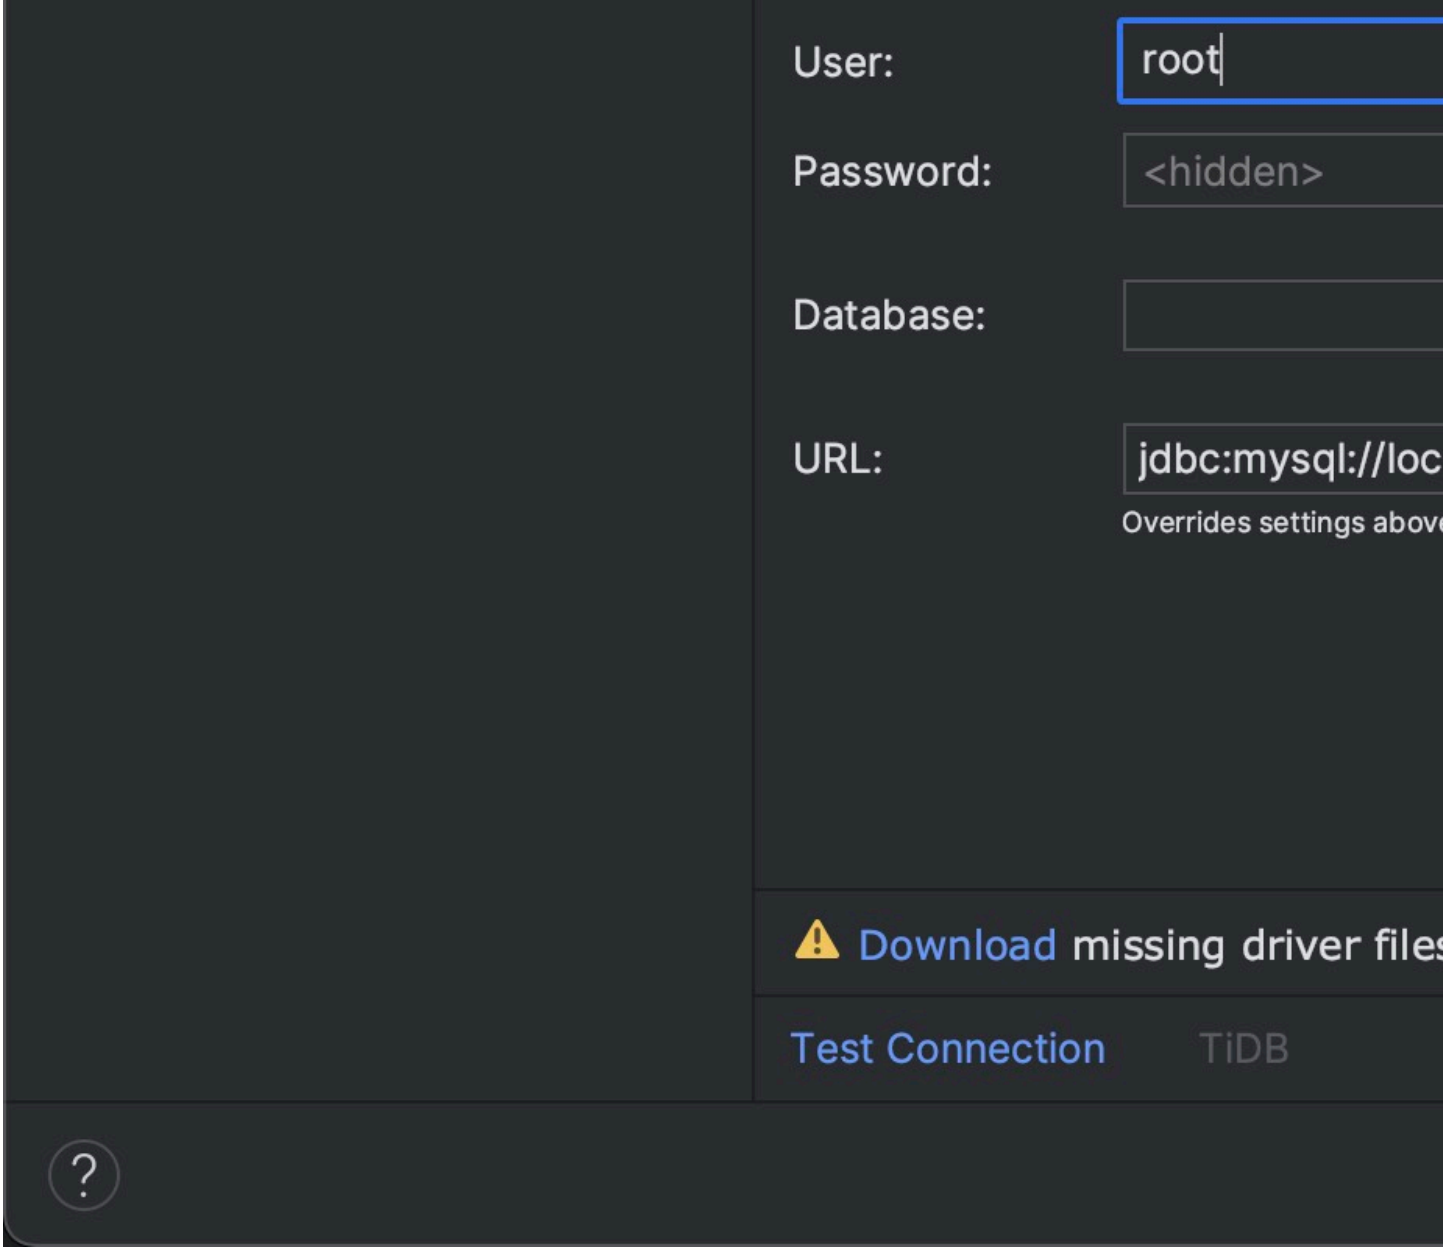

Figure 13: Configure the connection parameters for TiDB Self-Managed

If a **Download missing driver files** warning displays, click **Download** to acquire the driver files.

4. Click **Test Connection** to validate the connection to the TiDB Self-Managed cluster.

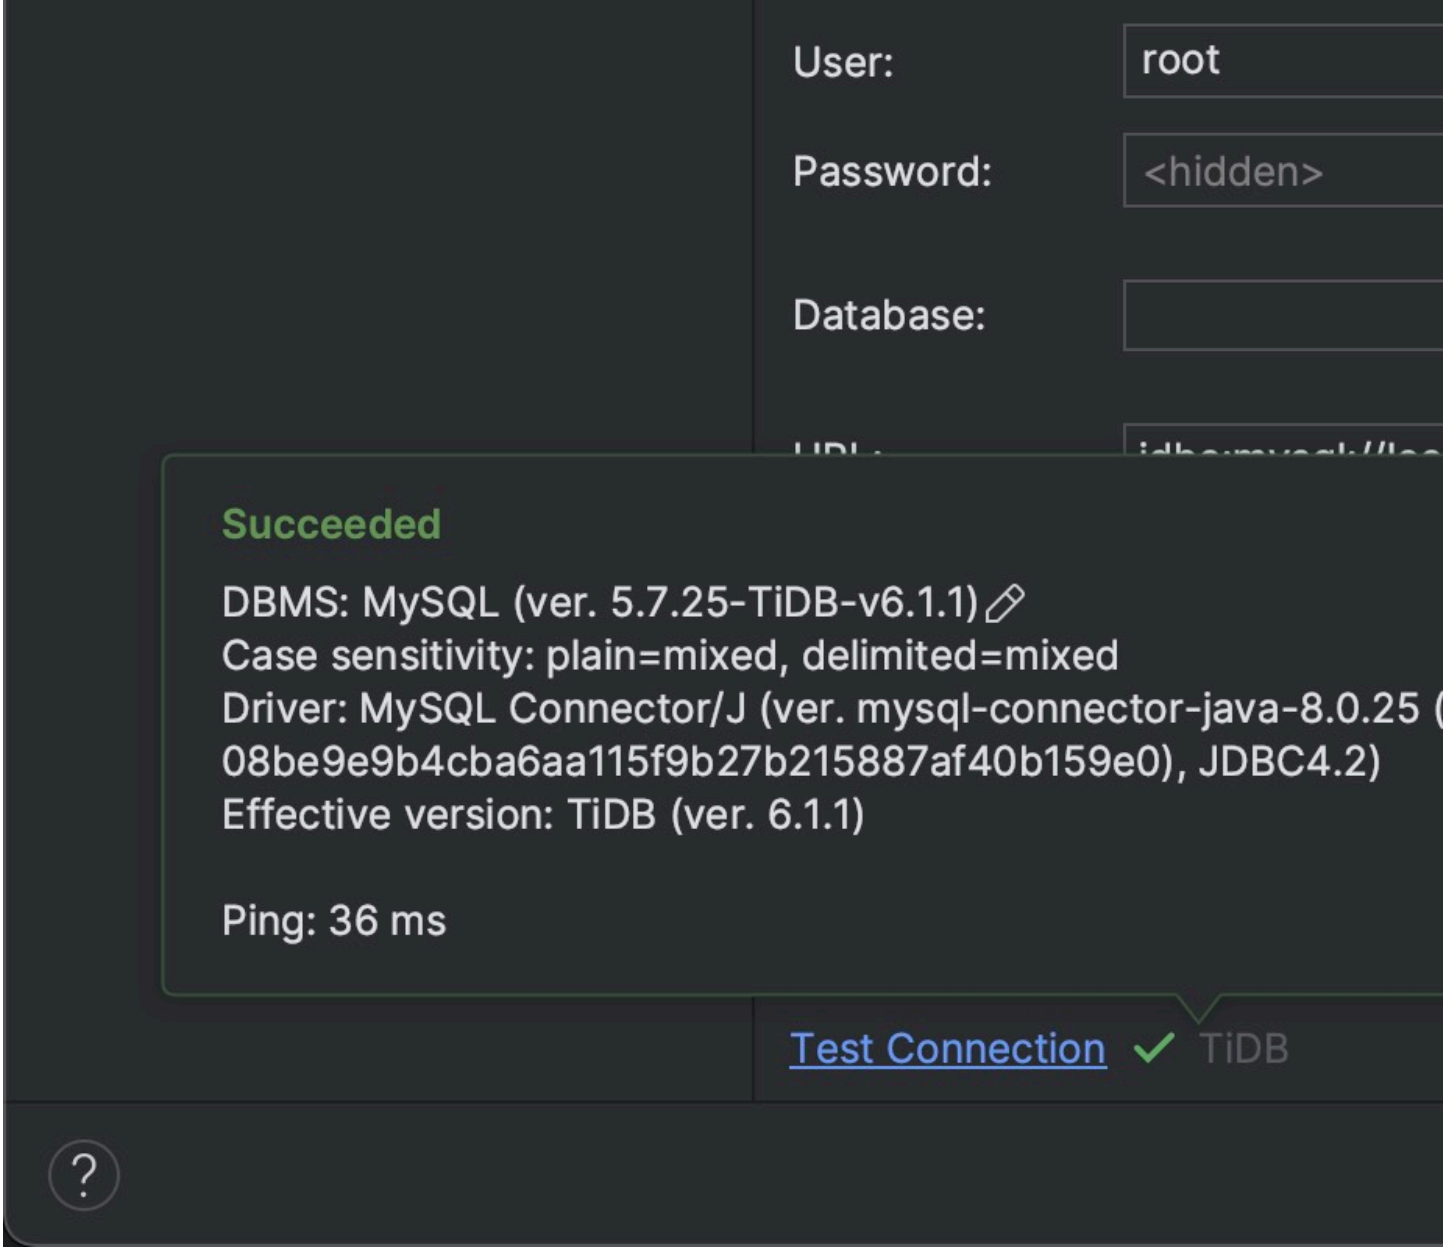

Figure 14: Test the connection to a TiDB Self-Managed cluster

5. Click **OK** to save the connection configuration.

4.4.1.1.3 Next steps

- Learn more usage of DataGrip from the documentation of DataGrip.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.4.1.2 Connect to TiDB with DBeaver

TiDB is a MySQL-compatible database, and DBeaver Community is a free cross-platform database tool for developers, database administrators, analysts, and everyone working with data.

In this tutorial, you can learn how to connect to your TiDB cluster using DBeaver Community.

> **Note:**
>
> This tutorial is compatible with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.4.1.2.1 Prerequisites

To complete this tutorial, you need:

- DBeaver Community **23.0.3** or higher.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.4.1.2.2 Connect to TiDB

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `DBeaver`
    - **Operating System** matches your environment.

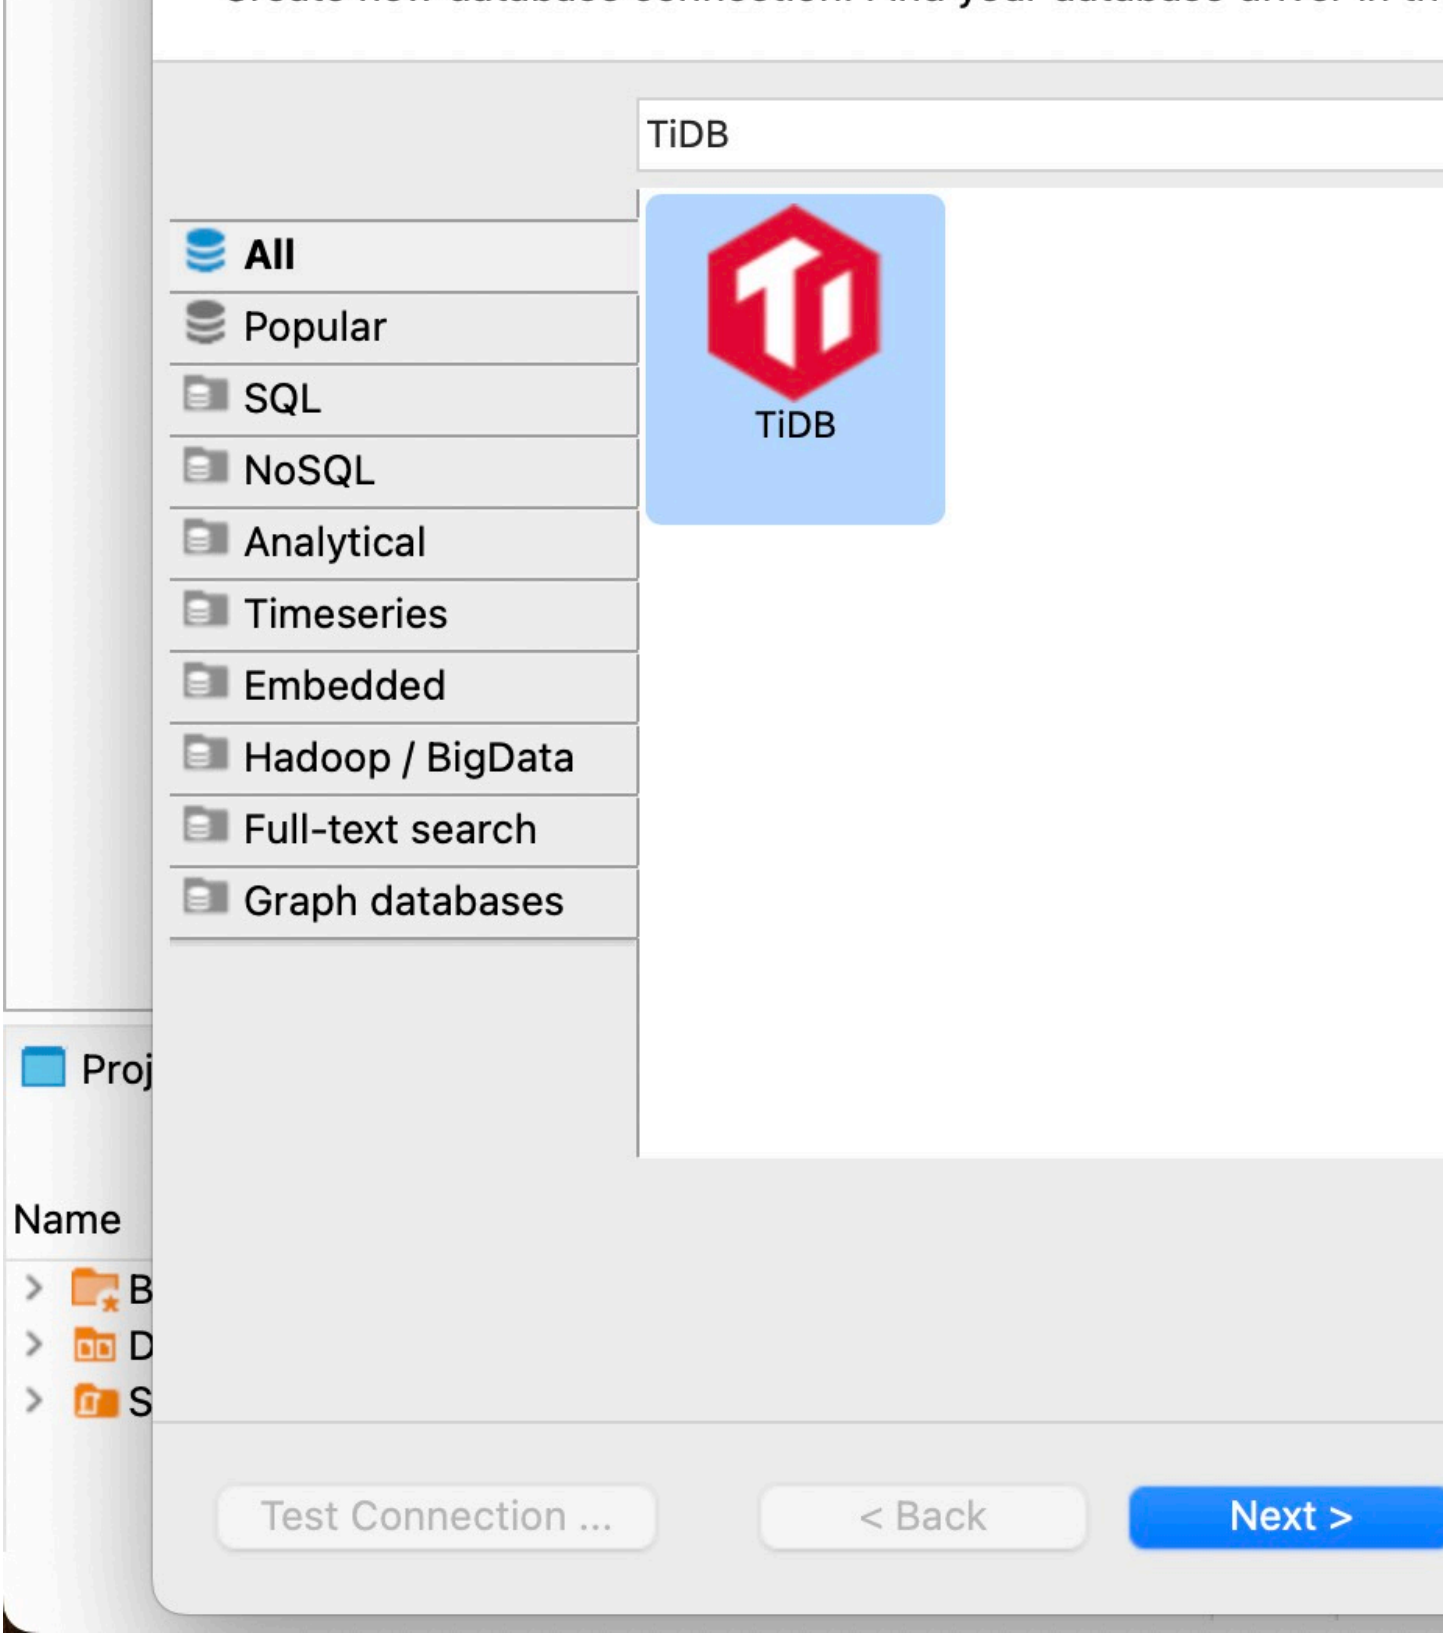

Figure 15: Select TiDB as the database in DBeaver

6. Copy the connection string from the TiDB Cloud connection dialog. In DBeaver, select **URL** for **Connect by** and paste the connection string into the **URL** field.

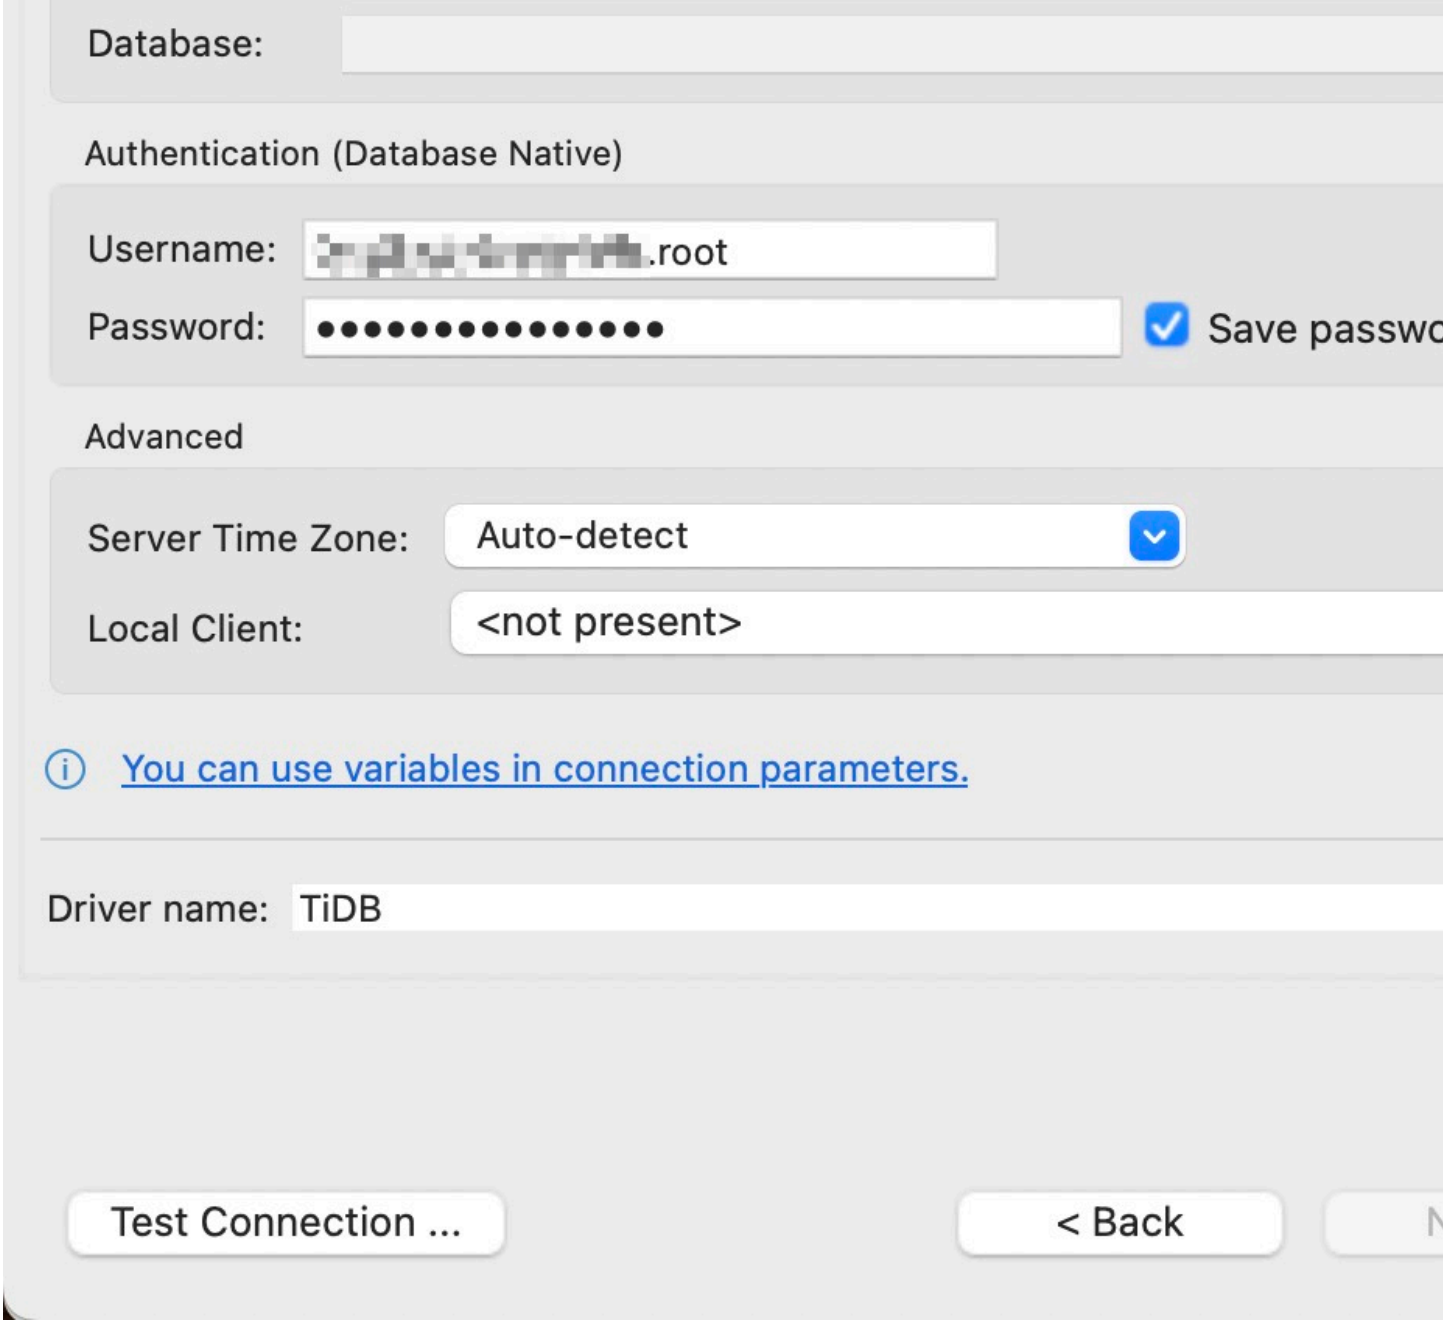

Figure 16: Configure connection settings for TiDB Cloud Serverless

8. Click **Test Connection** to validate the connection to the TiDB Cloud Serverless cluster.

   If the **Download driver files** dialog is displayed, click **Download** to get the driver files.

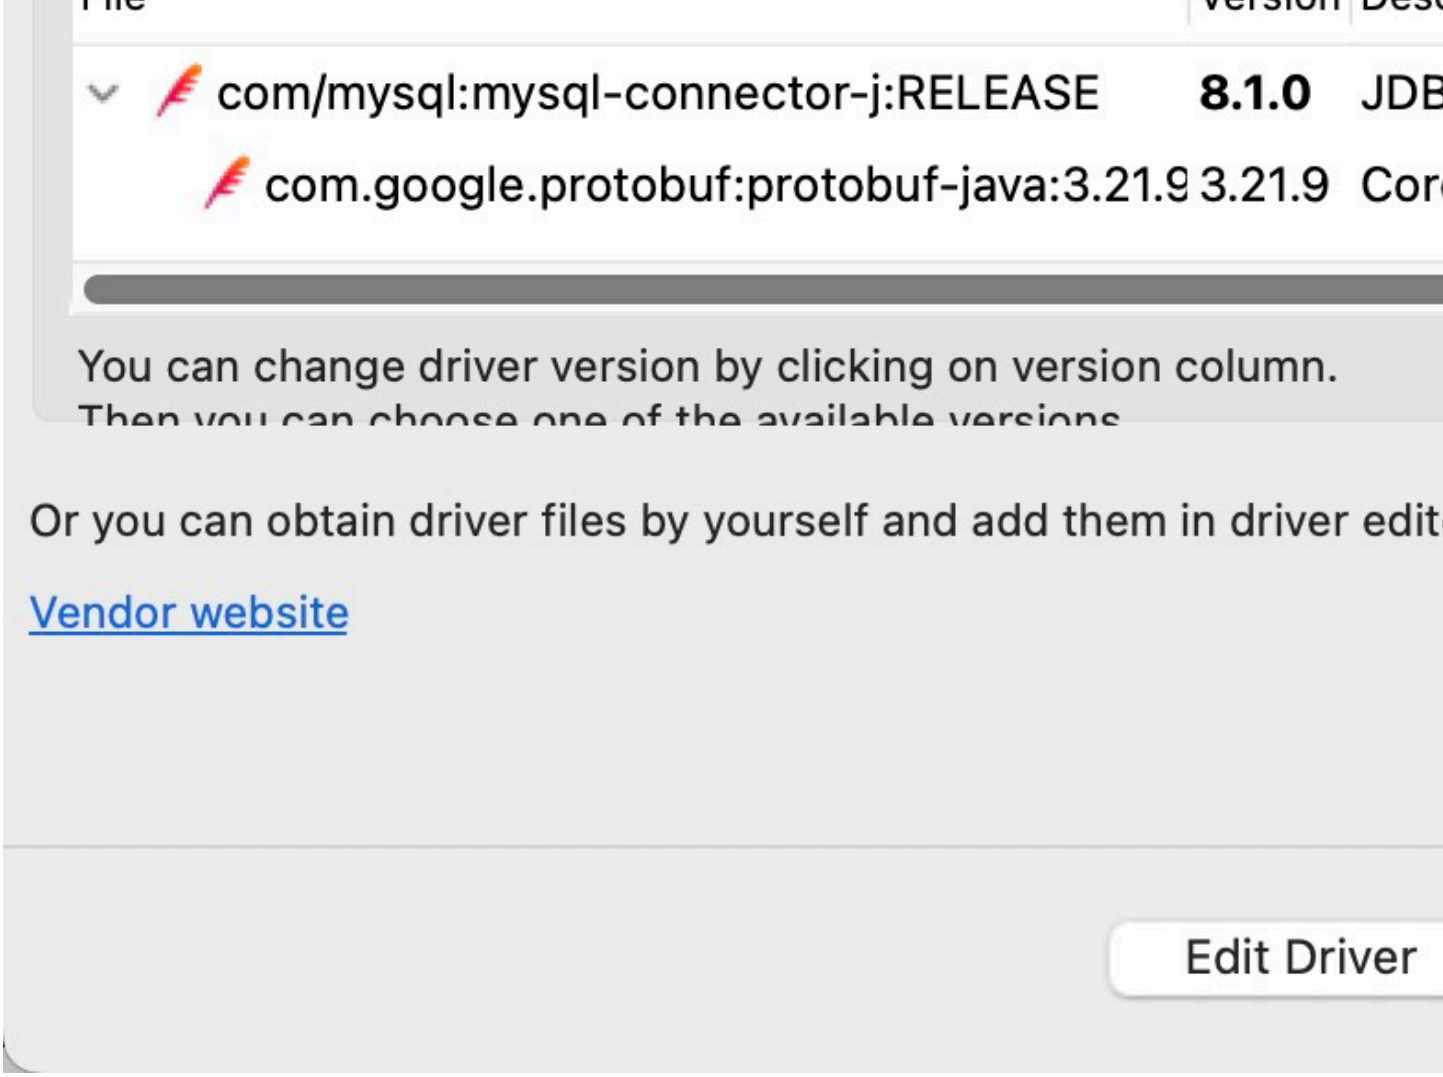

Figure 17: Download driver files

If the connection test is successful, the **Connection test** dialog is displayed as follows. Click **OK** to close it.

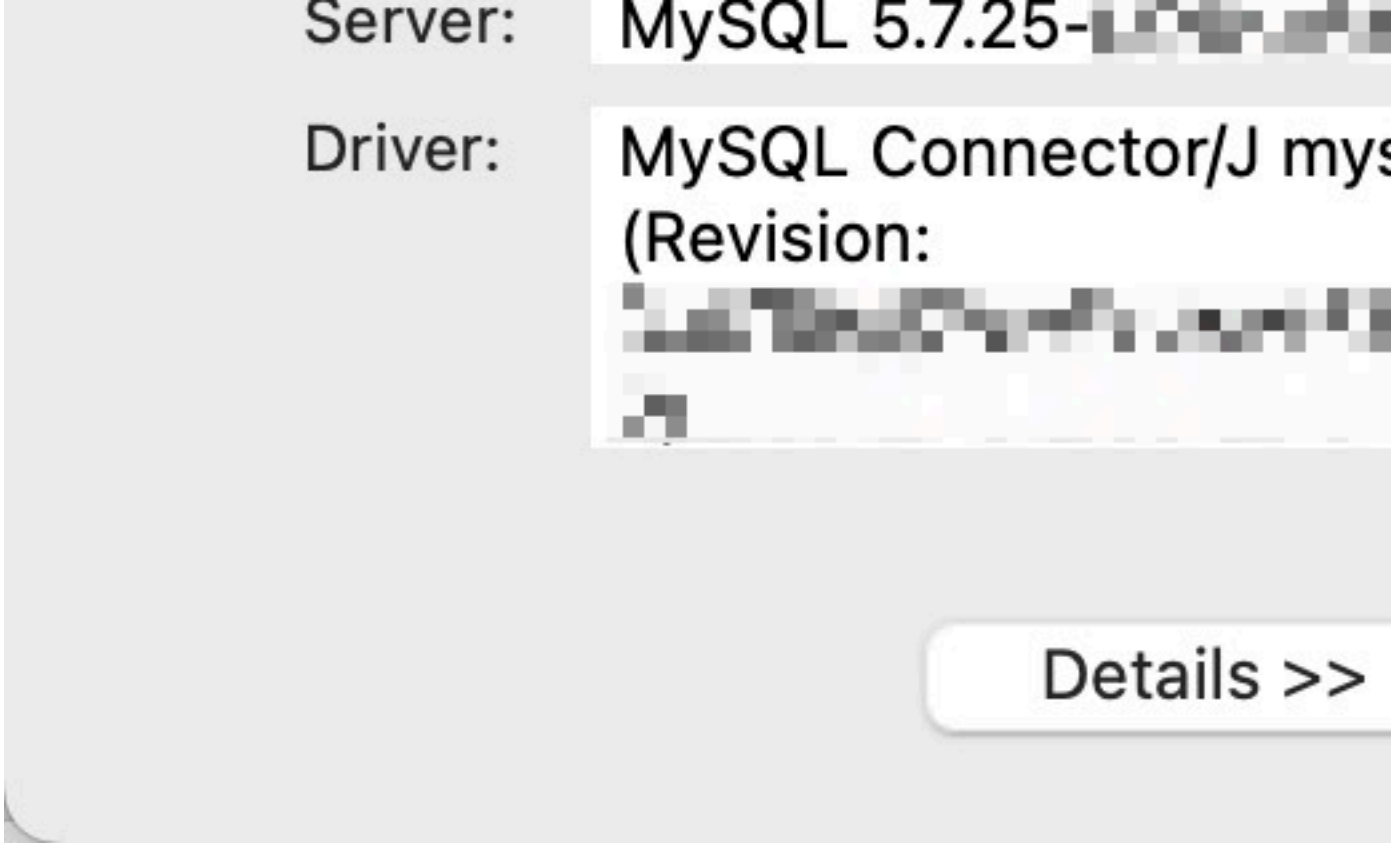

Figure 18: Connection test result

9. Click **Finish** to save the connection configuration.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.
4. Launch DBeaver and click **New Database Connection** in the upper-left corner. In the **Connect to a database** dialog, select **TiDB** from the list, and then click **Next**.

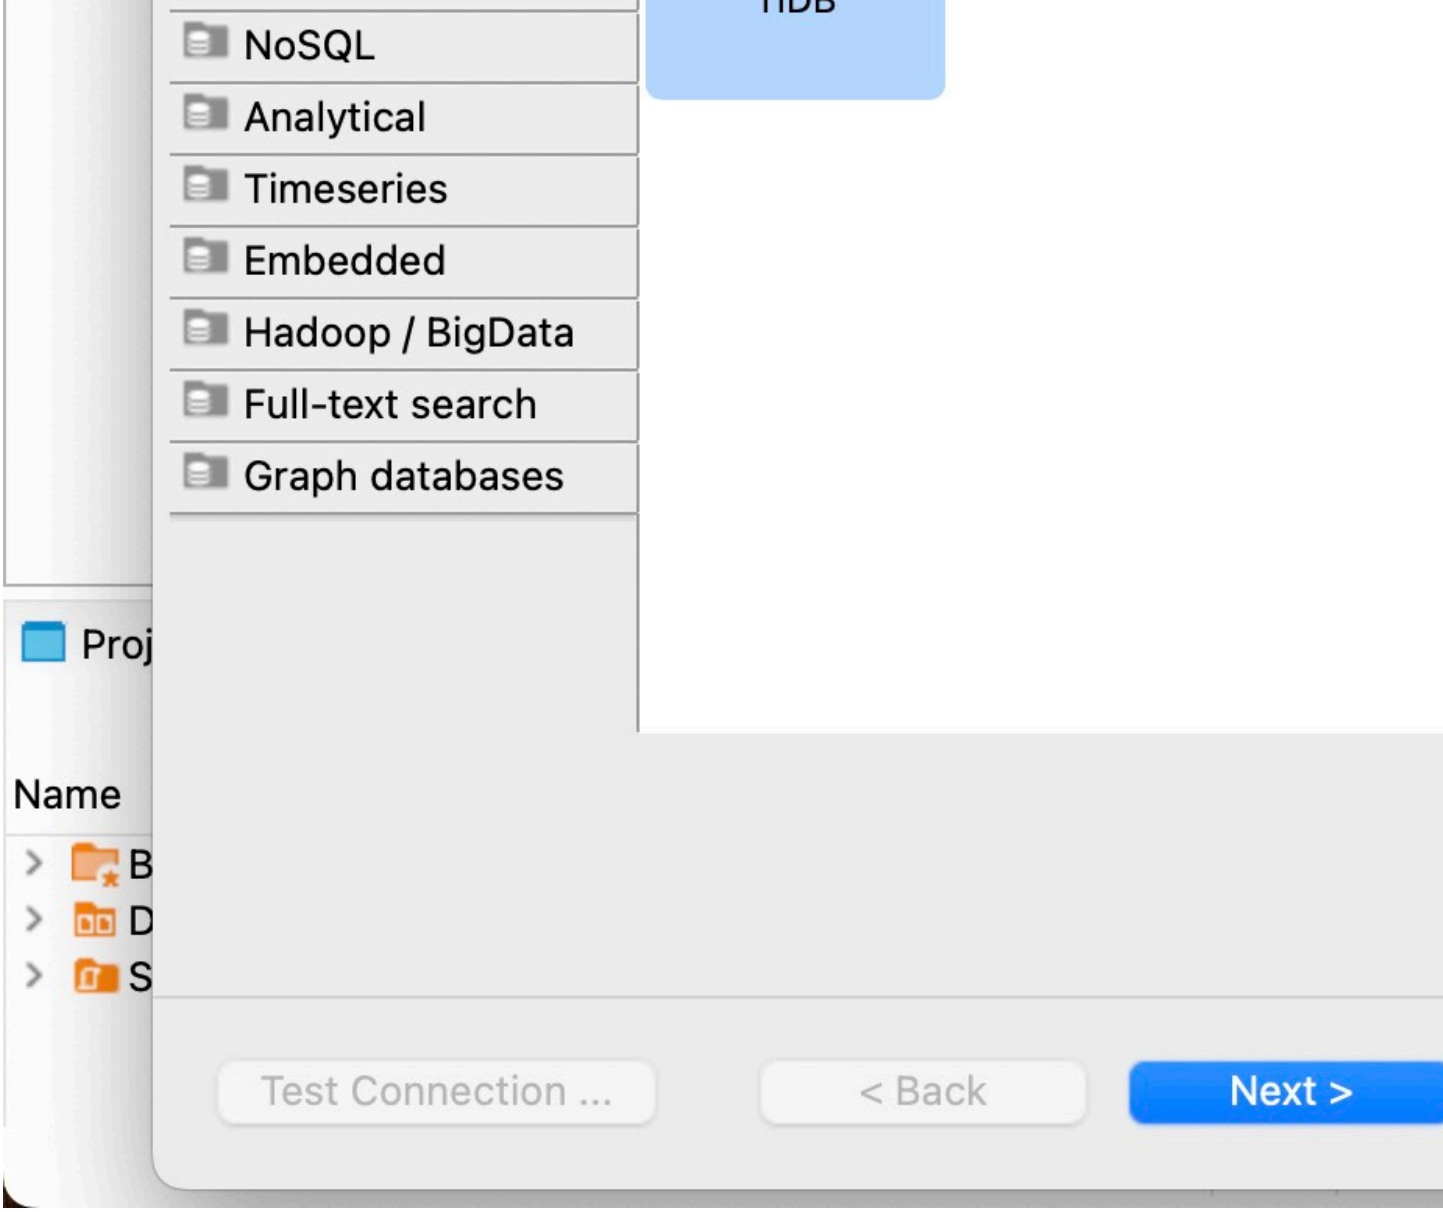

Figure 19: Select TiDB as the database in DBeaver

5. Copy and paste the appropriate connection string into the DBeaver connection panel. The mappings between DBeaver fields and TiDB Cloud Dedicated connection string are as follows:

DBeaver field	TiDB Cloud Dedicated connection string
Server Host	`{host}`
Port	`{port}`
Username	`{user}`
Password	`{password}`

An example is as follows:

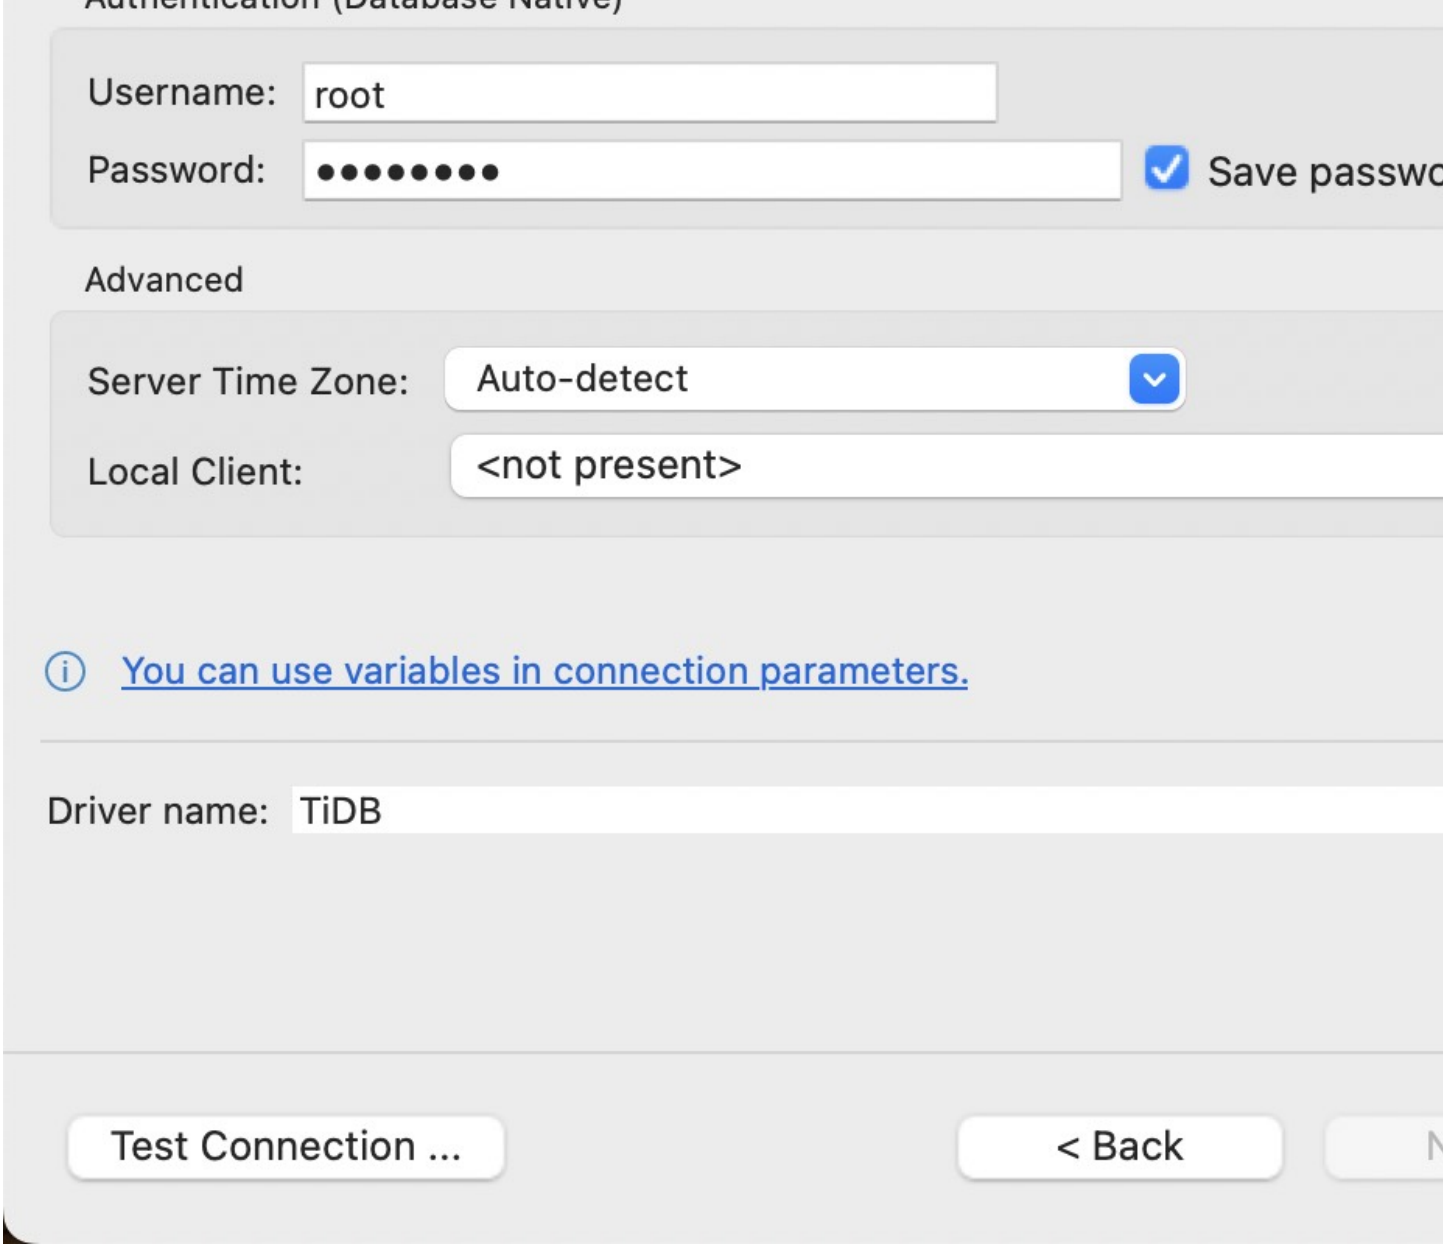

Figure 20: Configure connection settings for TiDB Cloud Dedicated

6. Click **Test Connection** to validate the connection to the TiDB Cloud Dedicated cluster.

   If the **Download driver files** dialog is displayed, click **Download** to get the driver files.

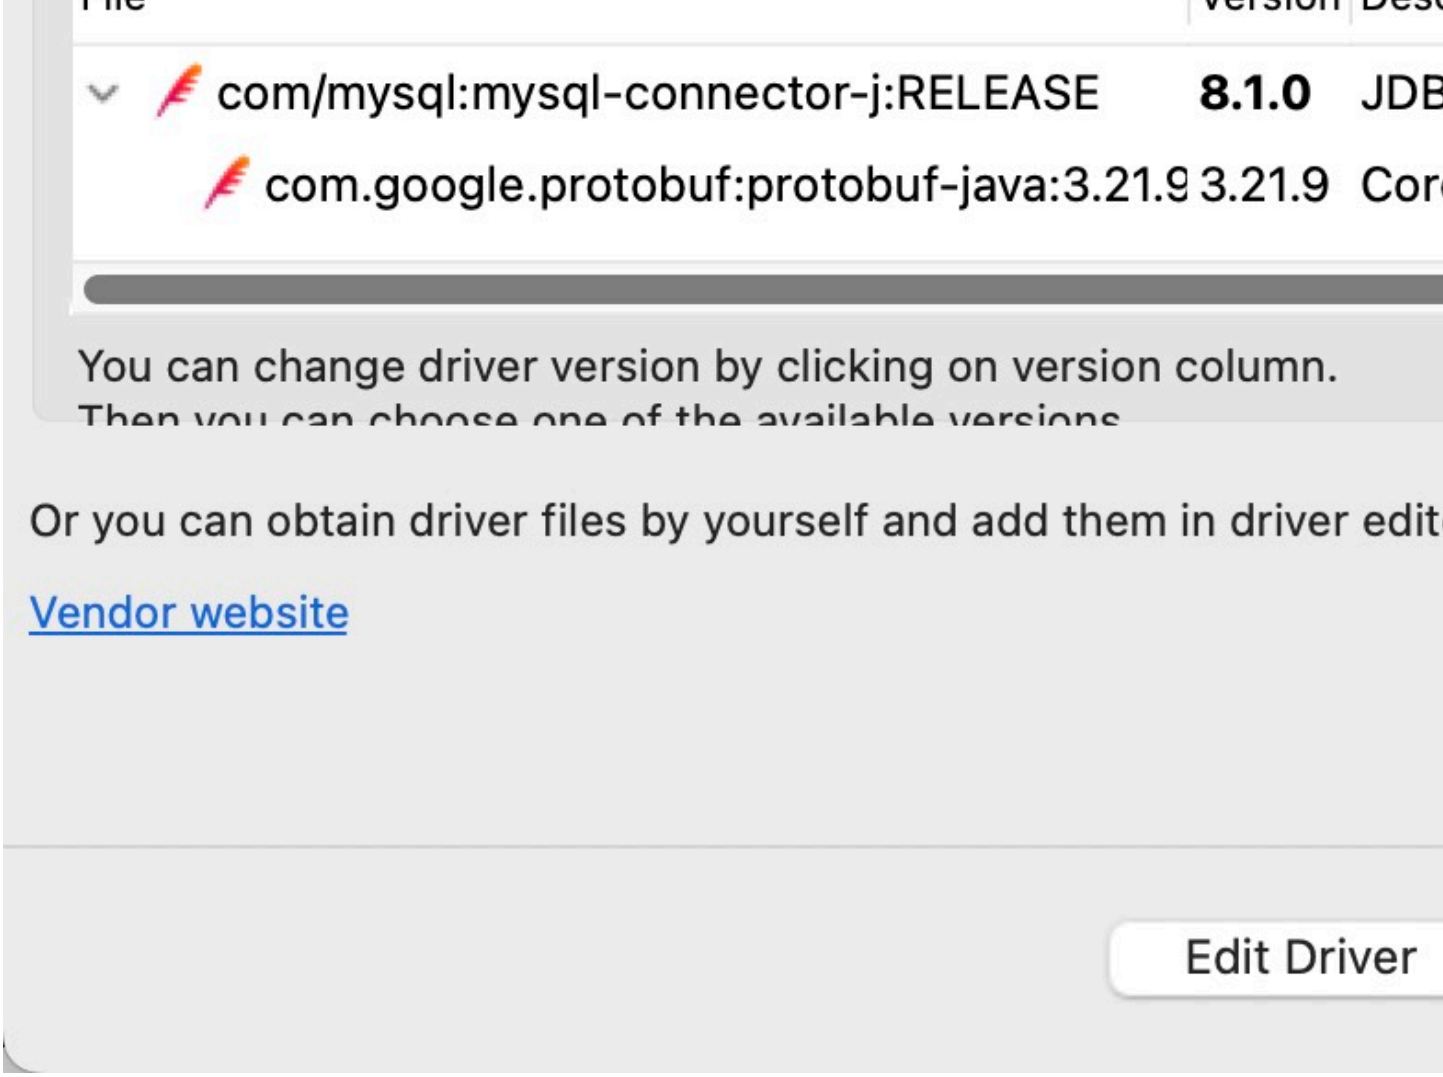

Figure 21: Download driver files

If the connection test is successful, the **Connection test** dialog is displayed as follows. Click **OK** to close it.

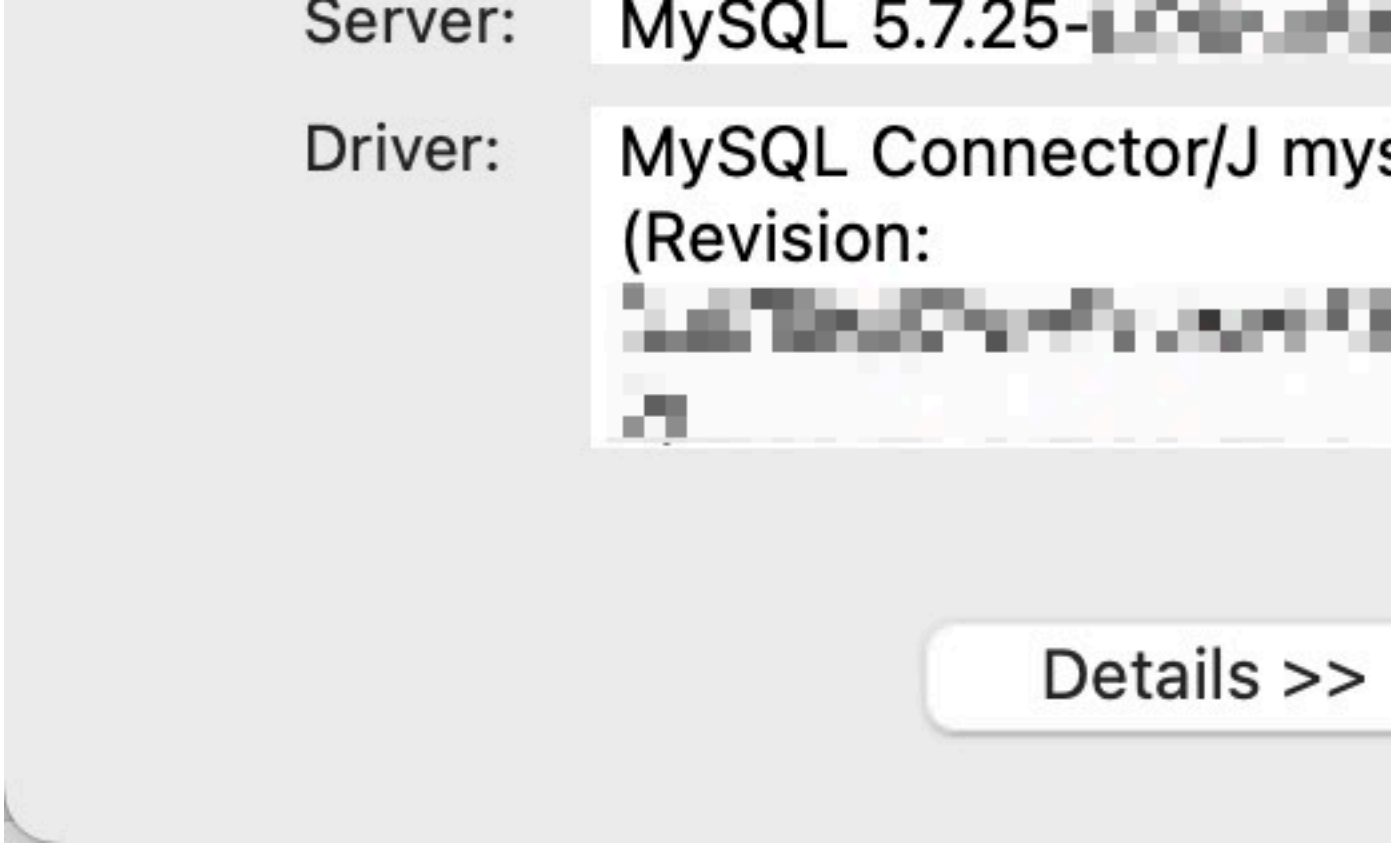

Figure 22: Connection test result

7. Click **Finish** to save the connection configuration.

1. Launch DBeaver and click **New Database Connection** in the upper-left corner. In the **Connect to a database** dialog, select **TiDB** from the list, and then click **Next**.

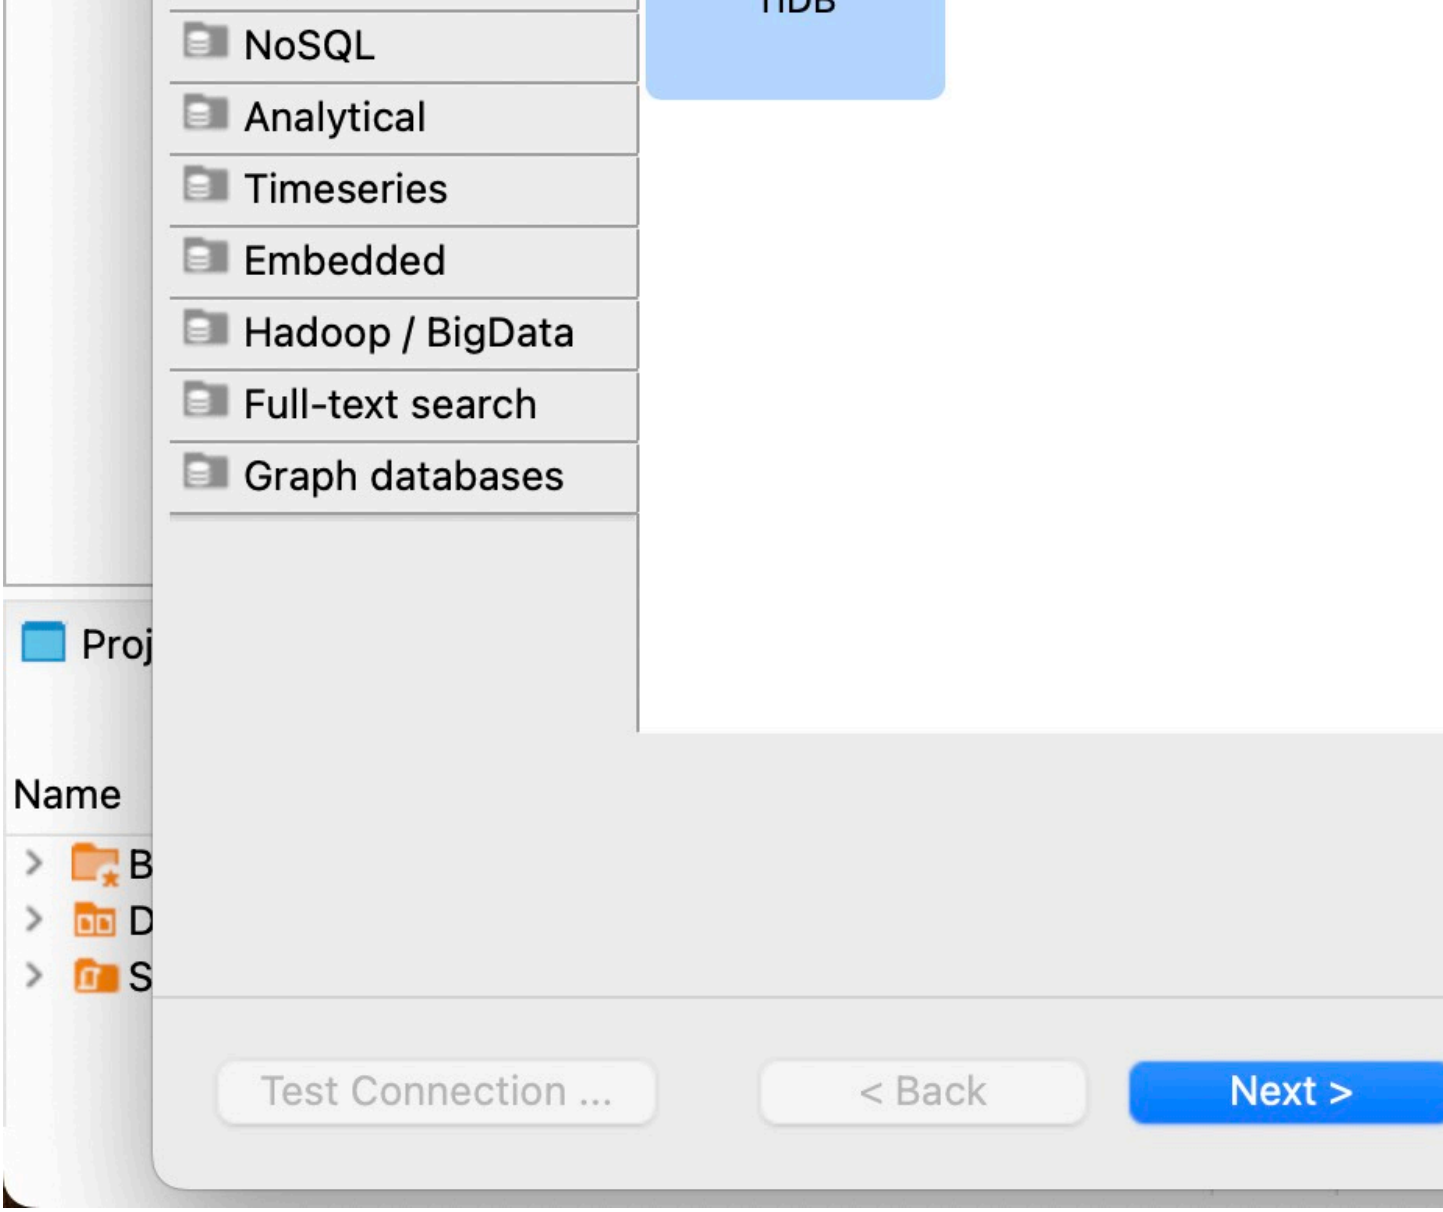

Figure 23: Select TiDB as the database in DBeaver

2. Configure the following connection parameters:

    - **Server Host**: The IP address or domain name of your TiDB Self-Managed cluster.
    - **Port**: The port number of your TiDB Self-Managed cluster.
    - **Username**: The username to use to connect to your TiDB Self-Managed cluster.
    - **Password**: The password of the username.

    An example is as follows:

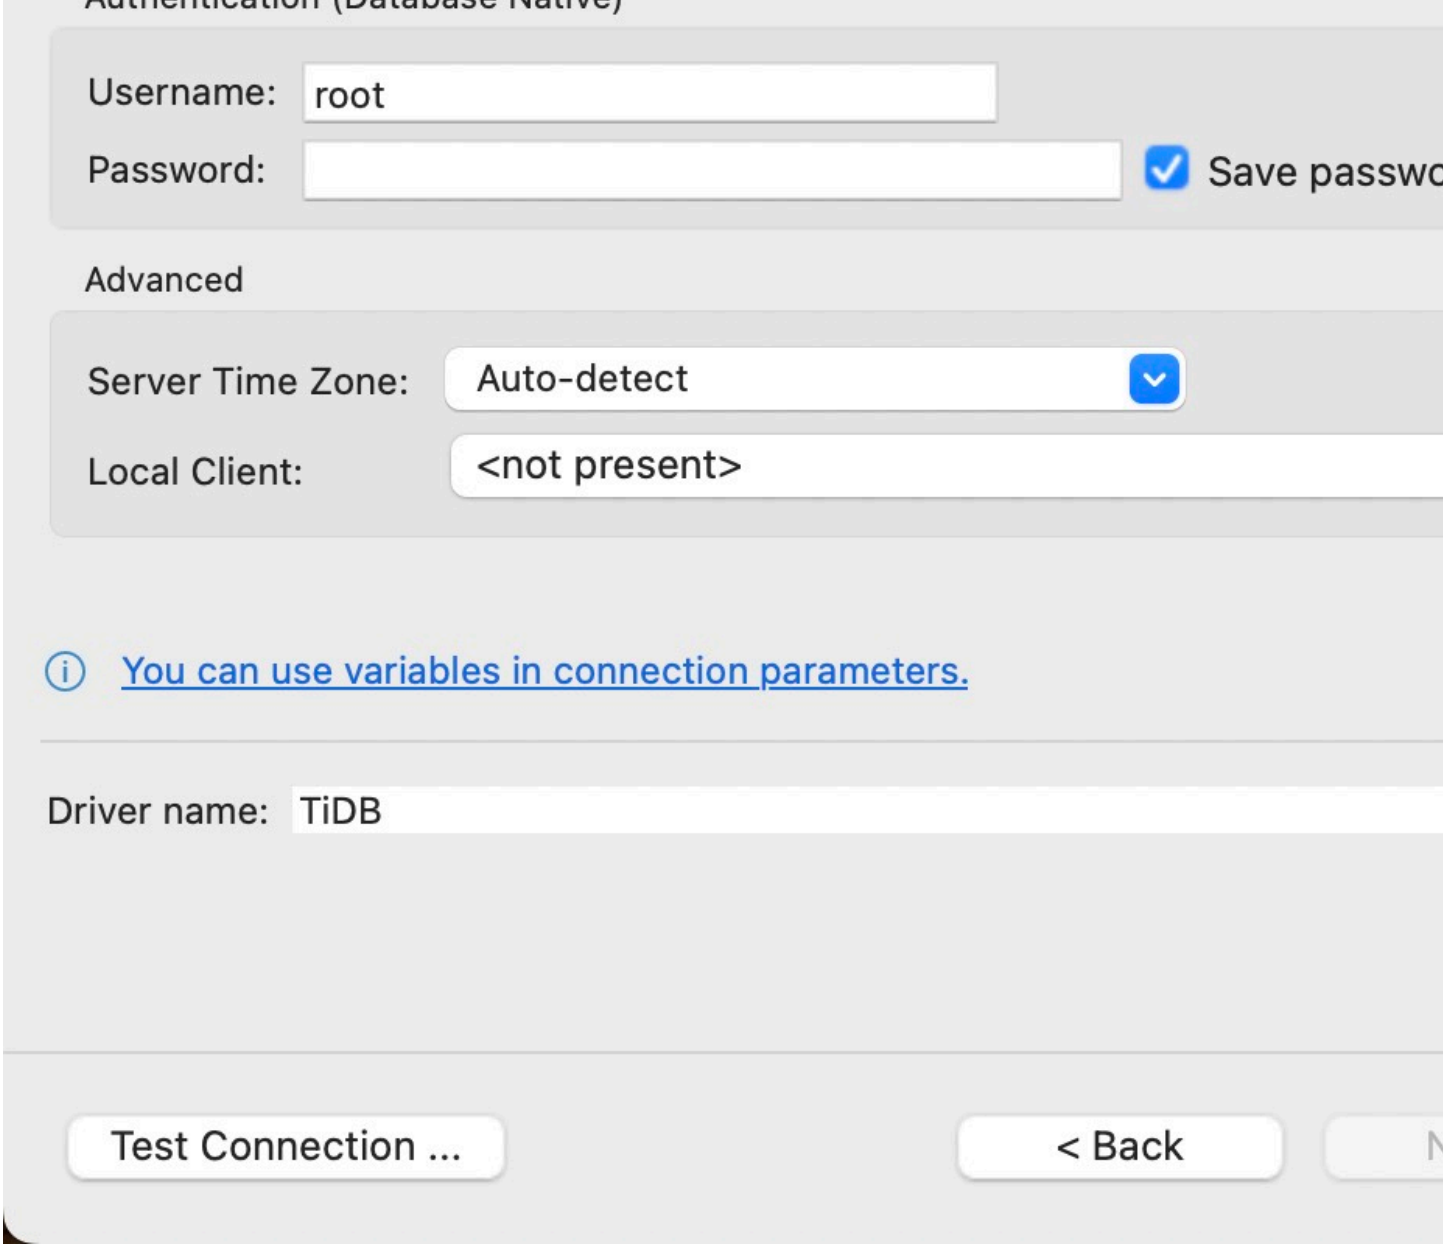

Figure 24: Configure connection settings for TiDB Self-Managed

3. Click **Test Connection** to validate the connection to the TiDB Self-Managed cluster.

   If the **Download driver files** dialog is displayed, click **Download** to get the driver files.

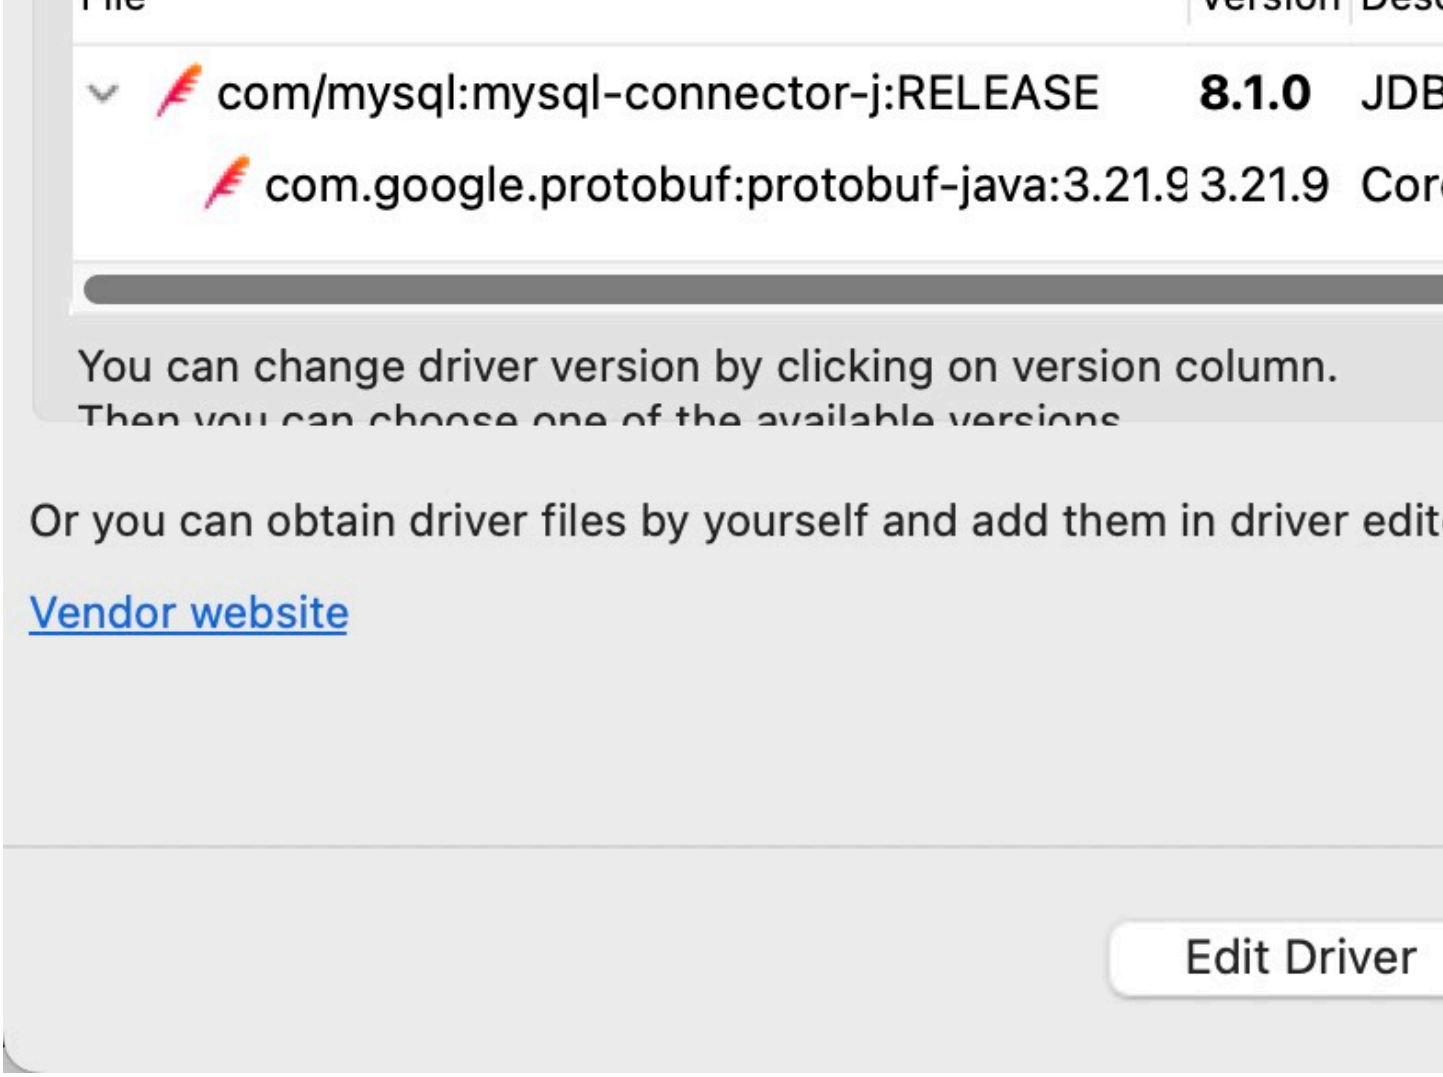

Figure 25: Download driver files

If the connection test is successful, the **Connection test** dialog is displayed as follows. Click **OK** to close it.

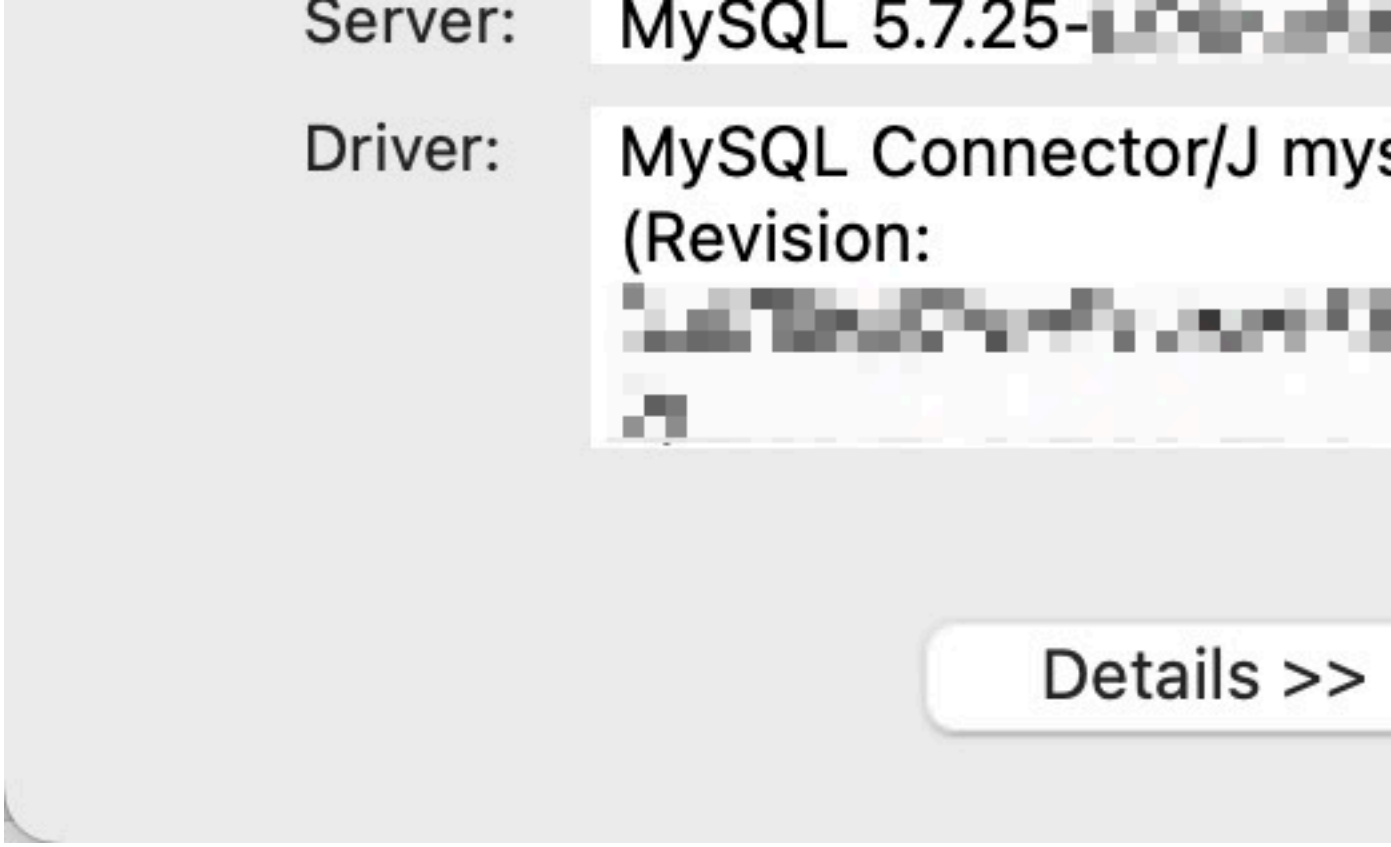

Figure 26: Connection test result

4. Click **Finish** to save the connection configuration.

4.4.1.2.3 Next steps

- Learn more usage of DBeaver from the documentation of DBeaver.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.4.1.2.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.4.1.3 Connect to TiDB with Visual Studio Code

TiDB is a MySQL-compatible database, and Visual Studio Code (VS Code) is a lightweight but powerful source code editor. This tutorial uses the SQLTools extension which supports TiDB as an official driver.

In this tutorial, you can learn how to connect to your TiDB cluster using Visual Studio Code.

Note:

- This tutorial is compatible with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.
- This tutorial also works with Visual Studio Code Remote Development environments, such as GitHub Codespaces, Visual Studio Code Dev Containers, and Visual Studio Code WSL.

4.4.1.3.1 Prerequisites

To complete this tutorial, you need:

- Visual Studio Code **1.72.0** or later versions.
- SQLTools MySQL/MariaDB/TiDB extension for Visual Studio Code. To install it, you can use one of the following methods:
  - Click this link to launch VS Code and install the extension directly.
  - Navigate to VS Code Marketplace and click **Install**.
  - On the **Extensions** tab of your VS Code, search for `mtxr.sqltools-driver-mysql` to get the **SQLTools MySQL/MariaDB/TiDB** extension, and then click **Install**.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.4.1.3.2 Connect to TiDB

Connect to your TiDB cluster depending on the TiDB deployment option you have selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

- **Connection Type** is set to `Public`.
- **Branch** is set to `main`.
- **Connect With** is set to `VS Code`.
- **Operating System** matches your environment.

> **Tip:**
> If your VS Code is running on a remote development environment, select the remote operating system from the list. For example, if you are using Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution. This is not necessary if you are using GitHub Codespaces.

4. Click **Generate Password** to create a random password.

> **Tip:**
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Launch VS Code and select the **SQLTools** extension on the navigation pane. Under the **CONNECTIONS** section, click **Add New Connection** and select **TiDB** as the database driver.

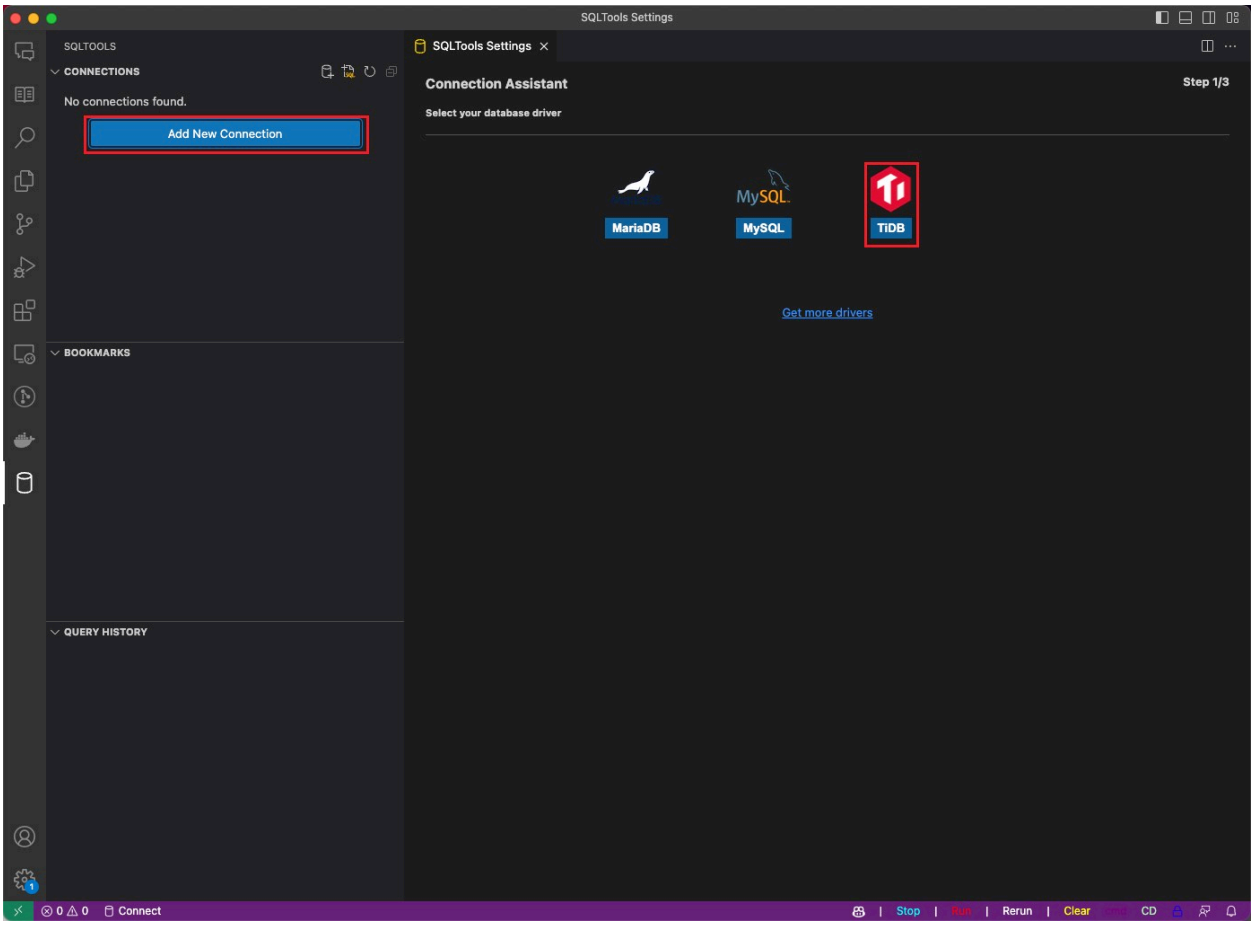

Figure 27: VS Code SQLTools: add new connection

6. In the setting pane, configure the following connection parameters:

    - **Connection name**: give this connection a meaningful name.
    - **Connection group**: (optional) give this group of connections a meaningful name. Connections with the same group name will be grouped together.
    - **Connect using**: select **Server and Port**.
    - **Server Address**: enter the `HOST` parameter from the TiDB Cloud connection dialog.
    - **Port**: enter the `PORT` parameter from the TiDB Cloud connection dialog.
    - **Database**: enter the database that you want to connect to.
    - **Username**: enter the `USERNAME` parameter from the TiDB Cloud connection dialog.
    - **Password mode**: select **SQLTools Driver Credentials**.
    - In the **MySQL driver specific options** area, configure the following parameters:

- **Authentication Protocol**: select **default**.
- **SSL**: select **Enabled**. TiDB Cloud Serverless requires a secure connection. In the **SSL Options (node.TLSSocket)** area, configure the **Certificate Authority (CA) Certificate File** field as the `CA` parameter from the TiDB Cloud connection dialog.

> **Note:**
> If you are running on Windows or GitHub Codespaces, you can leave **SSL** blank. By default SQLTools trusts well-known CAs curated by Let's Encrypt. For more information, see TiDB Cloud Serverless root certificate management.

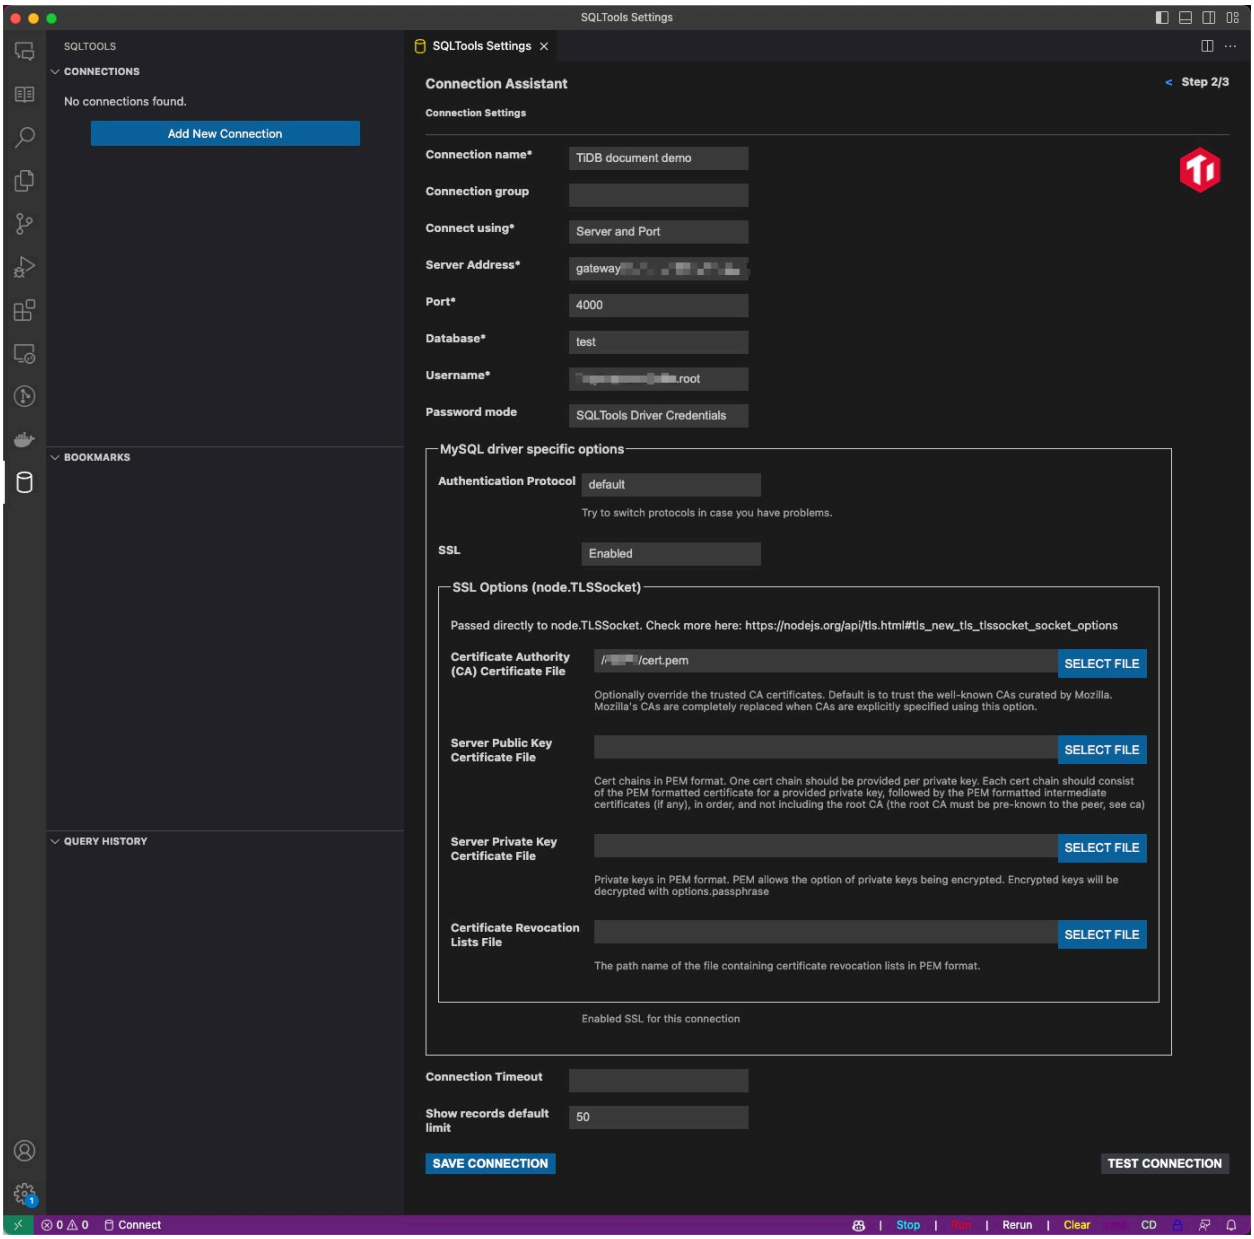

Figure 28: VS Code SQLTools: configure connection settings for TiDB Cloud Serverless

7. Click **TEST CONNECTION** to validate the connection to the TiDB Cloud Serverless cluster.

    1. In the pop-up window, click **Allow**.
    2. In the **SQLTools Driver Credentials** dialog, enter the password you created in step 4.

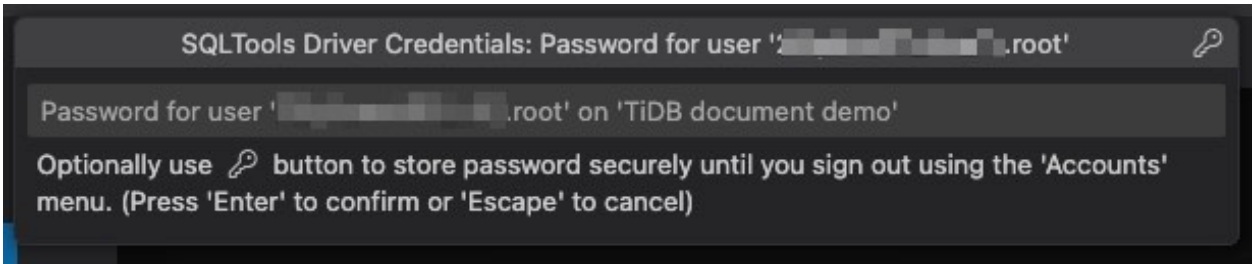

Figure 29: VS Code SQLTools: enter password to connect to TiDB Cloud Serverless

8. If the connection test is successful, you can see the **Successfully connected!** message. Click **SAVE CONNECTION** to save the connection configuration.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.
4. Launch VS Code and select the **SQLTools** extension on the navigation pane. Under the **CONNECTIONS** section, click **Add New Connection** and select **TiDB** as the database driver.

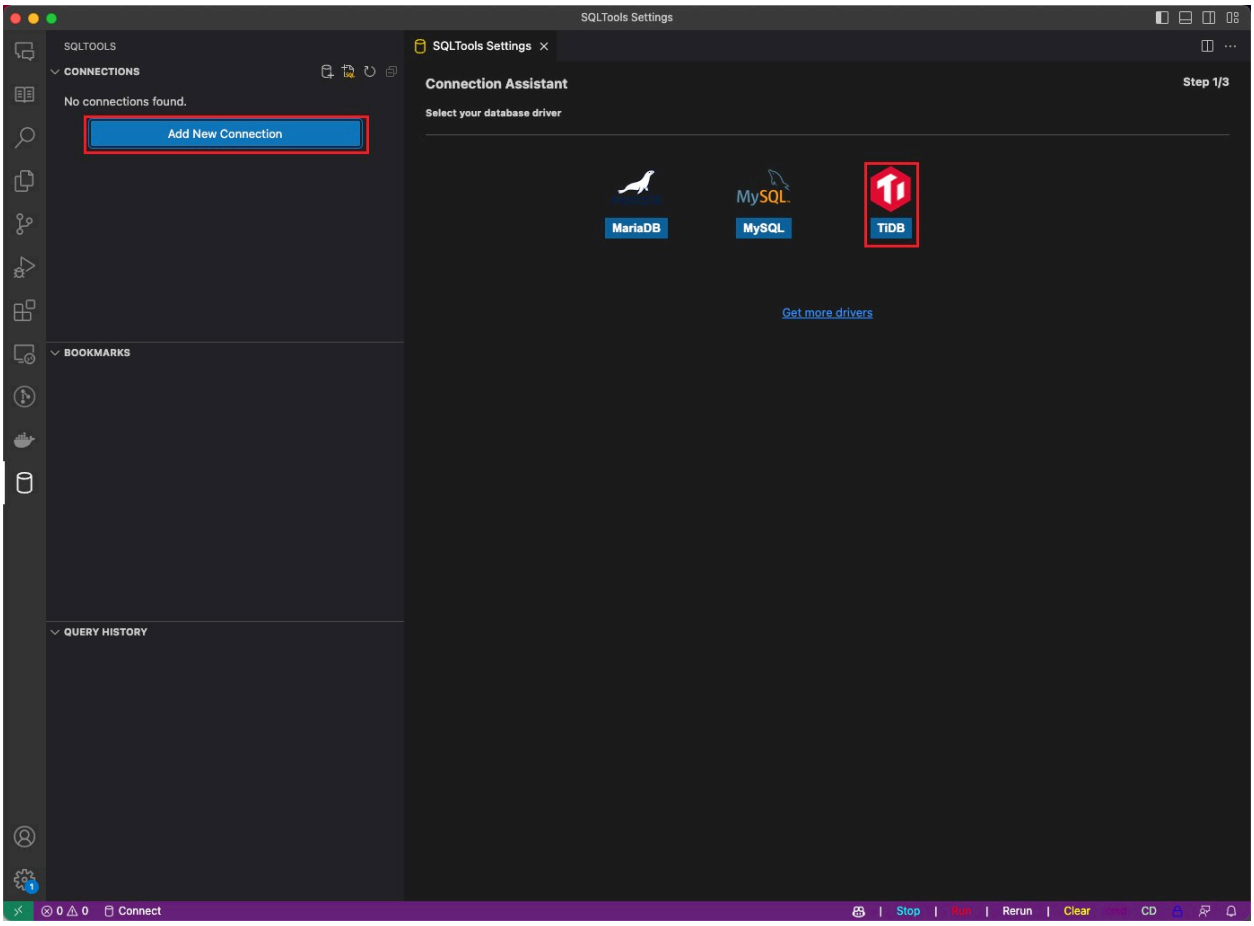

Figure 30: VS Code SQLTools: add new connection

5. In the setting pane, configure the following connection parameters:

    - **Connection name**: give this connection a meaningful name.
    - **Connection group**: (optional) give this group of connections a meaningful name. Connections with the same group name will be grouped together.
    - **Connect using**: select **Server and Port**.
    - **Server Address**: enter the `host` parameter from the TiDB Cloud connection dialog.
    - **Port**: enter the `port` parameter from the TiDB Cloud connection dialog.
    - **Database**: enter the database that you want to connect to.
    - **Username**: enter the `user` parameter from the TiDB Cloud connection dialog.
    - **Password mode**: select **SQLTools Driver Credentials**.
    - In the **MySQL driver specific options** area, configure the following parameters:
        - **Authentication Protocol**: select **default**.

- **SSL**: select **Disabled**.

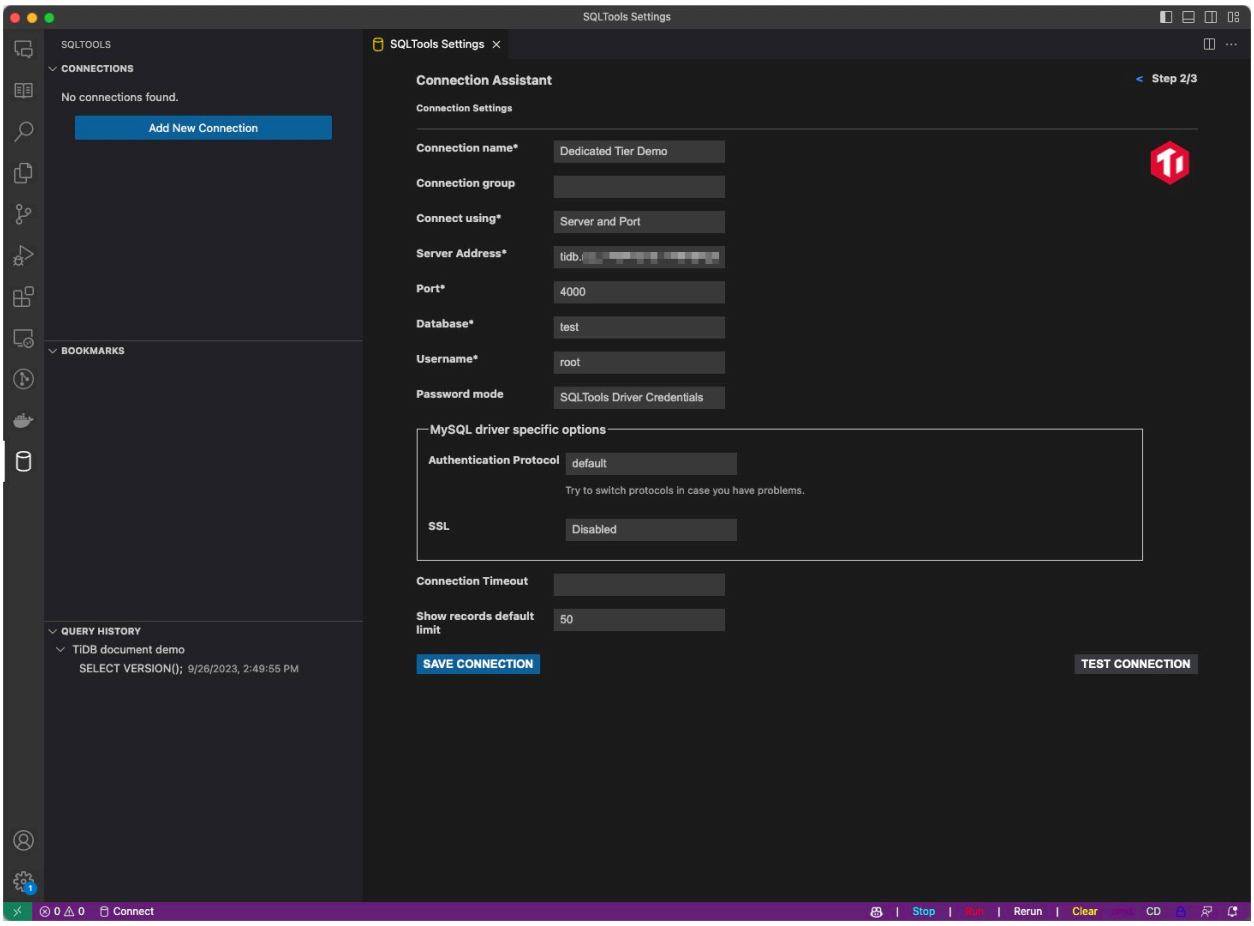

Figure 31: VS Code SQLTools: configure connection settings for TiDB Cloud Dedicated

6. Click **TEST CONNECTION** to validate the connection to the TiDB Cloud Dedicated cluster.

    1. In the pop-up window, click **Allow**.
    2. In the **SQLTools Driver Credentials** dialog, enter the password of the TiDB Cloud Dedicated cluster.

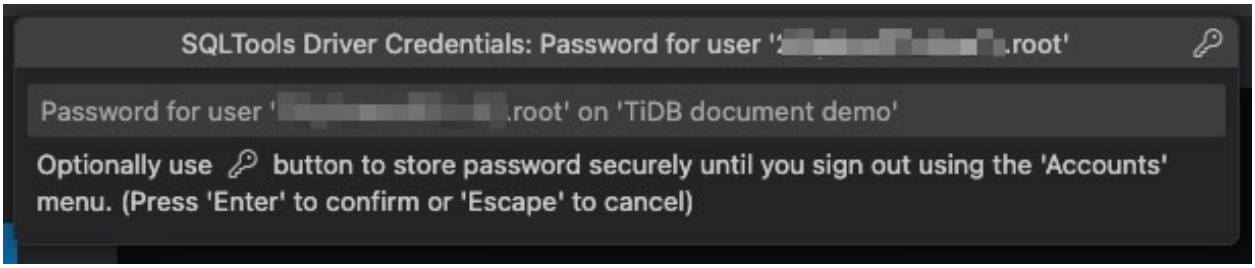

Figure 32: VS Code SQLTools: enter password to connect to TiDB Cloud Dedicated

7. If the connection test is successful, you can see the **Successfully connected!** message. Click **SAVE CONNECTION** to save the connection configuration.

1. Launch VS Code and select the **SQLTools** extension on the navigation pane. Under the **CONNECTIONS** section, click **Add New Connection** and select **TiDB** as the database driver.

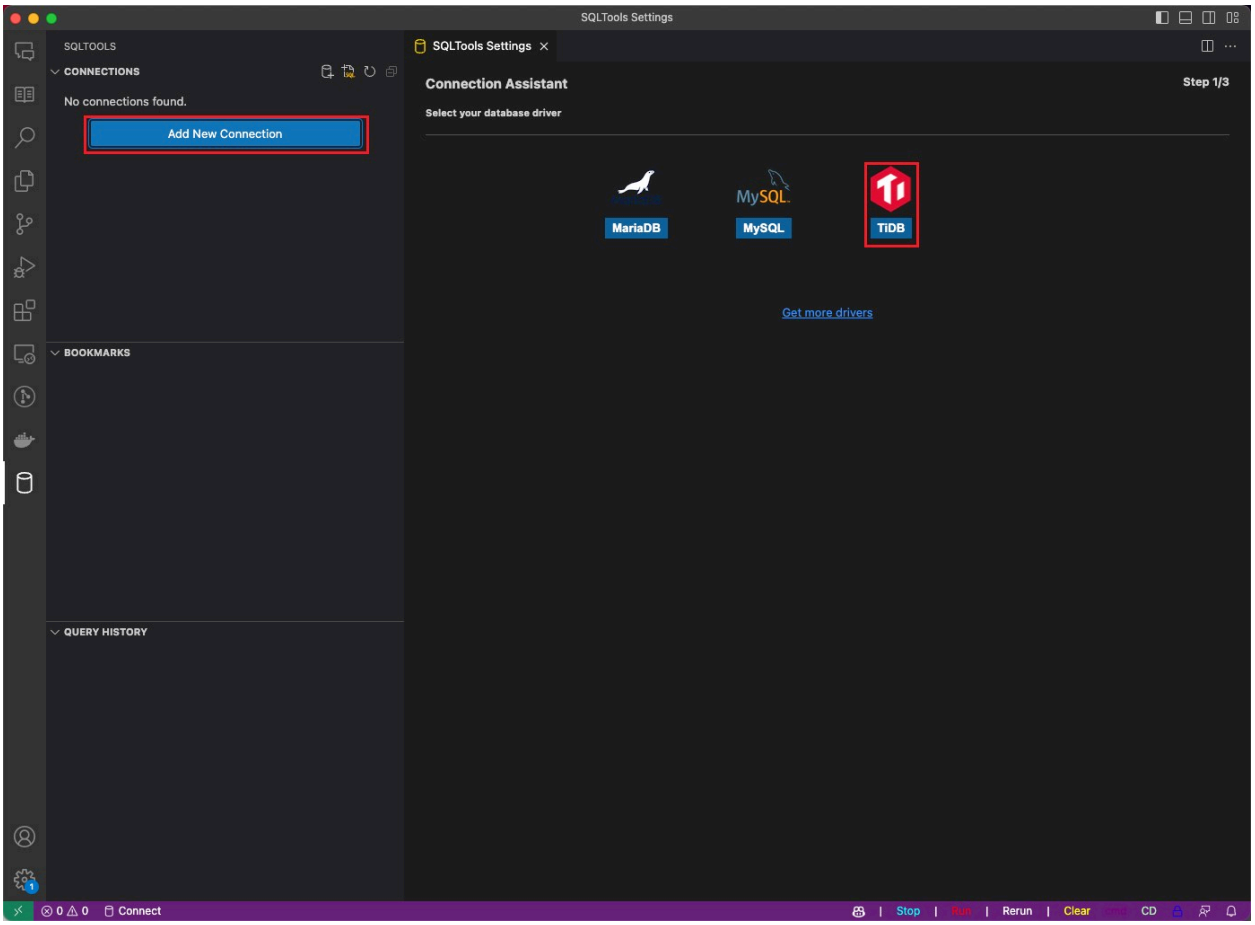

Figure 33: VS Code SQLTools: add new connection

2. In the setting pane, configure the following connection parameters:

    - **Connection name**: give this connection a meaningful name.
    - **Connection group**: (optional) give this group of connections a meaningful name. Connections with the same group name will be grouped together.
    - **Connect using**: select **Server and Port**.
    - **Server Address**: enter the IP address or domain name of your TiDB Self-Managed cluster.
    - **Port**: enter the port number of your TiDB Self-Managed cluster.
    - **Database**: enter the database that you want to connect to.
    - **Username**: enter the username to use to connect to your TiDB Self-Managed cluster.
    - **Password mode**:
        - If the password is empty, select **Use empty password**.
        - Otherwise, select **SQLTools Driver Credentials**.
    - In the **MySQL driver specific options** area, configure the following parameters:
        - **Authentication Protocol**: select **default**.
        - **SSL**: select **Disabled**.

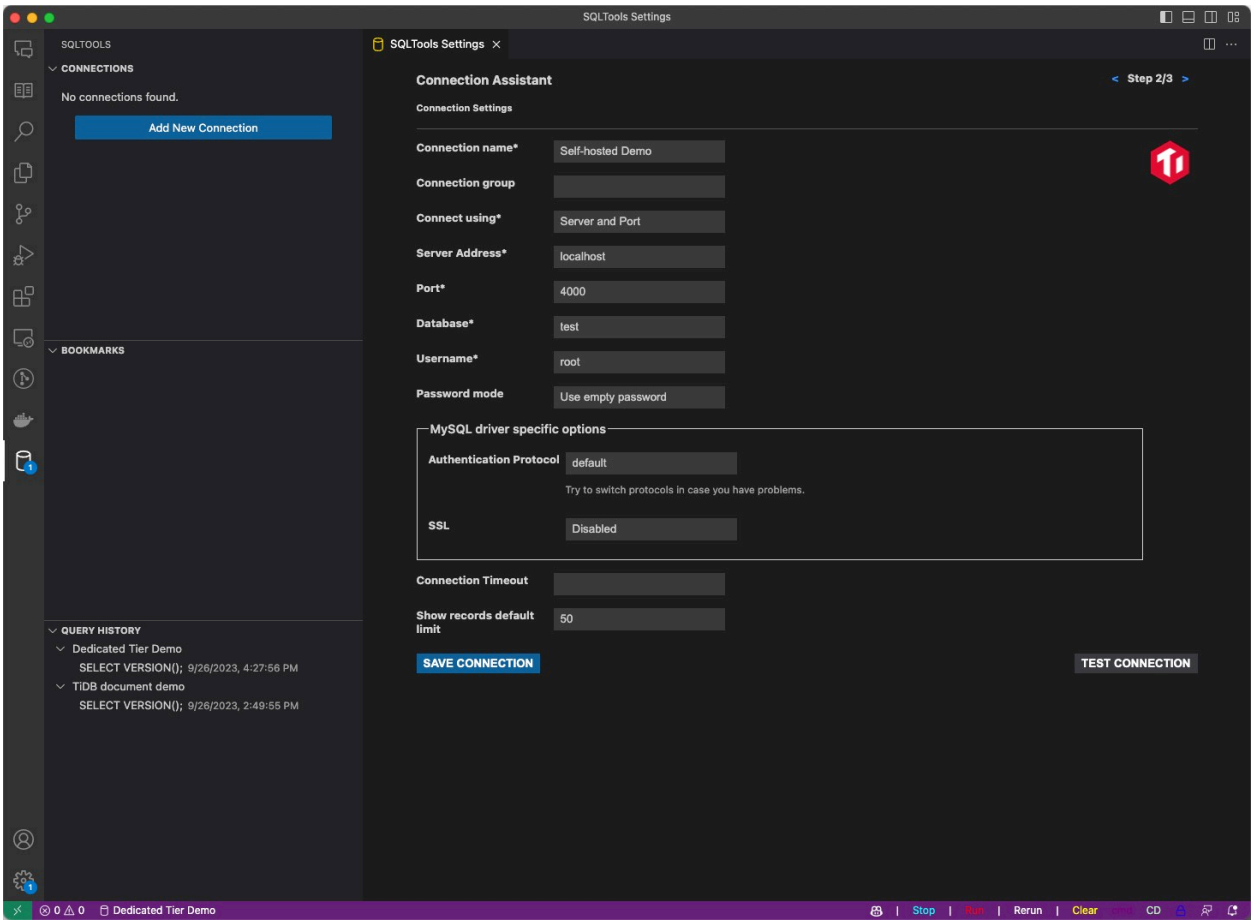

Figure 34: VS Code SQLTools: configure connection settings for TiDB Self-Managed

3. Click **TEST CONNECTION** to validate the connection to the TiDB Self-Managed cluster.

   If the password is not empty, click **Allow** in the pop-up window, and then enter the password of the TiDB Self-Managed cluster.

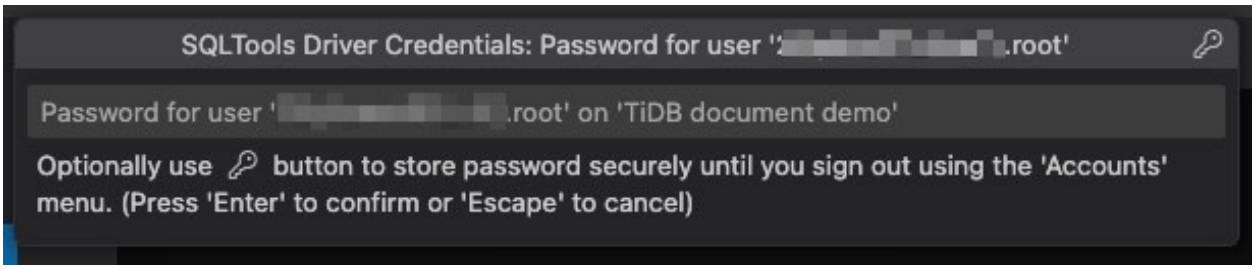

Figure 35: VS Code SQLTools: enter password to connect to TiDB Self-Managed

4. If the connection test is successful, you can see the **Successfully connected!** message.

Click **SAVE CONNECTION** to save the connection configuration.

4.4.1.4 Connect to TiDB with MySQL Workbench

TiDB is a MySQL-compatible database, and MySQL Workbench is a GUI tool set for MySQL database users.

Warning:

- Although you can use MySQL Workbench to connect to TiDB due to its MySQL compatibility, MySQL Workbench does not fully support TiDB. You might encounter some issues during usage as it treats TiDB as MySQL.
- It is recommended to use other GUI tools that officially support TiDB, such as DataGrip, DBeaver, and VS Code SQLTools. For a complete list of GUI tools that fully supported by TiDB, see Third-party tools supported by TiDB.

In this tutorial, you can learn how to connect to your TiDB cluster using MySQL Workbench.

Note:

This tutorial is compatible with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.4.1.4.1 Prerequisites

To complete this tutorial, you need:

- MySQL Workbench **8.0.31** or later versions.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.4.1.4.2 Connect to TiDB

Connect to your TiDB cluster depending on the TiDB deployment option you have selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `MySQL Workbench`.
    - **Operating System** matches your environment.
4. Click **Generate Password** to create a random password.

Tip:

If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Launch MySQL Workbench and click + near the **MySQL Connections** title.

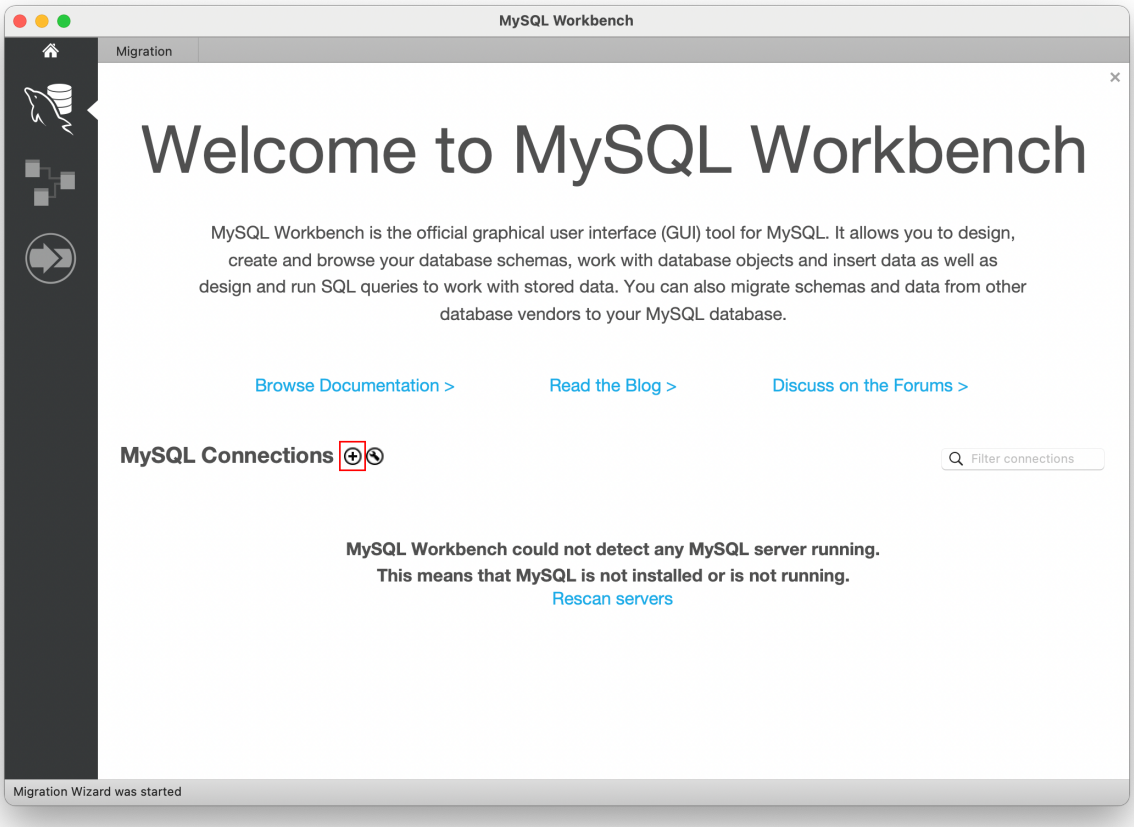

Figure 36: MySQL Workbench: add new connection

6. In the **Setup New Connection** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.
    - **Hostname**: enter the `HOST` parameter from the TiDB Cloud connection dialog.
    - **Port**: enter the `PORT` parameter from the TiDB Cloud connection dialog.
    - **Username**: enter the `USERNAME` parameter from the TiDB Cloud connection dialog.
    - **Password**: click **Store in Keychain ...** or **Store in Vault**, enter the password of the TiDB Cloud Serverless cluster, and then click **OK** to store the password.

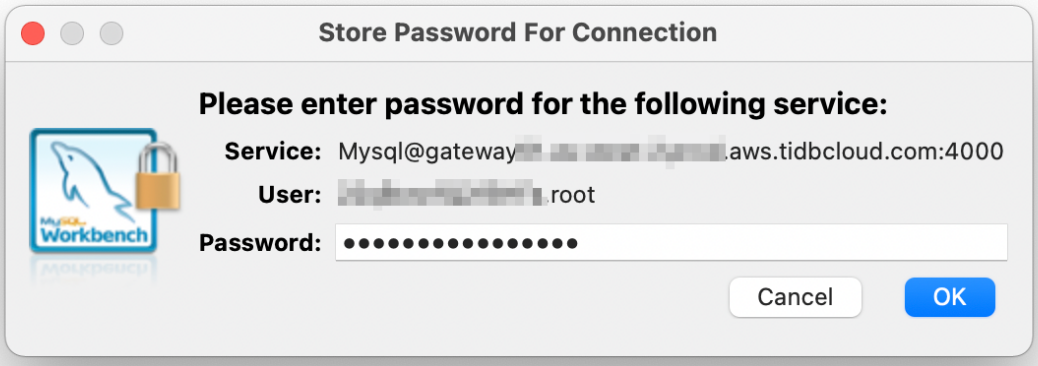

Figure 37: MySQL Workbench: store the password of TiDB Cloud Serverless in keychain

The following figure shows an example of the connection parameters:

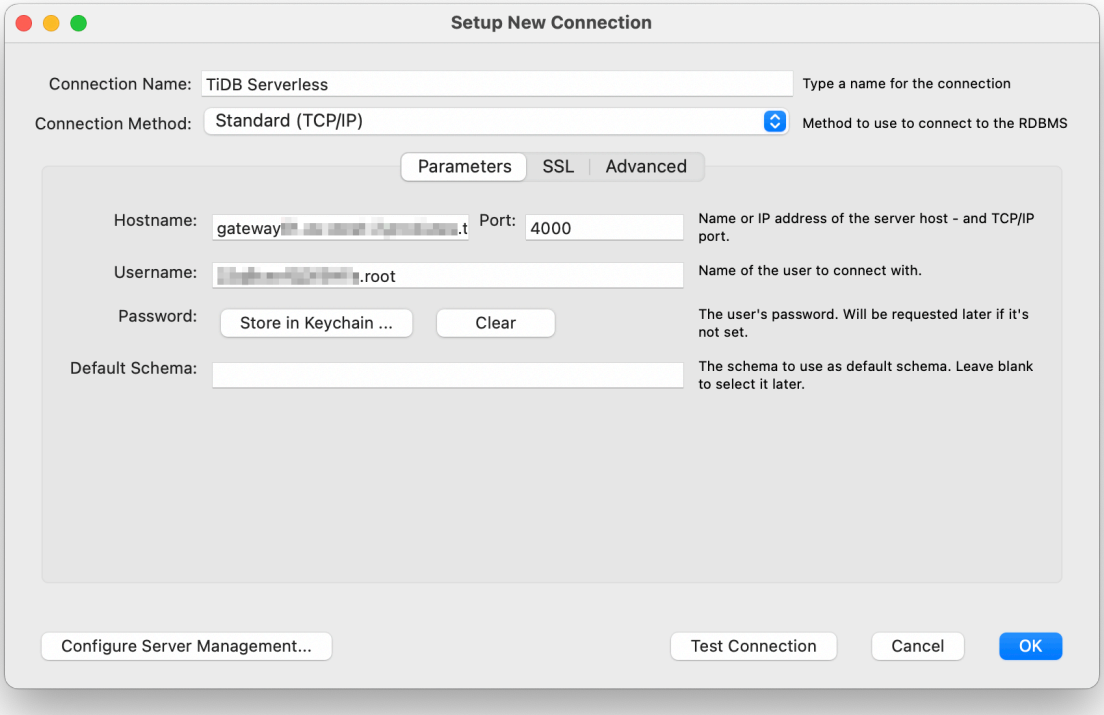

Figure 38: MySQL Workbench: configure connection settings for TiDB Cloud Serverless

7. Click **Test Connection** to validate the connection to the TiDB Cloud Serverless cluster.

8. If the connection test is successful, you can see the **Successfully made the MySQL connection** message. Click **OK** to save the connection configuration.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list, and then click **CA cert** to download the CA certificate.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

   In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Launch MySQL Workbench and click + near the **MySQL Connections** title.

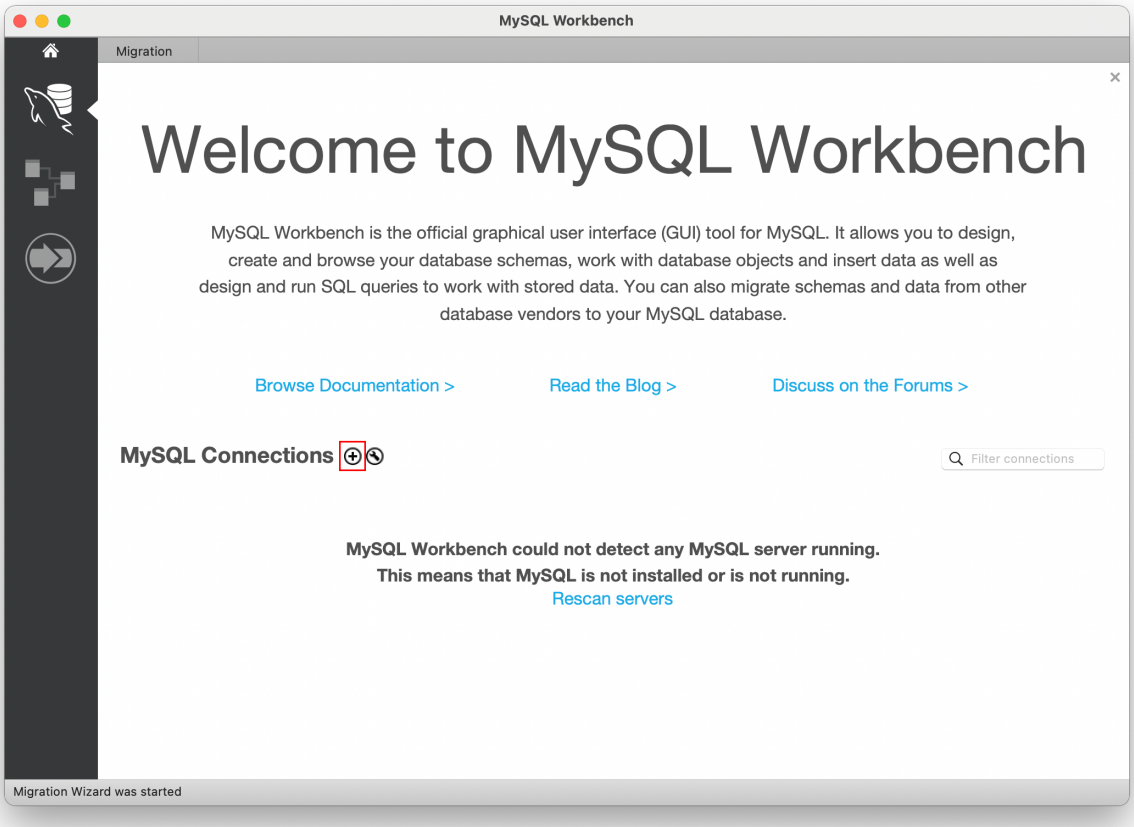

Figure 39: MySQL Workbench: add new connection

5. In the **Setup New Connection** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.
    - **Hostname**: enter the `HOST` parameter from the TiDB Cloud connection dialog.
    - **Port**: enter the `PORT` parameter from the TiDB Cloud connection dialog.
    - **Username**: enter the `USERNAME` parameter from the TiDB Cloud connection dialog.
    - **Password**: click **Store in Keychain ...**, enter the password of the TiDB Cloud Dedicated cluster, and then click **OK** to store the password.

6. Click **Test Connection** to validate the connection to the TiDB Cloud Dedicated cluster.

7. If the connection test is successful, you can see the **Successfully made the MySQL connection** message. Click **OK** to save the connection configuration.

1. Launch MySQL Workbench and click + near the **MySQL Connections** title.

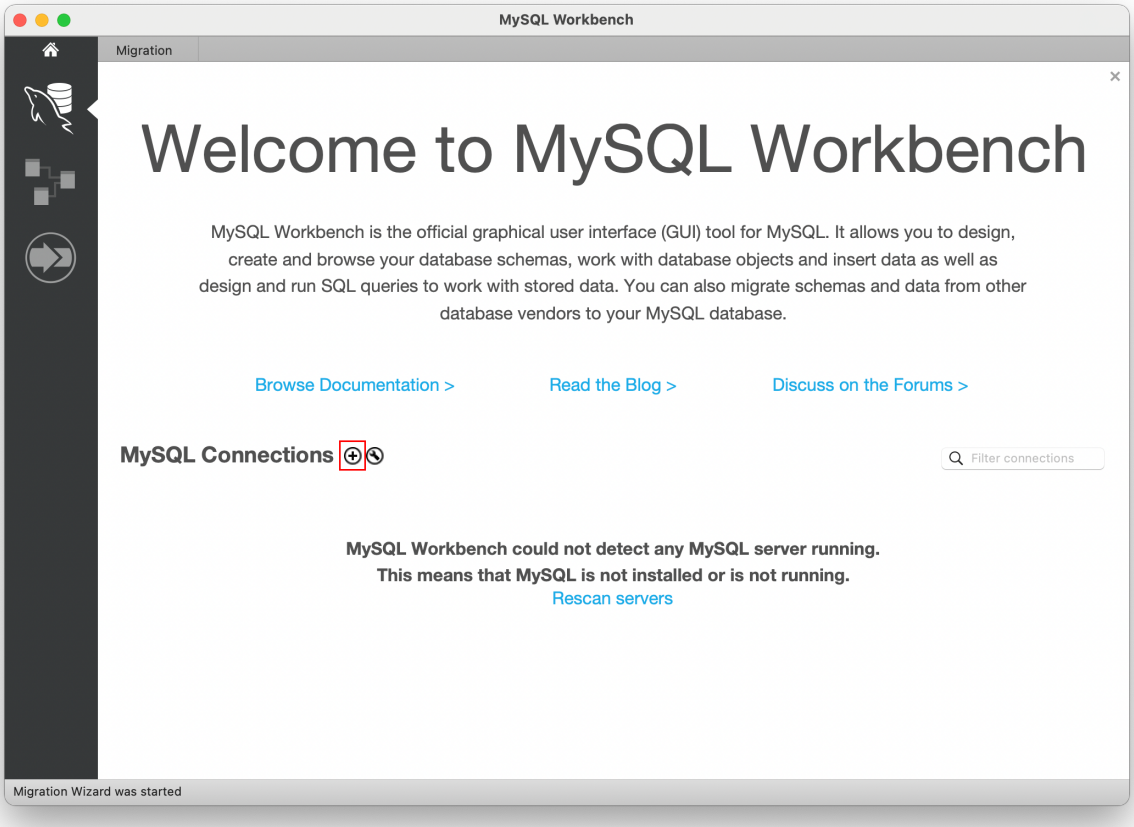

Figure 42: MySQL Workbench: add new connection

2. In the **Setup New Connection** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.
    - **Hostname**: enter the IP address or domain name of your TiDB Self-Managed cluster.
    - **Port**: enter the port number of your TiDB Self-Managed cluster.
    - **Username**: enter the username to use to connect to your TiDB.

- **Password**: click **Store in Keychain ...**, enter the password to use to connect to your TiDB cluster, and then click **OK** to store the password.

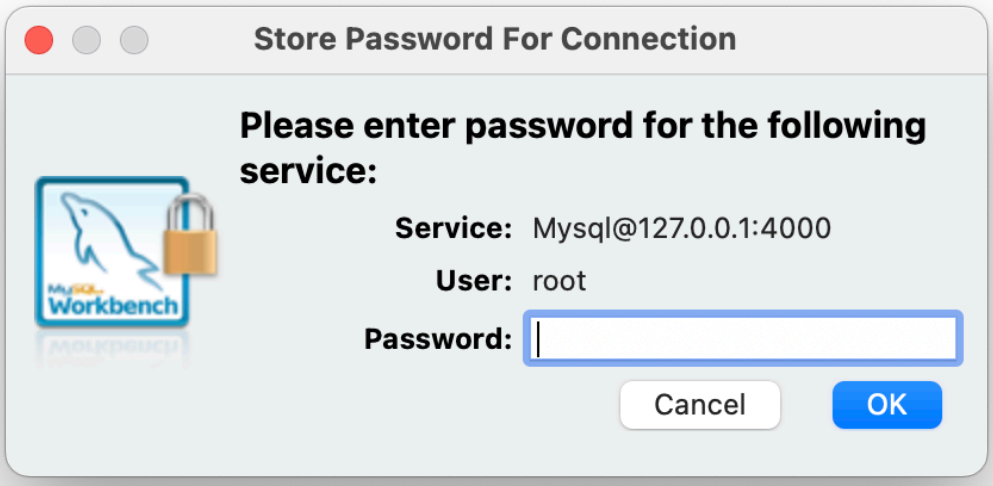

Figure 43: MySQL Workbench: store the password of TiDB Self-Managed in keychain

The following figure shows an example of the connection parameters:

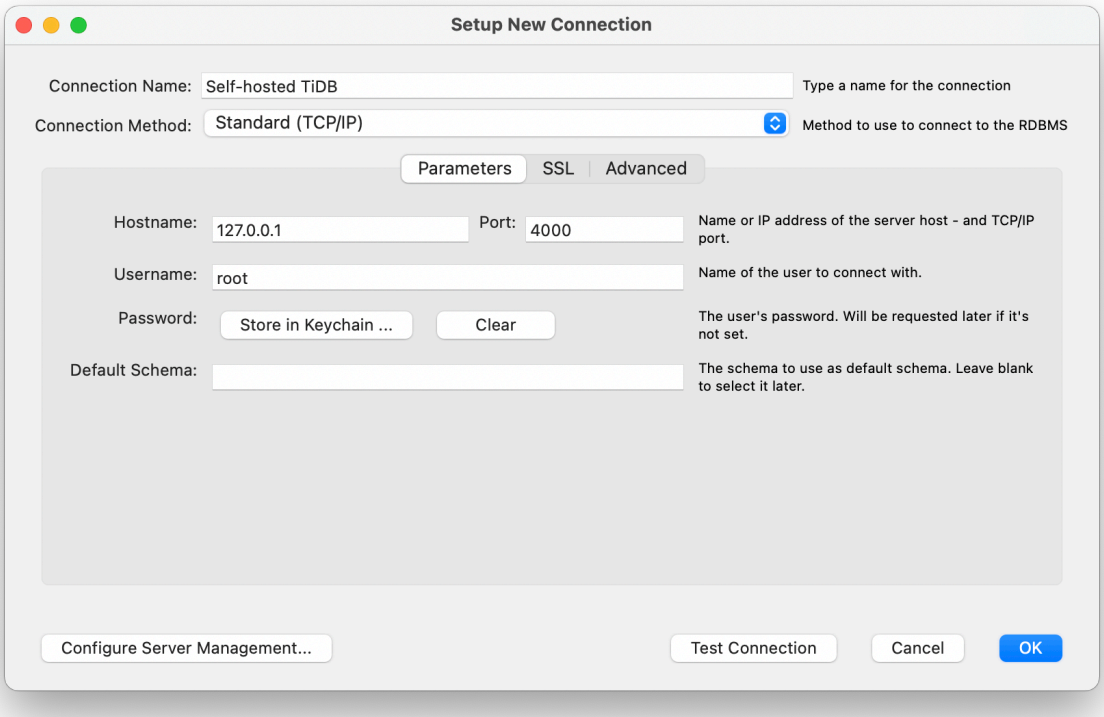

Figure 44: MySQL Workbench: configure connection settings for TiDB Self-Managed

3. Click **Test Connection** to validate the connection to the TiDB Self-Managed cluster.
4. If the connection test is successful, you can see the **Successfully made the MySQL connection** message. Click **OK** to save the connection configuration.

4.4.1.4.3 FAQs

How to handle the connection timeout error "Error Code: 2013. Lost connection to MySQL server during query"?

This error indicates that the query execution time exceeds the timeout limit. To resolve this issue, you can adjust the timeout settings by the following steps:

1. Launch MySQL Workbench and navigate to the **Workbench Preferences** page.
2. In the **SQL Editor** > **MySQL Session** section, configure the **DBMS connection read timeout interval (in seconds)** option. This sets the maximum amount of time (in seconds) that a query can take before MySQL Workbench disconnects from the server.

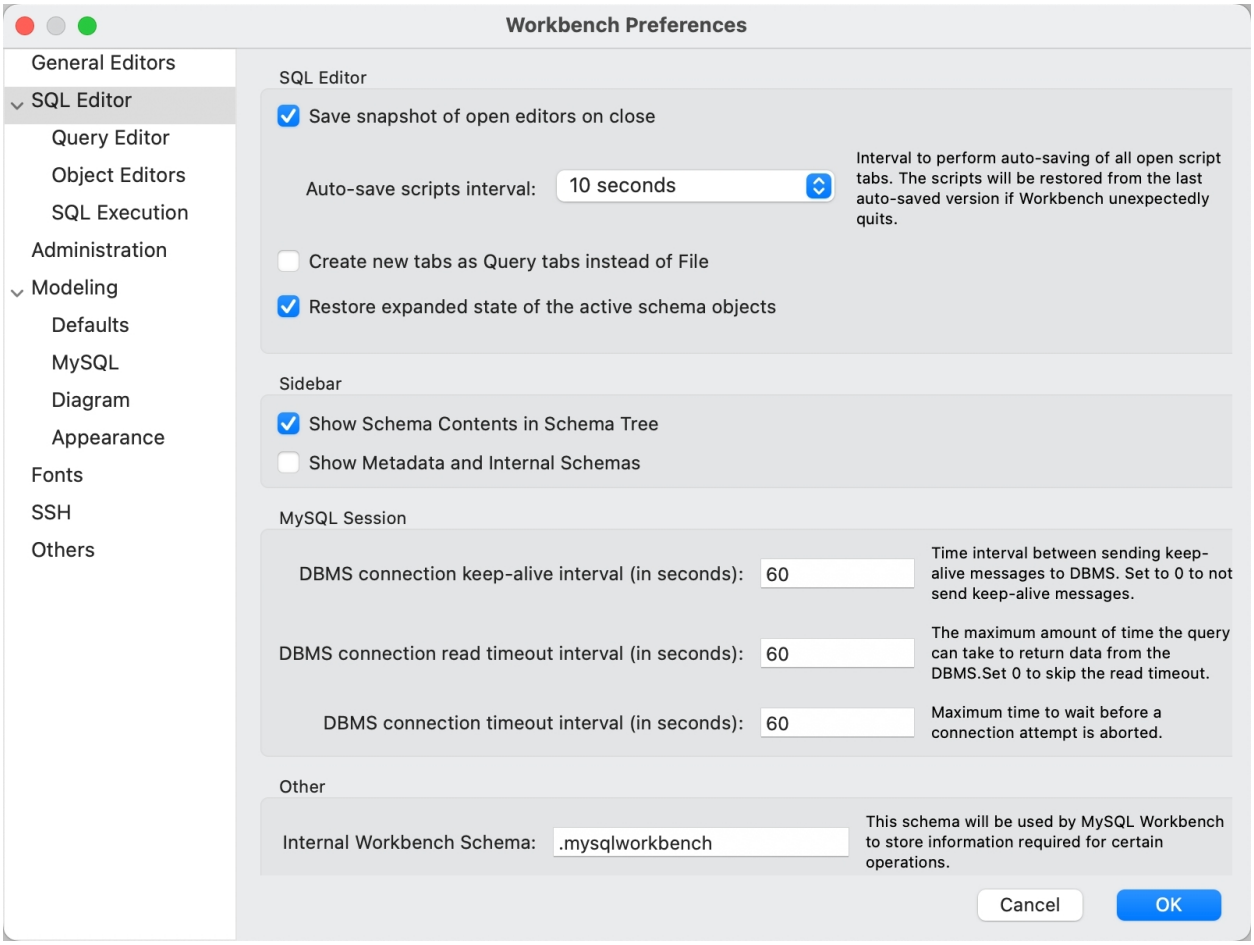

Figure 45: MySQL Workbench: adjust timeout option in SQL Editor settings

For more information, see MySQL Workbench frequently asked questions.

4.4.1.4.4 Next steps

- Learn more usage of MySQL Workbench from the documentation of MySQL Workbench.
- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

Ask the community on Discord or Slack, or submit a support ticket.

4.4.1.5 Connect to TiDB with Navicat

TiDB is a MySQL-compatible database, and Navicat is a GUI tool set for database users. This tutorial uses the Navicat Premium tool to connect to TiDB.

In this tutorial, you can learn how to connect to your TiDB cluster using Navicat.

> **Note:**
>
> This tutorial is compatible with TiDB Cloud Serverless, TiDB Cloud Dedicated, and TiDB Self-Managed.

4.4.1.5.1 Prerequisites

To complete this tutorial, you need:

- Navicat Premium **17.1.6** or later versions.
- A paid account for Navicat Premium.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- (Recommended) Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.
- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.

4.4.1.5.2 Connect to TiDB

Connect to your TiDB cluster depending on the TiDB deployment option you have selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `Navicat`.
    - **Operating System** matches your environment.

4. Click **Generate Password** to create a random password.

> **Tip:**
>
> If you have created a password before, you can either use the original password or click **Reset Password** to generate a new one.

5. Launch Navicat Premium, click **Connection** in the upper-left corner, select **PingCAP** from the **Vendor Filter** list, and double-click **TiDB** in the right panel.

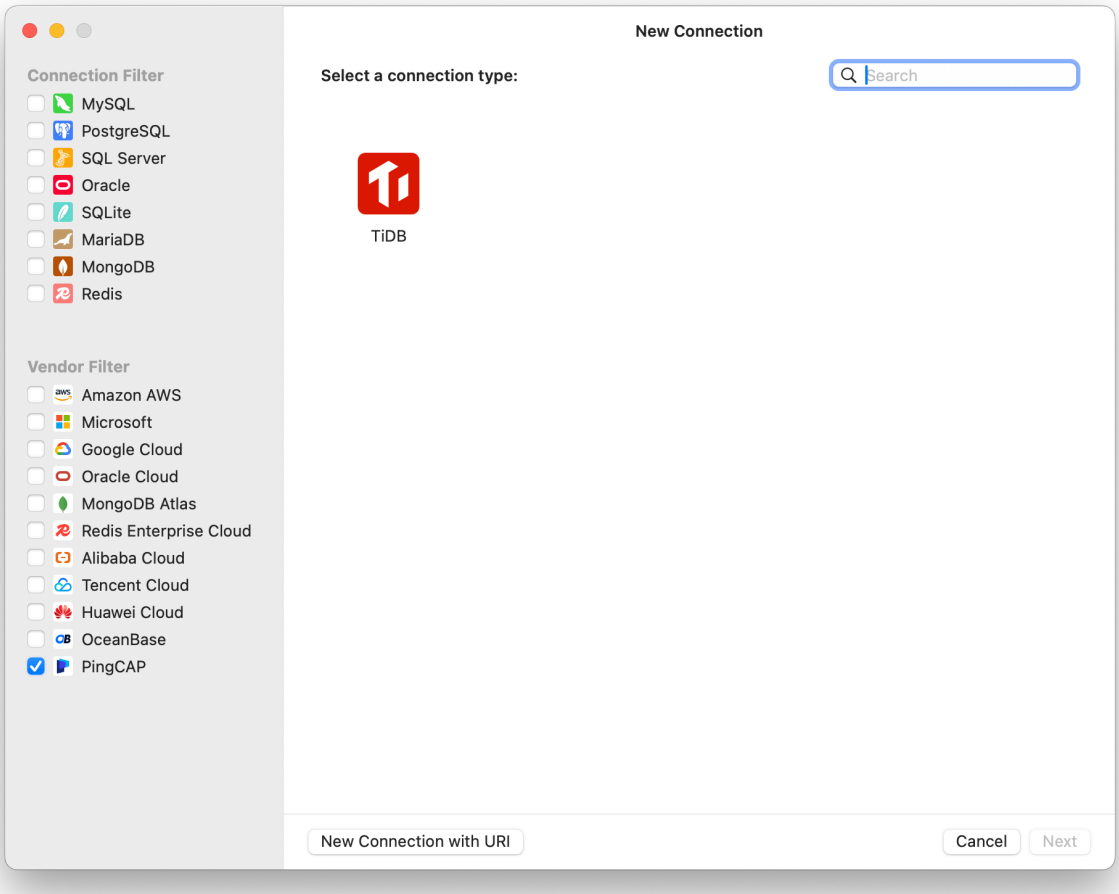

Figure 46: Navicat: add new connection

6. In the **New Connection (TiDB)** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.

- **Host**: enter the `HOST` parameter from the TiDB Cloud connection dialog.
- **Port**: enter the `PORT` parameter from the TiDB Cloud connection dialog.
- **User Name**: enter the `USERNAME` parameter from the TiDB Cloud connection dialog.
- **Password**: enter the password of the TiDB Cloud Serverless cluster.

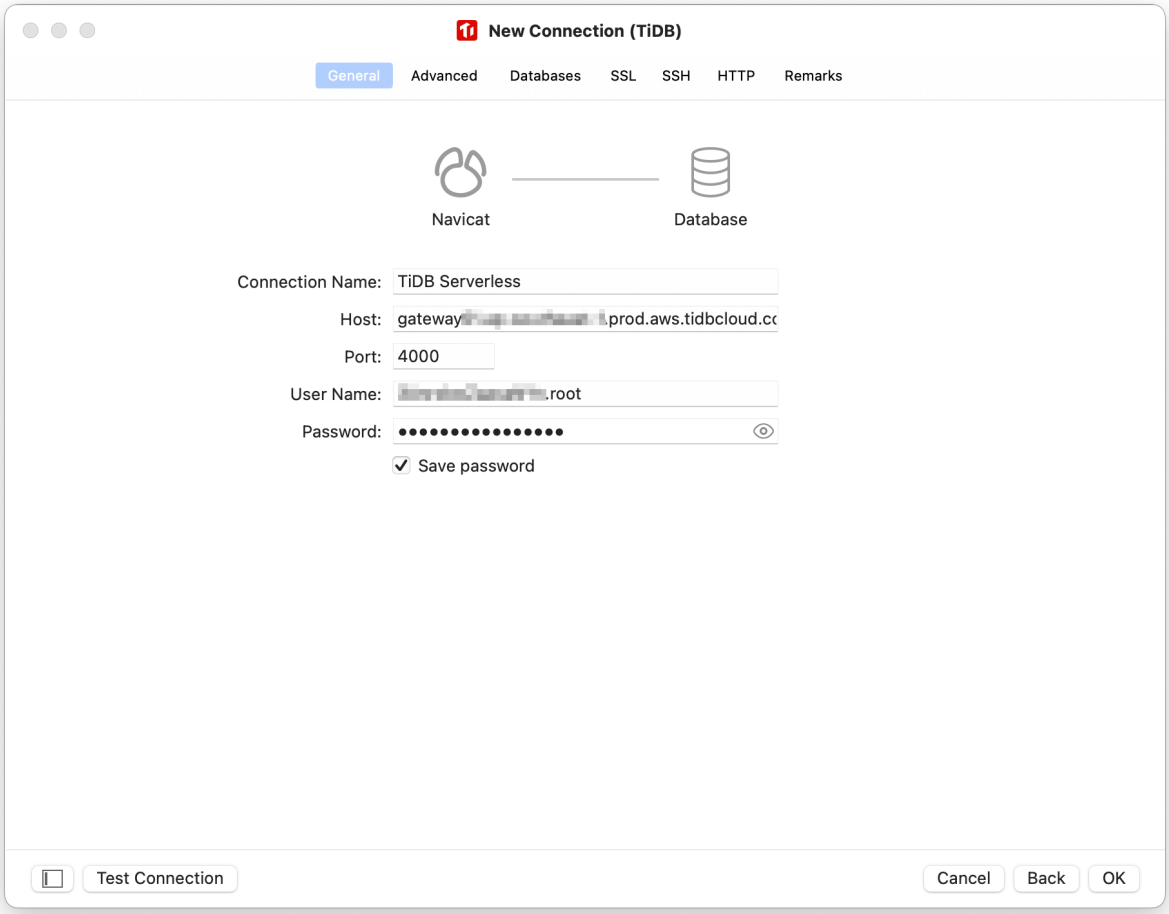

Figure 47: Navicat: configure connection general panel for TiDB Cloud Serverless

7. Click the **SSL** tab and select **Use SSL**, **Use authentication**, and **Verify server certificate against CA** checkboxes. Then, select the `CA` file from the TiDB Cloud connection dialog into the **CA Certificate** field.

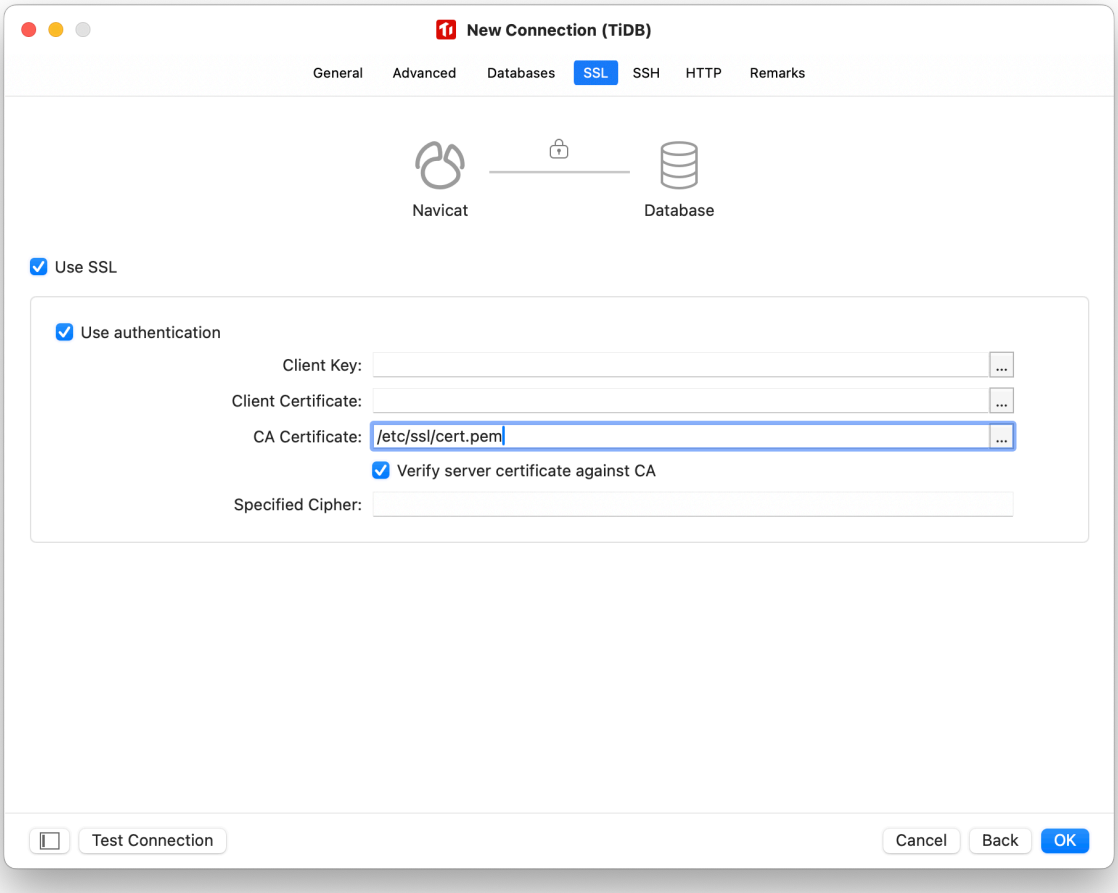

Figure 48: Navicat: configure connection SSL panel for TiDB Cloud Serverless

8. Click **Test Connection** to validate the connection to the TiDB Cloud Serverless cluster.

9. If the connection test is successful, you can see the **Connection Successful** message. Click **OK** to finish the connection configuration.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. In the connection dialog, select **Public** from the **Connection Type** drop-down list.

   If you have not configured the IP access list, click **Configure IP Access List** or follow the steps in Configure an IP Access List to configure it before your first connection.

In addition to the **Public** connection type, TiDB Dedicated supports **Private Endpoint** and **VPC Peering** connection types. For more information, see Connect to Your TiDB Dedicated Cluster.

4. Click **CA cert** to download the CA certificate.

5. Launch Navicat Premium, click **Connection** in the upper-left corner, select **PingCAP** from the **Vendor Filter** list, and double-click **TiDB** in the right panel.

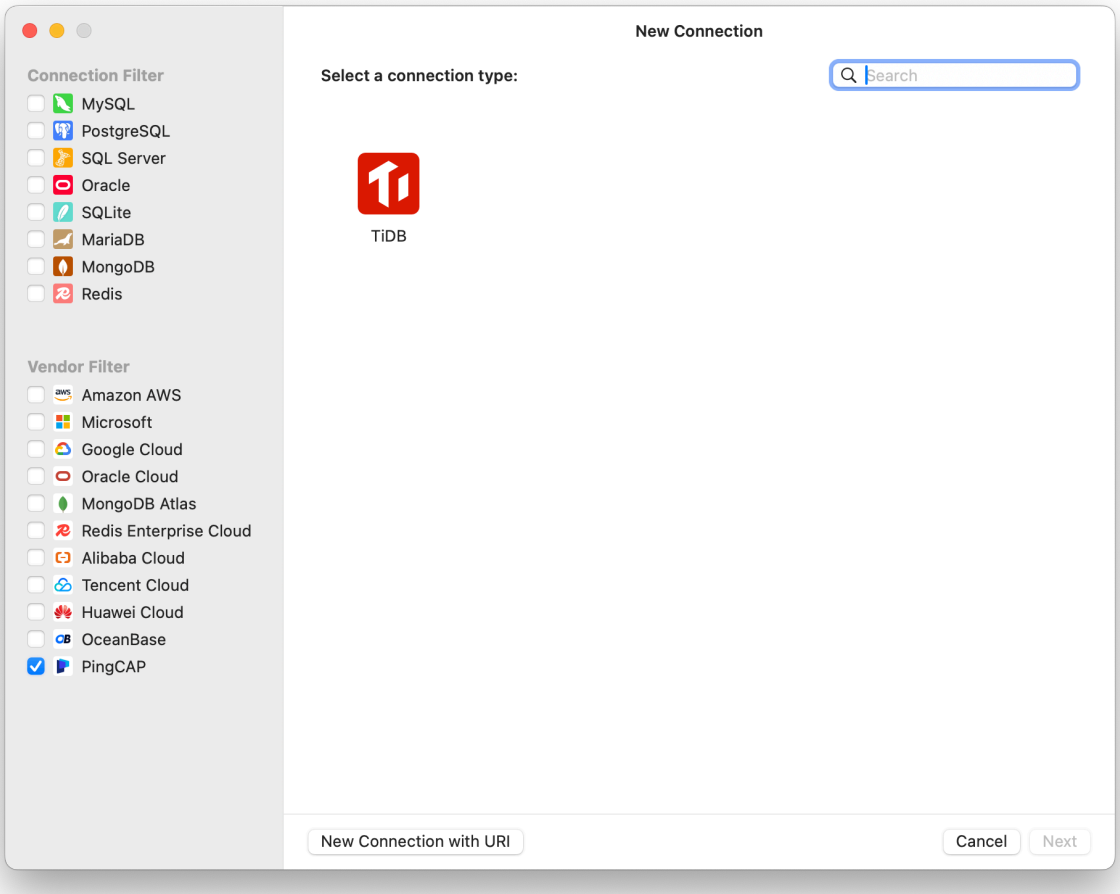

Figure 49: Navicat: add new connection

6. In the **New Connection (TiDB)** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.
    - **Host**: enter the `HOST` parameter from the TiDB Cloud connection dialog.
    - **Port**: enter the `PORT` parameter from the TiDB Cloud connection dialog.

- **User Name**: enter the `USERNAME` parameter from the TiDB Cloud connection dialog.
- **Password**: enter the password of the TiDB Cloud Dedicated cluster.

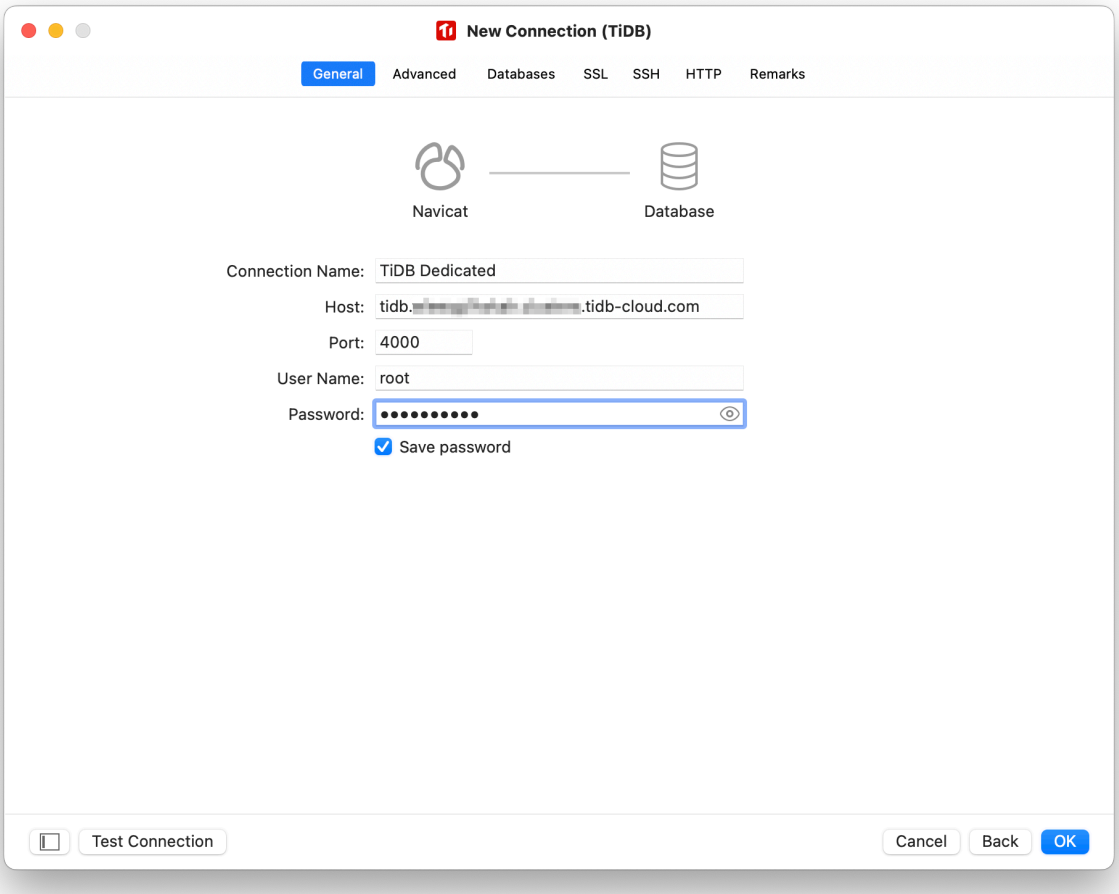

Figure 50: Navicat: configure connection general panel for TiDB Cloud Dedicated

7. Click the **SSL** tab and select **Use SSL**, **Use authentication**, and **Verify server certificate against CA** checkboxes. Then, select the CA file downloaded in step 4 into the **CA Certificate** field.

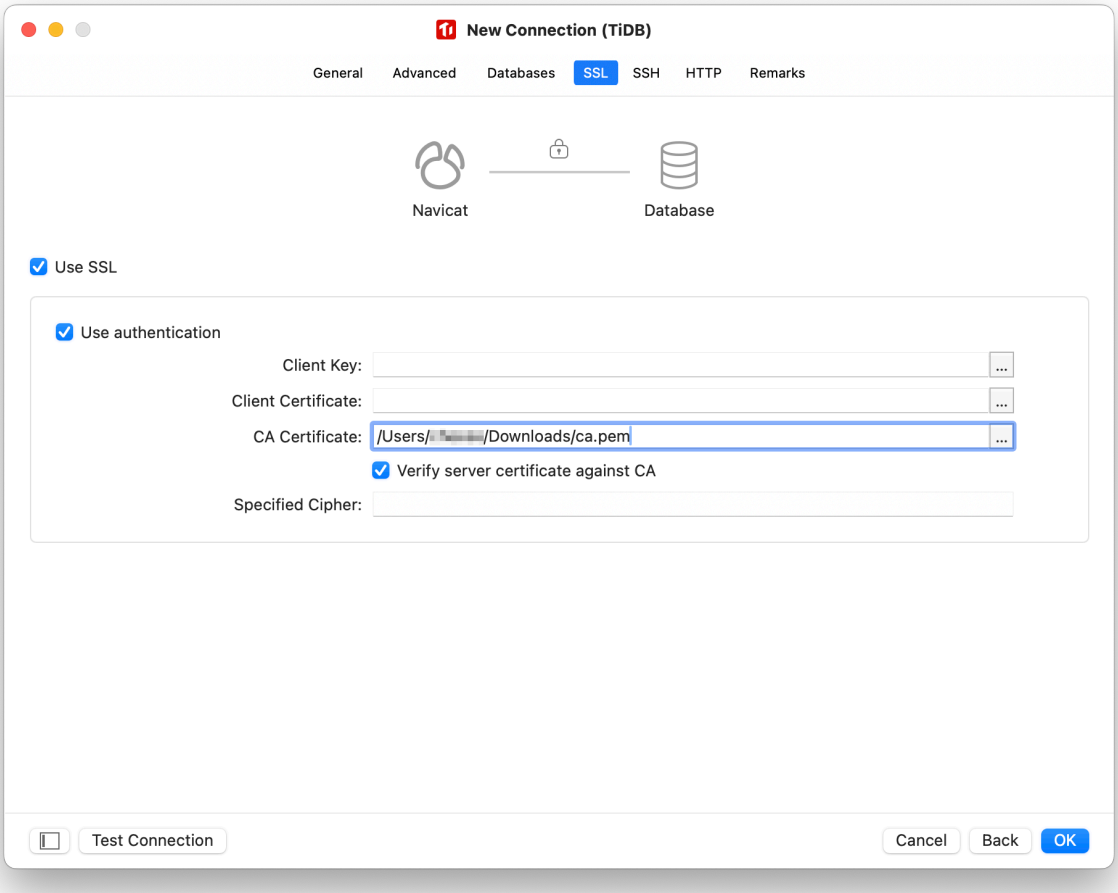

Figure 51: Navicat: configure connection SSL panel for TiDB Cloud Dedicated

8. **Test Connection** to validate the connection to the TiDB Cloud Dedicated cluster.

9. If the connection test is successful, you can see the **Connection Successful** message. Click **OK** to finish the connection configuration.

1. Launch Navicat Premium, click **Connection** in the upper-left corner, select **PingCAP** from the **Vendor Filter** list, and double-click **TiDB** in the right panel.

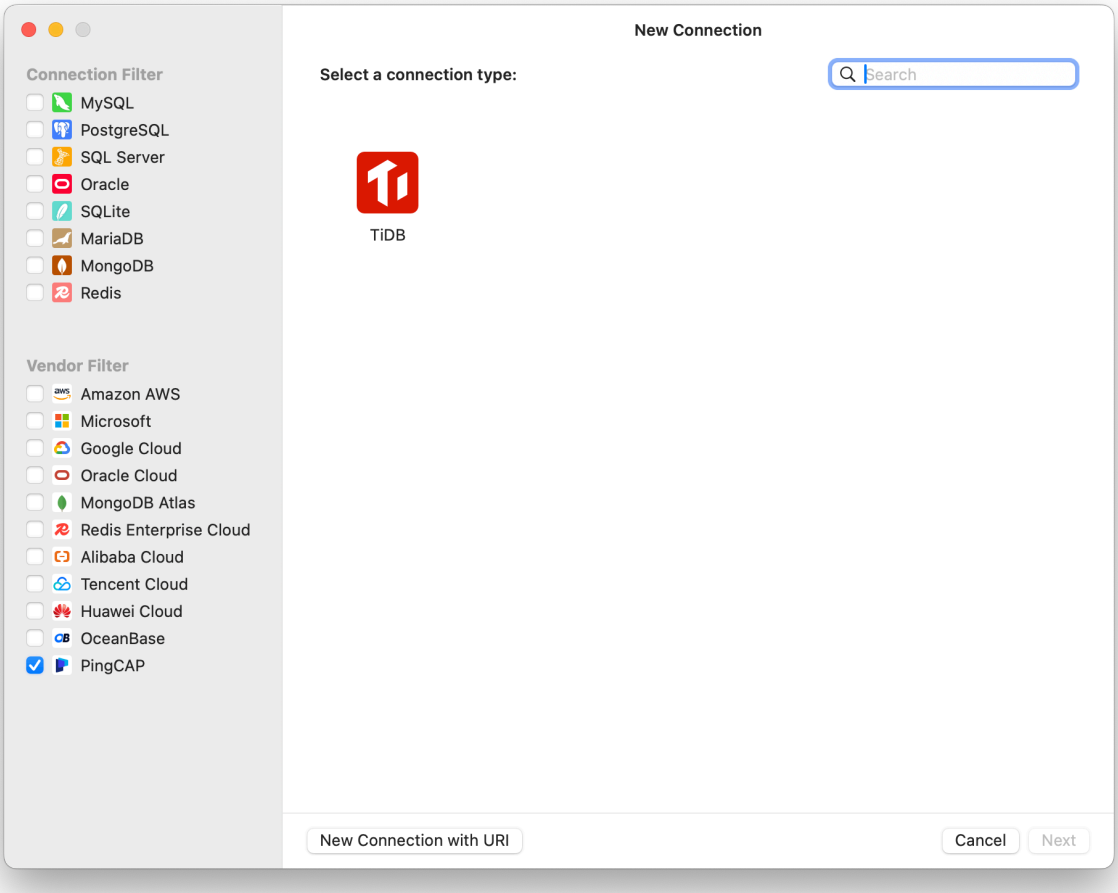

Figure 52: Navicat: add new connection

2. In the **New Connection (TiDB)** dialog, configure the following connection parameters:

    - **Connection Name**: give this connection a meaningful name.
    - **Host**: enter the IP address or domain name of your TiDB Self-Managed cluster.
    - **Port**: enter the port number of your TiDB Self-Managed cluster.
    - **User Name**: enter the username to use to connect to your TiDB.
    - **Password**: enter the password to use to connect to your TiDB.

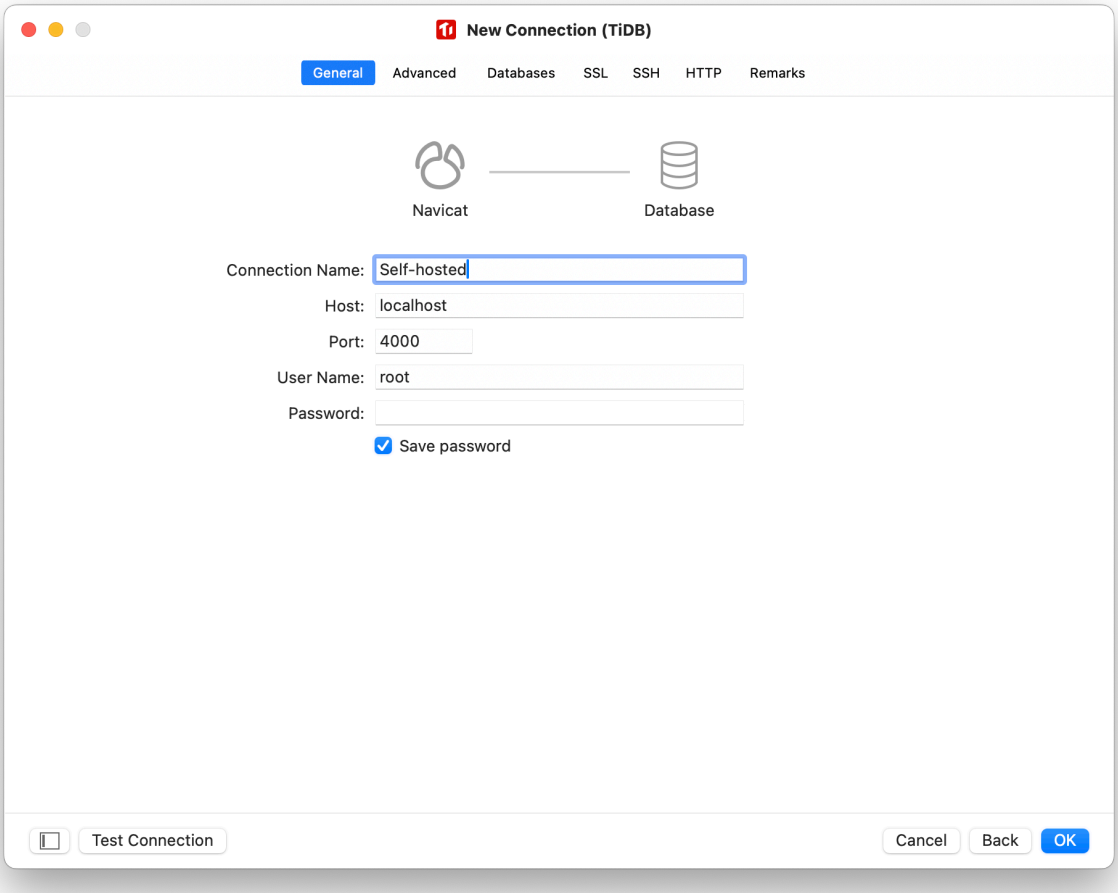

Figure 53: Navicat: configure connection general panel for self-hosted TiDB

3. Click **Test Connection** to validate the connection to the TiDB Self-Managed cluster.

4. If the connection test is successful, you can see the **Connection Successful** message. Click **OK** to finish the connection configuration.

4.4.1.5.3 Next steps

- Learn the best practices for TiDB application development with the chapters in the Developer guide, such as Insert data, Update data, Delete data, Single table reading, Transactions, and SQL performance optimization.
- Learn through the professional TiDB developer courses and earn TiDB certifications after passing the exam.

4.4.1.5.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.4.2 Choose Driver or ORM

> **Note:**
>
> TiDB provides the following two support levels for drivers and ORMs:
>
> - **Full**: indicates that TiDB is compatible with most features of the tool and maintains compatibility with its newer versions. PingCAP will periodically conduct compatibility tests with the latest version of Third-party tools supported by TiDB.
> - **Compatible**: indicates that because the corresponding third-party tool is adapted to MySQL and TiDB is highly compatible with the MySQL protocol, so TiDB can use most features of the tool. However, PingCAP has not completed a full test on all features of the tool, which might lead to some unexpected behaviors.
>
> For more information, refer to Third-Party Tools Supported by TiDB.

TiDB is highly compatible with the MySQL protocol but some features are incompatible with MySQL. For a full list of compatibility differences, see MySQL Compatibility.

4.4.2.1 Java

This section describes how to use drivers and ORM frameworks in Java.

4.4.2.1.1 Java drivers

Support level: **Full**

You can follow the MySQL documentation to download and configure a Java JDBC driver. It is recommended to use the latest GA version of MySQL Connector/J with TiDB v6.3.0 or later.

> **Warning:**
>
> There is a bug in the MySQL Connector/J 8.0 versions before 8.0.31 (see MySQL JDBC bugs for details), which might cause threads to hang when using TiDB versions earlier than v6.3.0. To avoid this issue, do **NOT** use MySQL Connector/J 8.0.31 or an earlier version.

For an example of how to build a complete application, see Build a simple CRUD app with TiDB and JDBC.

Support level: **Full**

TiDB-JDBC is a customized Java driver based on MySQL 8.0.29. Compiled based on MySQL official version 8.0.29, TiDB-JDBC fixes the bug of multi-parameter and multi-field EOF in the prepare mode in the original JDBC, and adds features such as automatic TiCDC snapshot maintenance and the SM3 authentication plugin.

The authentication based on SM3 is only supported in TiDB's TiDB-JDBC.

If you are using Maven, add the following content to the `<dependencies></dependencies>` section in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
```

If you need to enable SM3 authentication, add the following content to the `<dependencies></dependencies>` section in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
<dependency>
    <groupId>org.bouncycastle</groupId>
    <artifactId>bcprov-jdk15on</artifactId>
    <version>1.67</version>
</dependency>
<dependency>
    <groupId>org.bouncycastle</groupId>
    <artifactId>bcpkix-jdk15on</artifactId>
    <version>1.67</version>
</dependency>
```

If you use Gradle, add the following content to `dependencies`:

```
implementation group: 'io.github.lastincisor', name: 'mysql-connector-java',
    ↪  version: '8.0.29-tidb-1.0.0'
implementation group: 'org.bouncycastle', name: 'bcprov-jdk15on', version:
    ↪ '1.67'
implementation group: 'org.bouncycastle', name: 'bcpkix-jdk15on', version:
    ↪ '1.67'
```

4.4.2.1.2 Java ORM frameworks

Note:

- Currently, Hibernate does not support nested transactions.
- Since v6.2.0, TiDB supports savepoint. To use the `Propagation.NESTED` transaction propagation option in `@Transactional`, that is, to set `@Transactional(propagation = Propagation.NESTED)`, make sure that your TiDB is v6.2.0 or later.

Support level: **Full**

To avoid manually managing complex relationships between different dependencies of an application, you can use Gradle or Maven to get all dependencies of your application, including those indirect ones. Note that only Hibernate `6.0.0.Beta2` or above supports the TiDB dialect.

If you are using Maven, add the following to your `<dependencies></dependencies>`:

```
<dependency>
    <groupId>org.hibernate.orm</groupId>
    <artifactId>hibernate-core</artifactId>
    <version>6.2.3.Final</version>
</dependency>

<dependency>
    <groupId>mysql</groupId>
    <artifactId>mysql-connector-java</artifactId>
    <version>8.0.33</version>
</dependency>
```

If you are using Gradle, add the following to your `dependencies`:

```
implementation 'org.hibernate:hibernate-core:6.2.3.Final'
implementation 'mysql:mysql-connector-java:8.0.33'
```

- For an example of using Hibernate to build a TiDB application by native Java, see Build a simple CRUD app with TiDB and Hibernate.
- For an example of using Spring Data JPA or Hibernate to build a TiDB application by Spring, see Build a TiDB app using Spring Boot.

In addition, you need to specify the TiDB dialect in your Hibernate configuration file: `org.hibernate.dialect.TiDBDialect`, which is only supported by Hibernate `6.0.0.Beta2` or above. If your `Hibernate` version is earlier than `6.0.0.Beta2`, upgrade it first.

Note:

If you are unable to upgrade your `Hibernate` version, use the MySQL 5.7 dialect `org.hibernate.dialect.MySQL57Dialect` instead. However, this setting might cause unpredictable results and the absence of some TiDB-specific features, such as sequences.

Support level: **Full**

To avoid manually managing complex relationships between different dependencies of an application, you can use Gradle or Maven to get all dependencies of your application, including those indirect dependencies.

If you are using Maven, add the following to your `<dependencies></dependencies>`:

```
<dependency>
    <groupId>org.mybatis</groupId>
    <artifactId>mybatis</artifactId>
    <version>3.5.13</version>
</dependency>

<dependency>
    <groupId>mysql</groupId>
    <artifactId>mysql-connector-java</artifactId>
    <version>8.0.33</version>
</dependency>
```

If you are using Gradle, add the following to your `dependencies`:

```
implementation 'org.mybatis:mybatis:3.5.13'
implementation 'mysql:mysql-connector-java:8.0.33'
```

For an example of using MyBatis to build a TiDB application, see Build a simple CRUD app with TiDB and MyBatis.

4.4.2.1.3 Java client load balancing

tidb-loadbalance

Support level: **Full**

tidb-loadbalance is a load balancing component on the application side. With tidb-loadbalance, you can automatically maintain the node information of TiDB server and distribute JDBC connections on the client using the tidb-loadbalance policies. Using a direct JDBC connection between the client application and TiDB server has higher performance than using the load balancing component.

Currently, tidb-loadbalance supports the following policies: roundrobin, random, and weight.

> **Note:**
>
> tidb-loadbalance must be used with mysql-connector-j.

If you are using Maven, add the following content to the element body of `<dependencies></dependencies>` in the `pom.xml` file:

```
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>mysql-connector-java</artifactId>
  <version>8.0.29-tidb-1.0.0</version>
</dependency>
<dependency>
  <groupId>io.github.lastincisor</groupId>
  <artifactId>tidb-loadbalance</artifactId>
  <version>0.0.5</version>
</dependency>
```

If you are using Gradle, add the following content to `dependencies`:

```
implementation group: 'io.github.lastincisor', name: 'mysql-connector-java',
    ↪  version: '8.0.29-tidb-1.0.0'
implementation group: 'io.github.lastincisor', name: 'tidb-loadbalance',
    ↪ version: '0.0.5'
```

4.4.2.2 Golang

This section describes how to use drivers and ORM frameworks in Golang.

4.4.2.2.1 Golang drivers

go-sql-driver/mysql

Support level: **Full**

To download and configure a Golang driver, refer to the go-sql-driver/mysql documentation.

For an example of how to build a complete application, see Connect to TiDB with Go-MySQL-Driver.

4.4.2.2.2 Golang ORM frameworks

GORM

Support level: **Full**

GORM is a popular ORM framework for Golang. To get all dependencies in your application, you can use the `go get` command.

```
go get -u gorm.io/gorm
go get -u gorm.io/driver/mysql
```

For an example of using GORM to build a TiDB application, see Connect to TiDB with GORM.

4.4.2.3 Python

This section describes how to use drivers and ORM frameworks in Python.

4.4.2.3.1 Python drivers

Support level: **Compatible**

You can follow the PyMySQL documentation to download and configure the driver. It is recommended to use PyMySQL 1.0.2 or later versions.

For an example of using PyMySQL to build a TiDB application, see Connect to TiDB with PyMySQL.

Support level: **Compatible**

You can follow the mysqlclient documentation to download and configure the driver. It is recommended to use mysqlclient 2.1.1 or later versions.

For an example of using mysqlclient to build a TiDB application, see Connect to TiDB with mysqlclient.

Support level: **Compatible**

You can follow the MySQL Connector/Python documentation to download and configure the driver. It is recommended to use Connector/Python 8.0.31 or later versions.

For an example of using MySQL Connector/Python to build a TiDB application, see Connect to TiDB with MySQL Connector/Python.

4.4.2.3.2 Python ORM frameworks

Support level: **Full**

Django is a popular Python web framework. To solve the compatibility issue between TiDB and Django, PingCAP provides a TiDB dialect `django-tidb`. To install it, you can see the `django-tidb` documentation.

For an example of using Django to build a TiDB application, see Connect to TiDB with Django.

Support level: **Full**

SQLAlchemy is a popular ORM framework for Python. To get all dependencies in your application, you can use the `pip install SQLAlchemy==1.4.44` command. It is recommended to use SQLAlchemy 1.4.44 or later versions.

For an example of using SQLAlchemy to build a TiDB application, see Connect to TiDB with SQLAlchemy.

Support level: **Compatible**

peewee is a popular ORM framework for Python. To get all dependencies in your application, you can use the `pip install peewee==3.15.4` command. It is recommended to use peewee 3.15.4 or later versions.

For an example of using peewee to build a TiDB application, see Connect to TiDB with peewee.

4.4.2.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.4.3 Connect to TiDB

TiDB is highly compatible with the MySQL protocol. For a full list of client link parameters, see MySQL Client Options.

TiDB supports the MySQL Client/Server Protocol, which allows most client drivers and ORM frameworks to connect to TiDB just as they connect to MySQL.

4.4.3.1 MySQL

You can choose to use MySQL Client or MySQL Shell based on your personal preferences.

You can connect to TiDB using MySQL Client, which can be used as a command-line tool for TiDB. To install MySQL Client, follow the instructions below for YUM based Linux distributions.

```
sudo yum install mysql
```

After the installation, you can connect to TiDB using the following command:

```
mysql --host <tidb_server_host> --port 4000 -u root -p --comments
```

The MySQL v9.0 client on macOS cannot correctly load the `mysql_native_password` plugin, causing the error `ERROR 2059 (HY000): Authentication plugin 'mysql_native_password' cannot be loaded` when connecting to TiDB. To address this issue, it is

recommended to install and use the MySQL v8.0 client to connect to TiDB. Run the following commands to install it:

```
brew install mysql-client@8.0
brew unlink mysql
brew link mysql-client@8.0
```

If you still encounter errors, you can specify the installation path of the MySQL v8.0 client to connect to TiDB. Run the following command:

```
/opt/homebrew/opt/mysql-client@8.0/bin/mysql --comments --host ${YOUR_IP_
    ↪ ADDRESS} --port ${YOUR_PORT_NUMBER} -u ${your_user_name} -p
```

Replace `/opt/homebrew/opt/mysql-client@8.0/bin/mysql` in the preceding command with the installation path of the MySQL v8.0 client in your actual environment.

You can connect to TiDB using MySQL Shell, which can be used as a command-line tool for TiDB. To install MySQL Shell, follow the instructions in the MySQL Shell documentation. After the installation, you can connect to TiDB using the following command:

```
mysqlsh --sql mysql://root@<tidb_server_host>:4000
```

4.4.3.2 JDBC

You can connect to TiDB using the JDBC driver. To do that, you need to create a `MysqlDataSource` or `MysqlConnectionPoolDataSource` object (both objects support the `DataSource` interface), and then set the connection string using the `setURL` function.

For example:

```
MysqlDataSource mysqlDataSource = new MysqlDataSource();
mysqlDataSource.setURL("jdbc:mysql://{host}:{port}/{database}?user={username
    ↪ }&password={password}");
```

For more information on JDBC connections, see the JDBC documentation

4.4.3.2.1 Connection parameters

Parameter name	Description
{username}	A SQL user to connect to the TiDB cluster
{password}	The password of the SQL user
{host}	Host of a TiDB node
{port}	Port that the TiDB node is listening on
{database}	Name of an existing database

For more information about TiDB SQL users, see TiDB User Account Management.

4.4.3.3 Hibernate

You can connect to TiDB using the Hibernate ORM. To do that, you need to set `hibernate.connection.url` in the Hibernate configuration file to a legal TiDB connection string.

For example, if you use a `hibernate.cfg.xml` configuration file, set `hibernate.connection.url` as follows:

```
<?xml version='1.0' encoding='utf-8'?>
<!DOCTYPE hibernate-configuration PUBLIC
        "-//Hibernate/Hibernate Configuration DTD 3.0//EN"
        "http://www.hibernate.org/dtd/hibernate-configuration-3.0.dtd">
<hibernate-configuration>
    <session-factory>
        <property name="hibernate.connection.driver_class">com.mysql.cj.jdbc.
            ↪ Driver</property>
        <property name="hibernate.dialect">org.hibernate.dialect.TiDBDialect<
            ↪ /property>
        <property name="hibernate.connection.url">jdbc:mysql://{host}:{port
            ↪ }/{database}?user={user}&amp;password={password}</property>
    </session-factory>
</hibernate-configuration>
```

After the configuration is done, you can use the following command to read the configuration file and get the `SessionFactory` object:

```
SessionFactory sessionFactory = new Configuration().configure("hibernate.
    ↪ cfg.xml").buildSessionFactory();
```

Note the following:

- Because the `hibernate.cfg.xml` configuration file is in the XML format and `&` is a special character in XML, you need to change `&` to `&` when configuring the file. For example, you need to change the connection string `hibernate.connection.url` from `jdbc:mysql://{host}:{port}/{database}?user={user}&password={password}` to `jdbc:mysql://{host}:{ port}/{database}?user={user}&password={password}`.
- It is recommended that you use the `TiDB` dialect by setting `hibernate.dialect` to `org.hibernate.dialect.TiDBDialect`.
- Hibernate supports TiDB dialects starting from `6.0.0.Beta2`, so it is recommended that you use Hibernate `6.0.0.Beta2` or a later version to connect to TiDB.

For more information about Hibernate connection parameters, see Hibernate documentation.

4.4.3.3.1 Connection parameters

Parameter name	Description
{username}	A SQL user to connect to the TiDB cluster
{password}	The password of the SQL user
{host}	Host of a TiDB node
{port}	Port that the TiDB node is listening on
{database}	Name of an existing database

For more information about TiDB SQL users, see TiDB User Account Management.

4.4.3.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.4.4 Connection Pools and Connection Parameters

This document describes how to configure connection pools and connection parameters when you use a driver or ORM framework to connect to TiDB.

If you are interested in more tips about Java application development, see Best Practices for Developing Java Applications with TiDB

4.4.4.1 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least). Because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

Java has many connection pool implementations such as HikariCP, tomcat-jdbc, druid, c3p0, and dbcp. TiDB does not limit which connection pool you use, so you can choose whichever you like for your application.

4.4.4.1.1 Configure the number of connections

It is a common practice that the connection pool size is well adjusted according to the application's own needs. Take HikariCP as an example:

- **maximumPoolSize**: The maximum number of connections in the connection pool. If this value is too large, TiDB consumes resources to maintain useless connections. If this value is too small, the application gets slow connections. Therefore, you need to configure this value according to your application characteristics. For details, see About Pool Sizing.
- **minimumIdle**: The minimum number of idle connections in the connection pool. It is mainly used to reserve some connections to respond to sudden requests when the application is idle. You also need to configure it according to your application characteristics.

The application needs to return the connection after finishing using it. It is recommended that the application uses the corresponding connection pool monitoring (such as **metricRegistry**) to locate connection pool issues in time.

4.4.4.1.2 Probe configuration

The connection pool maintains persistent connections from clients to TiDB as follows:

- Before v5.4, TiDB does not proactively close client connections by default (unless an error is reported).
- Starting from v5.4, TiDB automatically closes client connections after `28800` seconds (this is, `8` hours) of inactivity by default. You can control this timeout setting using the TiDB and MySQL compatible `wait_timeout` variable. For more information, see JDBC Query Timeout.

Moreover, there might be network proxies such as LVS or HAProxy between clients and TiDB. These proxies typically proactively clean up connections after a specific idle period (determined by the proxy's idle configuration). In addition to monitoring the proxy's idle configuration, connection pools also need to maintain or probe connections for keep-alive.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time.
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections.

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

4.4.4.1.3 Formulas based on experience

According to the About Pool Sizing article of HikariCP, if you have no idea about how to set a proper size for the database connection pool, you can get started with a formula based on experience. Then, based on the performance result of the pool size calculated from the formula, you can further adjust the size to achieve the best performance.

The formula based on experience is as follows:

```
connections = ((core_count * 2) + effective_spindle_count)
```

The description of each parameter in the formula is as follows:

- **connections**: the size of connections obtained.
- **core_count**: the number of CPU cores.
- **effective_spindle_count**: the number of hard drives (not SSD). Because each spinning hard disk can be called a spindle. For example, if you are using a server with a RAID of 16 disks, the **effective_spindle_count** should be 16. Because **HDD** usually can handle only one request at a time, the formula here is actually measuring how many concurrent I/O requests your server can manage.

In particular, pay attention to the following note below the formula.

```
A formula which has held up pretty well across a lot of
    ↪ benchmarks for years is
that for optimal throughput the number of active connections
    ↪ should be somewhere
near ((core_count * 2) + effective_spindle_count). Core count
    ↪ should not include
HT threads, even if hyperthreading is enabled. Effective
    ↪ spindle count is zero if
the active data set is fully cached, and approaches the actual
    ↪ number of spindles
as the cache hit rate falls. ... There hasn't been any analysis
    ↪  so far regarding
how well the formula works with SSDs.
```

This note indicates that:

- **core_count** is the number of physical cores, regardless of whether you enable Hyper-Threading or not.

- When data is fully cached, you need to set **effective_spindle_count** to `0`. As the hit rate of cache decreases, the count is closer to the actual number of `HDD`.
- **Whether the formula works for *SSD* is not tested and unknown.**

When using SSDs, it is recommended that you use the following formula based on experience instead:

```
connections = (number of cores * 4)
```

Therefore, you can set the maximum connection size of the initial connection pool to `cores * 4` in the case of SSDs and further adjust the size to tune the performance.

4.4.4.1.4 Tuning direction

As you can see, a size calculated from the formulas based on experience is just a recommended base value. To get the optimal size on a specific machine, you need to try other values around the base value and test the performance.

Here are some basic rules to help you get the optimal size:

- If your network or storage latency is high, increase your maximum number of connections to reduce the latency waiting time. Once a thread is blocked by latency, other threads can take over and continue processing.
- If you have multiple services deployed on your server and each service has a separate connection pool, consider the sum of the maximum number of connections to all connection pools.

4.4.4.2 Connection parameters

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

4.4.4.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

> **Note:**
>
> In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.
>
> If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and saves them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time and waits until the client's memory is ready and it requests for the next batch.

The following two processing methods are usually used in JDBC:

- The first method: Set **FetchSize** to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

  When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection. Ensure that you have called .close()on any active streaming result sets before attempting more queries.` is returned.

To avoid such an error in queries before the client finishes reading or closes `resultset` ↪ , you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- The second method: Use Cursor Fetch by first setting `FetchSize` as a positive integer and then configuring `useCursorFetch = true` in the JDBC URL.

TiDB supports both methods, but it is recommended that you use the first method that sets `FetchSize` to `Integer.MIN_VALUE`, because it is a simpler implementation and has better execution efficiency.

For the second method, TiDB first loads all data to the TiDB node, and then returns data to the client according to the `FetchSize`. Therefore, it usually consumes more memory than the first method. If `tidb_enable_tmp_storage_on_oom` is set to `ON`, TiDB might temporarily write the result to the hard disk.

If the `tidb_enable_lazy_cursor_fetch` system variable is set to `ON`, TiDB tries to read part of the data only when the client fetches it, which uses less memory. For more details and limitations, read the complete descriptions for the `tidb_enable_lazy_cursor_fetch` system variable.

4.4.4.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

- **useServerPrepStmts**

  useServerPrepStmts is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

  To verify that this setting already takes effect, you can do:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

- **cachePrepStmts**

  Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

  To verify that this setting already takes effect, you can do:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

  In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

- **prepStmtCacheSqlLimit**

  After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` ↪ configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

  The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

  You need to check whether this setting is too small if you:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - And find that `cachePrepStmts=true` has been configured, but `COM_STMT_` ↪ `PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

- **prepStmtCacheSize**

  prepStmtCacheSize controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

  To verify that this setting already takes effect, you can do:

  - Go to TiDB monitoring dashboard and view the request command type through **Query Summary** > **CPS By Instance**.
  - If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare("INSERT INTO `t` (a) values(?)");
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
INSERT INTO `t` (`a`) VALUES(10);
INSERT INTO `t` (`a`) VALUES(11);
INSERT INTO `t` (`a`) VALUES(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
INSERT INTO `t` (`a`) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
INSERT INTO `t` (`a`) VALUES (10) ON DUPLICATE KEY UPDATE `a` = 10;
INSERT INTO `t` (`a`) VALUES (11) ON DUPLICATE KEY UPDATE `a` = 11;
INSERT INTO `t` (`a`) VALUES (12) ON DUPLICATE KEY UPDATE `a` = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
INSERT INTO `t` (`a`) VALUES (10) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
INSERT INTO `t` (`a`) VALUES (11) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
INSERT INTO `t` (`a`) VALUES (12) ON DUPLICATE KEY UPDATE `a` = VALUES(`a`)
    ↪ ;
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
INSERT INTO `t` (`a`) VALUES (10), (11), (12) ON DUPLICATE KEY UPDATE a =
    ↪ VALUES(`a`);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
UPDATE `t` SET `a` = 10 WHERE `id` = 1; UPDATE `t` SET `a` = 11 WHERE `id`
    ↪ = 2; UPDATE `t` SET `a` = 12 WHERE `id` = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements=true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` includes a group of configurations. To get the detailed configurations in MySQL Connector/J 8.0 and those in MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively.

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters to control the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. Since TiDB v5.4, the default value of `wait_timeout` is `28800` seconds, which is 8 hours. For TiDB versions earlier than v5.4, the default value is `0`, which means the timeout is unlimited. The default value of `max_execution_time` is `0`, which means the maximum execution time of a SQL statement is unlimited.

The default value of `wait_timeout` is relatively large. In scenarios where a transaction starts but is neither committed nor rolled back, you might need a finer-grained control and a shorter timeout to prevent prolonged lock holding. In this case, you can use `tidb_idle_transaction_timeout` (introduced in TiDB v7.6.0) to control the idle timeout for transactions in a user session.

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables=wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

4.5 Design Database Schema

4.5.1 TiDB Database Schema Design Overview

This document provides the basics of TiDB database schema design, including the objects in TiDB, access control, database schema changes, and object limitations.

In the subsequent documents, Bookshop will be taken as an example to show you how to design a database and perform data read and write operations in a database.

4.5.1.1 Objects in TiDB

To distinguish some general terms, here is a brief agreement on the terms used in TiDB:

- To avoid confusion with the generic term database, **database** in this document refers to a logical object, **TiDB** refers to TiDB itself, and **cluster** refers to a deployed instance of TiDB.
- TiDB uses MySQL-compatible syntax, in which **schema** means the generic term schema instead of a logical object in a database. For more information, see MySQL documentation. Make sure that you note this difference if you are migrating from databases that have schemas as logical objects (for example, PostgreSQL, Oracle, and Microsoft SQL Server).

4.5.1.1.1 Database

A database in TiDB is a collection of objects such as tables and indexes.

TiDB comes with a default database named `test`. However, it is recommended that you create your own database instead of using the `test` database.

4.5.1.1.2 Table

A table is a collection of related data in a database.

Each table consists of **rows** and **columns**. Each value in a row belongs to a specific **column**. Each column allows only a single data type. To further qualify columns, you can add some constraints. To accelerate calculations, you can add generated columns.

4.5.1.1.3 Index

An index is a copy of selected columns in a table. You can create an index using one or more columns of a table. With indexes, TiDB can quickly locate data without having to search every row in a table every time, which greatly improves your query performance.

There are two common types of indexes:

- **Primary Key**: indexes on the primary key column.
- **Secondary Index**: indexes on non-primary key columns.

> **Note:**
>
> In TiDB, the default definition of **Primary Key** is different from that in InnoDB (a common storage engine of MySQL).
>
> - In InnoDB, the definition of **Primary Key** is unique, not null, and a **clustered index**.
> - In TiDB, the definition of **Primary Key** is unique and not null. But the primary key is not guaranteed to be a **clustered index**. To specify whether the primary key is a clustered index, you can add non-reserved keywords `CLUSTERED` or `NONCLUSTERED` after `PRIMARY KEY` in a `CREATE TABLE` statement. If a statement does not explicitly specify these keywords, the default behavior is controlled by the system variable `@@global.tidb_enable_clustered_index`. For more information, see Clustered Indexes.

Specialized indexes

To improve query performance of various user scenarios, TiDB provides you with some specialized types of indexes. For details of each type, see Indexing and constraints.

4.5.1.1.4 Other supported logical objects

TiDB supports the following logical objects at the same level as **table**:

- View: a view acts as a virtual table, whose schema is defined by the `SELECT` statement that creates the view.
- Sequence: a sequence generates and stores sequential data.
- Temporary table: a table whose data is not persistent.

4.5.1.2 Access Control

TiDB supports both user-based and role-based access control. To allow users to view, modify, or delete data objects and data schemas, you can either grant privileges to users directly or grant privileges to users through roles.

4.5.1.3 Database schema changes

As a best practice, it is recommended that you use a MySQL client or a GUI client instead of a driver or ORM to execute database schema changes.

4.5.1.4 Object limitations

For more information, see TiDB Limitations.

4.5.1.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.5.2 Create a Database

This document describes how to create a database using SQL and various programming languages and lists the rules of database creation. In this document, the Bookshop application is taken as an example to walk you through the steps of database creation.

4.5.2.1 Before you start

Before creating a database, do the following:

- Build a TiDB Cloud Serverless Cluster.
- Read Schema Design Overview.

4.5.2.2 What is database

Database objects in TiDB contain **tables**, **views**, **sequences**, and other objects.

4.5.2.3 Create databases

To create a database, you can use the `CREATE DATABASE` statement.

For example, to create a database named `bookshop` if it does not exist, use the following statement:

```
CREATE DATABASE IF NOT EXISTS `bookshop`;
```

For more information and examples of the `CREATE DATABASE` statement, see the `CREATE DATABASE` document.

To execute the library build statement as the `root` user, run the following command:

```
mysql
    -u root \
    -h {host} \
    -P {port} \
    -p {password} \
    -e "CREATE DATABASE IF NOT EXISTS bookshop;"
```

4.5.2.4 View databases

To view the databases in a cluster, use the `SHOW DATABASES` statement.

For example:

```
mysql
    -u root \
    -h {host} \
    -P {port} \
    -p {password} \
    -e "SHOW DATABASES;"
```

The following is an example output:

```
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| bookshop           |
| mysql              |
| test               |
+--------------------+
```

4.5.2.5 Rules in database creation

- Follow the Database Naming Conventions and name your database meaningfully.
- TiDB comes with a default database named `test`. However, it is not recommended that you use it in a production environment if you do not have to. You can create your own database using the `CREATE DATABASE` statement and change the current database using the `USE {databasename};` statement in a SQL session.
- Use the `root` user to create objects such as database, roles, and users. Grant only the necessary privileges to roles and users.
- As a best practice, it is recommended that you use a **MySQL command-line client** or a **MySQL GUI client** instead of a driver or ORM to execute database schema changes.

4.5.2.6 Next step

After creating a database, you can add **tables** to it. For more information, see Create a Table.

4.5.2.7 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.5.3 Create a Table

This document introduces how to create tables using the SQL statement and the related best practices. An example of the TiDB-based Bookshop application is provided to illustrate the best practices.

4.5.3.1 Before you start

Before reading this document, make sure that the following tasks are completed:

- Build a TiDB Cloud Serverless Cluster.
- Read Schema Design Overview.
- Create a Database.

4.5.3.2 What is a table

A table is a logical object in TiDB cluster that is subordinate to the database. It is used to store the data sent from SQL statements. Tables save data records in the form of rows and columns. A table has at least one column. If you have defined `n` columns, each row of data has exactly the same fields as the `n` columns.

4.5.3.3 Name a table

The first step for creating a table is to give your table a name. Do not use meaningless names that will cause great distress to yourself or your colleagues in the future. It is recommended that you follow your company or organization's table naming convention.

The `CREATE TABLE` statement usually takes the following form:

```
CREATE TABLE {table_name} ( {elements} );
```

Parameter description

- `{table_name}`: The name of the table to be created.
- `{elements}`: A comma-separated list of table elements, such as column definitions and primary key definitions.

Suppose you need to create a table to store the user information in the `bookshop` database.

Note that you cannot execute the following SQL statement yet because not a single column has been added.

```
CREATE TABLE `bookshop`.`users` (
);
```

4.5.3.4 Define columns

A **column** is subordinate to a table. Each table has at least one column. Columns provide a structure to a table by dividing the values in each row into small cells of a single data type.

Column definitions typically take the following form.

```
{column_name} {data_type} {column_qualification}
```

Parameter description

- `{column_name}`: The column name.
- `{data_type}`: The column data type.
- `{column_qualification}`: Column qualifications, such as **column-level constraints** or generated column clauses.

You can add some columns to the `users` table, such as the unique identifier `id`, `balance` and `nickname`.

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint,
  `nickname` varchar(100),
  `balance` decimal(15,2)
);
```

In the above statement, a field is defined with the name `id` and the type bigint. This is used to represent a unique user identifier. This means that all user identifiers should be of the `bigint` type.

Then, a field named `nickname` is defined, which is the varchar type, with a length limit of 100 characters. This means that the `nicknames` of the users use the `varchar` type and are not longer than 100 characters.

Finally, a field named `balance` is added, which is the decimal type, with a **precision** of `15` and a **scale** of `2`. **Precision** represents the total number of digits in the field, and **scale** represents the number of decimal places. For example, `decimal(5,2)` means a precision of `5` and a scale of `2`, with the range from `-999.99` to `999.99`. `decimal(6,1)` means a precision of `6` and a scale of `1`, with the range from `-99999.9` to `99999.9`. **decimal** is a fixed-point

types, which can be used to store numbers accurately. In scenarios where accurate numbers are needed (for example, user property-related), make sure that you use the **decimal** type.

TiDB supports many other column data types, including the integer types, floating-point types, fixed-point types, date and time types, and the enum type. You can refer to the supported column data types and use the **data types** that match the data you want to save in the database.

To make it a bit more complex, you can define a `books` table which will be the core of the `bookshop` data. The `books` table contains fields for the book's ids, titles, types (for example, magazine, novel, life, arts), stock, prices, and publication dates.

```
CREATE TABLE `bookshop`.`books` (
  `id` bigint NOT NULL,
  `title` varchar(100),
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports'),
  `published_at` datetime,
  `stock` int,
  `price` decimal(15,2)
);
```

This table contains more data types than the `users` table.

- int: It is recommended to use the type of right size to avoid using too much disk or even affecting performance (too large a type range) or data overflow (too small a data type range).
- datetime: The **datetime** type can be used to store time values.
- enum: The enum type can be used to store a limited selection of values.

4.5.3.5 Select primary key

A primary key is a column or a set of columns in a table whose values uniquely identify a row in the table.

> **Note:**
>
> The default definition of **primary key** in TiDB is different from that in InnoDB(the common storage engine of MySQL).
>
> - In **InnoDB**: A **primary key** is unique, not null, and **index clustered**.
> - In TiDB: A **primary key** is unique and is not null. But the primary key is not guaranteed to be a **clustered index**. Instead, another set of

> keywords `CLUSTERED` / `NONCLUSTERED` additionally controls whether the **primary key** is a **clustered index**. If the keyword is not specified, it is controlled by the system variable `@@global.tidb_enable_clustered_index`, as described in clustered indexes.

The **primary key** is defined in the `CREATE TABLE` statement. The primary key constraint requires that all constrained columns contain only non-NULL values.

A table can be created without a **primary key** or with a non-integer **primary key**. In this case, TiDB creates a `_tidb_rowid` as an **implicit primary key**. The implicit primary key `_tidb_rowid`, because of its monotonically increasing nature, might cause write hotspots in write-intensive scenarios. Therefore, if your application is write-intensive, consider sharding data using the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` parameters. However, this might lead to read amplification, so you need to make your own trade-off.

When the **primary key** of a table is an integer type and `AUTO_INCREMENT` is used, hotspots cannot be avoided by using `SHARD_ROW_ID_BITS`. If you need to avoid hotspots and do not need a continuous and incremental primary key, you can use `AUTO_RANDOM` instead of `AUTO_INCREMENT` to eliminate row ID continuity.

For more information on how to handle hotspot issues, refer to Troubleshoot Hotspot Issues.

Following the guidelines for selecting primary key, the following example shows how an `AUTO_RANDOM` primary key is defined in the `users` table.

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100),
  PRIMARY KEY (`id`)
);
```

4.5.3.6 Clustered or not

TiDB supports the clustered index feature since v5.0. This feature controls how data is stored in tables containing primary keys. It provides TiDB the ability to organize tables in a way that can improve the performance of certain queries.

The term clustered in this context refers to the organization of how data is stored and not a group of database servers working together. Some database management systems refer to clustered index tables as index-organized tables (IOT).

Currently, tables ***containing primary*** keys in TiDB are divided into the following two categories:

- `NONCLUSTERED`: The primary key of the table is non-clustered index. In tables with non-clustered indexes, the keys for row data consist of internal `_tidb_rowid` implicitly assigned by TiDB. Because primary keys are essentially unique indexes, tables with non-clustered indexes need at least two key-value pairs to store a row, which are:
    - `_tidb_rowid` (key) - row data (value)
    - Primary key data (key) - `_tidb_rowid` (value)
- `CLUSTERED`: The primary key of the table is clustered index. In tables with clustered indexes, the keys for row data consist of primary key data given by the user. Therefore, tables with clustered indexes need only one key-value pair to store a row, which is:
    - Primary key data (key) - row data (value)

As described in select primary key, **clustered indexes** are controlled in TiDB using the keywords `CLUSTERED` and `NONCLUSTERED`.

> **Note:**
>
> TiDB supports clustering only by a table's `PRIMARY KEY`. With clustered indexes enabled, the terms *the* `PRIMARY KEY` and *the clustered index* might be used interchangeably. `PRIMARY KEY` refers to the constraint (a logical property), and clustered index describes the physical implementation of how the data is stored.

Following the guidelines for selecting clustered index, the following example creates a table with an association between `books` and `users`, which represents the `ratings` of a `book` by `users`. The example creates the table and constructs a composite primary key using `book_id` and `user_id`, and creates a **clustered index** on that **primary key**.

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
  `score` tinyint,
  `rated_at` datetime,
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

4.5.3.7 Add column constraints

In addition to primary key constraints, TiDB also supports other **column constraints** such as NOT NULL constraint, UNIQUE KEY constraint, and `DEFAULT`. For complete constraints, refer to the TiDB constraints document.

4.5.3.7.1 Set default value

To set a default value on a column, use the `DEFAULT` constraint. The default value allows you to insert data without specifying a value for each column.

You can use `DEFAULT` together with supported SQL functions to move the calculation of defaults out of the application layer, thus saving resources of the application layer. The resources consumed by the calculation do not disappear and are moved to the TiDB cluster. Commonly, you can insert data with the default time. The following exemplifies setting the default value in the `ratings` table:

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
  `score` tinyint,
  `rated_at` datetime DEFAULT NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

In addition, if the current time is also filled in by default when the data is being updated, the following statements can be used (but only the current-time related expressions can be filled in after `ON UPDATE`):

```
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint,
  `user_id` bigint,
  `score` tinyint,
  `rated_at` datetime DEFAULT NOW() ON UPDATE NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED
);
```

For more information on default values of different data types, see default values.

4.5.3.7.2 Prevent duplicate values

If you need to prevent duplicate values in a column, you can use the `UNIQUE` constraint.

For example, to make sure that users' nicknames are unique, you can rewrite the table creation SQL statement for the `users` table like this:

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100) UNIQUE,
  PRIMARY KEY (`id`)
);
```

If you try to insert the same `nickname` in the `users` table, an error is returned.

4.5.3.7.3 Prevent null values

If you need to prevent null values in a column, you can use the `NOT NULL` constraint.

Take user nicknames as an example. To ensure that a nickname is not only unique but is also not null, you can rewrite the SQL statement for creating the `users` table as follows:

```
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM,
  `balance` decimal(15,2),
  `nickname` varchar(100) UNIQUE NOT NULL,
  PRIMARY KEY (`id`)
);
```

4.5.3.8 Use HTAP capabilities

> **Note:**
>
> The steps provided in this guide is ***ONLY*** for quick start in the test environment. For production environments, refer to explore HTAP.

Suppose that you want to perform OLAP analysis on the `ratings` table using the `bookshop` application, for example, to query **whether the rating of a book has a significant correlation with the time of the rating**, which is to analyze whether the user's rating of the book is objective or not. Then you need to query the `score` and `rated_at` fields of the entire `ratings` table. This operation is resource-intensive for an OLTP-only database. Or you can use some ETL or other data synchronization tools to export the data from the OLTP database to a dedicated OLAP database for analysis.

In this scenario, TiDB, an **HTAP (Hybrid Transactional and Analytical Processing)** database that supports both OLTP and OLAP scenarios, is an ideal one-stop database solution.

4.5.3.8.1 Replicate column-based data

Currently, TiDB supports two data analysis engines, **TiFlash** and **TiSpark**. For the large data scenarios (100 T), **TiFlash MPP** is recommended as the primary solution for HTAP, and **TiSpark** as a complementary solution.

To learn more about TiDB HTAP capabilities, refer to the following documents: Quick Start with TiDB HTAP and Explore HTAP.

In this example, TiFlash has been chosen as the data analysis engine for the `bookshop` database.

TiFlash does not automatically replicate data after deployment. Therefore, you need to manually specify the tables to be replicated:

```
ALTER TABLE {table_name} SET TIFLASH REPLICA {count};
```

Parameter description

- `{table_name}`: The table name.
- `{count}`: The number of replicated replicas. If it is 0, replicated replicas are deleted.

TiFlash will then replicate the table. When a query is performed, TiDB automatically selects TiKV (row-based) or TiFlash (column-based) for the query based on cost optimization. Alternatively, you can manually specify whether the query uses a **TiFlash** replica. To learn how to specify it, refer to Use TiDB to read TiFlash replicas.

4.5.3.8.2 An example of using HTAP capabilities

The `ratings` table opens `1` replica of TiFlash:

```
ALTER TABLE `bookshop`.`ratings` SET TIFLASH REPLICA 1;
```

> **Note:**
>
> If your cluster does not contain **TiFlash** nodes, this SQL statement will report an error: `1105 - the tiflash replica count: 1 should be less than the total tiflash server count: 0`. You can use Build a TiDB Cloud Serverless Cluster to create a TiDB Cloud Serverless cluster that includes **TiFlash**.

Then you can go on to perform the following query:

```
SELECT HOUR(`rated_at`), AVG(`score`) FROM `bookshop`.`ratings` GROUP BY
    ↪ HOUR(`rated_at`);
```

You can also execute the `EXPLAIN ANALYZE` statement to see whether this statement is using the **TiFlash**:

```
EXPLAIN ANALYZE SELECT HOUR(`rated_at`), AVG(`score`) FROM `bookshop`.`
    ↪ ratings` GROUP BY HOUR(`rated_at`);
```

Running results:

```

    ↪
```

When the field `cop[tiflash]` appears, it means that the task is sent to **TiFlash** for processing.

4.5.3.9 Execute the `CREATE TABLE` statement

After creating all the tables as above rules, our database initialization script should look like this. If you need to see the table information in detail, please refer to Description of the Tables.

To name the database initialization script `init.sql` and save it, you can execute the following statement to initialize the database.

```
mysql
    -u root \
    -h {host} \
    -P {port} \
    -p {password} \
    < init.sql
```

To view all tables under the `bookshop` database, use the `SHOW TABLES` statement.

```
SHOW TABLES IN `bookshop`;
```

Running results:

```
+--------------------+
| Tables_in_bookshop |
+--------------------+
| authors            |
| book_authors       |
| books              |
| orders             |
| ratings            |
| users              |
+--------------------+
```

4.5.3.10 Guidelines to follow when creating a table

This section provides guidelines you need to follow when creating a table.

4.5.3.10.1 Guidelines to follow when naming a table

- Use a **fully-qualified** table name (for example, `CREATE TABLE {database_name}.{table_name}`). If you do not specify the database name, TiDB uses the current database in your **SQL session**. If you do not use `USE {databasename};` to specify the database in your SQL session, TiDB returns an error.
- Use meaningful table names. For example, if you need to create a user table, you can use names: `user`, `t_user`,`users`, or follow your company or organization's naming convention. If your company or organization does not have a naming convention, you can refer to the table naming convention. Do not use such table names as: `t1`, `table1`.
- Multiple words are separated by an underscore, and it is recommended that the name is no more than 32 characters.
- Create a separate `DATABASE` for tables of different business modules and add comments accordingly.

4.5.3.10.2 Guidelines to follow when defining columns

- Check the data types supported by columns and organize your data according to the data type restrictions. Select the appropriate type for the data you plan to store in the column.
- Check the guidelines to follow for selecting primary keys and decide whether to use primary key columns.
- Check the guidelines to follow for selecting clustered indexes and decide whether to specify **clustered indexes**.
- Check adding column constraints and decide whether to add constraints to the columns.
- Use meaningful column names. It is recommended that you follow your company or organization's table naming convention. If your company or organization does not have a corresponding naming convention, refer to the column naming convention.

4.5.3.10.3 Guidelines to follow when selecting primary key

- Define a **primary key** or **unique index** within the table.
- Try to select meaningful **columns** as **primary keys**.
- For performance reasons, try to avoid storing extra-wide tables. It is not recommended that the number of table fields is over `60` and that the total data size of a single row is over `64K`. It is recommended to split fields with too much data length to another table.
- It is not recommended to use complex data types.
- For the fields to be joined, ensure that the data types are consistent and avoid implicit conversion.
- Avoid defining **primary keys** on a single monotonic data column. If you use a single monotonic data column (for example, a column with the `AUTO_INCREMENT` attribute) to define the **primary key**, it might impact the write performance. If possible, use `AUTO_RANDOM` instead of `AUTO_INCREMENT`, which discards the continuous and incremental attribute of the primary key.

- If you really need to create an index on a single monotonic data column at write-intensive scenarios, instead of defining this monotonic data column as the **primary key**, you can use `AUTO_RANDOM` to create the **primary key** for that table, or use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` to shard `_tidb_rowid`.

4.5.3.10.4 Guidelines to follow when selecting clustered index

- Follow guidelines for selecting primary key to build **clustered indexes**.
- Compared to tables with non-clustered indexes, tables with clustered indexes offer greater performance and throughput advantages in the following scenarios:
  - When data is inserted, the clustered index reduces one write of the index data from the network.
  - When a query with an equivalent condition only involves the primary key, the clustered index reduces one read of index data from the network.
  - When a query with a range condition only involves the primary key, the clustered index reduces multiple reads of index data from the network.
  - When a query with an equivalent or range condition only involves the primary key prefix, the clustered index reduces multiple reads of index data from the network.
- On the other hand, tables with clustered indexes might have the following issues:
  - There might be write hotspot issues when you insert a large number of primary keys with close values. Follow the guidelines to follow when selecting primary key.
  - The table data takes up more storage space if the data type of the primary key is larger than 64 bits, especially when there are multiple secondary indexes.
- To control the default behavior of whether to use clustered indexes, you can explicitly specify whether to use clustered indexes instead of using the system variable `@@global.tidb_enable_clustered_index` and the configuration `alter-primary-key`.

4.5.3.10.5 Guidelines to follow when executing the `CREATE TABLE` statement

- It is not recommended to use a client-side Driver or ORM to perform database schema changes. It is recommended to use a MySQL client or use a GUI client to perform database schema changes. In this document, the **MySQL client** is used to pass in SQL files to perform database schema changes in most scenarios.
- Follow the SQL development specification for creating and deleting tables. It is recommended to wrap the build and delete statements inside the business application to add judgment logic.

4.5.3.11 One more step

Note that all the tables that have been created in this document do not contain secondary indexes. For a guide to add secondary indexes, refer to Creating Secondary Indexes.

4.5.3.12 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.5.4 Create a Secondary Index

This document describes how to create a secondary index using SQL and various programming languages and lists the rules of index creation. In this document, the Bookshop application is taken as an example to walk you through the steps of secondary index creation.

4.5.4.1 Before you start

Before creating a secondary index, do the following:

- Build a TiDB Cloud Serverless Cluster.
- Read Schema Design Overview.
- Create a Database.
- Create a Table.

4.5.4.2 What is secondary index

A secondary index is a logical object in a TiDB cluster. You can simply regard it as a sorting type of data that TiDB uses to improve the query performance. In TiDB, creating a secondary index is an online operation, which does not block any data read and write operations on a table. For each index, TiDB creates references for each row in a table and sorts the references by selected columns instead of by data directly.

For more information about secondary indexes, see Secondary Indexes.

In TiDB, you can either add a secondary index to an existing table or create a secondary index when creating a new table.

4.5.4.3 Add a secondary index to an existing table

To add a secondary index to an existing table, you can use the CREATE INDEX statement as follows:

```
CREATE INDEX {index_name} ON {table_name} ({column_names});
```

Parameter description:

- `{index_name}`: the name of a secondary index.
- `{table_name}`: the table name.
- `{column_names}`: the names of the columns to be indexed, separated by semi-colon commas.

4.5.4.4 Create a secondary index when creating a new table

To create a secondary index at the same time as table creation, you can add a clause containing the `KEY` keyword to the end of the CREATE TABLE statement:

```
KEY `{index_name}` (`{column_names}`)
```

Parameter description:

- `{index_name}`: the name of a secondary index.
- `{column_names}`: the names of the columns to be indexed, separated by semi-colon commas.

4.5.4.5 Rules in secondary index creation

See Best Practices for Indexing.

4.5.4.6 Example

Suppose you want the `bookshop` application to support **searching for all books published in a given year**.

The fields in the `books` table are as follows:

Field name	Type	Field description
id	bigint	Unique ID of the book
title	varchar(100)	Book title
type	enum	Types of books (for example, magazines, animations, and teaching aids)
stock	bigint	Stock
price	decimal(15,2)	Price
published_at	datetime	Date of publishing

The `books` table is created using the following SQL statement:

```
CREATE TABLE `bookshop`.`books` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

To support the searching by year feature, you need to write a SQL statement to **search for all books published in a given year**. Taking 2022 as an example, write a SQL statement as follows:

```
SELECT * FROM `bookshop`.`books` WHERE `published_at` >= '2022-01-01
    ↪ 00:00:00' AND `published_at` < '2023-01-01 00:00:00';
```

To check the execution plan of the SQL statement, you can use the `EXPLAIN` statement.

```
EXPLAIN SELECT * FROM `bookshop`.`books` WHERE `published_at` >= '
    ↪ 2022-01-01 00:00:00' AND `published_at` < '2023-01-01 00:00:00';
```

The following is an example output of the execution plan:

```
+------------------------+----------+-----------+---------------+----------------------
    ↪
| id                     | estRows | task      | access object | operator info
    ↪
    ↪ |
+------------------------+----------+-----------+---------------+----------------------
    ↪
| TableReader_7          | 346.32  | root      |               | data:Selection_6
    ↪
    ↪ |
|  ─Selection_6          | 346.32  | cop[tikv] |               | ge(bookshop.
    ↪ books.published_at, 2022-01-01 00:00:00.000000), lt(bookshop.books.
    ↪ published_at, 2023-01-01 00:00:00.000000) |
|    ─TableFullScan_5    | 20000.00 | cop[tikv] | table:books | keep order:
    ↪ false
    ↪
    ↪ |
+------------------------+----------+-----------+---------------+----------------------
    ↪
3 rows in set (0.61 sec)
```

In the example output, **TableFullScan** is displayed in the `id` column, which means that TiDB is ready to do a full table scan on the `books` table in this query. In the case of a large amount of data, however, a full table scan might be quite slow and cause a fatal impact.

To avoid such impact, you can add an index for the `published_at` column to the `books` table as follows:

```
CREATE INDEX `idx_book_published_at` ON `bookshop`.`books` (`bookshop`.`
    ↪ books`.`published_at`);
```

After adding the index, execute the `EXPLAIN` statement again to check the execution plan.

The following is an example output.

```
+------------------------------+---------+-----------+------------------------------
   ↪
| id                           | estRows | task      | access object
   ↪                                      | operator info
   ↪                                                  |
+------------------------------+---------+-----------+------------------------------
   ↪
| IndexLookUp_10               | 146.01 | root      |
   ↪                                                        |
   ↪                                                                 |
|  ─IndexRangeScan_8(Build)  | 146.01 | cop[tikv] | table:books, index:idx_
   ↪ book_published_at(published_at) | range:[2022-01-01
   ↪ 00:00:00,2023-01-01 00:00:00), keep order:false |
|  ─TableRowIDScan_9(Probe)  | 146.01 | cop[tikv] | table:books
   ↪                                      | keep order:false
   ↪                                            |
+------------------------------+---------+-----------+------------------------------
   ↪
3 rows in set (0.18 sec)
```

In the output, **IndexRangeScan** is displayed instead of **TableFullScan**, which means that TiDB is ready to use indexes to do this query.

The words such as **TableFullScan** and **IndexRangeScan** in the execution plan are operators in TiDB. For more information about execution plans and operators, see TiDB Query Execution Plan Overview.

The execution plan does not return the same operator every time. This is because TiDB uses a **Cost-Based Optimization (CBO)** approach, in which an execution plan depends on both rules and data distribution. For more information about TiDB SQL performance, see SQL Tuning Overview.

> **Note:**
>
> TiDB also supports explicit use of indexes when querying, and you can use Optimizer Hints or SQL Plan Management (SPM) to artificially control the use of indexes. But if you do not know well about indexes, optimizer hints, or SPM, **DO NOT** use this feature to avoid any unexpected results.

To query the indexes on a table, you can use the SHOW INDEXES statement:

```
SHOW INDEXES FROM `bookshop`.`books`;
```

The following is an example output:

```
+-------+------------+----------------------+-------------+-------------+-----------+
   ↪
| Table | Non_unique | Key_name             | Seq_in_index | Column_name |
   ↪ Collation | Cardinality | Sub_part | Packed | Null | Index_type |
   ↪ Comment | Index_comment | Visible | Expression | Clustered |
+-------+------------+----------------------+-------------+-------------+-----------+
   ↪
| books |          0 | PRIMARY              |            1 | id          | A
   ↪         |           0 |     NULL | NULL |      | BTREE     |         |
   ↪               | YES     | NULL       | YES       |
| books |          1 | idx_book_published_at |            1 | published_at | A
   ↪      |           0 |     NULL | NULL |      | BTREE     |         |
   ↪               | YES     | NULL       | NO        |
+-------+------------+----------------------+-------------+-------------+-----------+
   ↪
2 rows in set (1.63 sec)
```

4.5.4.7 Next step

After creating a database and adding tables and secondary indexes to it, you can start adding the data write and read features to your application.

4.5.4.8 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.6 Write Data

4.6.1 Insert Data

This document describes how to insert data into TiDB by using the SQL language with different programming languages.

4.6.1.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cloud Serverless Cluster.
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes

4.6.1.2 Insert rows

There are two ways to insert multiple rows of data. For example, if you need to insert **3** players' data.

- A **multi-line insertion statement**:

```
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1), (2,
    ↪ 230, 2), (3, 300, 5);
```

- Multiple **single-line insertion statements**:

```
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (2, 230, 2);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (3, 300, 5);
```

Generally the `multi-line insertion statement` runs faster than the multiple `single ↪ -line insertion statements`.

```
CREATE TABLE `player` (`id` INT, `coins` INT, `goods` INT);
INSERT INTO `player` (`id`, `coins`, `goods`) VALUES (1, 1000, 1), (2, 230,
    ↪ 2);
```

For more information on how to use this SQL, see Connecting to a TiDB Cluster and follow the steps to enter the SQL statement after connecting to a TiDB cluster using a client.

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    connection.setAutoCommit(false);

    PreparedStatement pstmt = connection.prepareStatement("INSERT INTO
        ↪ player (id, coins, goods) VALUES (?, ?, ?)"))

    // first player
    pstmt.setInt(1, 1);
    pstmt.setInt(2, 1000);
    pstmt.setInt(3, 1);
    pstmt.addBatch();

    // second player
    pstmt.setInt(1, 2);
    pstmt.setInt(2, 230);
    pstmt.setInt(3, 2);
    pstmt.addBatch();

    pstmt.executeBatch();
```

```
    connection.commit();
} catch (SQLException e) {
    e.printStackTrace();
}
```

Due to the default MySQL JDBC Driver settings, you need to change some parameters to get better bulk insert performance.

Parameter	Means	Recommended Scenario	Recommended Configuration
`useServerPrepStmts` ↪	Whether to use the server side to enable prepared statements	When you need to use a prepared statement more than once	`true`
`cachePrepStmts` ↪	Whether the client caches prepared statements	`useServerPrepStmts=true`	`true`
`prepStmtCacheSqlLimit` ↪	Maximum size of a prepared statement (256 characters by default)	When the prepared statement is greater than 256 characters	Configured according to the actual size of the prepared statement
`prepStmtCacheSize` ↪	Maximum number of prepared statement caches (25 by default)	When the number of prepared statements is greater than 25	Configured according to the actual number of prepared statements
`rewriteBatchedStatements` ↪	Whether to rewrite **Batched** statements	When batch operations are required	`true`

Parameter	Means	Recommended Scenario	Recommended Configuration
`allowMultiQueries` ↪	Send batch operations	Because a client bug requires this to be set when `rewriteBatchedStatements = true` and `useServerPrepStmts = true`	`true`

MySQL JDBC Driver also provides an integrated configuration: `useConfigs`. When it is configured with `maxPerformance`, it is equivalent to configuring a set of configurations. Taking `mysql:mysql-connector-java:8.0.28` as an example, `useConfigs=maxPerformance` contains:

```
cachePrepStmts=true
cacheCallableStmts=true
cacheServerConfiguration=true
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
connectionAttributes=none
useInformationSchema=true
```

You can check `mysql-connector-java-{version}.jar!/com/mysql/cj/configurations` ↪ `/maxPerformance.properties` to get the configurations contained in `useConfigs=` ↪ `maxPerformance` for the corresponding version of MySQL JDBC Driver.

The following is a typical scenario of JDBC connection string configurations. In this example, Host: `127.0.0.1`, Port: `4000`, User name: `root`, Password: null, Default database: `test`:

```
jdbc:mysql://127.0.0.1:4000/test?user=root&useConfigs=maxPerformance&
    ↪ useServerPrepStmts=true&prepStmtCacheSqlLimit=2048&prepStmtCacheSize
    ↪ =256&rewriteBatchedStatements=true&allowMultiQueries=true
```

For complete examples in Java, see:

- Connect to TiDB with JDBC
- Connect to TiDB with Hibernate
- Connect to TiDB with Spring Boot

```
package main

import (
    "database/sql"
    "strings"
```

```
    _ "github.com/go-sql-driver/mysql"
)

type Player struct {
    ID   string
    Coins int
    Goods int
}

func bulkInsertPlayers(db *sql.DB, players []Player, batchSize int) error {
    tx, err := db.Begin()
    if err != nil {
        return err
    }

    stmt, err := tx.Prepare(buildBulkInsertSQL(batchSize))
    if err != nil {
        return err
    }

    defer stmt.Close()

    for len(players) > batchSize {
        if _, err := stmt.Exec(playerToArgs(players[:batchSize])...); err !=
            ↪ nil {
            tx.Rollback()
            return err
        }

        players = players[batchSize:]
    }

    if len(players) != 0 {
        if _, err := tx.Exec(buildBulkInsertSQL(len(players)), playerToArgs(
            ↪ players)...); err != nil {
            tx.Rollback()
            return err
        }
    }

    if err := tx.Commit(); err != nil {
        tx.Rollback()
        return err
    }
```

```
    return nil
}

func playerToArgs(players []Player) []interface{} {
    var args []interface{}
    for _, player := range players {
        args = append(args, player.ID, player.Coins, player.Goods)
    }
    return args
}

func buildBulkInsertSQL(amount int) string {
    return "INSERT INTO player (id, coins, goods) VALUES (?, ?, ?)" +
        ↪ strings.Repeat(",(?,?,?)", amount-1)
}
```

For complete examples in Golang, see:

- Connect to TiDB with Go-MySQL-Driver
- Connect to TiDB with GORM

```
import MySQLdb
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)

with get_connection(autocommit=True) as connection:
    with connection.cursor() as cur:
        player_list = random_player(1919)
        for idx in range(0, len(player_list), 114):
            cur.executemany("INSERT INTO player (id, coins, goods) VALUES (%s
                ↪ , %s, %s)", player_list[idx:idx + 114])
```

- Connect to TiDB with MySQL Connector/Python
- Connect to TiDB with SQLAlchemy
- Connect to TiDB with peewee

4.6.1.3 Bulk-Insert

If you need to quickly import a large amount of data into a TiDB cluster, it is recommended that you use a range of tools provided by **PingCAP** for data migration. Using the `INSERT` statement is not the best way, because it is not efficient and requires to handle exceptions and other issues on your own.

The following are the recommended tools for bulk-insert:

- Data export: Dumpling. You can export MySQL or TiDB data to local or Amazon S3.

- Data import: TiDB Lightning. You can import **Dumpling** exported data, a **CSV** file, or Migrate Data from Amazon Aurora to TiDB. It also supports reading data from a local disk or Amazon S3 cloud disk.
- Data replication: TiDB Data Migration. You can replicate MySQL, MariaDB, and Amazon Aurora databases to TiDB. It also supports merging and migrating the sharded instances and tables from the source databases.
- Data backup and restore: Backup & Restore (BR). Compared to **Dumpling**, **BR** is more suitable for ***big data*** scenario.

4.6.1.4 Avoid hotspots

When designing a table, you need to consider if there is a large number of insert operations. If so, you need to avoid hotspots during table design. See the Select primary key section and follow the Rules when selecting primary key.

For more information on how to handle hotspot issues, see Troubleshoot Hotspot Issues.

4.6.1.5 Insert data to a table with the `AUTO_RANDOM` primary key

If the primary key of the table you insert has the `AUTO_RANDOM` attribute, then by default the primary key cannot be specified. For example, in the `bookshop` database, you can see that the `id` field of the `users` table contains the `AUTO_RANDOM` attribute.

In this case, you **cannot** use SQL like the following to insert:

```
INSERT INTO `bookshop`.`users` (`id`, `balance`, `nickname`) VALUES (1,
    ↪ 0.00, 'nicky');
```

An error will occur:

```
ERROR 8216 (HY000): Invalid auto random: Explicit insertion on auto_random
    ↪ column is disabled. Try to set @@allow_auto_random_explicit_insert =
    ↪ true.
```

It is not recommended to manually specify the `AUTO_RANDOM` column during insertion time.

There are two solutions to handle this error:

- (Recommended) Remove this column from the insert statement and use the `AUTO_RANDOM` value that TiDB initialized for you. This fits the semantics of `AUTO_RANDOM`.

```
INSERT INTO `bookshop`.`users` (`balance`, `nickname`) VALUES (0.00, '
    ↪ nicky');
```

- If you are sure that you ***must*** specify this column, then you can use the `SET` statement to allow the column of `AUTO_RANDOM` to be specified during insertion time by changing the user variable.

```
SET @@allow_auto_random_explicit_insert = true;
INSERT INTO `bookshop`.`users` (`id`, `balance`, `nickname`) VALUES
    ↪ (1, 0.00, 'nicky');
```

4.6.1.6 Use HTAP

In TiDB, HTAP capabilities save you from performing additional operations when inserting data. There is no additional insertion logic. TiDB automatically guarantees data consistency. All you need to do is turn on column-oriented replica synchronization after creating the table, and use the column-oriented replica to speed up your queries directly.

4.6.1.7 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.6.2 Update Data

This document describes how to use the following SQL statements to update the data in TiDB with various programming languages:

- UPDATE: Used to modify the data in the specified table.
- INSERT ON DUPLICATE KEY UPDATE: Used to insert data and update this data if there is a primary key or unique key conflict. It is **not recommended** to use this statement if there are multiple unique keys (including primary keys). This is because this statement updates the data once it detects any unique key (including primary key) conflict. When there are more than one row conflicts, it updates only one row.

4.6.2.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cloud Serverless Cluster.
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes.
- If you want to `UPDATE` data, you need to insert data first.

4.6.2.2 Use `UPDATE`

To update an existing row in a table, you need to use an `UPDATE` statement with a `WHERE` clause to filter the columns for updating.

> **Note:**
>
> If you need to update a large number of rows, for example, more than ten thousand, it is recommended that you do ***NOT*** doing a complete update at once, but rather updating a portion at a time iteratively until all rows are updated. You can write scripts or programs to loop this operation. See Bulk-update for details.

4.6.2.2.1 `UPDATE` SQL syntax

In SQL, the `UPDATE` statement is generally in the following form:

```
UPDATE {table} SET {update_column} = {update_value} WHERE {filter_column} =
    ↪ {filter_value}
```

Parameter Name	Description
`{table}`	Table Name
`{update_column}`	Column names to be updated
`{update_value}`	Column values to be updated
`{filter_column}`	Column names matching filters
`{filter_value}`	Column values matching filters

For detailed information, see UPDATE syntax.

4.6.2.2.2 `UPDATE` best practices

The following are some best practices for updating data:

- Always specify the `WHERE` clause in the `UPDATE` statement. If the `UPDATE` statement does not have a `WHERE` clause, TiDB will update ***ALL ROWS*** in the table.
- Use bulk-update when you need to update a large number of rows (for example, more than ten thousand). Because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default), too many data updates at once will result in holding locks for too long (pessimistic transactions) or cause conflicts (optimistic transactions).

4.6.2.2.3 `UPDATE` example

Suppose an author changes her name to **Helen Haruki**. You need to change the authors table. Assume that her unique `id` is **1**, and the filter should be: `id = 1`.

```
UPDATE `authors` SET `name` = "Helen Haruki" WHERE `id` = 1;
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    PreparedStatement pstmt = connection.prepareStatement("UPDATE `authors`
        ↪ SET `name` = ? WHERE `id` = ?");
    pstmt.setString(1, "Helen Haruki");
    pstmt.setInt(2, 1);
    pstmt.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.2.3 Use `INSERT ON DUPLICATE KEY UPDATE`

If you need to insert new data into a table, but if there are unique key (a primary key is also a unique key) conflicts, the first conflicted record will be updated. You can use `INSERT ... ON DUPLICATE KEY UPDATE ...` statement to insert or update.

4.6.2.3.1 `INSERT ON DUPLICATE KEY UPDATE` SQL Syntax

In SQL, the `INSERT ... ON DUPLICATE KEY UPDATE ...` statement is generally in the following form:

```
INSERT INTO {table} ({columns}) VALUES ({values})
    ON DUPLICATE KEY UPDATE {update_column} = {update_value};
```

Parameter Name	Description
{table}	Table name
{columns}	Column names to be inserted
{values}	Column values to be inserted
{update_column}	Column names to be updated
{update_value}	Column values to be updated

4.6.2.3.2 `INSERT ON DUPLICATE KEY UPDATE` best practices

- Use `INSERT ON DUPLICATE KEY UPDATE` only for a table with one unique key. This statement updates the data if any ***UNIQUE KEY*** (including the primary key) conflicts are detected. If there are more than one row of conflicts, only one row will

be updated. Therefore, it is not recommended to use the `INSERT ON DUPLICATE KEY UPDATE` statement in tables with multiple unique keys unless you can guarantee that there is only one row of conflict.
- Use this statement when you create data or update data.

4.6.2.3.3 `INSERT ON DUPLICATE KEY UPDATE` example

For example, you need to update the ratings table to include the user's ratings for the book. If the user has not yet rated the book, a new rating will be created. If the user has already rated it, his previous rating will be updated.

In the following example, the primary key is the joint primary keys of `book_id` and `user_id`. A user `user_id = 1` gives a rating of `5` to a book `book_id = 1000`.

```
INSERT INTO `ratings`
    (`book_id`, `user_id`, `score`, `rated_at`)
VALUES
    (1000, 1, 5, NOW())
ON DUPLICATE KEY UPDATE `score` = 5, `rated_at` = NOW();
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource

try (Connection connection = ds.getConnection()) {
    PreparedStatement p = connection.prepareStatement("INSERT INTO `ratings`
        ↪ (`book_id`, `user_id`, `score`, `rated_at`)
VALUES (?, ?, ?, NOW()) ON DUPLICATE KEY UPDATE `score` = ?, `rated_at` =
    ↪ NOW()");
    p.setInt(1, 1000);
    p.setInt(2, 1);
    p.setInt(3, 5);
    p.setInt(4, 5);
    p.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.2.4 Bulk-update

When you need to update multiple rows of data in a table, you can use `INSERT ON DUPLICATE KEY UPDATE` with the `WHERE` clause to filter the data that needs to be updated.

However, if you need to update a large number of rows (for example, more than ten thousand), it is recommended that you update the data iteratively, that is, updating only a portion of the data at each iteration until the update is complete. This is because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default). Too many data updates at once will result in holding locks for too long (pessimistic transactions, or

causing conflicts (optimistic transactions). You can use a loop in your program or script to complete the operation.

This section provides examples of writing scripts to handle iterative updates. This example shows how a combination of `SELECT` and `UPDATE` should be done to complete a bulk-update.

4.6.2.4.1 Write bulk-update loop

First, you should write a `SELECT` query in a loop of your application or script. The return value of this query can be used as the primary key for the rows that need to be updated. Note that when defining this `SELECT` query, you need to use the `WHERE` clause to filter the rows that need to be updated.

4.6.2.4.2 Example

Suppose that you have had a lot of book ratings from users on your `bookshop` website over the past year, but the original design of a 5-point scale has resulted in a lack of differentiation in book ratings. Most books are rated `3`. You decide to switch from a 5-point scale to a 10-point scale to differentiate ratings.

You need to multiply by `2` the data in the `ratings` table from the previous 5-point scale, and add a new column to the ratings table to indicate whether the rows have been updated. Using this column, you can filter out rows that have been updated in `SELECT`, which will prevent the script from crashing and updating the rows multiple times, resulting in unreasonable data.

For example, you create a column named `ten_point` with the data type BOOL as an identifier of whether it is a 10-point scale:

```
ALTER TABLE `bookshop`.`ratings` ADD COLUMN `ten_point` BOOL NOT NULL
    ↪ DEFAULT FALSE;
```

> **Note:**
>
> This bulk-update application uses the **DDL** statements to make schema changes to the data tables. All DDL change operations for TiDB are executed online. For more information, see ADD COLUMN.

In Golang, a bulk-update application is similar to the following:

```
package main

import (
    "database/sql"
```

```
    "fmt"
    _ "github.com/go-sql-driver/mysql"
    "strings"
    "time"
)

func main() {
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    bookID, userID := updateBatch(db, true, 0, 0)
    fmt.Println("first time batch update success")
    for {
        time.Sleep(time.Second)
        bookID, userID = updateBatch(db, false, bookID, userID)
        fmt.Printf("batch update success, [bookID] %d, [userID] %d\n", bookID
            ↪ , userID)
    }
}

// updateBatch select at most 1000 lines data to update score
func updateBatch(db *sql.DB, firstTime bool, lastBookID, lastUserID int64) (
    ↪ bookID, userID int64) {
    // select at most 1000 primary keys in five-point scale data
    var err error
    var rows *sql.Rows

    if firstTime {
        rows, err = db.Query("SELECT `book_id`, `user_id` FROM `bookshop`.`
            ↪ ratings` " +
            "WHERE `ten_point` != true ORDER BY `book_id`, `user_id` LIMIT
                ↪ 1000")
    } else {
        rows, err = db.Query("SELECT `book_id`, `user_id` FROM `bookshop`.`
            ↪ ratings` "+
            "WHERE `ten_point` != true AND `book_id` > ? AND `user_id` > ? "+
            "ORDER BY `book_id`, `user_id` LIMIT 1000", lastBookID,
                ↪ lastUserID)
    }

    if err != nil || rows == nil {
        panic(fmt.Errorf("error occurred or rows nil: %+v", err))
```

```
    }

    // joint all id with a list
    var idList []interface{}
    for rows.Next() {
        var tempBookID, tempUserID int64
        if err := rows.Scan(&tempBookID, &tempUserID); err != nil {
            panic(err)
        }
        idList = append(idList, tempBookID, tempUserID)
        bookID, userID = tempBookID, tempUserID
    }

    bulkUpdateSql := fmt.Sprintf("UPDATE `bookshop`.`ratings` SET `ten_point
        ↪ ` = true, "+
        "`score` = `score` * 2 WHERE (`book_id`, `user_id`) IN (%s)",
            ↪ placeHolder(len(idList)))
    db.Exec(bulkUpdateSql, idList...)

    return bookID, userID
}

// placeHolder format SQL place holder
func placeHolder(n int) string {
    holderList := make([]string, n/2, n/2)
    for i := range holderList {
        holderList[i] = "(?,?)"
    }
    return strings.Join(holderList, ",")
}
```

In each iteration, `SELECT` queries in order of the primary key. It selects primary key values for up to 1000 rows that have not been updated to the 10-point scale (`ten_point` is `false`). Each `SELECT` statement selects primary keys larger than the largest of the previous `SELECT` results to prevent duplication. Then, it uses bulk-update, multiples its `score` column by 2, and sets `ten_point` to `true`. The purpose of updating `ten_point` is to prevent the update application from repeatedly updating the same row in case of restart after crashing, which can cause data corruption. `time.Sleep(time.Second)` in each loop makes the update application pause for 1 second to prevent the update application from consuming too many hardware resources.

In Java (JDBC), a bulk-update application might be similar to the following:

Code:

```
package com.pingcap.bulkUpdate;
```

```
import com.mysql.cj.jdbc.MysqlDataSource;

import java.sql.*;
import java.util.LinkedList;
import java.util.List;
import java.util.concurrent.TimeUnit;

public class BatchUpdateExample {
    static class UpdateID {
        private Long bookID;
        private Long userID;

        public UpdateID(Long bookID, Long userID) {
            this.bookID = bookID;
            this.userID = userID;
        }

        public Long getBookID() {
            return bookID;
        }

        public void setBookID(Long bookID) {
            this.bookID = bookID;
        }

        public Long getUserID() {
            return userID;
        }

        public void setUserID(Long userID) {
            this.userID = userID;
        }

        @Override
        public String toString() {
            return "[bookID] " + bookID + ", [userID] " + userID ;
        }
    }

    public static void main(String[] args) throws InterruptedException {
        // Configure the example database connection.

        // Create a mysql data source instance.
        MysqlDataSource mysqlDataSource = new MysqlDataSource();
```

```
        // Set server name, port, database name, username and password.
        mysqlDataSource.setServerName("localhost");
        mysqlDataSource.setPortNumber(4000);
        mysqlDataSource.setDatabaseName("bookshop");
        mysqlDataSource.setUser("root");
        mysqlDataSource.setPassword("");

        UpdateID lastID = batchUpdate(mysqlDataSource, null);

        System.out.println("first time batch update success");
        while (true) {
            TimeUnit.SECONDS.sleep(1);
            lastID = batchUpdate(mysqlDataSource, lastID);
            System.out.println("batch update success, [lastID] " + lastID);
        }
    }

    public static UpdateID batchUpdate (MysqlDataSource ds, UpdateID lastID)
        ↪ {
        try (Connection connection = ds.getConnection()) {
            UpdateID updateID = null;

            PreparedStatement selectPs;

            if (lastID == null) {
                selectPs = connection.prepareStatement(
                        "SELECT `book_id`, `user_id` FROM `bookshop`.`ratings`
                            ↪ " +
                        "WHERE `ten_point` != true ORDER BY `book_id`, `user_id
                            ↪ ` LIMIT 1000");
            } else {
                selectPs = connection.prepareStatement(
                        "SELECT `book_id`, `user_id` FROM `bookshop`.`ratings`
                            ↪ "+
                            "WHERE `ten_point` != true AND `book_id` > ? AND `
                                ↪ user_id` > ? "+
                            "ORDER BY `book_id`, `user_id` LIMIT 1000");

                selectPs.setLong(1, lastID.getBookID());
                selectPs.setLong(2, lastID.getUserID());
            }

            List<Long> idList = new LinkedList<>();
            ResultSet res = selectPs.executeQuery();
            while (res.next()) {
```

```
                updateID = new UpdateID(
                        res.getLong("book_id"),
                        res.getLong("user_id")
                );
                idList.add(updateID.getBookID());
                idList.add(updateID.getUserID());
            }

            if (idList.isEmpty()) {
                System.out.println("no data should update");
                return null;
            }

            String updateSQL = "UPDATE `bookshop`.`ratings` SET `ten_point` =
                ↪ true, "+
                    "`score` = `score` * 2 WHERE (`book_id`, `user_id`) IN ("
                        ↪ +
                    placeHolder(idList.size() / 2) + ")";
            PreparedStatement updatePs = connection.prepareStatement(
                ↪ updateSQL);
            for (int i = 0; i < idList.size(); i++) {
                updatePs.setLong(i + 1, idList.get(i));
            }
            int count = updatePs.executeUpdate();
            System.out.println("update " + count + " data");

            return updateID;
        } catch (SQLException e) {
            e.printStackTrace();
        }

        return null;
    }

    public static String placeHolder(int n) {
        StringBuilder sb = new StringBuilder();
        for (int i = 0; i < n ; i++) {
            sb.append(i == 0 ? "(?,?)" : ",(?,?)");
        }

        return sb.toString();
    }
}
```

- `hibernate.cfg.xml` configuration:

```
<?xml version='1.0' encoding='utf-8'?>

        <property name="hibernate.show_sql">true</property>
        <property name="hibernate.format_sql">true</property>
    </session-factory>
</hibernate-configuration>
```

In each iteration, `SELECT` queries in order of the primary key. It selects primary key values for up to 1000 rows that have not been updated to the 10-point scale (`ten_point` is `false`). Each `SELECT` statement selects primary keys larger than the largest of the previous `SELECT` results to prevent duplication. Then, it uses bulk-update, multiples its `score` column by 2, and sets `ten_point` to `true`. The purpose of updating `ten_point` is to prevent the update application from repeatedly updating the same row in case of restart after crashing, which can cause data corruption. `TimeUnit.SECONDS.sleep(1);` in each loop makes the update application pause for 1 second to prevent the update application from consuming too many hardware resources.

4.6.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.6.3 Delete Data

This document describes how to use the DELETE SQL statement to delete the data in TiDB. If you need to periodically delete expired data, use the time to live feature.

4.6.3.1 Before you start

Before reading this document, you need to prepare the following:

- Build a TiDB Cloud Serverless Cluster
- Read Schema Design Overview, Create a Database, Create a Table, and Create Secondary Indexes
- Insert Data

4.6.3.2 SQL syntax

The `DELETE` statement is generally in the following form:

```
DELETE FROM {table} WHERE {filter}
```

Parameter Name	Description
`{table}`	Table name
`{filter}`	Matching conditions of the filter

This example only shows a simple use case of `DELETE`. For detailed information, see DELETE syntax.

4.6.3.3 Best practices

The following are some best practices to follow when you delete data:

- Always specify the `WHERE` clause in the `DELETE` statement. If the `WHERE` clause is not specified, TiDB will delete ***ALL ROWS*** in the table.

- Use bulk-delete when you delete a large number of rows (for example, more than ten thousand), because TiDB limits the size of a single transaction (txn-total-size-limit, 100 MB by default).

- If you delete all the data in a table, do not use the `DELETE` statement. Instead, use the `TRUNCATE` statement.
- For performance considerations, see Performance Considerations.
- In scenarios where large batches of data need to be deleted, Non-Transactional bulk-delete can significantly improve performance. However, this will lose the transactional of the deletion and therefore **CANNOT** be rolled back. Make sure that you select the correct operation.

4.6.3.4 Example

Suppose you find an application error within a specific time period and you need to delete all the data for the ratings within this period, for example, from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`. In this case, you can use the `SELECT` statement to check the number of records to be deleted.

```
SELECT COUNT(*) FROM `ratings` WHERE `rated_at` >= "2022-04-15 00:00:00"
    ↪ AND `rated_at` <= "2022-04-15 00:15:00";
```

If more than 10,000 records are returned, use Bulk-Delete to delete them.

If fewer than 10,000 records are returned, use the following example to delete them.

In SQL, the example is as follows:

```
DELETE FROM `ratings` WHERE `rated_at` >= "2022-04-15 00:00:00" AND `rated_
    ↪ at` <= "2022-04-15 00:15:00";
```

In Java, the example is as follows:

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource

try (Connection connection = ds.getConnection()) {
    String sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at` >= ? AND
        ↪  `rated_at` <= ?";
    PreparedStatement preparedStatement = connection.prepareStatement(sql);
    Calendar calendar = Calendar.getInstance();
    calendar.set(Calendar.MILLISECOND, 0);

    calendar.set(2022, Calendar.APRIL, 15, 0, 0, 0);
    preparedStatement.setTimestamp(1, new Timestamp(calendar.getTimeInMillis
        ↪ ()));

    calendar.set(2022, Calendar.APRIL, 15, 0, 15, 0);
    preparedStatement.setTimestamp(2, new Timestamp(calendar.getTimeInMillis
        ↪ ()));

    preparedStatement.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

In Golang, the example is as follows:

```
package main

import (
    "database/sql"
```

```
    "fmt"
    "time"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    startTime := time.Date(2022, 04, 15, 0, 0, 0, 0, time.UTC)
    endTime := time.Date(2022, 04, 15, 0, 15, 0, 0, time.UTC)

    bulkUpdateSql := fmt.Sprintf("DELETE FROM `bookshop`.`ratings` WHERE `
        ↪ rated_at` >= ? AND `rated_at` <= ?")
    result, err := db.Exec(bulkUpdateSql, startTime, endTime)
    if err != nil {
        panic(err)
    }
    _, err = result.RowsAffected()
    if err != nil {
        panic(err)
    }
}
```

In Python, the example is as follows:

```
import MySQLdb
import datetime
import time
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)
with connection:
    with connection.cursor() as cursor:
        start_time = datetime.datetime(2022, 4, 15)
        end_time = datetime.datetime(2022, 4, 15, 0, 15)
```

```
        delete_sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at` >= %s
            ↪  AND `rated_at` <= %s"
        affect_rows = cursor.execute(delete_sql, (start_time, end_time))
        print(f'delete {affect_rows} data')
```

The `rated_at` field is of the `DATETIME` type in Date and Time Types. You can assume that it is stored as a literal quantity in TiDB, independent of the time zone. On the other hand, the `TIMESTAMP` type stores a timestamp and thus displays a different time string in a different time zone.

> **Note:**
>
> Like MySQL, the `TIMESTAMP` data type is affected by the year 2038 problem. It is recommended to use the `DATETIME` type if you store values larger than 2038.

4.6.3.5 Performance considerations

4.6.3.5.1 TiDB GC mechanism

TiDB does not delete the data immediately after you run the `DELETE` statement. Instead, it marks the data as ready for deletion. Then it waits for TiDB GC (Garbage Collection) to clean up the outdated data. Therefore, the `DELETE` statement ***DOES NOT*** immediately reduce disk usage.

GC is triggered once every 10 minutes by default. Each GC calculates a time point called **safe_point**. Any data earlier than this time point will not be used again, so TiDB can safely clean it up.

For more information, see GC mechanism.

4.6.3.5.2 Update statistical information

TiDB uses statistical information to determine index selection. There is a high risk that the index is not correctly selected after a large volume of data is deleted. You can use manual collection to update the statistics. It provides the TiDB optimizer with more accurate statistical information for SQL performance optimization.

4.6.3.6 Bulk-delete

When you need to delete multiple rows of data from a table, you can choose the `DELETE` example and use the `WHERE` clause to filter the data that needs to be deleted.

However, if you need to delete a large number of rows (more than ten thousand), it is recommended that you delete the data in an iterative way, that is, deleting a portion of the

data at each iteration until the deletion is completed. This is because TiDB limits the size of a single transaction (`txn-total-size-limit`, 100 MB by default). You can use loops in your programs or scripts to perform such operations.

This section provides an example of writing a script to handle an iterative delete operation that demonstrates how you should do a combination of `SELECT` and `DELETE` to complete a bulk-delete.

4.6.3.6.1 Write a bulk-delete loop

You can write a `DELETE` statement in the loop of your application or script, use the `WHERE` clause to filter data, and use `LIMIT` to constrain the number of rows to be deleted in a single statement.

4.6.3.6.2 Bulk-delete example

Suppose you find an application error within a specific time period. You need to delete all the data for the rating within this period, for example, from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`, and more than 10,000 records are written in 15 minutes. You can perform as follows.

In Java, the bulk-delete example is as follows:

```
package com.pingcap.bulkDelete;

import com.mysql.cj.jdbc.MysqlDataSource;

import java.sql.*;
import java.util.*;
import java.util.concurrent.TimeUnit;

public class BatchDeleteExample
{
    public static void main(String[] args) throws InterruptedException {
        // Configure the example database connection.

        // Create a mysql data source instance.
        MysqlDataSource mysqlDataSource = new MysqlDataSource();

        // Set server name, port, database name, username and password.
        mysqlDataSource.setServerName("localhost");
        mysqlDataSource.setPortNumber(4000);
        mysqlDataSource.setDatabaseName("bookshop");
        mysqlDataSource.setUser("root");
        mysqlDataSource.setPassword("");

        while (true) {
```

```
            batchDelete(mysqlDataSource);
            TimeUnit.SECONDS.sleep(1);
        }
    }

    public static void batchDelete (MysqlDataSource ds) {
        try (Connection connection = ds.getConnection()) {
            String sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at`
                ↪ >= ? AND `rated_at` <= ? LIMIT 1000";
            PreparedStatement preparedStatement = connection.prepareStatement
                ↪ (sql);
            Calendar calendar = Calendar.getInstance();
            calendar.set(Calendar.MILLISECOND, 0);

            calendar.set(2022, Calendar.APRIL, 15, 0, 0, 0);
            preparedStatement.setTimestamp(1, new Timestamp(calendar.
                ↪ getTimeInMillis()));

            calendar.set(2022, Calendar.APRIL, 15, 0, 15, 0);
            preparedStatement.setTimestamp(2, new Timestamp(calendar.
                ↪ getTimeInMillis()));

            int count = preparedStatement.executeUpdate();
            System.out.println("delete " + count + " data");
        } catch (SQLException e) {
            e.printStackTrace();
        }
    }
}
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

In Golang, the bulk-delete example is as follows:

```
package main

import (
    "database/sql"
    "fmt"
    "time"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
```

```
    db, err := sql.Open("mysql", "root:@tcp(127.0.0.1:4000)/bookshop")
    if err != nil {
        panic(err)
    }
    defer db.Close()

    affectedRows := int64(-1)
    startTime := time.Date(2022, 04, 15, 0, 0, 0, 0, time.UTC)
    endTime := time.Date(2022, 04, 15, 0, 15, 0, 0, time.UTC)

    for affectedRows != 0 {
        affectedRows, err = deleteBatch(db, startTime, endTime)
        if err != nil {
            panic(err)
        }
    }
}

// deleteBatch delete at most 1000 lines per batch
func deleteBatch(db *sql.DB, startTime, endTime time.Time) (int64, error) {
    bulkUpdateSql := fmt.Sprintf("DELETE FROM `bookshop`.`ratings` WHERE `
        ↪ rated_at` >= ? AND `rated_at` <= ? LIMIT 1000")
    result, err := db.Exec(bulkUpdateSql, startTime, endTime)
    if err != nil {
        return -1, err
    }
    affectedRows, err := result.RowsAffected()
    if err != nil {
        return -1, err
    }

    fmt.Printf("delete %d data\n", affectedRows)
    return affectedRows, nil
}
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

In Python, the bulk-delete example is as follows:

```
import MySQLdb
import datetime
import time
connection = MySQLdb.connect(
    host="127.0.0.1",
    port=4000,
```

```
    user="root",
    password="",
    database="bookshop",
    autocommit=True
)
with connection:
    with connection.cursor() as cursor:
        start_time = datetime.datetime(2022, 4, 15)
        end_time = datetime.datetime(2022, 4, 15, 0, 15)
        affect_rows = -1
        while affect_rows != 0:
            delete_sql = "DELETE FROM `bookshop`.`ratings` WHERE `rated_at`
                ↪ >= %s AND `rated_at` <= %s LIMIT 1000"
            affect_rows = cursor.execute(delete_sql, (start_time, end_time))
            print(f'delete {affect_rows} data')
            time.sleep(1)
```

In each iteration, `DELETE` deletes up to 1000 rows from `2022-04-15 00:00:00` to `2022-04-15 00:15:00`.

4.6.3.7 Non-transactional bulk-delete

> **Note:**
>
> Since v6.1.0, TiDB supports the non-transactional DML statements. This feature is not available for versions earlier than TiDB v6.1.0.

4.6.3.7.1 Prerequisites of non-transactional bulk-delete

Before using the non-transactional bulk-delete, make sure you have read the Non-Transactional DML statements documentation first. The non-transactional bulk-delete improves the performance and ease of use in batch data processing scenarios but compromises transactional atomicity and isolation.

Therefore, you should use it carefully to avoid serious consequences (such as data loss) due to mishandling.

4.6.3.7.2 SQL syntax for non-transactional bulk-delete

The SQL syntax for non-transactional bulk-delete statement is as follows:

```
BATCH ON {shard_column} LIMIT {batch_size} {delete_statement};
```

Parameter Name	Description
{shard_column}	The column used to divide batches.
{batch_size}	Control the size of each batch.
{delete_statement}	The DELETE statement.

The preceding example only shows a simple use case of a non-transactional bulk-delete statement. For detailed information, see Non-transactional DML Statements.

4.6.3.7.3 Example of non-transactional bulk-delete

In the same scenario as the Bulk-delete example, the following SQL statement shows how to perform a non-transactional bulk-delete:

```
BATCH ON `rated_at` LIMIT 1000 DELETE FROM `ratings` WHERE `rated_at` >= "
    ↪ 2022-04-15 00:00:00" AND `rated_at` <= "2022-04-15 00:15:00";
```

4.6.3.8 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.6.4 Periodically Delete Expired Data Using TTL (Time to Live)

Time to live (TTL) is a feature that allows you to manage TiDB data lifetime at the row level. For a table with the TTL attribute, TiDB automatically checks data lifetime and deletes expired data at the row level. This feature can effectively save storage space and enhance performance in some scenarios.

The following are some common scenarios for TTL:

- Regularly delete verification codes and short URLs.
- Regularly delete unnecessary historical orders.
- Automatically delete intermediate results of calculations.

TTL is designed to help users clean up unnecessary data periodically and in a timely manner without affecting the online read and write workloads. TTL concurrently dispatches different jobs to different TiDB nodes to delete data in parallel in the unit of table. TTL does not guarantee that all expired data is deleted immediately, which means that even if some data is expired, the client might still read that data some time after the expiration time until that data is deleted by the background TTL job.

4.6.4.1 Syntax

You can configure the TTL attribute of a table using the CREATE TABLE or ALTER TABLE statement.

4.6.4.1.1 Create a table with a TTL attribute

- Create a table with a TTL attribute:

```
CREATE TABLE t1 (
    id int PRIMARY KEY,
    created_at TIMESTAMP
) TTL = `created_at` + INTERVAL 3 MONTH;
```

The preceding example creates a table `t1` and specifies `created_at` as the TTL timestamp column, which indicates the creation time of the data. The example also sets the longest time that a row is allowed to live in the table to 3 months through `INTERVAL 3 MONTH`. Data that lives longer than this value will be deleted later.

- Set the `TTL_ENABLE` attribute to enable or disable the feature of cleaning up expired data:

```
CREATE TABLE t1 (
    id int PRIMARY KEY,
    created_at TIMESTAMP
) TTL = `created_at` + INTERVAL 3 MONTH TTL_ENABLE = 'OFF';
```

If `TTL_ENABLE` is set to `OFF`, even if other TTL options are set, TiDB does not automatically clean up expired data in this table. For a table with the TTL attribute, `TTL_ENABLE` is `ON` by default.

- To be compatible with MySQL, you can set a TTL attribute using a comment:

```
CREATE TABLE t1 (
    id int PRIMARY KEY,
    created_at TIMESTAMP
) /*T![ttl] TTL = `created_at` + INTERVAL 3 MONTH TTL_ENABLE = 'OFF'
    ↪ */;
```

In TiDB, using the table TTL attribute or using comments to configure TTL is equivalent. In MySQL, the comment is ignored and an ordinary table is created.

4.6.4.1.2 Modify the TTL attribute of a table

- Modify the TTL attribute of a table:

```
ALTER TABLE t1 TTL = `created_at` + INTERVAL 1 MONTH;
```

You can use the preceding statement to modify a table with an existing TTL attribute or to add a TTL attribute to a table without a TTL attribute.

- Modify the value of `TTL_ENABLE` for a table with the TTL attribute:

```
ALTER TABLE t1 TTL_ENABLE = 'OFF';
```

- To remove all TTL attributes of a table:

```
ALTER TABLE t1 REMOVE TTL;
```

4.6.4.1.3 TTL and the default values of data types

You can use TTL together with default values of the data types. The following are two common usage examples:

- Use `DEFAULT CURRENT_TIMESTAMP` to specify the default value of a column as the current creation time and use this column as the TTL timestamp column. Records that were created 3 months ago are expired:

```
CREATE TABLE t1 (
    id int PRIMARY KEY,
    created_at TIMESTAMP DEFAULT CURRENT_TIMESTAMP
) TTL = `created_at` + INTERVAL 3 MONTH;
```

- Specify the default value of a column as the creation time or the latest update time and use this column as the TTL timestamp column. Records that have not been updated for 3 months are expired:

```
CREATE TABLE t1 (
    id int PRIMARY KEY,
    created_at TIMESTAMP DEFAULT CURRENT_TIMESTAMP ON UPDATE CURRENT_
        ↪ TIMESTAMP
) TTL = `created_at` + INTERVAL 3 MONTH;
```

4.6.4.1.4 TTL and generated columns

You can use TTL together with generated columns to configure complex expiration rules. For example:

```
CREATE TABLE message (
    id int PRIMARY KEY,
    created_at TIMESTAMP DEFAULT CURRENT_TIMESTAMP,
    image bool,
    expire_at TIMESTAMP AS (IF(image,
           created_at + INTERVAL 5 DAY,
           created_at + INTERVAL 30 DAY
    ))
) TTL = `expire_at` + INTERVAL 0 DAY;
```

The preceding statement uses the `expire_at` column as the TTL timestamp column and sets the expiration time according to the message type. If the message is an image, it expires in 5 days. Otherwise, it expires in 30 days.

You can use TTL together with the JSON type. For example:

```
CREATE TABLE orders (
    id INT NOT NULL AUTO_INCREMENT PRIMARY KEY,
    order_info JSON,
    created_at DATE AS (JSON_EXTRACT(order_info, '$.created_at')) VIRTUAL
) TTL = `created_at` + INTERVAL 3 month;
```

4.6.4.2 TTL job

For each table with a TTL attribute, TiDB internally schedules a background job to clean up expired data. You can customize the execution period of these jobs by setting the `TTL_JOB_INTERVAL` attribute for the table. The following example sets the background cleanup jobs for the table `orders` to run once every 24 hours:

```
ALTER TABLE orders TTL_JOB_INTERVAL = '24h';
```

`TTL_JOB_INTERVAL` is set to `1h` by default.

When executing a TTL job, TiDB will split the table into up to 64 tasks, with the Region being the smallest unit. These tasks will be executed distributedly. You can limit the number of concurrent TTL tasks across the entire cluster by setting the system variable `tidb_ttl_running_tasks`. However, not all TTL jobs for all kinds of tables can be split into tasks. For more details on which kinds of tables' TTL jobs cannot be split into tasks, refer to the Limitations section.

To disable the execution of TTL jobs, in addition to setting the `TTL_ENABLE='OFF'` table option, you can also disable the execution of TTL jobs in the entire cluster by setting the `tidb_ttl_job_enable` global variable:

```
SET @@global.tidb_ttl_job_enable = OFF;
```

In some scenarios, you might want to allow TTL jobs to run only in a certain time window. In this case, you can set the `tidb_ttl_job_schedule_window_start_time` and `tidb_ttl_job_schedule_window_end_time` global variables to specify the time window. For example:

```
SET @@global.tidb_ttl_job_schedule_window_start_time = '01:00 +0000';
SET @@global.tidb_ttl_job_schedule_window_end_time = '05:00 +0000';
```

The preceding statement allows TTL jobs to be scheduled only between 1:00 and 5:00 UTC. By default, the time window is set to `00:00 +0000` to `23:59 +0000`, which allows the jobs to be scheduled at any time.

4.6.4.3 Observability

TiDB collects runtime information about TTL periodically and provides visualized charts of these metrics in Grafana. You can see these metrics in the TiDB -> TTL panel in Grafana.

For details of the metrics, see the TTL section in TiDB Monitoring Metrics.

In addition, TiDB provides three tables to obtain more information about TTL jobs:

- The `mysql.tidb_ttl_table_status` table contains information about the previously executed TTL job and ongoing TTL job for all TTL tables

```
TABLE mysql.tidb_ttl_table_status LIMIT 1\G
```

```
*************************** 1. row ***************************
                  table_id: 85
             parent_table_id: 85
            table_statistics: NULL
                last_job_id: 0b4a6d50-3041-4664-9516-5525ee6d9f90
          last_job_start_time: 2023-02-15 20:43:46
         last_job_finish_time: 2023-02-15 20:44:46
          last_job_ttl_expire: 2023-02-15 19:43:46
             last_job_summary: {"total_rows":4369519,"success_rows
                ↪ ":4369519,"error_rows":0,"total_scan_task":64,"
                ↪ scheduled_scan_task":64,"finished_scan_task":64}
              current_job_id: NULL
        current_job_owner_id: NULL
      current_job_owner_addr: NULL
    current_job_owner_hb_time: NULL
       current_job_start_time: NULL
       current_job_ttl_expire: NULL
           current_job_state: NULL
          current_job_status: NULL
current_job_status_update_time: NULL
1 row in set (0.040 sec)
```

  The column `table_id` is the ID of the partitioned table, and the `parent_table_id` is the ID of the table, corresponding with the ID in `information_schema.tables`. If the table is not a partitioned table, the two IDs are the same.

  The columns `{last, current}_job_{start_time, finish_time, ttl_expire}` describe respectively the start time, finish time, and expiration time used by the TTL job of the last or current execution. The `last_job_summary` column describes the execution status of the last TTL task, including the total number of rows, the number of successful rows, and the number of failed rows.

- The `mysql.tidb_ttl_task` table contains information about the ongoing TTL subtasks. A TTL job is split into many subtasks, and this table records the subtasks that are currently being executed.

- The `mysql.tidb_ttl_job_history` table contains information about the TTL jobs that have been executed. The record of TTL job history is kept for 90 days.

```
TABLE mysql.tidb_ttl_job_history LIMIT 1\G
```

```
*************************** 1. row ***************************
         job_id: f221620c-ab84-4a28-9d24-b47ca2b5a301
       table_id: 85
  parent_table_id: 85
    table_schema: test_schema
      table_name: TestTable
   partition_name: NULL
     create_time: 2023-02-15 17:43:46
     finish_time: 2023-02-15 17:45:46
      ttl_expire: 2023-02-15 16:43:46
    summary_text: {"total_rows":9588419,"success_rows":9588419,"error_
       ↪ rows":0,"total_scan_task":63,"scheduled_scan_task":63,"
       ↪ finished_scan_task":63}
    expired_rows: 9588419
    deleted_rows: 9588419
error_delete_rows: 0
          status: finished
```

The column `table_id` is the ID of the partitioned table, and the `parent_table_id` is the ID of the table, corresponding with the ID in `information_schema.tables`. `table_schema`, `table_name`, and `partition_name` correspond to the database, table name, and partition name. `create_time`, `finish_time`, and `ttl_expire` indicate the creation time, end time, and expiration time of the TTL task. `expired_rows` and `deleted_rows` indicate the number of expired rows and the number of rows deleted successfully.

4.6.4.4 Compatibility with TiDB tools

TTL can be used with other TiDB migration, backup, and recovery tools.

Tool name	Minimum supported version	Description

Tool name	Minimum supported version	Description
Backup & Restore (BR)	v6.6.0	After you restore data using BR, the `TTL_ENABLE` attribute of the tables will be set to `OFF`. This prevents TiDB from immediately deleting expired data af-

Feature name	Description
FLASHBACK ↪ ↪ TABLE ↪	FLASHBACK ↪ ↪ TABLE ↪ will set the TTL_ ↪ ENABLE ↪ attribute of the tables to OFF. This prevents TiDB from immediately deleting expired data after the flashback. You need to manually turn on the TTL_ ↪ ENABLE ↪ attribute

Feature name	Description
FLASHBACK ↪ ↪ DATABASE ↪	FLASHBACK ↪ ↪ DATABASE ↪ will set the TTL_ ↪ ENABLE ↪ attribute of the tables to OFF, and the TTL_ ↪ ENABLE ↪ attribute will not be modified. This prevents TiDB from immediately deleting expired data after the flashback. You need to

Feature name	Description
FLASHBACK CLUSTER	FLASHBACK CLUSTER will set the system variable TIDB_TTL_JOB_ENABLE to OFF and do not change the value of the TTL_ENABLE attribute.

4.6.4.6 Limitations

Currently, the TTL feature has the following limitations:

- The TTL attribute cannot be set on temporary tables, including local temporary tables and global temporary tables.
- A table with the TTL attribute does not support being referenced by other tables as the primary table in a foreign key constraint.
- It is not guaranteed that all expired data is deleted immediately. The time when expired data is deleted depends on the scheduling interval and scheduling window of the background cleanup job.

- For tables that use clustered indexes, a TTL job can be split into multiple subtasks only in the following scenarios:
    - The first column of the primary key or composite primary key is of `INTEGER` or binary string types. The binary string types mainly refer to the following:
        - `CHAR(N)CHARACTER SET BINARY`
        - `VARCHAR(N)CHARACTER SET BINARY`
        - `BINARY(N)`
        - `VARBINARY(N)`
        - `BIT(N)`
    - The character set of the first column of the primary key or composite primary key is `utf8` or `utf8mb4`, and the collation is `utf8_bin`, `utf8mb4_bin`, or `utf8mb4_0900_bin`.
    - For tables where the character set type of the first column of the primary key is `utf8` or `utf8mb4`, subtasks are split only based on the range of visible ASCII characters. If many primary key values have the same ASCII prefix, it might cause uneven task splitting.
    - For tables that do not support splitting a TTL job into multiple subtasks, the TTL job will be executed sequentially on a single TiDB node. If the table contains a large amount of data, the execution of the TTL job might become slow.

4.6.4.7 FAQs

- How can I determine whether the deletion is fast enough to keep the data size relatively stable?

  In the Grafana `TiDB` dashboard, the panel `TTL Insert Rows Per Hour` records the total number of rows inserted in the previous hour. The corresponding `TTL Delete Rows Per Hour` records the total number of rows deleted by the TTL task in the previous hour. If `TTL Insert Rows Per Hour` is higher than `TTL Delete Rows Per Hour` for a long time, it means that the rate of insertion is higher than the rate of deletion and the total amount of data will increase. For example:

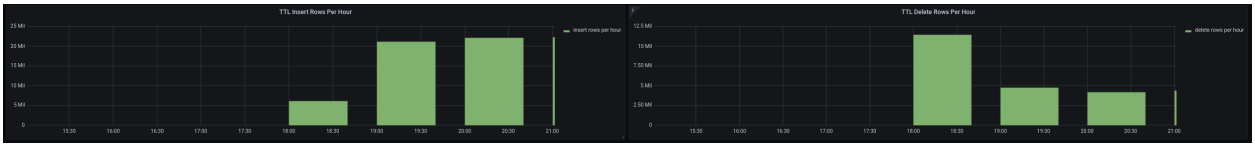

Figure 54: insert fast example

  It is worth noting that since TTL does not guarantee that the expired rows will be deleted immediately, and the rows currently inserted will be deleted in a future TTL task, even if the speed of TTL deletion is lower than the speed of insertion in a short period of time, it does not necessarily mean that the speed of TTL is too slow. You need to consider the situation in its context.

- How can I determine whether the bottleneck of a TTL task is in scanning or deleting?

  Look at the `TTL Scan Worker Time By Phase` and `TTL Delete Worker Time By Phase` panels. If the scan worker is in the `dispatch` phase for a large percentage of time and the delete worker is rarely in the `idle` phase, then the scan worker is waiting for the delete worker to finish the deletion. If the cluster resources are still free at this point, you can consider increasing `tidb_ttl_delete_worker_count` to increase the number of delete workers. For example:

Figure 55: scan fast example

  In contrast, if the scan worker is rarely in the `dispatch` phase and the delete worker is in the `idle` phase for a long time, then the scan worker is relatively busy. For example:

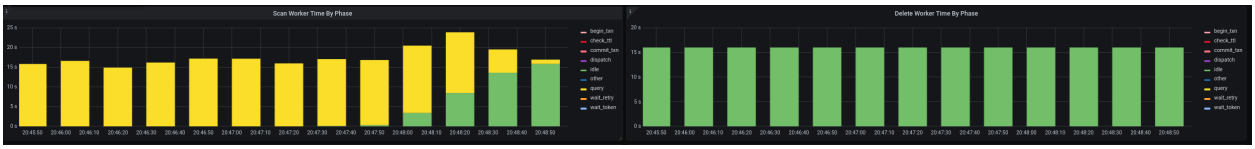

Figure 56: delete fast example

  The percentage of scan and delete in TTL jobs is related to the machine configuration and data distribution, so the monitoring data at each moment is only representative of the TTL Jobs being executed. You can read the table `mysql.tidb_ttl_job_history` to determine which TTL job is running at a certain moment and the corresponding table of the job.

- How to configure `tidb_ttl_scan_worker_count` and `tidb_ttl_delete_worker_count` properly?

  1. Refer to the question "How to determine whether the bottleneck of TTL tasks is in scanning or deleting?" to consider whether to increase the value of `tidb_ttl_scan_worker_count` or `tidb_ttl_delete_worker_count`.
  2. If the number of TiKV nodes is high, increase the value of `tidb_ttl_scan_worker_count` can make the TTL task workload more balanced.

Since too many TTL workers will cause a lot of pressure, you need to evaluate the CPU level of TiDB and the disk and CPU usage of TiKV together. Depending on different scenarios and needs (whether you need to speed up TTL as much as possible, or to reduce the impact of TTL on other queries), you can adjust the value of `tidb_ttl_scan_worker_count` and `tidb_ttl_delete_worker_count` to improve the speed of TTL scanning and deleting or reduce the performance impact brought by TTL tasks.

4.6.5 Prepared Statements

A prepared statement templatizes multiple SQL statements in which only parameters are different. It separates the SQL statements from the parameters. You can use it to improve the following aspects of SQL statements:

- **Security**: Because parameters and statements are separated, the risk of SQL injection attacks is avoided.
- **Performance**: Because the statement is parsed in advance on the TiDB server, only parameters are passed for subsequent executions, saving the cost of parsing the entire SQL statements, splicing SQL statement strings, and network transmission.

In most applications, SQL statements can be enumerated. You can use a limited number of SQL statements to complete data queries for the entire application. So using a prepared statement is a best practice.

4.6.5.1 SQL syntax

This section describes the SQL syntax for creating, running and deleting a prepared statement.

4.6.5.1.1 Create a prepared statement

```
PREPARE {prepared_statement_name} FROM '{prepared_statement_sql}';
```

Parameter Name	Description
`{prepared_statement_name}`	name of the prepared statement
`{prepared_statement_sql}`	the prepared statement SQL with a question mark as a placeholder

See PREPARE statement for more information.

4.6.5.1.2 Use the prepared statement

A prepared statement can only use **user variables** as parameters, so use the SET statement to set the variables before the EXECUTE statement can call the prepared statement.

```
SET @{parameter_name} = {parameter_value};
EXECUTE {prepared_statement_name} USING @{parameter_name};
```

Parameter Name	Description
{parameter_name}	user variable name
{parameter_value}	user variable value
{prepared_statement_name}	The name of the preprocessing statement, which must be the same as the name defined in the Create a prepared statement

See the EXECUTE statement for more information.

4.6.5.1.3 Delete the prepared statement

```
DEALLOCATE PREPARE {prepared_statement_name};
```

Parameter Name	Description
{prepared_statement_name}	The name of the preprocessing statement, which must be the same as the name defined in the Create a prepared statement

See the DEALLOCATE statement for more information.

4.6.5.2 Examples

This section describes two examples of prepared statements: SELECT data and INSERT data.

4.6.5.2.1 SELECT example

For example, you need to query a book with id = 1 in the bookshop application.

```
PREPARE `books_query` FROM 'SELECT * FROM `books` WHERE `id` = ?';
```

Running result:

```
Query OK, 0 rows affected (0.01 sec)
```

```
SET @id = 1;
```

Running result:

```
Query OK, 0 rows affected (0.04 sec)
```

```
EXECUTE `books_query` USING @id;
```

Running result:

```
+---------+-----------------------------------+--------+---------------------+-------+----
    ↪
| id      | title                             | type   | published_at        | stock |
    ↪ price |
+---------+-----------------------------------+--------+---------------------+-------+----
    ↪
| 1       | The Adventures of Pierce Wehner | Comics | 1904-06-06 20:46:25 |
    ↪ 586 | 411.66 |
+---------+-----------------------------------+--------+---------------------+-------+----
    ↪
1 row in set (0.05 sec)
```

```
// ds is an entity of com.mysql.cj.jdbc.MysqlDataSource
try (Connection connection = ds.getConnection()) {
    PreparedStatement preparedStatement = connection.prepareStatement("
        ↪ SELECT * FROM `books` WHERE `id` = ?");
    preparedStatement.setLong(1, 1);

    ResultSet res = preparedStatement.executeQuery();
    if(!res.next()) {
        System.out.println("No books in the table with id 1");
    } else {
        // got book's info, which id is 1
        System.out.println(res.getLong("id"));
        System.out.println(res.getString("title"));
        System.out.println(res.getString("type"));
    }
} catch (SQLException e) {
    e.printStackTrace();
}
```

4.6.5.2.2 INSERT example

Using the books table as an example, you need to insert a book with `title = TiDB ↪ Developer Guide`, `type = Science & Technology`, `stock = 100`, `price = 0.0`, and `published_at = NOW()` (current time of insertion). Note that you don't need to specify the `AUTO_RANDOM` attribute in the **primary key** of the `books` table. For more information about inserting data, see Insert Data.

```
PREPARE `books_insert` FROM 'INSERT INTO `books` (`title`, `type`, `stock`,
    ↪  `price`, `published_at`) VALUES (?, ?, ?, ?, ?);';
```

Running result:

```
Query OK, 0 rows affected (0.03 sec)
```

```
SET @title = 'TiDB Developer Guide';
SET @type = 'Science & Technology';
SET @stock = 100;
SET @price = 0.0;
SET @published_at = NOW();
```

Running result:

```
Query OK, 0 rows affected (0.04 sec)
```

```
EXECUTE `books_insert` USING @title, @type, @stock, @price, @published_at;
```

Running result:

```
Query OK, 1 row affected (0.03 sec)
```

```
try (Connection connection = ds.getConnection()) {
    String sql = "INSERT INTO `books` (`title`, `type`, `stock`, `price`, `
        ↪ published_at`) VALUES (?, ?, ?, ?, ?);";
    PreparedStatement preparedStatement = connection.prepareStatement(sql);

    preparedStatement.setString(1, "TiDB Developer Guide");
    preparedStatement.setString(2, "Science & Technology");
    preparedStatement.setInt(3, 100);
    preparedStatement.setBigDecimal(4, new BigDecimal("0.0"));
    preparedStatement.setTimestamp(5, new Timestamp(Calendar.getInstance().
        ↪ getTimeInMillis()));

    preparedStatement.executeUpdate();
} catch (SQLException e) {
    e.printStackTrace();
}
```

As you can see, JDBC helps you control the life cycle of prepared statements and you don't need to manually create, use, or delete prepared statements in your application. However, note that because TiDB is compatible with MySQL, the default configuration for using MySQL JDBC Driver on the client-side is not to enable the ***server-side*** prepared statement option, but to use the client-side prepared statement.

The following configurations help you use the TiDB server-side prepared statements under JDBC:

Parameter	Means	Recommended Scenario	Recommended Configuration
`useServerPrepStmts`	Whether to use the server side to enable prepared statements	When you need to use a prepared statement more than once	`true`
`cachePrepStmts`	Whether the client caches prepared statements	`useServerPrepStmts=true`	`true`
`prepStmtCacheSqlLimit`	Maximum size of a prepared statement (256 characters by default)	When the prepared statement is greater than 256 characters	Configured according to the actual size of the prepared statement
`prepStmtCacheSize`	Maximum number of prepared statements (25 by default)	When the number of prepared statements is greater than 25	Configured according to the actual number of prepared statements

The following is a typical scenario of JDBC connection string configurations. Host: `127.0.0.1`, Port: `4000`, User name: `root`, Password: null, Default database: `test`:

```
jdbc:mysql://127.0.0.1:4000/test?user=root&useConfigs=maxPerformance&
    ↪ useServerPrepStmts=true&prepStmtCacheSqlLimit=2048&prepStmtCacheSize
    ↪ =256&rewriteBatchedStatements=true&allowMultiQueries=true
```

You can also see the insert rows chapter if you need to change other JDBC parameters when inserting data.

For a complete example in Java, see:

- Connect to TiDB with JDBC
- Connect to TiDB with Hibernate
- Connect to TiDB with Spring Boot

Ask the community on Discord or Slack, or submit a support ticket.

4.7 Read Data

4.7.1 Query Data from a Single Table

This document describes how to use SQL and various programming languages to query data from a single table in a database.

4.7.1.1 Before you begin

The following content takes the Bookshop application as an example to show how to query data from a single table in TiDB.

Before querying data, make sure that you have completed the following steps:

1. Build a TiDB cluster (using TiDB Cloud or TiUP is recommended).
2. Import table schema and sample data of the Bookshop application.
3. Connect to TiDB.

4.7.1.2 Execute a simple query

In the database of the Bookshop application, the `authors` table stores the basic information of authors. You can use the `SELECT ... FROM ...` statement to query data from the database.

Execute the following SQL statement in a MySQL client:

```
SELECT id, name FROM authors;
```

The output is as follows:

```
+------------+--------------------------+
| id         | name                     |
+------------+--------------------------+
|       6357 | Adelle Bosco             |
|     345397 | Chanelle Koepp           |
```

```
|     807584 | Clementina Ryan      |
|     839921 | Gage Huel            |
|     850070 | Ray Armstrong        |
|     850362 | Ford Waelchi         |
|     881210 | Jayme Gutkowski      |
|    1165261 | Allison Kuvalis      |
|    1282036 | Adela Funk           |
...
| 4294957408 | Lyla Nitzsche        |
+------------+----------------------+
20000 rows in set (0.05 sec)
```

In Java, to store the basic information of authors, you can declare a class `Author`. You should choose appropriate Java data types according to the Data types and Value range in the database. For example:

- Use a variable of type `Int` to store data of type `int`.
- Use a variable of type `Long` to store data of type `bigint`.
- Use a variable of type `Short` to store data of type `tinyint`.
- Use a variable of type `String` to store data of type `varchar`.

```java
public class Author {
    private Long id;
    private String name;
    private Short gender;
    private Short birthYear;
    private Short deathYear;

    public Author() {}

     // Skip the getters and setters.
}
```

```java
public class AuthorDAO {

    // Omit initialization of instance variables.

    public List<Author> getAuthors() throws SQLException {
        List<Author> authors = new ArrayList<>();

        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("SELECT id, name FROM authors");
            while (rs.next()) {
```

```
                Author author = new Author();
                author.setId(rs.getLong("id"));
                author.setName(rs.getString("name"));
                authors.add(author);
            }
        }
        return authors;
    }
}
```

- After connecting to TiDB using the JDBC driver, you can create a `Statement` object with `conn.createStatus()`.

- Then call `stmt.executeQuery("query_sql")` to initiate a database query request to TiDB.
- The query results are stored in a `ResultSet` object. By traversing `ResultSet`, the returned results can be mapped to the `Author` object.

4.7.1.3 Filter results

To filter query results, you can use the `WHERE` statement.

For example, the following command queries authors who were born in 1998 among all authors:

Add filter conditions in the `WHERE` statement:

```
SELECT * FROM authors WHERE birth_year = 1998;
```

In Java, you can use the same SQL to handle data query requests with dynamic parameters.

This can be done by concatenating parameters into a SQL statement. However, this method poses a potential SQL Injection risk to the security of the application.

To deal with such queries, use a Prepared statement instead of a normal statement.

```
public List<Author> getAuthorsByBirthYear(Short birthYear) throws
    ↪ SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
        SELECT * FROM authors WHERE birth_year = ?;
        """);
        stmt.setShort(1, birthYear);
        ResultSet rs = stmt.executeQuery();
        while (rs.next()) {
```

```
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.1.4 Sort results

To sort query results, you can use the `ORDER BY` statement.

For example, the following SQL statement is to get a list of the youngest authors by sorting the `authors` table in descending order (`DESC`) according to the `birth_year` column.

```
SELECT id, name, birth_year
FROM authors
ORDER BY birth_year DESC;
```

```
public List<Author> getAuthorsSortByBirthYear() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
            SELECT id, name, birth_year
            FROM authors
            ORDER BY birth_year DESC;
            """);

        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            author.setBirthYear(rs.getShort("birth_year"));
            authors.add(author);
        }
    }
    return authors;
}
```

The result is as follows:

```
+----------+----------------------+------------+
| id       | name                 | birth_year |
+----------+----------------------+------------+
```

```
| 83420726 | Terrance Dach       | 2000      |
| 57938667 | Margarita Christiansen | 2000  |
| 77441404 | Otto Dibbert        | 2000      |
| 61338414 | Danial Cormier      | 2000      |
| 49680887 | Alivia Lemke        | 2000      |
| 45460101 | Itzel Cummings      | 2000      |
| 38009380 | Percy Hodkiewicz    | 2000      |
| 12943560 | Hulda Hackett       | 2000      |
| 1294029  | Stanford Herman     | 2000      |
| 111453184 | Jeffrey Brekke     | 2000      |
...
300000 rows in set (0.23 sec)
```

4.7.1.5 Limit the number of query results

To limit the number of query results, you can use the `LIMIT` statement.

```
SELECT id, name, birth_year
FROM authors
ORDER BY birth_year DESC
LIMIT 10;
```

```
public List<Author> getAuthorsWithLimit(Integer limit) throws SQLException
    ↪ {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
            SELECT id, name, birth_year
            FROM authors
            ORDER BY birth_year DESC
            LIMIT ?;
            """);
        stmt.setInt(1, limit);
        ResultSet rs = stmt.executeQuery();
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            author.setBirthYear(rs.getShort("birth_year"));
            authors.add(author);
        }
    }
    return authors;
}
```

The result is as follows:

```
+-----------+-----------------------+------------+
| id        | name                  | birth_year |
+-----------+-----------------------+------------+
| 83420726  | Terrance Dach         | 2000       |
| 57938667  | Margarita Christiansen | 2000      |
| 77441404  | Otto Dibbert          | 2000       |
| 61338414  | Danial Cormier        | 2000       |
| 49680887  | Alivia Lemke          | 2000       |
| 45460101  | Itzel Cummings        | 2000       |
| 38009380  | Percy Hodkiewicz      | 2000       |
| 12943560  | Hulda Hackett         | 2000       |
| 1294029   | Stanford Herman       | 2000       |
| 111453184 | Jeffrey Brekke        | 2000       |
+-----------+-----------------------+------------+
10 rows in set (0.11 sec)
```

With the `LIMIT` statement, the query time is significantly reduced from `0.23 sec` to `0.11 sec` in this example. For more information, see TopN and Limit.

4.7.1.6 Aggregate queries

To have a better understanding of the overall data situation, you can use the `GROUP BY` statement to aggregate query results.

For example, if you want to know which years there are more authors born, you can group the `authors` table by the `birth_year` column, and then count for each year:

```
SELECT birth_year, COUNT (DISTINCT id) AS author_count
FROM authors
GROUP BY birth_year
ORDER BY author_count DESC;
```

```
public class AuthorCount {
    private Short birthYear;
    private Integer authorCount;

    public AuthorCount() {}

     // Skip the getters and setters.
}

public List<AuthorCount> getAuthorCountsByBirthYear() throws SQLException {
    List<AuthorCount> authorCounts = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
```

```
        ResultSet rs = stmt.executeQuery("""
            SELECT birth_year, COUNT(DISTINCT id) AS author_count
            FROM authors
            GROUP BY birth_year
            ORDER BY author_count DESC;
            """);

        while (rs.next()) {
            AuthorCount authorCount = new AuthorCount();
            authorCount.setBirthYear(rs.getShort("birth_year"));
            authorCount.setAuthorCount(rs.getInt("author_count"));
            authorCounts.add(authorCount);
        }
    }
    return authorCount;
}
```

The result is as follows:

```
+------------+--------------+
| birth_year | author_count |
+------------+--------------+
|       1932 |          317 |
|       1947 |          290 |
|       1939 |          282 |
|       1935 |          289 |
|       1968 |          291 |
|       1962 |          261 |
|       1961 |          283 |
|       1986 |          289 |
|       1994 |          280 |
...
|       1972 |          306 |
+------------+--------------+
71 rows in set (0.00 sec)
```

In addition to the `COUNT` function, TiDB also supports other aggregate functions. For more information, see Aggregate (GROUP BY) Functions.

Ask the community on Discord or Slack, or submit a support ticket.

4.7.2 Multi-table Join Queries

In many scenarios, you need to use one query to get data from multiple tables. You can use the `JOIN` statement to combine the data from two or more tables.

4.7.2.1 Join types

This section describes the Join types in detail.

4.7.2.1.1 INNER JOIN

The join result of an inner join returns only rows that match the join condition.

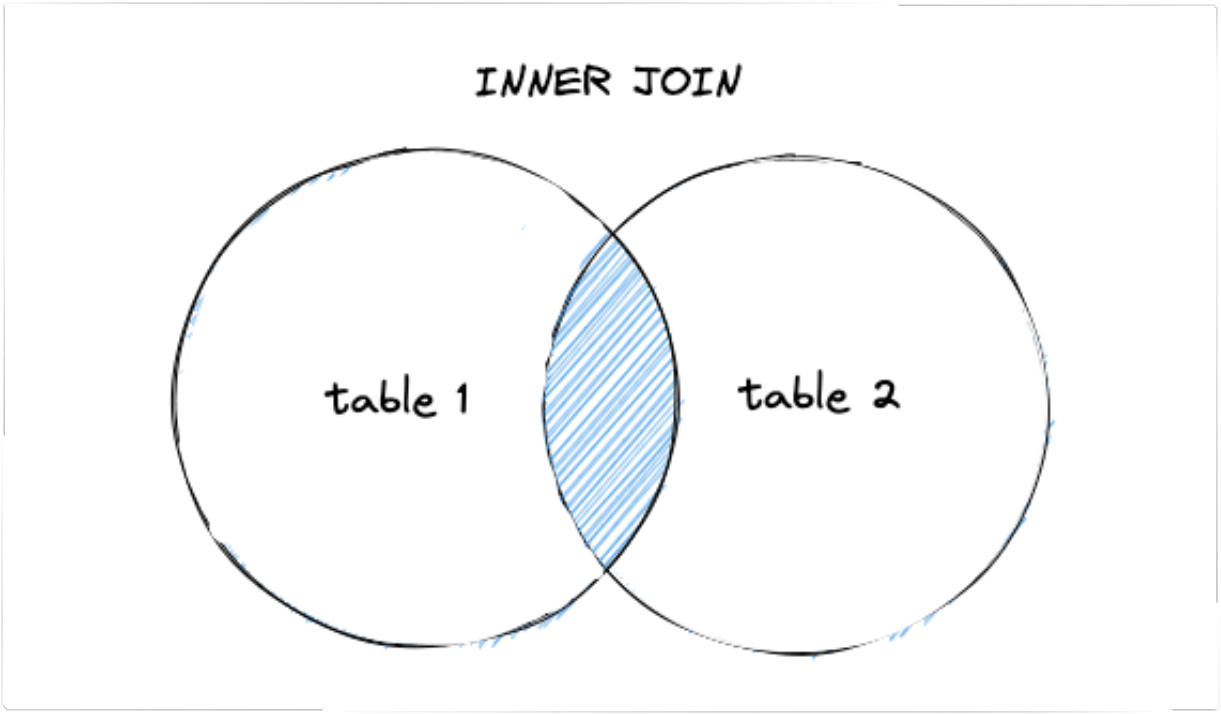

Figure 57: Inner Join

For example, if you want to know the most prolific author, you need to join the author table named `authors` with the book author table named `book_authors`.

In the following SQL statement, use the keyword `JOIN` to declare that you want to join the rows of the left table `authors` and the right table `book_authors` as an inner join with the join condition `a.id = ba.author_id`. The result set will only contain rows that satisfy the join condition. If an author has not written any books, then his record in `authors` table will not satisfy the join condition and will therefore not appear in the result set.

```
SELECT ANY_VALUE(a.id) AS author_id, ANY_VALUE(a.name) AS author_name,
    ↪ COUNT(ba.book_id) AS books
FROM authors a
JOIN book_authors ba ON a.id = ba.author_id
GROUP BY ba.author_id
ORDER BY books DESC
LIMIT 10;
```

The query results are as follows:

```
+------------+----------------+-------+
| author_id | author_name | books |
+------------+----------------+-------+
|  431192671 | Emilie Cassin |  7 |
|  865305676 | Nola Howell |    7 |
|  572207928 | Lamar Koch  |    6 |
| 3894029860 | Elijah Howe |    6 |
| 1150614082 | Cristal Stehr |  6 |
| 4158341032 | Roslyn Rippin |  6 |
| 2430691560 | Francisca Hahn | 6 |
| 3346415350 | Leta Weimann |   6 |
| 1395124973 | Albin Cole |    6 |
| 2768150724 | Caleb Wyman |    6 |
+------------+----------------+-------+
10 rows in set (0.01 sec)
```

```
public List<Author> getTop10AuthorsOrderByBooks() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
        SELECT ANY_VALUE(a.id) AS author_id, ANY_VALUE(a.name) AS author_name
            ↪ , COUNT(ba.book_id) AS books
        FROM authors a
        JOIN book_authors ba ON a.id = ba.author_id
        GROUP BY ba.author_id
        ORDER BY books DESC
        LIMIT 10;
        """);
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("author_id"));
            author.setName(rs.getString("author_name"));
            author.setBooks(rs.getInt("books"));
            authors.add(author);
```

```
        }
    }
    return authors;
}
```

4.7.2.1.2 LEFT OUTER JOIN

The left outer join returns all the rows in the left table and the values in the right table that match the join condition. If no rows are matched in the right table, it will be filled with `NULL`.

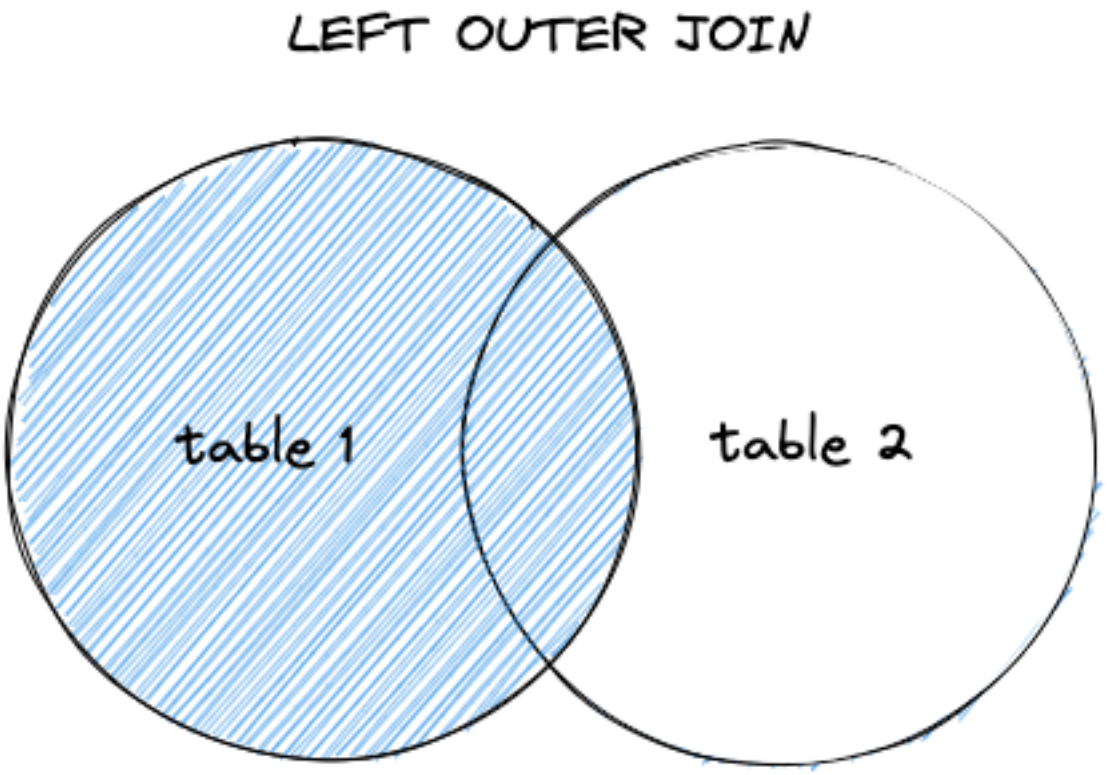

Figure 58: Left Outer Join

In some cases, you want to use multiple tables to complete the data query, but do not want the data set to become too small because the join condition are not met.

For example, on the homepage of the Bookshop app, you want to display a list of new books with average ratings. In this case, the new books may not have been rated by anyone yet. Using inner joins will cause the information of these unrated books to be filtered out, which is not what you expect.

In the following SQL statement, use the `LEFT JOIN` keyword to declare that the left table `books` will be joined to the right table `ratings` in a left outer join, thus ensuring that all rows in the `books` table are returned.

```
SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score) AS
    ↪ average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id
ORDER BY b.published_at DESC
LIMIT 10;
```

The query results are as follows:

```
+------------+--------------------------------+---------------+
| book_id    | book_title                     | average_score |
+------------+--------------------------------+---------------+
| 3438991610 | The Documentary of lion        |        2.7619 |
| 3897175886 | Torey Kuhn                     |        3.0000 |
| 1256171496 | Elmo Vandervort                |        2.5500 |
| 1036915727 | The Story of Munchkin          |        2.0000 |
|  270254583 | Tate Kovacek                   |        2.5000 |
| 1280950719 | Carson Damore                  |        3.2105 |
| 1098041838 | The Documentary of grasshopper |   2.8462 |
| 1476566306 | The Adventures of Vince Sanford | 2.3529 |
| 4036300890 | The Documentary of turtle      |        2.4545 |
| 1299849448 | Antwan Olson                   |        3.0000 |
+------------+--------------------------------+---------------+
10 rows in set (0.30 sec)
```

It seems that the latest published book already has a lot of ratings. To verify the above method, let's delete all the ratings of the book *The Documentary of lion* through the SQL statement:

```
DELETE FROM ratings WHERE book_id = 3438991610;
```

Query again. The book *The Documentary of lion* still appears in the result set, but the `average_score` column calculated from `score` of the right table `ratings` is filled with `NULL`.

```
+------------+--------------------------------+---------------+
| book_id    | book_title                     | average_score |
+------------+--------------------------------+---------------+
| 3438991610 | The Documentary of lion        |          NULL |
| 3897175886 | Torey Kuhn                     |        3.0000 |
| 1256171496 | Elmo Vandervort                |        2.5500 |
| 1036915727 | The Story of Munchkin          |        2.0000 |
|  270254583 | Tate Kovacek                   |        2.5000 |
| 1280950719 | Carson Damore                  |        3.2105 |
| 1098041838 | The Documentary of grasshopper |   2.8462 |
| 1476566306 | The Adventures of Vince Sanford | 2.3529 |
```

```
| 4036300890 | The Documentary of turtle |       2.4545 |
| 1299849448 | Antwan Olson              |       3.0000 |
+------------+-----------------------------------+--------------+
10 rows in set (0.30 sec)
```

What happens if you use `INNER JOIN`? It's up to you to have a try.

```java
public List<Book> getLatestBooksWithAverageScore() throws SQLException {
    List<Book> books = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
        SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score
            ↪ ) AS average_score
        FROM books b
        LEFT JOIN ratings r ON b.id = r.book_id
        GROUP BY b.id
        ORDER BY b.published_at DESC
        LIMIT 10;
        """);
        while (rs.next()) {
            Book book = new Book();
            book.setId(rs.getLong("book_id"));
            book.setTitle(rs.getString("book_title"));
            book.setAverageScore(rs.getFloat("average_score"));
            books.add(book);
        }
    }
    return books;
}
```

4.7.2.1.3 RIGHT OUTER JOIN

A right outer join returns all the records in the right table and the values in the left table that match the join condition. If there is no matching value, it is filled with `NULL`.

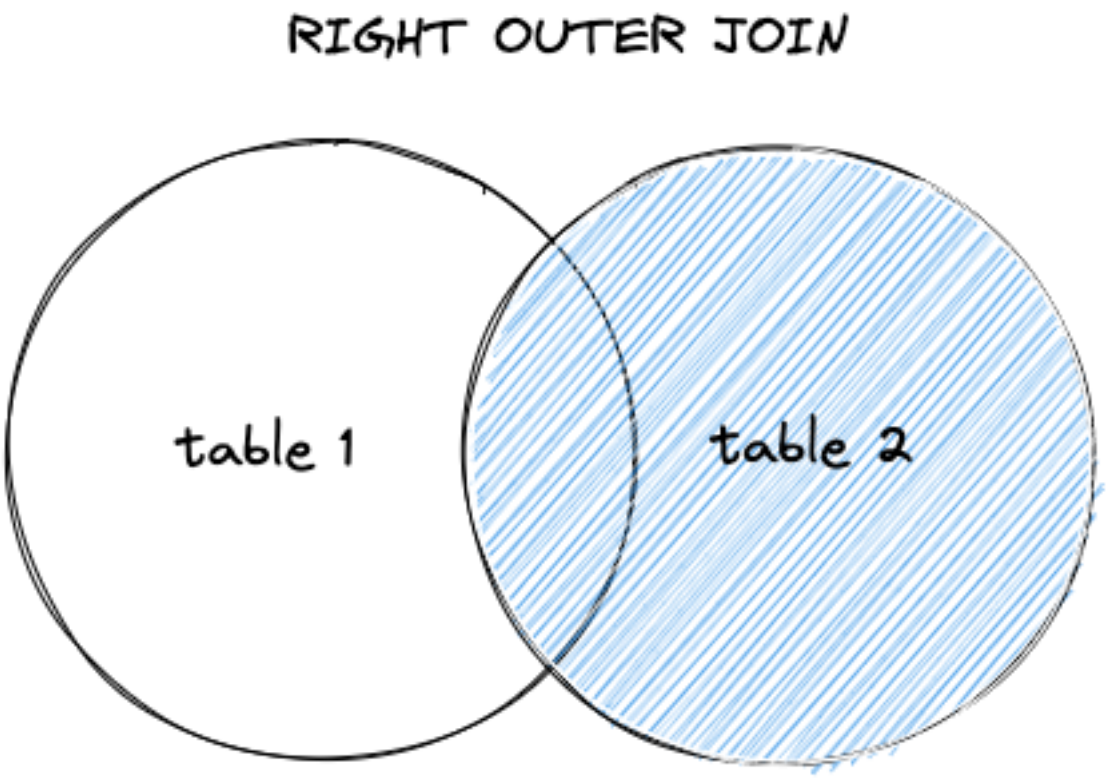

Figure 59: Right Outer Join

4.7.2.1.4 CROSS JOIN

When the join condition is constant, the inner join between the two tables is called a cross join. A cross join joins every record of the left table to all the records of the right table. If the number of records in the left table is `m` and the number of records in the right table is `n`, then `m \* n` records will be generated in the result set.

4.7.2.1.5 LEFT SEMI JOIN

TiDB does not support `LEFT SEMI JOIN table_name` at the SQL syntax level. But at the execution plan level, subquery-related optimizations will use `semi join` as the default join method for rewritten equivalent JOIN queries.

4.7.2.2 Implicit join

Before the `JOIN` statement that explicitly declared a join was added to the SQL standard, it was possible to join two or more tables in a SQL statement using the `FROM t1, t2` clause, and specify the conditions for the join using the `WHERE t1.id = t2.id` clause. You can understand it as an implicit join, which uses the inner join to join tables.

4.7.2.3 Join related algorithms

TiDB supports the following general table join algorithms.

- Index Join
- Hash Join
- Merge Join

The optimizer selects an appropriate join algorithm to execute based on the factors such as the data volume in the joined table. You can see which algorithm the query uses for Join by using the `EXPLAIN` statement.

If the optimizer of TiDB does not execute according to the optimal join algorithm, you can use Optimizer Hints to force TiDB to use a better join algorithm.

For example, assuming the example for the left join query above executes faster using the Hash Join algorithm, which is not chosen by the optimizer, you can append the hint `/*+ HASH_JOIN(b, r)*/` after the `SELECT` keyword. Note that If the table has an alias, use the alias in the hint.

```
EXPLAIN SELECT /*+ HASH_JOIN(b, r) */ b.id AS book_id, ANY_VALUE(b.title)
    ↪ AS book_title, AVG(r.score) AS average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id
ORDER BY b.published_at DESC
LIMIT 10;
```

Hints related to join algorithms:

- MERGE_JOIN(t1_name [, tl_name ...])
- INL_JOIN(t1_name [, tl_name ...])
- INL_HASH_JOIN(t1_name [, tl_name ...])
- HASH_JOIN(t1_name [, tl_name ...])

4.7.2.4 Join orders

In real business scenarios, join statements of multiple tables are very common. The execution efficiency of join is related to the order of each table in join. TiDB uses the Join Reorder algorithm to determine the order in which multiple tables are joined.

If the join order selected by the optimizer is not optimal as expected, you can use `STRAIGHT_JOIN` to enforce TiDB to join queries in the order of the tables used in the `FROM` clause.

```
EXPLAIN SELECT *
FROM authors a STRAIGHT_JOIN book_authors ba STRAIGHT_JOIN books b
WHERE b.id = ba.book_id AND ba.author_id = a.id;
```

For more information about the implementation details and limitations of this Join Reorder algorithm, see Introduction to Join Reorder Algorithm.

Ask the community on Discord or Slack, or submit a support ticket.

4.7.3 Subquery

This document introduces subquery statements and categories in TiDB.

4.7.3.1 Overview

A subquery is a query within another SQL query. With subquery, the query result can be used in another query.

The following takes the Bookshop application as an example to introduce subquery.

4.7.3.2 Subquery statement

In most cases, there are five types of subqueries:

- Scalar Subquery, such as `SELECT (SELECT s1 FROM t2)FROM t1`.
- Derived Tables, such as `SELECT t1.s1 FROM (SELECT s1 FROM t2)t1`.
- Existential Test, such as `WHERE NOT EXISTS(SELECT ... FROM t2)`, `WHERE t1.a IN (SELECT ... FROM t2)`.
- Quantified Comparison, such as `WHERE t1.a = ANY(SELECT ... FROM t2)`, `WHERE t1.a = ANY(SELECT ... FROM t2)`.
- Subquery as a comparison operator operand, such as `WHERE t1.a > (SELECT ... FROM t2)`.

4.7.3.3 Category of subquery

The subquery can be categorized as Correlated Subquery and Self-contained Subquery. TiDB treats these two types differently.

Whether a subquery is correlated or not depends on whether it refers to columns used in its outer query.

4.7.3.3.1 Self-contained subquery

For a self-contained subquery that uses subquery as operand of comparison operators (>, >=, < , <= , = , or ! =), the inner subquery queries only once, and TiDB rewrites it as a constant during the execution plan phase.

For example, to query authors in the `authors` table whose age is greater than the average age, you can use a subquery as a comparison operator operand.

```
SELECT * FROM authors a1 WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.
    ↪ birth_year) > (
    SELECT
        AVG(IFNULL(a2.death_year, YEAR(NOW())) - a2.birth_year) AS average_
            ↪ age
    FROM
        authors a2
)
```

The inner subquery is executed before TiDB executes the above query:

```
SELECT AVG(IFNULL(a2.death_year, YEAR(NOW())) - a2.birth_year) AS average_
    ↪ age FROM authors a2;
```

Suppose the result of the query is 34, that is, the average age is 34, and 34 will be used as a constant to replace the original subquery.

```
SELECT * FROM authors a1
WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.birth_year) > 34;
```

The result is as follows:

```
+--------+------------------+--------+------------+------------+
| id     | name             | gender | birth_year | death_year |
+--------+------------------+--------+------------+------------+
| 13514  | Kennith Kautzer  | 1      | 1956       | 2018       |
| 13748  | Dillon Langosh   | 1      | 1985       | NULL       |
| 99184  | Giovanny Emmerich | 1     | 1954       | 2012       |
| 180191 | Myrtie Robel     | 1      | 1958       | 2009       |
| 200969 | Iva Renner       | 0      | 1977       | NULL       |
| 209671 | Abraham Ortiz    | 0      | 1943       | 2016       |
| 229908 | Wellington Wiza  | 1      | 1932       | 1969       |
| 306642 | Markus Crona     | 0      | 1969       | NULL       |
| 317018 | Ellis McCullough | 0      | 1969       | 2014       |
| 322369 | Mozelle Hand     | 0      | 1942       | 1977       |
| 325946 | Elta Flatley     | 0      | 1933       | 1986       |
| 361692 | Otho Langosh     | 1      | 1931       | 1997       |
| 421294 | Karelle VonRueden | 0     | 1977       | NULL       |
...
```

For self-contained subqueries such as Existential Test and Quantified Comparison, TiDB rewrites and replaces them with equivalent queries for better performance. For more information, see Subquery Related Optimizations.

4.7.3.3.2 Correlated subquery

For correlated subquery, because the inner subquery references the columns from the outer query, each subquery is executed once for each row of the outer query. That is, assuming that the outer query gets 10 million results, the subquery will also be executed 10 million times, which will consume more time and resources.

Therefore, in the process of processing, TiDB will try to Decorrelate of Correlated Subquery to improve the query efficiency at the execution plan level.

The following statement is to query authors who are older than the average age of other authors of the same gender.

```
SELECT * FROM authors a1 WHERE (IFNULL(a1.death_year, YEAR(NOW())) - a1.
    ↪ birth_year) > (
    SELECT
        AVG(
            IFNULL(a2.death_year, YEAR(NOW())) - IFNULL(a2.birth_year, YEAR(
                ↪ NOW()))
        ) AS average_age
    FROM
        authors a2
    WHERE a1.gender = a2.gender
);
```

TiDB rewrites it to an equivalent `join` query:

```
SELECT *
FROM
    authors a1,
    (
        SELECT
            gender, AVG(
                IFNULL(a2.death_year, YEAR(NOW())) - IFNULL(a2.birth_year,
                    ↪ YEAR(NOW()))
            ) AS average_age
        FROM
            authors a2
        GROUP BY gender
    ) a2
WHERE
    a1.gender = a2.gender
    AND (IFNULL(a1.death_year, YEAR(NOW())) - a1.birth_year) > a2.average_
        ↪ age;
```

As a best practice, in actual development, it is recommended to avoid querying through a correlated subquery if you can write another equivalent query with better performance.

4.7.4 Paginate Results

To page through a large query result, you can get your desired part in a "paginated" manner.

4.7.4.1 Paginate query results

In TiDB, you can paginate query results using the `LIMIT` statement. For example:

```
SELECT * FROM table_a t ORDER BY gmt_modified DESC LIMIT offset, row_count;
```

`offset` indicates the beginning number of records and `row_count` indicates the number of records per page. TiDB also supports `LIMIT row_count OFFSET offset` syntax.

When pagination is used, it is recommended that you sort query results with the `ORDER BY` statement unless there is a need to display data randomly.

For example, to let users of the Bookshop application view the latest published books in a paginated manner, you can use the `LIMIT 0, 10` statement, which returns the first page of the result list, with a maximum of 10 records per page. To get the second page, you can change the statement to `LIMIT 10, 10`.

```
SELECT *
FROM books
ORDER BY published_at DESC
LIMIT 0, 10;
```

In application development, the backend program receives the `page_number` parameter (which means the number of the page being requested) and the `page_size` parameter (which controls how many records per page) from the frontend instead of the `offset` parameter. Therefore, some conversions needed to be done before querying.

```
public List<Book> getLatestBooksPage(Long pageNumber, Long pageSize) throws
    ↪ SQLException {
    pageNumber = pageNumber < 1L ? 1L : pageNumber;
    pageSize = pageSize < 10L ? 10L : pageSize;
    Long offset = (pageNumber - 1) * pageSize;
    Long limit = pageSize;
    List<Book> books = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        PreparedStatement stmt = conn.prepareStatement("""
        SELECT id, title, published_at
        FROM books
        ORDER BY published_at DESC
        LIMIT ?, ?;
        """);
        stmt.setLong(1, offset);
        stmt.setLong(2, limit);
        ResultSet rs = stmt.executeQuery();
        while (rs.next()) {
            Book book = new Book();
            book.setId(rs.getLong("id"));
            book.setTitle(rs.getString("title"));
            book.setPublishedAt(rs.getDate("published_at"));
            books.add(book);
        }
    }
    return books;
}
```

4.7.4.2 Paging batches for single-field primary key tables

Usually, you can write a pagination SQL statement using a primary key or unique index to sort results and the `offset` keyword in the `LIMIT` clause to split pages by a specified row count. Then the pages are wrapped into independent transactions to achieve flexible paging updates. However, the disadvantage is also obvious. As the primary key or unique index needs to be sorted, a larger offset consumes more computing resources, especially in the case of a large volume of data.

The following introduces a more efficient paging batching method:

First, sort the data by primary key and call the window function `row_number()` to generate a row number for each row. Then, call the aggregation function to group row numbers by the specified page size and calculate the minimum and maximum values of each page.

```
SELECT
```

```
    floor((t.row_num - 1) / 1000) + 1 AS page_num,
    min(t.id) AS start_key,
    max(t.id) AS end_key,
    count(*) AS page_size
FROM (
    SELECT id, row_number() OVER (ORDER BY id) AS row_num
    FROM books
) t
GROUP BY page_num
ORDER BY page_num;
```

The result is as follows:

```
+----------+------------+------------+-----------+
| page_num | start_key | end_key | page_size |
+----------+------------+------------+-----------+
|        1 |     268996 | 213168525 |    1000 |
|        2 |  213210359 | 430012226 |    1000 |
|        3 |  430137681 | 647846033 |    1000 |
|        4 |  647998334 | 848878952 |    1000 |
|        5 |  848899254 | 1040978080 |   1000 |
...
|       20 | 4077418867 | 4294004213 |  1000 |
+----------+------------+------------+-----------+
20 rows in set (0.01 sec)
```

Next, use the `WHERE id BETWEEN start_key AND end_key` statement to query the data of each slice. To update data more efficiently, you can use the above slice information when modifying the data.

To delete the basic information of all books on page 1, replace the `start_key` and `end_key` with values of page 1 in the above result:

```
DELETE FROM books
WHERE
    id BETWEEN 268996 AND 213168525
ORDER BY id;
```

In Java, define a `PageMeta` class to store page meta information.

```
public class PageMeta<K> {
    private Long pageNum;
    private K startKey;
    private K endKey;
    private Long pageSize;

    // Skip the getters and setters.
```

```
}
```

Define a `getPageMetaList()` method to get the page meta information list, and then define a `deleteBooksByPageMeta()` method to delete data in batches according to the page meta information.

```
public class BookDAO {
    public List<PageMeta<Long>> getPageMetaList() throws SQLException {
        List<PageMeta<Long>> pageMetaList = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT
                floor((t.row_num - 1) / 1000) + 1 AS page_num,
                min(t.id) AS start_key,
                max(t.id) AS end_key,
                count(*) AS page_size
            FROM (
                SELECT id, row_number() OVER (ORDER BY id) AS row_num
                FROM books
            ) t
            GROUP BY page_num
            ORDER BY page_num;
            """);
            while (rs.next()) {
                PageMeta<Long> pageMeta = new PageMeta<>();
                pageMeta.setPageNum(rs.getLong("page_num"));
                pageMeta.setStartKey(rs.getLong("start_key"));
                pageMeta.setEndKey(rs.getLong("end_key"));
                pageMeta.setPageSize(rs.getLong("page_size"));
                pageMetaList.add(pageMeta);
            }
        }
        return pageMetaList;
    }

    public void deleteBooksByPageMeta(PageMeta<Long> pageMeta) throws
        ↪ SQLException {
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("DELETE FROM books
                ↪  WHERE id >= ? AND id <= ?");
            stmt.setLong(1, pageMeta.getStartKey());
            stmt.setLong(2, pageMeta.getEndKey());
            stmt.executeUpdate();
```

```
        }
    }
}
```

The following statement is to delete the data on page 1:

```
List<PageMeta<Long>> pageMetaList = bookDAO.getPageMetaList();
if (pageMetaList.size() > 0) {
    bookDAO.deleteBooksByPageMeta(pageMetaList.get(0));
}
```

The following statement is to delete all book data in batches by paging:

```
List<PageMeta<Long>> pageMetaList = bookDAO.getPageMetaList();
pageMetaList.forEach((pageMeta) -> {
    try {
        bookDAO.deleteBooksByPageMeta(pageMeta);
    } catch (SQLException e) {
        e.printStackTrace();
    }
});
```

This method significantly improves the efficiency of batch processing by avoiding wasting computing resources caused by frequent data sorting operations.

4.7.4.3 Paging batches for composite primary key tables

4.7.4.3.1 Non-clustered index table

For non-clustered index tables (also known as "non-index-organized tables"), the internal field `_tidb_rowid` can be used as a pagination key, and the pagination method is the same as that of single-field primary key tables.

> **Tip:**
>
> You can use the `SHOW CREATE TABLE users;` statement to check whether the table primary key uses clustered index.

For example:

```
SELECT
    floor((t.row_num - 1) / 1000) + 1 AS page_num,
    min(t._tidb_rowid) AS start_key,
```

```
    max(t._tidb_rowid) AS end_key,
    count(*) AS page_size
FROM (
    SELECT _tidb_rowid, row_number () OVER (ORDER BY _tidb_rowid) AS row_num
    FROM users
) t
GROUP BY page_num
ORDER BY page_num;
```

The result is as follows:

```
+----------+-----------+---------+-----------+
| page_num | start_key | end_key | page_size |
+----------+-----------+---------+-----------+
|        1 |         1 |    1000 |      1000 |
|        2 |      1001 |    2000 |      1000 |
|        3 |      2001 |    3000 |      1000 |
|        4 |      3001 |    4000 |      1000 |
|        5 |      4001 |    5000 |      1000 |
|        6 |      5001 |    6000 |      1000 |
|        7 |      6001 |    7000 |      1000 |
|        8 |      7001 |    8000 |      1000 |
|        9 |      8001 |    9000 |      1000 |
|       10 |      9001 |    9990 |       990 |
+----------+-----------+---------+-----------+
10 rows in set (0.00 sec)
```

4.7.4.3.2 Clustered index table

For clustered index tables (also known as "index-organized tables"), you can use the `concat` function to concatenate values of multiple columns as a key, and then use a window function to query the paging information.

It should be noted that the key is a string at this time, and you must ensure that the length of the string is always the same, to obtain the correct `start_key` and `end_key` in the slice through the `min` and `max` aggregation function. If the length of the field for string concatenation is not fixed, you can use the `LPAD` function to pad it.

For example, you can implement a paging batch for the data in the `ratings` table as follows:

Create the meta information table by using the following statement. As the key concatenated by `book_id` and `user_id`, which are `bigint` types, is unable to convert to the same length, the `LPAD` function is used to pad the length with `0` according to the maximum bits 19 of `bigint`.

```
SELECT
```

```
    floor((t1.row_num - 1) / 10000) + 1 AS page_num,
    min(mvalue) AS start_key,
    max(mvalue) AS end_key,
    count(*) AS page_size
FROM (
    SELECT
        concat('(', LPAD(book_id, 19, 0), ',', LPAD(user_id, 19, 0), ')') AS
            ↪  mvalue,
        row_number() OVER (ORDER BY book_id, user_id) AS row_num
    FROM ratings
) t1
GROUP BY page_num
ORDER BY page_num;
```

> **Note:**
>
> The preceding SQL statement is executed as `TableFullScan`. When the data volume is large, the query will be slow, and you can use TiFlash to speed up it.

The result is as follows:

```
+----------+-----------------------------------------+-----------------------------------------
    ↪
| page_num | start_key                               | end_key
    ↪                                | page_size |
+----------+-----------------------------------------+-----------------------------------------
    ↪
|        1 | (0000000000000268996,0000000000092104804) |
    ↪ (0000000000140982742,0000000000374645100) | 10000 |
|        2 | (0000000000140982742,0000000000456757551) |
    ↪ (0000000000287195082,0000000004053200550) | 10000 |
|        3 | (0000000000287196791,0000000000191962769) |
    ↪ (0000000000434010216,0000000000237646714) | 10000 |
|        4 | (0000000000434010216,0000000000375066168) |
    ↪ (0000000000578893327,0000000002167504460) | 10000 |
|        5 | (0000000000578893327,0000000002457322286) |
    ↪ (0000000000718287668,0000000001502744628) | 10000 |
...
|       29 | (0000000004002523918,0000000000902930986) |
    ↪ (0000000004147203315,0000000004090920746) | 10000 |
|       30 | (0000000004147421329,0000000000319181561) |
    ↪ (0000000004294004213,0000000003586311166) | 9972 |
```

```
+----------+------------------------------------------+------------------------------
    ↪
30 rows in set (0.28 sec)
```

To delete all rating records on page 1, replace the `start_key` and `end_key` with values of page 1 in the above result:

```
SELECT *
FROM ratings
WHERE (
        268996 = 140982742
        AND book_id = 268996
        AND user_id >= 92104804
        AND user_id <= 374645100
    )
    OR (
        268996 != 140982742
        AND (
            (
                book_id > 268996
                AND book_id < 140982742
            )
            OR (
                book_id = 268996
                AND user_id >= 92104804
            )
            OR (
                book_id = 140982742
                AND user_id <= 374645100
            )
        )
    )
ORDER BY book_id, user_id;
```

Ask the community on Discord or Slack, or submit a support ticket.

4.7.5 Views

This document describes how to use views in TiDB.

4.7.5.1 Overview

TiDB supports views. A view acts as a virtual table, whose schema is defined by the `SELECT` statement that creates the view.

- You can create views to expose only safe fields and data to users, which ensures the security of sensitive fields and data in the underlying tables.
- You can create views for complex queries that are frequently used to make complex queries easier and more convenient.

4.7.5.2 Create a view

In TiDB, a complex query can be defined as a view with the `CREATE VIEW` statement. The syntax is as follows:

```
CREATE VIEW view_name AS query;
```

Note that you cannot create a view with the same name as an existing view or table.

For example, the multi-table join query gets a list of books with average ratings by joining the `books` table and the `ratings` table through a `JOIN` statement.

For the convenience of subsequent queries, you can define the query as a view using the following statement:

```
CREATE VIEW book_with_ratings AS
SELECT b.id AS book_id, ANY_VALUE(b.title) AS book_title, AVG(r.score) AS
    ↪ average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id;
```

4.7.5.3 Query views

Once a view is created, you can use the `SELECT` statement to query the view just like a normal table.

```
SELECT * FROM book_with_ratings LIMIT 10;
```

When TiDB queries a view, it queries the `SELECT` statement associated with the view.

4.7.5.4 Update views

Currently, the view in TiDB does not support the `ALTER VIEW view_name AS query;`, you can "update" a view in the following two ways:

- Delete the old view with the `DROP VIEW view_name;` statement, and then update the view by creating a new view with the `CREATE VIEW view_name AS query;` statement.

- Use the `CREATE OR REPLACE VIEW view_name AS query;` statement to overwrite an existing view with the same name.

```
CREATE OR REPLACE VIEW book_with_ratings AS
SELECT b.id AS book_id, ANY_VALUE(b.title), ANY_VALUE(b.published_at) AS
    ↪ book_title, AVG(r.score) AS average_score
FROM books b
LEFT JOIN ratings r ON b.id = r.book_id
GROUP BY b.id;
```

4.7.5.5 Get view related information

4.7.5.5.1 Using the `SHOW CREATE TABLE|VIEW view_name` statement

```
SHOW CREATE VIEW book_with_ratings\G
```

The result is as follows:

```
*************************** 1. row ***************************
             View: book_with_ratings
      Create View: CREATE ALGORITHM=UNDEFINED DEFINER=`root`@`%` SQL
          ↪ SECURITY DEFINER VIEW `book_with_ratings` (`book_id`, `ANY_
          ↪ VALUE(b.title)`, `book_title`, `average_score`) AS SELECT `b
          ↪ `.`id` AS `book_id`,ANY_VALUE(`b`.`title`) AS `ANY_VALUE(b.
          ↪ title)`,ANY_VALUE(`b`.`published_at`) AS `book_title`,AVG(`r
          ↪ `.`score`) AS `average_score` FROM `bookshop`.`books` AS `b`
          ↪ LEFT JOIN `bookshop`.`ratings` AS `r` ON `b`.`id`=`r`.`book_
          ↪ id` GROUP BY `b`.`id`
character_set_client: utf8mb4
collation_connection: utf8mb4_general_ci
1 row in set (0.00 sec)
```

4.7.5.5.2 Query the `INFORMATION_SCHEMA.VIEWS` table

```
SELECT * FROM information_schema.views WHERE TABLE_NAME = 'book_with_
    ↪ ratings'\G
```

The result is as follows:

```
*************************** 1. row ***************************
       TABLE_CATALOG: def
        TABLE_SCHEMA: bookshop
          TABLE_NAME: book_with_ratings
```

```
    VIEW_DEFINITION: SELECT `b`.`id` AS `book_id`,ANY_VALUE(`b`.`title`) AS
       ↪  `ANY_VALUE(b.title)`,ANY_VALUE(`b`.`published_at`) AS `book_
       ↪ title`,AVG(`r`.`score`) AS `average_score` FROM `bookshop`.`books
       ↪ ` AS `b` LEFT JOIN `bookshop`.`ratings` AS `r` ON `b`.`id`=`r`.`
       ↪ book_id` GROUP BY `b`.`id`
      CHECK_OPTION: CASCADED
      IS_UPDATABLE: NO
          DEFINER: root@%
    SECURITY_TYPE: DEFINER
CHARACTER_SET_CLIENT: utf8mb4
COLLATION_CONNECTION: utf8mb4_general_ci
1 row in set (0.00 sec)
```

4.7.5.6 Drop views

Use the `DROP VIEW view_name;` statement to drop a view.

```
DROP VIEW book_with_ratings;
```

4.7.5.7 Limitation

For limitations of views in TiDB, see Limitations of Views.

Ask the community on Discord or Slack, or submit a support ticket.

4.7.6 Temporary Tables

Temporary tables can be thought of as a technique for reusing query results.

If you want to know something about the eldest authors in the Bookshop application, you might write multiple queries that use the list of eldest authors.

For example, you can use the following statement to get the top 50 eldest authors from the `authors` table:

```
SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year) AS
    ↪ age
FROM authors a
ORDER BY age DESC
LIMIT 50;
```

The result is as follows:

```
+------------+--------------------+------+
| id         | name               | age |
+------------+--------------------+------+
| 4053452056 | Dessie Thompson |  80 |
| 2773958689 | Pedro Hansen    |  80 |
| 4005636688 | Wyatt Keeling   |  80 |
| 3621155838 | Colby Parker    |  80 |
| 2738876051 | Friedrich Hagenes | 80 |
| 2299112019 | Ray Macejkovic  |  80 |
| 3953661843 | Brandi Williamson | 80 |
...
| 4100546410 | Maida Walsh     |  80 |
+------------+--------------------+------+
50 rows in set (0.01 sec)
```

For the convenience of subsequent queries, you need to cache the result of this query. When using general tables for storage, you should pay attention to how to avoid the table name duplication problem between different sessions, and the need of cleaning up intermediate results in time, as these tables might not be used after a batch query.

4.7.6.1 Create a temporary table

To cache intermediate results, the temporary tables feature is introduced in TiDB v5.3.0. TiDB automatically drops a local temporary table after a session ends, which frees you from worrying about the management trouble caused by increasing intermediate results.

4.7.6.1.1 Types of temporary tables

Temporary tables in TiDB are divided into two types: local temporary tables and global temporary tables.

- For a local temporary table, the table definition and data in the table are visible only to the current session. This type is suitable for temporarily storing intermediate data in the session.
- For a global temporary table, the table definition is visible to the entire TiDB cluster, and the data in the table is visible only to the current transaction. This type is suitable for temporarily storing intermediate data in a transaction.

4.7.6.1.2 Create a local temporary table

Before creating a local temporary table, you need to add `CREATE TEMPORARY TABLES` permission to the current database user.

You can create a temporary table using the `CREATE TEMPORARY TABLE <table_name>` statement. The default type is a local temporary table, which is visible only to the current session.

```
CREATE TEMPORARY TABLE top_50_eldest_authors (
    id BIGINT,
    name VARCHAR(255),
    age INT,
    PRIMARY KEY(id)
);
```

After creating the temporary table, you can use the `INSERT INTO table_name SELECT ...` statement to insert the results of the above query into the temporary table you just created.

```
INSERT INTO top_50_eldest_authors
SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year) AS
    ↪ age
FROM authors a
ORDER BY age DESC
LIMIT 50;
```

The result is as follows:

```
Query OK, 50 rows affected (0.03 sec)
Records: 50 Duplicates: 0 Warnings: 0
```

```
public List<Author> getTop50EldestAuthorInfo() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        stmt.executeUpdate("""
            CREATE TEMPORARY TABLE top_50_eldest_authors (
                id BIGINT,
                name VARCHAR(255),
                age INT,
                PRIMARY KEY(id)
            );
        """);

        stmt.executeUpdate("""
            INSERT INTO top_50_eldest_authors
```

```
            SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth
                ↪ _year) AS age
            FROM authors a
            ORDER BY age DESC
            LIMIT 50;
        """);

        ResultSet rs = stmt.executeQuery("""
            SELECT id, name FROM top_50_eldest_authors;
        """);

        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.6.1.3 Create a global temporary table

To create a global temporary table, you can add the `GLOBAL` keyword and end with `ON COMMIT DELETE ROWS`, which means the table will be deleted after the current transaction ends.

```
CREATE GLOBAL TEMPORARY TABLE IF NOT EXISTS top_50_eldest_authors_global (
    id BIGINT,
    name VARCHAR(255),
    age INT,
    PRIMARY KEY(id)
) ON COMMIT DELETE ROWS;
```

When inserting data to global temporary tables, you must explicitly declare the start of the transaction via `BEGIN`. Otherwise, the data will be cleared after the `INSERT INTO` statement is executed. Because in the Auto Commit mode, the transaction is automatically committed after the `INSERT INTO` statement is executed, and the global temporary table is cleared when the transaction ends.

When using global temporary tables, you need to turn off Auto Commit mode first. In Java, you can do this with the `conn.setAutoCommit(false);` statement, and you can commit the transaction explicitly with `conn.commit();`. The data added to the global temporary table during the transaction will be cleared after the transaction is committed or canceled.

```
public List<Author> getTop50EldestAuthorInfo() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        conn.setAutoCommit(false);

        Statement stmt = conn.createStatement();
        stmt.executeUpdate("""
            CREATE GLOBAL TEMPORARY TABLE IF NOT EXISTS top_50_eldest_authors
                ↪  (
                id BIGINT,
                name VARCHAR(255),
                age INT,
                PRIMARY KEY(id)
            ) ON COMMIT DELETE ROWS;
        """);

        stmt.executeUpdate("""
            INSERT INTO top_50_eldest_authors
            SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth
                ↪ _year) AS age
            FROM authors a
            ORDER BY age DESC
            LIMIT 50;
        """);

        ResultSet rs = stmt.executeQuery("""
            SELECT id, name FROM top_50_eldest_authors;
        """);

        conn.commit();
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("id"));
            author.setName(rs.getString("name"));
            authors.add(author);
        }
    }
    return authors;
}
```

4.7.6.2 View temporary tables

With the `SHOW [FULL] TABLES` statement, you can view a list of existing global temporary tables, but you cannot see any local temporary tables in the list. For now, TiDB does

not have a similar `information_schema.INNODB_TEMP_TABLE_INFO` system table for storing temporary table information.

For example, you can see the global temporary table `top_50_eldest_authors_global` in the table list, but not the `top_50_eldest_authors` table.

```
+------------------------------+------------+
| Tables_in_bookshop           | Table_type |
+------------------------------+------------+
| authors                      | BASE TABLE |
| book_authors                 | BASE TABLE |
| books                        | BASE TABLE |
| orders                       | BASE TABLE |
| ratings                      | BASE TABLE |
| top_50_eldest_authors_global | BASE TABLE |
| users                        | BASE TABLE |
+------------------------------+------------+
9 rows in set (0.00 sec)
```

4.7.6.3 Query a temporary table

Once the temporary table is ready, you can query it as a normal data table:

```
SELECT * FROM top_50_eldest_authors;
```

You can reference data from temporary tables to your query via Multi-table join queries:

```
EXPLAIN SELECT ANY_VALUE(ta.id) AS author_id, ANY_VALUE(ta.age), ANY_VALUE(
    ↪ ta.name), COUNT(*) AS books
FROM top_50_eldest_authors ta
LEFT JOIN book_authors ba ON ta.id = ba.author_id
GROUP BY ta.id;
```

Different from view, querying a temporary table gets data directly from the temporary table instead of executing the original query used in the data insert. In some cases, this can improve the query performance.

4.7.6.4 Drop a temporary table

A local temporary table in a session is automatically dropped after the **session** ends, along with both data and table schema. A global temporary table in a transaction is automatically cleared at the end of the **transaction**, but the table schema remains and needs to be deleted manually.

To manually drop local temporary tables, use the `DROP TABLE` or `DROP TEMPORARY TABLE` syntax. For example:

```
DROP TEMPORARY TABLE top_50_eldest_authors;
```

To manually drop global temporary tables, use the `DROP TABLE` or `DROP GLOBAL TEMPORARY TABLE` syntax. For example:

```
DROP GLOBAL TEMPORARY TABLE top_50_eldest_authors_global;
```

4.7.6.5 Limitation

For limitations of temporary tables in TiDB, see Compatibility restrictions with other TiDB features.

4.7.7 Common Table Expression

In some transaction scenarios, due to application complexity, you might need to write a single SQL statement of up to 2,000 lines. The statement probably contains a lot of aggregations and multi-level subquery nesting. Maintaining such a long SQL statement can be a developer's nightmare.

To avoid such a long SQL statement, you can simplify queries by using Views or cache intermediate query results by using Temporary tables.

This document introduces the Common Table Expression (CTE) syntax in TiDB, which is a more convenient way to reuse query results.

Since TiDB v5.1, TiDB supports the CTE of the ANSI SQL99 standard and recursion. With CTE, you can write SQL statements for complex application logic more efficiently and maintain the code much easier.

4.7.7.1 Basic use

A Common Table Expression (CTE) is a temporary result set that can be referred to multiple times within a SQL statement to improve the statement readability and execution efficiency. You can apply the `WITH` statement to use CTE.

Common Table Expressions can be classified into two types: non-recursive CTE and recursive CTE.

4.7.7.1.1 Non-recursive CTE

Non-recursive CTE can be defined using the following syntax:

```
WITH <query_name> AS (
    <query_definition>
)
SELECT ... FROM <query_name>;
```

For example, if you want to know how many books each of the 50 oldest authors have written, take the following steps:

Change the statement in temporary tables to the following:

```
WITH top_50_eldest_authors_cte AS (
    SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.birth_year)
        ↪ AS age
    FROM authors a
    ORDER BY age DESC
    LIMIT 50
)
SELECT
    ANY_VALUE(ta.id) AS author_id,
    ANY_VALUE(ta.age) AS author_age,
    ANY_VALUE(ta.name) AS author_name,
    COUNT(*) AS books
FROM top_50_eldest_authors_cte ta
LEFT JOIN book_authors ba ON ta.id = ba.author_id
GROUP BY ta.id;
```

The result is as follows:

```
+------------+------------+--------------------+-------+
| author_id | author_age | author_name    | books |
+------------+------------+--------------------+-------+
| 1238393239 |       80 | Araceli Purdy    |     1 |
|  817764631 |       80 | Ivory Davis      |     3 |
| 3093759193 |       80 | Lysanne Harris   |     1 |
| 2299112019 |       80 | Ray Macejkovic   |     4 |
...
+------------+------------+--------------------+-------+
50 rows in set (0.01 sec)
```

```
public List<Author> getTop50EldestAuthorInfoByCTE() throws SQLException {
    List<Author> authors = new ArrayList<>();
    try (Connection conn = ds.getConnection()) {
        Statement stmt = conn.createStatement();
        ResultSet rs = stmt.executeQuery("""
```

```
            WITH top_50_eldest_authors_cte AS (
                SELECT a.id, a.name, (IFNULL(a.death_year, YEAR(NOW())) - a.
                    ↪ birth_year) AS age
                FROM authors a
                ORDER BY age DESC
                LIMIT 50
            )
            SELECT
                ANY_VALUE(ta.id) AS author_id,
                ANY_VALUE(ta.name) AS author_name,
                ANY_VALUE(ta.age) AS author_age,
                COUNT(*) AS books
            FROM top_50_eldest_authors_cte ta
            LEFT JOIN book_authors ba ON ta.id = ba.author_id
            GROUP BY ta.id;
        """);
        while (rs.next()) {
            Author author = new Author();
            author.setId(rs.getLong("author_id"));
            author.setName(rs.getString("author_name"));
            author.setAge(rs.getShort("author_age"));
            author.setBooks(rs.getInt("books"));
            authors.add(author);
        }
    }
    return authors;
}
```

It can be found that the author "Ray Macejkovic" wrote 4 books. With the CTE query, you can further get the order and rating information of these 4 books as follows:

```
WITH books_authored_by_rm AS (
    SELECT *
    FROM books b
    LEFT JOIN book_authors ba ON b.id = ba.book_id
    WHERE author_id = 2299112019
), books_with_average_ratings AS (
    SELECT
        b.id AS book_id,
        AVG(r.score) AS average_rating
    FROM books_authored_by_rm b
    LEFT JOIN ratings r ON b.id = r.book_id
    GROUP BY b.id
), books_with_orders AS (
    SELECT
```

```
        b.id AS book_id,
        COUNT(*) AS orders
    FROM books_authored_by_rm b
    LEFT JOIN orders o ON b.id = o.book_id
    GROUP BY b.id
)
SELECT
    b.id AS `book_id`,
    b.title AS `book_title`,
    br.average_rating AS `average_rating`,
    bo.orders AS `orders`
FROM
    books_authored_by_rm b
    LEFT JOIN books_with_average_ratings br ON b.id = br.book_id
    LEFT JOIN books_with_orders bo ON b.id = bo.book_id
;
```

The result is as follows:

```
+------------+------------------------+----------------+--------+
| book_id    | book_title             | average_rating | orders |
+------------+------------------------+----------------+--------+
|  481008467 | The Documentary of goat |    2.0000 |    16 |
| 2224531102 | Brandt Skiles          |    2.7143 |    17 |
| 2641301356 | Sheridan Bashirian     |    2.4211 |    12 |
| 4154439164 | Karson Streich         |    2.5833 |    19 |
+------------+------------------------+----------------+--------+
4 rows in set (0.06 sec)
```

Three CTE blocks, which are separated by `,`, are defined in this SQL statement.

First, check out the books written by the author (ID is `2299112019`) in the CTE block `books_authored_by_rm`. Then find the average rating and order for these books respectively in `books_with_average_ratings` and `books_with_orders`. Finally, aggregate the results by the `JOIN` statement.

Note that the query in `books_authored_by_rm` executes only once, and then TiDB creates a temporary space to cache its result. When the queries in `books_with_average_ratings` and `books_with_orders` refer to `books_authored_by_rm`, TiDB gets its result directly from this temporary space.

> **Tip:**
>
> If the efficiency of the default CTE queries is not good, you can use the `MERGE()` hint to expand the CTE subquery to the outer query to improve the efficiency.

4.7.7.1.2 Recursive CTE

Recursive CTE can be defined using the following syntax:

```
WITH RECURSIVE <query_name> AS (
    <query_definition>
)
SELECT ... FROM <query_name>;
```

A classic example is to generate a set of Fibonacci numbers with recursive CTE:

```
WITH RECURSIVE fibonacci (n, fib_n, next_fib_n) AS
(
  SELECT 1, 0, 1
  UNION ALL
  SELECT n + 1, next_fib_n, fib_n + next_fib_n FROM fibonacci WHERE n < 10
)
SELECT * FROM fibonacci;
```

The result is as follows:

```
+------+-------+------------+
| n    | fib_n | next_fib_n |
+------+-------+------------+
|    1 |     0 |          1 |
|    2 |     1 |          1 |
|    3 |     1 |          2 |
|    4 |     2 |          3 |
|    5 |     3 |          5 |
|    6 |     5 |          8 |
|    7 |     8 |         13 |
|    8 |    13 |         21 |
|    9 |    21 |         34 |
|   10 |    34 |         55 |
+------+-------+------------+
10 rows in set (0.00 sec)
```

4.7.8 Read Replica Data

4.7.8.1 Follower Read

This document introduces how to use Follower Read to optimize query performance.

4.7.8.1.1 Introduction

TiDB uses Region as the basic unit to distribute data to all nodes in the cluster. A Region can have multiple replicas, and the replicas are divided into a leader and multiple followers. When the data on the leader changes, TiDB will update the data to the followers synchronously.

By default, TiDB only reads and writes data on the leader of the same Region. When a read hotspot occurs in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader and improve the throughput of the whole system by balancing the load among multiple followers.

4.7.8.1.2 When to use

Reduce read hotspots

You can visually analyze whether your application has a hotspot Region on the TiDB Dashboard Key Visualizer Page. You can check whether a read hotspot occurs by selecting the "metrics selection box" to `Read (bytes)` or `Read (keys)`.

For more information about handling hotspot, see TiDB Hotspot Problem Handling.

If read hotspots are unavoidable or the changing cost is very high, you can try using the Follower Read feature to better load the balance of reading requests to the follower Region.

Reduce latency for geo-distributed deployments

If your TiDB cluster is deployed across districts or data centers, different replicas of a Region are distributed in different districts or data centers. In this case, you can configure Follower Read as `closest-adaptive` or `closest-replicas` to allow TiDB to prioritize reading from the current data center, which can significantly reduce the latency and traffic overhead of read operations. For implementation details, see Follower Read.

4.7.8.1.3 Enable Follower Read

To enable Follower Read, set the variable `tidb_replica_read` (default value is `leader` ↪) to `follower`, `leader-and-follower`, `prefer-leader`, `closest-replicas`, or `closest` ↪ `-adaptive`:

```
SET [GLOBAL] tidb_replica_read = 'follower';
```

For more details about this variable, see Follower Read Usage.

In Java, to enable Follower Read, define a `FollowerReadHelper` class.

```
public enum FollowReadMode {
    LEADER("leader"),
    FOLLOWER("follower"),
    LEADER_AND_FOLLOWER("leader-and-follower"),
    CLOSEST_REPLICA("closest-replica"),
    CLOSEST_ADAPTIVE("closest-adaptive"),
    PREFER_LEADER("prefer-leader");

    private final String mode;

    FollowReadMode(String mode) {
        this.mode = mode;
    }

    public String getMode() {
        return mode;
    }
}

public class FollowerReadHelper {

    public static void setSessionReplicaRead(Connection conn, FollowReadMode
        ↪  mode) throws SQLException {
        if (mode == null) mode = FollowReadMode.LEADER;
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_replica_read = ?;"
        );
        stmt.setString(1, mode.getMode());
        stmt.execute();
    }

    public static void setGlobalReplicaRead(Connection conn, FollowReadMode
        ↪ mode) throws SQLException {
        if (mode == null) mode = FollowReadMode.LEADER;
        PreparedStatement stmt = conn.prepareStatement(
            "SET GLOBAL @@tidb_replica_read = ?;"
        );
        stmt.setString(1, mode.getMode());
        stmt.execute();
```

```
    }

}
```

When reading data from the Follower node, use the `setSessionReplicaRead(conn, ↪ FollowReadMode.LEADER_AND_FOLLOWER)` method to enable the Follower Read feature, which can balance the load between the Leader node and the Follower node in the current session. When the connection is disconnected, it will be restored to the original mode.

```
public static class AuthorDAO {

    // Omit initialization of instance variables...

    public void getAuthorsByFollowerRead() throws SQLException {
        try (Connection conn = ds.getConnection()) {
            // Enable the follower read feature.
            FollowerReadHelper.setSessionReplicaRead(conn, FollowReadMode.
                ↪ LEADER_AND_FOLLOWER);

            // Read the authors list for 100000 times.
            Random random = new Random();
            for (int i = 0; i < 100000; i++) {
                Integer birthYear = 1920 + random.nextInt(100);
                List<Author> authors = this.getAuthorsByBirthYear(birthYear);
                System.out.println(authors.size());
            }
        }
    }

    public List<Author> getAuthorsByBirthYear(Integer birthYear) throws
        ↪ SQLException {
        List<Author> authors = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("SELECT id, name
                ↪ FROM authors WHERE birth_year = ?");
            stmt.setInt(1, birthYear);
            ResultSet rs = stmt.executeQuery();
            while (rs.next()) {
                Author author = new Author();
                author.setId( rs.getLong("id"));
                author.setName(rs.getString("name"));
                authors.add(author);
            }
        }
        return authors;
```

```
    }
}
```

4.7.8.2 Stale Read

Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data at a specific time or within a specified time range, and thus save the latency caused by data replication between storage nodes. When you are using Stale Read, TiDB randomly selects a replica for data reading, which means that all replicas are available for data reading.

In practice, consider carefully whether it is appropriate to enable Stale Read in TiDB based on the usage scenarios. Do not enable Stale Read if your application cannot tolerate reading non-real-time data.

TiDB provides three levels of Stale Read: statement level, transaction level, and session level.

4.7.8.2.1 Introduction

In the Bookshop application, you can query the latest published books and their prices through the following SQL statement:

```
SELECT id, title, type, price FROM books ORDER BY published_at DESC LIMIT
    ↪ 5;
```

The result is as follows:

```
+------------+------------------------------+----------------------+--------+
    ↪
| id         | title                        | type                 | price |
+------------+------------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel                | 100.00 |
```

```
| 1064253862 | Collin Rolfson          | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat  | Magazine              | 159.75 |
|  893930596 | Myrl Hills              | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman             | Life                  | 477.91 |
+------------+-----------------------------+----------------------+--------+
    ↪
5 rows in set (0.02 sec)
```

In the list at this time (2022-04-20 15:20:00), the price of *The Story of Droolius Caesar* is 100.0.

At the same time, the seller found that the book was very popular and raised the price of the book to 150.0 through the following SQL statement:

```
UPDATE books SET price = 150 WHERE id = 3181093216;
```

The result is as follows:

```
Query OK, 1 row affected (0.00 sec)
Rows matched: 1 Changed: 1 Warnings: 0
```

By querying the latest books list, you can see that the price of this book has increased.

```
+------------+-----------------------------+----------------------+--------+
    ↪
| id         | title                       | type                 | price |
+------------+-----------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel               | 150.00 |
| 1064253862 | Collin Rolfson          | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat  | Magazine              | 159.75 |
|  893930596 | Myrl Hills              | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman             | Life                  | 477.91 |
+------------+-----------------------------+----------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

If it is not necessary to use the latest data, you can query with Stale Read, which might return outdated data, to avoid the latency caused by data replication during a strongly consistent read.

Assuming that in the Bookshop application, the real-time price of a book is not required on the book lists page but only required on the book details and order pages. Stale Read can be used to improve throughout of the application.

4.7.8.2.2 Statement level

To query the price of a book before a specific time, add an `AS OF TIMESTAMP <datetime > ` clause in the above query statement.

```
SELECT id, title, type, price FROM books AS OF TIMESTAMP '2022-04-20 15:20:00' ORDER BY published_at DESC LIMIT 5;
```

The result is as follows:

```
+------------+------------------------------+----------------------+--------+
| id         | title                        | type                 | price |
+------------+------------------------------+----------------------+--------+
| 3181093216 | The Story of Droolius Caesar | Novel                | 100.00 |
| 1064253862 | Collin Rolfson               | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat       | Magazine             | 159.75 |
|  893930596 | Myrl Hills                   | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman                  | Life                 | 477.91 |
+------------+------------------------------+----------------------+--------+
5 rows in set (0.01 sec)
```

In addition to specifying an exact time, you can also specify the following:

- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND` queries the latest data 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')` queries the latest data between `2016-10-08 16:45:26` and `2016-10-08 16:45:29`.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()-INTERVAL 20 SECOND, NOW())` queries the latest data within 20 seconds.

Note that the specified timestamp or interval cannot be too early or later than the current time. Additionally, `NOW()` defaults to second precision. To achieve higher precision, you can add a parameter, such as using `NOW(3)` for millisecond precision. For more information, see MySQL documentation.

Expired data will be recycled by Garbage Collection in TiDB, and the data will be retained for a short period before being cleared. The period is called GC Life Time (default 10 minutes). When a GC starts, the current time minus the time period will be used as the **GC Safe Point**. If you try to read the data before GC Safe Point, TiDB will report the following error:

```
ERROR 9006 (HY000): GC life time is shorter than transaction duration...
```

If the given timestamp is a future time, TiDB will report the following error:

```
ERROR 9006 (HY000): cannot set read timestamp to a future time.
```

```java
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooks() throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }
        }
        return books;
    }

    public void updateBookPriceByID(Long id, Double price) throws
        ↪ SQLException {
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("""
            UPDATE books SET price = ? WHERE id = ?;
            """);
            stmt.setDouble(1, price);
            stmt.setLong(2, id);
            int affects = stmt.executeUpdate();
            if (affects == 0) {
                throw new SQLException("Failed to update the book with id: "
                    ↪ + id);
            }
        }
    }

    public List<Book> getTop5LatestBooksWithStaleRead(Integer seconds)
        ↪ throws SQLException {
```

```
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            PreparedStatement stmt = conn.prepareStatement("""
            SELECT id, title, type, price FROM books AS OF TIMESTAMP NOW() -
                ↪ INTERVAL ? SECOND ORDER BY published_at DESC LIMIT 5;
            """);
            stmt.setInt(1, seconds);
            ResultSet rs = stmt.executeQuery();
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪  9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

```
List<Book> top5LatestBooks = bookDAO.getTop5LatestBooks();

if (top5LatestBooks.size() > 0) {
    System.out.println("The latest book price (before update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    Book book = top5LatestBooks.get(0);
    bookDAO.updateBookPriceByID(book.getId(), book.price + 10);

    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after update): " +
        ↪ top5LatestBooks.get(0).getPrice());
```

```
    // Use the stale read.
    top5LatestBooks = bookDAO.getTop5LatestBooksWithStaleRead(5);
    System.out.println("The latest book price (maybe stale): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // Try to stale read the data at the future time.
    bookDAO.getTop5LatestBooksWithStaleRead(-5);

    // Try to stale read the data before 20 minutes.
    bookDAO.getTop5LatestBooksWithStaleRead(20 * 60);
}
```

The following result shows that the price returned by Stale Read is 100.00, which is the value before the update.

```
The latest book price (before update): 100.00
The latest book price (after update): 150.00
The latest book price (maybe stale): 100.00
WARN: cannot set read timestamp to a future time.
WARN: GC life time is shorter than transaction duration.
```

4.7.8.2.3 Transaction level

With the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement, you can start a read-only transaction based on historical time, which reads historical data from a specified historical timestamp.

For example:

```
START TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL 5 SECOND;
```

By querying the latest price of the book, you can see that the price of *The Story of Droolius Caesar* is still 100.0, which is the value before the update.

```
SELECT id, title, type, price FROM books ORDER BY published_at DESC LIMIT
    ↪ 5;
```

The result is as follows:

```
+------------+------------------------------+----------------------+--------+
    ↪
| id         | title                        | type                 | price |
+------------+------------------------------+----------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel                | 100.00 |
| 1064253862 | Collin Rolfson               | Education & Reference | 92.85 |
```

```
| 1748583991 | The Documentary of cat  | Magazine           | 159.75 |
|  893930596 | Myrl Hills              | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman             | Life               | 477.91 |
+------------+-------------------------+--------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

After the transaction with the `COMMIT;` statement is committed, you can read the latest data.

```
+------------+-------------------------+--------------------+--------+
    ↪
| id         | title                   | type               | price |
+------------+-------------------------+--------------------+--------+
    ↪
| 3181093216 | The Story of Droolius Caesar | Novel         | 150.00 |
| 1064253862 | Collin Rolfson          | Education & Reference | 92.85 |
| 1748583991 | The Documentary of cat  | Magazine           | 159.75 |
|  893930596 | Myrl Hills              | Education & Reference | 356.85 |
| 3062833277 | Keven Wyman             | Life               | 477.91 |
+------------+-------------------------+--------------------+--------+
    ↪
5 rows in set (0.01 sec)
```

You can define a helper class for transactions, which encapsulates the command to enable Stale Read at the transaction level as a helper method.

```
public static class StaleReadHelper {

    public static void startTxnWithStaleRead(Connection conn, Integer
        ↪ seconds) throws SQLException {
        conn.setAutoCommit(false);
        PreparedStatement stmt = conn.prepareStatement(
            "START TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL ?
                ↪ SECOND;"
        );
        stmt.setInt(1, seconds);
        stmt.execute();
    }

}
```

Then define a method to enable the Stale Read feature through a transaction in the `BookDAO` class. Use the method to query instead of adding `AS OF TIMESTAMP` to the query statement.

```
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooksWithTxnStaleRead(Integer seconds)
        ↪ throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            // Start a read only transaction.
            TxnHelper.startTxnWithStaleRead(conn, seconds);

            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }

            // Commit transaction.
            conn.commit();
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪  9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

```
List<Book> top5LatestBooks = bookDAO.getTop5LatestBooks();

if (top5LatestBooks.size() > 0) {
    System.out.println("The latest book price (before update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    Book book = top5LatestBooks.get(0);
    bookDAO.updateBookPriceByID(book.getId(), book.price + 10);

    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after update): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // Use the stale read.
    top5LatestBooks = bookDAO.getTop5LatestBooksWithTxnStaleRead(5);
    System.out.println("The latest book price (maybe stale): " +
        ↪ top5LatestBooks.get(0).getPrice());

    // After the stale read transaction is committed.
    top5LatestBooks = bookDAO.getTop5LatestBooks();
    System.out.println("The latest book price (after the transaction commit)
        ↪ : " + top5LatestBooks.get(0).getPrice());
}
```

The result is as follows:

```
The latest book price (before update): 100.00
The latest book price (after update): 150.00
The latest book price (maybe stale): 100.00
The latest book price (after the transaction commit): 150
```

With the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement, you can set the opened transaction or the next transaction to be a read-only transaction based on a specified historical time. The transaction will read historical data based on the provided historical time.

For example, you can use the following `AS OF TIMESTAMP` statement to switch the ongoing transactions to the read-only mode and read historical data 5 seconds ago.

```
SET TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL 5 SECOND;
```

You can define a helper class for transactions, which encapsulates the command to enable Stale Read at the transaction level as a helper method.

```
public static class TxnHelper {
```

```
    public static void setTxnWithStaleRead(Connection conn, Integer seconds)
        ↪ throws SQLException {
        PreparedStatement stmt = conn.prepareStatement(
            "SET TRANSACTION READ ONLY AS OF TIMESTAMP NOW() - INTERVAL ?
                ↪ SECOND;"
        );
        stmt.setInt(1, seconds);
        stmt.execute();
    }

}
```

Then define a method to enable the Stale Read feature through a transaction in the `BookDAO` class. Use the method to query instead of adding `AS OF TIMESTAMP` to the query statement.

```
public class BookDAO {

    // Omit some code...

    public List<Book> getTop5LatestBooksWithTxnStaleRead2(Integer seconds)
        ↪ throws SQLException {
        List<Book> books = new ArrayList<>();
        try (Connection conn = ds.getConnection()) {
            StaleReadHelper.setTxnWithStaleRead(conn, seconds);

            // Start a read only transaction.
            conn.setAutoCommit(false);

            Statement stmt = conn.createStatement();
            ResultSet rs = stmt.executeQuery("""
            SELECT id, title, type, price FROM books ORDER BY published_at
                ↪ DESC LIMIT 5;
            """);
            while (rs.next()) {
                Book book = new Book();
                book.setId(rs.getLong("id"));
                book.setTitle(rs.getString("title"));
                book.setType(rs.getString("type"));
                book.setPrice(rs.getDouble("price"));
                books.add(book);
            }

            // Commit transaction.
            conn.commit();
```

```
        } catch (SQLException e) {
            if ("HY000".equals(e.getSQLState()) && e.getErrorCode() == 1105)
                ↪ {
                System.out.println("WARN: cannot set read timestamp to a
                    ↪ future time.");
            } else if ("HY000".equals(e.getSQLState()) && e.getErrorCode() ==
                ↪  9006) {
                System.out.println("WARN: GC life time is shorter than
                    ↪ transaction duration.");
            } else {
                throw e;
            }
        }
        return books;
    }
}
```

4.7.8.2.4 Session level

To support reading historical data, TiDB has introduced a new system variable `tidb_read_staleness` since v5.4. you can use it to set the range of historical data that the current session is allowed to read. Its data type is `int` and its scope is `SESSION`.

Enable Stale Read in a session:

```
SET @@tidb_read_staleness="-5";
```

For example, if the value is set to `-5` and TiKV or TiFlash has the corresponding historical data, TiDB selects a timestamp as new as possible within a 5-second time range.

Disable Stale Read in the session:

```
set @@tidb_read_staleness="";
```

```
public static class StaleReadHelper{

    public static void enableStaleReadOnSession(Connection conn, Integer
        ↪ seconds) throws SQLException {
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_read_staleness= ?;"
        );
        stmt.setString(1, String.format("-%d", seconds));
        stmt.execute();
    }

    public static void disableStaleReadOnSession(Connection conn) throws
        ↪ SQLException {
```

```
        PreparedStatement stmt = conn.prepareStatement(
            "SET @@tidb_read_staleness=\"\";"
        );
        stmt.execute();
    }

}
```

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.7.9 HTAP Queries

HTAP stands for Hybrid Transactional and Analytical Processing. Traditionally, databases are often designed for transactional or analytical scenarios, so the data platform often needs to be split into Transactional Processing and Analytical Processing, and the data needs to be replicated from the transactional database to the analytical database for quick response to analytical queries. TiDB databases can perform both transactional and analytical tasks, which greatly simplifies the construction of data platforms and allows users to use fresher data for analysis.

TiDB uses TiKV, a row-based storage engine, for Online Transactional Processing (OLTP), and TiFlash, a columnar storage engine, for Online Analytical Processing (OLAP). The row-based storage engine and the columnar storage engine co-exist for HTAP. Both storage engines can replicate data automatically and keep strong consistency. The row-based storage engine optimizes OLTP performance, and the columnar storage engine optimizes OLAP performance.

The Create a table section introduces how to enable the HTAP capability of TiDB. The following describes how to use HTAP to analyze data faster.

4.7.9.1 Data preparation

Before starting, you can import more sample data via the `tiup demo` command. For example:

```
tiup demo bookshop prepare --users=200000 --books=500000 --authors=100000 --
    ↪ ratings=1000000 --orders=1000000 --host 127.0.0.1 --port 4000 --drop-
    ↪ tables
```

Or you can use the Import function of TiDB Cloud to import the pre-prepared sample data.

4.7.9.2 Window functions

When using a database, in addition to storing your data and providing application features (such as ordering and rating books), you might also need to analyze the data in the database to make further operations and decisions.

The Query data from a single table document introduces how to use aggregate queries to analyze data as a whole. In more complex scenarios, you might want to aggregate the results of multiple aggregation queries into a single query. If you want to know the historical trend of the order amount of a particular book, you can aggregate `sum` for all order data of each month, and then aggregate the `sum` results together to get the historical trend.

To facilitate such analysis, since TiDB v3.0, TiDB supports window functions. For each row of data, this function provides the ability to access data across multiple rows. Different from a regular aggregation query, the window function aggregates rows without merging results set into a single row.

Similar to aggregate functions, you also need to follow a fixed set of syntax when using the window function:

```
SELECT
    window_function() OVER ([partition_clause] [order_clause] [frame_clause
        ↪ ]) AS alias
FROM
    table_name
```

4.7.9.2.1 `ORDER BY` clause

With the aggregate window function `sum()`, you can analyze the historical trend of the order amount of a particular book. For example:

```
WITH orders_group_by_month AS (
  SELECT DATE_FORMAT(ordered_at, '%Y-%c') AS month, COUNT(*) AS orders
  FROM orders
  WHERE book_id = 3461722937
  GROUP BY 1
)
SELECT
month,
SUM(orders) OVER(ORDER BY month ASC) as acc
```

```
FROM orders_group_by_month
ORDER BY month ASC;
```

The `sum()` function accumulates the data in the order specified by the `ORDER BY` statement in the `OVER` clause. The result is as follows:

```
+---------+-------+
| month   | acc   |
+---------+-------+
| 2011-5  |     1 |
| 2011-8  |     2 |
| 2012-1  |     3 |
| 2012-2  |     4 |
| 2013-1  |     5 |
| 2013-3  |     6 |
| 2015-11 |     7 |
| 2015-4  |     8 |
| 2015-8  |     9 |
| 2017-11 |    10 |
| 2017-5  |    11 |
| 2019-5  |    13 |
| 2020-2  |    14 |
+---------+-------+
13 rows in set (0.01 sec)
```

Visualize the above data through a line chart with time as the horizontal axis and cumulative order amount as the vertical axis. You can easily know the historical ordering trend of the book through the change of the slope.

4.7.9.2.2 `PARTITION BY` clause

Suppose that you want to analyze the historical ordering trend of different types of books, and visualize it in the same line chart with multiple series.

You can use the `PARTITION BY` clause to group books by types and count history orders for each type separately.

```
WITH orders_group_by_month AS (
    SELECT
        b.type AS book_type,
        DATE_FORMAT(ordered_at, '%Y-%c') AS month,
        COUNT(*) AS orders
    FROM orders o
    LEFT JOIN books b ON o.book_id = b.id
    WHERE b.type IS NOT NULL
    GROUP BY book_type, month
), acc AS (
```

```
    SELECT
        book_type,
        month,
        SUM(orders) OVER(PARTITION BY book_type ORDER BY book_type, month
            ↪ ASC) as acc
    FROM orders_group_by_month
    ORDER BY book_type, month ASC
)
SELECT * FROM acc;
```

The result is as follows:

```
+-----------------------------+---------+------+
| book_type                   | month   | acc |
+-----------------------------+---------+------+
| Magazine                    | 2011-10 |   1 |
| Magazine                    | 2011-8 |    2 |
| Magazine                    | 2012-5 |    3 |
| Magazine                    | 2013-1 |    4 |
| Magazine                    | 2013-6 |    5 |
...
| Novel                       | 2011-3 |   13 |
| Novel                       | 2011-4 |   14 |
| Novel                       | 2011-6 |   15 |
| Novel                       | 2011-8 |   17 |
| Novel                       | 2012-1 |   18 |
| Novel                       | 2012-2 |   20 |
...
| Sports                      | 2021-4 |   49 |
| Sports                      | 2021-7 |   50 |
| Sports                      | 2022-4 |   51 |
+-----------------------------+---------+------+
1500 rows in set (1.70 sec)
```

4.7.9.2.3 Non-aggregate window functions

TiDB also provides some non-aggregated window functions for more analysis statements.

For example, the Pagination Query document introduces how to use the `row_number()` function to achieve efficient pagination batch processing.

4.7.9.3 Hybrid workload

When using TiDB for real-time online analytical processing in hybrid load scenarios, you only need to provide an entry point of TiDB to your data. TiDB automatically selects different processing engines based on the specific business.

4.7.9.3.1 Create TiFlash replicas

TiDB uses the row-based storage engine, TiKV, by default. To use the columnar storage engine, TiFlash, see Enable HTAP capability. Before querying data through TiFlash, you need to create TiFlash replicas for `books` and `orders` tables using the following statement:

```
ALTER TABLE books SET TIFLASH REPLICA 1;
ALTER TABLE orders SET TIFLASH REPLICA 1;
```

You can check the progress of the TiFlash replicas using the following statement:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '
    ↪ bookshop' and TABLE_NAME = 'books';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '
    ↪ bookshop' and TABLE_NAME = 'orders';
```

A `PROGRESS` column of 1 indicates that the progress is 100% complete, and a `AVAILABLE` column of 1 indicates that the replica is currently available.

```
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| bookshop     | books      |      143 |             1 |                 |         1 |
    ↪         1 |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
1 row in set (0.07 sec)
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| TABLE_SCHEMA | TABLE_NAME | TABLE_ID | REPLICA_COUNT | LOCATION_LABELS |
    ↪ AVAILABLE | PROGRESS |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
| bookshop     | orders     |      147 |             1 |                 |         1 |
    ↪         1 |
+--------------+------------+----------+---------------+-----------------+-----------+--
    ↪
1 row in set (0.07 sec)
```

After replicas are added, you can use the `EXPLAIN` statement to check the execution plan of the above window function `PARTITION BY` clause. If `cop[tiflash]` appears in the execution plan, it means that the TiFlash engine has started to work.

Then, execute the sample SQL statement in `PARTITION BY` clause again. The result is as follows:

```
+-----------------------------+---------+------+
| book_type                   | month   | acc |
+-----------------------------+---------+------+
| Magazine                    | 2011-10 |   1 |
| Magazine                    | 2011-8 |    2 |
| Magazine                    | 2012-5 |    3 |
| Magazine                    | 2013-1 |    4 |
| Magazine                    | 2013-6 |    5 |
...
| Novel                       | 2011-3 |   13 |
| Novel                       | 2011-4 |   14 |
| Novel                       | 2011-6 |   15 |
| Novel                       | 2011-8 |   17 |
| Novel                       | 2012-1 |   18 |
| Novel                       | 2012-2 |   20 |
...
| Sports                      | 2021-4 |   49 |
| Sports                      | 2021-7 |   50 |
| Sports                      | 2022-4 |   51 |
+-----------------------------+---------+------+
1500 rows in set (0.79 sec)
```

By comparing the two execution results, you can find that the query speed is significantly improved with TiFlash (the improvement is more significant with a large volume of data). This is because a window function usually relies on a full table scan for some columns, and columnar TiFlash is more suitable to handle this type of analytical task than row-based TiKV. For TiKV, if you use primary keys or indexes to reduce the number of rows to be queried, the queries can be fast too and consume fewer resources compared with TiFlash.

4.7.9.3.2 Specify a query engine

TiDB uses the Cost Based Optimizer (CBO) to automatically choose whether to use TiFlash replicas based on cost estimates. However, if you are sure whether your query is transactional or analytical, you can specify the query engine to be used with Optimizer Hints.

To specify which engine to be used in a query, you can use the `/*+ read_from_storage (engine_name[table_name])*/` hint as in the following statement.

Note:

- If a table has an alias, use the alias instead of the table name in the hint, otherwise, the hint does not work.

- The `read_from_storage` hint does not work for common table expression.

```
WITH orders_group_by_month AS (
    SELECT
        /*+ read_from_storage(tikv[o]) */
        b.type AS book_type,
        DATE_FORMAT(ordered_at, '%Y-%c') AS month,
        COUNT(*) AS orders
    FROM orders o
    LEFT JOIN books b ON o.book_id = b.id
    WHERE b.type IS NOT NULL
    GROUP BY book_type, month
), acc AS (
    SELECT
        book_type,
        month,
        SUM(orders) OVER(PARTITION BY book_type ORDER BY book_type, month
            ↪ ASC) as acc
    FROM orders_group_by_month mo
    ORDER BY book_type, month ASC
)
SELECT * FROM acc;
```

You can use the `EXPLAIN` statement to check the execution plan of the above SQL statement. If `cop[tiflash]` and `cop[tikv]` appear in the task column at the same time, it means that TiFlash and TiKV are both scheduled to complete this query. Note that TiFlash and TiKV storage engines usually use different TiDB nodes, so the two query types are not affected by each other.

For more information about how TiDB chooses to use TiFlash, see Use TiDB to read TiFlash replicas

Ask the community on Discord or Slack, or submit a support ticket.

4.8 Vector Search

4.8.1 Vector Search Overview

Vector search offers a powerful solution for semantic similarity searches across diverse data types, such as documents, images, audio, and video. It allows developers to leverage their MySQL expertise to build scalable applications enriched with generative AI capabilities, simplifying the integration of advanced search functionality.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.1.1 Concepts

Vector search is a search method that prioritizes the meaning of your data to deliver relevant results.

Unlike traditional full-text search, which relies on exact keyword matching and word frequency, vector search converts various data types (such as text, images, or audio) into high-dimensional vectors and queries based on the similarity between these vectors. This search method captures the semantic meaning and contextual information of the data, leading to a more precise understanding of user intent.

Even when the search terms do not exactly match the content in the database, vector search can still provide results that align with the user's intent by analyzing the semantics of the data.

For example, a full-text search for "a swimming animal" only returns results containing these exact keywords. In contrast, vector search can return results for other swimming animals, such as fish or ducks, even if these results do not contain the exact keywords.

4.8.1.1.1 Vector embedding

A vector embedding, also known as an embedding, is a sequence of numbers that represents real-world objects in a high-dimensional space. It captures the meaning and context of unstructured data, such as documents, images, audio, and videos.

Vector embeddings are essential in machine learning and serve as the foundation for semantic similarity searches.

TiDB introduces Vector data types and Vector search index designed to optimize the storage and retrieval of vector embeddings, enhancing their use in AI applications. You can store vector embeddings in TiDB and perform vector search queries to find the most relevant data using these data types.

4.8.1.1.2 Embedding model

Embedding models are algorithms that transform data into vector embeddings.

Choosing an appropriate embedding model is crucial for ensuring the accuracy and relevance of semantic search results. For unstructured text data, you can find top-performing text embedding models on the Massive Text Embedding Benchmark (MTEB) Leaderboard.

To learn how to generate vector embeddings for your specific data types, refer to integration tutorials or examples of embedding models.

4.8.1.2 How vector search works

After converting raw data into vector embeddings and storing them in TiDB, your application can execute vector search queries to find the data most semantically or contextually relevant to a user's query.

TiDB vector search identifies the top-k nearest neighbor (KNN) vectors by using a distance function to calculate the distance between the given vector and vectors stored in the database. The vectors closest to the given vector in the query represent the most similar data in meaning.

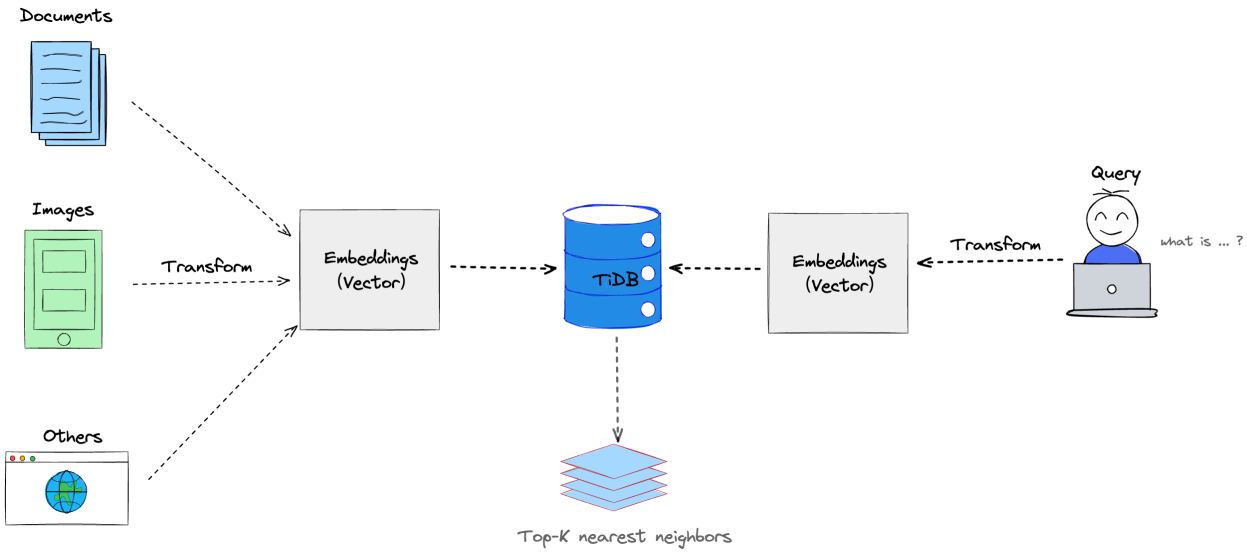

Figure 60: The Schematic TiDB Vector Search

As a relational database with integrated vector search capabilities, TiDB enables you to store data and their corresponding vector representations (that is, vector embeddings) together in one database. You can choose any of the following ways for storage:

- Store data and their corresponding vector representations in different columns of the same table.
- Store data and their corresponding vector representation in different tables. In this way, you need to use `JOIN` queries to combine the tables when retrieving data.

4.8.1.3 Use cases

4.8.1.3.1 Retrieval-Augmented Generation (RAG)

Retrieval-Augmented Generation (RAG) is an architecture designed to optimize the output of Large Language Models (LLMs). By using vector search, RAG applications can store vector embeddings in the database and retrieve relevant documents as additional context when the LLM generates responses, thereby improving the quality and relevance of the answers.

4.8.1.3.2 Semantic search

Semantic search is a search technology that returns results based on the meaning of a query, rather than simply matching keywords. It interprets the meaning across different languages and various types of data (such as text, images, and audio) using embeddings. Vector search algorithms then use these embeddings to find the most relevant data that satisfies the user's query.

4.8.1.3.3 Recommendation engine

A recommendation engine is a system that proactively suggests content, products, or services that are relevant and personalized to users. It accomplishes this by creating embeddings that represent user behavior and preferences. These embeddings help the system identify similar items that other users have interacted with or shown interest in. This increases the likelihood that the recommendations will be both relevant and appealing to the user.

4.8.1.4 See also

To get started with TiDB Vector Search, see the following documents:

- Get started with vector search using Python
- Get started with vector search using SQL

4.8.2 Get Started

4.8.2.1 Get Started with Vector Search via SQL

TiDB extends MySQL syntax to support Vector Search and introduce new Vector data types and several vector functions.

This tutorial demonstrates how to get started with TiDB Vector Search just using SQL statements. You will learn how to use the MySQL command-line client to complete the following operations:

- Connect to your TiDB cluster.
- Create a vector table.
- Store vector embeddings.
- Perform vector search queries.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.2.1.1 Prerequisites

To complete this tutorial, you need:

- MySQL command-line client (MySQL CLI) installed on your machine.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

4.8.2.1.2 Get started

Step 1. Connect to the TiDB cluster

Connect to your TiDB cluster depending on the TiDB deployment option you've selected.

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. In the connection dialog, select **MySQL CLI** from the **Connect With** drop-down list and keep the default setting of the **Connection Type** as **Public**.
4. If you have not set a password yet, click **Generate Password** to generate a random password.
5. Copy the connection command and paste it into your terminal. The following is an example for macOS:

```
mysql -u '<prefix>.root' -h '<host>' -P 4000 -D 'test' --ssl-mode=
    ↪ VERIFY_IDENTITY --ssl-ca=/etc/ssl/cert.pem -p'<password>'
```

After your TiDB Self-Managed cluster is started, execute your cluster connection command in the terminal.

The following is an example connection command for macOS:

```
mysql --comments --host 127.0.0.1 --port 4000 -u root
```

Step 2. Create a vector table

When creating a table, you can define a column as a vector column by specifying the `VECTOR` data type.

For example, to create a table `embedded_documents` with a three-dimensional `VECTOR` column, execute the following SQL statements using your MySQL CLI:

```
USE test;
CREATE TABLE embedded_documents (
    id       INT      PRIMARY KEY,
    -- Column to store the original content of the document.
    document TEXT,
    -- Column to store the vector representation of the document.
    embedding VECTOR(3)
);
```

The expected output is as follows:

```
Query OK, 0 rows affected (0.27 sec)
```

Step 3. Insert vector embeddings to the table

Insert three documents with their vector embeddings into the `embedded_documents` table:

```
INSERT INTO embedded_documents
VALUES
    (1, 'dog', '[1,2,1]'),
    (2, 'fish', '[1,2,4]'),
    (3, 'tree', '[1,0,0]');
```

The expected output is as follows:

```
Query OK, 3 rows affected (0.15 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

> **Note**
>
> This example simplifies the dimensions of the vector embeddings and uses only 3-dimensional vectors for demonstration purposes.
>
> In real-world applications, embedding models often produce vector embeddings with hundreds or thousands of dimensions.

Step 4. Query the vector table

To verify that the documents have been inserted correctly, query the `embedded_documents` table:

```
SELECT * FROM embedded_documents;
```

The expected output is as follows:

```
+----+----------+-----------+
| id | document | embedding |
+----+----------+-----------+
|  1 | dog      | [1,2,1]   |
|  2 | fish     | [1,2,4]   |
|  3 | tree     | [1,0,0]   |
+----+----------+-----------+
3 rows in set (0.15 sec)
```

Step 5. Perform a vector search query

Similar to full-text search, users provide search terms to the application when using vector search.

In this example, the search term is "a swimming animal", and its corresponding vector embedding is assumed to be `[1,2,3]`. In practical applications, you need to use an embedding model to convert the user's search term into a vector embedding.

Execute the following SQL statement, and TiDB will identify the top three documents closest to `[1,2,3]` by calculating and sorting the cosine distances (`vec_cosine_distance`) between the vector embeddings in the table.

```
SELECT id, document, vec_cosine_distance(embedding, '[1,2,3]') AS distance
FROM embedded_documents
ORDER BY distance
LIMIT 3;
```

The expected output is as follows:

```
+----+----------+--------------------+
| id | document | distance           |
+----+----------+--------------------+
|  2 | fish     | 0.00853986601633272 |
|  1 | dog      | 0.12712843905603044 |
|  3 | tree     |  0.7327387580875756 |
+----+----------+--------------------+
3 rows in set (0.15 sec)
```

The three terms in the search results are sorted by their respective distance from the queried vector: the smaller the distance, the more relevant the corresponding `document`.

Therefore, according to the output, the swimming animal is most likely a fish, or a dog with a gift for swimming.

- Vector Search Index

4.8.2.2 Get Started with TiDB + AI via Python

This tutorial demonstrates how to develop a simple AI application that provides **semantic search** features. Unlike traditional keyword search, semantic search intelligently understands the meaning behind your query and returns the most relevant result. For example, if you have documents titled "dog", "fish", and "tree", and you search for "a swimming animal", the application would identify "fish" as the most relevant result.

Throughout this tutorial, you will develop this AI application using TiDB Vector Search, Python, TiDB Vector SDK for Python, and AI models.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.2.2.1 Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

4.8.2.2.2 Get started

The following steps show how to develop the application from scratch. To run the demo directly, you can check out the sample code in the pingcap/tidb-vector-python repository.

Step 1. Create a new Python project

In your preferred directory, create a new Python project and a file named `example.py`:

```
mkdir python-client-quickstart
cd python-client-quickstart
touch example.py
```

Step 2. Install required dependencies

In your project directory, run the following command to install the required packages:

```
pip install sqlalchemy pymysql sentence-transformers tidb-vector python-
    ↪ dotenv
```

- `tidb-vector`: the Python client for interacting with TiDB vector search.
- `sentence-transformers`: a Python library that provides pre-trained models for generating vector embeddings from text.

Step 3. Configure the connection string to the TiDB cluster

Configure the cluster connection string depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `SQLAlchemy`.
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click the **PyMySQL** tab and copy the connection string.

> **Tip:**
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. In the root directory of your Python project, create a `.env` file and paste the connection string into it.

   The following is an example for macOS:

```
TIDB_DATABASE_URL="mysql+pymysql://<prefix>.root:<password>@gateway01.<
    ↪ region>.prod.aws.tidbcloud.com:4000/test?ssl_ca=/etc/ssl/cert.pem
    ↪ &ssl_verify_cert=true&ssl_verify_identity=true"
```

For a TiDB Self-Managed cluster, create a `.env` file in the root directory of your Python project. Copy the following content into the `.env` file, and modify the environment variable values according to the connection parameters of your TiDB cluster:

```
TIDB_DATABASE_URL="mysql+pymysql://<USER>:<PASSWORD>@<HOST>:<PORT>/<DATABASE
    ↪ >"
#### For example: TIDB_DATABASE_URL="mysql+pymysql://root@127.0.0.1:4000/
    ↪ test"
```

If you are running TiDB on your local machine, `<HOST>` is `127.0.0.1` by default. The initial `<PASSWORD>` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `<USER>`: The username to connect to the TiDB cluster.
- `<PASSWORD>`: The password to connect to the TiDB cluster.
- `<HOST>`: The host of the TiDB cluster.
- `<PORT>`: The port of the TiDB cluster.
- `<DATABASE>`: The name of the database you want to connect to.

Step 4. Initialize the embedding model

An embedding model transforms data into vector embeddings. This example uses the pre-trained model **msmarco-MiniLM-L12-cos-v5** for text embedding. This lightweight model, provided by the `sentence-transformers` library, transforms text data into 384-dimensional vector embeddings.

To set up the model, copy the following code into the `example.py` file. This code initializes a `SentenceTransformer` instance and defines a `text_to_embedding()` function for later use.

```
from sentence_transformers import SentenceTransformer

print("Downloading and loading the embedding model...")
embed_model = SentenceTransformer("sentence-transformers/msmarco-MiniLM-L12-
    ↪ cos-v5", trust_remote_code=True)
embed_model_dims = embed_model.get_sentence_embedding_dimension()

def text_to_embedding(text):
    """Generates vector embeddings for the given text."""
    embedding = embed_model.encode(text)
    return embedding.tolist()
```

Step 5. Connect to the TiDB cluster

Use the `TiDBVectorClient` class to connect to your TiDB cluster and create a table `embedded_documents` with a vector column.

> **Note**
>
> Make sure the dimension of your vector column in the table matches the dimension of the vectors generated by your embedding model. For example, the **msmarco-MiniLM-L12-cos-v5** model generates vectors with 384 dimensions, so the dimension of your vector columns in `embedded_documents` should be 384 as well.

```
import os
from tidb_vector.integrations import TiDBVectorClient
from dotenv import load_dotenv

#### Load the connection string from the .env file
load_dotenv()

vector_store = TiDBVectorClient(
   # The 'embedded_documents' table will store the vector data.
   table_name='embedded_documents',
   # The connection string to the TiDB cluster.
   connection_string=os.environ.get('TIDB_DATABASE_URL'),
   # The dimension of the vector generated by the embedding model.
   vector_dimension=embed_model_dims,
   # Recreate the table if it already exists.
   drop_existing_table=True,
)
```

Step 6. Embed text data and store the vectors

In this step, you will prepare sample documents containing single words, such as “dog”, “fish”, and “tree”. The following code uses the `text_to_embedding()` function to transform these text documents into vector embeddings, and then inserts them into the vector store.

```
documents = [
    {
        "id": "f8e7dee2-63b6-42f1-8b60-2d46710c1971",
        "text": "dog",
        "embedding": text_to_embedding("dog"),
        "metadata": {"category": "animal"},
    },
    {
        "id": "8dde1fbc-2522-4ca2-aedf-5dcb2966d1c6",
        "text": "fish",
        "embedding": text_to_embedding("fish"),
        "metadata": {"category": "animal"},
    },
    {
        "id": "e4991349-d00b-485c-a481-f61695f2b5ae",
        "text": "tree",
        "embedding": text_to_embedding("tree"),
        "metadata": {"category": "plant"},
    },
]

vector_store.insert(
    ids=[doc["id"] for doc in documents],
    texts=[doc["text"] for doc in documents],
    embeddings=[doc["embedding"] for doc in documents],
    metadatas=[doc["metadata"] for doc in documents],
)
```

Step 7. Perform semantic search

In this step, you will search for “a swimming animal”, which doesn’t directly match any words in existing documents.

The following code uses the `text_to_embedding()` function again to convert the query text into a vector embedding, and then queries with the embedding to find the top three closest matches.

```
def print_result(query, result):
   print(f"Search result (\"{query}\"):")
   for r in result:
      print(f"- text: \"{r.document}\", distance: {r.distance}")
```

```
query = "a swimming animal"
query_embedding = text_to_embedding(query)
search_result = vector_store.query(query_embedding, k=3)
print_result(query, search_result)
```

Run the `example.py` file and the output is as follows:

```
Search result ("a swimming animal"):
- text: "fish", distance: 0.4562914811223072
- text: "dog", distance: 0.6469335836410557
- text: "tree", distance: 0.798545178640937
```

The three terms in the search results are sorted by their respective distance from the queried vector: the smaller the distance, the more relevant the corresponding `document`.

Therefore, according to the output, the swimming animal is most likely a fish, or a dog with a gift for swimming.

4.8.3 Integrations

4.8.3.1 Vector Search Integration Overview

This document provides an overview of TiDB vector search integration, including supported AI frameworks, embedding models, and Object Relational Mapping (ORM) libraries.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.3.1.1 AI frameworks

TiDB provides official support for the following AI frameworks, enabling you to easily integrate AI applications developed based on these frameworks with TiDB Vector Search.

AI frameworks	Tutorial
Langchain	Integrate Vector Search with LangChain
LlamaIndex	Integrate Vector Search with LlamaIndex

Moreover, you can also use TiDB for various purposes, such as document storage and knowledge graph storage for AI applications.

4.8.3.1.2 Embedding models and services

TiDB Vector Search supports storing vectors of up to 16383 dimensions, which accommodates most embedding models.

You can either use self-deployed open-source embedding models or third-party embedding APIs provided by third-party embedding providers to generate vectors.

The following table lists some mainstream embedding service providers and the corresponding integration tutorials.

Embedding service providers	Tutorial
Jina AI	Integrate Vector Search with Jina AI Embeddings API

4.8.3.1.3 Object Relational Mapping (ORM) libraries

You can integrate TiDB Vector Search with your ORM library to interact with the TiDB database.

The following table lists the supported ORM libraries and the corresponding integration tutorials:

```
<th>Language</th>
<th>ORM/Client</th>
<th>How to install</th>
<th>Tutorial</th>
```

```
<td rowspan="4">Python</td>
<td>TiDB Vector Client</td>
<td><code>pip install tidb-vector[client]</code></td>
<td><a href="/tidb/v8.5/vector-search-get-started-using-python">Get Started
    ↪ with Vector Search Using Python</a></td>
```

```
<td>SQLAlchemy</td>
```

```
<td><code>pip install tidb-vector</code></td>
<td><a href="/tidb/v8.5/vector-search-integrate-with-sqlalchemy">Integrate
    ↪ TiDB Vector Search with SQLAlchemy</a></td>
```

```
<td>peewee</td>
<td><code>pip install tidb-vector</code></td>
<td><a href="/tidb/v8.5/vector-search-integrate-with-peewee">Integrate TiDB
    ↪ Vector Search with peewee</a></td>
```

```
<td>Django</td>
<td><code>pip install django-tidb[vector]</code></td>
<td><a href="/tidb/v8.5/vector-search-integrate-with-django-orm">Integrate
    ↪ TiDB Vector Search with Django</a></td>
```

4.8.3.2 AI Frameworks

4.8.3.2.1 Integrate Vector Search with LlamaIndex

This tutorial demonstrates how to integrate the vector search feature of TiDB with LlamaIndex.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

> **Tip**
>
> You can view the complete sample code on Jupyter Notebook, or run the sample code directly in the Colab online environment.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Jupyter Notebook installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Get started

This section provides step-by-step instructions for integrating TiDB Vector Search with LlamaIndex to perform semantic searches.

Step 1. Create a new Jupyter Notebook file

In the root directory, create a new Jupyter Notebook file named `integrate_with_llamaindex.ipynb`:

```
touch integrate_with_llamaindex.ipynb
```

Step 2. Install required dependencies

In your project directory, run the following command to install the required packages:

```
pip install llama-index-vector-stores-tidbvector
pip install llama-index
```

Open the `integrate_with_llamaindex.ipynb` file in Jupyter Notebook and add the following code to import the required packages:

```
import textwrap

from llama_index.core import SimpleDirectoryReader, StorageContext
from llama_index.core import VectorStoreIndex
from llama_index.vector_stores.tidbvector import TiDBVectorStore
```

Step 3. Configure environment variables

Configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `SQLAlchemy`.
    - **Operating System** matches your environment.

4. Click the **PyMySQL** tab and copy the connection string.

> **Tip:**
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. Configure environment variables.

    This document uses OpenAI as the embedding model provider. In this step, you need to provide the connection string obtained from the previous step and your OpenAI API key.

    To configure the environment variables, run the following code. You will be prompted to enter your connection string and OpenAI API key:

```
# Use getpass to securely prompt for environment variables in your
    ↪ terminal.
import getpass
import os

# Copy your connection string from the TiDB Cloud console.
# Connection string format: "mysql+pymysql://<USER>:<PASSWORD>@<HOST
    ↪ >:4000/<DB>?ssl_ca=/etc/ssl/cert.pem&ssl_verify_cert=true&ssl_
    ↪ verify_identity=true"
tidb_connection_string = getpass.getpass("TiDB Connection String:")
os.environ["OPENAI_API_KEY"] = getpass.getpass("OpenAI API Key:")
```

This document uses OpenAI as the embedding model provider. In this step, you need to provide the connection string of your TiDB cluster and your OpenAI API key.

To configure the environment variables, run the following code. You will be prompted to enter your connection string and OpenAI API key:

```
##### Use getpass to securely prompt for environment variables in your
    ↪ terminal.
import getpass
import os

##### Connection string format: "mysql+pymysql://<USER>:<PASSWORD>@<HOST
    ↪ >:4000/<DB>?ssl_ca=/etc/ssl/cert.pem&ssl_verify_cert=true&ssl_verify
    ↪ _identity=true"
tidb_connection_string = getpass.getpass("TiDB Connection String:")
os.environ["OPENAI_API_KEY"] = getpass.getpass("OpenAI API Key:")
```

Taking macOS as an example, the cluster connection string is as follows:

```
TIDB_DATABASE_URL="mysql+pymysql://<USERNAME>:<PASSWORD>@<HOST>:<PORT>/<
    ↪ DATABASE_NAME>"
##### For example: TIDB_DATABASE_URL="mysql+pymysql://root@127.0.0.1:4000/
    ↪ test"
```

You need to modify the parameters in the connection string according to your TiDB cluster. If you are running TiDB on your local machine, `<HOST>` is `127.0.0.1` by default. The initial `<PASSWORD>` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `<USERNAME>`: The username to connect to the TiDB cluster.
- `<PASSWORD>`: The password to connect to the TiDB cluster.
- `<HOST>`: The host of the TiDB cluster.
- `<PORT>`: The port of the TiDB cluster.
- `<DATABASE>`: The name of the database you want to connect to.

Step 4. Load the sample document

Step 4.1 Download the sample document

In your project directory, create a directory named `data/paul_graham/` and download the sample document `paul_graham_essay.txt` from the run-llama/llama_index GitHub repository.

```
!mkdir -p 'data/paul_graham/'
!wget 'https://raw.githubusercontent.com/run-llama/llama_index/main/docs/
    ↪ docs/examples/data/paul_graham/paul_graham_essay.txt' -O 'data/paul_
    ↪ graham/paul_graham_essay.txt'
```

Step 4.2 Load the document

Load the sample document from `data/paul_graham/paul_graham_essay.txt` using the `SimpleDirectoryReader` class.

```
documents = SimpleDirectoryReader("./data/paul_graham").load_data()
print("Document ID:", documents[0].doc_id)

for index, document in enumerate(documents):
   document.metadata = {"book": "paul_graham"}
```

Step 5. Embed and store document vectors

Step 5.1 Initialize the TiDB vector store

The following code creates a table named `paul_graham_test` in TiDB, which is optimized for vector search.

```
tidbvec = TiDBVectorStore(
   connection_string=tidb_connection_url,
   table_name="paul_graham_test",
   distance_strategy="cosine",
   vector_dimension=1536,
   drop_existing_table=False,
)
```

Upon successful execution, you can directly view and access the `paul_graham_test` table in your TiDB database.

Step 5.2 Generate and store embeddings

The following code parses the documents, generates embeddings, and stores them in the TiDB vector store.

```
storage_context = StorageContext.from_defaults(vector_store=tidbvec)
index = VectorStoreIndex.from_documents(
   documents, storage_context=storage_context, show_progress=True
)
```

The expected output is as follows:

```
Parsing nodes: 100%|      | 1/1 [00:00<00:00, 8.76it/s]
Generating embeddings: 100%|      | 21/21 [00:02<00:00, 8.22it/s]
```

Step 6. Perform a vector search

The following creates a query engine based on the TiDB vector store and performs a semantic similarity search.

```
query_engine = index.as_query_engine()
response = query_engine.query("What did the author do?")
print(textwrap.fill(str(response), 100))
```

> **Note**
>
> `TiDBVectorStore` only supports the `default` query mode.

The expected output is as follows:

```
The author worked on writing, programming, building microcomputers, giving
    ↪ talks at conferences,
publishing essays online, developing spam filters, painting, hosting dinner
    ↪ parties, and purchasing
a building for office use.
```

Step 7. Search with metadata filters

To refine your searches, you can use metadata filters to retrieve specific nearest-neighbor results that match the applied filters.

Query with `book != "paul_graham"` filter

The following example excludes results where the `book` metadata field is `"paul_graham"`:

```
from llama_index.core.vector_stores.types import (
   MetadataFilter,
   MetadataFilters,
)

query_engine = index.as_query_engine(
   filters=MetadataFilters(
      filters=[
         MetadataFilter(key="book", value="paul_graham", operator="!="),
      ]
   ),
   similarity_top_k=2,
)
response = query_engine.query("What did the author learn?")
print(textwrap.fill(str(response), 100))
```

The expected output is as follows:

```
Empty Response
```

Query with `book == "paul_graham"` filter

The following example filters results to include only documents where the `book` metadata field is `"paul_graham"`:

```
from llama_index.core.vector_stores.types import (
   MetadataFilter,
   MetadataFilters,
)

query_engine = index.as_query_engine(
   filters=MetadataFilters(
      filters=[
         MetadataFilter(key="book", value="paul_graham", operator="=="),
      ]
   ),
   similarity_top_k=2,
)
response = query_engine.query("What did the author learn?")
print(textwrap.fill(str(response), 100))
```

The expected output is as follows:

```
The author learned programming on an IBM 1401 using an early version of
    ↪ Fortran in 9th grade, then
later transitioned to working with microcomputers like the TRS-80 and Apple
    ↪ II. Additionally, the
author studied philosophy in college but found it unfulfilling, leading to a
    ↪  switch to studying AI.
Later on, the author attended art school in both the US and Italy, where
    ↪ they observed a lack of
substantial teaching in the painting department.
```

Step 8. Delete documents

Delete the first document from the index:

```
tidbvec.delete(documents[0].doc_id)
```

Check whether the documents had been deleted:

```
query_engine = index.as_query_engine()
response = query_engine.query("What did the author learn?")
print(textwrap.fill(str(response), 100))
```

The expected output is as follows:

```
Empty Response
```

4.8.3.2.2 Integrate Vector Search with LangChain

This tutorial demonstrates how to integrate the vector search feature of TiDB with LangChain.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

> **Tip**
>
> You can view the complete sample code on Jupyter Notebook, or run the sample code directly in the Colab online environment.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Jupyter Notebook installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Get started

This section provides step-by-step instructions for integrating TiDB Vector Search with LangChain to perform semantic searches.

Step 1. Create a new Jupyter Notebook file

In your preferred directory, create a new Jupyter Notebook file named `integrate_with_langchain.ipynb`:

```
touch integrate_with_langchain.ipynb
```

Step 2. Install required dependencies

In your project directory, run the following command to install the required packages:

```
!pip install langchain langchain-community
!pip install langchain-openai
!pip install pymysql
!pip install tidb-vector
```

Open the `integrate_with_langchain.ipynb` file in Jupyter Notebook, and then add the following code to import the required packages:

```
from langchain_community.document_loaders import TextLoader
from langchain_community.vectorstores import TiDBVectorStore
from langchain_openai import OpenAIEmbeddings
from langchain_text_splitters import CharacterTextSplitter
```

Step 3. Set up your environment

Configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `SQLAlchemy`.
    - **Operating System** matches your environment.
4. Click the **PyMySQL** tab and copy the connection string.

> **Tip:**
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. Configure environment variables.

   This document uses OpenAI as the embedding model provider. In this step, you need to provide the connection string obtained from the previous step and your OpenAI API key.

   To configure the environment variables, run the following code. You will be prompted to enter your connection string and OpenAI API key:

```
# Use getpass to securely prompt for environment variables in your
    ↪ terminal.
import getpass
import os

# Copy your connection string from the TiDB Cloud console.
# Connection string format: "mysql+pymysql://<USER>:<PASSWORD>@<HOST
    ↪ >:4000/<DB>?ssl_ca=/etc/ssl/cert.pem&ssl_verify_cert=true&ssl_
    ↪ verify_identity=true"
tidb_connection_string = getpass.getpass("TiDB Connection String:")
os.environ["OPENAI_API_KEY"] = getpass.getpass("OpenAI API Key:")
```

This document uses OpenAI as the embedding model provider. In this step, you need to provide the connection string obtained from the previous step and your OpenAI API key.

To configure the environment variables, run the following code. You will be prompted to enter your connection string and OpenAI API key:

```
##### Use getpass to securely prompt for environment variables in your
    ↪ terminal.
import getpass
import os

##### Connection string format: "mysql+pymysql://<USER>:<PASSWORD>@<HOST
    ↪ >:4000/<DB>?ssl_ca=/etc/ssl/cert.pem&ssl_verify_cert=true&ssl_verify
    ↪ _identity=true"
tidb_connection_string = getpass.getpass("TiDB Connection String:")
os.environ["OPENAI_API_KEY"] = getpass.getpass("OpenAI API Key:")
```

Taking macOS as an example, the cluster connection string is as follows:

```
TIDB_DATABASE_URL="mysql+pymysql://<USERNAME>:<PASSWORD>@<HOST>:<PORT>/<
    ↪ DATABASE_NAME>"
##### For example: TIDB_DATABASE_URL="mysql+pymysql://root@127.0.0.1:4000/
    ↪ test"
```

You need to modify the values of the connection parameters according to your TiDB cluster. If you are running TiDB on your local machine, `<HOST>` is `127.0.0.1` by default. The initial `<PASSWORD>` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `<USERNAME>`: The username to connect to the TiDB cluster.
- `<PASSWORD>`: The password to connect to the TiDB cluster.
- `<HOST>`: The host of the TiDB cluster.
- `<PORT>`: The port of the TiDB cluster.
- `<DATABASE>`: The name of the database you want to connect to.

Step 4. Load the sample document

Step 4.1 Download the sample document

In your project directory, create a directory named `data/how_to/` and download the sample document `state_of_the_union.txt` from the langchain-ai/langchain GitHub repository.

```
!mkdir -p 'data/how_to/'
!wget 'https://raw.githubusercontent.com/langchain-ai/langchain/master/docs/
    ↪ docs/how_to/state_of_the_union.txt' -O 'data/how_to/state_of_the_
    ↪ union.txt'
```

Step 4.2 Load and split the document

Load the sample document from `data/how_to/state_of_the_union.txt` and split it into chunks of approximately 1,000 characters each using a `CharacterTextSplitter`.

```
loader = TextLoader("data/how_to/state_of_the_union.txt")
documents = loader.load()
text_splitter = CharacterTextSplitter(chunk_size=1000, chunk_overlap=0)
docs = text_splitter.split_documents(documents)
```

Step 5. Embed and store document vectors

TiDB vector store supports both cosine distance (`consine`) and Euclidean distance (`l2`) for measuring similarity between vectors. The default strategy is cosine distance.

The following code creates a table named `embedded_documents` in TiDB, which is optimized for vector search.

```
embeddings = OpenAIEmbeddings()
vector_store = TiDBVectorStore.from_documents(
    documents=docs,
    embedding=embeddings,
    table_name="embedded_documents",
    connection_string=tidb_connection_string,
    distance_strategy="cosine", # default, another option is "l2"
)
```

Upon successful execution, you can directly view and access the `embedded_documents` table in your TiDB database.

Step 6. Perform a vector search

This step demonstrates how to query "What did the president say about Ketanji Brown Jackson" from the document `state_of_the_union.txt`.

```
query = "What did the president say about Ketanji Brown Jackson"
```

Option 1: Use `similarity_search_with_score()`

The `similarity_search_with_score()` method calculates the vector space distance between the documents and the query. This distance serves as a similarity score, determined by the chosen `distance_strategy`. The method returns the top `k` documents with the lowest scores. A lower score indicates a higher similarity between a document and your query.

```
docs_with_score = vector_store.similarity_search_with_score(query, k=3)
for doc, score in docs_with_score:
   print("-" * 80)
   print("Score: ", score)
   print(doc.page_content)
   print("-" * 80)
```

Expected output

```
--------------------------------------------------------------------------------
    ↪
Score: 0.18472413652518527
Tonight. I call on the Senate to: Pass the Freedom to Vote Act. Pass the
    ↪ John Lewis Voting Rights Act. And while you' re at it, pass the
    ↪ Disclose Act so Americans can know who is funding our elections.

Tonight, I' d like to honor someone who has dedicated his life to serve this
    ↪  country: Justice Stephen Breyer—an Army veteran, Constitutional
    ↪ scholar, and retiring Justice of the United States Supreme Court.
    ↪ Justice Breyer, thank you for your service.
```

```
One of the most serious constitutional responsibilities a President has is
    ↪ nominating someone to serve on the United States Supreme Court.

And I did that 4 days ago, when I nominated Circuit Court of Appeals Judge
    ↪ Ketanji Brown Jackson. One of our nation' s top legal minds, who will
    ↪  continue Justice Breyer' s legacy of excellence.
--------------------------------------------------------------------------------
    ↪
--------------------------------------------------------------------------------
    ↪
Score: 0.21757513022785557
A former top litigator in private practice. A former federal public defender
    ↪ . And from a family of public school educators and police officers. A
    ↪  consensus builder. Since she' s been nominated, she' s received a
    ↪ broad range of support—from the Fraternal Order of Police to former
    ↪ judges appointed by Democrats and Republicans.

And if we are to advance liberty and justice, we need to secure the Border
    ↪ and fix the immigration system.

We can do both. At our border, we' ve installed new technology like cutting-
    ↪ edge scanners to better detect drug smuggling.

We' ve set up joint patrols with Mexico and Guatemala to catch more human
    ↪ traffickers.

We' re putting in place dedicated immigration judges so families fleeing
    ↪ persecution and violence can have their cases heard faster.

We' re securing commitments and supporting partners in South and Central
    ↪ America to host more refugees and secure their own borders.
--------------------------------------------------------------------------------
    ↪
--------------------------------------------------------------------------------
    ↪
Score: 0.22676987253721725
And for our LGBTQ+ Americans, let' s finally get the bipartisan Equality Act
    ↪  to my desk. The onslaught of state laws targeting transgender
    ↪ Americans and their families is wrong.

As I said last year, especially to our younger transgender Americans, I will
    ↪  always have your back as your President, so you can be yourself and
    ↪ reach your God-given potential.
```

```
While it often appears that we never agree, that isn' t true. I signed 80
    ↪ bipartisan bills into law last year. From preventing government
    ↪ shutdowns to protecting Asian-Americans from still-too-common hate
    ↪ crimes to reforming military justice.

And soon, we' ll strengthen the Violence Against Women Act that I first
    ↪ wrote three decades ago. It is important for us to show the nation
    ↪ that we can come together and do big things.

So tonight I' m offering a Unity Agenda for the Nation. Four big things we
    ↪ can do together.

First, beat the opioid epidemic.
--------------------------------------------------------------------------------
    ↪
```

Option 2: Use `similarity_search_with_relevance_scores()`

The `similarity_search_with_relevance_scores()` method returns the top `k` documents with the highest relevance scores. A higher score indicates a higher degree of similarity between a document and your query.

```
docs_with_relevance_score = vector_store.similarity_search_with_relevance_
    ↪ scores(query, k=2)
for doc, score in docs_with_relevance_score:
    print("-" * 80)
    print("Score: ", score)
    print(doc.page_content)
    print("-" * 80)
```

Expected output

```
--------------------------------------------------------------------------------
    ↪
Score: 0.8152758634748147

```

Use as a retriever

In Langchain, a retriever is an interface that retrieves documents in response to an unstructured query, providing more functionality than a vector store. The following code demonstrates how to use TiDB vector store as a retriever.

```python
retriever = vector_store.as_retriever(
   search_type="similarity_score_threshold",
   search_kwargs={"k": 3, "score_threshold": 0.8},
)
docs_retrieved = retriever.invoke(query)
for doc in docs_retrieved:
   print("-" * 80)
   print(doc.page_content)
```

```
    print("-" * 80)
```

The expected output is as follows:

```
--------------------------------------------------------------------------------
    ↪
Tonight. I call on the Senate to: Pass the Freedom to Vote Act. Pass the
    ↪ John Lewis Voting Rights Act. And while you' re at it, pass the
    ↪ Disclose Act so Americans can know who is funding our elections.

Tonight, I' d like to honor someone who has dedicated his life to serve this
    ↪  country: Justice Stephen Breyer—an Army veteran, Constitutional
    ↪ scholar, and retiring Justice of the United States Supreme Court.
    ↪ Justice Breyer, thank you for your service.

One of the most serious constitutional responsibilities a President has is
    ↪ nominating someone to serve on the United States Supreme Court.

And I did that 4 days ago, when I nominated Circuit Court of Appeals Judge
    ↪ Ketanji Brown Jackson. One of our nation' s top legal minds, who will
    ↪  continue Justice Breyer' s legacy of excellence.
--------------------------------------------------------------------------------
    ↪
```

Remove the vector store

To remove an existing TiDB vector store, use the `drop_vectorstore()` method:

```
vector_store.drop_vectorstore()
```

Search with metadata filters

To refine your searches, you can use metadata filters to retrieve specific nearest-neighbor results that match the applied filters.

Supported metadata types

Each document in the TiDB vector store can be paired with metadata, structured as key-value pairs within a JSON object. Keys are always strings, while values can be any of the following types:

- String
- Number: integer or floating point
- Boolean: `true` or `false`

For example, the following is a valid metadata payload:

```
{
  "page": 12,
  "book_title": "Siddhartha"
}
```

Metadata filter syntax

Available filters include the following:

- `$or`: Selects vectors that match any one of the specified conditions.
- `$and`: Selects vectors that match all the specified conditions.
- `$eq`: Equal to the specified value.
- `$ne`: Not equal to the specified value.
- `$gt`: Greater than the specified value.
- `$gte`: Greater than or equal to the specified value.
- `$lt`: Less than the specified value.
- `$lte`: Less than or equal to the specified value.
- `$in`: In the specified array of values.
- `$nin`: Not in the specified array of values.

If the metadata of a document is as follows:

```
{
  "page": 12,
  "book_title": "Siddhartha"
}
```

The following metadata filters can match this document:

```
{ "page": 12 }
```

```
{ "page": { "$eq": 12 } }
```

```
{
  "page": {
    "$in": [11, 12, 13]
  }
}
```

```
{ "page": { "$nin": [13] } }
```

```
{ "page": { "$lt": 11 } }
```

```
{
  "$or": [{ "page": 11 }, { "page": 12 }],
  "$and": [{ "page": 12 }, { "page": 13 }]
}
```

In a metadata filter, TiDB treats each key-value pair as a separate filter clause and combines these clauses using the `AND` logical operator.

Example

The following example adds two documents to `TiDBVectorStore` and adds a `title` field to each document as the metadata:

```
vector_store.add_texts(
    texts=[
        "TiDB Vector offers advanced, high-speed vector processing
            ↪ capabilities, enhancing AI workflows with efficient data
            ↪ handling and analytics support.",
        "TiDB Vector, starting as low as $10 per month for basic usage",
    ],
    metadatas=[
        {"title": "TiDB Vector functionality"},
        {"title": "TiDB Vector Pricing"},
    ],
)
```

The expected output is as follows:

```
[UUID('c782cb02-8eec-45be-a31f-fdb78914f0a7'),
 UUID('08dcd2ba-9f16-4f29-a9b7-18141f8edae3')]
```

Perform a similarity search with metadata filters:

```
docs_with_score = vector_store.similarity_search_with_score(
    "Introduction to TiDB Vector", filter={"title": "TiDB Vector
        ↪ functionality"}, k=4
)
for doc, score in docs_with_score:
    print("-" * 80)
    print("Score: ", score)
    print(doc.page_content)
    print("-" * 80)
```

The expected output is as follows:

```
--------------------------------------------------------------------------------
    ↪
```

```
Score: 0.12761409169211535
TiDB Vector offers advanced, high-speed vector processing capabilities,
    ↪ enhancing AI workflows with efficient data handling and analytics
    ↪ support.
--------------------------------------------------------------------------------
    ↪
```

Advanced usage example: travel agent

This section demonstrates a use case of integrating vector search with Langchain for a travel agent. The goal is to create personalized travel reports for clients, helping them find airports with specific amenities, such as clean lounges and vegetarian options.

The process involves two main steps:

1. Perform a semantic search across airport reviews to identify airport codes that match the desired amenities.
2. Execute a SQL query to merge these codes with route information, highlighting airlines and destinations that align with user's preferences.

Prepare data

First, create a table to store airport route data:

```
##### Create a table to store flight plan data.
vector_store.tidb_vector_client.execute(
    """CREATE TABLE airplan_routes (
        id INT AUTO_INCREMENT PRIMARY KEY,
        airport_code VARCHAR(10),
        airline_code VARCHAR(10),
        destination_code VARCHAR(10),
        route_details TEXT,
        duration TIME,
        frequency INT,
        airplane_type VARCHAR(50),
        price DECIMAL(10, 2),
        layover TEXT
    );"""
)

##### Insert some sample data into airplan_routes and the vector table.
vector_store.tidb_vector_client.execute(
    """INSERT INTO airplan_routes (
        airport_code,
        airline_code,
        destination_code,
        route_details,
```

```
        duration,
        frequency,
        airplane_type,
        price,
        layover
    ) VALUES
    ('JFK', 'DL', 'LAX', 'Non-stop from JFK to LAX.', '06:00:00', 5, 'Boeing
        ↪  777', 299.99, 'None'),
    ('LAX', 'AA', 'ORD', 'Direct LAX to ORD route.', '04:00:00', 3, 'Airbus
        ↪ A320', 149.99, 'None'),
    ('EFGH', 'UA', 'SEA', 'Daily flights from SFO to SEA.', '02:30:00', 7, '
        ↪ Boeing 737', 129.99, 'None');
    """
)
vector_store.add_texts(
    texts=[
        "Clean lounges and excellent vegetarian dining options. Highly
            ↪ recommended.",
        "Comfortable seating in lounge areas and diverse food selections,
            ↪ including vegetarian.",
        "Small airport with basic facilities.",
    ],
    metadatas=[
        {"airport_code": "JFK"},
        {"airport_code": "LAX"},
        {"airport_code": "EFGH"},
    ],
)
```

The expected output is as follows:

```
[UUID('6dab390f-acd9-4c7d-b252-616606fbc89b'),
 UUID('9e811801-0e6b-4893-8886-60f4fb67ce69'),
 UUID('f426747c-0f7b-4c62-97ed-3eeb7c8dd76e')]
```

Perform a semantic search

The following code searches for airports with clean facilities and vegetarian options:

```
retriever = vector_store.as_retriever(
    search_type="similarity_score_threshold",
    search_kwargs={"k": 3, "score_threshold": 0.85},
)
semantic_query = "Could you recommend a US airport with clean lounges and
    ↪ good vegetarian dining options?"
reviews = retriever.invoke(semantic_query)
```

```
for r in reviews:
    print("-" * 80)
    print(r.page_content)
    print(r.metadata)
    print("-" * 80)
```

The expected output is as follows:

```
--------------------------------------------------------------------------------
    ↪
Clean lounges and excellent vegetarian dining options. Highly recommended.
{'airport_code': 'JFK'}
--------------------------------------------------------------------------------
    ↪
--------------------------------------------------------------------------------
    ↪
Comfortable seating in lounge areas and diverse food selections, including
    ↪ vegetarian.
{'airport_code': 'LAX'}
--------------------------------------------------------------------------------
    ↪
```

Retrieve detailed airport information

Extract airport codes from the search results and query the database for detailed route information:

```
##### Extracting airport codes from the metadata
airport_codes = [review.metadata["airport_code"] for review in reviews]

##### Executing a query to get the airport details
search_query = "SELECT * FROM airplan_routes WHERE airport_code IN :codes"
params = {"codes": tuple(airport_codes)}

airport_details = vector_store.tidb_vector_client.execute(search_query,
    ↪ params)
airport_details.get("result")
```

The expected output is as follows:

```
[(1, 'JFK', 'DL', 'LAX', 'Non-stop from JFK to LAX.', datetime.timedelta(
    ↪ seconds=21600), 5, 'Boeing 777', Decimal('299.99'), 'None'),
 (2, 'LAX', 'AA', 'ORD', 'Direct LAX to ORD route.', datetime.timedelta(
     ↪ seconds=14400), 3, 'Airbus A320', Decimal('149.99'), 'None')]
```

Streamline the process

Alternatively, you can streamline the entire process using a single SQL query:

```
search_query = f"""
    SELECT
        VEC_Cosine_Distance(se.embedding, :query_vector) as distance,
        ar.*,
        se.document as airport_review
    FROM
        airplan_routes ar
    JOIN
        {TABLE_NAME} se ON ar.airport_code = JSON_UNQUOTE(JSON_EXTRACT(se.
            ↪ meta, '$.airport_code'))
    ORDER BY distance ASC
    LIMIT 5;
"""
query_vector = embeddings.embed_query(semantic_query)
params = {"query_vector": str(query_vector)}
airport_details = vector_store.tidb_vector_client.execute(search_query,
    ↪ params)
airport_details.get("result")
```

The expected output is as follows:

```
[(0.1219207353407008, 1, 'JFK', 'DL', 'LAX', 'Non-stop from JFK to LAX.',
    ↪ datetime.timedelta(seconds=21600), 5, 'Boeing 777', Decimal('299.99')
    ↪ , 'None', 'Clean lounges and excellent vegetarian dining options.
    ↪ Highly recommended.'),
 (0.14613754359804654, 2, 'LAX', 'AA', 'ORD', 'Direct LAX to ORD route.',
     ↪ datetime.timedelta(seconds=14400), 3, 'Airbus A320', Decimal
     ↪ ('149.99'), 'None', 'Comfortable seating in lounge areas and diverse
     ↪  food selections, including vegetarian.'),
 (0.19840519342700513, 3, 'EFGH', 'UA', 'SEA', 'Daily flights from SFO to
     ↪ SEA.', datetime.timedelta(seconds=9000), 7, 'Boeing 737', Decimal
     ↪ ('129.99'), 'None', 'Small airport with basic facilities.')]
```

Clean up data

Finally, clean up the resources by dropping the created table:

```
vector_store.tidb_vector_client.execute("DROP TABLE airplan_routes")
```

The expected output is as follows:

```
{'success': True, 'result': 0, 'error': None}
```

4.8.3.3 Embedding Models/Services

4.8.3.3.1 Integrate TiDB Vector Search with Jina AI Embeddings API

This tutorial walks you through how to use Jina AI to generate embeddings for text data, and then store the embeddings in TiDB vector storage and search similar texts based on embeddings.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Run the sample app

You can quickly learn about how to integrate TiDB Vector Search with JinaAI Embedding by following the steps below.

Step 1. Clone the repository

Clone the `tidb-vector-python` repository to your local machine:

```
git clone https://github.com/pingcap/tidb-vector-python.git
```

Step 2. Create a virtual environment

Create a virtual environment for your project:

```
cd tidb-vector-python/examples/jina-ai-embeddings-demo
python3 -m venv .venv
source .venv/bin/activate
```

Step 3. Install required dependencies

Install the required dependencies for the demo project:

```
pip install -r requirements.txt
```

Step 4. Configure the environment variables

Get the Jina AI API key from the Jina AI Embeddings API page, and then configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.
    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `SQLAlchemy`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Switch to the **PyMySQL** tab and click the **Copy** icon to copy the connection string.

> **Tip:**
> If you have not set a password yet, click **Create password** to generate a random password.

5. Set the Jina AI API key and the TiDB connection string as environment variables in your terminal, or create a `.env` file with the following environment variables:

```
JINAAI_API_KEY="****"
TIDB_DATABASE_URL="{tidb_connection_string}"
```

The following is an example connection string for macOS:

```
TIDB_DATABASE_URL="mysql+pymysql://<prefix>.root:<password>@gateway01.<
    ↪ region>.prod.aws.tidbcloud.com:4000/test?ssl_ca=/etc/ssl/cert.pem
    ↪ &ssl_verify_cert=true&ssl_verify_identity=true"
```

For a TiDB Self-Managed cluster, set the environment variables for connecting to your TiDB cluster in your terminal as follows:

```
export JINA_API_KEY="****"
export TIDB_DATABASE_URL="mysql+pymysql://<USERNAME>:<PASSWORD>@<HOST>:<PORT
    ↪ >/<DATABASE>"
##### For example: export TIDB_DATABASE_URL="mysql+pymysql://root@127
    ↪ .0.0.1:4000/test"
```

You need to replace parameters in the preceding command according to your TiDB cluster. If you are running TiDB on your local machine, `<HOST>` is `127.0.0.1` by default. The initial `<PASSWORD>` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `<USERNAME>`: The username to connect to the TiDB cluster.
- `<PASSWORD>`: The password to connect to the TiDB cluster.
- `<HOST>`: The host of the TiDB cluster.
- `<PORT>`: The port of the TiDB cluster.
- `<DATABASE>`: The name of the database you want to connect to.

Step 5. Run the demo

```
python jina-ai-embeddings-demo.py
```

Example output:

```
- Inserting Data to TiDB...
  - Inserting: Jina AI offers best-in-class embeddings, reranker and prompt
      ↪ optimizer, enabling advanced multimodal AI.
  - Inserting: TiDB is an open-source MySQL-compatible database that
      ↪ supports Hybrid Transactional and Analytical Processing (HTAP)
      ↪ workloads.
- List All Documents and Their Distances to the Query:
```

```
  - distance: 0.3585317326132522
    content: Jina AI offers best-in-class embeddings, reranker and prompt
       ↪ optimizer, enabling advanced multimodal AI.
  - distance: 0.10858102967720984
    content: TiDB is an open-source MySQL-compatible database that supports
       ↪ Hybrid Transactional and Analytical Processing (HTAP) workloads.
- The Most Relevant Document and Its Distance to the Query:
  - distance: 0.10858102967720984
    content: TiDB is an open-source MySQL-compatible database that supports
       ↪ Hybrid Transactional and Analytical Processing (HTAP) workloads.
```

Sample code snippets

Get embeddings from Jina AI

Define a `generate_embeddings` helper function to call Jina AI embeddings API:

```python
import os
import requests
import dotenv

dotenv.load_dotenv()

JINAAI_API_KEY = os.getenv('JINAAI_API_KEY')

def generate_embeddings(text: str):
    JINAAI_API_URL = 'https://api.jina.ai/v1/embeddings'
    JINAAI_HEADERS = {
        'Content-Type': 'application/json',
        'Authorization': f'Bearer {JINAAI_API_KEY}'
    }
    JINAAI_REQUEST_DATA = {
        'input': [text],
        'model': 'jina-embeddings-v2-base-en' # with dimension 768.
    }
    response = requests.post(JINAAI_API_URL, headers=JINAAI_HEADERS, json=
       ↪ JINAAI_REQUEST_DATA)
    return response.json()['data'][0]['embedding']
```

Connect to the TiDB cluster

Connect to the TiDB cluster through SQLAlchemy:

```python
import os
import dotenv

from tidb_vector.sqlalchemy import VectorType
from sqlalchemy.orm import Session, declarative_base
```

```
dotenv.load_dotenv()

TIDB_DATABASE_URL = os.getenv('TIDB_DATABASE_URL')
assert TIDB_DATABASE_URL is not None
engine = create_engine(url=TIDB_DATABASE_URL, pool_recycle=300)
```

Define the vector table schema

Create a table named `jinaai_tidb_demo_documents` with a `content` column for storing texts and a vector column named `content_vec` for storing embeddings:

```
from sqlalchemy import Column, Integer, String, create_engine
from sqlalchemy.orm import declarative_base

Base = declarative_base()

class Document(Base):
    __tablename__ = "jinaai_tidb_demo_documents"

    id = Column(Integer, primary_key=True)
    content = Column(String(255), nullable=False)
    content_vec = Column(
        # DIMENSIONS is determined by the embedding model,
        # for Jina AI's jina-embeddings-v2-base-en model it's 768.
        VectorType(dim=768),
        comment="hnsw(distance=cosine)"
```

Note:

- The dimension of the vector column must match the dimension of the embeddings generated by the embedding model.
- In this example, the dimension of embeddings generated by the `jina-embeddings-v2-base-en` model is `768`.

Create embeddings with Jina AI and store in TiDB

Use the Jina AI Embeddings API to generate embeddings for each piece of text and store the embeddings in TiDB:

```
TEXTS = [
   'Jina AI offers best-in-class embeddings, reranker and prompt optimizer,
      ↪ enabling advanced multimodal AI.',
```

```
    'TiDB is an open-source MySQL-compatible database that supports Hybrid
        ↪ Transactional and Analytical Processing (HTAP) workloads.',
]
data = []

for text in TEXTS:
    # Generate embeddings for the texts via Jina AI API.
    embedding = generate_embeddings(text)
    data.append({
        'text': text,
        'embedding': embedding
    })

with Session(engine) as session:
    print('- Inserting Data to TiDB...')
    for item in data:
        print(f' - Inserting: {item["text"]}')
        session.add(Document(
            content=item['text'],
            content_vec=item['embedding']
        ))
    session.commit()
```

Perform semantic search with Jina AI embeddings in TiDB

Generate the embedding for the query text via Jina AI embeddings API, and then search for the most relevant document based on the cosine distance between **the embedding of the query text** and **each embedding in the vector table**:

```
query = 'What is TiDB?'
##### Generate the embedding for the query via Jina AI API.
query_embedding = generate_embeddings(query)

with Session(engine) as session:
    print('- The Most Relevant Document and Its Distance to the Query:')
    doc, distance = session.query(
        Document,
        Document.content_vec.cosine_distance(query_embedding).label('distance
            ↪ ')
    ).order_by(
        'distance'
    ).limit(1).first()
    print(f' - distance: {distance}\n'
          f'   content: {doc.content}')
```

4.8.3.4 ORM Libraries

4.8.3.4.1 Integrate TiDB Vector Search with SQLAlchemy

This tutorial walks you through how to use SQLAlchemy to interact with TiDB Vector Search, store embeddings, and perform vector search queries.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Run the sample app

You can quickly learn about how to integrate TiDB Vector Search with SQLAlchemy by following the steps below.

Step 1. Clone the repository

Clone the `tidb-vector-python` repository to your local machine:

```
git clone https://github.com/pingcap/tidb-vector-python.git
```

Step 2. Create a virtual environment

Create a virtual environment for your project:

```
cd tidb-vector-python/examples/orm-sqlalchemy-quickstart
python3 -m venv .venv
source .venv/bin/activate
```

Step 3. Install the required dependencies

Install the required dependencies for the demo project:

```
pip install -r requirements.txt
```

Alternatively, you can install the following packages for your project:

```
pip install pymysql python-dotenv sqlalchemy tidb-vector
```

Step 4. Configure the environment variables

Configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your environment.

    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `SQLAlchemy`.
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Click the **PyMySQL** tab and copy the connection string.

> **Tip:**
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. In the root directory of your Python project, create a `.env` file and paste the connection string into it.

   The following is an example for macOS:

```
TIDB_DATABASE_URL="mysql+pymysql://<prefix>.root:<password>@gateway01.<
    ↪ region>.prod.aws.tidbcloud.com:4000/test?ssl_ca=/etc/ssl/cert.pem
    ↪ &ssl_verify_cert=true&ssl_verify_identity=true"
```

For a TiDB Self-Managed cluster, create a `.env` file in the root directory of your Python project. Copy the following content into the `.env` file, and modify the environment variable values according to the connection parameters of your TiDB cluster:

```
TIDB_DATABASE_URL="mysql+pymysql://<USER>:<PASSWORD>@<HOST>:<PORT>/<DATABASE
    ↪ >"
##### For example: TIDB_DATABASE_URL="mysql+pymysql://root@127.0.0.1:4000/
    ↪ test"
```

If you are running TiDB on your local machine, `<HOST>` is `127.0.0.1` by default. The initial `<PASSWORD>` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `<USER>`: The username to connect to the TiDB cluster.
- `<PASSWORD>`: The password to connect to the TiDB cluster.
- `<HOST>`: The host of the TiDB cluster.
- `<PORT>`: The port of the TiDB cluster.
- `<DATABASE>`: The name of the database you want to connect to.

Step 5. Run the demo

```
python sqlalchemy-quickstart.py
```

Example output:

```
Get 3-nearest neighbor documents:
  - distance: 0.00853986601633272
    document: fish
```

```
  - distance: 0.12712843905603044
    document: dog
  - distance: 0.7327387580875756
    document: tree
Get documents within a certain distance:
  - distance: 0.00853986601633272
    document: fish
  - distance: 0.12712843905603044
    document: dog
```

Sample code snippets

You can refer to the following sample code snippets to develop your application.

Create vector tables

Connect to TiDB cluster

```
import os
import dotenv

from sqlalchemy import Column, Integer, create_engine, Text
from sqlalchemy.orm import declarative_base, Session
from tidb_vector.sqlalchemy import VectorType

dotenv.load_dotenv()

tidb_connection_string = os.environ['TIDB_DATABASE_URL']
engine = create_engine(tidb_connection_string)
```

Define a vector column

Create a table with a column named `embedding` that stores a 3-dimensional vector.

```
Base = declarative_base()

class Document(Base):
    __tablename__ = 'sqlalchemy_demo_documents'
    id = Column(Integer, primary_key=True)
    content = Column(Text)
    embedding = Column(VectorType(3))
```

Store documents with embeddings

```
with Session(engine) as session:
   session.add(Document(content="dog", embedding=[1, 2, 1]))
   session.add(Document(content="fish", embedding=[1, 2, 4]))
   session.add(Document(content="tree", embedding=[1, 0, 0]))
   session.commit()
```

Search the nearest neighbor documents

Search for the top-3 documents that are semantically closest to the query vector `[1, 2, 3]` based on the cosine distance function.

```
with Session(engine) as session:
  distance = Document.embedding.cosine_distance([1, 2, 3]).label('distance'
    ↪ )
  results = session.query(
    Document, distance
  ).order_by(distance).limit(3).all()
```

Search documents within a certain distance

Search for documents whose cosine distance from the query vector `[1, 2, 3]` is less than 0.2.

```
with Session(engine) as session:
    distance = Document.embedding.cosine_distance([1, 2, 3]).label('distance
      ↪ ')
    results = session.query(
        Document, distance
    ).filter(distance < 0.2).order_by(distance).limit(3).all()
```

4.8.3.4.2 Integrate TiDB Vector Search with peewee

This tutorial walks you through how to use peewee to interact with the TiDB Vector Search, store embeddings, and perform vector search queries.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Run the sample app

You can quickly learn about how to integrate TiDB Vector Search with peewee by following the steps below.

Step 1. Clone the repository

Clone the `tidb-vector-python` repository to your local machine:

```
git clone https://github.com/pingcap/tidb-vector-python.git
```

Step 2. Create a virtual environment

Create a virtual environment for your project:

```
cd tidb-vector-python/examples/orm-peewee-quickstart
python3 -m venv .venv
source .venv/bin/activate
```

Step 3. Install required dependencies

Install the required dependencies for the demo project:

```
pip install -r requirements.txt
```

Alternatively, you can install the following packages for your project:

```
pip install peewee pymysql python-dotenv tidb-vector
```

Step 4. Configure the environment variables

Configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.

2. Click **Connect** in the upper-right corner. A connection dialog is displayed.

3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`.
    - **Branch** is set to `main`.
    - **Connect With** is set to `General`.
    - **Operating System** matches your environment.

> **Tip:**
>
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Copy the connection parameters from the connection dialog.

> **Tip:**
>
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. In the root directory of your Python project, create a `.env` file and paste the connection parameters to the corresponding environment variables.

    - `TIDB_HOST`: The host of the TiDB cluster.
    - `TIDB_PORT`: The port of the TiDB cluster.
    - `TIDB_USERNAME`: The username to connect to the TiDB cluster.
    - `TIDB_PASSWORD`: The password to connect to the TiDB cluster.
    - `TIDB_DATABASE`: The database name to connect to.
    - `TIDB_CA_PATH`: The path to the root certificate file.

    The following is an example for macOS:

```
TIDB_HOST=gateway01.****.prod.aws.tidbcloud.com
TIDB_PORT=4000
TIDB_USERNAME=********.root
TIDB_PASSWORD=********
TIDB_DATABASE=test
TIDB_CA_PATH=/etc/ssl/cert.pem
```

For a TiDB Self-Managed cluster, create a `.env` file in the root directory of your Python project. Copy the following content into the `.env` file, and modify the environment variable values according to the connection parameters of your TiDB cluster:

```
TIDB_HOST=127.0.0.1
TIDB_PORT=4000
TIDB_USERNAME=root
TIDB_PASSWORD=
TIDB_DATABASE=test
```

If you are running TiDB on your local machine, `TIDB_HOST` is `127.0.0.1` by default. The initial `TIDB_PASSWORD` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `TIDB_HOST`: The host of the TiDB cluster.
- `TIDB_PORT`: The port of the TiDB cluster.
- `TIDB_USERNAME`: The username to connect to the TiDB cluster.
- `TIDB_PASSWORD`: The password to connect to the TiDB cluster.
- `TIDB_DATABASE`: The name of the database you want to connect to.

Step 5. Run the demo

```
python peewee-quickstart.py
```

Example output:

```
Get 3-nearest neighbor documents:
  - distance: 0.00853986601633272
    document: fish
  - distance: 0.12712843905603044
    document: dog
  - distance: 0.7327387580875756
    document: tree
Get documents within a certain distance:
  - distance: 0.00853986601633272
    document: fish
  - distance: 0.12712843905603044
    document: dog
```

Sample code snippets

You can refer to the following sample code snippets to develop your application.

Create vector tables

Connect to TiDB cluster

```
import os
import dotenv

from peewee import Model, MySQLDatabase, SQL, TextField
from tidb_vector.peewee import VectorField

dotenv.load_dotenv()

##### Using `pymysql` as the driver.
connect_kwargs = {
    'ssl_verify_cert': True,
    'ssl_verify_identity': True,
}

##### Using `mysqlclient` as the driver.
##### connect_kwargs = {
#####     'ssl_mode': 'VERIFY_IDENTITY',
#####     'ssl': {
#####         # Root certificate default path
#####         # https://docs.pingcap.com/tidbcloud/secure-connections-to-
    ↪ serverless-clusters/#root-certificate-default-path
#####         'ca': os.environ.get('TIDB_CA_PATH', '/path/to/ca.pem'),
#####     },
##### }

db = MySQLDatabase(
    database=os.environ.get('TIDB_DATABASE', 'test'),
    user=os.environ.get('TIDB_USERNAME', 'root'),
    password=os.environ.get('TIDB_PASSWORD', ''),
    host=os.environ.get('TIDB_HOST', 'localhost'),
    port=int(os.environ.get('TIDB_PORT', '4000')),
    **connect_kwargs,
)
```

Define a vector column

Create a table with a column named `peewee_demo_documents` that stores a 3-dimensional vector.

```
class Document(Model):
    class Meta:
        database = db
        table_name = 'peewee_demo_documents'

    content = TextField()
```

```
    embedding = VectorField(3)
```

Store documents with embeddings

```
Document.create(content='dog', embedding=[1, 2, 1])
Document.create(content='fish', embedding=[1, 2, 4])
Document.create(content='tree', embedding=[1, 0, 0])
```

Search the nearest neighbor documents

Search for the top-3 documents that are semantically closest to the query vector `[1, 2, 3]` based on the cosine distance function.

```
distance = Document.embedding.cosine_distance([1, 2, 3]).alias('distance')
results = Document.select(Document, distance).order_by(distance).limit(3)
```

Search documents within a certain distance

Search for the documents whose cosine distance from the query vector `[1, 2, 3]` is less than 0.2.

```
distance_expression = Document.embedding.cosine_distance([1, 2, 3])
distance = distance_expression.alias('distance')
results = Document.select(Document, distance).where(distance_expression <
    ↪ 0.2).order_by(distance).limit(3)
```

4.8.3.4.3 Integrate TiDB Vector Search with Django ORM

This tutorial walks you through how to use Django ORM to interact with the TiDB Vector Search, store embeddings, and perform vector search queries.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

Note:

The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

Prerequisites

To complete this tutorial, you need:

- Python 3.8 or higher installed.
- Git installed.
- A TiDB cluster.

If you don't have a TiDB cluster, you can create one as follows:

- Follow Deploy a local test TiDB cluster or Deploy a production TiDB cluster to create a local cluster.
- Follow Creating a TiDB Cloud Serverless cluster to create your own TiDB Cloud cluster.

Run the sample app

You can quickly learn about how to integrate TiDB Vector Search with Django ORM by following the steps below.

Step 1. Clone the repository

Clone the `tidb-vector-python` repository to your local machine:

```
git clone https://github.com/pingcap/tidb-vector-python.git
```

Step 2. Create a virtual environment

Create a virtual environment for your project:

```
cd tidb-vector-python/examples/orm-django-quickstart
python3 -m venv .venv
source .venv/bin/activate
```

Step 3. Install required dependencies

Install the required dependencies for the demo project:

```
pip install -r requirements.txt
```

Alternatively, you can install the following packages for your project:

```
pip install Django django-tidb mysqlclient numpy python-dotenv
```

If you encounter installation issues with mysqlclient, refer to the mysqlclient official documentation.

What is `django-tidb`

`django-tidb` is a TiDB dialect for Django, which enhances the Django ORM to support TiDB-specific features (for example, Vector Search) and resolves compatibility issues between TiDB and Django.

To install `django-tidb`, choose a version that matches your Django version. For example, if you are using `django==4.2.*`, install `django-tidb==4.2.*`. The minor version does not need to be the same. It is recommended to use the latest minor version.

For more information, refer to django-tidb repository.

Step 4. Configure the environment variables

Configure the environment variables depending on the TiDB deployment option you've selected.

For a TiDB Cloud Serverless cluster, take the following steps to obtain the cluster connection string and configure environment variables:

1. Navigate to the **Clusters** page, and then click the name of your target cluster to go to its overview page.
2. Click **Connect** in the upper-right corner. A connection dialog is displayed.
3. Ensure the configurations in the connection dialog match your operating environment.

    - **Connection Type** is set to `Public`
    - **Branch** is set to `main`
    - **Connect With** is set to `General`
    - **Operating System** matches your environment.

> **Tip:**
> If your program is running in Windows Subsystem for Linux (WSL), switch to the corresponding Linux distribution.

4. Copy the connection parameters from the connection dialog.

> **Tip:**
> If you have not set a password yet, click **Generate Password** to generate a random password.

5. In the root directory of your Python project, create a `.env` file and paste the connection parameters to the corresponding environment variables.

    - `TIDB_HOST`: The host of the TiDB cluster.
    - `TIDB_PORT`: The port of the TiDB cluster.
    - `TIDB_USERNAME`: The username to connect to the TiDB cluster.
    - `TIDB_PASSWORD`: The password to connect to the TiDB cluster.
    - `TIDB_DATABASE`: The database name to connect to.
    - `TIDB_CA_PATH`: The path to the root certificate file.

    The following is an example for macOS:

```
TIDB_HOST=gateway01.****.prod.aws.tidbcloud.com
TIDB_PORT=4000
TIDB_USERNAME=********.root
TIDB_PASSWORD=********
TIDB_DATABASE=test
TIDB_CA_PATH=/etc/ssl/cert.pem
```

For a TiDB Self-Managed cluster, create a `.env` file in the root directory of your Python project. Copy the following content into the `.env` file, and modify the environment variable values according to the connection parameters of your TiDB cluster:

```
TIDB_HOST=127.0.0.1
TIDB_PORT=4000
TIDB_USERNAME=root
TIDB_PASSWORD=
TIDB_DATABASE=test
```

If you are running TiDB on your local machine, `TIDB_HOST` is `127.0.0.1` by default. The initial `TIDB_PASSWORD` is empty, so if you are starting the cluster for the first time, you can omit this field.

The following are descriptions for each parameter:

- `TIDB_HOST`: The host of the TiDB cluster.
- `TIDB_PORT`: The port of the TiDB cluster.
- `TIDB_USERNAME`: The username to connect to the TiDB cluster.
- `TIDB_PASSWORD`: The password to connect to the TiDB cluster.
- `TIDB_DATABASE`: The name of the database you want to connect to.

Step 5. Run the demo

Migrate the database schema:

```
python manage.py migrate
```

Run the Django development server:

```
python manage.py runserver
```

Open your browser and visit `http://127.0.0.1:8000` to try the demo application. Here are the available API paths:

API Path	Description
`POST: /insert_documents`	Insert documents with embeddings.
`GET: /get_nearest_neighbors_documents`	Get the 3-nearest neighbor documents.
`GET: /get_documents_within_distance`	Get documents within a certain distance.

Sample code snippets

You can refer to the following sample code snippets to complete your own application development.

Connect to the TiDB cluster

In the file `sample_project/settings.py`, add the following configurations:

```
dotenv.load_dotenv()

DATABASES = {
    "default": {
        # https://github.com/pingcap/django-tidb
        "ENGINE": "django_tidb",
        "HOST": os.environ.get("TIDB_HOST", "127.0.0.1"),
        "PORT": int(os.environ.get("TIDB_PORT", 4000)),
        "USER": os.environ.get("TIDB_USERNAME", "root"),
        "PASSWORD": os.environ.get("TIDB_PASSWORD", ""),
        "NAME": os.environ.get("TIDB_DATABASE", "test"),
        "OPTIONS": {
            "charset": "utf8mb4",
        },
    }
}

TIDB_CA_PATH = os.environ.get("TIDB_CA_PATH", "")
if TIDB_CA_PATH:
    DATABASES["default"]["OPTIONS"]["ssl_mode"] = "VERIFY_IDENTITY"
    DATABASES["default"]["OPTIONS"]["ssl"] = {
        "ca": TIDB_CA_PATH,
    }
```

You can create a `.env` file in the root directory of your project and set up the environment variables `TIDB_HOST`, `TIDB_PORT`, `TIDB_USERNAME`, `TIDB_PASSWORD`, `TIDB_DATABASE`,

and `TIDB_CA_PATH` with the actual values of your TiDB cluster.

Create vector tables

Define a vector column

`tidb-django` provides a `VectorField` to store vector embeddings in a table.

Create a table with a column named `embedding` that stores a 3-dimensional vector.

```
class Document(models.Model):
   content = models.TextField()
   embedding = VectorField(dimensions=3)
```

Store documents with embeddings

```
Document.objects.create(content="dog", embedding=[1, 2, 1])
Document.objects.create(content="fish", embedding=[1, 2, 4])
Document.objects.create(content="tree", embedding=[1, 0, 0])
```

Search the nearest neighbor documents

TiDB Vector support the following distance functions:

- `L1Distance`
- `L2Distance`
- `CosineDistance`
- `NegativeInnerProduct`

Search for the top-3 documents that are semantically closest to the query vector `[1, 2, 3]` based on the cosine distance function.

```
results = Document.objects.annotate(
   distance=CosineDistance('embedding', [1, 2, 3])
).order_by('distance')[:3]
```

Search documents within a certain distance

Search for the documents whose cosine distance from the query vector `[1, 2, 3]` is less than 0.2.

```
results = Document.objects.annotate(
   distance=CosineDistance('embedding', [1, 2, 3])
).filter(distance__lt=0.2).order_by('distance')[:3]
```

4.8.4 Improve Vector Search Performance

TiDB Vector Search enables you to perform Approximate Nearest Neighbor (ANN) queries that search for results similar to an image, document, or other input. To improve the query performance, review the following best practices.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.4.1 Add vector search index for vector columns

The vector search index dramatically improves the performance of vector search queries, usually by 10x or more, with a trade-off of only a small decrease of recall rate.

4.8.4.2 Ensure vector indexes are fully built

After you insert a large volume of vector data, some of it might be in the Delta layer waiting for persistence. The vector index for such data will be built after the data is persisted. Until all vector data is indexed, vector search performance is suboptimal. To check the index build progress, see View index build progress.

4.8.4.3 Reduce vector dimensions or shorten embeddings

The computational complexity of vector search indexing and queries increases significantly as the dimension of vectors grows, requiring more floating-point comparisons.

To optimize performance, consider reducing vector dimensions whenever feasible. This usually needs switching to another embedding model. When switching models, you need to evaluate the impact of the model change on the accuracy of vector queries.

Certain embedding models like OpenAI `text-embedding-3-large` support shortening embeddings, which removes some numbers from the end of vector sequences without losing the embedding's concept-representing properties. You can also use such an embedding model to reduce the vector dimensions.

4.8.4.4 Exclude vector columns from the results

Vector embedding data is usually large and only used during the search process. By excluding vector columns from query results, you can greatly reduce the data transferred between the TiDB server and your SQL client, thereby improving query performance.

To exclude vector columns, explicitly list the columns you want to retrieve in the `SELECT` clause, instead of using `SELECT *` to retrieve all columns.

4.8.4.5 Warm up the index

When accessing an index that has never been used or has not been accessed for a long time (cold access), TiDB needs to load the entire index from cloud storage or disk (instead of from memory). This process takes time and often results in higher query latency. Additionally, if there are no SQL queries for an extended period (for example, several hours), computing resources are reclaimed, causing subsequent access to become cold access.

To avoid such query latency, warm up your index before actual workload by running similar vector search queries that hit the vector index.

4.8.5 Vector Search Limitations

This document describes the known limitations of TiDB vector search.

> **Warning:**
>
> The vector search feature is experimental. It is not recommended that you use it in the production environment. This feature might be changed without prior notice. If you find a bug, you can report an issue on GitHub.

> **Note:**
>
> The vector search feature is only available for TiDB Self-Managed clusters and TiDB Cloud Serverless clusters.

4.8.5.1 Vector data type limitations

- Each vector supports up to 16383 dimensions.
- Vector data types cannot store `NaN`, `Infinity`, or `-Infinity` values.

- Vector data types cannot store double-precision floating-point numbers. If you insert or store double-precision floating-point numbers in vector columns, TiDB converts them to single-precision floating-point numbers.
- Vector columns cannot be used as primary keys or as part of a primary key.
- Vector columns cannot be used as unique indexes or as part of a unique index.
- Vector columns cannot be used as partition keys or as part of a partition key.
- Currently, TiDB does not support modifying a vector column to other data types (such as `JSON` and `VARCHAR`).

4.8.5.2 Vector index limitations

See Vector search restrictions.

4.8.5.3 Compatibility with TiDB tools

- Make sure that you are using v8.4.0 or a later version of BR to back up and restore data. Restoring tables with vector data types to TiDB clusters earlier than v8.4.0 is not supported.
- TiDB Data Migration (DM) does not support migrating or replicating MySQL 9.0 vector data types to TiDB.
- When TiCDC replicates vector data to a downstream that does not support vector data types, it will change the vector data types to another type. For more information, see Compatibility with vector data types.

4.9 Transaction

4.9.1 Transaction overview

TiDB supports complete distributed transactions, providing optimistic transactions and pessimistic transactions (introduced in TiDB 3.0). This article mainly introduces transaction statements, optimistic transactions and pessimistic transactions, transaction isolation levels, and application-side retry and error handling in optimistic transactions.

4.9.1.1 Common statements

This chapter introduces how to use transactions in TiDB. The following example demonstrates the process of a simple transaction:

Bob wants to transfer $20 to Alice. This transaction includes two operations:

- Bob's account is reduced by $20.
- Alice's account is increased by $20.

Transactions can ensure that both of the above operations are executed successfully or both fail.

Insert some sample data into the table using the `users` table in the bookshop database:

```
INSERT INTO users (id, nickname, balance)
  VALUES (2, 'Bob', 200);
INSERT INTO users (id, nickname, balance)
  VALUES (1, 'Alice', 100);
```

Run the following transactions and explain what each statement means:

```
BEGIN;
  UPDATE users SET balance = balance - 20 WHERE nickname = 'Bob';
  UPDATE users SET balance = balance + 20 WHERE nickname= 'Alice';
COMMIT;
```

After the above transaction is executed successfully, the table should look like this:

```
+----+--------------+---------+
| id | account_name | balance |
+----+--------------+---------+
|  1 | Alice        |  120.00 |
|  2 | Bob          |  180.00 |
+----+--------------+---------+
```

4.9.1.1.1 Start a transaction

To explicitly start a new transaction, you can use either `BEGIN` or `START TRANSACTION`.

```
BEGIN;
```

```
START TRANSACTION;
```

The default transaction mode of TiDB is pessimistic. You can also explicitly specify the optimistic transaction model:

```
BEGIN OPTIMISTIC;
```

Enable the pessimistic transaction mode:

```
BEGIN PESSIMISTIC;
```

If the current session is in the middle of a transaction when the above statement is executed, TiDB commits the current transaction first, and then starts a new transaction.

4.9.1.1.2 Commit a transaction

You can use the `COMMIT` statement to commit all modifications made by TiDB in the current transaction.

```
COMMIT;
```

Before enabling optimistic transactions, make sure that your application can properly handle errors that may be returned by a `COMMIT` statement. If you are not sure how your application will handle it, it is recommended to use the pessimistic transaction mode instead.

4.9.1.1.3 Roll back a transaction

You can use the `ROLLBACK` statement to roll back modifications of the current transaction.

```
ROLLBACK;
```

In the previous transfer example, if you roll back the entire transaction, Alice's and Bob's balances will remain unchanged, and all modifications of the current transaction are canceled.

```
TRUNCATE TABLE `users`;

INSERT INTO `users` (`id`, `nickname`, `balance`) VALUES (1, 'Alice', 100),
    ↪  (2, 'Bob', 200);

SELECT * FROM `users`;
+----+--------------+---------+
| id | nickname   | balance |
+----+--------------+---------+
|  1 | Alice      |  100.00 |
|  2 | Bob        |  200.00 |
+----+--------------+---------+

BEGIN;
  UPDATE `users` SET `balance` = `balance` - 20 WHERE `nickname`='Bob';
  UPDATE `users` SET `balance` = `balance` + 20 WHERE `nickname`='Alice';
ROLLBACK;

SELECT * FROM `users`;
```

```
+----+-------------+---------+
| id | nickname    | balance |
+----+-------------+---------+
|  1 | Alice       |  100.00 |
|  2 | Bob         |  200.00 |
+----+-------------+---------+
```

The transaction is also automatically rolled back if the client connection is stopped or closed.

4.9.1.2 Transaction isolation levels

The transaction isolation levels are the basis of database transaction processing. The "I" (Isolation) in **ACID** refers to the isolation of the transactions.

The SQL-92 standard defines four isolation levels:

- read uncommitted (`READ UNCOMMITTED`)
- read committed (`READ COMMITTED`)
- repeatable read (`REPEATABLE READ`)
- serializable (`SERIALIZABLE`).

See the table below for details:

Isolation Level	Dirty Write	Dirty Read	Fuzzy Read	Phantom
READ UNCOMMITTED	Not Possible	Possible	Possible	Possible
READ COMMITTED	Not Possible	Not possible	Possible	Possible
REPEATABLE READ	Not Possible	Not possible	Not possible	Possible
SERIALIZABLE	Not Possible	Not possible	Not possible	Not possible

TiDB supports the following isolation levels: `READ COMMITTED` and `REPEATABLE READ`:

```
mysql> SET TRANSACTION ISOLATION LEVEL READ UNCOMMITTED;
ERROR 8048 (HY000): The isolation level 'READ-UNCOMMITTED' is not supported
    ↪ . Set tidb_skip_isolation_level_check=1 to skip this error
mysql> SET TRANSACTION ISOLATION LEVEL READ COMMITTED;
Query OK, 0 rows affected (0.00 sec)

mysql> SET TRANSACTION ISOLATION LEVEL REPEATABLE READ;
Query OK, 0 rows affected (0.00 sec)

mysql> SET TRANSACTION ISOLATION LEVEL SERIALIZABLE;
ERROR 8048 (HY000): The isolation level 'SERIALIZABLE' is not supported.
    ↪ Set tidb_skip_isolation_level_check=1 to skip this error
```

TiDB implements Snapshot Isolation (SI) level consistency, also known as "repeatable read" for consistency with MySQL. This isolation level is different from ANSI Repeatable Read Isolation Level and MySQL Repeatable Read Isolation Level. For more details, see TiDB Transaction Isolation Levels.

4.9.1.3 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.9.2 Optimistic Transactions and Pessimistic Transactions

The optimistic transaction model commits the transaction directly, and rolls back when there is a conflict. By contrast, the pessimistic transaction model tries to lock the resources that need to be modified before actually committing the transaction, and only starts committing after ensuring that the transaction can be successfully executed.

The optimistic transaction model is suitable for scenarios with low conflict rates, because the direct commit has a high probability of success. But once a transaction conflict occurs, the cost of rollback is relatively high.

The advantage of the pessimistic transaction model is that for scenarios with high conflict rates, the cost of locking ahead is less than the cost of rollback afterwards. Moreover, it can solve the problem that multiple concurrent transactions fail to commit due to conflicts. However, the pessimistic transaction model is not as efficient as the optimistic transaction model in scenarios with low conflict rates.

The pessimistic transaction model is more intuitive and easier to implement on the application side. The optimistic transaction model requires complex application-side retry mechanisms.

The following is an example of a bookshop. It uses an example of buying books to show the pros and cons of optimistic and pessimistic transactions. The process of buying books mainly consists of the following:

1. Update the stock quantity
2. Create an order
3. Make the payment

These operations must either all succeed or all fail. You must ensure that overselling does not happen in the case of concurrent transactions.

4.9.2.1 Pessimistic transactions

The following code uses two threads to simulate the process that two users buy the same book in a pessimistic transaction mode. There are 10 books left in the bookstore. Bob buys

6 books, and Alice buys 4 books. They complete the orders at nearly the same time. As a result, all books in inventory are sold out.

Because you use multiple threads to simulate the situation that multiple users insert data simultaneously, you need to use a connection object with safe threads. Here use Java's popular connection pool HikariCP for demo.

`sql.DB` in Golang is concurrency-safe, so there is no need to import a third-party package.

To adapt TiDB transactions, write a toolkit util according to the following code:

```
package util

import (
    "context"
    "database/sql"
)

type TiDBSqlTx struct {
    *sql.Tx
    conn       *sql.Conn
    pessimistic bool
}

func TiDBSqlBegin(db *sql.DB, pessimistic bool) (*TiDBSqlTx, error) {
    ctx := context.Background()
    conn, err := db.Conn(ctx)
    if err != nil {
        return nil, err
    }
    if pessimistic {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "pessimistic
            ↪ ")
    } else {
        _, err = conn.ExecContext(ctx, "set @@tidb_txn_mode=?", "optimistic")
    }
    if err != nil {
        return nil, err
    }
    tx, err := conn.BeginTx(ctx, nil)
    if err != nil {
        return nil, err
    }
    return &TiDBSqlTx{
        conn:       conn,
        Tx:         tx,
        pessimistic: pessimistic,
```

```
    }, nil
}

func (tx *TiDBSqlTx) Commit() error {
    defer tx.conn.Close()
    return tx.Tx.Commit()
}

func (tx *TiDBSqlTx) Rollback() error {
    defer tx.conn.Close()
    return tx.Tx.Rollback()
}
```

To ensure thread safety, you can use the mysqlclient driver to open multiple connections that are not shared between threads.

4.9.2.1.1 Write a pessimistic transaction example

Configuration file

If you use Maven to manage the package, in the `<dependencies>` node in `pom.xml`, add the following dependencies to import `HikariCP`, and set the packaging target, and the main class of the JAR package startup. The following is an example of `pom.xml`.

```
<?xml version="1.0" encoding="UTF-8"?>

<project xmlns="http://maven.apache.org/POM/4.0.0" xmlns:xsi="http://www.w3.
    ↪ org/2001/XMLSchema-instance"
  xsi:schemaLocation="http://maven.apache.org/POM/4.0.0 http://maven.apache.
      ↪ org/xsd/maven-4.0.0.xsd">
  <modelVersion>4.0.0</modelVersion>

  <groupId>com.pingcap</groupId>
  <artifactId>plain-java-txn</artifactId>
  <version>0.0.1</version>

  <name>plain-java-jdbc</name>

  <properties>
    <project.build.sourceEncoding>UTF-8</project.build.sourceEncoding>
    <maven.compiler.source>17</maven.compiler.source>
    <maven.compiler.target>17</maven.compiler.target>
  </properties>

  <dependencies>
    <dependency>
```

```
    <groupId>junit</groupId>
    <artifactId>junit</artifactId>
    <version>4.13.2</version>
    <scope>test</scope>
  </dependency>

  <!-- https://mvnrepository.com/artifact/mysql/mysql-connector-java -->
  <dependency>
    <groupId>mysql</groupId>
    <artifactId>mysql-connector-java</artifactId>
    <version>8.0.28</version>
  </dependency>

  <dependency>
    <groupId>com.zaxxer</groupId>
    <artifactId>HikariCP</artifactId>
    <version>5.0.1</version>
  </dependency>
</dependencies>

<build>
  <plugins>
    <plugin>
      <groupId>org.apache.maven.plugins</groupId>
      <artifactId>maven-assembly-plugin</artifactId>
      <version>3.3.0</version>
      <configuration>
        <descriptorRefs>
          <descriptorRef>jar-with-dependencies</descriptorRef>
        </descriptorRefs>
        <archive>
          <manifest>
            <mainClass>com.pingcap.txn.TxnExample</mainClass>
          </manifest>
        </archive>

      </configuration>
      <executions>
        <execution>
          <id>make-assembly</id>
          <phase>package</phase>
          <goals>
            <goal>single</goal>
          </goals>
        </execution>
```

```
      </executions>
    </plugin>
  </plugins>
 </build>

</project>
```

Coding

Then write the code:

```
package com.pingcap.txn;

import com.zaxxer.hikari.HikariDataSource;

import java.math.BigDecimal;
import java.sql.*;
import java.util.Arrays;
import java.util.concurrent.*;

public class TxnExample {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        System.out.println(Arrays.toString(args));
        int aliceQuantity = 0;
        int bobQuantity = 0;

        for (String arg: args) {
            if (arg.startsWith("ALICE_NUM")) {
                aliceQuantity = Integer.parseInt(arg.replace("ALICE_NUM=", "")
                    ↪ );
            }

            if (arg.startsWith("BOB_NUM")) {
                bobQuantity = Integer.parseInt(arg.replace("BOB_NUM=", ""));
            }
        }

        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/bookshop?
            ↪ useServerPrepStmts=true&cachePrepStmts=true");
        ds.setUsername("root");
        ds.setPassword("");

        // prepare data
        Connection connection = ds.getConnection();
```

```

        // insert order
        insertOrder := "insert into `orders` (`id`, `book_id`, `user_id`, `
            ↪ quality`) values (?, ?, ?, ?)"
        if _, err := txn.Exec(insertOrder,
            orderID, bookID, userID, amount); err != nil {
            return err
        }
        fmt.Println(txnComment + insertOrder + " successful")

        // update user
        updateUser := "update `users` set `balance` = `balance` - ? where id
            ↪ = ?"
        if _, err := txn.Exec(updateUser,
            price.Mul(decimal.NewFromInt(int64(amount))), userID); err != nil
                ↪  {
            return err
        }
        fmt.Println(txnComment + updateUser + " successful")

        return nil
    })
}

func createBook(txn *util.TiDBSqlTx, id int, title, bookType string,
    publishedAt time.Time, price decimal.Decimal, stock int) error {
    _, err := txn.ExecContext(context.Background(),
        "INSERT INTO `books` (`id`, `title`, `type`, `published_at`, `price`,
            ↪  `stock`) values (?, ?, ?, ?, ?, ?)",
        id, title, bookType, publishedAt, price, stock)
    return err
}

func createUser(txn *util.TiDBSqlTx, id int, nickname string, balance
    ↪ decimal.Decimal) error {
    _, err := txn.ExecContext(context.Background(),
        "INSERT INTO `users` (`id`, `nickname`, `balance`) VALUES (?, ?, ?)",
        id, nickname, balance)
    return err
}
```

Then write a `txn.go` with a `main` function to call `helper.go` and handle the incoming command line arguments:

```
package main

import (
    "database/sql"
    "flag"
    "fmt"
    "sync"
)

func main() {
    optimistic, alice, bob := parseParams()

    openDB("mysql", "root:@tcp(127.0.0.1:4000)/bookshop?charset=utf8mb4",
        ↪ func(db *sql.DB) {
        prepareData(db, optimistic)
        buy(db, optimistic, alice, bob)
    })
}

func buy(db *sql.DB, optimistic bool, alice, bob int) {
    buyFunc := buyOptimistic
    if !optimistic {
        buyFunc = buyPessimistic
    }

    wg := sync.WaitGroup{}
    wg.Add(1)
    go func() {
        defer wg.Done()
        buyFunc(db, 1, 1000, 1, 1, bob)
    }()

    wg.Add(1)
    go func() {
        defer wg.Done()
        buyFunc(db, 2, 1001, 1, 2, alice)
    }()

    wg.Wait()
}
```

```
func openDB(driverName, dataSourceName string, runnable func(db *sql.DB)) {
    db, err := sql.Open(driverName, dataSourceName)
    if err != nil {
        panic(err)
    }
    defer db.Close()

    runnable(db)
}

func parseParams() (optimistic bool, alice, bob int) {
    flag.BoolVar(&optimistic, "o", false, "transaction is optimistic")
    flag.IntVar(&alice, "a", 4, "Alice bought num")
    flag.IntVar(&bob, "b", 6, "Bob bought num")

    flag.Parse()

    fmt.Println(optimistic, alice, bob)

    return optimistic, alice, bob
}
```

The Golang example already includes optimistic transactions.

```
import time

import MySQLdb
import os
import datetime

alice_thread.start()
bob_thread.join(timeout=10)
alice_thread.join(timeout=10)
```

The Python example already includes optimistic transactions.

4.9.2.1.2 An example that does not involve overselling

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=6
```

```
go build -o bin/txn
./bin/txn -a 4 -b 6
```

```
OPTIMISTIC=False ALICE=4 BOB=6 python3 txn_example.py
```

SQL logs:

```
/* txn 1 */ BEGIN PESSIMISTIC
    /* txn 2 */ BEGIN PESSIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
        ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
        ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
        ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
/* txn 1 */ COMMIT
```

Finally, check that the order is created, the user balance is deducted, and the book inventory is deducted as expected.

```
mysql> SELECT * FROM `books`;
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
| id | title                                | type               | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 0 | 100.00 |
```

```
+--
    ↪ --+--------------------------------------+--------------------+-------------
    ↪
1 row in set (0.00 sec)

mysql> SELECT * FROM orders;

+------+---------+---------+---------+--------------------+
2 rows in set (0.01 sec)

mysql> SELECT * FROM users;
+----+---------+----------+
| id | balance | nickname |
+----+---------+----------+
|  1 | 9400.00 | Bob      |
|  2 | 9600.00 | Alice    |
+----+---------+----------+
2 rows in set (0.00 sec)
```

4.9.2.1.3 An example that prevents overselling

The task in this example is more challenging. Suppose there are 10 books left in stock. Bob buys 7 books, Alice buys 4 books, and they place orders almost at the same time. What will happen? You can reuse the code from the previous example to solve this challenge, and change Bob's purchase quantity from 6 to 7.

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=7
```

```
go build -o bin/txn
./bin/txn -a 4 -b 7
```

```
OPTIMISTIC=False ALICE=4 BOB=7 python3 txn_example.py
```

```
/* txn 1 */ BEGIN PESSIMISTIC
    /* txn 2 */ BEGIN PESSIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
        ↪  `stock` - 4 >= 0
```

```
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
       ↪  values (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
       ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 7 WHERE `id` = 1 AND `
   ↪ stock` - 7 >= 0
/* txn 1 */ ROLLBACK
```

Since `txn 2` preemptively gets the lock resource and updates the stock, the return value of `affected_rows` in `txn 1` is 0, and it enters the `rollback` process.

Let's check the order creation, user balance deduction, and book inventory deduction. Alice successfully ordered 4 books, Bob failed to order 7 books, and the remaining 6 books are in stock as expected.

```
mysql> SELECT * FROM books;
+--
   ↪ --+--------------------------------------+---------------------+-------------
   ↪
| id | title                                | type                | published_at
   ↪      | stock | price |
+--
   ↪ --+--------------------------------------+---------------------+-------------
   ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
   ↪ 2018-09-01 00:00:00 | 6 | 100.00 |
+--
   ↪ --+--------------------------------------+---------------------+-------------
   ↪
1 row in set (0.00 sec)

mysql> SELECT * FROM orders;
+------+---------+---------+---------+---------------------+
| id   | book_id | user_id | quality | ordered_at          |
+------+---------+---------+---------+---------------------+
| 1001 |       1 |       1 |       4 | 2022-04-19 11:03:03 |
+------+---------+---------+---------+---------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM users;
+----+----------+----------+
| id | balance | nickname |
+----+----------+----------+
|  1 | 10000.00 | Bob      |
```

```
|  2 | 9600.00 | Alice  |
+----+----------+----------+
2 rows in set (0.01 sec)
```

4.9.2.2 Optimistic transactions

The following code uses two threads to simulate the process that two users buy the same book in an optimistic transaction, just like the pessimistic transaction example. There are 10 books left in inventory. Bob buys 6 and Alice buys 4. They complete the order at about the same time. In the end, no books are left in inventory.

4.9.2.2.1 Write an optimistic transaction example

Coding

```
package com.pingcap.txn.optimistic;

import com.zaxxer.hikari.HikariDataSource;

import java.math.BigDecimal;
import java.sql.*;
import java.util.Arrays;
import java.util.concurrent.*;

public class TxnExample {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        System.out.println(Arrays.toString(args));
        int aliceQuantity = 0;
        int bobQuantity = 0;

        for (String arg: args) {
            if (arg.startsWith("ALICE_NUM")) {
                aliceQuantity = Integer.parseInt(arg.replace("ALICE_NUM=", "")
                    ↪ );
            }

            if (arg.startsWith("BOB_NUM")) {
                bobQuantity = Integer.parseInt(arg.replace("BOB_NUM=", ""));
            }
        }

        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/bookshop?
            ↪ useServerPrepStmts=true&cachePrepStmts=true");
```

```
        ds.setUsername("root");
        ds.setPassword("");

        // prepare data
        Connection connection = ds.getConnection();
        createBook(connection, 1L, "Designing Data-Intensive Application", "
            ↪ Science & Technology",
                Timestamp.valueOf("2018-09-01 00:00:00"), new BigDecimal(100)
                    ↪ , 10);
        createUser(connection, 1L, "Bob", new BigDecimal(10000));
        createUser(connection, 2L, "Alice", new BigDecimal(10000));

        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        final int finalBobQuantity = bobQuantity;
        threadPool.execute(() -> {
            buy(ds, 1, 1000L, 1L, 1L, finalBobQuantity, 5);
            countDownLatch.countDown();

                        }
                }
            }
        }
    } catch (SQLException e) {
        e.printStackTrace();
    }
  }
}
```

Configuration changes

Change the startup class in `pom.xml`:

```
<mainClass>com.pingcap.txn.TxnExample</mainClass>
```

Change it to the following to point to the optimistic transaction example.

```
<mainClass>com.pingcap.txn.optimistic.TxnExample</mainClass>
```

The Golang example in the Write a pessimistic transaction example section already supports optimistic transactions and can be used directly without changes.

The Python example in the Write a pessimistic transaction example section already supports optimistic transactions and can be used directly without changes.

4.9.2.2.2 An example that does not involve overselling

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=6
```

```
go build -o bin/txn
./bin/txn -a 4 -b 6 -o true
```

```
OPTIMISTIC=True ALICE=4 BOB=6 python3 txn_example.py
```

SQL statement execution process:

```
    /* txn 2 */ BEGIN OPTIMISTIC
/* txn 1 */ BEGIN OPTIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
       ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
       ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
       ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 for UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
retry 1 times for 9007 Write conflict, txnStartTS=432618733006225412,
    ↪ conflictStartTS=432618733006225411, conflictCommitTS
    ↪ =432618733006225414, key={tableID=126, handle=1} primary={tableID
    ↪ =114, indexID=1, indexValues={1, 1000, }} [try again later]
/* txn 1 */ BEGIN OPTIMISTIC
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 6 WHERE `id` = 1 AND `
    ↪ stock` - 6 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 6)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 600.0 WHERE `id` = 1
/* txn 1 */ COMMIT
```

In the optimistic transaction mode, because the intermediate state is not necessarily correct, it is not possible to judge whether a statement is successfully executed through `affected_rows` as in the pessimistic transaction mode. You need to regard the transaction as a whole, and judge whether the current transaction has a write conflict by checking whether the final `COMMIT` statement returns an exception.

As you can see from the above SQL log, because two transactions are executed concurrently and the same record is modified, a `9007 Write conflict` exception is thrown after `txn 1` COMMIT. For write conflicts in the optimistic transaction mode, you can safely retry on the application side. After one retry, the data is committed successfully. The final execution result is as expected:

```
mysql> SELECT * FROM books;
+--
    ↪ --+-------------------------------------+---------------------+-------------
    ↪
```

```
| id | title                                | type                | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 0 | 100.00 |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
1 row in set (0.01 sec)

mysql> SELECT * FROM orders;
+------+---------+---------+---------+---------------------+
| id   | book_id | user_id | quality | ordered_at          |
+------+---------+---------+---------+---------------------+
| 1000 |       1 |       1 |       6 | 2022-04-19 03:18:19 |
| 1001 |       1 |       1 |       4 | 2022-04-19 03:18:17 |
+------+---------+---------+---------+---------------------+
2 rows in set (0.01 sec)

mysql> SELECT * FROM users;
+----+---------+----------+
| id | balance | nickname |
+----+---------+----------+
|  1 | 9400.00 | Bob      |
|  2 | 9600.00 | Alice    |
+----+---------+----------+
2 rows in set (0.00 sec)
```

4.9.2.2.3 An example that prevents overselling

This section describes an optimistic transaction example that prevents overselling. Suppose there are 10 books left in inventory. Bob buys 7 books,and Alice buys 4 books. They place orders almost at the same time. What will happen? You can reuse the code from the optimistic transaction example to address this requirement. Change Bob's purchases from 6 to 7.

Run the sample program:

```
mvn clean package
java -jar target/plain-java-txn-0.0.1-jar-with-dependencies.jar ALICE_NUM=4
    ↪ BOB_NUM=7
```

```
go build -o bin/txn
```

```
./bin/txn -a 4 -b 7 -o true
```

```
OPTIMISTIC=True ALICE=4 BOB=7 python3 txn_example.py
```

```
/* txn 1 */ BEGIN OPTIMISTIC
    /* txn 2 */ BEGIN OPTIMISTIC
    /* txn 2 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
    /* txn 2 */ UPDATE `books` SET `stock` = `stock` - 4 WHERE `id` = 1 AND
       ↪  `stock` - 4 >= 0
    /* txn 2 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
       ↪  VALUES (1001, 1, 1, 4)
    /* txn 2 */ UPDATE `users` SET `balance` = `balance` - 400.0 WHERE `id`
       ↪ = 2
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
/* txn 1 */ UPDATE `books` SET `stock` = `stock` - 7 WHERE `id` = 1 AND `
    ↪ stock` - 7 >= 0
/* txn 1 */ INSERT INTO `orders` (`id`, `book_id`, `user_id`, `quality`)
    ↪ VALUES (1000, 1, 1, 7)
/* txn 1 */ UPDATE `users` SET `balance` = `balance` - 700.0 WHERE `id` = 1
retry 1 times for 9007 Write conflict, txnStartTS=432619094333980675,
    ↪ conflictStartTS=432619094333980676, conflictCommitTS
    ↪ =432619094333980678, key={tableID=126, handle=1} primary={tableID
    ↪ =114, indexID=1, indexValues={1, 1000, }} [try again later]
/* txn 1 */ BEGIN OPTIMISTIC
/* txn 1 */ SELECT * FROM `books` WHERE `id` = 1 FOR UPDATE
Fail -> out of stock
/* txn 1 */ ROLLBACK
```

You can see from the above SQL log that `txn 1` is retried on the application side due to a write conflict in the first execution. By comparing the latest snapshots, you can find that the stock is running out. The application side throws `out of stock`, and ends abnormally.

```
mysql> SELECT * FROM books;
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
| id | title                                | type                | published_at
    ↪      | stock | price |
+--
    ↪ --+--------------------------------------+---------------------+-------------
    ↪
|  1 | Designing Data-Intensive Application | Science & Technology |
    ↪ 2018-09-01 00:00:00 | 6 | 100.00 |
```

```
+--
    ↪ --+-------------------------------------+--------------------+-----------
    ↪
1 row in set (0.00 sec)

mysql> SELECT * FROM orders;
+------+---------+---------+---------+--------------------+
| id   | book_id | user_id | quality | ordered_at         |
+------+---------+---------+---------+--------------------+
| 1001 |       1 |       1 |       4 | 2022-04-19 03:41:16 |
+------+---------+---------+---------+--------------------+
1 row in set (0.00 sec)

mysql> SELECT * FROM users;
+----+----------+----------+
| id | balance | nickname |
+----+----------+----------+
|  1 | 10000.00 | Bob      |
|  2 |  9600.00 | Alice    |
+----+----------+----------+
2 rows in set (0.00 sec)
```

4.9.3 Transaction Restraints

This document briefly introduces the transaction restraints in TiDB.

4.9.3.1 Isolation levels

The isolation levels supported by TiDB are **RC (Read Committed)** and **SI (Snapshot Isolation)**, where **SI** is basically equivalent to the **RR (Repeatable Read)** isolation level.

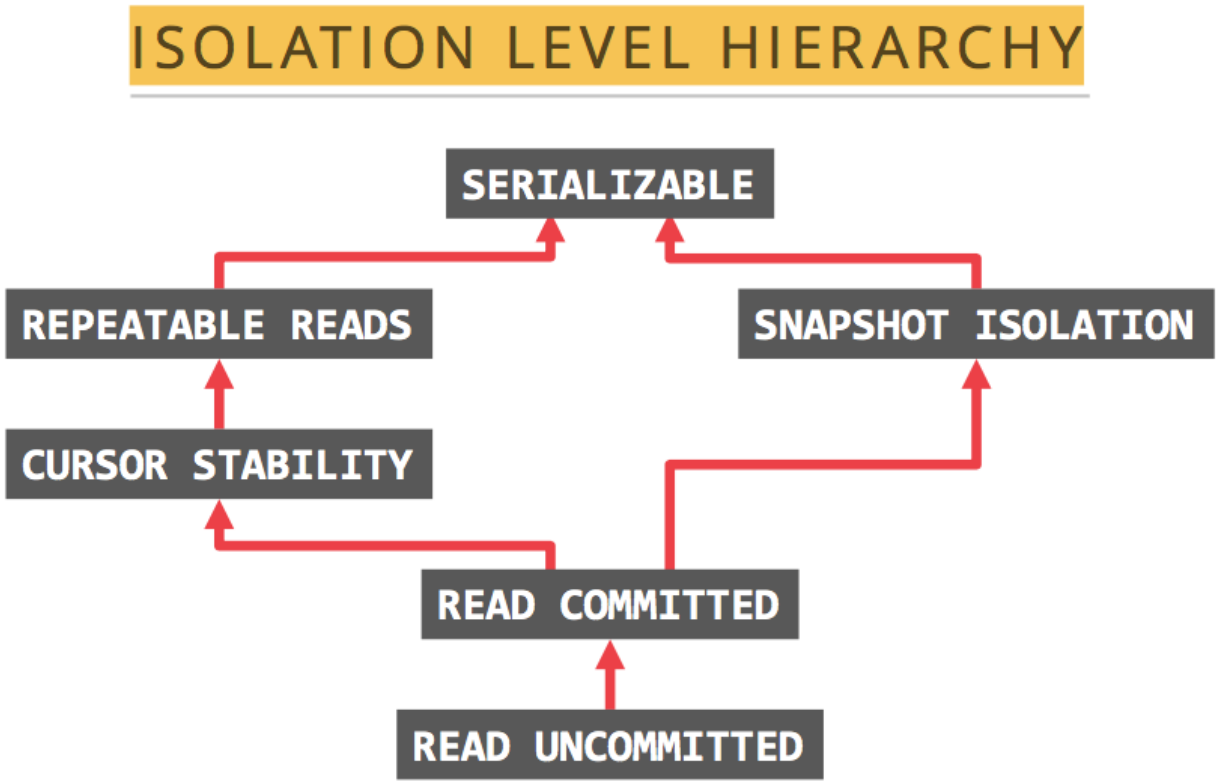

Figure 61: isolation level

4.9.3.2 Snapshot Isolation can avoid phantom reads

The `SI` isolation level of TiDB can avoid **Phantom Reads**, but the `RR` in ANSI/ISO SQL standard cannot.

The following two examples show what **phantom reads** is.

- Example 1: **Transaction A** first gets `n` rows according to the query, and then **Transaction B** changes `m` rows other than these `n` rows or adds `m` rows that match the query of **Transaction A**. When **Transaction A** runs the query again, it finds that there are `n+m` rows that match the condition. It is like a phantom, so it is called a **phantom read**.
- Example 2: **Admin A** changes the grades of all students in the database from specific scores to ABCDE grades, but **Admin B** inserts a record with a specific score at this time. When **Admin A** finishes changing and finds that there is still a record (the one inserted by **Admin B**) that has not been changed yet. That is a **phantom read**.

4.9.3.3 SI cannot avoid write skew

TiDB's SI isolation level cannot avoid **write skew** exceptions. You can use the `SELECT FOR UPDATE` syntax to avoid **write skew** exceptions.

A **write skew** exception occurs when two concurrent transactions read different but related records, and then each transaction updates the data it reads and eventually commits the transaction. If there is a constraint between these related records that cannot be modified concurrently by multiple transactions, then the end result will violate the constraint.

For example, suppose you are writing a doctor shift management program for a hospital. Hospitals typically require several doctors to be on call at the same time, but the minimum requirement is that at least one doctor is on call. Doctors can drop their shifts (for example, if they are feeling sick) as long as at least one doctor is on call during that shift.

Now there is a situation where doctors `Alice` and `Bob` are on call. Both are feeling sick, so they decide to take sick leave. They happen to click the button at the same time. Let's simulate this process with the following program:

```
package com.pingcap.txn.write.skew;

import com.zaxxer.hikari.HikariDataSource;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Semaphore;

public class EffectWriteSkew {
    public static void main(String[] args) throws SQLException,
        ↪ InterruptedException {
        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/test?useServerPrepStmts=
            ↪ true&cachePrepStmts=true");
        ds.setUsername("root");

        // prepare data
        Connection connection = ds.getConnection();
        createDoctorTable(connection);
        createDoctor(connection, 1, "Alice", true, 123);
        createDoctor(connection, 2, "Bob", true, 123);
        createDoctor(connection, 3, "Carol", false, 123);

        Semaphore txn1Pass = new Semaphore(0);
        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        threadPool.execute(() -> {
```

```
            askForLeave(ds, txn1Pass, 1, 1);
            countDownLatch.countDown();
        });

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 2, 2);
            countDownLatch.countDown();
        });

        countDownLatch.await();
    }

    public static void createDoctorTable(Connection connection) throws
        ↪ SQLException {
        connection.createStatement().executeUpdate("CREATE TABLE `doctors` ("
            ↪ +
                "    `id` int NOT NULL," +
                "    `name` varchar(255) DEFAULT NULL," +
                "    `on_call` tinyint DEFAULT NULL," +

                "  ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
                    ↪ ");
    }

    public static void createDoctor(Connection connection, Integer id,
        ↪ String name, Boolean onCall, Integer shiftID) throws SQLException
        ↪ {
        PreparedStatement insert = connection.prepareStatement(
                "INSERT INTO `doctors` (`id`, `name`, `on_call`, `shift_id`)
                    ↪ VALUES (?, ?, ?, ?)");
        insert.setInt(1, id);
        insert.setString(2, name);
        insert.setBoolean(3, onCall);
        insert.setInt(4, shiftID);
        insert.executeUpdate();
    }

    public static void askForLeave(HikariDataSource ds, Semaphore txn1Pass,
        ↪ Integer txnID, Integer doctorID) {
        try(Connection connection = ds.getConnection()) {
            try {
                connection.setAutoCommit(false);
```

```
            String comment = txnID == 2 ? " " : "" + "/* txn #{txn_id} */
                ↪ ";
            connection.createStatement().executeUpdate(comment + "BEGIN");

            // Txn 1 should be waiting for txn 2 done
            if (txnID == 1) {
                txn1Pass.acquire();
            }

            PreparedStatement currentOnCallQuery = connection.
                ↪ prepareStatement(comment +
                    "SELECT COUNT(*) AS `count` FROM `doctors` WHERE `on_
                        ↪ call` = ? AND `shift_id` = ?");
            currentOnCallQuery.setBoolean(1, true);
            currentOnCallQuery.setInt(2, 123);
            ResultSet res = currentOnCallQuery.executeQuery();

            if (!res.next()) {
                throw new RuntimeException("error query");

```

To adapt TiDB transactions, write a util according to the following code:

```
package main

import (
    "database/sql"
    "fmt"
    "sync"

    "github.com/pingcap-inc/tidb-example-golang/util"

    _ "github.com/go-sql-driver/mysql"
)

func main() {
    openDB("mysql", "root:@tcp(127.0.0.1:4000)/test", func(db *sql.DB) {
        writeSkew(db)
    })
}

func openDB(driverName, dataSourceName string, runnable func(db *sql.DB)) {
    db, err := sql.Open(driverName, dataSourceName)
    if err != nil {
        panic(err)
    }
    defer db.Close()

    runnable(db)
}

func writeSkew(db *sql.DB) {
    err := prepareData(db)
    if err != nil {
        panic(err)
    }
```

```
    waitingChan, waitGroup := make(chan bool), sync.WaitGroup{}

    waitGroup.Add(1)
    go func() {
        defer waitGroup.Done()
        err = askForLeave(db, waitingChan, 1, 1)
        if err != nil {
            panic(err)
        }
    }()

    waitGroup.Add(1)
    go func() {
        defer waitGroup.Done()
        err = askForLeave(db, waitingChan, 2, 2)
        if err != nil {
            panic(err)
        }
    }()

    waitGroup.Wait()
}

func askForLeave(db *sql.DB, waitingChan chan bool, goroutineID, doctorID
    ↪ int) error {
    txnComment := fmt.Sprintf("/* txn %d */ ", goroutineID)
    if goroutineID != 1 {
        txnComment = "\t" + txnComment
    }

    txn, err := util.TiDBSqlBegin(db, true)
    if err != nil {
        return err
    }
    fmt.Println(txnComment + "start txn")

    // Txn 1 should be waiting until txn 2 is done.
    if goroutineID == 1 {
        <-waitingChan
    }

    txnFunc := func() error {
        queryCurrentOnCall := "SELECT COUNT(*) AS `count` FROM `doctors`
            ↪ WHERE `on_call` = ? AND `shift_id` = ?"
```

```
        rows, err := txn.Query(queryCurrentOnCall, true, 123)
        if err != nil {
            return err
        }
        defer rows.Close()
        fmt.Println(txnComment + queryCurrentOnCall + " successful")

        count := 0
        if rows.Next() {

            ↪ shift_id` = ?"
        _, err = txn.Exec(shift, false, doctorID, 123)
        if err == nil {
            fmt.Println(txnComment + shift + " successful")
        }
        return err
    }

    err = txnFunc()
    if err == nil {
        txn.Commit()
        fmt.Println("[runTxn] commit success")
    } else {
        txn.Rollback()
        fmt.Printf("[runTxn] got an error, rollback: %+v\n", err)
    }

    // Txn 2 is done. Let txn 1 run again.
    if goroutineID == 2 {
        waitingChan <- true
    }

    return nil
}
```

```
func prepareData(db *sql.DB) error {
    err := createDoctorTable(db)
    if err != nil {
        return err
    }

    err = createDoctor(db, 1, "Alice", true, 123)
    if err != nil {
        return err
    }
    err = createDoctor(db, 2, "Bob", true, 123)
    if err != nil {
        return err
    }
    err = createDoctor(db, 3, "Carol", false, 123)
    if err != nil {
        return err
    }
    return nil
}

func createDoctorTable(db *sql.DB) error {
    _, err := db.Exec("CREATE TABLE IF NOT EXISTS `doctors` (" +
        "    `id` int NOT NULL," +
        "    `name` varchar(255) DEFAULT NULL," +
        "    `on_call` tinyint DEFAULT NULL," +
        "    `shift_id` int DEFAULT NULL," +
        "    PRIMARY KEY (`id`)," +
        "    KEY `idx_shift_id` (`shift_id`)" +
        "  ) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin")
    return err
}

func createDoctor(db *sql.DB, id int, name string, onCall bool, shiftID int)
    ↪  error {
    _, err := db.Exec("INSERT INTO `doctors` (`id`, `name`, `on_call`, `
        ↪ shift_id`) VALUES (?, ?, ?, ?)",
        id, name, onCall, shiftID)
    return err
}
```

SQL log:

```
/* txn 1 */ BEGIN
```

```
    /* txn 2 */ BEGIN
    /* txn 2 */ SELECT COUNT(*) as `count` FROM `doctors` WHERE `on_call` =
       ↪  1 AND `shift_id` = 123
    /* txn 2 */ UPDATE `doctors` SET `on_call` = 0 WHERE `id` = 2 AND `
       ↪ shift_id` = 123
    /* txn 2 */ COMMIT
/* txn 1 */ SELECT COUNT(*) AS `count` FROM `doctors` WHERE `on_call` = 1
    ↪ and `shift_id` = 123
/* txn 1 */ UPDATE `doctors` SET `on_call` = 0 WHERE `id` = 1 AND `shift_id
    ↪ ` = 123
/* txn 1 */ COMMIT
```

Running result:

```
mysql> SELECT * FROM doctors;
+----+-------+---------+----------+
| id | name | on_call | shift_id |
+----+-------+---------+----------+
|  1 | Alice |       0 |      123 |
|  2 | Bob   |       0 |      123 |
|  3 | Carol |       0 |      123 |
+----+-------+---------+----------+
```

In both transactions, the application first checks if two or more doctors are on call; if so, it assumes that one doctor can safely take leave. Since the database uses the snapshot isolation, both checks return `2`, so both transactions move on to the next stage. `Alice` updates her record to be off duty, and so does `Bob`. Both transactions are successfully committed. Now there are no doctors on duty which violates the requirement that at least one doctor should be on call. The following diagram (quoted from ***Designing Data-Intensive Applications***) illustrates what actually happens.

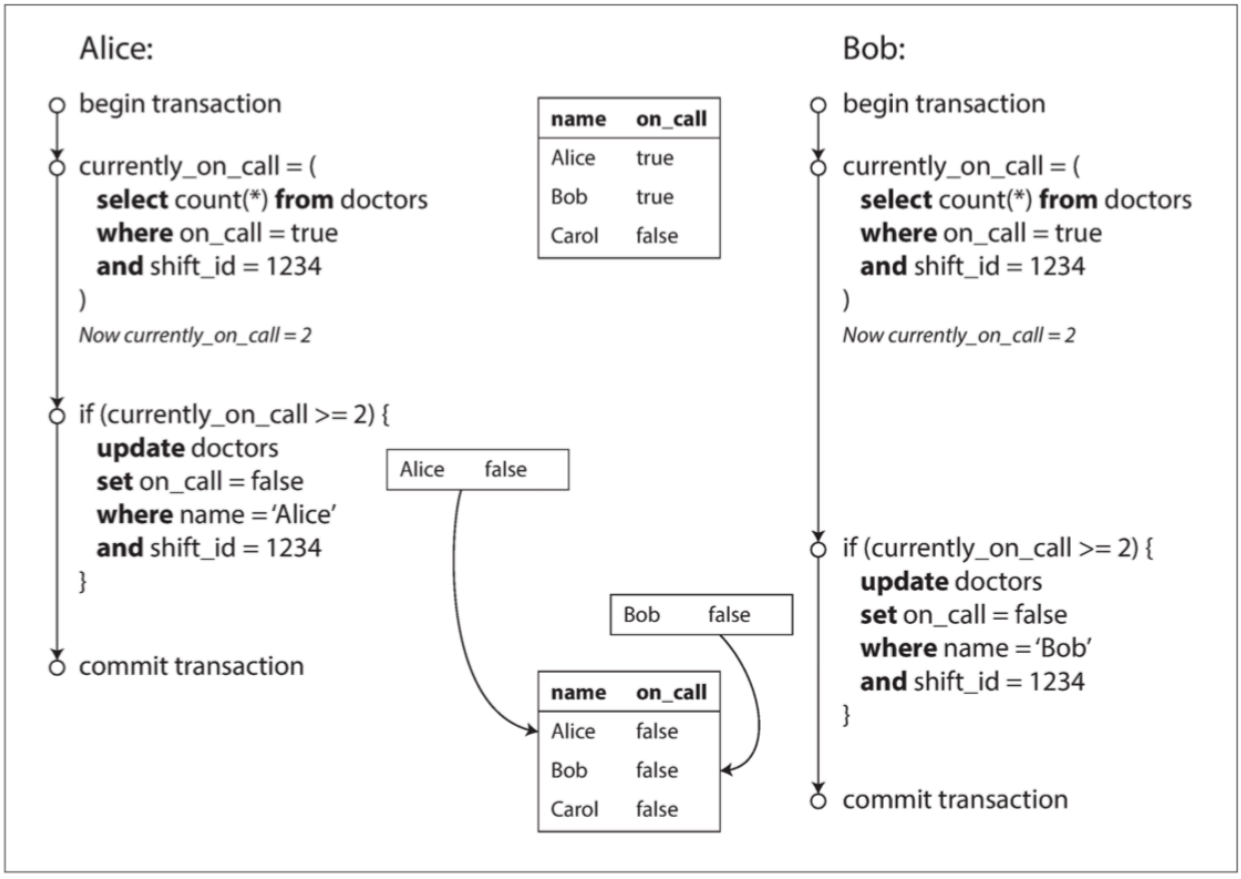

Figure 62: Write Skew

Now let's change the sample program to use `SELECT FOR UPDATE` to avoid the write skew problem:

```
package com.pingcap.txn.write.skew;

import com.zaxxer.hikari.HikariDataSource;

import java.sql.Connection;
import java.sql.PreparedStatement;
import java.sql.ResultSet;
import java.sql.SQLException;
import java.util.concurrent.CountDownLatch;
import java.util.concurrent.ExecutorService;
import java.util.concurrent.Executors;
import java.util.concurrent.Semaphore;

public class EffectWriteSkew {
    public static void main(String[] args) throws SQLException,
```

```
        ↪ InterruptedException {
        HikariDataSource ds = new HikariDataSource();
        ds.setJdbcUrl("jdbc:mysql://localhost:4000/test?useServerPrepStmts=
            ↪ true&cachePrepStmts=true");
        ds.setUsername("root");

        // prepare data
        Connection connection = ds.getConnection();
        createDoctorTable(connection);
        createDoctor(connection, 1, "Alice", true, 123);
        createDoctor(connection, 2, "Bob", true, 123);
        createDoctor(connection, 3, "Carol", false, 123);

        Semaphore txn1Pass = new Semaphore(0);
        CountDownLatch countDownLatch = new CountDownLatch(2);
        ExecutorService threadPool = Executors.newFixedThreadPool(2);

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 1, 1);
            countDownLatch.countDown();
        });

        threadPool.execute(() -> {
            askForLeave(ds, txn1Pass, 2, 2);
            countDownLatch.countDown();
        });

        countDownLatch.await();
    }

    public static void createDoctorTable(Connection connection) throws
        ↪ SQLException {
        connection.createStatement().executeUpdate("CREATE TABLE `doctors` ("

>
> Starting from v6.2.0, TiDB supports the savepoint feature. If your TiDB cluster is earlier than v6.2.0, your TiDB cluster does not support the

> `PROPAGATION_NESTED` behavior. It is recommended to upgrade to v6.2.0 or a later version. If upgrading TiDB is not possible, and your applications are based on the **Java Spring** framework that uses the `PROPAGATION_NESTED` propagation behavior, you need to adapt it on the application side to remove the logic for nested transactions.

The `PROPAGATION_NESTED` propagation behavior supported by **Spring** triggers a nested transaction, which is a child transaction that is started independently of the current transaction. A `savepoint` is recorded when the nested transaction starts. If the nested transaction fails, the transaction will roll back to the `savepoint` state. The nested transaction is part of the outer transaction and will be committed together with the outer transaction.

The following example demonstrates the `savepoint` mechanism:

```
mysql> BEGIN;
mysql> INSERT INTO T2 VALUES(100);
mysql> SAVEPOINT svp1;
mysql> INSERT INTO T2 VALUES(200);
mysql> ROLLBACK TO SAVEPOINT svp1;
mysql> RELEASE SAVEPOINT svp1;
mysql> COMMIT;
mysql> SELECT * FROM T2;
+------+
|  ID  |
+------+
|  100 |
+------+
```

4.9.3.5 Large transaction restrictions

The basic principle is to limit the size of the transaction. At the KV level, TiDB has a restriction on the size of a single transaction. At the SQL level, one row of data is mapped to one KV entry, and each additional index will add one KV entry. The restriction is as follows at the SQL level:

- The maximum single row record size is 120 MiB.
    - You can adjust it by using the `performance.txn-entry-size-limit` configuration parameter of tidb-server for TiDB v4.0.10 and later v4.0.x versions, TiDB v5.0.0 and later versions. The value is `6 MB` for versions earlier than v4.0.10.
    - Starting from v7.6.0, you can use the `tidb_txn_entry_size_limit` system variable to dynamically modify the value of this configuration item.

- The maximum single transaction size supported is 1 TiB.
    - For TiDB v4.0 and later versions, You can configure it by `performance.txn-total-size-limit`). The value is `100 MB` for earlier versions.
    - For TiDB v6.5.0 and later versions, this configuration is no longer recommended. For more information, see `performance.txn-total-size-limit`).

Note that for both the size restrictions and row restrictions, you should also consider the overhead of encoding and additional keys for the transaction during the transaction execution. To achieve optimal performance, it is recommended to write one transaction every 100 ~ 500 rows.

4.9.3.6 Auto-committed `SELECT FOR UPDATE` statements do NOT wait for locks

Currently locks are not added to auto-committed `SELECT FOR UPDATE` statements. The effect is shown in the following figure:

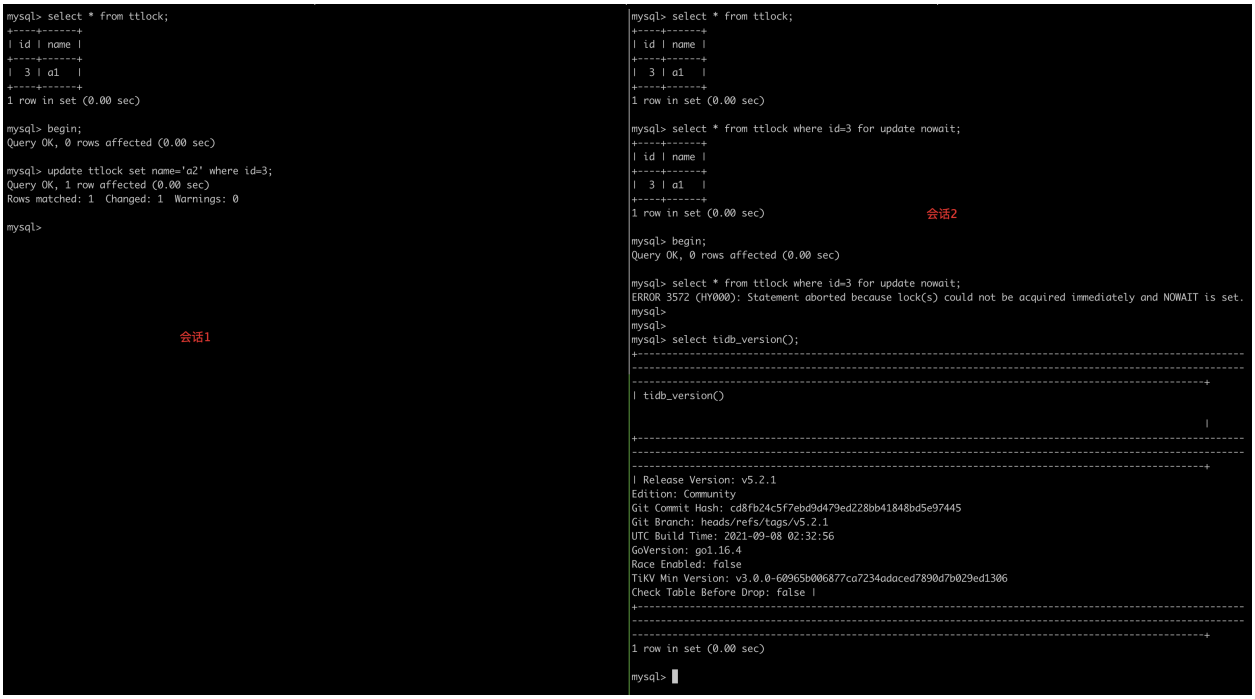

Figure 63: The situation in TiDB

This is a known incompatibility issue with MySQL. You can solve this issue by using the explicit `BEGIN;COMMIT;` statements.

4.9.3.7 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.9.4 Handle Transaction Errors

This document introduces how to handle transaction errors, such as deadlocks and application retry errors.

4.9.4.1 Deadlocks

The following error in your application indicates a deadlock issue:

```
ERROR 1213: Deadlock found when trying to get lock; try restarting
    ↪ transaction
```

A deadlock occurs when two or more transactions are waiting for each other to release the lock they already hold, or the inconsistent lock order results in a loop waiting for the lock resources.

The following is an example of a deadlock using the table `books` in the `bookshop` database:

First, insert 2 rows into the table `books`:

```
INSERT INTO books (id, title, stock, published_at) VALUES (1, 'book-1', 10,
    ↪ now()), (2, 'book-2', 10, now());
```

In TiDB pessimistic transaction mode, if two clients execute the following statements respectively, a deadlock will occur:

Client-A	Client-B
BEGIN;	
	BEGIN;
UPDATE books SET stock=stock-1 WHERE id=1;	
	UPDATE books SET s
UPDATE books SET stock=stock-1 WHERE id=2; – execution will be blocked	
	UPDATE books SET s

After client-B encounters a deadlock error, TiDB automatically rolls back the transaction in client-B. Updating `id=2` in client-A will be executed successfully. You can then run `COMMIT` to finish the transaction.

4.9.4.1.1 Solution 1: avoid deadlocks

To get better performance, you can avoid deadlocks at the application level by adjusting the business logic or schema design. In the example above, if client-B also uses the same update order as client-A, that is, they update books with `id=1` first, and then update books with `id=2`. The deadlock can then be avoided:

Client-A	Client-B
BEGIN;	
	BEGIN;
UPDATE books SET stock=stock-1 WHERE id=1;	
	UPDATE books SET stock=stock-1 WHERE id=1
UPDATE books SET stock=stock-1 WHERE id=2;	
COMMIT;	
	UPDATE books SET stock=stock-1 WHERE id=2
	COMMIT;

Alternatively, you can update 2 books with 1 SQL statement, which can also avoid the deadlock and execute more efficiently:

```
UPDATE books SET stock=stock-1 WHERE id IN (1, 2);
```

4.9.4.1.2 Solution 2: reduce transaction granularity

If you only update 1 book in each transaction, you can also avoid deadlocks. However, the trade-off is that too small transaction granularity may affect performance.

4.9.4.1.3 Solution 3: use optimistic transactions

There are no deadlocks in the optimistic transaction model. But in your application, you need to add the optimistic transaction retry logic in case of failure. For details, see Application retry and error handling.

4.9.4.1.4 Solution 4: retry

Add the retry logic in the application as suggested in the error message. For details, see Application retry and error handling.

4.9.4.2 Application retry and error handling

Although TiDB is as compatible as possible with MySQL, the nature of its distributed system leads to certain differences. One of them is the transaction model.

The Adapters and ORMs that developers use to connect with databases are tailored for traditional databases such as MySQL and Oracle. In these databases, transactions rarely fail to commit at the default isolation level, so retry mechanisms are not required. When a transaction fails to commit, these clients abort due to an error, as it is treated as an exception in these databases.

Different from traditional databases such as MySQL, in TiDB, if you use the optimistic transaction model and want to avoid commit failure, you need to add a mechanism to handle related exceptions in your applications.

The following Python pseudocode shows how to implement application-level retries. It does not require your driver or ORM to implement advanced retry logic. It can be used in any programming language or environment.

Your retry logic must follow the following rules:

- Throws an error if the number of failed retries reaches the `max_retries` limit.
- Use `try ... catch ...` to catch SQL execution exceptions. Retry when encountering the following errors. Roll back when encountering other errors.
    - `Error 8002: can not retry select for update statement`: SELECT FOR UPDATE write conflict error
    - `Error 8022: Error: KV error safe to retry`: transaction commit failed error.
    - `Error 8028: Information schema is changed during the execution of the statement`: Table schema has been changed by DDL operation, resulting in an error in the transaction commit.
    - `Error 9007: Write conflict`: Write conflict error, usually caused by multiple transactions modifying the same row of data when the optimistic transaction mode is used.
- `COMMIT` the transaction at the end of the try block.

For more information about error codes, see Error Codes and Troubleshooting.

```
while True:
    n++
    if n == max_retries:
        raise("did not succeed within #{n} retries")
    try:
        connection.execute("your sql statement here")
        connection.exec('COMMIT')
        break
    catch error:
        if (error.code != "9007" && error.code != "8028" && error.code != "
            ↪ 8002" && error.code != "8022"):
            raise error
        else:
            connection.exec('ROLLBACK')

            # Capture the error types that require application-side retry,
            # wait for a short period of time,
            # and exponentially increase the wait time for each transaction
                ↪ failure
            sleep_ms = int(((1.5 ** n) + rand) * 100)
            sleep(sleep_ms) # make sure your sleep() takes milliseconds
```

Note:

If you frequently encounter `Error 9007: Write conflict`, you may need to check your schema design and the data access patterns of your workload to find the root cause of the conflict and try to avoid conflicts by a better design.

For information about how to troubleshoot and resolve transaction conflicts, see Troubleshoot Lock Conflicts.

Ask the community on Discord or Slack, or submit a support ticket.

4.10 Optimize

4.10.1 Overview of Optimizing SQL Performance

This document introduces how to optimize the performance of SQL statements in TiDB. To get good performance, you can start with the following aspects:

- SQL performance tuning
- Schema design: Based on your application workload patterns, you might need to change the table schema to avoid transaction contention or hot spots.

4.10.1.1 SQL performance tuning

To get good SQL statement performance, you can follow these guidelines:

- Scan as few rows as possible. It is recommended to scan only the data you need and avoid scanning excess data.
- Use the right index. Ensure that there is a corresponding index for the column in the `WHERE` clause in SQL. If not, the statement entails a full table scan and thus causes poor performance.

- Use the right join type. It is important to choose the right join type based on the relative size of the tables involved in the query. In general, TiDB's cost-based optimizer picks the best-performing join type. However, in a few cases, you might need to manually specify a better join type.
- Use the right storage engine. For hybrid OLTP and OLAP workloads, the TiFlash engine is recommended. For details, see HTAP Query.

4.10.1.2 Schema design

After tuning SQL performance, if your application still cannot get good performance, you might need to check your schema design and data access patterns to avoid the following issues:

- Transaction contention. For how to diagnose and resolve transaction contention, see Troubleshoot Lock Conflicts.
- Hot spots. For how to diagnose and resolve hot spots, see Troubleshoot Hotspot Issues.

4.10.1.2.1 See also

- SQL Performance Tuning

4.10.1.3 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.10.2 SQL Performance Tuning

This document introduces some common reasons for slow SQL statements and techniques for tuning SQL performance.

4.10.2.1 Before you begin

You can use `tiup demo` import to prepare data:

```
tiup demo bookshop prepare --host 127.0.0.1 --port 4000 --books 1000000
```

Or using the Import feature of TiDB Cloud to import the pre-prepared sample data.

4.10.2.2 Issue: Full table scan

The most common reason for slow SQL queries is that the `SELECT` statements perform full table scan or use incorrect indexes.

When TiDB retrieves a small number of rows from a large table based on a column that is not the primary key or in the secondary index, the performance is usually poor:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| id         | title      | type                 | published_at       | stock |
    ↪ price |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| 65670536   | Marian Yost | Arts                 | 1950-04-09 06:28:58 | 542 |
    ↪ 435.01 |
| 1164070689 | Marian Yost | Education & Reference | 1916-05-27 12:15:35 |
    ↪ 216 | 328.18 |
| 1414277591 | Marian Yost | Arts                 | 1932-06-15 09:18:14 | 303 |
    ↪ 496.52 |
| 2305318593 | Marian Yost | Arts                 | 2000-08-15 19:40:58 | 398 |
    ↪ 402.90 |
| 2638226326 | Marian Yost | Sports               | 1952-04-02 12:40:37 | 191 |
    ↪ 174.64 |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
5 rows in set
Time: 0.582s
```

To understand why this query is slow, you can use `EXPLAIN` to see the execution plan:

```
EXPLAIN SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ ------------------+-----------+----------+--------------+--------------------
    ↪
| id                | estRows   | task     | access object | operator info
    ↪                    |
+--
    ↪ ------------------+-----------+----------+--------------+--------------------
    ↪
| TableReader_7     | 1.27      | root     |               | data:Selection_6
    ↪                    |
|  ─Selection_6     | 1.27      | cop[tikv] |              | eq(bookshop.books.
    ↪ title, "Marian Yost") |
|    ─TableFullScan_5 | 1000000.00 | cop[tikv] | table:books | keep order:
    ↪ false              |
```

```
+--
    ↪ ------------------+-----------+----------+--------------+-------------------
    ↪
```

As can be seen from `TableFullScan_5` in the execution plan, TiDB performs a full table scan on the `books` table and checks whether `title` satisfies the condition for each row. The `estRows` value of `TableFullScan_5` is `1000000.00`, which means the optimizer estimates that this full table scan takes `1000000.00` rows of data.

For more information about the usage of `EXPLAIN`, see EXPLAIN Walkthrough.

4.10.2.2.1 Solution: Use secondary index

To speed up this query above, add a secondary index on the `books.title` column:

```
CREATE INDEX title_idx ON books (title);
```

The query execution is much faster:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| id         | title      | type                 | published_at       | stock |
    ↪ price |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
| 1164070689 | Marian Yost | Education & Reference | 1916-05-27 12:15:35 |
    ↪ 216 | 328.18 |
| 1414277591 | Marian Yost | Arts                 | 1932-06-15 09:18:14 | 303 |
    ↪ 496.52 |
| 2305318593 | Marian Yost | Arts                 | 2000-08-15 19:40:58 | 398 |
    ↪ 402.90 |
| 2638226326 | Marian Yost | Sports               | 1952-04-02 12:40:37 | 191 |
    ↪ 174.64 |
| 65670536   | Marian Yost | Arts                 | 1950-04-09 06:28:58 | 542 |
    ↪ 435.01 |
+--
    ↪ ----------+------------+----------------------+--------------------+-------+-
    ↪
5 rows in set
Time: 0.007s
```

To understand why the performance is improved, use `EXPLAIN` to see the new execution plan:

```
EXPLAIN SELECT * FROM books WHERE title = 'Marian Yost';
```

```
+--
   ↪ ------------------------+---------+-----------+-------------------------------
   ↪
| id                        | estRows | task      | access object
   ↪                       | operator info                                        |
+--
   ↪ ------------------------+---------+-----------+-------------------------------
   ↪
| IndexLookUp_10            | 1.27    | root      |
   ↪                                     |
   ↪                                                 |
|  ─IndexRangeScan_8(Build) | 1.27 | cop[tikv] | table:books, index:title_
   ↪ idx(title) | range:["Marian Yost","Marian Yost"], keep order:false |
|  ─TableRowIDScan_9(Probe) | 1.27 | cop[tikv] | table:books
   ↪                       | keep order:false                                     |
+--
   ↪ ------------------------+---------+-----------+-------------------------------
   ↪
```

As can be seen from `IndexLookup_10` in the execution plan, TiDB queries the data by the `title_idx` index. Its `estRows` value is `1.27`, which means that the optimizer estimates that only `1.27` rows are scanned. The estimated rows scanned are much fewer than the `1000000.00` rows of data in the full table scan.

The `IndexLookup_10` execution plan is to first use the `IndexRangeScan_8` operator to read the index data that meets the condition through the `title_idx` index, and then use the `TableLookup_9` operator to query the corresponding rows according to the Row ID stored in the index data.

For more information on the TiDB execution plan, see TiDB Query Execution Plan Overview.

4.10.2.2.2 Solution: Use covering index

If the index is a covering index, which contains all the columns queried by the SQL statements, scanning the index data is sufficient for the query.

For example, in the following query, you only need to query the corresponding `price` based on `title`:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+-------------+--------+
| title       | price |
```

```
+-------------+--------+
| Marian Yost | 435.01 |
| Marian Yost | 328.18 |
| Marian Yost | 496.52 |
| Marian Yost | 402.90 |
| Marian Yost | 174.64 |
+-------------+--------+
5 rows in set
Time: 0.007s
```

Because the `title_idx` index only contains data in the `title` column, TiDB still needs to first scan the index data and then query the `price` column from the table.

```
EXPLAIN SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+--
   ↪ ------------------------+---------+-----------+-----------------------------
   ↪
| id                        | estRows | task      | access object
   ↪                       | operator info                                      |
+--
   ↪ ------------------------+---------+-----------+-----------------------------
   ↪
| IndexLookUp_10            | 1.27    | root      |
   ↪                                     |
   ↪                                                 |
|  ─IndexRangeScan_8(Build) | 1.27 | cop[tikv] | table:books, index:title_
   ↪ idx(title) | range:["Marian Yost","Marian Yost"], keep order:false |
|  ─TableRowIDScan_9(Probe) | 1.27 | cop[tikv] | table:books
   ↪                       | keep order:false                                   |
+--
   ↪ ------------------------+---------+-----------+-----------------------------
   ↪
```

To optimize the performance, drop the `title_idx` index and create a new covering index `title_price_idx`:

```
ALTER TABLE books DROP INDEX title_idx;
```

```
CREATE INDEX title_price_idx ON books (title, price);
```

Because the `price` data is stored in the `title_price_idx` index, the following query only needs to scan the index data:

```
EXPLAIN SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
--
    ↪ -----------------+---------+----------+-----------------------------------
    ↪
| id                | estRows | task    | access object
    ↪                                | operator info
    ↪                                   |
+--
    ↪ -----------------+---------+----------+-----------------------------------
    ↪
| IndexReader_6     | 1.27    | root     |
    ↪                                                | index:IndexRangeScan_5
    ↪                            |
|  ─IndexRangeScan_5 | 1.27 | cop[tikv] | table:books, index:title_price_
    ↪ idx(title, price) | range:["Marian Yost","Marian Yost"], keep order:
    ↪ false |
+--
    ↪ -----------------+---------+----------+-----------------------------------
    ↪
```

Now this query runs faster:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

```
+-------------+--------+
| title       | price |
+-------------+--------+
| Marian Yost | 174.64 |
| Marian Yost | 328.18 |
| Marian Yost | 402.90 |
| Marian Yost | 435.01 |
| Marian Yost | 496.52 |
+-------------+--------+
5 rows in set
Time: 0.004s
```

Since the `books` table will be used in later examples, drop the `title_price_idx` index:

```
ALTER TABLE books DROP INDEX title_price_idx;
```

4.10.2.2.3 Solution: Use primary index

If a query uses the primary key to filter data, the query runs fast. For example, the primary key of the `books` table is the `id` column, so you can use the `id` column to query data:

```
SELECT * FROM books WHERE id = 896;
```

```
+--
    ↪ ---+---------------+--------------------+--------------------+-------+------
    ↪
| id  | title         | type               | published_at       | stock | price
    ↪ |
+--
    ↪ ---+---------------+--------------------+--------------------+-------+------
    ↪
| 896 | Kathryne Doyle | Science & Technology | 1969-03-18 01:34:15 | 468 |
    ↪ 281.32 |
+--
    ↪ ---+---------------+--------------------+--------------------+-------+------
    ↪
1 row in set
Time: 0.004s
```

Use `EXPLAIN` to see the execution plan:

```
EXPLAIN SELECT * FROM books WHERE id = 896;
```

```
+-------------+---------+------+--------------+--------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+--------------+--------------+
| Point_Get_1 | 1.00 | root | table:books | handle:896 |
+-------------+---------+------+--------------+--------------+
```

`Point_Get` is a very fast execute plan.

4.10.2.3 Use the right join type

See JOIN Execution Plan.

Ask the community on Discord or Slack, or submit a support ticket.

4.10.3 Performance Tuning Best Practices

This document introduces some best practices for using TiDB databases.

4.10.3.1 DML best practices

This section describes the best practices involved when you use DML with TiDB.

4.10.3.1.1 Use multi-row statements

When you need to modify multiple rows of table, it is recommended to use multi-row statements:

```
INSERT INTO t VALUES (1, 'a'), (2, 'b'), (3, 'c');

DELETE FROM t WHERE id IN (1, 2, 3);
```

It is not recommended to use multiple single-row statements:

```
INSERT INTO t VALUES (1, 'a');
INSERT INTO t VALUES (2, 'b');
INSERT INTO t VALUES (3, 'c');

DELETE FROM t WHERE id = 1;
DELETE FROM t WHERE id = 2;
DELETE FROM t WHERE id = 3;
```

4.10.3.1.2 Use `PREPARE`

When you need to execute a SQL statement for multiple times, it is recommended to use the `PREPARE` statement to avoid the overhead of repeatedly parsing the SQL syntax.

```
func BatchInsert(db *sql.DB) error {
    stmt, err := db.Prepare("INSERT INTO t (id) VALUES (?), (?), (?), (?),
        ↪ (?)")
    if err != nil {
        return err
    }
    for i := 0; i < 1000; i += 5 {
        values := []interface{}{i, i + 1, i + 2, i + 3, i + 4}
        _, err = stmt.Exec(values...)
        if err != nil {
            return err
        }
    }
    return nil
}
```

```
public void batchInsert(Connection connection) throws SQLException {
    PreparedStatement statement = connection.prepareStatement(
            "INSERT INTO `t` (`id`) VALUES (?), (?), (?), (?), (?)");
    for (int i = 0; i < 1000; i ++) {
        statement.setInt(i % 5 + 1, i);

        if (i % 5 == 4) {
            statement.executeUpdate();
        }
    }
}
```

Do not execute the `PREPARE` statement repeatedly. Otherwise, the execution efficiency cannot be improved.

4.10.3.1.3 Only query the columns you need

If you do not need data from all columns, do not use `SELECT *` to return all columns data. The following query is inefficient:

```
SELECT * FROM books WHERE title = 'Marian Yost';
```

You should only query the columns you need. For example:

```
SELECT title, price FROM books WHERE title = 'Marian Yost';
```

4.10.3.1.4 Use bulk delete

When you delete a large amount of data, it is recommended to use bulk delete.

4.10.3.1.5 Use bulk update

When you update a large amount of data, it is recommended to use bulk update.

4.10.3.1.6 Use `TRUNCATE` instead of `DELETE` for full table data

When you need to delete all data from a table, it is recommended to use the `TRUNCATE` statement:

```
TRUNCATE TABLE t;
```

It is not recommended to use `DELETE` for full table data:

```
DELETE FROM t;
```

4.10.3.2 DDL best practices

This section describes the best practices involved when using TiDB's DDL.

4.10.3.2.1 Primary key best practices

See the rules to follow when selecting the primary key.

4.10.3.3 Index best practices

See Index Best Practices.

4.10.3.3.1 Add index best practices

TiDB supports the online index add operation. You can use ADD INDEX or CREATE INDEX statement to add an index. It does not block data reads and writes in the table. You can adjust the concurrency and the batch size during the `re-organize` phase of the index add operation by modifying the following system variables:

- `tidb_ddl_reorg_worker_cnt`
- `tidb_ddl_reorg_batch_size`

To reduce the impact on the online application, the default speed of add index operation is slow. When the target column of add index operation only involves read load or is not directly related to online workload, you can appropriately increase the value of the above variables to speed up the add index operation:

```
SET @@global.tidb_ddl_reorg_worker_cnt = 16;
SET @@global.tidb_ddl_reorg_batch_size = 4096;
```

When the target column of the add index operation is updated frequently (including `UPDATE`, `INSERT` and `DELETE`), increasing the above variables causes more write conflicts, which impacts the online workload. Accordingly, the add index operation might take a long time to complete due to constant retries. In this case, it is recommended to decrease the value of the above variables to avoid write conflicts with the online application:

```
SET @@global.tidb_ddl_reorg_worker_cnt = 4;
SET @@global.tidb_ddl_reorg_batch_size = 128;
```

4.10.3.4 Transaction conflicts

For how to locate and resolve transaction conflicts, see Troubleshoot Lock Conflicts.

4.10.3.5 Best practices for developing Java applications with TiDB

Ask the community on Discord or Slack, or submit a support ticket.

4.10.4 Best Practices for Indexing

This document introduces some best practices for creating and using indexes in TiDB.

4.10.4.1 Before you begin

This section takes the `books` table in the bookshop database as an example.

```
CREATE TABLE `books` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

4.10.4.2 Best practices for creating indexes

- Creating a combined index with multiple columns, which is an optimization called covering index optimization. **Covering index optimization** allows TiDB to query data directly on indexes, which helps improve performance.
- Avoid creating a secondary index on columns that you do not query often. A useful secondary index can speed up queries, but be aware that it also has side effects. Each time you add an index, an additional Key-Value is added when you insert a row. The more indexes you have, the slower you write, and the more space it consumes. In addition, too many indexes affect optimizer runtime, and inappropriate indexes can mislead the optimizer. So, more indexes do not always mean better performance.
- Create an appropriate index based on your application. In principle, create indexes only on the columns to be used in queries to improve performance. The following cases are suitable for creating an index:

- Columns with a high distinction degree can significantly reduce the number of filtered rows. For example, it is recommended to create an index on the personal ID number, but not on the gender.
- Use combined indexes when querying with multiple conditions. Note that columns with equivalent conditions need to be placed in the front of the combined index. Here is an example: if the `select* from t where c1 = 10 and c2 = 100 and c3 > 10` query is frequently used, consider creating a combined index `Index cidx (c1, c2, c3)`, so that an index prefix can be constructed to scan by query conditions.

- Name your secondary index meaningfully, and it is recommended to follow the table naming conventions of your company or organization. If such naming conventions do not exist, follow the rules in Index Naming Specification.

4.10.4.3 Best practices for using indexes

- Indexes are to speed up queries, so make sure that the existing indexes are actually used by some queries. If an index is not used by any query, the index is meaningless, and you need to drop it.

- When using a combined index, follow the left-prefix rule.

  Suppose that you create a new combined index on the `title` and `published_at` columns:

  ```
  CREATE INDEX title_published_at_idx ON books (title, published_at);
  ```

  The following query can still use the combined index:

  ```
  SELECT * FROM books WHERE title = 'database';
  ```

  However, the following query cannot use the combined index because the condition for the leftmost first column in the index is not specified:

  ```
  SELECT * FROM books WHERE published_at = '2018-08-18 21:42:08';
  ```

- When using an index column as a condition in a query, do not use calculation, function, or type conversion on it, which will prevent the TiDB optimizer from using the index.

  Suppose that you create a new index on the time type column `published_at`:

  ```
  CREATE INDEX published_at_idx ON books (published_at);
  ```

  However, the following query cannot use the index on `published_at`:

  ```
  SELECT * FROM books WHERE YEAR(published_at)=2022;
  ```

  To use the index on `published_at`, you can rewrite the query as follows, which avoids using any function on the index column:

```
SELECT * FROM books WHERE published_at >= '2022-01-01' AND published_
    ↪ at < '2023-01-01';
```

You can also use an expression index to create an expression index for `YEAR(Published ↪ at)` in the query condition:

```
CREATE INDEX published_year_idx ON books ((YEAR(published_at)));
```

Now, if you execute the `SELECT * FROM books WHERE YEAR(published_at)=2022;` query, the query can use the `published_year_idx` index to speed up the execution.

> **Warning:**
>
> Currently, expression index is an experimental feature, and it needs to be enabled in the TiDB configuration file. For more details, see expression index.

- Try to use a covering index, in which the columns in the index contain the columns to be queried, and avoid querying all columns with `SELECT *` statements.

  The following query only needs to scan the index `title_published_at_idx` to get the data:

  ```
  SELECT title, published_at FROM books WHERE title = 'database';
  ```

  Although the following query statement can use the combined index `(title, ↪ published_at)`, it causes an extra cost to query the non-indexed column, which requires TiDB to query row data according to the reference stored in the index data (usually the primary key information).

  ```
  SELECT * FROM books WHERE title = 'database';
  ```

- A query cannot use indexes when the query condition contains `!=` or `NOT IN`. For example, the following query cannot use any indexes:

  ```
  SELECT * FROM books WHERE title != 'database';
  ```

- A query cannot use indexes if the `LIKE` condition starts with wildcard `%` in the query. For example, the following query cannot use any indexes:

  ```
  SELECT * FROM books WHERE title LIKE '%database';
  ```

- When the query condition has multiple indexes available, and you know which index is the best in practice, it is recommended to use Optimizer Hint to force the TiDB optimizer to use this index. This can prevent the TiDB optimizer from selecting the wrong index due to inaccurate statistics or other problems.

In the following query, assuming that indexes `id_idx` and `title_idx` are available on the column `id` and `title` respectively, if you know that `id_idx` is better, you can use `USE INDEX` hint in SQL to force the TiDB optimizer to use the `id_idx` index.

```
SELECT * FROM t USE INDEX(id_idx) WHERE id = 1 and title = 'database';
```

- When using the `IN` expression in a query condition, it is recommended that the number of value matched after it does not exceed 300, otherwise the execution efficiency will be poor.

4.10.5 Other Optimization Methods

4.10.5.1 Avoid Implicit Type Conversions

This document introduces the rules and possible consequences of implicit type conversions in TiDB and how to avoid implicit type conversions.

4.10.5.1.1 Conversion rules

When the data types on the two sides of the predicate in a SQL statement do not match, TiDB implicitly convert the data types on one or both sides to a compatible data type for predicate operations.

The rules for implicit type conversion in TiDB are as follows:

- If one or both arguments are `NULL`, the result of the comparison is `NULL`. The NULL-safe `<=>` equivalent comparison operator does not require conversion, because NULL `<=>` NULL results in `true`.
- If both arguments in the comparison operation are strings, they are compared as strings.
- If both arguments are integers, they are compared as integers.
- If no comparison is made with numbers, the hexadecimal value is treated as a binary string.
- If one of the arguments is a decimal value, the comparison depends on the other argument. If the other argument is a decimal or integer value, the argument is compared with the decimal value. If the other argument is a floating-point value, the argument is compared with the floating-point value.
- If one of the arguments is a `TIMESTAMP` or `DATETIME` column and the other argument is a constant, the constant is converted to a timestamp before the comparison is performed.
- In all other cases, the arguments are compared as floating-point numbers (the `DOUBLE` type).

4.10.5.1.2 Consequences caused by implicit type conversion

Implicit type conversions increase the usability of human-computer interaction. However, avoid using implicit type conversions in application code, because they might lead to the following issues:

- Index invalidity
- Loss of precision

Index invalidity

In the following case, `account_id` is the primary key and its data type is `varchar`. In the execution plan, this SQL statement has an implicit type conversion and cannot use the index.

```
DESC SELECT * FROM `account` WHERE `account_id`=6010000000009801;
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
| id                    | estRows       | task     | access object | operator
   ↪ info                                       |
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
| TableReader_7         | 8000628000.00 | root     |               | data:
   ↪ Selection_6                                |
| ─Selection_6          | 8000628000.00 | cop[tikv] |              | eq(cast(
   ↪ findpt.account.account_id), 6.010000000009801e+15) |
|   ─TableFullScan_5    | 10000785000.00 | cop[tikv] | table:account | keep
   ↪ order:false                                |
+--
   ↪ ----------------------+---------------+----------+--------------+----------
   ↪
3 rows in set (0.00 sec)
```

Brief description of run results: From the above execution plan, the `Cast` operator is visible.

Loss of precision

In the following case, the data type of the `a` field is `decimal(32,0)`. In the execution plan, an implicit type conversion occurs, and both the decimal field and the string constant are converted to the double type. Because the precision of the double type is not as high as decimal, there is a loss of precision. In this case, the SQL statement incorrectly filters the result set out of range.

```
DESC SELECT * FROM `t1` WHERE `a` BETWEEN '12123123' AND '
   ↪ 1111222211111111200000';
```

```
+--
   ↪ ----------------------+---------+-----------+--------------+------------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                                                              |
+--
   ↪ ----------------------+---------+-----------+--------------+------------------
   ↪
| TableReader_7         | 0.80    | root      |               | data:Selection_6
   ↪                                                                 |
|  ─Selection_6         | 0.80    | cop[tikv] |               | ge(cast(findpt.t1
   ↪ .a), 1.2123123e+07), le(cast(findpt.t1.a), 1.1112222111111112e+21) |
|    ─TableFullScan_5   | 1.00    | cop[tikv] | table:t1      | keep order:false,
   ↪  stats:pseudo                                                   |
+--
   ↪ ----------------------+---------+-----------+--------------+------------------
   ↪
3 rows in set (0.00 sec)
```

Brief description of run results: From the above execution plan, the `Cast` operator is visible.

```
SELECT * FROM `t1` WHERE `a` BETWEEN '12123123' AND '1111222211111111200000
   ↪ ';
+------------------------+
| a                      |
+------------------------+
| 1111222211111111222211 |
+------------------------+
1 row in set (0.01 sec)
```

Brief description of run results: The above execution gives a wrong result.

4.10.5.1.3 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.10.5.2 Unique Serial Number Generation

This document introduces the unique serial number generation scheme to help developers who generate their own unique IDs.

4.10.5.2.1 Auto-increment column

`AUTO_INCREMENT` is a column attribute of many RDBMSs that are compatible with the MySQL protocol. With the `AUTO_INCREMENT` attribute, a database can automatically assign values to this column without user intervention. As the number of records in the table increases, the value of this column automatically increments and are guaranteed to be unique. In most scenarios, `AUTO_INCREMENT` columns are used as proxy primary keys with no actual meaning.

The limitation of `AUTO_INCREMENT` columns is that the column must be of the integer type and the values assigned to them must be integer. If the serial numbers required by the application are sliced by letters, numbers, and other characters, it is difficult for the user to get the auto-increment numbers required in the serial number through the `AUTO_INCREMENT` column.

4.10.5.2.2 Sequence

A **Sequence** is a database object that an application can invoke to produce incremental sequence values. Applications can flexibly use the sequence values to assign values to one or more tables. Applications can also use the sequence values for more complex processing to produce a combination of text and numbers. This approach gives some tracking and classification meaning to proxy keys.

Sequence is available starting with TiDB v4.0. For details, refer to sequence documentation.

4.10.5.2.3 Snowflake-like solutions

Snowflake is a distributed ID generation solution proposed by Twitter. There are several implementations, the more popular ones are Baidu's **uid-generator** and Meituan's **leaf**. This section uses `uid-generator` as an example.

The 64-bit ID structure generated by `uid-generator` is as follows:

```
| sign | delta seconds | worker node id | sequencs |
|------|---------------|----------------|----------|
| 1bit |    28bits     | 22bits         | 13bits   |
```

- sign: Fixed length of 1 bit. Fixed to `0` to indicate that the generated ID is always a positive number.
- delta seconds: 28 bits by default. The current time, presented as an incremental value in seconds relative to a preset time base (defaults to `2016-05-20`). 28 bits can support up to about 8.7 years.
- worker node id: 22 bits by default. Represents the machine ID, usually obtained from a centralized ID generator when the application process is started. Common centralized ID generators include auto-increment columns and ZooKeeper. The default allocation policy is discard-as-you-go, and the process re-acquires a new worker node ID on restart. 22 bits can support up to about 4.2 million starts.
- sequence: 13 bits by default. The sequence of concurrency per second. 13 bits can support 8192 concurrent sequences per second.

4.10.5.2.4 Number allocation solution

The number allocation solution can be understood as bulk acquisition of auto-increment IDs from the database. This scheme requires a sequence number generation table, with each row representing a sequence object. An example of table definition is as follows:

Field Name	Field Type	Field Description
`SEQ_NAME`	varchar(128)	The name of the sequence, used to distinguish different applications.
`MAX_ID`	bigint	The maximum value of the current sequence that has been allocated.
`STEP`	int	The step, which indicates the length of each assigned segment.

Every time, the application gets a segment of sequence numbers at the configured step. It updates the database at the same time to persist the maximum value of the current sequence that has been allocated. The processing and allocation of sequence numbers are completed in the application's memory. After a segment of sequence numbers is used up, the application gets a new segment of sequence numbers, which effectively alleviates the pressure on the database write. In practice, you can also adjust the step to control the frequency of database updates.

Finally, note that the IDs generated by the above two solutions are not random enough to be directly used as **primary keys** for TiDB tables. In practice, you can perform bit-reverse on the generated IDs to get more random new IDs. For example, after performing bit-reverse, the ID `00000010100101000001111010011100` becomes `00111001011110000010100101000000`, and `11111111111111111111111111111101` becomes `10111111111111111111111111111111`.

- TiDB FAQs

4.11.1.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.11.2 Unstable Result Set

This document describes how to solve unstable result set errors.

4.11.2.1 GROUP BY

For convenience, MySQL "extends" the `GROUP BY` syntax to allow the `SELECT` clause to refer to non-aggregated fields not declared in the `GROUP BY` clause, that is, the `NON-FULL GROUP BY` syntax. In other databases, this is considered a syntax ***ERROR*** because it causes unstable result sets.

For example, you have two tables:

- `stu_info` stores the student information
- `stu_score` stores the student test scores.

Then you can write a SQL query statement like this:

```
SELECT
    `a`.`class`,
    `a`.`stuname`,
    max( `b`.`courscore` )
FROM
    `stu_info` `a`
    JOIN `stu_score` `b` ON `a`.`stuno` = `b`.`stuno`
GROUP BY
    `a`.`class`,
    `a`.`stuname`
ORDER BY
    `a`.`class`,
    `a`.`stuname`;
```

Result:

```
+-----------+-------------+-----------------+
| class     | stuname     | max(b.courscore) |
+-----------+-------------+-----------------+
| 2018_CS_01 | MonkeyDLuffy |        95.5 |
| 2018_CS_03 | PatrickStar |         99.0 |
| 2018_CS_03 | SpongeBob |           95.0 |
+-----------+-------------+-----------------+
3 rows in set (0.00 sec)
```

The `a.class` and `a.stuname` fields are specified in the `GROUP BY` statement, and the selected columns are `a.class`, `a.stuname` and `b.courscore`. The only column that is not in the `GROUP BY` condition, `b.courscore`, is also specified with a unique value using the `max()` function. There is ***ONLY ONE*** result that satisfies this SQL statement without any ambiguity, which is called the `FULL GROUP BY` syntax.

A counterexample is the `NON-FULL GROUP BY` syntax. For example, in these two tables, write the following SQL query (delete `a.stuname` in `GROUP BY`).

```
SELECT
    `a`.`class`,
    `a`.`stuname`,
    max( `b`.`courscore` )
FROM
    `stu_info` `a`
    JOIN `stu_score` `b` ON `a`.`stuno` = `b`.`stuno`
GROUP BY
    `a`.`class`
ORDER BY
    `a`.`class`,
    `a`.`stuname`;
```

Then two values that match this SQL are returned.

The first returned value:

```
+-----------+-------------+----------------------+
| class     | stuname     | max( `b`.`courscore` ) |
+-----------+-------------+----------------------+
| 2018_CS_01 | MonkeyDLuffy |                95.5 |
| 2018_CS_03 | PatrickStar |                99.0 |
+-----------+-------------+----------------------+
```

The second returned value:

```
+-----------+-------------+-----------------+
| class     | stuname     | max(b.courscore) |
+-----------+-------------+-----------------+
| 2018_CS_01 | MonkeyDLuffy |            95.5 |
| 2018_CS_03 | SpongeBob |              99.0 |
+-----------+-------------+-----------------+
```

There are two results because you did ***NOT*** specify how to get the value of the `a.stuname` field in SQL, and two results are both satisfied by SQL semantics. It results in an unstable result set. Therefore, if you want to guarantee the stability of the result set of the `GROUP BY` statement, use the `FULL GROUP BY` syntax.

MySQL provides a `sql_mode` switch `ONLY_FULL_GROUP_BY` to control whether to check the `FULL GROUP BY` syntax or not. TiDB is also compatible with this `sql_mode` switch.

```
mysql> select a.class, a.stuname, max(b.courscore) from stu_info a join stu
    ↪ _score b on a.stuno=b.stuno group by a.class order by a.class, a.
    ↪ stuname;
+-----------+-------------+-----------------+
| class     | stuname     | max(b.courscore) |
+-----------+-------------+-----------------+
| 2018_CS_01 | MonkeyDLuffy |            95.5 |
| 2018_CS_03 | PatrickStar |            99.0 |
+-----------+-------------+-----------------+
2 rows in set (0.01 sec)

mysql> set @@sql_mode='STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION,ONLY_FULL
    ↪ _GROUP_BY';
Query OK, 0 rows affected (0.01 sec)

mysql> select a.class, a.stuname, max(b.courscore) from stu_info a join stu
    ↪ _score b on a.stuno=b.stuno group by a.class order by a.class, a.
    ↪ stuname;
ERROR 1055 (42000): Expression #2 of ORDER BY is not in GROUP BY clause and
    ↪  contains nonaggregated column '' which is not functionally dependent
```

```
    ↪  on columns in GROUP BY clause; this is incompatible with sql_mode=
    ↪ only_full_group_by
```

Run results: The above example shows the effect when you set `ONLY_FULL_GROUP_BY` for `sql_mode`.

4.11.2.2 ORDER BY

In SQL semantics, the result set is output in order only if the `ORDER BY` syntax is used. For a single-instance database, since the data is stored on one server, the results of multiple executions are often stable without data reorganization. Some databases (especially the MySQL InnoDB storage engine) can even output the result sets in order of the primary key or index.

As a distributed database, TiDB stores data on multiple servers. In addition, the TiDB layer does not cache data pages, so the result set order of SQL statements without `ORDER BY` is easily perceived as unstable. To output a sequential result set, you need to explicitly add the order field into the `ORDER BY` clause, which conforms to SQL semantics.

In the following example, only one field is added to the `ORDER BY` clause, and TiDB only sorts the results by that one field.

```
mysql> select a.class, a.stuname, b.course, b.courscore from stu_info a
    ↪ join stu_score b on a.stuno=b.stuno order by a.class;
+-----------+-------------+-------------------------+-----------+

36 rows in set (0.01 sec)
```

Results are unstable when the `ORDER BY` values are the same. To reduce randomness, `ORDER BY` values should be unique. If you can't guarantee the uniqueness, you need to add more `ORDER BY` fields until the combination of the `ORDER BY` fields in `ORDER BY` is unique, then the result will be stable.

4.11.2.3 The result set is unstable because order by is not used in `GROUP_CONCAT()`

The result set is unstable because TiDB reads data from the storage layer in parallel, so the result set order returned by `GROUP_CONCAT()` without `ORDER BY` is easily perceived as unstable.

To let `GROUP_CONCAT()` get the result set output in order, you need to add the sorting fields to the `ORDER BY` clause, which conforms to the SQL semantics. In the following example, `GROUP_CONCAT()` that splices `customer_id` without `ORDER BY` causes an unstable result set.

1. Excluded `ORDER BY`

   First query:

```
mysql> select GROUP_CONCAT( customer_id SEPARATOR ',' ) FROM customer
    ↪ where customer_id like '200002%';
+--
    ↪ ------------------------------------------------------------------+
    ↪
| GROUP_CONCAT(customer_id SEPARATOR ',')                          |
```

```
+--
    ↪ ----------------------------------------------------------------------+
    ↪
|
    ↪ 20000200992,20000200993,20000200994,20000200995,20000200996,20000200...
    ↪  |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
```

Second query:

```
mysql> select GROUP_CONCAT( customer_id SEPARATOR ',' ) FROM customer
    ↪ where customer_id like '200002%';
+--
    ↪ ----------------------------------------------------------------------+
    ↪
| GROUP_CONCAT(customer_id SEPARATOR ',')                              |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
|
    ↪ 20000203040,20000203041,20000203042,20000203043,20000203044,20000203...
    ↪  |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
```

2. Include `ORDER BY`

First query:

```
mysql> select GROUP_CONCAT( customer_id order by customer_id SEPARATOR
    ↪  ',' ) FROM customer where customer_id like '200002%';
+--
    ↪ ----------------------------------------------------------------------+
    ↪
| GROUP_CONCAT(customer_id SEPARATOR ',')                              |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
|
    ↪ 20000200000,20000200001,20000200002,20000200003,20000200004,20000200...
    ↪  |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
```

Second query:

```
mysql> select GROUP_CONCAT( customer_id order by customer_id SEPARATOR
    ↪  ',' ) FROM customer where customer_id like '200002%';
+--
    ↪ ----------------------------------------------------------------------+
    ↪
| GROUP_CONCAT(customer_id SEPARATOR ',')                                    |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
|
    ↪ 20000200000,20000200001,20000200002,20000200003,20000200004,20000200...
    ↪  |
+--
    ↪ ----------------------------------------------------------------------+
    ↪
```

4.11.2.4 Unstable results in `SELECT * FROM T LIMIT N`

The returned result is related to the distribution of data on the storage node (TiKV). If multiple queries are performed, different storage units (Regions) of the storage nodes (TiKV) return results at different speeds, which can cause unstable results.

4.11.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.11.3 Timeouts in TiDB

This document describes various timeouts in TiDB to help you troubleshoot errors.

4.11.3.1 GC timeout

TiDB's transaction implementation uses the MVCC (Multiple Version Concurrency Control) mechanism. When the newly written data overwrites the old data, the old data will not be replaced, but kept together with the newly written data. The versions are distinguished by the timestamp. TiDB uses the mechanism of periodic Garbage Collection (GC) to clean up the old data that is no longer needed.

- For TiDB versions earlier than v4.0:

By default, each MVCC version (consistency snapshots) is kept for 10 minutes. Transactions that take longer than 10 minutes to read will receive an error `GC life time is shorter than transaction duration`.

- For TiDB v4.0 and later versions:

  For running transactions that do not exceed a duration of 24 hours, garbage collection (GC) are blocked during the transaction execution. The error `GC life time is shorter than transaction duration` does not occur.

If you need longer read time temporarily in some cases, you can increase the retention time of MVCC versions:

- For TiDB versions earlier than v5.0: adjust `tikv_gc_life_time` in the `mysql.tidb` table in TiDB.
- For TiDB v5.0 and later versions: adjust the system variable `tidb_gc_life_time`.

Note that the system variable configuration takes effect globally and immediately. Increasing its value will increase the life time of all existing snapshots, and decreasing it will immediately shorten the life time of all snapshots. Too many MVCC versions will impact the performance of the TiDB cluster. So you need to change this variable back to the previous setting in time.

Tip:

Specifically, when Dumpling is exporting data from TiDB (less than 1 TB), if the TiDB version is v4.0.0 or later and Dumpling can access the PD address and the `INFORMATION_SCHEMA.CLUSTER_INFO` table of the TiDB cluster, Dumpling automatically adjusts the GC safe point to block GC without affecting the original cluster.

However, in either of the following scenarios, Dumpling cannot automatically adjust the GC time:

- The data size is very large (more than 1 TB).
- Dumpling cannot connect directly to PD, for example, the TiDB cluster is on TiDB Cloud or on Kubernetes that is separated from Dumpling.

In such scenarios, you must manually extend the GC time in advance to avoid export failure due to GC during the export process.

For more details, see Manually set the TiDB GC time.

For more information about GC, see GC Overview.

4.11.3.2 Transaction timeout

In scenarios where a transaction starts but is neither committed nor rolled back, you might need a finer-grained control and a shorter timeout to prevent prolonged lock holding. In this case, you can use `tidb_idle_transaction_timeout` (introduced in TiDB v7.6.0) to control the idle timeout for transactions in a user session.

GC does not affect ongoing transactions. However, there is still an upper limit to the number of pessimistic transactions that can run, with a limit on the transaction timeout and a limit on the memory used by the transaction. You can modify the transaction timeout by `max-txn-ttl` under the `[performance]` category of the TiDB profile, `60` minutes by default.

SQL statements such as `INSERT INTO t10 SELECT * FROM t1` are not affected by GC, but will be rolled back due to timeout after exceeding `max-txn-ttl`.

4.11.3.3 SQL execution timeout

TiDB also provides a system variable (`max_execution_time`, `0` by default, indicating no limit) to limit the execution time of a single SQL statement. Currently, the system variable only takes effect for read-only SQL statements. The unit of `max_execution_time` is `ms`, but the actual precision is at the `100ms` level instead of the millisecond level.

4.11.3.4 JDBC query timeout

Starting from v6.1.0, when the `enable-global-kill` configuration item is set to its default value `true`, you can use the `setQueryTimeout()` method provided by MySQL JDBC to control the query timeout.

> **Note:**
>
> When your TiDB version is earlier than v6.1.0 or `enable-global-kill` is set to `false`, `setQueryTimeout()` does not work for TiDB. This is because the client sends a `KILL` command to the database when it detects the query timeout. However, because the TiDB service is load balanced, TiDB does not execute the `KILL` command to avoid termination of the connection on a wrong TiDB node. In such cases, you can use `max_execution_time` to control query timeout.

TiDB provides the following MySQL-compatible timeout control parameters.

- **wait_timeout**, controls the non-interactive idle timeout for the connection to Java applications. Since TiDB v5.4, the default value of `wait_timeout` is `28800` seconds, which is 8 hours. For TiDB versions earlier than v5.4, the default value is `0`, which means the timeout is unlimited.

- **interactive_timeout**, controls the interactive idle timeout for the connection to Java applications. The value is `8 hours` by default.
- **max_execution_time**, controls the timeout for SQL execution in the connection, only effective for read-only SQL statements. The value is `0` by default, which allows the connection to be infinitely busy, that is, an SQL statement is executed for an infinitely long time.

However, in a real production environment, idle connections and indefinitely executing SQL statements have a negative effect on both the database and the application. You can avoid idle connections and indefinitely executing SQL statements by configuring these two session-level variables in your application's connection string. For example, set the following:

- `sessionVariables=wait_timeout=3600` (1 hour)
- `sessionVariables=max_execution_time=300000` (5 minutes)

Ask the community on Discord or Slack, or submit a support ticket.

4.12 Reference

4.12.1 Bookshop Example Application

Bookshop is a virtual online bookstore application through which you can buy books of various categories and rate the books you have read.

To make your reading on the application developer guide more smoothly, we present the example SQL statements based on the table structures and data of the Bookshop application. This document focuses on the methods of importing the table structures and data as well as the definitions of the table structures.

4.12.1.1 Import table structures and data

You can import Bookshop table structures and data either via TiUP or via the import feature of TiDB Cloud.

4.12.1.1.1 Method 1: Via `tiup demo`

If your TiDB cluster is deployed using TiUP or you can connect to your TiDB server, you can quickly generate and import sample data for the Bookshop application by running the following command:

```
tiup demo bookshop prepare
```

By default, this command enables your application to connect to port `4000` on address `127.0.0.1`, enables you to log in as the `root` user without a password, and creates a table structure in the database named `bookshop`.

Configure connection information

The following table lists the connection parameters. You can change their default settings to match your environment.

Parameter	Abbreviation	Default value	Description
`--password`	`-p`	None	Database user password
`--host`	`-H`	`127.0.0.1`	Database address
`--port`	`-P`	`4000`	Database port
`--db`	`-D`	`bookshop`	Database name
`--user`	`-U`	`root`	Database user

For example, if you want to connect to a database on TiDB Cloud, you can specify the connection information as follows:

```
tiup demo bookshop prepare -U <username> -H <endpoint> -P 4000 -p <password>
```

Set the data volume

You can specify the volume of data to be generated in each database table by configuring the following parameters:

Parameter	Default value	Description
`--users`	`10000`	The number of rows of data to be generated in the `users` table
`--authors`	`20000`	The number of rows to be generated in the `authors` table
`--books`	`20000`	The number of rows of data to be generated in the `books` table
`--orders`	`300000`	The number of rows of data to be generated in the `orders` table
`--ratings`	`300000`	The number of rows of data to be generated in the `ratings` table

For example, the following command is executed to generate:

- 200,000 rows of user information via the `--users` parameter
- 500,000 rows of book information via the `--books` parameter
- 100,000 rows of author information via the `--authors` parameter
- 1,000,000 rows of rating records via the `--ratings` parameter
- 1,000,000 rows of order records via the `--orders` parameter

```
tiup demo bookshop prepare --users=200000 --books=500000 --authors=100000 --
    ↪ ratings=1000000 --orders=1000000 --drop-tables
```

You can delete the original table structure through the `--drop-tables` parameter. For more parameter descriptions, run the `tiup demo bookshop --help` command.

4.12.1.1.2 Method 2: Via TiDB Cloud Import

1. Open the **Import** page for your target cluster.

    1. Log in to the TiDB Cloud console and navigate to the **Clusters** page of your project.

    > **Tip:**
    > If you have multiple projects, you can click in the lower-left corner and switch to another project.

    2. Click the name of your target cluster to go to its overview page, and then click **Import** in the left navigation pane.

2. Select **Import data from Cloud Storage**, and then click **Amazon S3**.

3. On the **Import Data from Amazon S3** page, configure the following source data information:

    - **Import File Count**: for TiDB Cloud Serverless, select **Multiple files**. This field is not available in TiDB Cloud Dedicated.
    - **Included Schema Files**: select **Yes**.
    - **Data Format**: select **SQL**.
    - **Folder URI**: enter `s3://developer.pingcap.com/bookshop/`.
    - **Bucket Access**: select **AWS Role ARN**.
    - **Role ARN**: enter `arn:aws:iam::494090988690:role/s3-tidb-cloud-developer-access`.

    In this example, the following data is generated in advance:

    - 200,000 rows of user information
    - 500,000 rows of book information
    - 100,000 rows of author information
    - 1,000,000 rows of rating records
    - 1,000,000 rows of order records

4. Click **Connect** > **Start Import** to start the import process and wait for TiDB Cloud to complete the import.

For more information about how to import or migrate data to TiDB Cloud, see TiDB Cloud Migration Overview.

4.12.1.1.3 View data import status

After the import is completed, you can view the data volume information of each table by executing the following SQL statement:

```
SELECT
    CONCAT(table_schema,'.',table_name) AS 'Table Name',
    table_rows AS 'Number of Rows',
    CONCAT(ROUND(data_length/(1024*1024*1024),4),'G') AS 'Data Size',
    CONCAT(ROUND(index_length/(1024*1024*1024),4),'G') AS 'Index Size',
    CONCAT(ROUND((data_length+index_length)/(1024*1024*1024),4),'G') AS '
        ↪ Total'
FROM
    information_schema.TABLES
WHERE table_schema LIKE 'bookshop';
```

The result is as follows:

```
+----------------------+---------------+-----------+------------+---------+
    ↪
| Table Name           | Number of Rows | Data Size | Index Size | Total |
+----------------------+---------------+-----------+------------+---------+
    ↪
| bookshop.orders      |       1000000 | 0.0373G | 0.0075G  | 0.0447G |
| bookshop.book_authors |    1000000 | 0.0149G | 0.0149G  | 0.0298G |
| bookshop.ratings     |       4000000 | 0.1192G | 0.1192G  | 0.2384G |
| bookshop.authors     |        100000 | 0.0043G | 0.0000G  | 0.0043G |
| bookshop.users       |        195348 | 0.0048G | 0.0021G  | 0.0069G |
| bookshop.books       |       1000000 | 0.0546G | 0.0000G  | 0.0546G |
+----------------------+---------------+-----------+------------+---------+
    ↪
6 rows in set (0.03 sec)
```

4.12.1.2 Description of the tables

This section describes the database tables of the Bookshop application in detail.

4.12.1.2.1 books table

This table stores the basic information of books.

Field name	Type	Description
id	bigint	Unique ID of a book
title	varchar(100)	Title of a book
type	enum	Type of a book (for example, magazine, animation, or teaching aids)
stock	bigint	Stock

Field name	Type	Description
price	decimal(15,2)	Price
published_at	datetime	Date of publish

4.12.1.2.2 `authors` table

This table stores basic information of authors.

Field name	Type	Description
id	bigint	Unique ID of an author
name	varchar(100)	Name of an author
gender	tinyint	Biological gender (0: female, 1: male, NULL: unknown)
birth_year	smallint	Year of birth
death_year	smallint	Year of death

4.12.1.2.3 `users` table

This table stores information of Bookshop users.

Field name	Type	Description
id	bigint	Unique ID of a user
balance	decimal(15,2)	Balance
nickname	varchar(100)	Nickname

4.12.1.2.4 `ratings` table

This table stores records of user ratings on books.

Field name	Type	Description
book_id	bigint	Unique ID of a book (linked to books)
user_id	bigint	User's unique identifier (linked to users)
score	tinyint	User rating (1-5)
rated_at	datetime	Rating time

4.12.1.2.5 `book_authors` table

An author may write multiple books, and a book may involve more than one author. This table stores the correspondence between books and authors.

Field name	Type	Description
book_id	bigint	Unique ID of a book (linked to books)
author_id	bigint	Unique ID of an author (Link to authors)

4.12.1.2.6 `orders` table

This table stores user purchase information.

Field name	Type	Description
id	bigint	Unique ID of an order
book_id	bigint	Unique ID of a book (linked to books)
user_id	bigint	User unique identifier (associated with users)
quantity	tinyint	Purchase quantity
ordered_at	datetime	Purchase time

4.12.1.3 Database initialization script `dbinit.sql`

If you want to manually create database table structures in the Bookshop application, run the following SQL statements:

```
CREATE DATABASE IF NOT EXISTS `bookshop`;

DROP TABLE IF EXISTS `bookshop`.`books`;
CREATE TABLE `bookshop`.`books` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `title` varchar(100) NOT NULL,
  `type` enum('Magazine', 'Novel', 'Life', 'Arts', 'Comics', 'Education &
    ↪ Reference', 'Humanities & Social Sciences', 'Science & Technology',
    ↪ 'Kids', 'Sports') NOT NULL,
  `published_at` datetime NOT NULL,
  `stock` int DEFAULT '0',
  `price` decimal(15,2) DEFAULT '0.0',
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`authors`;
CREATE TABLE `bookshop`.`authors` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `name` varchar(100) NOT NULL,
  `gender` tinyint DEFAULT NULL,
  `birth_year` smallint DEFAULT NULL,
  `death_year` smallint DEFAULT NULL,
  PRIMARY KEY (`id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`book_authors`;
CREATE TABLE `bookshop`.`book_authors` (
  `book_id` bigint NOT NULL,
  `author_id` bigint NOT NULL,
```

```
  PRIMARY KEY (`book_id`,`author_id`) CLUSTERED
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`ratings`;
CREATE TABLE `bookshop`.`ratings` (
  `book_id` bigint NOT NULL,
  `user_id` bigint NOT NULL,
  `score` tinyint NOT NULL,
  `rated_at` datetime NOT NULL DEFAULT NOW() ON UPDATE NOW(),
  PRIMARY KEY (`book_id`,`user_id`) CLUSTERED,
  UNIQUE KEY `uniq_book_user_idx` (`book_id`,`user_id`)
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
ALTER TABLE `bookshop`.`ratings` SET TIFLASH REPLICA 1;

DROP TABLE IF EXISTS `bookshop`.`users`;
CREATE TABLE `bookshop`.`users` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `balance` decimal(15,2) DEFAULT '0.0',
  `nickname` varchar(100) UNIQUE NOT NULL,
  PRIMARY KEY (`id`)
) DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;

DROP TABLE IF EXISTS `bookshop`.`orders`;
CREATE TABLE `bookshop`.`orders` (
  `id` bigint AUTO_RANDOM NOT NULL,
  `book_id` bigint NOT NULL,
  `user_id` bigint NOT NULL,
  `quality` tinyint NOT NULL,
  `ordered_at` datetime NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
    ↪ CURRENT_TIMESTAMP,
  PRIMARY KEY (`id`) CLUSTERED,
  KEY `orders_book_id_idx` (`book_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin
```

4.12.1.4 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.12.2 Guidelines

4.12.2.1 Object Naming Convention

This document introduces the rules to name database objects, such as database, table, index, and user.

4.12.2.1.1 General rules

- It is recommended to use meaningful English words separated by underscores.
- Use only letters, numbers, and underscores in a name.
- Avoid using TiDB reserved words, such as `group` and `order`, as column names.
- It is recommended to use lowercase letters for all database objects.

4.12.2.1.2 Database naming convention

It is recommended to differentiate database names by business, product, or other metrics and use no more than 20 characters in a database name. For example, you can name a temporary library as `tmp_crm` or a test library as `test_crm`.

4.12.2.1.3 Table naming convention

- Use the same prefix for tables of the same business or module, and make sure that the table name is self-explanatory as much as possible.
- Separate words in a name by underscores. It is recommended to use no more than 32 characters in a table name.
- It is recommended to annotate the purpose of the table for a better understanding. For example:
  - Temporary table: `tmp_t_crm_relation_0425`
  - Backup table: `bak_t_crm_relation_20170425`
  - Temporary table of business operations: `tmp_st_{business code}_{creator abbreviation}_{date}`
  - Record table of accounts period: `t_crm_ec_record_YYYY{MM}{dd}`
- Create separate databases for tables of different business modules and add annotations accordingly.

4.12.2.1.4 Column naming convention

- The column naming is the actual meaning or abbreviation of the column.
- It is recommended to use the same column name between tables with the same meaning.
- It is recommended to add annotations to columns and specify named values for enumerated types, such as "0: offline, 1: online".
- It is recommended to name the boolean column as `is_{description}`. For example, the column of a `member` table that indicates whether the member is enabled, can be named as `is_enabled`.
- It is not recommended to name a column with more than 30 characters, and the number of columns should be less than 60.
- Avoid using TiDB reserved words as column names, such as `order`, `from`, and `desc`. To check whether a keyword is reserved, see TiDB keywords.

4.12.2.1.5 Index naming convention

- Primary key index: `pk_{table_name_abbreviation}_{field_name_abbreviation}`
- Unique index: `uk_{table_name_abbreviation}_{field_name_abbreviation}`
- Common index: `idx_{table_name_abbreviation}_{field_name_abbreviation}`
- Column name with multiple words: use meaningful abbreviations

4.12.2.1.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.12.2.2 SQL Development Specifications

This document introduces some general development specifications for using SQL.

4.12.2.2.1 Create and delete tables

- Basic principle: under the premise of following the table naming convention, it is recommended that the application internally packages the table creation and deletion statements and adds judgment logic to prevent abnormal interruption of business processes.
- Details: `create table if not exists table_name` or `drop table if exists table_name` statements are recommended to add `if` judgments to avoid abnormal interruptions caused by SQL commands running abnormally on the application side.

4.12.2.2.2 `SELECT *` usage

- Basic principle: avoid using `SELECT *` for queries.
- Details: select the appropriate columns as required and avoid using `SELECT *` to read all fields because such operations consume network bandwidth. Consider adding the queried fields to the index to make effective use of the covering index.

4.12.2.2.3 Use functions on fields

- Basic principle: You can use related functions on the queried fields. To avoid index failure, do not use any functions on the filtered fields in the `WHERE` clause, including data type conversion functions. You may consider using the expression index.
- Detailed description:

  NOT recommended:

```
SELECT gmt_create
FROM ...
WHERE DATE_FORMAT(gmt_create, '%Y%m%d %H:%i:%s') = '20090101 00:00:00'
```

Recommended:

```
SELECT DATE_FORMAT(gmt_create, '%Y%m%d %H:%i:%s')
FROM ...
WHERE gmt_create = str_to_date('20090101 00:00:00', '%Y%m%d %H:%i:%s')
```

4.12.2.2.4 Other specifications

- Do not perform mathematical operations or functions on the index column in the `WHERE` condition.
- Replace `OR` with `IN` or `UNION`. The number of `IN` must be less than `300`.
- Avoid using the `%` prefix for fuzzy prefix queries.
- If the application uses **Multi Statements** to execute SQL, that is, multiple SQLs are joined with semicolons and sent to the client for execution at once, TiDB only returns the result of the first SQL execution.
- When you use expressions, check if the expressions support computing push-down to the storage layer (TiKV or TiFlash). If not, you should expect more memory consumption and even OOM at the TiDB layer. Computing that can be pushed down to the storage layer is as follows:
  - TiFlash supported push-down calculations.
  - TiKV - List of Expressions for Pushdown.
  - Predicate push down.

4.12.2.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.13 Cloud Native Development Environment

4.13.1 Gitpod

With Gitpod, you can get a full development environment in your browser with the click of a button or link, and you can write code right away.

Gitpod is an open-source Kubernetes application (GitHub repository address: https://github.com/gitpod-io/gitpod) for direct-to-code development environments, which spins up fresh, automated development environments for each task, in the cloud, in seconds. It enables you to describe your development environment as code and start instant, remote and cloud-based development environments directly from your browser or your Desktop IDE.

4.13.1.1 Quick start

1. Fork the example code repository pingcap-inc/tidb-example-java for TiDB application development.
2. Start your Gitpod workspace by prefixing the URL of the sample code repository with `https://gitpod.io/#` in the address bar of your browser.

- For example, `https://gitpod.io/#https://github.com/pingcap-inc/tidb-example-java`.
- You can configure environment variables in the URL. For example, `https://gitpod.io/#targetFile=spring-jpa-hibernate_Makefile,targetMode=spring-jpa-hibernate/https://github.com/pingcap-inc/tidb-example-java`.

3. Log in and start the workspace using one of the providers listed. For example, `Github`.

4.13.1.2 Use the default Gitpod configuration and environment

After completing the quick-start steps, it will take a while for Gitpod to set up your workspace.

Take the Spring Boot Web application as an example. You can create a new workspace by the `https://gitpod.io/#targetFile=spring-jpa-hibernate_Makefile,targetMode=spring-jpa-hibernate/https://github.com/pingcap-inc/tidb-example-java` URL.

After that, you will see a page similar to the following:

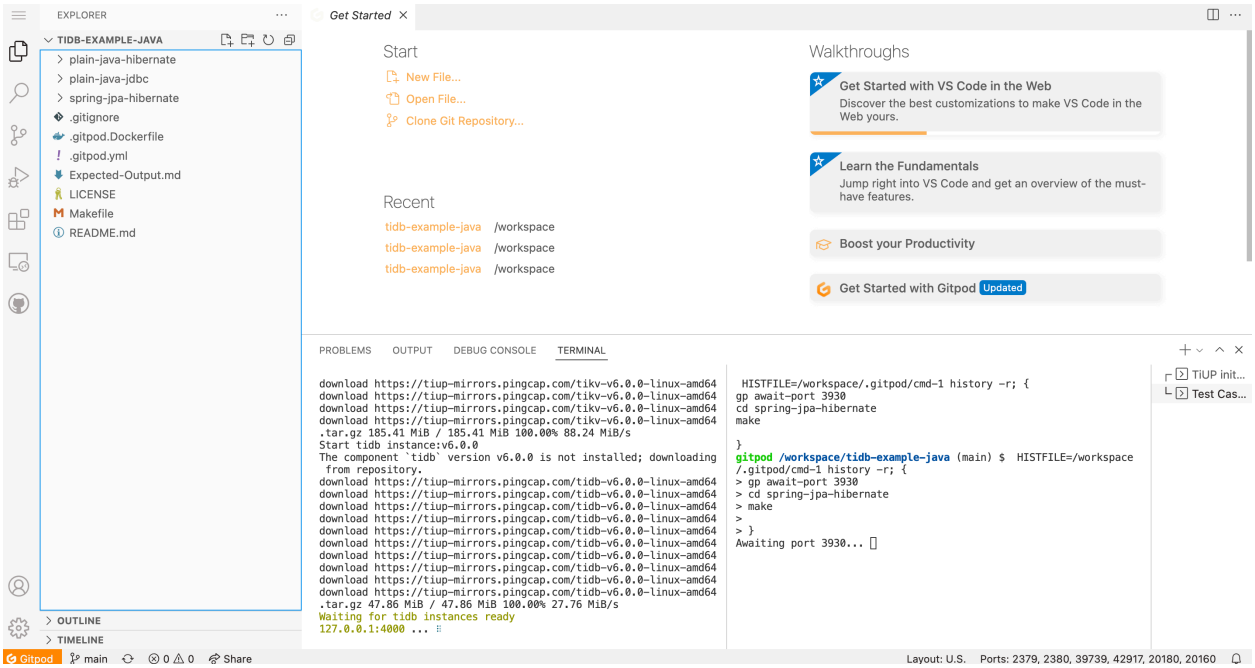

Figure 64: playground gitpod workspace init

This scenario in the page uses TiUP to build a TiDB Playground. You can check the progress on the left side of the terminal area.

Once the TiDB Playground is ready, another `Spring JPA Hibernate` task will run. You can check the progress on the right side of the terminal area.

After all these tasks are finished, you will see a page similar to the following. On this page, check the `REMOTE EXPLORER` area in the left navigation pane (Gitpod supports URL-based port forwarding) and find the URL of your port `8080`.

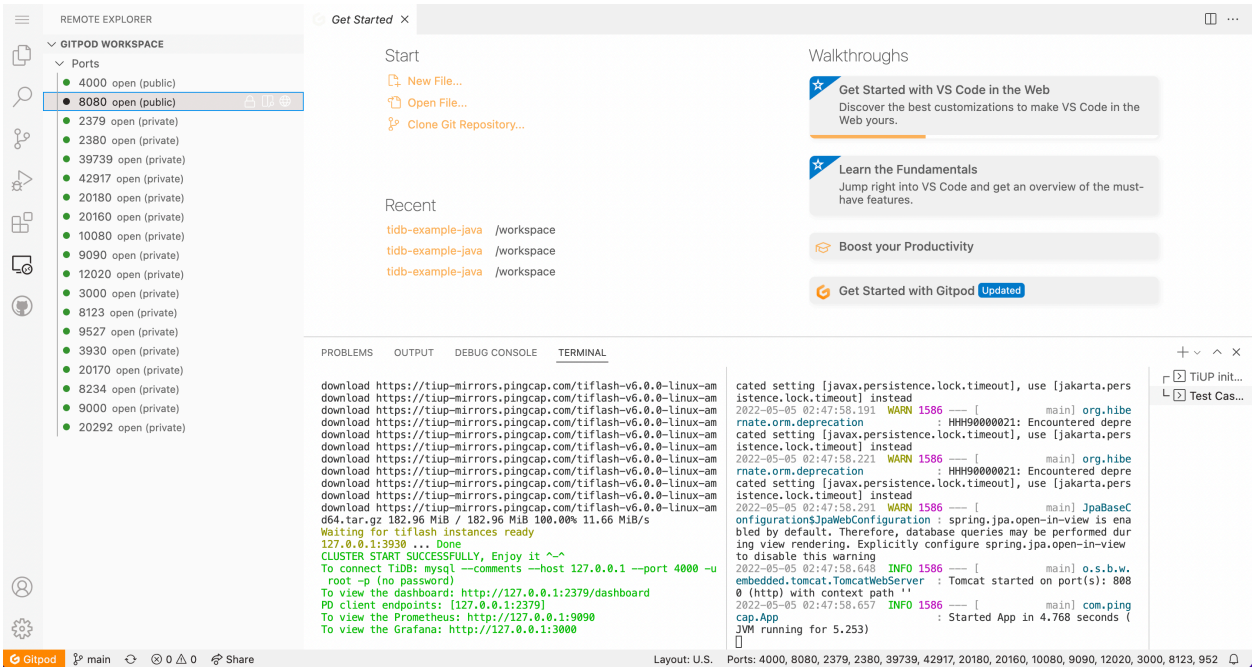

Figure 65: playground gitpod workspace ready

4.13.1.3 Using custom Gitpod configuration and Docker image

4.13.1.3.1 Customize Gitpod configurations

Referring to example.gitpod.yml, create a `.gitpod. yml` file in the root directory of your project to configure the Gitpod workspace.

```
### This configuration file was automatically generated by Gitpod.
### Please adjust to your needs (see https://www.gitpod.io/docs/config-
    ↪ gitpod-file)
### and commit this file to your remote git repository to share the goodness
    ↪  with others.

### image:
###   file: .gitpod.Dockerfile

tasks:
  - name: Open Target File
    command: |
      if [ -n "$targetFile" ]; then code ${targetFile//[_]//}; fi
  - name: TiUP init playground
    command: |
      $HOME/.tiup/bin/tiup playground
  - name: Test Case
```

```
    openMode: split-right
    init: echo "*** Waiting for TiUP Playground Ready! ***"
    command: |
      gp await-port 3930
      if [ "$targetMode" == "plain-java-jdbc" ]
      then
        cd plain-java-jdbc
        code src/main/resources/dbinit.sql
        code src/main/java/com/pingcap/JDBCExample.java
        make mysql
      elif [ "$targetMode" == "plain-java-hibernate" ]
      then
        cd plain-java-hibernate
        make
      elif [ "$targetMode" == "spring-jpa-hibernate" ]
      then
        cd spring-jpa-hibernate
        make
      fi
ports:
  - port: 8080
    visibility: public
  - port: 4000
    visibility: public
  - port: 2379-36663
    onOpen: ignore
```

4.13.1.3.2 Customize Gitpod Docker images

By default, Gitpod uses a standard Docker image named Workspace-Full as the basis for the workspace. Workspaces launched from this default image are pre-installed with Docker, Go, Java, Node.js, C/C++, Python, Ruby, Rust, PHP, and tools such as Homebrew, Tailscale, and Nginx.

You can use a public Docker image or a Dockerfile and also install any required dependencies for your project.

For example, you can use a Dockerfile (see also Example `.gitpod.Dockerfile`) as follows:

```
FROM gitpod/workspace-java-17

RUN sudo apt install mysql-client -y
RUN curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

Then, you need to update `.gitpod.yml`:

```
### This configuration file was automatically generated by Gitpod.
### Please adjust to your needs (see https://www.gitpod.io/docs/config-
    ↪ gitpod-file)
### and commit this file to your remote git repository to share the goodness
    ↪  with others.

image:
  # Import your Dockerfile here.
  file: .gitpod.Dockerfile

tasks:
  - name: Open Target File
    command: |
      if [ -n "$targetFile" ]; then code ${targetFile//[_]//}; fi
  - name: TiUP init playground
    command: |
      $HOME/.tiup/bin/tiup playground
  - name: Test Case
    openMode: split-right
    init: echo "*** Waiting for TiUP Playground Ready! ***"
    command: |
      gp await-port 3930
      if [ "$targetMode" == "plain-java-jdbc" ]
      then
        cd plain-java-jdbc
        code src/main/resources/dbinit.sql
        code src/main/java/com/pingcap/JDBCExample.java
        make mysql
      elif [ "$targetMode" == "plain-java-hibernate" ]
      then
        cd plain-java-hibernate
        make
      elif [ "$targetMode" == "spring-jpa-hibernate" ]
      then
        cd spring-jpa-hibernate
        make
      fi
ports:
  - port: 8080
    visibility: public
  - port: 4000
    visibility: public
  - port: 2379-36663
```

```
onOpen: ignore
```

4.13.1.3.3 Apply changes

After completing the configuration of the `.gitpod.yml` file, make sure that the latest code is available in your corresponding GitHub repository.

Visit `https://gitpod.io/#<YOUR_REPO_URL>` to create a new Gitpod workspace with the latest code applied.

Visit `https://gitpod.io/workspaces` for all established workspaces.

4.13.1.4 Summary

Gitpod provides a complete, automated, and pre-configured cloud-native development environment. You can develop, run, and test code directly in the browser without any local configurations.

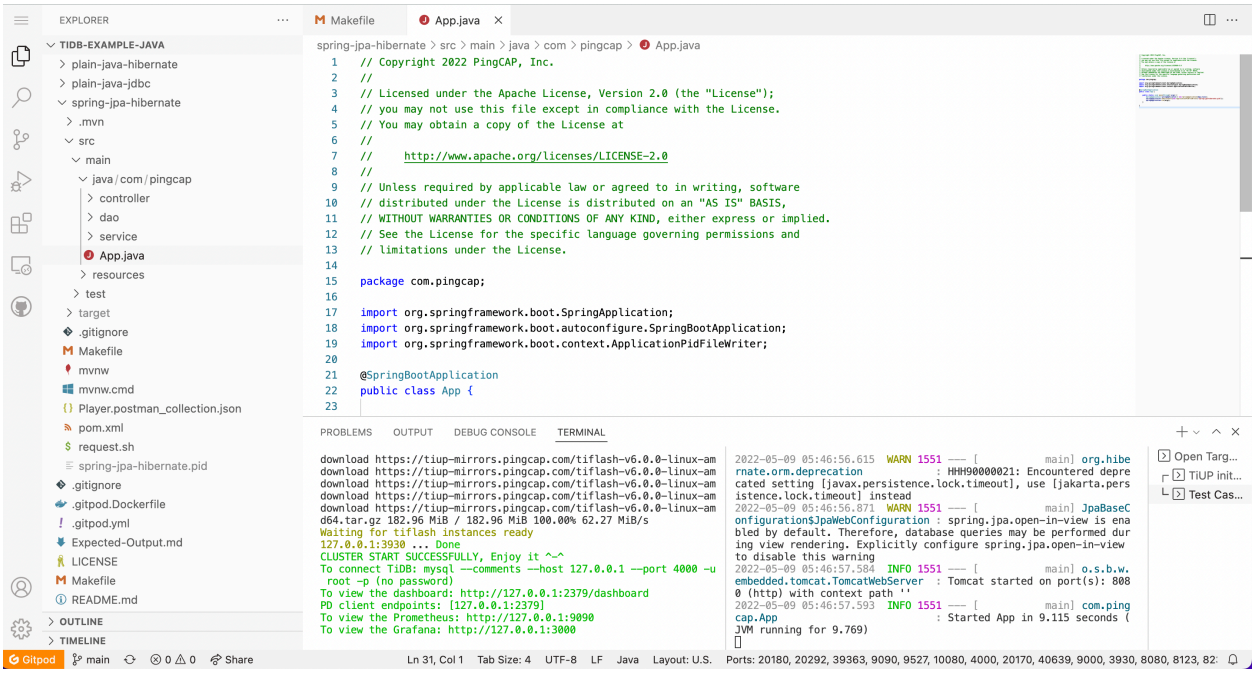

Figure 66: playground gitpod summary

4.13.1.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

4.14 Third-Party Support

4.14.1 Third-Party Tools Supported by TiDB

> **Note:**
>
> This document only lists common third-party tools supported by TiDB. Some other third-party tools are not listed, not because they are not supported, but because PingCAP is not sure whether they use features that are incompatible with TiDB.

TiDB is highly compatible with the MySQL protocol, so most of the MySQL drivers, ORM frameworks, and other tools that adapt to MySQL are compatible with TiDB. This document focuses on these tools and their support levels for TiDB.

4.14.1.1 Support Level

PingCAP works with the community and provides the following support levels for third-party tools:

- ***Full***: Indicates that TiDB is already compatible with most functionalities of the corresponding third-party tool, and maintains compatibility with its newer versions. PingCAP will periodically conduct compatibility tests with the latest version of the tool.
- ***Compatible***: Indicates that because the corresponding third-party tool is adapted to MySQL and TiDB is highly compatible with the MySQL protocol, so TiDB can use most features of the tool. However, PingCAP has not completed a full test on all features of the tool, which might lead to some unexpected behaviors.

> **Note:**
>
> Unless specified, support for Application retry and error handling is not included for **Driver** or **ORM frameworks**.

If you encounter problems when connecting to TiDB using the tools listed in this document, please submit an issue on GitHub with details to promote support on this tool.

4.14.2 Known Incompatibility Issues with Third-Party Tools

> **Note:**
>
> The Unsupported features section lists the unsupported features in TiDB, including:
>
> - Stored procedures and functions
> - Triggers
> - Events
> - User-defined functions
> - `SPATIAL` functions, data types and indexes
> - `XA` syntax
>
> The preceding unsupported features are expected behavior and are not listed in this document. For more details, see MySQL Compatibility.

The incompatibility issues listed in this document are found in some third-party tools supported by TiDB.

4.14.2.1 General incompatibility

4.14.2.1.1 `SELECT CONNECTION_ID()` returns a 64-bit integer in TiDB

Description

The `SELECT CONNECTION_ID()` function returns a 64-bit integer in TiDB, such as `2199023260887`, while it returns a 32-bit integer in MySQL, such as `391650`.

Way to avoid

In a TiDB application, to avoid data overflow, you should use a 64-bit integer or string type to store the result of `SELECT CONNECTION_ID()`. For example, you can use `Long` or `String` in Java and use `string` in JavaScript or TypeScript.

4.14.2.1.2 TiDB does not maintain `Com_*` counters

Description

MySQL maintains a series of server status variables starting with `Com_` to keep track of the total number of operations you have performed on the database. For example, `Com_select` records the total number of `SELECT` statements initiated by MySQL since it was last started (even if the statements were not queried successfully). TiDB does not maintain these variables. You can use the statement SHOW GLOBAL STATUS LIKE 'Com_%' to see the difference between TiDB and MySQL.

Way to avoid

Do not use these variables. One common scenario is monitoring. TiDB is well observable and does not require querying from server status variables. For custom monitoring tools, refer to TiDB Monitoring Framework Overview.

4.14.2.1.3 TiDB distinguishes between `TIMESTAMP` and `DATETIME` in error messages

Description

TiDB error messages distinguish between `TIMESTAMP` and `DATETIME`, while MySQL does not, and returns them all as `DATETIME`. That is, MySQL incorrectly converts `TIMESTAMP` type error messages to `DATETIME` type.

Way to avoid

Do not use the error messages for string matching. Instead, use Error Codes for troubleshooting.

4.14.2.1.4 TiDB does not support the `CHECK TABLE` statement

Description

The `CHECK TABLE` statement is not supported in TiDB.

Way to avoid

To check the consistency of data and corresponding indexes, you can use the `ADMIN CHECK [TABLE|INDEX]` statement in TiDB.

4.14.2.2 Compatibility with MySQL JDBC

The test version is MySQL Connector/J 8.0.29.

4.14.2.2.1 The default collation is inconsistent

Description

The collations of MySQL Connector/J are stored on the client side and distinguished by the server version.

The following table lists known client-side and server-side collation inconsistencies in character sets:

Character	Client-side default collation	Server-side default collation
`ascii`	`ascii_general_ci`	`ascii_bin`
`latin1`	`latin1_swedish_ci`	`latin1_bin`
`utf8mb4`	`utf8mb4_0900_ai_ci`	`utf8mb4_bin`

Way to avoid

Set the collation manually, and do not rely on the client-side default collation. The client-side default collation is stored by the MySQL Connector/J configuration file.

4.14.2.2.2 The `NO_BACKSLASH_ESCAPES` parameter does not take effect

Description

In TiDB, you cannot use the `NO_BACKSLASH_ESCAPES` parameter without escaping the `\` character. For more details, track this issue.

Way to avoid

Do not use `NO_BACKSLASH_ESCAPES` with `\` in TiDB, but use `\\` in SQL statements.

4.14.2.2.3 The `INDEX_USED` related parameters are not supported

Description

TiDB does not set the `SERVER_QUERY_NO_GOOD_INDEX_USED` and `SERVER_QUERY_NO_INDEX_USED` parameters in the protocol. This will cause the following parameters to be returned inconsistently with the actual situation:

- `com.mysql.cj.protocol.ServerSession.noIndexUsed()`

- `com.mysql.cj.protocol.ServerSession.noGoodIndexUsed()`

Way to avoid

Do not use the `noIndexUsed()` and `noGoodIndexUsed()` functions in TiDB.

4.14.2.2.4 The `enablePacketDebug` parameter is not supported

Description

TiDB does not support the enablePacketDebug parameter. It is a MySQL Connector/J parameter used for debugging that will keep the buffer of the data packet. This might cause the connection to close unexpectedly. **DO NOT** turn it on.

Way to avoid

Do not set the `enablePacketDebug` parameter in TiDB.

4.14.2.2.5 The UpdatableResultSet is not supported

Description

TiDB does not support `UpdatableResultSet`. **DO NOT** specify the `ResultSet.CONCUR_UPDATABLE` parameter and **DO NOT** update data inside the `ResultSet`.

Way to avoid

To ensure data consistency by transaction, you can use `UPDATE` statements to update data.

4.14.2.3 MySQL JDBC bugs

4.14.2.3.1 `useLocalTransactionState` and `rewriteBatchedStatements` are true at the same time will cause the transaction to fail to commit or roll back

Description

When using MySQL Connector/J 8.0.32 or an earlier version, if the `useLocalTransactionState` and `rewriteBatchedStatements` parameters are set to `true` at the same time, the transaction might fail to commit. You can reproduce with this code.

Way to avoid

> **Note:**
>
> `useConfigs=maxPerformance` includes a group of configurations. For detailed configurations in MySQL Connector/J 8.0 and MySQL Connector/J 5.1, see mysql-connector-j 8.0 and mysql-connector-j 5.1 respectively. You

need to disable `useLocalTransactionState` when using `maxPerformance`. That is, use `useConfigs=maxPerformance&useLocalTransactionState=false`.

This bug has been fixed in MySQL Connector/J 8.0.33. Considering updates for the 8.0.x series have ceased, it is strongly recommended to upgrade your MySQL Connector/J to the latest General Availability (GA) version for improved stability and performance.

4.14.2.3.2 Connector is incompatible with the server version earlier than 5.7.5

Description

The database connection might hang under certain conditions when using MySQL Connector/J 8.0.31 or an earlier version with a MySQL server < 5.7.5 or a database using the MySQL server < 5.7.5 protocol (such as TiDB earlier than v6.3.0). For more details, see the Bug Report.

Way to avoid

This bug has been fixed in MySQL Connector/J 8.0.32. Considering updates for the 8.0.x series have ceased, it is strongly recommended to upgrade your MySQL Connector/J to the latest General Availability (GA) version for improved stability and performance.

TiDB also fixes it in the following ways:

- Client side: This bug has been fixed in **pingcap/mysql-connector-j** and you can use the pingcap/mysql-connector-j instead of the official MySQL Connector/J.
- Server side: This compatibility issue has been fixed since TiDB v6.3.0 and you can upgrade the server to v6.3.0 or later versions.

4.14.2.4 Compatibility with Sequelize

The compatibility information described in this section is based on Sequelize v6.32.1.

According to the test results, TiDB supports most of the Sequelize features (using `MySQL` as the dialect).

Unsupported features are:

- `GEOMETRY` is not supported.
- Modification of integer primary key is not supported.
- `PROCEDURE` is not supported.
- The `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels are not supported.
- Modification of a column's `AUTO_INCREMENT` attribute is not allowed by default.
- `FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported.

- `sequelize.queryInterface.showIndex(Model.tableName);` is not supported.
- `sequelize.options.databaseVersion` is not supported.
- Adding a foreign key reference using `queryInterface.addColumn` is not supported.

4.14.2.4.1 Modification of integer primary key is not supported

Description

Modification of integer primary key is not supported. TiDB uses primary key as an index for data organization if the primary key is integer type. Refer to Issue #18090 and Clustered Indexes for more details.

4.14.2.4.2 The `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels are not supported

Description

TiDB does not support the `READ-UNCOMMITTED` and `SERIALIZABLE` isolation levels. If the isolation level is set to `READ-UNCOMMITTED` or `SERIALIZABLE`, TiDB throws an error.

Way to avoid

Use only the isolation level that TiDB supports: `REPEATABLE-READ` or `READ-COMMITTED`.

If you want TiDB to be compatible with other applications that set the `SERIALIZABLE` isolation level but not depend on `SERIALIZABLE`, you can set `tidb_skip_isolation_level_check` to `1`. In such case, TiDB ignores the unsupported isolation level error.

4.14.2.4.3 Modification of a column's `AUTO_INCREMENT` attribute is not allowed by default

Description

Adding or removing the `AUTO_INCREMENT` attribute of a column via `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE` command is not allowed by default.

Way to avoid

Refer to the restrictions of `AUTO_INCREMENT`.

To allow the removal of the `AUTO_INCREMENT` attribute, set `@@tidb_allow_remove_auto_inc` to `true`.

4.14.2.4.4 `FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported

Description

`FULLTEXT`, `HASH`, and `SPATIAL` indexes are not supported.

4.14.2.5 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.14.3 Integrate TiDB with ProxySQL

This document provides a high-level introduction to ProxySQL, describes how to integrate ProxySQL with TiDB in a development environment and a production environment, and demonstrates the key integration benefits through the scenario of query routing.

If you are interested in learning more about TiDB and ProxySQL, you can find some useful links as follows:

- TiDB Cloud
- TiDB Developer Guide
- ProxySQL Documentation

4.14.3.1 What is ProxySQL?

ProxySQL is a high-performance, open-source SQL proxy. It has a flexible architecture and can be deployed in several different ways, making it ideal for a variety of use cases. For example, ProxySQL can be used to improve performance by caching frequently-accessed data.

ProxySQL is designed from the ground up to be fast, efficient, and easy to use. It is fully compatible with MySQL, and supports all of the features you would expect from a high quality SQL proxy. In addition, ProxySQL comes with a number of unique features that make it an ideal choice for a wide range of applications.

4.14.3.2 Why ProxySQL integration?

- ProxySQL can help boost application performance by reducing latency when interacting with TiDB. Irrespective of what you are building, whether it is a scalable application using serverless functions like Lambda, where the workload is nondeterministic and can spike, or if you are building an application to execute queries that load tons of data. By leveraging powerful capabilities of ProxySQL such as connection pooling and caching frequently-used queries, applications can gain immediate benefits.
- ProxySQL can act as an additional layer of application security protection against SQL vulnerabilities such as SQL injection with the help of query rules, an easy-to-configure feature available in ProxySQL.
- As both ProxySQL and TiDB are open-source projects, you can get the benefits of zero vendor lock-in.

4.14.3.3 Deployment architecture

The most obvious way to deploy ProxySQL with TiDB is to add ProxySQL as a standalone intermediary between the application layer and TiDB. However, the scalability and failure tolerance are not guaranteed, and it also adds additional latency due to network hop. To avoid these problems, an alternate deployment architecture is to deploy ProxySQL as a sidecar as below:

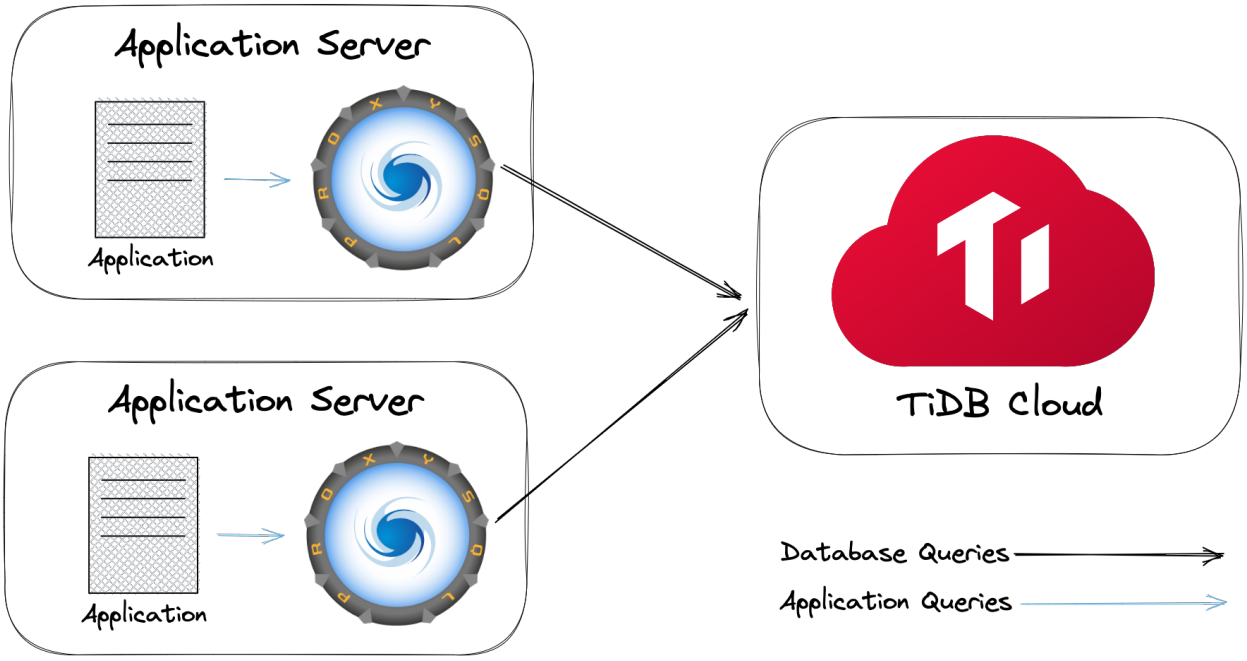

Figure 67: proxysql-client-side-tidb-cloud

Note:

The preceding illustration is only for reference. You must adapt it according to your actual deployment architecture.

4.14.3.4 Development environment

This section describes how to integrate TiDB with ProxySQL in a development environment. To get started with the ProxySQL integration, you can choose either of the following options depending on your TiDB cluster type after you have all the prerequisites in place.

- Option 1: Integrate TiDB Cloud with ProxySQL
- Option 2: Integrate TiDB (self-hosted) with ProxySQL

4.14.3.4.1 Prerequisites

Depending on the option you choose, you might need the following packages:

- Git
- Docker

- Python 3
- Docker Compose
- MySQL Client

You can follow the installation instructions as below:

1. Download and start Docker (the Docker Desktop already includes the Docker Compose).
2. Run the following command to install Python and `mysql-client`:

```
/bin/bash -c "$(curl -fsSL https://raw.githubusercontent.com/Homebrew/
    ↪ install/HEAD/install.sh)"
brew install python mysql-client
```

```
curl -fsSL https://get.docker.com | bash -s docker
yum install -y git python39 docker-ce docker-ce-cli containerd.io docker-
    ↪ compose-plugin mysql
systemctl start docker
```

- Download and install Git.

    1. Download the **64-bit Git for Windows Setup** package from the Git Windows Download page.
    2. Install the Git package by following the setup wizard. You can click **Next** for a few times to use the default installation settings.

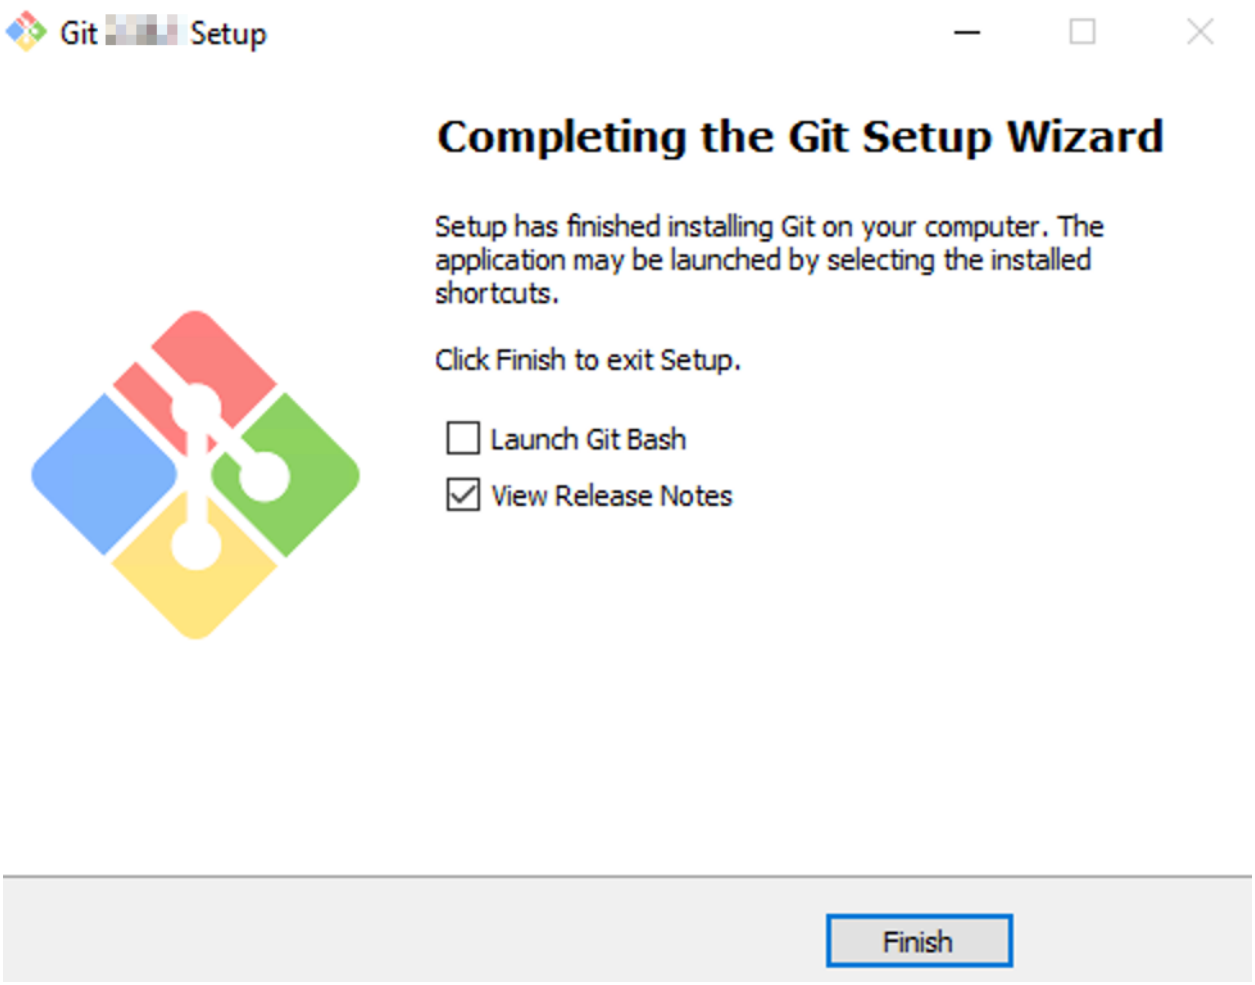

Figure 68: proxysql-windows-git-install

- Download and install MySQL Shell.

    1. Download the ZIP file of MySQL Installer from the MySQL Community Server Download page.
    2. Unzip the file, and locate `mysql.exe` in the `bin` folder. You need to add the path of the `bin` folder to the system variable and set it into the `PATH` variable at Git Bash:

    ```
    echo 'export PATH="(your bin folder)":$PATH' >>~/.bash_profile
    source ~/.bash_profile
    ```

    For example:

    ```
    echo 'export PATH="/c/Program Files (x86)/mysql-8.0.31-winx64/bin"
        ↪ :$PATH' >>~/.bash_profile
    source ~/.bash_profile
    ```

- Download and install Docker.

    1. Download Docker Desktop installer from the Docker Download page.
    2. Double-click the installer to run it. After the installation is completed, you will be prompted for a restart.

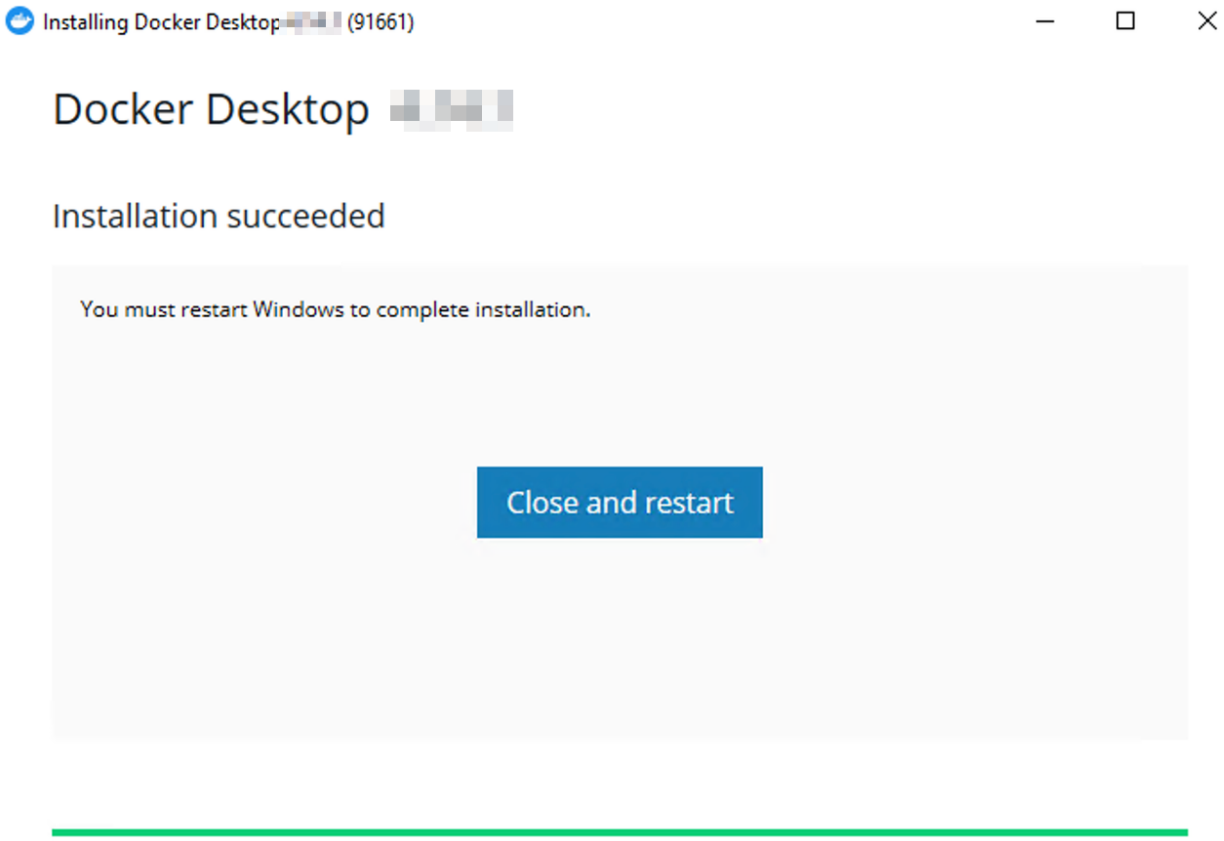

Figure 69: proxysql-windows-docker-install

- Download the latest Python 3 installer from the Python Download page and run it.

4.14.3.4.2 Option 1: Integrate TiDB Cloud with ProxySQL

For this integration, you will be using the ProxySQL Docker image along with a TiDB Cloud Serverless cluster. The following steps will set up ProxySQL on port `16033`, so make sure this port is available.

Step 1. Create a TiDB Cloud Serverless cluster

1. Create a free TiDB Cloud Serverless cluster. Remember the root password that you set for your cluster.

2. Get your cluster hostname, port, and username for later use.

    1. On the Clusters page, click your cluster name to go to the cluster overview page.
    2. On the cluster overview page, locate the **Connection** pane, and then copy the `Endpoint`, `Port`, and `User` fields, where the `Endpoint` is your cluster hostname.

Step 2. Generate ProxySQL configuration files

1. Clone the integration example code repository for TiDB and ProxySQL:

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

2. Change to the `tidb-cloud-connect` folder:

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

```
cd tidb-proxysql-integration/example/tidb-cloud-connect
```

3. Generate ProxySQL configuration files by running `proxysql-config.py`:

```
python3 proxysql-config.py
```

```
python3 proxysql-config.py
```

```
python proxysql-config.py
```

When prompted, enter the endpoint of your cluster for `Serverless Tier Host`, and then enter the username and the password of your cluster.

The following is an example output. You will see that three configuration files are generated under the current `tidb-cloud-connect` folder.

```
[Begin] generating configuration files..
tidb-cloud-connect.cnf generated successfully.
proxysql-prepare.sql generated successfully.
proxysql-connect.py generated successfully.
[End] all files generated successfully and placed in the current folder
    ↪ .
```

Step 3. Configure ProxySQL

1. Start Docker. If Docker has already started, skip this step:

   Double-click the icon of the installed Docker to start it.

   ```
   systemctl start docker
   ```

   Double-click the icon of the installed Docker to start it.

2. Pull the ProxySQL image and start a ProxySQL container in the background:

   ```
   docker compose up -d
   ```

   ```
   docker compose up -d
   ```

   ```
   docker compose up -d
   ```

3. Integrate with ProxySQL by running the following command, which executes `proxysql -prepare.sql` inside **ProxySQL Admin Interface**:

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

   ```
   docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -P6032 < ./proxysql-prepare.sql"
   ```

Note:

The `proxysql-prepare.sql` script does the following:

1. Adds a user using the username and password of your cluster.
2. Assigns the user to the monitoring account.
3. Adds your TiDB Cloud Serverless cluster to the list of hosts.
4. Enables a secure connection between ProxySQL and the TiDB Cloud Serverless cluster.

To have a better understanding, it is strongly recommended that you check the `proxysql-prepare.sql` file. To learn more about ProxySQL configuration, see ProxySQL documentation.

The following is an example output. You will see that the hostname of your cluster is shown in the output, which means that the connectivity between ProxySQL and the TiDB Cloud Serverless cluster is established.

```
*************************** 1. row ***************************
   hostgroup_id: 0
       hostname: gateway01.us-west-2.prod.aws.tidbcloud.com
           port: 4000
       gtid_port: 0
           status: ONLINE
           weight: 1
       compression: 0
   max_connections: 1000
max_replication_lag: 0
           use_ssl: 1
   max_latency_ms: 0
           comment:
```

Step 4. Connect to your TiDB cluster through ProxySQL

1. To connect to your TiDB cluster, run `proxysql-connect.py`. The script will automatically launch the MySQL client and use the username and password you specified in Step 2 for connection.

```
python3 proxysql-connect.py
```

```
python3 proxysql-connect.py
```

```
python proxysql-connect.py
```

2. After connecting to your TiDB cluster, you can use the following SQL statement to validate the connection:

```
SELECT VERSION();
```

If the TiDB version is displayed, you are successfully connected to your TiDB Cloud Serverless cluster through ProxySQL. To exit from the MySQL client anytime, enter `quit` and press enter.

> **Note:**
>
> ***For Debugging:*** If you are unable to connect to the cluster, check the files `tidb-cloud-connect.cnf`, `proxysql-prepare.sql`, and `proxysql -connect.py`. Make sure that the server information you provided is available and correct.

3. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.14.3.4.3 Option 2: Integrate TiDB (self-hosted) with ProxySQL

For this integration, you will set up an environment using Docker images of TiDB and ProxySQL. You are encouraged to try other ways of installing TiDB (self-hosted) in your own interest.

The following steps will set up ProxySQL and TiDB on ports `6033` and `4000` respectively, so make sure these ports are available.

1. Start Docker. If Docker has already started, skip this step:

   Double-click the icon of the installed Docker to start it.

   ```
   systemctl start docker
   ```

   Double-click the icon of the installed Docker to start it.

2. Clone the integration example code repository for TiDB and ProxySQL:

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

   ```
   git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
   ```

3. Pull the latest images of ProxySQL and TiDB:

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

   ```
   cd tidb-proxysql-integration && docker compose pull
   ```

4. Start an integrated environment using both TiDB and ProxySQL running as containers:

   ```
   docker compose up -d
   ```

```
docker compose up -d
```

```
docker compose up -d
```

To log in to the ProxySQL `6033` port, you can use the `root` username with an empty password.

5. Connect to TiDB via ProxySQL:

```
mysql -u root -h 127.0.0.1 -P 6033
```

```
mysql -u root -h 127.0.0.1 -P 6033
```

```
mysql -u root -h 127.0.0.1 -P 6033
```

6. After connecting to your TiDB cluster, you can use the following SQL statement to validate the connection:

```
SELECT VERSION();
```

If the TiDB version is displayed, you are successfully connected to your TiDB containers through ProxySQL.

7. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.14.3.5 Production environment

For a production environment, it is recommended that you use TiDB Cloud Dedicated directly for a fully-managed experience.

4.14.3.5.1 Prerequisite

Download and install a MySQL client. For example, MySQL Shell.

4.14.3.5.2 Integrate TiDB Cloud with ProxySQL on CentOS

ProxySQL can be installed on many different platforms. The following takes CentOS as an example.

For a full list of supported platforms and the corresponding version requirements, see ProxySQL documentation.

Step 1. Create a TiDB Cloud Dedicated cluster

For detailed steps, see Create a TiDB Cluster.

Step 2. Install ProxySQL

1. Add ProxySQL to the YUM repository:

```
cat > /etc/yum.repos.d/proxysql.repo << EOF
[proxysql]
name=ProxySQL YUM repository
baseurl=https://repo.proxysql.com/ProxySQL/proxysql-2.4.x/centos/\
    ↪ $releasever
gpgcheck=1
gpgkey=https://repo.proxysql.com/ProxySQL/proxysql-2.4.x/repo_pub_key
EOF
```

2. Install ProxySQL:

```
yum install -y proxysql
```

3. Start ProxySQL:

```
systemctl start proxysql
```

To learn more about the supported platforms of ProxySQL and their installation, refer to ProxySQL README or ProxySQL installation documentation.

Step 3. Configure ProxySQL

To use ProxySQL as a proxy for TiDB, you need to configure ProxySQL. To do so, you can either execute SQL statements inside ProxySQL Admin Interface (recommended) or use the configuration file.

> **Note:**
>
> The following sections list only the required configuration items of ProxySQL. For a comprehensive list of configurations, see ProxySQL documentation.

Option 1: Configure ProxySQL using the Admin Interface

1. Reconfigure ProxySQL's internals using the standard ProxySQL Admin interface, accessible via any MySQL command line client (available by default on port `6032`):

```
mysql -u admin -padmin -h 127.0.0.1 -P6032 --prompt 'ProxySQL Admin> '
```

   The above step will take you to the ProxySQL admin prompt.

2. Configure the TiDB clusters to be used, where you can add one or multiple TiDB clusters to ProxySQL. The following statement will add one TiDB Cloud Dedicated cluster for example. You need to replace `<tidb cloud dedicated cluster host>` and `<tidb cloud dedicated cluster port>` with your TiDB Cloud endpoint and port (the default port is `4000`).

```
INSERT INTO mysql_servers(hostgroup_id, hostname, port)
VALUES
  (
    0,
    '<tidb cloud dedicated cluster host>',
    <tidb cloud dedicated cluster port>
  );
LOAD mysql servers TO runtime;
SAVE mysql servers TO DISK;
```

Note:

- `hostgroup_id`: specify an ID of the hostgroup. ProxySQL manages clusters using hostgroup. To distribute SQL traffic to these clusters evenly, you can configure several clusters that need load balancing to the same hostgroup. To distinguish the clusters, such as for read and write purposes, you can configure them to use different hostgroups.
- `hostname`: the endpoint of the TiDB cluster.
- `port`: the port of the TiDB cluster.

3. Configure Proxy login users to make sure that the users have appropriate permissions on the TiDB cluster. In the following statements, you need to replace '*tidb cloud dedicated cluster username*' and '*tidb cloud dedicated cluster password*' with the actual username and password of your cluster.

```
INSERT INTO mysql_users(
  username, password, active, default_hostgroup,
  transaction_persistent
)
VALUES
  (
    '<tidb cloud dedicated cluster username>',
```

```
    '<tidb cloud dedicated cluster password>',
    1, 0, 1
  );
LOAD mysql users TO runtime;
SAVE mysql users TO DISK;
```

Note:

- `username`: TiDB username.
- `password`: TiDB password.
- `active`: controls whether the user is active. `1` indicates that the user is **active** and can be used for login, while `0` indicates that the user is inactive.
- `default_hostgroup`: the default hostgroup used by the user, where SQL traffic is distributed unless the query rule overrides the traffic to a specific hostgroup.
- `transaction_persistent`: `1` indicates a persistent transaction. When a user starts a transaction within a connection, all query statements are routed to the same hostgroup until the transaction is committed or rolled back.

Option 2: Configure ProxySQL using a configuration file

This option should only be considered as an alternate method for configuring ProxySQL. For more information, see Configuring ProxySQL through the config file.

1. Delete any existing SQLite database (where configurations are stored internally):

```
rm /var/lib/proxysql/proxysql.db
```

Warning:

If you delete the SQLite database file, any configuration changes made using ProxySQL Admin interface will be lost.

2. Modify the configuration file `/etc/proxysql.cnf` according to your need. For example:

```
mysql_servers:
(
    {
        address="<tidb cloud dedicated cluster host>"
        port=<tidb cloud dedicated cluster port>
        hostgroup=0
```

```
        max_connections=2000
    }
)

mysql_users:
(
    {
        username = "<tidb cloud dedicated cluster username>"
        password = "<tidb cloud dedicated cluster password>"
        default_hostgroup = 0
        max_connections = 1000
        default_schema = "test"
        active = 1
        transaction_persistent = 1
    }
)
```

In the preceding example:

- `address` and `port`: specify the endpoint and port of your TiDB Cloud cluster.
- `username` and `password`: specify the username and password of your TiDB Cloud cluster.

3. Restart ProxySQL:

```
systemctl restart proxysql
```

After the restart, the SQLite database will be created automatically.

> **Warning:**
>
> Do not run ProxySQL with default credentials in production. Before starting the `proxysql` service, you can change the defaults in the `/etc/proxysql.cnf` file by changing the `admin_credentials` variable.

4.14.3.6 Typical scenario

This section takes query routing as an example to show some of the benefits that you can leverage by integrating ProxySQL with TiDB.

4.14.3.6.1 Query rules

Databases can be overloaded by high traffic, faulty code, or malicious spam. With query rules of ProxySQL, you can respond to these issues quickly and effectively by rerouting, rewriting, or rejecting queries.

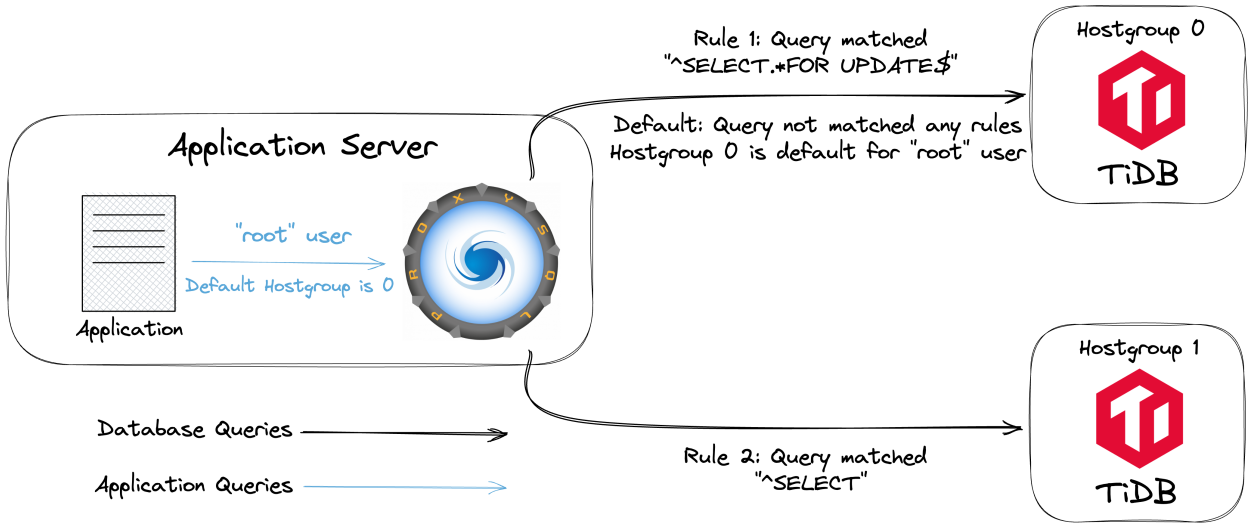

Figure 70: proxysql-client-side-rules

> **Note:**
>
> In the following steps, you will be using the container images of TiDB and ProxySQL to configure query rules. If you have not pulled them, you can check the integration section for detailed steps.

1. Clone the integration example code repository for TiDB and ProxySQL. Skip this step if you have already cloned it in the previous steps.

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

```
git clone https://github.com/pingcap-inc/tidb-proxysql-integration.git
```

2. Change to the example directory for ProxySQL rules:

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

```
cd tidb-proxysql-integration/example/proxy-rule-admin-interface
```

3. Run the following command to start two TiDB containers and a ProxySQL container:

```
docker compose up -d
```

```
docker compose up -d
```

```
docker compose up -d
```

If everything goes well, the following containers are started:

- Two Docker containers of TiDB clusters exposed via ports 4001, 4002
- One ProxySQL Docker container exposed via port 6034.

4. In the two TiDB containers, using `mysql` to create a table with a similar schema definition and then insert different data (`'tidb-server01-port-4001'`, `'tidb-server02-port-4002'`) to identify these containers.

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
```

```
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

```
mysql -u root -h 127.0.0.1 -P 4001 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server01-port
    ↪ -4001');
EOF

mysql -u root -h 127.0.0.1 -P 4002 << EOF
DROP TABLE IF EXISTS test.tidb_server;
CREATE TABLE test.tidb_server (server_name VARCHAR(255));
INSERT INTO test.tidb_server (server_name) VALUES ('tidb-server02-port
    ↪ -4002');
EOF
```

5. Configure ProxySQL by running the following command, which executes `proxysql-prepare.sql` inside ProxySQL Admin Interface to establish a proxy connection between the TiDB containers and ProxySQL.

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

```
docker compose exec proxysql sh -c "mysql -uadmin -padmin -h127.0.0.1 -
    ↪ P6032 < ./proxysql-prepare.sql"
```

Note:

The `proxysql-prepare.sql` does the following:

- Adds the TiDB clusters in ProxySQL with `hostgroup_id` as `0` and `1`.
- Adds a user `root` with an empty password and sets `default_hostgroup` as `0`.
- Adds the rule `^SELECT.*FOR UPDATE$` with `rule_id` as `1` and `destination_hostgroup` as `0`. If a SQL statement matches this rule, the request will be forwarded to the TiDB cluster with `hostgroup` as `0`.

- Adds the rule `^SELECT` with `rule_id` as `2` and `destination_hostgroup` as `1`. If a SQL statement matches this rule, the request will be forwarded to the TiDB cluster with `hostgroup` as `1`.

To have a better understanding, it is strongly recommended that you check the `proxysql-prepare.sql` file. To learn more about ProxySQL configuration, see ProxySQL documentation.

The following is some additional information about how ProxySQL patterns match query rules:

- ProxySQL tries to match the rules one by one in the ascending order of `rule_id`.
- `^` symbol matches the beginning of a SQL statement and `$` matches the end.

For more information about ProxySQL regular expression and pattern matching, see mysql-query_processor_regex in ProxySQL documentation.

For a full list of parameters, see mysql_query_rules in ProxySQL documentation.

6. Verify the configuration and check whether the query rules work.

    1. Log into ProxySQL MySQL Interface as the `root` user:

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    ```
    mysql -u root -h 127.0.0.1 -P 6034
    ```

    2. Execute the following SQL statements:

        - Execute a `SELECT` statement:

        ```
        SELECT * FROM test.tidb_server;
        ```

        This statement will match rule_id `2` and forward the statement to the TiDB cluster on `hostgroup 1`.

        - Execute a `SELECT ... FOR UPDATE` statement:

        ```
        SELECT * FROM test.tidb_server FOR UPDATE;
        ```

        This statement will match rule_id `1` and forward the statement to the TiDB cluster on `hostgroup 0`.

        - Start a transaction:

```
BEGIN;
INSERT INTO test.tidb_server (server_name) VALUES ('insert this
    ↪ and rollback later');
SELECT * FROM test.tidb_server;
ROLLBACK;
```

In this transaction, the `BEGIN` statement will not match any rules. It uses the default hostgroup (`hostgroup 0` in this example). Because ProxySQL enables user transaction_persistent by default, which will execute all statements within the same transaction in the same hostgroup, the `INSERT` and `SELECT * FROM test.tidb_server;` statements will also be forwarded to the TiDB cluster `hostgroup 0`.

The following is an example output. If you get a similar output, you have successfully configured the query rules with ProxySQL.

```
+-------------------------+
| server_name             |
+-------------------------+
| tidb-server02-port-4002 |
+-------------------------+
+-------------------------+
| server_name             |
+-------------------------+
| tidb-server01-port-4001 |
+-------------------------+
+--------------------------------+
| server_name                    |
+--------------------------------+
| tidb-server01-port-4001        |
| insert this and rollback later |
+--------------------------------+
```

3. To exit from the MySQL client anytime, enter `quit` and press enter.

7. To stop and remove containers, and go to the previous directory, run the following command:

```
docker compose down
cd -
```

```
docker compose down
cd -
```

```
docker compose down
cd -
```

4.14.3.7 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

4.14.4 Integrate TiDB with Amazon AppFlow

Amazon AppFlow is a fully managed API integration service that you use to connect your software as a service (SaaS) applications to AWS services, and securely transfer data. With Amazon AppFlow, you can import and export data from and to TiDB into many types of data providers, such as Salesforce, Amazon S3, LinkedIn, and GitHub. For more information, see Supported source and destination applications in AWS documentation.

This document describes how to integrate TiDB with Amazon AppFlow and takes integrating a TiDB Cloud Serverless cluster as an example.

If you do not have a TiDB cluster, you can create a TiDB Cloud Serverless cluster, which is free and can be created in approximately 30 seconds.

4.14.4.1 Prerequisites

- Git
- JDK 11 or above
- Maven 3.8 or above
- AWS CLI version 2
- AWS Serverless Application Model Command Line Interface (AWS SAM CLI) 1.58.0 or above
- An AWS Identity and Access Management (IAM) user with the following requirements:
  - The user can access AWS using an access key.
  - The user has the following permissions:
    - `AWSCertificateManagerFullAccess`: used for reading and writing the AWS Secrets Manager.
    - `AWSCloudFormationFullAccess`: SAM CLI uses AWS CloudFormation to proclaim the AWS resources.
    - `AmazonS3FullAccess`: AWS CloudFormation uses Amazon S3 to publish.
    - `AWSLambda_FullAccess`: currently, AWS Lambda is the only way to implement a new connector for Amazon AppFlow.
    - `IAMFullAccess`: SAM CLI needs to create a `ConnectorFunctionRole` for the connector.
- A SalesForce account.

4.14.4.2 Step 1. Register a TiDB connector

4.14.4.2.1 Clone the code

Clone the integration example code repository for TiDB and Amazon AppFlow:

```
git clone https://github.com/pingcap-inc/tidb-appflow-integration
```

4.14.4.2.2 Build and upload a Lambda

1. Build the package:

```
cd tidb-appflow-integration
mvn clean package
```

2. (Optional) Configure your AWS access key ID and secret access key if you have not.

```
aws configure
```

3. Upload your JAR package as a Lambda:

```
sam deploy --guided
```

Note:

- The `--guided` option uses prompts to guide you through the deployment. Your input will be stored in a configuration file, which is `samconfig.toml` by default.
- `stack_name` specifies the name of AWS Lambda that you are deploying.
- This prompted guide uses AWS as the cloud provider of TiDB Cloud Serverless. To use Amazon S3 as the source or destination, you need to set the `region` of AWS Lambda as the same as that of Amazon S3.
- If you have already run `sam deploy --guided` before, you can just run `sam deploy` instead, and SAM CLI will use the configuration file `samconfig.toml` to simplify the interaction.

If you see a similar output as follows, this Lambda is successfully deployed.

```
Successfully created/updated stack - <stack_name> in <region>
```

4. Go to the AWS Lambda console, and you can see the Lambda that you just uploaded. Note that you need to select the correct region in the upper-right corner of the window.

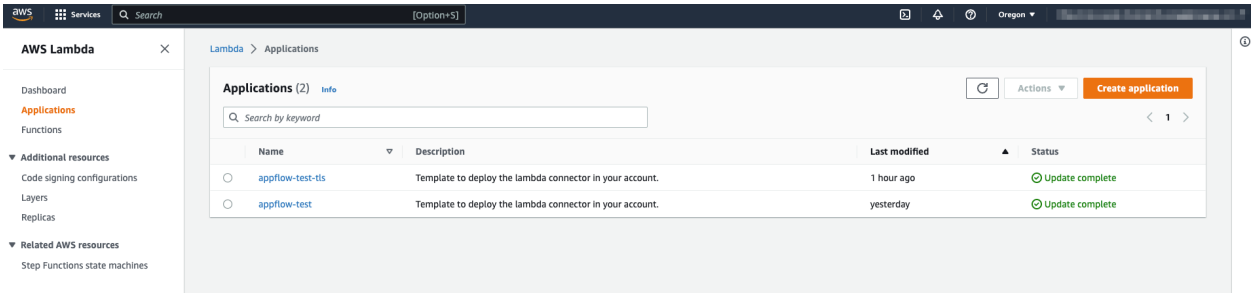

Figure 71: lambda dashboard

4.14.4.2.3 Use Lambda to register a connector

1. In the AWS Management Console, navigate to Amazon AppFlow > Connectors and click **Register new connector**.

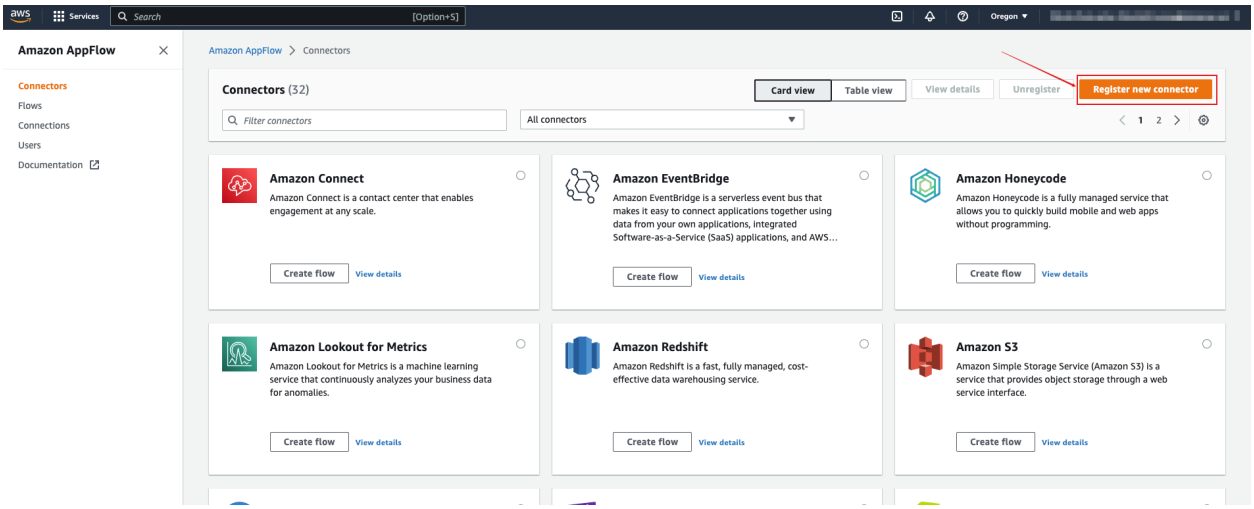

Figure 72: register connector

2. In the **Register a new connector** dialog, choose the Lambda function you uploaded and specify the connector label using the connector name.

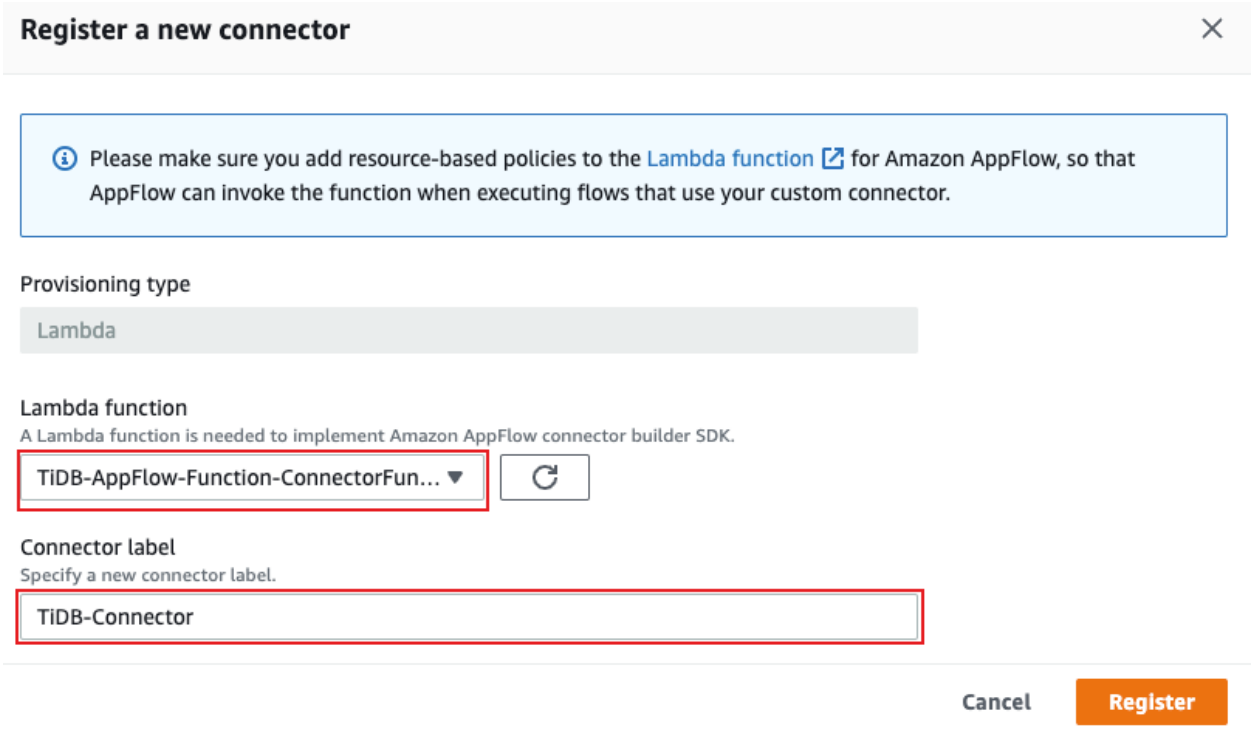

Figure 73: register connector dialog

3. Click **Register**. Then, a TiDB connector is registered successfully.

4.14.4.3 Step 2. Create a flow

Navigate to Amazon AppFlow > Flows and click **Create flow**.

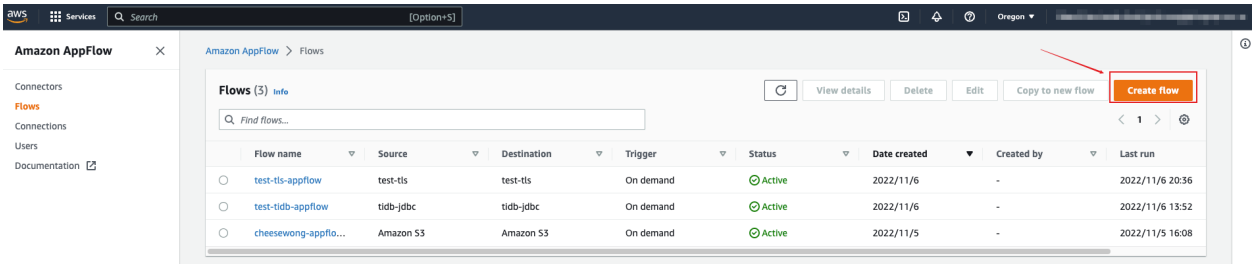

Figure 74: create flow

4.14.4.3.1 Set the flow name

Enter the flow name, and then click **Next**.

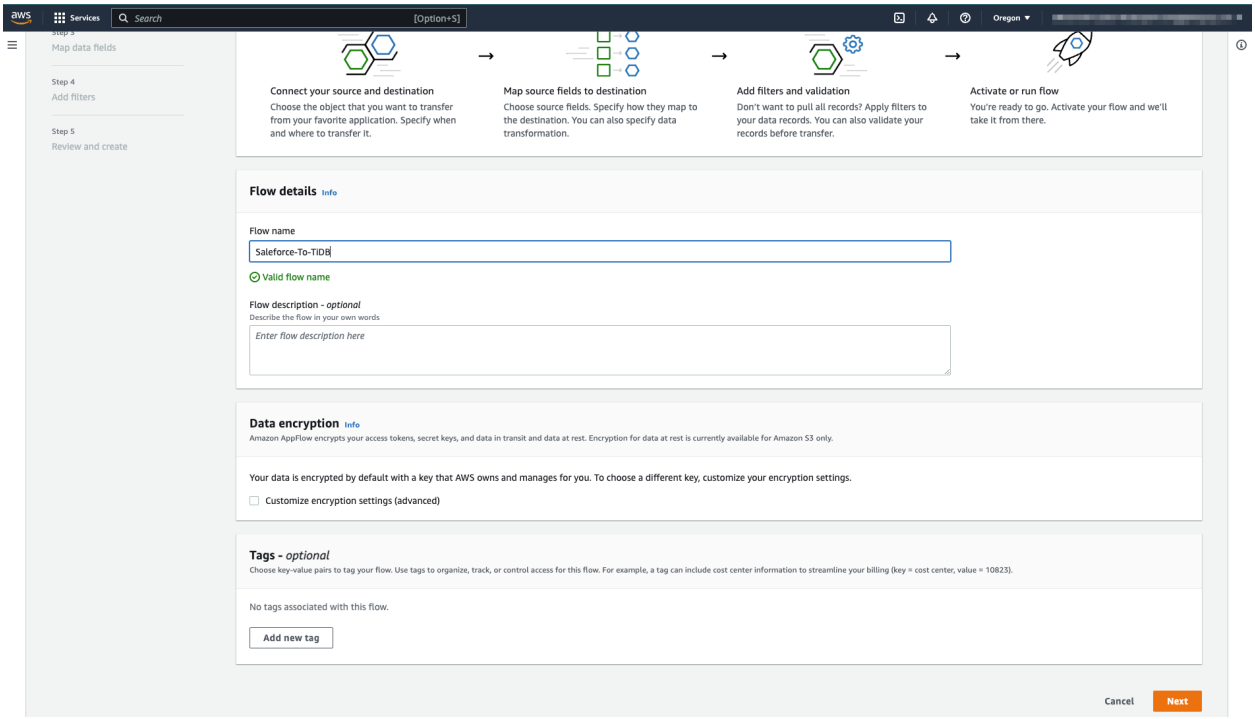

Figure 75: name flow

4.14.4.3.2 Set the source and destination tables

Choose the **Source details** and **Destination details**. TiDB connector can be used in both of them.

1. Choose the source name. This document uses **Salesforce** as an example source.

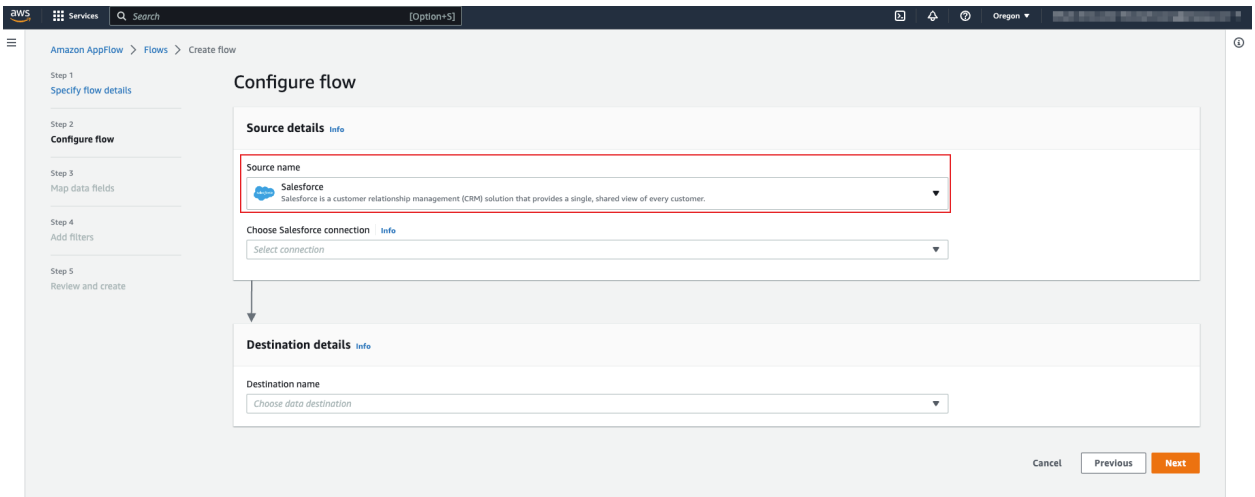

Figure 76: salesforce source

After you register to Salesforce, Salesforce will add some example data to your platform. The following steps will use the **Account** object as an example source object.

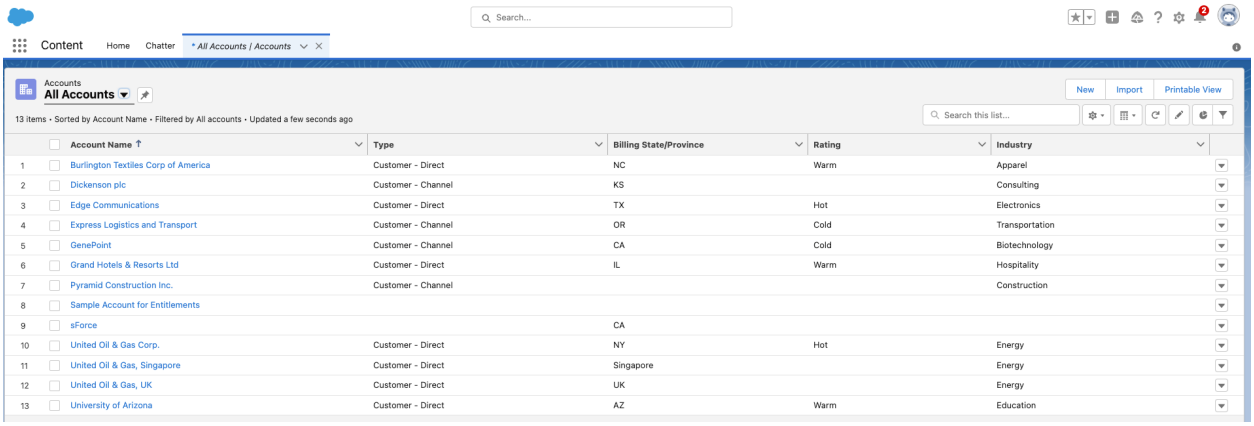

Figure 77: salesforce data

2. Click **Connect**.

    1. In the **Connect to Salesforce** dialog, specify the name of this connection, and then click **Continue**.

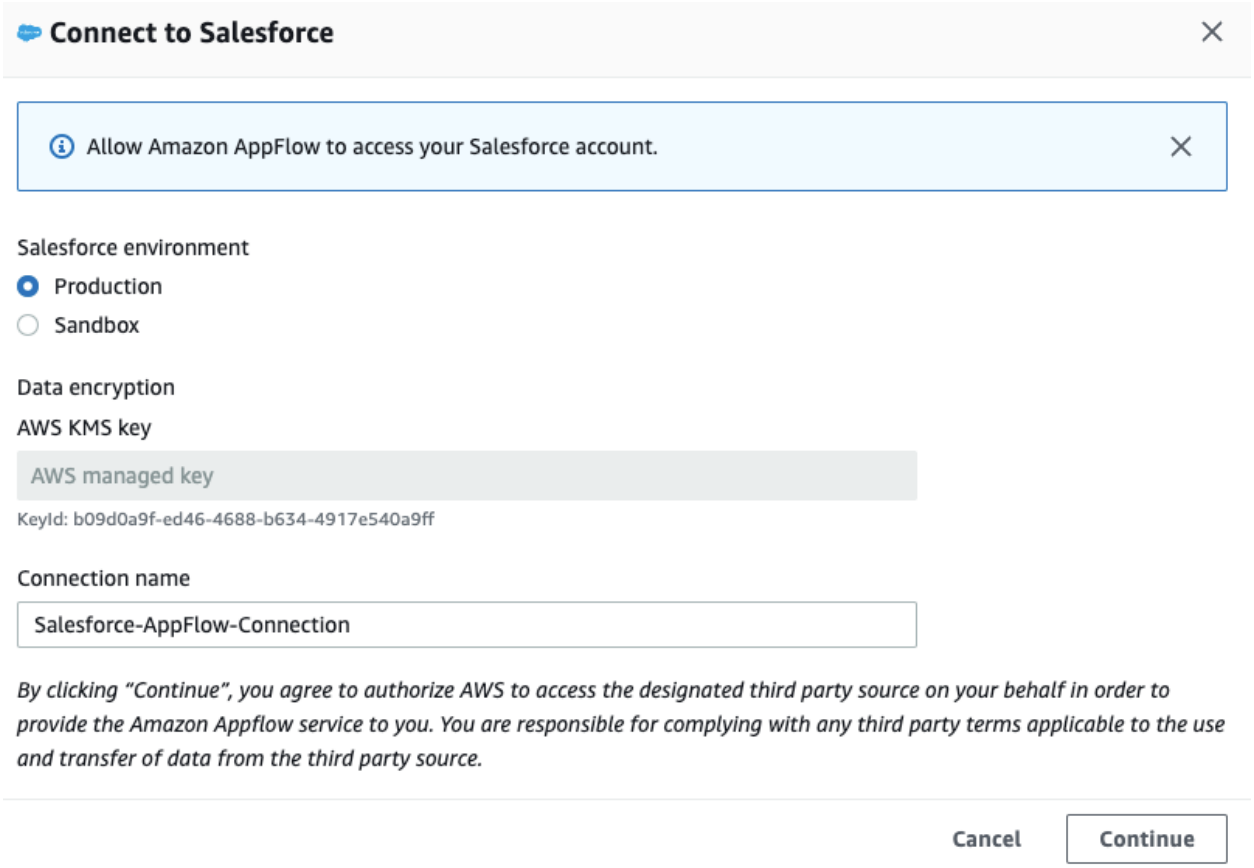

Figure 78: connect to salesforce

2. Click **Allow** to confirm that AWS can read your Salesforce data.

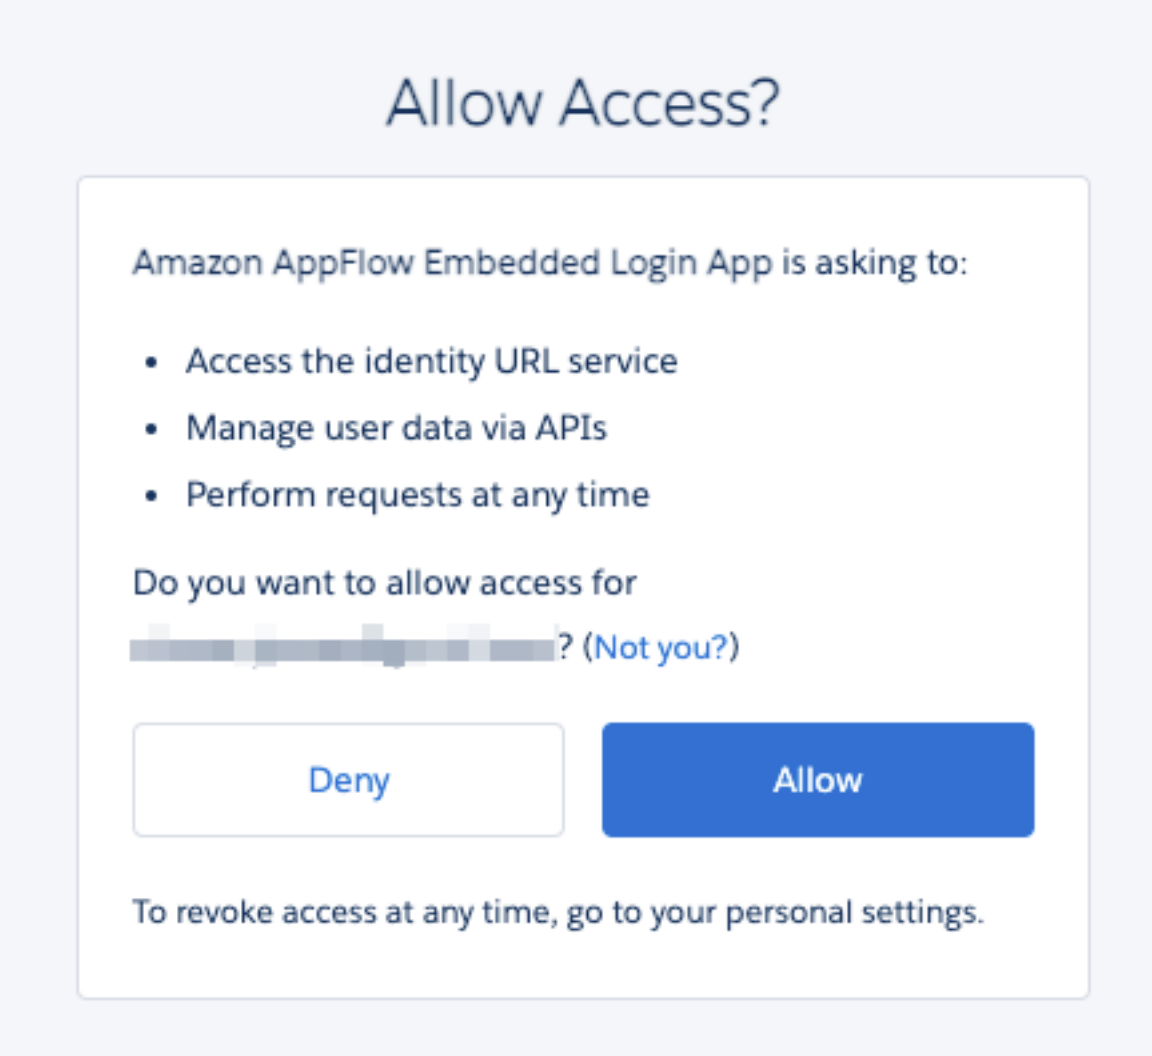

Figure 79: allow salesforce

> **Note:**
> If your company has already used the Professional Edition of Salesforce, the REST API is not enabled by default. You might need to register a new Developer Edition to use the REST API. For more information, refer to Salesforce Forum Topic.

3. In the **Destination details** area, choose **TiDB-Connector** as the destination. The **Connect** button is displayed.

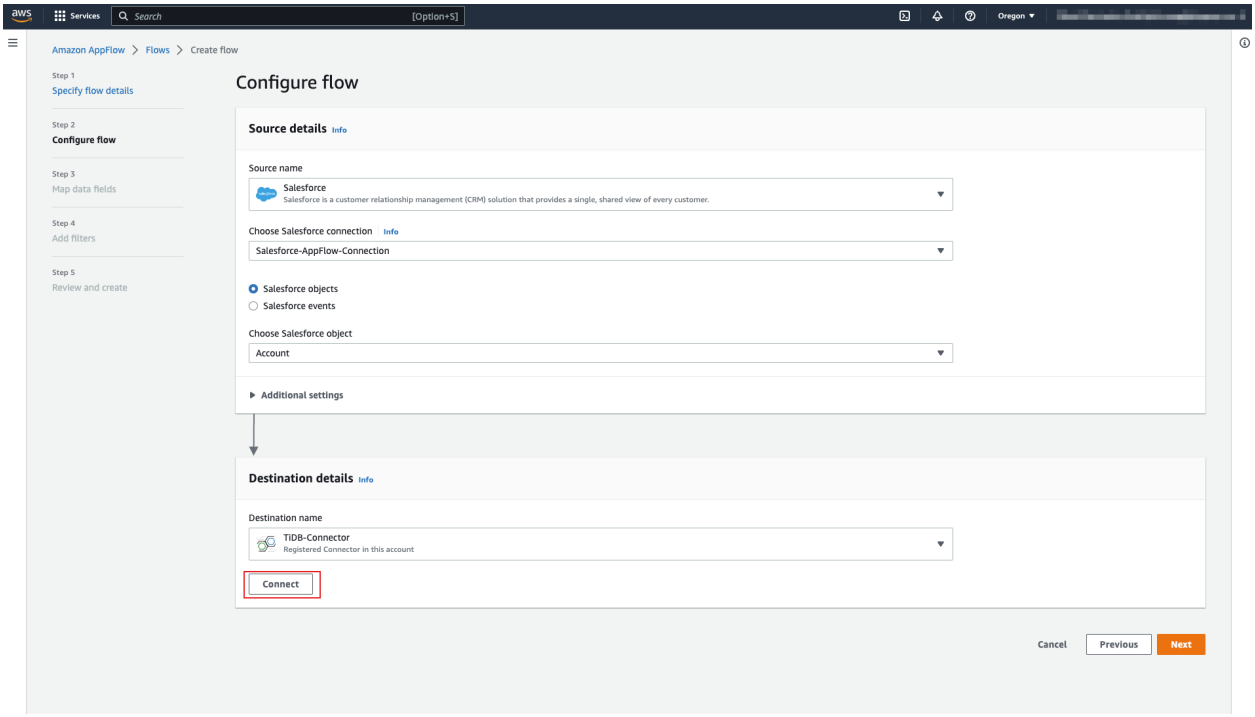

Figure 80: tidb dest

4. Before clicking **Connect**, you need to create a `sf_account` table in TiDB for the Salesforce **Account** object. Note that this table schema is different from the sample data in Tutorial of Amazon AppFlow.

```
CREATE TABLE `sf_account` (
    `id` varchar(255) NOT NULL,
    `name` varchar(150) NOT NULL DEFAULT '',
    `type` varchar(150) NOT NULL DEFAULT '',
    `billing_state` varchar(255) NOT NULL DEFAULT '',
    `rating` varchar(255) NOT NULL DEFAULT '',
    `industry` varchar(255) NOT NULL DEFAULT '',
    PRIMARY KEY (`id`)
);
```

5. After the `sf_account` table is created, click **Connect**. A connection dialog is displayed.

6. In the **Connect to TiDB-Connector** dialog, enter the connection properties of the TiDB cluster. If you use a TiDB Cloud Serverless cluster, you need to set the **TLS** option to `Yes`, which lets the TiDB connector use the TLS connection. Then, click **Connect**.

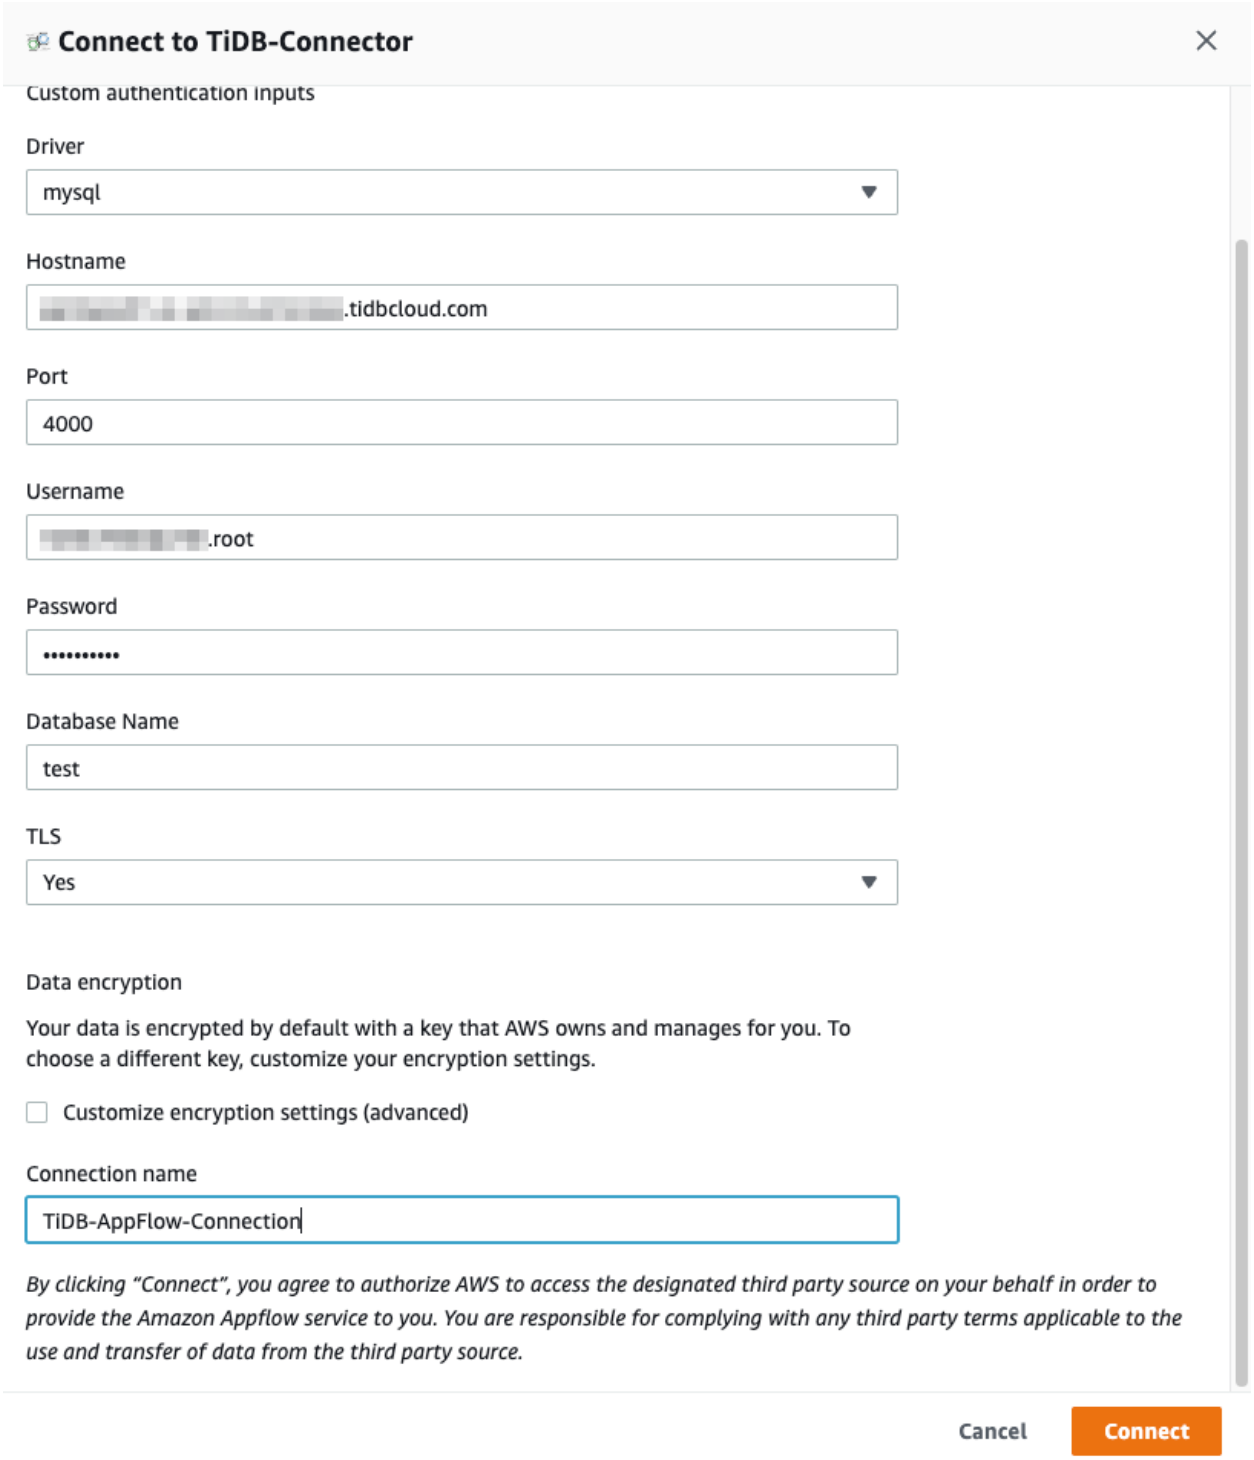

Figure 81: tidb connection message

7. Now you can get all tables in the database that you specified for connection. Choose the **sf_account** table from the drop-down list.

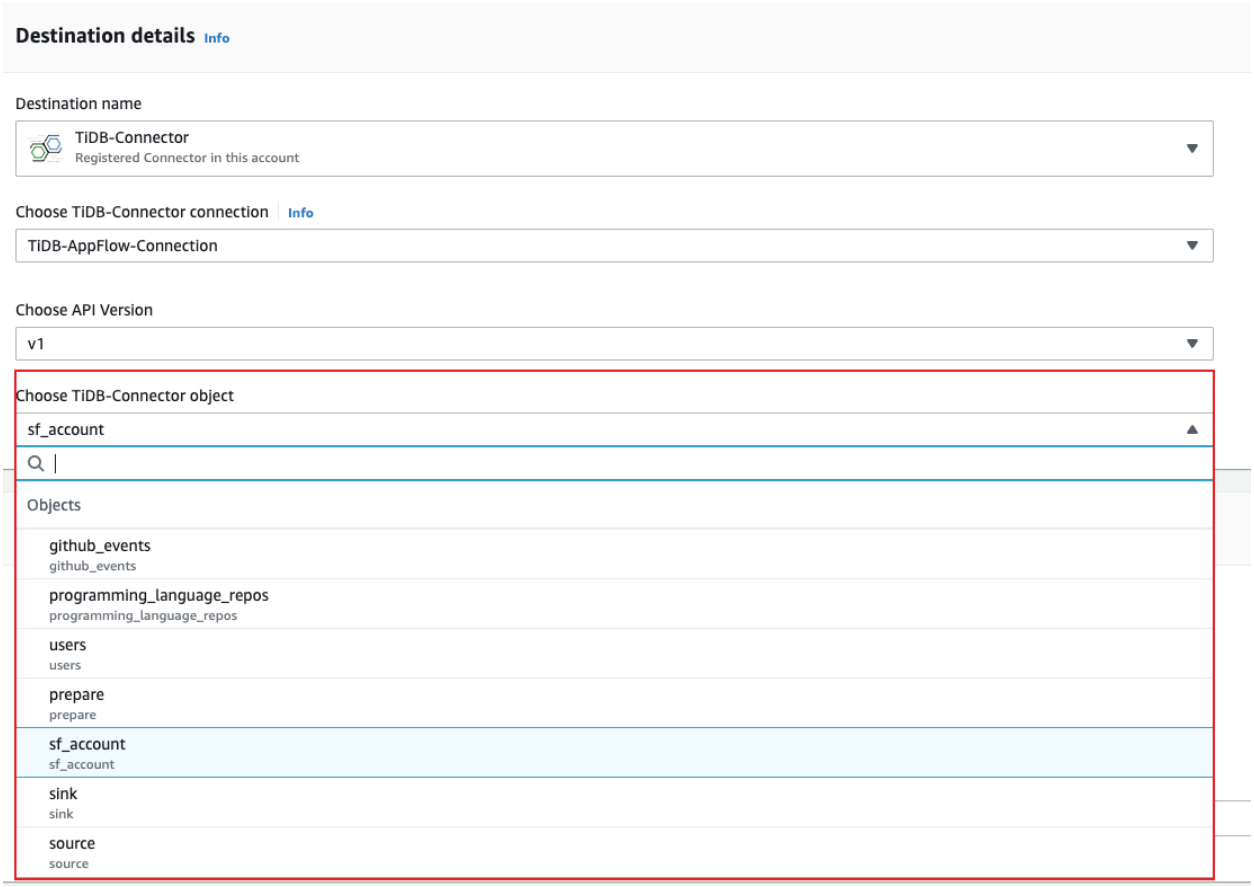

Figure 82: database

The following screenshot shows the configurations to transfer data from the Salesforce **Account** object to the `sf_account` table in TiDB:

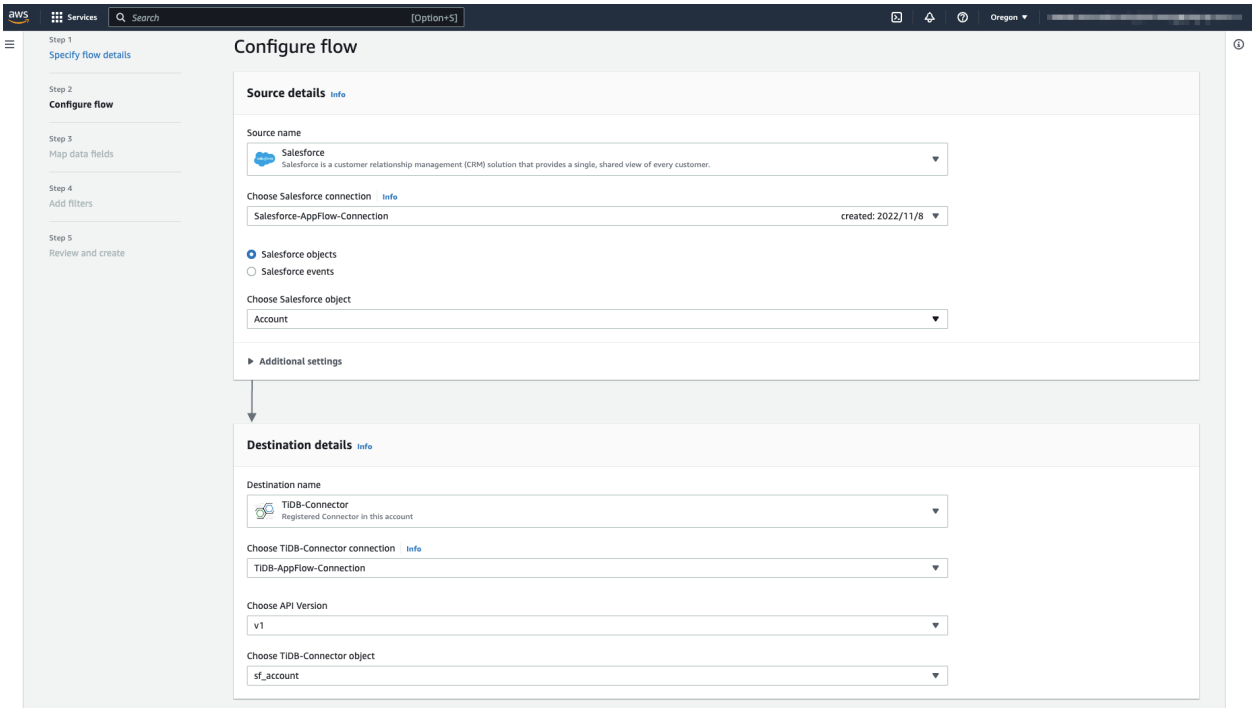

Figure 83: complete flow

8. In the **Error handling** area, choose **Stop the current flow run**. In the **Flow trigger** area, choose the **Run on demand** trigger type, which means you need to run the flow manually. Then, click **Next**.

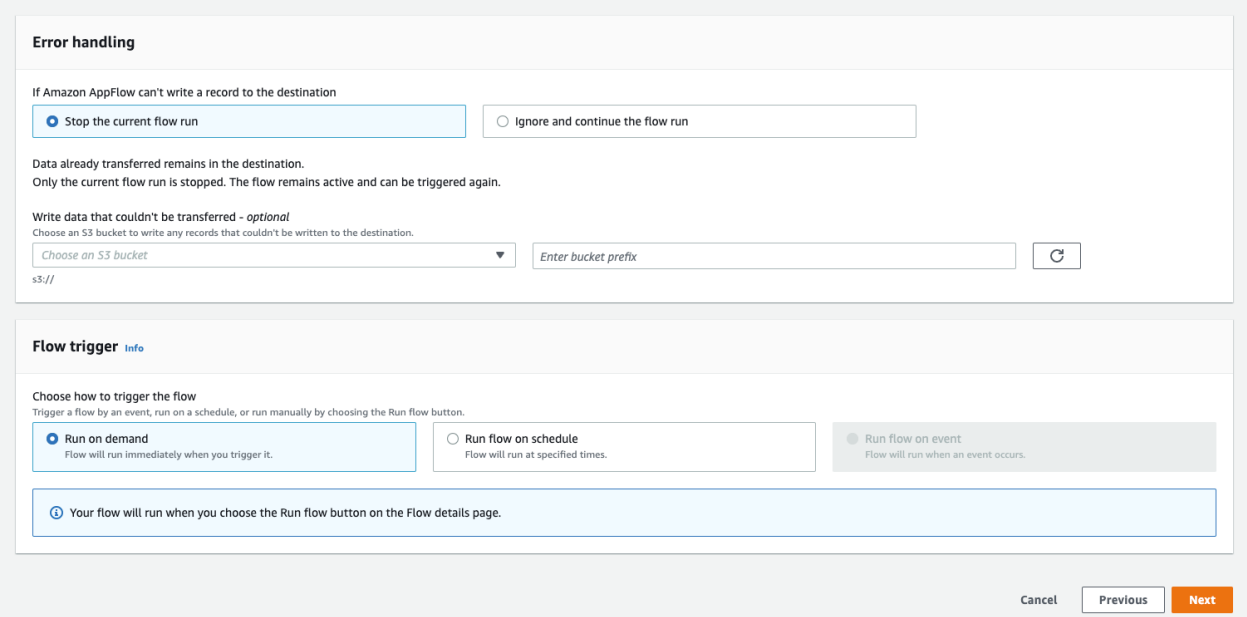

Figure 84: complete step1

4.14.4.3.3 Set mapping rules

Map the fields of the **Account** object in Salesforce to the `sf_account` table in TiDB, and then click **Next**.

- The `sf_account` table is newly created in TiDB and it is empty.

```
test> SELECT * FROM sf_account;
+----+------+------+---------------+--------+----------+
| id | name | type | billing_state | rating | industry |
+----+------+------+---------------+--------+----------+
+----+------+------+---------------+--------+----------+
```

- To set a mapping rule, you can select a source field name on the left, and select a destination field name on the right. Then, click **Map fields**, and a rule is set.

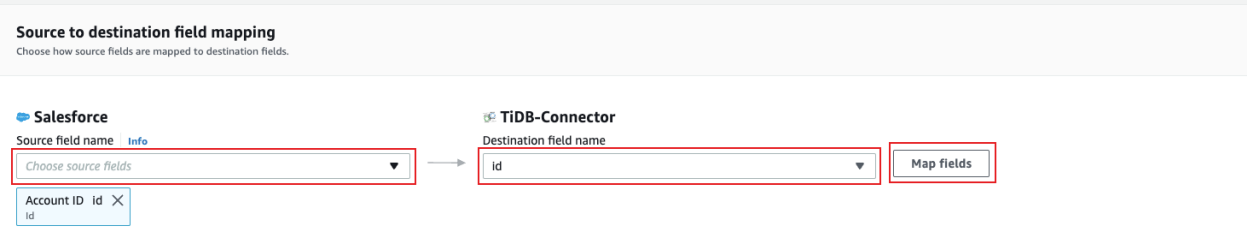

Figure 85: add mapping rule

- The following mapping rules (Source field name -> Destination field name) are needed in this document:

    - Account ID -> id
    - Account Name -> name
    - Account Type -> type
    - Billing State/Province -> billing_state
    - Account Rating -> rating
    - Industry -> industry

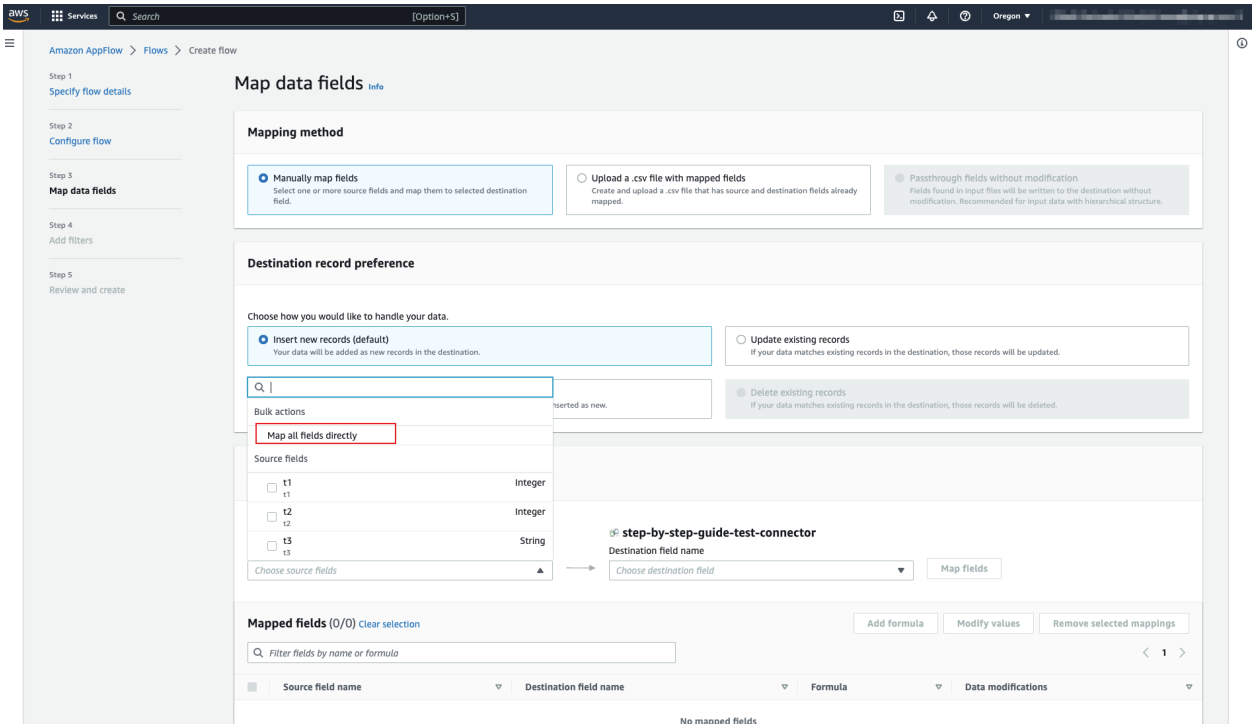

Figure 86: mapping a rule

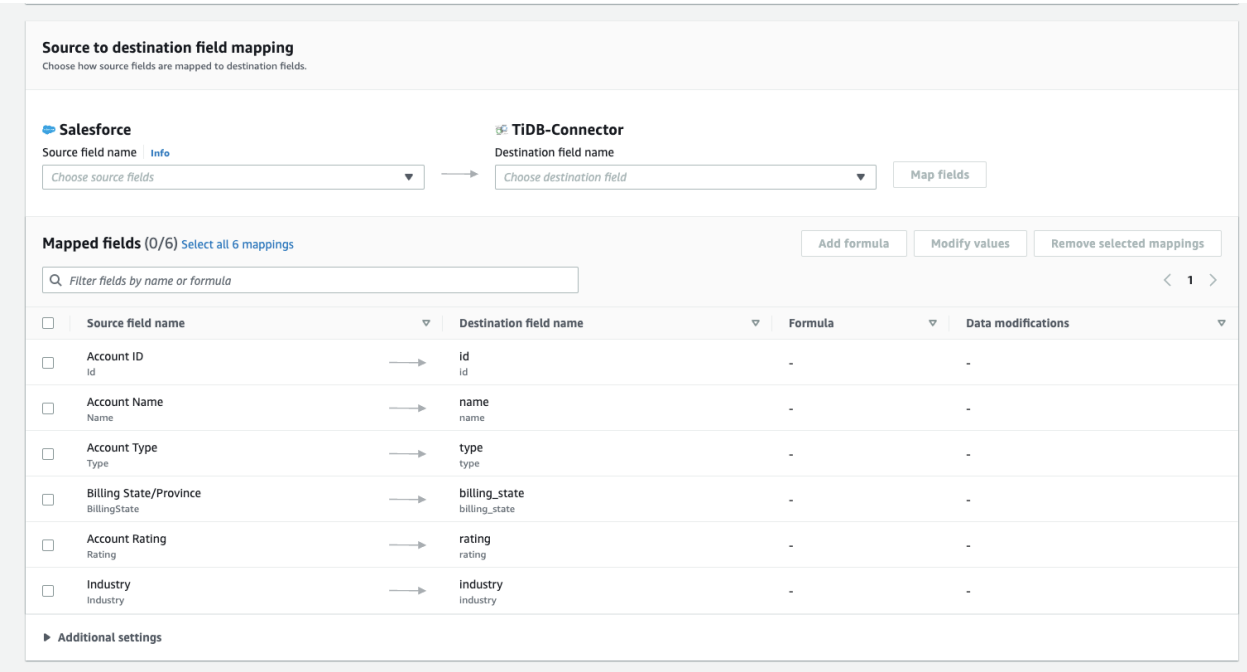

Figure 87: show all mapping rules

4.14.4.3.4 (Optional) Set filters

If you want to add some filters to your data fields, you can set them here. Otherwise, skip this step and click **Next**.

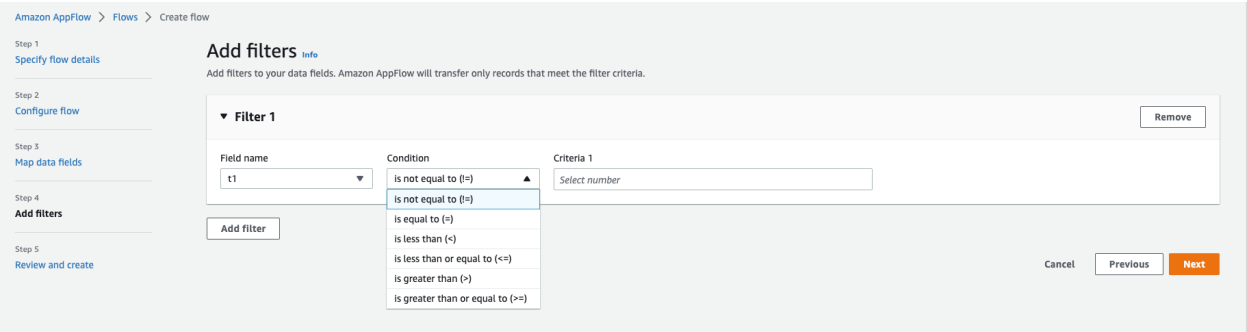

Figure 88: filters

4.14.4.3.5 Confirm and create the flow

Confirm the information of the flow to be created. If everything looks fine, click **Create flow**.

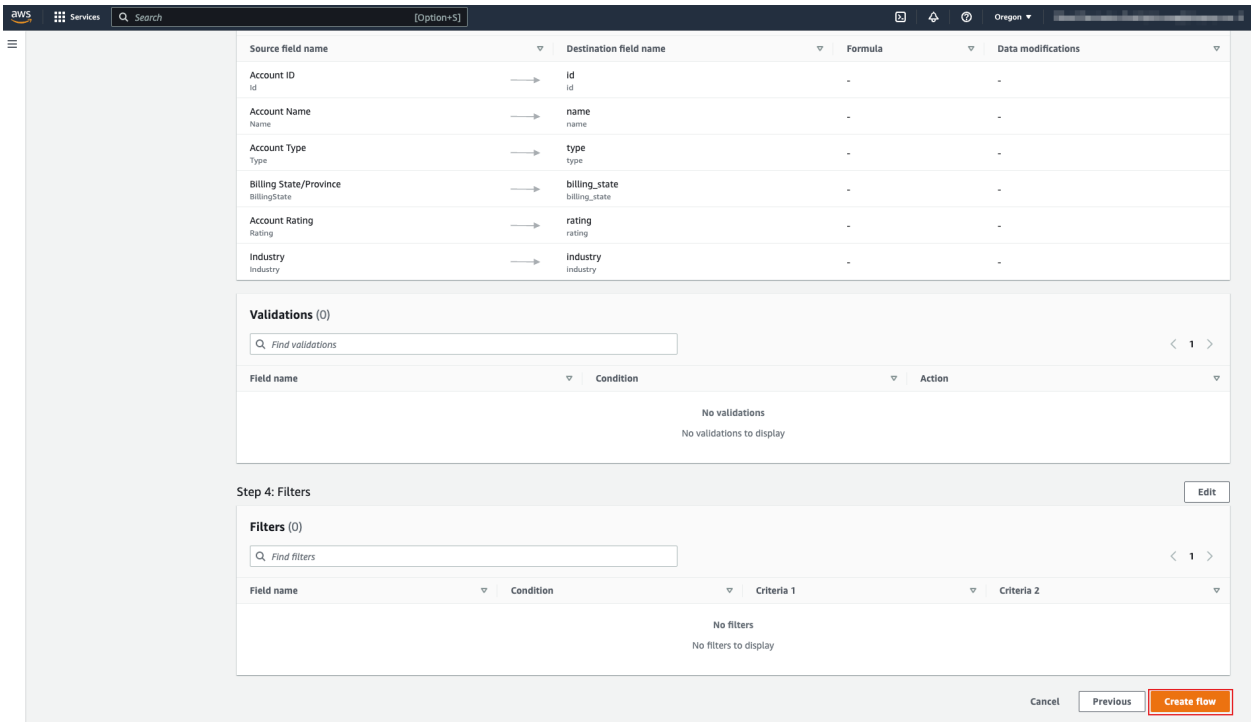

Figure 89: review

4.14.4.4 Step 3. Run the flow

On the page of the newly created flow, click **Run flow** in the upper-right corner.

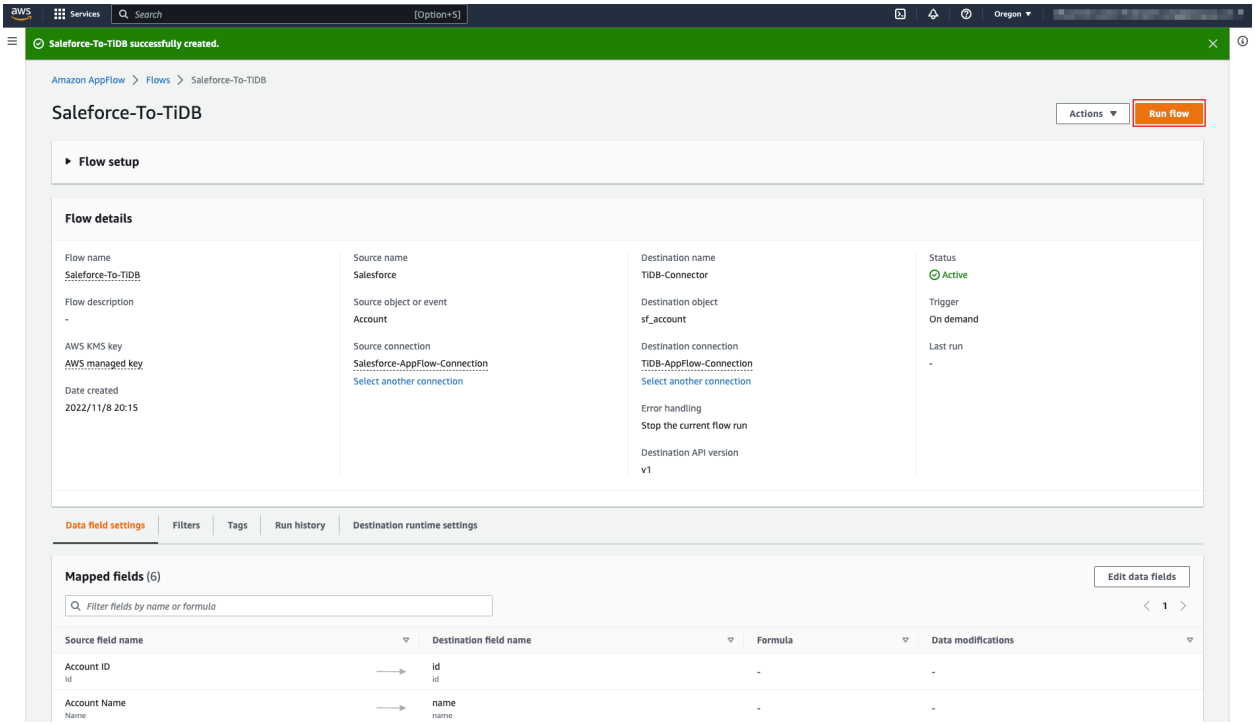

Figure 90: run flow

The following screenshot shows an example that the flow runs successfully:

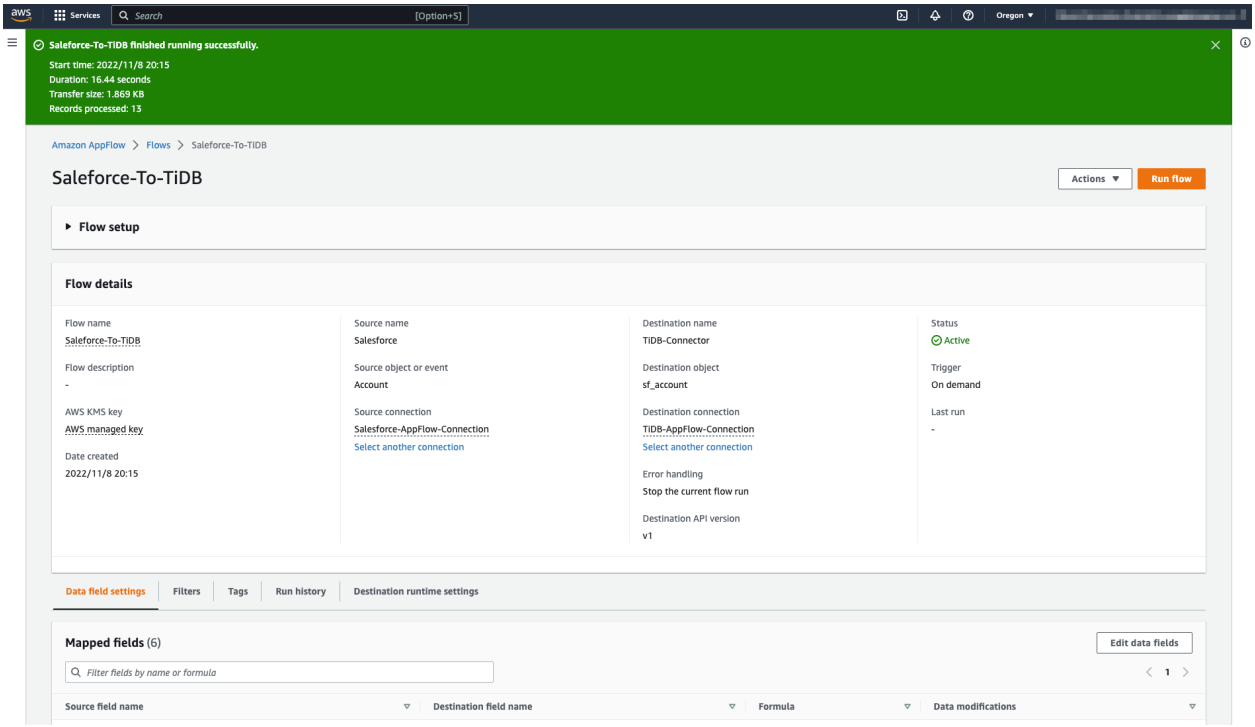

Figure 91: run success

Query the `sf_account` table, and you can see that the records from the Salesforce **Account** object have been written to it:

```
test> SELECT * FROM sf_account;
+--
    ↪ ------------------+----------------------------------------+--------------------+--
    ↪
| id                 | name                                   | type               |
    ↪ billing_state | rating | industry  |

   ↪
```

4.14.4.5 Noteworthy things

- If anything goes wrong, you can navigate to the CloudWatch page on the AWS Management Console to get logs.
- The steps in this document are based on Building custom connectors using the Amazon AppFlow Custom Connector SDK.
- TiDB Cloud Serverless is **NOT** a production environment.
- To prevent excessive length, the examples in this document only show the `Insert` strategy, but `Update` and `Upsert` strategies are also tested and can be used.

4.14.4.6 Need help?

Ask the community on Discord or Slack, or submit a support ticket.

Ask the community on Discord or Slack, or submit a support ticket.

5 Deploy

5.1 TiDB Software and Hardware Requirements

This document describes the software and hardware requirements for deploying and running the TiDB database. As an open-source distributed SQL database with high performance, TiDB can be deployed in the Intel architecture server, ARM architecture server,

and major virtualization environments and runs well. TiDB supports most of the major hardware networks and Linux operating systems.

5.1.1 OS and platform requirements

In v8.5 LTS, TiDB ensures multi-level quality standards for various combinations of operating systems and CPU architectures.

- For the following combinations of operating systems and CPU architectures, TiDB **provides enterprise-level production quality**, and the product features have been comprehensively and systematically verified:

```
<th>Operating systems</th>
<th>Supported CPU architectures</th>
```

```
<td>Red Hat Enterprise Linux 8.4 or a later 8.x version</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Amazon Linux 2</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Amazon Linux 2023</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Rocky Linux 9.1 or later</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Kylin V10 SP1/SP2/SP3 (SP3 is supported starting from v7.5.5)</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>UnionTech OS (UOS) V20</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>openEuler 22.03 LTS SP1/SP3</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

Warning:

- According to CentOS Linux EOL, the upstream support for CentOS Linux 7 ended on June 30, 2024.

    - Before upgrading TiDB, make sure to check your operating system version. TiDB v8.4.0 DMR and v8.5.0 removed the support of glibc 2.17, and dropped support and testing with CentOS Linux 7. It is recommended to use Rocky Linux 9.1 or a later version. Upgrading a TiDB cluster on CentOS 7 to v8.4.0 or v8.5.0 will cause the risk of cluster unavailability.
    - Starting from v8.5.1, to assist users still using CentOS Linux 7, TiDB resumes the support of glibc 2.17, resumes testing of CentOS Linux 7, and is now compatible with CentOS Linux 7. However, due to the EOL status of CentOS Linux, it is strongly recommended that you review the official announcements and security guidance for CentOS Linux 7 and migrate to an operating system supported by TiDB for production use, such as Rocky Linux 9.1 or later.
  - According to Red Hat Enterprise Linux Life Cycle, the maintenance support for Red Hat Enterprise Linux 7 ended on June 30, 2024. TiDB ends the support for Red Hat Enterprise Linux 7 starting from the 8.4 DMR version. It is recommended to use Rocky Linux 9.1 or a later version. Upgrading a TiDB cluster on Red Hat Enterprise Linux 7 to v8.4.0 or later will cause the cluster to become unavailable. Before upgrading TiDB, make sure to check your operating system version.

- For the following combinations of operating systems and CPU architectures, you can compile, build, and deploy TiDB. In addition, you can also use the basic features of OLTP, OLAP, and the data tools. However, TiDB **does not guarantee enterprise-level production quality**:

```
<th>Operating systems</th>
<th>Supported CPU architectures</th>
```

```
<td>macOS 12 (Monterey) or later</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Oracle Enterprise Linux 8 or a later</td>
<td>x86_64</td>
```

```
<td>Ubuntu LTS 20.04 or later</td>
<td>x86_64</td>
```

```
<td>CentOS Stream 8</td>
<td><ul><li>x86_64</li><li>ARM 64</li></ul></td>
```

```
<td>Debian 10 (Buster) or later</td>
<td>x86_64</td>
```

```
<td>Fedora 38 or later</td>
<td>x86_64</td>
```

```
<td>openSUSE Leap later than v15.5 (not including Tumbleweed)</td>
<td>x86_64</td>
```

```
<td>SUSE Linux Enterprise Server 15</td>
<td>x86_64</td>
```

Note:

- For Oracle Enterprise Linux, TiDB supports the Red Hat Compatible Kernel (RHCK) and does not support the Unbreakable Enterprise Kernel provided by Oracle Enterprise Linux.
- Support for Ubuntu 16.04 will be removed in future versions of TiDB. Upgrading to Ubuntu 18.04 or later is strongly recommended.
- CentOS Stream 8 reaches End of Builds on May 31, 2024.

- If you are using the 32-bit version of an operating system listed in the preceding two tables, TiDB **is not guaranteed** to be compilable, buildable or deployable on the 32-bit operating system and the corresponding CPU architecture, or TiDB does not actively adapt to the 32-bit operating system.
- Other operating system versions not mentioned above might work but are not officially supported.

5.1.1.1 Libraries required for compiling and running TiDB

Libraries required for compiling and running TiDB	Version
Golang	1.23 or later
Rust	nightly-2023-12-28 or later
GCC	7.x
LLVM	17.0 or later

Library required for running TiDB: glibc (2.28-151.el8 version)

5.1.1.2 Docker image dependencies

The following CPU architectures are supported:

- x86_64. Starting from TiDB v6.6.0, the x86-64-v2 instruction set is required.
- ARM 64

5.1.2 Software requirements

5.1.2.1 Control machine

Software	Version
sshpass	1.06 or later
TiUP	1.5.0 or later

> **Note:**
>
> It is required that you deploy TiUP on the control machine to operate and manage TiDB clusters.

5.1.2.2 Target machines

Software	Version
sshpass	1.06 or later
numa	2.0.12 or later
tar	any

5.1.3 Server requirements

You can deploy and run TiDB on the 64-bit generic hardware server platform in the Intel x86-64 architecture or on the hardware server platform in the ARM architecture. The requirements and recommendations about server hardware configuration (ignoring the resources occupied by the operating system itself) for development, test, and production environments are as follows:

5.1.3.1 Development and test environments

Component	CPU	Memory	Local Storage	Network	Number of Instances (Minimum Requirement)
TiDB	8 core+	16 GB+	Disk space requirements	Gigabit network card	1 (can be deployed on the same machine with PD)
PD	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1 (can be deployed on the same machine with TiDB)
TiKV	8 core+	32 GB+	SAS, 200 GB+	Gigabit network card	3
TiFlash	32 core+	64 GB+	SSD, 200 GB+	Gigabit network card	1
TiCDC	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the test environment, the TiDB and PD instances can be deployed on the same server.
- For performance-related test, do not use low-performance storage and network hardware configuration, in order to guarantee the correctness of the test result.
- For the TiKV server, it is recommended to use NVMe SSDs to ensure faster reads and writes.
- If you only want to test and verify the features, follow Quick Start Guide for TiDB to deploy TiDB on a single machine.
- Starting from v6.3.0, to deploy TiFlash under the Linux AMD64 architecture, the CPU must support the AVX2 instruction set. Ensure that `grep avx2 /proc/cpuinfo` has output. To deploy TiFlash under the Linux ARM64 architecture, the CPU must support the ARMv8 instruction set architecture. Ensure that `grep 'crc32' /proc/cpuinfo | grep 'asimd'` has output. By using the instruction set extensions, TiFlash's vectorization engine can deliver better performance.

5.1.3.2 Production environment

Component	CPU	Memory	Hard Disk Type	Network	Number o
TiDB	16 core+	48 GB+	SSD	10 Gigabit network card (2 preferred)	
PD	8 core+	16 GB+	SSD	10 Gigabit network card (2 preferred)	
TiKV	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
TiFlash	48 core+	128 GB+	1 or more SSDs	10 Gigabit network card (2 preferred)	
TiCDC	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
Monitor	8 core+	16 GB+	SAS	Gigabit network card	

Note:

- In the production environment, the TiDB and PD instances can be deployed on the same server. If you have a higher requirement for performance and reliability, try to deploy them separately.
- It is strongly recommended to configure TiDB, TiKV, and TiFlash with at least 8 CPU cores each in the production environment. To get better performance, a higher configuration is recommended.
- It is recommended to keep the size of TiKV hard disk within 4 TB if you are using PCIe SSDs or within 1.5 TB if you are using regular SSDs.
- If you deploy TiKV on a cloud provider, such as AWS, Google Cloud, or Azure, it is recommended to use cloud disks for TiKV nodes. Data on local disks might be lost if the TiKV instance crashes in the cloud environment.

Before you deploy TiFlash, note the following items:

- TiFlash can be deployed on multiple disks.
- It is recommended to use a high-performance SSD as the first disk of the TiFlash data directory to buffer the real-time replication of TiKV data. The performance of this disk should not be lower than that of TiKV, such as PCIe SSD. The disk capacity should be no less than 10% of the total capacity; otherwise, it might become the bottleneck of this node. You can deploy ordinary SSDs for other disks, but note that a better PCIe SSD brings better performance.
- It is recommended to deploy TiFlash on different nodes from TiKV. If you must deploy TiFlash and TiKV on the same node, increase the number of CPU cores and memory, and try to deploy TiFlash and TiKV on different disks to avoid interfering each other.
- The total capacity of the TiFlash disks is calculated in this way: `the data volume of the entire TiKV cluster to be replicated / the number of TiKV replicas * the number of TiFlash replicas`. For example, if the overall

planned capacity of TiKV is 1 TB, the number of TiKV replicas is 3, and the number of TiFlash replicas is 2, then the recommended total capacity of TiFlash is `1024 GB / 3 * 2`. You can replicate only the data of some tables. In such case, determine the TiFlash capacity according to the data volume of the tables to be replicated.

Before you deploy TiCDC, note that it is recommended to deploy TiCDC on PCIe SSD disks larger than 500 GB.

5.1.4 Network requirements

As an open-source distributed SQL database, TiDB requires the following network port configuration to run. Based on the TiDB deployment in actual environments, the administrator can open relevant ports in the network side and host side.

Component	Default Port	Description
TiDB	4000	the communication port for the application and DBA tools
TiDB	10080	the communication port to report TiDB status

Component	Default Port	Description
TiKV	20160	the TiKV communication port
TiKV	20180	the communication port to report TiKV status
PD	2379	the communication port between TiDB and PD

Component	Default Port	Description
PD	2380	the inter-node com-mu-nica-tion port within the PD clus-ter
TiFlash	9000	the Ti-Flash TCP ser-vice port
TiFlash	3930	the Ti-Flash RAFT and Co-pro-ces-sor ser-vice port
TiFlash	20170	the Ti-Flash Proxy ser-vice port

Component	Default Port	Description
TiFlash	20292	the port for Prometheus to pull TiFlash Proxy metrics
TiFlash	8234	the port for Prometheus to pull TiFlash metrics
TiCDC	8300	the TiCDC communication port
Monitoring	9090	the communication port for the Prometheus service

Component	Default Port	Description
Monitoring	12020	the communication port for the Ng-Monitoring service
Node_exporter	9100	the communication port to report the system information of every TiDB cluster node

Component	Default Port	Description
Blackbox_exporter	9115	the Blackbox_exporter communication port, used to monitor the ports in the TiDB cluster
Grafana	3000	the port for the external Web monitoring service and client (Browser) access

Component	Default Port	Description
Alertmanager	9093	the port for the alert web service
Alertmanager	9094	the alert communication port

5.1.5 Disk space requirements

```
<th>Component</th>
<th>Disk space requirement</th>
<th>Healthy disk usage</th>
```

```
<td>TiDB</td>
<td><ul><li>At least 30 GB for the log disk</li><li>Starting from v6.5.0,
    ↪ Fast Online DDL (controlled by the <a href="https://docs.pingcap.com/
    ↪ tidb/dev/system-variables#tidb_ddl_enable_fast_reorg-new-in-v630">
    ↪ tidb_ddl_enable_fast_reorg</a> variable) is enabled by default to
    ↪ accelerate DDL operations, such as adding indexes. If DDL operations
    ↪ involving large objects exist in your application, or you want to use

```

5.1.6 Web browser requirements

TiDB relies on Grafana to provide visualization of database metrics. A recent version of Microsoft Edge, Safari, Chrome or Firefox with Javascript enabled is sufficient.

5.1.7 Hardware and software requirements for TiFlash disaggregated storage and compute architecture

The preceding TiFlash software and hardware requirements are for the coupled storage and compute architecture. Starting from v7.0.0, TiFlash supports the disaggregated storage and compute architecture. In this architecture, TiFlash is divided into two types of nodes: the Write Node and the Compute Node. The requirements for these nodes are as follows:

- Software: remain the same as the coupled storage and compute architecture, see OS and platform requirements.
- Network port: remain the same as the coupled storage and compute architecture, see Network.
- Disk space:
  - TiFlash Write Node: it is recommended to configure at least 200 GB of disk space, which is used as a local buffer when adding TiFlash replicas and migrating Region replicas before uploading data to Amazon S3. In addition, an object storage compatible with Amazon S3 is required.
  - TiFlash Compute Node: it is recommended to configure at least 100 GB of disk space, which is mainly used to cache the data read from the Write Node to improve performance. The cache of the Compute Node might be fully used, which is normal.
- CPU and memory requirements are described in the following sections.

5.1.7.1 Development and test environments

Component	CPU	Memory	Local Storage	Network	Number of Instances (Minimum Requirement)
TiFlash Write Node	16 cores+	32 GB+	SSD, 200 GB+	Gigabit Ethernet	1
TiFlash Compute Node	16 cores+	32 GB+	SSD, 100 GB+	Gigabit Ethernet	0 (see the following note)

5.1.7.2 Production environment

Component	CPU	Memory	Disk Type	Network	Number of Instances (Minimum Requirement)
TiFlash Write Node	32 cores+	64 GB+	1 or more SSDs	10 Gigabit Ethernet (2 recommended)	1
TiFlash Compute Node	32 cores+	64 GB+	1 or more SSDs	10 Gigabit Ethernet (2 recommended)	0 (see the following note)

Note:

You can use deployment tools such as TiUP to quickly scale in or out the TiFlash Compute Node, within the range of `[0, +inf]`.

5.2 TiDB Environment and System Configuration Check

This document describes the environment check operations before deploying TiDB. The following steps are ordered by priorities.

5.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV

For production deployments, it is recommended to use NVMe SSD of EXT4 filesystem to store TiKV data. This configuration is the best practice, whose reliability, security, and stability have been proven in a large number of online scenarios.

Log in to the target machines using the `root` user account.

Format your data disks to the ext4 filesystem and add the `nodelalloc` and `noatime` mount options to the filesystem. It is required to add the `nodelalloc` option, or else the TiUP deployment cannot pass the precheck. The `noatime` option is optional.

> **Note:**
>
> If your data disks have been formatted to ext4 and have added the mount options, you can uninstall it by running the `umount /dev/nvme0n1p1` command, skip directly to the fifth step below to edit the `/etc/fstab` file, and add the options again to the filesystem.

Take the `/dev/nvme0n1` data disk as an example:

1. View the data disk.

```
fdisk -l
```

```
Disk /dev/nvme0n1: 1000 GB
```

2. Create the partition.

```
parted -s -a optimal /dev/nvme0n1 mklabel gpt -- mkpart primary ext4 1
    ↪ -1
```

For large NVMe devices, you can create multiple partitions:

```
parted -s -a optimal /dev/nvme0n1 mklabel gpt -- mkpart primary ext4 1
    ↪ 2000GB
parted -s -a optimal /dev/nvme0n1 -- mkpart primary ext4 2000GB -1
```

> **Note:**
>
> Use the `lsblk` command to view the device number of the partition: for a NVMe disk, the generated device number is usually `nvme0n1p1`; for a regular disk (for example, `/dev/sdb`), the generated device number is usually `sdb1`.

3. Format the data disk to the ext4 filesystem.

```
mkfs.ext4 /dev/nvme0n1p1
```

4. View the partition UUID of the data disk.

   In this example, the UUID of nvme0n1p1 is `c51eb23b-195c-4061-92a9-3fad812cc12f`.

```
lsblk -f
```

```
NAME    FSTYPE LABEL UUID                                 MOUNTPOINT
sda
 ─sda1  ext4         237b634b-a565-477b-8371-6dff0c41f5ab /boot
 ─sda2  swap         f414c5c0-f823-4bb1-8fdf-e531173a72ed
 ─sda3  ext4         547909c1-398d-4696-94c6-03e43e317b60 /
sr0
nvme0n1
 ─nvme0n1p1 ext4       c51eb23b-195c-4061-92a9-3fad812cc12f
```

5. Edit the `/etc/fstab` file and add the `nodelalloc` mount options.

```
vi /etc/fstab
```

```
UUID=c51eb23b-195c-4061-92a9-3fad812cc12f /data1 ext4 defaults,
    ↪ nodelalloc,noatime 0 2
```

6. Mount the data disk.

```
mkdir /data1 && \
systemctl daemon-reload && \
mount -a
```

7. Check using the following command.

```
mount -t ext4
```

```
/dev/nvme0n1p1 on /data1 type ext4 (rw,noatime,nodelalloc,data=ordered)
```

   If the filesystem is ext4 and `nodelalloc` is included in the mount options, you have successfully mount the data disk ext4 filesystem with options on the target machines.

5.2.2 Check and disable system swap

TiDB needs a sufficient amount of memory for operation. If the memory that TiDB uses gets swapped out and later gets swapped back in, this can cause latency spikes. If you want to maintain stable performance, it is recommended that you permanently disable the system swap, but it might trigger OOM issues when there is insufficient memory. If you want to avoid such OOM issues, you can just decrease the swap priority, instead of permanently disabling it.

- Enabling and using swap might introduce performance jitter issues. It is recommended that you permanently disable the operating system tier swap for low-latency and stability-critical database services. To permanently disable swap, you can use the following method:
  - During the initialization phase of the operating system, do not partition the swap partition disk separately.
  - If you have already partitioned a separate swap partition disk during the initialization phase of the operating system and enabled swap, run the following command to disable it:

```
echo "vm.swappiness = 0">> /etc/sysctl.conf
sysctl -p
swapoff -a && swapon -a
```

- If the host memory is insufficient, disabling the system swap might be more likely to trigger OOM issues. You can run the following command to decrease the swap priority instead of disabling it permanently:

```
echo "vm.swappiness = 0">> /etc/sysctl.conf
sysctl -p
```

5.2.3 Set temporary spaces for TiDB instances (Recommended)

Some operations in TiDB require writing temporary files to the server, so it is necessary to ensure that the operating system user that runs TiDB has sufficient permissions to read and write to the target directory. If you do not start the TiDB instance with the `root` privilege, you need to check the directory permissions and set them correctly.

- TiDB work area

  Operations that consume a significant amount of memory, such as hash table construction and sorting, might write temporary data to disk to reduce memory consumption and improve stability. The disk location for writing is defined by the configuration item `tmp-storage-path`. With the default configuration, make sure that the user that runs TiDB has read and write permissions to the temporary folder (usually `/tmp`) of the operating system.

- `Fast Online DDL` work area

  When the variable `tidb_ddl_enable_fast_reorg` is set to `ON` (the default value in v6.5.0 and later versions), `Fast Online DDL` is enabled, and some DDL operations need to read and write temporary files in filesystems. The location is defined by the configuration item `temp-dir`. You need to ensure that the user that runs TiDB has read and write permissions for that directory of the operating system. The default directory `/tmp/tidb` uses tmpfs (temporary file system). It is recommended to explicitly specify a disk directory. The following uses `/data/tidb-deploy/tempdir` as an example:

> **Note:**
> If DDL operations on large objects exist in your application, it is highly recommended to configure an independent large file system for `temp-dir`.

```
sudo mkdir -p /data/tidb-deploy/tempdir
```

If the `/data/tidb-deploy/tempdir` directory already exists, make sure the write permission is granted.

```
sudo chmod -R 777 /data/tidb-deploy/tempdir
```

> **Note:**
> If the directory does not exist, TiDB will automatically create it upon startup. If the directory creation fails or TiDB does not have the read and write permissions for that directory, `Fast Online DDL` will be disabled during runtime.

5.2.4 Check the firewall service of target machines

In TiDB clusters, the access ports between nodes must be open to ensure the transmission of information such as read and write requests and data heartbeats. In common online scenarios, the data interaction between the database and the application service and between the database nodes are all made within a secure network. Therefore, if there are no special security requirements, it is recommended to stop the firewall of the target machine. Otherwise, refer to the port usage and add the needed port information to the allowlist of the firewall service.

5.2.4.1 Stop and disable firewalld

This section describes how to stop and disable the firewall service of a target machine.

1. Check the firewall status. The following example uses CentOS Linux release 7.7.1908 (Core):

```
sudo firewall-cmd --state
sudo systemctl status firewalld.service
```

2. Stop the firewall service:

```
sudo systemctl stop firewalld.service
```

3. Disable automatic startup of the firewall service:

```
sudo systemctl disable firewalld.service
```

4. Check the firewall status:

```
sudo systemctl status firewalld.service
```

5.2.4.2 Change the firewall zone

Instead of disabling the firewall completely, you can use a less restrictive zone. The default `public` zone allows only specific services and ports, while the `trusted` zone allows all traffic by default.

To set the default zone to `trusted`:

```
firewall-cmd --set-default-zone trusted
```

To verify the default zone:

```
firewall-cmd --get-default-zone
## trusted
```

To list the policy for a zone:

```
firewall-cmd --zone=trusted --list-all
## trusted
##   target: ACCEPT
##   icmp-block-inversion: no
##   interfaces:
##   sources:
##   services:
##   ports:
##   protocols:
##   forward: yes
##   masquerade: no
##   forward-ports:
##   source-ports:
```

```
##   icmp-blocks:
##   rich rules:
```

5.2.4.3 Configure the firewall

To configure the firewall for TiDB cluster components, use the following commands. These examples are for reference only. Adjust the zone names, ports, and services based on your specific environment.

Configure the firewall for the TiDB component:

```
firewall-cmd --permanent --new-service tidb
firewall-cmd --permanent --service tidb --set-description="TiDB Server"
firewall-cmd --permanent --service tidb --set-short="TiDB"
firewall-cmd --permanent --service tidb --add-port=4000/tcp
firewall-cmd --permanent --service tidb --add-port=10080/tcp
firewall-cmd --permanent --zone=public --add-service=tidb
```

Configure the firewall for the TiKV component:

```
firewall-cmd --permanent --new-service tikv
firewall-cmd --permanent --service tikv --set-description="TiKV Server"
firewall-cmd --permanent --service tikv --set-short="TiKV"
firewall-cmd --permanent --service tikv --add-port=20160/tcp
firewall-cmd --permanent --service tikv --add-port=20180/tcp
firewall-cmd --permanent --zone=public --add-service=tikv
```

Configure the firewall for the PD component:

```
firewall-cmd --permanent --new-service pd
firewall-cmd --permanent --service pd --set-description="PD Server"
firewall-cmd --permanent --service pd --set-short="PD"
firewall-cmd --permanent --service pd --add-port=2379/tcp
firewall-cmd --permanent --service pd --add-port=2380/tcp
firewall-cmd --permanent --zone=public --add-service=pd
```

Configure the firewall for Prometheus:

```
firewall-cmd --permanent --zone=public --add-service=prometheus
firewall-cmd --permanent --service=prometheus --add-port=12020/tcp
```

Configure the firewall for Grafana:

```
firewall-cmd --permanent --zone=public --add-service=grafana
```

5.2.5 Check and install the NTP service

TiDB is a distributed database system that requires clock synchronization between nodes to guarantee linear consistency of transactions in the ACID model.

At present, the common solution to clock synchronization is to use the Network Time Protocol (NTP) services. You can use the `pool.ntp.org` timing service on the Internet, or build your own NTP service in an offline environment.

To check whether the NTP service is installed and whether it synchronizes with the NTP server normally, take the following steps:

1. Run the following command. If it returns `running`, then the NTP service is running.

```
sudo systemctl status ntpd.service
```

```
ntpd.service - Network Time Service
Loaded: loaded (/usr/lib/systemd/system/ntpd.service; disabled; vendor
   ↪ preset: disabled)
Active: active (running) since — 2017-12-18 13:13:19 CST; 3s ago
```

   - If it returns `Unit ntpd.service could not be found.`, then try the following command to see whether your system is configured to use `chronyd` instead of `ntpd` to perform clock synchronization with NTP:

```
sudo systemctl status chronyd.service
```

```
chronyd.service - NTP client/server
Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled;
   ↪ vendor preset: enabled)
Active: active (running) since Mon 2021-04-05 09:55:29 EDT; 3 days
   ↪ ago
```

     If the result shows that neither `chronyd` nor `ntpd` is configured, it means that neither of them is installed in your system. You should first install `chronyd` or `ntpd` and ensure that it can be automatically started. By default, `ntpd` is used.

     If your system is configured to use `chronyd`, proceed to step 3.

2. Run the `ntpstat` command to check whether the NTP service synchronizes with the NTP server.

> **Note:**
>
> For the Ubuntu system, you need to install the `ntpstat` package.

```
ntpstat
```

- If it returns `synchronised to NTP server` (synchronizing with the NTP server), then the synchronization process is normal.

```
synchronised to NTP server (85.199.214.101) at stratum 2
time correct to within 91 ms
polling server every 1024 s
```

- The following situation indicates the NTP service is not synchronizing normally:

```
unsynchronised
```

- The following situation indicates the NTP service is not running normally:

```
Unable to talk to NTP daemon. Is it running?
```

3. Run the `chronyc tracking` command to check whether the Chrony service synchronizes with the NTP server.

> **Note:**
>
> This only applies to systems that use Chrony instead of NTPd.

```
chronyc tracking
```

- If the command returns `Leap status     : Normal`, the synchronization process is normal.

```
Reference ID    : 5EC69F0A (ntp1.time.nl)
Stratum         : 2
Ref time (UTC)  : Thu May 20 15:19:08 2021
System time     : 0.000022151 seconds slow of NTP time
Last offset     : -0.000041040 seconds
RMS offset      : 0.000053422 seconds
Frequency       : 2.286 ppm slow
Residual freq   : -0.000 ppm
Skew            : 0.012 ppm
Root delay      : 0.012706812 seconds
Root dispersion : 0.000430042 seconds
Update interval : 1029.8 seconds
Leap status     : Normal
```

- If the command returns the following result, an error occurs in the synchronization:

```
Leap status  : Not synchronised
```

- If the command returns the following result, the `chronyd` service is not running normally:

```
506 Cannot talk to daemon
```

- If the offset appears to be too high, you can run the `chronyc makestep` command to immediately correct the time offset. Otherwise, `chronyd` will gradually correct the time offset.

To make the NTP service start synchronizing as soon as possible, run the following command. Replace `pool.ntp.org` with your NTP server.

```
sudo systemctl stop ntpd.service && \
sudo ntpdate pool.ntp.org && \
sudo systemctl start ntpd.service
```

To install the NTP service manually on the CentOS 7 system, run the following command:

```
sudo yum install ntp ntpdate && \
sudo systemctl start ntpd.service && \
sudo systemctl enable ntpd.service
```

5.2.6 Check and configure the optimal parameters of the operating system

For TiDB in the production environment, it is recommended to optimize the operating system configuration in the following ways:

1. Disable THP (Transparent Huge Pages). The memory access pattern of databases tends to be sparse rather than consecutive. If the high-level memory fragmentation is serious, higher latency will occur when THP pages are allocated.

2. Set the I/O Scheduler of the storage media.

    - For the high-speed SSD storage, the kernel's default I/O scheduling operations might cause performance loss. It is recommended to set the I/O Scheduler to first-in-first-out (FIFO), such as `noop` or `none`. This configuration allows the kernel to pass I/O requests directly to hardware without scheduling, thus improving performance.
    - For NVMe storage, the default I/O Scheduler is `none`, so no adjustment is needed.

3. Choose the `performance` mode for the cpufrequ module which controls the CPU frequency. The performance is maximized when the CPU frequency is fixed at its highest supported operating frequency without dynamic adjustment.

Take the following steps to check the current operating system configuration and configure optimal parameters:

1. Execute the following command to see whether THP is enabled or disabled:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
[always] madvise never
```

> **Note:**
> If `[always] madvise never` is output, THP is enabled. You need to disable it.

2. Execute the following command to see the I/O Scheduler of the disk where the data directory is located.

   If your data directory uses an SD or VD device, run the following command to check the I/O Scheduler:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
noop [deadline] cfq
noop [deadline] cfq
```

> **Note:**
> If `noop [deadline] cfq` is output, the I/O Scheduler for the disk is in the `deadline` mode. You need to change it to `noop`.

   If your data directory uses an NVMe device, run the following command to check the I/O Scheduler:

```
cat /sys/block/nvme[01]*/queue/scheduler
```

```
[none] mq-deadline kyber bfq
[none] mq-deadline kyber bfq
```

> **Note:**
>
> `[none] mq-deadline kyber bfq` indicates that the NVMe device uses the `none` I/O Scheduler, and no changes are needed.

3. Execute the following command to see the `ID_SERIAL` of the disk:

```
udevadm info --name=/dev/sdb | grep ID_SERIAL
```

```
E: ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81
E: ID_SERIAL_SHORT=6d0946606d79f90025f3e09a0c1f9e81
```

> **Note:**
>
> - If multiple disks are allocated with data directories, you need to execute the above command for each disk to record the `ID_SERIAL` of each disk.
> - If your device uses the `noop` or `none` Scheduler, you do not need to record the `ID_SERIAL` or configure udev rules or the tuned profile.

4. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
```

```
analyzing CPU 0:
current policy: frequency should be within 1.20 GHz and 3.10 GHz.
            The governor "powersave" may decide which speed to use
               ↪ within this range.
```

> **Note:**
>
> If `The governor "powersave"` is output, the power policy of the cpufreq module is `powersave`. You need to modify it to `performance`. If you use a virtual machine or a cloud host, the output is usually `Unable to ↪ determine current policy`, and you do not need to change anything.

5. Configure optimal parameters of the operating system:

    - Method one: Use tuned (Recommended)

1. Execute the `tuned-adm list` command to see the tuned profile of the current operating system:

```
tuned-adm list
```

```
Available profiles:
- balanced                  - General non-specialized tuned
    ↪ profile
- desktop                   - Optimize for the desktop use-case
- hpc-compute               - Optimize for HPC compute workloads
- latency-performance       - Optimize for deterministic
    ↪ performance at the cost of increased power consumption
- network-latency           - Optimize for deterministic
    ↪ performance at the cost of increased power consumption,
    ↪ focused on low latency network performance
- network-throughput        - Optimize for streaming network
    ↪ throughput, generally only necessary on older CPUs or 40G
    ↪ + networks
- powersave                 - Optimize for low power consumption
- throughput-performance    - Broadly applicable tuning that
    ↪ provides excellent performance across a variety of common
    ↪  server workloads
- virtual-guest             - Optimize for running inside a
    ↪ virtual guest
- virtual-host              - Optimize for running KVM guests
Current active profile: balanced
```

   The output `Current active profile: balanced` means that the tuned profile of the current operating system is `balanced`. It is recommended to optimize the configuration of the operating system based on the current profile.

2. Create a new tuned profile:

```
mkdir /etc/tuned/balanced-tidb-optimal/
vi /etc/tuned/balanced-tidb-optimal/tuned.conf
```

```
[main]
include=balanced

[cpu]
governor=performance

[vm]
transparent_hugepages=never

[disk]
devices_udev_regex=(ID_SERIAL=36d0946606d79f90025f3e09a0c1fc035
    ↪ )|(ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81)
```

```
elevator=noop
```

The output `include=balanced` means to add the optimization configuration of the operating system to the current `balanced` profile.

3. Apply the new tuned profile:

> **Note:**
> If your device uses the `noop` or `none` I/O Scheduler, skip this step. No Scheduler configuration is needed in the tuned profile.

```
tuned-adm profile balanced-tidb-optimal
```

- Method two: Configure using scripts. Skip this method if you already use method one.

1. Execute the `grubby` command to see the default kernel version:

> **Note:**
> Install the `grubby` package first before you execute `grubby`.

```
grubby --default-kernel
```

```
/boot/vmlinuz-3.10.0-957.el7.x86_64
```

2. Execute `grubby --update-kernel` to modify the kernel configuration:

```
grubby --args="transparent_hugepage=never" --update-kernel `
    ↪ grubby --default-kernel`
```

> **Note:**
> You can also specify the actual version number after `--update ↪ -kernel`, for example, `--update-kernel /boot/vmlinuz ↪ -3.10.0-957.el7.x86_64` or `ALL`.

3. Execute `grubby --info` to see the modified default kernel configuration:

```
grubby --info /boot/vmlinuz-3.10.0-957.el7.x86_64
```

> **Note:**
> `--info` is followed by the actual default kernel version.

```
index=0
kernel=/boot/vmlinuz-3.10.0-957.el7.x86_64
```

```
args="ro crashkernel=auto rd.lvm.lv=centos/root rd.lvm.lv=
    ↪ centos/swap rhgb quiet LANG=en_US.UTF-8 transparent_
    ↪ hugepage=never"
root=/dev/mapper/centos-root
initrd=/boot/initramfs-3.10.0-957.el7.x86_64.img
title=CentOS Linux (3.10.0-957.el7.x86_64) 7 (Core)
```

4. Modify the current kernel configuration to immediately disable THP:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

5. Configure the I/O Scheduler in the udev script:

```
vi /etc/udev/rules.d/60-tidb-schedulers.rules
```

```
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1fc035", ATTR{queue/scheduler}="
    ↪ noop"
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1f9e81", ATTR{queue/scheduler}="
    ↪ noop"
```

6. Apply the udev script:

> **Note:**
> If your device uses the `noop` or `none` I/O Scheduler, skip this step. No udev rules configuration is needed.

```
udevadm control --reload-rules
udevadm trigger --type=devices --action=change
```

7. Create a service to configure the CPU power policy:

```
cat >> /etc/systemd/system/cpupower.service << EOF
[Unit]
Description=CPU performance
[Service]
Type=oneshot
ExecStart=/usr/bin/cpupower frequency-set --governor
    ↪ performance
[Install]
WantedBy=multi-user.target
EOF
```

8. Apply the CPU power policy configuration service:

```
systemctl daemon-reload
systemctl enable cpupower.service
systemctl start cpupower.service
```

6. Execute the following command to verify the THP status:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
always madvise [never]
```

7. Execute the following command to verify the I/O Scheduler of the disk where the data directory is located:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
[noop] deadline cfq
[noop] deadline cfq
```

8. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
  ```
```

analyzing CPU 0: current policy: frequency should be within 1.20 GHz and 3.10 GHz. The governor "performance" may decide which speed to use within this range. "'

9. Execute the following commands to modify the `sysctl` parameters:

```
echo "fs.file-max = 1000000">> /etc/sysctl.conf
echo "net.core.somaxconn = 32768">> /etc/sysctl.conf
echo "net.ipv4.tcp_syncookies = 0">> /etc/sysctl.conf
echo "vm.overcommit_memory = 1">> /etc/sysctl.conf
echo "vm.min_free_kbytes = 1048576">> /etc/sysctl.conf
sysctl -p
```

Warning:

It is not recommended to increase the value of `vm.min_free_kbytes` on systems with less than 16 GiB of memory, because it might cause instability and boot failures.

Note:
```

- `vm.min_free_kbytes` is a Linux kernel parameter that controls the minimum amount of free memory reserved by the system, measured in KiB.
- The setting of `vm.min_free_kbytes` affects the memory reclaim mechanism. Setting it too large reduces the available memory, while setting it too small might cause memory request speeds to exceed background reclaim speeds, leading to memory reclamation and consequent delays in memory allocation.
- It is recommended to set `vm.min_free_kbytes` to `1048576` KiB (1 GiB) at least. If NUMA is installed, it is recommended to set it to `number of NUMA nodes * 1048576` KiB.
- For systems running Linux kernel 4.11 or earlier, it is recommended to set `net.ipv4.tcp_tw_recycle = 0`.

10. Execute the following command to configure the user's `limits.conf` file:

```
cat << EOF >>/etc/security/limits.conf
tidb            soft    nofile          1000000
tidb            hard    nofile          1000000
tidb            soft    stack           32768
tidb            hard    stack           32768
tidb            soft    core            unlimited
tidb            hard    core            unlimited
EOF
```

5.2.7 Manually configure the SSH mutual trust and sudo without password

This section describes how to manually configure the SSH mutual trust and sudo without password. It is recommended to use TiUP for deployment, which automatically configure SSH mutual trust and login without password. If you deploy TiDB clusters using TiUP, ignore this section.

1. Log in to the target machine respectively using the `root` user account, create the `tidb` user and set the login password.

```
useradd tidb && \
passwd tidb
```

2. To configure sudo without password, run the following command, and add `tidb ALL =(ALL)NOPASSWD: ALL` to the end of the file:

```
visudo
```

```
tidb ALL=(ALL) NOPASSWD: ALL
```

3. Use the `tidb` user to log in to the control machine, and run the following command. Replace `10.0.1.1` with the IP of your target machine, and enter the `tidb` user password of the target machine as prompted. After the command is executed, SSH mutual trust is already created. This applies to other machines as well. Newly created `tidb` users do not have the `.ssh` directory. To create such a directory, execute the command that generates the RSA key. To deploy TiDB components on the control machine, configure mutual trust for the control machine and the control machine itself.

```
ssh-keygen -t rsa
ssh-copy-id -i ~/.ssh/id_rsa.pub 10.0.1.1
```

4. Log in to the control machine using the `tidb` user account, and log in to the IP of the target machine using `ssh`. If you do not need to enter the password and can successfully log in, then the SSH mutual trust is successfully configured.

```
ssh 10.0.1.1
```

```
[tidb@10.0.1.1 ~]$
```

5. After you log in to the target machine using the `tidb` user, run the following command. If you do not need to enter the password and can switch to the `root` user, then sudo without password of the `tidb` user is successfully configured.

```
sudo -su root
```

```
[root@10.0.1.1 tidb]#
```

5.2.8 Install the `numactl` tool

This section describes how to install the NUMA tool. In online environments, because the hardware configuration is usually higher than required, to better plan the hardware resources, multiple instances of TiDB or TiKV can be deployed on a single machine. In such scenarios, you can use NUMA tools to prevent the competition for CPU resources which might cause reduced performance.

Note:

- Binding cores using NUMA is a method to isolate CPU resources and is suitable for deploying multiple instances on highly configured physical machines.

- After completing deployment using `tiup cluster deploy`, you can use the `exec` command to perform cluster level management operations.

To install the NUMA tool, take either of the following two methods:

Method 1: Log in to the target node to install NUMA. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo yum -y install numactl
```

Method 2: Install NUMA on an existing cluster in batches by running the `tiup cluster exec` command.

1. Follow Deploy a TiDB Cluster Using TiUP to deploy a cluster `tidb-test`. If you have installed a TiDB cluster, you can skip this step.

```
tiup cluster deploy tidb-test v6.1.0 ./topology.yaml --user root [-p]
    ↪ [-i /home/root/.ssh/gcp_rsa]
```

2. Run the `tiup cluster exec` command using the `sudo` privilege to install NUMA on all the target machines in the `tidb-test` cluster:

```
tiup cluster exec tidb-test --sudo --command "yum -y install numactl"
```

   To get help information of the `tiup cluster exec` command, run the `tiup cluster exec --help` command.

5.2.9 Disable SELinux

SELinux must be disabled or set to permissive mode. To check the current status, use the getenforce(8) utility.

If SELinux is not disabled, open the `/etc/selinux/config` file, locate the line starting with `SELINUX=`, and change it to `SELINUX=disabled`. After making this change, you need to reboot the system because switching from `enforcing` or `permissive` to `disabled` does not take effect without a reboot.

On some systems (such as Ubuntu), the `/etc/selinux/config` file might not exist, and the getenforce utility might not be installed. In that case, you can skip this step.

5.3 Plan Cluster Topology

5.3.1 Minimal Deployment Topology

This document describes the minimal deployment topology of TiDB clusters.

5.3.1.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	2	16 VCore 32 GiB 100 GiB for storage	10.0.1.1 10.0.1.2	Default port Global directory configuration
PD	3	4 VCore 8 GiB 100 GiB for storage	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32 GiB 2 TiB (NVMe SSD) for storage	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8 GiB 500 GiB (SSD) for storage	10.0.1.10	Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.1.1.1 Topology templates

- The simple template for the minimal topology
- The complex template for the minimal topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.

- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.2 TiFlash Deployment Topology

This document describes the deployment topology of TiFlash based on the minimal TiDB topology.

TiFlash is a columnar storage engine, and gradually becomes the standard cluster topology. It is suitable for real-time HTAP applications.

5.3.2.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
TiFlash	1	32 VCore 64 GB 2TB (nvme ssd) * 1	10.0.1.11	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.2.1.1 Topology templates

- The simple template for the TiFlash topology
- The complex template for the TiFlash topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.2.1.2 Key parameters

- To enable the Placement Rules feature of PD, set the value of `replication.enable-placement-rules` in the configuration template to `true`.
- The instance level `"-host"` configuration in `tiflash_servers` only supports IP, not domain name.

- For detailed TiFlash parameter description, see TiFlash Configuration.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.3 PD Microservice Deployment Topology

This document describes the deployment topology of PD microservices based on the minimal TiDB topology.

5.3.3.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	2	16 VCore 32GB * 1	10.0.1.1 10.0.1.2	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.3 10.0.1.4 10.0.1.5	Default port Global directory configuration
TSO	2	4 VCore 8GB * 1	10.0.1.6 10.0.1.7	Default port Global directory configuration
Scheduling	2	4 VCore 8GB * 1	10.0.1.8 10.0.1.9	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.10 10.0.1.11 10.0.1.12	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.13	Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.3.1.1 Topology template

Simple template for the PD microservice topology

```
### # Global variables are applied to all deployments and used as the
   ↪ default value of
### # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"
  listen_host: 0.0.0.0
  arch: "amd64"
  pd_mode: "ms" # To enable PD microservices, you must specify this field as
     ↪  "ms".

monitored:
  node_exporter_port: 9200
  blackbox_exporter_port: 9215

### # Specifies the configuration of PD servers.
pd_servers:
  - host: 10.0.1.3
  - host: 10.0.1.4
  - host: 10.0.1.5

### # Specifies the configuration of TiDB servers.
tidb_servers:
  - host: 10.0.1.1
  - host: 10.0.1.2

### # Specifies the configuration of TiKV servers.
tikv_servers:
  - host: 10.0.1.10
  - host: 10.0.1.11
  - host: 10.0.1.12
```

```
### # Specifies the configuration of TSO servers.
tso_servers:
  - host: 10.0.1.6
  - host: 10.0.1.7

### # Specifies the configuration of Scheduling servers.
scheduling_servers:
  - host: 10.0.1.8
  - host: 10.0.1.9

### # Specifies the configuration of Prometheus servers.
monitoring_servers:
  - host: 10.0.1.13

### # Specifies the configuration of Grafana servers.
grafana_servers:
  - host: 10.0.1.13
```

For detailed descriptions of the configuration items in the preceding TiDB cluster topology file, see Topology configuration file for deploying TiDB using TiUP.

5.3.3.1.2 Key parameters

- The instance-level `host` configuration in `tso_servers` only supports IP address, not domain name.
- For detailed descriptions of TSO configuration items, see TSO configuration file.
- The instance-level `host` configuration in `scheduling_servers` only supports IP address, not domain name.
- For detailed descriptions of Scheduling configuration items, see Scheduling configuration file.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.4 TiProxy Deployment Topology

This document describes the deployment topology of TiProxy based on the minimal TiDB topology.

For other deployment methods, refer to the following documents:

- To deploy TiProxy using TiDB Operator, see the TiDB Operator documentation.
- To quickly deploy TiProxy locally using TiUP, see Deploy TiProxy.
- To deploy TiProxy using TiUP, see Installation and usage.

TiProxy is a L7 proxy server for TiDB, which can balance connections and migrate sessions when possible.

5.3.4.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 3	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
PD	3	4 VCore 8GB * 3	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 3	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration
TiProxy	2	4 VCore 8 GB * 1	10.0.1.11 10.0.1.12	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.13	Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.4.1.1 Topology templates

For more information about the template for TiProxy, see The simple template for the TiProxy topology.

For detailed descriptions of the configuration items in the preceding TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.4.1.2 Key parameters

- The instance level `"-host"` configuration in `tiproxy_servers` only supports IP, not domain name.
- For detailed TiProxy parameter description, see TiProxy Configuration.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.5 TiCDC Deployment Topology

Note:

TiCDC is a feature for general availability (GA) since v4.0.6. You can use it in the production environment.

This document describes the deployment topology of TiCDC based on the minimal cluster topology.

TiCDC is a tool for replicating the incremental data of TiDB, introduced in TiDB 4.0. It supports multiple downstream platforms, such as TiDB, MySQL, Kafka, MQ, and storage services. TiCDC has low latency and native high availability.

5.3.5.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration
CDC	3	8 VCore 16GB * 1	10.0.1.11 10.0.1.12 10.0.1.13	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.5.1.1 Topology templates

- The simple template for the TiCDC topology
- The complex template for the TiCDC topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.6 TiSpark Deployment Topology

Warning:

TiSpark support in the TiUP cluster is deprecated. It is **NOT** recommended to use it.

This document introduces the TiSpark deployment topology and how to deploy TiSpark based on the minimum cluster topology.

TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer complex OLAP queries. It brings benefits of both the Spark platform and the distributed

TiKV cluster to TiDB and makes TiDB a one-stop solution for both online transactions and analytics.

For more information about the TiSpark architecture and how to use it, see TiSpark User Guide.

5.3.6.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration
TiSpark	3	8 VCore 16GB * 1	10.0.1.21 (master) 10.0.1.22 (worker) 10.0.1.23 (worker)	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

> **Note:**
>
> The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.6.2 Topology templates

- Simple TiSpark topology template
- Complex TiSpark topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

> **Note:**
>
> - You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
> - If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.6.3 Prerequisites

TiSpark is based on the Apache Spark cluster, so before you start the TiDB cluster that contains TiSpark, you must ensure that Java Runtime Environment (JRE) 8 is installed on the server that deploys TiSpark. Otherwise, TiSpark cannot be started.

TiUP does not support installing JRE automatically. You need to install it on your own. For detailed installation instruction, see How to download and install prebuilt OpenJDK packages.

If JRE 8 has already been installed on the deployment server but is not in the path of the system's default package management tool, you can specify the path of the JRE environment to be used by setting the `java_home` parameter in the topology configuration. This parameter corresponds to the `JAVA_HOME` system environment variable.

5.3.7 Geo-Distributed Deployment Topology

This document takes the typical architecture of three data centers (DC) in two cities as an example, and introduces the geo-distributed deployment architecture and the key configuration. The cities used in this example are Shanghai (referred to as `sha`) and Beijing (referred to as `bja` and `bjb`).

5.3.7.1 Topology information

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
TiDB	5	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3 10.0.1.4	10.0.1.5	Default port Global directory configuration
PD	5	4 VCore 8GB * 1	10.0.1.6 10.0.1.7 10.0.1.8 10.0.1.9	10.0.1.10	Default port Global directory configuration

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
TiKV	5	16 VCore 32GB 4TB (nvme ssd) * 1	10.0.1.11 10.0.1.12 10.0.1.13 10.0.1.14	10.0.1.15	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.16		Default port Global directory configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.7.1.1 Topology templates

- The geo-distributed topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.7.1.2 Key parameters

This section describes the key parameter configuration of the TiDB geo-distributed deployment.

TiKV parameters

- The gRPC compression format (`none` by default):

  To increase the transmission speed of gRPC packages between geo-distributed target nodes, set this parameter to `gzip`.

```
server.grpc-compression-type: gzip
```

- The label configuration:

  Since TiKV is deployed across different data centers, if the physical machines go down, the Raft Group might lose three of the default five replicas, which causes the cluster unavailability. To address this issue, you can configure the labels to enable the smart scheduling of PD, which ensures that the Raft Group does not allow three replicas to be located in TiKV instances on the same machine in the same cabinet of the same data center.

- The TiKV configuration:

  The same host-level label information is configured for the same physical machine.

```
config:
  server.labels:
    zone: bj
    dc: bja
    rack: rack1
    host: host2
```

- To prevent remote TiKV nodes from launching unnecessary Raft elections, it is required to increase the minimum and maximum number of ticks that the remote TiKV nodes need to launch an election. The two parameters are set to `0` by default.

```
raftstore.raft-min-election-timeout-ticks: 50
raftstore.raft-max-election-timeout-ticks: 60
```

Note:

Using `raftstore.raft-min-election-timeout-ticks` and `raftstore.raft-max-election-timeout-ticks` to configure larger election timeout ticks for a TiKV node can significantly decrease the likelihood of Regions on that node becoming Leaders. However, in a disaster scenario where some TiKV nodes are offline and the remaining active TiKV nodes lag behind in Raft logs, only Regions on this TiKV node with large election timeout ticks can become Leaders. Because Regions on this TiKV node must wait for at least the duration set by `raftstore.raft-min-election-timeout-ticks` before initiating an election, it is recommended to avoid setting these values excessively large to prevent potential impact on the cluster availability in such scenarios.

PD parameters

- The PD metadata information records the topology of the TiKV cluster. PD schedules the Raft Group replicas on the following four dimensions:

```
replication.location-labels: ["zone","dc","rack","host"]
```

- To ensure high availability of the cluster, adjust the number of Raft Group replicas to be 5:

```
replication.max-replicas: 5
```

- Forbid the remote TiKV Raft replica being elected as Leader:

```
label-property:
     reject-leader:
       - key: "dc"
         value: "sha"
```

Note:

Since TiDB 5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the placement rules.

For the further information about labels and the number of Raft Group replicas, see Schedule Replicas by Topology Labels.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.3.8 Hybrid Deployment Topology

This document describes the topology and key parameters of the TiKV and TiDB hybrid deployment.

The hybrid deployment is usually used in the following scenario:

The deployment machine has multiple CPU processors with sufficient memory. To improve the utilization rate of the physical machine resources, multiple instances can be deployed on a single machine, that is, TiDB and TiKV's CPU resources are isolated through NUMA node bindings. PD and Prometheus are deployed together, but their data directories need to use separate file systems.

5.3.8.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	6	32 VCore 64GB	10.0.1.1 10.0.1.2 10.0.1.3	Configure NUMA to bind CPU cores

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	16 VCore 32 GB	10.0.1.4 10.0.1.5 10.0.1.6	Configure the `location_labels` parameter

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	6	32 VCore 64GB	10.0.1.7 10.0.1.8 10.0.1.9	1. Separate the instance-level port and status_port; 2. Configure the global parameters `readpool` ↪ , `storage` ↪ and `raftstore` ↪ ; 3. Configure labels of the instance-level host; 4. Con-

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default configuration

Note:

The IP addresses of the instances are given as examples only. In your actual deployment, replace the IP addresses with your actual IP addresses.

5.3.8.1.1 Topology templates

- The simple template for the hybrid deployment
- The complex template for the hybrid deployment

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

5.3.8.1.2 Key parameters

This section introduces the key parameters when you deploy multiple instances on a single machine, which is mainly used in scenarios when multiple instances of TiDB and TiKV are deployed on a single machine. You need to fill in the results into the configuration template according to the calculation methods provided below.

- Optimize the configuration of TiKV
    - To configure `readpool` to be self-adaptive to the thread pool. By configuring the `readpool.unified.max-thread-count` parameter, you can make `readpool.storage` and `readpool.coprocessor` share a unified thread pool, and set the self-adaptive switch respectively.

- Enable `readpool.storage` and `readpool.coprocessor`:

```
readpool.storage.use-unified-pool: true
readpool.coprocessor.use-unified-pool: true
```

- The calculation method:

```
readpool.unified.max-thread-count = cores * 0.8 / the number of
    ↪ TiKV instances
```

- To configure the storage CF (all RocksDB column families) to be self-adaptive to memory. By configuring the `storage.block-cache.capacity` parameter, you can make CF automatically balance the memory usage.
  - The calculation method:

```
storage.block-cache.capacity = (MEM_TOTAL * 0.5 / the number of
    ↪ TiKV instances)
```

- If multiple TiKV instances are deployed on the same physical disk, add the `capacity` parameter in the TiKV configuration:

```
raftstore.capacity = disk total capacity / the number of TiKV
    ↪ instances
```

- The label scheduling configuration

  Since multiple instances of TiKV are deployed on a single machine, if the physical machines go down, the Raft Group might lose two of the default three replicas, which causes the cluster unavailability. To address this issue, you can use the label to enable the smart scheduling of PD, which ensures that the Raft Group has more than two replicas in multiple TiKV instances on the same machine.

  - The TiKV configuration

    The same host-level label information is configured for the same physical machine:

```
config:
  server.labels:
    host: tikv1
```

  - The PD configuration

    To enable PD to identify and scheduling Regions, configure the labels type for PD:

```
pd:
  replication.location-labels: ["host"]
```

- `numa_node` core binding

- In the instance parameter module, configure the corresponding `numa_node` parameter and add the number of CPU cores.
- Before using NUMA to bind cores, make sure that the numactl tool is installed, and confirm the information of CPUs in the physical machines. After that, configure the parameters.
- The `numa_node` parameter corresponds to the `numactl --membind` configuration.

Note:

- When editing the configuration file template, modify the required parameter, IP, port, and directory.
- Each component uses the global `<deploy_dir>/<components_name>-<port>` as their `deploy_dir` by default. For example, if TiDB specifies the `4001` port, its `deploy_dir` is `/tidb-deploy/tidb-4001` by default. Therefore, in multi-instance scenarios, when specifying a non-default port, you do not need to specify the directory again.
- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

5.4 Deploy a TiDB Cluster Using TiUP

This guide describes how to deploy a TiDB Self-Managed cluster using TiUP in the production environment.

TiUP is a cluster operation and maintenance tool introduced in TiDB v4.0. It provides TiUP cluster, a Golang-based component for managing TiDB clusters. By using the TiUP cluster, you can easily perform routine database operations, such as deploying, starting, stopping, destroying, scaling, upgrading TiDB clusters, and managing TiDB cluster parameters.

TiUP also supports deploying TiDB, TiFlash, TiCDC, and the monitoring system. This guide introduces how to deploy TiDB clusters with different topologies.

5.4.1 Step 1. Prerequisites and prechecks

Make sure that you have read the following documents:

- TiDB Software and Hardware Requirements

- TiDB Environment and System Configuration Check

In addition, it is recommended to learn the Best Practices for TiDB Security Configuration.

5.4.2 Step 2. Deploy TiUP on the control machine

You can deploy TiUP on the control machine in either of the two ways: online deployment and offline deployment.

5.4.2.1 Deploy TiUP online

> **Note:**
>
> If the TiUP environment switches to offline, refer to Deploy TiUP offline for deployment. Otherwise, TiUP cannot work properly.

Log in to the control machine using a regular user account (take the `tidb` user as an example). Subsequent TiUP installation and cluster management can be performed by the `tidb` user.

1. Install TiUP by running the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Set TiUP environment variables:

    1. Redeclare the global environment variables:

    ```
    source .bash_profile
    ```

    2. Confirm whether TiUP is installed:

    ```
    which tiup
    ```

3. Install the TiUP cluster component:

```
tiup cluster
```

4. If TiUP is already installed, update the TiUP cluster component to the latest version:

```
tiup update --self && tiup update cluster
```

If `Updated successfully!` is displayed, the TiUP cluster is updated successfully.

5. Verify the current version of your TiUP cluster:

```
tiup --binary cluster
```

5.4.2.2 Deploy TiUP offline

Perform the following steps in this section to deploy a TiDB cluster offline using TiUP:

5.4.2.2.1 Prepare the TiUP offline component package

Method 1: Download the offline binary packages (TiUP offline package included) of the target TiDB version using the following links. You need to download both the server and toolkit packages. Note that your downloading means you agree to the Privacy Policy.

```
https://download.pingcap.org/tidb-community-server-{version}-linux-{arch}.
    ↪ tar.gz
```

```
https://download.pingcap.org/tidb-community-toolkit-{version}-linux-{arch}.
    ↪ tar.gz
```

> **Tip:**
>
> `{version}` in the link indicates the version number of TiDB and `{arch ↪ }` indicates the architecture of the system, which can be `amd64` or `arm64`. For example, the download link for `v8.5.1` in the `amd64` architecture is `https://download.pingcap.org/tidb-community-toolkit- ↪ v8.5.1-linux-amd64.tar.gz`.

Method 2: Manually pack an offline component package using `tiup mirror clone`. The detailed steps are as follows:

1. Install the TiUP package manager online.

    1. Install the TiUP tool:

    ```
    curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.
        ↪ com/install.sh | sh
    ```

2. Redeclare the global environment variables:

```
source .bash_profile
```

3. Confirm whether TiUP is installed:

```
which tiup
```

2. Pull the mirror using TiUP.

1. Pull the needed components on a machine that has access to the Internet:

```
tiup mirror clone tidb-community-server-${version}-linux-amd64 ${
    ↪ version} --os=linux --arch=amd64
```

The command above creates a directory named `tidb-community-server-${version}-linux-amd64` in the current directory, which contains the component package necessary for starting a cluster.

2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

```
tar czvf tidb-community-server-${version}-linux-amd64.tar.gz tidb-
    ↪ community-server-${version}-linux-amd64
```

`tidb-community-server-${version}-linux-amd64.tar.gz` is an independent offline environment package.

3. Customize the offline mirror, or adjust the contents of an existing offline mirror.

If you want to adjust an existing offline mirror (such as adding a new version of a component), take the following steps:

1. When pulling an offline mirror, you can get an incomplete offline mirror by specifying specific information via parameters, such as the component and version information. For example, you can pull an offline mirror that includes only the offline mirror of TiUP v1.12.3 and TiUP Cluster v1.12.3 by running the following command:

```
tiup mirror clone tiup-custom-mirror-v1.12.3 --tiup v1.12.3 --
    ↪ cluster v1.12.3
```

If you only need the components for a particular platform, you can specify them using the `--os` or `--arch` parameters.

2. Refer to the step 2 of "Pull the mirror using TiUP", and send this incomplete offline mirror to the control machine in the isolated environment.

3. Check the path of the current offline mirror on the control machine in the isolated environment. If your TiUP tool is of a recent version, you can get the current mirror address by running the following command:

```
tiup mirror show
```

If the output of the above command indicates that the `show` command does not exist, you might be using an older version of TiUP. In this case, you can get the current mirror address from `$HOME/.tiup/tiup.toml`. Record this mirror address. In the following steps, `${base_mirror}` is used to refer to this address.

4. Merge an incomplete offline mirror into an existing offline mirror:

   First, copy the `keys` directory in the current offline mirror to the `$HOME/.tiup` directory:

   ```
   cp -r ${base_mirror}/keys $HOME/.tiup/
   ```

   Then use the TiUP command to merge the incomplete offline mirror into the mirror in use:

   ```
   tiup mirror merge tiup-custom-mirror-v1.12.3
   ```

5. When the above steps are completed, check the result by running the `tiup list` command. In this document's example, the outputs of both `tiup list tiup` and `tiup list cluster` show that the corresponding components of `v1.12.3` are available.

5.4.2.2.2 Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following commands:

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz && \
sh tidb-community-server-${version}-linux-amd64/local_install.sh && \
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically runs the `tiup mirror set tidb-community-server-${version}-linux-amd64` command to set the current mirror address to `tidb-community-server-${version}-linux-amd64`.

5.4.2.2.3 Merge offline packages

If you download the offline packages via download links, you need to merge the server package and the toolkit package into an offline mirror. If you manually package the offline component packages using the `tiup mirror clone` command, you can skip this step.

Run the following commands to merge the offline toolkit package into the server package directory:

```
tar xf tidb-community-toolkit-${version}-linux-amd64.tar.gz
ls -ld tidb-community-server-${version}-linux-amd64 tidb-community-toolkit-${version}-linux-amd64
```

```
cd tidb-community-server-${version}-linux-amd64/
cp -rp keys ~/.tiup/
tiup mirror merge ../tidb-community-toolkit-${version}-linux-amd64
```

To switch the mirror to another directory, run the `tiup mirror set <mirror-dir>` command. To switch the mirror to the online environment, run the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

5.4.3 Step 3. Initialize the cluster topology file

Run the following command to create a cluster topology file:

```
tiup cluster template > topology.yaml
```

In the following two common scenarios, you can generate recommended topology templates by running commands:

- For hybrid deployment: Multiple instances are deployed on a single machine. For details, see Hybrid Deployment Topology.

  ```
  tiup cluster template --full > topology.yaml
  ```

- For geo-distributed deployment: TiDB clusters are deployed in geographically distributed data centers. For details, see Geo-Distributed Deployment Topology.

  ```
  tiup cluster template --multi-dc > topology.yaml
  ```

Run `vi topology.yaml` to see the content of the configuration file:

```
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"
server_configs: {}
pd_servers:
  - host: 10.0.1.4
  - host: 10.0.1.5
  - host: 10.0.1.6
tidb_servers:
  - host: 10.0.1.7
  - host: 10.0.1.8
  - host: 10.0.1.9
tikv_servers:
  - host: 10.0.1.1
```

```
  - host: 10.0.1.2
  - host: 10.0.1.3
monitoring_servers:
  - host: 10.0.1.4
grafana_servers:
  - host: 10.0.1.4
alertmanager_servers:
  - host: 10.0.1.4
```

The following examples cover six common scenarios. You need to modify the configuration file (named `topology.yaml`) according to the topology description and templates in the corresponding links. For other scenarios, edit the configuration template accordingly.

Application	Configuration task	Configuration file template	Topology description
OLTP	Deploy minimal topology	Simple minimal configuration template Full minimal configuration template	This is the basic cluster topology, including tidb-server, tikv-server, and pd-server.

Application	Configuration task	Configuration file template	Topology description
HTAP	Deploy the TiFlash topology	Simple TiFlash configuration template Full TiFlash configuration template	This is to deploy TiFlash along with the minimal cluster topology. TiFlash is a columnar storage engine, and gradually becomes a standard cluster topology.

Application	Configuration task	Configuration file template	Topology description
Replicate incremental data using TiCDC	Deploy the TiCDC topology	Simple TiCDC configuration template Full TiCDC configuration template	This is to deploy TiCDC along with the minimal cluster topology. TiCDC supports multiple downstream platforms, such as TiDB, MySQL, Kafka, MQ, and storage services.

Application	Configuration task	Configuration file template	Topology description
Use OLAP on Spark	Deploy the TiSpark topology	Simple TiSpark configuration template Full TiSpark configuration template	This is to deploy TiSpark along with the minimal cluster topology. TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer the OLAP queries. Currently, TiUP cluster's support

Application	Configuration task	Configuration file template	Topology description
Deploy multiple instances on a single machine	Deploy a hybrid topology	Simple configuration template for hybrid deployment Full configuration template for hybrid deployment	The deployment topologies also apply when you need to add extra configurations for the directory, port, resource ratio, and label.

Application	Configuration task	Configuration file template	Topology description
Deploy TiDB clusters across data centers	Deploy a geo-distributed deployment topology	Configuration template for geo-distributed deployment	This topology takes the typical architecture of three data centers in two cities as an example. It introduces the geo-distributed deployment architecture and the key configura-

Application	Configuration task	Configuration file template	Topology description

Note:

- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in the `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow-threshold`. For more formats, see TiUP configuration template.
- If you need to specify the user group name to be created on the target machine, see this example.

For more configuration description, see the following configuration examples:

- TiDB `config.toml.example`
- TiKV `config.toml.example`
- PD `config.toml.example`
- TiFlash `config.toml.example`

5.4.4 Step 4. Run the deployment command

Note:

You can securely authenticate users used for initialization when deploying a cluster via TiUP (specified via `--user`) using either a key or a cross-password:

- If you use secret keys, specify the path of the keys through `-i` or `--identity_file`.
- If you use passwords, add the `-p` flag to enter the password interaction window.
- If password-free login to the target machine has been configured, no authentication is required.

In general, the users and groups used by TiUP to actually execute the processes (specified via `topology.yaml`, and the default value is `tidb`) are created automatically on the target machine, with the following exceptions:

- The user name configured in `topology.yaml` already exists on the target machine.
- You have used the `--skip-create-user` option in the command line to explicitly skip the step of creating the user.

Regardless of whether the users and groups agreed upon in `topology.yaml` are created automatically, TiUP automatically generates a pair of ssh keys and sets up a secret-free login for that user on each machine. This user and ssh key will be used to manage the machine for all subsequent operations, while the user and password used for initialization will not be used any more after the deployment is complete.

Before you run the `deploy` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

1. Check for potential risks:

```
tiup cluster check ./topology.yaml --user root [-p] [-i /home/root/.ssh
    ↪ /gcp_rsa]
```

2. Enable automatic repair:

```
tiup cluster check ./topology.yaml --apply --user root [-p] [-i /home/
    ↪ root/.ssh/gcp_rsa]
```

3. Deploy a TiDB cluster:

```
tiup cluster deploy tidb-test v8.5.1 ./topology.yaml --user root [-p]
    ↪ [-i /home/root/.ssh/gcp_rsa]
```

In the `tiup cluster deploy` command above:

- `tidb-test` is the name of the TiDB cluster to be deployed.
- `v8.5.1` is the version of the TiDB cluster to be deployed. You can see the latest supported versions by running `tiup list tidb`.
- `topology.yaml` is the initialization configuration file.

- `--user root` indicates logging into the target machine as the `root` user to complete the cluster deployment. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

At the end of the output log, you will see `Deployed cluster` `tidb-test` `successfully`. This indicates that the deployment is successful.

5.4.5 Step 5. Check the clusters managed by TiUP

```
tiup cluster list
```

TiUP supports managing multiple TiDB clusters. The preceding command outputs information of all the clusters currently managed by TiUP, including the cluster name, deployment user, version, and secret key information:

5.4.6 Step 6. Check the status of the deployed TiDB cluster

For example, run the following command to check the status of the `tidb-test` cluster:

```
tiup cluster display tidb-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information.

5.4.7 Step 7. Start a TiDB cluster

Since TiUP cluster v1.9.0, safe start is introduced as a new start method. Starting a database using this method improves the security of the database. It is recommended that you use this method.

After safe start, TiUP automatically generates a password for the TiDB root user and returns the password in the command-line interface.

Note:

- After safe start of a TiDB cluster, you cannot log in to TiDB using a root user without a password. Therefore, you need to record the password returned in the command output for future logins.

- The password is generated only once. If you do not record it or you forgot it, refer to Forget the `root` password to change the password.

Method 1: Safe start

```
tiup cluster start tidb-test --init
```

If the output is as follows, the start is successful:

```
Started cluster `tidb-test` successfully.
The root password of TiDB database has been changed.
The new password is: 'y_+3Hwp=*AWz8971s6'.
Copy and record it to somewhere safe, it is only displayed once, and will
    ↪ not be stored.
The generated password can NOT be got again in future.
```

Method 2: Standard start

```
tiup cluster start tidb-test
```

If the output log includes `Started cluster `tidb-test` successfully`, the start is successful. After standard start, you can log in to a database using a root user without a password.

5.4.8 Step 8. Verify the running status of the TiDB cluster

```
tiup cluster display tidb-test
```

If the output log shows `Up` status, the cluster is running properly.

5.4.9 See also

If you have deployed TiFlash along with the TiDB cluster, see the following documents:

- Use TiFlash
- Maintain a TiFlash Cluster
- TiFlash Alert Rules and Solutions
- Troubleshoot TiFlash

If you have deployed TiCDC along with the TiDB cluster, see the following documents to stream data:

- Changefeed Overview

- Manage Changefeed
- Troubleshoot TiCDC
- TiCDC FAQs

If you want to scale out or scale in your TiDB cluster without interrupting the online services, see Scale a TiDB Cluster Using TiUP.

5.5 Deploy a TiDB Cluster on Kubernetes

You can use TiDB Operator to deploy TiDB clusters on Kubernetes. TiDB Operator is an automatic operation system for TiDB clusters on Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB on Kubernetes documentation is independent of the TiDB documentation. For detailed steps on how to deploy TiDB clusters on Kubernetes using TiDB Operator, learn the relationship between TiDB Operator and TiDB versions, and see the corresponding TiDB on Kubernetes documentation.

5.6 Check Cluster Status

After a TiDB cluster is deployed, you need to check whether the cluster runs normally. This document introduces how to check the cluster status using TiUP commands, TiDB Dashboard and Grafana, and how to log into the TiDB database to perform simple SQL operations.

5.6.1 Check the TiDB cluster status

This section describes how to check the TiDB cluster status using TiUP commands, TiDB Dashboard, and Grafana.

5.6.1.1 Use TiUP

Use the `tiup cluster display <cluster-name>` command to check the cluster status. For example:

```
tiup cluster display tidb-test
```

Expected output: If the `Status` information of each node is `Up`, the cluster runs normally.

5.6.1.2 Use TiDB Dashboard

1. Log in to TiDB Dashboard at `${pd-ip}:${pd-port}/dashboard`. The username and password is the same as that of the TiDB `root` user. If you have modified the `root` password, enter the modified password. The password is empty by default.

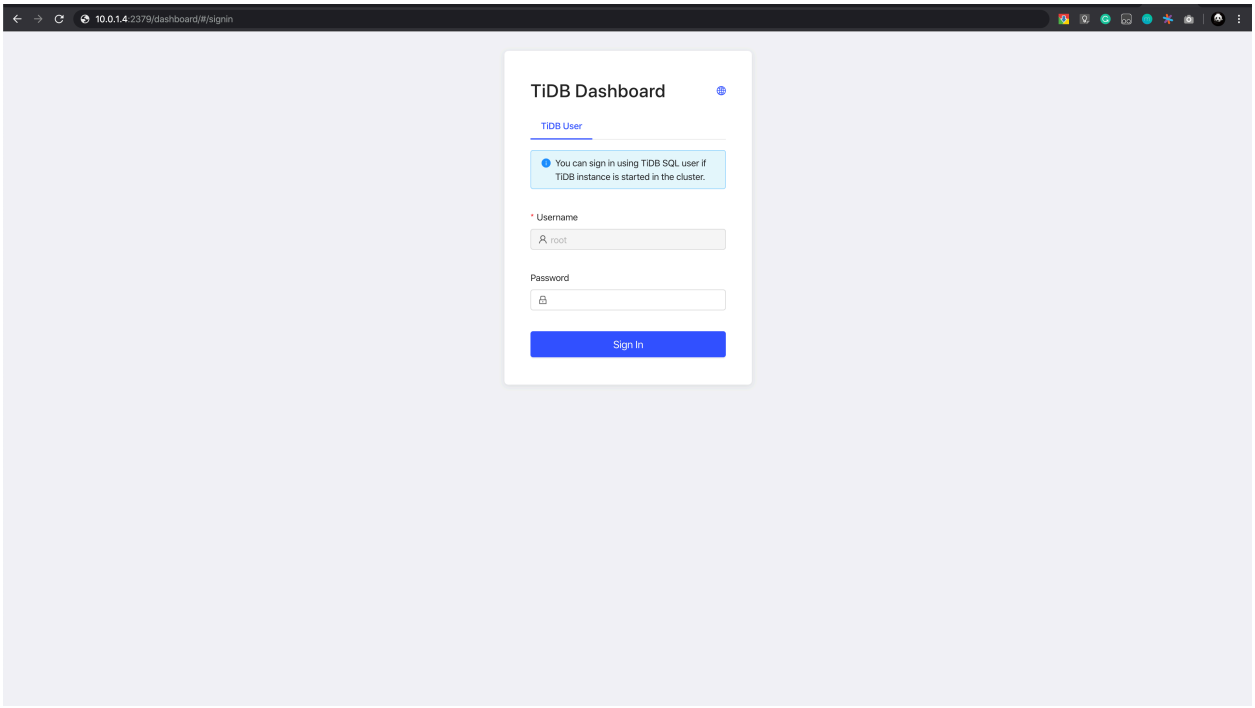

Figure 92: TiDB-Dashboard

2. The home page displays the node information in the TiDB cluster.

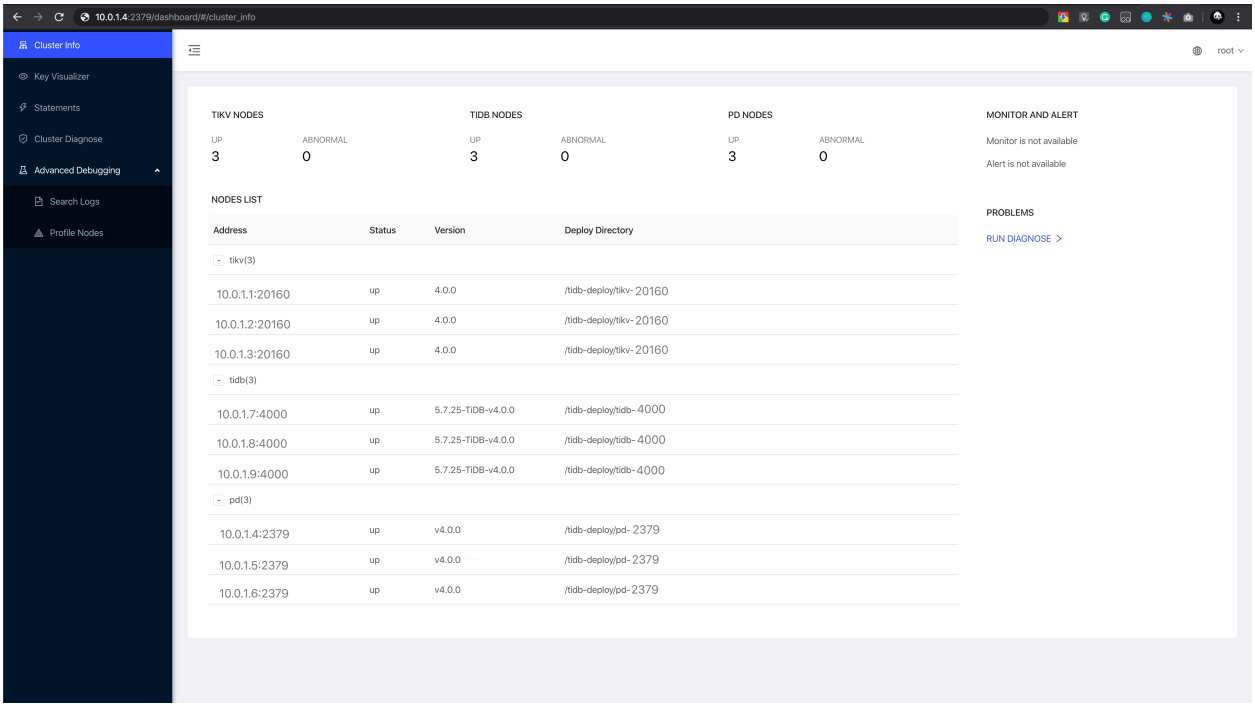

Figure 93: TiDB-Dashboard-status

5.6.1.3 Use Grafana

1. Log in to the Grafana monitoring at `${Grafana-ip}:3000`. The default username and password are both `admin`.

2. To check the TiDB port status and load monitoring information, click **Overview**.

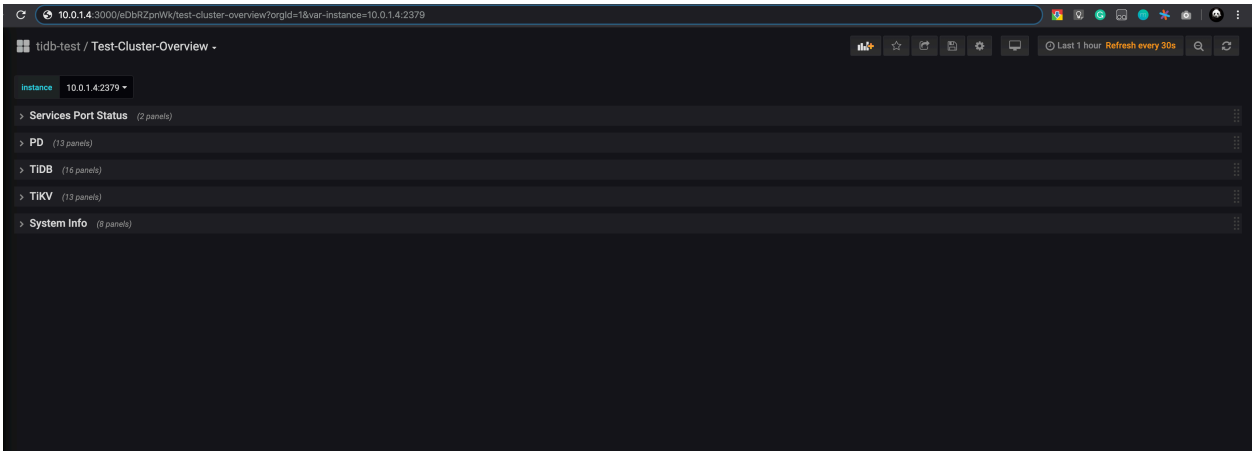

Figure 94: Grafana-overview

5.6.2 Log in to the database and perform simple operations

> **Note:**
>
> Install the MySQL client before you log in to the database.

Log in to the database by running the following command:

```
mysql -u root -h ${tidb_server_host_IP_address} -P 4000
```

`${tidb_server_host_IP_address}` is one of the IP addresses set for `tidb_servers` when you initialize the cluster topology file, such as `10.0.1.7`.

The following information indicates successful login:

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 8.0.11-TiDB-v8.5.1 TiDB Server (Apache License 2.0)
    ↪ Community Edition, MySQL 8.0 compatible

affiliates. Other names may be trademarks of their respective
owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
    ↪ statement.
```

5.6.2.1 Database operations

- Check the version of TiDB:

  ```
  select tidb_version()\G
  ```

  Expected output:

  ```
  *************************** 1. row ***************************
  tidb_version(): Release Version: v5.0.0
  Edition: Community
  Git Commit Hash: 689a6b6439ae7835947fcaccf329a3fc303986cb
  Git Branch: HEAD
  UTC Build Time: 2020-05-28 11:09:45
  GoVersion: go1.13.4
  ```

```
Race Enabled: false
TiKV Min Version: v3.0.0-60965b006877ca7234adaced7890d7b029ed1306
Check Table Before Drop: false
1 row in set (0.00 sec)
```

- Create a database named `pingcap`:

```
create database pingcap;
```

Expected output:

```
Query OK, 0 rows affected (0.10 sec)
```

Switch to the `pingcap` database:

```
use pingcap;
```

Expected output:

```
Database changed
```

- Create a table named `tab_tidb`:

```
CREATE TABLE `tab_tidb` (
`id` int NOT NULL AUTO_INCREMENT,
`name` varchar(20) NOT NULL DEFAULT '',
`age` int NOT NULL DEFAULT 0,
`version` varchar(20) NOT NULL DEFAULT '',
PRIMARY KEY (`id`),
KEY `idx_age` (`age`));
```

Expected output:

```
Query OK, 0 rows affected (0.11 sec)
```

- Insert data:

```
insert into `tab_tidb` values (1,'TiDB',5,'TiDB-v5.0.0');
```

Expected output:

```
Query OK, 1 row affected (0.03 sec)
```

- View the entries in `tab_tidb`:

```
select * from tab_tidb;
```

Expected output:

```
+----+------+-----+-------------+
| id | name | age | version |
+----+------+-----+-------------+
|  1 | TiDB |  5 | TiDB-v5.0.0 |
+----+------+-----+-------------+
1 row in set (0.00 sec)
```

- View the store state, `store_id`, capacity, and uptime of TiKV:

```
select STORE_ID,ADDRESS,STORE_STATE,STORE_STATE_NAME,CAPACITY,AVAILABLE
    ↪ ,UPTIME from INFORMATION_SCHEMA.TIKV_STORE_STATUS;
```

Expected output:

```
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
| STORE_ID | ADDRESS         | STORE_STATE | STORE_STATE_NAME | CAPACITY
    ↪  | AVAILABLE | UPTIME    |
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-

```
exit
```

Expected output:

```
Bye
```

5.7 Test Cluster Performance

5.7.1 How to Test TiDB Using Sysbench

It is recommended to use Sysbench 1.0 or later, which can be downloaded here.

5.7.1.1 Test plan

5.7.1.1.1 TiDB configuration

Higher log level means fewer logs to be printed and thus positively influences TiDB performance. Specifically, you can add the following command in the TiUP configuration file:

```
server_configs:
  tidb:
    log.level: "error"
```

It is also recommended to make sure `tidb_enable_prepared_plan_cache` is enabled and that you allow sysbench to use prepared statements by using `--db-ps-mode=auto`. See the SQL Prepared Execution Plan Cache for documentation about what the SQL plan cache does and how to monitor it.

> **Note:**
>
> In different versions of Sysbench, the default value of `db-ps-mode` might be different. It is recommended to explicitly specify it in the command.

5.7.1.1.2 TiKV configuration

Higher log level also means better performance for TiKV.

There are multiple Column Families on TiKV cluster which are mainly used to store different types of data, including Default CF, Write CF, and Lock CF. For the Sysbench test, you only need to focus on Default CF and Write CF. The Column Family that is used to import data has a constant proportion among TiDB clusters:

Default CF : Write CF = 4 : 1

Configuring the block cache of RocksDB on TiKV should be based on the machine's memory size, in order to make full use of the memory. To deploy a TiKV cluster on a 40GB virtual machine, it is recommended to configure the block cache as follows:

```
server_configs:
  tikv:
    log-level: "error"
    rocksdb.defaultcf.block-cache-size: "24GB"
    rocksdb.writecf.block-cache-size: "6GB"
```

You can also configure TiKV to share block cache:

```
server_configs:
  tikv:
    storage.block-cache.capacity: "30GB"
```

For more detailed information on TiKV performance tuning, see Tune TiKV Performance.

5.7.1.2 Test process

> **Note:**
>
> The test in this document was performed without load balancing tools such as HAproxy. We run the Sysbench test on individual TiDB node and added the results up. The load balancing tools and the parameters of different versions might also impact the performance.

5.7.1.2.1 Sysbench configuration

This is an example of the Sysbench configuration file:

```
mysql-host={TIDB_HOST}
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads={8, 16, 32, 64, 128, 256}
report-interval=10
db-driver=mysql
```

The above parameters can be adjusted according to actual needs. Among them, `TIDB_HOST` is the IP address of the TiDB server (because we cannot include multiple addresses in the configuration file), `threads` is the number of concurrent connections in the test, which can be adjusted in "8, 16, 32, 64, 128, 256". When importing data, it is recommended to set threads = 8 or 16. After adjusting `threads`, save the file named **config**.

See the following as a sample **config** file:

```
mysql-host=172.16.30.33
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
```

```
time=600
threads=16
report-interval=10
db-driver=mysql
```

5.7.1.2.2 Data import

> **Note:**
>
> If you enable the optimistic transaction model (TiDB uses the pessimistic transaction mode by default), TiDB rolls back transactions when a concurrency conflict is found. Setting `tidb_disable_txn_auto_retry` to `off` turns on the automatic retry mechanism after meeting a transaction conflict, which can prevent Sysbench from quitting because of the transaction conflict error.

Before importing the data, it is necessary to make some settings to TiDB. Execute the following command in MySQL client:

```
set global tidb_disable_txn_auto_retry = off;
```

Then exit the client.

Restart MySQL client and execute the following SQL statement to create a database `sbtest`:

```
create database sbtest;
```

Adjust the order in which Sysbench scripts create indexes. Sysbench imports data in the order of "Build Table -> Insert Data -> Create Index", which takes more time for TiDB to import data. Users can adjust the order to speed up the import of data. Suppose that you use the Sysbench version 1.0.20. You can adjust the order in either of the following two ways:

- Download the modified oltp_common.lua file for TiDB and overwrite the `/usr/share/sysbench/oltp_common.lua` file with it.
- In `/usr/share/sysbench/oltp_common.lua`, move the lines 235-240 to be right behind the line 198.

> **Note:**
>
> This operation is optional and is only to save the time consumed by data import.

At the command line, enter the following command to start importing data. The config file is the one configured in the previous step:

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 prepare
```

5.7.1.2.3 Warming data and collecting statistics

To warm data, we load data from disk into the block cache of memory. The warmed data has significantly improved the overall performance of the system. It is recommended to warm data once after restarting the cluster.

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 prewarm
```

5.7.1.2.4 Point select test command

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 --db-ps-mode=auto --rand-type=uniform run
```

5.7.1.2.5 Update index test command

```
sysbench --config-file=config oltp_update_index --tables=32 --table-size
    ↪ =10000000 --db-ps-mode=auto --rand-type=uniform run
```

5.7.1.2.6 Read-only test command

```
sysbench --config-file=config oltp_read_only --tables=32 --table-size
    ↪ =10000000 --db-ps-mode=auto --rand-type=uniform run
```

5.7.1.3 Common issues

5.7.1.3.1 TiDB and TiKV are both properly configured under high concurrency, why is the overall performance still low?

This issue often has things to do with the use of a proxy. You can add pressure on single TiDB server, sum each result up and compare the summed result with the result with proxy.

Take HAproxy as an example. The parameter `nbproc` can increase the number of processes it can start at most. Later versions of HAproxy also support `nbthread` and `cpu-map`. All of these can mitigate the negative impact of proxy use on performance.

5.7.1.3.2 Under high concurrency, why is the CPU utilization rate of TiKV still low?

Although the overall CPU utilization rate is low for TiKV, the CPU utilization rate of some modules in the cluster might be high.

The maximum concurrency limits for other modules on TiKV, such as storage readpool, coprocessor, and gRPC, can be adjusted through the TiKV configuration file.

The actual CPU usage can be observed through Grafana's TiKV Thread CPU monitor panel. If there is a bottleneck on the modules, it can be adjusted by increasing the concurrency of the modules.

5.7.1.3.3 Given that TiKV has not yet reached the CPU usage bottleneck under high concurrency, why is TiDB's CPU utilization rate still low?

CPU of NUMA architecture is used on some high-end equipment where cross-CPU access to remote memory will greatly reduce performance. By default, TiDB will use all CPUs of the server, and goroutine scheduling will inevitably lead to cross-CPU memory access.

Therefore, it is recommended to deploy n TiDBs (n is the number of NUMA CPUs) on the server of NUMA architecture, and meanwhile set the TiDB parameter `max-procs` to a value that is the same as the number of NUMA CPU cores.

5.7.2 How to Run TPC-C Test on TiDB

This document describes how to test TiDB using TPC-C.

TPC-C is an online transaction processing (OLTP) benchmark. It tests the OLTP system by using a commodity sales model that involves the following five transactions of different types:

- NewOrder
- Payment
- OrderStatus
- Delivery
- StockLevel

5.7.2.1 Prepare

Before testing, TPC-C Benchmark specifies the initial state of the database, which is the rule for data generation in the database. The `ITEM` table contains a fixed number of 100,000 items, while the number of warehouses can be adjusted. If there are W records in the `WAREHOUSE` table, then:

- The `STOCK` table has W * 100,000 records (Each warehouse corresponds to the stock data of 100,000 items)

- The `DISTRICT` table has W * 10 records (Each warehouse provides services to 10 districts)
- The `CUSTOMER` table has W * 10 * 3,000 records (Each district has 3,000 customers)
- The `HISTORY` table has W * 10 * 3,000 records (Each customer has one transaction history)
- The `ORDER` table has W * 10 * 3,000 records (Each district has 3,000 orders and the last 900 orders generated are added to the `NEW-ORDER` table. Each order randomly generates 5 ~ 15 ORDER-LINE records.)

In this document, the testing uses 1,000 warehouses as an example to test TiDB.

TPC-C uses tpmC (transactions per minute) to measure the maximum qualified throughput (MQTh, Max Qualified Throughput). The transactions are the NewOrder transactions and the final unit of measure is the number of new orders processed per minute.

The test in this document is implemented based on go-tpc. You can download the test program using TiUP commands.

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see TiUP Bench.

Assume that you have deployed a TiDB cluster with two TiDB servers located at 172.16.5.140 and 172.16.5.141, and both servers are listening on port 4000. You can run a TPC-C test with the following steps.

5.7.2.2 Load data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test. This section provides the following command to load data.

Execute the following TiUP command in Shell:

```
tiup bench tpcc -H 172.16.5.140,172.16.5.141 -P 4000 -D tpcc --warehouses
    ↪ 1000 --threads 20 prepare
```

Based on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller `WAREHOUSE` value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

5.7.2.3 Run the test

Execute the following command to run the test:

```
tiup bench tpcc -H 172.16.5.140,172.16.5.141 -P 4000 -D tpcc --warehouses
    ↪ 1000 --threads 100 --time 10m run
```

During the test, test results are continuously printed on the console:

```
[Current] NEW_ORDER - Takes(s): 4.6, Count: 5, TPM: 65.5, Sum(ms): 4604, Avg
    ↪ (ms): 920, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms): 1500
[Current] ORDER_STATUS - Takes(s): 1.4, Count: 1, TPM: 42.2, Sum(ms): 256,
    ↪ Avg(ms): 256, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
[Current] PAYMENT - Takes(s): 6.9, Count: 5, TPM: 43.7, Sum(ms): 2208, Avg(
    ↪ ms): 441, 90th(ms): 512, 99th(ms): 512, 99.9th(ms): 512
[Current] STOCK_LEVEL - Takes(s): 4.4, Count: 1, TPM: 13.8, Sum(ms): 224,
    ↪ Avg(ms): 224, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
...
```

After the test is finished, the test summary results are printed:

```
[Summary] DELIVERY - Takes(s): 455.2, Count: 32, TPM: 4.2, Sum(ms): 44376,
    ↪ Avg(ms): 1386, 90th(ms): 2000, 99th(ms): 4000, 99.9th(ms): 4000
[Summary] DELIVERY_ERR - Takes(s): 455.2, Count: 1, TPM: 0.1, Sum(ms): 953,
    ↪ Avg(ms): 953, 90th(ms): 1000, 99th(ms): 1000, 99.9th(ms): 1000
[Summary] NEW_ORDER - Takes(s): 487.8, Count: 314, TPM: 38.6, Sum(ms):
    ↪ 282377, Avg(ms): 899, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms):
    ↪ 1500
[Summary] ORDER_STATUS - Takes(s): 484.6, Count: 29, TPM: 3.6, Sum(ms):
    ↪ 8423, Avg(ms): 290, 90th(ms): 512, 99th(ms): 1500, 99.9th(ms): 1500
[Summary] PAYMENT - Takes(s): 490.1, Count: 321, TPM: 39.3, Sum(ms): 144708,
    ↪  Avg(ms): 450, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1500
[Summary] STOCK_LEVEL - Takes(s): 487.6, Count: 41, TPM: 5.0, Sum(ms): 9318,
    ↪  Avg(ms): 227, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1000
```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

5.7.2.4 Clean up test data

Execute the following command to clean up the test data:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 cleanup
```

5.7.3 How to Run CH-benCHmark Test on TiDB

This document describes how to test TiDB using CH-benCHmark.

CH-benCHmark is a mixed workload containing both TPC-C and TPC-H tests. It is the most common workload to test HTAP systems. For more information, see The mixed workload CH-benCHmark.

Before running the CH-benCHmark test, you need to deploy TiFlash first, which is a TiDB's HTAP component. After you deploy TiFlash and create TiFlash replicas, TiKV will replicate the latest data of TPC-C online transactions to TiFlash in real time, and the TiDB

optimizer will automatically push down OLAP queries from TPC-H workload to the MPP engine of TiFlash for efficient execution.

The CH-benCHmark test in this document is implemented based on go-tpc. You can download the test program using the following TiUP command:

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see TiUP Bench.

5.7.3.1 Load data

5.7.3.1.1 Load TPC-C data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test.

Taking 1000 warehouses as an example, you can execute the following TiUP command in shell for data load and test. Note that you need to replace `172.16.5.140` and `4000` in this document with your TiDB host and port values.

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 prepare -T
    ↪ 32
```

Depending on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller warehouse value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 check` command to validate the data correctness.

5.7.3.1.2 Load additional tables and views required for TPC-H

Run the following TiUP command in the shell:

```
tiup bench ch -H 172.16.5.140 -P 4000 -D tpcc prepare
```

The following is the log output:

```
creating nation
creating region
creating supplier
generating nation table
generate nation table done
generating region table
generate region table done
generating suppliers table
generate suppliers table done
creating view revenue1
```

5.7.3.2 Create TiFlash replicas

After TiFlash is deployed, TiFlash does not automatically replicate TiKV data. You need to execute the following SQL statement to create TiFlash replicas for the `tpcc` database. Once the specified TiFlash replicas are created, TiKV automatically replicates the latest data to TiFlash in real-time. In the following example, two TiFlash nodes are deployed in the cluster and the replica number is set to 2.

```
ALTER DATABASE tpcc SET tiflash replica 2;
```

To check whether the replication of all tables in the `tpcc` database is complete, execute the following statement, in which the `WHERE` clause is used to specify the databases and tables to be checked. If you want to check the replication status of all databases, remove the `WHERE` clause from the statement.

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'tpcc
    ↪ ';
```

In the result of the above statement:

- `AVAILABLE` indicates whether the TiFlash replica of a specific table is available or not. `1` means available and `0` means unavailable. Once a replica becomes available, this status does not change anymore.
- `PROGRESS` means the progress of the replication. The value is between `0` and `1`. `1` means that the replication is complete for the TiFlash replica.

5.7.3.3 Collect statistics

To ensure that the TiDB optimizer can generate the optimal execution plan, execute the following SQL statements to collect statistics in advance. **Be sure to set `tidb_analyze_column_options` to `ALL`, otherwise collecting statistics can result in a significant drop in query performance.**

```
set global tidb_analyze_column_options='ALL';
analyze table customer;
analyze table district;
analyze table history;
analyze table item;
analyze table new_order;
analyze table order_line;
analyze table orders;
analyze table stock;
analyze table warehouse;
analyze table nation;
analyze table region;
analyze table supplier;
```

5.7.3.4 Run the test

Taking 50 TP concurrency and 1 AP concurrency as an example, execute the following command to run the test:

```
tiup bench ch --host 172.16.5.140 -P4000 --warehouses 1000 run -D tpcc -T 50
    ↪  -t 1 --time 1h
```

During the test, test results are continuously printed on the console. For example:

```
[Current] NEW_ORDER - Takes(s): 10.0, Count: 13524, TPM: 81162.0, Sum(ms):
    ↪ 998317.6, Avg(ms): 73.9, 50th(ms): 71.3, 90th(ms): 100.7, 95th(ms):
    ↪ 113.2, 99th(ms): 159.4, 99.9th(ms): 209.7, Max(ms): 243.3
[Current] ORDER_STATUS - Takes(s): 10.0, Count: 1132, TPM: 6792.7, Sum(ms):
    ↪ 16196.6, Avg(ms): 14.3, 50th(ms): 13.1, 90th(ms): 24.1, 95th(ms):
    ↪ 27.3, 99th(ms): 37.7, 99.9th(ms): 50.3, Max(ms): 52.4
[Current] PAYMENT - Takes(s): 10.0, Count: 12977, TPM: 77861.1, Sum(ms):
    ↪ 773982.0, Avg(ms): 59.7, 50th(ms): 56.6, 90th(ms): 88.1, 95th(ms):
    ↪ 100.7, 99th(ms): 151.0, 99.9th(ms): 201.3, Max(ms): 243.3
[Current] STOCK_LEVEL - Takes(s): 10.0, Count: 1134, TPM: 6806.0, Sum(ms):
    ↪ 31220.9, Avg(ms): 27.5, 50th(ms): 25.2, 90th(ms): 37.7, 95th(ms):
    ↪ 44.0, 99th(ms): 71.3, 99.9th(ms): 117.4, Max(ms): 125.8
[Current] Q11  - Count: 1, Sum(ms): 3682.9, Avg(ms): 3683.6
[Current] DELIVERY - Takes(s): 10.0, Count: 1167, TPM: 7002.6, Sum(ms):
    ↪ 170712.9, Avg(ms): 146.3, 50th(ms): 142.6, 90th(ms): 192.9, 95th(ms):
    ↪  209.7, 99th(ms): 251.7, 99.9th(ms): 335.5, Max(ms): 385.9
[Current] NEW_ORDER - Takes(s): 10.0, Count: 13238, TPM: 79429.5, Sum(ms):
    ↪ 1010795.3, Avg(ms): 76.4, 50th(ms): 75.5, 90th(ms): 104.9, 95th(ms):
    ↪ 117.4, 99th(ms): 159.4, 99.9th(ms): 234.9, Max(ms): 352.3
[Current] ORDER_STATUS - Takes(s): 10.0, Count: 1224, TPM: 7350.6, Sum(ms):
    ↪ 17874.1, Avg(ms): 14.6, 50th(ms): 13.6, 90th(ms): 23.1, 95th(ms):
    ↪ 27.3, 99th(ms): 37.7, 99.9th(ms): 54.5, Max(ms): 60.8
[Current] PAYMENT - Takes(s): 10.0, Count: 12650, TPM: 75901.1, Sum(ms):
    ↪ 761981.3, Avg(ms): 60.3, 50th(ms): 56.6, 90th(ms): 88.1, 95th(ms):
    ↪ 104.9, 99th(ms): 159.4, 99.9th(ms): 218.1, Max(ms): 318.8
[Current] STOCK_LEVEL - Takes(s): 10.0, Count: 1179, TPM: 7084.9, Sum(ms):
    ↪ 32829.8, Avg(ms): 27.9, 50th(ms): 26.2, 90th(ms): 37.7, 95th(ms):
    ↪ 44.0, 99th(ms): 71.3, 99.9th(ms): 100.7, Max(ms): 117.4
[Current] Q12  - Count: 1, Sum(ms): 9945.8, Avg(ms): 9944.7
[Current] Q13  - Count: 1, Sum(ms): 1729.6, Avg(ms): 1729.6
...
```

After the test is finished, the test summary results are printed. For example:

```
Finished: 50 OLTP workers, 1 OLAP workers
[Summary] DELIVERY - Takes(s): 3599.7, Count: 501795, TPM: 8363.9, Sum(ms):
    ↪ 63905178.8, Avg(ms): 127.4, 50th(ms): 125.8, 90th(ms): 167.8, 95th(ms
    ↪ ): 184.5, 99th(ms): 226.5, 99.9th(ms): 318.8, Max(ms): 604.0
```

```
[Summary] DELIVERY_ERR - Takes(s): 3599.7, Count: 14, TPM: 0.2, Sum(ms):
   ↪ 1027.7, Avg(ms): 73.4, 50th(ms): 71.3, 90th(ms): 109.1, 95th(ms):
   ↪ 109.1, 99th(ms): 113.2, 99.9th(ms): 113.2, Max(ms): 113.2
[Summary] NEW_ORDER - Takes(s): 3599.7, Count: 5629221, TPM: 93826.9, Sum(ms
   ↪ ): 363758020.7, Avg(ms): 64.6, 50th(ms): 62.9, 90th(ms): 88.1, 95th(
   ↪ ms): 100.7, 99th(ms): 130.0, 99.9th(ms): 184.5, Max(ms): 570.4
[Summary] NEW_ORDER_ERR - Takes(s): 3599.7, Count: 20, TPM: 0.3, Sum(ms):
   ↪ 404.2, Avg(ms): 20.2, 50th(ms): 18.9, 90th(ms): 37.7, 95th(ms): 50.3,
   ↪  99th(ms): 56.6, 99.9th(ms): 56.6, Max(ms): 56.6
[Summary] ORDER_STATUS - Takes(s): 3599.8, Count: 500318, TPM: 8339.0, Sum(

```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 check` command to validate the data correctness.

6 Migrate

6.1 Data Migration Overview

This document gives an overview of the data migration solutions that you can use with TiDB. The data migration solutions are as follows:

- Full data migration.
    - To import Amazon Aurora snapshots, CSV files, or SQL dump files into TiDB, you can use TiDB Lightning to perform the full migration.
    - To export all TiDB data as CSV files or SQL dump files, you can use Dumpling to perform the full migration, which makes data migration from MySQL or MariaDB easier.
    - To migrate all data from a database with a small data size volume (for example, less than 1 TiB), you can also use TiDB Data Migration (DM).
- Quick initialization of TiDB. TiDB Lightning supports quickly importing data and can quickly initialize a specific table in TiDB. Before you use this feature, pay attention that the quick initialization has a great impact on TiDB and the cluster does not provide services during the initialization period.
- Incremental replication. You can use TiDB DM to replicate binlogs from MySQL, MariaDB, or Aurora to TiDB, which greatly reduces the window downtime during the replication period.
- Data replication between TiDB clusters. TiDB supports backup and restore. This feature can initialize a snapshot in an existing TiDB cluster to a new TiDB cluster.
- Incremental replication between TiDB clusters. TiDB supports disaster recovery between homogeneous databases to ensure eventual data consistency of primary and secondary databases after a disaster event. It works only when both primary and secondary clusters are TiDB.

You might choose different migration solutions according to the database type, deployment location, application data size, and application needs. The following sections introduce some common migration scenarios, and you can refer to these sections to determine the most suitable solution according to your needs.

6.1.1 Migrate data from Aurora MySQL to TiDB

When you migrate data from Aurora to a TiDB cluster deployed on AWS, your data migration takes two operations: full data migration and incremental replication. You can choose the corresponding operation according to your application needs.

- Migrate Data from Amazon Aurora to TiDB.

6.1.2 Migrate data from MySQL to TiDB

If cloud storage (S3) service is not used, the network connectivity is good, and the network latency is low, you can follow instructions in Migrate Small Datasets from MySQL to TiDB to migrate data from MySQL to TiDB.

If you have a high demand on migration speed, or if the data size is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly import data. Then, you can use DM to replicate incremental data (binlog) based on your application needs. See Migrate Large Datasets from MySQL to TiDB.

6.1.3 Migrate and merge MySQL shards into TiDB

Suppose that your application uses MySQL shards for data storage, and you need to migrate these shards into TiDB as one table. In this case, you can use DM to perform the shard merge and migration.

- Migrate and Merge MySQL Shards of Small Datasets to TiDB

If the data size of the sharded tables is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly merge and import the sharded tables. Then, you can use DM to replicate incremental sharding data (binlog) based on your application needs.

- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.1.4 Migrate data from Vitess to TiDB

To migrate data from Vitess to TiDB, the following guide is available:

- Migrate Data from Vitess to TiDB

6.1.5 Migrate data from files to TiDB

- Migrate data from CSV files to TiDB
- Migrate data from SQL files to TiDB
- Migrate data from Parquet files to TiDB

6.1.6 Incremental replication between TiDB clusters

You can use TiCDC for incremental data replication between TiDB clusters. For details, refer to TiCDC Overview.

6.1.7 More advanced migration solutions

The following features can improve the migration process and might meet more needs in your application.

- Continuous Replication from Databases that Use gh-ost or pt-osc
- Migrate Data to a Downstream TiDB Table with More Columns
- Filter Binlog Events
- Filter DML Events Using SQL Expressions

6.2 TiDB Migration Tools Overview

TiDB provides multiple data migration tools for different scenarios such as full data migration, incremental data migration, backup and restore, and data replication.

This document introduces the user scenarios, supported upstreams and downstreams, advantages, and limitations of these tools. You can choose the right tool according to your needs.

6.2.1 TiDB Data Migration (DM)

- **User scenario**: Data migration from MySQL-compatible databases to TiDB
- **Upstream**: MySQL, MariaDB, Aurora
- **Downstream**: TiDB
- **Advantages**:
  - A convenient and unified data migration task management tool that supports full data migration and incremental replication
  - Support filtering tables and operations
  - Support shard merge and migration
- **Limitation**: Data import speed is roughly the same as that of TiDB Lightning's logical import mode, and a lot lower than that of TiDB Lightning's physical import mode. So it is recommended to use DM to migrate full data with a size of less than 1 TiB.

6.2.2 TiDB Lightning

- **User scenario**: Full data import into TiDB
- **Upstream (the imported source file)**:

  - Files exported from Dumpling
  - Parquet files exported by Amazon Aurora, Apache Hive, and Snowflake
  - CSV files
  - Data from local disks or Amazon S3
- **Downstream**: TiDB
- **Advantages**:
  - Support quickly importing a large amount of data and quickly initializing a specific table in a TiDB cluster
  - Support checkpoints to store the import progress, so that `tidb-lightning` continues importing from where it lefts off after restarting
  - Support data filtering
- **Limitation**:
  - If physical import mode is used for data import, during the import process, the TiDB cluster cannot provide services.
  - If you do not want the TiDB services to be impacted, perform the data import according to TiDB Lightning logical import mode.

6.2.3 Dumpling

- **User scenario**: Full data export from MySQL or TiDB
- **Upstream**: MySQL, TiDB
- **Downstream (the output file)**: SQL, CSV
- **Advantages**:
  - Support the table-filter feature that enables you to filter data easier
  - Support exporting data to Amazon S3
- **Recommendation**:
  - If you want to restore the exported data to a database other than TiDB, it is recommended to use Dumpling.
  - If you want to restore the exported data to another TiDB cluster, it is recommended to use Backup & Restore (BR).

6.2.4 TiCDC

- **User scenario**: This tool is implemented by pulling TiKV change logs. It can restore cluster data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes.
- **Upstream**: TiDB
- **Downstream**: TiDB, MySQL, Kafka, MQ, Confluent, storage services such as Amazon S3, GCS, Azure Blob Storage, and NFS.
- **Advantages**: Provide TiCDC Open Protocol

- **Limitation**: TiCDC only replicates tables that have at least one valid index. The following scenarios are not supported:
    - The TiKV cluster that uses RawKV alone.
    - The DDL operation `CREATE SEQUENCE` and the `SEQUENCE` function in TiDB.

6.2.5 Backup & Restore (BR)

- **User scenario**: Migrate a large amount of TiDB cluster data by backing up and restoring data
- **Upstream**: TiDB
- **Downstream (the output file)**: SST, backup.meta files, backup.lock files
- **Advantages**:
    - Suitable for migrating data to another TiDB cluster
    - Support backing up data to an external storage for disaster recovery
- **Limitation**:
    - When BR restores data to the upstream cluster of TiCDC, the restored data cannot be replicated to the downstream by TiCDC.
    - BR supports operations only between clusters that have the same `new_collation_enabled` value in the `mysql.tidb` table.

6.2.6 sync-diff-inspector

- **User scenario**: Comparing data stored in the databases with the MySQL protocol
- **Upstream**: TiDB, MySQL
- **Downstream**: TiDB, MySQL
- **Advantages**: Can be used to repair data in the scenario where a small amount of data is inconsistent
- **Limitation**:
    - Online check is not supported for data migration between MySQL and TiDB.
    - JSON, BIT, BINARY, BLOB and other types of data are not supported.

6.2.7 Install tools using TiUP

Since TiDB v4.0, TiUP acts as a package manager that helps you manage different cluster components in the TiDB ecosystem. Now you can manage any cluster component using a single command.

6.2.7.1 Step 1. Install TiUP

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

Redeclare the global environment variable:

```
source ~/.bash_profile
```

6.2.7.2 Step 2. Install components

You can use the following command to see the available components:

```
tiup list
```

The command outputs the available components:

```
Available components:
Name          Owner     Description
----          -----     -----------
PCC           community A tool used to capture plan changes among different
   ↪ versions of TiDB
bench         pingcap   Benchmark database with different workloads
br            pingcap   TiDB/TiKV cluster backup restore tool.
cdc           pingcap   CDC is a change data capture tool for TiDB
chaosd        community An easy-to-use Chaos Engineering tool used to inject
   ↪  failures to a physical node
client        pingcap   Client to connect playground
cloud         pingcap   CLI tool to manage TiDB Cloud
cluster       pingcap   Deploy a TiDB cluster for production
ctl           pingcap   TiDB controller suite
dm            pingcap   Data Migration Platform manager
dmctl         pingcap   dmctl component of Data Migration Platform.
errdoc        pingcap   Document about TiDB errors
pd-recover    pingcap   PD Recover is a disaster recovery tool of PD, used
   ↪ to recover the PD cluster which cannot start or provide services
   ↪ normally.
playground    pingcap   Bootstrap a local TiDB cluster for fun
tidb          pingcap   TiDB is an open source distributed HTAP database
   ↪ compatible with the MySQL protocol.
tidb-dashboard pingcap  TiDB Dashboard is a Web UI for monitoring,
   ↪ diagnosing, and managing the TiDB cluster
tidb-lightning pingcap  TiDB Lightning is a tool used for fast full import
   ↪ of large amounts of data into a TiDB cluster
tikv-br       pingcap   TiKV cluster backup restore tool
tikv-cdc      pingcap   TiKV-CDC is a change data capture tool for TiKV
tiproxy       pingcap   TiProxy is a database proxy that is based on TiDB.
tiup          pingcap   TiUP is a command-line component management tool
   ↪ that can help to download and install TiDB platform components to the
   ↪  local system
```

Install one or more components that you need. For example:

```
tiup install dm
```

```
tiup install dm tidb-lightning
```

> **Note:**
>
> To install a component of a specific version, use the `tiup install <component>[:version]` command.

6.2.7.3 Step 3. Update TiUP and its components (optional)

It is recommended to see the release log and compatibility notes of the new version.

```
tiup update --self && tiup update dm
```

6.2.8 See also

- Deploy TiUP offline
- Download and install tools in binary

6.3 Best Practices for Importing 50 TiB Data

This document provides best practices for importing large volumes of data into TiDB, including some key factors and steps that affect data import. We have successfully imported data of a large single table over 50 TiB into both the internal environment and customer's environment, and have accumulated best practices based on these real application scenarios, which can help you import data more smoothly and efficiently.

TiDB Lightning (Physical Import Mode) is a comprehensive and efficient data import tool used for importing data into empty tables and initializing empty clusters, and uses files as the data source. TiDB Lightning provides two running modes: a single instance and parallel import. You can import source files of different sizes.

- If the data size of the source files is within 10 TiB, it is recommended to use a single instance of TiDB Lightning for the import.
- If the data size of the source files exceeds 10 TiB, it is recommended to use multiple instances of TiDB Lightning for Parallel Import.
- If the source file data scale is exceptionally large (larger than 50 TiB), in addition to parallel importing, you need to make certain preparations and optimizations based on the characteristics of the source data, table definitions, and parameter configurations to achieve smoother and faster large-scale data import.

The following sections apply to both importing multiple tables and importing large single tables:

- Key factors
- Prepare source files
- Estimate storage space
- Change configuration parameters
- Resolve the "checksum mismatch" error
- Enable checkpoint
- Troubleshooting

The best practices for importing large single tables are described separately in the following section because of its special requirements:

- Best practices for importing a large single table

6.3.1 Key factors

When you import data, some key factors can affect import performance and might even cause import to fail. Some common critical factors are as follows:

- Source files
    - Whether the data within a single file is sorted by the primary key. Sorted data can achieve optimal import performance.
    - Whether overlapping primary keys or non-null unique indexes exist between source files imported by multiple TiDB Lightning instances. The smaller the overlap is, the better the import performance.
- Table definitions
    - The number and size of secondary indexes per table can affect the import speed. Fewer indexes result in faster imports and less space consumption after import.
    - Index data size = Number of indexes * Index size * Number of rows.
- Compression ratio
    - Data imported into a TiDB cluster is stored in a compressed format. The compression ratio cannot be calculated in advance. It can only be determined after the data is actually imported into the TiKV cluster.
    - As a best practice, you can first import a small portion of the data (for example, 10%) to obtain the corresponding compression ratio of the cluster, and then use it to estimate the compression ratio of the entire data import.
- Configuration parameters

- `region-concurrency`: The concurrency of TiDB Lightning main logical processing.
- `send-kv-pairs`: The number of Key-Value pairs sent by TiDB Lightning to TiKV in a single request.
- `disk-quota`: The disk quota used by TiDB Lightning local temp files when using the physical import mode.
- `GOMEMLIMIT`: TiDB Lightning is implemented in the Go language. Configure `GOMEMLIMIT` properly.

- Data validation

  After data and index import is completed, the `ADMIN CHECKSUM` statement is executed on each table, and the checksum value is compared with the local checksum value of TiDB Lightning. When many tables exist, or an individual table has a large number of rows, the checksum phase can take a long time.

- The analyze operation

  After the checksum is successfully completed, the `ANALYZE TABLE` statement is executed on each table to generate the optimal execution plan. The analyze operation can be time-consuming when dealing with a large number of tables or an individual table with a significant amount of data.

- Relevant issues

  During the actual process of importing 50 TiB of data, certain issues might occur that are only exposed when dealing with a massive number of source files and large-scale clusters. When choosing a product version, it is recommended to check whether the corresponding issues have been fixed.

  The following issues have been resolved in v6.5.3, v7.1.0, and later versions:

  - Issue-14745: After the import is completed, a large number of temporary files are left in the TiKV import directory.
  - Issue-6426: The PD range scheduling interface might fail to scatter regions, resulting in timeout issues. Before v6.2.0, global scheduling is disabled by default, which can avoid triggering this problem.
  - Issue-43079: TiDB Lightning fails to refresh the Region Peers information during retry for NotLeader errors.
  - Issue-43291: TiDB Lightning does not retry in cases where temporary files are not found (the "No such file or directory" error).

6.3.2 Prepare source files

- When generating source files, it is preferable to sort them by the primary key within a single file. If the table definition does not have a primary key, you can add an auto-increment primary key. In this case, the order of the file content does not matter.

- When assigning source files to multiple TiDB Lightning instances, try to avoid the situation where overlapping primary keys or non-null unique indexes exist between multiple source files. If the generated files are globally sorted, they can be distributed into different TiDB Lightning instances based on ranges to achieve optimal import performance.
- Control each file to be less than 96 MiB in size during file generation.
- If a file is exceptionally large and exceeds 256 MiB, enable `strict-format`.

6.3.3 Estimate storage space

You can use either of the following two methods to estimate the storage space required for importing data:

- Assuming the total data size is **A**, the total index size is **B**, the replication factor is **3**, and the compression ratio is (typically around 2.5), the overall occupied space can be calculated as: **(A+B)*3/** . This method is primarily used for estimating without performing any data import, to plan the cluster topology.
- Import only 10% of the data and multiply the actual occupied space by 10 to estimate the final space usage for that batch of data. This method is more accurate, especially when you import a large amount of data.

Note that it is recommended to reserve 20% of storage space, because background tasks such as compaction and snapshot replication also consume a portion of the storage space.

6.3.4 Change configuration parameters

- `region-concurrency`: The concurrency of TiDB Lightning main logical processing. During parallel importing, it is recommended to set it to 75% of the CPU cores to prevent resource overload and potential OOM issues.
- `send-kv-pairs`: The number of Key-Value pairs sent by TiDB Lightning to TiKV in a single request. It is recommended to adjust this value based on the formula send-kv-pairs * row-size < 1 MiB. Starting from v7.2.0, this parameter is replaced by `send-kv-size`, and no additional setting is required.
- `disk-quota`: It is recommended to ensure that the sorting directory space of TiDB Lightning is larger than the size of the data source. If you cannot ensure that, you can set `disk-quota` to 80% of the sorting directory space of TiDB Lightning. In this way, TiDB Lightning will sort and write data in batches according to the specified `disk-quota`, but note that this approach might result in lower import performance compared to a complete sorting process.
- `GOMEMLIMIT`: TiDB Lightning is implemented in the Go language. Setting `GOMEMLIMIT` to 80% of the instance memory to reduce the probability of OOM caused by the Go GC mechanism.

For more information about TiDB Lightning parameters, see TiDB Lightning configuration parameters.

6.3.5 Resolve the "checksum mismatch" error

Conflicts might occur during data validation. The error message is "checksum mismatch". To resolve this issue, take the following steps as needed:

1. In the source data, check for conflicted primary keys or unique keys, and resolve the conflicts before reimporting. In most cases, this is the most common cause.
2. Check if the table primary key or unique key definition is reasonable. If not, modify the table definition and reimport data.
3. If the issue persists after following the preceding two steps, further examination is required to determine whether a small amount (less than 10%) of unexpected conflicting data exists in the source data. To let TiDB Lightning detect and resolve conflicting data, enable conflict detection.

6.3.6 Enable checkpoint

For importing a large volume of data, it is essential to refer to Lightning Checkpoints and enable checkpoints. It is recommended to prioritize using MySQL as the driver to avoid losing the checkpoint information if TiDB Lightning is running in a container environment where the container might exit and delete the checkpoint information.

If you encounter insufficient space in downstream TiKV during import, you can manually run the `kill` command (without the `-9` option) on all TiDB Lightning instances. After scaling up the capacity, you can resume the import based on the checkpoint information.

6.3.7 Best practices for importing a large single table

Importing multiple tables can increase the time required for checksum and analyze operations, sometimes exceeding the time required for data import itself. However, it is generally not necessary to adjust the configuration. If one or more large tables exist among the multiple tables, it is recommended to separate the source files of these large tables and import them separately.

This section provides the best practices for importing large single tables. There is no strict definition for a large single table, but it is generally considered to meet one of the following criteria:

- The table size exceeds 10 TiB.
- The number of rows exceeds 1 billion and the number of columns exceeds 50 in a wide table.

6.3.7.1 Generate source files

Follow the steps outlined in the Prepare source files.

For a large single table, if global sorting is not achievable but sorting within each file based on the primary key is possible, and the file is a standard CSV file, it is recommended to generate large single files with each around 20 GiB.

Then, enable `strict-format`. This approach reduces the overlap of primary and unique keys in the imported files between TiDB Lightning instances, and TiDB Lightning instances can split the large files before importing to achieve optimal import performance.

6.3.7.2 Plan cluster topology

Prepare TiDB Lightning instances to make each instance process 5 TiB to 10 TiB of source data. Deploy one TiDB Lightning instance on each node. For the specifications of the nodes, refer to the environment requirements of TiDB Lightning instances.

6.3.7.3 Change configuration parameters

- Set `region-concurrency` to 75% of the number of cores of the TiDB Lightning instance.
- Set `send-kv-pairs` to `3200`. This method applies to TiDB v7.1.0 and earlier versions. Starting from v7.2.0, this parameter is replaced by `send-kv-size`, and no additional setting is required.
- Adjust `GOMEMLIMIT` to 80% of the memory on the node where the instance is located.

If the PD Scatter Region latency during the import process exceeds 30 minutes, consider the following optimizations:

- Check whether the TiKV cluster encounters any I/O bottlenecks.
- Increase TiKV `raftstore.apply-pool-size` from the default value of `2` to `4` or `8`.
- Reduce TiDB Lightning `region-split-concurrency` to half the number of CPU cores, with a minimum value of `1`.

6.3.7.4 Disable the analyze operation

In the case of a large single table (for example, with over 1 billion rows and more than 50 columns), it is recommended to disable the `analyze` operation (`analyze="off"`) during the import process, and manually execute the `ANALYZE TABLE` statement after the import is completed.

For more information about the configuration of `analyze`, see TiDB Lightning task configuration.

6.3.8 Troubleshooting

If you encounter problems while using TiDB Lightning, see Troubleshoot TiDB Lightning.

6.4 Migration Scenarios

6.4.1 Migrate Data from Amazon Aurora to TiDB

This document describes how to migrate data from Amazon Aurora to TiDB. The migration process uses DB snapshot, which saves a lot of space and time.

The whole migration has two processes:

- Import full data to TiDB using TiDB Lightning
- Replicate incremental data to TiDB using DM (optional)

6.4.1.1 Prerequisites

- Install Dumpling and TiDB Lightning. If you want to create the corresponding tables manually on the target side, do not install Dumpling.
- Get the upstream database privileges required by Dumpling.
- Get the target database privileges required for TiDB Lightning.

6.4.1.2 Import full data to TiDB

6.4.1.2.1 Step 1. Export and import the schema file

This section describes how to export the schema file from Amazon Aurora and import it to TiDB. If you have manually created the table in the target database, you can skip this step.

1.1 Export the schema file from Amazon Aurora

Because the snapshot file from Amazon Aurora does not contain the DDL statements, you need to export the schema using Dumpling and create the schema in the target database using TiDB Lightning.

Export the schema using Dumpling by running the following command. The command includes the `--filter` parameter to only export the desired table schema. For more information about the parameters, see the Option list of Dumpling.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
tiup dumpling --host ${host} --port 3306 --user root --password ${password}
    ↪ --filter 'my_db1.table[12],mydb.*' --consistency none --no-data --
    ↪ output 's3://my-bucket/schema-backup'
```

Record the URI of the schema exported in the above command, such as 's3://my-bucket/schema-backup', which will be used when importing the schema file later.

To get access to Amazon S3, you can pass the secret access key and access key of the account that has access to this Amazon S3 storage path into the Dumpling or TiDB Lightning node as environment variables. Dumpling and TiDB Lightning also support reading credential files from `~/.aws/credentials`. This method eliminates the need to provide the secret access key and access key again for all tasks on that Dumpling or TiDB Lightning node.

1.2 Create the TiDB Lightning configuration file for the schema file

Create a new `tidb-lightning-schema.toml` file, copy the following content into the file, and replace the corresponding content.

```
[tidb]

### The target TiDB cluster information.
host = ${host}
port = ${port}
user = "${user_name}"
password = "${password}"
status-port = ${status-port} # The TiDB status port. Usually the port is
    ↪ 10080.
pd-addr = "${ip}:${port}" # The cluster PD address. Usually the port is
    ↪ 2379.

[tikv-importer]
### "local": Use the default Physical Import Mode (the "local" backend).
### During the import, the target TiDB cluster cannot provide any service.
### For more information about import modes, see https://docs.pingcap.com/
    ↪ tidb/stable/tidb-lightning-overview
backend = "local"

### Set the temporary storage directory for the sorted Key-Value files.
### The directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported.
### For better import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage,
### which can use I/O exclusively.
sorted-kv-dir = "${path}"

[mydumper]
### Set the directory of the schema file exported from Amazon Aurora
data-source-dir = "s3://my-bucket/schema-backup"
```

If you need to enable TLS in the TiDB cluster, refer to TiDB Lightning Configuration.

1.3 Import the schema file to TiDB

Use TiDB Lightning to import the schema file to the downstream TiDB.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning-schema.toml > nohup.out
    ↪ 2>&1 &
```

6.4.1.2.2 Step 2. Export and import an Amazon Aurora snapshot to Amazon S3

This section describes how to export an Amazon Aurora snapshot to Amazon S3 and import it into TiDB by TiDB Lightning.

2.1 Export an Amazon Aurora snapshot to Amazon S3

1. Get the name and location of the Amazon Aurora binlog for subsequent incremental migration. In Amazon Aurora, run the `SHOW MASTER STATUS` command and record the current binlog position:

   ```
   SHOW MASTER STATUS;
   ```

   The output is similar to the following. Record the binlog name and position for later use.

   ```
   +----------------------------+----------+--------------+------------------+--------
      ↪
   | File                       | Position | Binlog_Do_DB | Binlog_Ignore_DB
      ↪ | Executed_Gtid_Set |
   +----------------------------+----------+--------------+------------------+--------
      ↪
   | mysql-bin-changelog.018128 | 52806 |          |                  |
      ↪                  |
   +----------------------------+----------+--------------+------------------+--------
      ↪
   1 row in set (0.012 sec)
   ```

2. Export the Amazon Aurora snapshot. For detailed steps, refer to Exporting DB snapshot data to Amazon S3. After you obtain the binlog position, export the snapshot within 5 minutes. Otherwise, the recorded binlog position might be outdated and thus cause data conflict during the incremental replication.

2.2 Create the TiDB Lightning configuration file for the data file

Create a new `tidb-lightning-data.toml` configuration file, copy the following content into the file, and replace the corresponding content.

```
[tidb]

### The target TiDB cluster information.
host = ${host}
port = ${port}
user = "${user_name}"
password = "${password}"
status-port = ${status-port} # The TiDB status port. Usually the port is
    ↪ 10080.
pd-addr = "${ip}:${port}" # The cluster PD address. Usually the port is
    ↪ 2379.

[tikv-importer]
### "local": Use the default Physical Import Mode (the "local" backend).
### During the import, the target TiDB cluster cannot provide any service.
### For more information about import modes, see https://docs.pingcap.com/
    ↪ tidb/stable/tidb-lightning-overview
backend = "local"

### Set the temporary storage directory for the sorted Key-Value files.
### The directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported.
### For better import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage,
### which can use I/O exclusively.
sorted-kv-dir = "${path}"

[mydumper]
### Set the directory of the snapshot file exported from Amazon Aurora
data-source-dir = "${s3_path}" # eg: s3://my-bucket/sql-backup

[[mydumper.files]]
### The expression that parses the parquet file.
pattern = '(?i)^(?:[^/]*/)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[^/]*/)*(?:[a-z0
    ↪ -9\-_.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

If you need to enable TLS in the TiDB cluster, refer to TiDB Lightning Configuration.

2.3 Import full data to TiDB

1. Use TiDB Lightning to import data from an Amazon Aurora snapshot to TiDB.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning-data.toml > nohup.out
    ↪ 2>&1 &
```

2. After the import starts, you can check the progress of the import by either of the following methods:

    - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
    - Check progress in the monitoring dashboard.
    - Check progress in the TiDB Lightning web interface.

3. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If you encounter any problem during the import, refer to TiDB Lightning FAQ for troubleshooting.

6.4.1.3 Replicate incremental data to TiDB (optional)

6.4.1.3.1 Prerequisites

- Install DM.
- Get the source database and target database privileges required for DM.

6.4.1.3.2 Step 1: Create the data source

1. Create the `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"
# Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
    ↪ must also enable GTID. If the upstream MySQL service is
    ↪ configured to switch master between different nodes automatically
    ↪ , GTID mode is required.
enable-gtid: false

from:
  host: "${host}"      # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use
      ↪ plaintext password. It is recommended to use `dmctl encrypt` to
      ↪  encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
    ↪ source1.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
--master-addr	The {advertise-addr} of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:826
operate-source create	Loads the data source to the DM cluster.

6.4.1.3.3 Step 2: Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Multiple tasks that are running at the same time must each have a unique name.
name: "test"
### Task mode. Options are:
### - full: only performs full data migration.
```

```
### - incremental: only performs binlog real-time replication.
### - all: full data migration + binlog real-time replication.
task-mode: "incremental"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"               # e.g.: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}"       # Supported but not recommended to use a
     ↪ plaintext password. It is recommended to use `dmctl encrypt` to
     ↪ encrypt the plaintext password before using it.

### Global configuration for block and allow lists. Each instance can
   ↪ reference the configuration by name.
block-allow-list:                # If the DM version is earlier than v2
   ↪ .0.0-beta.2, use black-white-list.
  listA:                         # Name.
    do-tables:                   # Allow list for the upstream tables to be
       ↪  migrated.
    - db-name: "test_db"         # Name of databases to be migrated.
      tbl-name: "test_table"     # Name of tables to be migrated.

### Configures the data source.
mysql-instances:
  - source-id: "mysql-01"          # Data source ID, i.e., source-id in
     ↪ source1.yaml
    block-allow-list: "listA"      # References the block-allow-list
       ↪ configuration above.
###      syncer-config-name: "global" # Name of the syncer configuration.
    meta:                          # The position where the binlog
       ↪ replication starts when `task-mode` is `incremental` and the
       ↪ downstream database checkpoint does not exist. If the checkpoint
       ↪ exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.
      binlog-name: "mysql-bin.000004" # The binlog position recorded in "
         ↪ Step 1. Export an Amazon Aurora snapshot to Amazon S3". When the
         ↪  upstream database has source-replica switching, GTID mode is
         ↪ required.
      binlog-pos: 109227
      # binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

### (Optional) If you need to incrementally replicate data that has already
   ↪ been migrated in the full data migration, you need to enable the safe
```

```
  ↪  mode to avoid the incremental data replication error.
# This scenario is common in the following case: the full migration data
   ↪ does not belong to the data source's consistency snapshot, and
   ↪ after that, DM starts to replicate incremental data from a position
   ↪  earlier than the full migration.
# syncers:          # The running configurations of the sync processing
   ↪ unit.
#   global:          # Configuration name.
#     safe-mode: true # If this field is set to true, DM changes INSERT of
   ↪  the data source to REPLACE for the target database, and changes
   ↪ UPDATE of the data source to DELETE and REPLACE for the target
   ↪ database. This is to ensure that when the table schema contains a
   ↪ primary key or unique index, DML statements can be imported
   ↪ repeatedly. In the first minute of starting or resuming an
   ↪ incremental replication task, DM automatically enables the safe
   ↪ mode.
```

The YAML file above is the minimum configuration required for the migration task. For more configuration items, refer to DM Advanced Task Configuration File.

6.4.1.3.4 Step 3. Run the migration task

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

After that, start the migration task by running `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	The `{advertise-addr}` of any DM-master in the cluster where `dmctl` is to be connected, e.g.: 172.16.10.71:826
`start-task`	Starts the migration task.

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to DM error handling and DM FAQ.

6.4.1.3.5 Step 4. Check the migration task status

To learn whether the DM cluster has an ongoing migration task and the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.4.1.3.6 Step 5. Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.4.1.4 What's next

- Pause the migration task.
- Resume the migration task.
- Stop the migration task.
- Export and import the cluster data source and task configuration.
- Handle failed DDL statements.

6.4.2 Migrate Small Datasets from MySQL to TiDB

This document describes how to use TiDB Data Migration (DM) to migrate small datasets from MySQL to TiDB in the full migration mode and incremental replication mode. "Small datasets" in this document mean data size less than 1 TiB.

The migration speed varies from 30 GB/h to 50 GB/h, depending on multiple factors such as the number of indexes in the table schema, hardware, and network environment.

6.4.2.1 Prerequisites

- Deploy a DM Cluster Using TiUP
- Grant the required privileges for the source database and the target database of DM

6.4.2.2 Step 1. Create the data source

First, create the `source1.yaml` file as follows:

```
### The ID must be unique.
source-id: "mysql-01"
```

```
### Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable GTID, the upstream MySQL must have
    ↪ enabled GTID. If the upstream MySQL has automatic source-replica
    ↪ switching, the GTID mode is required.
enable-gtid: true

from:
  host: "${host}"      # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext password is supported but not
      ↪ recommended. It is recommended to use dmctl encrypt to encrypt the
      ↪ plaintext password before using the password.
  port: 3306
```

Then, load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	`{ "advertise-addr": "-" }`
`operate-source create`	Load the data source to the DM cluster.

6.4.2.3 Step 2. Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Each of the multiple tasks running at the same time must have a unique name.
name: "test"
```

```
### Task mode. Options are:
### full: only performs full data migration.
### incremental: only performs binlog real-time replication.
### all: full data migration + binlog real-time replication.
task-mode: "all"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"               # For example: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}"       # Plaintext password is supported but not
     ↪ recommended. It is recommended to use dmctl encrypt to encrypt the
     ↪ plaintext password before using the password.

### The configuration of all MySQL instances of source database required for
   ↪  the current migration task.
mysql-instances:
-
  # The ID of an upstream instance or a replication group
  source-id: "mysql-01"
  # The names of the block list and allow list configuration of the schema
     ↪ name or table name that is to be migrated. These names are used to
     ↪ reference the global configuration of the block and allowlist. For
     ↪ the global configuration, refer to the `block-allow-list`
     ↪ configuration below.
  block-allow-list: "listA"

### The global configuration of blocklist and allowlist. Each instance is
   ↪ referenced by a configuration item name.
block-allow-list:
  listA:                         # name
    do-tables:                   # The allowlist of upstream tables that
       ↪ need to be migrated.
    - db-name: "test_db"         # The schema name of the table to be
       ↪ migrated.
      tbl-name: "test_table"     # The name of the table to be migrated.
```

The above is the minimum task configuration to perform the migration. For more configuration items regarding the task, refer to DM task complete configuration file introduction.

6.4.2.4 Step 3. Start the migration task

To avoid errors, before starting the migration task, it is recommended to use the `check -task` command to check whether the configuration meets the requirements of DM configuration.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Start the migration task by running the following command with `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	`{advertise-addr}` - the `advertise-addr` of any DM-master node in the cluster where `dmctl` is to connect. For example: 172.16.10.71:826
`start-task`	Start the migration task

If the task fails to start, after changing the configuration according to the returned result,

you can run the `start-task task.yaml` command to restart the task. If you encounter problems, refer to Handle Errors and FAQ.

6.4.2.5 Step 4: Check the migration task status

To learn whether the DM cluster has an ongoing migration task, the task status and some other information, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.4.2.6 Step 5. Monitor the task and view logs (optional)

To view the historical status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when deploying DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select the DM dashboard to view DM-related monitoring metrics.

- The log directory of DM-master: specified by the DM-master process parameter `--log-file`. If you have deployed DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- The log directory of DM-worker: specified by the DM-worker process parameter `--log-file`. If you have deployed DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.4.2.7 What's next

- Pause the migration task
- Resume the migration task
- Stop the migration task
- Export and import the cluster data source and task configuration
- Handle failed DDL statements

6.4.3 Migrate Large Datasets from MySQL to TiDB

When the data volume to be migrated is small, you can easily use DM to migrate data, both for full migration and incremental replication. However, because DM imports data at a slow speed (30~50 GiB/h), when the data volume is large, the migration might take a long time. "Large datasets" in this document usually mean data around one TiB or more.

This document describes how to perform the full migration using Dumpling and TiDB Lightning. TiDB Lightning Physical Import Mode can import data at a speed of up to 500 GiB/h. Note that this speed is affected by various factors such as hardware configuration, table schema, and the number of indexes. After the full migration is completed, you can replicate the incremental data using DM.

6.4.3.1 Prerequisites

- Install DM.
- Install Dumpling and TiDB Lightning.
- Grant the source database and target database privileges required for DM.
- Grant the target database privileges required for TiDB Lightning.
- Grant the source database privileges required for Dumpling.

6.4.3.2 Resource requirements

Operating system: The example in this document uses fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU: Because TiDB Lightning consumes high resources, it is recommended to allocate more than 64 GiB of memory and more than 32 CPU cores. To get the best performance, make sure that the CPU core to memory (GiB) ratio is greater than 1:2.

Disk space:

- Dumpling requires a disk space that can store the whole data source (or to store all upstream tables to be exported). SSD is recommended. To calculate the required space, see Downstream storage space requirements.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.
- If the full data volume is large, you can increase the binlog storage time in the upstream. This is to ensure that the binlogs are not lost during the incremental replication.

Note: It is difficult to calculate the exact data volume exported by Dumpling from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `DATA_LENGTH` field in the `information_schema.tables` table:

```
-- Calculate the size of all schemas
SELECT
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(DATA_LENGTH)) AS 'Data Size',
  FORMAT_BYTES(SUM(INDEX_LENGTH)) 'Index Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_SCHEMA;
```

```
-- Calculate the 5 largest tables
SELECT
  TABLE_NAME,
  TABLE_SCHEMA,
  FORMAT_BYTES(SUM(data_length)) AS 'Data Size',
  FORMAT_BYTES(SUM(index_length)) AS 'Index Size',
  FORMAT_BYTES(SUM(data_length+index_length)) AS 'Total Size'
FROM
  information_schema.tables
GROUP BY
  TABLE_NAME,
  TABLE_SCHEMA
ORDER BY
  SUM(DATA_LENGTH+INDEX_LENGTH) DESC
LIMIT
  5;
```

6.4.3.2.1 Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to the standard hardware requirements, the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has `x 2` because:

- Index might take extra space.
- RocksDB has a space amplification effect.

6.4.3.3 Step 1. Export all data from MySQL

1. Export all data from MySQL by running the following command:

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MiB -B my_
    ↪ db1 -f 'my_db1.table[12]' -o 's3://my-bucket/sql-backup'
```

Dumpling exports data in SQL files by default. You can specify a different file format by adding the `--filetype` option.

The parameters used above are as follows. For more Dumpling parameters, refer to Dumpling Overview.

parameters	Description
- ↪ u ↪ or -- ↪ user ↪	MySQL user
- ↪ p ↪ or -- ↪ password ↪	MySQL user password
- ↪ P ↪ or -- ↪ port ↪	MySQL port
- ↪ h ↪ or -- ↪ host ↪	MySQL IP address
- ↪ t ↪ or -- ↪ thread ↪	The number of threads used for export

parameters	Description
- ↪ o ↪ or -- ↪ output ↪	The directory that stores the exported file. Supports a local path or an external storage URI
- ↪ r ↪ or -- ↪ row ↪	The maximum number of rows in a single file

parameters	Description
- ↪ F ↪	The maximum size of a single file, in MiB. Recommended value: 256 MiB.
- B or -- ↪ database ↪	Specifies a database to be exported
- ↪ f ↪ or -- ↪ filter ↪	Exports tables that match the pattern. Refer to table-filter for the syntax.

Make sure `${data-path}` has the space to store all exported upstream tables. To calculate the required space, see Downstream storage space requirements. To prevent the export from being interrupted by a large table consuming all the spaces, it is strongly recommended to use the `-F` option to limit the size of a single file.

2. View the `metadata` file in the `${data-path}` directory. This is a Dumpling-generated metadata file. Record the binlog position information, which is required for the incremental replication in Step 3.

```
SHOW MASTER STATUS:
Log: mysql-bin.000004
Pos: 109227
GTID:
```

6.4.3.4 Step 2. Import full data to TiDB

1. Create the `tidb-lightning.toml` configuration file:

```
[lightning]
# log.
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the
    ↪ target TiDB cluster cannot provide any service.
# "tidb": The "tidb" backend is recommended to import data less than 1
    ↪ TiB. During the import, the target TiDB cluster can provide
    ↪ service normally. For more information on the backends, refer to
    ↪ https://docs.pingcap.com/tidb/stable/tidb-lightning-backends.
backend = "local"
# Sets the temporary storage directory for the sorted Key-Value files.
    ↪ The directory must be empty, and the storage space must be
    ↪ greater than the size of the dataset to be imported. For better
    ↪ import performance, it is recommended to use a directory
    ↪ different from `data-source-dir` and use flash storage, which can
    ↪  use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
# The data source directory. The same directory where Dumpling exports
    ↪ data in "Step 1. Export all data from MySQL".
data-source-dir = "${data-path}" # A local path or S3 path. For example
    ↪ , 's3://my-bucket/sql-backup'.
```

```
[tidb]
# The target TiDB cluster information.
host = ${host}             # e.g.: 172.16.32.1
port = ${port}             # e.g.: 4000
user = "${user_name}"      # e.g.: "root"
password = "${password}"   # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs
    ↪ to obtain the table schema information from the TiDB status port.
    ↪  e.g.: 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD
    ↪ . When backend = "local", you must specify status-port and pd-
    ↪ addr correctly. Otherwise, the import will be abnormal.
```

For more information on TiDB Lightning configuration, refer to TiDB Lightning Configuration.

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a SIGHUP signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

   If you import data from S3, pass the SecretKey and AccessKey that have access to the S3 storage path as environment variables to the TiDB Lightning node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can check the progress of the import by one of the following methods:

   - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
   - Check progress in the monitoring dashboard.
   - Check progress in the TiDB Lightning web interface.

4. After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

Note:

Whether the import is successful or not, the last line of the log shows `tidb lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

6.4.3.5 Step 3. Replicate incremental data to TiDB

6.4.3.5.1 Add the data source

1. Create a `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"

# Configures whether DM-worker uses the global transaction identifier (
    ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
    ↪ must also enable GTID. If the upstream MySQL service is
    ↪ configured to switch master between different nodes automatically
    ↪ , GTID mode is required.
enable-gtid: true

from:
  host: "${host}"        # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use a
      ↪ plaintext password. It is recommended to use `dmctl encrypt` to
      ↪  encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
    ↪ source1.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
--master-addr	The {advertise-addr} of any DM-master in the cluster where dmctl is to be connected, e.g.: 172.16.10.71:826
operate-source create	Loads the data source to the DM cluster.

6.4.3.5.2 Add a replication task

1. Edit the `task.yaml` file. Configure the incremental replication mode and the starting point of each data source:

```
name: task-test                     # Task name. Must be globally unique.
task-mode: incremental              # Task mode. The "incremental" mode only performs incremental data replication.
```

```
# Configures the target TiDB database.
target-database:                # The target database instance.
  host: "${host}"               # e.g.: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}"       # It is recommended to use `dmctl
    ↪ encrypt` to encrypt the plaintext password before using it.

# Use block and allow lists to specify the tables to be replicated.
block-allow-list:               # The collection of filtering rules
  ↪ that matches the tables in the source database instance. If the
  ↪ DM version is earlier than v2.0.0-beta.2, use black-white-list.
  bw-rule-1:                    # The block-allow-list configuration
    ↪ item ID.
    do-dbs: ["${db-name}"]      # Name of databases to be replicated.

# Configures the data source.
mysql-instances:
  - source-id: "mysql-01"       # Data source ID, i.e., source-id in
    ↪ source1.yaml
    block-allow-list: "bw-rule-1" # You can use the block-allow-list
      ↪ configuration above.
    # syncer-config-name: "global" # You can use the syncers
      ↪ incremental data configuration below.
    meta:                       # The position where the binlog
      ↪ replication starts when `task-mode` is `incremental` and the
      ↪ downstream database checkpoint does not exist. If the
      ↪ checkpoint exists, the checkpoint is used. If neither the `
      ↪ meta` configuration item nor the downstream database
      ↪ checkpoint exists, the migration starts from the latest
      ↪ binlog position of the upstream.
      # binlog-name: "mysql-bin.000004" # The binlog position recorded
        ↪ in "Step 1. Export all data from MySQL". If the upstream
        ↪ database service is configured to switch master between
        ↪ different nodes automatically, GTID mode is required.
      # binlog-pos: 109227
      binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

# (Optional) If you need to incrementally replicate data that has
  ↪ already been migrated in the full data migration, you need to
  ↪ enable the safe mode to avoid the incremental data replication
  ↪ error.
# This scenario is common in the following case: the full migration
  ↪ data does not belong to the data source's consistency snapshot,
```

```
    ↪ and after that, DM starts to replicate incremental data from a
    ↪ position earlier than the full migration.
# syncers:          # The running configurations of the sync processing
    ↪ unit.
#   global:         # Configuration name.
#     safe-mode: true # If this field is set to true, DM changes INSERT
    ↪ of the data source to REPLACE for the target database, and
    ↪ changes UPDATE of the data source to DELETE and REPLACE for the
    ↪ target database. This is to ensure that when the table schema
    ↪ contains a primary key or unique index, DML statements can be
    ↪ imported repeatedly. In the first minute of starting or resuming
    ↪ an incremental replication task, DM automatically enables the
    ↪ safe mode.
```

The YAML above is the minimum configuration required for the migration task. For more configuration items, refer to DM Advanced Task Configuration File.

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

2. Start the migration task by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
`--master-addr`	The {advertise-addr} of any DM-master in the cluster where `dmctl` is to be connected, e.g.: 172.16.10.71:826
`start-task`	Starts the migration task.

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to DM error handling and DM FAQ.

6.4.3.5.3 Check the migration task status

To learn whether the DM cluster has an ongoing migration task and view the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to Query Status.

6.4.3.5.4 Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

6.4.3.6 What's next

- Pause a Data Migration Task
- Resume a Data Migration Task
- Stop a Data Migration Task
- Export and Import Data Sources and Task Configuration of Clusters
- Handle Failed DDL Statements

6.4.4 Migrate and Merge MySQL Shards of Small Datasets to TiDB

If you want to migrate and merge multiple MySQL database instances upstream to one TiDB database downstream, and the amount of data is not too large, you can use DM to migrate MySQL shards. "Small datasets" in this document usually mean data around or less than one TiB. Through examples in this document, you can learn the operation steps, precautions, and troubleshooting of the migration.

This document applies to migrating MySQL shards less than 1 TiB in total. If you want to migrate MySQL shards with a total of more than 1 TiB of data, it will take a long time to migrate only using DM. In this case, it is recommended that you follow the operation introduced in Migrate and Merge MySQL Shards of Large Datasets to TiDB to perform migration.

This document takes a simple example to illustrate the migration procedure. The MySQL shards of the two data source MySQL instances in the example are migrated to the downstream TiDB cluster.

In this example, both MySQL Instance 1 and MySQL Instance 2 contain the following schemas and tables. In this example, you migrate and merge tables from `store_01` and `store_02` schemas with a `sale` prefix in both instances, into the downstream `sale` table in the `store` schema.

Schema	Table
store_01	sale_01, sale_02
store_02	sale_01, sale_02

Target schemas and tables:

Schema	Table
store	sale

6.4.4.1 Prerequisites

Before starting the migration, make sure you have completed the following tasks:

- Deploy a DM Cluster Using TiUP
- Privileges required by DM-worker

6.4.4.1.1 Check conflicts for the sharded tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid the conflicts. For more details, see Handle conflicts between primary keys or unique indexes across multiple sharded tables. The following is a brief description.

In this example, `sale_01` and `sale_02` have the same table structure as follows

```
CREATE TABLE `sale_01` (
  `id` bigint NOT NULL AUTO_INCREMENT,
  `sid` bigint NOT NULL,
  `pid` bigint NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The `id` column is the primary key, and the `sid` column is the sharding key. The `id` column is auto-incremental, and duplicated multiple sharded table ranges will cause data conflicts. The `sid` can ensure that the index is globally unique, so you can follow the steps in Remove the primary key attribute of the auto-increment primary key to bypasses the `id` column.

```
CREATE TABLE `sale` (
  `id` bigint NOT NULL,
  `sid` bigint NOT NULL,
  `pid` bigint NOT NULL,
```

```
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.4.4.2 Step 1. Load data sources

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.
source-id: "mysql-01" # Must be unique.
### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction
    ↪ Identifier).
### The prerequisite is that you have already enabled GTID in the upstream
    ↪ MySQL.
### If you have configured the upstream database service to switch master
    ↪ between different nodes automatically, you must enable GTID.
enable-gtid: true
from:
  host: "${host}"        # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext passwords are supported but not
      ↪ recommended. It is recommended that you use dmctl encrypt to encrypt
      ↪  plaintext passwords.
  port: ${port}          # For example: 3306
```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters are described as follows.

Parameter	Description
--master-addr	{advertise-addr} of any DM-master node in the cluster that dm-ctl connects to. For example: 172.16.10.71:826
operate-source create	Load data sources to the DM clusters.

Repeat the above steps until all data sources are added to the DM cluster.

6.4.4.3 Step 2. Configure the migration task

Create a task configuration file named `task1.yaml` and writes the following content to it:

```
name: "shard_merge"           # The name of the task. Should be globally
    ↪ unique.
```

```
### Task mode. You can set it to the following:
### - full: Performs only full data migration (incremental replication is
    ↪ skipped)
### - incremental: Only performs real-time incremental replication using
    ↪ binlog. (full data migration is skipped)
### - all: Performs both full data migration and incremental replication.
    ↪ For migrating small to medium amount of data here, use this option.
task-mode: all
### Required for the MySQL shards. By default, the "pessimistic" mode is
    ↪ used.
### If you have a deep understanding of the principles and usage limitations
    ↪  of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
    ↪ https://docs.pingcap.com/tidb/dev/feature-shard-merge/)
shard-mode: "pessimistic"
meta-schema: "dm_meta"                  # A schema will be created in the
    ↪ downstream database to store the metadata
ignore-checking-items: ["auto_increment_ID"] # In this example, there are
    ↪ auto-incremental primary keys upstream, so you do not need to check
    ↪ this item.

target-database:
  host: "${host}"                       # For example: 192.168.0.1
  port: 4000
  user: "root"
  password: "${password}"               # Plaintext passwords are supported
      ↪  but not recommended. It is recommended that you use dmctl encrypt
      ↪ to encrypt plaintext passwords.

mysql-instances:
  -
    source-id: "mysql-01"                             # ID of the data
        ↪ source, which is source-id in source1.yaml
    route-rules: ["sale-route-rule"]                  # Table route rules
        ↪ applied to the data source
    filter-rules: ["store-filter-rule", "sale-filter-rule"] # Binlog event
        ↪ filter rules applied to the data source
    block-allow-list: "log-bak-ignored"               # Block & Allow Lists
        ↪ rules applied to the data source
  -
    source-id: "mysql-02"
    route-rules: ["sale-route-rule"]
    filter-rules: ["store-filter-rule", "sale-filter-rule"]
    block-allow-list: "log-bak-ignored"
```

```
### Configurations for merging MySQL shards
routes:
  sale-route-rule:
    schema-pattern: "store_*"                          # Merge schemas store_
       ↪ 01 and store_02 to the store schema in the downstream
    table-pattern: "sale_*"                            # Merge tables sale_01
       ↪ and sale_02 of schemas store_01 and store_02 to the sale table in
       ↪ the downstream
    target-schema: "store"
    target-table: "sale"
    # Optional. Used for extracting the source information of sharded
       ↪ schemas and tables and writing the information to the user-defined
       ↪  columns in the downstream. If these options are configured, you
       ↪ need to manually create a merged table in the downstream. For
       ↪ details, see the following table routing setting.
    # extract-table:                                   # Extracts and writes
       ↪ the table name suffix without the sale_ part to the c-table column
       ↪  of the merged table. For example, 01 is extracted and written to
       ↪ the c-table column for the sharded table sale_01.
    #   table-regexp: "sale_(.*)"
    #   target-column: "c_table"
    # extract-schema:                                  # Extracts and writes
       ↪ the schema name suffix without the store_ part to the c_schema
       ↪ column of the merged table. For example, 02 is extracted and
       ↪ written to the c_schema column for the sharded schema store_02.
    #   schema-regexp: "store_(.*)"
    #   target-column: "c_schema"
    # extract-source:                                  # Extracts and writes
       ↪ the source instance information to the c_source column of the
       ↪ merged table. For example, mysql-01 is extracted and written to
       ↪ the c_source column for the data source mysql-01.
    #   source-regexp: "(.*)"
    #   target-column: "c_source"

### Filters out some DDL events.
filters:
  sale-filter-rule:       # Filter name.
    schema-pattern: "store_*" # The binlog events or DDL SQL statements of
       ↪ upstream MySQL instance schemas that match schema-pattern are
       ↪ filtered by the rules below.
    table-pattern: "sale_*" # The binlog events or DDL SQL statements of
       ↪ upstream MySQL instance tables that match table-pattern are
       ↪ filtered by the rules below.
    events: ["truncate table", "drop table", "delete"] # The binlog event
       ↪ array.
```

```
    action: Ignore                                  # The string (`Do`/`Ignore
       ↪ `). `Do` is the allow list. `Ignore` is the block list.
  store-filter-rule:
    schema-pattern: "store_*"
    events: ["drop database"]
    action: Ignore

### Block and allow list
block-allow-list:       # filter or only migrate all operations of some
    ↪ databases or some tables.
  log-bak-ignored:      # Rule name.
    do-dbs: ["store_*"]  # The allow list of the schemas to be migrated,
       ↪ similar to replicate-do-db in MySQL.
```

The above example is the minimum configuration to perform the migration task. For more information, see DM Advanced Task Configuration File.

For more information on `routes`, `filters` and other configurations in the task file, see the following documents:

- Table routing
- Block & Allow Table Lists
- Binlog event filter
- Filter Certain Row Changes Using SQL Expressions

6.4.4.4 Step 3. Start the task

Before starting a migration task, run the `check-task` subcommand in `tiup dmctl` to check whether the configuration meets the requirements of DM so as to avoid possible errors.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Run the following command in `tiup dmctl` to start a migration task:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

Parameter	Description
`--master-addr`	{ `--advertise-addr` } of any DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:826
`start-task`	Starts the data migration task.

If the migration task fails to start, modify the configuration information according to the error information, and then run `start-task task.yaml` again to start the migration task. If you encounter problems, see Handle Errors and FAQ.

6.4.4.5 Step 4. Check the task

After starting the migration task, you can use `dmtcl tiup` to run `query-status` to view the status of the task.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

If you encounter errors, use `query-status ${task-name}` to view more detailed information. For details about the query results, task status and sub task status of the `query-status` command, see TiDB Data Migration Query Status.

6.4.4.6 Step 5. Monitor tasks and check logs (optional)

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

  If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

  When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

  - DM-master log directory: It is specified by the DM-master process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/`.
  - DM-worker log directory: It is specified by the DM-worker process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/`.

- Handle Performance Issues
- FAQ

6.4.5 Migrate and Merge MySQL Shards of Large Datasets to TiDB

If you want to migrate a large MySQL dataset (for example, more than 1 TiB) from different partitions into TiDB, and you are able to suspend all the TiDB cluster write operations from your business during the migration, you can use TiDB Lightning to do the

migration quickly. After migration, you can also use TiDB DM to perform incremental replication according to your business needs. "Large datasets" in this document usually mean data around one TiB or more.

This document uses an example to walk through the whole procedure of such kind of migration.

If the data size of the MySQL shards is less than 1 TiB, you can follow the procedure described in Migrate and Merge MySQL Shards of Small Datasets to TiDB, which supports both full and incremental migration and the steps are easier.

The example in this document assumes that you have two databases, `my_db1` and `my_db2`. You use Dumpling to export two tables `table1` and `table2` from `my_db1`, and two tables `table3` and `table4` from `my_db2`, respectively. After that, you use TiDB Lightning to import and merge the four exported tables into the same `table5` from `mydb` in the target TiDB.

In this document, you can migrate data following this procedure:

1. Use Dumpling to export full data. In this example, you export 2 tables respectively from 2 upstream databases:
    - Export `table1` and `table2` from `my_db1`
    - Export `table3` and `table4` from `my_db2`
2. Start TiDB Lightning to migrate data to `mydb.table5` in TiDB.
3. (Optional) Use TiDB DM to perform incremental replication.

6.4.5.1 Prerequisites

Before getting started, see the following documents to prepare for the migration task.

- Deploy a DM Cluster Using TiUP
- Use TiUP to Deploy Dumpling and Lightning
- Downstream privilege requirements for Dumpling
- Downstream privilege requirements for TiDB Lightning
- Downstream storage space for TiDB Lightning
- Privileges required by DM-worker

6.4.5.1.1 Check conflicts for Sharded Tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid conflicts. For more details, see Handle conflicts between primary keys or unique indexes across multiple sharded tables. The following is a brief description.

Assume that tables 1~4 have the same table structure as follows.

```
CREATE TABLE `table1` (
  `id` bigint NOT NULL AUTO_INCREMENT,
  `sid` bigint NOT NULL,
  `pid` bigint NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

For those four tables, the `id` column is the primary key. It is auto-incremental, which will cause different sharded tables to generate duplicated `id` ranges and cause the primary key conflict on the target table during the migration. On the other hand, the `sid` column is the sharding key, which ensures that the index is unique globally. So you can remove the unique constraint of the `id` column in the target `table5` to avoid the data merge conflicts.

```
CREATE TABLE `table5` (
  `id` bigint NOT NULL,
  `sid` bigint NOT NULL,
  `pid` bigint NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.4.5.2 Step1. Use Dumpling to export full data

If those multiple sharded tables to be exported are in the same upstream MySQL instance, you can directly use the `-f` parameter of Dumpling to export them in a single operation.

If the sharded tables are stored in different MySQL instances, you can use Dumpling to export them respectively and place the exported results in the same parent directory.

In the following example, both methods are used, and then the exported data is stored in the same parent directory.

First, run the following command to use Dumpling to export `table1` and `table2` from `my_db1`:

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db1 -f
    ↪  'my_db1.table[12]' -o ${data-path}/my_db1
```

The following table describes parameters in the command above. For more information about Dumpling parameters, see Dumpling Overview.

Parameter	Description
`-u` or `--user`	Specifies the user name to be used.
`-p` or `--password`	Specifies the password to be used.
`-P` or `--port`	Specifies the port to be used.
`-h` or `--host`	Specifies the IP address of the data source.

Parameter	Description
- ↪ t ↪ or -- ↪ thread ↪	Specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and increases the database's memory consumption. Therefore, it is not rec-om-

Parameter	Description

`-o`
or
`--output`
	Specifies the export directory of the storage, which supports a local file path or an external storage URI.

Parameter	Description
`-r` or `--row`	Specifies the maximum number of rows in a single file. If you use this parameter, Dumpling enables the in-table concurrency to speed up the export and reduce the memory usage.

Parameter	Description
`-F`	Specifies the maximum size of a single file. The unit is `MiB`. It is recommended to keep the value to 256 MiB.
`-B` or `--database`	Specifies databases to be exported.

Parameter	Description
- ↪ f ↪ or -- ↪ filter ↪	Exports tables that match the filter pattern. For the filter syntax, see table-filter.

Ensure that there is enough free space in `${data-path}`. It is strongly recommended to use the `-F` option to avoid interruptions in the backup process due to oversized single tables.

Then, run the following command to use Dumpling to export `table3` and `table4` from `my_db2`. Note that the path is `${data-path}/my_db2` instead of `${data-path}/my_db1`.

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db2 -f
    ↪  'my_db2.table[34]' -o ${data-path}/my_db2
```

After the preceding procedures, all source data tables are now exported to the `${data-path}` directory. Putting all the exported data on the same directory makes subsequent import by TiDB Lightning convenient.

The starting position information needed for incremental replication is in the `metadata` files in `my_db1` and `my_db2` sub-directories of `${data-path}` directory respectively. They are meta-information files automatically generated by Dumpling. To perform incremental replication, you need to record the binlog locations information in these files.

6.4.5.3 Step 2. Start TiDB Lightning to import full exported data

Before starting TiDB Lightning for migration, it is recommended that you understand how to handle checkpoints, and then choose the appropriate way to proceed according to your needs.

6.4.5.3.1 Checkpoints

Migrating a large volume of data usually takes hours or even days. There is a certain chance that the long-running process is interrupted unexpectedly. It can be very frustrating to redo everything from scratch, even if some part of data has already been imported.

Fortunately, TiDB Lightning provides a feature called `checkpoints`, which makes TiDB Lightning save the import progress as `checkpoints` from time to time, so that an interrupted import task can be resumed from the latest checkpoint upon restart.

If the TiDB Lightning task crashes due to unrecoverable errors (for example, data corruption), it will not pick up from the checkpoint, but will report an error and quit the task. To ensure the safety of the imported data, you must resolve these errors by using the `tidb-lightning-ctl` command before proceeding with other steps. The options include:

- –checkpoint-error-destroy: This option allows you to restart importing data into failed target tables from scratch by destroying all the existing data in those tables first.
- –checkpoint-error-ignore: If migration has failed, this option clears the error status as if no errors ever happened.
- –checkpoint-remove: This option simply clears all checkpoints, regardless of errors.

For more information, see TiDB Lightning Checkpoints.

6.4.5.3.2 Create a target schema

Create `mydb.table5` at downstream.

```
CREATE TABLE `table5` (
  `id` bigint NOT NULL,
  `sid` bigint NOT NULL,
  `pid` bigint NOT NULL,
  `comment` varchar(255) DEFAULT NULL,
  INDEX (`id`),
  UNIQUE KEY `sid` (`sid`)
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

6.4.5.3.3 Start the migration task

Follow these steps to start `tidb-lightning`:

1. Edit the toml file. `tidb-lightning.toml` is used in the following example:

```
[lightning]
# Logs
level = "info"
file = "tidb-lightning.log"
```

```
[mydumper]
data-source-dir = ${data-path}

[tikv-importer]
# Choose a local backend.
# "local": The default mode. It is used for large data volumes greater
    ↪ than 1 TiB. During migration, downstream TiDB cannot provide
    ↪ services.
# "tidb": Used for data volumes less than 1 TiB. During migration,
    ↪ downstream TiDB can provide services normally.
# For more information, see [TiDB Lightning Backends](https://docs.
    ↪ pingcap.com/tidb/stable/tidb-lightning-backends)
backend = "local"
# Set the temporary directory for the sorted key value pairs. It must
    ↪ be empty.
# The free space must be greater than the size of the dataset to be
    ↪ imported.
# It is recommended that you use a directory different from `data-
    ↪ source-dir` to get better migration performance by consuming I/O
    ↪ resources exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

# Set the renaming rules ('routes') from source to target tables, in
    ↪ order to support merging different table shards into a single
    ↪ target table. Here you migrate `table1` and `table2` in `my_db1`,
    ↪  and `table3` and `table4` in `my_db2`, to the target `table5` in
    ↪  downstream `my_db`.
[[mydumper.files]]
pattern = '(^|/)my_db1\.table[1-2]\..*\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

[[mydumper.files]]
pattern = '(^|/)my_db2\.table[3-4]\..*\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

# Information of the target TiDB cluster. For example purposes only.
    ↪ Replace the IP address with your IP address.
[tidb]
# Information of the target TiDB cluster.
# Values here are only for illustration purpose. Replace them with your
    ↪  own values.
```

```
host = ${host}        # For example: "172.16.31.1"
port = ${port}        # For example: 4000
user = "${user_name}" # For example: "root"
password = "${password}" # For example: "rootroot"
status-port = ${status-port} # The table information is read from the
    ↪ status port. For example: 10080
# the IP address of the PD cluster. TiDB Lightning gets some
    ↪ information through the PD cluster.
# For example: "172.16.31.3:2379".
# When backend = "local", make sure that the values of status-port and
    ↪ pd-addr are correct. Otherwise an error will occur.
pd-addr = "${ip}:${port}"
```

2. Run `tidb-lightning`. If you run the program by directly invoking the program name in a shell, the process may quit unexpectedly after receiving a SIGHUP signal. It is recommended that you run the program using tools such as `nohup` or `screen` or `tiup`, and put the process to the shell background. If you migrate from S3, the SecretKey and AccessKey of the account that has access to the Amazon S3 backend store needs to be passed into the Lightning node as environment variables. Reading credential files from `~/.aws/credentials` is also supported. For example:

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After starting the migration task, you can check the progress by using either of the following methods:

- Use `grep` tool to search the keyword `progress` in the log. By default, a message reporting the progress is flushed into the log file every 5 minutes.
- View progress via the monitoring dashboard. For more information, see TiDB Lightning Monitoring.
- View the progress via the Web page. See Web Interface.

After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

Note:

> Whether the migration is successful or not, the last line in the log will always be `tidb lightning exit`. It just means that TiDB Lightning quits normally, and does not guarantee that the importing task is completed successfully.

If you encounter any problems during migration, see TiDB Lightning FAQs.

6.4.5.4 Step 3. (Optional) Use DM to perform incremental replication

To replicate the data changes based on binlog from a specified position in the source database to TiDB, you can use TiDB DM to perform incremental replication.

6.4.5.4.1 Add the data source

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.
source-id: "mysql-01" # Must be unique.

### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction
    ↪ Identifier).
### The prerequisite is that you have already enabled GTID in the upstream
    ↪ MySQL.
### If you have configured the upstream database service to switch master
    ↪ between different nodes automatically, you must enable GTID.
enable-gtid: true

from:
  host: "${host}"        # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext passwords are supported but not
      ↪ recommended. It is recommended that you use dmctl encrypt to encrypt
      ↪  plaintext passwords.
  port: ${port}          # For example: 3306
```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml
```

The parameters are described as follows.

Parameter	Description
--master-addr ↪ - ↪ addr ↪	{advertise-addr} of any DM-master node in the cluster that dm-ctl connects to. For example: 172.16.10.71:826
operate-source ↪ create ↪	Load data sources to DM clusters.

Repeat the above steps until all MySQL upstream instances are added to the DM as data sources.

6.4.5.4.2 Create a replication task

Edit a task configuration file called `task.yaml`, to configure the incremental replication mode and replication starting point for each data source.

```
name: task-test           # The name of the task. Should be globally unique
   ↪ .
task-mode: incremental    # The mode of the task. "incremental" means full
   ↪ data migration is skipped and only incremental replication is
   ↪ performed.
```

```
### Required for incremental replication from sharded tables. By default,
   ↪ the "pessimistic" mode is used.
### If you have a deep understanding of the principles and usage limitations
   ↪  of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
   ↪ https://docs.pingcap.com/tidb/dev/feature-shard-merge/).

shard-mode: "pessimistic"

### Configure the access information of the target TiDB database instance:
target-database:          # The target database instance
  host: "${host}"         # For example: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}" # It is recommended to use a dmctl encrypted
     ↪ password.

### Use block-allow-list to configure tables that require sync:
block-allow-list:         # The set of filter rules on matching tables in
   ↪ the data sources, to decide which tables need to migrate and which
   ↪ not. Use the black-white-list if the DM version is earlier than or
   ↪ equal to v2.0.0-beta.2.
  bw-rule-1:              # The ID of the block and allow list rule.
    do-dbs: ["my_db1"]    # The databases to be migrated. Here, my_db1 of
       ↪ instance 1 and my_db2 of instance 2 are configured as two separate
       ↪  rules to demonstrate how to prevent my_db2 of instance 1 from
       ↪ being replicated.
  bw-rule-2:
    do-dbs: ["my_db2"]
routes:                           # Table renaming rules ('routes') from
   ↪ upstream to downstream tables, in order to support merging different
   ↪ sharded table into a single target table.
  route-rule-1:                   # Rule name. Migrate and merge table1 and
     ↪ table2 from my_db1 to the downstream my_db.table5.
    schema-pattern: "my_db1"      # Rule for matching upstream schema names.
       ↪  It supports the wildcards "*" and "?".
    table-pattern: "table[1-2]"   # Rule for matching upstream table names.
       ↪ It supports the wildcards "*" and "?".
    target-schema: "my_db"        # Name of the target schema.
    target-table: "table5"        # Name of the target table.
  route-rule-2:                   # Rule name. Migrate and merge table3 and
     ↪ table4 from my_db2 to the downstream my_db.table5.
    schema-pattern: "my_db2"
    table-pattern: "table[3-4]"
    target-schema: "my_db"
```

```
    target-table: "table5"

### Configure data sources. The following uses two data sources as an
    ↪ example.
mysql-instances:
  - source-id: "mysql-01"         # Data source ID. It is the source-id in
      ↪ source1.yaml.
    block-allow-list: "bw-rule-1" # Use the block and allow list
       ↪ configuration above. Replicate `my_db1` in instance 1.
    route-rules: ["route-rule-1"] # Use the configured routing rule above to
       ↪  merge upstream tables.
###      syncer-config-name: "global" # Use the syncers configuration below.
    meta:                         # The position where the binlog
       ↪ replication starts when `task-mode` is `incremental` and the
       ↪ downstream database checkpoint does not exist. If the checkpoint
       ↪ exists, the checkpoint is used. If neither the `meta`
       ↪ configuration item nor the downstream database checkpoint exists,
       ↪ the migration starts from the latest binlog position of the
       ↪ upstream.
      binlog-name: "${binlog-name}" # The log location recorded in ${data-
         ↪ path}/my_db1/metadata in Step 1. You can either specify binlog-
         ↪ name + binlog-pos or binlog-gtid. When the upstream database
         ↪ service is configured to switch master between different nodes
         ↪ automatically, use binlog GTID here.
      binlog-pos: ${binlog-position}
      # binlog-gtid:              " For example: 09bec856-ba95-11ea-850a-58
         ↪ f2b4af5188:1-9"
  - source-id: "mysql-02"         # Data source ID. It is the source-id in
      ↪ source1.yaml.
    block-allow-list: "bw-rule-2" # Use the block and allow list
       ↪ configuration above. Replicate `my_db2` in instance2.
    route-rules: ["route-rule-2"] # Use the routing rule configured above.

###      syncer-config-name: "global" # Use the syncers configuration below.
    meta:                         # The migration starting point of binlog
       ↪ when task-mode is incremental and there is no checkpoint in the
       ↪ downstream database. If there is a checkpoint, the checkpoint will
       ↪  be used.
      # binlog-name: "${binlog-name}" # The log location recorded in ${data-
         ↪ path}/my_db2/metadata in Step 1. You can either specify binlog-
         ↪ name + binlog-pos or binlog-gtid. When the upstream database
         ↪ service is configured to switch master between different nodes
         ↪ automatically, use binlog GTID here.
      # binlog-pos: ${binlog-position}
      binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"
```

```
### (Optional) If you need to incrementally replicate some data changes that
    ↪  have been covered in the full migration, you need to enable the safe
    ↪  mode to avoid data migration errors during incremental replication.
### This scenario is common when the fully migrated data is not part of a
    ↪ consistent snapshot of the data source, and the incremental data is
    ↪ replicated from a location earlier than the fully migrated data.
### syncers:         # The running parameters of the sync processing unit.
### global:          # Configuration name.
### If set to true, DM changes INSERT to REPLACE, and changes UPDATE to a
    ↪ pair of DELETE and REPLACE for data source replication operations.
### Thus, it can apply DML repeatedly during replication when primary keys
    ↪ or unique indexes exist in the table structure.
### TiDB DM automatically starts safe mode within 1 minute before starting
    ↪ or resuming an incremental replication task.
###   safe-mode: true
```

For more configurations, see DM Advanced Task Configuration File.

Before you start the data migration task, it is recommended to use the `check-task` ↪ subcommand in `tiup dmctl` to check if the configuration meets the DM configuration requirements.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Use `tiup dmctl` to run the following command to start the data migration task.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters in this command are described as follows.

Parameter	Description
–master-addr	{advertise-addr} of any DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:826
start-task	Starts the data migration task.

If the task fails to start, first make configuration changes according to the prompt messages from the returned result, and then run the `start-task task.yaml` subcommand in `tiup dmctl` to restart the task. If you encounter problems, see Handle Errors and TiDB Data Migration FAQ.

6.4.5.4.3 Check the migration status

You can check if there are running migration tasks in the DM cluster and their status by running the `query-status` command in `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For more information, see Query Status.

6.4.5.4.4 Monitor tasks and view logs

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

  If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

  When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

  - DM-master log directory: It is specified by the DM-master command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/`.
  - DM-worker log directory: It is specified by the DM-worker command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/`.

6.4.6 Migrate Data from Vitess to TiDB

This document describes the tools that you can use to migrate data from Vitess to TiDB.

Because the backend of Vitess is based on MySQL, when migrating data from Vitess to TiDB, you can use the same migration tools that apply to MySQL, such as Dumpling, TiDB Lightning, and TiDB Data Migration (DM). Note that these tools should be set up for each shard in Vitess for data migration.

Generally, before data migration, it is recommended to configure the DM task to set `task-mode` to `all` and `import-mode` to `physical`. For more information, see Task configuration file template (advanced).

If your data size exceeds 10 TiB, it is recommended to do the import in two steps:

1. Use Dumpling and TiDB Lightning to import existing data.
2. Use DM to import incremental data.

In addition to these tools, you can also use Debezium connector for Vitess. This connector enables you to use Kafka Connect or Apache Flink to stream changes from Vitess to TiDB.

Because both Vitess and TiDB support the MySQL protocol and SQL dialect, changes at the application level are expected to be small. For tasks directly managing sharding or other implementation-specific aspects, however, the changes might be larger. To facilitate the data migration from Vitess to TiDB, TiDB introduces the `VITESS_HASH()` function, which returns the hash of a string that is compatible with Vitess' HASH function.

6.4.6.1 Examples

6.4.6.1.1 Dumpling and TiDB Lightning

The following two examples show how Dumpling and TiDB Lightning work together to migrate data from Vitess to TiDB.

- In this example, TiDB Lightning uses the logical import mode, which first encodes data into SQL statements and then runs the SQL statements to import data.

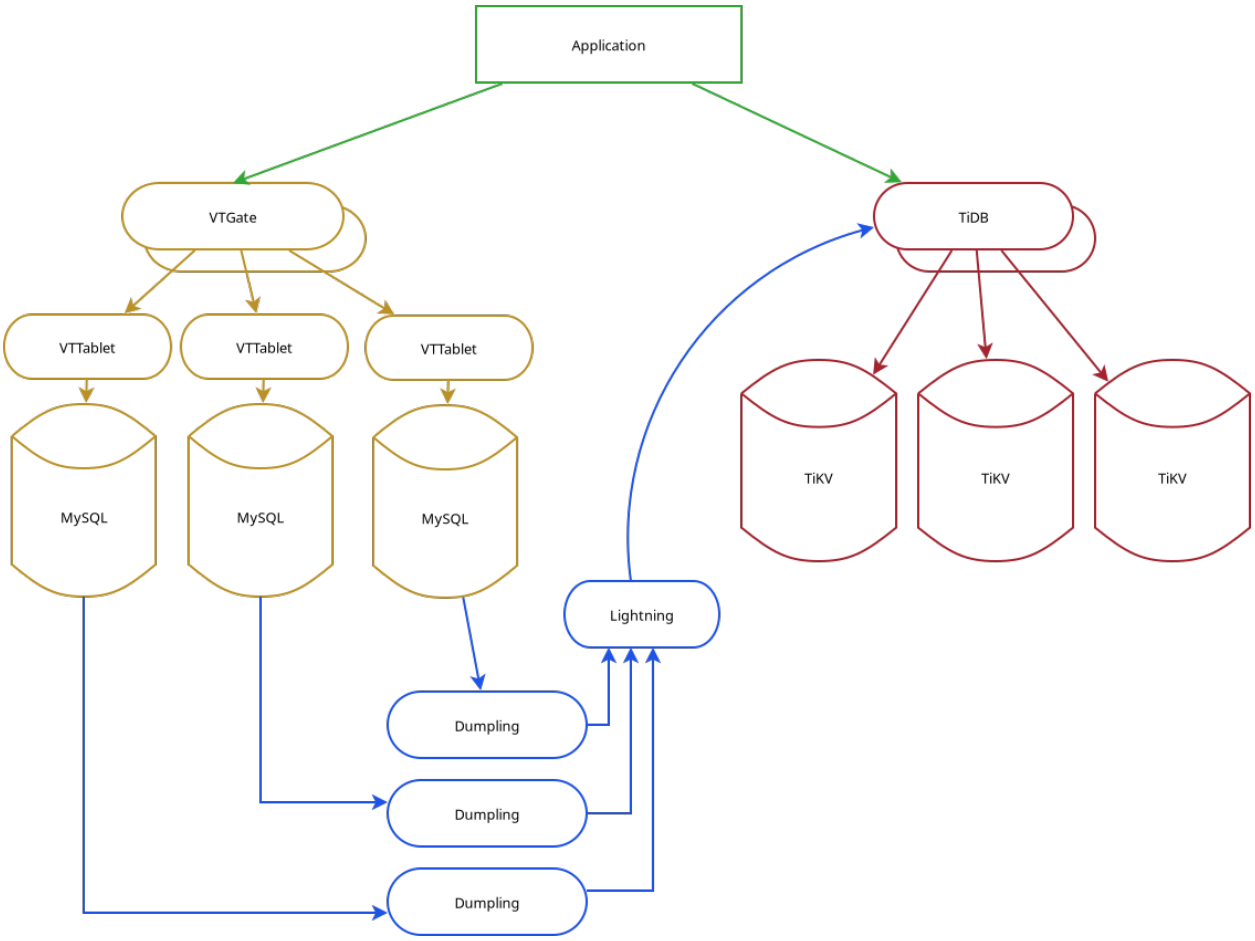

Figure 95: Vitess to TiDB Migration with TiDB backend

- In this example, TiDB Lightning uses the physical import mode to directly ingest data into TiKV.

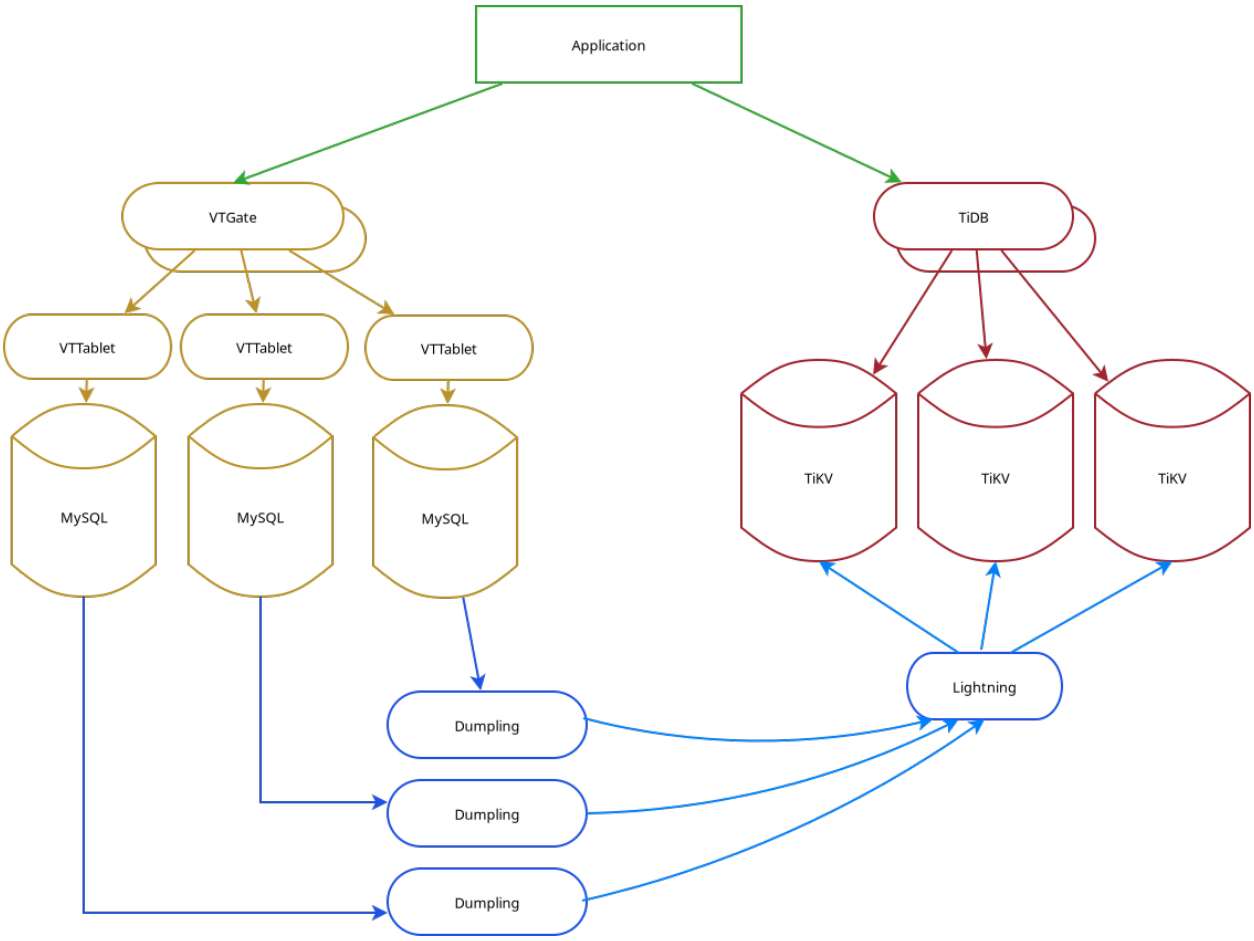

Figure 96: Vitess to TiDB Migration with local backend

6.4.6.1.2 DM

The following example shows how DM migrates data from Vitess to TiDB.

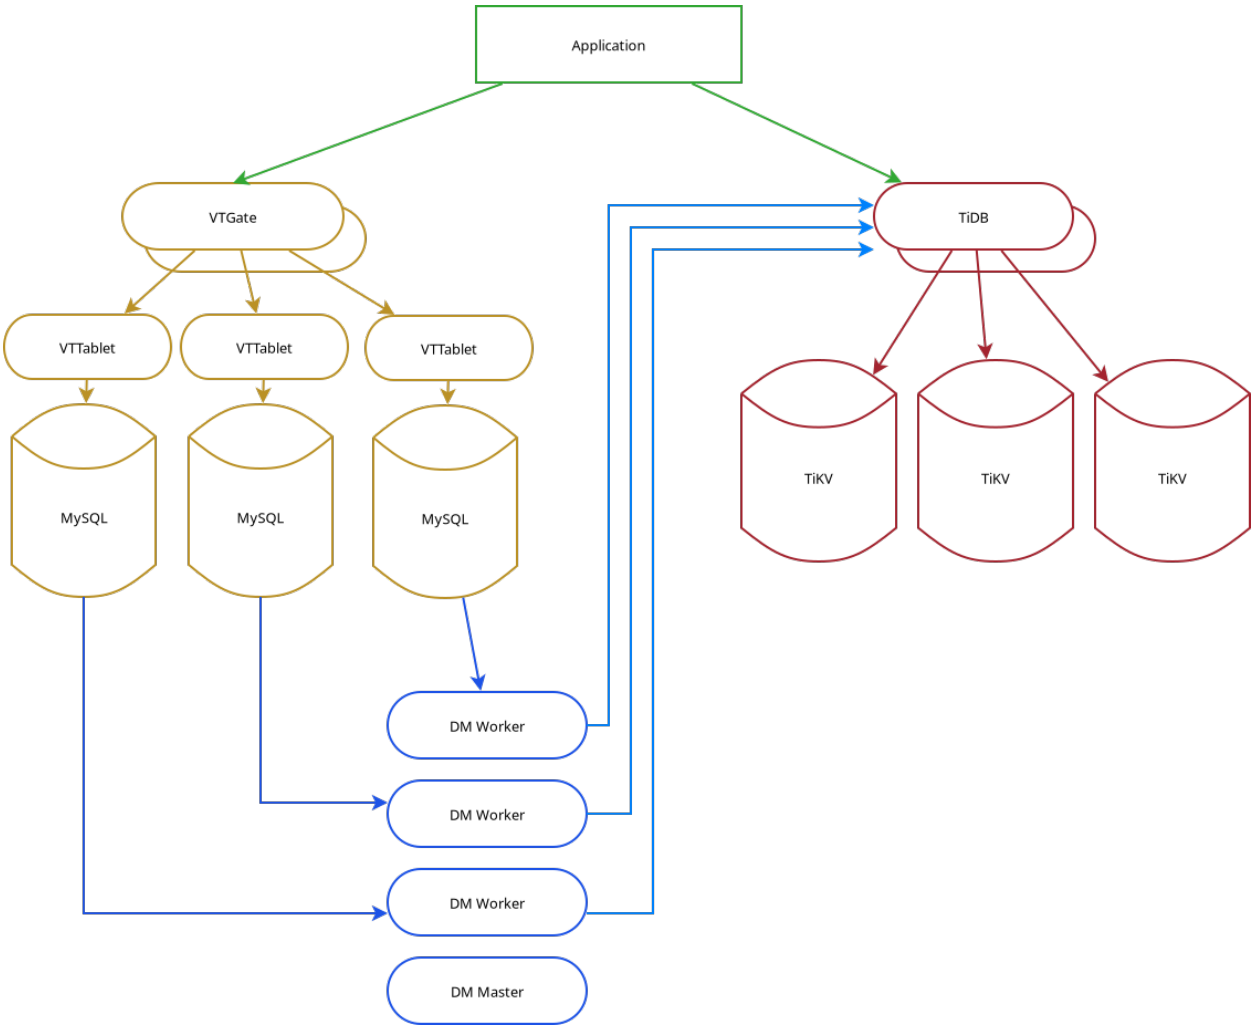

Figure 97: Vitess to TiDB with DM

6.4.7 Migrate Data from MariaDB to TiDB

This document describes how to migrate data from a MariaDB server installation to a TiDB cluster.

6.4.7.1 Prerequisites

Choose the right migration strategy:

- The first strategy is to dump data with Dumpling and restore data with TiDB Lightning. This works for all versions of MariaDB. The drawback of this strategy is that it needs more downtime.
- The second strategy is to Replicate data with DM from MariaDB to TiDB with DM. DM does not support all versions of MariaDB. Supported versions are listed on the DM Compatibility Catalog.

Besides these two strategies, there might be other strategies available specifically to your situation. For example:

- Use the functionality of your Object Relational Mapping (ORM) to re-deploy and migrate your data.
- Modify your application to write from both MariaDB and TiDB while the migration is ongoing.

This document only covers the first two strategies.

Prepare the following based on the strategy you choose:

- For the **dump and restore** strategy:
  - Install Dumpling and TiDB Lightning.
  - Make sure you have the required privileges on the MariaDB server for Dumpling to export data.
- For the **data replication** strategy, set up Data Migration (DM).

6.4.7.2 Check compatibility

TiDB is compatible with MySQL, and MySQL and MariaDB have a lot of functionality in common. However, there might be MariaDB-specific features that might not be compatible with TiDB that you should be aware of before migrating.

Besides checking the items in this section, it is recommended that you also check the Compatibility & Differences in the MariaDB documentation.

6.4.7.2.1 Authentication

The Security Compatibility with MySQL document lists authentication methods that TiDB supports. TiDB does not support a few authentication methods in MariaDB. This means that you might have to create a new password hash for the account or take other specific measures.

To check what authentication methods are used, you can run the following statement:

```
SELECT
  plugin,
  COUNT(*)
FROM
  mysql.user
GROUP BY
  plugin;
```

```
+----------------------+----------+
| plugin               | COUNT(*) |
+----------------------+----------+
| mysql_native_password |   11 |
+----------------------+----------+
1 row in set (0.002 sec)
```

6.4.7.2.2 System-versioned tables

TiDB does not support system-versioned tables. However, TiDB does support `AS OF TIMESTAMP` which might replace some of the use cases of system-versioned tables.

You can check for affected tables with the following statement:

```
SELECT
  TABLE_SCHEMA,
  TABLE_NAME
FROM
  information_schema.tables
WHERE
  TABLE_TYPE='SYSTEM VERSIONED';
```

```
+--------------+------------+
| TABLE_SCHEMA | TABLE_NAME |
+--------------+------------+
| test         | t          |
+--------------+------------+
1 row in set (0.005 sec)
```

To remove system versioning, execute the `ALTER TABLE` statement:

```
MariaDB [test]> ALTER TABLE t DROP SYSTEM VERSIONING;
Query OK, 0 rows affected (0.071 sec)
Records: 0 Duplicates: 0 Warnings: 0
```

6.4.7.2.3 Sequences

Both MariaDB and TiDB support `CREATE SEQUENCE`. However, it is currently not supported by DM. It is recommended that you do not create, modify, or remove sequences during the migration and test this specifically after migration.

To check if you are using sequences, execute the following statement:

```
SELECT
  TABLE_SCHEMA,
  TABLE_NAME
```

```
FROM
  information_schema.tables
WHERE
  TABLE_TYPE='SEQUENCE';
```

```
+--------------+------------+
| TABLE_SCHEMA | TABLE_NAME |
+--------------+------------+
| test         | s1         |
+--------------+------------+
1 row in set (0.016 sec)
```

6.4.7.2.4 Storage engines

MariaDB offers storage engines for local data such as `InnoDB`, `MyISAM` and `Aria`. While the data format is not directly supported by TiDB, migrating these works fine. However, some engines place data outside of the server, such as the `CONNECT` storage engine and `Spider` ↪ . While you can migrate such tables to TiDB, TiDB does not provide the functionality to store data outside of the TiDB cluster.

To check what storage engines you are using, execute the following statement:

```
SELECT
  ENGINE,
  COUNT(*)
FROM
  information_schema.tables
GROUP BY
  ENGINE;
```

```
+--------------------+----------+
| ENGINE             | COUNT(*) |
+--------------------+----------+
| NULL               |      101 |
| Aria               |       38 |
| CSV                |        2 |
| InnoDB             |        6 |
| MEMORY             |       67 |
| MyISAM             |        1 |
| PERFORMANCE_SCHEMA |       81 |
+--------------------+----------+
7 rows in set (0.009 sec)
```

6.4.7.2.5 Syntax

MariaDB supports the `RETURNING` keyword for `DELETE`, `INSERT`, and `REPLACE` statements. TiDB does not support them. You might want to look into your application and query logging to see if it affects your migration.

6.4.7.2.6 Data types

MariaDB supports some data types that TiDB does not support, such as `UUID`, `INET4`, and `INET6`.

To check for these datatypes, execute the following statement:

```
SELECT
  TABLE_SCHEMA,
  TABLE_NAME,
  COLUMN_NAME,
  DATA_TYPE
FROM
  information_schema.columns
WHERE
  DATA_TYPE IN('INET4','INET6','UUID');
```

```
+--------------+------------+-------------+-----------+
| TABLE_SCHEMA | TABLE_NAME | COLUMN_NAME | DATA_TYPE |
+--------------+------------+-------------+-----------+
| test         | u1         | u           | uuid      |
| test         | u1         | i4          | inet4     |
| test         | u1         | i6          | inet6     |
+--------------+------------+-------------+-----------+
3 rows in set (0.026 sec)
```

6.4.7.2.7 Character set and collation

TiDB does not support the `latin1_swedish_ci` collation that is often used in MariaDB.

To see what collations TiDB supports, execute this statement on TiDB:

```
SHOW COLLATION;
```

```
+--
   ↪ -----------------+---------+-----+---------+----------+---------+-------------
   ↪
| Collation       | Charset | Id | Default | Compiled | Sortlen | Pad_
   ↪ attribute |
+--
   ↪ -----------------+---------+-----+---------+----------+---------+-------------
   ↪
| ascii_bin       | ascii   |  65 | Yes     | Yes      |       1 | PAD SPACE   |
```

```
| binary           | binary  |  63 | Yes    | Yes     |       1 | NO PAD     |
| gbk_bin          | gbk     |  87 |        | Yes     |       1 | PAD SPACE  |
| gbk_chinese_ci   | gbk     |  28 | Yes    | Yes     |       1 | PAD SPACE  |
| latin1_bin       | latin1  |  47 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8_bin         | utf8    |  83 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8_general_ci  | utf8    |  33 |        | Yes     |       1 | PAD SPACE  |
| utf8_unicode_ci  | utf8    | 192 |        | Yes     |       8 | PAD SPACE  |
| utf8mb4_0900_ai_ci | utf8mb4 | 255 |    | Yes     |       0 | NO PAD     |
| utf8mb4_0900_bin | utf8mb4 | 309 |      | Yes     |       1 | NO PAD     |
| utf8mb4_bin      | utf8mb4 |  46 | Yes    | Yes     |       1 | PAD SPACE  |
| utf8mb4_general_ci | utf8mb4 | 45 |     | Yes     |       1 | PAD SPACE  |
| utf8mb4_unicode_ci | utf8mb4 | 224 |    | Yes     |       8 | PAD SPACE  |
+--
    ↪ -----------------+---------+-----+---------+---------+---------+-------------
    ↪
13 rows in set (0.00 sec)
```

To check what collations the columns of your current tables are using, you can use this statement:

```
SELECT
  TABLE_SCHEMA,
  COLLATION_NAME,
  COUNT(*)
FROM
  information_schema.columns
GROUP BY
  TABLE_SCHEMA, COLLATION_NAME
ORDER BY
  COLLATION_NAME;
```

```
+--------------------+--------------------+----------+
| TABLE_SCHEMA       | COLLATION_NAME     | COUNT(*) |
+--------------------+--------------------+----------+
| sys                | NULL               |      562 |
| test               | NULL               |       14 |
| mysql              | NULL               |       84 |
| performance_schema | NULL               |      892 |
| information_schema | NULL               |      421 |
| mysql              | latin1_swedish_ci  |       34 |
| performance_schema | utf8mb3_bin        |       38 |
| mysql              | utf8mb3_bin        |       61 |
| sys                | utf8mb3_bin        |       40 |
| information_schema | utf8mb3_general_ci |      375 |
| performance_schema | utf8mb3_general_ci |      244 |
```

```
| sys                | utf8mb3_general_ci |   386 |
| mysql              | utf8mb3_general_ci |    67 |
| mysql              | utf8mb4_bin        |     8 |
+--------------------+--------------------+-------+
14 rows in set (0.045 sec)
```

See also Character Set and Collation.

6.4.7.3 Dump data with Dumpling and restore data with TiDB Lightning

This method assumes that you take your application offline, migrate the data, and then re-configure your application to use the migrated data.

> **Note:**
>
> It is strongly recommended to first do this on a test or development instance of your application before doing it in production. This is both to check for possible compatibility issues as to get insight into how much time the migration will take.

Perform the following steps to migrate data from MariaDB to TiDB:

1. Stop your application. Take your application offline. This ensures there are no modifications made to the data in MariaDB during or after the migration.
2. Dump data in MariaDB with the `tiup dumpling` command.

```
tiup dumpling --port 3306 --host 127.0.0.1 --user root --password
    ↪ secret -F 256MB -o /data/backup
```

3. Restore the data by using the `tiup tidb-lightning` command. For more information about how to configure TiDB Lightning and how to run it, see Get Started with TiDB Lightning.
4. Migrate user accounts and permissions. For more information about how to migrate your users and permissions, see Export users and grants.
5. Reconfigure your application. You need to change the application configuration so that it can connect to the TiDB server.
6. Clean up. Once you have verified that the migration is successful you can make a final backup of the data in MariaDB and stop the server. This also means you can remove tools such as TiUP, Dumpling, and TiDB Lightning.

6.4.7.4 Replicate data with DM

This method assumes you would set up replication, stop your application and wait for the replication to catch up, and then re-configure your application to use TiDB.

To use DM, you need to deploy a set of DM services either with a TiUP cluster or with TiDB Operator. After that, use `dmctl` to configure the DM services.

> **Note:**
>
> It is strongly recommended to first do this on a test or development instance of your application before doing it in production. This is both to check for possible compatibility issues as to get insight into how much time the migration will take.

6.4.7.4.1 Step 1. Prepare

Make sure that binlogs are enabled on MariaDB and that the `binlog_format` is set to `ROW`. It is also recommended to set `binlog_annotate_row_events=OFF` and `log_bin_compress=OFF`.

You also need an account with the `SUPER` permission or with the `BINLOG MONITOR` and `REPLICATION MASTER ADMIN` permissions. This account also needs read permission for the schemas you are going to migrate.

If you are not using an account with the `SUPER` permission, then you might have to add the following to the DM configuration, because TiDB does not yet know how to check for MariaDB specific permissions.

```
ignore-checking-items: ["replication_privilege"]
```

Before you use DM to migrate data from upstream to downstream, a precheck helps detect errors in the upstream database configurations and ensures that the migration goes smoothly. For more information, see Migration Task Precheck

6.4.7.4.2 Step 2. Replicate data

Follow the Quick Start Guide for TiDB Data Migration to replicate your data from MariaDB to TiDB.

Note that it is not required to first copy the initial data as you would do with MariaDB to MariaDB replication, DM will do this for you.

6.4.7.4.3 Step 3. Migrate user accounts and permissions

See Export users and grants for how to migrate your users and permissions.

6.4.7.4.4 Step 4. Test your data

Once your data is replicated, you can run read-only queries on it to validate it. For more information, see Test your application.

6.4.7.4.5 Step 5. Switch over

To switch over to TiDB, you need to do the following:

1. Stop your application.
2. Monitor the replication delay, which should go to 0 seconds.
3. Change the configuration of your application so that it connects to TiDB and start it again.

To check for replication delay, run `query-status <taskname>` via `dmctl` and check for `"synced: true"` in the `subTaskStatus`.

6.4.7.4.6 Step 6. Clean up

Once you have verified that the migration is successful, you can make a final backup of the data in MariaDB and stop the server. It also means you can stop and remove the DM cluster.

6.4.7.5 Export users and grants

You can use `pt-show-grants`. It is part of the Percona Toolkit to export users and grants from MariaDB and load these into TiDB.

6.4.7.6 Test your application

While it is possible to use generic tools such as `sysbench` for testing, it is highly recommended to test some specific features of your application. For example, run a copy of your application against a TiDB cluster with a temporary copy of your data.

Such a test makes sure your application compatibility and performance with TiDB is verified. You need to monitor the log files of your application and TiDB to see if there are any warnings that might need to be addressed. Make sure that the database driver that your application is using (for example MySQL Connector/J for Java based applications) is tested. You might want to use an application such as JMeter to put some load on your application if needed.

6.4.7.7 Validate data

You can use sync-diff-inspector to validate if the data in MariaDB and TiDB are identical.

6.4.8 Migrate Data from CSV Files to TiDB

This document describes how to migrate data from CSV files to TiDB.

TiDB Lightning can read data from CSV files and other delimiter formats, such as tab-separated values (TSV). For other flat file data sources, you can also refer to this document and migrate data to TiDB.

6.4.8.1 Prerequisites

- Install TiDB Lightning.
- Get the target database privileges required for TiDB Lightning.

6.4.8.2 Step 1. Prepare the CSV files

Put all the CSV files in the same directory. If you need TiDB Lightning to recognize all CSV files, the file names should meet the following requirements:

- If a CSV file contains the data for an entire table, name the file `${db_name}.${table_name}.csv`.
- If the data of one table is separated into multiple CSV files, append a numeric suffix to these CSV files. For example, `${db_name}.${table_name}.003.csv`. The numeric suffixes can be inconsecutive but must be in ascending order. You also need to add extra zeros before the number to ensure all the suffixes are in the same length.

TiDB Lightning recursively searches for all `.csv` files in this directory and its subdirectories.

6.4.8.3 Step 2. Create the target table schema

Because CSV files do not contain schema information, before importing data from CSV files into TiDB, you need to create the target table schema. You can create the target table schema by either of the following two methods:

- **Method 1**: create the target table schema using TiDB Lightning.

  Create SQL files that contain the required DDL statements:

  - Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
  - Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2**: create the target table schema manually.

6.4.8.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the target
    ↪ TiDB cluster cannot provide any service.
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
    ↪ . During the import, the target TiDB cluster can provide service
    ↪ normally.
### For more information on import mode, refer to <https://docs.pingcap.com/
    ↪ tidb/stable/tidb-lightning-overview#tidb-lightning-architecture>
backend = "local"
### Set the temporary storage directory for the sorted Key-Value files. The
    ↪ directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
### Directory of the data source.
data-source-dir = "${data-path}" # A local path or S3 path. For example, 's3
    ↪ ://my-bucket/sql-backup'.

### Defines CSV format.
[mydumper.csv]
### Field separator of the CSV file. Must not be empty. If the source file
    ↪ contains fields that are not string or numeric, such as binary, blob,
    ↪  or bit, it is recommended not to usesimple delimiters such as ",",
    ↪ and use an uncommon character combination like "|+|" instead.
separator = ','
### Delimiter. Can be zero or multiple characters.
delimiter = '"'
### Line terminator. By default, \r, \n, and \r\n are all treated as line
    ↪ terminators.
### terminator = "\r\n"
### Configures whether the CSV file has a table header.
### If this item is set to true, TiDB Lightning uses the first line of the
    ↪ CSV file to parse the corresponding relationship of fields.
```

```
header = true
### Configures whether the CSV file contains NULL.
### If this item is set to true, any column of the CSV file cannot be parsed
    ↪  as NULL.
not-null = false
### If `not-null` is set to false (CSV contains NULL),
### The following value is parsed as NULL.
null = '\N'
### Whether to treat the backslash ('\') in the string as an escape
    ↪ character.
backslash-escape = true
### Whether to trim the last separator at the end of each line.
trim-last-separator = false

[tidb]
### The target cluster.
host = ${host}         # e.g.: 172.16.32.1
port = ${port}         # e.g.: 4000
user = "${user_name}"  # e.g.: "root"
password = "${password}" # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs to
    ↪ obtain the table schema information from the TiDB status port. e.g.:
    ↪ 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD.
    ↪ When backend = "local", you must specify status-port and pd-addr
    ↪ correctly. Otherwise, the import will be abnormal.
```

For more information on the configuration file, refer to TiDB Lightning Configuration.

6.4.8.5 Step 4. Tune the import performance (optional)

When you import data from CSV files with a uniform size of about 256 MiB, TiDB Lightning works in the best performance. However, if you import data from a single large CSV file, TiDB Lightning can only use one thread to process the import by default, which might slow down the import speed.

To speed up the import, you can split a large CSV file into smaller ones. For a CSV file in a common format, before TiDB Lightning reads the entire file, it is hard to quickly locate the beginning and ending positions of each line. Therefore, TiDB Lightning does not automatically split CSV files by default. But if your CSV files to be imported meet certain format requirements, you can enable the `strict-format` mode. In this mode, TiDB Lightning automatically splits a single large CSV file into multiple files, each in about 256 MiB, and processes them in parallel.

> **Note:**
>
> If a CSV file is not in a strict format but the `strict-format` mode is set to `true` by mistake, a field that spans multiple lines will be split into two fields. This causes the parsing to fail, and TiDB Lightning might import the corrupted data without reporting any error.

In a strict-format CSV file, each field only takes up one line. It must meet the following requirements:

- The delimiter is empty.
- Each field does not contain CR (`\r`) or LF (`\n`).

You need to explicitly specify the line terminator `terminator` for a `strict-format` CSV file.

If your CSV file meets the above requirements, you can speed up the import by enabling the `strict-format` mode as follows:

```
[mydumper]
strict-format = true
```

6.4.8.6 Step 5. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the process might exit unexpectedly after receiving a SIGHUP signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

```
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

After the import starts, you can check the progress of the import by either of the following methods:

- `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
- Check progress in the monitoring dashboard.
- Check progress in the TiDB Lightning web interface.

After TiDB Lightning completes the import, it exits automatically. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

6.4.8.7 Other file formats

If your data source is in other formats, to migrate data from your data source, you must end the file name with `.csv` and make corresponding changes in the `[mydumper.csv ↪ ]` section of the `tidb-lightning.toml` configuration file. Here are example changes for common formats:

TSV:

```
### Format example
### ID   Region   Count
### 1    East     32
### 2    South    NULL
### 3    West     10
### 4    North    39

### Format configuration
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
trim-last-separator = false
```

TPC-H DBGEN:

```
### Format example
### 1|East|32|
### 2|South|0|
### 3|West|10|
### 4|North|39|

### Format configuration
[mydumper.csv]
```

```
separator = '|'
delimiter = ''
header = false
not-null = true
backslash-escape = false
trim-last-separator = true
```

6.4.8.8 What's next

- CSV Support and Restrictions.

6.4.9 Migrate Data from SQL Files to TiDB

This document describes how to migrate data from MySQL SQL files to TiDB using TiDB Lightning. For how to generate MySQL SQL files, refer to Export to SQL files using Dumpling.

6.4.9.1 Prerequisites

- Install TiDB Lightning using TiUP
- Grant the required privileges to the target database for TiDB Lightning

6.4.9.2 Step 1. Prepare SQL files

Put all the SQL files in the same directory, like `/data/my_datasource/` or `s3://my-bucket/sql-backup`. TiDB Lightning recursively searches for all `.sql` files in this directory and its subdirectories.

6.4.9.3 Step 2. Define the target table schema

To import data to TiDB, you need to create the table schema for the target database.

If you use Dumpling to export data, the table schema file is automatically exported. For the data exported in other ways, you can create the table schema in one of the following methods:

- **Method 1**: Create the target table schema using TiDB Lightning.

  Create SQL files that contain the required DDL statements:

  - Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
  - Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2**: Create the target table schema manually.

6.4.9.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default. The local backend is used to import large volumes of
    ↪ data (around or more than 1 TiB). During the import, the target TiDB
    ↪ cluster cannot provide any service.
### "tidb": The "tidb" backend can also be used to import small volumes of
    ↪ data (less than 1 TiB). During the import, the target TiDB cluster
    ↪ can provide service normally. For the information about backend mode,
    ↪  refer to https://docs.pingcap.com/tidb/stable/tidb-lightning-
    ↪ backends.

backend = "local"
### Sets the temporary storage directory for the sorted key-value files. The
    ↪  directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage and exclusive I/O for the directory.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
### Directory of the data source
data-source-dir = "${data-path}" # Local or S3 path, such as 's3://my-bucket
    ↪ /sql-backup'

[tidb]
### The information of target cluster
host = ${host}             # For example, 172.16.32.1
port = ${port}             # For example, 4000
user = "${user_name}"      # For example, "root"
password = "${password}"   # For example, "rootroot"
status-port = ${status-port} # During the import process, TiDB Lightning
    ↪ needs to obtain table schema information from the "Status Port" of
    ↪ TiDB, such as 10080.
pd-addr = "${ip}:${port}" # The address of the cluster's PD. TiDB Lightning
    ↪  obtains some information through PD, such as 172.16.31.3:2379. When
    ↪ backend = "local", you must correctly specify status-port and pd-addr
    ↪ . Otherwise, the import will encounter errors.
```

For more information about the configuration file, refer to TiDB Lightning Configuration.

6.4.9.5 Step 4. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the program might exit because of the `SIGHUP` signal. In this case, it is recommended to run the program with a `nohup` or `screen` tool.

If you import the data from S3, you need to pass in `SecretKey` and `AccessKey` of the account as environment variables. The account has the permission to access the S3 backend storage.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

TiDB Lightning also supports reading credential files from `~/.aws/credentials`.

After the import is started, you can check the progress in one of the following ways:

- Search the `progress` keyword in the `grep` log, which is updated every 5 minutes by default.
- Use the Grafana dashboard. For details, see TiDB Lightning Monitoring.
- Use web interface. For details, see TiDB Lightning Web Interface.

After the import is completed, TiDB Lightning automatically exits. Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> No matter whether the import is successful or not, the last line displays `tidb lightning exit`. It only means that TiDB Lightning has exited normally, not the completion of the task. If you encounter problems during the import process, refer to TiDB Lightning FAQ for troubleshooting.

6.4.10 Migrate Data from Parquet Files to TiDB

This document describes how to generate parquet files from Apache Hive and how to migrate data from parquet files to TiDB using TiDB Lightning.

If you export parquet files from Amazon Aurora, refer to Migrate data from Amazon Aurora to TiDB.

6.4.10.1 Prerequisites

- Install TiDB Lightning using TiUP.
- Get the target database privileges required for TiDB Lightning.

6.4.10.2 Step 1. Prepare the parquet files

This section describes how to export parquet files from Hive that can be read by TiDB Lightning.

Each table in Hive can be exported to parquet files by annotating `STORED AS PARQUET LOCATION '/path/in/hdfs'`. Therefore, if you need to export a table named `test`, perform the following steps:

1. Run the following SQL statement in Hive:

```
CREATE TABLE temp STORED AS PARQUET LOCATION '/path/in/hdfs'
AS SELECT * FROM test;
```

   After executing the preceding statement, the table data is successfully exported to the HDFS system.

2. Export the parquet files to the local file system using the `hdfs dfs -get` command:

```
hdfs dfs -get /path/in/hdfs /path/in/local
```

   After the export is complete, if you need to delete the exported parquet files in HDFS, you can directly delete the temporary table (`temp`):

```
DROP TABLE temp;
```

3. The parquet files exported from Hive might not have the `.parquet` suffix and cannot be correctly identified by TiDB Lightning. Therefore, before importing the files, you need to rename the exported files and add the `.parquet` suffix to change the full filename to a format that TiDB Lightning recognizes, for example, `${db_name}.${table_name}.parquet`. For more information about file types and patterns, see TiDB Lightning Data Sources. You can also match data files by setting correct customized expressions.

4. Put all the parquet files in a unified directory, for example, `/data/my_datasource/` or `s3://my-bucket/sql-backup`. TiDB Lightning will recursively search for all `.parquet` files in this directory and its subdirectories.

6.4.10.3 Step 2. Create the target table schema

Before importing data from parquet files into TiDB, you need to create the target table schema. You can create the target table schema by either of the following two methods:

- **Method 1**: create the target table schema using TiDB Lightning.

  Create SQL files that contain the required DDL statements:

  - Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
  - Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2**: create the target table schema manually.

6.4.10.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the target
    ↪ TiDB cluster cannot provide any service.
backend = "local"
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
    ↪ . During the import, the target TiDB cluster can provide service
    ↪ normally.
### For more information on import mode, refer to <https://docs.pingcap.com/
    ↪ tidb/stable/tidb-lightning-overview#tidb-lightning-architecture>
### Set the temporary storage directory for the sorted Key-Value files. The
    ↪ directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
### Directory of the data source.
data-source-dir = "${data-path}" # A local path or S3 path. For example, 's3
    ↪ ://my-bucket/sql-backup'.

[tidb]
### The target cluster.
host = ${host}         # e.g.: 172.16.32.1
port = ${port}         # e.g.: 4000
user = "${user_name}"  # e.g.: "root"
password = "${password}" # e.g.: "rootroot"
```

```
status-port = ${status-port} # During the import, TiDB Lightning needs to
    ↪ obtain the table schema information from the TiDB status port. e.g.:
    ↪ 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD.
    ↪ When backend = "local", you must specify status-port and pd-addr
    ↪ correctly. Otherwise, the import will be abnormal.
```

For more information on the configuration file, refer to TiDB Lightning configuration.

6.4.10.5 Step 4. Import the data

1. Run `tidb-lightning`.

    - If you import data from Amazon S3, you need to set the SecretKey and AccessKey of the account that has permission to access the S3 backend storage as environment variables before running TiDB Lightning.

        ```
        export AWS_ACCESS_KEY_ID=${access_key}
        export AWS_SECRET_ACCESS_KEY=${secret_key}
        ```

        In addition to the preceding method, TiDB Lightning also supports reading the credential file from `~/.aws/credentials`.

    - If you launch the program in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

        ```
        nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out
            ↪ 2>&1 &
        ```

2. After the import starts, you can check the progress of the import by either of the following methods:

    - Search for the keyword `progress` in the log using `grep`. The progress is updated every 5 minutes by default.
    - Check progress in the monitoring dashboard.
    - Check progress in TiDB Lightning web interface.

    After TiDB Lightning completes the import, it exits automatically.

3. Check if the import is successful.

    Check whether `tidb-lightning.log` contains `the whole procedure completed` in the last lines. If yes, the import is successful. If no, the import encounters an error. Address the error as instructed in the error message.

> **Note:**
>
> Whether the import is successful or not, the last line of the log shows `tidb lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to TiDB Lightning FAQ for troubleshooting.

6.4.11 Migrate from One TiDB Cluster to Another TiDB Cluster

This document describes how to migrate data from one TiDB cluster to another TiDB cluster. This function applies to the following scenarios:

- Split databases: You can split databases when a TiDB cluster is excessively large, or you want to avoid impact between services of a cluster.
- Relocate databases: Physically relocate databases, such as changing the data center.
- Migrate data to a TiDB cluster of a newer version: Migrate data to a TiDB cluster of a newer version to satisfy data security and accuracy requirements.

This document exemplifies the whole migration process and contains the following steps:

1. Set up the environment.
2. Migrate full data.
3. Migrate incremental data.
4. Migrate services to the new TiDB cluster.

6.4.11.1 Step 1. Set up the environment

1. Deploy TiDB clusters.

   Deploy two TiDB clusters, one upstream and the other downstream by using TiUP Playground. For more information, refer to Deploy and Maintain an Online TiDB Cluster Using TiUP.

```
# Create an upstream cluster
tiup --tag upstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# Create a downstream cluster
tiup --tag downstream playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --
    ↪ tiflash 0 --ticdc 1
# View cluster status
tiup status
```

2. Initialize data.

   By default, test databases are created in the newly deployed clusters. Therefore, you can use sysbench to generate test data and simulate data in real scenarios.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=10 --
    ↪ table-size=10000 prepare
```

   In this document, we use sysbench to run the `oltp_write_only` script. This script generates 10 tables in the test database, each with 10,000 rows. The tidb-config is as follows:

```
mysql-host=172.16.6.122 # Replace the value with the IP address of your
    ↪  upstream cluster
mysql-port=4000
mysql-user=root
mysql-password=
db-driver=mysql      # Set database driver to MySQL
mysql-db=test        # Set the database as a test database
report-interval=10   # Set data collection period to 10s
threads=10           # Set the number of worker threads to 10
time=0               # Set the time required for executing the script.
    ↪ 0 indicates time unlimited
rate=100             # Set average TPS to 100
```

3. Simulate service workload.

   In real scenarios, service data is continuously written to the upstream cluster. In this document, we use sysbench to simulate this workload. Specifically, run the following command to enable 10 workers to continuously write data to three tables, sbtest1, sbtest2, and sbtest3, with a total TPS not exceeding 100.

```
sysbench oltp_write_only --config-file=./tidb-config --tables=3 run
```

4. Prepare external storage.

   In full data backup, both the upstream and downstream clusters need to access backup files. It is recommended that you use External storage to store backup files. In this document, Minio is used to simulate an S3-compatible storage service.

```
wget https://dl.min.io/server/minio/release/linux-amd64/minio
chmod +x minio
# Configure access-key access-screct-id to access minio
export HOST_IP='172.16.6.122' # Replace the value with the IP address
    ↪ of your upstream cluster
export MINIO_ROOT_USER='minio'
export MINIO_ROOT_PASSWORD='miniostorage'
# Create the database directory. backup is the bucket name.
```

```
mkdir -p data/backup
# Start minio at port 6060
./minio server ./data --address :6060 &
```

The preceding command starts a minio server on one node to simulate S3 services. Parameters in the command are configured as follows:

- Endpoint: `http://${HOST_IP}:6060/`
- Access-key: `minio`
- Secret-access-key: `miniostorage`
- Bucket: `backup`

The access link is as follows:

```
s3://backup?access-key=minio&secret-access-key=miniostorage&endpoint=
    ↪ http://${HOST_IP}:6060&force-path-style=true
```

6.4.11.2 Step 2. Migrate full data

After setting up the environment, you can use the backup and restore functions of BR to migrate full data. BR can be started in three ways. In this document, we use the SQL statements, `BACKUP` and `RESTORE`.

Note:

- `BACKUP` and `RESTORE` SQL statements are experimental. It is not recommended that you use them in the production environment. They might be changed or removed without prior notice. If you find a bug, you can report an issue on GitHub.
- In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you back up data in off-peak hours, and set `RATE_LIMIT` to a proper value to avoid performance degradation.
- If the versions of the upstream and downstream clusters are different, you should check BR compatibility. In this document, we assume that the upstream and downstream clusters are the same version.

1. Disable GC.

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before backup. In this way, history data is not deleted.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+--------------------------+:
| @@global.tidb_gc_enable |
+--------------------------+
|                        0 |
+--------------------------+
1 row in set (0.00 sec)
```

> **Note:**
>
> TiCDC `gc-ttl` is 24 hours by default. If the backup and restore takes a long time, the default `gc-ttl` might not be sufficient, which could cause the subsequent incremental replication task to fail. To avoid this situation, adjust the `gc-ttl` value according to your specific needs when starting the TiCDC server. For more information, see What is `gc-ttl` in TiCDC.

2. Back up data.

   Run the `BACKUP` statement in the upstream cluster to back up data:

```
MySQL [(none)]> BACKUP DATABASE * TO 's3://backup?access-key=minio&
    ↪ secret-access-key=miniostorage&endpoint=http://${HOST_IP}:6060&
    ↪ force-path-style=true' RATE_LIMIT = 120 MB/SECOND;
```

```
+---------------+----------+--------------------+---------------------+------------
    ↪
| Destination | Size     | BackupTS           | Queue Time          |
    ↪ Execution Time    |
+---------------+----------+--------------------+---------------------+------------
    ↪
| s3://backup | 10315858 | 431434047157698561 | 2022-02-25 19:57:59 |
    ↪ 2022-02-25 19:57:59 |
+---------------+----------+--------------------+---------------------+------------
    ↪
1 row in set (2.11 sec)
```

After the `BACKUP` command is executed, TiDB returns metadata about the backup data. Pay attention to `BackupTS`, because data generated before it is backed up. In this document, we use `BackupTS` as **the end of data check** and **the start of incremental migration scanning by TiCDC**.

3. Restore data.

   Run the `RESTORE` command in the downstream cluster to restore data:

```
mysql> RESTORE DATABASE * FROM 's3://backup?access-key=minio&secret-
    ↪ access-key=miniostorage&endpoint=http://${HOST_IP}:6060&force-
    ↪ path-style=true';
```

```
+--------------+-----------+--------------------+---------------------+------------
    ↪
| Destination | Size    | BackupTS         | Queue Time        |
    ↪ Execution Time    |
+--------------+-----------+--------------------+---------------------+------------
    ↪
| s3://backup | 10315858 | 431434141450371074 | 2022-02-25 20:03:59 |
    ↪ 2022-02-25 20:03:59 |
+--------------+-----------+--------------------+---------------------+------------
    ↪
1 row in set (41.85 sec)
```

4. (Optional) Validate data.

   You can use sync-diff-inspector to check data consistency between upstream and downstream at a certain time. The preceding `BACKUP` output shows that the upstream cluster finishes backup at 431434047157698561. The preceding `RESTORE` output shows that the downstream finishes restoration at 431434141450371074.

```
sync_diff_inspector -C ./config.yaml
```

   For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Datasource config ##########################
[data-sources]
[data-sources.upstream]
    host = "172.16.6.122" # Replace the value with the IP address of
        ↪ your upstream cluster
    port = 4000
    user = "root"
    password = ""
    snapshot = "431434047157698561" # Set snapshot to the actual backup
        ↪  time (BackupTS in the "Back up data" section in [Step 2.
        ↪ Migrate full data](#step-2-migrate-full-data))
```

```
[data-sources.downstream]
    host = "172.16.6.125" # Replace the value with the IP address of
        ↪ your downstream cluster
    port = 4000
    user = "root"
    password = ""

########################## Task config ##########################
[task]
    output-dir = "./output"
    source-instances = ["upstream"]
    target-instance = "downstream"
    target-check-tables = ["*.*"]
```

6.4.11.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test clusters. Therefore, you can skip the step of deploying TiCDC and proceed with changefeed configuration.

2. Create a changefeed.

   In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

   ```
   tiup cdc cli changefeed create --server=http://172.16.6.122:8300 --sink
       ↪ -uri="mysql://root:@172.16.6.125:4000" --changefeed-id="upstream-
       ↪ to-downstream" --start-ts="431434047157698561"
   ```

   In this command, the parameters are as follows:

   - `--server`: IP address of any node in the TiCDC cluster
   - `--sink-uri`: URI of the downstream cluster
   - `--changefeed-id`: changefeed ID, must be in the format of a regular expression, [7]+(-[a-zA-Z0-9]+)*$
   - `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS in the "Back up data" section in Step 2. Migrate full data)

   For more information about the changefeed configurations, see Task configuration file.

[7] a-zA-Z0-9

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint?.

   To enable GC, run the following command:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

   To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+
| @@global.tidb_gc_enable |
+-------------------------+
|                       1 |
+-------------------------+
1 row in set (0.00 sec)
```

6.4.11.4 Step 4. Migrate services to the new TiDB cluster

After creating a changefeed, data written to the upstream cluster is replicated to the downstream cluster with low latency. You can migrate read traffic to the downstream cluster gradually. Observe for a period. If the downstream cluster is stable, you can migrate write traffic to the downstream cluster by performing the following steps:

1. Stop write services in the upstream cluster. Make sure that all upstream data are replicated to downstream before stopping the changefeed.

```
# Stop the changefeed from the upstream cluster to the downstream
   ↪ cluster
tiup cdc cli changefeed pause -c "upstream-to-downstream" --server=http
   ↪ ://172.16.6.122:8300

# View the changefeed status
tiup cdc cli changefeed list
```

```
[
  {
    "id": "upstream-to-downstream",
    "summary": {
    "state": "stopped", # Ensure that the status is stopped
```

```
    "tso": 431747241184329729,
    "checkpoint": "2022-03-11 15:50:20.387", # This time must be later
       ↪ than the time of stopping writing
    "error": null
    }
  }
]
```

2. Create a changefeed from downstream to upstream. You can leave `start-ts` unspecified so as to use the default setting, because the upstream and downstream data are consistent and there is no new data written to the cluster.

```
tiup cdc cli changefeed create --server=http://172.16.6.125:8300 --sink
   ↪ -uri="mysql://root:@172.16.6.122:4000" --changefeed-id="
   ↪ downstream -to-upstream"
```

3. After migrating writing services to the downstream cluster, observe for a period. If the downstream cluster is stable, you can discard the upstream cluster.

6.4.12 Migrate Data from TiDB to MySQL-compatible Databases

This document describes how to migrate data from TiDB clusters to MySQL-compatible databases, such as Aurora, MySQL, and MariaDB. The whole process contains four steps:

1. Set up the environment.
2. Migrate full data.
3. Migrate incremental data.
4. Migrate services to the MySQL-compatible cluster.

6.4.12.1 Step 1. Set up the environment

1. Deploy a TiDB cluster upstream.

   Deploy a TiDB cluster by using TiUP Playground. For more information, refer to Deploy and Maintain an Online TiDB Cluster Using TiUP.

```
# Create a TiDB cluster
tiup playground --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc 1
# View cluster status
tiup status
```

2. Deploy a MySQL instance downstream.

   - In a lab environment, you can use Docker to quickly deploy a MySQL instance by running the following command:

```
docker run --name some-mysql -e MYSQL_ROOT_PASSWORD=my-secret-pw -p
    ↪ 3306:3306 -d mysql
```

- In a production environment, you can deploy a MySQL instance by following instructions in Installing MySQL.

3. Simulate service workload.

   In the lab environment, you can use `go-tpc` to write data to the TiDB cluster upstream. This is to generate event changes in the TiDB cluster. Run the following command to create a database named `tpcc` in the TiDB cluster, and then use TiUP bench to write data to this database.

```
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
    ↪ 300s
```

   For more details about `go-tpc`, refer to How to Run TPC-C Test on TiDB.

6.4.12.2 Step 2. Migrate full data

After setting up the environment, you can use Dumpling to export the full data from the upstream TiDB cluster.

> **Note:**
>
> In production clusters, performing a backup with GC disabled might affect cluster performance. It is recommended that you complete this step in off-peak hours.

1. Disable Garbage Collection (GC).

   To ensure that newly written data is not deleted during incremental migration, you should disable GC for the upstream cluster before exporting full data. In this way, history data is not deleted. For TiDB v4.0.0 and later versions, Dumpling might automatically adjust the GC safe point to block GC. Nevertheless, manually disabling GC is still necessary because the GC process might begin after Dumpling exits, leading to the failure of incremental changes migration.

   Run the following command to disable GC:

```
MySQL [test]> SET GLOBAL tidb_gc_enable=FALSE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+
| @@global.tidb_gc_enable |
+-------------------------+
|                       0 |
+-------------------------+
1 row in set (0.00 sec)
```

2. Back up data.

    1. Export data in SQL format using Dumpling:

    ```
    tiup dumpling -u root -P 4000 -h 127.0.0.1 --filetype sql -t 8 -o
        ↪ ./dumpling_output -r 200000 -F256MiB
    ```

    2. After finishing exporting data, run the following command to check the metadata. `Pos` in the metadata is the TSO of the export snapshot and can be recorded as the BackupTS.

    ```
    cat dumpling_output/metadata
    ```

    ```
    Started dump at: 2022-06-28 17:49:54
    SHOW MASTER STATUS:
            Log: tidb-binlog
            Pos: 434217889191428107
            GTID:
    Finished dump at: 2022-06-28 17:49:57
    ```

3. Restore data.

    Use MyLoader (an open-source tool) to import data to the downstream MySQL instance. For details about how to install and use MyLoader, see MyDumpler/MyLoader. Note that you need to use MyLoader v0.10 or earlier versions. Higher versions cannot process metadata files exported by Dumpling.

    Run the following command to import full data exported by Dumpling to MySQL:

    ```
    myloader -h 127.0.0.1 -P 3306 -d ./dumpling_output/
    ```

4. (Optional) Validate data.

    You can use sync-diff-inspector to check data consistency between upstream and downstream at a certain time.

    ```
    sync_diff_inspector -C ./config.yaml
    ```

For details about how to configure the sync-diff-inspector, see Configuration file description. In this document, the configuration is as follows:

```
# Diff Configuration.
######################### Datasource config #########################
[data-sources]
[data-sources.upstream]
       host = "127.0.0.1" # Replace the value with the IP address of
          ↪ your upstream cluster
       port = 4000
       user = "root"
       password = ""
       snapshot = "434217889191428107" # Set snapshot to the actual
          ↪ backup time (BackupTS in the "Back up data" section in [
          ↪ Step 2. Migrate full data](#step-2-migrate-full-data))
[data-sources.downstream]
       host = "127.0.0.1" # Replace the value with the IP address of
          ↪ your downstream cluster
       port = 3306
       user = "root"
       password = ""
######################### Task config #########################
[task]
       output-dir = "./output"
       source-instances = ["upstream"]
       target-instance = "downstream"
       target-check-tables = ["*.*"]
```

6.4.12.3 Step 3. Migrate incremental data

1. Deploy TiCDC.

   After finishing full data migration, deploy and configure a TiCDC cluster to replicate incremental data. In production environments, deploy TiCDC as instructed in Deploy TiCDC. In this document, a TiCDC node has been started upon the creation of the test cluster. Therefore, you can skip the step of deploying TiCDC and proceed with the next step to create a changefeed.

2. Create a changefeed.

   In the upstream cluster, run the following command to create a changefeed from the upstream to the downstream clusters:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed create --server=http
   ↪ ://127.0.0.1:8300 --sink-uri="mysql://root:@127.0.0.1:3306" --
   ↪ changefeed-id="upstream-to-downstream" --start-ts
   ↪ ="434217889191428107"
```

In this command, the parameters are as follows:

- `--server`: IP address of any node in the TiCDC cluster
- `--sink-uri`: URI of the downstream cluster
- `--changefeed-id`: changefeed ID, must be in the format of a regular expression, `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$`
- `--start-ts`: start timestamp of the changefeed, must be the backup time (or BackupTS in the "Back up data" section in Step 2. Migrate full data)

For more information about the changefeed configurations, see Task configuration file.

3. Enable GC.

   In incremental migration using TiCDC, GC only removes history data that is replicated. Therefore, after creating a changefeed, you need to run the following command to enable GC. For details, see What is the complete behavior of TiCDC garbage collection (GC) safepoint.

To enable GC, run the following command:

````
```sql
MySQL [test]> SET GLOBAL tidb_gc_enable=TRUE;
```

```
Query OK, 0 rows affected (0.01 sec)
```

To verify that the change takes effect, query the value of `tidb_gc_enable`:

```sql
MySQL [test]> SELECT @@global.tidb_gc_enable;
```

```
+-------------------------+
| @@global.tidb_gc_enable |
+-------------------------+
|                       1 |
+-------------------------+
1 row in set (0.00 sec)
```
````

6.4.12.4 Step 4. Migrate services

After creating a changefeed, data written to the upstream cluster is replicated to the downstream cluster with low latency. You can migrate read traffic to the downstream cluster gradually. Observe the read traffic for a period. If the downstream cluster is stable, you can migrate write traffic to the downstream cluster as well in the following steps:

1. Stop write services in the upstream cluster. Make sure that all upstream data are replicated to downstream before stopping the changefeed.

```
# Stop the changefeed from the upstream cluster to the downstream
    ↪ cluster
tiup cdc cli changefeed pause -c "upstream-to-downstream" --pd=http
    ↪ ://172.16.6.122:2379
# View the changefeed status
tiup cdc cli changefeed list
```

```
[

    "error": null
    }
  }
]
```

2. After migrating writing services to the downstream cluster, observe for a period. If the downstream cluster is stable, you can discard the upstream cluster.

6.5 Advanced Migration

6.5.1 Continuous Replication from Databases that Use gh-ost or pt-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are gh-ost and pt-osc.

When using DM to migrate data from MySQL to TiDB, you can enable `online-ddl` to allow collaboration of DM and gh-ost or pt-osc.

For the detailed replication instructions, refer to the following documents by scenarios:

- Migrate Small Datasets from MySQL to TiDB

- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.5.1.1 Enable online-ddl on DM

In the task configuration file of DM, set the global parameter `online-ddl` to `true`, as shown below:

```
### ----------- Global configuration -----------
#### ********* Basic configuration *********
name: test                    # The name of the task. Should be globally
    ↪ unique.
task-mode: all                # The task mode. Can be set to `full`, `
    ↪ incremental`, or `all`.
shard-mode: "pessimistic"     # The shard merge mode. Optional modes are `
    ↪ pessimistic` and `optimistic`. The `pessimistic` mode is used by
    ↪ default. After understanding the principles and restrictions of the "
    ↪ optimistic" mode, you can set it to the "optimistic" mode.
meta-schema: "dm_meta"        # The downstream database that stores the `meta`
    ↪  information.
online-ddl: true              # Enable online-ddl support on DM to support
    ↪ automatic processing of "gh-ost" and "pt-osc" for the upstream
    ↪ database.
```

6.5.1.2 Workflow after enabling online-ddl

After online-ddl is enabled on DM, the DDL statements generated by DM replicating gh-ost or pt-osc will change.

The workflow of gh-ost or pt-osc:

- Create a ghost table according to the table schema of the DDL real table.
- Apply DDLs on the ghost table.
- Replicate the data of the DDL real table to the ghost table.
- After the data are consistent between the two tables, use the rename statement to replace the real table with the ghost table.

The workflow of DM:

- Skip creating the ghost table downstream.
- Record DDLs applied to the ghost table.

- Replicate data only from the ghost table.
- Apply DDLs recorded downstream.

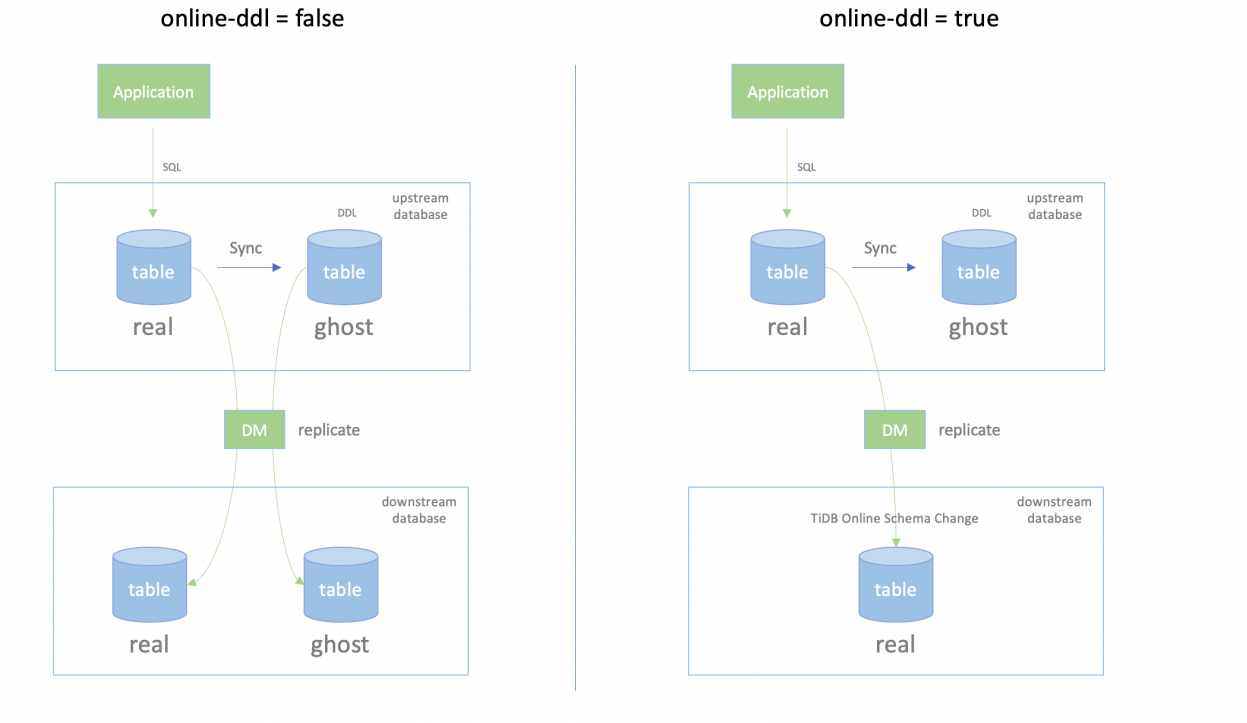

Figure 98: dm-online-ddl

The change in the workflow brings the following advantages:

- The downstream TiDB does not need to create and replicate the ghost table, saving the storage space and network transmission overhead.
- When you migrate and merge data from sharded tables, the RENAME operation is ignored for each sharded ghost table to ensure the correctness of the replication.

Working details for DM with online DDL tools

6.5.2 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- Migrate Small Datasets from MySQL to TiDB
- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.5.2.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
    {
        "ErrCode": 36027,
        "ErrClass": "sync-unit",
        "ErrScope": "internal",
        "ErrLevel": "high",
        "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
            ↪ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9 ], endLocation: [
            ↪  position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
            ↪ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
            ↪ log, table: messages: Column count doesn't match value count:
            ↪ 3 (columns) vs 2 (values)",
        "RawCause": "",
        "Workaround": ""
    }
]
```

The following is an example upstream table schema:

```
### Upstream table schema
CREATE TABLE `messages` (
  `id` int NOT NULL,
  PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
### Downstream table schema
CREATE TABLE `messages` (
  `id` int NOT NULL,
  `message` varchar(255) DEFAULT NULL, # This is the additional column that
     ↪  only exists in the downstream table.
  PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `binlog-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`. For DM v6.0 or later versions, you can update the table schema by adding the `--from-source` or `--from-target` flag without creating a SQL file. For details, see Manage Table Schemas of Tables to be Migrated.

```
# Upstream table schema
CREATE TABLE `messages` (
`id` int NOT NULL,
PRIMARY KEY (`id`)
)
```

2. Use the `binlog-schema` command to set the table schema for the table to be migrated from the data source. At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error.

```
tiup dmctl --master-addr ${advertise-addr} binlog-schema update -s ${
    ↪ source-id} ${task-name} ${database-name} ${table-name} ${schema-
    ↪ file}
```

   The descriptions of parameters in this command are as follows:

Parameter	Description

`-`
`↪ master`
`↪ -`
`↪ addr`
`↪`
	Specifies
	`${`
	`↪ advertise`
	`↪ -`
	`↪ addr`
	`↪ }`
	of
	any
	DM-
	master
	node
	in
	the
	clus-
	ter
	where
	dm-
	ctl is
	to be
	con-
	nected.
	`${`
	`↪ advertise`
	`↪ -`
	`↪ addr`
	`↪ }`
	indi-
	cates
	the
	ad-
	dress
	that
	DM-
	master
	ad-
	ver-
	tises
	to
	the
	out-
	side
	world.

Parameter	Description
`binlog -schema set`	Manually set the schema information.
`-s`	Specifies the source. `${source -id}` indicates the source ID of MySQL data.

Parameter	Description
`${ ↪ task ↪ - ↪ name ↪ } ↪ `	Specifies the name of the migration task defined in the `task ↪ . ↪ yaml ↪ ` configuration file of the data migration task.

Parameter	Description
${ ↪ database ↪ - ↪ name ↪ } ↪	Specifies the database. ${ ↪ database ↪ - ↪ name ↪ } indicates the name of the upstream database.
${ ↪ table ↪ - ↪ name ↪ } ↪	Specifies the name of the upstream table.
${ ↪ schema ↪ - ↪ file ↪ } ↪	Specifies the table schema file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 binlog-schema update -s
    ↪ mysql-01 task-test -d log -t message log.message.sql
```

3. Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

6.5.3 Filter Binlog Events

This document describes how to filter binlog events when you use DM to perform continuous incremental data replication. For the detailed replication instructions, refer to the following documents by scenarios:

- Migrate Small Datasets from MySQL to TiDB
- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

6.5.3.1 Configuration

To use binlog event filter, add a `filter` to the task configuration file of DM, as shown below:

```
filters:
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table"]
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
    action: Ignore
```

- `schema-pattern/table-pattern`: Filters matching schemas or tables
- `events`: Filters binlog events. Supported events are listed in the table below:

Event	Category	Description
all		Includes all events
all dml		Includes all DML events
all ddl		Includes all DDL events
none		Includes no event
none ddl		Excludes all DDL events
none dml		Excludes all DML events
insert	DML	Insert DML event
update	DML	Update DML event
delete	DML	Delete DML event
create database	DDL	Create database event

Event	Category	Description
drop database	DDL	Drop database event
create table	DDL	Create table event
create index	DDL	Create index event
drop table	DDL	Drop table event
truncate table	DDL	Truncate table event
rename table	DDL	Rename table event
drop index	DDL	Drop index event
alter table	DDL	Alter table event

- `sql-pattern`: Filters specified DDL SQL statements. The matching rule supports using a regular expression.
- `action`: `Do` or `Ignore`
  - `Do`: the allow list. A binlog event is replicated if meeting either of the following two conditions:
    - The event matches the rule setting.
    - sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.
  - `Ignore`: the block list. A binlog event is filtered out if meeting either of the following two conditions:
    - The event matches the rule setting.
    - sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.

  If both `Do` and `Ignore` are configured, `Ignore` has higher priority over `Do`. That is, an event satisfying both `Ignore` and `Do` conditions will be filtered out.

6.5.3.2 Application scenarios

This section describes the application scenarios of binlog event filter.

6.5.3.2.1 Filter out all sharding deletion operations

To filter out all deletion operations, configure a `filter-table-rule` and a `filter-schema-rule`, as shown below:

```
filters:
  filter-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table", "delete"]
    action: Ignore
```

```
  filter-schema-rule:
    schema-pattern: "test_*"
    events: ["drop database"]
    action: Ignore
```

6.5.3.2.2 Migrate only DML operations of sharded schemas and tables

To replicate only DML statements, configure two `Binlog event filter rule`, as shown below:

```
filters:
  do-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["create table", "all dml"]
    action: Do
  do-schema-rule:
    schema-pattern: "test_*"
    events: ["create database"]
    action: Do
```

6.5.3.2.3 Filter out SQL statements not supported by TiDB

To filter out SQL statements not supported by TiDB, configure a `filter-procedure-rule`, as shown below:

```
filters:
  filter-procedure-rule:
    schema-pattern: "*"
    sql-pattern: [".*\\s+DROP\\s+PROCEDURE", ".*\\s+CREATE\\s+PROCEDURE", "
      ↪ ALTER\\s+TABLE[\\s\\S]*ADD\\s+PARTITION", "ALTER\\s+TABLE[\\s\\S]*
      ↪ DROP\\s+PARTITION"]
    action: Ignore
```

> **Warning:**
>
> To avoid filtering out data that needs to be migrated, configure the global filtering rule as strictly as possible.

6.5.3.3 See also

Filter Binlog Events Using SQL Expressions

6.5.4 Filter DML Events Using SQL Expressions

This document introduces how to filter binlog events using SQL expressions when you use DM to perform continuous incremental data replication. For the detailed replication instruction, refer to the following documents:

- Migrate Small Datasets from MySQL to TiDB
- Migrate Large Datasets from MySQL to TiDB
- Migrate and Merge MySQL Shards of Small Datasets to TiDB
- Migrate and Merge MySQL Shards of Large Datasets to TiDB

When performing incremental data replication, you can use the Binlog Event Filter to filter certain types of binlog events. For example, you can choose not to replicate `DELETE` events to the downstream for the purposes like archiving and auditing. However, the Binlog Event Filter cannot determine whether to filter the `DELETE` event of a row that requires finer granularity.

To address the issue, since v2.0.5, DM supports using `binlog value filter` in incremental data replication to filter data. Among the DM-supported and `ROW`-formatted binlog, the binlog events carry values of all columns, and you can configure SQL expressions based on these values. If the expression calculates a row change as `TRUE`, DM does not replicate this row change to the downstream.

Similar to Binlog Event Filter, you need to configure `binlog value filter` in the task configuration file. For details, see the following configuration example. For the advanced task configuration and the description, refer to DM advanced task configuration file.

```
name: test
task-mode: all

mysql-instances:
  - source-id: "mysql-replica-01"
    expression-filters: ["even_c"]

expression-filter:
  even_c:
    schema: "expr_filter"
    table: "tbl"
    insert-value-expr: "c % 2 = 0"
```

In the above configuration example, the `even_c` rule is configured and referenced by the data source `mysql-replica-01`. According to this rule, for the `tb1` table in the `expr_filter` schema, when an even number is inserted into the `c` column (`c % 2 = 0`), this `insert` statement is not replicated to the downstream. The following example shows the effect of this rule.

Incrementally insert the following data in the upstream data source:

```
INSERT INTO tbl(id, c) VALUES (1, 1), (2, 2), (3, 3), (4, 4);
```

Then query the `tb1` table on downstream. You can see that only the rows with odd numbers on `c` are replicated.

```
MySQL [test]> select * from tbl;
+------+------+
| id   | c    |
+------+------+
|    1 |    1 |
|    3 |    3 |
+------+------+
2 rows in set (0.001 sec)
```

6.5.4.1 Configuration parameters and description

- `schema`: The name of the upstream schema to match. Wildcard matching or regular matching is not supported.
- `table`: The name of the upstream table to match. Wildcard matching or regular matching is not supported.
- `insert-value-expr`: Configures an expression that takes effect on values carried by the `INSERT` type binlog events (WRITE_ROWS_EVENT). You cannot use this expression together with `update-old-value-expr`, `update-new-value-expr` or `delete-value-expr` in the same configuration item.
- `update-old-value-expr`: Configures an expression that takes effect on the old values carried by the `UPDATE` type binlog events (UPDATE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.
- `update-new-value-expr`: Configures an expression that takes effect on the new values carried by the `UPDATE` type binlog events (UPDATE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.
- `delete-value-expr`: Configures an expression that takes effect on values carried by the `DELETE` type binlog events (DELETE_ROWS_EVENT). You cannot use this expression together with `insert-value-expr`, `update-old-value-expr` or `update-new-value-expr`.

Note:

- You can configure `update-old-value-expr` and `update-new-value-expr` together.

- When `update-old-value-expr` and `update-new-value-expr` are configured together, the rows whose "update + old values" meet `update-old-value-expr` **and** whose "update + new values" meet `update-new-value-expr` are filtered.
- When one of `update-old-value-expr` and `update-new-value-expr` is configured, the configured expression determines whether to filter the **entire row change**, which means that the deletion of old values and the insertion of new values are filtered as a whole.

You can use the SQL expression on one column or on multiple columns. You can also use the SQL functions supported by TiDB, such as `c % 2 = 0`, `a*a + b*b = c*c`, and `ts > NOW()`.

The `TIMESTAMP` default time zone is the time zone specified in the task configuration file. The default value is the time zone of the downstream. You can explicitly specify the time zone in a way like `c_timestamp = '2021-01-01 12:34:56.5678+08:00'`.

You can configure multiple filtering rules under the `expression-filter` configuration item. The upstream data source references the required rule in `expression-filters` to make it effective. When multiple rules are used, if **any** one of the rules are matched, the entire row change is filtered.

Note:

Configuring too many expression filtering rules increases the calculation overhead of DM and slows down the data replication.

7 Stream Data

7.1 TiCDC Overview

TiCDC is a tool used to replicate incremental data from TiDB. Specifically, TiCDC pulls TiKV change logs, sorts captured data, and exports row-based incremental data to downstream databases. For detailed data replication capabilities, see TiCDC Data Replication Capabilities.

7.1.1 Usage scenarios

TiCDC has multiple usage scenarios, including:

- Providing high availability and disaster recovery solutions for multiple TiDB clusters. TiCDC ensures eventual data consistency between primary and secondary clusters in case of a disaster.
- Replicating real-time data changes to homogeneous systems. This provides data sources for various scenarios, such as monitoring, caching, global indexing, data analysis, and primary-secondary replication between heterogeneous databases.

7.1.2 Major features

7.1.2.1 Key capabilities

TiCDC has the following key capabilities:

- Replicating incremental data between TiDB clusters with second-level RPO and minute-level RTO.
- Bidirectional replication between TiDB clusters, allowing the creation of a multi-active TiDB solution using TiCDC.
- Replicating incremental data from a TiDB cluster to a MySQL database or other MySQL-compatible databases with low latency.
- Replicating incremental data from a TiDB cluster to a Kafka cluster. The recommended data format includes Canal-JSON, Avro, and Debezium.
- Replicating incremental data from a TiDB cluster to storage services, such as Amazon S3, GCS, Azure Blob Storage, and NFS.
- Replicating tables with the ability to filter databases, tables, DMLs, and DDLs.
- High availability with no single point of failure, supporting dynamically adding and deleting TiCDC nodes.
- Cluster management through Open API, including querying task status, dynamically modifying task configuration, and creating or deleting tasks.

7.1.2.2 Replication order

- For all DDL or DML statements, TiCDC outputs them **at least once**.
- When the TiKV or TiCDC cluster encounters a failure, TiCDC might send the same DDL/DML statement repeatedly. For duplicated DDL/DML statements:
    - The MySQL sink can execute DDL statements repeatedly. For DDL statements that can be executed repeatedly in the downstream, such as `TRUNCATE TABLE` ↪ , the statement is executed successfully. For those that cannot be executed repeatedly, such as `CREATE TABLE`, the execution fails, and TiCDC ignores the error and continues with the replication process.
    - The Kafka sink provides different strategies for data distribution.
        - You can distribute data to different Kafka partitions based on the table, primary key, or timestamp. This ensures that the updated data of a row is sent to the same partition in order.

- All these distribution strategies send `Resolved TS` messages to all topics and partitions periodically. This indicates that all messages earlier than the `Resolved TS` have already been sent to the topics and partitions. The Kafka consumer can use the `Resolved TS` to sort the messages received.
- The Kafka sink sometimes sends duplicated messages, but these duplicated messages do not affect the constraints of `Resolved Ts`. For example, if a changefeed is paused and then resumed, the Kafka sink might send `msg1` ↪ , `msg2`, `msg3`, `msg2`, and `msg3` in order. You can filter out the duplicated messages from Kafka consumers.

7.1.2.3 Replication consistency

- MySQL sink
  - TiCDC enables the redo log to ensure eventual consistency of data replication.
  - TiCDC ensures that the order of single-row updates is consistent with the upstream.
  - TiCDC does not ensure that the downstream transactions are executed in the same order as the upstream transactions.

> **Note:**
>
> Since v6.2, you can use the sink URI parameter `transaction-atomicity` to control whether to split single-table transactions. Splitting single-table transactions can greatly reduce the latency and memory consumption of replicating large transactions.

7.1.3 TiCDC architecture

TiCDC is an incremental data replication tool for TiDB, which is highly available through PD's etcd. The replication process consists of the following steps:

1. Multiple TiCDC processes pull data changes from TiKV nodes.
2. TiCDC sorts and merges the data changes.
3. TiCDC replicates the data changes to multiple downstream systems through multiple replication tasks (changefeeds).

The architecture of TiCDC is illustrated in the following figure:

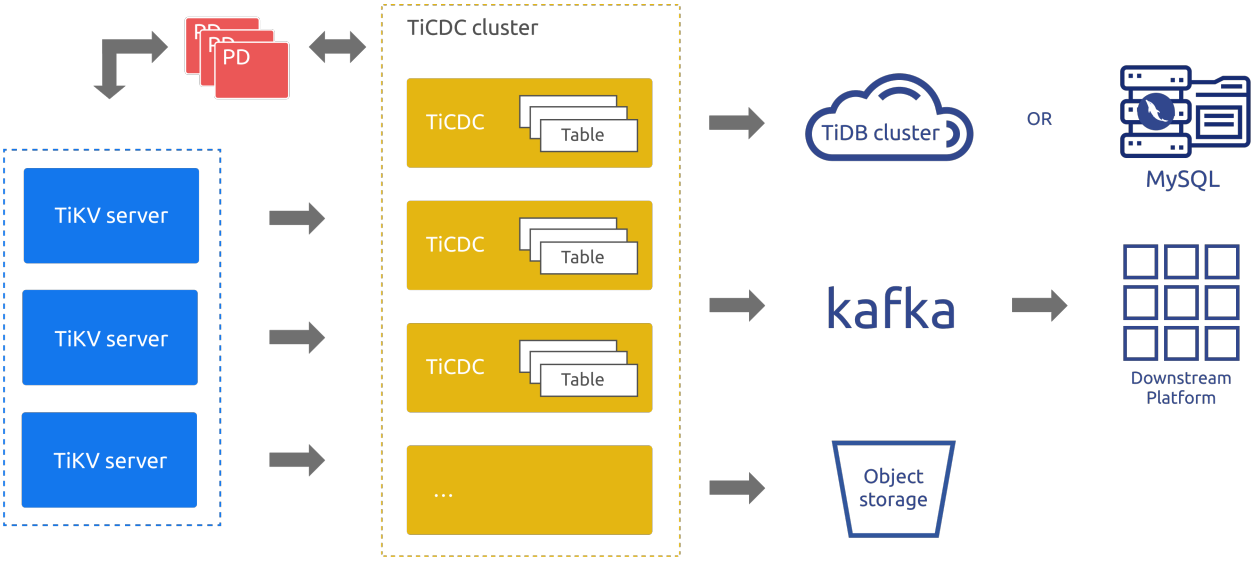

Figure 99: TiCDC architecture

The components in the architecture diagram are described as follows:

- TiKV Server: TiKV nodes in a TiDB cluster. When data changes occur, TiKV nodes send the changes as change logs (KV change logs) to TiCDC nodes. If TiCDC nodes detect that the change logs are not continuous, they will actively request the TiKV nodes to provide change logs.
- TiCDC: TiCDC nodes where TiCDC processes run. Each node runs a TiCDC process. Each process pulls data changes from one or more tables in TiKV nodes and replicates the changes to the downstream system through the sink component.
- PD: The scheduling module in a TiDB cluster. This module is responsible for scheduling cluster data and usually consists of three PD nodes. PD provides high availability through the etcd cluster. In the etcd cluster, TiCDC stores its metadata, such as node status information and changefeed configurations.

As shown in the architecture diagram, TiCDC supports replicating data to TiDB, MySQL, Kafka, and storage services.

7.1.4 Valid index

Generally, TiCDC only replicates tables that have at least one valid index to the downstream. If an index in a table meets one of the following requirements, it is valid.

- A primary key (`PRIMARY KEY`) is a valid index.
- A unique index (`UNIQUE INDEX`) is valid if every column of the index is explicitly defined as non-nullable (`NOT NULL`) and the index does not have a virtual generated column (`VIRTUAL GENERATED COLUMNS`).

Note:

When you set `force-replicate` to `true`, TiCDC will forcibly replicate tables without a valid index.

7.1.5 Best practices

- When you use TiCDC to replicate data between two TiDB clusters, if the network latency between the two clusters is higher than 100 ms:
  - For TiCDC versions earlier than v6.5.2, it is recommended to deploy TiCDC in the region (IDC) where the downstream TiDB cluster is located.
  - With a series of improvements introduced starting from TiCDC v6.5.2, it is recommended to deploy TiCDC in the region (IDC) where the upstream TiDB cluster is located.
- Each table to be replicated by TiCDC has at least one valid index.
- To ensure eventual consistency when using TiCDC for disaster recovery, you need to configure redo log and ensure that the storage system where the redo log is written can be read normally when a disaster occurs in the upstream.

7.1.6 Implementation of processing data changes

This section mainly describes how TiCDC processes data changes generated by upstream DML operations.

For data changes generated by upstream DDL operations, TiCDC obtains the complete DDL SQL statement, converts it into the corresponding format based on the sink type of the downstream, and sends it to the downstream. This section does not elaborate on this.

Note:

The logic of how TiCDC processes data changes might be adjusted in subsequent versions.

MySQL binlog directly records all DML SQL statements executed in the upstream. Unlike MySQL, TiCDC listens to the real-time information of each Region Raft Log in the upstream TiKV, and generates data change information based on the difference between the data before and after each transaction, which corresponds to multiple SQL statements.

TiCDC only guarantees that the output change events are equivalent to the changes in the upstream TiDB, and does not guarantee that it can accurately restore the SQL statements that caused the data changes in the upstream TiDB.

Data change information includes the data change types and the data values before and after the change. The difference between the data before and after the transaction can result in three types of events:

1. The `DELETE` event: corresponds to a `DELETE` type data change message, which contains the data before the change.
2. The `INSERT` event: corresponds to a `PUT` type data change message, which contains the data after the change.
3. The `UPDATE` event: corresponds to a `PUT` type data change message, which contains the data both before and after the change.

Based on the data change information, TiCDC generates data in the appropriate formats for different downstream types, and sends the data to the downstream. For example, it generates data in formats such as Canal-JSON and Avro, and writes the data to Kafka, or converts the data back into SQL statements and sends them to the downstream MySQL or TiDB.

Currently, when TiCDC adapts data change information for the corresponding protocol, for specific `UPDATE` events, it might split them into one `DELETE` event and one `INSERT` event. For more information, see Split `UPDATE` events for MySQL sinks and Split primary or unique key `UPDATE` events for non-MySQL sinks.

When the downstream is MySQL or TiDB, TiCDC cannot guarantee that the SQL statements written to the downstream are exactly the same as the SQL statements executed in the upstream. This is because TiCDC does not directly obtain the original DML statements executed in the upstream, but generates SQL statements based on the data change information. However, TiCDC ensures the consistency of the final results.

For example, the following SQL statement is executed in the upstream:

```
Create Table t1 (A int Primary Key, B int);

BEGIN;
Insert Into t1 values(1,2);
Insert Into t1 values(2,2);
Insert Into t1 values(3,3);
Commit;

Update t1 set b = 4 where b = 2;
```

TiCDC generates the following two SQL statements based on the data change information, and writes them to the downstream:

```
INSERT INTO `test.t1` (`A`,`B`) VALUES (1,2),(2,2),(3,3);
UPDATE `test`.`t1`
SET `A` = CASE
       WHEN `A` = 1 THEN 1
       WHEN `A` = 2 THEN 2
END, `B` = CASE
       WHEN `A` = 1 THEN 4
       WHEN `A` = 2 THEN 4
END
WHERE `A` = 1 OR `A` = 2;
```

7.1.7 Unsupported scenarios

Currently, the following scenarios are not supported:

- A TiKV cluster that uses RawKV alone.
- The `CREATE SEQUENCE` DDL operation and the `SEQUENCE` function in TiDB. When the upstream TiDB uses `SEQUENCE`, TiCDC ignores `SEQUENCE` DDL operations/functions performed upstream. However, DML operations using `SEQUENCE` functions can be correctly replicated.
- Currently, performing TiDB Lightning physical import on tables and databases that are being replicated by TiCDC is not supported. For more information, see Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning and BR from upstream.
- Before v8.2.0, BR does not support restoring data for a cluster with TiCDC replication tasks. For more information, see Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning and BR from upstream.
- Starting from v8.2.0, BR relaxes the restrictions on data restoration for TiCDC: if the `BackupTS` (the backup time) of the data to be restored is earlier than the changefeed `CheckpointTS` (the timestamp that indicates the current replication progress), BR can proceed with the data restoration normally. Considering that the `BackupTS` is usually much earlier, it can be assumed that in most scenarios, BR supports restoring data for a cluster with TiCDC replication tasks.

TiCDC only partially supports scenarios involving large transactions in the upstream. For details, refer to the TiCDC FAQ, where you can find details on whether TiCDC supports replicating large transactions and any associated risks.

7.2 Deploy and Maintain TiCDC

This document describes how to deploy and maintain a TiCDC cluster, including the hardware and software recommendations. You can either deploy TiCDC along with a new TiDB cluster or add the TiCDC component to an existing TiDB cluster.

7.2.1 Software and hardware recommendations

In production environments, the recommendations of hardware for TiCDC are as follows:

CPU	Memory	Disk	Network	Number of TiCDC cluster instances (minimum requirements for production environment)
16 core+	64 GB+	500 GB+ SSD	10 Gigabit network card (2 preferred)	2

For more information, see Software and Hardware Recommendations.

7.2.2 Deploy a new TiDB cluster that includes TiCDC using TiUP

When you deploy a new TiDB cluster using TiUP, you can also deploy TiCDC at the same time. You only need to add the `cdc_servers` section in the configuration file that TiUP uses to start the TiDB cluster. The following is an example:

```
cdc_servers:
  - host: 10.0.1.20
    gc-ttl: 86400
    data_dir: "/cdc-data"
  - host: 10.0.1.21
    gc-ttl: 86400
    data_dir: "/cdc-data"
```

More references:

- For detailed operations, see Edit the initialization configuration file.
- For detailed configurable fields, see Configure `cdc_servers` using TiUP.
- For detailed steps to deploy a TiDB cluster, see Deploy a TiDB Cluster Using TiUP.

> **Note:**
>
> Before installing TiCDC, ensure that you have manually configured the SSH mutual trust and sudo without password between the TiUP control machine and the TiCDC host.

7.2.3 Add or scale out TiCDC to an existing TiDB cluster using TiUP

The method of scaling out a TiCDC cluster is similar to that of deploying one. It is recommended to use TiUP to perform the scale-out.

1. Create a `scale-out.yml` file to add the TiCDC node information. The following is an example:

```
cdc_servers:
  - host: 10.1.1.1
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.1.1.2
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
```

2. Run the scale-out command on the TiUP control machine:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

For more use cases, see Scale out a TiCDC cluster.

7.2.4 Delete or scale in TiCDC from an existing TiDB cluster using TiUP

It is recommended that you use TiUP to scale in TiCDC nodes. The following is the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

For more use cases, see Scale in a TiCDC cluster.

7.2.5 Upgrade TiCDC using TiUP

You can upgrade TiDB clusters using TiUP, during which TiCDC is upgraded as well. After you execute the upgrade command, TiUP automatically upgrades the TiCDC component. The following is an example:

```
tiup update --self && \
tiup update --all && \
tiup cluster upgrade <cluster-name> <version> --transfer-timeout 600
```

> **Note:**
>
> In the preceding command, you need to replace `<cluster-name>` and `<version>` with the actual cluster name and cluster version. For example, the version can be v8.5.1.

7.2.5.1 Upgrade cautions

When you upgrade a TiCDC cluster, you need to pay attention to the following:

- TiCDC v4.0.2 reconfigured `changefeed`. For details, see Configuration file compatibility notes.
- If you encounter any problem during the upgrade, you can refer to upgrade FAQs for solutions.
- Since v6.3.0, TiCDC supports rolling upgrade. During the upgrade, the replication latency is stable and does not fluctuate significantly. Rolling upgrade takes effect automatically if the following conditions are met:
- TiCDC is v6.3.0 or later.
    - TiUP is v1.11.3 or later.
    - At least two TiCDC instances are running in the cluster.

7.2.6 Modify TiCDC cluster configurations using TiUP

This section describes how to use the `tiup cluster edit-config` command to modify the configurations of TiCDC. In the following example, it is assumed that you need to change the default value of `gc-ttl` from `86400` to `172800` (48 hours).

1. Run the `tiup cluster edit-config` command. Replace `<cluster-name>` with the actual cluster name:

```
tiup cluster edit-config <cluster-name>
```

2. In the vi editor, modify the `cdc server-configs`:

```
server_configs:
  tidb: {}
  tikv: {}
  pd: {}
  tiflash: {}
  tiflash-learner: {}
  cdc:
    gc-ttl: 172800
```

   In the preceding command, `gc-ttl` is set to 48 hours.

3. Run the `tiup cluster reload -R cdc` command to reload the configuration.

7.2.7 Stop and start TiCDC using TiUP

You can use TiUP to easily stop and start TiCDC nodes. The commands are as follows:

- Stop TiCDC: `tiup cluster stop -R cdc`
- Start TiCDC: `tiup cluster start -R cdc`
- Restart TiCDC: `tiup cluster restart -R cdc`

7.2.8 Enable TLS for TiCDC

See Enable TLS Between TiDB Components.

7.2.9 View TiCDC status using the command-line tool

Run the following command to view the TiCDC cluster status. Note that you need to replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v8.5.1`:

```
tiup cdc:v<CLUSTER_VERSION> cli capture list --server=http://10.0.10.25:8300
```

```
[
  {
    "id": "806e3a1b-0e31-477f-9dd6-f3f2c570abdd",
    "is-owner": true,
    "address": "127.0.0.1:8300",
    "cluster-id": "default"
  },
  {
    "id": "ea2a4203-56fe-43a6-b442-7b295f458ebc",
    "is-owner": false,
    "address": "127.0.0.1:8301",
    "cluster-id": "default"
  }
]
```

- `id`: Indicates the ID of the service process.
- `is-owner`: Indicates whether the service process is the owner node.
- `address`: Indicates the address via which the service process provides interface to the outside.
- `cluster-id`: Indicates the ID of the TiCDC cluster. The default value is `default`.

7.3 Changefeed

7.3.1 Changefeed Overview

A changefeed is a replication task in TiCDC, which replicates the data change logs of specified tables in a TiDB cluster to the designated downstream. You can run and manage multiple changefeeds in a TiCDC cluster.

7.3.1.1 Changefeed state transfer

The state of a replication task represents the running status of the replication task. During the running of TiCDC, replication tasks might fail with errors, be manually paused, resumed, or reach the specified `TargetTs`. These behaviors can lead to the change of the replication task state. This section describes the states of TiCDC replication tasks and the transfer relationships between states.

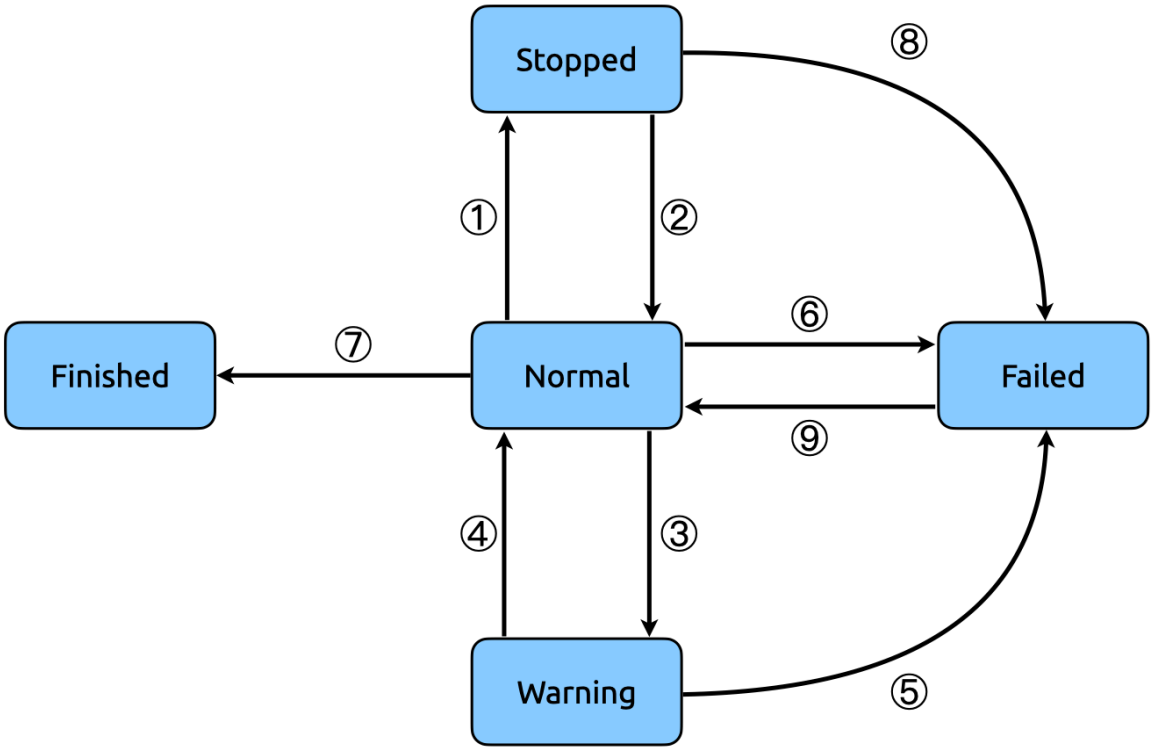

Figure 100: TiCDC state transfer

The states in the preceding state transfer diagram are described as follows:

- `Normal`: The replication task runs normally and the checkpoint-ts proceeds normally. A changefeed in this state blocks GC to advance.
- `Stopped`: The replication task is stopped, because the user manually pauses the changefeed. The changefeed in this state blocks GC operations.
- `Warning`: The replication task returns an error. The replication cannot continue due to some recoverable errors. The changefeed in this state keeps trying to resume until the state transfers to `Normal`. The default retry time is 30 minutes (which can be adjusted by `changefeed-error-stuck-duration`). If it exceeds this time, the changefeed enters a failed state. The changefeed in this state blocks GC operations.
- `Finished`: The replication task is finished and has reached the preset `TargetTs`. The changefeed in this state does not block GC operations.
- `Failed`: The replication task fails. The changefeed in this state does not keep trying to resume. To give you enough time to handle the failure, the changefeed in this state blocks GC operations. The duration of the blockage is specified by the `gc-ttl` parameter, with a default value of 24 hours. If the underlying issue is resolved within this duration, you can manually resume the changefeed. Otherwise, if the changefeed remains in this state beyond the `gc-ttl` duration, the replication task cannot resume and cannot be recovered.

Note:

- If GC is blocked by a changefeed, the changefeed will block GC advancement for up to the time specified by `gc-ttl`. After that, the changefeed will be set to the `failed` state, with an error type of `ErrGCTTLExceeded`, and will no longer block GC advancement.
- If the changefeed encounters errors with error codes `ErrGCTTLExceeded`, `ErrSnapshotLostByGC`, or `ErrStartTsBeforeGC`, it does not block GC operations.

The numbers in the preceding state transfer diagram are described as follows.

- Run the `changefeed pause` command.
- Run the `changefeed resume` command to resume the replication task.
- Recoverable errors occur during the `changefeed` operation, and the operation is retried automatically.
- The changefeed automatic retry succeeds, and `checkpoint-ts` continues to advance.
- The changefeed automatic retry exceeds 30 minutes and fails. The changefeed enters the failed state. At this time, the changefeed continues to block upstream GC for a duration specified by `gc-ttl`.
- The changefeed encounters an unrecoverable error and directly enters the failed state. At this time, the changefeed continues to block upstream GC for a duration specified by `gc-ttl`.
- The replication progress of the changefeed reaches the value set by `target-ts`, and the replication is completed.
- The changefeed has been suspended for a duration longer than the value specified by `gc-ttl`, thus encountering GC advancement errors, and cannot be resumed.
- If the cause of the failure has been resolved, and the changefeed was suspended for a duration shorter than the value specified by `gc-ttl`, run the `changefeed resume` command to resume the replication task.

7.3.1.2 Operate changefeeds

You can manage a TiCDC cluster and its replication tasks using the command-line tool `cdc cli`. For details, see Manage TiCDC changefeeds.

You can also use the HTTP interface (the TiCDC OpenAPI feature) to manage a TiCDC cluster and its replication tasks. For details, see TiCDC OpenAPI.

If your TiCDC is deployed using TiUP, you can start `cdc cli` by running the `tiup cdc :v<CLUSTER_VERSION> cli` command. Replace `v<CLUSTER_VERSION>` with the TiCDC cluster version, such as `v8.5.1`. You can also run `cdc cli` directly.

7.3.2 Create Changefeeds

7.3.2.1 Replicate Data to MySQL-compatible Databases

This document describes how to replicate incremental data to the downstream TiDB database or other MySQL-compatible databases using TiCDC. It also introduces how to use the eventually consistent replication feature in disaster scenarios.

7.3.2.1.1 Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
    --sink-uri="mysql://root:123456@127.0.0.1:3306/" \
    --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"mysql://root:123456@127.0.0.1:3306/","opts":{},"create-
    ↪ time":"2023-11-28T22:04:08.103600025+08:00","start-ts
    ↪ ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine":"
    ↪ unified","sort-dir":".","config":{"case-sensitive":false,"filter":{"
    ↪ rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
    ↪ mounter":{"worker-num":16},"sink":{"dispatchers":null},"scheduler":{"
    ↪ type":"table-number","polling-time":-1}},"state":"normal","history":
    ↪ null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see Configure sink URI with `mysql/tidb`.
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see TiCDC Changefeed Configuration Parameters.

Note:

- TiCDC only replicates incremental data. To initialize full data, use Dumpling/TiDB Lightning or BR.
- After the full data is initialized, you need to specify the `start-ts` as the TSO when the upstream backup is performed. For example, the `pos` value in the metadata file under the Dumpling directory, or the `backupTS` value in the log output after BR completes the backup.

7.3.2.1.2 Configure sink URI for MySQL or TiDB

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
```

Note:

`/path` is not used for the MySQL sink.

Sample configuration for MySQL:

```
--sink-uri="mysql://root:12345678@127.0.0.1:3306"
```

The following are descriptions of sink URI parameters and parameter values that can be configured for MySQL or TiDB:

Parameter/Parameter value	Description
`root`	The username of the downstream database. To replicate data to TiDB or other MySQL-compatible databases, make sure that the downstream database user has certain permissions.
`12345678`	The password of the downstream database (can be encoded using Base64).
`127.0.0.1`	The IP address of the downstream database.
`3306`	The port for the downstream database.
`worker-count`	The number of SQL statements that can be concurrently executed to the downstream (optional, the default value is `16`, and the maximum value is `1024`).

Parameter/Parameter value	Description
`cache-prep-stmts`	Controls whether to use prepared statements when executing SQL in the downstream and enable prepared statement cache on the client side (optional, `true` by default).
`max-txn-row`	The batch size of SQL statements executed to the downstream (optional, the default value is `256`, and the maximum value is `2048`).
`max-multi-update-row`	The batch size of `UPDATE ROWS` SQL statements executed to the downstream when batch write (`batch-dml-enable`) is enabled, always less than `max-txn-row` (optional, the default value is `40`, and the maximum value is `256`).
`max-multi-update-row-size`	The size limit of `UPDATE ROWS` SQL statements executed to the downstream when batch write (`batch-dml-enable`) is enabled. If the size exceeds this limit, each row is executed as a separate SQL statement (optional, the default value is `1024`, and the maximum value is `8192`).
`ssl-ca`	The path of the CA certificate file needed to connect to the downstream MySQL instance (optional).
`ssl-cert`	The path of the certificate file needed to connect to the downstream MySQL instance (optional).
`ssl-key`	The path of the certificate key file needed to connect to the downstream MySQL instance (optional).
`time-zone`	The time zone used when connecting to the downstream MySQL instance, which is effective since v4.0.8. This is an optional parameter. If this parameter is not specified, the time zone of TiCDC service processes is used. If this parameter is set to an empty value, such as `time-zone=""`, no time zone is specified when TiCDC connects to the downstream MySQL instance and the default time zone of the downstream is used.
`transaction-atomicity`	The atomicity level of a transaction. This is an optional parameter, with the default value of `none`. When the value is `table`, TiCDC ensures the atomicity of a single-table transaction. When the value is `none`, TiCDC splits the single-table transaction.
`batch-dml-enable`	Enables the batch write (batch-dml) feature (optional, the default value is `true`).

Parameter/Parameter value	Description
`read-timeout`	The go-sql-driver parameter, I/O read timeout (optional, the default value is `2m`).
`write-timeout`	The go-sql-driver parameter, I/O write timeout (optional, the default value is `2m`).
`timeout`	The go-sql-driver parameter, timeout for establishing connections, also known as dial timeout (optional, the default value is `2m`).
`tidb-txn-mode`	Specifies the `tidb_txn_mode` environment variable (optional, the default value is `optimistic`).
`safe-mode`	Specifies how TiCDC handles `INSERT` and `UPDATE` statements when replicating data to the downstream. When it is `true`, TiCDC converts all upstream `INSERT` statements to `REPLACE INTO` statements, and all `UPDATE` statements to `DELETE` + `REPLACE INTO` statements. Before v6.1.3, the default value of this parameter is `true`. Starting from v6.1.3, the default value is changed to `false`. When TiCDC starts, it obtains a current timestamp `ThresholdTs`. For `INSERT` and `UPDATE` statements with `CommitTs` less than `ThresholdTs`, TiCDC converts them to `REPLACE INTO` statements and `DELETE` + `REPLACE INTO` statements respectively. For `INSERT` and `UPDATE` statements with `CommitTs` greater than or equal to `ThresholdTs`, `INSERT` statements are directly replicated to the downstream, while the behavior of `UPDATE` statements follows the TiCDC Behavior in Splitting UPDATE Events.

To encode the database password in the sink URI using Base64, use the following command:

```
echo -n '12345678' | base64 # '12345678' is the password to be encoded.
```

The encoded password is as follows:

```
MTIzNDU2Nzg=
```

Note:

When the sink URI parameters contain special characters such as `! * ' ( ) ; : @ & = + $ , / ? % # [ ]`, you need to escape the special characters,

for example, in URI Encoder.

For example, if the username for connecting to the downstream database is `R&D (2)` and the certificate file path is `/data1/R&D (2).pem`, you need to escape these parameters as follows:

```
--sink-uri="mysql://R%26D%20%282%29:MTIzNDU2Nzg%3D@127
    ↪ .0.0.1:3306/?ssl-cert=/data1/R%26D%20%282%29.pem"
#                   ^~~ ^~~^~~ ^~~          ^~~
    ↪                                 ^~~ ^~~^~~ ^~~
```

7.3.2.1.3 Permissions required for the downstream database user

To replicate data to TiDB or other MySQL-compatible databases, the downstream database user needs the following permissions:

- `Select`
- `Index`
- `Insert`
- `Update`
- `Delete`
- `Create`
- `Drop`
- `Alter`
- `Create View`

To replicate `RECOVER TABLE` to the downstream TiDB, the downstream database user also needs the `Super` permission.

If the downstream TiDB cluster has read-only mode enabled, the downstream database user also needs the `RESTRICTED_REPLICA_WRITER_ADMIN` permission.

7.3.2.1.4 Eventually consistent replication in disaster scenarios

Starting from v6.1.1, this feature becomes GA. Starting from v5.3.0, TiCDC supports backing up incremental data from an upstream TiDB cluster to an object storage or an NFS of the downstream cluster. When the upstream cluster encounters a disaster and becomes unavailable, TiCDC can restore the downstream data to the recent eventually consistent state. This is the eventually consistent replication capability provided by TiCDC. With this capability, you can switch applications to the downstream cluster quickly, avoiding long-time downtime and improving service continuity.

Currently, TiCDC can replicate incremental data from a TiDB cluster to another TiDB cluster or a MySQL-compatible database system (including Aurora, MySQL, and MariaDB).

In case the upstream cluster crashes, TiCDC can restore data in the downstream cluster within 5 minutes, given the conditions that TiCDC replicates data normally before the crash, and the replication lag is small. It allows data loss of 10s at most, that is, RTO <= 5 min, and P95 RPO <= 10s.

TiCDC replication lag increases in the following scenarios:

- The TPS increases significantly in a short time.
- Large or long transactions occur in the upstream.
- The TiKV or TiCDC cluster in the upstream is reloaded or upgraded.
- Time-consuming DDL statements, such as `add index`, are executed in the upstream.
- The PD is configured with aggressive scheduling strategies, resulting in frequent transfer of Region leaders, or frequent Region merge or Region split.

> **Note:**
>
> Starting from v6.1.1, the eventually consistent replication feature of TiCDC supports Amazon S3-compatible object storage. Starting from v6.1.4, this feature supports GCS- and Azure-compatible object storage.

Prerequisites

- Prepare a highly available object storage or NFS for storing TiCDC's real-time incremental data backup files. These files can be accessed in case of a disaster in the upstream.
- Enable this feature for changefeeds that need to have eventual consistency in disaster scenarios. To enable it, you can add the following configuration to the changefeed configuration file.

```
[consistent]
#### Consistency level. Options include:
#### - none: the default value. In a non-disaster scenario, eventual
   ↪ consistency is only guaranteed if and only if finished-ts is
   ↪ specified.
#### - eventual: Uses redo log to guarantee eventual consistency in case of
   ↪ the primary cluster disasters.
level = "eventual"

#### Individual redo log file size, in MiB. By default, it's 64. It is
   ↪ recommended to be no more than 128.
max-log-size = 64
```

```
#### The interval for flushing or uploading redo logs to Amazon S3, in
    ↪ milliseconds. It is recommended that this configuration be equal to
    ↪ or greater than 2000.
flush-interval = 2000

#### The path under which redo log backup is stored. The scheme can be nfs (
    ↪ NFS directory), or Amazon S3, GCS, and Azure (uploaded to object
    ↪ storage).
storage = "$SCHEME://logbucket/test-changefeed?endpoint=http://$ENDPOINT/"
```

Disaster recovery

When a disaster happens in the primary cluster, you need to recover manually in the secondary cluster by running the `cdc redo` command. The recovery process is as follows.

1. Ensure that all the TiCDC processes have exited. This is to prevent the primary cluster from resuming service during data recovery and prevent TiCDC from restarting data synchronization.
2. Use cdc binary for data recovery. Run the following command:

```
cdc redo apply --tmp-dir="/tmp/cdc/redo/apply" \
    --storage="s3://logbucket/test-changefeed?endpoint=http
        ↪ ://10.0.10.25:24927/" \
    --sink-uri="mysql://normal:123456@10.0.10.55:3306/"
```

In this command:

- `tmp-dir`: Specifies the temporary directory for downloading TiCDC incremental data backup files.
- `storage`: Specifies the address for storing the TiCDC incremental data backup files, either a URI of object storage or an NFS directory.
- `sink-uri`: Specifies the secondary cluster address to restore the data to. Scheme can only be `mysql`.

7.3.2.2 Replicate Data to Kafka

This document describes how to create a changefeed that replicates incremental data to Apache Kafka using TiCDC.

7.3.2.2.1 Create a replication task

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
```

```
    --sink-uri="kafka://127.0.0.1:9092,127.0.0.1:9093,127.0.0.1:9094/topic-
        ↪ name?protocol=canal-json&kafka-version=2.4.0&partition-num=6&max-
        ↪ message-bytes=67108864&replication-factor=1" \
    --changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"kafka://127.0.0.1:9092,127.0.0.1:9093,127.0.0.1:9094/
    ↪ topic-name?protocol=canal-json&kafka-version=2.4.0&partition-num=6&
    ↪ max-message-bytes=67108864&replication-factor=1","opts":{},"create-
    ↪ time":"2023-11-28T22:04:08.103600025+08:00","start-ts
    ↪ ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine":"
    ↪ unified","sort-dir":".","config":{"case-sensitive":false,"filter":{"
    ↪ rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
    ↪ mounter":{"worker-num":16},"sink":{"dispatchers":null},"scheduler":{"
    ↪ type":"table-number","polling-time":-1}},"state":"normal","history":
    ↪ null,"error":null}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. For details, see Configure sink URI with `kafka`.
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.
- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the changefeed configuration file. For details, see TiCDC Changefeed Configuration Parameters.

7.3.2.2.2 Supported Kafka versions

The following table shows the minimum supported Kafka versions for each TiCDC version:

TiCDC version	Minimum supported Kafka version
TiCDC >= v8.1.0	2.1.0
v7.6.0 <= TiCDC < v8.1.0	2.4.0
v7.5.2 <= TiCDC < v8.0.0	2.1.0
v7.5.0 <= TiCDC < v7.5.2	2.4.0
v6.5.0 <= TiCDC < v7.5.0	2.1.0
v6.1.0 <= TiCDC < v6.5.0	2.0.0

7.3.2.2.3 Configure sink URI for Kafka

Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[host]:[port][/path]?[query_parameters]
```

Tip:

If there are multiple hosts or ports for the downstream Kafka, you can configure multiple `[host]:[port]` in the sink URI. For example:

```
[scheme]://[host]:[port],[host]:[port],[host]:[port][/path]?[
    ↪ query_parameters]
```

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=canal-json&kafka-
    ↪ version=2.4.0&partition-num=6&max-message-bytes=67108864&replication-
    ↪ factor=1"
```

The following are descriptions of sink URI parameters and values that can be configured for Kafka:

Parameter/Parameter value	Description
`host`	The IP address of the downstream Kafka services.
`port`	The port for the downstream Kafka.
`topic-name`	Variable. The name of the Kafka topic.
`protocol`	The protocol with which messages are output to Kafka. The value options are `canal-json`, `open-protocol`, `avro`, `debezium` and `simple`.
`kafka-version`	The version of the downstream Kafka. This value needs to be consistent with the actual version of the downstream Kafka.
`kafka-client-id`	Specifies the Kafka client ID of the replication task (optional. `TiCDC_sarama_producer_replication ID` by default).
`partition-num`	The number of the downstream Kafka partitions (optional. The value must be **no greater than** the actual number of partitions; otherwise, the replication task cannot be created successfully. `3` by default).
`max-message-bytes`	The maximum size of data that is sent to Kafka broker each time (optional, `10MB` by default). From v5.0.6 and v4.0.6, the default value has changed from `64MB` and `256MB` to `10MB`.

Parameter/Parameter value	Description
`replication-factor`	The number of Kafka message replicas that can be saved (optional, `1` by default). This value must be greater than or equal to the value of `min.insync.replicas` in Kafka.
`required-acks`	A parameter used in the `Produce` request, which notifies the broker of the number of replica acknowledgements it needs to receive before responding. Value options are `0` (`NoResponse`: no response, only `TCP ACK` is provided), `1` (`WaitForLocal`: responds only after local commits are submitted successfully), and `-1` (`WaitForAll`: responds after all replicated replicas are committed successfully. You can configure the minimum number of replicated replicas using the `min.insync.replicas` configuration item of the broker). (Optional, the default value is `-1`).
`compression`	The compression algorithm used when sending messages (value options are `none`, `lz4`, `gzip`, `snappy`, and `zstd`; `none` by default). Note that the Snappy compressed file must be in the official Snappy format. Other variants of Snappy compression are not supported.
`auto-create-topic`	Determines whether TiCDC creates the topic automatically when the `topic-name` passed in does not exist in the Kafka cluster (optional, `true` by default).
`enable-tidb-extension`	Optional. `false` by default. When the output protocol is `canal-json`, if the value is `true`, TiCDC sends WATERMARK events and adds the TiDB extension field to Kafka messages. From v6.1.0, this parameter is also applicable to the `avro` protocol. If the value is `true`, TiCDC adds three TiDB extension fields to the Kafka message.
`max-batch-size`	New in v4.0.9. If the message protocol supports outputting multiple data changes to one Kafka message, this parameter specifies the maximum number of data changes in one Kafka message. It currently takes effect only when Kafka's `protocol` is `open-protocol` (optional, `16` by default).
`enable-tls`	Whether to use TLS to connect to the downstream Kafka instance (optional, `false` by default).
`ca`	The path of the CA certificate file needed to connect to the downstream Kafka instance (optional).
`cert`	The path of the certificate file needed to connect to the downstream Kafka instance (optional).
`key`	The path of the certificate key file needed to connect to the downstream Kafka instance (optional).
`insecure-skip-verify`	Whether to skip certificate verification when connecting to the downstream Kafka instance (optional, `false` by default).

Parameter/Parameter value	Description
`sasl-user`	The identity (authcid) of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional).
`sasl-password`	The password of SASL/PLAIN or SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional). If it contains special characters, they need to be URL encoded.
`sasl-mechanism`	The name of SASL authentication needed to connect to the downstream Kafka instance. The value can be `plain`, `scram-sha-256`, `scram-sha-512`, or `gssapi`.
`sasl-gssapi-auth-type`	The gssapi authentication type. Values can be `user` or `keytab` (optional).
`sasl-gssapi-keytab-path`	The gssapi keytab path (optional).
`sasl-gssapi-kerberos-config-path`	The gssapi kerberos configuration path (optional).
`sasl-gssapi-service-name`	The gssapi service name (optional).
`sasl-gssapi-user`	The user name of gssapi authentication (optional).
`sasl-gssapi-password`	The password of gssapi authentication (optional). If it contains special characters, they need to be URL encoded.
`sasl-gssapi-realm`	The gssapi realm name (optional).
`sasl-gssapi-disable-pafxfast`	Whether to disable the gssapi PA-FX-FAST (optional).
`dial-timeout`	The timeout in establishing a connection with the downstream Kafka. The default value is `10s`.
`read-timeout`	The timeout in getting a response returned by the downstream Kafka. The default value is `10s`.
`write-timeout`	The timeout in sending a request to the downstream Kafka. The default value is `10s`.
`avro-decimal-handling-mode`	Only effective with the `avro` protocol. Determines how Avro handles the DECIMAL field. The value can be `string` or `precise`, indicating either mapping the DECIMAL field to a string or a precise floating number.
`avro-bigint-unsigned-handling-mode`	Only effective with the `avro` protocol. Determines how Avro handles the BIGINT UNSIGNED field. The value can be `string` or `long`, indicating either mapping the BIGINT UNSIGNED field to a 64-bit signed number or a string.

Best practices

- It is recommended that you create your own Kafka Topic. At a minimum, you need to set the maximum amount of data of each message that the Topic can send to the Kafka broker, and the number of downstream Kafka partitions. When you create a changefeed, these two settings correspond to `max-message-bytes` and `partition-num`, respectively.
- If you create a changefeed with a Topic that does not yet exist, TiCDC will try to create the Topic using the `partition-num` and `replication-factor` parameters. It is recommended that you specify these parameters explicitly.
- In most cases, it is recommended to use the `canal-json` protocol.

> **Note:**
>
> When `protocol` is `open-protocol`, TiCDC encodes multiple events into one Kafka message and avoids generating messages that exceed the length specified by `max-message-bytes`. If the encoded result of a single row change event exceeds the value of `max-message-bytes`, the changefeed reports an error and prints logs.

TiCDC uses the authentication and authorization of Kafka

The following are examples when using Kafka SASL authentication:

- SASL/PLAIN

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-user=alice-user&sasl-password=alice-secret&sasl-mechanism=plain"
```

- SASL/SCRAM

SCRAM-SHA-256 and SCRAM-SHA-512 are similar to the PLAIN method. You just need to specify `sasl-mechanism` as the corresponding authentication method.

- SASL/GSSAPI

SASL/GSSAPI `user` authentication:

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=user&sasl-gssapi-kerberos-
↪ config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-password=alice-secret&sasl-gssapi-realm
↪ =example.com"
```

Values of `sasl-gssapi-user` and `sasl-gssapi-realm` are related to the principle specified in kerberos. For example, if the principle is set as `alice/for-kafka@example.com`, then `sasl-gssapi-user` and `sasl-gssapi-realm` are specified as `alice/for-kafka` and `example.com` respectively.

SASL/GSSAPI `keytab` authentication:

```
shell  --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&
↪ sasl-mechanism=gssapi&sasl-gssapi-auth-type=keytab&sasl-gssapi-kerberos
↪ -config-path=/etc/krb5.conf&sasl-gssapi-service-name=kafka&sasl-gssapi-
↪ user=alice/for-kafka&sasl-gssapi-keytab-path=/var/lib/secret/alice.key&
↪ sasl-gssapi-realm=example.com"
```

For more information about SASL/GSSAPI authentication methods, see Configuring GSSAPI.

- TLS/SSL encryption

  If the Kafka broker has TLS/SSL encryption enabled, you need to add the `-enable ↪ -tls=true` parameter to `--sink-uri`. If you want to use self-signed certificates, you also need to specify `ca`, `cert` and `key` in `--sink-uri`.

- ACL authorization

  The minimum set of permissions required for TiCDC to function properly is as follows.

  - The `Create`, `Write`, and `Describe` permissions for the Topic resource type.
  - The `DescribeConfig` permission for the Cluster resource type.

The usage scenarios for each permission are as follows:

```
| Resource type | Type of operation |  Scenario                          |
| :-------------| :-------------- | :----------------------------------|
| Cluster     | `DescribeConfig`| Gets the cluster metadata while the
   ↪ changefeed is running |
| Topic       | `Describe`    | Tries to create a topic when the changefeed
   ↪ starts |
| Topic       | `Create`      | Tries to create a topic when the changefeed
   ↪ starts |
| Topic       | `Write`       | Sends data to the topic              |

When creating or starting a changefeed, you can disable the `Describe` and `
   ↪ Create` permissions if the specified Kafka topic already exists.
```

Integrate TiCDC with Kafka Connect (Confluent Platform)

To use the data connectors provided by Confluent to stream data to relational or non-relational databases, you need to use the `avro` protocol and provide a URL for Confluent Schema Registry in `schema-registry`.

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?&protocol=avro&replication-
    ↪ factor=3" --schema-registry="http://127.0.0.1:8081" --config
    ↪ changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

For detailed integration guide, see Quick Start Guide on Integrating TiDB with Confluent Platform.

Integrate TiCDC with AWS Glue Schema Registry

Starting from v7.4.0, TiCDC supports using the AWS Glue Schema Registry as the Schema Registry when users choose the Avro protocol for data replication. The configuration example is as follows:

```
./cdc cli changefeed create --server=127.0.0.1:8300 --changefeed-id="kafka-
    ↪ glue-test" --sink-uri="kafka://127.0.0.1:9092/topic-name?&protocol=
    ↪ avro&replication-factor=3" --config changefeed_glue.toml
```

```
[sink]
[sink.kafka-config.glue-schema-registry-config]
region="us-west-1"
registry-name="ticdc-test"
access-key="xxxx"
secret-access-key="xxxx"
token="xxxx"
```

In the above configuration, `region` and `registry-name` are required fields, while `access-key`, `secret-access-key`, and `token` are optional fields. The best practice is to set the AWS credentials as environment variables or store them in the `~/.aws/credentials` file instead of setting them in the changefeed configuration file.

For more information, refer to the official AWS SDK for Go V2 documentation.

7.3.2.2.4 Customize the rules for Topic and Partition dispatchers of Kafka Sink

Matcher rules

Take the following configuration of `dispatchers` as an example:

```
[sink]
dispatchers = [
  {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1", partition
     ↪  = "ts" },
```

```
  {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2", partition
    ↪  = "index-value" },
  {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3", partition
    ↪  = "table"},
  {matcher = ['test6.*'], partition = "ts"}
]
```

- For the tables that match the matcher rule, they are dispatched according to the policy specified by the corresponding topic expression. For example, the `test3.aa` table is dispatched according to "Topic expression 2"; the `test5.aa` table is dispatched according to "Topic expression 3".
- For a table that matches multiple matcher rules, it is dispatched according to the first matching topic expression. For example, the `test1.aa` table is distributed according to "Topic expression 1".
- For tables that do not match any matcher rule, the corresponding data change events are sent to the default topic specified in `--sink-uri`. For example, the `test10.aa` table is sent to the default topic.
- For tables that match the matcher rule but do not specify a topic dispatcher, the corresponding data changes are sent to the default topic specified in `--sink-uri`. For example, the `test6.aa` table is sent to the default topic.

Topic dispatchers

You can use topic = "xxx" to specify a Topic dispatcher and use topic expressions to implement flexible topic dispatching policies. It is recommended that the total number of topics be less than 1000.

The format of the Topic expression is `[prefix]{schema}[middle][{table}][suffix]`.

- `prefix`: optional. Indicates the prefix of the Topic Name.
- `{schema}`: required. Used to match the schema name. Starting from v7.1.4, this parameter is optional.
- `middle`: optional. Indicates the delimiter between schema name and table name.
- `{table}`: optional. Used to match the table name.
- `suffix`: optional. Indicates the suffix of the Topic Name.

`prefix`, `middle` and `suffix` can only include the following characters: `a-z`, `A-Z`, `0-9`, `.`, `_` and `-`. `{schema}` and `{table}` are both lowercase. Placeholders such as `{Schema}` and `{TABLE}` are invalid.

Some examples:

- `matcher = ['test1.table1', 'test2.table2'], topic = "hello_{schema}_{table}"`

    - The data change events corresponding to `test1.table1` are sent to the topic named `hello_test1_table1`.
    - The data change events corresponding to `test2.table2` are sent to the topic named `hello_test2_table2`.
- `matcher = ['test3.*', 'test4.*'], topic = "hello_{schema}_world"`
    - The data change events corresponding to all tables in `test3` are sent to the topic named `hello_test3_world`.
    - The data change events corresponding to all tables in `test4` are sent to the topic named `hello_test4_world`.
- `matcher = ['test5.*, 'test6.*'], topic = "hard_code_topic_name"`
    - The data change events corresponding to all tables in `test5` and `test6` are sent to the topic named `hard_code_topic_name`. You can specify the topic name directly.
- `matcher = ['*.*'], topic = "{schema}_{table}"`
    - All tables listened by TiCDC are dispatched to separate topics according to the "schema_table" rule. For example, for the `test.account` table, TiCDC dispatches its data change log to a Topic named `test_account`.

Dispatch DDL events

Schema-level DDLs

DDLs that are not related to a specific table are called schema-level DDLs, such as `create database` and `drop database`. The events corresponding to schema-level DDLs are sent to the default topic specified in `--sink-uri`.

Table-level DDLs

DDLs that are related to a specific table are called table-level DDLs, such as `alter table` and `create table`. The events corresponding to table-level DDLs are sent to the corresponding topic according to dispatcher configurations.

For example, for a dispatcher like `matcher = ['test.*'], topic = {schema}_{table}`, DDL events are dispatched as follows:

- If a single table is involved in the DDL event, the DDL event is sent to the corresponding topic as is. For example, for the DDL event `drop table test.table1`, the event is sent to the topic named `test_table1`.
- If multiple tables are involved in the DDL event (`rename table` / `drop table` / `drop view` may involve multiple tables), the DDL event is split into multiple events and sent to the corresponding topics. For example, for the DDL event `rename table test.table1 to test.table10, test.table2 to test.table20`, the event `rename table test.table1 to test.table10` is sent to the topic named `test_table1` and the event `rename table test.table2 to test.table20` is sent to the topic named `test.table2`.

Partition dispatchers

You can use `partition = "xxx"` to specify a partition dispatcher. It supports five dispatchers: `default`, `index-value`, `columns`, `table`, and `ts`. The dispatcher rules are as follows:

- `default`: uses the `table` dispatcher rule by default. It calculates the partition number using the schema name and table name, ensuring data from a table is sent to the same partition. As a result, the data from a single table only exists in one partition and is guaranteed to be ordered. However, this dispatcher rule limits the send throughput, and the consumption speed cannot be improved by adding consumers.
- `index-value`: calculates the partition number using either the primary key, a unique index, or an index explicitly specified by `index`, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers.
- `columns`: calculates the partition number using the values of explicitly specified columns, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers.
- `table`: calculates the partition number using the schema name and table name.
- `ts`: calculates the partition number using the commitTs of the row change, distributing table data across multiple partitions. The data from a single table is sent to multiple partitions, and the data in each partition is ordered. You can improve the consumption speed by adding consumers. However, multiple changes of a data item might be sent to different partitions and the consumer progress of different consumers might be different, which might cause data inconsistency. Therefore, the consumer needs to sort the data from multiple partitions by commitTs before consuming.

Take the following configuration of `dispatchers` as an example:

```
[sink]
dispatchers = [
    {matcher = ['test.*'], partition = "index-value"},
    {matcher = ['test1.*'], partition = "index-value", index = "index1"},
    {matcher = ['test2.*'], partition = "columns", columns = ["id", "a"]},
    {matcher = ['test3.*'], partition = "table"},
]
```

- Tables in the `test` database use the `index-value` dispatcher, which calculates the partition number using the value of the primary key or unique index. If a primary key exists, the primary key is used; otherwise, the shortest unique index is used.
- Tables in the `test1` table use the `index-value` dispatcher and calculate the partition number using values of all columns in the index named `index1`. If the specified index does not exist, an error is reported. Note that the index specified by `index` must be a unique index.

- Tables in the `test2` database use the `columns` dispatcher and calculate the partition number using the values of columns `id` and `a`. If any of the columns does not exist, an error is reported.
- Tables in the `test3` database use the `table` dispatcher.
- Tables in the `test4` database use the `default` dispatcher, that is the `table` dispatcher, as they do not match any of the preceding rules.

If a table matches multiple dispatcher rules, the first matching rule takes precedence.

Note:

Since v6.1.0, to clarify the meaning of the configuration, the configuration used to specify the partition dispatcher has been changed from `dispatcher` to `partition`, with `partition` being an alias for `dispatcher`. For example, the following two rules are exactly equivalent.

```
[sink]
dispatchers = [
   {matcher = ['*.*'], dispatcher = "index-value"},
   {matcher = ['*.*'], partition = "index-value"},
]
```

However, `dispatcher` and `partition` cannot appear in the same rule. For example, the following rule is invalid.

```
{matcher = ['*.*'], dispatcher = "index-value", partition = "
    ↪ table"},
```

7.3.2.2.5 Column selectors

The column selector feature supports selecting columns from events and sending only the data changes related to those columns to the downstream.

Take the following configuration of `column-selectors` as an example:

```
[sink]
column-selectors = [
    {matcher = ['test.t1'], columns = ['a', 'b']},
    {matcher = ['test.*'], columns = ["*", "!b"]},
    {matcher = ['test1.t1'], columns = ['column*', '!column1']},
    {matcher = ['test3.t'], columns = ["column?", "!column1"]},
]
```

- For table `test.t1`, only columns `a` and `b` are sent.
- For tables in the `test` database (excluding the `t1` table), all columns except `b` are sent.
- For table `test1.t1`, any column starting with `column` is sent, except for `column1`.
- For table `test3.t`, any 7-character column starting with `column` is sent, except for `column1`.
- For tables that do not match any rule, all columns are sent.

> **Note:**
>
> After being filtered by the `column-selectors` rules, the data in the table must have a primary key or unique key to be replicated. Otherwise, the changefeed reports an error when it is created or running.

7.3.2.2.6 Scale out the load of a single large table to multiple TiCDC nodes

This feature splits the data replication range of a single large table into multiple ranges, according to the data volume and the number of modified rows per minute, and it makes the data volume and the number of modified rows replicated in each range approximately the same. This feature distributes these ranges to multiple TiCDC nodes for replication, so that multiple TiCDC nodes can replicate a large single table at the same time. This feature can solve the following two problems:

- A single TiCDC node cannot replicate a large single table in time.
- The resources (such as CPU and memory) consumed by TiCDC nodes are not evenly distributed.

> **Warning:**
>
> TiCDC v7.0.0 only supports scaling out the load of a large single table on Kafka changefeeds.

Sample configuration:

```
[scheduler]
#### The default value is "false". You can set it to "true" to enable this
    ↪ feature.
enable-table-across-nodes = true
#### When you enable this feature, it only takes effect for tables with the
    ↪ number of regions greater than the `region-threshold` value.
```

```
region-threshold = 100000
#### When you enable this feature, it takes effect for tables with the
    ↪ number of rows modified per minute greater than the `write-key-
    ↪ threshold` value.
#### Note:
#### * The default value of `write-key-threshold` is 0, which means that the
    ↪  feature does not split the table replication range according to the
    ↪ number of rows modified in a table by default.
#### * You can configure this parameter according to your cluster workload.
    ↪ For example, if it is configured as 30000, it means that the feature
    ↪ will split the replication range of a table when the number of
    ↪ modified rows per minute in the table exceeds 30000.
#### * When `region-threshold` and `write-key-threshold` are configured at
    ↪ the same time:
####  TiCDC will check whether the number of modified rows is greater than
    ↪ `write-key-threshold` first.
####  If not, next check whether the number of Regions is greater than `
    ↪ region-threshold`.
write-key-threshold = 30000
```

You can query the number of Regions a table contains by the following SQL statement:

```
SELECT COUNT(*) FROM INFORMATION_SCHEMA.TIKV_REGION_STATUS WHERE DB_NAME="
    ↪ database1" AND TABLE_NAME="table1" AND IS_INDEX=0;
```

7.3.2.2.7 Handle messages that exceed the Kafka topic limit

Kafka topic sets a limit on the size of messages it can receive. This limit is controlled by the `max.message.bytes` parameter. If TiCDC Kafka sink sends data that exceeds this limit, the changefeed reports an error and cannot proceed to replicate data. To solve this problem, TiCDC adds a new configuration `large-message-handle-option` and provides the following solution.

Currently, this feature supports two encoding protocols: Canal-JSON and Open Protocol. When using the Canal-JSON protocol, you must specify `enable-tidb-extension=true` in `sink-uri`.

TiCDC data compression

Starting from v7.4.0, TiCDC Kafka sink supports compressing data immediately after encoding and comparing the compressed data size with the message size limit. This feature can effectively reduce the occurrence of messages exceeding the size limit.

An example configuration is as follows:

```
[sink.kafka-config.large-message-handle]
#### This configuration is introduced in v7.4.0.
```

```
#### "none" by default, which means that the compression feature is disabled
    ↪ .
#### Possible values are "none", "lz4", and "snappy". The default value is "
    ↪ none".
large-message-handle-compression = "none"
```

When `large-message-handle-compression` is enabled, the message received by the consumer is encoded using a specific compression protocol, and the consumer application needs to use the specified compression protocol to decode the data.

This feature is different from the compression feature of the Kafka producer:

- The compression algorithm specified in `large-message-handle-compression` compresses a single Kafka message. The compression is performed before comparing with the message size limit.
- At the same time, you can also configure the compression algorithm by using the `compression` parameter in `sink-uri`. This compression algorithm is applied to the entire data sending request, which contains multiple Kafka messages.

If you set `large-message-handle-compression`, when TiCDC receives a message, it first compares it to the value of the message size limit parameter, and messages larger than the size limit are compressed. If you also set `compression` in `sink-uri`, TiCDC compresses the entire sending data request again at the sink level based on the `sink-uri` setting.

The compression ratio for the two preceding compression methods is calculated as follows: `compression ratio = size before compression / size after compression * 100`.

Send handle keys only

Starting from v7.3.0, TiCDC Kafka sink supports sending only the handle keys when the message size exceeds the limit. This can significantly reduce the message size and avoid changefeed errors and task failures caused by the message size exceeding the Kafka topic limit. Handle Key refers to the following:

- If the table to be replicated has primary key, the primary key is the handle key.
- If the table does not have primary key but has NOT NULL Unique Key, the NOT NULL Unique Key is the handle key.

The sample configuration is as follows:

```
[sink.kafka-config.large-message-handle]
#### large-message-handle-option is introduced in v7.3.0.
#### Defaults to "none". When the message size exceeds the limit, the
    ↪ changefeed fails.
#### When set to "handle-key-only", if the message size exceeds the limit,
    ↪ only the handle key is sent in the data field. If the message size
    ↪ still exceeds the limit, the changefeed fails.
large-message-handle-option = "claim-check"
```

Consume messages with handle keys only

The message format with handle keys only is as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "id": 4
    },
    "mysqlType": {
        "id": "int"
    },
    "data": [
        {
          "id": "2"
        }
    ],
    "old": null,
    "_tidb": {   // TiDB extension fields
        "commitTs": 429918007904436226, // A TiDB TSO timestamp
        "onlyHandleKey": true
    }
}
```

When a Kafka consumer receives a message, it first checks the `onlyHandleKey` field. If this field exists and is `true`, it means that the message only contains the handle key of the complete data. In this case, to get the complete data, you need to query the upstream TiDB and use `tidb_snapshot` to read historical data.

> **Warning:**
>
> When the Kafka consumer processes data and queries TiDB, the data might have been deleted by GC. You need to modify the GC Lifetime of the TiDB cluster to a larger value to avoid this situation.

Send large messages to external storage

Starting from v7.4.0, TiCDC Kafka sink supports sending large messages to external storage when the message size exceeds the limit. Meanwhile, TiCDC sends a message to Kafka that contains the address of the large message in the external storage. This can avoid changefeed failures caused by the message size exceeding the Kafka topic limit.

An example configuration is as follows:

```
[sink.kafka-config.large-message-handle]
#### large-message-handle-option is introduced in v7.3.0.
#### Defaults to "none". When the message size exceeds the limit, the
    ↪ changefeed fails.
#### When set to "handle-key-only", if the message size exceeds the limit,
    ↪ only the handle key is sent in the data field. If the message size
    ↪ still exceeds the limit, the changefeed fails.
#### When set to "claim-check", if the message size exceeds the limit, the
    ↪ message is sent to external storage.
large-message-handle-option = "claim-check"
claim-check-storage-uri = "s3://claim-check-bucket"
```

When `large-message-handle-option` is set to `"claim-check"`, `claim-check-storage ↪ -uri` must be set to a valid external storage address. Otherwise, creating the changefeed will fail.

> **Tip**
>
> For more information about the URI parameters of Amazon S3, GCS, and Azure Blob Storage in TiCDC, see URI Formats of External Storage Services.

TiCDC does not clean up messages on external storage services. Data consumers need to manage external storage services on their own.

Consume large messages from external storage

The Kafka consumer receives a message that contains the address of the large message in the external storage. The message format is as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
```

```
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "id": 4
    },
    "mysqlType": {
        "id": "int"
    },
    "data": [
        {
          "id": "2"
        }
    ],
    "old": null,
    "_tidb": {   // TiDB extension fields
        "commitTs": 429918007904436226, // A TiDB TSO timestamp
        "claimCheckLocation": "s3:/claim-check-bucket/${uuid}.json"
    }
}
```

If the message contains the `claimCheckLocation` field, the Kafka consumer reads the large message data stored in JSON format according to the address provided by the field. The message format is as follows:

```
{
  key: "xxx",
  value: "xxx",
}
```

The `key` and `value` fields correspond to the same-named fields in the Kafka message. Consumers can get the original large message by parsing the data in these two fields. Only Kafka messages encoded with the Open Protocol contain valid content in the `key` field. TiCDC encodes both `key` and `value` into a single JSON object to deliver the complete message at once. For other protocols, the `key` field is always empty.

Send the `value` field to external storage only

Starting from v8.4.0, TiCDC supports sending only the `value` field of Kafka messages to external storage. This feature is only applicable to non-Open Protocol scenarios. You can control this feature by setting the `claim-check-raw-value` parameter, which defaults to `false`.

> **Note:**
>
> When using the Open Protocol, if you set `claim-check-raw-value` to `true`, an error will occur.

When `claim-check-raw-value` is set to `true`, the changefeed sends the `value` field of Kafka messages directly to external storage without additional JSON serialization of `key` and `value`. This reduces CPU overhead. Additionally, consumers can read directly consumable data from external storage, reducing deserialization overhead.

An example configuration is as follows:

```
protocol = "simple"

[sink.kafka-config.large-message-handle]
large-message-handle-option = "claim-check"
claim-check-storage-uri = "s3://claim-check-bucket"
claim-check-raw-value = true
```

7.3.2.3 Replicate Data to Pulsar

This document describes how to create a changefeed that replicates incremental data to Pulsar using TiCDC.

7.3.2.3.1 Create a replication task to replicate incremental data to Pulsar

Create a replication task by running the following command:

```
cdc cli changefeed create \
    --server=http://127.0.0.1:8300 \
--sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
    ↪ protocol=canal-json" \
--config=./t_changefeed.toml \
--changefeed-id="simple-replication-task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7277814241002263370,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"pulsar://127.0.0.1:6650/consumer-test?
    ↪ protocol=canal-json","create_time":"2025-01-17T14
    ↪ :42:32.000904+08:00","start_ts":444203257406423044,"config":{"memory_
    ↪ quota":1073741824,"case_sensitive":false,"force_replicate":false,"
```

```
↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"enable_
↪ sync_point":false,"bdr_mode":false,"sync_point_interval
↪ ":600000000000,"sync_point_retention":86400000000000,"filter":{"rules
↪ ":["pulsar_test.*"]},"mounter":{"worker_num":16},"sink":{"protocol":"
↪ canal-json","csv":{"delimiter":",","quote":"\"","null":"\\N","include
↪ _commit_ts":false,"binary_encoding_method":"base64"},"dispatchers
↪ ":[{"matcher":["pulsar_test.*"],"partition":"","topic":"test_{schema}
↪ _{table}"}],"encoder_concurrency":16,"terminator":"\r\n","date_
↪ separator":"day","enable_partition_separator":true,"only_output_
↪ updated_columns":false,"delete_only_output_handle_key_columns":false
↪ ,"pulsar_config":{"connection-timeout":30,"operation-timeout":30,"
↪ batching-max-messages":1000,"batching-max-publish-delay":10,"send-
↪ timeout":30},"advance_timeout":150},"consistent":{"level":"none","max
↪ _log_size":64,"flush_interval":2000,"use_file_backend":false},"
↪ scheduler":{"enable_table_across_nodes":false,"region_threshold
↪ ":100000,"write_key_threshold":0},"integrity":{"integrity_check_level
↪ ":"none","corruption_handle_level":"warn"}},"state":"normal","creator
↪ _version":"v8.5.1","resolved_ts":444203257406423044,"checkpoint_ts
↪ ":444203257406423044,"checkpoint_time":"2025-01-17 14:42:31.410"}
```

The meaning of each parameter is as follows:

- `--server`: the address of a TiCDC server in the TiCDC cluster.
- `--changefeed-id`: the ID of the replication task. The format must match the regular expression `^[a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$`. If the ID is not specified, TiCDC automatically generates a UUID (in the version 4 format) as the ID.
- `--sink-uri`: the downstream address of the replication task. See Use Sink URI to configure Pulsar.
- `--start-ts`: the start TSO of the changefeed. The TiCDC cluster starts pulling data from this TSO. The default value is the current time.
- `--target-ts`: the target TSO of the changefeed. The TiCDC cluster stops pulling data at this TSO. It is empty by default, which means that TiCDC does not automatically stop pulling data.
- `--config`: the changefeed configuration file. See TiCDC changefeed configuration parameters.

7.3.2.3.2 Use Sink URI and changefeed config to configure Pulsar

You can use Sink URI to specify the connection information for the TiCDC target system, and use changefeed config to configure parameters related to Pulsar.

Sink URI

A Sink URI follows the following format:

```
[scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
```

Configuration example 1:

```
--sink-uri="pulsar://127.0.0.1:6650/persistent://abc/def/yktest?protocol=
   ↪ canal-json"
```

Configuration example 2:

```
--sink-uri="pulsar://127.0.0.1:6650/yktest?protocol=canal-json"
```

The configurable parameters in a URI are as follows:

Parameter	Description
`pulsar`	The scheme for the downstream Pulsar. The value can be `pulsar`, `pulsar+ssl`, `pulsar+http`, or `pulsar+https`, in which `pulsar+http` and `pulsar+https` are supported starting from v8.2.0.
`127.0.0.1`	The IP address by which the downstream Pulsar provides service.
`6650`	The connection port for the downstream Pulsar.
`persistent://abc/ ↪ def/yktest`	As shown in the preceding configuration example 1, this parameter is used to specify the tenant, namespace, and topic of Pulsar.
`yktest`	As shown in the preceding configuration example 2, if the topic you want to specify is in the default namespace `default` of the default tenant `public` in Pulsar, you can configure the URI with just the topic name, for example, `yktest`. This is equivalent to specifying the topic as `persistent://public/default/yktest`.

Changefeed config parameters

The following are examples of changefeed config parameters:

```
[sink]
#### `dispatchers` is used to specify matching rules.
#### Note: When the downstream MQ is Pulsar, if the routing rule for `
   ↪ partition` is not specified as any of `ts`, `index-value`, `table`,
   ↪ or `default`, each Pulsar message will be routed using the string you
   ↪  set as the key.
#### For example, if you specify the routing rule for a matcher as the
   ↪ string `code`, then all Pulsar messages that match that matcher will
   ↪ be routed with `code` as the key.
#### dispatchers = [
####   {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1",
   ↪ partition = "ts" },
####   {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2",
   ↪ partition = "index-value" },
```

```
####   {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3",
   ↪ partition = "table"},
####   {matcher = ['test6.*'], partition = "default"},
####   {matcher = ['test7.*'], partition = "test123"}
#### ]

#### `protocol` is used to specify the protocol format for encoding messages
   ↪ .
#### When the downstream is Pulsar, the protocol can only be canal-json.
#### protocol = "canal-json"

#### The following parameters only take effect when the downstream is Pulsar
   ↪ .
[sink.pulsar-config]
#### Authentication on the Pulsar server is done using a token. Specify the
   ↪ value of the token.
authentication-token = "xxxxxxxxxxxxx"
#### When you use a token for Pulsar server authentication, specify the path
   ↪  to the file where the token is located.
token-from-file="/data/pulsar/token-file.txt"
#### Pulsar uses the basic account and password to authenticate the identity
   ↪ . Specify the account.
basic-user-name="root"
#### Pulsar uses the basic account and password to authenticate the identity
   ↪ . Specify the password.
basic-password="password"
#### The certificate path on the client, which is required when Pulsar
   ↪ enables the mTLS authentication.
auth-tls-certificate-path="/data/pulsar/certificate"
#### The private key path on the client, which is required when Pulsar
   ↪ enables the mTLS authentication.
auth-tls-private-key-path="/data/pulsar/certificate.key"
#### The path to the trusted certificate file of the Pulsar TLS
   ↪ authentication, which is required when Pulsar enables the mTLS
   ↪ authentication or TLS encrypted transmission.
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
#### The path to the encrypted private key on the client, which is required
   ↪ when Pulsar enables TLS encrypted transmission.
tls-key-file-path="/data/pulsar/tls-key-file"
#### The path to the encrypted certificate file on the client, which is
   ↪ required when Pulsar enables TLS encrypted transmission.
tls-certificate-file="/data/pulsar/tls-certificate-file"
#### Pulsar oauth2 issuer-url. For more information, see the Pulsar website:
   ↪  https://pulsar.apache.org/docs/2.10.x/client-libraries-go/#tls-
   ↪ encryption-and-authentication
```

```
oauth2.oauth2-issuer-url="https://xxxx.auth0.com"
#### Pulsar oauth2 audience
oauth2.oauth2-audience="https://xxxx.auth0.com/api/v2/"
#### Pulsar oauth2 private-key
oauth2.oauth2-private-key="/data/pulsar/privateKey"
#### Pulsar oauth2 client-id
oauth2.oauth2-client-id="0Xx...Yyxeny"
#### Pulsar oauth2 oauth2-scope
oauth2.oauth2-scope="xxxx"
#### The number of cached Pulsar producers in TiCDC. The value is 10240 by
    ↪ default. Each Pulsar producer corresponds to one topic. If the number
    ↪  of topics you need to replicate is larger than the default value,
    ↪ you need to increase the number.
pulsar-producer-cache-size=10240
#### Pulsar data compression method. No compression is used by default.
    ↪ Optional values are "lz4", "zlib", and "zstd".
compression-type=""
#### The timeout for the Pulsar client to establish a TCP connection with
    ↪ the server. The value is 5 seconds by default.
connection-timeout=5
#### The timeout for Pulsar clients to initiate operations such as creating
    ↪ and subscribing to a topic. The value is 30 seconds by default.
operation-timeout=30
#### The maximum number of messages in a single batch for a Pulsar producer
    ↪ to send. The value is 1000 by default.
batching-max-messages=1000
#### The interval at which Pulsar producer messages are saved for batching.
    ↪ The value is 10 milliseconds by default.
batching-max-publish-delay=10
#### The timeout for a Pulsar producer to send a message. The value is 30
    ↪ seconds by default.
send-timeout=30
```

Best practice

- You need to specify the `protocol` parameter when creating a changefeed. Currently, only the `canal-json` protocol is supported for replicating data to Pulsar.
- The `pulsar-producer-cache-size` parameter indicates the number of producers cached in the Pulsar client. Because each producer in Pulsar can only correspond to one topic, TiCDC adopts the LRU method to cache producers, and the default limit is 10240. If the number of topics you need to replicate is larger than the default value, you need to increase the number.

TLS encrypted transmission

Starting from v7.5.1 and v8.0.0, TiCDC supports TLS encrypted transmission for Pulsar. The configuration example is as follows:

Sink URI:

```
--sink-uri="pulsar+ssl://127.0.0.1:6651/persistent://public/default/yktest?
    ↪ protocol=canal-json"
```

Configuration:

```
[sink.pulsar-config]
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
```

If the `tlsRequireTrustedClientCertOnConnect=true` parameter is configured for your Pulsar server, you also need to configure the `tls-key-file-path` and `tls-certificate-file` parameters in the changefeed configuration file. For example:

```
[sink.pulsar-config]
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
tls-certificate-file="/data/pulsar/tls-certificate-file"
tls-key-file-path="/data/pulsar/tls-key-file"
```

TiCDC authentication and authorization for Pulsar

The following is a sample configuration when you use token authentication with Pulsar:

- Token

  Sink URI:

  ```
  --sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
      ↪ protocol=canal-json"
  ```

  Config parameter:

  ```
  [sink.pulsar-config]
  authentication-token = "xxxxxxxxxxxxx"
  ```

- Token from file

  Sink URI:

  ```
  --sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
      ↪ protocol=canal-json"
  ```

  Config parameter:

  ```
  [sink.pulsar-config]
  # Pulsar uses tokens for authentication on the Pulsar server. Specify
      ↪ the path to the token file, which will be read from the TiCDC
      ↪ server.
  token-from-file="/data/pulsar/token-file.txt"
  ```

- mTLS authentication

  Sink URI:

```
--sink-uri="pulsar+ssl://127.0.0.1:6651/persistent://public/default/
    ↪ yktest?protocol=canal-json"
```

  Config parameters:

```
[sink.pulsar-config]
# Certificate path of the Pulsar mTLS authentication
auth-tls-certificate-path="/data/pulsar/certificate"
# Private key path of the Pulsar mTLS authentication
auth-tls-private-key-path="/data/pulsar/certificate.key"
# Path to the trusted certificate file of the Pulsar mTLS
    ↪ authentication
tls-trust-certs-file-path="/data/pulsar/tls-trust-certs-file"
```

- OAuth2 authentication

  Starting from v7.5.1 and v8.0.0, TiCDC supports the OAuth2 authentication for Pulsar.

  Sink URI:

```
--sink-uri="pulsar://127.0.0.1:6650/persistent://public/default/yktest?
    ↪ protocol=canal-json"
```

  Config parameters:

```
[sink.pulsar-config]
# Pulsar oauth2 issuer-url. For more information, see the Pulsar
    ↪ website: https://pulsar.apache.org/docs/2.10.x/client-libraries-
    ↪ go/#oauth2-authentication
oauth2.oauth2-issuer-url="https://xxxx.auth0.com"
# Pulsar oauth2 audience
oauth2.oauth2-audience="https://xxxx.auth0.com/api/v2/"
# Pulsar oauth2 private-key
oauth2.oauth2-private-key="/data/pulsar/privateKey"
# Pulsar oauth2 client-id
oauth2.oauth2-client-id="0Xx...Yyxeny"
# Pulsar oauth2 oauth2-scope
oauth2.oauth2-scope="xxxx"
```

7.3.2.3.3 Customize the dispatching rules for topics and partitions in Pulsar Sink

Matching rules for Matcher

Take the `dispatchers` configuration item in the following sample configuration file as an example:

```
[sink]
dispatchers = [
  {matcher = ['test1.*', 'test2.*'], topic = "Topic expression 1", partition
     ↪  = "ts" },
  {matcher = ['test3.*', 'test4.*'], topic = "Topic expression 2", partition
     ↪  = "index-value" },
  {matcher = ['test1.*', 'test5.*'], topic = "Topic expression 3", partition
     ↪  = "table"},
  {matcher = ['test6.*'], partition = "default"},
  {matcher = ['test7.*'], partition = "test123"}
]
```

- The tables that match a matcher rule are dispatched according to the policy specified by the corresponding topic expression. For example, the table `test3.aa` is dispatched according to `Topic expression 2`, and the table `test5.aa` is dispatched according to `Topic expression 3`.
- For a table that matches more than one matcher rule, it is dispatched according to the first matching topic expression. For example, the table `test1.aa` is dispatched according to `Topic expression 1`.
- For tables that do not match any matcher, the corresponding data change events are sent to the default topic specified in `-sink-uri`. For example, the table `test10.aa` is sent to the default topic.
- For tables that match the matcher rule but do not have a topic dispatcher specified, the corresponding data changes are sent to the default topic specified in `-sink-uri`. For example, the table `test6.abc` is sent to the default topic.

Topic dispatcher

You can use `topic = "xxx"` to specify a topic dispatcher and use topic expressions to implement flexible topic dispatching policies. It is recommended that the total number of topics be less than 1000.

The format of a topic expression is `[tenant_and_namespace][prefix]{schema}[middle][{table}][suffix]`. The following are the meanings of each part:

- `tenant_and_namespace`: Optional. Represents the tenant and namespace of the topic, such as `persistent://abc/def/`. If not configured, it means that the topic is in the default namespace `default` under the default tenant `public` of Pulsar.
- `prefix`: Optional. Represents the prefix of the topic name.
- `{schema}`: Optional. Represents the database name.
- `middle`: Optional. Represents the separator between a database name and a table name.

- `{table}`: Optional. Represents the table name.
- `suffix`: Optional. Represents the suffix of the topic name.

`prefix`, `middle`, and `suffix` only support uppercase and lowercase letters (`a-z`, `A-Z`), numbers (`0-9`), dots (`.`), underscores (`_`), and hyphens (`-`). `{schema}` and `{table}` must be lowercase. Placeholders such as `{Schema}` and `{TABLE}` that contain uppercase letters are invalid.

The following are some examples:

- `matcher = ['test1.table1', 'test2.table2'], topic = "hello_{schema}_{table}"`
  - Data change events corresponding to the table `test1.table1` are despatched to a topic named `hello_test1_table1`.
  - Data change events corresponding to the table `test2.table2` are despatched to a topic named `hello_test2_table2`.
- `matcher = ['test3.*', 'test4.*'], topic = "hello_{schema}_world"`
  - Data change events for all tables under `test3` are despatched to a topic named `hello_test3_world`.
  - Data change events for all tables under `test4` are despatched to a topic named `hello_test4_world`.
- `matcher = ['*.*'], topic = "{schema}_{table}"`
  - For all tables that TiCDC listens on, they are despatched to separate topics according to the `databaseName_tableName` rule. For example, for the table `test.account`, TiCDC despatches its data change log to a topic named `test_account`.

Dispatch DDL events

Database-level DDL events

DDL statements such as `CREATE DATABASE` and `DROP DATABASE` that are not related to a specific table are called database-level DDL statements. Events corresponding to database-level DDL statements are dispatched to the default topic specified in `--sink-uri`.

Table-level DDL events

DDL statements such as `ALTER TABLE` and `CREATE TABLE` that are related to a specific table are called table-level DDL statements. Events corresponding to table-level DDL statements are dispatched to an appropriate topic according to the configuration of `dispatchers`.

For example, for a `dispatchers` configuration like `matcher = ['test.*'], topic = {schema}_{table}`, the DDL events are despatched as follows:

- If a DDL event only involves a single table, the DDL event is dispatched to the appropriate topic as it is. For example, for the DDL event `DROP TABLE test.table1`, the event is dispatched to the topic named `test_table1`.
- If a DDL event involves more than one table (`RENAME TABLE`, `DROP TABLE`, and `DROP VIEW` might all involve more than one table), the single DDL event is split into multiple ones and dispatched to appropriate topics. For example, for the DDL event `RENAME TABLE test.table1 TO test.table10, test.table2 TO test.table20`, the processing is as follows:
    - Dispatch the DDL event for `RENAME TABLE test.table1 TO test.table10` to a topic named `test_table1`.
    - Dispatch the DDL event for `RENAME TABLE test.table2 TO test.table20` to a topic named `test_table2`.

Partition dispatcher

Currently, TiCDC only supports consumers to consume messages using the exclusive subscription model, that is, each consumer can consume messages from all partitions in a topic.

You can specify a partition dispatcher with `partition = "xxx"`. The following partition dispatches are supported: `default`, `ts`, `index-value`, and `table`. If you fill in any other string, TiCDC will pass that string as the `key` of the message in the messages sent to the Pulsar server.

The dispatching rules are as follows:

- `default`: By default, events are dispatched by the schema name and table name, which is the same as when `table` is specified.
- `ts`: Use commitTs of row changes to perform hash calculation and dispatch events.
- `index-value`: Use the value of the table primary key or unique index to perform hash calculation and dispatch events.
- `table`: Use the schema name and table name to perform hash calculation and dispatch events.
- Other self-defined string: The self-defined string is used directly as the key for the Pulsar message, and the Pulsar producer uses this key value for dispatching.

7.3.2.4 Replicate Data to Storage Services

Starting from TiDB v6.5.0, TiCDC supports saving row change events to storage services, including Amazon S3, GCS, Azure Blob Storage, and NFS. This document describes how to create a changefeed that replicates incremental data to such storage services using TiCDC, and how data is stored. The organization of this document is as follows:

- How to replicate data to storage services.
- How data is stored in storage services.

7.3.2.4.1 Replicate change data to storage services

Run the following command to create a changefeed task:

```
cdc cli changefeed create \
    --server=http://10.0.10.25:8300 \
    --sink-uri="s3://logbucket/storage_test?protocol=canal-json" \
    --changefeed-id="simple-replication-task"
```

The output is as follows:

```
Info: {"upstream_id":7171388873935111376,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"s3://logbucket/storage_test?protocol=
    ↪ canal-json","create_time":"2025-01-17T18:52:05.566016967+08:00","
    ↪ start_ts":437706850431664129,"engine":"unified","config":{"case_
    ↪ sensitive":false,"enable_old_value":true,"force_replicate":false,"
    ↪ ignore_ineligible_table":false,"check_gc_safe_point":true,"enable_
    ↪ sync_point":false,"sync_point_interval":600000000000,"sync_point_
    ↪ retention":86400000000000,"filter":{"rules":["*.*"],"event_filters":
    ↪ null},"mounter":{"worker_num":16},"sink":{"protocol":"canal-json","
    ↪ schema_registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N
    ↪ ","include_commit_ts":false},"column_selectors":null,"transaction_
    ↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"none","enable_partition_separator":false},"consistent":{"
    ↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
    ↪ ":""}},"state":"normal","creator_version":"v8.5.1"}
```

- `--server`: The address of any TiCDC server in the TiCDC cluster.
- `--changefeed-id`: The ID of the changefeed. The format must match the `^[a-zA-Z0 ↪ -9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the changefeed. For details, see Configure sink URI.
- `--start-ts`: The starting TSO of the changefeed. TiCDC starts pulling data from this TSO. The default value is the current time.
- `--target-ts`: The ending TSO of the changefeed. TiCDC stops pulling data until this TSO. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: The configuration file of the changefeed. For details, see TiCDC changefeed configuration parameters.

7.3.2.4.2 Configure sink URI

This section describes how to configure Sink URI for storage services, including Amazon S3, GCS, Azure Blob Storage, and NFS. Sink URI is used to specify the connection information of the TiCDC target system. The format is as follows:

```
[scheme]://[host]/[path]?[query_parameters]
```

For `[query_parameters]` in the URI, the following parameters can be configured:

Parameter	Description	Default value	Value range
`worker-count`	Concurrency for saving data changes to cloud storage in the downstream.	`16`	`[1, 512]`
`flush-interval`	Interval for saving data changes to cloud storage in the downstream.	`5s`	`[2s, 10m]`
`file-size`	A data change file is stored to cloud storage if the number of bytes exceeds the value of this parameter.	`67108864`	`[1048576, 536870912]`
`protocol`	The protocol format of the messages sent to the downstream.	N/A	`canal-json` and `csv`

Parameter	Description	Default value	Value range
`enable-tidb-extension`	When `protocol` is set to `canal-json` and `enable-tidb-extension` is set to `true`, TiCDC sends WATERMARK events and adds the TiDB extension field to Canal-JSON messages.	`false`	`false` and `true`

> **Note:**
>
> Data change files are saved to the downstream when either `flush-interval` or `file-size` meets the requirements. The `protocol` parameter is mandatory. If TiCDC does not receive this parameter when creating a changefeed, the `CDC:ErrSinkUnknownProtocol` error is returned.

Configure sink URI for external storage

When storing data in a cloud storage system, you need to set different authentication parameters depending on the cloud service provider. This section describes the authentication methods when using Amazon S3, Google Cloud Storage (GCS), and Azure Blob Storage, and how to configure accounts to access the corresponding storage services.

The following is an example configuration for Amazon S3:

```
--sink-uri="s3://bucket/prefix?protocol=canal-json"
```

Before replicating data, you need to set appropriate access permissions for the directory in Amazon S3:

- Minimum permissions required by TiCDC: `s3:ListBucket`, `s3:PutObject`, and `s3:GetObject`.
- If the changefeed configuration item `sink.cloud-storage-config.flush-concurrency` is greater than 1, which means parallel uploading of single files is enabled, you need to additionally add permissions related to ListParts:
    - `s3:AbortMultipartUpload`
    - `s3:ListMultipartUploadParts`
    - `s3:ListBucketMultipartUploads`

If you have not created a replication data storage directory, refer to Create a bucket to create an S3 bucket in the specified region. If necessary, you can also create a folder in the bucket by referring to Organize objects in the Amazon S3 console by using folders.

You can configure an account to access Amazon S3 in the following ways:

- Method 1: Specify the access key

  If you specify an access key and a secret access key, authentication is performed according to them. In addition to specifying the key in the URI, the following methods are supported:

    - TiCDC reads the `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables.
    - TiCDC reads the `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables.
    - TiCDC reads the shared credentials file in the path specified by the `$AWS_SHARED_CREDENTIALS_FILE` environment variable.
    - TiCDC reads the shared credentials file in the `~/.aws/credentials` path.

- Method 2: Access based on an IAM role

  Associate an IAM role with configured permissions to access Amazon S3 to the EC2 instance running the TiCDC server. After successful setup, TiCDC can directly access the corresponding directories in Amazon S3 without additional settings.

The following is an example configuration for GCS:

```
--sink-uri="gcs://bucket/prefix?protocol=canal-json"
```

You can configure the account used to access GCS by specifying an access key. Authentication is performed according to the specified `credentials-file`. In addition to specifying the key in the URI, the following methods are supported:

- TiCDC reads the file in the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS` environment variable.
- TiCDC reads the file `~/.config/gcloud/application_default_credentials.json`.

- TiCDC obtains credentials from the metadata server when the cluster is running in GCE or GAE.

The following is an example configuration for Azure Blob Storage:

```
--sink-uri="azure://bucket/prefix?protocol=canal-json"
```

You can configure an account to access Azure Blob Storage in the following ways:

- Method 1: Specify a shared access signature

  If you configure `account-name` and `sas-token` in the URI, the storage account name and shared access signature token specified by this parameter are used. Because the shared access signature token has the `&` character, you need to encode it as `%26` before adding it to the URI. You can also directly encode the entire `sas-token` using percent-encoding.

- Method 2: Specify the access key

  If you configure `account-name` and `account-key` in the URI, the storage account name and key specified by this parameter are used. In addition to specifying the key file in the URI, TiCDC can also read the key from the environment variable `$AZURE_STORAGE_KEY`.

- Method 3: Use Azure AD to restore the backup

  Configure the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET`.

> **Tip:**
>
> For more information about the URI parameters of Amazon S3, GCS, and Azure Blob Storage in TiCDC, see URI Formats of External Storage Services.

Configure sink URI for NFS

The following is an example configuration for NFS:

```
--sink-uri="file:///my-directory/prefix?protocol=canal-json"
```

7.3.2.4.3 Storage path structure

This section describes the storage path structure of data change records, metadata, and DDL events.

Data change records

Data change records are saved to the following path:

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/{partition-
    ↪ separator}/{date-separator}/CDC{num}.{extension}
```

- `scheme`: specifies the storage type, for example, `s3`, `gcs`, `azure`, or `file`.
- `prefix`: specifies the user-defined parent directory, for example, s3://**bucket/bbb/ccc**.
- `schema`: specifies the schema name, for example, s3://bucket/bbb/ccc/**test**.
- `table`: specifies the table name, for example, s3://bucket/bbb/ccc/test/**table1**.
- `table-version-separator`: specifies the separator that separates the path by the table version, for example, s3://bucket/bbb/ccc/test/table1/**9999**.
- `partition-separator`: specifies the separator that separates the path by the table partition, for example, s3://bucket/bbb/ccc/test/table1/9999/**20**.
- `date-separator`: classifies the files by the transaction commit date. The default value is `day`. Value options are:
    - `none`: no `date-separator`. For example, all files with `test.table1` version being `9999` are saved to `s3://bucket/bbb/ccc/test/table1/9999`.
    - `year`: the separator is the year of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022**.
    - `month`: the separator is the year and month of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022-01**.
    - `day`: the separator is the year, month, and day of the transaction commit date, for example, s3://bucket/bbb/ccc/test/table1/9999/**2022-01-02**.
- `num`: saves the serial number of the file that records the data change, for example, s3://bucket/bbb/ccc/test/table1/9999/2022-01-02/CDC**000005**.csv.
- `extension`: specifies the extension of the file. TiDB v6.5.0 supports the CSV and Canal-JSON formats.

> **Note:**
>
> The table version changes in the following scenarios:
>
> - The upstream TiDB performs a DDL operation on the table.
> - TiCDC schedules the table across nodes.
> - The changefeed to which the table belongs restarts.
>
> Note that the change of the table version does not mean the change of the table schema. For example, adding a comment to a column does not cause the schema file content to change.

Index files

An index file is used to prevent written data from being overwritten by mistake. It is stored in the same path as the data change records.

```
{scheme}://{prefix}/{schema}/{table}/{table-version-separator}/{partition-
    ↪ separator}/{date-separator}/meta/CDC.index
```

The index file records the largest file name used in the current directory. For example:

```
CDC000005.csv
```

In this example, the files `CDC000001.csv` through `CDC000004.csv` in this directory are occupied. When a table scheduling or node restart occurs in the TiCDC cluster, the new node reads the index file and determines if `CDC000005.csv` is occupied. If it is not occupied, the new node writes the file starting from `CDC000005.csv`. If it is occupied, it starts writing from `CDC000006.csv`, which prevents overwriting data written by other nodes.

Metadata

Metadata is saved in the following path:

```
{protocol}://{prefix}/metadata
```

Metadata is a JSON-formatted file, for example:

```
{
    "checkpoint-ts":433305438660591626
}
```

- `checkpoint-ts`: Transactions with `commit-ts` smaller than `checkpoint-ts` are written to the target storage in the downstream.

DDL events

DDL events at the table level

When a DDL event of an upstream table causes a table version change, TiCDC automatically does the following:

- Switches to a new path to write data change records. For example, when the version of `test.table1` changes to `441349361156227074`, TiCDC changes to the `s3://bucket/bbb/ccc/test/table1/441349361156227074/2022-01-02/` path to write data change records.
- Generates a schema file in the following path to store the table schema information:

```
{scheme}://{prefix}/{schema}/{table}/meta/schema_{table-version}_{hash
    ↪ }.json
```

Taking the `schema_441349361156227074_3131721815.json` schema file as an example, the table schema information in this file is as follows:

```
{
    "Table":"table1",
    "Schema":"test",
    "Version":1,
    "TableVersion":441349361156227074,
    "Query":"ALTER TABLE test.table1 ADD OfficeLocation blob(20)",
    "Type":5,
    "TableColumns":[
        {
            "ColumnName":"Id",
            "ColumnType":"INT",
            "ColumnNullable":"false",
            "ColumnIsPk":"true"
        },
        {
            "ColumnName":"LastName",
            "ColumnType":"CHAR",
            "ColumnLength":"20"
        },
        {
            "ColumnName":"FirstName",
            "ColumnType":"VARCHAR",
            "ColumnLength":"30"
        },
        {
            "ColumnName":"HireDate",
            "ColumnType":"DATETIME"
        },
        {
            "ColumnName":"OfficeLocation",
            "ColumnType":"BLOB",
            "ColumnLength":"20"
        }
    ],
    "TableColumnsTotal":"5"
}
```

- `Table`: Table name.
- `Schema`: Schema name.
- `Version`: Protocol version of the storage sink.
- `TableVersion`: Table version.
- `Query`: DDL statement.

- `Type`: DDL type.
- `TableColumns`: An array of one or more maps, each of which describes a column in the source table.
    - `ColumnName`: Column name.
    - `ColumnType`: Column type. For details, see Data type.
    - `ColumnLength`: Column length. For details, see Data type.
    - `ColumnPrecision`: Column precision. For details, see Data type.
    - `ColumnScale`: The number of digits following the decimal point (the scale). For details, see Data type.
    - `ColumnNullable`: The column can be NULL when the value of this option is `true`.
    - `ColumnIsPk`: The column is part of the primary key when the value of this option is `true`.
- `TableColumnsTotal`: The size of the `TableColumns` array.

DDL events at the database level

When a database-level DDL event is performed in the upstream database, TiCDC automatically generates a schema file in the following path to store the database schema information:

```
{scheme}://{prefix}/{schema}/meta/schema_{table-version}_{hash}.json
```

Taking the `schema_441349361156227000_3131721815.json` schema file as an example, the database schema information in this file is as follows:

```
{
  "Table": "",
  "Schema": "schema1",
  "Version": 1,
  "TableVersion": 441349361156227000,
  "Query": "CREATE DATABASE `schema1`",
  "Type": 1,
  "TableColumns": null,
  "TableColumnsTotal": 0
}
```

Data type

This section describes the data types used in the `schema_{table-version}_{hash}.json` file (hereafter referred to as "schema file" in the following sections). The data types are defined as `T(M[, D])`. For details, see Data Types.

Integer types

Integer types in TiDB are defined as `IT[(M)] [UNSIGNED]`, where

- `IT` is the integer type, which can be `TINYINT`, `SMALLINT`, `MEDIUMINT`, `INT`, `BIGINT`, or `BIT`.
- `M` is the display width of the type.

Integer types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{IT} [UNSIGNED]",
    "ColumnPrecision":"{M}"
}
```

Decimal types

Decimal types in TiDB are defined as `DT[(M,D)][UNSIGNED]`, where

- `DT` is the floating-point type, which can be `FLOAT`, `DOUBLE`, `DECIMAL`, or `NUMERIC`.
- `M` is the precision of the data type, or the total number of digits.
- `D` is the number of digits following the decimal point.

Decimal types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{DT} [UNSIGNED]",
    "ColumnPrecision":"{M}",
    "ColumnScale":"{D}"
}
```

Date and time types

Date types in TiDB are defined as `DT`, where

- `DT` is the date type, which can be `DATE` or `YEAR`.

The date types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{DT}"
}
```

The time types in TiDB are defined as `TT[(M)]`, where

- `TT` is the time type, which can be `TIME`, `DATETIME`, or `TIMESTAMP`.
- `M` is the precision of seconds in the range from 0 to 6.

The time types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{TT}",
    "ColumnScale":"{M}"
}
```

String types

The string types in TiDB are defined as `ST[(M)]`, where

- `ST` is the string type, which can be `CHAR`, `VARCHAR`, `TEXT`, `BINARY`, `BLOB`, or `JSON`.
- `M` is the maximum length of the string.

The string types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{ST}",
    "ColumnLength":"{M}"
}
```

Enum and Set types

The Enum and Set types are defined as follows in the schema file:

```
{
    "ColumnName":"COL1",
    "ColumnType":"{ENUM/SET}",
}
```

7.3.3 Manage Changefeeds

This document describes how to create and manage TiCDC changefeeds by using the TiCDC command-line tool `cdc cli`. You can also manage changefeeds via the HTTP interface of TiCDC. For details, see TiCDC OpenAPI.

7.3.3.1 Create a replication task

Run the following command to create a replication task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
    ↪ -zone=","create_time":"2025-01-17T15:05:46.679218+08:00","start_ts
    ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":
    ↪ false,"enable_old_value":true,"force_replicate":false,"ignore_
    ↪ ineligible_table":false,"check_gc_safe_point":true,"enable_sync_point
    ↪ ":true,"bdr_mode":false,"sync_point_interval":30000000000,"sync_point
    ↪ _retention":3600000000000,"filter":{"rules":["test.*"],"event_filters
    ↪ ":null},"mounter":{"worker_num":16},"sink":{"protocol":"","schema_
    ↪ registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N","
    ↪ include_commit_ts":false},"column_selectors":null,"transaction_
    ↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"none","enable_partition_separator":false},"consistent":{"
    ↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
    ↪ ":""}},"state":"normal","creator_version":"v8.5.1"}
```

7.3.3.2 Query the replication task list

Run the following command to query the replication task list:

```
cdc cli changefeed list --server=http://10.0.10.25:8300
```

```
[{
    "id": "simple-replication-task",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
}]
```

- `checkpoint` indicates that TiCDC has already replicated data before this time point to the downstream.
- `state` indicates the state of the replication task.
    - `normal`: The replication task runs normally.
    - `stopped`: The replication task is stopped (manually paused).
    - `error`: The replication task is stopped (by an error).
    - `removed`: The replication task is removed. Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

- `finished`: The replication task is finished (data is replicated to the `target-ts`). Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, run the `changefeed query` command.

7.3.3.3 Query a specific replication task

To query a specific replication task, run the `changefeed query` command. The query result includes the task information and the task state. You can specify the `--simple` or `-s` argument to simplify the query result that will only include the basic replication state and the checkpoint information. If you do not specify this argument, detailed task configuration, replication states, and replication table information are output.

```
cdc cli changefeed query -s --server=http://10.0.10.25:8300 --changefeed-id=
    ↪ simple-replication-task
```

```
{
 "state": "normal",
 "tso": 419035700154597378,
 "checkpoint": "2020-08-27 10:12:19.579",
 "error": null
}
```

In the preceding command and result:

- `state` is the replication state of the current changefeed. Each state must be consistent with the state in `changefeed list`.
- `tso` represents the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- `checkpoint` represents the corresponding time of the largest transaction TSO in the current changefeed that has been successfully replicated to the downstream.
- `error` records whether an error has occurred in the current changefeed.

```
cdc cli changefeed query --server=http://10.0.10.25:8300 --changefeed-id=
    ↪ simple-replication-task
```

```
{
  "info": {
    "sink-uri": "mysql://127.0.0.1:3306/?max-txn-row=20\u0026worker-count
        ↪ =4",
    "opts": {},
    "create-time": "2020-08-27T10:33:41.687983832+08:00",
    "start-ts": 419036036249681921,
    "target-ts": 0,
    "admin-job-type": 0,
```

```
  "sort-engine": "unified",
  "sort-dir": ".",
  "config": {
    "case-sensitive": false,
    "filter": {
      "rules": [
        "*.*"
      ],
      "ignore-txn-start-ts": null,
      "ddl-allow-list": null
    },
    "mounter": {
      "worker-num": 16
    },
    "sink": {
      "dispatchers": null,
    },
    "scheduler": {
      "type": "table-number",
      "polling-time": -1
    }
  },
  "state": "normal",
  "history": null,
  "error": null
},
"status": {
  "resolved-ts": 419036036249681921,
  "checkpoint-ts": 419036036249681921,
  "admin-job-type": 0
},
"count": 0,
"task-status": [
  {
    "capture-id": "97173367-75dc-490c-ae2d-4e990f90da0f",
    "status": {
      "tables": {
        "47": {
          "start-ts": 419036036249681921
        }
      },
      "operation": null,
      "admin-job-type": 0
    }
  }
```

```
  ]
}
```

In the preceding command and result:

- `info` is the replication configuration of the queried changefeed.
- `status` is the replication state of the queried changefeed.
    - `resolved-ts`: The largest transaction `TS` in the current changefeed. Note that this `TS` has been successfully sent from TiKV to TiCDC.
    - `checkpoint-ts`: The largest transaction `TS` in the current `changefeed`. Note that this `TS` has been successfully written to the downstream.
    - `admin-job-type`: The status of a changefeed:
        - `0`: The state is normal.
        - `1`: The task is paused. When the task is paused, all replicated `processors` exit. The configuration and the replication status of the task are retained, so you can resume the task from `checkpoint-ts`.
        - `2`: The task is resumed. The replication task resumes from `checkpoint-ts`.
        - `3`: The task is removed. When the task is removed, all replicated `processors` are ended, and the configuration information of the replication task is cleared up. Only the replication status is retained for later queries.
- `task-status` indicates the state of each replication sub-task in the queried changefeed.

7.3.3.4 Pause a replication task

Run the following command to pause a replication task:

```
cdc cli changefeed pause --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

In the preceding command:

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to pause.

7.3.3.5 Resume a replication task

Run the following command to resume a paused replication task:

```
cdc cli changefeed resume --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to resume.

- `--overwrite-checkpoint-ts`: starting from v6.2.0, you can specify the starting TSO of resuming the replication task. TiCDC starts pulling data from the specified TSO. The argument accepts `now` or a specific TSO (such as 434873584621453313). The specified TSO must be in the range of (GC safe point, CurrentTSO]. If this argument is not specified, TiCDC replicates data from the current `checkpoint-ts` by default. You can use the `cdc cli changefeed list` command to check the current value of `checkpoint-ts`.
- `--no-confirm`: when the replication is resumed, you do not need to confirm the related information. Defaults to `false`.

Note:

- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is larger than the current checkpoint TSO in the changefeed (`t1`), data between `t1` and `t2` will not be replicated to the downstream. This causes data loss. You can obtain `t1` by running `cdc cli changefeed query`.
- If the TSO specified in `--overwrite-checkpoint-ts` (`t2`) is smaller than the current checkpoint TSO in the changefeed (`t1`), TiCDC pulls data from an old time point (`t2`), which might cause data duplication (for example, if the downstream is MQ sink).

7.3.3.6 Remove a replication task

Run the following command to remove a replication task:

```
cdc cli changefeed remove --server=http://10.0.10.25:8300 --changefeed-id
    ↪ simple-replication-task
```

In the preceding command:

- `--changefeed-id=uuid` represents the ID of the changefeed that corresponds to the replication task you want to remove.

7.3.3.7 Update task configuration

TiCDC supports modifying the configuration of the replication task (not dynamically). To modify the changefeed configuration, pause the task, modify the configuration, and then resume the task.

```
cdc cli changefeed pause -c test-cf --server=http://10.0.10.25:8300
cdc cli changefeed update -c test-cf --server=http://10.0.10.25:8300 --sink-
    ↪ uri="mysql://127.0.0.1:3306/?max-txn-row=20&worker-count=8" --config=
    ↪ changefeed.toml
```

```
cdc cli changefeed resume -c test-cf --server=http://10.0.10.25:8300
```

Currently, you can modify the following configuration items:

- `sink-uri` of the changefeed.
- The changefeed configuration file and all configuration items in the file.
- The `target-ts` of the changefeed.

7.3.3.8 Manage processing units of replication sub-tasks (`processor`)

- Query the `processor` list:

```
cdc cli processor list --server=http://10.0.10.25:8300
```

```
[
        {
                "id": "9f84ff74-abf9-407f-a6e2-56aa35b33888",
                "capture-id": "b293999a-4168-4988-a4f4-35d9589b226b",
                "changefeed-id": "simple-replication-task"
        }
]
```

- Query a specific changefeed which corresponds to the status of a specific replication task:

```
cdc cli processor query --server=http://10.0.10.25:8300 --changefeed-id
    ↪ =simple-replication-task --capture-id=b293999a-4168-4988-a4f4-35
    ↪ d9589b226b
```

```
{
  "status": {
    "tables": {
      "56": {   # 56 ID of the replication table, corresponding to tidb_
          ↪ table_id of a table in TiDB
        "start-ts": 417474117955485702
      }
    },
    "operation": null,
    "admin-job-type": 0
  },
  "position": {
    "checkpoint-ts": 417474143881789441,
    "resolved-ts": 417474143881789441,
    "count": 0
  }
}
```

In the preceding command:

- `status.tables`: Each key number represents the ID of the replication table, corresponding to `tidb_table_id` of a table in TiDB.
- `resolved-ts`: The largest TSO among the sorted data in the current processor.
- `checkpoint-ts`: The largest TSO that has been successfully written to the downstream in the current processor.

7.3.3.9 Replicate tables with the new framework for collations enabled

Starting from v4.0.15, v5.0.4, v5.1.1 and v5.2.0, TiCDC supports tables that have enabled new framework for collations.

7.3.3.10 Replicate tables without a valid index

Since v4.0.8, TiCDC supports replicating tables that have no valid index by modifying the task configuration. To enable this feature, configure in the changefeed configuration file as follows:

```
force-replicate = true
```

Warning:

When `force-replicate` is set to `true`, data consistency is not guaranteed. For tables without a valid index, operations such as `INSERT` and `REPLACE` are not reentrant, so there is a risk of data redundancy. TiCDC guarantees that data is distributed only at least once during the replication process. Therefore, enabling this feature to replicate tables without a valid index will definitely cause data redundancy. If you do not accept data redundancy, it is recommended to add an effective index, such as adding a primary key column with the `AUTO RANDOM` attribute.

7.3.3.11 Unified Sorter

Note:

Starting from v6.0.0, TiCDC uses the DB Sorter engine by default, and no longer uses the Unified Sorter. It is recommended that you do not configure the `sort engine` item.

Unified sorter is the sorting engine in TiCDC. It can mitigate OOM problems caused by the following scenarios:

- The data replication task in TiCDC is paused for a long time, during which a large amount of incremental data is accumulated and needs to be replicated.
- The data replication task is started from an early timestamp so it becomes necessary to replicate a large amount of incremental data.

For the changefeeds created using `cdc cli` after v4.0.13, Unified Sorter is enabled by default; for the changefeeds that have existed before v4.0.13, the previous configuration is used.

To check whether or not the Unified Sorter feature is enabled on a changefeed, you can run the following example command (assuming the IP address of the PD instance is `http://10.0.10.25:2379`):

```
cdc cli --server="http://10.0.10.25:8300" changefeed query --changefeed-id=
    ↪ simple-replication-task | grep 'sort-engine'
```

In the output of the above command, if the value of `sort-engine` is "unified", it means that Unified Sorter is enabled on the changefeed.

Note:

- If your servers use mechanical hard drives or other storage devices that have high latency or limited bandwidth, the performance of Unified Sorter will be affected significantly.
- By default, Unified Sorter uses `data_dir` to store temporary files. It is recommended to ensure that the free disk space is greater than or equal to 500 GiB. For production environments, it is recommended to ensure that the free disk space on each node is greater than (the maximum `checkpoint-ts` delay allowed by the business) * (upstream write traffic at business peak hours). In addition, if you plan to replicate a large amount of historical data after `changefeed` is created, make sure that the free space on each node is greater than the amount of the replicated data.

7.3.4 Changefeed Log Filters

TiCDC supports filtering data by tables and events. This document introduces how to use the two types of filters.

7.3.4.1 Table filter

Table filter is a feature that allows you to keep or filter out specific databases and tables by specifying the following configurations:

```
[filter]
### Filter rules
rules = ['*.*', '!test.*']
```

Common filter rules:

- `rules = ['*.*']`
  - Replicate all tables (not including system tables)
- `rules = ['test1.*']`
  - Replicate all tables in the `test1` database
- `rules = ['*.*', '!scm1.tbl2']`
  - Replicate all tables except for the `scm1.tbl2` table
- `rules = ['scm1.tbl2', 'scm1.tbl3']`
  - Only replicate tables `scm1.tbl2` and `scm1.tbl3`
- `rules = ['scm1.tidb_*']`
  - Replicate all tables in the `scm1` database whose names start with `tidb_`

For more information, see Table filter syntax.

7.3.4.2 Event filter rules

Starting in v6.2.0, TiCDC supports event filter. You can configure event filter rules to filter out the DML and DDL events that meet the specified conditions.

The following is an example of event filter rules:

```
[filter]
### The event filter rules must be under the `[filter]` configuration. You
    ↪ can configure multiple event filters at the same time.

[[filter.event-filters]]
matcher = ["test.worker"] # matcher is an allow list, which means this rule
    ↪ only applies to the worker table in the test database.
ignore-event = ["insert"] # Ignore insert events.
ignore-sql = ["^drop", "add column"] # Ignore DDLs that start with "drop" or
    ↪  contain "add column".
```

```
ignore-delete-value-expr = "name = 'john'" # Ignore delete DMLs that contain
    ↪  the condition "name = 'john'".
ignore-insert-value-expr = "id >= 100" # Ignore insert DMLs that contain the
    ↪  condition "id >= 100".
ignore-update-old-value-expr = "age < 18 or name = 'lili'" # Ignore update
    ↪ DMLs whose old value contains "age < 18" or "name = 'lili'".
ignore-update-new-value-expr = "gender = 'male' and age > 18" # Ignore
    ↪ update DMLs whose new value contains "gender = 'male'" and "age >
    ↪ 18".
```

Description of configuration parameters:

- `matcher`: the database and table that this event filter rule applies to. The syntax is the same as table filter.
- `ignore-event`: the event type to be ignored. This parameter accepts an array of strings. You can configure multiple event types. Currently, the following event types are supported:

Event	Type	Alias	Description
all dml			Matches all DML events
all ddl			Matches all DDL events
insert	DML		Matches `insert` DML event
update	DML		Matches `update` DML event
delete	DML		Matches `delete` DML event
create schema	DDL	create database	Matches `create database` event
drop schema	DDL	drop database	Matches `drop database` event
create table	DDL		Matches `create table` event
drop table	DDL		Matches `drop table` event
rename table	DDL		Matches `rename table` event
truncate table	DDL		Matches `truncate table` event
alter table	DDL		Matches `alter table` event, including all clauses of `alter table`, `create index` and `drop index`

Event	Type	Alias	Description
add table partition	DDL		Matches `add table partition` event
drop table partition	DDL		Matches `drop table partition` event
truncate table partition	DDL		Matches `truncate table partition` event
create view	DDL		Matches `create view`event
drop view	DDL		Matches `drop view` event
modify schema charset and collate	DDL		Matches `modify schema charset and collate` event
recover table	DDL		Matches `recover table` event
rebase auto id	DDL		Matches `rebase auto id` event
modify table comment	DDL		Matches `modify table comment` event
modify table charset and collate	DDL		Matches `modify table charset and collate` event
exchange table partition	DDL		Matches `exchange table partition` event
reorganize table partition	DDL		Matches `reorganize table partition` event
alter table partitioning	DDL		Matches `alter table partitioning` event
remove table partitioning	DDL		Matches `remove table partitioning` event
add column	DDL		Matches `add column` event
drop column	DDL		Matches `drop column` event
modify column	DDL		Matches `modify column` event

Event	Type	Alias	Description
set default value	DDL		Matches `set default value` event
add primary key	DDL		Matches `add primary key` event
drop primary key	DDL		Matches `drop primary key` event
rename index	DDL		Matches `rename index` event
alter index visibility	DDL		Matches `alter index visibility` event
alter ttl info	DDL		Matches `alter ttl info` event
alter ttl remove	DDL		Matches DDL events that remove all TTL attributes of a table
multi schema change	DDL		Matches DDL events that change multiple attributes of a table within the same DDL statement

> **Note:**
>
> TiDB's DDL statements support changing multiple attributes of a single table at the same time, such as `ALTER TABLE t MODIFY COLUMN a INT ↪ , ADD COLUMN b INT, DROP COLUMN c;`. This operation is defined as MultiSchemaChange. If you want to filter out this type of DDL, you need to configure `"multi schema change"` in `ignore-event`.

- `ignore-sql`: the regular expressions of the DDL statements to be filtered out. This parameter accepts an array of strings, in which you can configure multiple regular expressions. This configuration only applies to DDL events.
- `ignore-delete-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `DELETE` type of DML events with a specified value.
- `ignore-insert-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `INSERT` type of DML events with a specified value.
- `ignore-update-old-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `UPDATE` type of DML events with a specified old value.

- `ignore-update-new-value-expr`: this parameter accepts a SQL expression that follows the default SQL mode, used to filter out the `UPDATE` DML events with a specified new value.

Note:

- When TiDB updates a value in the column of the clustered index, TiDB splits an `UPDATE` event into a `DELETE` event and an `INSERT` event. TiCDC does not identify such events as an `UPDATE` event and thus cannot correctly filter out such events.
- When you configure a SQL expression, make sure all tables that matches `matcher` contain all the columns specified in the SQL expression. Otherwise, the replication task cannot be created. In addition, if the table schema changes during the replication, which results in a table no longer containing a required column, the replication task fails and cannot be resumed automatically. In such a situation, you must manually modify the configuration and resume the task.

7.3.5 Changefeed DDL Replication

This document describes the rules and special cases of DDL replication in TiCDC.

7.3.5.1 DDL allow list

Currently, TiCDC uses an allow list to determine whether to replicate a DDL statement. Only the DDL statements in the allow list are replicated to the downstream. The DDL statements not in the allow list are not replicated.

In addition, TiCDC determines whether to replicate a DDL statement to the downstream based on whether the table has a valid index and whether the configuration item `force-replicate` is set to `true`. When `force-replicate=true`, the replication task attempts to forcibly replicate tables without a valid index.

The following is the allow list of DDL statements supported by TiCDC. The abbreviations in the table:

- Y: Replication to the downstream is supported in this condition.
- N: Replication to the downstream is not supported in this condition.

Note

- When the upstream table has no valid index and `force-replicate=true` is not configured, the table will not be replicated. However, subsequent DDL statements (including `CREATE INDEX`, `ADD INDEX`, and `ADD PRIMARY KEY`) that create a valid index on this table will be replicated, which might cause inconsistency between downstream and upstream table schemas and lead to subsequent data replication failure.
- DDL statements (including `DROP INDEX` and `DROP PRIMARY KEY`) that drop the last valid index will not be replicated, causing subsequent data replication to fail.

DDL	A valid index exists	A valid index does not exist and `force-replicate` is `false` (default)	A valid index does not exist and `force-replicate` is set to `true`
`CREATE DATABASE`	Y	Y	Y

7.3.5.2 DDL replication considerations

7.3.5.2.1 Asynchronous execution of `ADD INDEX` and `CREATE INDEX` DDLs

When the downstream is TiDB, TiCDC executes `ADD INDEX` and `CREATE INDEX` DDL operations asynchronously to minimize the impact on changefeed replication latency. This means that, after replicating `ADD INDEX` and `CREATE INDEX` DDLs to the downstream TiDB for execution, TiCDC returns immediately without waiting for the completion of the DDL execution. This avoids blocking subsequent DML executions.

During the execution of the `ADD INDEX` or `CREATE INDEX` DDL operation in the downstream, when TiCDC executes the next DDL operation of the same table, this DDL operation might be blocked in the `queueing` state for a long time. This can cause TiCDC to repeatedly execute this DDL operation, and if retries take too long, it might lead to replication task failure. Starting from v8.4.0, if TiCDC has the `SUPER` permission of the downstream database, it periodically runs `ADMIN SHOW DDL JOBS` to check the status of asynchronously executed DDL tasks. TiCDC will wait for index creation to complete before proceeding with replication. Although this might increase replication latency, it avoids replication task failure.

Note:

- If the execution of certain downstream DMLs relies on indexes that have not completed replication, these DMLs might be executed slowly, thereby affecting TiCDC replication latency.
- Before replicating DDLs to the downstream, if a TiCDC node crashes or if the downstream is performing other write operations, the DDL replication has an extremely low probability of failure. You can check the downstream to see whether that occurs.

7.3.5.2.2 DDL replication considerations for renaming tables

Due to the lack of some context during the replication process, TiCDC has some constraints on the replication of `RENAME TABLE` DDLs.

Rename a single table in a DDL statement

If a DDL statement renames a single table, TiCDC only replicates the DDL statement when the old table name matches the filter rule. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']
```

TiCDC processes this type of DDL as follows:

DDL	Whether to replicate	Reason for the handling
`RENAME TABLE test.t1 TO test.t2`	Replicate	`test.t1` matches the filter rule
`RENAME TABLE test.t1 TO ignore.t1`	Replicate	`test.t1` matches the filter rule

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `ignore` ↪ `.` ↪ `t2` ↪	Ignore	`ignore` ↪ `.` ↪ `t1` ↪ ↪ does not match the filter rule

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `n1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪	Report an error and exit the replication	The old table name `test` ↪ `.` ↪ `n1` ↪ ↪ does not match the filter rule, but the new table name `test` ↪ `.` ↪ `t1` ↪ ↪ matches the filter rule. This operation is illegal. In this case, refer to the

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪	Report an error and exit the replication	Same reason as above.

Rename multiple tables in a DDL statement

If a DDL statement renames multiple tables, TiCDC replicates the DDL statement only when the **old database name**, **old table names**, and **new database name** all match the filter rule.

In addition, TiCDC does not support the `RENAME TABLE` DDL that swaps the table names. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']
```

TiCDC processes this type of DDL as follows:

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t3` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t4` ↪	Replicate	All database names and table names match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore1` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t3` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore2` ↪	Replicate	The old database name, the old table names, and the new database name match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `ignore` ↪ `.` ↪ `t1` ↪ `,` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t22` ↪ `;` ↪	Report an error	The new database name `ignore` ↪ does not match the filter rule.

DDL	Whether to replicate	Reason for the handling
`RENAME TABLE test.t1 TO test.t4, test.t3 TO test.t1, test.t4 TO test.t3;`	Report an error	The `RENAME TABLE` DDL swaps the names of `test.t1` and `test.t3` in one DDL statement, which TiCDC cannot handle correctly. In this case, refer to the error message for han-

DDL	Whether to replicate	Reason for the handling

7.3.5.2.3 DDL statement considerations

When executing cross-database DDL statements (such as `CREATE TABLE db1.t1 LIKE t2`) in the upstream, it is recommended that you explicitly specify all relevant database names in DDL statements (such as `CREATE TABLE db1.t1 LIKE db2.t2`). Otherwise, cross-database DDL statements might not be executed correctly in the downstream due to the lack of database name information.

7.3.5.2.4 Notes on using event filter rules to filter DDL events

If a filtered DDL statement involves table creation or deletion, TiCDC only filters out the DDL statement without affecting the replication behavior of DML statements. The following is an example.

Assume that the configuration file of your changefeed is as follows:

```
[filter]
rules = ['test.t*']

[[filter.event-filters]]
matcher = ["test.t1"] # This filter rule applies only to the t1 table in the test database.
ignore-event = ["create table", "drop table", "truncate table", "rename table"]
```

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Ignore	Replicate	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `CREATE` ↪ ↪ `TABLE` ↪ ↪ event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Replicate	Replicate	`test` ↪ `.` ↪ `t2` ↪ ↪ does not match the event filter rule.

DDL	DDL behavior	DML behavior	Explanation
`CREATE` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `ignore` ↪ ↪ `(` ↪ `id` ↪ ↪ `INT` ↪ `,` ↪ ↪ `name` ↪ ↪ `VARCHAR` ↪ `(50)` ↪ `)` ↪ `;` ↪	Ignore	Ignore	`test` ↪ `.` ↪ `ignore` ↪ ↪ matches the event filter rule, so both DDL and DML events are ignored.

DDL	DDL behavior	DML behavior	Explanation
`DROP` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ `;` ↪	Ignore	-	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `DROP` ↪ ↪ `TABLE` ↪ ↪ event is ignored. Because the table is deleted, TiCDC no longer replicates DML events for `t1`.

DDL	DDL behavior	DML behavior	Explanation
`TRUNCATE TABLE test . t1 ;`	Ignore	Replicate	`test . t1` matches the event filter rule, so the `TRUNCATE TABLE` event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `t2` ↪ `;` ↪	Ignore	Replicate	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `RENAME` ↪ ↪ `TABLE` ↪ ↪ event is ignored. The replication of DML events remains unaffected.

DDL	DDL behavior	DML behavior	Explanation
`RENAME` ↪ ↪ `TABLE` ↪ ↪ `test` ↪ `.` ↪ `t1` ↪ ↪ `TO` ↪ ↪ `test` ↪ `.` ↪ `ignore` ↪ `;` ↪	Ignore	Ignore	`test` ↪ `.` ↪ `t1` ↪ ↪ matches the event filter rule, so the `RENAME` ↪ ↪ `TABLE` ↪ ↪ event is ignored. `test` ↪ `.` ↪ `ignore` ↪ ↪ matches the event filter rule, so both DDL and DML events are ignored.

Note:

- When replicating data to a database, use the event filter to filter DDL events with caution. Ensure that the upstream and downstream database schemas remain consistent during replication. Otherwise, TiCDC might report errors or cause undefined replication behavior.
- For versions earlier than v6.5.8, v7.1.4, and v7.5.1, using the event filter to filter DDL events involving table creation or deletion affects DML replication. It is not recommended to use this feature in these versions.

7.3.6 Bidirectional Replication

TiCDC supports bi-directional replication (BDR) among two TiDB clusters. Based on this feature, you can create a multi-active TiDB solution using TiCDC.

This section describes how to use bi-directional replication taking two TiDB clusters as an example.

7.3.6.1 Deploy bi-directional replication

TiCDC only replicates incremental data changes that occur after a specified timestamp to the downstream cluster. Before starting the bi-directional replication, you need to take the following steps:

1. (Optional) According to your needs, import the data of the two TiDB clusters into each other using the data export tool Dumpling and data import tool TiDB Lightning.
2. Deploy two TiCDC clusters between the two TiDB clusters. The cluster topology is as follows. The arrows in the diagram indicate the directions of data flow.

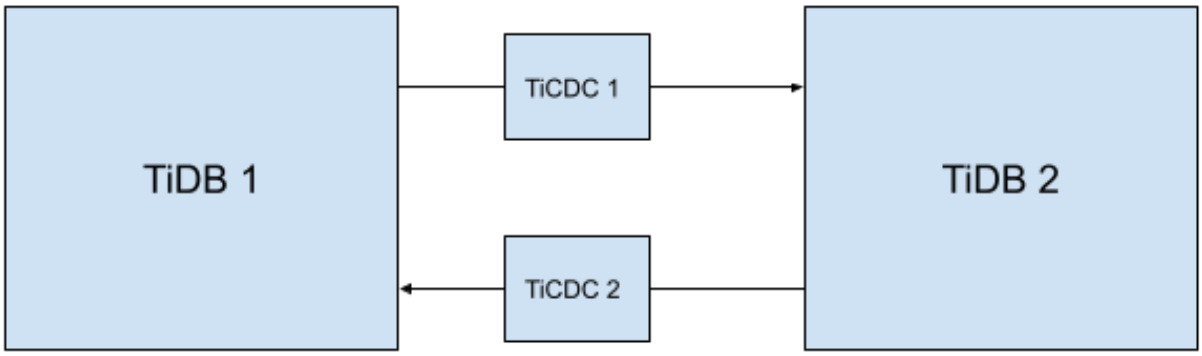

Figure 101: TiCDC bidirectional replication

3. Specify the starting time point of data replication for the upstream and downstream clusters.

    1. Check the time point of the upstream and downstream clusters. In the case of two TiDB clusters, make sure that data in the two clusters are consistent at certain time points. For example, the data of TiDB A at `ts=1` and the data of TiDB B at `ts=2` are consistent.
    2. When you create the changefeed, set the `--start-ts` of the changefeed for the upstream cluster to the corresponding `tso`. That is, if the upstream cluster is TiDB A, set `--start-ts=1`; if the upstream cluster is TiDB B, set `--start-ts =2`.

4. In the configuration file specified by the `--config` parameter, add the following configuration:

```
# Whether to enable the bi-directional replication mode
bdr-mode = true
```

After the configuration takes effect, the clusters can perform bi-directional replication.

7.3.6.2 DDL types

Starting from v7.6.0, to support DDL replication as much as possible in bi-directional replication, TiDB divides the DDLs that TiCDC originally supports into two types: replicable DDLs and non-replicable DDLs, according to the impact of DDLs on the business.

7.3.6.2.1 Replicable DDLs

Replicable DDLs are the DDLs that can be directly executed and replicated to other TiDB clusters in bi-directional replication.

Replicable DDLs include:

- CREATE DATABASE
- CREATE TABLE
- ADD COLUMN: the column can be null, or has not null and default value at the same time
- ADD NON-UNIQUE INDEX
- DROP INDEX
- MODIFY COLUMN: you can only modify the default value and comment of the column
- ALTER COLUMN DEFAULT VALUE
- MODIFY TABLE COMMENT
- RENAME INDEX
- ADD TABLE PARTITION
- DROP PRIMARY KEY
- ALTER TABLE INDEX VISIBILITY
- ALTER TABLE TTL
- ALTER TABLE REMOVE TTL
- CREATE VIEW
- DROP VIEW

7.3.6.2.2 Non-replicable DDLs

Non-replicable DDLs are the DDLs that have a great impact on the business, and might cause data inconsistency between clusters. Non-replicable DDLs cannot be directly replicated to other TiDB clusters in bi-directional replication through TiCDC. Non-replicable DDLs must be executed through specific operations.

Non-replicable DDLs include:

- DROP DATABASE
- DROP TABLE
- ADD COLUMN: the column is not null and does not have a default value
- DROP COLUMN
- ADD UNIQUE INDEX
- TRUNCATE TABLE
- MODIFY COLUMN: you can modify the attributes of the column except default value and comment
- RENAME TABLE
- DROP PARTITION
- TRUNCATE PARTITION
- ALTER TABLE CHARACTER SET
- ALTER DATABASE CHARACTER SET
- RECOVER TABLE
- ADD PRIMARY KEY
- REBASE AUTO ID
- EXCHANGE PARTITION
- REORGANIZE PARTITION

7.3.6.3 DDL replication

To solve the problem of replicable DDLs and non-replicable DDLs, TiDB introduces the following BDR roles:

- `PRIMARY`: You can execute replicable DDLs, but not non-replicable DDLs. Replicable DDLs executed in a PRIMARY cluster will be replicated to the downstream by TiCDC.
- `SECONDARY`: You cannot execute replicable DDLs or non-replicable DDLs. However, DDLs executed in a PRIMARY cluster can be replicated to a SECONDARY cluster by TiCDC.

When no BDR role is set, you can execute any DDL. However, the changefeed in BDR mode does not replicate any DDL on that cluster.

In short, in BDR mode, TiCDC only replicates replicable DDLs in the PRIMARY cluster to the downstream.

7.3.6.3.1 Replication scenarios of replicable DDLs

1. Choose a TiDB cluster and execute `ADMIN SET BDR ROLE PRIMARY` to set it as the primary cluster.

```
ADMIN SET BDR ROLE PRIMARY;
Query OK, 0 rows affected
Time: 0.003s

ADMIN SHOW BDR ROLE;
+----------+
| BDR_ROLE |
+----------+
| primary |
+----------+
```

2. On other TiDB clusters, execute `ADMIN SET BDR ROLE SECONDARY` to set them as the secondary clusters.
3. Execute **replicable DDLs** on the primary cluster. The successfully executed DDLs will be replicated to the secondary clusters by TiCDC.

> **Note:**
>
> To prevent misuse:

- If you try to execute **non-replicable DDLs** on the primary cluster, you will get the Error 8263.
- If you try to execute **replicable DDLs** or **non-replicable DDLs** on the secondary clusters, you will get the Error 8263.

7.3.6.3.2 Replication scenarios of non-replicable DDLs

1. Execute `ADMIN UNSET BDR ROLE` on all TiDB clusters to unset the BDR role.
2. Stop writing data to the tables that need to execute DDLs in all clusters.
3. Wait until all writes to the corresponding tables in all clusters are replicated to other clusters, and then manually execute all DDLs on each TiDB cluster.
4. Wait until the DDLs are completed, and then resume writing data.
5. Follow the steps in Replication scenarios of replicable DDLs to switch back to the replication scenario of replicable DDLs.

Warning:

After you execute `ADMIN UNSET BDR ROLE` on all TiDB clusters, none of the DDLs are replicated by TiCDC. You need to manually execute the DDLs on each cluster separately.

7.3.6.4 Stop bi-directional replication

After the application has stopped writing data, you can insert a special record into each cluster. By checking the two special records, you can make sure that data in two clusters are consistent.

After the check is completed, you can stop the changefeed to stop bi-directional replication, and execute `ADMIN UNSET BDR ROLE` on all TiDB clusters.

7.3.6.5 Limitations

- Use BDR role only in the following scenarios:
  - 1 `PRIMARY` cluster and n `SECONDARY` clusters (replication scenarios of replicable DDLs)
  - n clusters that have no BDR roles (replication scenarios in which you can manually execute non-replicable DDLs on each cluster)

> **Note:**
>
> Do not set the BDR role in other scenarios, for example, setting `PRIMARY` ↪ , `SECONDARY`, and no BDR roles at the same time. If you set the BDR role incorrectly, TiDB cannot guarantee data correctness and consistency during data replication.

- Usually do not use `AUTO_INCREMENT` or `AUTO_RANDOM` to avoid data conflicts in the replicated tables. If you need to use `AUTO_INCREMENT` or `AUTO_RANDOM`, you can set different `auto_increment_increment` and `auto_increment_offset` for different clusters to ensure that different clusters can be assigned different primary keys. For example, if there are three TiDB clusters (A, B, and C) in bi-directional replication, you can set them as follows:

    - In Cluster A, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2000`
    - In Cluster B, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2001`
    - In Cluster C, set `auto_increment_increment=3` and `auto_increment_offset` ↪ `=2002`

    This way, A, B, and C will not conflict with each other in the implicitly assigned `AUTO_` ↪ `INCREMENT` ID and `AUTO_RANDOM` ID. If you need to add a cluster in BDR mode, you need to temporarily stop writing data of the related application, set the appropriate values for `auto_increment_increment` and `auto_increment_offset` on all clusters, and then resume writing data of the related application.

- Bi-directional replication clusters cannot detect write conflicts, which might cause undefined behaviors. Therefore, you must ensure that there are no write conflicts from the application side.

- Bi-directional replication supports more than two clusters, but does not support multiple clusters in cascading mode, that is, a cyclic replication like TiDB A -> TiDB B -> TiDB C -> TiDB A. In such a topology, if one cluster fails, the whole data replication will be affected. Therefore, to enable bi-directional replication among multiple clusters, you need to connect each cluster with every other clusters, for example, `TiDB A <-> TiDB B`, `TiDB B <-> TiDB C`, `TiDB C <-> TiDB A`.

7.4 Monitor and Alert

7.4.1 TiCDC Monitoring Metrics Summary

Starting from v7.0.0, when you deploy Grafana using TiUP, the TiCDC Summary Dashboard is automatically added to the Grafana monitoring page. Through this dashboard, you can quickly understand the status of TiCDC servers and changefeeds.

The following image shows the monitoring panels of the TiCDC Summary Dashboard:

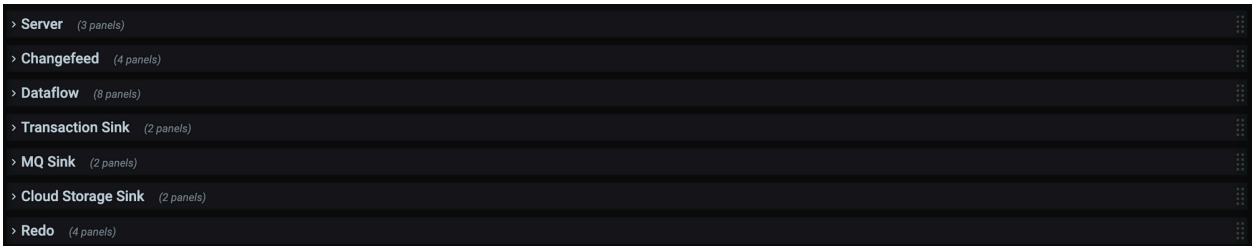

Figure 102: TiCDC Summary Dashboard - Overview

Each monitoring panel is described as follows:

- Server: summary of TiCDC nodes in the cluster.
- Changefeed: the latency and status information of TiCDC changefeeds.
- Dataflow: statistics of data changes processed by TiCDC internal modules.
- Transaction Sink: the write latency of the downstream MySQL or TiDB.
- MQ Sink: the write latency of the downstream MQ system.
- Cloud Storage Sink: the write speed of the downstream cloud storage.
- Redo: the write latency when the redo feature is enabled.

7.4.1.1 Server panel

The **Server** panel is as follows:

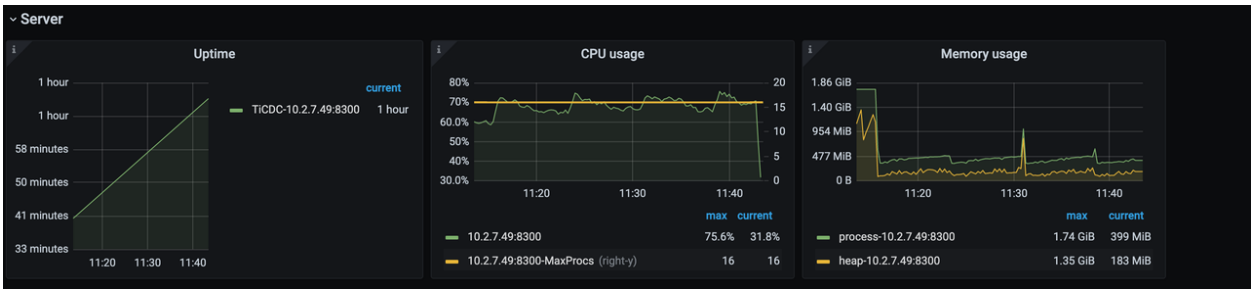

Figure 103: TiCDC Summary Dashboard - Server metrics

- **Uptime**: the time that TiCDC nodes have been running.
- **CPU usage**: the CPU usage of TiCDC nodes.
- **Memory usage**: the memory usage of TiCDC nodes.

7.4.1.2 Changefeed panel

The **Changefeed** panel is as follows:

Figure 104: TiCDC Summary Dashboard - Changefeed metrics

- **Changefeed checkpoint lag**: indicates the data replication latency between the upstream TiDB cluster and the downstream system, measured in time. In general, this metric reflects the overall health of the data replication task. Usually, the smaller the lag, the better the status of the replication task. When the lag increases, it usually indicates that the replication ability of the changefeed or the consumption ability of the downstream system cannot keep up with the write speed of the upstream.
- **Changefeed resolved ts lag**: indicates the data latency between the upstream TiDB cluster and the TiCDC node, measured in time. This metric reflects the ability of the changefeed to pull the data changes from the upstream. When the lag increases, it means that the changefeed cannot pull the data changes generated by the upstream in time.

7.4.1.3 Dataflow panel

Figure 105: TiCDC Summary Dashboard - Puller metrics

- **Puller output events/s**: the number of data changes output by the Puller module to the Sorter module per second in the TiCDC node. This metric reflects the speed at which TiCDC pulls the data changes from the upstream.

- **Puller output events**: the total number of data changes output by the Puller module to the Sorter module in the TiCDC node.

Figure 106: TiCDC Summary Dashboard - Sorter metrics

- **Sorter output events/s**: the number of data changes output by the Sorter module per second to the Sink module in the TiCDC node. Note that the data output rate of Sorter is affected by the Sink module. Therefore, when you find that the output rate of the Sorter module is lower than that of the Puller module, it does not necessarily mean that the sorting speed of the Sorter module is too slow. You need to first observe the metrics related to the Sink module to confirm whether the Sink module takes a long time to flush data, resulting in a decrease in Sorter module output.
- **Sorter output event**: the total number of data changes output by the Sorter module to the Sink module in the TiCDC node.

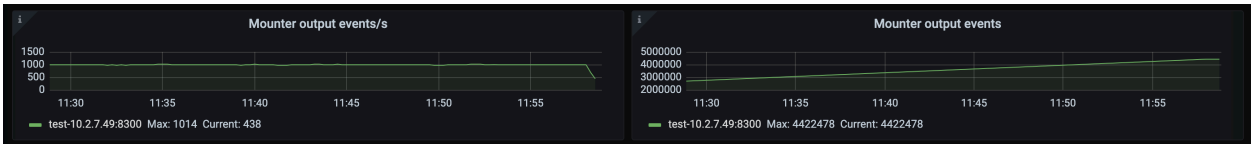

Figure 107: TiCDC Summary Dashboard - Mounter metrics

- **Mounter output events/s**: the number of data changes decoded by the Mounter module per second in the TiCDC node. When the upstream data changes involve a large number of fields, the decoding speed of the Mounter module might be affected.
- **Mounter output event**: the total number of data changes decoded by the Mounter module in the TiCDC node.

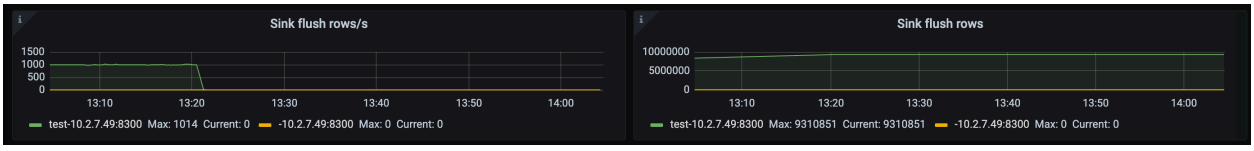

Figure 108: TiCDC Summary Dashboard - Sink metrics

- **Sink flush rows/s**: the number of data changes output by the Sink module to the downstream per second in the TiCDC node. This metric reflects the speed at which the data changes are replicated to the downstream. When **Sink flush rows/s** is lower than **Puller output events/s**, the replication latency might increase.
- **Sink flush rows**: the total number of data changes output by the Sink module to the downstream in the TiCDC node.

7.4.1.4 Transaction Sink panel

The **Transaction Sink** panel displays data only when the downstream is MySQL or TiDB.

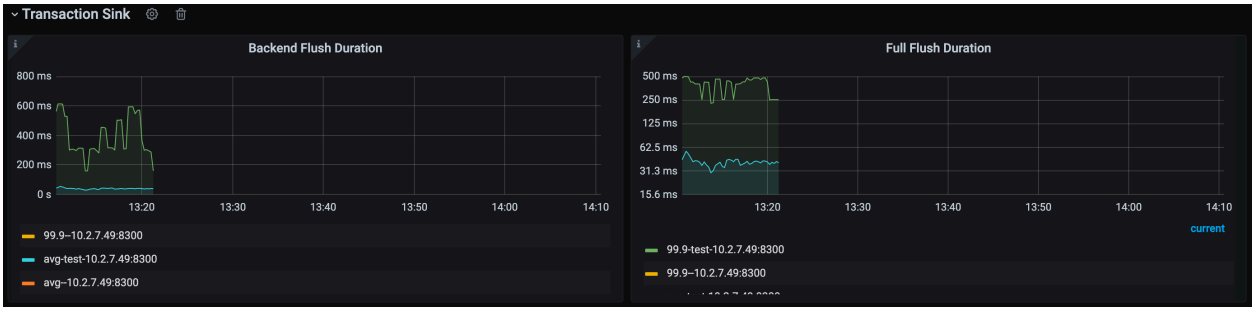

Figure 109: TiCDC Summary Dashboard - Transaction Sink metrics

- **Backend Flush Duration**: the duration that the TiCDC Transaction Sink module takes to execute a SQL statement on the downstream. By observing this metric, you can determine whether the performance of the downstream is the bottleneck of the replication speed. Generally, the p999 value should be below 500 ms. When the value exceeds this limit, the replication speed might be affected, resulting in an increase in the Changefeed checkpoint lag.
- **Full Flush Duration**: the total duration consumed by each transaction in TiCDC from sorting by Sorter to sending downstream. By subtracting the **Backend Flush Duration** value from this value, you can get the total queueing time of a transaction before it is executed on the downstream. If the queueing time is too long, you can consider allocating more memory quota to the replication task.

7.4.1.5 MQ Sink panel

The **MQ Sink** panel displays data only when the downstream is Kafka.

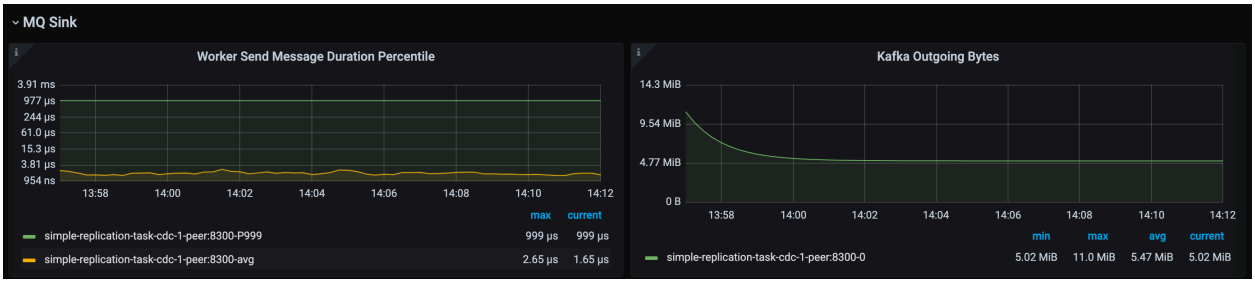

Figure 110: TiCDC Summary Dashboard - Transaction Sink metrics

- **Worker Send Message Duration Percentile**: The latency of TiCDC MQ Sink worker sending data to the downstream.
- **Kafka Ongoing Bytes**: The speed at which TiCDC MQ Sink sends data to the downstream.

7.4.1.6 Cloud Storage Sink panel

The **Cloud Storage Sink** panel displays data only when the downstream is Cloud Storage.

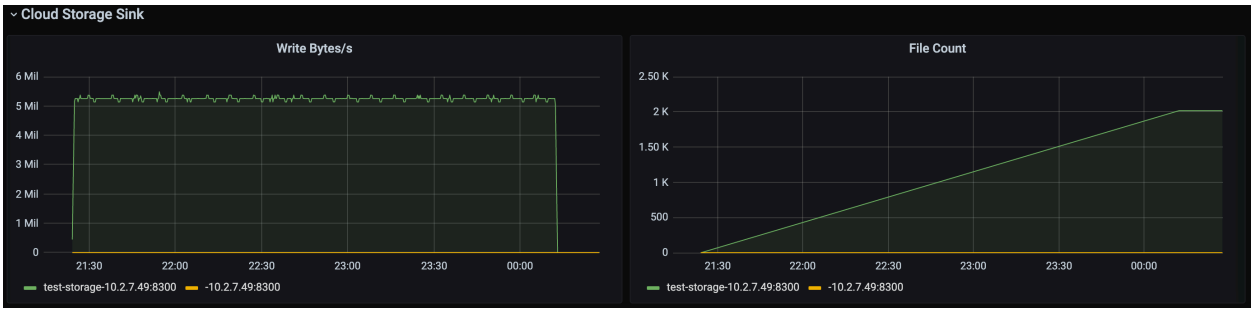

Figure 111: TiCDC Summary Dashboard - Transaction Sink metrics

- **Write Bytes/s**: The speed at which the Cloud Storage Sink module writes data to the downstream.
- **File Count**: the total number of files written by the Cloud Storage Sink module.

7.4.1.7 Redo panel

The **Redo** panel displays data only when the Redo Log feature is enabled.

Figure 112: TiCDC Summary Dashboard - Transaction Sink metrics

- **Redo Write rows/s**: the number of rows written per second by the Redo module. When the Redo feature is enabled, if the latency of a replication task increases, you can observe whether there is a significant difference between this metric and the value of Puller Output event/s. If so, the increase in latency might be due to the insufficient writing capacity of the Redo module.
- **Redo Write byte/s**: the speed at which data is written per second by the Redo module.
- **Redo flush log duration**: the time taken for the Redo module to flush data to the downstream. If this metric value is high, this operation might affect the replication speed.
- **Redo flushall duration**: the total time that data changes stay in the Redo module.

7.4.2 TiCDC Monitoring Metrics Details

If you use TiUP to deploy the TiDB cluster, you can see a sub-dashboard for TiCDC in the monitoring system which is deployed at the same time. You can get an overview of TiCDC's current status from the TiCDC dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

The metric description in this document is based on the following replication task example, which replicates data to MySQL using the default configuration.

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

The TiCDC dashboard contains four monitoring panels. See the following screenshot:

Figure 113: TiCDC Dashboard - Overview

The description of each panel is as follows:

- **Server**: The summary information of TiKV nodes and TiCDC nodes in the TiDB cluster
- **Changefeed**: The detailed information of TiCDC replication tasks
- **Events**: The detail information about the data flow within the TiCDC cluster
- **TiKV**: TiKV information related to TiCDC

7.4.2.1 Server

The following is an example of the **Server** panel:

Figure 114: TiCDC Dashboard - Server metrics

The description of each metric in the **Server** panel is as follows:

- Uptime: The time for which TiKV nodes and TiCDC nodes have been running
- Goroutine count: The number of goroutines of a TiCDC node
- Open FD count: The number of file handles opened by TiCDC nodes
- Ownership: The current status of nodes in the TiCDC cluster
- Ownership history: The ownership history of the TiCDC cluster
- CPU usage: The CPU usage of TiCDC nodes
- Memory usage: The memory usage of TiCDC nodes

7.4.2.2 Changefeed

The following is an example of the **Changefeed** panel:

Figure 115: TiCDC Dashboard - Changefeed metrics 1

- Changefeed table count: The number of tables that each TiCDC node needs to replicate in the replication task
- Processor resolved ts: The timestamps that have been resolved in the TiCDC cluster
- Table resolved ts: The replication progress of each table in the replication task
- Changefeed checkpoint: The progress of replicating data to the downstream. Normally, the green bars are connected to the yellow line
- PD etcd requests/s: The number of requests that a TiCDC node sends to PD per second
- Exit error count/m: The number of errors that interrupt the replication task per minute
- Changefeed checkpoint lag: The progress lag of data replication (the unit is second) between the upstream and the downstream
- Processor resolved ts lag: The progress lag of data replication (the unit is second) between the upstream and TiCDC nodes

Figure 116: TiCDC Dashboard - Changefeed metrics 2

- Sink write duration: The histogram of the time spent by TiCDC writing a transaction change to the downstream
- Sink write duration percentile: The time (P95, P99, and P999) spent by TiCDC writing a transaction change to the downstream within one second
- Flush sink duration: The histogram of the time spent by TiCDC asynchronously flushing data to the downstream
- Flush sink duration percentile: The time (P95, P99, and P999) spent by TiCDC asynchronously flushing data to the downstream within one second

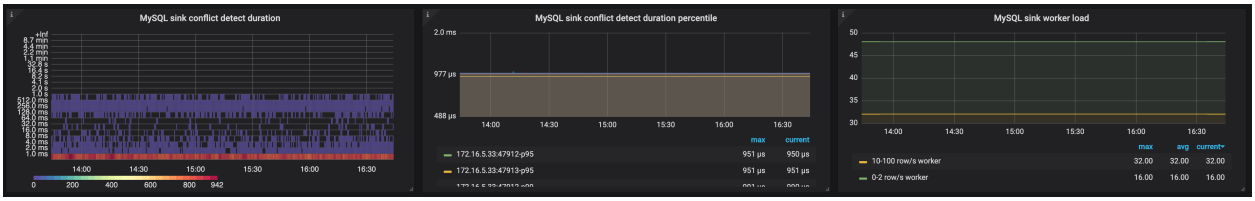

Figure 117: TiCDC Dashboard - Changefeed metrics 3

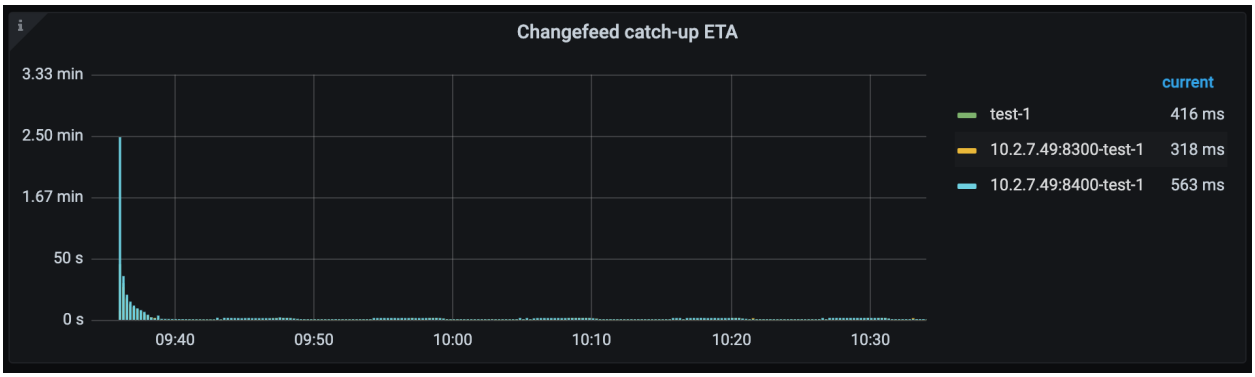
- MySQL sink conflict detect duration: The histogram of the time spent on detecting MySQL sink conflicts
- MySQL sink conflict detect duration percentile: The time (P95, P99, and P999) spent on detecting MySQL sink conflicts within one second
- MySQL sink worker load: The workload of MySQL sink workers of TiCDC nodes



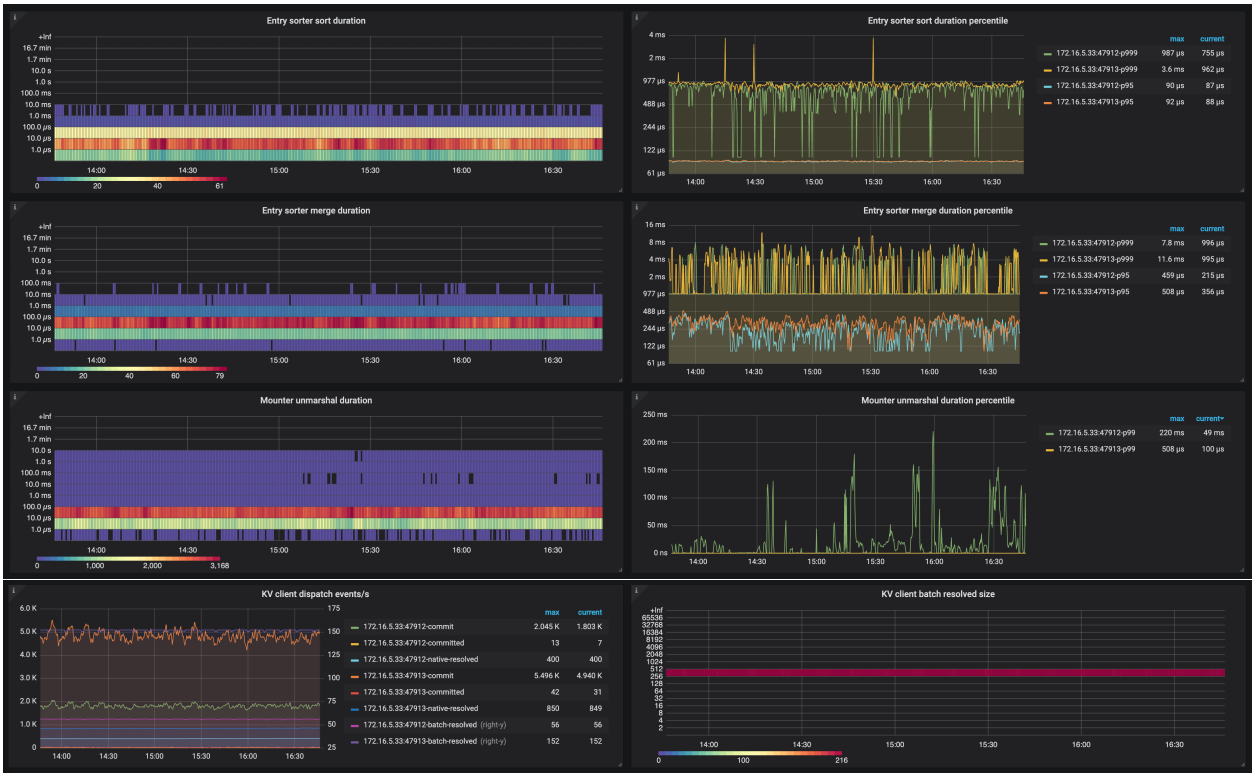


Figure 118: TiCDC Dashboard - Changefeed metrics 4

- Changefeed catch-up ETA: The estimated time needed for the replication task to catch up with the upstream cluster data. When the upstream write speed is faster than the TiCDC replication speed, the metric might be extremely large. Because TiCDC replication speed is subject to many factors, this metric is for reference only and might not be the actual replication time.

7.4.2.3 Events

The following is an example of the **Events** panel:

The description of each metric in the **Events** panel is as follows:

- Eventfeed count: The number of Eventfeed RPC requests of TiCDC nodes
- Event size percentile: The event size (P95, P99, and P999) which TiCDC receives from TiKV within one second
- Eventfeed error/m: The number of errors reported by Eventfeed RPC requests of TiCDC nodes per minute
- KV client receive events/s: The number of events that the KV client module of TiCDC nodes receives from TiKV per second
- Puller receive events/s: The number of events that the Puller module of TiCDC nodes receives from the KV client per second
- Puller output events/s: The number of events that the Puller module of TiCDC nodes sends to the Sorter module per second
- Sink flush rows/s: The number of events that TiCDC nodes write to the downstream per second
- Puller buffer size: The number of events that TiCDC nodes cache in the Puller module
- Entry sorter buffer size: The number of events that TiCDC nodes cache in the Sorter module
- Processor/Mounter buffer size: The number of events that TiCDC nodes cache in the Processor module and the Mounter module
- Sink row buffer size: The number of events that TiCDC nodes cache in the Sink module
- Entry sorter sort duration: The histogram of the time spent by TiCDC nodes sorting events
- Entry sorter sort duration percentile: The time (P95, P99, and P999) spent by TiCDC

sorting events within one second

- Entry sorter merge duration: The histogram of the time spent by TiCDC nodes merging sorted events
- Entry sorter merge duration percentile: The time (P95, P99, and P999) spent by TiCDC merging sorted events within one second
- Mounter unmarshal duration: The histogram of the time spent by TiCDC nodes unmarshalling events
- Mounter unmarshal duration percentile: The time (P95, P99, and P999) spent by TiCDC unmarshalling events within one second
- KV client dispatch events/s: The number of events that the KV client module dispatches among the TiCDC nodes
- KV client batch resolved size: The batch size of resolved timestamp messages that TiKV sends to TiCDC

7.4.2.4 TiKV

The following is an example of the **TiKV** panel:

The description of each metric in the **TiKV** panel is as follows:

- CDC endpoint CPU: The CPU usage of the CDC endpoint threads on TiKV nodes
- CDC worker CPU: The CPU usage of the CDC worker threads on TiKV nodes
- Min resolved ts: The minimum resolved timestamp on TiKV nodes
- Min resolved region: The Region ID of the minimum resolved timestamp on TiKV nodes
- Resolved ts lag duration percentile: The lag between the minimum resolved timestamp on TiKV nodes and the current time
- Initial scan duration: The histogram of the time spent on incremental scan when TiKV nodes connect to TiCDC nodes
- Initial scan duration percentile: The time (P95, P99, and P999) spent on the incremental scan of TiKV nodes within one second
- Memory without block cache: The memory usage of TiKV nodes excluding the RocksDB block cache
- CDC pending bytes in memory: The memory usage of CDC module on TiKV nodes
- Captured region count: The number of event-capturing Regions on TiKV nodes

7.4.3 TiCDC Alert Rules

This document describes the TiCDC alert rules and the corresponding solutions. In descending order, the severity levels are: **Critical**, **Warning**.

7.4.3.1 Critical alerts

This section introduces critical alerts and solutions.

7.4.3.1.1 `cdc_checkpoint_high_delay`

For critical alerts, you need to pay close attention to abnormal monitoring metrics.

- Alert rule:

  `ticdc_owner_checkpoint_ts_lag > 600`

- Description:

  A replication task is delayed more than 10 minutes.

- Solution:

  See TiCDC Handles Replication Interruption.

7.4.3.1.2 `cdc_resolvedts_high_delay`

- Alert rule:

  `ticdc_owner_resolved_ts_lag > 300`

- Description:

  The Resolved TS of a replication task is delayed more than 5 minutes.

- Solution:

  See TiCDC Handles Replication Interruption.

7.4.3.1.3 `ticdc_changefeed_failed`

- Alert rule:

  `(max_over_time(ticdc_owner_status[1m])== 2)> 0`

- Description:

  A replication task encounters an unrecoverable error and enters the failed state.

- Solution:

  This alert is similar to replication interruption. See TiCDC Handles Replication Interruption.

7.4.3.2 Warning alerts

Warning alerts are a reminder for an issue or error.

7.4.3.2.1 `cdc_multiple_owners`

- Alert rule:

  `sum(rate(ticdc_owner_ownership_counter[30s]))>= 2`

- Description:

  There are multiple owners in the TiCDC cluster.

- Solution:

  Collect TiCDC logs to locate the root cause.

7.4.3.2.2 `cdc_no_owner`

- Alert rule:

  `sum(rate(ticdc_owner_ownership_counter[240s]))< 0.5`

- Description:

  There is no owner in the TiCDC cluster for more than 10 minutes.

- Solution:

  Collect TiCDC logs to identify the root cause.

7.4.3.2.3 `ticdc_changefeed_meet_error`

- Alert rule:

```
(max_over_time(ticdc_owner_status[1m])== 1 or max_over_time(ticdc_owner
↪ _status[1m])== 6)> 0
```

- Description:

  A replication task encounters an error.

- Solution:

  See TiCDC Handles Replication Interruption.

7.4.3.2.4 `ticdc_processor_exit_with_error_count`

- Alert rule:

```
changes(ticdc_processor_exit_with_error_count[1m])> 0
```

- Description:

  A replication task reports an error and exits.

- Solution:

  See TiCDC Handles Replication Interruption.

7.4.3.2.5 `tikv_cdc_min_resolved_ts_no_change_for_1m`

- Alert rule:

```
changes(tikv_cdc_min_resolved_ts[1m])< 1 and ON (instance)tikv_cdc_
↪ region_resolve_status{status="resolved"} > 0 and ON (instance)tikv_
↪ cdc_captured_region_total > 0
```

- Description:

  The minimum Resolved TS 1 of TiKV CDC has not advanced for 1 minute.

- Solution:

  Collect TiKV logs to locate the root cause.

7.4.3.2.6 tikv_cdc_scan_duration_seconds_more_than_10min

- Alert rule:

```
histogram_quantile(0.9, rate(tikv_cdc_scan_duration_seconds_bucket{}[1m
↪ ]))> 600
```

- Description:

  The TiKV CDC module has scanned for incremental replication for more than 10 minutes.

- Solution:

  Collect TiCDC monitoring metrics and TiKV logs to locate the root cause.

7.4.3.2.7 ticdc_sink_execution_error

- Alert rule:

```
changes(ticdc_sink_execution_error[1m])> 0
```

- Description:

  An error occurs when a replication task writes data to the downstream.

- Solution:

  There are many possible root causes. See Troubleshoot TiCDC.

7.4.3.2.8 ticdc_memory_abnormal

- Alert rule:

```
go_memstats_heap_alloc_bytes{job="ticdc"} > 1e+10
```

- Description:

  The TiCDC heap memory usage exceeds 10 GiB.

- Solution:

  Collect TiCDC logs to locate the root cause.

7.5 Integration Scenarios

7.5.1 Data Integration Overview

Data integration means the flow, transfer, and consolidation of data among various data sources. As data grows exponentially in volume and data value is more profoundly explored, data integration has become increasingly popular and urgent. To avoid the situation that TiDB becomes data silos and to integrate data with different platforms, TiCDC offers the capability to replicate TiDB incremental data change logs to other data platforms. This document describes the data integration applications using TiCDC. You can choose an integration solution that suits your business scenarios.

7.5.1.1 Integrate with Confluent Cloud and Snowflake

You can use TiCDC to replicate incremental data from TiDB to Confluent Cloud, and replicate the data to Snowflake, ksqlDB, and SQL Server via Confluent Cloud. For details, see Integrate with Confluent Cloud and Snowflake.

7.5.1.2 Integrate with Apache Kafka and Apache Flink

You can use TiCDC to replicate incremental data from TiDB to Apache Kafka, and consume the data using Apache Flink. For details, see Integrate with Apache Kafka and Apache Flink.

7.5.2 Integrate Data with Confluent Cloud and Snowflake

Confluent is an Apache Kafka-compatible streaming data platform that provides strong data integration capabilities. On this platform, you can access, store, and manage non-stop real-time streaming data.

Starting from TiDB v6.1.0, TiCDC supports replicating incremental data to Confluent in Avro format. This document introduces how to replicate TiDB incremental data to Confluent using TiCDC, and further replicate data to Snowflake, ksqlDB, and SQL Server via Confluent Cloud. The organization of this document is as follows:

1. Quickly deploy a TiDB cluster with TiCDC included.
2. Create a changefeed that replicates data from TiDB to Confluent Cloud.
3. Create Connectors that replicate data from Confluent Cloud to Snowflake, ksqlDB, and SQL Server.
4. Write data to TiDB using go-tpc, and observe data changes in Snowflake, ksqlDB, and SQL Server.

The preceding steps are performed in a lab environment. You can also deploy a cluster in a production environment by referring to these steps.

7.5.2.1 Replicate incremental data to Confluent Cloud

7.5.2.1.1 Step 1. Set up the environment

1. Deploy a TiDB cluster with TiCDC included.

   In a lab or testing environment, you can deploy a TiDB cluster with TiCDC included quickly by using TiUP Playground.

```
tiup playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc
    ↪ 1
# View cluster status
tiup status
```

   If TiUP is not installed yet, refer to Install TiUP. In a production environment, you can deploy a TiCDC as instructed in Deploy TiCDC.

2. Register Confluent Cloud and create a Confluent cluster.

   Create a Basic cluster and make it accessible via Internet. For details, see Quick Start for Confluent Cloud.

7.5.2.1.2 Step 2. Create an access key pair

1. Create a cluster API key.

   Sign in to Confluent Cloud. Choose **Data integration** > **API keys** > **Create key**. On the **Select scope for API key** page that is displayed, select **Global access**.

   After creation, a key pair file is generated, as shown below.

```
=== Confluent Cloud API key: xxx-xxxxx ===

API key:
L5WWA4GK4NAT2EQV

API secret:
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx

Bootstrap server:
xxx-xxxxx.ap-east-1.aws.confluent.cloud:9092
```

2. Record the Schema Registry Endpoints.

   In the Confluent Cloud Console, choose **Schema Registry** > **API endpoint**. Record the Schema Registry Endpoints. The following is an example:

```
https://yyy-yyyyy.us-east-2.aws.confluent.cloud
```

3. Create a Schema Registry API key.

   In the Confluent Cloud Console, choose **Schema Registry** > **API credentials**. Click **Edit** and then **Create key**.

   After creation, a key pair file is generated, as shown below:

```
=== Confluent Cloud API key: yyy-yyyyy ===
API key:
7NBH2CAFM2LMGTH7
API secret:
xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx
```

   You can also perform this step by using Confluent CLI. For details, see Connect Confluent CLI to Confluent Cloud Cluster.

7.5.2.1.3 Step 3. Create a Kafka changefeed

1. Create a changefeed configuration file.

   As required by Avro and Confluent Connector, incremental data of each table must be sent to an independent topic, and a partition must be dispatched for each event based on the primary key value. Therefore, you need to create a changefeed configuration file `changefeed.conf` with the following contents:

```
[sink]
dispatchers = [
{matcher = ['*.*'], topic = "tidb_{schema}_{table}", partition="index-
    ↪ value"},
]
```

   For detailed description of `dispatchers` in the configuration file, see Customize the rules for Topic and Partition dispatchers of Kafka Sink.

2. Create a changefeed to replicate incremental data to Confluent Cloud:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed create --server="http
    ↪ ://127.0.0.1:8300" --sink-uri="kafka://<broker_endpoint>/ticdc-
    ↪ meta?protocol=avro&replication-factor=3&enable-tls=true&auto-
    ↪ create-topic=true&sasl-mechanism=plain&sasl-user=<broker_api_key
    ↪ >&sasl-password=<broker_api_secret>" --schema-registry="https://<
    ↪ schema_registry_api_key>:<schema_registry_api_secret>@<schema_
    ↪ registry_endpoint>" --changefeed-id="confluent-changefeed" --
    ↪ config changefeed.conf
```

   You need to replace the values of the following fields with those created or recorded in Step 2. Create an access key pair:

   - `<broker_endpoint>`

- <broker_api_key>
- <broker_api_secret>
- <schema_registry_api_key>
- <schema_registry_api_secret>
- <schema_registry_endpoint>

Note that you should encode <schema_registry_api_secret> based on HTML URL Encoding Reference before replacing its value. After you replace all the preceding fields, the configuration file is as follows:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed create --server="http
    ↪ ://127.0.0.1:8300" --sink-uri="kafka://xxx-xxxxx.ap-east-1.aws.
    ↪ confluent.cloud:9092/ticdc-meta?protocol=avro&replication-factor
    ↪ =3&enable-tls=true&auto-create-topic=true&sasl-mechanism=plain&
    ↪ sasl-user=L5WWA4GK4NAT2EQV&sasl-password=
    ↪ xxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxxx" --schema-registry="https://7
    ↪ NBH2CAFM2LMGTH7:xxxxxxxxxxxxxxxxx@yyy-yyyyy.us-east-2.aws.
    ↪ confluent.cloud" --changefeed-id="confluent-changefeed" --config
    ↪ changefeed.conf
```

- Run the command to create a changefeed.
  - If the changefeed is successfully created, changefeed information, such as changefeed ID, is displayed, as shown below:

    ```
    Create changefeed successfully!
    ID: confluent-changefeed
    Info: {... changfeed info json struct ...}
    ```

  - If no result is returned after you run the command, check the network connectivity between the server where you run the command and Confluent Cloud. For details, see Test connectivity to Confluent Cloud.

3. After creating the changefeed, run the following command to check the changefeed status:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed list --server="http
    ↪ ://127.0.0.1:8300"
```

You can refer to Manage TiCDC Changefeeds to manage the changefeed.

7.5.2.1.4 Step 4. Write data to generate change logs

After the preceding steps are done, TiCDC sends change logs of incremental data in the TiDB cluster to Confluent Cloud. This section describes how to write data into TiDB to generate change logs.

1. Simulate service workload.

   To generate change logs in a lab environment, you can use go-tpc to write data to the TiDB cluster. Specifically, run the following command to create a database `tpcc` in the TiDB cluster. Then, use TiUP bench to write data to this new database.

   ```
   tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
   tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
       ↪ 300s
   ```

   For more details about go-tpc, refer to How to Run TPC-C Test on TiDB.

2. Observe data in Confluent Cloud.

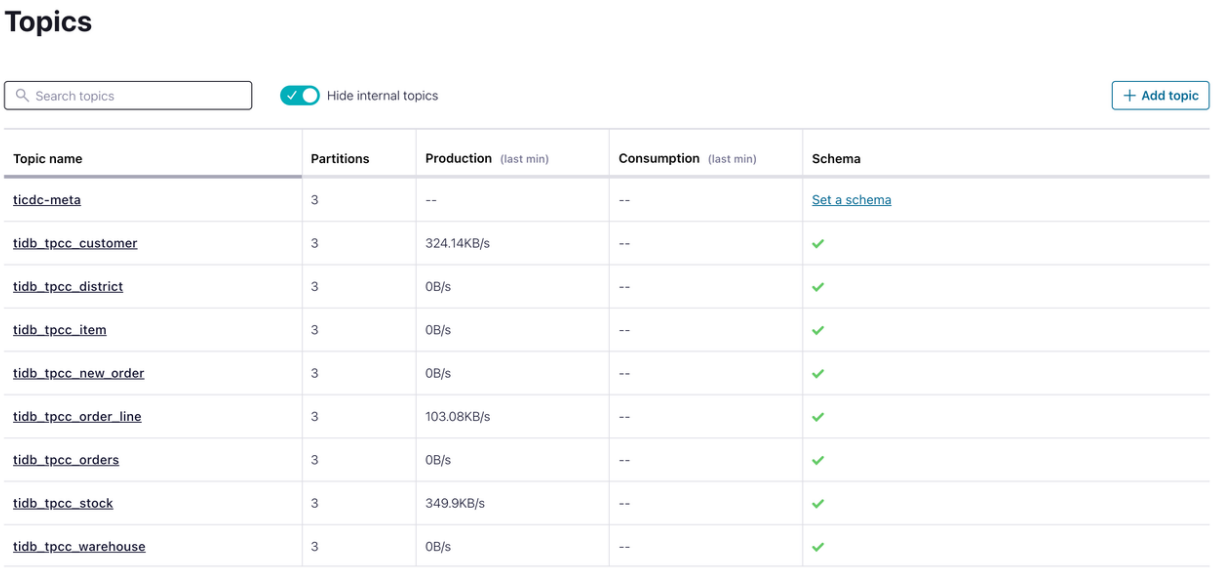

Figure 119: Confluent topics

In the Confluent Cloud Console, click **Topics**. You can see that the target topics have been created and are receiving data. At this time, incremental data of the TiDB database is successfully replicated to Confluent Cloud.

7.5.2.2 Integrate data with Snowflake

Snowflake is a cloud native data warehouse. With Confluent, you can replicate TiDB incremental data to Snowflake by creating Snowflake Sink Connectors.

7.5.2.2.1 Prerequisites

- You have registered and created a Snowflake cluster. See Getting Started with Snowflake.

- Before connecting to the Snowflake cluster, you have generated a private key for it. See Key Pair Authentication & Key Pair Rotation.

7.5.2.2.2 Integration procedure

1. Create a database and a schema in Snowflake.

   In the Snowflake control console, choose **Data** > **Database**. Create a database named `TPCC` and a schema named `TiCDC`.

2. In the Confluent Cloud Console, choose **Data integration** > **Connectors** > **Snowflake Sink**. The page shown below is displayed.

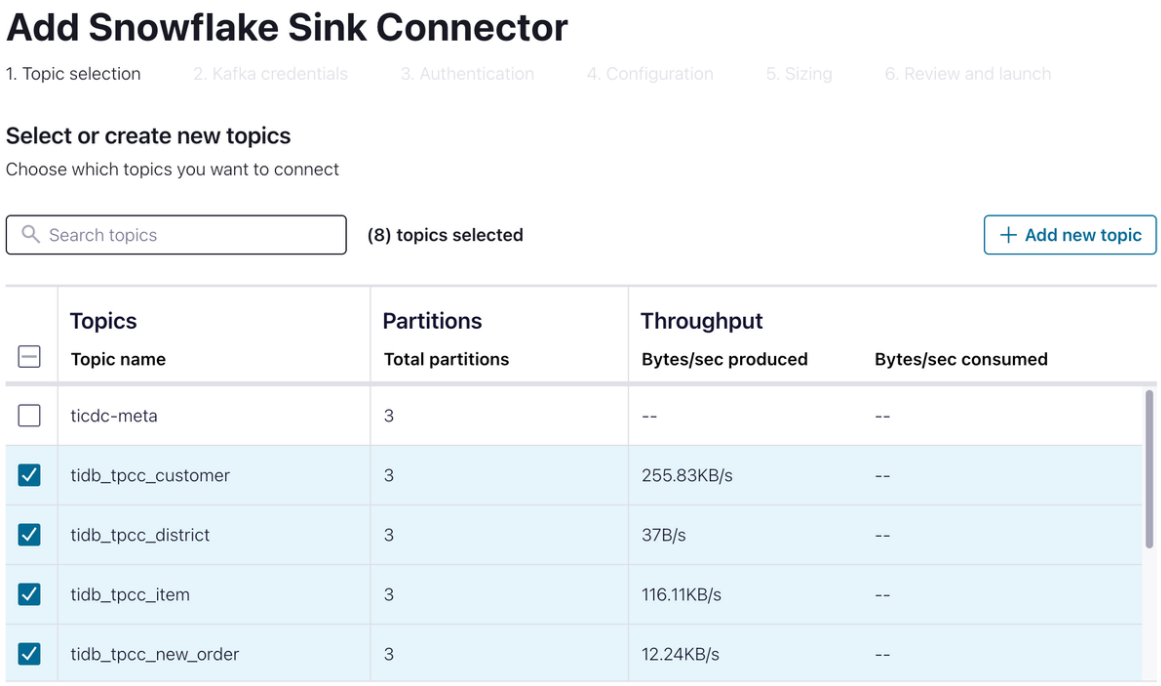

Figure 120: Add snowflake sink connector

3. Select the topic you want to replicate to Snowflake. Then go to the next page.

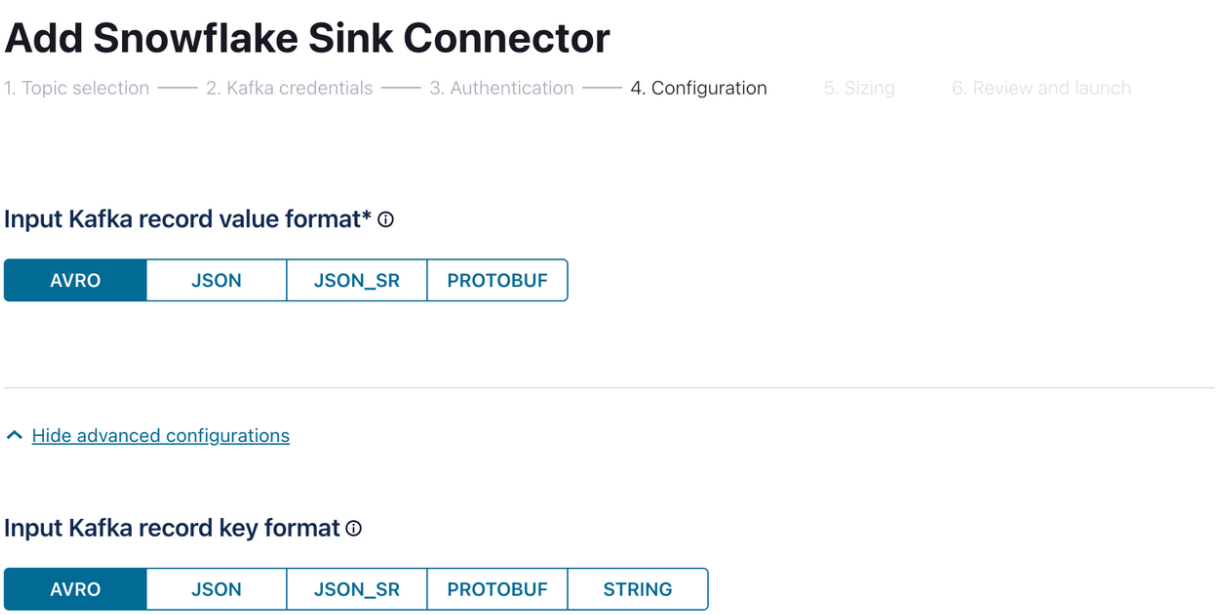

Figure 121: Configuration

4. Specify the authentication information for connecting Snowflake. Fill in **Database name** and **Schema name** with the values you created in the previous step. Then go to the next page.

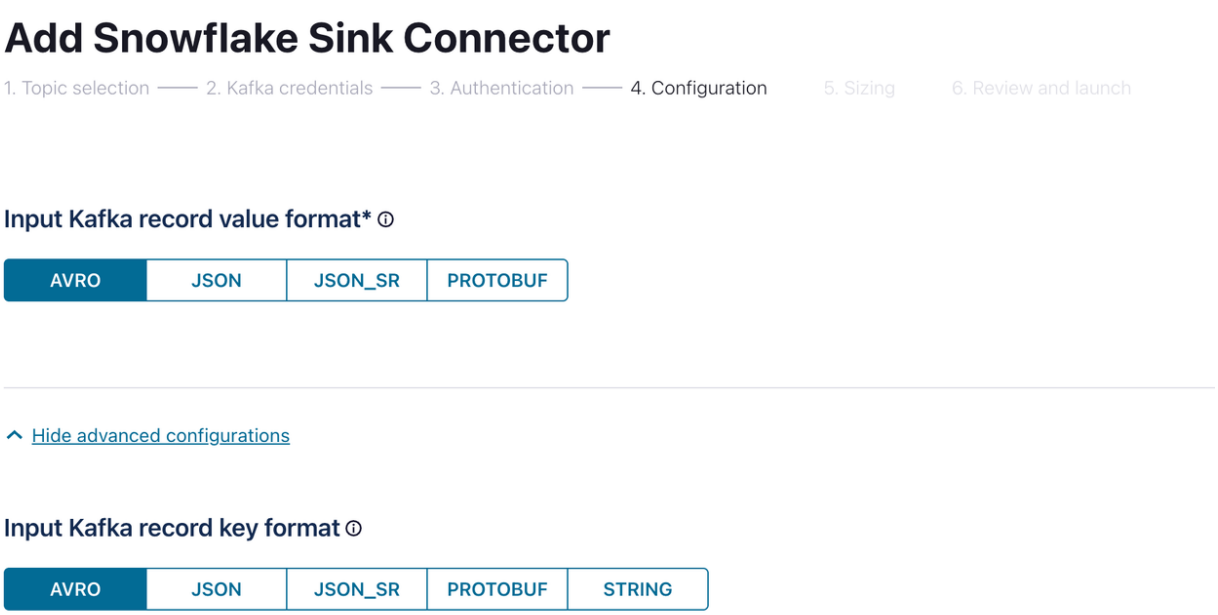

Figure 122: Configuration

5. On the **Configuration** page, select `AVRO` for both **Input Kafka record value format** and **Input Kafka record key format**. Then click **Continue**. Wait until the connector is created and the status becomes **Running**, which might take several minutes.

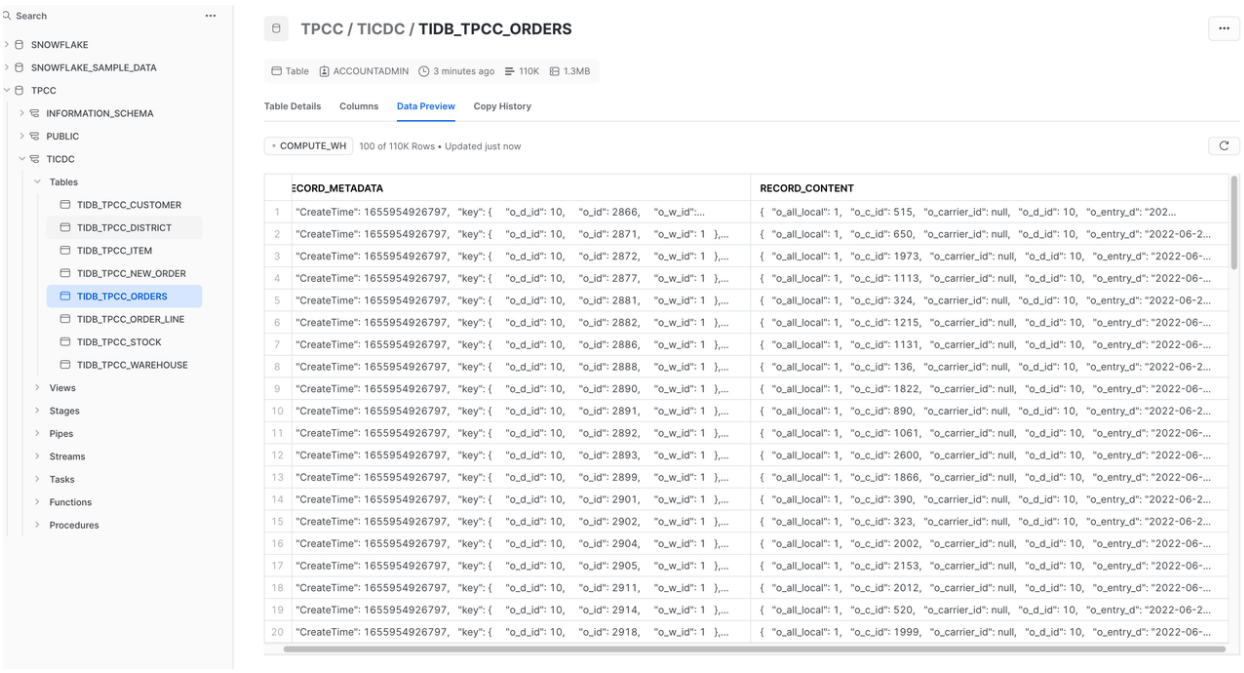

Figure 123: Data preview

6. In the Snowflake console, choose **Data** > **Database** > **TPCC** > **TiCDC**. You can see that TiDB incremental data has been replicated to Snowflake. Data integration with Snowflake is done (see the preceding figure). However, the table structure in Snowflake is different from that in TiDB, and data is inserted into Snowflake incrementally. In most scenarios, you expect the data in Snowflake to be a replica of the data in TiDB, rather than storing TiDB change logs. This problem will be addressed in the next section.

7.5.2.2.3 Create data replicas of TiDB tables in Snowflake

In the previous section, the change logs of TiDB incremental data have been replicated to Snowflake. This section describes how to process these change logs using the TASK and STREAM features of Snowflake according to the event type of `INSERT`, `UPDATE`, and `DELETE` ↪ , and then write them to a table with the same structure as that in upstream, thereby creating a data replica of the TiDB table in Snowflake. The following takes the `ITEM` table as an example.

The structure of the `ITEM` table is as follows:

```
CREATE TABLE `item` (
  `i_id` int NOT NULL,
  `i_im_id` int DEFAULT NULL,
  `i_name` varchar(24) DEFAULT NULL,
  `i_price` decimal(5,2) DEFAULT NULL,
  `i_data` varchar(50) DEFAULT NULL,
```

```
  PRIMARY KEY (`i_id`)
);
```

In Snowflake, there is a table named `TIDB_TEST_ITEM`, which is automatically created by the Confluent Snowflake Sink Connector. The table structure is as follows:

```
create or replace TABLE TIDB_TEST_ITEM (
       RECORD_METADATA VARIANT,
       RECORD_CONTENT VARIANT
);
```

1. In Snowflake, create a table with the same structure as that in TiDB:

   ```
   create or replace table TEST_ITEM (
       i_id INTEGER primary key,
       i_im_id INTEGER,
       i_name VARCHAR,
       i_price DECIMAL(36,2),
       i_data VARCHAR
   );
   ```

2. Create a stream for `TIDB_TEST_ITEM` and set `append_only` to `true` as follows.

   ```
   create or replace stream TEST_ITEM_STREAM on table TIDB_TEST_ITEM
       ↪ append_only=true;
   ```

   In this way, the created stream captures only `INSERT` events in real time. Specifically, when a new change log is generated for `ITEM` in TiDB, the change log will be inserted into `TIDB_TEST_ITEM` and be captured by the stream.

3. Process the data in the stream. According to the event type, insert, update, or delete the stream data in the `TEST_ITEM` table.

   ```
   --Merge data into the TEST_ITEM table
   merge into TEST_ITEM n
     using
         -- Query TEST_ITEM_STREAM
         (SELECT RECORD_METADATA:key as k, RECORD_CONTENT:val as v from
             ↪ TEST_ITEM_STREAM) stm
         -- Match the stream with table on the condition that i_id is equal
         on k:i_id = n.i_id
     -- If the TEST_ITEM table contains a record that matches i_id and v
         ↪ is empty, delete this record
     when matched and IS_NULL_VALUE(v) = true then
         delete
   ```

```
  -- If the TEST_ITEM table contains a record that matches i_id and v
     ↪ is not empty, update this record
  when matched and IS_NULL_VALUE(v) = false then
     update set n.i_data = v:i_data, n.i_im_id = v:i_im_id, n.i_name =
        ↪ v:i_name, n.i_price = v:i_price

  -- If the TEST_ITEM table does not contain a record that matches i_id
     ↪ , insert this record
  when not matched then
     insert
        (i_data, i_id, i_im_id, i_name, i_price)
     values
        (v:i_data, v:i_id, v:i_im_id, v:i_name, v:i_price)
;
```

In the preceding example, the `MERGE INTO` statement of Snowflake is used to match the stream and the table on a specific condition, and then execute corresponding operations, such as deleting, updating, or inserting a record. In this example, three `WHERE` clauses are used for the following three scenarios:

- Delete the record in the table when the stream and the table match and the data in the stream is empty.
- Update the record in the table when the stream and the table match and the data in the stream is not empty.
- Insert the record in the table when the stream and the table do not match.

4. Periodically execute the statement in Step 3 to ensure that data is always up-to-date. You can also use the `SCHEDULED TASK` feature of Snowflake:

```
-- Create a TASK to periodically execute the MERGE INTO statement
create or replace task STREAM_TO_ITEM
    warehouse = test
    -- Execute the TASK every minute
    schedule = '1 minute'
when
    -- Skip the TASK when there is no data in TEST_ITEM_STREAM
    system$stream_has_data('TEST_ITEM_STREAM')
as
-- Merge data into the TEST_ITEM table. The statement is the same as
    ↪ that in the preceding example
merge into TEST_ITEM n
  using
     (select RECORD_METADATA:key as k, RECORD_CONTENT:val as v from
        ↪ TEST_ITEM_STREAM) stm
     on k:i_id = n.i_id
  when matched and IS_NULL_VALUE(v) = true then
```

```
    delete
  when matched and IS_NULL_VALUE(v) = false then
    update set n.i_data = v:i_data, n.i_im_id = v:i_im_id, n.i_name =
      ↪ v:i_name, n.i_price = v:i_price
  when not matched then
    insert
      (i_data, i_id, i_im_id, i_name, i_price)
    values
      (v:i_data, v:i_id, v:i_im_id, v:i_name, v:i_price)
;
```

At this time, you have established a data channel with certain ETL capabilities. Through this data channel, you can replicate TiDB's incremental data change logs to Snowflake, maintain a data replica of TiDB, and use the data in Snowflake.

The last step is to regularly clean up the useless data in the `TIDB_TEST_ITEM` table:

```
-- Clean up the TIDB_TEST_ITEM table every two hours
create or replace task TRUNCATE_TIDB_TEST_ITEM
    warehouse = test
    schedule = '120 minute'
when
    system$stream_has_data('TIDB_TEST_ITEM')
as
    TRUNCATE table TIDB_TEST_ITEM;
```

7.5.2.3 Integrate data with ksqlDB

ksqlDB is a database purpose-built for stream processing applications. You can create ksqlDB clusters on Confluent Cloud and access incremental data replicated by TiCDC.

1. Select **ksqlDB** in the Confluent Cloud Console and create a ksqlDB cluster as instructed.

   Wait until the ksqlDB cluster status is **Running**. This process takes several minutes.

2. In the ksqlDB Editor, run the following command to create a stream to access the `tidb_tpcc_orders` topic:

   ```
   CREATE STREAM orders (o_id INTEGER, o_d_id INTEGER, o_w_id INTEGER, o_
     ↪ c_id INTEGER, o_entry_d STRING, o_carrier_id INTEGER, o_ol_cnt
     ↪ INTEGER, o_all_local INTEGER) WITH (kafka_topic='tidb_tpcc_
     ↪ orders', partitions=3, value_format='AVRO');
   ```

3. Run the following command to check the orders STREAM data:

```
SELECT * FROM ORDERS EMIT CHANGES;
```

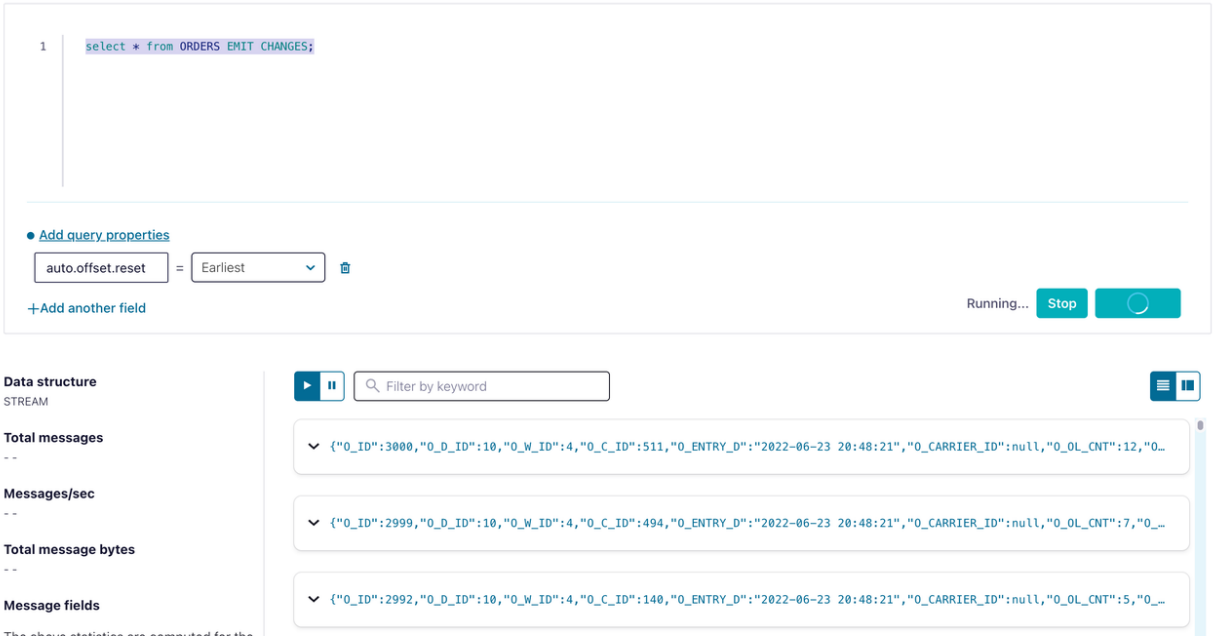

Figure 124: Select from orders

You can see that the incremental data has been replicated to ksqlDB, as shown in the preceding figure. Data integration with ksqlDB is done.

7.5.2.4 Integrate data with SQL Server

Microsoft SQL Server is a relational database management system (RDBMS) developed by Microsoft. With Confluent, you can replicate TiDB incremental data to SQL Server by creating SQL Server Sink Connectors.

1. Connect to SQL Server and create a database named `tpcc`.

```
[ec2-user@ip-172-1-1-1 bin]$ sqlcmd -S 10.61.43.14,1433 -U admin
Password:
1> create database tpcc
2> go
1> select name from master.dbo.sysdatabases
2> go
name
----------------------------------------------------------------------
master
tempdb
```

```
model
msdb
rdsadmin
tpcc
(6 rows affected)
```

2. In the Confluent Cloud Console, choose **Data integration** > **Connectors** > **Microsoft SQL Server Sink**. The page shown below is displayed.

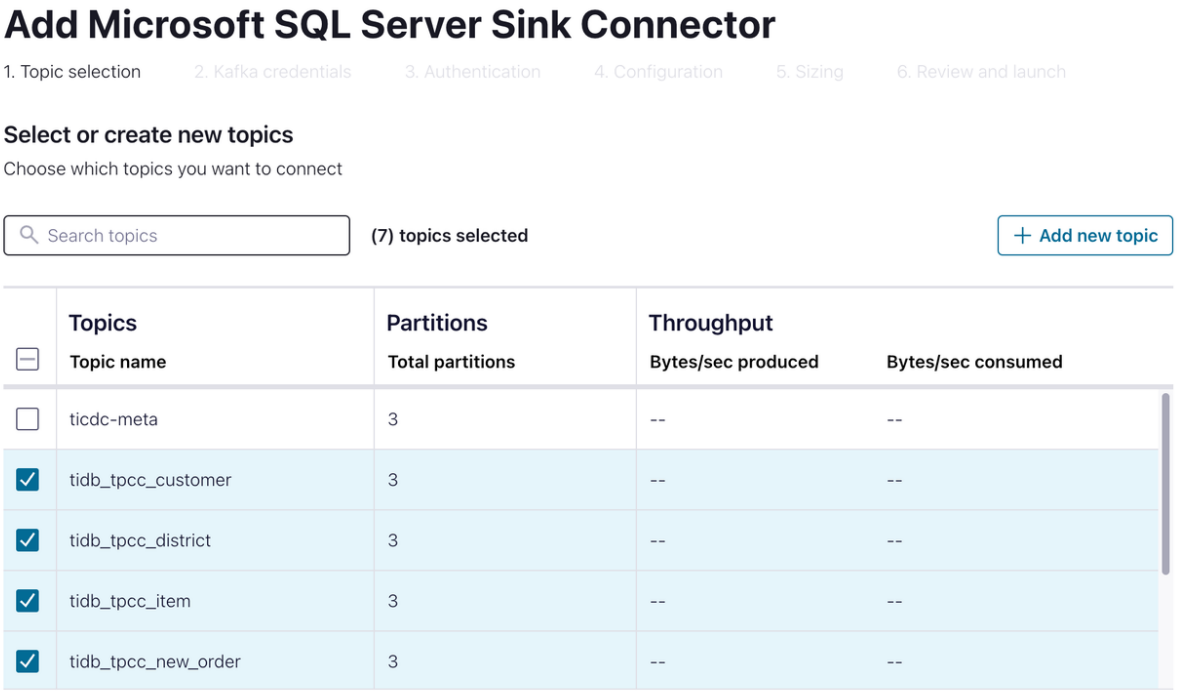

Figure 125: Topic selection

3. Select the topic you want to replicate to SQL Server. Then go to the next page.

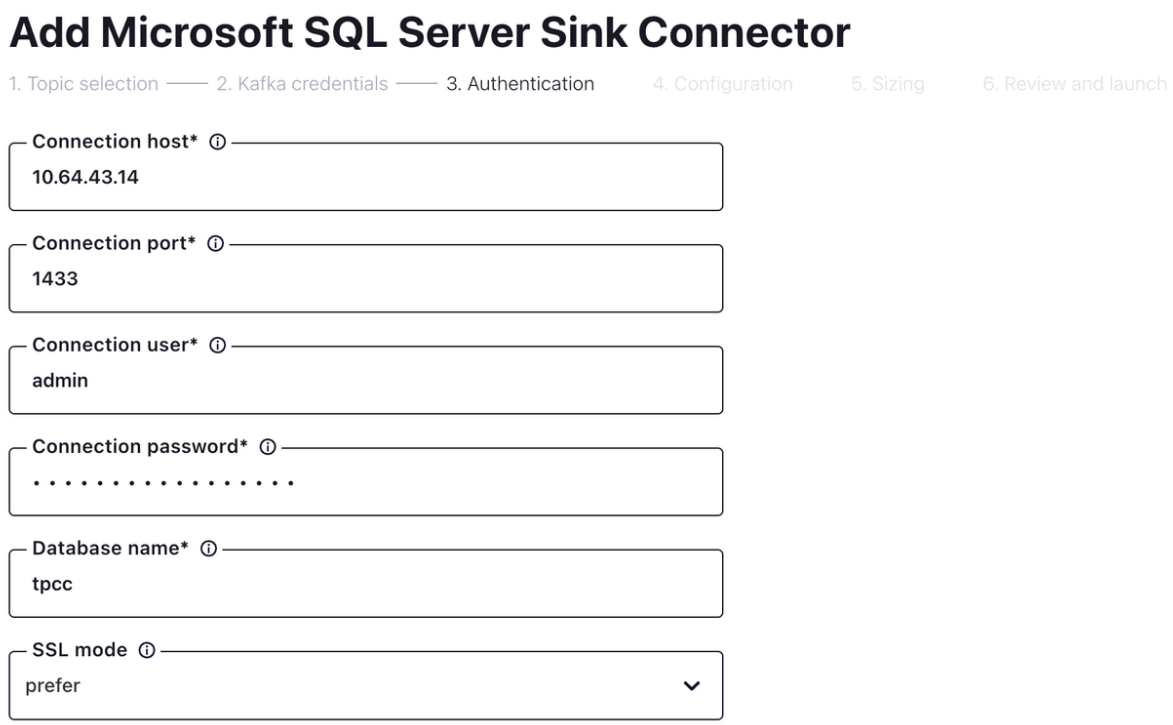

Figure 126: Authentication

4. Fill in the connection and authentication information. Then go to the next page.

5. On the **Configuration** page, configure the following fields and click **Continue**.

Field	Value
Input Kafka record value format	AVRO
Insert mode	UPSERT
Auto create table	true
Auto add columns	true
PK mode	record_key
Input Kafka record key format	AVRO
Delete on null	true

6. After configuration, click **Continue**. Wait until the connector status becomes **Running**, which might take several minutes.

Run Cancel | Disconnect Change Connection | tpcc

```
SELECT TOP (1000) [o_id]
      ,[o_d_id]
      ,[o_w_id]
      ,[o_c_id]
      ,[o_entry_d]
      ,[o_carrier_id]
      ,[o_ol_cnt]
      ,[o_all_local]
  FROM [tpcc].[dbo].[tidb_tpcc_orders]
```

Results Messages

	o_id	o_d_id	o_w_id	o_c_id	o_entry_d	o_carrier_id	o_ol_cnt	o_all_local
1	1	1	1	1860	2022-06-22 22:08:06	3	6	1

Figure 127: Results

7. Connect SQL Server and observe the data. You can see that the incremental data has been replicated to SQL Server, as shown in the preceding figure. Data integration with SQL Server is done.

7.5.3 Integrate Data with Apache Kafka and Apache Flink

This document describes how to replicate TiDB data to Apache Kafka and Apache Flink using TiCDC. The organization of this document is as follows:

1. Quickly deploy a TiDB cluster with TiCDC included, and create a Kafka cluster and a Flink cluster.
2. Create a changefeed that replicates data from TiDB to Kafka.
3. Write data to TiDB using go-tpc.
4. Observe data on Kafka console consumer and check that the data is replicated to a specified Kafka topic.
5. (Optional) Configure the Flink cluster to consume Kafka data.

The preceding steps are performed in a lab environment. You can also deploy a cluster in a production environment by referring to these steps.

7.5.3.1 Step 1. Set up the environment

1. Deploy a TiDB cluster with TiCDC included.

   In a lab or testing environment, you can deploy a TiDB cluster with TiCDC included quickly by using TiUP Playground.

   ```
   tiup playground --host 0.0.0.0 --db 1 --pd 1 --kv 1 --tiflash 0 --ticdc
       ↪ 1
   # View cluster status
   tiup status
   ```

   If TiUP is not installed yet, refer to Install TiUP. In a production environment, you can deploy a TiCDC as instructed in Deploy TiCDC.

2. Create a Kafka cluster.

   - Lab environment: refer to Apache Kafka Quickstart to start a Kafka cluster.
   - Production environment: refer to Running Kafka in Production to deploy a Kafka production cluster.

3. (Optional) Create a Flink cluster.

   - Lab environment: refer to Apache Flink First steps to start a Flink cluster.
   - Production environment: refer to Apache Kafka Deployment to deploy a Flink production cluster.

7.5.3.2 Step 2. Create a Kafka changefeed

1. Create a changefeed configuration file.

   As required by Flink, incremental data of each table must be sent to an independent topic, and a partition must be dispatched for each event based on the primary key value. Therefore, you need to create a changefeed configuration file `changefeed.conf` with the following contents:

   ```
   [sink]
   dispatchers = [
   {matcher = ['*.*'], topic = "tidb_{schema}_{table}", partition="index-
       ↪ value"},
   ]
   ```

   For detailed description of `dispatchers` in the configuration file, see Customize the rules for Topic and Partition dispatchers of Kafka Sink.

2. Create a changefeed to replicate incremental data to Kafka:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed create --server="http
    ↪ ://127.0.0.1:8300" --sink-uri="kafka://127.0.0.1:9092/kafka-topic
    ↪ -name?protocol=canal-json" --changefeed-id="kafka-changefeed" --
    ↪ config="changefeed.conf"
```

- If the changefeed is successfully created, changefeed information, such as changefeed ID, is displayed, as shown below:

```
Create changefeed successfully!
ID: kafka-changefeed
Info: {... changfeed info json struct ...}
```

- If no result is returned after you run the command, check the network connectivity between the server where you run the command and the Kafka machine specified in the sink URI.

In a production environment, a Kafka cluster has multiple broker nodes. Therefore, you can add the addresses of multiple brokers to the sink UIR. This ensures stable access to the Kafka cluster. When the Kafka cluster is down, the changefeed still works. Suppose that a Kafka cluster has three broker nodes, with IP addresses being 127.0.0.1:9092, 127.0.0.2:9092, and 127.0.0.3:9092, respectively. You can create a changefeed with the following sink URI.

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed create --server="http
    ↪ ://127.0.0.1:8300" --sink-uri="kafka
    ↪ ://127.0.0.1:9092,127.0.0.2:9092,127.0.0.3:9092/kafka-topic-name?
    ↪ protocol=canal-json&partition-num=3&replication-factor=1&max-
    ↪ message-bytes=1048576" --config="changefeed.conf"
```

3. After creating the changefeed, run the following command to check the changefeed status:

```
tiup cdc:v<CLUSTER_VERSION> cli changefeed list --server="http
    ↪ ://127.0.0.1:8300"
```

You can refer to Manage TiCDC Changefeeds to manage the changefeed.

7.5.3.3 Step 3. Write data to generate change logs

After the preceding steps are done, TiCDC sends change logs of incremental data in the TiDB cluster to Kafka. This section describes how to write data into TiDB to generate change logs.

1. Simulate service workload.

To generate change logs in a lab environment, you can use go-tpc to write data to the TiDB cluster. Specifically, run the following command to use TiUP bench to create a `tpcc` database and write data to this new database.

```
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 prepare
tiup bench tpcc -H 127.0.0.1 -P 4000 -D tpcc --warehouses 4 run --time
    ↪ 300s
```

For more details about go-tpc, refer to How to Run TPC-C Test on TiDB.

2. Consume data in the Kafka topic.

   When a changefeed works normally, it writes data to the Kafka topic. Run `kafka-console-consumer.sh`. You can see that data is successfully written to the Kafka topic.

```
./bin/kafka-console-consumer.sh --bootstrap-server 127.0.0.1:9092 --
    ↪ from-beginning --topic `${topic-name}`
```

At this time, incremental data of the TiDB database is successfully replicated to Kafka. Next, you can use Flink to consume Kafka data. Alternatively, you can develop a Kafka consumer client yourself for specific service scenarios.

7.5.3.4 (Optional) Step 4. Configure Flink to consume Kafka data

1. Install a Flink Kafka connector.

   In the Flink ecosystem, a Flink Kafka connector is used to consume Kafka data and output data to Flink. However, Flink Kafka connectors are not automatically installed. To use it, add a Flink Kafka connector and its dependencies to the Flink installation directory after installing Flink. Specifically, download the following jar files to the `lib` directory of the Flink installation directory. If you have already run the Flink cluster, restart it to load the new plugin.

   - flink-connector-kafka-1.15.0.jar
   - flink-sql-connector-kafka-1.15.0.jar
   - kafka-clients-3.2.0.jar

2. Create a table.

   In the directory where Flink is installed, run the following command to start the Flink SQL client:

```
[root@flink flink-1.15.0]# ./bin/sql-client.sh
```

   Then, run the following command to create a table named `tpcc_orders`.

```
CREATE TABLE tpcc_orders (
    o_id INTEGER,
    o_d_id INTEGER,
    o_w_id INTEGER,
    o_c_id INTEGER,
    o_entry_d STRING,
    o_carrier_id INTEGER,
    o_ol_cnt INTEGER,
    o_all_local INTEGER
) WITH (
'connector' = 'kafka',
'topic' = 'tidb_tpcc_orders',
'properties.bootstrap.servers' = '127.0.0.1:9092',
'properties.group.id' = 'testGroup',
'format' = 'canal-json',
'scan.startup.mode' = 'earliest-offset',
'properties.auto.offset.reset' = 'earliest'
)
```

Replace `topic` and `properties.bootstrap.servers` with the actual values in the environment.

3. Query data of the table.

   Run the following command to query data of the `tpcc_orders` table:

```
SELECT * FROM tpcc_orders;
```

   After this command is executed, you can see that there is new data in the table, as shown in the following figure.

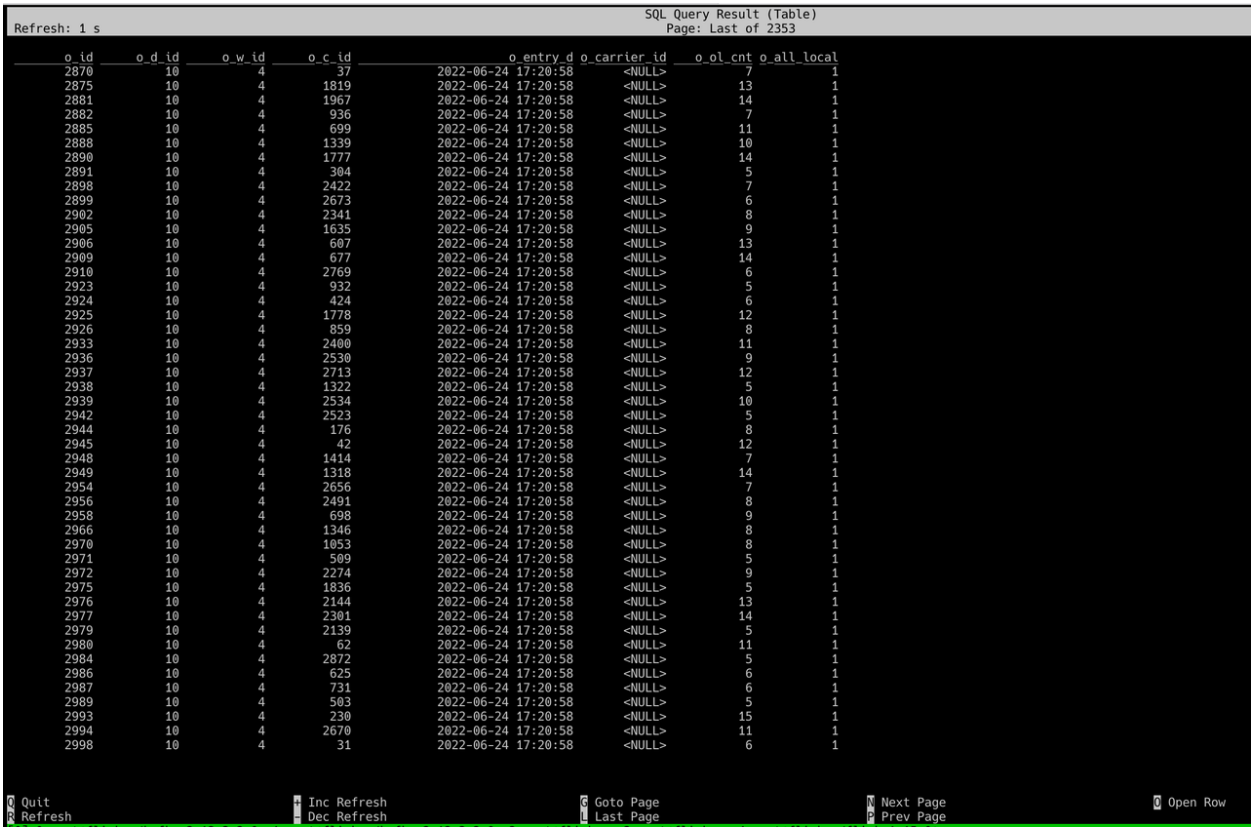

Figure 128: SQL query result

Data integration with Kafka is done.

7.5.4 Architecture and Principles of TiCDC

7.5.4.1 TiCDC architecture

Consisting of multiple TiCDC nodes, a TiCDC cluster uses a distributed and stateless architecture. The design of TiCDC and its components is as follows:

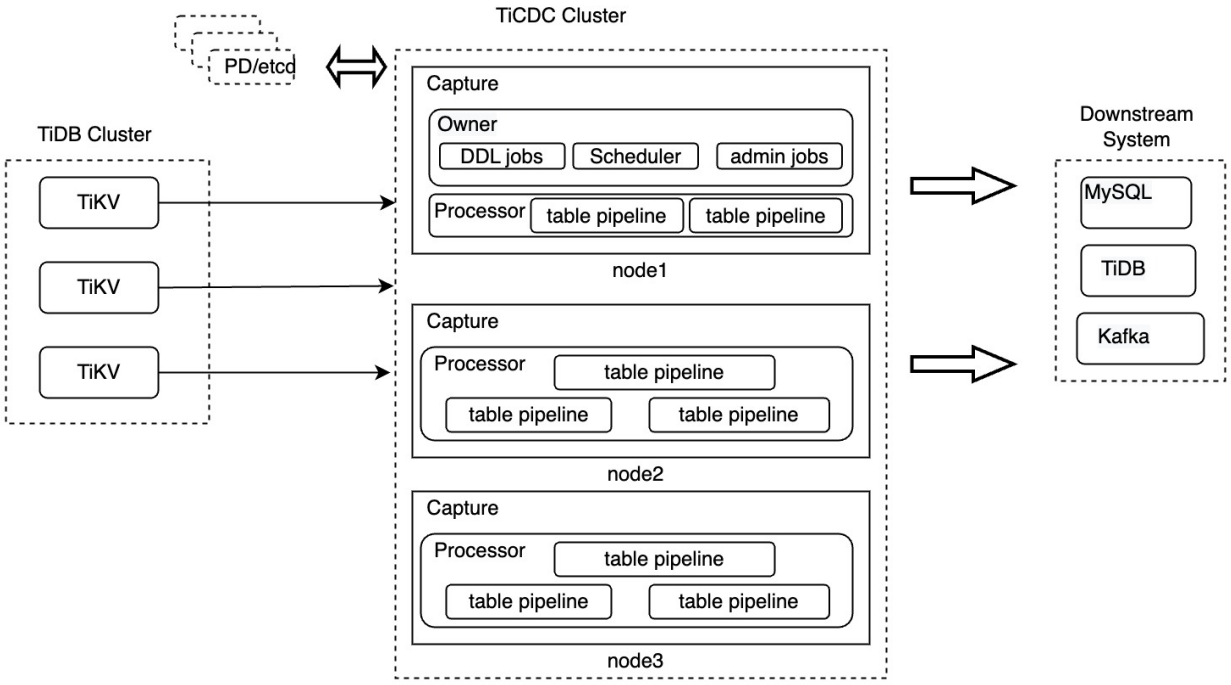

Figure 129: TiCDC architecture

7.5.4.2 TiCDC components

In the preceding diagram, a TiCDC cluster consists of multiple nodes running TiCDC instances. Each TiCDC instance carries a Capture process. One of the Capture processes is elected as the owner Capture, which is responsible for scheduling workload, replicating DDL statements, and performing management tasks.

Each Capture process contains one or multiple Processor threads for replicating data from tables in the upstream TiDB. Because table is the minimum unit of data replication in TiCDC, a Processor is composed of multiple table pipelines.

Each pipeline contains the following components: Puller, Sorter, Mounter, and Sink.

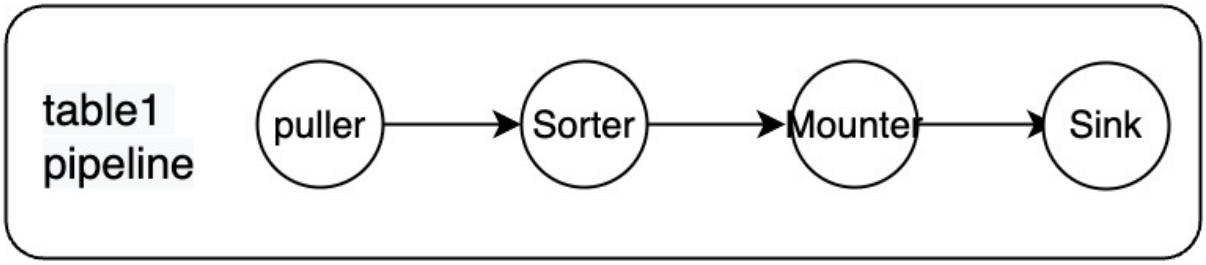

Figure 130: TiCDC architecture

These components work in serial with each other to complete the replication process, including pulling data, sorting data, loading data, and replicating data from the upstream to the downstream. The components are described as follows:

- Puller: pulls DDL and row changes from TiKV nodes.
- Sorter: sorts the changes received from TiKV nodes in ascending order of timestamps.
- Mounter: converts the changes into a format that TiCDC sink can process based on the schema information.
- Sink: replicates the changes to the downstream system.

To realize high availability, each TiCDC cluster runs multiple TiCDC nodes. These nodes regularly report their status to the etcd cluster in PD, and elect one of the nodes as the owner of the TiCDC cluster. The owner node schedules data based on the status stored in etcd and writes the scheduling results to etcd. The Processor completes tasks according to the status in etcd. If the node running the Processor fails, the cluster schedules tables to other nodes. If the owner node fails, the Capture processes in other nodes will elect a new owner. See the following figure:

TiCDC architecture

7.5.4.3 Changefeeds and tasks

Changefeed and Task in TiCDC are two logical concepts. The specific description is as follows:

- Changefeed: Represents a replication task. It carries the information about the tables to be replicated and the downstream.
- Task: After TiCDC receives a replication task, it splits this task into several subtasks. Such a subtask is called Task. These Tasks are assigned to the Capture processes of the TiCDC nodes for processing.

For example:

```
cdc cli changefeed create --server="http://127.0.0.1:8300" --sink-uri="kafka
    ↪ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&partition-num=6&max-
    ↪ message-bytes=67108864&replication-factor=1"
cat changefeed.toml
......
[sink]
dispatchers = [
    {matcher = ['test1.tab1', 'test2.tab2'], topic = "{schema}_{table}"},
    {matcher = ['test3.tab3', 'test4.tab4'], topic = "{schema}_{table}"},
]
```

For a detailed description of the parameters in the preceding `cdc cli changefeed create` command, see TiCDC Changefeed Configuration Parameters.

The preceding `cdc cli changefeed create` command creates a changefeed task that replicates `test1.tab1`, `test1.tab2`, `test3.tab3`, and `test4.tab4` to the Kafka cluster. The processing flow after TiCDC receives this command is as follows:

1. TiCDC sends this task to the owner Capture process.
2. The owner Capture process saves information about this changefeed task in etcd in PD.
3. The owner Capture process splits the changefeed task into several Tasks and notifies other Capture processes of the Tasks to be completed.
4. The Capture processes start pulling data from TiKV nodes, process the data, and complete replication.

The following is the TiCDC architecture diagram with Changefeed and Task included:

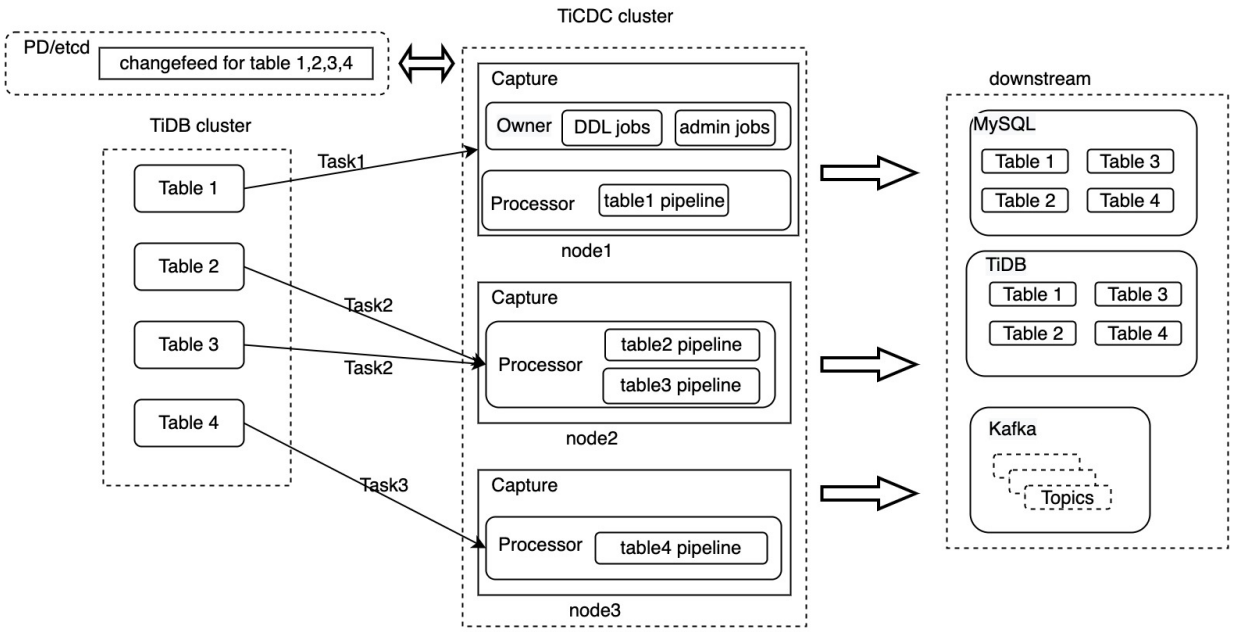

Figure 131: TiCDC architecture

In the preceding diagram, a changefeed is created to replicate four tables to downstream. This changefeed is split into three Tasks, which are sent to the three Capture processes respectively in the TiCDC cluster. After TiCDC processes the data, the data is replicated to the downstream system.

TiCDC supports replicating data to MySQL, TiDB, and Kafka databases. The preceding diagram only illustrates the process of data transfer at the changefeed level. The following

sections describe in detail how TiCDC processes data, using Task1 that replicates table `table1` as an example.

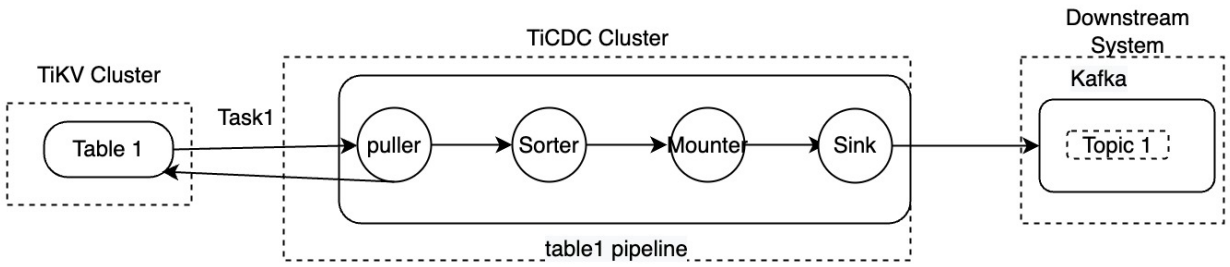

Figure 132: TiCDC architecture

1. Push data: When a data change occurs, TiKV pushes data to the Puller module.
2. Scan incremental data: The Puller module pulls data from TiKV when it finds the data changes received not continuous.
3. Sort data: The Sorter module sorts the data received from TiKV based on the timestamps and sends the sorted data to the Mounter module.
4. Mount data: After receiving the data changes, the Mounter module loads the data in a format that TiCDC sink can understand.
5. Replicate data: The Sink module replicates the data changes to the downstream.

The upstream of TiCDC is the distributed relational database TiDB that supports transactions. When TiCDC replicates data, it should ensure the consistency of data and that of transactions when replicating multiple tables, which is a great challenge. The following sections introduce the key technologies and concepts used by TiCDC to address this challenge.

7.5.4.4 Key concepts of TiCDC

For the downstream relational databases, TiCDC ensures the consistency of transactions in a single table and eventual transaction consistency in multiple tables. In addition, TiCDC ensures that any data change that has occurred in the upstream TiDB cluster can be replicated to the downstream at least once.

7.5.4.4.1 Architecture-related concepts

- Capture: The process that runs the TiCDC node. Multiple Capture processes constitute a TiCDC cluster. Each Capture process is responsible for replicating data changes in TiKV, including receiving and actively pulling data changes, and replicating the data to the downstream.

- Capture Owner: The owner Capture among multiple Capture processes. Only one owner role exists in a TiCDC cluster at a time. The Capture Owner is responsible for scheduling data within the cluster.
- Processor: The logical thread inside Capture. Each Processor is responsible for processing the data of one or more tables in the same replication stream. A Capture node can run multiple Processors.
- Changefeed: A task that replicates data from an upstream TiDB cluster to a downstream system. A changefeed contains multiple Tasks, and each Task is processed by a Capture node.

7.5.4.4.2 Timestamp-related concepts

TiCDC introduces a series of timestamps (TS) to indicate the status of data replication. These timestamps are used to ensure that data is replicated to the downstream at least once and that the consistency of data is guaranteed.

ResolvedTS

This timestamp exists in both TiKV and TiCDC.

- ResolvedTS in TiKV: Represents the start time of the earliest transaction in a Region leader, that is, `ResolvedTS` = max(`ResolvedTS`, min(`StartTS`)). Because a TiDB cluster contains multiple TiKV nodes, the minimum ResolvedTS of the Region leader on all TiKV nodes is called the global ResolvedTS. The TiDB cluster ensures that all transactions before the global ResolvedTS are committed. Alternatively, you can assume that there are no uncommitted transactions before this timestamp.

- ResolvedTS in TiCDC:

    - table ResolvedTS: Each table has a table-level ResolvedTS, which indicates all data changes in the table that are smaller than the Resolved TS have been received. To make it simple, this timestamp is the same as the minimum value of the ResolvedTS of all Regions corresponding to this table on the TiKV node.
    - global ResolvedTS: The minimum ResolvedTS of all Processors on all TiCDC nodes. Because each TiCDC node has one or more Processors, each Processor corresponds to multiple table pipelines.

  For TiCDC, the ResolvedTS sent by TiKV is a special event in the format of `<resolvedTS: timestamp>`. In general, the ResolvedTS satisfies the following constraints:

```
table ResolvedTS >= global ResolvedTS
```

CheckpointTS

This timestamp exists only in TiCDC. It means that the data changes that occur before this timestamp have been replicated to the downstream system.

- table CheckpointTS: Because TiCDC replicates data in tables, the table checkpointTS indicates all data changes that occur before CheckpointTS have been replicated at the table level.
- processor CheckpointTS: Indicates the minimum table CheckpointTS on a Processor.
- global CheckpointTS: Indicates the minimum CheckpointTS among all Processors.

Generally, a checkpointTS satisfies the following constraint:

```
table CheckpointTS >= global CheckpointTS
```

Because TiCDC only replicates data smaller than the global ResolvedTS to the downstream, the complete constraint is as follows:

```
table ResolvedTS >= global ResolvedTS >= table CheckpointTS >= global
    ↪ CheckpointTS
```

After data changes and transactions are committed, the ResolvedTS on the TiKV node will continue to advance, and the Puller module on the TiCDC node keeps receiving data pushed by TiKV. The Puller module also decides whether to scan incremental data based on the data changes it has received, which ensures that all data changes are sent to the TiCDC node.

The Sorter module sorts data received by the Puller module in ascending order according to the timestamp. This process ensures data consistency at the table level. Next, the Mounter module assembles the data changes from the upstream into a format that the Sink module can consume, and sends it to the Sink module. The Sink module replicates the data changes between the CheckpointTS and the ResolvedTS to the downstream in the order of the timestamp, and advances the checkpointTS after the downstream receives the data changes.

The preceding sections only cover data changes of DML statements and do not include DDL statements. The following sections introduce the timestamp related to DDL statements.

Barrier TS

Barrier TS is generated when there are DDL change events or a Syncpoint is used.

- DDL change events: Barrier TS ensures that all changes before the DDL statement are replicated to the downstream. After this DDL statement is executed and replicated, TiCDC starts replicating other data changes. Because DDL statements are processed by the Capture Owner, the Barrier TS corresponding to a DDL statement is only generated by the owner node.
- Syncpoint: When you enable the Syncpoint feature of TiCDC, a Barrier TS is generated by TiCDC according to the `sync-point-interval` you specified. When all table changes before this Barrier TS are replicated, TiCDC inserts the current global CheckpointTS as the primary TS to the table recording tsMap in downstream. Then TiCDC continues data replication.

After a Barrier TS is generated, TiCDC ensures that only data changes that occur before this Barrier TS are replicated to downstream. Before these data changes are replicated to downstream, the replication task does not proceed. The owner TiCDC checks whether all target data has been replicated by continuously comparing the global CheckpointTS and the Barrier TS. If the global CheckpointTS equals to the Barrier TS, TiCDC continues replication after performing a designated operation (such as executing a DDL statement or recording the global CheckpointTS downstream). Otherwise, TiCDC waits for all data changes that occur before the Barrier TS to be replicated to the downstream.

7.5.4.5 Major processes

This section describes the major processes of TiCDC to help you better understand its working principles.

Note that the following processes occur only within TiCDC and are transparent to users. Therefore, you do not need to care about which TiCDC node you are starting.

7.5.4.5.1 Start TiCDC

- For a TiCDC node that is not an owner, it works as follows:

    1. Starts the Capture process.
    2. Starts the Processor.
    3. Receives the Task scheduling command executed by the Owner.
    4. Starts or stops tablePipeline according to the scheduling command.

- For an owner TiCDC node, it works as follows:

    1. Starts the Capture process.
    2. The node is elected as the Owner and the corresponding thread is started.
    3. Reads the changefeed information.
    4. Starts the changefeed management process.
    5. Reads the schema information in TiKV according to the changefeed configuration and the latest CheckpointTS to determine the tables to be replicated.
    6. Reads the list of tables currently replicated by each Processor and distributes the tables to be added.
    7. Updates the replication progress.

7.5.4.5.2 Stop TiCDC

Usually, you stop a TiCDC node when you need to upgrade it or perform some planned maintenance operations. The process of stopping a TiCDC node is as follows:

1. The node receives the command to stop itself.
2. The node sets its service status to unavailable.

3. The node stops receiving new replication tasks.
4. The node notifies the Owner node to transfer its data replication tasks to other nodes.
5. The node stops after the replication tasks are transferred to other nodes.

7.5.5 TiCDC Data Replication Capabilities

TiCDC (TiDB Change Data Capture) is a core component in the TiDB ecosystem for real-time data replication. This document provides a detailed explanation of TiCDC data replication capabilities.

7.5.5.1 How TiCDC works

- TiCDC listens to TiKV change logs (Raft logs) and converts row-level data changes (`INSERT`, `UPDATE`, and `DELETE` operations) into downstream-compatible SQL statements. TiCDC does not rely on the original SQL statements executed on the upstream database. For details, see how TiCDC processes data changes.
- TiCDC generates logical operations (such as `INSERT`, `UPDATE`, and `DELETE`) equivalent to SQL semantics, rather than restoring the original SQL statements executed on the upstream database one by one. For details, see how TiCDC processes data changes.
- TiCDC ensures eventual consistency of transactions. With redo log enabled, TiCDC can guarantee eventual consistency in disaster recovery scenarios. With Syncpoint enabled, TiCDC supports consistent snapshot reads and data consistency validation.

7.5.5.2 Supported downstream systems

TiCDC supports replicating data to various downstream systems, including the following:

- TiDB database or other MySQL-compatible databases
- Apache Kafka
- Message Queue (MQ)-type sinks, such as Pulsar
- Storage services (Amazon S3, GCS, Azure Blob Storage, and NFS)
- Snowflake, ksqlDB, SQL Server via Confluent Cloud integration
- Apache Flink for consuming Kafka-replicated data

7.5.5.3 Scope of data replication

TiCDC supports the following types of upstream data changes:

- **Supported:**
  - DDL and DML statements (excluding system tables).

- Index operations (`ADD INDEX`, `CREATE INDEX`): to reduce the impact on changefeed replication latency, if the downstream is TiDB, TiCDC asynchronously executes the `ADD INDEX` and `CREATE INDEX` DDL operations.
- Foreign key constraint DDL statements (`ADD FOREIGN KEY`): TiCDC does **not** replicate upstream system variable settings. You need to manually configure `foreign_key_checks` in the downstream to determine whether the downstream foreign key constraint check is enabled. Additionally, when writing data to the downstream, TiCDC automatically enables the session-level setting `SET SESSION foreign_key_checks = OFF;`. Therefore, even if global foreign key checks are enabled in the downstream, the data written by TiCDC will not trigger foreign key constraint validation.

- **Not supported**:
  - DDL and DML statements executed in upstream system tables (including `mysql.*` and `information_schema.*`).
  - DDL and DML statements executed in upstream temporary tables.
  - DQL (Data Query Language) and DCL (Data Control Language) statements.

7.5.5.4 Limitations

- TiCDC does not support certain scenarios. For details, see unsupported scenarios.
- TiCDC only verifies the integrity of upstream data changes. It does not validate whether the changes conform to upstream or downstream constraints. If the data violates downstream constraints, TiCDC will return an error when writing to the downstream.

  For example: When a changefeed is configured to filter out all DDL events, if the upstream executes a `DROP COLUMN` operation but continues to write `INSERT` statements involving that column, TiCDC will fail to replicate these DML changes to the downstream because of table schema mismatches.

7.5.6 TiCDC Server Configurations

This document describes the CLI and configuration file parameters used in TiCDC.

7.5.6.1 `cdc server` CLI parameters

The following are descriptions of options available in a `cdc server` command:

- `addr`: The listening address of TiCDC, the HTTP API address, and the Prometheus address of the TiCDC service. The default value is `127.0.0.1:8300`.
- `advertise-addr`: The advertised address via which clients access TiCDC. If unspecified, the value is the same as that of `addr`.

- `pd`: A comma-separated list of PD endpoints.
- `config`: The address of the configuration file that TiCDC uses (optional). This option is supported since TiCDC v5.0.0. This option can be used in the TiCDC deployment since TiUP v1.4.0. For detailed configuration description, see TiCDC Changefeed Configurations
- `data-dir`: Specifies the directory that TiCDC uses when it needs to use disks to store files. The sort engine used by TiCDC and redo logs use this directory to store temporary files. It is recommended to ensure that the free disk space for this directory is greater than or equal to 500 GiB. If you are using TiUP, you can configure `data_dir` in the `cdc_servers` section, or directly use the default `data_dir` path in `global`.
- `gc-ttl`: The TTL (Time To Live) of the service level `GC safepoint` in PD set by TiCDC, and the duration that the replication task can suspend, in seconds. The default value is `86400`, which means 24 hours. Note: Suspending of the TiCDC replication task affects the progress of TiCDC GC safepoint, which means that it affects the progress of upstream TiDB GC, as detailed in Complete Behavior of TiCDC GC safepoint.
- `log-file`: The path to which logs are output when the TiCDC process is running. If this parameter is not specified, logs are written to the standard output (stdout).
- `log-level`: The log level when the TiCDC process is running. The default value is `"info"`.
- `ca`: Specifies the path of the CA certificate file in PEM format for TLS connection (optional).
- `cert`: Specifies the path of the certificate file in PEM format for TLS connection (optional).
- `cert-allowed-cn`: Specifies the path of the common name in PEM format for TLS connection (optional).
- `key`: Specifies the path of the private key file in PEM format for TLS connection (optional).
- `tz`: Time zone used by the TiCDC service. TiCDC uses this time zone when it internally converts time data types such as `TIMESTAMP` or when it replicates data to the downstream. The default is the local time zone in which the process runs. If you specify `time-zone` (in `sink-uri`) and `tz` at the same time, the internal TiCDC processes use the time zone specified by `tz`, and the sink uses the time zone specified by `time-zone` for replicating data to the downstream. Make sure that the time zone specified by `tz` is the same as that specified by `time-zone` (in `sink-uri`).
- `cluster-id`: (optional) The ID of the TiCDC cluster. The default value is `default`. `cluster-id` is the unique identifier of a TiCDC cluster. TiCDC nodes with the same `cluster-id` belong to the same cluster. The length of a `cluster-id` is 128 characters at most. `cluster-id` must follow the pattern of `^[a-zA-Z0-9]+(-[a-zA-Z0-9]+)*$` and cannot be one of the following: `owner`, `capture`, `task`, `changefeed`, `job`, and `meta`.

7.5.6.2 `cdc server` configuration file parameters

The following describes the configuration file specified by the `config` option in the `cdc server` command. You can find the default configuration file in `pkg/cmd/util/ticdc`

↪ .toml.

7.5.6.2.1 addr

- Example: "127.0.0.1:8300"

7.5.6.2.2 advertise-addr

- Example: ""

7.5.6.2.3 log-file

- Example: ""

7.5.6.2.4 log-level

- Example: "info"

7.5.6.2.5 data-dir

- Example: ""

7.5.6.2.6 gc-ttl

- Example: 86400 (24h)

7.5.6.2.7 tz

- Example: "System"

7.5.6.2.8 cluster-id

- Example: "default"

7.5.6.2.9 gc-tuner-memory-threshold

- Specifies the maximum memory threshold for tuning GOGC. Setting a smaller threshold increases the GC frequency. Setting a larger threshold reduces GC frequency and consumes more memory resources for the TiCDC process. Once the memory usage exceeds this threshold, GOGC Tuner stops working.
- Default value: 0, indicating that GOGC Tuner is disabled
- Unit: Bytes

7.5.6.2.10 security

`ca-path`

- Example: `""`

`cert-path`

- Example: `""`

`key-path`

- Example: `""`

`mtls`

- Controls whether to enable the TLS client authentication.
- Default value: `false`

`client-user-required`

- Controls whether to use username and password for client authentication. The default value is false.
- Default value: `false`

`client-allowed-user`

- Lists the usernames that are allowed for client authentication. Authentication requests with usernames not in this list will be rejected.
- Default value: `null`

7.5.6.2.11 capture-session-ttl

- Specifies the session duration between TiCDC and etcd services. This parameter is optional.
- Default value: `10`
- Unit: Seconds

7.5.6.2.12 `owner-flush-interval`

- Specifies the interval at which the Owner module in the TiCDC cluster attempts to push the replication progress. This parameter is optional and its default value is `50000000` nanoseconds (that is, 50 milliseconds).
- You can configure this parameter in two ways: specifying only the number (for example, configuring it as `40000000` represents 40000000 nanoseconds, which is 40 milliseconds), or specifying both the number and unit (for example, directly configuring it as `40ms`).
- Default value: `50000000`, that is, 50 milliseconds

7.5.6.2.13 `processor-flush-interval`

- Specifies the interval at which the Processor module in the TiCDC cluster attempts to push the replication progress. This parameter is optional and its default value is `50000000` nanoseconds (that is, 50 milliseconds).
- The configuration method of this parameter is the same as that of `owner-flush-interval`.
- Default value: `50000000`, that is, 50 milliseconds

7.5.6.2.14 log

`error-output`

- Specifies the output location for internal error logs of the zap log module. This parameter is optional.
- Default value: `"stderr"`

log.file

`max-size`

- Specifies the maximum size of a single log file. This parameter is optional.
- Default value: `300`
- Unit: MiB

`max-days`

- Specifies the maximum number of days to retain log files. This parameter is optional.
- Default value: `0`, indicating never to delete

`max-backups`

- Specifies the number of log files to retain. This parameter is optional.
- Default value: `0`, indicating to keep all log files

7.5.6.2.15 sorter

`cache-size-in-mb`

- Specifies the size of the shared pebble block cache in the Sorter module for the 8 pebble DBs started by default.
- Default value: `128`
- Unit: MiB

`sorter-dir`

- Specifies the directory where sorter files are stored relative to the data directory (`data-dir`). This parameter is optional.
- Default value: `"/tmp/sorter"`

7.5.6.2.16 kv-client

`worker-concurrent`

- Specifies the number of threads that can be used in a single Region worker. This parameter is optional.
- Default value: `8`

`worker-pool-size`

- Specifies the number of threads in the shared thread pool of TiCDC, mainly used for processing KV events. This parameter is optional.
- Default value: `0`, indicating that the default pool size is twice the number of CPU cores

`region-retry-duration`

- Specifies the retry duration of Region connections. This parameter is optional.
- You can configure this parameter in two ways:
  - Specify only the number, for example, `50000000` represents 50000000 nanoseconds (50 milliseconds)
  - Specify both the number and the unit, for example, `50ms`
- Default value: `60000000000` (1 minute)

7.5.7 CLI and Configuration Parameters of TiCDC Changefeeds

7.5.7.1 Changefeed CLI parameters

This section introduces the command-line parameters of TiCDC changefeeds by illustrating how to create a replication (changefeed) task:

```
cdc cli changefeed create --server=http://10.0.10.25:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"upstream_id":7178706266519722477,"namespace":"default","id":"simple-
    ↪ replication-task","sink_uri":"mysql://root:xxxxx@127.0.0.1:4000/?time
    ↪ -zone=","create_time":"2025-01-17T15:05:46.679218+08:00","start_ts
    ↪ ":438156275634929669,"engine":"unified","config":{"case_sensitive":
    ↪ false,"enable_old_value":true,"force_replicate":false,"ignore_
    ↪ ineligible_table":false,"check_gc_safe_point":true,"enable_sync_point
    ↪ ":true,"bdr_mode":false,"sync_point_interval":30000000000,"sync_point
    ↪ _retention":3600000000000,"filter":{"rules":["test.*"],"event_filters
    ↪ ":null},"mounter":{"worker_num":16},"sink":{"protocol":"","schema_
    ↪ registry":"","csv":{"delimiter":",","quote":"\"","null":"\\N","
    ↪ include_commit_ts":false},"column_selectors":null,"transaction_
    ↪ atomicity":"none","encoder_concurrency":16,"terminator":"\r\n","date_
    ↪ separator":"none","enable_partition_separator":false},"consistent":{"
    ↪ level":"none","max_log_size":64,"flush_interval":2000,"storage
    ↪ ":""}},"state":"normal","creator_version":"v8.5.1"}
```

- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.
- `--sink-uri`: The downstream address of the replication task. Configure `--sink-uri` according to the following format. Currently, the scheme supports `mysql`, `tidb`, and `kafka`.

  ```
  [scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
  ```

  When the sink URI parameters contain special characters such as `! * ' ( ) ; : @ ↪ & = + $ , / ? % # [ ]`, you need to escape the special characters, for example, in URI Encoder.
- `--start-ts`: Specifies the starting TSO of the changefeed. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.

- `--target-ts`: Specifies the ending TSO of the changefeed. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--config`: Specifies the configuration file of the changefeed.

7.5.7.2 Changefeed configuration parameters

This section introduces the configuration of a replication task.

7.5.7.2.1 `memory-quota`

- Specifies the memory quota (in bytes) that can be used in the capture server by the sink manager. If the value is exceeded, the overused part will be recycled by the go runtime.
- Default value: `1073741824` (1 GiB)

7.5.7.2.2 `case-sensitive`

- Specifies whether the database names and tables in the configuration file are case-sensitive. Starting from v6.5.6, v7.1.3, and v7.5.0, the default value changes from `true` to `false`.
- This configuration item affects configurations related to filter and sink.
- Default value: `false`

7.5.7.2.3 `force-replicate`

- Specifies whether to forcibly replicate tables without a valid index.
- Default value: `false`

7.5.7.2.4 `enable-sync-point` New in v6.3.0

- Specifies whether to enable the Syncpoint feature, which is supported starting from v6.3.0 and is disabled by default.
- Starting from v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.
- This configuration item only takes effect if the downstream is TiDB.
- Default value: `false`

7.5.7.2.5 `sync-point-interval`

- Specifies the interval at which Syncpoint aligns the upstream and downstream snapshots.
- This configuration item only takes effect if the downstream is TiDB.
- The format is `"h m s"`. For example, `"1h30m30s"`.
- Default value: `"10m"`
- Minimum value: `"30s"`

7.5.7.2.6 `sync-point-retention`

- Specifies how long the data is retained by Syncpoint in the downstream table. When this duration is exceeded, the data is cleaned up.
- This configuration item only takes effect if the downstream is TiDB.
- The format is `"h m s"`. For example, `"24h30m30s"`.
- Default value: `"24h"`

7.5.7.2.7 `sql-mode` New in v6.5.6, v7.1.3, and v7.5.0

- Specifies the SQL mode used when parsing DDL statements. Multiple modes are separated by commas.
- Default value: `"ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION"`, which is the same as the default SQL mode of TiDB

7.5.7.2.8 `bdr-mode`

- To set up BDR (Bidirectional replication) clusters using TiCDC, modify this parameter to `true` and set the TiDB clusters to BDR mode. For more information, see Bidirectional Replication.
- Default value: `false`, indicating that bi-directional replication (BDR) mode is not enabled

7.5.7.2.9 `changefeed-error-stuck-duration`

- Specifies the duration for which the changefeed is allowed to automatically retry when internal errors or exceptions occur.
- The changefeed enters the failed state if internal errors or exceptions occur in the changefeed and persist longer than the duration set by this parameter.
- When the changefeed is in the failed state, you need to restart the changefeed manually for recovery.
- The format is `"h m s"`. For example, `"1h30m30s"`.
- Default value: `"30m"`

7.5.7.2.10 mounter

`worker-num`

- Specifies the number of threads with which the mounter decodes KV data.
- Default value: `16`

7.5.7.2.11 filter

`ignore-txn-start-ts`

- Ignores the transaction of specified start_ts.

`rules`

- Specifies the filter rules. For more information, see Syntax.

filter.event-filters

For more information, see Event filter rules.

`matcher`

- `matcher` is an allow list. `matcher = ["test.worker"]` means this rule only applies to the `worker` table in the `test` database.

`ignore-event`

- `ignore-event = ["insert"]` ignores `INSERT` events.
- `ignore-event = ["drop table", "delete"]` ignores the `DROP TABLE` DDL events and the `DELETE` DML events. Note that when a value in the clustered index column is updated in TiDB, TiCDC splits an `UPDATE` event into `DELETE` and `INSERT` events. TiCDC cannot identify such events as `UPDATE` events and thus cannot correctly filter out such events.

`ignore-sql`

- `ignore-sql = ["^drop", "add column"]` ignores DDLs that start with `DROP` or contain `ADD COLUMN`.

`ignore-delete-value-expr`

- `ignore-delete-value-expr = "name = 'john'"` ignores `DELETE` DMLs that contain the condition `name = 'john'`.

`ignore-insert-value-expr`

- `ignore-insert-value-expr = "id >= 100"` ignores `INSERT` DMLs that contain the condition `id >= 100`

`ignore-update-old-value-expr`

- `ignore-update-old-value-expr = "age < 18"` ignores `UPDATE` DMLs whose old value contains `age < 18`

`ignore-update-new-value-expr`

- `ignore-update-new-value-expr = "gender = 'male'"` ignores `UPDATE` DMLs whose new value contains `gender = 'male'`

7.5.7.2.12 scheduler

`enable-table-across-nodes`

- Allocate tables to multiple TiCDC nodes for replication on a per-Region basis.
- This configuration item only takes effect on Kafka changefeeds and is not supported on MySQL changefeeds.
- When `enable-table-across-nodes` is enabled, there are two allocation modes:
    1. Allocate tables based on the number of Regions, so that each TiCDC node handles roughly the same number of Regions. If the number of Regions for a table exceeds the value of `region-threshold`, the table will be allocated to multiple nodes for replication. The default value of `region-threshold` is `100000`.
    2. Allocate tables based on the write traffic, so that each TiCDC node handles roughly the same number of modified rows. Only when the number of modified rows per minute in a table exceeds the value of `write-key-threshold`, will this allocation take effect.

You only need to configure one of the two modes. If both `region-threshold` and `write-key-threshold` are configured, TiCDC prioritizes the traffic allocation mode, namely `write-key-threshold`.

- The value is `false` by default. Set it to `true` to enable this feature.
- Default value: `false`

`region-threshold`

- Default value: `100000`

`write-key-threshold`

- Default value: `0`, which means that the traffic allocation mode is not used by default

7.5.7.2.13 sink

`dispatchers`

- For the sink of MQ type, you can use dispatchers to configure the event dispatcher.
- Starting from v6.1.0, TiDB supports two types of event dispatchers: partition and topic.
- The matching syntax of matcher is the same as the filter rule syntax.
- This configuration item only takes effect if the downstream is MQ.
- When the downstream MQ is Pulsar, if the routing rule for `partition` is not specified as any of `ts`, `index-value`, `table`, or `default`, each Pulsar message will be routed using the string you set as the key. For example, if you specify the routing rule for a matcher as the string `code`, then all Pulsar messages that match that matcher will be routed with `code` as the key.

`column-selectors` New in v7.5.0

- Selects specific columns for replication. This only takes effect when the downstream is Kafka.

`protocol`

- Specifies the protocol format used for encoding messages.
- This configuration item only takes effect if the downstream is Kafka, Pulsar, or a storage service.
- When the downstream is Kafka, the protocol can be canal-json, avro, debezium, open-protocol, or simple.
- When the downstream is Pulsar, the protocol can only be canal-json.
- When the downstream is a storage service, the protocol can only be canal-json or csv.

`delete-only-output-handle-key-columns` New in v7.2.0

- Specifies the output of DELETE events. This parameter is valid only for canal-json and open-protocol protocols.
- This parameter is incompatible with `force-replicate`. If both this parameter and `force-replicate` are set to `true`, TiCDC reports an error when creating a changefeed.
- The Avro protocol is not controlled by this parameter and always outputs only the primary key columns or unique index columns.
- The CSV protocol is not controlled by this parameter and always outputs all columns.
- Default value: `false`, which means outputting all columns
- When you set it to `true`, only primary key columns or unique index columns are output.

`schema-registry`

- Specifies the schema registry URL.
- This configuration item only takes effect if the downstream is MQ.

`encoder-concurrency`

- Specifies the number of encoder threads used when encoding data.
- This configuration item only takes effect if the downstream is MQ.
- Default value: `32`

`enable-kafka-sink-v2`

> **Warning:**
>
> This configuration is an experimental feature. It is not recommended to use it in production environments.

- Specifies whether to enable kafka-sink-v2 that uses the kafka-go sink library.
- This configuration item only takes effect if the downstream is MQ.
- Default value: `false`

`only-output-updated-columns` New in v7.1.0

- Specifies whether to only output the updated columns.
- This configuration item only applies to the MQ downstream using the open-protocol and canal-json.
- Default value: `false`

`terminator`

- This configuration item is only used when you replicate data to storage sinks and can be ignored when replicating data to MQ or MySQL sinks.
- Specifies the row terminator, used for separating two data change events.
- Default value: `""`, which means `\r\n` is used

`date-separator`

- Specifies the date separator type used in the file directory. For more information, see Data change records.
- This configuration item only takes effect if the downstream is a storage service.
- Default value: `day`, which means separating files by day

- Value options: `none`, `year`, `month`, `day`

`enable-partition-separator`

- Controls whether to use partitions as the separation string.
- This configuration item only takes effect if the downstream is a storage service.
- Default value: `true`, which means that partitions in a table are stored in separate directories
- Note that this configuration will be deprecated in future versions and will be forcibly set to `true`. It is recommended to keep this configuration at its default value to avoid potential data loss in downstream partitioned tables. For more information, see Issue #11979. For usage examples, see Data change records.

`debezium-disable-schema`

- Controls whether to disable the output of schema information.
- Default value: `false`, which means enabling the output of schema information
- This parameter only takes effect when the sink type is MQ and the output protocol is Debezium.

sink.csv New in v6.5.0

Starting from v6.5.0, TiCDC supports saving data changes to storage services in CSV format. Ignore the following configurations if you replicate data to MQ or MySQL sinks.

`delimiter`

- Specifies the character used to separate fields in the CSV file. The value must be an ASCII character.
- Default value: `,`

`quote`

- Specifies the quotation character used to surround fields in the CSV file. If the value is empty, no quotation is used.
- Default value: `"`

`null`

- Specifies the character displayed when a CSV column is NULL.
- Default value: `\N`

`include-commit-ts`

- Controls whether to include commit-ts in CSV rows.
- Default value: `false`

`binary-encoding-method`

- Specifies the encoding method of binary data.
- Default value: `base64`
- Value option: `base64`, `hex`

`output-handle-key`

- Controls whether to output handle key information. This configuration parameter is for internal implementation only, so it is not recommended to set it.
- Default value: `false`

`output-old-value`

- Controls whether to output the value before the row data changes. The default value is false.
- When it is enabled (setting it to `true`), the `UPDATE` event will output two rows of data: the first row is a `DELETE` event that outputs the data before the change; the second row is an `INSERT` event that outputs the changed data.
- When it is enabled, the `"is-update"` column will be added before the column with data changes. This added column is used to identify whether the data change of the current row comes from the `UPDATE` event or the original `INSERT` or `DELETE` event. If the data change of the current row comes from the `UPDATE` event, the value of the `"is-update"` column is `true`. Otherwise, it is `false`.
- Default value: `false`

Starting from v8.0.0, TiCDC supports the Simple message encoding protocol. The following are the configuration parameters for the Simple protocol. For more information about the protocol, see TiCDC Simple Protocol.

The following configuration parameters control the sending behavior of bootstrap messages.

`send-bootstrap-interval-in-sec`

- Controls the time interval for sending bootstrap messages, in seconds.
- Default value: `120`, which means that a bootstrap message is sent every 120 seconds for each table
- Unit: Seconds

`send-bootstrap-in-msg-count`

- Controls the message interval for sending bootstrap, in message count.
- Default value: `10000`, which means that a bootstrap message is sent every 10000 row changed messages for each table
- If you want to disable the sending of bootstrap messages, set both `send-bootstrap-interval-in-sec` and `send-bootstrap-in-msg-count` to `0`.

`send-bootstrap-to-all-partition`

- Controls whether to send bootstrap messages to all partitions.
- Setting it to `false` means bootstrap messages are sent to only the first partition of the corresponding table topic.
- Default value: `true`, which means that bootstrap messages are sent to all partitions of the corresponding table topic

sink.kafka-config.codec-config

`encoding-format`

- Controls the encoding format of the Simple protocol messages. Currently, the Simple protocol message supports `json` and `avro` encoding formats.
- Default value: `json`
- Value options: `json`, `avro`

sink.open

`output-old-value`

- Controls whether to output the value before the row data changes. The default value is true. When it is disabled, the `UPDATE` event does not output the "p" field.
- Default value: `true`

sink.debezium

`output-old-value`

- Controls whether to output the value before the row data changes. The default value is true. When it is disabled, the `UPDATE` event does not output the "before" field.
- Default value: `true`

7.5.7.2.14 consistent

Specifies the replication consistency configurations for a changefeed when using the redo log. For more information, see Eventually consistent replication in disaster scenarios.

Note: The consistency-related configuration items only take effect when the downstream is a database and the redo log feature is enabled.

`level`

- The data consistency level. `"none"` means that the redo log is disabled.
- Default value: `"none"`
- Value options: `"none"`, `"eventual"`

`max-log-size`

- The max redo log size.
- Default value: `64`
- Unit: MiB

`flush-interval`

- The flush interval for redo log.
- Default value: `2000`
- Unit: milliseconds

`storage`

- The storage URI of the redo log.
- Default value: `""`

`use-file-backend`

- Specifies whether to store the redo log in a local file.
- Default value: `false`

`encoding-worker-num`

- The number of encoding and decoding workers in the redo module.
- Default value: `16`

`flush-worker-num`

- The number of flushing workers in the redo module.

- Default value: `8`

`compression` New in v6.5.6, v7.1.3, v7.5.1, and v7.6.0

- The behavior to compress redo log files.
- Default value: `""`, which means no compression
- Value options: `""`, `"lz4"`

`flush-concurrency` New in v6.5.6, v7.1.3, v7.5.1, and v7.6.0

- The concurrency for uploading a single redo file.
- Default value: `1`, which means concurrency is disabled

7.5.7.2.15 integrity

`integrity-check-level`

- Controls whether to enable the checksum validation for single-row data.
- Default value: `"none"`, which means to disable the feature
- Value options: `"none"`, `"correctness"`

`corruption-handle-level`

- Specifies the log level of the changefeed when the checksum validation for single-row data fails.
- Default value: `"warn"`
- Value options: `"warn"`, `"error"`

7.5.7.2.16 sink.kafka-config

The following configuration items only take effect when the downstream is Kafka.

`sasl-mechanism`

- Specifies the mechanism of Kafka SASL authentication.
- Default value: `""`, indicating that SASL authentication is not used

`sasl-oauth-client-id`

- Specifies the client-id in the Kafka SASL OAUTHBEARER authentication. This parameter is required when the OAUTHBEARER authentication is used.
- Default value: `""`

`sasl-oauth-client-secret`

- Specifies the client-secret in the Kafka SASL OAUTHBEARER authentication. This parameter is required when the OAUTHBEARER authentication is used.
- Default value: `""`

`sasl-oauth-token-url`

- Specifies the token-url in the Kafka SASL OAUTHBEARER authentication to obtain the token. This parameter is required when the OAUTHBEARER authentication is used.
- Default value: `""`

`sasl-oauth-scopes`

- Specifies the scopes in the Kafka SASL OAUTHBEARER authentication. This parameter is optional when the OAUTHBEARER authentication is used.
- Default value: `""`

`sasl-oauth-grant-type`

- Specifies the grant-type in the Kafka SASL OAUTHBEARER authentication. This parameter is optional when the OAUTHBEARER authentication is used.
- Default value: `"client_credentials"`

`sasl-oauth-audience`

- Specifies the audience in the Kafka SASL OAUTHBEARER authentication. This parameter is optional when the OAUTHBEARER authentication is used.
- Default value: `""`

`output-raw-change-event`

- Controls whether to output the original data change event. For more information, see Control whether to split primary or unique key `UPDATE` events.
- Default value: `false`

7.5.7.2.17 sink.kafka-config.glue-schema-registry-config

The following configuration is only required when using Avro as the protocol and AWS Glue Schema Registry:

```
region="us-west-1"
registry-name="ticdc-test"
access-key="xxxx"
secret-access-key="xxxx"
token="xxxx"
```

For more information, see Integrate TiCDC with AWS Glue Schema Registry.

7.5.7.2.18 sink.pulsar-config

The following parameters take effect only when the downstream is Pulsar.

`authentication-token`

- Authentication on the Pulsar server is done using a token. Specify the value of the token.

`token-from-file`

- When you use a token for Pulsar server authentication, specify the path to the file where the token is located.

`basic-user-name`

- Pulsar uses the basic account and password to authenticate the identity. Specify the account.

`basic-password`

- Pulsar uses the basic account and password to authenticate the identity. Specify the password.

`auth-tls-certificate-path`

- Specifies the certificate path for Pulsar TLS encrypted authentication.

`auth-tls-private-key-path`

- Specifies the private key path for Pulsar TLS encrypted authentication.

`tls-trust-certs-file-path`

- Specifies the path to trusted certificate file of the Pulsar TLS encrypted authentication.

`oauth2.oauth2-issuer-url`

- Pulsar oauth2 issuer-url.
- For more information, see Pulsar documentation website.

`oauth2.oauth2-audience`

- Pulsar oauth2 audience.
- For more information, see the Pulsar website.

`oauth2.oauth2-private-key`

- Pulsar oauth2 private-key.
- For more information, see the Pulsar website.

`oauth2.oauth2-client-id`

- Pulsar oauth2 client-id
- For more information, see the Pulsar website.

`oauth2.oauth2-scope`

- Pulsar oauth2 oauth2-scope.
- For more information, see the Pulsar website.

`pulsar-producer-cache-size`

- Specifies the number of cached Pulsar producers in TiCDC. Each Pulsar producer corresponds to one topic. If the number of topics you need to replicate is larger than the default value, you need to increase the number.
- Default value: `10240`

`compression-type`

- Pulsar data compression method.
- Default value: `""`, which means no compression is used
- Value options: `"lz4"`, `"zlib"`, `"zstd"`

`connection-timeout`

- The timeout for the Pulsar client to establish a TCP connection with the server.
- Default value: `5` (seconds)

`operation-timeout`

- The timeout for Pulsar clients to initiate operations such as creating and subscribing to a topic.
- Default value: `30` (seconds)

`batching-max-messages`

- The maximum number of messages in a single batch for a Pulsar producer to send.
- Default value: `1000`

`batching-max-publish-delay`

- The interval at which Pulsar producer messages are saved for batching.
- Default value: `10` (milliseconds)

`send-timeout`

- The timeout for a Pulsar producer to send a message.
- Default value: `30` (seconds)

`output-raw-change-event`

- Controls whether to output the original data change event. For more information, see Control whether to split primary or unique key `UPDATE` events.
- Default value: `false`

7.5.7.2.19 sink.cloud-storage-config

`worker-count`

- The concurrency for saving data changes to the downstream cloud storage.
- Default value: `16`

`flush-interval`

- The interval for saving data changes to the downstream cloud storage.
- Default value: `"2s"`

`file-size`

- A data change file is saved to the cloud storage when the number of bytes in this file exceeds `file-size`.
- Default value: `67108864`, that is 64 MiB

`file-expiration-days`

- The duration to retain files, which takes effect only when `date-separator` is configured as `day`.
- Default value: `0`, which means file cleanup is disabled
- Assume that `file-expiration-days = 1` and `file-cleanup-cron-spec = "0 0 0 * * *"`, then TiCDC performs daily cleanup at 00:00:00 for files saved beyond 24 hours. For example, at 00:00:00 on 2023/12/02, TiCDC cleans up files generated before 2023/12/01, while files generated on 2023/12/01 remain unaffected.

`file-cleanup-cron-spec`

- The running cycle of the scheduled cleanup task, compatible with the crontab configuration.
- The format is `<Second> <Minute> <Hour> <Day of the month> <Month> <Day of the week (Optional)>`
- Default value: `"0 0 2 * * *"`, which means that the cleanup task is executed every day at 2 AM

`flush-concurrency`

- The concurrency for uploading a single file.
- Default value: `1`, which means concurrency is disabled

`output-raw-change-event`

- Controls whether to output the original data change event. For more information, see Control whether to split primary or unique key `UPDATE` events.
- Default value: `false`

7.5.8 TiCDC Client Authentication

Starting from v8.1.0, TiCDC supports client authentication using Mutual Transport Layer Security (mTLS) or TiDB username and password.

- mTLS authentication provides security control at the transport layer, enabling TiCDC to verify the client identity.
- TiDB username and password authentication provides security control at the application layer, ensuring that only authorized users can log in through the TiCDC node.

These two authentication methods can be used either independently or in combination to meet different scenarios and security requirements.

Note:

To ensure the security of network access, it is strongly recommended to use TiCDC client authentication only when TLS is enabled. If TLS is not enabled, the username and password are transmitted as plaintext over the network, which can lead to serious credential leaks.

7.5.8.1 Use mTLS for client authentication

1. In the TiCDC server, configure the `security.mtls` parameter as `true` to enable mTLS authentication:

```
[security]
# This parameter controls whether to enable the TLS client
    ↪ authentication. The default value is false.
mtls = true
```

2. Configure the client certificate.

   When using the TiCDC command-line tool, you can specify the client certificate using the following methods. TiCDC will attempt to read the client certificate in the following order:

   1. Specify the certificate and private key using the command-line parameters `--cert` and `--key`. If the server uses a self-signed certificate, you also need to specify the trusted CA certificate using the `--ca` parameter.

```
cdc cli changefeed list --cert client.crt --key client.key --ca ca.
    ↪ crt
```

   2. Specify the paths to the certificate, private key, and CA certificate using the environment variables `TICDC_CERT_PATH`, `TICDC_KEY_PATH`, and `TICDC_CA_PATH`.

```
export TICDC_CERT_PATH=client.crt
export TICDC_KEY_PATH=client.key
export TICDC_CA_PATH=ca.crt
```

   3. Specify the certificate using the shared credential file `~/.ticdc/credentials`. You can modify the configuration using the `cdc cli configure-credentials` command.

   When using TiCDC OpenAPI, you can specify the client certificate and private key using `--cert` and `--key`. If the server uses a self-signed certificate, you also need to specify the trusted CA certificate using the `--cacert` parameter. For example:

```
curl -X GET http://127.0.0.1:8300/api/v2/status --cert client.crt --key
    ↪  client.key --cacert ca.crt
```

7.5.8.2 Use TiDB username and password for client authentication

1. Create a user in TiDB and grant the user permission to log in from the TiCDC node.

```
CREATE USER 'test'@'ticdc_ip_address' IDENTIFIED BY 'password';
```

2. In the TiCDC server, configure `security.client-user-required` and `security.client-allowed-user` to enable username and password authentication:

```
[security]
# This parameter controls whether to use username and password for client authentication. The default value is false.
client-user-required = true
# This parameter lists the usernames that are allowed for client authentication. Authentication requests with usernames not in this list will be rejected. The default value is null.
client-allowed-user = ["test"]
```

3. Specify the username and password of the user created in step 1.

   When using the TiCDC command-line tool, you can specify the username and password using the following methods. TiCDC will attempt to read the client certificate in the following order:

   1. Specify the username and password using the command-line parameters `--user` and `--password`:

```
cdc cli changefeed list --user test --password password
```

   2. Specify the username using the command-line parameter `--user`. Then, enter the password in the terminal:

```
cdc cli changefeed list --user test
```

   3. Specify the username and password using the environment variables `TICDC_USER` and `TICDC_PASSWORD`:

```
export TICDC_USER=test
export TICDC_PASSWORD=password
```

   4. Specify the username and password using the shared credential file `~/.ticdc/credentials`. You can modify the configuration using the `cdc cli configure-credentials` command.

When using TiCDC OpenAPI, you can specify the username and password using `--user <user>:<password>`. For example:

```
curl -X GET http://127.0.0.1:8300/api/v2/status --user test:password
```

7.5.9 TiCDC Data Integrity Validation for Single-Row Data

Starting from v7.1.0, TiCDC introduces the data integrity validation feature, which uses a checksum algorithm to validate the integrity of single-row data. This feature helps verify whether any error occurs in the process of writing data from TiDB, replicating it through TiCDC, and then writing it to a Kafka cluster. Currently, only changefeeds using Kafka as the downstream and Simple or Avro as the protocol support this feature. For more information about the checksum algorithm, see Algorithm for checksum calculation.

7.5.9.1 Enable the feature

TiCDC disables data integrity validation by default. To enable it, perform the following steps:

1. Enable the checksum integrity validation feature for single-row data in the upstream TiDB cluster by setting the `tidb_enable_row_level_checksum` system variable:

   ```
   SET GLOBAL tidb_enable_row_level_checksum = ON;
   ```

   This configuration only takes effect for newly created sessions, so you need to reconnect to TiDB.

2. In the configuration file specified by the `--config` parameter when you create a changefeed, add the following configurations:

   ```
   [integrity]
   integrity-check-level = "correctness"
   corruption-handle-level = "warn"
   ```

3. When using Avro as the data encoding format, you need to set `enable-tidb-extension=true` in the `sink-uri`. To prevent numerical precision loss during network transmission, which can cause checksum validation failures, you also need to set `avro-decimal-handling-mode=string` and `avro-bigint-unsigned-handling-mode=string`. The following is an example:

   ```
   cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="kafka-avro-checksum" --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=avro&enable-tidb-extension=true&avro-decimal-handling-mode=string&avro-bigint-unsigned-handling-mode=string" --schema-registry=http://127.0.0.1:8081 --config changefeed_config.toml
   ```

With the preceding configuration, each message written to Kafka by the changefeed will include the corresponding data's checksum. You can verify data consistency based on these checksum values.

> **Note:**
>
> For existing changefeeds, if `avro-decimal-handling-mode` and `avro-bigint-unsigned-handling-mode` are not set, enabling the checksum validation feature might cause schema compatibility issues. To resolve this issue, you can modify the compatibility type of the Schema Registry to `NONE`. For more details, see Schema Registry.

7.5.9.2 Disable the feature

TiCDC disables data integrity validation by default. To disable this feature after enabling it, perform the following steps:

1. Follow the `Pause Task -> Modify Configuration -> Resume Task` process described in Update task configuration and remove all `[integrity]` configurations in the configuration file specified by the `--config` parameter of the changefeed.

```
[integrity]
integrity-check-level = "none"
corruption-handle-level = "warn"
```

2. Execute the following SQL statement in the upstream TiDB to disable the checksum integrity validation feature (`tidb_enable_row_level_checksum`):

```
SET GLOBAL tidb_enable_row_level_checksum = OFF;
```

   The preceding configuration only takes effect for newly created sessions. After all clients writing to TiDB have reconnected, the messages written by changefeed to Kafka will no longer include the checksum for the corresponding data.

7.5.9.3 Checksum algorithms

7.5.9.3.1 Checksum V1

Before v8.4.0, TiDB and TiCDC use Checksum V1 for checksum calculation and verification.

After you enable the checksum integrity validation feature for single-row data, TiDB uses the CRC32 algorithm to calculate the checksum of each row and writes it to TiKV along with the data. TiCDC reads the data from TiKV and recalculates the checksum using

the same algorithm. If the two checksums are equal, it indicates that the data is consistent during the transmission from TiDB to TiCDC.

TiCDC then encodes the data into a specific format and sends it to Kafka. After the Kafka consumer reads the data, it calculates a new checksum using the same CRC32 algorithm as TiDB. If the new checksum is equal to the checksum in the data, it indicates that the data is consistent during the transmission from TiCDC to the Kafka consumer.

7.5.9.3.2 Checksum V2

Starting from v8.4.0, TiDB and TiCDC introduce Checksum V2 to address issues of Checksum V1 in verifying old values in Update or Delete events after `ADD COLUMN` or `DROP COLUMN` operations.

For clusters created in v8.4.0 or later, or clusters upgraded to v8.4.0 or later, TiDB uses Checksum V2 by default when single-row data checksum verification is enabled. TiCDC supports handling both Checksum V1 and V2. This change only affects TiDB and TiCDC internal implementation and does not affect checksum calculation methods for downstream Kafka consumers.

7.5.9.4 Algorithm for checksum calculation

The pseudocode for the checksum calculation algorithm is as follows:

```
fn checksum(columns) {
    let result = 0
    for column in sort_by_schema_order(columns) {
        result = crc32.update(result, encode(column))
    }
    return result
}
```

- `columns` should be sorted by column ID. In the Avro schema, fields are already sorted by column ID, so you can directly use the order in `columns`.
- The `encode(column)` function encodes the column value into bytes. Encoding rules vary based on the data type of the column. The specific rules are as follows:
    - TINYINT, SMALLINT, INT, BIGINT, MEDIUMINT, and YEAR types are converted to UINT64 and encoded in little-endian. For example, the number `0x0123456789abcdef` is encoded as `hex'0x0123456789abcdef'`.
    - FLOAT and DOUBLE types are converted to DOUBLE and then encoded as UINT64 in IEEE754 format.
    - BIT, ENUM, and SET types are converted to UINT64.
        - BIT type is converted to UINT64 in binary format.

  - ENUM and SET types are converted to their corresponding INT values in UINT64. For example, if the data value of a `SET('a','b','c')` type column is `'a,c'`, the value is encoded as `0b101`, which is `5` in decimal.
- TIMESTAMP, DATE, DURATION, DATETIME, JSON, and DECIMAL types are first converted to STRING and then converted to bytes.
- CHAR, VARCHAR, VARSTRING, STRING, TEXT, and BLOB types (including TINY, MEDIUM, and LONG) are directly converted to bytes.
- NULL and GEOMETRY types are excluded from the checksum calculation and this function returns empty bytes.

For more information about the implementation of data consumption and checksum verification using Golang, see TiCDC row data checksum verification.

Note:

- After enabling the checksum validation feature, DECIMAL and UNSIGNED BIGINT types data will be converted to STRING types. Therefore, in the downstream consumer code, you need to convert them back to their corresponding numerical types before calculating checksum values.
- The checksum verification process does not include DELETE events. This is because DELETE events only contain the handle key column, while the checksum is calculated based on all columns.

7.5.10 Upstream and Downstream Clusters Data Validation and Snapshot Read

When you use TiCDC to build upstream and downstream clusters of TiDB, you might need to perform consistent snapshot read or data consistency validation on the upstream and downstream without stopping the replication. In the regular replication mode, TiCDC only guarantees that the data is eventually consistent, but cannot guarantee that the data is consistent during the replication process. Therefore, it is difficult to perform consistent read of dynamically changing data. To meet such a need, TiCDC provides the Syncpoint feature.

Syncpoint uses the snapshot feature provided by TiDB and enables TiCDC to maintain a `ts-map` that has consistency between upstream and downstream snapshots during the replication process. In this way, the issue of verifying the consistency of dynamic data is converted to the issue of verifying the consistency of static snapshot data, which achieves the effect of nearly real-time verification.

7.5.10.1 Enable Syncpoint

After enabling the Syncpoint feature, you can use Consistent snapshot read and Data consistency validation.

To enable the Syncpoint feature, set the value of the TiCDC configuration item `enable-sync-point` to `true` when creating a replication task. After enabling Syncpoint, TiCDC writes the following information to the downstream TiDB cluster:

1. During the replication, TiCDC periodically (configured by `sync-point-interval`) aligns snapshots between the upstream and downstream and saves the upstream and downstream TSO correspondences in the downstream `tidb_cdc.syncpoint_v1` table.
2. During the replication, TiCDC also periodically (configured by `sync-point-interval`) executes `SET GLOBAL tidb_external_ts = @@tidb_current_ts`, which sets a consistent snapshot point that has been replicated in backup clusters.

The following TiCDC configuration example enables Syncpoint when creating a replication task:

```
### Enables SyncPoint.
enable-sync-point = true

### Aligns the upstream and downstream snapshots every 5 minutes
sync-point-interval = "5m"

### Cleans up the ts-map data in the downstream tidb_cdc.syncpoint_v1 table every hour
sync-point-retention = "1h"
```

7.5.10.2 Consistent snapshot read

Note:

Before you perform consistent snapshot read, make sure that you have enabled the Syncpoint feature. If multiple replication tasks use the same downstream TiDB cluster and have Syncpoint enabled, each of these tasks updates `tidb_external_ts` and `ts-map` based on their respective replication progress. In this case, you need to set up consistent snapshot read at the replication task level by reading records from the `ts-map` table. Meanwhile, you need to avoid downstream applications reading data using `tidb_enable_external_ts_read`, because multiple replication tasks might interfere with each other and result in inconsistent results.

When you need to query the data from the backup cluster, you can set `SET GLOBAL|SESSION tidb_enable_external_ts_read = ON;` for the application to obtain transactionally consistent data on the backup cluster.

In addition, you can also select a previous point in time for snapshot read by querying `ts-map`.

7.5.10.3 Data consistency validation

> **Note:**
>
> Before you perform data consistency validation, make sure that you have enabled the Syncpoint feature.

To validate the data of upstream and downstream clusters, you only need to configure `snapshot` in sync-diff-inspector.

7.5.10.3.1 Step 1: obtain `ts-map`

You can execute the following SQL statement in the downstream TiDB cluster to obtain the upstream TSO (`primary_ts`) and downstream TSO (`secondary_ts`):

```
select * from tidb_cdc.syncpoint_v1;
+--
   ↪ ---------------+---------------+--------------------+--------------------+----
   ↪
| ticdc_cluster_id | changefeed | primary_ts      | secondary_ts     |
   ↪ created_at        |
+--
   ↪ ---------------+---------------+--------------------+--------------------+----
   ↪
| default        | test-2 | 435953225454059520 | 435953235516456963 |
   ↪ 2022-09-13 08:40:15 |
+--
   ↪ ---------------+---------------+--------------------+--------------------+----
   ↪
```

The fields in the preceding `syncpoint_v1` table are described as follows:

- `ticdc_cluster_id`: The ID of the TiCDC cluster in this record.
- `changefeed`: The ID of the changefeed in this record. Because different TiCDC clusters might have changefeeds with the same name, you need to confirm the `ts-map` inserted by a changefeed with the TiCDC cluster ID and changefeed ID.

- `primary_ts`: The timestamp of the upstream database snapshot.
- `secondary_ts`: The timestamp of the downstream database snapshot.
- `created_at`: The time when this record is inserted.

7.5.10.3.2 Step 2: configure snapshot

Then configure the snapshot information of the upstream and downstream databases by using the `ts-map` information obtained in Step 1.

Here is a configuration example of the `Datasource config` section:

```
########################## Datasource config ########################
[data-sources.uptidb]
    host = "172.16.0.1"
    port = 4000
    user = "root"
    password = ""
    snapshot = "435953225454059520"

[data-sources.downtidb]
    host = "172.16.0.2"
    port = 4000
    user = "root"
    snapshot = "435953235516456963"
```

7.5.10.4 Notes

- Before TiCDC creates a changefeed, make sure that the value of the TiCDC configuration item `enable-sync-point` is set to `true`. Only in this way, Syncpoint is enabled and the `ts-map` is saved in the downstream. The default format of the configuration item `sync-point-interval` is `"h m s"`, for example `"1h30m30s"`, and the minimum value is `"30s"`. For the complete configuration information, see TiCDC task configuration file.
- When you perform data validation using Syncpoint, you need to modify the Garbage Collection (GC) time of TiKV to ensure that the historical data corresponding to snapshot is not collected by GC during the data check. It is recommended that you modify the GC time to 1 hour and recover the setting after the check.
- The above example only shows the section of `Datasource config`. For complete configuration, refer to sync-diff-inspector User Guide.
- Starting from v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.
- Starting from v8.2.0, TiCDC makes the following adjustments to the generation rules of `primary_ts` values:
    - Whenever TiCDC generates a new `primary_ts`, its value must be an integer multiple of `sync-point-interval`.

- For each new changefeed, TiCDC calculates an initial `primary_ts`. This initial value is greater than or equal to the changefeed start time (`startTs`), and is the smallest integer multiple of `sync-point-interval`.

This setting is used to align the Syncpoints of different changefeeds during data replication. For example, multiple downstream clusters can restore to the `secondary_ts` of a Syncpoint with the same `primary_ts` by executing the `FLASHBACK TABLE` statement, achieving data consistency across downstream clusters.

7.5.11 TiCDC Behavior in Splitting UPDATE Events

7.5.11.1 Split `UPDATE` events for MySQL sinks

Starting from v6.5.10, v7.1.6, v7.5.2, v8.1.1, and v8.2.0, when using the MySQL sink, any TiCDC node that receives a request for replicating a table will fetch the current timestamp `thresholdTS` from PD before starting the replication to the downstream. Based on the value of this timestamp, TiCDC decides whether to split `UPDATE` events:

- For transactions containing one or multiple `UPDATE` changes, if the transaction `commitTS` is less than `thresholdTS`, TiCDC splits the `UPDATE` event into a `DELETE` event and an `INSERT` event before writing them to the Sorter module.
- For `UPDATE` events with the transaction `commitTS` greater than or equal to `thresholdTS` ↪ , TiCDC does not split them. For more information, see GitHub issue #10918.

> **Note:**
>
> In v8.1.0, when using MySQL Sink, TiCDC also decides whether to split `UPDATE` events based on the value of `thresholdTS`, but `thresholdTS` is obtained differently. Specifically, in v8.1.0, `thresholdTS` is the current timestamp fetched from PD at TiCDC startup, but this way might cause data inconsistency issues in multi-node scenarios. For more information, see GitHub issue #11219.

This behavior change (that is, deciding whether to split `UPDATE` events based on `thresholdTS`) addresses the issue of downstream data inconsistencies caused by the potentially incorrect order of `UPDATE` events received by TiCDC, which can lead to an incorrect order of split `DELETE` and `INSERT` events.

Take the following SQL statements as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
INSERT INTO t VALUES (2, 2);
```

```
BEGIN;
UPDATE t SET a = 3 WHERE a = 2;
UPDATE t SET a = 2 WHERE a = 1;
COMMIT;
```

In this example, the two `UPDATE` statements within the transaction have a sequential dependency on execution. The primary key `a` is changed from `2` to `3`, and then the primary key `a` is changed from `1` to `2`. After this transaction is executed, the records in the upstream database are `(2, 1)` and `(3, 2)`.

However, the order of `UPDATE` events received by TiCDC might differ from the actual execution order of the upstream transaction. For example:

```
UPDATE t SET a = 2 WHERE a = 1;
UPDATE t SET a = 3 WHERE a = 2;
```

- Before this behavior change, TiCDC writes these `UPDATE` events to the Sorter module and then splits them into `DELETE` and `INSERT` events. After the split, the actual execution order of these events in the downstream is as follows:

  ```
  BEGIN;
  DELETE FROM t WHERE a = 1;
  REPLACE INTO t VALUES (2, 1);
  DELETE FROM t WHERE a = 2;
  REPLACE INTO t VALUES (3, 2);
  COMMIT;
  ```

  After the downstream executes the transaction, the records in the database are `(3, 2)`, which are different from the records in the upstream database (`(2, 1)` and `(3, 2)`), indicating a data inconsistency issue.

- After this behavior change, if the transaction `commitTS` is less than the `thresholdTS` ↪ fetched from PD when TiCDC starts replicating the corresponding table to the downstream, TiCDC splits these `UPDATE` events into `DELETE` and `INSERT` events before writing them to the Sorter module. After the sorting by the Sorter module, the actual execution order of these events in the downstream is as follows:

  ```
  BEGIN;
  DELETE FROM t WHERE a = 1;
  DELETE FROM t WHERE a = 2;
  REPLACE INTO t VALUES (2, 1);
  REPLACE INTO t VALUES (3, 2);
  COMMIT;
  ```

  After the downstream executes the transaction, the records in the downstream database are the same as those in the upstream database, which are `(2, 1)` and `(3, 2)`, ensuring data consistency.

As you can see from the preceding example, splitting the `UPDATE` event into `DELETE` and `INSERT` events before writing them to the Sorter module ensures that all `DELETE` events are executed before `INSERT` events after the split, thereby maintaining data consistency regardless of the order of `UPDATE` events received by TiCDC.

> **Note:**
>
> After this behavior change, when using the MySQL sink, TiCDC does not split the `UPDATE` event in most cases. Consequently, there might be primary key or unique key conflicts during changefeed runtime, causing the changefeed to restart automatically. After the restart, TiCDC will split the conflicting `UPDATE` events into `DELETE` and `INSERT` events before writing them to the Sorter module. This ensures that all events within the same transaction are correctly ordered, with all `DELETE` events preceding `INSERT` events, thus correctly completing data replication.

7.5.11.2 Split primary or unique key `UPDATE` events for non-MySQL sinks

7.5.11.2.1 Transactions containing a single `UPDATE` change

Starting from v6.5.3, v7.1.1, and v7.2.0, when using a non-MySQL sink, for transactions that only contain a single update change, if the primary key or non-null unique index value is modified in an `UPDATE` event, TiCDC splits this event into `DELETE` and `INSERT` events. For more information, see GitHub issue #9086.

This change primarily addresses the issue that TiCDC only outputs the new value without the old value by default when using the CSV and AVRO protocols. Due to this issue, when the primary key or non-null unique index value changes, the consumer can only receive the new value, making it impossible to process the value before the change (for example, delete the old value). Take the following SQL as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
UPDATE t SET a = 2 WHERE a = 1;
```

In this example, the primary key `a` is updated from `1` to `2`. If the `UPDATE` event is not split, the consumer can only obtain the new value `a = 2` and cannot obtain the old value `a = 1` when using the CSV and AVRO protocols. This might cause the downstream consumer to only insert the new value `2` without deleting the old value `1`.

7.5.11.2.2 Transactions containing multiple `UPDATE` changes

Starting from v6.5.4, v7.1.2, and v7.4.0, for transactions containing multiple changes, if the primary key or non-null unique index value is modified in the `UPDATE` event, TiCDC splits

the event into DELETE and INSERT events and ensures that all events follow the sequence of DELETE events preceding INSERT events. For more information, see GitHub issue #9430.

This change primarily addresses the potential issue of primary key or unique key conflicts that consumers might encounter when writing data changes from the Kafka sink or other sinks to a relational database or performing a similar operation. This issue is caused by the potentially incorrect order of UPDATE events received by TiCDC.

Take the following SQL as an example:

```
CREATE TABLE t (a INT PRIMARY KEY, b INT);
INSERT INTO t VALUES (1, 1);
INSERT INTO t VALUES (2, 2);

BEGIN;
UPDATE t SET a = 3 WHERE a = 1;
UPDATE t SET a = 1 WHERE a = 2;
UPDATE t SET a = 2 WHERE a = 3;
COMMIT;
```

In this example, by executing three SQL statements to swap the primary keys of two rows, TiCDC only receives two update change events, that is, changing the primary key a from 1 to 2 and changing the primary key a from 2 to 1. If consumers directly write these two UPDATE events to the downstream, a primary key conflict will occur, leading to changefeed errors.

Therefore, TiCDC splits these two events into four events, that is, deleting records (1, 1) and (2, 2) and writing records (2, 1) and (1, 2).

7.5.11.2.3 Control whether to split primary or unique key UPDATE events

Starting from v6.5.10, v7.1.6, v7.5.3, and v8.1.1, when using a non-MySQL sink, TiCDC supports controlling whether to split primary or unique key UPDATE events via the output-raw-change-event parameter, as described in the GitHub issue #11211. The specific behavior of this parameter is as follows:

- When you set output-raw-change-event = false, if the primary key or non-null unique index value is modified in an UPDATE event, TiCDC splits the event into DELETE and INSERT events and ensures that all events follow the sequence of DELETE events preceding INSERT events.
- When you set output-raw-change-event = true, TiCDC does not split UPDATE events, and the consumer side is responsible for dealing with the problems described in Split primary or unique key UPDATE events for non-MySQL sinks. Otherwise there might be a risk of data inconsistency. Note that when the primary key of a table is a clustered index, updates to the primary key are still split into DELETE and INSERT events in TiDB, and such behavior is not affected by the output-raw-change-event parameter.

Note

In the following tables, UK/PK stands for primary key or unique key.

Release 6.5 compatibility

Version	Protocol	Split UK/PK `UPDATE` ↪ events	Not split UK/PK `UPDATE` ↪ events	Comments

7.5.12 Output Protocols

7.5.12.1 TiCDC Avro Protocol

TiCDC Avro protocol is a third-party implementation of the Confluent Avro data exchange protocol defined by Confluent Platform. Avro is a data format defined by Apache Avro™

This document describes how TiCDC implements the Confluent Avro protocol, and the interaction between Avro and Confluent Schema Registry.

> **Warning:**
>
> Starting from v7.3.0, if you enable TiCDC to replicate tables without a valid index, TiCDC will report an error when you create a changefeed that uses the Avro protocol.

7.5.12.1.1 Use Avro

The following is a configuration example using Avro:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro" --sink-uri="kafka://127.0.0.1:9092/topic-name?protocol=
    ↪ avro" --schema-registry=http://127.0.0.1:8081 --config changefeed_
    ↪ config.toml
```

The value of `--schema-registry` supports the `https` protocol and `username:password` authentication. The username and password must be URL-encoded. For example, `--schema ↪ -registry=https://username:password@schema-registry-uri.com`.

> **Note:**
>
> When using the Avro protocol, one Kafka topic can only contain data for one table. You need to configure the Topic dispatcher in the configuration file.

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

7.5.12.1.2 Definition of the data format

TiCDC converts a DML event into a Kafka event, and the Key and Value of an event are encoded according to the Avro protocol.

Key data format

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
    ]
}
```

- `{{TableName}}` indicates the name of the table where the event occurs.
- `{{Namespace}}` is the namespace of Avro.
- `{{ColumnValueBlock}}` defines the format of each column of data.

The `fields` in the key contains only primary key columns or unique index columns.

Value data format

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
    ]
}
```

The data format of Value is the same as that of Key, by default. However, `fields` in the Value contains all columns.

Note:

The Avro protocol encodes DML events as follows:

- For Delete events, Avro only encodes the Key part. The Value part is empty.
- For Insert events, Avro encodes all column data to the Value part.
- For Update events, Avro encodes only all column data that is updated to the Value part.

The Avro protocol does not encode the old values for Update and Delete events. Additionally, to be compatible with most Confluent sink connectors that rely on `null` records to identify deletions (`delete.on.null`), Delete events do not include extension information, such as `_tidb_commit_ts`, even when `enable-tidb-extension` is enabled. If you need these features, consider using other protocols such as Canal-JSON or Debezium.

7.5.12.1.3 TiDB extension fields

By default, Avro only collects data of changed rows in DML events and does not collect the type of data changes or TiDB-specific CommitTS (the unique identifiers of transactions). To address this issue, TiCDC introduces the following three TiDB extension fields to the Avro protocol message. When `enable-tidb-extension` is set to `true` (`false` by default) in `sink-uri`, TiCDC adds these three fields to the Avro messages during message generation.

- `_tidb_op`: The DML type. "c" indicates insert and "u" indicates updates.
- `_tidb_commit_ts`: The unique identifier of a transaction.
- `_tidb_commit_physical_time`: The physical timestamp in a transaction identifier.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro-enable-extension" --sink-uri="kafka://127.0.0.1:9092/topic
    ↪ -name?protocol=avro&enable-tidb-extension=true" --schema-registry=
    ↪ http://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

After you enable `enable-tidb-extension`, the data format of the Value will be as follows:

```
{
    "name":"{{TableName}}",
    "namespace":"{{Namespace}}",
    "type":"record",
    "fields":[
        {{ColumnValueBlock}},
        {{ColumnValueBlock}},
        {
            "name":"_tidb_op",
            "type":"string"
        },
        {
            "name":"_tidb_commit_ts",
            "type":"long"
        },
        {
            "name":"_tidb_commit_physical_time",
            "type":"long"
        }
    ]
}
```

Compared with the Value data format with `enable-tidb-extension` disabled, three new fields are added: `_tidb_op`, `_tidb_commit_ts`, and `_tidb_commit_physical_time`.

Column data format

The Column data is the `{{ColumnValueBlock}}` part of the Key/Value data format. TiCDC generates the Column data format based on the SQL Type. The basic Column data format is as follows:

```
{
    "name":"{{ColumnName}}",
```

```
    "type":{
        "connect.parameters":{
            "tidb_type":"{{TIDB_TYPE}}"
        },
        "type":"{{AVRO_TYPE}}"
    }
}
```

If one column can be NULL, the Column data format can be:

```
{
    "default":null,
    "name":"{{ColumnName}}",
    "type":[
        "null",
        {
            "connect.parameters":{
                "tidb_type":"{{TIDB_TYPE}}"
            },
            "type":"{{AVRO_TYPE}}"
        }
    ]
}
```

- `{{ColumnName}}` indicates the column name.
- `{{TIDB_TYPE}}` indicates the type in TiDB, which is not a one-to-one mapping with the SQL type.
- `{{AVRO_TYPE}}` indicates the type in the Avro Specification.

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
BOOL	INT	int	
TINYINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
SMALLINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
MEDIUMINT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED.
INT	INT	int	When it is unsigned, TIDB_TYPE is INT UNSIGNED and AVRO_TYPE is long.
BIGINT	BIGINT	long	When it is unsigned, TIDB_TYPE is BIGINT UNSIGNED. If `avro-bigint-unsigned-handling-mode` is string, AVRO_TYPE is string.
TINYBLOB	BLOB	bytes	-
BLOB	BLOB	bytes	-
MEDIUMBLOB	BLOB	bytes	-

SQL TYPE	TIDB_TYPE	AVRO_TYPE	Description
LONGBLOB	BLOB	bytes	-
BINARY	BLOB	bytes	-
VARBINARY	BLOB	bytes	-
TINYTEXT	TEXT	string	-
TEXT	TEXT	string	-
MEDIUMTEXT	TEXT	string	-
LONGTEXT	TEXT	string	-
CHAR	TEXT	string	-
VARCHAR	TEXT	string	-
FLOAT	FLOAT	double	-
DOUBLE	DOUBLE	double	-
DATE	DATE	string	-
DATETIME	DATETIME	string	-
TIMESTAMP	TIMESTAMP	string	-
TIME	TIME	string	-
YEAR	YEAR	int	-
BIT	BIT	bytes	-
JSON	JSON	string	-
ENUM	ENUM	string	-
SET	SET	string	-
DECIMAL	DECIMAL	bytes	When `avro-decimal-handling-mode` is string, AVRO_TYPE is string.
TiDBVECTORFloat32	TiDBVECTORFloat32	string	-

In the Avro protocol, two other `sink-uri` parameters might affect the Column data format as well: `avro-decimal-handling-mode` and `avro-bigint-unsigned-handling-mode`.

- `avro-decimal-handling-mode` controls how Avro handles decimal fields, including:
    - string: Avro handles decimal fields as strings.
    - precise: Avro handles decimal fields as bytes.
- `avro-bigint-unsigned-handling-mode` controls how Avro handles BIGINT UNSIGNED fields, including:
    - string: Avro handles BIGINT UNSIGNED fields as strings.
    - long: Avro handles BIGINT UNSIGNED fields as 64-bit signed integers. When the value is greater than `9223372036854775807`, overflow will occur.

The following is a configuration example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-avro-string-option" --sink-uri="kafka://127.0.0.1:9092/topic-
    ↪ name?protocol=avro&avro-decimal-handling-mode=string&avro-bigint-
    ↪ unsigned-handling-mode=string" --schema-registry=http
    ↪ ://127.0.0.1:8081 --config changefeed_config.toml
```

```
[sink]
dispatchers = [
 {matcher = ['*.*'], topic = "tidb_{schema}_{table}"},
]
```

Most SQL types are mapped to the base Column data format. Some other SQL types extend the base data format to provide more information.

BIT(64)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
            "tidb_type":"BIT",
            "length":"64"
        },
        "type":"bytes"
    }
}
```

ENUM/SET(a,b,c)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
            "tidb_type":"ENUM/SET",
            "allowed":"a,b,c"
        },
        "type":"string"
    }
}
```

DECIMAL(10, 4)

```
{
    "name":"{{ColumnName}}",
    "type":{
        "connect.parameters":{
```

```
            "tidb_type":"DECIMAL",
        },
        "logicalType":"decimal",
        "precision":10,
        "scale":4,
        "type":"bytes"
    }
}
```

7.5.12.1.4 DDL events and schema changes

Avro does not send DDL events and Watermark events to downstream. It checks whether a schema changes each time a DML event occurs. If a schema changes, Avro generates a new schema and registers it with the Schema Registry. If the schema change does not pass the compatibility check, the registration fails. TiCDC does not resolve any schema compatibility issues.

For example, the default compatibility policy of Confluent Schema Registry is `BACKWARD`, and you add a non-empty column to the source table. In this situation, Avro generates a new schema but fails to register it with Schema Registry due to compatibility issues. At this time, the changefeed enters an error state.

Note that, even if a schema change passes the compatibility check and a new version is registered, the data producers and consumers still need to acquire the new schema for data encoding and decoding.

For more information about schemas, refer to Schema Registry related documents.

7.5.12.1.5 Consumer implementation

The TiCDC Avro protocol can be deserialized by `io.confluent.kafka.serializers.KafkaAvroDeserializer`.

The consumer program can acquire the latest schema via Schema Registry API, and then use the schema to deserialize the data encoded by the TiCDC Avro protocol.

Distinguish event types

The consumer program can distinguish DML event types by the following rules:

- If there is only the Key part, it is a Delete event.
- If there are both Key and Value parts, it is either an Insert or an Update event. If the TiDB extension fields are enabled, you can use the `_tidb_op` field to identify if it is an Insert or Update event. If the TiDB extension fields are not enabled, you cannot distinguish them.

7.5.12.1.6 Topic distribution

Schema Registry supports three Subject Name Strategies: TopicNameStrategy, RecordNameStrategy, and TopicRecordNameStrategy. Currently, TiCDC Avro only supports TopicNameStrategy, which means that a Kafka topic can only receive data in one data format. Therefore, TiCDC Avro prohibits mapping multiple tables to the same topic. When you create a changefeed, an error will be reported if the topic rule does not include the `{schema}` and `{table}` placeholders in the configured distribution rule.

7.5.12.1.7 Compatibility

When upgrading the TiCDC cluster to v7.0.0, if a table replicated using Avro contains the `FLOAT` data type, you need to manually adjust the compatibility policy of Confluent Schema Registry to `None` before upgrading so that the changefeed can successfully update the schema. Otherwise, after upgrading, the changefeed will be unable to update the schema and enter an error state. For more information, see #8490.

7.5.12.2 TiCDC Canal-JSON Protocol

Canal-JSON is a data exchange format protocol defined by Alibaba Canal. In this document, you can learn how Canal-JSON data formats are implemented in TiCDC, including the TiDB extension field, the definitions of the Canal-JSON data formats, and comparison with the official Canal.

7.5.12.2.1 Use Canal-JSON

When using Message Queue (MQ) as the downstream Sink, you can specify Canal-JSON in `sink-uri`. TiCDC wraps and constructs Canal-JSON messages with Event as the basic unit, and sends TiDB data change Events to the downstream.

There are three types of Events:

- DDL Event: Represents a DDL change record. It is sent after an upstream DDL statement is successfully executed. The DDL Event is sent to the MQ Partition with the index being 0.
- DML Event: Represents a row data change record. This type of Event is sent when a row change occurs. It contains the information about the row after the change occurs.
- WATERMARK Event: Represents a special time point. It indicates that the Events received before this point is complete. It applies only to the TiDB extension field and takes effect when you set `enable-tidb-extension` to `true` in `sink-uri`.

The following is an example of using `Canal-JSON`:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-canal-json" --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka
    ↪ -version=2.4.0&protocol=canal-json"
```

7.5.12.2.2 TiDB extension field

The Canal-JSON protocol is originally designed for MySQL. It does not contain important fields such as the TiDB-specific unique identifier for the CommitTS transaction. To solve this problem, TiCDC appends a TiDB extension field to the Canal-JSON protocol format. After you set `enable-tidb-extension` to `true` (`false` by default) in `sink-uri`, TiCDC behaves as follows when generating Canal-JSON messages:

- TiCDC sends DML Event and DDL Event messages that contain a field named `_tidb`.
- TiCDC sends WATERMARK Event messages.

The following is an example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-canal-json-enable-tidb-extension" --sink-uri="kafka
    ↪ ://127.0.0.1:9092/topic-name?kafka-version=2.4.0&protocol=canal-json&
    ↪ enable-tidb-extension=true"
```

7.5.12.2.3 Definitions of message formats

This section describes the formats of DDL Event, DML Event and WATERMARK Event, and how the data is parsed on the consumer side.

DDL Event

TiCDC encodes a DDL Event into the following Canal-JSON format.

```
{
    "id": 0,
    "database": "test",
    "table": "",
    "pkNames": null,
    "isDdl": true,
    "type": "QUERY",
    "es": 1639633094670,
    "ts": 1639633095489,
    "sql": "drop database if exists test",
    "sqlType": null,
    "mysqlType": null,
    "data": null,
    "old": null,
    "_tidb": {   // TiDB extension field
        "commitTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

The fields are explained as follows.

Field	Type	Description
id	Number	The default value is 0 in TiCDC.
database	String	The name of the database where the row is located
table	String	The name of the table where the row is located
pkNames	Array	The names of all the columns that make up the primary key
isDdl	Bool	Whether the message is a DDL event
type	String	Event types defined by Canal-JSON
es	Number	13-bit (millisecond) timestamp when the event that generated the message happened
ts	Number	13-bit (millisecond) timestamp when TiCDC generated the message
sql	String	When isDdl is `true`, records the corresponding DDL statement
sqlType	Object	When isDdl is `false`, records how the data type of each column is represented in Java
mysqlType	object	When isDdl is `false`, records how the data type of each column is represented in MySQL
data	Object	When isDdl is `false`, records the name of each column and its data value
old	Object	Only if the message is generated by an update Event, records the name of each column and the data value before the update
_tidb	Object	TiDB extension field. It exists only if you set `enable-tidb-extension` to `true`. The value of `commitTs` is the TSO of the transaction that caused the row to change.

DML Event

TiCDC encodes a row of DML data change event as follows:

```
{
    "id": 0,
    "database": "test",
    "table": "tp_int",
    "pkNames": [
        "id"
    ],
    "isDdl": false,
    "type": "INSERT",
    "es": 1639633141221,
    "ts": 1639633142960,
    "sql": "",
    "sqlType": {
        "c_bigint": -5,
        "c_int": 4,
        "c_mediumint": 4,
        "c_smallint": 5,
```

```
        "c_tinyint": -6,
        "id": 4
    },
    "mysqlType": {
        "c_bigint": "bigint",
        "c_int": "int",
        "c_mediumint": "mediumint",
        "c_smallint": "smallint",
        "c_tinyint": "tinyint",
        "id": "int"
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "2147483647",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "127",
            "id": "2"
        }
    ],
    "old": null,
    "_tidb": {   // TiDB extension field
        "commitTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

WATERMARK Event

TiCDC sends a WATERMARK Event only when you set `enable-tidb-extension` to `true`. The value of the `type` field is `TIDB_WATERMARK`. The Event contains the `_tidb` field, and the field contains only one parameter `watermarkTs`. The value of `watermarkTs` is the TSO recorded when the Event is sent.

When you receive an Event of this type, all Events with `commitTs` less than `watermarkTs` have been sent. Because TiCDC provides the "At Least Once" semantics, data might be sent repeatedly. If a subsequent Event with `commitTs` less than `watermarkTs` is received, you can safely ignore this Event.

The following is an example of the WATERMARK Event.

```
{
    "id": 0,
    "database": "",
    "table": "",
    "pkNames": null,
    "isDdl": false,
```

```
    "type": "TIDB_WATERMARK",
    "es": 1640007049196,
    "ts": 1640007050284,
    "sql": "",
    "sqlType": null,
    "mysqlType": null,
    "data": null,
    "old": null,
    "_tidb": {   // TiDB extension field
        "watermarkTs": 429918007904436226 // A TiDB TSO timestamp
    }
}
```

Data parsing on the consumer side

As you can see from the example above, Canal-JSON has a unified data format, with different field filling rules for different Event types. Consumers can parse data in this JSON format using a unified method, and then determine the Event type by checking the field values:

- When `isDdl` is `true`, the message contains a DDL Event.
- When `isDdl` is `false`, you need to further check the `type` field. If `type` is `TIDB_WATERMARK`, it is a WATERMARK Event; otherwise, it is a DML Event.

7.5.12.2.4 Field descriptions

The Canal-JSON format records the corresponding data type in the `mysqlType` field and the `sqlType` field.

MySQL Type field

In the `mysqlType` field, the Canal-JSON format records the string of MySQL Type in each column. For more information, see TiDB Data Types.

SQL Type field

In the `sqlType` field, the Canal-JSON format records Java SQL Type of each column, which is the data type corresponding to the data in JDBC. Its value can be calculated by MySQL Type and the specific data value. The mapping is as follows:

MySQL Type	Java SQL Type Code
Boolean	-6
Float	7
Double	8
Decimal	3
Char	1
Varchar	12

MySQL Type	Java SQL Type Code
Binary	2004
Varbinary	2004
Tinytext	2005
Text	2005
Mediumtext	2005
Longtext	2005
Tinyblob	2004
Blob	2004
Mediumblob	2004
Longblob	2004
Date	91
Datetime	93
Timestamp	93
Time	92
Year	12
Enum	4
Set	-7
Bit	-7
JSON	12
TiDBVectorFloat32	12

7.5.12.2.5 Integer types

You need to consider whether integer types have the `Unsigned` constraint and the value size, which corresponds to different Java SQL Type Codes respectively, as shown in the following table.

MySQL Type String	Value Range	Java SQL Type Code
tinyint	[-128, 127]	-6
tinyint unsigned	[0, 127]	-6
tinyint unsigned	[128, 255]	5
smallint	[-32768, 32767]	5
smallint unsigned	[0, 32767]	5
smallint unsigned	[32768, 65535]	4
mediumint	[-8388608, 8388607]	4
mediumint unsigned	[0, 8388607]	4
mediumint unsigned	[8388608, 16777215]	4
int	[-2147483648, 2147483647]	4
int unsigned	[0, 2147483647]	4
int unsigned	[2147483648, 4294967295]	-5
bigint	[-9223372036854775808, 9223372036854775807]	-5
bigint unsigned	[0, 9223372036854775807]	-5
bigint unsigned	[9223372036854775808, 18446744073709551615]	3

The following table shows the mapping relationships between Java SQL Types in TiCDC and their codes.

Java SQL Type	Java SQL Type Code
CHAR	1
DECIMAL	3
INTEGER	4
SMALLINT	5
REAL	7
DOUBLE	8
VARCHAR	12
DATE	91
TIME	92
TIMESTAMP	93
BLOB	2004
CLOB	2005
BIGINT	-5
TINYINT	-6
Bit	-7

For more information about Java SQL Types, see Java SQL Class Types.

7.5.12.2.6 Binary and Blob types

TiCDC encodes binary types in the Canal-JSON format by converting each byte to its character representation as follows:

- Printable characters are represented using the ISO/IEC 8859-1 character encodings.
- Non-printable characters and certain characters with special meaning in HTML are represented using their UTF-8 escape sequence.

The following table shows the detailed representation information.

Character type	Value range	Character representation
Control characters	[0, 31]	UTF-8 escape (such as `\u0000` through `\u001F`)
Horizontal tab	[9]	`\t`
Line feed	[10]	`\n`
Carriage return	[13]	`\r`
Printable characters	[32, 127]	Literal character (such as `A`)
Ampersand	[38]	`\u0026`
Less-than sign	[60]	`\u0038`
Greater-than sign	[62]	`\u003E`
Extended control characters	[128, 159]	Literal character
ISO 8859-1 (Latin-1)	[160, 255]	Literal character

Example of the encoding

For example, the following 16 bytes `[5 7 10 15 36 50 43 99 120 60 38 255 254 45 55 70]` stored in a `VARBINARY` column called `c_varbinary` are encoded in a Canal-JSON `Update` event as follows:

```
{
    ...
    "data": [
        {
            ...
            "c_varbinary": "\u0005\u0007\n\u000f$2+cx\u003c\u0026ÿþ-7F"
        }
    ]
    ...
}
```

7.5.12.2.7 Comparison of TiCDC Canal-JSON and the official Canal

The way that TiCDC implements the Canal-JSON data format, including the `Update` Event and the `mysqlType` field, differs from the official Canal. The following table shows the main differences.

Item	TiCDC Canal-JSON	Canal
Event of `Update` Type	By default, the `old` field contains all the column data. When `only_output_updated_columns` is `true`, the `old` field contains only the modified column data.	The `old` field contains only the modified column data
`mysqlType` field	For types with parameters, it does not contain the information of the type parameter	For types with parameters, it contains the full information of the type parameter

Compatibility with the official Canal

Starting from v6.5.6, v7.1.3, and v7.6.0, TiCDC Canal-JSON supports compatibility with the data format of the official Canal. When creating a changefeed, you can set `content-compatible=true` in `sink-uri` to enable this feature. In this mode, TiCDC outputs Canal-JSON format data that is compatible with the official Canal. The specific changes are as follows:

- The `mysqlType` field contains the full information of the type parameter for each type.
- An Event of `Update` Type only outputs the modified column data.

Event of `Update` Type

For an Event of `Update` Type:

- In TiCDC, the `old` field contains all the column data
- In the official Canal, the `old` field contains only the modified column data

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table tp_int
(
    id         int auto_increment,
    c_tinyint  tinyint  null,
    c_smallint smallint null,
    c_mediumint mediumint null,
    c_int      int      null,
    c_bigint   bigint   null,
    constraint pk
        primary key (id)
);

insert into tp_int(c_tinyint, c_smallint, c_mediumint, c_int, c_bigint)
values (127, 32767, 8388607, 2147483647, 9223372036854775807);

update tp_int set c_int = 0, c_tinyint = 0 where c_smallint = 32767;
```

For the `update` statement, TiCDC outputs an Event message with `type` as `UPDATE`, as shown below. The `update` statement only modifies the `c_int` and `c_tinyint` columns. The `old` field in the output event message contains all the column data.

```
{
    "id": 0,
    ...
    "type": "UPDATE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
```

```
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ],
    "old": [                          // In TiCDC, this field contains all
        ↪ the column data.
        {
            "c_bigint": "9223372036854775807",
            "c_int": "2147483647",    // Modified column
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "127",       // Modified column
            "id": "2"
        }
    ]
}
```

For the official Canal, the `old` field in the output event message contains only the modified column data, as shown below.

```
{
    "id": 0,
    ...
    "type": "UPDATE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ],
    "old": [                          // In Canal, this field contains only
        ↪ the modified column data.
```

```
        {
            "c_int": "2147483647",     // Modified column
            "c_tinyint": "127",        // Modified column
        }
    ]
}
```

`mysqlType` field

For the `mysqlType` field, if a type contains parameters, the official Canal contains the full information of the type parameter. TiCDC does not contain such information.

In the following example, the table-defining SQL statement contains a parameter for each column, such as the ones for `decimal`, `char`, `varchar` and `enum`. By comparing the Canal-JSON formats generated by TiCDC and the official Canal, you can see that TiCDC only contains the basic MySQL information in the `mysqlType` field. If you need the full information of the type parameter, you need to implement it by other means.

Assume that the following SQL statements are executed sequentially in the upstream TiDB:

```
create table t (
    id    int auto_increment,
    c_decimal  decimal(10, 4) null,
    c_char     char(16)    null,
    c_varchar  varchar(16) null,
    c_binary   binary(16)  null,
    c_varbinary varbinary(16) null,
    c_enum enum('a','b','c') null,
    c_set set('a','b','c') null,
    c_bit bit(64)          null,
    constraint pk
        primary key (id)
);

insert into t (c_decimal, c_char, c_varchar, c_binary, c_varbinary, c_enum,
    ↪ c_set, c_bit)
values (123.456, "abc", "abc", "abc", "abc", 'a', 'a,b', b'1000001');
```

The output of TiCDC is as follows:

```
{
    "id": 0,
    ...
    "isDdl": false,
    "sqlType": {
        ...
    },
```

```
    "mysqlType": {
        "c_binary": "binary",
        "c_bit": "bit",
        "c_char": "char",
        "c_decimal": "decimal",
        "c_enum": "enum",
        "c_set": "set",
        "c_varbinary": "varbinary",
        "c_varchar": "varchar",
        "id": "int"
    },
    "data": [
        {
            ...
        }
    ],
    "old": null,
}
```

The output of the official Canal is as follows:

```
{
    "id": 0,
    ...
    "isDdl": false,
    "sqlType": {
        ...
    },
    "mysqlType": {
        "c_binary": "binary(16)",
        "c_bit": "bit(64)",
        "c_char": "char(16)",
        "c_decimal": "decimal(10, 4)",
        "c_enum": "enum('a','b','c')",
        "c_set": "set('a','b','c')",
        "c_varbinary": "varbinary(16)",
        "c_varchar": "varchar(16)",
        "id": "int"
    },
    "data": [
        {
            ...
        }
    ],
    "old": null,
```

```
}
```

7.5.12.2.8 Changes in TiCDC Canal-JSON

Changes in the `Old` field of the `Delete` events

From v5.4.0, the `old` field of the `Delete` events has changed.

The following is a `Delete` event message. Before v5.4.0, the `old` field contains the same content as the "data" field. In v5.4.0 and later versions, the `old` field is set to null. You can get the deleted data by using the "data" field.

```
{
    "id": 0,
    "database": "test",
    ...
    "type": "DELETE",
    ...
    "sqlType": {
        ...
    },
    "mysqlType": {
        ...
    },
    "data": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
    ],
    "old": null,
    // The following is an example before v5.4.0. The `old` field contains
        ↪ the same content as the "data" field.
    "old": [
        {
            "c_bigint": "9223372036854775807",
            "c_int": "0",
            "c_mediumint": "8388607",
            "c_smallint": "32767",
            "c_tinyint": "0",
            "id": "2"
        }
```

```
    ]
}
```

7.5.12.3 TiCDC CSV Protocol

When using a cloud storage service as the downstream sink, you can send DML events to the cloud storage service in CSV format.

7.5.12.3.1 Use CSV

The following is an example of the configuration when using the CSV protocol:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ csv-test" --sink-uri="s3://bucket/prefix" --config changefeed.toml
```

The configuration in the `changefeed.toml` file is as follows:

```
[sink]
protocol = "csv"
terminator = "\n"

[sink.csv]
delimiter = ',' # Before v7.6.0, you can only set the delimiter to a single
    ↪ character. Starting from v7.6.0, you can set it to 1-3 characters.
    ↪ For example, `$^` or `|@|`.
quote = '"'
null = '\N'
include-commit-ts = true
output-old-value = false
```

7.5.12.3.2 Transactional constraints

- In a single CSV file, the `commit-ts` of a row is equal to or smaller than that of the subsequent row.
- The same transactions of a single table are stored in the same CSV file.
- Multiple tables of the same transaction can be stored in different CSV files.

7.5.12.3.3 Data storage path structure

For more information about the storage path structure of the data, see Storage path structure.

7.5.12.3.4 Definition of the data format

In the CSV file, each column is defined as follows:

- Column 1: The operation-type indicator, including `I`, `U`, and `D`. `I` means `INSERT`, `U` means `UPDATE`, and `D` means `DELETE`.
- Column 2: Table name.
- Column 3: Schema name.
- Column 4: The `commit-ts` of the source transaction. This column is optional.
- Column 5: The `is-update` column only exists when the value of `output-old-value` is true, which is used to identify whether the row data change comes from the UPDATE event (the value of the column is true) or the INSERT/DELETE event (the value is false).
- Column 6 to the last column: One or more columns with data changes.

Assume that table `hr.employee` is defined as follows:

```
CREATE TABLE `employee` (
  `Id` int NOT NULL,
  `LastName` varchar(20) DEFAULT NULL,
  `FirstName` varchar(30) DEFAULT NULL,
  `HireDate` date DEFAULT NULL,
  `OfficeLocation` varchar(20) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4;
```

When `include-commit-ts = true` and `output-old-value = false`, the DML events of this table are stored in the CSV format as follows:

```
"I","employee","hr",433305438660591626,101,"Smith","Bob","2014-06-04","New
    ↪ York"
"U","employee","hr",433305438660591627,101,"Smith","Bob","2015-10-08","Los
    ↪ Angeles"
"D","employee","hr",433305438660591629,101,"Smith","Bob","2017-03-13","
    ↪ Dallas"
"I","employee","hr",433305438660591630,102,"Alex","Alice","2017-03-14","
    ↪ Shanghai"
"U","employee","hr",433305438660591630,102,"Alex","Alice","2018-06-15","
    ↪ Beijing"
```

When `include-commit-ts = true` and `output-old-value = true`, the DML events of this table are stored in the CSV format as follows:

```
"I","employee","hr",433305438660591626,false,101,"Smith","Bob
    ↪ ","2014-06-04","New York"
"D","employee","hr",433305438660591627,true,101,"Smith","Bob","2015-10-08","
    ↪ Shanghai"
```

```
"I","employee","hr",433305438660591627,true,101,"Smith","Bob","2015-10-08","
    ↪ Los Angeles"
"D","employee","hr",433305438660591629,false,101,"Smith","Bob
    ↪ ","2017-03-13","Dallas"
"I","employee","hr",433305438660591630,false,102,"Alex","Alice
    ↪ ","2017-03-14","Shanghai"
"D","employee","hr",433305438660591630,true,102,"Alex","Alice
    ↪ ","2017-03-14","Beijing"
"I","employee","hr",433305438660591630,true,102,"Alex","Alice
    ↪ ","2018-06-15","Beijing"
```

7.5.12.3.5 Data type mapping

MySQL type	CSV type	Example	Description
`BOOLEAN/TINYINT/SMALLINT ↪ /INT/MEDIUMINT/BIGINT`	Integer	`123`	-
`FLOAT/DOUBLE`	Float	`153.123`	-
`NULL`	Null	`\N`	-
`TIMESTAMP/DATETIME`	String	`"1973-12-30 ↪ 15:30:00.123456" ↪`	Format: `yyyy-MM-dd ↪ HH:mm:ss.%06d`
`DATE`	String	`"2000-01-01"`	Format: `yyyy-MM-dd`
`TIME`	String	`"23:59:59"`	Format: `yyyy-MM-dd`
`YEAR`	Integer	`1970`	-
`VARCHAR/JSON/TINYTEXT ↪ /MEDIUMTEXT/LONGTEXT ↪ /TEXT/CHAR`	String	`"test"`	UTF-8 encoded
`VARBINARY/TINYBLOB ↪ /MEDIUMBLOB/LONGBLOB ↪ /BLOB/BINARY`	String	`"6Zi/5pav"` or `"e998bfe696af"`	Base64 or hex encoded
`BIT`	Integer	`81`	-
`DECIMAL`	String	`"129012.1230000" ↪`	-
`ENUM`	String	`"a"`	-
`SET`	String	`"a,b"`	-
`TiDBVectorFloat32`	String	`"[1.23, -0.4]"`	-

7.5.12.4 TiCDC Debezium Protocol

Debezium is a tool for capturing database changes. It converts each captured database change into a message called an "event" and sends these events to Kafka. Starting from v8.0.0, TiCDC supports sending TiDB changes to Kafka using a Debezium style output

format, simplifying migration from MySQL databases for users who had previously been using Debezium's MySQL integration.

7.5.12.4.1 Use the Debezium message format

When you use Kafka as the downstream sink, specify the `protocol` field as `debezium` in `sink-uri` configuration. Then TiCDC encapsulates the Debezium messages based on the events and sends TiDB data change events to the downstream.

Currently, the Debezium protocol only supports Row Changed events and directly ignores DDL events and WATERMARK events. A Row changed event represents a data change in a row. When a row changes, the Row Changed event is sent, including relevant information about the row both before and after the change. A WATERMARK event marks the replication progress of a table, indicating that all events earlier than the watermark have been sent to the downstream.

The configuration example for using the Debezium message format is as follows:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --changefeed-id="
    ↪ kafka-debezium" --sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-
    ↪ version=2.4.0&protocol=debezium"
```

The Debezium output format contains the schema information of the current row so that downstream consumers can better understand the data structure of the current row. For scenarios where schema information is unnecessary, you can also disable the schema output by setting the `debezium-disable-schema` parameter to `true` in the changefeed configuration file or `sink-uri`.

In addition, the original Debezium format does not include important fields such as the unique transaction identifier of the `CommitTS` in TiDB. To ensure data integrity, TiCDC adds two fields, `CommitTs` and `ClusterID`, to the Debezium format to identify the relevant information of TiDB data changes.

7.5.12.4.2 Message format definition

This section describes the format definition of the DML event output in the Debezium format.

DML event

TiCDC encodes a DML event into a Kafka message, with both the key and value encoded in the Debezium format.

Key format

```
{
    "payload": {
        "a": 4
    },
    "schema": {
```

```
        "fields": [
            {
                "field": "a",
                "optional": true,
                "type": "int32"
            }
        ],
        "name": "default.test.t2.Key",
        "optional": false,
        "type": "struct"
    }
}
```

The fields in the key only include primary key or unique index columns. The fields are explained as follows:

Field	Type	Description
`payload`	JSON	The information about primary key or unique index columns. The key and value in each field represent the column name and its current value, respectively.
`schema.` ↪ `fields`	JSON	The type information of each field in the payload, including the schema information of the row data before and after the change.
`schema.name`	String	The name of the schema, in the `"{cluster-name}.{schema-name}.{table-name}.Key"` format.
`schema.` ↪ `optional`	Boolean	Indicates whether the field is optional. When it is `true`, the field is optional.
`schema.type`	String	The data type of the field.

Value format

```
{
    "payload":{
        "ts_ms":1707103832957,
        "transaction":null,
        "op":"c",
        "before":null,
        "after":{
            "a":4,
            "b":2
        },
        "source":{
            "version":"2.4.0.Final",
```

```
        "connector":"TiCDC",
        "name":"default",
        "ts_ms":1707103832263,
        "snapshot":"false",
        "db":"test",
        "table":"t2",
        "server_id":0,
        "gtid":null,
        "file":"",
        "pos":0,
        "row":0,
        "thread":0,
        "query":null,
        "commit_ts":447507027004751877,
        "cluster_id":"default"
    }
},
"schema":{
    "type":"struct",
    "optional":false,
    "name":"default.test.t2.Envelope",
    "version":1,
    "fields":{
        {
            "type":"struct",
            "optional":true,
            "name":"default.test.t2.Value",
            "field":"before",
            "fields":[
                {
                    "type":"int32",
                    "optional":false,
                    "field":"a"
                },
                {
                    "type":"int32",
                    "optional":true,
                    "field":"b"
                }
            ]
        },
        {
            "type":"struct",
            "optional":true,
            "name":"default.test.t2.Value",
```

```
                "field":"after",
                "fields":[
                    {
                        "type":"int32",
                        "optional":false,
                        "field":"a"
                    },
                    {
                        "type":"int32",
                        "optional":true,
                        "field":"b"
                    }
                ]
            },
            {
                "type":"string",
                "optional":false,
                "field":"op"
            },
            ...
        }
    }
}
```

The key fields of the preceding JSON data are explained as follows:

Field	Type	Description
payload.op	String	The type of the change event. `"c"` indicates an `INSERT` event, `"u"` indicates an `UPDATE` event, and `"d"` indicates a `DELETE` event.
payload.ts_ms	Number	The timestamp (in milliseconds) when TiCDC generates this message.
payload.before	JSON	The data value before the change event of a statement. For `"c"` events, the value of the `before` field is `null`.
payload.after	JSON	The data value after the change event of a statement. For `"d"` events, the value of the `after` field is `null`.
payload.source.commit_ts	Number	The `CommitTs` identifier when TiCDC generates this message.
payload.source.db	String	The name of the database where the event occurs.
payload.source.table	String	The name of the table where the event occurs.
schema.fields	JSON	The type information of each field in the payload, including the schema information of the row data before and after the change.

Field	Type	Description
schema.name	String	The name of the schema, in the `"{cluster-name}.{schema-name}.{table-name}.Envelope"` format.
schema.optional	Boolean	Indicates whether the field is optional. When it is `true`, the field is optional.
schema.type	String	The data type of the field.

Data type mapping

The data format mapping in the TiCDC Debezium message basically follows the Debezium data type mapping rules, which is generally consistent with the native message of the Debezium Connector for MySQL. However, for some data types, the following differences exist between TiCDC Debezium and Debezium Connector messages:

- Currently, TiDB does not support spatial data types, including GEOMETRY, LINESTRING, POLYGON, MULTIPOINT, MULTILINESTRING, MULTIPOLYGON, and GEOMETRYCOLLECTION.
- For string-like data types, including Varchar, String, VarString, TinyBlob, MediumBlob, BLOB, and LongBlob, when the column has the BINARY flag, TiCDC encodes it as a String type after encoding it in Base64; when the column does not have the BINARY flag, TiCDC encodes it directly as a String type. The native Debezium Connector encodes it in different ways according to `binary.handling.mode`.
- For the Decimal data type, including `DECIMAL` and `NUMERIC`, TiCDC uses the float64 type to represent it. The native Debezium Connector encodes it in float32 or float64 according to the different precision of the data type.

7.5.12.5 TiCDC Open Protocol

TiCDC Open Protocol is a row-level data change notification protocol that provides data sources for monitoring, caching, full-text indexing, analysis engines, and primary-secondary replication between different databases. TiCDC complies with TiCDC Open Protocol and replicates data changes of TiDB to third-party data medium such as MQ (Message Queue).

TiCDC Open Protocol uses Event as the basic unit to replicate data change events to the downstream. The Event is divided into three categories:

- Row Changed Event: Represents the data change in a row. When a row is changed, this Event is sent and contains information about the changed row.
- DDL Event: Represents the DDL change. This Event is sent after a DDL statement is successfully executed in the upstream. The DDL Event is broadcasted to every MQ Partition.
- Resolved Event: Represents a special time point before which the Event received is complete.

7.5.12.5.1 Restrictions

- In most cases, the Row Changed Event of a version is sent only once, but in special situations such as node failure and network partition, the Row Changed Event of the same version might be sent multiple times.
- On the same table, the Row Changed Events of each version which is first sent are incremented in the order of timestamps (TS) in the Event stream.
- Resolved Events are periodically broadcasted to each MQ Partition. The Resolved Event means that any Event with a TS earlier than Resolved Event TS has been sent to the downstream.
- DDL Events are broadcasted to each MQ Partition.
- Multiple Row Changed Events of a row are sent to the same MQ Partition.

7.5.12.5.2 Message format

A Message contains one or more Events, arranged in the following format:

Key:

Offset(Byte)	0~7	8~15	16~(15+length1)	...	...
Parameter	Protocol version	Length1	Event Key1	LengthN	Event KeyN

Value:

Offset(Byte)	0~7	8~(7+length1)	...	...
Parameter	Length1	Event Value1	LengthN	Event ValueN

- `LengthN` represents the length of the `N`th key/value.
- The length and protocol version are the big-endian `int64` type.
- The version of the current protocol is `1`.

7.5.12.5.3 Event format

This section introduces the formats of Row Changed Event, DDL Event, and Resolved Event.

Row Changed Event

- **Key:**

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
```

```
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that causes the row change.
Schema Name	String	The name of the schema where the row is in.
Table Name	String	The name of the table where the row is in.

- **Value:**

  `Insert` event. The newly added row data is output.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

  `Update` event. The newly added row data ("u") and the row data before the update ("p") are output.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
```

```
    },
    "p":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

`Delete` event. The deleted row data is output.

```
{
    "d":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

Parameter	Type	Description
Column Name	String	The column name.
Column Type	Number	The column type. For details, see Column Type Code.

Parameter	Type	Description
Where Handle	Boolean	Determines whether this column can be the filter condition of the `Where` clause. When this column is unique on the table, `Where Handle` is `true`.
Flag	Number	The bit flags of columns. For details, see Bit flags of columns.
Column Value	Any	The Column value.

DDL Event

- **Key:**

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":2
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that performs the DDL change.
Schema Name	String	The schema name of the DDL change, which might be an empty string.
Table Name	String	The table name of the DDL change, which might be am empty string.

- **Value:**

```
{
    "q":<DDL Query>,
    "t":<DDL Type>
}
```

Parameter	Type	Description
DDL Query	String	DDL Query SQL
DDL Type	String	The DDL type. For details, see DDL Type Code.

Resolved Event

- **Key:**

```
{
    "ts":<TS>,
    "t":3
}
```

Parameter	Type	Description
TS	Number	The Resolved timestamp. Any TS earlier than this Event has been sent.

- **Value:** None

7.5.12.5.4 Examples of the Event stream output

This section shows and displays the output logs of the Event stream.

Suppose that you execute the following SQL statement in the upstream and the MQ Partition number is 2:

```
CREATE TABLE test.t1(id int primary key, val varchar(16));
```

From the following Log 1 and Log 3, you can see that the DDL Event is broadcasted to all MQ Partitions, and that the Resolved Event is periodically broadcasted to each MQ Partition.

```
1. [partition=0] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
2. [partition=0] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
3. [partition=1] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
4. [partition=1] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
INSERT INTO test.t1(id, val) VALUES (1, 'aa');
INSERT INTO test.t1(id, val) VALUES (2, 'aa');
```

```
UPDATE test.t1 SET val = 'bb' WHERE id = 2;
INSERT INTO test.t1(id, val) VALUES (3, 'cc');
COMMIT;
```

- From the following Log 5 and Log 6, you can see that Row Changed Events on the same table might be sent to different partitions based on the primary key, but changes to the same row are sent to the same partition so that the downstream can easily process the Event concurrently.
- From Log 6, multiple changes to the same row in a transaction are only sent in one Row Changed Event.
- Log 8 is a repeated event of Log 7. Row Changed Event might be repeated, but the first Event of each version is sent orderly.

```
5. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":1},\"val\":{\"t\":15,\"v\":\"aa\"}}}"]
6. [partition=1] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":2},\"val\":{\"t\":15,\"v\":\"bb\"}}}"]
7. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"cc\"}}}"]
8. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"cc\"}}}"]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
DELETE FROM test.t1 WHERE id = 1;
UPDATE test.t1 SET val = 'dd' WHERE id = 3;
UPDATE test.t1 SET id = 4, val = 'ee' WHERE id = 2;
COMMIT;
```

- Log 9 is the Row Changed Event of the `Delete` type. This type of Event only contains primary key columns or unique index columns.
- Log 13 and Log 14 are Resolved Events. The Resolved Event means that in this Partition, any events smaller than the Resolved TS (including Row Changed Event and DDL Event) have been sent.

```
9. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"d\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":1}}}"]
```

```
10. [partition=1] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
    ↪ \":\"t1\",\"t\":1}"] [value="{\"d\":{\"id\":{\"t\":3,\"h\":true,\"v
    ↪ \":2}}}"]
11. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
    ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
    ↪ \":3},\"val\":{\"t\":15,\"v\":\"ZGQ=\"}}}"]
12. [partition=0] [key="{\"ts\":415508881418485761,\"scm\":\"test\",\"tbl
    ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
    ↪ \":4},\"val\":{\"t\":15,\"v\":\"ZWU=\"}}}"]
13. [partition=0] [key="{\"ts\":415508881038376963,\"t\":3}"] [value=]
14. [partition=1] [key="{\"ts\":415508881038376963,\"t\":3}"] [value=]
```

7.5.12.5.5 Protocol parsing for consumers

Currently, TiCDC does not provide the standard parsing library for TiCDC Open Protocol, but the Golang version and Java version of parsing examples are provided. You can refer to the data format provided in this document and the following examples to implement the protocol parsing for consumers.

- Golang examples
- Java examples

7.5.12.5.6 Column type code

`Column Type Code` represents the column data type of the Row Changed Event.

Type	Code	Output Example	Description
TINYINT/BOOLEAN	1	{“t”:1,“v”:1}	
SMALLINT	2	{“t”:2,“v”:1}	
INT	3	{“t”:3,“v”:123}	
FLOAT	4	{“t”:4,“v”:153.123}	
DOUBLE	5	{“t”:5,“v”:153.123}	
NULL	6	{“t”:6,“v”:null}	
TIMESTAMP	7	{“t”:7,“v”:“1973-12-30 15:30:00”}	
BIGINT	8	{“t”:8,“v”:123}	
MEDIUMINT	9	{“t”:9,“v”:123}	
DATE	10/14	{“t”:10,“v”:“2000-01-01”}	
TIME	11	{“t”:11,“v”:“23:59:59”}	

Type	Code	Output Example	Description
DATETIME	12	{“t”:12,“v”:“2015-12-20 23:58:58”}	
YEAR	13	{“t”:13,“v”:1970}	
VARCHAR/VARBINARY	15/253	{“t”:15,“v”:“test”} / {“t”:15,“v”:“\\x89PNG\\r\\n\\x1a\\n”}	The value is encoded in UTF-8. When the upstream type is VARBINARY, invisible characters are escaped.
BIT	16	{“t”:16,“v”:81}	
JSON	245	{“t”:245,“v”:“{\”key1\“:\”value1\“}”}

7.5.12.5.7 DDL Type Code

`DDL Type Code` represents the DDL statement type of the DDL Event.

Type	Code
Create Schema	1
Drop Schema	2
Create Table	3
Drop Table	4
Add Column	5
Drop Column	6
Add Index	7

Type	Code
Drop Index	8
Add Foreign Key	9
Drop Foreign Key	10
Truncate Table	11
Modify Column	12
Rebase Auto ID	13
Rename Table	14
Set Default Value	15
Shard RowID	16
Modify Table Comment	17
Rename Index	18
Add Table Partition	19
Drop Table Partition	20
Create View	21
Modify Table Charset And Collate	22
Truncate Table Partition	23
Drop View	24
Recover Table	25
Modify Schema Charset And Collate	26
Lock Table	27
Unlock Table	28
Repair Table	29
Set TiFlash Replica	30
Update TiFlash Replica Status	31
Add Primary Key	32
Drop Primary Key	33
Create Sequence	34
Alter Sequence	35
Drop Sequence	36

7.5.12.5.8 Bit flags of columns

The bit flags represent specific attributes of columns.

Bit	Value	Name	Description
1	0x01	BinaryFlag	Whether the column is a binary-encoded column.
2	0x02	HandleKeyFlag	Whether the column is a Handle index column.
3	0x04	GeneratedColumnFlag	Whether the column is a generated column.
4	0x08	PrimaryKeyFlag	Whether the column is a primary key column.
5	0x10	UniqueKeyFlag	Whether the column is a unique index column.
6	0x20	MultipleKeyFlag	Whether the column is a composite index column.
7	0x40	NullableFlag	Whether the column is a nullable column.
8	0x80	UnsignedFlag	Whether the column is an unsigned column.

Example:

If the value of a column flag is `85`, the column is a nullable column, a unique index column, a generated column, and a binary-encoded column.

```
85 == 0b_101_0101
   == NullableFlag | UniqueKeyFlag | GeneratedColumnFlag | BinaryFlag
```

If the value of a column is `46`, the column is a composite index column, a primary key column, a generated column, and a Handle key column.

```
46 == 0b_010_1110
   == MultipleKeyFlag | PrimaryKeyFlag | GeneratedColumnFlag | HandleKeyFlag
```

Note:

- `BinaryFlag` is meaningful only when the column type is BLOB/TEXT (including TINYBLOB/TINYTEXT and BINARY/CHAR). When the upstream column is the BLOB type, the `BinaryFlag` value is set to `1`. When the upstream column is the TEXT type, the `BinaryFlag` value is set to `0`.
- To replicate a table from the upstream, TiCDC selects a valid index as the Handle index. The `HandleKeyFlag` value of the Handle index column is set to `1`.

7.5.12.6 TiCDC Simple Protocol

Starting from v8.0.0, TiCDC supports the Simple protocol. This document describes how to use the TiCDC Simple protocol and the data format implementation.

7.5.12.6.1 Use the TiCDC Simple protocol

When you use Kafka as the downstream, specify `protocol` as `"simple"` in the changefeed configuration. Then TiCDC encodes each row change or DDL event as a message, and sends the data change event to the downstream.

The configuration example for using the Simple protocol is as follows:

`sink-uri` configuration:

```
--sink-uri = "kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0"
```

Changefeed configuration:

```
[sink]
protocol = "simple"

#### The following configuration parameters control the sending behavior of
   ↪ bootstrap messages.
#### send-bootstrap-interval-in-sec controls the time interval for sending
   ↪ bootstrap messages, in seconds.
#### The default value is 120 seconds, which means that a bootstrap message
   ↪ is sent every 120 seconds for each table.
send-bootstrap-interval-in-sec = 120

#### send-bootstrap-in-msg-count controls the message interval for sending
   ↪ bootstrap, in message count.
#### The default value is 10000, which means that a bootstrap message is
   ↪ sent every 10000 row changed messages for each table.
send-bootstrap-in-msg-count = 10000
#### Note: If you want to disable the sending of bootstrap messages, set
   ↪ both send-bootstrap-interval-in-sec and send-bootstrap-in-msg-count
   ↪ to 0.

#### send-bootstrap-to-all-partition controls whether to send bootstrap
   ↪ messages to all partitions.
#### The default value is true, which means that bootstrap messages are sent
   ↪  to all partitions of the corresponding table topic.
#### Setting it to false means bootstrap messages are sent to only the first
   ↪  partition of the corresponding table topic.
send-bootstrap-to-all-partition = true

[sink.kafka-config.codec-config]
#### encoding-format controls the encoding format of the Simple protocol
   ↪ messages. Currently, the Simple protocol message supports "json" and
   ↪ "avro" encoding formats.
#### The default value is "json".
encoding-format = "json"
```

7.5.12.6.2 Message types

The TiCDC Simple protocol has the following message types.

DDL:

- `CREATE`: the creating table event.
- `RENAME`: the renaming table event.
- `CINDEX`: the creating index event.

- `DINDEX`: the deleting index event.
- `ERASE`: the deleting table event.
- `TRUNCATE`: the truncating table event.
- `ALTER`: the altering table event, including adding columns, dropping columns, modifying column types, and other `ALTER TABLE` statements supported by TiCDC.
- `QUERY`: other DDL events.

DML:

- `INSERT`: the inserting event.
- `UPDATE`: the updating event.
- `DELETE`: the deleting event.

Other:

- `WATERMARK`: containing a TSO (that is, a 64-bit timestamp) of the upstream TiDB cluster, which marks the table replication progress. All events earlier than the watermark have been sent to the downstream.
- `BOOTSTRAP`: containing the schema information of a table, used to build the table schema for the downstream.

7.5.12.6.3 Message format

In the Simple protocol, each message contains only one event. The Simple protocol supports encoding messages in JSON and Avro formats. This document uses JSON format as an example. For Avro format messages, their fields and meanings are the same as those in JSON format messages, but the encoding format is different. For details about the Avro format, see Simple Protocol Avro Schema.

DDL

TiCDC encodes a DDL event in the following JSON format:

```
{
   "version":1,
   "type":"ALTER",
   "sql":"ALTER TABLE `user` ADD COLUMN `createTime` TIMESTAMP",
   "commitTs":447987408682614795,
   "buildTs":1708936343598,
   "tableSchema":{
      "schema":"simple",
      "table":"user",
      "tableID":148,
      "version":447987408682614791,
      "columns":[
         {
```

```
      "name":"id",
      "dataType":{
         "mysqlType":"int",
         "charset":"binary",
         "collate":"binary",
         "length":11
      },
      "nullable":false,
      "default":null
   },
   {
      "name":"name",
      "dataType":{
         "mysqlType":"varchar",
         "charset":"utf8mb4",
         "collate":"utf8mb4_bin",
         "length":255
      },
      "nullable":true,
      "default":null
   },
   {
      "name":"age",
      "dataType":{
         "mysqlType":"int",
         "charset":"binary",
         "collate":"binary",
         "length":11
      },
      "nullable":true,
      "default":null
   },
   {
      "name":"score",
      "dataType":{
         "mysqlType":"float",
         "charset":"binary",
         "collate":"binary",
         "length":12
      },
      "nullable":true,
      "default":null
   },
   {
      "name":"createTime",
```

```
            "dataType":{
               "mysqlType":"timestamp",
               "charset":"binary",
               "collate":"binary",
               "length":19
            },
            "nullable":true,
            "default":null
         }
      ],
      "indexes":[
         {
            "name":"primary",
            "unique":true,
            "primary":true,
            "nullable":false,
            "columns":[
               "id"
            ]
         }
      ]
   },
   "preTableSchema":{
      "schema":"simple",
      "table":"user",
      "tableID":148,
      "version":447984074911121426,
      "columns":[
         {
            "name":"id",
            "dataType":{
               "mysqlType":"int",
               "charset":"binary",
               "collate":"binary",
               "length":11
            },
            "nullable":false,
            "default":null
         },
         {
            "name":"name",
            "dataType":{
               "mysqlType":"varchar",
               "charset":"utf8mb4",
               "collate":"utf8mb4_bin",
```

```
            "length":255
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"age",
         "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"score",
         "dataType":{
            "mysqlType":"float",
            "charset":"binary",
            "collate":"binary",
            "length":12
         },
         "nullable":true,
         "default":null
      }
   ],
   "indexes":[
      {
         "name":"primary",
         "unique":true,
         "primary":true,
         "nullable":false,
         "columns":[
            "id"
         ]
      }
   ]
  }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The DDL event type, including `CREATE`, `RENAME`, `CINDEX`, `DINDEX`, `ERASE`, `TRUNCATE`, `ALTER`, and `QUERY`.
`sql`	String	The DDL statement.
`commitTs`	Number	The commit timestamp when the DDL statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`tableSchema`	Object	The current schema information of the table. For more information, see TableSchema definition.
`preTableSchema` ↪	Object	The schema information of the table before the DDL statement is executed. All DDL events, except the `CREATE` type of DDL event, have this field.

DML

INSERT

TiCDC encodes an `INSERT` event in the following JSON format:

```
{
   "version":1,
   "database":"simple",
   "table":"user",
   "tableID":148,
   "type":"INSERT",
   "commitTs":447984084414103554,
   "buildTs":1708923662983,
   "schemaVersion":447984074911121426,
   "data":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"90.5"
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.

Field	Type	Description
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`data`	Object	The inserted data, where the field name is the column name and the field value is the column value.

The `INSERT` event contains the `data` field, and does not contain the `old` field.

UPDATE

TiCDC encodes an `UPDATE` event in the following JSON format:

```
{
   "version":1,
   "database":"simple",
   "table":"user",
   "tableID":148,
   "type":"UPDATE",
   "commitTs":447984099186180098,
   "buildTs":1708923719184,
   "schemaVersion":447984074911121426,
   "data":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"95"
   },
   "old":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"90.5"
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.

Field	Type	Description
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`data`	Object	The data after updating, where the field name is the column name and the field value is the column value.
`old`	Object	The data before updating, where the field name is the column name and the field value is the column value.

The `UPDATE` event contains both the `data` and `old` fields, which represent the data after and before updating respectively.

DELETE

TiCDC encodes a `DELETE` event in the following JSON format:

```
{
   "version":1,
   "database":"simple",
   "table":"user",
   "tableID":148,
   "type":"DELETE",
   "commitTs":447984114259722243,
   "buildTs":1708923776484,
   "schemaVersion":447984074911121426,
   "old":{
      "age":"25",
      "id":"1",
      "name":"John Doe",
      "score":"95"
   }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.

Field	Type	Description
`database`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`type`	String	The DML event type, including `INSERT`, `UPDATE`, and `DELETE`.
`commitTs`	Number	The commit timestamp when the DML statement execution is completed in the upstream.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`schemaVersion` ↪	Number	The schema version number of the table when the DML message is encoded.
`old`	Object	The deleted data, where the field name is the column name and the field value is the column value.

The `DELETE` event contains the `old` field, and does not contain the `data` field.

WATERMARK

TiCDC encodes a `WATERMARK` event in the following JSON format:

```
{
   "version":1,
   "type":"WATERMARK",
   "commitTs":447984124732375041,
   "buildTs":1708923816911
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The `WATERMARK` event type.
`commitTs`	Number	The commit timestamp of the `WATERMARK`.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.

BOOTSTRAP

TiCDC encodes a `BOOTSTRAP` event in the following JSON format:

```
{
   "version":1,
   "type":"BOOTSTRAP",
   "commitTs":0,
   "buildTs":1708924603278,
```

```
"tableSchema":{
   "schema":"simple",
   "table":"new_user",
   "tableID":148,
   "version":447984074911121426,
   "columns":[
      {
         "name":"id",
         "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
         },
         "nullable":false,
         "default":null
      },
      {
         "name":"name",
         "dataType":{
            "mysqlType":"varchar",
            "charset":"utf8mb4",
            "collate":"utf8mb4_bin",
            "length":255
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"age",
         "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
         },
         "nullable":true,
         "default":null
      },
      {
         "name":"score",
         "dataType":{
            "mysqlType":"float",
            "charset":"binary",
            "collate":"binary",
```

```
            "length":12
         },
         "nullable":true,
         "default":null
      }
   ],
   "indexes":[
      {
         "name":"primary",
         "unique":true,
         "primary":true,
         "nullable":false,
         "columns":[
            "id"
         ]
      }
   ]
  }
}
```

The fields in the preceding JSON data are explained as follows:

Field	Type	Description
`version`	Number	The version number of the protocol, which is currently `1`.
`type`	String	The `BOOTSTRAP` event type.
`commitTs`	Number	The `commitTs` of the `BOOTSTRAP` is `0`. Because it is generated internally by TiCDC, its `commitTs` is meaningless.
`buildTs`	Number	The UNIX timestamp when the message is successfully encoded within TiCDC.
`tableSchema`	Object	The schema information of the table. For more information, see TableSchema definition.

7.5.12.6.4 Message generation and sending rules

DDL

- Generation time: TiCDC sends a DDL event after all transactions before this DDL event have been sent.
- Destination: TiCDC sends DDL events to all partitions of the corresponding topic.

DML

- Generation time: TiCDC sends DML events in the order of the `commitTs` of the transaction.

- Destination: TiCDC sends DDL events to the corresponding partition of the corresponding topic according to the user-configured dispatch rules.

WATERMARK

- Generation time: TiCDC sends `WATERMARK` events periodically to mark the replication progress of a changefeed. The current interval is 1 second.
- Destination: TiCDC sends `WATERMARK` events to all partitions of the corresponding topic.

BOOTSTRAP

- Generation time:
  - After creating a new changefeed, before the first DML event of a table is sent, TiCDC sends a `BOOTSTRAP` event to the downstream to build the table schema.
  - Additionally, TiCDC sends `BOOTSTRAP` events periodically to allow newly joined consumers to build the table schema. The default interval is 120 seconds or every 10000 messages. You can adjust the sending interval by configuring the `send-bootstrap-interval-in-sec` and `send-bootstrap-in-msg-count` parameters in the `sink` configuration.
  - If a table does not receive any new DML messages within 30 minutes, the table is considered inactive. TiCDC stops sending `BOOTSTRAP` events for the table until new DML events are received.
- Destination: By default, TiCDC sends `BOOTSTRAP` events to all partitions of the corresponding topic. You can adjust the sending strategy by configuring the `send-bootstrap-to-all-partition` parameter in the sink configuration.

7.5.12.6.5 Message consumption methods

Because the TiCDC Simple protocol does not include the schema information of the table when sending a DML message, the downstream needs to receive the DDL or BOOTSTRAP message and cache the schema information of the table before consuming a DML message. When receiving a DML message, the downstream obtains the corresponding table schema information from the cache by searching the `table` name and `schemaVersion` fields of the DML message, and then correctly consumes the DML message.

The following describes how the downstream consumes DML messages based on DDL or BOOTSTRAP messages. According to preceding descriptions, the following information is known:

- Each DML message contains a `schemaVersion` field to mark the schema version number of the table corresponding to the DML message.
- Each DDL message contains a `tableSchema` and `preTableSchema` field to mark the schema information of the table before and after the DDL event.

- Each BOOTSTRAP message contains a `tableSchema` field to mark the schema information of the table corresponding to the BOOTSTRAP message.

The consumption methods are introduced in the following two scenarios.

Scenario 1: The consumer starts consuming from the beginning

In this scenario, the consumer starts consuming from the creation of a table, so the consumer can receive all DDL and BOOTSTRAP messages of the table. In this case, the consumer can obtain the schema information of the table through the `table` name and `schemaVersion` field of the DML message. The detailed process is as follows:

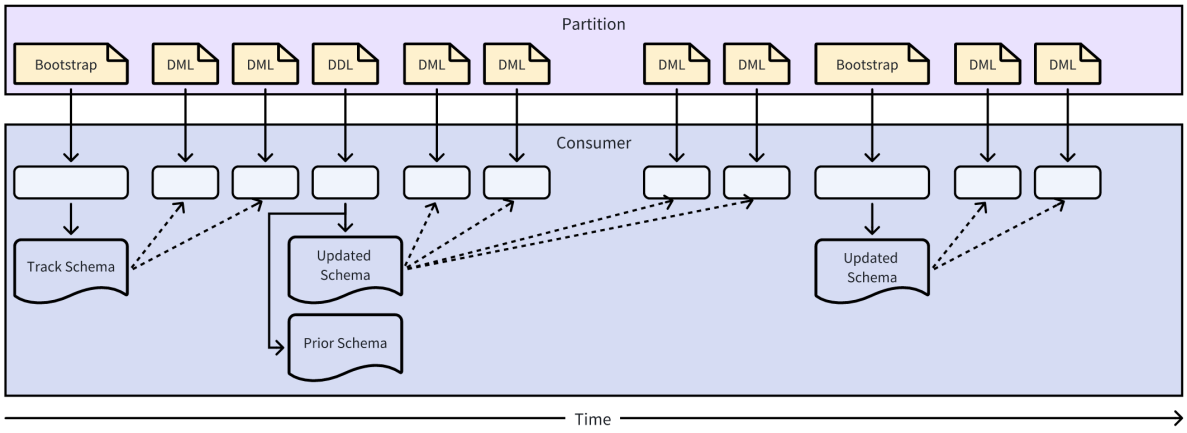

Figure 133: TiCDC Simple Protocol consumer scene 1

Scenario 2: The consumer starts consuming from the middle

When a new consumer joins the consumer group, it might start consuming from the middle, so it might miss earlier DDL and BOOTSTRAP messages of the table. In this case, the consumer might receive some DML messages before obtaining the schema information of the table. Therefore, the consumer needs to wait for a period of time until it receives the DDL or BOOTSTRAP message to obtain the schema information of the table. Because TiCDC sends BOOTSTRAP messages periodically, the consumer can always obtain the schema information of the table within a period of time. The detailed process is as follows:

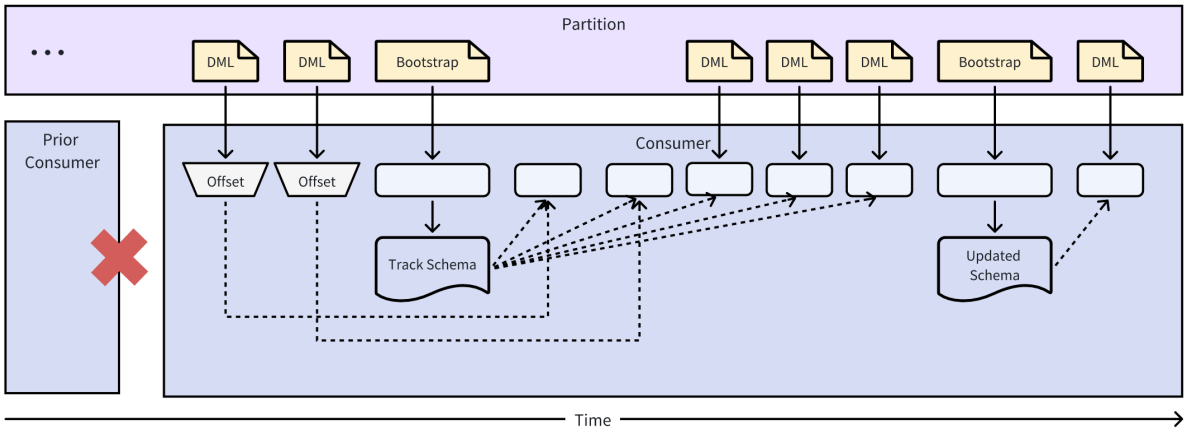

Figure 134: TiCDC Simple Protocol consumer scene 2

7.5.12.6.6 Reference

TableSchema definition

TableSchema is a JSON object that contains the schema information of the table, including the table name, table ID, table version number, column information, and index information. The JSON message format is as follows:

```
{
    "schema":"simple",
    "table":"user",
    "tableID":148,
    "version":447984074911121426,
    "columns":[
        {
        "name":"id",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":false,
        "default":null
        },
        {
        "name":"name",
        "dataType":{
            "mysqlType":"varchar",
            "charset":"utf8mb4",
```

```
            "collate":"utf8mb4_bin",
            "length":255
        },
        "nullable":true,
        "default":null
        },
        {
        "name":"age",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":true,
        "default":null
        },
        {
        "name":"score",
        "dataType":{
            "mysqlType":"float",
            "charset":"binary",
            "collate":"binary",
            "length":12
        },
        "nullable":true,
        "default":null
        }
    ],
    "indexes":[
        {
        "name":"primary",
        "unique":true,
        "primary":true,
        "nullable":false,
        "columns":[
            "id"
        ]
        }
    ]
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`schema`	String	The name of the database.
`table`	String	The name of the table.
`tableID`	Number	The ID of the table.
`version`	Number	The schema version number of the table.
`columns`	Array	The column information, including the column name, data type, whether it can be null, and the default value.
`indexes`	Array	The index information, including the index name, whether it is unique, whether it is a primary key, and the index columns.

You can uniquely identify the schema information of a table by the table name and the schema version number.

> **Note:**
>
> Due to the implementation limitations of TiDB, the schema version number of a table does not change when the `RENAME TABLE` DDL operation is executed.

Column definition

Column is a JSON object that contains the schema information of the column, including the column name, data type, whether it can be null, and the default value.

```
{
        "name":"id",
        "dataType":{
            "mysqlType":"int",
            "charset":"binary",
            "collate":"binary",
            "length":11
        },
        "nullable":false,
        "default":null
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`name`	String	The name of the column.
`dataType`	Object	The data type information, including the MySQL data type, character set, collation, and field length.
`nullable`	Boolean	Whether the column can be null.
`default`	String	The default value of the column.

Index definition

Index is a JSON object that contains the schema information of the index, including the index name, whether it is unique, whether it is a primary key, and the index column.

```
{
        "name":"primary",
        "unique":true,
        "primary":true,
        "nullable":false,
        "columns":[
            "id"
        ]
}
```

The preceding JSON data is explained as follows:

Field	Type	Description
`name`	String	The name of the index.
`unique`	Boolean	Whether the index is unique.
`primary`	Boolean	Whether the index is a primary key.
`nullable`	Boolean	Whether the index can be null.
`columns`	Array	The column names included in the index.

mysqlType reference table

The following table describes the value range of the `mysqlType` field in the TiCDC Simple protocol and its type in TiDB (Golang) and Avro (Java). When you need to parse DML messages, you can correctly parse the data according to this table and the `mysqlType` field in the DML message, depending on the protocol and language you use.

TiDB type (Golang) represents the type of the corresponding `mysqlType` when it is processed in TiDB and TiCDC (Golang). **Avro type (Java)** represents the type of the corresponding `mysqlType` when it is encoded into Avro format messages.

mysqlType	Value range	TiDB type (Golang)	Avro type
tinyint	[-128, 127]	int64	long
tinyint unsigned	[0, 255]	uint64	long
smallint	[-32768, 32767]	int64	long
smallint unsigned	[0, 65535]	uint64	long
mediumint	[-8388608, 8388607]	int64	long
mediumint unsigned	[0, 16777215]	uint64	long
int	[-2147483648, 2147483647]	int64	long
int unsigned	[0, 4294967295]	uint64	long
bigint	[-9223372036854775808, 9223372036854775807]	int64	long
bigint unsigned	[0, 9223372036854775807]	uint64	long

mysqlType	Value range	TiDB type (Golang)	Avro type
bigint unsigned	[9223372036854775808, 18446744073709551615]	uint64	string
float	/	float32	float
double	/	float64	double
decimal	/	string	string
varchar	/	[]uint8	string
char	/	[]uint8	string
varbinary	/	[]uint8	bytes
binary	/	[]uint8	bytes
tinytext	/	[]uint8	string
text	/	[]uint8	string
mediumtext	/	[]uint8	string
longtext	/	[]uint8	string
tinyblob	/	[]uint8	bytes
blob	/	[]uint8	bytes
mediumblob	/	[]uint8	bytes
longblob	/	[]uint8	bytes
date	/	string	string
datetime	/	string	string
timestamp	/	string	string
time	/	string	string
year	/	int64	long
enum	/	uint64	long
set	/	uint64	long
bit	/	uint64	long
json	/	string	string
bool	/	int64	long
TiDBVectorFloat32	/	string	string

Avro schema definition

The Simple protocol supports outputting messages in Avro format. For details about the Avro format, see Simple Protocol Avro Schema.

7.5.13 TiCDC OpenAPI v2

TiCDC provides the OpenAPI feature for querying and operating the TiCDC cluster. The OpenAPI feature is a subset of the `cdc cli` tool.

> **Note:**
>
> TiCDC OpenAPI v1 will be removed in the future. It is recommended to use TiCDC OpenAPI v2.

You can use the APIs to perform the following maintenance operations on the TiCDC cluster:

- Get the status information of a TiCDC node
- Check the health status of a TiCDC cluster
- Create a replication task
- Remove a replication task
- Update the replication configuration
- Query the replication task list
- Query a specific replication task
- Pause a replication task
- Resume a replication task
- Query the replication subtask list
- Query a specific replication subtask
- Query the TiCDC service process list
- Evict an owner node
- Dynamically adjust the log level of the TiCDC server

The request body and returned values of all APIs are in JSON format. A successful request returns a `200 OK` message. The following sections describe the specific usage of the APIs.

In the following examples, the listening IP address of the TiCDC server is `127.0.0.1` ↪ and the port is `8300`. You can specify the IP address and port bound to TiCDC via `--addr=ip:port` when starting the TiCDC server.

7.5.13.1 API error message template

After an API request is sent, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

In the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

7.5.13.2 Return format of the API List interface

If an API request returns a list of resources (for example, a list of all `Captures`), the TiCDC return format is as follows:

```
{
  "total": 2,
```

```
  "items": [
    {
      "id": "d2912e63-3349-447c-90ba-wwww",
      "is_owner": true,
      "address": "127.0.0.1:8300"
    },
    {
      "id": "d2912e63-3349-447c-90ba-xxxx",
      "is_owner": false,
      "address": "127.0.0.1:8302"
    }
  ]
}
```

In the above example:

- `total`: indicates the total number of resources.
- `items`: an array that contains all the resources returned by this request. All elements of the array are of the same resource.

7.5.13.3 Get the status information of a TiCDC node

This API is a synchronous interface. If the request is successful, the status information of the corresponding node is returned.

7.5.13.3.1 Request URI

```
GET /api/v2/status
```

7.5.13.3.2 Example

The following request gets the status information of the TiCDC node whose IP address is `127.0.0.1` and port number is `8300`.

```
curl -X GET http://127.0.0.1:8300/api/v2/status
```

```
{
  "version": "v8.5.1",
  "git_hash": "10413bded1bdb2850aa6d7b94eb375102e9c44dc",
  "id": "d2912e63-3349-447c-90ba-72a4e04b5e9e",
  "pid": 1447,
  "is_owner": true,
  "liveness": 0
}
```

The parameters of the above output are described as follows:

- `version`: the current version number of TiCDC.
- `git_hash`: the Git hash value.
- `id`: the capture ID of the node.
- `pid`: the capture process ID (PID) of the node.
- `is_owner`: indicates whether the node is an owner.
- `liveness`: whether this node is live. `0` means normal. `1` means that the node is in the `graceful shutdown` state.

7.5.13.4 Check the health status of a TiCDC cluster

This API is a synchronous interface. If the cluster is healthy, `200 OK` is returned.

7.5.13.4.1 Request URI

`GET /api/v2/health`

7.5.13.4.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v2/health
```

If the cluster is healthy, the response is `200 OK` and an empty JSON object:

```
{}
```

If the cluster is not healthy, the response is a JSON object containing the error message.

7.5.13.5 Create a replication task

This interface is used to submit a replication task to TiCDC. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.13.5.1 Request URI

`POST /api/v2/changefeeds`

7.5.13.5.2 Parameter descriptions

```
{
  "changefeed_id": "string",
  "replica_config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,
    "consistent": {
      "flush_interval": 0,
```

```
    "level": "string",
    "max_log_size": 0,
    "storage": "string"
  },
  "enable_old_value": true,
  "enable_sync_point": true,
  "filter": {
    "event_filters": [
      {
        "ignore_delete_value_expr": "string",
        "ignore_event": [
          "string"
        ],
        "ignore_insert_value_expr": "string",
        "ignore_sql": [
          "string"
        ],
        "ignore_update_new_value_expr": "string",
        "ignore_update_old_value_expr": "string",
        "matcher": [
          "string"
        ]
      }
    ],
    "ignore_txn_start_ts": [
      0
    ],
    "rules": [
      "string"
    ]
  },
  "force_replicate": true,
  "ignore_ineligible_table": true,
  "memory_quota": 0,
  "mounter": {
    "worker_num": 0
  },
  "sink": {
    "column_selectors": [
      {
        "columns": [
          "string"
        ],
        "matcher": [
          "string"
```

```
        ]
      }
    ],
    "csv": {
      "delimiter": "string",
      "include_commit_ts": true,
      "null": "string",
      "quote": "string"
    },
    "date_separator": "string",
    "dispatchers": [
      {
        "matcher": [
          "string"
        ],
        "partition": "string",
        "topic": "string"
      }
    ],
    "enable_partition_separator": true,
    "encoder_concurrency": 0,
    "protocol": "string",
    "schema_registry": "string",
    "terminator": "string",
    "transaction_atomicity": "string"
  },
  "sync_point_interval": "string",
  "sync_point_retention": "string"
 },
 "sink_uri": "string",
 "start_ts": 0,
 "target_ts": 0
}
```

The parameters are described as follows:

Parameter name	Description
`changefeed_id`	`STRING` type. The ID of the replication task. (Optional)
`replica_config`	Configuration parameters for the replication task. (Optional)
`sink_uri`	`STRING` type. The downstream address of the replication task. (**Required**)
`start_ts`	`UINT64` type. Specifies the start TSO of the changefeed. The TiCDC cluster will start pulling data from this TSO. The default value is the current time. (Optional)

Parameter name	Description
`target_ts`	`UINT64` type. Specifies the target TSO of the changefeed. The TiCDC cluster stops pulling data when reaching this TSO. The default value is empty, meaning TiCDC does not stop automatically. (Optional)

The meaning and format of `changefeed_id`, `start_ts`, `target_ts`, and `sink_uri` are the same as those described in the Use `cdc cli` to create a replication task document. For the detailed description of these parameters, see that document. Note that when you specify the certificate path in `sink_uri`, make sure you have uploaded the corresponding certificate to the corresponding TiCDC server.

The descriptions of the `replica_config` parameters are as follows.

Parameter name	Description
`bdr_mode`	`BOOLEAN` type. Determines whether to enable bidirectional replication. The default value is `false`. (Optional)
`case_sensitive`	`BOOLEAN` type. Determines whether to be case-sensitive when filtering table names. Starting from v6.5.6, v7.1.3, and v7.5.0, the default value changes from `true` to `false`. (Optional)
`check_gc_safe_point`	`BOOLEAN` type. Determines whether to check that the start time of the replication task is earlier than the GC time. The default value is `true`. (Optional)
`consistent`	The configuration parameters of redo log. (Optional)
`enable_sync_point`	`BOOLEAN` type. Determines whether to enable `sync point`. (Optional)
`filter`	The configuration parameters of `filter`. (Optional)
`force_replicate`	`BOOLEAN` type. The default value is `false`. When you set it to `true`, the replication task forcibly replicates the tables without unique indexes. (Optional)

Parameter name	Description
ignore_ineligible_table	BOOLEAN type. The default value is false. When you set it to true, the replication task ignores the tables that cannot be replicated. (Optional)
memory_quota	UINT64 type. The memory quota for the replication task. (Optional)
mounter	The configuration parameters of mounter. (Optional)
sink	The configuration parameters of sink. (Optional)
sync_point_interval	STRING type. Note that the returned value is a time in nanosecond of the UINT64 type. When the sync point feature is enabled, this parameter specifies the interval at which Syncpoint aligns the upstream and downstream snapshots. The default value is 10m and the minimum value is 30s. (Optional)
sync_point_retention	STRING type. Note that the returned value is a time in nanosecond of the UINT64 type. When the sync point feature is enabled, this parameter specifies how long the data is retained by Syncpoint in the downstream table. When this duration is exceeded, the data is cleaned up. The default value is 24h. (Optional)

The consistent parameters are described as follows:

Parameter name	Description
flush_interval	UINT64 type. The interval to flush redo log files. (Optional)
level	STRING type. The consistency level of the replicated data. (Optional)
max_log_size	UINT64 type. The maximum value of redo log. (Optional)
storage	STRING type. The destination address of the storage. (Optional)
use_file_backend	BOOL type. Specifies whether to store the redo log in a local file. (Optional)
encoding_worker_num	INT type. The number of encoding and decoding workers in the redo module. (Optional)
flush_worker_num	INT type. The number of flushing workers in the redo module. (Optional)

Parameter name	Description
`compression`	`STRING` type. The behavior to compress redo log files. Available options are `""` and `"lz4"`. The default value is `""`, which means no compression. (Optional)
`flush_concurrency`	`INT` type. The concurrency for uploading a single file. The default value is `1`, which means concurrency is disabled. (Optional)

The `filter` parameters are described as follows:

Parameter name	Description
`event_filters`	The configuration to filter events. (Optional)
`ignore_txn_start_ts`	`UINT64 ARRAY` type. Specifying this will ignore transactions that specify `start_ts`, such as `[1, 2]`. (Optional)
`rules`	`STRING ARRAY` type. The rules for table schema filtering, such as `['foo*.*', 'bar*.*']`. For more information, see Table Filter. (Optional)

The `filter.event_filters` parameters are described as follows. For more information, see Changefeed Log Filters.

Parameter name	Description
`ignore_delete_value_expr`	`STRING ARRAY` type. For example, `"name = 'john'"` means to filter out DELETE DML statements containing the `name = 'john'` condition. (Optional)
`ignore_event`	`STRING ARRAY` type. For example, `["insert"]` indicates that the INSERT events are filtered out. (Optional)
`ignore_insert_value_expr`	`STRING ARRAY` type. For example, `"id >= 100"` means to filter out INSERT DML statements that match the `id >= 100` condition. (Optional)
`ignore_sql`	`STRING ARRAY` type. For example, `["^drop", "add column"]` means to filter out DDL statements that start with `DROP` or contain `ADD COLUMN`. (Optional)

Parameter name	Description
`ignore_update_new_value_expr`	`STRING ARRAY` type. For example, `"gender = 'male'"` means to filter out the UPDATE DML statements with the new value `gender = 'male'`. (Optional)
`ignore_update_old_value_expr`	`STRING ARRAY` type. For example, `"age < 18"` means to filter out the UPDATE DML statements with the old value `age < 18`. (Optional)
`matcher`	`STRING ARRAY` type. It works as an allowlist. For example, `["test.worker"]` means that the filter rule applies only to the `worker` table in the `test` database. (Optional)

The `mounter` parameter is described as follows:

Parameter name	Description
`worker_num`	`INT` type. The number of Mounter threads. Mounter is used to decode the data output from TiKV. The default value is `16`. (Optional)

The `sink` parameters are described as follows:

Parameter name	Description
`column_selectors`	The column selector configuration. (Optional)
`csv`	The CSV configuration. (Optional)
`date_separator`	`STRING` type. Indicates the date separator type of the file directory. Value options are `none`, `year`, `month`, and `day`. `none` is the default value and means that the date is not separated. (Optional)
`dispatchers`	An configuration array for event dispatching. (Optional)
`encoder_concurrency`	`INT` type. The number of encoder threads in the MQ sink. The default value is `16`. (Optional)

Parameter name	Description
protocol	STRING type. For MQ sinks, you can specify the protocol format of the message. The following protocols are currently supported: canal-json, open-protocol, avro, debezium, and simple.
schema_registry	STRING type. The schema registry address. (Optional)
terminator	STRING type. The terminator is used to separate two data change events. The default value is null, which means "\r\n" is used as the terminator. (Optional)
transaction_atomicity	STRING type. The atomicity level of the transaction. (Optional)
only_output_updated_columns	BOOLEAN type. For MQ sinks using the canal-json or open-protocol protocol, you can specify whether only output the modified columns. The default value is false. (Optional)
cloud_storage_config	The storage sink configuration. (Optional)
open	The Open Protocol configuration. (Optional)
debezium	The Debezium Protocol configuration. (Optional)

sink.column_selectors is an array. The parameters are described as follows:

Parameter name	Description
columns	STRING ARRAY type. The column array.
matcher	STRING ARRAY type. The matcher configuration. It has the same matching syntax as the filter rule does.

The sink.csv parameters are described as follows:

Parameter name	Description
`delimiter`	`STRING` type. The character used to separate fields in the CSV file. The value must be an ASCII character and defaults to `,`.
`include_commit_ts`	`BOOLEAN` type. Whether to include commit-ts in CSV rows. The default value is `false`.
`null`	`STRING` type. The character that is displayed when a CSV column is null. The default value is `\N`.
`quote`	`STRING` type. The quotation character used to surround fields in the CSV file. If the value is empty, no quotation is used. The default value is `"`.
`binary_encoding_method`	`STRING` type. The encoding method of binary data, which can be `"base64"` or `"hex"`. The default value is `"base64"`.

`sink.dispatchers`: for the sink of MQ type, you can use this parameter to configure the event dispatcher. The following dispatchers are supported: `default`, `ts`, `index-value`, and `table`. The dispatcher rules are as follows:

- `default`: dispatches events in the `table` mode.
- `ts`: uses the commitTs of the row change to create the hash value and dispatch events.
- `index-value`: uses the name and value of the selected HandleKey column to create the hash value and dispatch events.
- `table`: uses the schema name of the table and the table name to create the hash value and dispatch events.

`sink.dispatchers` is an array. The parameters are described as follows:

Parameter name	Description
`matcher`	`STRING ARRAY` type. It has the same matching syntax as the filter rule does.
`partition`	`STRING` type. The target partition for dispatching events.
`topic`	`STRING` type. The target topic for dispatching events.

`sink.cloud_storage_config` parameters are described as follows:

Parameter name	Description
`worker_count`	`INT` type. The concurrency for saving data changes to the downstream cloud storage.
`flush_interval`	`STRING` type. The interval for saving data changes to the downstream cloud storage.
`file_size`	`INT` type. A data change file is saved to the cloud storage when the number of bytes in this file exceeds the value of this parameter.
`file_expiration_days`	`INT` type. The duration to retain files, which takes effect only when `date-separator` is configured as `day`.
`file_cleanup_cron_spec`	`STRING` type. The running cycle of the scheduled cleanup task, compatible with the crontab configuration, with a format of `<Second> <Minute> <Hour> <Day of the month> <Month> <Day of the week (Optional)>`.
`flush_concurrency`	`INT` type. The concurrency for uploading a single file.
`output_raw_change_event`	`BOOLEAN` type. Controls whether to output the original data change event for a non-MySQL sink.

`sink.open` parameters are described as follows:

Parameter name	Description
`output_old_value`	`BOOLEAN` type. It controls whether to output the value before the row data changes. The default value is `true`. When it is disabled, the UPDATE event does not output the “p” field.

`sink.debezium` parameters are described as follows:

Parameter name	Description
`output_old_value`	`BOOLEAN` type. It controls whether to output the value before the row data changes. The default value is true. When it is disabled, the UPDATE event does not output the “before” field.

7.5.13.5.3 Example

The following request creates a replication task with an ID of `test5` and `sink_uri` of `blackhome://`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/changefeeds -d '{"changefeed_id":"test5","sink_uri":"blackhole
    ↪ ://"}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.13.5.4 Response body format

```
{
  "admin_job_type": 0,
  "checkpoint_time": "string",
  "checkpoint_ts": 0,
  "config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,
    "consistent": {
      "flush_interval": 0,
      "level": "string",
      "max_log_size": 0,

        "matcher": [
          "string"
        ],
        "partition": "string",
        "topic": "string"
      }
    ],
    "enable_partition_separator": true,
    "encoder_concurrency": 0,
    "protocol": "string",
```

```
      "schema_registry": "string",
      "terminator": "string",
      "transaction_atomicity": "string"
    },
    "sync_point_interval": "string",
    "sync_point_retention": "string"
  },
  "create_time": "string",
  "creator_version": "string",
  "error": {
    "addr": "string",
    "code": "string",
    "message": "string"
  },
  "id": "string",
  "resolved_ts": 0,
  "sink_uri": "string",
  "start_ts": 0,
  "state": "string",
  "target_ts": 0,
  "task_status": [
    {
      "capture_id": "string",
      "table_ids": [
        0
      ]
    }
  ]
}
```

The parameters are described as follows:

Parameter name	Description
`admin_job_type`	`INTEGER` type. The admin job type.
`checkpoint_time`	`STRING` type. The formatted time of the current checkpoint for the replication task.
`checkpoint_ts`	`STRING` type. The TSO of the current checkpoint for the replication task.
`config`	The replication task configuration. The structure and meaning are the same as that of the `replica_config` configuration in creating the replication task.
`create_time`	`STRING` type. The time when the replication task is created.

Parameter name	Description
`creator_version`	`STRING` type. The TiCDC version when the replication task is created.
`error`	The replication task error.
`id`	`STRING` type. The replication task ID.
`resolved_ts`	`UINT64` type. The replication task resolved ts.
`sink_uri`	`STRING` type. The replication task sink URI.
`start_ts`	`UINT64` type. The replication task start ts.
`state`	`STRING` type. The replication task status. It can be `normal`, `stopped`, `error`, `failed`, or `finished`.
`target_ts`	`UINT64` type. The replication task target ts.
`task_status`	The detailed status of dispatching the replication task.

The `task_status` parameters are described as follows:

Parameter name	Description
`capture_id`	`STRING` type. The capture ID.
`table_ids`	`UINT64 ARRAY` type. The ID of the table being replicated on this capture.

The `error` parameters are described as follows:

Parameter name	Description
`addr`	`STRING` type. The capture address.
`code`	`STRING` type. The error code.
`message`	`STRING` type. The details of the error.

7.5.13.6 Remove a replication task

This API is an idempotent interface (that is, it can be applied multiple times without changing the result beyond the initial application) for removing a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.13.6.1 Request URI

```
DELETE /api/v2/changefeeds/{changefeed_id}
```

7.5.13.6.2 Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be removed.

7.5.13.6.3 Example

The following request removes the replication task with the ID `test1`.

```
curl -X DELETE http://127.0.0.1:8300/api/v2/changefeeds/test1
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.13.7 Update the replication configuration

This API is used for updating a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

To modify the changefeed configuration, follow the steps of `pause the replication task -> modify the configuration -> resume the replication task`.

7.5.13.7.1 Request URI

`PUT /api/v2/changefeeds/{changefeed_id}`

7.5.13.7.2 Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be updated.

Parameters for the request body

```
{
  "replica_config": {
    "bdr_mode": true,
    "case_sensitive": false,
    "check_gc_safe_point": true,
    "consistent": {
      "flush_interval": 0,
      "level": "string",
```

```
    "max_log_size": 0,
    "storage": "string"
  },
  "enable_old_value": true,
  "enable_sync_point": true,
  "filter": {
    "event_filters": [
      {
        "ignore_delete_value_expr": "string",
        "ignore_event": [
          "string"
        ],
        "ignore_insert_value_expr": "string",
        "ignore_sql": [
          "string"
        ],
        "ignore_update_new_value_expr": "string",
        "ignore_update_old_value_expr": "string",
        "matcher": [
          "string"
        ]
      }
    ],
    "ignore_txn_start_ts": [
      0
    ],
    "rules": [
      "string"
    ]
  },
  "force_replicate": true,
  "ignore_ineligible_table": true,
  "memory_quota": 0,
  "mounter": {
    "worker_num": 0
  },
  "sink": {
    "column_selectors": [
      {
        "columns": [
          "string"
        ],
        "matcher": [
          "string"
        ]
```

```
      }
    ],
    "csv": {
      "delimiter": "string",
      "include_commit_ts": true,
      "null": "string",
      "quote": "string"
    },
    "date_separator": "string",
    "dispatchers": [
      {
        "matcher": [
          "string"
        ],
        "partition": "string",
        "topic": "string"
      }
    ],
    "enable_partition_separator": true,
    "encoder_concurrency": 0,
    "protocol": "string",
    "schema_registry": "string",
    "terminator": "string",
    "transaction_atomicity": "string"
  },
  "sync_point_interval": "string",
  "sync_point_retention": "string"
 },
 "sink_uri": "string",
 "target_ts": 0
}
```

Currently, only the following configurations can be modified via the API.

Parameter name	Description
`target_ts`	`UINT64` type. Specifies the target TSO of the changefeed. (Optional)
`sink_uri`	`STRING` type. The downstream address of the replication task. (Optional)
`replica_config`	The configuration parameters of sink. It must be complete. (Optional)

The meanings of the above parameters are the same as those in the Create a replication task section. See that section for details.

7.5.13.7.3 Example

The following request updates the `target_ts` of the replication task with the ID `test1` to 32.

```
curl -X PUT -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/changefeeds/test1 -d '{"target_ts":32}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned. The meanings of the JSON response body are the same as those in the Create a replication task section. See that section for details.

7.5.13.8 Query the replication task list

This API is a synchronous interface. If the request is successful, the basic information of all replication tasks (changefeed) in the TiCDC cluster is returned.

7.5.13.8.1 Request URI

`GET /api/v2/changefeeds`

7.5.13.8.2 Parameter descriptions

Query parameter

Parameter name	Description
`state`	When this parameter is specified, the information of replication tasks in this specified state is returned. (Optional)

The value options for `state` are `all`, `normal`, `stopped`, `error`, `failed`, and `finished`.

If this parameter is not specified, the basic information of replication tasks in the `normal`, `stopped`, or `failed` state is returned by default.

7.5.13.8.3 Example

The following request queries the basic information of all replication tasks in the `normal` state.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeeds?state=normal
```

```
{
  "total": 2,
  "items": [
    {
```

```
    "id": "test",
    "state": "normal",
    "checkpoint_tso": 439749918821711874,
    "checkpoint_time": "2023-02-27 23:46:52.888",
    "error": null
  },
  {
    "id": "test2",
    "state": "normal",
    "checkpoint_tso": 439749918821711874,
    "checkpoint_time": "2023-02-27 23:46:52.888",
    "error": null
  }
 ]
}
```

The parameters in the returned result above are described as follows:

- `id`: the ID of the replication task.
- `state`: the current state of the replication task.
- `checkpoint_tso`: the TSO of the current checkpoint of the replication task.
- `checkpoint_time`: the formatted time of the current checkpoint of the replication task.
- `error`: the error information of the replication task.

7.5.13.9 Query a specific replication task

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication task (changefeed) is returned.

7.5.13.9.1 Request URI

`GET /api/v2/changefeeds/{changefeed_id}`

7.5.13.9.2 Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

7.5.13.9.3 Example

The following request queries the detailed information of the replication task with the

ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeeds/test1
```

The meanings of the JSON response body are the same as those in the Create a replication task section. See that section for details.

7.5.13.10 Query whether a specific replication task is completed

This API is a synchronous interface. If the request is successful, it returns the synchronization status of the specified replication task (changefeed), including whether the task is completed and additional details.

7.5.13.10.1 Request URI

`GET /api/v2/changefeeds/{changefeed_id}/synced`

7.5.13.10.2 Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

7.5.13.10.3 Examples

The following request queries the synchronization status of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v2/changefeeds/test1/synced
```

Example 1: The synchronization is completed

```
{
  "synced": true,
  "sink_checkpoint_ts": "2023-11-30 15:14:11.015",
  "puller_resolved_ts": "2023-11-30 15:14:12.215",
  "last_synced_ts": "2023-11-30 15:08:35.510",
  "now_ts": "2023-11-30 15:14:11.511",
  "info": "Data syncing is finished"
}
```

The response includes the following fields:

- `synced`: whether this replication task is completed. `true` means the task is completed, and `false` means potential incompleteness. If it is `false`, you need to check both the `info` field and other fields for the specific status.

- `sink_checkpoint_ts`: the checkpoint-ts value of the sink module, in PD time.
- `puller_resolved_ts`: the resolved-ts value of the puller module, in PD time.
- `last_synced_ts`: the commit-ts value of the latest data processed by TiCDC, in PD time.
- `now_ts`: current PD time.
- `info`: supplementary information to assist in determining the synchronization status, especially when `synced` is `false`.

Example 2: The synchronization is not completed

```
{
  "synced": false,
  "sink_checkpoint_ts": "2023-11-30 15:26:31.519",
  "puller_resolved_ts": "2023-11-30 15:26:23.525",
  "last_synced_ts": "2023-11-30 15:24:30.115",
  "now_ts": "2023-11-30 15:26:31.511",
  "info": "The data syncing is not finished, please wait"
}
```

This example shows the response of an ongoing replication task. By checking both `synced` and `info` fields, you can learn that the replication task is not completed yet and further waiting is expected.

Example 3: The synchronization status needs further check

```
{
  "synced":false,
  "sink_checkpoint_ts":"2023-12-13 11:45:13.515",
  "puller_resolved_ts":"2023-12-13 11:45:13.525",
  "last_synced_ts":"2023-12-13 11:45:07.575",
  "now_ts":"2023-12-13 11:50:24.875",
  "info":"Please check whether PD is online and TiKV Regions are all
     ↪ available. If PD is offline or some TiKV regions are not available,
     ↪ it means that the data syncing process is complete. To check whether
     ↪  TiKV regions are all available, you can view 'TiKV-Details' > '
     ↪ Resolved-Ts' > 'Max Leader Resolved TS gap' on Grafana. If the gap
     ↪ is large, such as a few minutes, it means that some regions in TiKV
     ↪ are unavailable. Otherwise, if the gap is small and PD is online, it
     ↪  means the data syncing is incomplete, so please wait"
}
```

This API enables you to query the synchronization status even when the upstream cluster encounters disasters. In certain situations, you might not be able to directly determine whether the current data replication task of TiCDC is completed or not. In such cases, you can request this API, and then check both the `info` field in the response and the current status of the upstream cluster to determine the specific status.

In this example, `sink_checkpoint_ts` is behind `now_ts` in time, either because TiCDC is still catching up with data replication, or because the PD or TiKV has failed. If this is due to TiCDC still catching up with data replication, it means that the replication task is not completed yet. If this is due to a PD or TiKV failure, it means that the replication task is completed. Therefore, you need to check the `info` field to assist in determining the cluster status.

Example 4: Query error

```
{
  "error_msg": "[CDC:ErrPDEtcdAPIError]etcd api call error: context deadline
    ↪  exceeded",
  "error_code": "CDC:ErrPDEtcdAPIError"
}
```

In cases where PD in the upstream cluster fails for a long period of time, querying this API might return an error similar to the preceding one, which provides no information for further check. Because PD failures directly affect TiCDC data replication, when getting such errors, you can assume that TiCDC has completed the data replication as much as possible, but data loss might still occur in the downstream cluster due to PD failures.

7.5.13.11 Pause a replication task

This API pauses a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.13.11.1 Request URI

`POST /api/v2/changefeeds/{changefeed_id}/pause`

7.5.13.11.2 Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be paused.

7.5.13.11.3 Example

The following request pauses the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v2/changefeeds/test1/pause
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.13.12 Resume a replication task

This API resumes a replication task. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.13.12.1 Request URI

`POST /api/v2/changefeeds/{changefeed_id}/resume`

7.5.13.12.2 Parameter description

Path parameter

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be resumed.

Parameters for the request body

```
{
  "overwrite_checkpoint_ts": 0
}
```

Parameter name	Description
`overwrite_` ↪ `checkpoint_` ↪ `ts`	`UINT64` type. Reassign a checkpoint TSO when resuming a replication task (changefeed).

7.5.13.12.3 Example

The following request resumes the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v2/changefeeds/test1/resume -d '{}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.13.13 Query the replication subtask list

This API is a synchronous interface. If the request is successful, the basic information of all replication subtasks (`processor`) is returned.

7.5.13.13.1 Request URI

`GET /api/v2/processors`

7.5.13.13.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v2/processors
```

```
{
  "total": 3,
  "items": [
    {
      "changefeed_id": "test2",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    },
    {
      "changefeed_id": "test1",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    },
    {
      "changefeed_id": "test",
      "capture_id": "d2912e63-3349-447c-90ba-72a4e04b5e9e"
    }
  ]
}
```

The parameters are described as follows:

- `changefeed_id`: the changefeed ID.
- `capture_id`: the capture ID.

7.5.13.14 Query a specific replication subtask

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication subtask (`processor`) is returned.

7.5.13.14.1 Request URI

`GET /api/v2/processors/{changefeed_id}/{capture_id}`

7.5.13.14.2 Parameter descriptions

Path parameters

Parameter name	Description
`changefeed_id`	The changefeed ID of the replication subtask to be queried.
`capture_id`	The capture ID of the replication subtask to be queried.

7.5.13.14.3 Example

The following request queries the detailed information of a subtask whose `changefeed_id` is `test` and `capture_id` is `561c3784-77f0-4863-ad52-65a3436db6af`. A subtask can be identified by `changefeed_id` and `capture_id`.

```
curl -X GET http://127.0.0.1:8300/api/v2/processors/test/561c3784-77f0-4863-ad52-65a3436db6af
```

```
{
  "table_ids": [
    80
  ]
}
```

The parameter is described as follows:

- `table_ids`: The table ID to be replicated on this capture.

7.5.13.15 Query the TiCDC service process list

This API is a synchronous interface. If the request is successful, the basic information of all replication processes (`capture`) is returned.

7.5.13.15.1 Request URI

`GET /api/v2/captures`

7.5.13.15.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v2/captures
```

```
{
  "total": 1,
  "items": [
    {
      "id": "d2912e63-3349-447c-90ba-72a4e04b5e9e",
      "is_owner": true,
      "address": "127.0.0.1:8300"
    }
  ]
}
```

The parameters are described as follows:

- `id`: the capture ID.
- `is_owner`: whether the capture is the owner.
- `address`: the address of the capture.

7.5.13.16 Evict an owner node

This API is an asynchronous interface. If the request is successful, `200 OK` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.13.16.1 Request URI

`POST /api/v2/owner/resign`

7.5.13.16.2 Example

The following request evicts the current owner node of TiCDC and triggers a new round of elections to generate a new owner node.

```
curl -X POST http://127.0.0.1:8300/api/v2/owner/resign
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.13.17 Dynamically adjust the log level of the TiCDC server

This API is a synchronous interface. If the request is successful, `200 OK` is returned.

7.5.13.17.1 Request URI

`POST /api/v2/log`

7.5.13.17.2 Request parameter

Parameter for the request body

Parameter name	Description
`log_level`	The log level you want to set.

`log_level` supports the log levels provided by zap: “debug”, “info”, “warn”, “error”, “dpanic” , “panic”, and “fatal”.

7.5.13.17.3 Example

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v2/log -d '{"log_level":"debug"}'
```

If the request is successful, `200 OK` is returned. If the request fails, an error message and error code are returned.

7.5.14 TiCDC OpenAPI v1

> **Note**
>
> TiCDC OpenAPI v1 is deprecated and will be deleted in the future. It is recommended to use TiCDC OpenAPI v2.

TiCDC provides the OpenAPI feature for querying and operating the TiCDC cluster, which is similar to the feature of `cdc cli` tool.

You can use the APIs to perform the following maintenance operations on the TiCDC cluster:

- Get the status information of a TiCDC node
- Check the health status of a TiCDC cluster
- Create a replication task
- Remove a replication task
- Update the replication configuration
- Query the replication task list
- Query a specific replication task
- Pause a replication task
- Resume a replication task
- Query the replication subtask list
- Query a specific replication subtask
- Query the TiCDC service process list
- Evict an owner node
- Manually trigger the load balancing of all tables in a replication task
- Manually schedule a table to another node
- Dynamically adjust the log level of the TiCDC server

The request body and returned value of all APIs are in JSON format. The following sections describe the specific usage of the APIs.

In the following examples, the listening IP address of the TiCDC server is `127.0.0.1` and the port is `8300`. You can bind a specified IP and port via `--addr=ip:port` when starting the TiCDC server.

7.5.14.1 API error message template

After sending an API request, if an error occurs, the returned error message is in the following format:

```
{
    "error_msg": "",
    "error_code": ""
}
```

From the above JSON output, `error_msg` describes the error message and `error_code` is the corresponding error code.

7.5.14.2 Get the status information of a TiCDC node

This API is a synchronous interface. If the request is successful, the status information of the corresponding node is returned.

7.5.14.2.1 Request URI

`GET /api/v1/status`

7.5.14.2.2 Example

The following request gets the status information of the TiCDC node whose IP address is `127.0.0.1` and port number is `8300`.

```
curl -X GET http://127.0.0.1:8300/api/v1/status
```

```
{
    "version": "v5.2.0-master-dirty",
    "git_hash": "f191cd00c53fdf7a2b1c9308a355092f9bf8824e",
    "id": "c6a43c16-0717-45af-afd6-8b3e01e44f5d",
    "pid": 25432,
    "is_owner": true
}
```

The fields of the above output are described as follows:

- version: The current TiCDC version number.
- git_hash: The Git hash value.
- id: The capture ID of the node.
- pid: The capture process PID of the node.
- is_owner: Indicates whether the node is an owner.

7.5.14.3 Check the health status of a TiCDC cluster

This API is a synchronous interface. If the cluster is healthy, `200 OK` is returned.

7.5.14.3.1 Request URI

`GET /api/v1/health`

7.5.14.3.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v1/health
```

7.5.14.4 Create a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.4.1 Request URI

`POST /api/v1/changefeeds`

7.5.14.4.2 Parameter description

Compared to the optional parameters for creating a replication task using the `cli` command, the optional parameters for creating such task using the API are not as complete. This API supports the following parameters.

Parameters for the request body

Parameter name | Description |
:—————— | :————- ——————- |
`changefeed_id` | `STRING` type. The ID of the replication task. (Optional) |
`start_ts` | `UINT64` type. Specifies the start TSO of the changefeed. (Optional) |
`target_ts` | `UINT64` type. Specifies the target TSO of the changefeed. (Optional) |
`sink_uri` | `STRING` type. The downstream address of the replication task. (**Required**) |
`force_replicate` | `BOOLEAN` type. Determines whether to forcibly replicate the tables without unique indexes. (Optional) |
`ignore_ineligible_table` | `BOOLEAN` type. Determines whether to ignore the tables that cannot be replicated. (Optional) |
`filter_rules` | `STRING` type array. The rules for table schema filtering. (Optional) |
`ignore_txn_start_ts` | `UINT64` type array. Ignores the transaction of a specified start_ts. (Optional) |
`mounter_worker_num` | `INT` type. The mounter thread number. (Optional) |
`sink_config` | The configuration parameters of sink. (Optional) |

The meaning and format of `changefeed_id`, `start_ts`, `target_ts`, and `sink_uri` are the same as those described in the Use `cdc cli` to create a replication task document. For the detailed description of these parameters, see this document. Note that when you specify the certificate path in `sink_uri`, make sure you have uploaded the corresponding certificate to the corresponding TiCDC server.

Some other parameters in the above table are described further as follows.

`force_replicate`: This parameter defaults to `false`. When it is specified as `true`, TiCDC tries to forcibly replicate tables that do not have a unique index.

`ignore_ineligible_table`: This parameter defaults to `false`. When it is specified as `true`, TiCDC ignores tables that cannot be replicated.

`filter_rules`: The rules for table schema filtering, such as `filter_rules = ['foo *.*','bar*.*']`. For details, see the Table Filter document.

`ignore_txn_start_ts`: When this parameter is specified, the specified start_ts is ignored. For example, `ignore-txn-start-ts = [1, 2]`.

`mounter_worker_num`: The thread number of mounter. Mounter is used to decode the data output from TiKV. The default value is `16`.

The configuration parameters of sink are as follows:

```
{
  "dispatchers":[
    {"matcher":["test1.*", "test2.*"], "dispatcher":"ts"},
    {"matcher":["test3.*", "test4.*"], "dispatcher":"index-value"}
  ],
  "protocol":"canal-json"
}
```

`dispatchers`: For the sink of MQ type, you can use dispatchers to configure the event dispatcher. Four dispatchers are supported: `default`, `ts`, `index-value`, and `table`. The dispatcher rules are as follows:

- `default`: dispatches events in the `table` mode.
- `ts`: uses the commitTs of the row change to create the hash value and dispatch events.
- `index-value`: uses the name and value of the selected HandleKey column to create the hash value and dispatch events.
- `table`: uses the schema name of the table and the table name to create the hash value and dispatch events.

`matcher`: The matching syntax of matcher is the same as the filter rule syntax.

`protocol`: For the sink of MQ type, you can specify the protocol format of the message. Currently the following protocols are supported: `canal-json`, `open-protocol`, `avro`, `debezium`, and `simple`.

7.5.14.4.3 Example

The following request creates a replication task with an ID of `test5` and a `sink_uri` of `blackhole://`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds -d '{"changefeed_id":"test5","sink_uri":"blackhole
    ↪ ://"}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.5 Remove a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.5.1 Request URI

`DELETE /api/v1/changefeeds/{changefeed_id}`

7.5.14.5.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be removed.

7.5.14.5.3 Example

The following request removes the replication task with the ID `test1`.

```
curl -X DELETE http://127.0.0.1:8300/api/v1/changefeeds/test1
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.6 Update the replication configuration

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

To modify the changefeed configuration, follow the steps of `pause the replication task -> modify the configuration -> resume the replication task`.

7.5.14.6.1 Request URI

`PUT /api/v1/changefeeds/{changefeed_id}`

7.5.14.6.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be updated.

Parameters for the request body

Currently, only the following configuration can be modified via the API.

Parameter name | Description |
:—————— | :————————— ——————— |
`target_ts` | `UINT64` type. Specifies the target TSO of the changefeed. (Optional) |
`sink_uri` | `STRING` type. The downstream address of the replication task. (Optional) |
`filter_rules` | `STRING` type array. The rules for table schema filtering. (Optional) |
`ignore_txn_start_ts` | `UINT64` type array. Ignores the transaction of a specified start_ts. (Optional) |
`mounter_worker_num` | `INT` type. The mounter thread number. (Optional) |
`sink_config` | The configuration parameters of sink. (Optional) |

The meanings of the above parameters are the same as those in the Create a replication task section. See that section for details.

7.5.14.6.3 Example

The following request updates the `mounter_worker_num` of the replication task with the ID `test1` to `32`.

```
curl -X PUT -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds/test1 -d '{"mounter_worker_num":32}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.7 Query the replication task list

This API is a synchronous interface. If the request is successful, the basic information of all nodes in the TiCDC cluster is returned.

7.5.14.7.1 Request URI

`GET /api/v1/changefeeds`

7.5.14.7.2 Parameter description

Query parameters

Parameter name | Description |
:—— | :————————————- —— |
`state` | When this parameter is specified, the replication status information only of this state is returned.(Optional) |

The value options for `state` are `all`, `normal`, `stopped`, `error`, `failed`, and `finished`.

If this parameter is not specified, the basic information of replication tasks whose state is normal, stopped, or failed is returned by default.

7.5.14.7.3 Example

The following request queries the basic information of all replication tasks whose state is `normal`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds?state=normal
```

```
[
    {
        "id": "test1",
        "state": "normal",
        "checkpoint_tso": 426921294362574849,
        "checkpoint_time": "2021-08-10 14:04:54.242",
        "error": null
    },
    {
        "id": "test2",
        "state": "normal",
        "checkpoint_tso": 426921294362574849,
        "checkpoint_time": "2021-08-10 14:04:54.242",
        "error": null
    }
]
```

The fields in the returned result above are described as follows:

- id: The ID of the replication task.
- state: The current state of the replication task.
- checkpoint_tso: The TSO representation of the current checkpoint of the replication task.
- checkpoint_time: The formatted time representation of the current checkpoint of the replication task.
- error: The error information of the replication task.

7.5.14.8 Query a specific replication task

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication task is returned.

7.5.14.8.1 Request URI

`GET /api/v1/changefeeds/{changefeed_id}`

7.5.14.8.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be queried.

7.5.14.8.3 Example

The following request queries the detailed information of the replication task with the ID `test1`.

```
curl -X GET http://127.0.0.1:8300/api/v1/changefeeds/test1
```

```
{
    "id": "test1",
    "sink_uri": "blackhole://",
    "create_time": "2021-08-10 11:41:30.642",
    "start_ts": 426919038970232833,
    "target_ts": 0,
    "checkpoint_tso": 426921014615867393,
    "checkpoint_time": "2021-08-10 13:47:07.093",
    "sort_engine": "unified",
    "state": "normal",
    "error": null,
    "error_history": null,
    "creator_version": "",
    "task_status": [
        {
            "capture_id": "d8924259-f52f-4dfb-97a9-c48d26395945",
            "table_ids": [
                63,
                65
            ],
            "table_operations": {}
        }
    ]
}
```

7.5.14.9 Pause a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.9.1 Request URI

`POST /api/v1/changefeeds/{changefeed_id}/pause`

7.5.14.9.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be paused.

7.5.14.9.3 Example

The following request pauses the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/pause
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.10 Resume a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.10.1 Request URI

`POST /api/v1/changefeeds/{changefeed_id}/resume`

7.5.14.10.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be resumed.

7.5.14.10.3 Example

The following request resumes the replication task with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/resume
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.11 Query the replication subtask list

This API is a synchronous interface. If the request is successful, the basic information of all replication subtasks (`processor`) is returned.

7.5.14.11.1 Request URI

```
GET /api/v1/processors
```

7.5.14.11.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v1/processors
```

```
[
    {
        "changefeed_id": "test1",
        "capture_id": "561c3784-77f0-4863-ad52-65a3436db6af"
    }
]
```

7.5.14.12 Query a specific replication subtask

This API is a synchronous interface. If the request is successful, the detailed information of the specified replication subtask (`processor`) is returned.

7.5.14.12.1 Request URI

```
GET /api/v1/processors/{changefeed_id}/{capture_id}
```

7.5.14.12.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The changefeed ID of the replication subtask to be queried.
`capture_id`	The capture ID of the replication subtask to be queried.

7.5.14.12.3 Example

The following request queries the detailed information of a subtask whose `changefeed`

↪ `_id` is `test` and `capture_id` is `561c3784-77f0-4863-ad52-65a3436db6af`. A subtask can be indentifed by `changefeed_id` and `capture_id`.

```
curl -X GET http://127.0.0.1:8300/api/v1/processors/test1/561c3784-77f0
    ↪ -4863-ad52-65a3436db6af
```

```
{
    "checkpoint_ts": 426919123303006208,
    "resolved_ts": 426919123369066496,
    "table_ids": [
        63,
        65
    ],
    "error": null
}
```

7.5.14.13 Query the TiCDC service process list

This API is a synchronous interface. If the request is successful, the basic information of all replication processes (`capture`) is returned.

7.5.14.13.1 Request URI

`GET /api/v1/captures`

7.5.14.13.2 Example

```
curl -X GET http://127.0.0.1:8300/api/v1/captures
```

```
[
    {
        "id": "561c3784-77f0-4863-ad52-65a3436db6af",
        "is_owner": true,
        "address": "127.0.0.1:8300"
    }
]
```

7.5.14.14 Evict an owner node

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.14.1 Request URI

`POST /api/v1/owner/resign`

7.5.14.14.2 Example

The following request evicts the current owner node of TiCDC and triggers a new round of elections to generate a new owner node.

```
curl -X POST http://127.0.0.1:8300/api/v1/owner/resign
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.15 Manually trigger the load balancing of all tables in a replication task

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.15.1 Request URI

`POST /api/v1/changefeeds/{changefeed_id}/tables/rebalance_table`

7.5.14.15.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be scheduled.

7.5.14.15.3 Example

The following request triggers the load balancing of all tables in the changefeed with the ID `test1`.

```
curl -X POST http://127.0.0.1:8300/api/v1/changefeeds/test1/tables/
    ↪ rebalance_table
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.16 Manually schedule a table to another node

This API is an asynchronous interface. If the request is successful, `202 Accepted` is returned. The returned result only means that the server agrees to run the command but does not guarantee that the command will be run successfully.

7.5.14.16.1 Request URI

`POST /api/v1/changefeeds/{changefeed_id}/tables/move_table`

7.5.14.16.2 Parameter description

Path parameters

Parameter name	Description
`changefeed_id`	The ID of the replication task (changefeed) to be scheduled.

Parameters for the request body

Parameter name	Description
`target_capture_id`	The ID of the target capture.
`table_id`	The ID of the table to be scheduled.

7.5.14.16.3 Example

The following request schedules the table with the ID `49` in the changefeed with the ID `test1` to the capture with the ID `6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5`.

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/changefeeds/changefeed-test1/tables/move_table -d '{"capture_
    ↪ id":"6f19a6d9-0f8c-4dc9-b299-3ba7c0f216f5","table_id":49}'
```

If the request is successful, `202 Accepted` is returned. If the request fails, an error message and error code are returned.

7.5.14.17 Dynamically adjust the log level of the TiCDC server

This API is a synchronous interface. If the request is successful, `202 OK` is returned.

7.5.14.17.1 Request URI

`POST /api/v1/log`

7.5.14.17.2 Request parameters

Parameters for the request body

Parameter name	Description
`log_level`	The log level you want to set.

`log_level` supports the log levels provided by zap: “debug”, “info”, “warn”, “error”, “dpanic” , “panic”, and “fatal”.

7.5.14.17.3 Example

```
curl -X POST -H "'Content-type':'application/json'" http://127.0.0.1:8300/
    ↪ api/v1/log -d '{"log_level":"debug"}'
```

If the request is successful, `202 OK` is returned. If the request fails, an error message and error code are returned.

7.5.15 TiCDC Data Consumption

7.5.15.1 TiCDC Row Data Checksum Verification Based on Avro

This document introduces how to consume data sent to Kafka by TiCDC and encoded by Avro protocol using Golang, and how to perform data verification using the Single-row data checksum feature.

The source code of this example is available in the `avro-checksum-verification` directory.

The example in this document uses kafka-go to create a simple Kafka consumer program. This program continuously reads data from a specified topic, calculates the checksum, and verifies its value.

```
package main

import (
    "context"
    "encoding/binary"
    "encoding/json"
    "hash/crc32"
    "io"
    "math"
    "net/http"
    "strconv"
    "strings"

    "github.com/linkedin/goavro/v2"
    "github.com/pingcap/log"
    "github.com/pingcap/tidb/parser/mysql"
    "github.com/pingcap/tidb/types"
    "github.com/pingcap/tiflow/pkg/errors"
    "github.com/segmentio/kafka-go"
    "go.uber.org/zap"
)

const (
    // The first byte of the Confluent Avro wire format is always 0.
```

```
    // For more details, see https://docs.confluent.io/platform/current/
       ↪ schema-registry/fundamentals/serdes-develop/index.html#wire-format
       ↪ .
    magicByte = uint8(0)
)

func main() {
    var (
        kafkaAddr       = "127.0.0.1:9092"
        schemaRegistryURL = "http://127.0.0.1:8081"

        topic         = "avro-checksum-test"
        consumerGroupID = "avro-checksum-test"
    )

    consumer := kafka.NewReader(kafka.ReaderConfig{
        Brokers: []string{kafkaAddr},
        GroupID: consumerGroupID,
        Topic:   topic,
        MaxBytes: 10e6, // 10MB
    })
    defer consumer.Close()

    ctx := context.Background()
    log.Info("start consuming ...", zap.String("kafka", kafkaAddr), zap.
       ↪ String("topic", topic), zap.String("groupID", consumerGroupID))
    for {
        // 1. Fetch the kafka message.
        message, err := consumer.FetchMessage(ctx)
        if err != nil {
            log.Error("read kafka message failed", zap.Error(err))
        }

        value := message.Value
        if len(value) == 0 {
            log.Info("delete event does not have value, skip checksum
               ↪ verification", zap.String("topic", topic))
        }

        // 2. Decode the value to get the corresponding value map and schema
           ↪ map.
        valueMap, valueSchema, err := getValueMapAndSchema(value,
           ↪ schemaRegistryURL)
        if err != nil {
            log.Panic("decode kafka value failed", zap.String("topic", topic)
```

```
            ↪ , zap.ByteString("value", value), zap.Error(err))
        }

        // 3. Calculate and verify checksum value using the value map and
            ↪ schema map obtained in the previous step.
        err = CalculateAndVerifyChecksum(valueMap, valueSchema)
        if err != nil {
            log.Panic("calculate checksum failed", zap.String("topic", topic)
                ↪ , zap.ByteString("value", value), zap.Error(err))
        }

        // 4. Commit offset after the data is successfully consumed.
        if err := consumer.CommitMessages(ctx, message); err != nil {
            log.Error("commit kafka message failed", zap.Error(err))
            break
        }
    }
}
```

The key steps for calculating the checksum value are `getValueMapAndSchema()` and `CalculateAndVerifyChecksum()`. The following sections describe the implementation of these two functions.

7.5.15.1.1 Decode data and get the corresponding schema

The `getValueMapAndSchema()` method decodes data and gets the corresponding schema. This method returns both the data and schema as a `map[string]interface{}` type.

```
// data is the key or value of the received kafka message, and url is the
    ↪ schema registry url.
// This function returns the decoded value and corresponding schema as map.
func getValueMapAndSchema(data []byte, url string) (map[string]interface{},
    ↪ map[string]interface{}, error) {
    schemaID, binary, err := extractSchemaIDAndBinaryData(data)
    if err != nil {
        return nil, nil, err
    }

    codec, err := GetSchema(url, schemaID)
    if err != nil {
        return nil, nil, err
    }

    native, _, err := codec.NativeFromBinary(binary)
    if err != nil {
        return nil, nil, err
```

```
    }

    result, ok := native.(map[string]interface{})
    if !ok {
        return nil, nil, errors.New("raw avro message is not a map")
    }

    schema := make(map[string]interface{})
    if err := json.Unmarshal([]byte(codec.Schema()), &schema); err != nil {
        return nil, nil, errors.Trace(err)
    }

    return result, schema, nil
}

// extractSchemaIDAndBinaryData
func extractSchemaIDAndBinaryData(data []byte) (int, []byte, error) {
    if len(data) < 5 {
        return 0, nil, errors.ErrAvroInvalidMessage.FastGenByArgs()
    }
    if data[0] != magicByte {
        return 0, nil, errors.ErrAvroInvalidMessage.FastGenByArgs()
    }
    return int(binary.BigEndian.Uint32(data[1:5])), data[5:], nil
}

// GetSchema fetches the schema from the schema registry by the schema ID.
// This function returns a goavro.Codec that can be used to encode and
    ↪ decode the data.
func GetSchema(url string, schemaID int) (*goavro.Codec, error) {
    requestURI := url + "/schemas/ids/" + strconv.Itoa(schemaID)

    req, err := http.NewRequest("GET", requestURI, nil)
    if err != nil {
        log.Error("Cannot create the request to look up the schema", zap.
            ↪ Error(err))
        return nil, errors.WrapError(errors.ErrAvroSchemaAPIError, err)
    }
    req.Header.Add(
        "Accept",
        "application/vnd.schemaregistry.v1+json, application/vnd.
            ↪ schemaregistry+json, "+
            "application/json",
    )
```

```
    httpClient := &http.Client{}
    resp, err := httpClient.Do(req)
    if err != nil {
        return nil, err
    }
    defer resp.Body.Close()

    body, err := io.ReadAll(resp.Body)
    if err != nil {
        log.Error("Cannot parse the lookup schema response", zap.Error(err))
        return nil, errors.WrapError(errors.ErrAvroSchemaAPIError, err)
    }

    if resp.StatusCode == 404 {
        log.Warn("Specified schema not found in Registry", zap.String("
            ↪ requestURI", requestURI), zap.Int("schemaID", schemaID))
        return nil, errors.ErrAvroSchemaAPIError.GenWithStackByArgs("Schema
            ↪ not found in Registry")
    }

    if resp.StatusCode != 200 {
        log.Error("Failed to query schema from the Registry, HTTP error",
            zap.Int("status", resp.StatusCode), zap.String("uri", requestURI)
                ↪ , zap.ByteString("responseBody", body))
        return nil, errors.ErrAvroSchemaAPIError.GenWithStack("Failed to
            ↪ query schema from the Registry, HTTP error")
    }

    var jsonResp lookupResponse
    err = json.Unmarshal(body, &jsonResp)
    if err != nil {
        log.Error("Failed to parse result from Registry", zap.Error(err))
        return nil, errors.WrapError(errors.ErrAvroSchemaAPIError, err)
    }

    codec, err := goavro.NewCodec(jsonResp.Schema)
    if err != nil {
        return nil, errors.WrapError(errors.ErrAvroSchemaAPIError, err)
    }
    return codec, nil
}

type lookupResponse struct {
    Name    string `json:"name"`
    SchemaID int  `json:"id"`
```

```
    Schema  string `json:"schema"`
}
```

7.5.15.1.2 Calculate and verify the checksum value

The `valueMap` and `valueSchema` obtained in the previous step contain all the elements used for checksum calculation and verification.

The checksum calculation and verification process on the consumer side includes the following steps:

1. Get the expected checksum value.
2. Iterate over each column, generate a byte slice according to the column value and the corresponding MySQL type, and update the checksum value continuously.
3. Compare the checksum value calculated in the previous step with the checksum value obtained from the received message. If they are not the same, the checksum verification fails and the data might be corrupted.

The sample code is as follows:

```
func CalculateAndVerifyChecksum(valueMap, valueSchema map[string]interface
    ↪ {}) error {
    // The fields variable stores the column type information for each data
        ↪ change event. The column IDs are used to sort the fields, which is
        ↪  the same as the order in which the checksum is calculated.
    fields, ok := valueSchema["fields"].([]interface{})
    if !ok {
        return errors.New("schema fields should be a map")
    }

    // 1. Get the expected checksum value from valueMap, which is encoded as
        ↪  a string.
    // If the expected checksum value is not found, it means that the
        ↪ checksum feature is not enabled when TiCDC sends the data. In this
        ↪  case, this function returns directly.
    o, ok := valueMap["_tidb_row_level_checksum"]
    if !ok {
        return nil
    }
    expected := o.(string)
    if expected == "" {
        return nil
    }

    // expectedChecksum is the expected checksum value passed from TiCDC.
```

```
expectedChecksum, err := strconv.ParseUint(expected, 10, 64)
if err != nil {
    return errors.Trace(err)
}

// 2. Iterate over each field and calculate the checksum value.
var actualChecksum uint32
// buf stores the byte slice used to update the checksum value each time
    ↪ .
buf := make([]byte, 0)
for _, item := range fields {
    field, ok := item.(map[string]interface{})
    if !ok {
        return errors.New("schema field should be a map")
    }

    // The tidbOp and subsequent columns are not involved in the checksum
        ↪ calculation, because they are used to assist data consumption
        ↪ and not real TiDB column data.
    colName := field["name"].(string)
    if colName == "_tidb_op" {
        break
    }

    // The holder variable stores the type information of each column.
    var holder map[string]interface{}
    switch ty := field["type"].(type) {
    case []interface{}:
        for _, item := range ty {
            if m, ok := item.(map[string]interface{}); ok {
                holder = m["connect.parameters"].(map[string]interface{})
                break
            }

7.5.15.2 Guide for Developing a Storage Sink Consumer

This document describes how to design and implement a TiDB data change consumer.

> **Note:**
>
> The storage sink cannot handle the `DROP DATABASE` DDL. Therefore, avoid executing this DDL. If you do need to execute this DDL, execute it manually in the downstream MySQL.

TiCDC does not provide any standard way for implementing a consumer. This document provides a consumer example program written in Golang. This program can read data from the storage service and write the data to a MySQL-compatible database. You can refer to the data format and instructions provided in this example to implement a consumer on your own.

Consumer program written in Golang

7.5.15.2.1 Design a consumer

The following diagram shows the overall consumption process of the consumer:

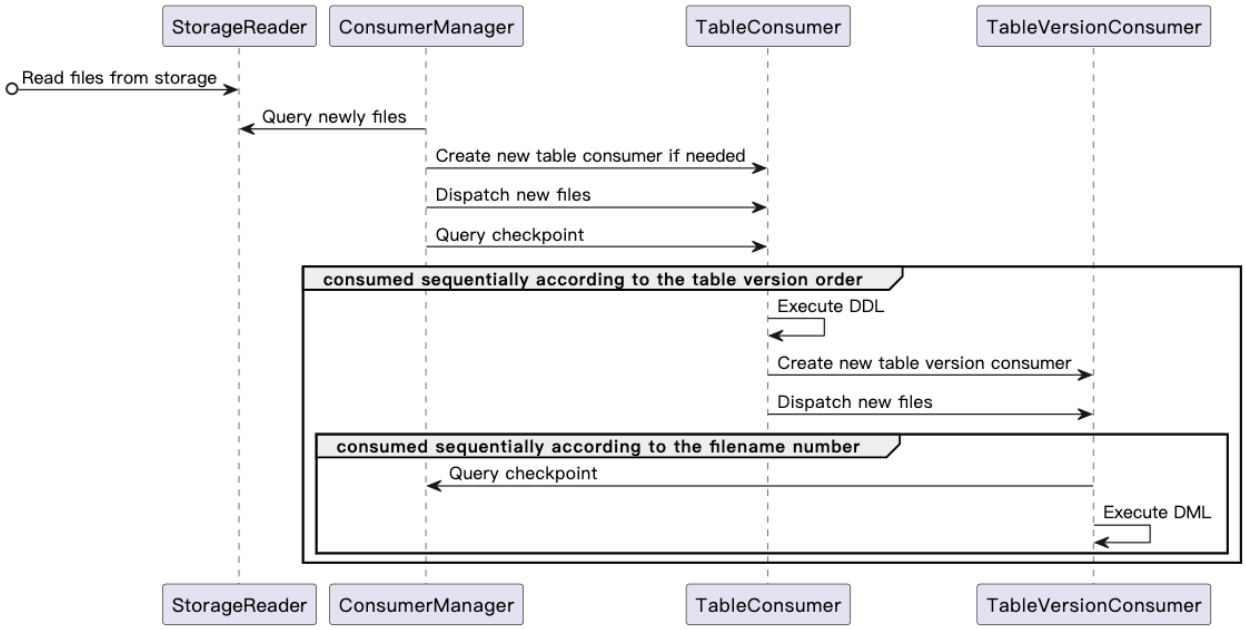

Figure 135: TiCDC storage consumer overview

The components of the consumer and their features are described as follows:

```
type StorageReader struct {
}
// Read the files from storage.
// Add new files and delete files that do not exist in storage.
func (c *StorageReader) ReadFiles() {}

// Query newly added files and the latest checkpoint from storage. One file
    ↪ can only be returned once.
func (c *StorageReader) ExposeNewFiles() (int64, []string) {}
```

```
// ConsumerManager is responsible for assigning tasks to TableConsumer.
// Different consumers can consume data concurrently,
// but data of one table must be processed by the same TableConsumer.
type ConsumerManager struct {
  // StorageCheckpoint is recorded in the metadata file, and it can be
     ↪ fetched by calling `StorageReader.ExposeNewFiles()`.
  // This checkpoint indicates that the data whose transaction commit time
     ↪ is less than this checkpoint has been stored in storage.
  StorageCheckpoint int64
  // This checkpoint indicates where the consumer has consumed.
  // ConsumerManager periodically collects TableConsumer.Checkpoint,
  // then Checkpoint is updated to the minimum value of all TableConsumer.
     ↪ Checkpoint.
  Checkpoint int64

  tableFiles[schema][table]*TableConsumer
}

// Query newly added files from StorageReader.
// For a newly created table, create a TableConsumer for it.
// If any, send new files to the corresponding TableConsumer.
func (c *ConsumerManager) Dispatch() {}
type TableConsumer struct {
  // This checkpoint indicates where this TableConsumer has consumed.
  // Its initial value is ConsumerManager.Checkpoint.
  // TableConsumer.Checkpoint is equal to TableVersionConsumer.Checkpoint.
  Checkpoint int64

  schema,table string
  // Must be consumed sequentially according to the order of table versions.
  verConsumers map[version int64]*TableVersionConsumer
  currentVer, previousVer int64
}

// Send newly added files to the corresponding TableVersionConsumer.
// For any DDL, assign a TableVersionConsumer for the new table version.
func (tc *TableConsumer) Dispatch() {}

// If DDL query is empty or its tableVersion is less than TableConsumer.
   ↪ Checkpoint,
// - ignore this DDL, and consume the data under the table version.
// Otherwise,
// - execute the DDL first, and then consume the data under the table
   ↪ version.
```

```
// - For tables that are dropped, auto-recycling is performed after the drop
   ↪ table DDL is executed.
func (tc *TableConsumer) ExecuteDDL() {}

type TableVersionConsumer struct {
  // This checkpoint indicates where the TableVersionConsumer has consumed.
  // Its initial value is TableConsumer.Checkpoint.
  Checkpoint int64

  schema,table,version string
  // For the same table version, data in different partitions can be
     ↪ consumed concurrently.
  # partitionNum int64
  // Must be consumed sequentially according to the data file number.
  fileSet map[filename string]*TableVersionConsumer
  currentVersion
}
// If data commit ts is less than TableConsumer.Checkpoint
// or bigger than ConsumerManager.StorageCheckpoint,
// - ignore this data.
// Otherwise,
// - process this data and write it to MySQL.
func (tc *TableVersionConsumer) ExecuteDML() {}
```

7.5.15.2.2 Process DDL events

The consumer traverses the directory for the first time. The following is an example:

```
├── metadata
├── test
    ├── tbl_1
        ├── 437752935075545091
            ├── CDC000001.json
            ├── schema.json
```

The consumer parses the table schema of the `schema.json` file and obtains the DDL Query statements:

- If no Query statement is found or `TableVersion` is less than the consumer checkpoint, the consumer skips this statement.
- If Query statements exist or `TableVersion` is equal to or greater than the consumer checkpoint, the consumer executes the DDL statements in the downstream MySQL.

Then the consumer starts replicating the `CDC000001.json` file.

In the following example, the DDL Query statement in the `test/tbl_1/437752935075545091/schema.json` file is not empty:

```
{
    "Table":"test",
    "Schema":"tbl_1",
    "Version": 1,
    "TableVersion":437752935075545091,
    "Query": "create table tbl_1 (Id int primary key, LastName char(20),
        ↪ FirstName varchar(30), HireDate datetime, OfficeLocation Blob(20))
        ↪ ",
    "TableColumns":[
        {
            "ColumnName":"Id",
            "ColumnType":"INT",
            "ColumnNullable":"false",
            "ColumnIsPk":"true"
        },
        {
            "ColumnName":"LastName",
            "ColumnType":"CHAR",
            "ColumnLength":"20"
        },
        {
            "ColumnName":"FirstName",
            "ColumnType":"VARCHAR",
            "ColumnLength":"30"
        },
        {
            "ColumnName":"HireDate",
            "ColumnType":"DATETIME"
        },
        {
            "ColumnName":"OfficeLocation",
            "ColumnType":"BLOB",
            "ColumnLength":"20"
        }
    ],
    "TableColumnsTotal":"5"
}
```

When the consumer traverses the directory again, it finds a new version directory of the table. Note that the consumer can consume data in the new directory only after all files in the `test/tbl_1/437752935075545091` directory have been consumed.

```
└── metadata
```

```
├── test
│   ├── tbl_1
│   │   ├── 437752935075545091
│   │   │   ├── CDC000001.json
│   │   │   └── schema.json
│   │   └── 437752935075546092
│   │       ├── CDC000001.json
│   │       └── schema.json
```

The consumption logic is consistent. Specifically, the consumer parses the table schema of the `schema.json` file and obtains and processes DDL Query statements accordingly. Then the consumer starts replicating the `CDC000001.json` file.

7.5.15.2.3 Process DML events

After DDL events are properly processed, you can process DML events in the `{schema ↪ }/{table}/{table-version-separator}/` directory based on the specific file format (CSV or Canal-JSON) and file number.

TiCDC ensures that data is replicated at least once. Therefore, there might be duplicate data. You need to compare the commit ts of the change data with the consumer checkpoint. If the commit ts is less than the consumer checkpoint, you need to perform deduplication.

7.5.16 TiCDC Compatibility

This section describes compatibility issues related to TiCDC and how to handle them.

7.5.16.1 Compatibility with TiDB Lightning

TiDB Lightning provides two data import modes: logical import mode and physical import mode. This section describes the compatibility of these modes with TiCDC and the steps to use TiDB Lightning and TiCDC together in a cluster.

In the logical import mode, TiDB Lightning imports data by executing SQL statements. This mode is compatible with TiCDC. To use TiDB Lightning's logical import mode with TiCDC for data replication, perform the following steps:

1. Create a changefeed. For more information, see Create a replication task.
2. Start TiDB Lightning and import data using the logical import mode. For more information, see Use logical import mode.

In the physical import mode, TiDB Lightning imports data by inserting SST files into TiKV. TiCDC is not compatible with this mode and does not support replicating data imported through physical import mode. If you need to use both TiDB Lightning's physical import mode and TiCDC, choose one of the following solutions based on your downstream system:

- If the downstream is a TiDB cluster, perform the following steps:

    1. Use TiDB Lightning to import data into both the upstream and downstream TiDB clusters to ensure data consistency.
    2. Create a changefeed to replicate subsequent incremental data written through SQL. For more information, see Create a replication task.

- If the downstream is not a TiDB cluster, perform the following steps:

    1. Use the offline import tool provided by your downstream system to import TiDB Lightning's input files.
    2. Create a changefeed to replicate subsequent incremental data written through SQL. For more information, see Create a replication task.

7.5.16.2 Compatibility with TiFlash

Currently, when you use TiCDC to replicate tables to a downstream TiDB cluster, creating TiFlash replicas for the tables is not supported, which means that TiCDC does not support replicating TiFlash-related DDL statements, such as:

- `ALTER TABLE table_name SET TIFLASH REPLICA count;`
- `ALTER DATABASE db_name SET TIFLASH REPLICA count;`

7.5.16.3 CLI and configuration file compatibility

- In TiCDC v4.0.0, `ignore-txn-commit-ts` is removed and `ignore-txn-start-ts` is added, which uses start_ts to filter transactions.
- In TiCDC v4.0.2, `db-dbs/db-tables/ignore-dbs/ignore-tables` are removed and `rules` is added, which uses new filter rules for databases and tables. For detailed filter syntax, see Table Filter.
- Starting from TiCDC v6.2.0, `cdc cli` can directly interact with TiCDC server via TiCDC Open API. You can specify the address of the TiCDC server using the `--server` parameter. `--pd` is deprecated.
- Since v6.4.0, only the changefeed with the `SYSTEM_VARIABLES_ADMIN` or `SUPER` privilege can use the TiCDC Syncpoint feature.

7.5.16.4 Handle compatibility issues

This section describes compatibility issues related to TiCDC and how to handle them.

7.5.16.4.1 Incompatibility issue caused by using the TiCDC v5.0.0-rc `cdc cli` tool to operate a v4.0.x cluster

When using the `cdc cli` tool of TiCDC v5.0.0-rc to operate a v4.0.x TiCDC cluster, you might encounter the following abnormal situations:

- If the TiCDC cluster is v4.0.8 or an earlier version, using the v5.0.0-rc `cdc cli` tool to create a replication task might cause cluster anomalies and get the replication task stuck.
- If the TiCDC cluster is v4.0.9 or a later version, using the v5.0.0-rc `cdc cli` tool to create a replication task will cause the old value and unified sorter features to be unexpectedly enabled by default.

Solutions:

Use the `cdc` executable file corresponding to the TiCDC cluster version to perform the following operations:

1. Delete the changefeed created using the v5.0.0-rc `cdc cli` tool. For example, run the `tiup cdc:v4.0.9 cli changefeed remove -c xxxx --pd=xxxxx --force` command.
2. If the replication task is stuck, restart the TiCDC cluster. For example, run the `tiup cluster restart <cluster_name> -R cdc` command.
3. Re-create the changefeed. For example, run the `tiup cdc:v4.0.9 cli changefeed create --sink-uri=xxxx --pd=xxx` command.

> **Note:**
>
> This issue exists only when `cdc cli` is v5.0.0-rc. `cdc cli` tool of other v5.0.x versions is compatible with v4.0.x clusters.

7.5.16.4.2 Compatibility notes for `sort-dir` and `data-dir`

The `sort-dir` configuration is used to specify the temporary file directory for the TiCDC sorter. Its functionalities might vary in different versions. The following table lists `sort-dir`'s compatibility changes across versions.

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v4.0.11 or earlier v4.0 version, v5.0.0-rc	It is a changefeed configuration item and specifies temporary file directory for the file sorter and unified ↪ sorter.	In these versions, file ↪ sorter and unified ↪ sorter are **experimental features** and **NOT** recommended for the production environment. If mul-	It is not recommended to use unified ↪ sorter in the production environment.

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v4.0.12, v4.0.13, v5.0.0, and v5.0.1	It is a configuration item of changefeed or of cdc ↪ server ↪ .	By default, the sort ↪ - ↪ dir ↪ configuration of a changefeed does not take effect, and the sort ↪ - ↪ dir ↪ configuration of cdc ↪ ↪ server ↪ defaults to /	You need to configure sort ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

Version	sort ↪ - ↪ engine ↪ function-ality	Note	Recommendation
v4.0.14 and later v4.0 versions, v5.0.3 and later v5.0 versions, later TiDB versions	sort ↪ - ↪ dir ↪ is deprecated. It is recommended to configure data ↪ - ↪ dir ↪ .	You can configure data ↪ - ↪ dir ↪ using the latest version of TiUP. In these TiDB versions, unified ↪ sorter is enabled by default. Make sure that data ↪ - ↪ dir ↪ has been con-	You need to configure data ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

Version	sort ↪ - ↪ engine ↪ functionality	Note	Recommendation
v6.0.0 and later versions	data ↪ - ↪ dir ↪ is used for saving the temporary files generated by TiCDC.	Starting from v6.0.0, TiCDC uses db ↪ sorter ↪ as the sort engine by default. data ↪ - ↪ dir ↪ is the disk directory for this engine.	You need to configure data ↪ - ↪ dir ↪ using the cdc ↪ ↪ server ↪ command-line parameter (or TiUP).

7.5.16.4.3 Compatibility with temporary tables

Since v5.3.0, TiCDC supports global temporary tables. Replicating global temporary tables to the downstream using TiCDC of a version earlier than v5.3.0 causes table definition error.

If the upstream cluster contains a global temporary table, the downstream TiDB cluster

is expected to be v5.3.0 or a later version. Otherwise, an error occurs during the replication process.

7.5.16.4.4 Compatibility with vector data types

Starting from v8.4.0, TiCDC supports replicating tables with vector data types to downstream (experimental).

When the downstream is Kafka or a storage service (such as Amazon S3, GCS, Azure Blob Storage, or NFS), TiCDC converts vector data types into string types before writing to the downstream.

When the downstream is a MySQL-compatible database that does not support vector data types, TiCDC fails to write DDL events involving vector types to the downstream. In this case, add the `has-vector-type=true` parameter to `sink-url`, which allows TiCDC to convert vector data types into the `LONGTEXT` type before writing.

7.6 Troubleshoot TiCDC

This document introduces the common errors you might encounter when using TiCDC, and the corresponding maintenance and troubleshooting methods.

> **Note:**
>
> In this document, the server address specified in `cdc cli` commands is `server =http://127.0.0.1:8300`. When you use the command, replace the address with your actual TiCDC Server address.

7.6.1 TiCDC replication interruptions

7.6.1.1 How do I know whether a TiCDC replication task is interrupted?

- Check the `changefeed checkpoint` monitoring metric of the replication task (choose the right `changefeed id`) in the Grafana dashboard. If the metric value stays unchanged, or the `checkpoint lag` metric keeps increasing, the replication task might be interrupted.
- Check the `exit error count` monitoring metric. If the metric value is greater than `0`, an error has occurred in the replication task.
- Execute `cdc cli changefeed list` and `cdc cli changefeed query` to check the status of the replication task. `stopped` means the task has stopped, and the `error` item provides the detailed error message. After the error occurs, you can search `error on running processor` in the TiCDC server log to see the error stack for troubleshooting.

- In some extreme cases, the TiCDC service is restarted. You can search the `FATAL` level log in the TiCDC server log for troubleshooting.

7.6.1.2 How do I know whether the replication task is stopped manually?

You can know whether the replication task is stopped manually by executing `cdc cli`. For example:

```
cdc cli changefeed query --server=http://127.0.0.1:8300 --changefeed-id 28
    ↪ c43ffc-2316-4f4f-a70b-d1a7c59ba79f
```

In the output of the above command, `admin-job-type` shows the state of this replication task. For more information about each state and its meaning, see Changefeed states.

7.6.1.3 How do I handle replication interruptions?

A replication task might be interrupted in the following known scenarios:

- The downstream continues to be abnormal, and TiCDC still fails after many retries.
    - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
    - Handling method: You can resume the replication task by executing `cdc cli changefeed resume` after the downstream is back to normal.
- Replication cannot continue because of incompatible SQL statement(s) in the downstream.
    - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
    - Handling procedures:
        1. Query the status information of the replication task using the `cdc cli changefeed query` command and record the value of `checkpoint-ts`.
        2. Use the new task configuration file and add the `ignore-txn-start-ts` parameter to skip the transaction corresponding to the specified `start-ts`.
        3. Pause the replication task by executing `cdc cli changefeed pause -c <changefeed-id>`.
        4. Specify the new task configuration file by executing `cdc cli changefeed update -c <changefeed-id> --config <config-file-path>`.
        5. Resume the replication task by executing `cdc cli changefeed resume -c <changefeed-id>`.

7.6.1.4 What should I do to handle the OOM that occurs after TiCDC is restarted after a task interruption?

- Update your TiDB cluster and TiCDC cluster to the latest versions. The OOM problem has already been resolved in **v4.0.14 and later v4.0 versions, v5.0.2 and later v5.0 versions, and the latest versions**.

7.6.2 How do I handle the `Error 1298: Unknown or incorrect time zone: 'UTC'` error when creating the replication task or replicating data to MySQL?

This error is returned when the downstream MySQL does not load the time zone. You can load the time zone by running `mysql_tzinfo_to_sql`. After loading the time zone, you can create tasks and replicate data normally.

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql -p
```

If the output of the command above is similar to the following one, the import is successful:

```
Enter password:
Warning: Unable to load '/usr/share/zoneinfo/iso3166.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/leap-seconds.list' as time zone
    ↪ . Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone1970.tab' as time zone.
    ↪ Skipping it.
```

If the downstream is a special MySQL environment (a public cloud RDS or some MySQL derivative versions) and importing the time zone using the preceding method fails, you can use the default time zone of the downstream by setting `time-zone` to an empty value, such as `time-zone=""`.

When using time zones in TiCDC, it is recommended to explicitly specify the time zone, such as `time-zone="Asia/Shanghai"`. Also, make sure that the `tz` specified in TiCDC server configurations and the `time-zone` specified in Sink URI are consistent with the time zone configuration of the downstream database. This prevents data inconsistency caused by inconsistent time zones.

7.6.3 How do I handle the incompatibility issue of configuration files caused by TiCDC upgrade?

Refer to Notes for compatibility.

7.6.4 The `start-ts` timestamp of the TiCDC task is quite different from the current time. During the execution of this task, replication is interrupted and an error `[CDC:ErrBufferReachLimit]` occurs. What should I do?

Since v4.0.9, you can try to enable the unified sorter feature in your replication task, or use the BR tool for an incremental backup and restore, and then start the TiCDC replication task from a new time.

7.6.5 When the downstream of a changefeed is a database similar to MySQL and TiCDC executes a time-consuming DDL statement, all other changefeeds are blocked. What should I do?

1. Pause the execution of the changefeed that contains the time-consuming DDL statement. Then you can see that other changefeeds are no longer blocked.
2. Search for the `apply job` field in the TiCDC log and confirm the `start-ts` of the time-consuming DDL statement.
3. Manually execute the DDL statement in the downstream. After the execution finishes, go on performing the following operations.
4. Modify the changefeed configuration and add the above `start-ts` to the `ignore-txn-start-ts` configuration item.
5. Resume the paused changefeed.

7.6.6 The `[tikv:9006]GC life time is shorter than transaction duration, transaction starts at xx, GC safe point is yy` error is reported when I use TiCDC to create a changefeed. What should I do?

You need to run the `pd-ctl service-gc-safepoint --pd <pd-addrs>` command to query the current GC safepoint and service GC safepoint. If the GC safepoint is smaller than the `start-ts` of the TiCDC replication task (changefeed), you can directly add the `--disable-gc-check` option to the `cdc cli create changefeed` command to create a changefeed.

If the result of `pd-ctl service-gc-safepoint --pd <pd-addrs>` does not have `gc_worker service_id`:

- If your PD version is v4.0.8 or earlier, refer to PD issue #3128 for details.
- If your PD is upgraded from v4.0.8 or an earlier version to a later version, refer to PD issue #3366 for details.

7.6.7 When I use TiCDC to replicate messages to Kafka, Kafka returns the `Message was too large` error. Why?

For TiCDC v4.0.8 or earlier versions, you cannot effectively control the size of the message output to Kafka only by configuring the `max-message-bytes` setting for Kafka in the Sink URI. To control the message size, you also need to increase the limit on the bytes of messages

to be received by Kafka. To add such a limit, add the following configuration to the Kafka server configuration.

```
## The maximum byte number of a message that the broker receives
message.max.bytes=2147483648
## The maximum byte number of a message that the broker copies
replica.fetch.max.bytes=2147483648
## The maximum message byte number that the consumer side reads
fetch.message.max.bytes=2147483648
```

7.6.8 How can I find out whether a DDL statement fails to execute in downstream during TiCDC replication? How to resume the replication?

If a DDL statement fails to execute, the replication task (changefeed) automatically stops. The checkpoint-ts is the DDL statement's finish-ts. If you want TiCDC to retry executing this statement in the downstream, use `cdc cli changefeed resume` to resume the replication task. For example:

```
cdc cli changefeed resume -c test-cf --server=http://127.0.0.1:8300
```

If you want to skip this DDL statement that goes wrong, set the start-ts of the changefeed to the checkpoint-ts (the timestamp at which the DDL statement goes wrong) plus one, and then run the `cdc cli changefeed create` command to create a new changefeed task. For example, if the checkpoint-ts at which the DDL statement goes wrong is `415241823337054209`, run the following commands to skip this DDL statement:

To skip this DDL statement that goes wrong, you can configure the `ignore-txn-start-ts` parameter to skip the transactions corresponding to the specified `start-ts`. For example:

1. Search the TiCDC log for the `apply job` field, and identify the `start-ts` of the DDLs that are taking a long time.
2. Modify the changefeed configuration. Add the above `start-ts` to the `ignore-txn-start-ts` configuration item.
3. Resume the suspended changefeed.

> **Note:**
>
> Although setting the changefeed `start-ts` to the value of `checkpoint-ts` (at the time of the error) plus one and then recreating the task can skip the DDL statement, it can also cause TiCDC to lose the DML data change at the time of `checkpointTs+1`. Therefore, this operation is strictly prohibited in production environments.

```
cdc cli changefeed remove --server=http://127.0.0.1:8300 --changefeed-id
    ↪ simple-replication-task
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="mysql
    ↪ ://root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-
    ↪ task" --sort-engine="unified" --start-ts 415241823337054210
```

7.6.9 The `Kafka: client has run out of available brokers to talk to: EOF` error is reported when I use TiCDC to replicate messages to Kafka. What should I do?

This error is typically caused by the connection failure between TiCDC and the Kafka cluster. To troubleshoot, you can check the Kafka logs and network status. One possible reason is that you did not specify the correct `kafka-version` parameter when creating the replication task, causing the Kafka client inside TiCDC to use the wrong Kafka API version when accessing the Kafka server. You can fix this issue by specifying the correct `kafka-version` parameter in the `--sink-uri` configuration. For example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri "kafka
    ↪ ://127.0.0.1:9092/test?topic=test&protocol=open-protocol&kafka-
    ↪ version=2.4.0"
```

7.7 TiCDC FAQs

This document introduces the common questions that you might encounter when using TiCDC.

> **Note:**
>
> In this document, the server address specified in `cdc cli` commands is `--server=http://127.0.0.1:8300`. When you use the command, replace the address with your actual PD address.

7.7.1 How do I choose `start-ts` when creating a task in TiCDC?

The `start-ts` of a replication task corresponds to a Timestamp Oracle (TSO) in the upstream TiDB cluster. TiCDC requests data from this TSO in a replication task. Therefore, the `start-ts` of the replication task must meet the following requirements:

- The value of `start-ts` is larger than the `tikv_gc_safe_point` value of the current TiDB cluster. Otherwise, an error occurs when you create a task.

- Before starting a task, ensure that the downstream has all data before `start-ts`. For scenarios such as replicating data to message queues, if the data consistency between upstream and downstream is not required, you can relax this requirement according to your application need.

If you do not specify `start-ts`, or specify `start-ts` as `0`, when a replication task is started, TiCDC gets a current TSO and starts the task from this TSO.

7.7.2 Why can't some tables be replicated when I create a task in TiCDC?

When you execute `cdc cli changefeed create` to create a replication task, TiCDC checks whether the upstream tables meet the replication requirements. If some tables do not meet the requirements, `some tables are not eligible to replicate` is returned with a list of ineligible tables. You can choose `Y` or `y` to continue creating the task, and all updates on these tables are automatically ignored during the replication. If you choose an input other than `Y` or `y`, the replication task is not created.

7.7.3 How do I view the state of TiCDC replication tasks?

To view the status of TiCDC replication tasks, use `cdc cli`. For example:

```
cdc cli changefeed list --server=http://127.0.0.1:8300
```

The expected output is as follows:

```
[{
    "id": "4e24dde6-53c1-40b6-badf-63620e4940dc",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
}]
```

- `checkpoint`: TiCDC has replicated all data before this timestamp to downstream.
- `state`: The state of this replication task. For more information about each state and its meaning, see Changefeed states.

> **Note:**
>
> This feature is introduced in TiCDC 4.0.3.

7.7.4 How to verify if TiCDC has replicated all updates after upstream stops updating?

After the upstream TiDB cluster stops updating, you can verify if replication is complete by comparing the latest TSO timestamp of the upstream TiDB cluster with the replication progress in TiCDC. If the TiCDC replication progress timestamp is greater than or equal to the upstream TiDB cluster's TSO, then all updates have been replicated. To verify replication completeness, perform the following steps:

1. Get the latest TSO timestamp from the upstream TiDB cluster.

> **Note:**
> Use the `TIDB_CURRENT_TSO()` function to get the current TSO, instead of using functions like `NOW()` that return the current time.

The following example uses `TIDB_PARSE_TSO()` to convert the TSO to a readable time format for further comparison:

```
BEGIN;
SELECT TIDB_PARSE_TSO(TIDB_CURRENT_TSO());
ROLLBACK;
```

The output is as follows:

```
+-----------------------------------+
| TIDB_PARSE_TSO(TIDB_CURRENT_TSO()) |
+-----------------------------------+
| 2024-11-12 20:35:34.848000     |
+-----------------------------------+
```

2. Get the replication progress in TiCDC.

   You can check the replication progress in TiCDC using one of the following methods:

   - **Method 1**: query the checkpoint of the changefeed (recommended).

     Use the TiCDC command-line tool `cdc cli` to view the checkpoint for all replication tasks:

     ```
     cdc cli changefeed list --server=http://127.0.0.1:8300
     ```

     The output is as follows:

     ```
     [
       {
         "id": "syncpoint",
     ```

```
    "namespace": "default",
    "summary": {
      "state": "normal",
      "tso": 453880043653562372,
      "checkpoint": "2024-11-12 20:36:01.447",
      "error": null
    }
  }
]
```

In the output, `"checkpoint": "2024-11-12 20:36:01.447"` indicates that TiCDC has replicated all upstream TiDB changes before this time. If this timestamp is greater than or equal to the upstream TiDB cluster's TSO obtained in step 1, then all updates have been replicated downstream.

- **Method 2**: query Syncpoint from the downstream TiDB.

  If the downstream is a TiDB cluster and the TiCDC Syncpoint feature is enabled, you can get the replication progress by querying the Syncpoint in the downstream TiDB.

> **Note:**
> The Syncpoint update interval is controlled by the `sync-point-interval` configuration item. For the most up-to-date replication progress, use method 1.

Execute the following SQL statement in the downstream TiDB to get the upstream TSO (`primary_ts`) and downstream TSO (`secondary_ts`):

```
SELECT * FROM tidb_cdc.syncpoint_v1;
```

The output is as follows:

```
+--
   ↪ ----------------+------------+--------------------+--------------------
   ↪
| ticdc_cluster_id | changefeed | primary_ts   | secondary_ts     |
   ↪ created_at        |
+--
   ↪ ----------------+------------+--------------------+--------------------
   ↪
| default          | syncpoint | 453879870259200000 |
   ↪ 453879870545461257 | 2024-11-12 20:25:01 |
| default          | syncpoint | 453879948902400000 |
   ↪ 453879949214351361 | 2024-11-12 20:30:01 |
| default          | syncpoint | 453880027545600000 |
   ↪ 453880027751907329 | 2024-11-12 20:35:00 |
```

```
+--
    ↪ ----------------+------------+-------------------+--------------------
    ↪
```

In the output, each row shows the upstream TiDB snapshot at `primary_ts` matches the downstream TiDB snapshot at `secondary_ts`.

To view the replication progress, convert the latest `primary_ts` to a readable time format:

```
SELECT TIDB_PARSE_TSO(453880027545600000);
```

The output is as follows:

```
+-----------------------------------+
| TIDB_PARSE_TSO(453880027545600000) |
+-----------------------------------+
| 2024-11-12 20:35:00               |
+-----------------------------------+
```

If the time corresponding to the latest `primary_ts` is greater than or equal to the upstream TiDB cluster's TSO obtained in step 1, then TiCDC has replicated all updates downstream.

7.7.5 What is `gc-ttl` in TiCDC?

Since v4.0.0-rc.1, PD supports external services in setting the service-level GC safepoint. Any service can register and update its GC safepoint. PD ensures that the key-value data later than this GC safepoint is not cleaned by GC.

When the replication task is unavailable or interrupted, this feature ensures that the data to be consumed by TiCDC is retained in TiKV without being cleaned by GC.

When starting the TiCDC server, you can specify the Time To Live (TTL) duration of GC safepoint by configuring `gc-ttl`. You can also use TiUP to modify `gc-ttl`. The default value is 24 hours. In TiCDC, this value means:

- The maximum time the GC safepoint is retained at the PD after the TiCDC service is stopped.
- When TiKV's GC is blocked by TiCDC's GC safepoint, `gc-ttl` indicates the maximum replication delay of a TiCDC replication task. If the delay of the replication task exceeds the value set by `gc-ttl`, the replication task enters into the `failed` state and reports the `ErrGCTTLExceeded` error. It cannot be recovered, and no longer blocks GC safepoint to advance.

The second behavior above is introduced in TiCDC v4.0.13 and later versions. The purpose is to prevent a replication task in TiCDC from suspending for too long, causing the GC safepoint of the upstream TiKV cluster not to continue for a long time and retaining too many outdated data versions, thus affecting the performance of the upstream cluster.

Note:

In some scenarios, for example, when you use TiCDC for incremental replication after full replication with Dumpling/BR, the default 24 hours of `gc-ttl` may not be sufficient. You need to specify an appropriate value for `gc-ttl` when you start the TiCDC server.

7.7.6 What is the complete behavior of TiCDC garbage collection (GC) safepoint?

If a replication task starts after the TiCDC service starts, the TiCDC owner updates the PD service GC safepoint with the smallest value of `checkpoint-ts` among all replication tasks. The service GC safepoint ensures that TiCDC does not delete data generated at that time and after that time. If the replication task is interrupted, or manually stopped, the `checkpoint-ts` of this task does not change. Meanwhile, PD's corresponding service GC safepoint is not updated either.

If the replication task is suspended longer than the time specified by `gc-ttl`, the replication task enters the `failed` status and cannot be resumed. The PD corresponding service GC safepoint will continue.

The default Time-To-Live (TTL) that TiCDC sets for a service GC safepoint is 24 hours, which means that the GC mechanism does not delete the data required by TiCDC for continuing replication if the TiCDC service can be recovered within 24 hours after it is interrupted.

7.7.7 How to recover a replication task after it fails?

1. Use `cdc cli changefeed query` to query the error information of the replication task and fix the error as soon as possible.
2. Increase the value of `gc-ttl` to allow more time to fix the error, ensuring that the replication task does not enter the `failed` status due to the replication delay exceeding `gc-ttl` after the error is fixed.
3. After evaluating the impact on the system, increase the value of `tidb_gc_life_time` in TiDB to block GC and retain data, ensuring that the replication task does not enter the `failed` status due to GC cleaning data after the error is fixed.

7.7.8 How to understand the relationship between the TiCDC time zone and the time zones of the upstream/downstream databases?

	Upstream time zone	TiCDC time zone	Downstream time zone
Configuration method	See Time Zone Support	Configured using the `--tz` parameter when you start the TiCDC server	Configured using the `time-zone` parameter in `sink-uri`

	Upstream time zone	TiCDC time zone	Downstream time zone
Description	The time zone of the upstream TiDB, which affects DML operations of the timestamp type and DDL operations related to timestamp type columns.	TiCDC assumes that the upstream TiDB's time zone is the same as the TiCDC time zone configuration, and performs related operations on the timestamp column.	The downstream MySQL processes the timestamp in the DML and DDL operations according to the downstream time zone setting.

Note:

Be careful when you set the time zone of the TiCDC server, because this time zone is used for converting the time type. Keep the upstream time zone, TiCDC time zone, and the downstream time zone consistent. The TiCDC server chooses its time zone in the following priority:

- TiCDC first uses the time zone specified using `--tz`.
- When `--tz` is not available, TiCDC tries to read the time zone set using the `TZ` environment variable.
- When the `TZ` environment variable is not available, TiCDC uses the default time zone of the machine.

7.7.9 What is the default behavior of TiCDC if I create a replication task without specifying the configuration file in `--config`?

If you use the `cdc cli changefeed create` command without specifying the `-config` parameter, TiCDC creates the replication task in the following default behaviors:

- Replicates all tables except system tables
- Only replicates tables that contain valid indexes

7.7.10 Does TiCDC support outputting data changes in the Canal protocol?

Yes. Note that for the Canal protocol, TiCDC only supports the JSON output format, while the protobuf format is not officially supported yet. To enable Canal output, specify `protocol` as `canal-json` in the `--sink-uri` configuration. For example:

```
cdc cli changefeed create --server=http://127.0.0.1:8300 --sink-uri="kafka
    ↪ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&protocol=canal-json"
    ↪ --config changefeed.toml
```

Note:

- This feature is introduced in TiCDC 4.0.2.
- TiCDC currently supports outputting data changes in the Canal-JSON format only to MQ sinks such as Kafka.

For more information, refer to TiCDC changefeed configurations.

7.7.11 Why does the latency from TiCDC to Kafka become higher and higher?

- Check how do I view the state of TiCDC replication tasks.
- Adjust the following parameters of Kafka:
    - Increase the `message.max.bytes` value in `server.properties` to `1073741824` (1 GB).
    - Increase the `replica.fetch.max.bytes` value in `server.properties` to `1073741824` (1 GB).
    - Increase the `fetch.message.max.bytes` value in `consumer.properties` to make it larger than the `message.max.bytes` value.

7.7.12 When TiCDC replicates data to Kafka, can I control the maximum size of a single message in TiDB?

When `protocol` is set to `avro` or `canal-json`, messages are sent per row change. A single Kafka message contains only one row change and is generally no larger than Kafka's limit. Therefore, there is no need to limit the size of a single message. If the size of a single Kafka message does exceed Kafka's limit, refer to Why does the latency from TiCDC to Kafka become higher and higher?.

When `protocol` is set to `open-protocol`, messages are sent in batches. Therefore, one Kafka message might be excessively large. To avoid this situation, you can configure the `max-message-bytes` parameter to control the maximum size of data sent to the Kafka broker each time (optional, `10MB` by default). You can also configure the `max-batch-size` parameter (optional, `16` by default) to specify the maximum number of change records in each Kafka message.

7.7.13 If I modify a row multiple times in a transaction, will TiCDC output multiple row change events?

No. When you modify the same row in one transaction multiple times, TiDB only sends the latest modification to TiKV. Therefore, TiCDC can only obtain the result of the latest modification.

7.7.14 When TiCDC replicates data to Kafka, does a message contain multiple types of data changes?

Yes. A single message might contain multiple `updates` or `deletes`, and `update` and `delete` might co-exist.

7.7.15 When TiCDC replicates data to Kafka, how do I view the timestamp, table name, and schema name in the output of TiCDC Open Protocol?

The information is included in the key of Kafka messages. For example:

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
}
```

For more information, refer to TiCDC Open Protocol event format.

7.7.16 When TiCDC replicates data to Kafka, how do I know the timestamp of the data changes in a message?

You can get the unix timestamp by moving `ts` in the key of the Kafka message by 18 bits to the right.

7.7.17 How does TiCDC Open Protocol represent `null`?

In TiCDC Open Protocol, the type code `6` represents `null`.

Type	Code	Output Example	Note
Null	6	`{"t":6,"v":null}`	

For more information, refer to TiCDC Open Protocol column type code.

7.7.18 How can I tell if a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event?

- `UPDATE` event contains both `"p"` and `"u"` fields
- `INSERT` event only contains the `"u"` field
- `DELETE` event only contains the `"d"` field

For more information, refer to Open protocol Row Changed Event format.

7.7.19 How much PD storage does TiCDC use?

When using TiCDC, you might encounter the `etcdserver: mvcc: database space exceeded` error, which is primarily related to the mechanism that TiCDC uses etcd in PD to store metadata.

etcd uses Multi-Version Concurrency Control (MVCC) to store data, and the default compaction interval in PD is 1 hour. This means that etcd retains multiple versions of all data for 1 hour before compaction.

Before v6.0.0, TiCDC uses etcd in PD to store and update metadata for all tables in a changefeed. Therefore, the PD storage space used by TiCDC is proportional to the number of tables being replicated by the changefeed. When TiCDC is replicating a large number of tables, the etcd storage space could fill up quickly, increasing the probability of the `etcdserver: mvcc: database space exceeded` error.

If you encounter this error, refer to etcd maintenance space-quota to clean up the etcd storage space.

Starting from v6.0.0, TiCDC optimizes its metadata storage mechanism, effectively avoiding the etcd storage space issues caused by the preceding reasons. If your TiCDC version is earlier than v6.0.0, it is recommended to upgrade to v6.0.0 or later versions.

7.7.20 Does TiCDC support replicating large transactions? Is there any risk?

TiCDC provides partial support for large transactions (more than 5 GB in size). Depending on different scenarios, the following risks might exist:

- The latency of primary-secondary replication might greatly increase.
- When TiCDC's internal processing capacity is insufficient, the replication task error `ErrBufferReachLimit` might occur.
- When TiCDC's internal processing capacity is insufficient or the throughput capacity of TiCDC's downstream is insufficient, out of memory (OOM) might occur.

Since v6.2, TiCDC supports splitting a single-table transaction into multiple transactions. This can greatly reduce the latency and memory consumption of replicating large transactions. Therefore, if your application does not have a high requirement on transaction atomicity, it is recommended to enable the splitting of large transactions to avoid possible replication latency and OOM. To enable the splitting, set the value of the sink uri parameter `transaction-atomicity` to `none`.

If you still encounter an error above, it is recommended to use BR to restore the incremental data of large transactions. The detailed operations are as follows:

1. Record the `checkpoint-ts` of the changefeed that is terminated due to large transactions, use this TSO as the `--lastbackupts` of the BR incremental backup, and execute incremental data backup.
2. After backing up the incremental data, you can find a log record similar to `["Full backup Failed summary : total backup ranges: 0, total success: 0, total failed: 0"] [BackupTS=421758868510212097]` in the BR log output. Record the `BackupTS` in this log.
3. Restore the incremental data.
4. Create a new changefeed and start the replication task from `BackupTS`.
5. Delete the old changefeed.

7.7.21 Does TiCDC replicate data changes caused by lossy DDL operations to the downstream?

Lossy DDL refers to DDL that might cause data changes when executed in TiDB. Some common lossy DDL operations include:

- Modifying the type of a column, for example, INT -> VARCHAR
- Modifying the length of a column, for example, VARCHAR(20) -> VARCHAR(10)
- Modifying the precision of a column, for example, DECIMAL(10, 3) -> DECIMAL(10, 2)
- Modifying the UNSIGNED or SIGNED attribute of a column, for example, INT UNSIGNED -> INT SIGNED

Before TiDB v7.1.0, TiCDC replicates DML events with identical old and new data to the downstream. When the downstream is MySQL, these DML events do not cause any data changes until the downstream receives and executes the DDL statement. However, when the downstream is Kafka or a cloud storage service, TiCDC writes a row of redundant data to the downstream.

Starting from TiDB v7.1.0, TiCDC eliminates these redundant DML events and no longer replicates them to downstream.

7.7.22 The default value of the time type field is inconsistent when replicating a DDL statement to the downstream MySQL 5.7. What can I do?

Suppose that the `create table test (id int primary key, ts timestamp)` statement is executed in the upstream TiDB. When TiCDC replicates this statement to the downstream MySQL 5.7, MySQL uses the default configuration. The table schema after the replication is as follows. The default value of the `timestamp` field becomes `CURRENT_TIMESTAMP`:

```
mysql root@127.0.0.1:test> show create table test;
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| Table | Create Table
   ↪                                                                    |
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| test | CREATE TABLE `test` (
   ↪                                                        |
|      |   `id` int NOT NULL,
   ↪                                                      |
|      |   `ts` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
   ↪ CURRENT_TIMESTAMP, |
```

```
|       |   PRIMARY KEY (`id`)
    ↪                                                                |
|       | ) ENGINE=InnoDB DEFAULT CHARSET=latin1
    ↪                                      |
+--
    ↪ -----+-------------------------------------------------------------------------
    ↪
1 row in set
```

From the result, you can see that the table schema before and after the replication is inconsistent. This is because the default value of `explicit_defaults_for_timestamp` in TiDB is different from that in MySQL. See MySQL Compatibility for details.

Since v5.0.1 or v4.0.13, for each replication to MySQL, TiCDC automatically sets `explicit_defaults_for_timestamp = ON` to ensure that the time type is consistent between the upstream and downstream. For versions earlier than v5.0.1 or v4.0.13, pay attention to the compatibility issue caused by the inconsistent `explicit_defaults_for_timestamp` value when using TiCDC to replicate the time type data.

7.7.23 Why do `INSERT/UPDATE` statements from the upstream become `REPLACE INTO` after being replicated to the downstream if I set `safe-mode` to `true` when I create a TiCDC replication task?

TiCDC guarantees that all data is replicated at least once. When there is duplicate data in the downstream, write conflicts occur. To avoid this problem, TiCDC converts `INSERT` and `UPDATE` statements into `REPLACE INTO` statements. This behavior is controlled by the `safe-mode` parameter.

In versions earlier than v6.1.3, the default value of `safe-mode` is `true`, which means all `INSERT` and `UPDATE` statements are converted into `REPLACE INTO` statements.

In v6.1.3 and later versions, the default value of `safe-mode` changes to `false`, and TiCDC can automatically determine whether the downstream has duplicate data. If no duplicate data is detected, TiCDC directly replicates `INSERT` and `UPDATE` statements without conversion; otherwise, TiCDC converts `INSERT` and `UPDATE` statements into `REPLACE INTO` statements and then replicates them.

7.7.24 Why does TiCDC use disks? When does TiCDC write to disks? Does TiCDC use memory buffer to improve replication performance?

When upstream write traffic is at peak hours, the downstream may fail to consume all data in a timely manner, resulting in data pile-up. TiCDC uses disks to process the data that is piled up. TiCDC needs to write data to disks during normal operation. However, this is not usually the bottleneck for replication throughput and replication latency, given that writing to disks only results in latency within a hundred milliseconds. TiCDC also uses memory to accelerate reading data from disks to improve replication performance.

7.7.25 Why does replication using TiCDC stall or even stop after data restore using TiDB Lightning physical import mode and BR from upstream?

Currently, TiCDC is not yet fully compatible with TiDB Lightning physical import mode and BR. Therefore, avoid using TiDB Lightning physical import mode and BR on tables that are replicated by TiCDC. Otherwise, unknown errors might occur, such as TiCDC replication getting stuck, a significant spike in replication latency, or data loss.

If you need to use TiDB Lightning physical import mode or BR to restore data for some tables replicated by TiCDC, take these steps:

1. Remove the TiCDC replication task related to these tables.
2. Use TiDB Lightning physical import mode or BR to restore data separately in the upstream and downstream clusters of TiCDC.
3. After the restoration is complete and data consistency between the upstream and downstream clusters is verified, create a new TiCDC replication task for incremental replication, with the timestamp (TSO) from the upstream backup as the `start-ts` for the task. For example, assuming the snapshot timestamp of the BR backup in the upstream cluster is `431434047157698561`, you can create a new TiCDC replication task using the following command:

```
cdc cli changefeed create -c "upstream-to-downstream-some-tables" --
    ↪ start-ts=431434047157698561 --sink-uri="mysql://root@127
    ↪ .0.0.1:4000? time-zone="
```

7.7.26 After a changefeed resumes from pause, its replication latency gets higher and higher and returns to normal only after a few minutes. Why?

When a changefeed is resumed, TiCDC needs to scan the historical versions of data in TiKV to catch up with the incremental data logs generated during the pause. The replication process proceeds only after the scan is completed. The scan process might take several to tens of minutes.

7.7.27 How should I deploy TiCDC to replicate data between two TiDB cluster located in different regions?

For TiCDC versions earlier than v6.5.2, it is recommended that you deploy TiCDC in the downstream TiDB cluster. If the network latency between the upstream and downstream is high, for example, more than 100 ms, the latency produced when TiCDC executes SQL statements to the downstream might increase dramatically due to the MySQL transmission protocol issues. This results in a decrease in system throughput. However, deploying TiCDC in the downstream can greatly ease this problem. After optimization, starting from TiCDC v6.5.2, it is recommended that you deploy TiCDC in the upstream TiDB cluster.

7.7.28 What is the order of executing DML and DDL statements?

Currently, TiCDC adopts the following order:

1. TiCDC blocks the replication progress of the tables affected by DDL statements until the DDL `commitTS`. This ensures that DML statements executed before DDL `commitTS` can be successfully replicated to the downstream first.
2. TiCDC continues with the replication of DDL statements. If there are multiple DDL statements, TiCDC replicates them in a serial manner.
3. After the DDL statements are executed in the downstream, TiCDC will continue with the replication of DML statements executed after DDL `commitTS`.

7.7.29 How should I check whether the upstream and downstream data is consistent?

If the downstream is a TiDB cluster or MySQL instance, it is recommended that you compare the data using sync-diff-inspector.

7.7.30 Replication of a single table can only be run on a single TiCDC node. Will it be possible to use multiple TiCDC nodes to replicate data of multiple tables?

Starting from v7.1.0, TiCDC supports the MQ sink to replicate data change logs at the granularity of TiKV Regions, which achieves scalable processing capability and allows TiCDC to replicate a single table with a large number of Regions. To enable this feature, you can configure the following parameter in the TiCDC configuration file:

```
[scheduler]
enable-table-across-nodes = true
```

7.7.31 Does TiCDC replication get stuck if the upstream has long-running uncommitted transactions?

TiDB has a transaction timeout mechanism. When a transaction runs for a period longer than `max-txn-ttl`, TiDB forcibly rolls it back. TiCDC waits for the transaction to be committed before proceeding with the replication, which causes replication delay.

7.7.32 Why can't I use the `cdc cli` command to operate a TiCDC cluster deployed by TiDB Operator?

This is because the default port number of the TiCDC cluster deployed by TiDB Operator is `8301`, while the default port number of the `cdc cli` command to connect to the TiCDC server is `8300`. When using the `cdc cli` command to operate the TiCDC cluster deployed by TiDB Operator, you need to explicitly specify the `--server` parameter, as follows:

```
./cdc cli changefeed list --server "127.0.0.1:8301"
[
  {
    "id": "4k-table",
    "namespace": "default",
    "summary": {
      "state": "stopped",
      "tso": 441832628003799353,
      "checkpoint": "2023-05-30 22:41:57.910",
      "error": null
    }
  },
  {
    "id": "big-table",
    "namespace": "default",
    "summary": {
      "state": "normal",
      "tso": 441872834546892882,
      "checkpoint": "2023-06-01 17:18:13.700",
      "error": null
    }
  }
]
```

7.7.33 Does TiCDC replicate generated columns of DML operations?

Generated columns include virtual generated columns and stored generated columns. TiCDC ignores virtual generated columns and only replicates stored generated columns to the downstream. However, stored generated columns are also ignored when the downstream is MySQL or another MySQL-compatible database (rather than Kafka or other storage services).

> **Note:**
>
> When replicating stored generated columns to Kafka or a storage service and then writing them back to MySQL, `Error 3105 (HY000): The value ↪ specified for generated column 'xx' in table 'xxx' is not ↪ allowed` might occur. To avoid this error, you can use Open Protocol for replication. The output of this protocol includes bit flags of columns, which can distinguish whether a column is a generated column.

7.7.34 How do I resolve frequent `CDC:ErrMySQLDuplicateEntryCDC` errors?

When using TiCDC to replicate data to TiDB or MySQL, you might encounter the following error if SQL statements in the upstream are executed in a specific pattern:

```
CDC:ErrMySQLDuplicateEntryCDC
```

The cause of the error: TiDB combines `DELETE + INSERT` operations on the same row within the same transaction into a single `UPDATE` row change. When TiCDC replicates these changes as updates to the downstream, the `UPDATE` operations attempting to swap unique key values might result in conflicts.

Taking the following table as an example:

```
CREATE TABLE data_table (
    id BIGINT(20) NOT NULL PRIMARY KEY,
    value BINARY(16) NOT NULL,
    UNIQUE KEY value_index (value)
) CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

If the upstream attempts to swap the `value` field of the two rows in the table:

```
DELETE FROM data_table WHERE id = 1;
DELETE FROM data_table WHERE id = 2;
INSERT INTO data_table (id, value) VALUES (1, 'v3');
INSERT INTO data_table (id, value) VALUES (2, 'v1');
```

TiDB generates two `UPDATE` row changes, so TiCDC converts them into two `UPDATE` statements for replication to the downstream:

```
UPDATE data_table SET value = 'v3' WHERE id = 1;
UPDATE data_table SET value = 'v1' WHERE id = 2;
```

If the downstream table still contains `v1` when executing the second `UPDATE` statement, it violates the unique key constraint on the `value` column, resulting in the `CDC:ErrMySQLDuplicateEntryCDC` error.

If the `CDC:ErrMySQLDuplicateEntryCDC` error occurs frequently, you can enable TiCDC safe mode by setting the `safe-mode=true` parameter in the `sink-uri` configuration:

```
mysql://user:password@host:port/?safe-mode=true
```

In safe mode, TiCDC splits the `UPDATE` operation into `DELETE + REPLACE INTO` for execution, thus avoiding the unique key conflict error.

7.8 TiCDC Glossary

This glossary provides TiCDC-related terms and definitions. These terms appear in TiCDC logs, monitoring metrics, configurations, and documents.

For TiDB-related terms and definitions, see TiDB glossary.

7.8.1 C

7.8.1.1 Capture

A single TiCDC instance on which the replication task of the cluster runs. Multiple captures form a TiCDC cluster.

7.8.1.2 Changed data

The data to be written to TiCDC from the upstream TiDB cluster, including the DML-caused data changes and the DDL-caused table schema changes.

7.8.1.3 Changefeed

An incremental replication task in TiCDC, which outputs the data change logs of several tables in a TiDB cluster to the designated downstream.

7.8.2 O

7.8.2.1 Owner

A capture of a special role that manages the TiCDC cluster and schedules replication tasks of the cluster. An owner is elected by captures and there is at most one owner at any time.

7.8.3 P

7.8.3.1 Processor

TiCDC replication tasks allocate data tables on TiCDC instances, and the processor refers to the replication processing unit of these tables. Processor tasks include pulling, sorting, restoring, and distributing changed data.

8 Maintain

8.1 Security

8.1.1 Best Practices for TiDB Security Configuration

The security of TiDB is crucial for protecting data integrity and confidentiality. This document provides guidelines for configuring TiDB clusters securely during deployment. By following these best practices, you can effectively reduce potential security risks, prevent data breaches, and ensure the continuous, stable, and reliable operation of your TiDB database system.

Note:

This document offers general recommendations on TiDB security configurations. PingCAP does not guarantee the completeness or accuracy of the information, and it assumes no responsibility for any issues arising from the use of this guide. Users should assess these recommendations based on their specific needs and consult professionals for tailored advice.

8.1.1.1 Set the initial password for the root user

By default, the root user in a newly created TiDB cluster has no password, which poses a potential security risk. If a password is not set, anyone can attempt to log in to the TiDB database as the root user, potentially gaining access to and modifying data.

To avoid this risk, it is recommended to set a root password during deployment:

- For deployments using TiUP, refer to Deploy TiDB Cluster Using TiUP to generate a random password for the root user.
- For deployments using TiDB Operator, refer to Set initial account and password to set the root password.

8.1.1.2 Enable password complexity checks

By default, TiDB does not enforce password complexity policies, which might lead to the use of weak or empty passwords, increasing security risks.

To ensure that database users create strong passwords, it is recommended to configure a reasonable password complexity policy. For example, configure a policy that requires passwords to include a combination of uppercase letters, lowercase letters, numbers, and special characters. By enforcing password complexity checks, you can improve database security, prevent brute force attacks, reduce internal threats, ensure compliance with regulations, and lower the risk of data breaches, thus enhancing overall security.

8.1.1.3 Change the default Grafana password

TiDB installation includes the Grafana component by default, and the default username and password are typically `admin/admin`. If the password is not changed promptly, attackers could exploit this to gain control of the system.

It is recommended to immediately change the Grafana password to a strong one during the TiDB deployment, and regularly update the password to ensure system security. Here are the steps to change the Grafana password:

- Upon first login to Grafana, follow the prompts to change the password.

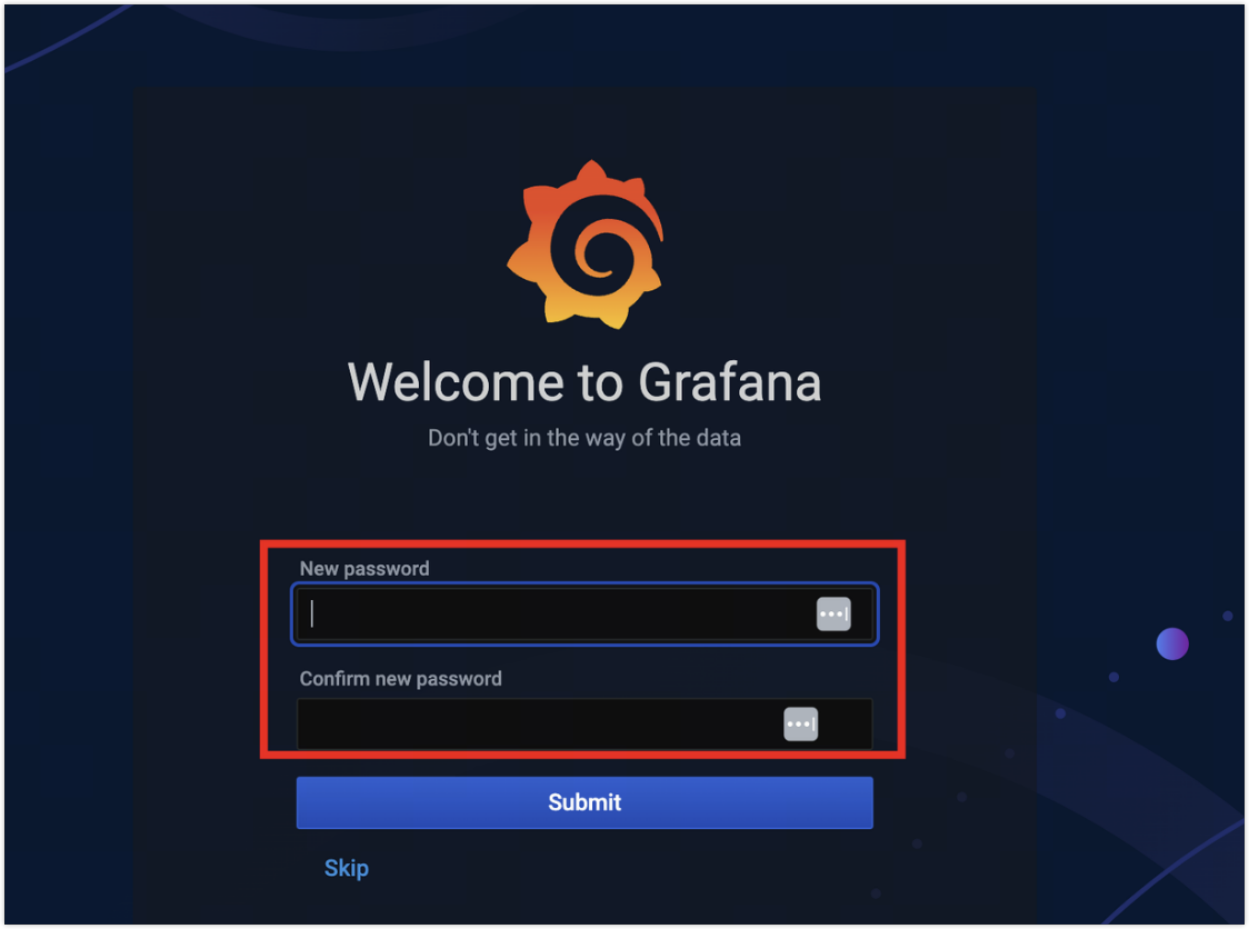

Figure 136: Grafana Password Reset Guide

- Access the Grafana personal configuration center to change the password.

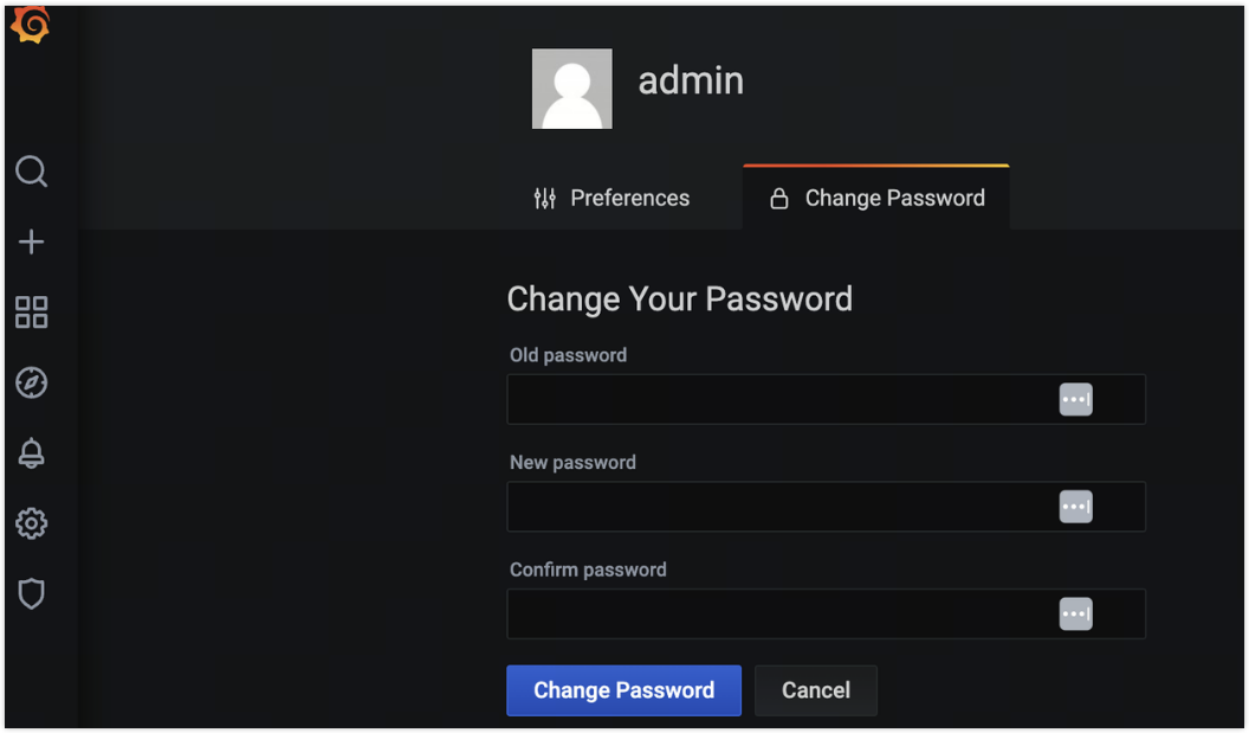

Figure 137: Grafana Password Reset Guide

8.1.1.4 Enhance TiDB Dashboard security

8.1.1.4.1 Use a least privilege user

TiDB Dashboard shares the account system with TiDB SQL users, and TiDB Dashboard authorization is based on TiDB SQL user permissions. TiDB Dashboard requires minimal permissions and can even operate with read-only access.

To enhance security, it is recommended to create a least-privilege SQL user for accessing the TiDB Dashboard and to avoid using high-privilege users.

8.1.1.4.2 Restrict access control

By default, TiDB Dashboard is designed for trusted users. The default port includes additional API interfaces besides TiDB Dashboard. If you want to allow access to TiDB Dashboard from external networks or untrusted users, take the following measures to avoid security vulnerabilities:

- Use a firewall or other mechanisms to restrict the default 2379 port to trusted domains, preventing access by external users.

> **Note:**
> TiDB, TiKV, and other components need to communicate with the PD component via the PD client port. Do not block internal network access between components, which will make the cluster unavailable.

- Configure a reverse proxy to securely provide TiDB Dashboard services to external users on a different port.

8.1.1.5 Protect internal ports

By default, TiDB installation includes several privileged interfaces for inter-component communication. These ports typically do not need to be accessible to users, because they are primarily for internal communication. Exposing these ports on public networks increases the attack surface, violates the principle of least privilege, and raises the risk of security vulnerabilities. The following table lists the default listening ports in a TiDB cluster:

Component	Default port	Protocol
TiDB	4000	MySQL
TiDB	10080	HTTP
TiKV	20160	Protocol
TiKV	20180	HTTP
PD	2379	HTTP/Protocol
PD	2380	Protocol
TiFlash	3930	Protocol
TiFlash	20170	Protocol
TiFlash	20292	HTTP
TiFlash	8234	HTTP
TiFlow	8261	HTTP
TiFlow	8291	HTTP
TiFlow	8262	HTTP
TiFlow	8300	HTTP
TiDB Lightning	8289	HTTP
TiDB Operator	6060	HTTP
TiDB Dashboard	2379	HTTP
TiDB Binlog	8250	HTTP
TiDB Binlog	8249	HTTP
TMS	8082	HTTP
TEM	8080	HTTP
TEM	8000	HTTP
TEM	4110	HTTP
TEM	4111	HTTP
TEM	4112	HTTP
TEM	4113	HTTP

Component	Default port	Protocol
TEM	4124	HTTP
Prometheus	9090	HTTP
Grafana	3000	HTTP
AlertManager	9093	HTTP
AlertManager	9094	Protocol
Node Exporter	9100	HTTP
Blackbox Exporter	9115	HTTP
NG Monitoring	12020	HTTP

It is recommended to only expose the `4000` port for the database and the `9000` port for the Grafana dashboard to ordinary users, while restricting access to other ports using network security policies or firewalls. The following is an example of using `iptables` to restrict port access:

```
### Allow internal port communication from the whitelist of component IP
    ↪ addresses
sudo iptables -A INPUT -s internal IP address range -j ACCEPT

### Only open ports 4000 and 9000 to external users
sudo iptables -A INPUT -p tcp --dport 4000 -j ACCEPT
sudo iptables -A INPUT -p tcp --dport 9000 -j ACCEPT

### Deny all other traffic by default
sudo iptables -P INPUT DROP
```

If you need to access TiDB Dashboard, it is recommended to configure a reverse proxy to securely provide services to external networks on a separate port.

8.1.1.6 Resolving false positives from third-party MySQL vulnerability scanners

Most vulnerability scanners detect MySQL vulnerabilities based on version information. Because TiDB is MySQL protocol-compatible but not MySQL itself, version-based vulnerability scans might lead to false positives. It is recommended to focus vulnerability scans on principle-based assessments. If compliance scanning tools require a specific MySQL version, you can modify the server version number to meet the requirement.

By changing the server version number, you can avoid false positives from vulnerability scanners. The `server-version` value is used by TiDB nodes to verify the current TiDB version. Before upgrading the TiDB cluster, ensure that the `server-version` value is either empty or the actual version of TiDB to avoid unexpected behavior.

8.1.2 Enable TLS between TiDB Clients and Servers

By default, TiDB allows insecure connections between the server and clients. This enables third parties that monitor channel traffic to know and possibly modify the data sent and received between the server and the client, including query content and query results. If a channel is untrustworthy (such as if the client is connected to the TiDB server via a public network), an insecure connection is prone to information leakage. In this case, for security reasons, it is recommended to require a connection that is secured with TLS.

The TiDB server supports secure connections based on the TLS (Transport Layer Security) protocol. The protocol is consistent with MySQL secure connections and is directly supported by existing MySQL clients such as MySQL Client, MySQL Shell and MySQL drivers. TLS is sometimes referred to as SSL (Secure Sockets Layer). Because the SSL protocol has known security vulnerabilities, TiDB does not support SSL. TiDB supports the following protocols: TLSv1.2 and TLSv1.3.

When a TLS secured connection is used, the connection has the following security properties:

- Confidentiality: the traffic plaintext is encrypted to avoid eavesdropping
- Integrity: the traffic plaintext cannot be tampered
- Authentication: (optional) the client can verify the identity of the server and the server can verify the identity of the client to avoid man-in-the-middle attacks

To use connections secured with TLS, you first need to configure the TiDB server to enable TLS. Then you need to configure the client application to use TLS. Most client libraries enable TLS automatically when the server has TLS support configured correctly.

Similar to MySQL, TiDB allows TLS and non-TLS connections on the same TCP port. For a TiDB server with TLS enabled, you can choose to securely connect to the TiDB server through an encrypted connection, or to use an unencrypted connection. You can use the following ways to require the use of secure connections:

- Configure the system variable `require_secure_transport` to require secure connections to the TiDB server for all users.
- Specify `REQUIRE SSL` when you create a user (`create user`), or modify an existing user (`alter user`), which is to specify that specified users must use TLS connections to access TiDB. The following is an example of creating a user:

```
CREATE USER 'u1'@'%' IDENTIFIED BY 'my_random_password' REQUIRE SSL;
```

> **Note:**
>
> If the login user has configured using the TiDB Certificate-Based Authentication for Login, the user is implicitly required to enable the encrypted connection to TiDB.

8.1.2.1 Configure TiDB server to use secure connections

See the following descriptions about the related parameters to enable secure connections:

- `auto-tls`: enables automatic certificate generation (since v5.2.0)
- `ssl-cert`: specifies the file path of the SSL certificate
- `ssl-key`: specifies the private key that matches the certificate
- `ssl-ca`: (optional) specifies the file path of the trusted CA certificate
- `tls-version`: (optional) specifies the minimum TLS version, e.g. "TLSv1.2"

`auto-tls` allows secure connections but does not provide client certificate validation. For certificate validation, and to control how certificates are generated, see the advice on configuring the `ssl-cert`, `ssl-key` and `ssl-ca` variables below.

To enable secure connections with your own certificates in the TiDB server, you must specify both of the `ssl-cert` and `ssl-key` parameters in the configuration file when you start the TiDB server. You can also specify the `ssl-ca` parameter for client authentication (see Enable authentication).

All the files specified by the parameters are in PEM (Privacy Enhanced Mail) format. Currently, TiDB does not support the import of a password-protected private key, so it is required to provide a private key file without a password. If the certificate or private key is invalid, the TiDB server starts as usual, but the client cannot connect to the TiDB server through a TLS connection.

If the certificate parameters are correct, TiDB outputs `mysql protocol server secure connection is enabled` to the logs on `"INFO"` level when started.

8.1.2.2 Configure the MySQL client to use TLS connections

The client of MySQL 5.7 or later versions attempts to establish a TLS connection by default. If the server does not support TLS connections, it automatically returns to unencrypted connections. The client of MySQL earlier than version 5.7 uses the non-TLS connections by default.

You can change the connection behavior of the client using the following `--ssl-mode` parameters:

- `--ssl-mode=REQUIRED`: The client requires a TLS connection. The connection cannot be established if the server side does not support TLS connections.
- In the absence of the `--ssl-mode` parameter: The client attempts to use a TLS connection, but the encrypted connection cannot be established if the server side does not support encrypted connections. Then the client uses an unencrypted connection.
- `--ssl-mode=DISABLED`: The client uses an unencrypted connection.

MySQL 8.x clients have two SSL modes in addition to this parameter:

- `--ssl-mode=VERIFY_CA`: Validates the certificate from the server against the CA that requires `--ssl-ca`.
- `--ssl-mode=VERIFY_IDENTITY`: The same as `VERIFY_CA`, but also validating whether the hostname you are connecting to matches the certificate.

For MySQL 5.7 and MariaDB clients and earlier you can use `--ssl-verify-server-cert` to enable validation of the server certificate.

For more information, see Client-Side Configuration for Encrypted Connections in MySQL.

8.1.2.3 Enable authentication

If the `ssl-ca` parameter is not specified in the TiDB server or MySQL client, the client or the server does not perform authentication by default and cannot prevent man-in-the-middle attack. For example, the client might "securely" connect to a disguised client. You can configure the `ssl-ca` parameter for authentication in the server and client. Generally, you only need to authenticate the server, but you can also authenticate the client to further enhance the security.

- To authenticate the TiDB server from the MySQL client:

1. Specify the `ssl-cert` and `ssl-key` parameters in the TiDB server.
2. Specify the `--ssl-ca` parameter in the MySQL client.
3. Specify the `--ssl-mode` to `VERIFY_CA` at least in the MySQL client.
4. Make sure that the certificate (`ssl-cert`) configured in the TiDB server is signed by the CA specified by the client `--ssl-ca` parameter; otherwise, the authentication fails.

- To authenticate the MySQL client from the TiDB server:

1. Specify the `ssl-cert`, `ssl-key`, and `ssl-ca` parameters in the TiDB server.
2. Specify the `--ssl-cert` and `--ssl-key` parameters in the client.
3. Make sure the server-configured certificate and the client-configured certificate are both signed by the `ssl-ca` specified by the server.

- To perform mutual authentication, meet both of the above requirements.

By default, the server-to-client authentication is optional. Even if the client does not present its certificate of identification during the TLS handshake, the TLS connection can be still established. You can also require the client to be authenticated by specifying `REQUIRE x509` when creating a user (`CREATE USER`), or modifying an existing user (`ALTER USER`). The following is an example of creating a user:

```
CREATE USER 'u1'@'%' REQUIRE X509;
```

> **Note:**
>
> If the login user has configured using the TiDB Certificate-Based Authentication for Login, the user is implicitly required to enable the TLS connection to TiDB.

8.1.2.4 Check whether the current connection uses encryption

Use the `SHOW STATUS LIKE "%Ssl%";` statement to get the details of the current connection, including whether encryption is used, the encryption protocol used by encrypted connections and the TLS version number.

See the following example of the result in an encrypted connection. The results change according to different TLS versions or encryption protocols supported by the client.

```
SHOW STATUS LIKE "Ssl%";
```

```
+-----------------------+-------------------------------------------------------->
   ↪
| Variable_name         | Value                                                  >
+-----------------------+-------------------------------------------------------->
   ↪
| Ssl_cipher            | TLS_AES_128_GCM_SHA256                                 >
| Ssl_cipher_list       | RC4-SHA:DES-CBC3-SHA:AES128-SHA:AES256-SHA:AES128-
   ↪ SHA2>
| Ssl_server_not_after  | Apr 23 07:59:47 2024 UTC                               >
| Ssl_server_not_before | Jan 24 07:59:47 2024 UTC                               >
| Ssl_verify_mode       | 5                                                      >
| Ssl_version           | TLSv1.3                                                >
+-----------------------+-------------------------------------------------------->
   ↪
6 rows in set (0.0062 sec)
```

For the official MySQL client, you can also use the `STATUS` or `\s` statement to view the connection status:

```
mysql> \s
...
SSL: Cipher in use is TLS_AES_128_GCM_SHA256
...
```

8.1.2.5 Supported TLS versions, key exchange protocols, and encryption algorithms

The TLS versions, key exchange protocols and encryption algorithms supported by TiDB are determined by the official Go libraries.

The crypto policy for your operating system and the client library you are using might also impact the list of supported protocols and cipher suites.

8.1.2.5.1 Supported TLS versions

- TLSv1.2
- TLSv1.3

You can use the `tls-version` configuration option to limit the TLS versions that can be used.

The actual TLS versions that can be used depend on the OS crypto policy, MySQL client version and the SSL/TLS library that is used by the client.

8.1.2.5.2 Supported key exchange protocols and encryption algorithms

- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_128_GCM_SHA256
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256
- TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256
- TLS_AES_128_GCM_SHA256
- TLS_AES_256_GCM_SHA384
- TLS_CHACHA20_POLY1305_SHA256

8.1.2.6 Reload certificate, key, and CA

To replace the certificate, the key or CA, first replace the corresponding files, then execute the `ALTER INSTANCE RELOAD TLS` statement on the running TiDB instance to reload

the certificate (ssl-cert), the key (ssl-key), and the CA (ssl-ca) from the original configuration path. In this way, you do not need to restart the TiDB instance.

The newly loaded certificate, key, and CA take effect on the connection that is established after the statement is successfully executed. The connection established before the statement execution is not affected.

8.1.2.7 Monitoring

Since TiDB v5.2.0, you can use the `Ssl_server_not_after` and `Ssl_server_not_before` status variables to monitor the start and end dates of the validity of the certificate.

```
SHOW GLOBAL STATUS LIKE 'Ssl\_server\_not\_%';
```

```
+----------------------+--------------------------+
| Variable_name        | Value                    |
+----------------------+--------------------------+
| Ssl_server_not_after | Nov 28 06:42:32 2021 UTC |
| Ssl_server_not_before | Aug 30 06:42:32 2021 UTC |
+----------------------+--------------------------+
2 rows in set (0.0076 sec)
```

8.1.2.8 See also

- Enable TLS Between TiDB Components.

8.1.3 Enable TLS Between TiDB Components

This document describes how to enable encrypted data transmission between components within a TiDB cluster. Once enabled, encrypted transmission is used between the following components:

- Communication between TiDB, TiKV, PD, and TiFlash
- TiDB Control and TiDB; TiKV Control and TiKV; PD Control and PD
- Internal communication within each TiDB, TiKV, PD, and TiFlash cluster

Currently, it is not supported to only enable encrypted transmission of some specific components.

8.1.3.1 Configure and enable encrypted data transmission

1. Prepare certificates.

   It is recommended to prepare a server certificate for TiDB, TiKV, and PD separately. Make sure that these components can authenticate each other. The Control tools of TiDB, TiKV, and PD can choose to share one client certificate.

   You can use tools like `openssl`, `easy-rsa` and `cfssl` to generate self-signed certificates.

   If you choose `openssl`, you can refer to generating self-signed certificates.

2. Configure certificates.

   To enable mutual authentication among TiDB components, configure the certificates of TiDB, TiKV, and PD as follows.

   - TiDB

     Configure in the configuration file or command-line arguments:

```
[security]
# Path of the file that contains list of trusted SSL CAs for
   ↪ connection with cluster components.
cluster-ssl-ca = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format for
   ↪  connection with cluster components.
cluster-ssl-cert = "/path/to/tidb-server.pem"
# Path of the file that contains X509 key in PEM format for
   ↪ connection with cluster components.
cluster-ssl-key = "/path/to/tidb-server-key.pem"
```

   - TiKV

     Configure in the configuration file or command-line arguments, and set the corresponding URL to `https`:

```
[security]
## The path for certificates. An empty string means that secure
   ↪ connections are disabled.
# Path of the file that contains a list of trusted SSL CAs. If it
   ↪ is set, the following settings `cert_path` and `key_path`
   ↪ are also needed.
ca-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/tikv-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/tikv-server-key.pem"
```

- PD

  Configure in the configuration file or command-line arguments, and set the corresponding URL to `https`:

```
[security]
## The path for certificates. An empty string means that secure
   ↪ connections are disabled.
# Path of the file that contains a list of trusted SSL CAs. If it
   ↪ is set, the following settings `cert_path` and `key_path`
   ↪ are also needed.
cacert-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/pd-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/pd-server-key.pem"
```

- TiFlash (New in v4.0.5)

  Configure in the `tiflash.toml` file:

```
[security]
## The path for certificates. An empty string means that secure
   ↪ connections are disabled.
# Path of the file that contains a list of trusted SSL CAs. If it
   ↪ is set, the following settings `cert_path` and `key_path`
   ↪ are also needed.
ca_path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert_path = "/path/to/tiflash-server.pem"
# Path of the file that contains X509 key in PEM format.
key_path = "/path/to/tiflash-server-key.pem"
```

  Configure in the `tiflash-learner.toml` file:

```
[security]
# Path of the file that contains a list of trusted SSL CAs. If it
   ↪ is set, the following settings `cert_path` and `key_path`
   ↪ are also needed.
ca-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/tiflash-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/tiflash-server-key.pem"
```

- TiCDC

  Configure in the configuration file:

```
[security]
```

```
ca-path = "/path/to/ca.pem"
cert-path = "/path/to/cdc-server.pem"
key-path = "/path/to/cdc-server-key.pem"
```

Alternatively, configure in the command-line arguments and set the corresponding URL to `https`:

```
cdc server --pd=https://127.0.0.1:2379 --log-file=ticdc.log --addr
    ↪ =0.0.0.0:8301 --advertise-addr=127.0.0.1:8301 --ca=/path/to/
    ↪ ca.pem --cert=/path/to/ticdc-cert.pem --key=/path/to/ticdc-
    ↪ key.pem
```

Now, encrypted transmission among TiDB components is enabled.

Note:

After enabling encrypted transmission in a TiDB cluster, if you need to connect to the cluster using tidb-ctl, tikv-ctl, or pd-ctl, specify the client certificate. For example:

```
./tidb-ctl -u https://127.0.0.1:10080 --ca /path/to/ca.pem --ssl-cert /
    ↪ path/to/client.pem --ssl-key /path/to/client-key.pem
```

```
tiup ctl:v<CLUSTER_VERSION> pd -u https://127.0.0.1:2379 --cacert /path
    ↪ /to/ca.pem --cert /path/to/client.pem --key /path/to/client-key.
    ↪ pem
```

```
./tikv-ctl --host="127.0.0.1:20160" --ca-path="/path/to/ca.pem" --cert-
    ↪ path="/path/to/client.pem" --key-path="/path/to/clinet-key.pem"
```

8.1.3.1.1 Verify component caller's identity

In general, the callee needs to verify the caller's identity using `Common Name`, in addition to verifying the key, the certificates, and the CA provided by the caller. For example, TiKV can only be accessed by TiDB, and other visitors are blocked even though they have legitimate certificates.

To verify the caller's identity for a component, you need to mark the certificate user identity using `Common Name` when generating the certificate, and check the caller's identity by configuring `cluster-verify-cn` (in TiDB) or `cert-allowed-cn` (in other components) for the callee.

Note:

- Starting from v8.4.0, the PD configuration item `cert-allowed-cn` supports multiple values. You can configure multiple `Common Name` in the `cluster-verify-cn` configuration item for TiDB and in the `cert-allowed-cn` configuration item for other components as needed. Note that TiUP uses a separate identifier when querying component status. For example, if the cluster name is `test`, TiUP uses `test-client` as the `Common Name`.
- For v8.3.0 and earlier versions, the PD configuration item `cert-allowed-cn` can only be set to a single value. Therefore, the `Common Name` of all authentication objects must be set to the same value. For related configuration examples, see v8.3.0 documentation.

- TiDB

  Configure in the configuration file or command-line arguments:

```
[security]
cluster-verify-cn = ["tidb", "test-client", "prometheus"]
```

- TiKV

  Configure in the configuration file or command-line arguments:

```
[security]
cert-allowed-cn = ["tidb", "pd", "tikv", "tiflash", "prometheus"]
```

- PD

  Configure in the configuration file or command-line arguments:

```
[security]
cert-allowed-cn = ["tidb", "pd", "tikv", "tiflash", "test-client", "
    ↪ prometheus"]
```

- TiFlash (New in v4.0.5)

  Configure in the `tiflash.toml` file or command-line arguments:

```
[security]
cert_allowed_cn = ["tidb", "tikv", "prometheus"]
```

  Configure in the `tiflash-learner.toml` file:

```
[security]
cert-allowed-cn = ["tidb", "tikv", "tiflash", "prometheus"]
```

8.1.3.2 Reload certificates

- If your TiDB cluster is deployed in a local data center, to reload the certificates and keys, TiDB, PD, TiKV, TiFlash, TiCDC, and all kinds of clients reread the current certificates and key files each time a new connection is created, without restarting the TiDB cluster.
- If your TiDB cluster is deployed on your own managed cloud, make sure that the issuance of TLS certificates is integrated with the certificate management service of the cloud provider. The TLS certificates of the TiDB, PD, TiKV, TiFlash, and TiCDC components can be automatically rotated without restarting the TiDB cluster.

8.1.3.3 Certificate validity

You can customize the validity period of TLS certificates for each component in a TiDB cluster. For example, when using OpenSSL to issue and generate TLS certificates, you can set the validity period via the **days** parameter. For more information, see Generate self-signed certificates.

8.1.3.4 See also

- Enable TLS Between TiDB Clients and Servers

8.1.4 Generate Self-Signed Certificates

> **Note:**
>
> To enable TLS between clients and servers, you only need to set `auto-tls`.

This document provides an example of using `openssl` to generate a self-signed certificate. You can also generate certificates and keys that meet requirements according to your demands.

Assume that the topology of the instance cluster is as follows:

Name	Host IP	Services
node1	172.16.10.11	PD1, TiDB1
node2	172.16.10.12	PD2
node3	172.16.10.13	PD3
node4	172.16.10.14	TiKV1
node5	172.16.10.15	TiKV2
node6	172.16.10.16	TiKV3

8.1.4.1 Install OpenSSL

- For Debian or Ubuntu OS:

```
apt install openssl
```

- For RedHat or CentOS OS:

```
yum install openssl
```

You can also refer to OpenSSL's official download document for installation.

8.1.4.2 Generate the CA certificate

A certificate authority (CA) is a trusted entity that issues digital certificates. In practice, contact your administrator to issue the certificate or use a trusted CA. CA manages multiple certificate pairs. Here you only need to generate an original pair of certificates as follows.

1. Generate the root key:

```
openssl genrsa -out root.key 4096
```

2. Generate root certificates:

```
openssl req -new -x509 -days 1000 -key root.key -out root.crt
```

3. Validate root certificates:

```
openssl x509 -text -in root.crt -noout
```

8.1.4.3 Issue certificates for individual components

This section describes how to issue certificates for individual components.

8.1.4.3.1 Certificates that might be used in the cluster

- tidb-server certificate: used by TiDB to authenticate TiDB for other components and clients
- tikv-server certificate: used by TiKV to authenticate TiKV for other components and clients
- pd-server certificate: used by PD to authenticate PD for other components and clients
- client certificate: used to authenticate the clients from PD, TiKV and TiDB, such as `pd-ctl`, `tikv-ctl`

8.1.4.3.2 Issue certificates to TiKV instances

To issue a certificate to a TiKV instance, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out tikv.key 2048
```

2. Make a copy of the OpenSSL configuration template file (Refer to the actual location of your template file because it might have more than one location):

```
cp /usr/lib/ssl/openssl.cnf .
```

   If you do not know the actual location, look for it in the root directory:

```
find / -name openssl.cnf
```

3. Edit `openssl.cnf`, add `req_extensions = v3_req` under the `[ req ]` field, and add `subjectAltName = @alt_names` under the `[ v3_req ]` field. Finally, create a new field and edit the information of SAN.

```
[ alt_names ]
IP.1 = 127.0.0.1
IP.2 = 172.16.10.14
IP.3 = 172.16.10.15
IP.4 = 172.16.10.16
```

4. Save the `openssl.cnf` file, and generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key tikv.key -out tikv.csr -config openssl.cnf
```

5. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA root.crt -CAkey root.key -
    ↪ CAcreateserial -in tikv.csr -out tikv.crt -extensions v3_req -
    ↪ extfile openssl.cnf
```

6. Verify that the certificate includes the SAN field (optional):

```
openssl x509 -text -in tikv.crt -noout
```

7. Confirm that the following files exist in your current directory:

```
root.crt
tikv.crt
tikv.key
```

The process of issuing certificates for other TiDB components is similar and will not be repeated in this document.

8.1.4.3.3 Issue certificates for clients

To issue a certificate to a client, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out client.key 2048
```

2. Generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key client.key -out client.csr
```

3. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA root.crt -CAkey root.key -
    ↪ CAcreateserial -in client.csr -out client.crt
```

8.1.5 Encryption at Rest

> **Note:**
>
> If your cluster is deployed on AWS and uses the EBS storage, it is recommended to use the EBS encryption. See AWS documentation - EBS Encryption. You are using the non-EBS storage on AWS such as the local NVMe storage, it is recommended to use encryption at rest introduced in this document.

Encryption at rest means that data is encrypted when it is stored. For databases, this feature is also referred to as TDE (transparent data encryption). This is opposed to encryption in flight (TLS) or encryption in use (rarely used). Different things could be doing

encryption at rest (such as SSD drive, file system, and cloud vendor), but by having TiKV do the encryption before storage this helps ensure that attackers must authenticate with the database to gain access to data. For example, when an attacker gains access to the physical machine, data cannot be accessed by copying files on disk.

8.1.5.1 Encryption support in different TiDB components

In a TiDB cluster, different components use different encryption methods. This section introduces the encryption supports in different TiDB components such as TiKV, TiFlash, PD, and Backup & Restore (BR).

When a TiDB cluster is deployed, the majority of user data is stored on TiKV and TiFlash nodes. Some metadata is stored on PD nodes (for example, secondary index keys used as TiKV Region boundaries). To get the full benefits of encryption at rest, you need to enable encryption for all components. Backups, log files, and data transmitted over the network should also be considered when you implement encryption.

8.1.5.1.1 TiKV

TiKV supports encryption at rest. This feature allows TiKV to transparently encrypt data files using AES or SM4 in CTR mode. To enable encryption at rest, an encryption key must be provided by the user and this key is called master key. TiKV automatically rotates data keys that it used to encrypt actual data files. Manually rotating the master key can be done occasionally. Note that encryption at rest only encrypts data at rest (namely, on disk) and not while data is transferred over network. It is advised to use TLS together with encryption at rest.

You can use Key Management Service (KMS) for both cloud and self-hosted deployments or supply the plaintext master key in a file.

TiKV currently does not exclude encryption keys and user data from core dumps. It is advised to disable core dumps for the TiKV process when using encryption at rest. This is not currently handled by TiKV itself.

TiKV tracks encrypted data files using the absolute path of the files. As a result, once encryption is turned on for a TiKV node, the user should not change data file paths configuration such as `storage.data-dir`, `raftstore.raftdb-path`, `rocksdb.wal-dir` and `raftdb.wal-dir`.

SM4 encryption is only supported in v6.3.0 and later versions of TiKV. TiKV versions earlier than v6.3.0 only support AES encryption. SM4 encryption affects performance. In the worst-case scenario, it might cause a 50% to 80% throughput degradation. However, a sufficiently large `storage.block-cache` can significantly mitigate this impact, reducing the throughput degradation to around 10%.

8.1.5.1.2 TiFlash

TiFlash supports encryption at rest. Data keys are generated by TiFlash. All files (including data files, schema files, and temporary files) written into TiFlash (including TiFlash

Proxy) are encrypted using the current data key. The encryption algorithms, the encryption configuration (in the `tiflash-learner.toml` file supported by TiFlash), and the meanings of monitoring metrics are consistent with those of TiKV.

If you have deployed TiFlash with Grafana, you can check the **TiFlash-Proxy-Details -> Encryption** panel.

SM4 encryption is only supported in v6.4.0 and later versions of TiFlash. TiFlash versions earlier than v6.4.0 only support AES encryption.

8.1.5.1.3 PD

Encryption-at-rest for PD is an experimental feature, which is configured in the same way as in TiKV.

8.1.5.1.4 Backups with BR

BR supports S3 server-side encryption (SSE) when backing up data to S3. A customer-owned AWS KMS key can also be used together with S3 server-side encryption. See BR S3 server-side encryption for details.

8.1.5.1.5 Logging

TiKV, TiDB, and PD info logs might contain user data for debugging purposes. The info log and this data in it are not encrypted. It is recommended to enable log redaction.

8.1.5.2 TiKV encryption at rest

8.1.5.2.1 Overview

TiKV currently supports encrypting data using AES128, AES192, AES256, or SM4 (only in v6.3.0 and later versions), in CTR mode. TiKV uses envelope encryption. As a result, two types of keys are used in TiKV when encryption is enabled.

- Master key. The master key is provided by user and is used to encrypt the data keys TiKV generates. Management of master key is external to TiKV.
- Data key. The data key is generated by TiKV and is the key actually used to encrypt data.

The same master key can be shared by multiple instances of TiKV. The recommended way to provide a master key in production is via KMS. Currently, TiKV supports KMS encryption on AWS, Google Cloud, and Azure. To enable KMS encryption, you need to create a customer master key (CMK) through KMS, and then provide the CMK key ID to TiKV using the configuration file. If TiKV fails to get access to the KMS CMK, it will fail to start or restart.

Alternatively, if using custom key is desired, supplying the master key via file is also supported. The file must contain a 256 bits (or 32 bytes) key encoded as hex string, end with a newline (namely, `\n`), and contain nothing else. Persisting the key on disk, however, leaks the key, so the key file is only suitable to be stored on the `tempfs` in RAM.

Data keys are passed to the underlying storage engine (namely, RocksDB). All files written by RocksDB, including SST files, WAL files, and the MANIFEST file, are encrypted by the current data key. Other temporary files used by TiKV that may include user data are also encrypted using the same data key. Data keys are automatically rotated by TiKV every week by default, but the period is configurable. On key rotation, TiKV does not rewrite all existing files to replace the key, but RocksDB compaction are expected to rewrite old data into new data files, with the most recent data key, if the cluster gets constant write workload. TiKV keeps track of the key and encryption method used to encrypt each of the files and use the information to decrypt the content on reads.

Regardless of data encryption method, data keys are encrypted using AES256 in GCM mode for additional authentication. This required the master key to be 256 bits (32 bytes), when passing from file instead of KMS.

8.1.5.2.2 Configure encryption

To enable encryption, you can add the encryption section in the configuration files of TiKV and PD:

```
[security.encryption]
data-encryption-method = "aes128-ctr"
data-key-rotation-period = "168h" # 7 days
```

- `data-encryption-method` specifies the encryption algorithm. The possible values are `"aes128-ctr"`, `"aes192-ctr"`, `"aes256-ctr"`, `"sm4-ctr"` (only for v6.3.0 and later versions), and `"plaintext"`. The default value is `"plaintext"`, which means that encryption is disabled by default.
    - For a new TiKV cluster or an existing TiKV cluster, only data written after encryption has been enabled is guaranteed to be encrypted.
    - To disable encryption after it is enabled, remove `data-encryption-method` from the configuration file or set its value to `"plaintext"`, and then restart TiKV.
    - To change the encryption algorithm, replace the value of `data-encryption-method` with a supported encryption algorithm, and then restart TiKV. After the replacement, as new data is written in, the encryption files generated by the previous encryption algorithm are gradually rewritten to files generated by the new encryption algorithm.
- `data-key-rotation-period` specifies how often TiKV rotates keys.

If encryption is enabled (that is, the value of `data-encryption-method` is not `"plaintext"`), you must specify a master key in either of the following ways:

- Specify a master key via KMS
- Specify a master key via a file

Specify a master key via KMS

TiKV supports KMS encryption for three platforms: AWS, Google Cloud, and Azure. Depending on the platform where your service is deployed, you can choose one of them to configure KMS encryption.

Step 1. Create a master key

To create a key on AWS, take the following steps:

1. Go to the AWS KMS on the AWS console.
2. Make sure that you have selected the correct region on the top right corner of your console.
3. Click **Create key** and select **Symmetric** as the key type.
4. Set an alias for the key.

You can also perform the operations using the AWS CLI:

```
aws --region us-west-2 kms create-key
aws --region us-west-2 kms create-alias --alias-name "alias/tidb-tde" --
    ↪ target-key-id 0987dcba-09fe-87dc-65ba-ab0987654321
```

The `--target-key-id` to enter in the second command is in the output of the first command.

Step 2. Configure the master key

To specify the master key using AWS KMS, add the `[security.encryption.master-key]` configuration after the `[security.encryption]` section in the TiKV configuration file:

```
[security.encryption.master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
endpoint = "https://kms.us-west-2.amazonaws.com"
```

The `key-id` specifies the key ID for the KMS CMK. The `region` is the AWS region name for the KMS CMK. The `endpoint` is optional and you do not need to specify it normally unless you are using an AWS KMS-compatible service from a non-AWS vendor or need to use a VPC endpoint for KMS.

You can also use multi-Region keys in AWS. For this, you need to set up a primary key in a specific region and add replica keys in the regions you require.

Step 1. Create a master key

To create a key on Google Cloud, take the following steps:

1. Go to the Key Management page in the Google Cloud console.
2. Click **Create key ring**. Enter a name for the key ring, select a location of the key ring, and then click **Create**. Note that the location of the key ring needs to cover the region where the TiDB cluster is deployed.
3. Select the key ring you created in the previous step, and then click **Create Key** on the key ring details page.
4. Enter a name for the key, set the key information as follows, and then click **Create**.

    - **Protection level**: **Software** or **HSM**
    - **Key Material**: **Generated key**
    - **Purpose**: **Symmetric encrypt/decrypt**

You can also perform this operation using the gcloud CLI:

```
gcloud kms keyrings create "key-ring-name" --location "global"
gcloud kms keys create "key-name" --keyring "key-ring-name" --location "
    ↪ global" --purpose "encryption" --rotation-period "30d"
```

Make sure to replace the values of `"key-ring-name"`, `"key-name"`, `"global"`, and `"30d"` in the preceding command with the names and configurations corresponding to your actual key.

Step 2. Configure the master key

To specify the master key using Google Cloud KMS, add the `[security.encryption.master-key]` configuration after the `[security.encryption]` section:

```
[security.encryption.master-key]
type = "kms"
key-id = "projects/project-name/locations/global/keyRings/key-ring-name/
    ↪ cryptoKeys/key-name"
vendor = "gcp"

[security.encryption.master-key.gcp]
credential-file-path = "/path/to/credential.json"
```

- `key-id` specifies the key ID of the KMS CMK.
- `credential-file-path` specifies the path of the authentication credentials file, which currently supports two types of credentials: Service Account and Authentication User. If the TiKV environment is already configured with application default credentials, there is no need to configure `credential-file-path`.

Step 1. Create a master key

To create a key on Azure, refer to the instructions in Set and retrieve a key from Azure Key Vault using the Azure portal.

Step 2. Configure the master key

To specify the master key using Azure KMS, add the `[security.encryption.master-key]` configuration after the `[security.encryption]` section in the TiKV configuration file:

```
[security.encryption.master-key]
type = 'kms'
key-id = 'your-kms-key-id'
region = 'region-name'
endpoint = 'endpoint'
vendor = 'azure'

[security.encryption.master-key.azure]
tenant-id = 'tenant_id'
client-id = 'client_id'
keyvault-url = 'keyvault_url'
hsm-name = 'hsm_name'
hsm-url = 'hsm_url'
### The following four fields are optional, used to set client authentication credentials. You can configure them according to the requirements of your scenario.
client_certificate = ""
client_certificate_path = ""
client_certificate_password = ""
client_secret = ""
```

Except `vendor`, you need to modify the values of other fields in the preceding configuration to the corresponding configuration of the actual key.

Specify a master key via a file

To specify a master key that's stored in a file, the master key configuration would look like the following:

```
[security.encryption.master-key]
type = "file"
path = "/path/to/key/file"
```

Here `path` is the path to the key file. The file must contain a 256 bits (or 32 bytes) key encoded as hex string, end with a newline (`\n`) and contain nothing else. Example of the file content:

```
3b5896b5be691006e0f71c3040a29495ddcad20b14aff61806940ebd780d3c62
```

8.1.5.2.3 Rotate the master key

To rotate master key, you have to specify both of the new master key and old master key in the configuration, and restart TiKV. Use `security.encryption.master-key` to specify the new master key, and use `security.encryption.previous-master-key` to specify the old master key. The configuration format for `security.encryption.previous-master-key` ↪ is the same as `encryption.master-key`. On restart TiKV must access both of the old and new master key, but once TiKV is up and running, TiKV will only need access to the new key. It is okay to leave the `encryption.previous-master-key` configuration in the configuration file from that on. Even on restart, TiKV only tries to use the old key if it fails to decrypt existing data using the new master key.

Currently online master key rotation is not supported, so you need to restart TiKV. It is advised to do a rolling restart to a running TiKV cluster serving online query.

Here is an example configuration for rotating the KMS CMK:

```
[security.encryption.master-key]
type = "kms"
key-id = "50a0c603-1c6f-11e6-bb9e-3fadde80ce75"
region = "us-west-2"

[security.encryption.previous-master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
```

8.1.5.2.4 Monitoring and debugging

To monitor encryption at rest, if you deploy TiKV with Grafana, you can look at the **Encryption** panel in the **TiKV-Details** dashboard. There are a few metrics to look for:

- Encryption initialized: 1 if encryption is initialized during TiKV startup, 0 otherwise. In case of master key rotation, after encryption is initialized, TiKV do not need access to the previous master key.
- Encryption data keys: number of existing data keys. The number is bumped by 1 after each time data key rotation happened. Use this metrics to monitor if data key rotation works as expected.
- Encrypted files: number of encrypted data files currently exists. Compare this number to existing data files in the data directory to estimate portion of data being encrypted, when turning on encryption for a previously unencrypted cluster.
- Encryption meta file size: size of the encryption meta data files.
- Read/Write encryption meta duration: the extra overhead to operate on metadata for encryption.

For debugging, the `tikv-ctl` command can be used to dump encryption metadata such as encryption method and data key id used to encryption the file, as well as list of data keys.

Since the operation can expose sensitive data, it is not recommended to use in production. Please refer to TiKV Control document.

8.1.5.2.5 Compatibility between TiKV versions

To reduce the overhead caused by I/O and mutex contention when TiKV manages the encryption metadata, an optimization is introduced in TiKV v4.0.9 and controlled by `security.encryption.enable-file-dictionary-log` in the TiKV configuration file. This configuration parameter takes effect only on TiKV v4.0.9 or later versions.

When it is enabled (by default), the data format of encryption metadata is unrecognizable by TiKV v4.0.8 or earlier versions. For example, assume that you use TiKV v4.0.9 or later with encryption at rest and the default `enable-file-dictionary-log` configuration. If you downgrade your cluster to TiKV v4.0.8 or earlier, TiKV will fail to start, with an error in the info log similar to the following one:

```
[2020/12/07 07:26:31.106 +08:00] [ERROR] [mod.rs:110] ["encryption: failed
   ↪ to load file dictionary."]
[2020/12/07 07:26:33.598 +08:00] [FATAL] [lib.rs:483] ["called `Result::
   ↪ unwrap()` on an `Err` value: Other(\"[components/encryption/src/
   ↪ encrypted_file/header.rs:18]: unknown version 2\")"]
```

To avoid the error above, you can first set `security.encryption.enable-file-` ↪ `dictionary-log` to `false` and start TiKV with v4.0.9 or later. Once TiKV starts successfully, the data format of encryption metadata is downgraded to the version recognizable to earlier TiKV versions. At this point, you can then downgrade your TiKV cluster to an earlier version.

8.1.5.3 TiFlash encryption at rest

8.1.5.3.1 Overview

The encryption algorithm currently supported by TiFlash is consistent with that supported by TiKV, including AES128, AES192, AES256, and SM4 (only in v6.4.0 and later versions), in CTR mode. TiFlash also uses envelope encryption. Therefore, two types of keys are used in TiFlash when encryption is enabled.

- Master key. The master key is provided by user and is used to encrypt the data keys TiFlash generates. Management of master key is external to TiFlash.
- Data key. The data key is generated by TiFlash and is the key actually used to encrypt data.

The same master key can be shared by multiple instances of TiFlash, and can also be shared among TiFlash and TiKV. The recommended way to provide a master key in production is via AWS KMS. Alternatively, if using custom key is desired, supplying the

master key via file is also supported. The specific method to generate master key and the format of the master key are the same as TiKV.

TiFlash uses the current data key to encrypt all data placed on the disk, including data files, Schema files, and temporary data files generated during calculations. Data keys are automatically rotated by TiFlash every week by default, and the period is configurable. On key rotation, TiFlash does not rewrite all existing files to replace the key, but background compaction tasks are expected to rewrite old data into new data files, with the most recent data key, if the cluster gets constant write workload. TiFlash keeps track of the key and encryption method used to encrypt each of the files and use the information to decrypt the content on reads.

8.1.5.3.2 Key creation

To create a key on AWS, refer to the steps to create a key for TiKV.

8.1.5.3.3 Configure encryption

To enable encryption, you can add the encryption section in the `tiflash-learner.toml` configuration file:

```
[security.encryption]
data-encryption-method = "aes128-ctr"
data-key-rotation-period = "168h" # 7 days
```

Alternatively, add the following contents in the TiUP cluster template:

```
server_configs:
  tiflash-learner:
    security.encryption.data-encryption-method: "aes128-ctr"
    security.encryption.data-key-rotation-period: "168h" # 7 days
```

Possible values for `data-encryption-method` are “aes128-ctr”, “aes192-ctr”, “aes256-ctr”, “sm4-ctr” (only in v6.4.0 and later versions) and “plaintext”. The default value is “plaintext”, which means encryption is not turned on. `data-key-rotation-period` defines how often TiFlash rotates the data key. Encryption can be turned on for a fresh TiFlash cluster, or an existing TiFlash cluster, though only data written after encryption is enabled is guaranteed to be encrypted. To disable encryption, remove `data-encryption-method` ↪ in the configuration file, or reset it to “plaintext”, and restart TiFlash. To change encryption method, update `data-encryption-method` in the configuration file and restart TiFlash. To change the encryption algorithm, replace `data-encryption-method` with a supported encryption algorithm and then restart TiFlash. After the replacement, as new data is written in, the encryption file generated by the previous encryption algorithm is gradually rewritten to a file generated by the new encryption algorithm.

The master key has to be specified if encryption is enabled (that is,`data-encryption` ↪ `-method` is not “plaintext”). To specify an AWS KMS CMK as the master key, add

the `encryption.master-key` section after the `encryption` section in the `tiflash-learner.toml` configuration file:

```
[security.encryption.master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
endpoint = "https://kms.us-west-2.amazonaws.com"
```

Alternatively, add the following contents in the TiUP cluster template:

```
server_configs:
  tiflash-learner:
    security.encryption.master-key.type: "kms"
    security.encryption.master-key.key-id: "0987dcba-09fe-87dc-65ba-
      ↪ ab0987654321"
    security.encryption.master-key.region: "us-west-2"
    security.encryption.master-key.endpoint: "https://kms.us-west-2.
      ↪ amazonaws.com"
```

The meanings of the preceding configuration items are the same as those of TiKV.

To specify a master key that is stored in a file, add the following configuration in the `tiflash-learner.toml` configuration file:

```
[security.encryption.master-key]
type = "file"
path = "/path/to/key/file"
```

Alternatively, add the following contents in the TiUP cluster template:

```
server_configs:
  tiflash-learner:
    security.encryption.master-key.type: "file"
    security.encryption.master-key.path: "/path/to/key/file"
```

The meanings of the preceding configuration items and the content format of the key file are the same as those of TiKV.

8.1.5.3.4 Rotate the master key

To rotate the master key of TiFlash, follow the steps to rotate the master key of TiKV. Currently, TiFlash does not support online master key rotation, either. Therefore, you need to restart TiFlash to make the rotation effective. It is recommended to do a rolling restart to a running TiFlash cluster serving online query.

To rotate the KMS CMK, add the following contents in the `tiflash-learner.toml` configuration file:

```
[security.encryption.master-key]
type = "kms"
key-id = "50a0c603-1c6f-11e6-bb9e-3fadde80ce75"
region = "us-west-2"

[security.encryption.previous-master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
```

Alternatively, add the following contents in the TiUP cluster template:

```
server_configs:
  tiflash-learner:
    security.encryption.master-key.type: "kms"
    security.encryption.master-key.key-id: "50a0c603-1c6f-11e6-bb9e-3
       ↪ fadde80ce75"
    security.encryption.master-key.region: "us-west-2"
    security.encryption.previous-master-key.type: "kms"
    security.encryption.previous-master-key.key-id: "0987dcba-09fe-87dc-65ba
       ↪ -ab0987654321"
    security.encryption.previous-master-key.region: "us-west-2"
```

8.1.5.3.5 Monitoring and debugging

To monitor encryption at rest, if you deploy TiFlash with Grafana, you can look at the **Encryption** panel in the **TiFlash-Proxy-Details** dashboard. The meaning of monitoring items is the same as that of TiKV.

For debugging, since TiFlash reuses TiKV's logic for managing encrypted metadata, the `tikv-ctl` command can be used to dump encryption metadata such as encryption method and data key ID used to encryption the file, as well as list of data keys. This operation can expose sensitive data and is therefore not recommended in production. Refer to TiKV Control for more details.

8.1.5.3.6 Compatibility between TiKV versions

TiFlash also optimizes encrypted metadata operations in v4.0.9, and its compatibility requirements are the same as those of TiKV. For details, see Compatibility between TiKV versions.

8.1.5.4 BR S3 server-side encryption

To enable S3 server-side encryption when backup to S3 using BR, pass `--s3.sse` argument and set value to "aws:kms". S3 will use its own KMS key for encryption. Example:

```
tiup br backup full --pd <pd-address> --storage "s3://<bucket>/<prefix>" --
    ↪ s3.sse aws:kms
```

To use a custom AWS KMS CMK that you created and owned, pass `--s3.sse-kms-key-id` in addition. In this case, both the BR process and all the TiKV nodes in the cluster would need access to the KMS CMK (for example, via AWS IAM), and the KMS CMK needs to be in the same AWS region as the S3 bucket used to store the backup. It is advised to grant access to the KMS CMK to BR process and TiKV nodes via AWS IAM. Refer to AWS documentation for usage of IAM. For example:

```
tiup br backup full --pd <pd-address> --storage "s3://<bucket>/<prefix>" --
    ↪ s3.sse aws:kms --s3.sse-kms-key-id 0987dcba-09fe-87dc-65ba-
    ↪ ab0987654321
```

When restoring the backup, both `--s3.sse` and `--s3.sse-kms-key-id` should NOT be used. S3 will figure out encryption settings by itself. The BR process and TiKV nodes in the cluster to restore the backup to would also need access to the KMS CMK, or the restore will fail. Example:

```
tiup br restore full --pd <pd-address> --storage "s3://<bucket>/<prefix>"
```

8.1.5.5 BR Azure Blob Storage server-side encryption

When backing up data to Azure Blob Storage using BR, you can specify either an encryption scope or an encryption key for server-side encryption.

8.1.5.5.1 Method 1: use an encryption scope

To specify an encryption scope for the backup data, you can use one of the following two ways:

- Include the `--azblob.encryption-scope` option in the `backup` command and set it to the scope name:

  ```
  tiup br backup full --pd <pd-address> --storage "azure://<bucket>/<
      ↪ prefix>" --azblob.encryption-scope scope1
  ```

- Include `encryption-scope` in the URI and set it to the scope name:

  ```
  tiup br backup full --pd <pd-address> --storage "azure://<bucket>/<
      ↪ prefix>?encryption-scope=scope1"
  ```

For more information, see the Azure documentation: Upload a blob with an encryption scope.

When restoring the backup, you do not need to specify the encryption scope. Azure Blob Storage automatically decrypts the data. For example:

```
tiup br restore full --pd <pd-address> --storage "azure://<bucket>/<prefix>"
```

8.1.5.5.2 Method 2: use an encryption key

To specify an encryption key for the backup data, you can use one of the following three ways:

- Include the `--azblob.encryption-key` option in the `backup` command and set it to an AES256 encryption key:

```
tiup br backup full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>" --azblob.encryption-key <aes256-key>
```

- Include `encryption-key` in the URI and set it to an AES256 encryption key. If the key contains URI reserved characters such as `&` and `%`, you need to percent-encode it first:

```
tiup br backup full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>?encryption-key=<aes256-key>"
```

- Set the `AZURE_ENCRYPTION_KEY` environment variable to an AES256 encryption key. Before running, make sure that you remember the encryption key in the environment variable to avoid forgetting it.

```
export AZURE_ENCRYPTION_KEY=<aes256-key>
tiup br backup full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>"
```

For more information, see the Azure documentation: Provide an encryption key on a request to Blob storage.

When restoring the backup, you need to specify the encryption key. For example:

- Include the `--azblob.encryption-key` option in the `restore` command:

```
tiup br restore full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>" --azblob.encryption-key <aes256-key>
```

- Include `encryption-key` in the URI:

```
tiup br restore full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>?encryption-key=<aes256-key>"
```

- Set the `AZURE_ENCRYPTION_KEY` environment variable:

```
export AZURE_ENCRYPTION_KEY=<aes256-key>
tiup br restore full --pd <pd-address> --storage "azure://<bucket>/<
    ↪ prefix>"
```

8.1.6 Enable Encryption for Disk Spill

When the system variable `tidb_enable_tmp_storage_on_oom` is set to `ON`, if the memory usage of a single SQL statement exceeds the limit of the system variable `tidb_mem_quota_query`, some operators can save the intermediate results during execution as a temporary file to the disk and delete the file after the query is completed.

You can enable encryption for disk spill to prevent attackers from accessing data by reading these temporary files.

8.1.6.1 Configure

To enable encryption for the disk spill files, you can configure the item `spilled-file-encryption-method` in the `[security]` section of the TiDB configuration file.

```
[security]
spilled-file-encryption-method = "aes128-ctr"
```

Value options for `spilled-file-encryption-method` are `aes128-ctr` and `plaintext`. The default value is `plaintext`, which means that encryption is disabled.

8.1.7 Log Redaction

When TiDB provides detailed log information, it might print sensitive data (for example, user data) in the log, which causes data security risks. To avoid such risks, each component (TiDB, TiKV, and PD) provides a configuration item that enables log redaction to shield user data values.

8.1.7.1 Log redaction in TiDB side

To enable log redaction in the TiDB side, set the value of `global.tidb_redact_log` to `ON` or `MARKER`. This configuration value defaults to `OFF`, which means that log redaction is disabled.

You can use the `set` syntax to set the global variable `tidb_redact_log`:

```
set @@global.tidb_redact_log = ON;
```

After the setting, all logs generated in new sessions are redacted:

```
create table t (a int, unique key (a));
Query OK, 0 rows affected (0.00 sec)

insert into t values (1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 't.a'
```

The error log for the `INSERT` statement above is printed as follows:

```
[2024/07/02 11:35:32.686 +08:00] [INFO] [conn.go:1146] ["command dispatched
    ↪ failed"] [conn=1482686470] [session_alias=] [connInfo="id:1482686470,
    ↪  addr:127.0.0.1:52258 status:10, collation:utf8mb4_0900_ai_ci, user:
    ↪ root"] [command=Query] [status="inTxn:0, autocommit:1"] [sql="insert
    ↪ into `t` values ( ... )"] [txn_mode=PESSIMISTIC] [timestamp
    ↪ =450859193514065921] [err="[kv:1062]Duplicate entry '?' for key 't.a
    ↪ '"]
```

From the preceding error log, you can see that when the value of `tidb_redact_log` is set to `ON`, sensitive information is replaced by the `?` mark in the TiDB log to avoid data security risks.

In addition, TiDB provides the `MARKER` option. When the value of `tidb_redact_log` is set to `MARKER`, TiDB marks sensitive information in the log with `<>` instead of replacing it directly, so you can customize the redaction rules.

```
set @@global.tidb_redact_log = MARKER;
```

After the preceding configuration, the sensitive information is marked rather than replaced in all logs generated by new sessions:

```
create table t (a int, unique key (a));
Query OK, 0 rows affected (0.07 sec)

insert into t values (1),(1);
ERROR 1062 (23000): Duplicate entry '<1>' for key 't.a'
```

The error log is as follows:

```
[2024/07/02 11:35:01.426 +08:00] [INFO] [conn.go:1146] ["command dispatched
    ↪ failed"] [conn=1482686470] [session_alias=] [connInfo="id:1482686470,
    ↪  addr:127.0.0.1:52258 status:10, collation:utf8mb4_0900_ai_ci, user:
    ↪ root"] [command=Query] [status="inTxn:0, autocommit:1"] [sql="insert
    ↪ into `t` values ( <1> ) , ( <1> )"] [txn_mode=PESSIMISTIC] [timestamp
    ↪ =450859185309483010] [err="[kv:1062]Duplicate entry '<1>' for key 't.
    ↪ a'"]
```

As you can see from the preceding error log, after you set `tidb_redact_log` to `MARKER`, TiDB marks sensitive information using `< >` in the log. You can customize redaction rules to handle sensitive information in the log as needed.

8.1.7.2 Log redaction in TiKV side

To enable log redaction in the TiKV side, set the value of `security.redact-info-log` to `true` or `"marker"`. This configuration value defaults to `false`, which means that log redaction is disabled.

8.1.7.3 Log redaction in PD side

To enable log redaction in the PD side, set the value of `security.redact-info-log` to `true` or `"marker"`. This configuration value defaults to `false`, which means that log redaction is disabled.

8.1.7.4 Log redaction in TiFlash side

To enable log redaction in the TiFlash side, set both the `security.redact_info_log` value in tiflash-server and the `security.redact-info-log` value in tiflash-learner to `true` or `"marker"`. Both configuration values default to `false`, which means that log redaction is disabled.

8.2 Upgrade

8.2.1 Upgrade TiDB Using TiUP

This document applies to upgrading to TiDB v8.5.x from the following versions: v6.1.x, v6.5.x, v7.1.x, v7.5.x, v8.1.x, v8.2.0, v8.3.0, and v8.4.0

Warning:

1. Before upgrading TiDB, ensure that your operating system version meets the OS and platform requirements. If you plan to upgrade your cluster running on CentOS Linux 7 to v8.5, ensure you use TiDB v8.5.1 or a later version to avoid the risk of cluster unavailability. For more information, see TiDB v8.5.1 Release Notes.
2. You cannot upgrade TiFlash online from versions earlier than 5.3 to 5.3 or later. Instead, you must first stop all the TiFlash instances of the early version, and then upgrade the cluster offline. If other components (such as TiDB and TiKV) do not support an online upgrade, follow the instructions in warnings in Online upgrade.
3. **DO NOT** run DDL statements during the upgrade process. Otherwise, the issue of undefined behavior might occur.
4. **DO NOT** upgrade a TiDB cluster when a DDL statement is being executed in the cluster (usually for the time-consuming DDL statements such as `ADD INDEX` and the column type changes). Before the upgrade, it is recommended to use the `ADMIN SHOW DDL` command to check whether the TiDB cluster has an ongoing DDL job. If the cluster has a DDL job, to upgrade the cluster, wait until the DDL execution is finished or use the `ADMIN CANCEL DDL` command to cancel the DDL job before you upgrade the cluster.

5. If the TiDB version before upgrade is 7.1.0 or later, you can ignore the preceding warnings 3 and 4. For more information, see limitations on using TiDB smooth upgrade.
6. Be sure to read limitations on user operations before upgrading your TiDB cluster using TiUP.

Note:

- If your cluster to be upgraded is earlier than v6.2, the upgrade might get stuck when you upgrade the cluster to v6.2 or later versions in some scenarios. You can refer to How to fix the issue.
- TiDB nodes use the value of the `server-version` configuration item to verify the current TiDB version. Therefore, to avoid unexpected behaviors, before upgrading the TiDB cluster, you need to set the value of `server-version` to empty or the real version of the current TiDB cluster.
- Setting the `performance.force-init-stats` configuration item to `ON` prolongs the TiDB startup time, which might cause startup timeouts and upgrade failures. To avoid this issue, it is recommended to set a longer waiting timeout for TiUP.
  - Scenarios that might be affected:
    - The original cluster version is earlier than v6.5.7 and v7.1.0 (which does not support `performance.force-init-stats` yet), and the target version is v7.2.0 or later.
    - The original cluster version is equal to or later than v6.5.7 and v7.1.0, and the `performance.force-init-stats` configuration item is set to `ON`.
  - Check the value of the `performance.force-init-stats` configuration item:

    ```
    SHOW CONFIG WHERE type = 'tidb' AND name = 'performance
        ↪ .force-init-stats';
    ```

  - You can increase the TiUP waiting timeout by adding the command-line option `--wait-timeout`. For example, execute the following command to set the waiting timeout to 1200 seconds (20 minutes).

    ```
    tiup update cluster --wait-timeout 1200 [other options]
    ```

    Generally, a 20-minute waiting timeout is sufficient for most scenarios. For a more precise estimate, search for `init stats info time`

in the TiDB log to get the statistics loading time during the previous startup as a reference. For example:

```
[domain.go:2271] ["init stats info time"] [lite=true]
    ↪ ["take time"=2.151333ms]
```

If the original cluster is v7.1.0 or earlier, when upgrading to v7.2.0 or later, because of the introduction of `performance.lite-init-stats`, the statistics loading time is greatly reduced. In this case, the `init stats info time` before the upgrade is longer than the loading time after the upgrade.

- If you want to shorten the rolling upgrade duration of TiDB and the potential performance impact of missing initial statistical information during the upgrade is acceptable for your cluster, you can set `performance.force-init-stats` to `OFF` before the upgrade by modifying the configuration of the target instance with TiUP. After the upgrade is completed, you can reassess and revert this setting if necessary.

8.2.1.1 Upgrade caveat

- TiDB currently does not support version downgrade or rolling back to an earlier version after the upgrade.
- Support upgrading the versions of TiCDC, TiFlash, and other components.
- When upgrading TiFlash from versions earlier than v6.3.0 to v6.3.0 and later versions, note that the CPU must support the AVX2 instruction set under the Linux AMD64 architecture and the ARMv8 instruction set architecture under the Linux ARM64 architecture. For details, see the description in v6.3.0 Release Notes.
- For detailed compatibility changes of different versions, see the Release Notes of each version. Modify your cluster configuration according to the "Compatibility Changes" section of the corresponding release notes.
- When updating clusters from versions earlier than v5.3 to v5.3 or later versions, note that there is a time format change in the alerts generated by the default deployed Prometheus. This format change is introduced starting from Prometheus v2.27.1. For more information, see Prometheus commit.

8.2.1.2 Preparations

This section introduces the preparation works needed before upgrading your TiDB cluster, including upgrading TiUP and the TiUP Cluster component.

8.2.1.2.1 Step 1: Review compatibility changes

Review compatibility changes in TiDB release notes. If any changes affect your upgrade, take actions accordingly.

The following provides release notes you need to know when you upgrade from v8.4.0 to the current version (v8.5.1). If you are upgrading from v8.3.0 or earlier versions to the current version, you might also need to check the release notes of the intermediate versions.

- TiDB v8.5.0 compatibility changes
- TiDB v8.5.1 release notes

8.2.1.2.2 Step 2: Upgrade TiUP or TiUP offline mirror

Before upgrading your TiDB cluster, you first need to upgrade TiUP or TiUP mirror.

Upgrade TiUP and TiUP Cluster

> **Note:**
>
> If the control machine of the cluster to upgrade cannot access `https://tiup-mirrors.pingcap.com`, skip this section and see Upgrade TiUP offline mirror.

1. Upgrade the TiUP version. It is recommended that the TiUP version is `1.11.3` or later.

```
tiup update --self
tiup --version
```

2. Upgrade the TiUP Cluster version. It is recommended that the TiUP Cluster version is `1.11.3` or later.

```
tiup update cluster
tiup cluster --version
```

Upgrade TiUP offline mirror

> **Note:**
>
> If the cluster to upgrade was deployed not using the offline method, skip this step.

Refer to Deploy a TiDB Cluster Using TiUP - Deploy TiUP offline to download the TiUP mirror of the new version and upload it to the control machine. After executing `local_install.sh`, TiUP will complete the overwrite upgrade.

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz
sh tidb-community-server-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

After the overwrite upgrade, run the following command to merge the server and toolkit offline mirrors to the server directory:

```
tar xf tidb-community-toolkit-${version}-linux-amd64.tar.gz
ls -ld tidb-community-server-${version}-linux-amd64 tidb-community-toolkit-$
    ↪ {version}-linux-amd64
cd tidb-community-server-${version}-linux-amd64/
cp -rp keys ~/.tiup/
tiup mirror merge ../tidb-community-toolkit-${version}-linux-amd64
```

After merging the mirrors, run the following command to upgrade the TiUP Cluster component:

```
tiup update cluster
```

Now, the offline mirror has been upgraded successfully. If an error occurs during TiUP operation after the overwriting, it might be that the `manifest` is not updated. You can try `rm -rf ~/.tiup/manifests/*` before running TiUP again.

8.2.1.2.3 Step 3: Edit TiUP topology configuration file

Note:

Skip this step if one of the following situations applies:

- You have not modified the configuration parameters of the original cluster. Or you have modified the configuration parameters using `tiup ↪ cluster` but no more modification is needed.
- After the upgrade, you want to use v8.5.1's default parameter values for the unmodified configuration items.

1. Enter the `vi` editing mode to edit the topology file:

```
tiup cluster edit-config <cluster-name>
```

2. Refer to the format of topology configuration template and fill the parameters you want to modify in the `server_configs` section of the topology file.

3. After the modification, enter : + w + q to save the change and exit the editing mode. Enter Y to confirm the change.

8.2.1.2.4 Step 4: Check the DDL and backup status of the cluster

To avoid undefined behaviors or other unexpected problems during the upgrade, it is recommended to check the following items before the upgrade.

- Cluster DDLs:
    - If you use smooth upgrade to upgrade TiDB to v8.1.0 or later, and the Distributed eXecution Framework (DXF) is enabled, it is recommended to disable the DXF before upgrading. Otherwise, the indexes added during the upgrade process might be inconsistent with the data, leading to upgrade failures.
    - If you do not use smooth upgrade, it is recommended to use the `ADMIN SHOW DDL` statement to check whether ongoing DDL jobs exist. If an ongoing DDL job exists, wait for the completion of its execution or cancel it using the `ADMIN CANCEL DDL` statement before performing an upgrade.
- Cluster backup: It is recommended to execute the `SHOW [BACKUPS|RESTORES]` statement to check whether there is an ongoing backup or restore task in the cluster. If yes, wait for its completion before performing an upgrade.

8.2.1.2.5 Step 5: Check the health status of the current cluster

To avoid the undefined behaviors or other issues during the upgrade, it is recommended to check the health status of Regions of the current cluster before the upgrade. To do that, you can use the `check` sub-command.

```
tiup cluster check <cluster-name> --cluster
```

After the command is executed, the "Region status" check result will be output.

- If the result is "All Regions are healthy", all Regions in the current cluster are healthy and you can continue the upgrade.
- If the result is "Regions are not fully healthy: m miss-peer, n pending-peer" with the "Please fix unhealthy regions before other operations." prompt, some Regions in the current cluster are abnormal. You need to troubleshoot the anomalies until the check result becomes "All Regions are healthy". Then you can continue the upgrade.

8.2.1.3 Upgrade the TiDB cluster

This section describes how to upgrade the TiDB cluster and verify the version after the upgrade.

8.2.1.3.1 Upgrade the TiDB cluster to a specified version

You can upgrade your cluster in one of the two ways: online upgrade and offline upgrade.

By default, TiUP Cluster upgrades the TiDB cluster using the online method, which means that the TiDB cluster can still provide services during the upgrade process. With the online method, the leaders are migrated one by one on each node before the upgrade and restart. Therefore, for a large-scale cluster, it takes a long time to complete the entire upgrade operation.

If your application has a maintenance window for the database to be stopped for maintenance, you can use the offline upgrade method to quickly perform the upgrade operation.

Online upgrade

```
tiup cluster upgrade <cluster-name> <version>
```

For example, if you want to upgrade the cluster to v8.5.1:

```
tiup cluster upgrade <cluster-name> v8.5.1
```

Note:

- An online upgrade upgrades all components one by one. During the upgrade of TiKV, all leaders in a TiKV instance are evicted before stopping the instance. The default timeout time is 5 minutes (300 seconds). The instance is directly stopped after this timeout time.
- You can use the `--force` parameter to upgrade the cluster immediately without evicting the leader. However, the errors that occur during the upgrade will be ignored, which means that you are not notified of any upgrade failure. Therefore, use the `--force` parameter with caution.
- To keep a stable performance, make sure that all leaders in a TiKV instance are evicted before stopping the instance. You can set `--transfer-timeout` to a larger value, for example, `--transfer-timeout 3600` (unit: second).
- To upgrade TiFlash from versions earlier than v5.3.0 to v5.3.0 or later, you must stop TiFlash and then upgrade it, and the TiUP version must be earlier than v1.12.0. For more information, see Upgrade TiFlash using TiUP.

Specify the component version during upgrade

Starting from tiup-cluster v1.14.0, you can specify certain components to a specific version during cluster upgrade. These components will remain at their fixed version in the subsequent upgrade unless you specify a different version.

> **Note:**
>
> For components that share a version number, such as TiDB, TiKV, PD, and TiCDC, there are no complete tests to ensure that they work properly in a mixed-version deployment scenario. Ensure that you use this section only in test environments, or with the help of technical support.

```
tiup cluster upgrade -h | grep "version"
      --alertmanager-version string    Fix the version of alertmanager and no
         ↪  longer follows the cluster version.
      --blackbox-exporter-version string Fix the version of blackbox-
         ↪ exporter and no longer follows the cluster version.
      --cdc-version string             Fix the version of cdc and no longer
         ↪ follows the cluster version.
      --ignore-version-check           Ignore checking if target version is
         ↪ bigger than current version.
      --node-exporter-version string   Fix the version of node-exporter and
         ↪ no longer follows the cluster version.
      --pd-version string              Fix the version of pd and no longer
         ↪ follows the cluster version.
      --tidb-dashboard-version string Fix the version of tidb-dashboard and
         ↪ no longer follows the cluster version.
      --tiflash-version string         Fix the version of tiflash and no
         ↪ longer follows the cluster version.
      --tikv-cdc-version string        Fix the version of tikv-cdc and no
         ↪ longer follows the cluster version.
      --tikv-version string            Fix the version of tikv and no longer
         ↪ follows the cluster version.
      --tiproxy-version string         Fix the version of tiproxy and no
         ↪ longer follows the cluster version.
```

Offline upgrade

1. Before the offline upgrade, you first need to stop the entire cluster.

   ```
   tiup cluster stop <cluster-name>
   ```

2. Use the `upgrade` command with the `--offline` option to perform the offline upgrade. Fill in the name of your cluster for `<cluster-name>` and the version to upgrade to for `<version>`, such as `v8.5.1`.

   ```
   tiup cluster upgrade <cluster-name> <version> --offline
   ```

3. After the upgrade, the cluster will not be automatically restarted. You need to use the `start` command to restart it.

```
tiup cluster start <cluster-name>
```

8.2.1.3.2 Verify the cluster version

Execute the `display` command to view the latest cluster version `TiDB Version`:

```
tiup cluster display <cluster-name>
```

```
Cluster type:     tidb
Cluster name:     <cluster-name>
Cluster version:  v8.5.1
```

8.2.1.4 FAQ

This section describes common problems encountered when updating the TiDB cluster using TiUP.

8.2.1.4.1 If an error occurs and the upgrade is interrupted, how to resume the upgrade after fixing this error?

Re-execute the `tiup cluster upgrade` command to resume the upgrade. The upgrade operation restarts the nodes that have been previously upgraded. If you do not want the upgraded nodes to be restarted, use the `replay` sub-command to retry the operation:

1. Execute `tiup cluster audit` to see the operation records:

```
tiup cluster audit
```

   Find the failed upgrade operation record and keep the ID of this operation record. The ID is the `<audit-id>` value in the next step.

2. Execute `tiup cluster replay <audit-id>` to retry the corresponding operation:

```
tiup cluster replay <audit-id>
```

8.2.1.4.2 How to fix the issue that the upgrade gets stuck when upgrading to v6.2.0 or later versions?

Starting from v6.2.0, TiDB enables the concurrent DDL framework by default to execute concurrent DDLs. This framework changes the DDL job storage from a KV queue to a table queue. This change might cause the upgrade to get stuck in some scenarios. The following are some scenarios that might trigger this issue and the corresponding solutions:

- Upgrade gets stuck due to plugin loading

  During the upgrade, loading certain plugins that require executing DDL statements might cause the upgrade to get stuck.

  Solution: avoid loading plugins during the upgrade. Instead, load plugins only after the upgrade is completed.

- Upgrade gets stuck due to using the `kill -9` command for offline upgrade

  - Precautions: avoid using the `kill -9` command to perform the offline upgrade. If it is necessary, restart the new version TiDB node after 2 minutes.
  - If the upgrade is already stuck, restart the affected TiDB node. If the issue has just occurred, it is recommended to restart the node after 2 minutes.

- Upgrade gets stuck due to DDL Owner change

  In multi-instance scenarios, network or hardware failures might cause DDL Owner change. If there are unfinished DDL statements in the upgrade phase, the upgrade might get stuck.

  Solution:

  1. Terminate the stuck TiDB node (avoid using `kill -9`).
  2. Restart the new version TiDB node.

8.2.1.4.3 The evict leader has waited too long during the upgrade. How to skip this step for a quick upgrade?

You can specify `--force`. Then the processes of transferring PD leader and evicting TiKV leader are skipped during the upgrade. The cluster is directly restarted to update the version, which has a great impact on the cluster that runs online. In the following command, `<version>` is the version to upgrade to, such as `v8.5.1`.

```
tiup cluster upgrade <cluster-name> <version> --force
```

8.2.1.4.4 How to update the version of tools such as pd-ctl after upgrading the TiDB cluster?

You can upgrade the tool version by using TiUP to install the `ctl` component of the corresponding version:

```
tiup install ctl:v8.5.1
```

8.2.2 Use TiDB Operator

8.2.3 TiDB Smooth Upgrade

This document introduces the smooth upgrade feature of TiDB, which supports upgrading TiDB clusters without manually canceling DDL operations.

Starting from v7.1.0, when you upgrade TiDB to a later version, TiDB supports smooth upgrade. This feature removes the limitations during the upgrade process and provides a more user-friendly upgrade experience. Note that you need to ensure that there are no user-initiated DDL operations during the upgrade process.

8.2.3.1 Supported versions

Depending on whether the feature needs to be controlled by a switch, there are two ways to use smooth upgrade:

- The feature is enabled by default and does not need to be controlled by a switch. Currently, the versions that support this method are v7.1.0, v7.1.1, v7.2.0, and v7.3.0. The specific supported versions are as follows:
  - Upgrade from v7.1.0 to v7.1.1, v7.2.0, or v7.3.0
  - Upgrade from v7.1.1 to v7.2.0 or v7.3.0
  - Upgrade from v7.2.0 to v7.3.0
- The feature is disabled by default, and can be enabled by sending the `/upgrade/start` request. For details, see TiDB HTTP API. The supported versions are as follows:
  - Upgrade from v7.1.2 and later v7.1 versions (that is, v7.1.x, where x >= 2) to v7.4.0 and later versions
  - Upgrade from v7.4.0 to later versions

Refer to the following table for the upgrade methods supported by specific versions:

Original version	Upgraded version	Upgrade methods	Note
< v7.1.0	Any version	Does not support smooth upgrade.	
v7.1.0	v7.1.1, v7.2.0, or v7.3.0	Smooth upgrade is automatically supported. No additional operations are required.	Experimental feature. It might encounter the issue #44760.

Original version	Upgraded version	Upgrade methods	Note
v7.1.1	v7.2.0 or v7.3.0	Smooth upgrade is automatically supported. No additional operations are required.	Experimental feature.
v7.2.0	v7.3.0	Smooth upgrade is automatically supported. No additional operations are required.	Experimental feature.
[v7.1.2, v7.2.0)	[v7.1.2, v7.2.0)	Enable smooth upgrade by sending the `/upgrade/start` HTTP request. There are two methods: Use TiUP and Other upgrade methods	When smooth upgrade is not enabled, ensure that no DDL operations are performed during the upgrade.
[v7.1.2, v7.2.0) or >= v7.4.0	>= v7.4.0	Enable smooth upgrade by sending the `/upgrade/start` HTTP request. There are two methods: Use TiUP and Other upgrade methods	When smooth upgrade is not enabled, ensure that no DDL operations are performed during the upgrade.

Original version	Upgraded version	Upgrade methods	Note
v7.1.0, v7.1.1, v7.2.0, and v7.3.0	>= v7.4.0	Does not support smooth upgrade.	

8.2.3.2 Feature introduction

Before the smooth upgrade feature is introduced, there are the following limitations on DDL operations during the upgrade process:

- Running DDL operations during the upgrade process might cause undefined behavior in TiDB.
- Upgrading TiDB during the DDL operations might cause undefined behavior in TiDB.

These limitations can be summarized as that you need to ensure that there are no user-initiated DDL operations during the upgrade process. After the smooth upgrade feature is introduced, TiDB is no longer subject to this limitation during the upgrade process.

For more information, see the **Warning** content in Upgrade TiDB Using TiUP.

8.2.3.2.1 Upgrade steps

Use TiUP to upgrade

Starting from v1.14.0, TiUP automatically supports this feature. That is, you can directly use the `tiup cluster upgrade` command to upgrade TiDB clusters. Note that the `tiup cluster patch` command is not supported currently.

Use TiDB Operator to upgrade

Currently, this feature is not supported. It will be supported as soon as possible.

Other upgrade methods

You can take the following steps to upgrade TiDB manually or by using a script:

1. Send the HTTP upgrade start request to any TiDB node in the cluster: `curl -X POST http://{TiDBIP}:10080/upgrade/start`.

- The TiDB cluster enters the **Upgrading** state.
- The DDL operations to be performed are paused.

2. Replace the TiDB binary and perform a rolling upgrade. This process is the same as the original upgrade process.

- The system DDL operations are performed during the upgrade process.

3. After all TiDB nodes in the cluster are upgraded successfully, send the HTTP upgrade finish request to any TiDB node: `curl -X POST http://{TiDBIP}:10080/upgrade/finish`.
    - The paused DDL operations of users are resumed.

8.2.3.3 Limitations

When using the smooth upgrade feature, note the following limitations.

> **Note:**
>
> The limitations in this section apply not only to scenarios using the smooth upgrade feature, but also to upgrading TiDB using TiUP.

8.2.3.3.1 Limitations on user operations

- Before the upgrade, consider the following restrictions:
    - If there is a canceling DDL job in the cluster, that is, an ongoing DDL job is being canceled by a user, because the job in the canceling state cannot be paused, TiDB will retry canceling the job. If the retry fails, an error is reported and the upgrade is exited.
    - If your current TiDB version is earlier than v8.1.0 and the TiDB Distributed eXecution Framework (DXF) is enabled, disable it by setting `tidb_enable_dist_task` to `OFF`. Make sure that all ongoing distributed `ADD INDEX` and `IMPORT INTO` tasks are completed. Alternatively, you can cancel these tasks and wait until the upgrade is complete to restart them. Otherwise, the `ADD INDEX` operations during the upgrade might cause data index inconsistency. If your current TiDB version is v8.1.0 or later, you do not need to disable the DXF, and you can just ignore this limitation.
- In scenarios of using TiUP to upgrade TiDB, because TiUP upgrade has a timeout period, if the cluster has a large number of DDL jobs (more than 300) waiting in queues before the upgrade, the upgrade might fail.
- During the upgrade, the following operations are not allowed:
    - Run DDL operations on system tables (`mysql.*`, `information_schema.*`, `performance_schema.*`, and `metrics_schema.*`).
    - Manually cancel DDL jobs: `ADMIN CANCEL DDL JOBS job_id [, job_id] ...;` .
    - Import data.

8.2.3.3.2 Limitations on tools

- During the upgrade, use of the following tools is not supported:
    - BR: BR might replicate the paused DDL jobs to TiDB. The paused DDL jobs cannot be automatically resumed, which might cause the DDL jobs to be stuck later.
    - DM and TiCDC: If you use DM or TiCDC to import SQL statements to TiDB during the upgrade process, and if one of the SQL statements contains DDL operations, the import operation is blocked and undefined errors might occur.

8.2.3.3.3 Limitation on plugins

The plugins installed in TiDB might contain DDL operations. However, during the upgrade, if the DDL operations in the plugins are performed on non-system tables, the upgrade might fail.

8.2.4 Migrate and Upgrade a TiDB Cluster

This document describes how to migrate and upgrade a TiDB cluster (also known as a blue-green upgrade) using BR for full backup and restore, along with TiCDC for incremental data replication. This solution uses dual-cluster redundancy and incremental replication to enable smooth traffic switchover and fast rollback, providing a reliable and low-risk upgrade path for critical systems. It is recommended to regularly upgrade the database version to continuously benefit from performance improvements and new features, helping you maintain a secure and efficient database system. The key advantages of this solution include:

- **Controllable risk**: supports rollback to the original cluster within minutes, ensuring business continuity.
- **Data integrity**: uses a multi-stage verification mechanism to prevent data loss.
- **Minimal business impact**: requires only a brief maintenance window for the final switchover.

The core workflow for migration and upgrade is as follows:

1. **Pre-check risks**: verify cluster status and solution feasibility.
2. **Prepare the new cluster**: create a new cluster from a full backup of the old cluster and upgrade it to the target version.
3. **Replicate incremental data**: establish a forward data replication channel using TiCDC.
4. **Switch and verify**: perform multi-dimensional verification, switch business traffic to the new cluster, and set up a TiCDC reverse replication channel.
5. **Observe status**: maintain the reverse replication channel. After the observation period, clean up the environment.

Rollback plan: if the new cluster encounters issues during the migration and upgrade process, you can switch business traffic back to the original cluster at any time.

The following sections describe the standardized process and general steps for migrating and upgrading a TiDB cluster. The example commands are based on a TiDB Self-Managed environment.

8.2.4.1 Step 1: Evaluate solution feasibility

Before migrating and upgrading, evaluate the compatibility of relevant components and check cluster health status.

- Check the TiDB cluster version: this solution applies to TiDB v6.5.0 or later versions.
- Verify TiCDC compatibility:
    - **Table schema requirements**: ensure that tables to be replicated contain valid indexes. For more information, see TiCDC valid index.
    - **Feature limitations**: TiCDC does not support Sequence or TiFlash DDL replication. For more information, see TiCDC unsupported scenarios.
    - **Best practices**: avoid executing DDL operations on the upstream cluster of TiCDC during switchover.
- Verify BR compatibility:
    - Review the compatibility matrix of BR full backup. For more information, see BR version compatibility matrix.
    - Check the known limitations of BR backup and restore. For more information, see BR usage restrictions.
- Check the health status of the cluster, such as Region health and node resource utilization.

8.2.4.2 Step 2: Prepare the new cluster

8.2.4.2.1 1. Adjust the GC lifetime of the old cluster

To ensure data replication stability, adjust the system variable `tidb_gc_life_time` to a value that covers the total duration of the following operations and intervals: BR backup, BR restore, cluster upgrade, and TiCDC Changefeed replication setup. Otherwise, the replication task might enter an unrecoverable `failed` state, requiring a restart of the entire migration and upgrade process from a new full backup.

The following example sets `tidb_gc_life_time` to `60h`:

```
-- Check the current GC lifetime setting.
SHOW VARIABLES LIKE '%tidb_gc_life_time%';
-- Set GC lifetime.
SET GLOBAL tidb_gc_life_time=60h;
```

> **Note:**
>
> Increasing `tidb_gc_life_time` increases storage usage for MVCC data and might affect query performance. For more information, see GC Overview. Adjust the GC duration based on estimated operation time while considering storage and performance impacts.

8.2.4.2.2 2. Migrate full data to the new cluster

When migrating full data to the new cluster, note the following:

- **Version compatibility**: the BR version used for backup and restore must match the major version of the old cluster.
- **Performance impact**: BR backup consumes system resources. To minimize business impact, perform backups during off-peak hours.
- **Time estimation**: under optimal hardware conditions (no disk I/O or network bandwidth bottlenecks), estimated times are:
  - Backup speed: backing up 1 TiB of data per TiKV node with 8 threads takes approximately 1 hour.
  - Restore speed: restoring 1 TiB of data per TiKV node takes approximately 20 minutes.
- **Configuration consistency**: ensure that the `new_collations_enabled_on_first_bootstrap` configuration is identical between the old and new clusters. Otherwise, BR restore will fail.
- **System table restore**: Use the `--with-sys-table` option during BR restore to recover system table data.

To migrate full data to the new cluster, take the following steps:

1. Perform a full backup on the old cluster:

```
tiup br:${cluster_version} backup full --pd ${pd_host}:${pd_port} -s ${
    ↪ backup_location}
```

2. Record the TSO of the old cluster for later TiCDC Changefeed creation:

```
tiup br:${cluster_version} validate decode --field="end-version" \
--storage "s3://xxx?access-key=${access-key}&secret-access-key=${secret
    ↪ -access-key}" | tail -n1
```

3. Deploy the new cluster:

```
tiup cluster deploy ${new_cluster_name} ${cluster_version} tidb-cluster
    ↪ .yaml
```

4. Restore the full backup to the new cluster:

```
tiup br:${cluster_version} restore full --pd ${pd_host}:${pd_port} -s $
    ↪ {backup_location} --with-sys-table
```

8.2.4.2.3 3. Upgrade the new cluster to the target version

To save time, you can perform an offline upgrade using the following commands. For more upgrade methods, see Upgrade TiDB Using TiUP.

```
tiup cluster stop <new_cluster_name> # Stop the cluster
tiup cluster upgrade <new_cluster_name> <v_target_version> --offline #
    ↪ Perform offline upgrade
tiup cluster start <new_cluster_name> # Start the cluster
```

To maintain business continuity, you need to replicate essential configurations from the old cluster to the new cluster, such as configuration items and system variables.

8.2.4.3 Step 3: Replicate incremental data

8.2.4.3.1 1. Establish a forward data replication channel

At this stage, the old cluster remains at its original version, while the new cluster has been upgraded to the target version. In this step, you need to establish a forward data replication channel from the old cluster to the new cluster.

> **Note:**
>
> The TiCDC component version must match the major version of the old cluster.

- Create a Changefeed task and set the incremental replication starting point (`${tso}`) to the exact backup TSO recorded in Step 2 to prevent data loss:

```
tiup ctl:${cluster_version} cdc changefeed create --server http://${cdc
    ↪ _host}:${cdc_port} --sink-uri="mysql://${username}:${password}@${
    ↪ tidb_endpoint}:${port}" --config config.toml --start-ts ${tso}
```

- Check the replication task status and confirm that `tso` or `checkpoint` is continuously advancing:

```
tiup ctl:${cluster_version} cdc changefeed list --server http://${cdc_
    ↪ host}:${cdc_port}
```

  The output is as follows:

```
[{
    "id": "cdcdb-cdc-task-standby",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "202x-xx-xx xx:xx:xx.xxx",
      "error": null
    }
}]
```

During incremental data replication, continuously monitor the replication channel status and adjust settings if needed:

- Latency metrics: ensure that `Changefeed checkpoint lag` remains within an acceptable range, such as within 5 minutes.
- Throughput health: ensure that `Sink flush rows/s` consistently exceeds the business write rate.
- Errors and alerts: regularly check TiCDC logs and alert information.
- (Optional) Test data replication: update test data and verify that Changefeed correctly replicates it to the new cluster.
- (Optional) Adjust the TiCDC configuration item `gc-ttl` (defaults to 24 hours).

  If a replication task is unavailable or interrupted and cannot be resolved in time, `gc-ttl` ensures that data needed by TiCDC is retained in TiKV without being cleaned by garbage collection (GC). If this duration is exceeded, the replication task enters a `failed` state and cannot recover. In this case, PD's GC safe point continues advancing, requiring a new backup to restart the process.

  Increasing the value of `gc-ttl` accumulates more MVCC data, similar to increasing `tidb_gc_life_time`. It is recommended to set it to a reasonably long but appropriate value.

8.2.4.3.2 2. Verify data consistency

After data replication is complete, verify data consistency between the old and new clusters using the following methods:

- Use the sync-diff-inspector tool:

```
./sync_diff_inspector --config=./config.toml
```

- Use the snapshot configuration of sync-diff-inspector with the Syncpoint feature of TiCDC to verify data consistency without stopping Changefeed replication. For more information, see Upstream and Downstream Clusters Data Validation and Snapshot Read.
- Perform manual validation of business data, such as comparing table row counts.

8.2.4.3.3 3. Finalize the environment setup

This migration procedure restores some system table data using the BR `--with-sys-table` option. For tables that are not included in the scope, you need to manually restore. Common items to check and supplement include:

- User privileges: compare the `mysql.user` table.
- Configuration settings: ensure that configuration items and system variables are consistent.
- Auto-increment columns: clear auto-increment ID caches in the new cluster.
- Statistics: collect statistics manually or enable automatic collection in the new cluster.

Additionally, you can scale out the new cluster to handle expected workloads and migrate operational tasks, such as alert subscriptions, scheduled statistics collection scripts, and data backup scripts.

8.2.4.4 Step 4: Switch business traffic and rollback

8.2.4.4.1 1. Prepare for the switchover

- Confirm replication status:
  - Monitor the latency of TiCDC Changefeed replication.
  - Ensure that the incremental replication throughput is greater than or equal to the peak business write rate.
- Perform multi-dimensional validation, such as:
  - Ensure that all data validation steps are complete and perform any necessary additional checks.
  - Conduct sanity or integration tests on the application in the new cluster.

8.2.4.4.2 2. Execute the switchover

1. Stop application services to prevent the old cluster from handling business traffic. To further restrict access, you can use one of the following methods:

    - Lock user accounts in the old cluster:

    ```
    ALTER USER ACCOUNT LOCK;
    ```

    - Set the old cluster to read-only mode. It is recommended to restart TiDB nodes in the old cluster to clear active business sessions and prevent connections that have not entered read-only mode:

    ```
    SET GLOBAL tidb_super_read_only=ON;
    ```

2. Ensure TiCDC catches up:

    - After setting the old cluster to read-only mode, retrieve the current `up-tso`:

    ```
    SELECT tidb_current_ts();
    ```

    - Monitor the Changefeed `checkpointTs` to confirm it has surpassed `up-tso`, indicating that TiCDC has completed data replication.

3. Verify data consistency between the new and old clusters:

    - After TiCDC catches up, obtain the `down-tso` from the new cluster.
    - Use the sync-diff-inspector tool to compare data consistency between the new and old clusters at `up-tso` and `down-tso`.

4. Pause the forward Changefeed replication task:

    ```
    tiup ctl:${cluster_version} cdc changefeed pause --server http://${cdc_
        ↪ host}:${cdc_port} -c <changefeedid>
    ```

5. Restart the TiDB nodes in the new cluster to clear the auto-increment ID cache.

6. Check the operational status of the new cluster using the following methods:

    - Verify that the TiDB version matches the target version:

    ```
    tiup cluster display <cluster-name>
    ```

    - Log into the database and confirm component versions:

    ```
    SELECT * FROM INFORMATION_SCHEMA.CLUSTER_INFO;
    ```

- Use Grafana to monitor service status: navigate to **Overview > Services Port Status** and confirm that all services are in the **Up** state.

7. Set up reverse replication from the new cluster to the old cluster.

    1. Unlock user accounts in the old cluster and restore read-write mode:

    ```
    ALTER USER ACCOUNT UNLOCK;
    SET GLOBAL tidb_super_read_only=OFF;
    ```

    2. Record the current TSO of the new cluster:

    ```
    SELECT tidb_current_ts();
    ```

    3. Configure the reverse replication link and ensure the Changefeed task is running properly:

        - Because business operations are stopped at this stage, you can use the current TSO.
        - Ensure that `sink-uri` is set to the address of the old cluster to avoid loopback writing risks.

    ```
    tiup ctl:${cluster_version} cdc changefeed create --server http://$
        ↪ {cdc_host}:${cdc_port} --sink-uri="mysql://${username}:${
        ↪ password}@${tidb_endpoint}:${port}" --config config.toml --
        ↪ start-ts ${tso}

    tiup ctl:${cluster_version} cdc changefeed list --server http://${
        ↪ cdc_host}:${cdc_port}
    ```

8. Redirect business traffic to the new cluster.

9. Monitor the load and operational status of the new cluster using the following Grafana panels:

    - **TiDB Dashboard > Query Summary**: check the Duration, QPS, and Failed Query OPM metrics.
    - **TiDB Dashboard > Server**: monitor the **Connection Count** metric to ensure even distribution of connections across nodes.

At this point, business traffic has successfully switched to the new cluster, and the TiCDC reverse replication channel is established.

8.2.4.4.3 3. Execute emergency rollback

The rollback plan is as follows:

- Check data consistency between the new and old clusters regularly to ensure the reverse replication link is operating properly.
- Monitor the system for a specified period, such as one week. If issues occur, switch back to the old cluster.
- After the observation period, remove the reverse replication link and delete the old cluster.

The following introduces the usage scenario and steps for an emergency rollback, which redirects traffic back to the old cluster:

- Usage scenario: execute the rollback plan if critical issues cannot be resolved.
- Steps:

    1. Stop business access to the new cluster.
    2. Reauthorize business accounts and restore read-write access to the old cluster.
    3. Check the reverse replication link, confirm TiCDC has caught up, and verify data consistency between the new and old clusters.
    4. Redirect business traffic back to the old cluster.

8.2.4.5 Step 5: Clean up

After monitoring the new cluster for a period and confirming stable business operations, you can remove the TiCDC reverse replication and delete the old cluster.

- Remove the TiCDC reverse replication:

```
tiup ctl:${cluster_version} cdc changefeed remove --server http://${cdc
    ↪ _host}:${cdc_port} -c <changefeedid>
```

- Delete the old cluster. If you choose to retain it, restore `tidb_gc_life_time` to its original value:

```
-- Restore to the original value before modification.
SET GLOBAL tidb_gc_life_time=10m;
```

8.2.5 TiFlash Upgrade Guide

This document describes the function changes and recommended actions that you need to learn when you upgrade TiFlash.

To learn the standard upgrade process, see the following documents:

- Upgrade TiDB Using TiUP
- Upgrade TiDB on Kubernetes

> **Note:**
>
> - FastScan is introduced in v6.2.0 as an experimental feature and becomes generally available (GA) in v7.0.0. It provides more efficient query performance at the cost of strong data consistency.
> - It is not recommended that you upgrade TiDB that includes TiFlash across major versions, for example, from v4.x to v6.x. Instead, you need to upgrade from v4.x to v5.x first, and then to v6.x.
> - v4.x is near the end of its life cycle. It is recommended that you upgrade to v5.x or later as soon as possible. For more information, see TiDB Release Support Policy.
> - PingCAP does not provide bug fixes for non-LTS versions, such as v6.0. It is recommended that you upgrade to v6.1 and later LTS versions whenever possible.

8.2.5.1 Upgrade TiFlash using TiUP

To upgrade TiFlash from versions earlier than v5.3.0 to v5.3.0 or later, you must stop TiFlash and then upgrade it. When you upgrade TiFlash using TiUP, note the following:

- If the TiUP cluster version is v1.12.0 or later, you cannot stop TiFlash and then upgrade it. If the target version requires a TiUP cluster version of v1.12.0 or later, it is recommended that you first use `tiup cluster:v1.11.3 <subcommand>` to upgrade TiFlash to an intermediate version, perform an online upgrade of the TiDB cluster, upgrade the TiUP version, and then upgrade the TiDB cluster to the target version directly without stopping it.
- If the TiUP cluster version is earlier than v1.12.0, perform the following steps to upgrade TiFlash.

The following steps help you use TiUP to upgrade TiFlash without interrupting other components:

1. Stop the TiFlash instance:

```
tiup cluster stop <cluster-name> -R tiflash
```

2. Upgrade the TiDB cluster without restarting it (only updating the files):

```
tiup cluster upgrade <cluster-name> <version> --offline
```

For example:

```
tiup cluster upgrade <cluster-name> v5.3.0 --offline
```

3. Reload the TiDB cluster. After the reload, the TiFlash instance is started and you do not need to manually start it.

```
tiup cluster reload <cluster-name>
```

8.2.5.2 From 5.x or v6.0 to v6.1

When you upgrade TiFlash from v5.x or v6.0 to v6.1, pay attention to the functional changes in TiFlash Proxy and dynamic pruning.

8.2.5.2.1 TiFlash Proxy

TiFlash Proxy is upgraded in v6.1.0 (aligned with TiKV v6.0.0). The new version has upgraded the RocksDB version. After you upgrade TiFlash to v6.1, the data format is converted to the new version automatically.

In regular upgrades, the data conversion does not involve any risks. However, if you need to downgrade TiFlash from v6.1 to any earlier version in special scenarios (for example, testing or verification scenarios), the earlier version might fail to parse the new RocksDB configuration. As result, TiFlash will fail to restart. It is recommended that you fully test and verify the upgrade process and prepare an emergency plan.

Workaround for downgrading TiFlash in testing or other special scenarios

You can forcibly scale in the target TiFlash node and then replicate data from TiKV again. For detailed steps, see Scale in a TiFlash cluster.

8.2.5.2.2 Dynamic pruning

If you do not enable dynamic pruning mode and will not use it in the future, you can skip this section.

- Newly installed TiDB v6.1.0: Dynamic pruning is enabled by default.

- TiDB v6.0 and earlier: Dynamic pruning is disabled by default. The setting of dynamic pruning after an upgrade inherits that of the previous version. That is, dynamic pruning will not be enabled (or disabled) automatically after an upgrade.

  After an upgrade, to enable dynamic pruning, set `tidb_partition_prune_mode` to `dynamic` and manually update global statistics of partitioned tables. For details, see Dynamic pruning mode.

8.2.5.3 From v5.x or v6.0 to v6.2

In TiDB v6.2, TiFlash upgrades its data storage format to the V3 version. Therefore, when you upgrade TiFlash from v5.x or v6.0 to v6.2, besides functional changes in TiFlash Proxy and Dynamic pruning, you also need to pay attention to the functional change in PageStorage.

8.2.5.3.1 PageStorage

By default, TiFlash v6.2.0 uses PageStorage V3 version `format_version = 4`. This new data format significantly reduces the peak write I/O traffic. In scenarios with high update traffic and high concurrency or heavy queries, it effectively relieves excessive CPU usage caused by TiFlash data GC. Meanwhile, compared with the earlier storage format, the V3 version significantly reduces space amplification and resource consumption.

- After an upgrade to v6.2.0, as new data is written to the existing TiFlash nodes, earlier data will be gradually converted to the new format.
- However, earlier data cannot be completely converted to the new format during the upgrade, because the conversion consumes a certain amount of system overhead (services are not affected, but you still need to pay attention). After the upgrade, it is recommended that you run the `Compact` command to convert the data to the new format. The steps are as follows:

  1. Run the following command for each table containing TiFlash replicas:

     ```
     ALTER TABLE <table_name> COMPACT tiflash replica;
     ```

  2. Restart the TiFlash node.

You can check whether tables still use the old data format on Grafana: **TiFlash-Summary** > **Storage Pool** > **Storage Pool Run Mode**.

- Only V2: Number of tables using PageStorage V2 (including partitions)
- Only V3: Number of tables using PageStorage V3 (including partitions)
- Mix Mode: Number of tables with data format converted from PageStorage V2 to PageStorage V3 (including partitions)

Workaround for downgrading TiFlash in testing or other special scenarios

You can forcibly scale in the target TiFlash node and then replicate data from TiKV again. For detailed steps, see Scale in a TiFlash cluster.

8.2.5.4 From v6.1 to v6.2

When you upgrade TiFlash from v6.1 to v6.2, pay attention to the change in data storage format. For details, see PageStorage.

8.2.5.5 From v6.x or v7.x to v7.3 with `storage.format_version = 5` configured

Starting from v7.3, TiFlash introduces a new DTFile version: DTFile V3 (experimental). This new DTFile version can merge multiple small files into a single larger file to reduce the total number of files. In v7.3, the default DTFile version is still V2. To use V3, you can set the TiFlash configuration parameter `storage.format_version = 5`. After the setting, TiFlash can still read V2 DTFiles and will gradually rewrite existing V2 DTFiles to V3 DTFiles during subsequent data compaction.

After upgrading TiFlash to v7.3 and configuring TiFlash to use V3 DTFiles, if you need to revert TiFlash to an earlier version, you can use the DTTool offline to rewrite V3 DTFiles back to V2 DTFiles. For more information, see DTTool Migration Tool.

8.2.5.6 From v6.x or v7.x to v7.4 or a later version

Starting from v7.4, to reduce the read and write amplification generated during data compaction, TiFlash optimizes the data compaction logic of PageStorage V3, which leads to changes to some of the underlying storage file names. Therefore, after TiFlash is upgraded to v7.4 or a later version, in-place downgrading to the original version is not supported.

8.2.5.7 From v7.x to v8.4 or a later version

Starting from v8.4, the underlying storage format of TiFlash is updated to support vector search. Therefore, after TiFlash is upgraded to v8.4 or a later version, in-place downgrading to the original version is not supported.

Workaround for downgrading TiFlash in testing or other special scenarios

To downgrade TiFlash in testing or other special scenarios, you can forcibly scale in the target TiFlash node and then replicate data from TiKV again. For detailed steps, see Scale in a TiFlash cluster.

8.3 Scale

8.3.1 Scale a TiDB Cluster Using TiUP

The capacity of a TiDB cluster can be increased or decreased without interrupting the online services.

This document describes how to scale the TiDB, TiKV, PD, TiCDC, or TiFlash cluster using TiUP. If you have not installed TiUP, refer to the steps in Step 2. Deploy TiUP on the control machine.

To view the current cluster name list, run `tiup cluster list`.

For example, if the original topology of the cluster is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.1 Scale out a TiDB/PD/TiKV cluster

This section exemplifies how to add a TiDB node to the `10.0.1.5` host.

> **Note:**
>
> You can take similar steps to add a PD node. Before you add a TiKV node, it is recommended that you adjust the PD scheduling parameters in advance according to the cluster load.

1. Configure the scale-out topology:

> **Note:**
>
> - The port and directory information is not required by default.
> - If multiple instances are deployed on a single machine, you need to allocate different ports and directories for them. If the ports or directories have conflicts, you will receive a notification during deployment or scaling.
> - Since TiUP v1.0.0, the scale-out configuration inherits the global configuration of the original cluster.

Add the scale-out topology configuration in the `scale-out.yml` file:

```
vi scale-out.yml
```

```
tidb_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 4000
```

```
  status_port: 10080
  deploy_dir: /tidb-deploy/tidb-4000
  log_dir: /tidb-deploy/tidb-4000/log
```

Here is a TiKV configuration file template:

```
tikv_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 20160
  status_port: 20180
  deploy_dir: /tidb-deploy/tikv-20160
  data_dir: /tidb-data/tikv-20160
  log_dir: /tidb-deploy/tikv-20160/log
```

Here is a PD configuration file template:

```
pd_servers:
- host: 10.0.1.5
  ssh_port: 22
  name: pd-1
  client_port: 2379
  peer_port: 2380
  deploy_dir: /tidb-deploy/pd-2379
  data_dir: /tidb-data/pd-2379
  log_dir: /tidb-deploy/pd-2379/log
```

To view the configuration of the current cluster, run `tiup cluster edit-config <cluster-name>`. Because the parameter configuration of `global` and `server_configs` is inherited by `scale-out.yml` and thus also takes effect in `scale-out.yml`.

2. Run the scale-out command:

   Before you run the `scale-out` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

   1. Check for potential risks:

      ```
      tiup cluster check <cluster-name> scale-out.yml --cluster --user root [-p] [-i /home/root/.ssh/gcp_rsa]
      ```

   2. Enable automatic repair:

      ```
      tiup cluster check <cluster-name> scale-out.yml --cluster --apply --user root [-p] [-i /home/root/.ssh/gcp_rsa]
      ```

   3. Run the `scale-out` command:

```
tiup cluster scale-out <cluster-name> scale-out.yml [-p] [-i /home/
    ↪ root/.ssh/gcp_rsa]
```

In the preceding commands:

- `scale-out.yml` is the scale-out configuration file.
- `--user root` indicates logging in to the target machine as the `root` user to complete the cluster scale out. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

If you see `Scaled cluster <cluster-name> out successfully`, the scale-out operation succeeds.

3. Refresh the cluster configuration.

Note:

- Refreshing cluster configuration is only required after you add PD nodes. If you only add TiDB or TiKV nodes, skip this step.
- If you are using TiUP v1.15.0 or a later version, skip this step because TiUP does it. If you are using a TiUP version earlier than v1.15.0, perform the following sub-steps.

1. Refresh the cluster configuration:

```
tiup cluster reload <cluster-name> --skip-restart
```

2. Refresh the Prometheus configuration and restart Prometheus:

```
tiup cluster reload <cluster-name> -R prometheus
```

4. Check the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser to monitor the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	**TiDB** + TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.2 Scale out a TiFlash cluster

This section exemplifies how to add a TiFlash node to the `10.0.1.4` host.

> **Note:**
>
> When adding a TiFlash node to an existing TiDB cluster, note the following:
>
> - Confirm that the current TiDB version supports using TiFlash. Otherwise, upgrade your TiDB cluster to v5.0 or later versions.
> - Run the `tiup ctl:v<CLUSTER_VERSION> pd -u http://<pd_ip>:<pd_port> config set enable-placement-rules true` command to enable the Placement Rules feature. Or run the corresponding command in pd-ctl.

1. Add the node information to the `scale-out.yml` file:

   Create the `scale-out.yml` file to add the TiFlash node information.

   ```
   tiflash_servers:
   - host: 10.0.1.4
   ```

   Currently, you can only add IP addresses but not domain names.

2. Run the scale-out command:

   ```
   tiup cluster scale-out <cluster-name> scale-out.yml
   ```

> **Note:**
>
> The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD + **TiFlash**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.3 Scale out a TiCDC cluster

This section exemplifies how to add two TiCDC nodes to the `10.0.1.3` and `10.0.1.4` hosts.

1. Add the node information to the `scale-out.yml` file:

   Create the `scale-out.yml` file to add the TiCDC node information.

```
cdc_servers:
  - host: 10.0.1.3
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
```

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

> **Note:**
> The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + **TiCDC**
10.0.1.4	TiDB + PD + TiFlash + **TiCDC**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.4 Scale in a TiDB/PD/TiKV cluster

This section exemplifies how to remove a TiKV node from the `10.0.1.5` host.

Note:

- You can take similar steps to remove a TiDB or PD node.
- Because the TiKV and TiFlash components are taken offline asynchronously and the stopping process takes a long time, TiUP takes them offline in different methods. For details, see Particular handling of components' offline process.
- The PD Client in TiKV caches the list of PD nodes. The current version of TiKV has a mechanism to automatically and regularly update PD nodes, which can help mitigate the issue of an expired list of PD nodes cached by TiKV. However, after scaling out PD, you should try to avoid directly removing all PD nodes at once that exist before the scaling. If necessary, before making all the previously existing PD nodes offline, make sure to switch the PD leader to a newly added PD node.

1. View the node ID information:

```
tiup cluster display <cluster-name>
```

```
Starting /root/.tiup/components/cluster/v1.12.3/cluster display <
    ↪ cluster-name>
```

```
TiDB Cluster: <cluster-name>
TiDB Version: v8.5.1
ID            Role        Host       Ports                            Status

   ↪      -                     deploy/tidb-4000
10.0.1.5:4000 tidb        10.0.1.5   4000/10080                       Up
   ↪      -                     deploy/tidb-4000
10.0.1.3:9000 tiflash     10.0.1.3   9000/8123/3930/20170/20292/8234 Up
   ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.4:9000 tiflash     10.0.1.4   9000/8123/3930/20170/20292/8234 Up
   ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.5:9090 prometheus  10.0.1.5   9090                             Up
   ↪      data/prometheus-9090 deploy/prometheus-9090
10.0.1.5:3000 grafana     10.0.1.5   3000                             Up
   ↪      -                     deploy/grafana-3000
10.0.1.5:9093 alertmanager 10.0.1.5 9093/9294                        Up
   ↪      data/alertmanager-9093 deploy/alertmanager-9093
```

2. Run the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.5:20160
```

   The `--node` parameter is the ID of the node to be taken offline.

   If you see `Scaled cluster <cluster-name> in successfully`, the scale-in operation succeeds.

3. Refresh the cluster configuration.

Note:

- Refreshing cluster configuration is only required after you remove PD nodes. If you only remove TiDB or TiKV nodes, skip this step.
- If you are using TiUP v1.15.0 or a later version, skip this step because TiUP does it. If you are using a TiUP version earlier than v1.15.0, perform the following sub-steps.

1. Refresh the cluster configuration:

```
tiup cluster reload <cluster-name> --skip-restart
```

2. Refresh the Prometheus configuration and restart Prometheus:

```
tiup cluster reload <cluster-name> -R prometheus
```

4. Check the cluster status:

   The scale-in process takes some time. You can run the following command to check the scale-in status:

```
tiup cluster display <cluster-name>
```

   If the node to be scaled in becomes `Tombstone`, the scale-in operation succeeds.

   Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiFlash + TiCDC
10.0.1.5	TiDB + Monitor **(TiKV is deleted)**
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.5 Scale in a TiFlash cluster

This section exemplifies how to remove a TiFlash node from the `10.0.1.4` host.

8.3.1.5.1 1. Adjust the number of replicas of the tables according to the number of remaining TiFlash nodes

1. Query whether any table has TiFlash replicas more than the number of TiFlash nodes

after scale-in. `tobe_left_nodes` means the number of TiFlash nodes after scale-in. If the query result is empty, you can start scaling in TiFlash. If the query result is not empty, you need to modify the number of TiFlash replicas of the related table(s).

```
SELECT * FROM information_schema.tiflash_replica WHERE REPLICA_COUNT >
    ↪ 'tobe_left_nodes';
```

2. Execute the following statement for all tables with TiFlash replicas more than the number of TiFlash nodes after scale-in. `new_replica_num` must be less than or equal to `tobe_left_nodes`:

```
ALTER TABLE <db-name>.<table-name> SET tiflash replica 'new_replica_
    ↪ num';
```

After executing this statement, TiDB modifies or deletes PD placement rules accordingly. Then, PD schedules data based on the updated placement rules.

3. Perform step 1 again and make sure that there is no table with TiFlash replicas more than the number of TiFlash nodes after scale-in.

8.3.1.5.2 2. Perform the scale-in operation

Perform the scale-in operation with one of the following solutions.

Solution 1. Use TiUP to remove a TiFlash node

1. Confirm the name of the node to be taken down:

```
tiup cluster display <cluster-name>
```

2. Remove the TiFlash node (assume that the node name is `10.0.1.4:9000` from Step 1):

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:9000
```

3. View the status of the removed TiFlash node:

```
tiup cluster display <cluster-name>
```

4. After the status of the removed TiFlash node becomes `Tombstone`, delete the information of the removed node from the TiUP topology (TiUP will automatically clean up the related data files of the `Tombstone` node):

```
tiup cluster prune <cluster-name>
```

Solution 2. Manually remove a TiFlash node

In special cases (such as when a node needs to be forcibly taken down), or if the TiUP scale-in operation fails, you can manually remove a TiFlash node with the following steps.

1. Use the store command of pd-ctl to view the store ID corresponding to this TiFlash node.

    - Enter the store command in pd-ctl (the binary file is under `resources/bin` in the tidb-ansible directory).
    - If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:v<CLUSTER_VERSION > pd`:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://<pd_ip>:<pd_port> store
```

> **Note:**
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

2. Remove the TiFlash node in pd-ctl:

    - Enter `store delete <store_id>` in pd-ctl (`<store_id>` is the store ID of the TiFlash node found in the previous step.
    - If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:v<CLUSTER_VERSION > pd`:

```
tiup ctl:v<CLUSTER_VERSION> pd -u http://<pd_ip>:<pd_port> store
    ↪ delete <store_id>
```

> **Note:**
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

3. Wait for the store of the TiFlash node to disappear or for the `state_name` to become `Tombstone` before you stop the TiFlash process.

4. Delete the information of the removed node from the TiUP topology (TiUP will automatically clean up the related data files of the `Tombstone` node):

```
tiup cluster prune <cluster-name>
```

8.3.1.5.3 3. View the cluster status

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new nodes.

After the scaling, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiCDC **(TiFlash is deleted)**
10.0.1.5	TiDB+ Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.1.6 Scale in a TiCDC cluster

This section exemplifies how to remove the TiCDC node from the `10.0.1.4` host.

1. Take the node offline:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

2. View the cluster status:

```
tiup cluster display <cluster-name>
```

   Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + **(TiCDC is deleted)**
10.0.1.5	TiDB + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

8.3.2 Use TiDB Operator

8.4 Backup and Restore

8.4.1 TiDB Backup & Restore Overview

Based on the Raft protocol and a reasonable deployment topology, TiDB realizes high availability of clusters. When a few nodes in the cluster fail, the cluster can still be available. On this basis, to further ensure data safety, TiDB provides the Backup & Restore (BR) feature as the last resort to recover data from natural disasters and misoperations.

BR satisfies the following requirements:

- Back up cluster data to a disaster recovery (DR) system with an RPO as short as 5 minutes, reducing data loss in disaster scenarios.
- Handle the cases of misoperations from applications by rolling back data to a time point before the error event.
- Perform history data auditing to meet the requirements of judicial supervision.
- Clone the production environment, which is convenient for troubleshooting, performance tuning, and simulation testing.

8.4.1.1 Before you use

This section describes the prerequisites for using TiDB backup and restore, including restrictions, usage tips and compatibility issues. For more information about the compatibility of the BR tool with other features or versions, see Compatibility.

8.4.1.1.1 Restrictions

- PITR only supports restoring data to **an empty cluster**.
- PITR only supports cluster-level restore and does not support database-level or table-level restore.
- PITR does not support restoring the data of user tables or privilege tables from system tables.
- BR does not support running multiple backup tasks on a cluster **at the same time**.
- It is not recommended to back up tables that are being restored, because the backed-up data might be problematic.
- When restoring a cluster using PITR, you cannot run a log backup task or use TiCDC to replicate data to a downstream cluster.

8.4.1.1.2 Some tips

Snapshot backup:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- It is recommended that you execute multiple backup or restore tasks one by one. Running multiple backup tasks in parallel leads to low performance. Worse still, a lack of collaboration between multiple tasks might result in task failures and affect cluster performance.

Snapshot restore:

- BR uses resources of the target cluster as much as possible. Therefore, it is recommended that you restore data to a new cluster or an offline cluster. Avoid restoring data to a production cluster. Otherwise, your application will be affected inevitably.

Backup storage and network configuration:

- It is recommended that you store backup data to a storage system that is compatible with Amazon S3, GCS, or Azure Blob Storage.
- You need to ensure that BR, TiKV, and the backup storage system have enough network bandwidth, and that the backup storage system can provide sufficient read and write performance (IOPS). Otherwise, they might become a performance bottleneck during backup and restore.

8.4.1.2 Use backup and restore

The way to use BR varies with the deployment method of TiDB. This document introduces how to use the br command-line tool to back up and restore TiDB cluster data in an on-premise deployment.

For information about how to use this feature in other deployment scenarios, see the following documents:

- Back Up and Restore TiDB Deployed on TiDB Cloud: It is recommended that you create TiDB clusters on TiDB Cloud. TiDB Cloud offers fully managed databases to let you focus on your applications.
- Back Up and Restore Data Using TiDB Operator: If you deploy a TiDB cluster using TiDB Operator on Kubernetes, it is recommended to back up and restore data using Kubernetes CustomResourceDefinition (CRD).

8.4.1.3 BR features

TiDB BR provides the following features:

- Back up cluster data: You can back up full data (**full backup**) of the cluster at a certain time point, or back up the data changes in TiDB (**log backup**, in which log means KV changes in TiKV).
- Restore backup data:
  - You can **restore a full backup** or **specific databases or tables** in a full backup.
  - Based on backup data (full backup and log backup), you can restore the target cluster to any time point of the backup cluster. This type of restore is called point-in-time recovery, or PITR for short.

8.4.1.3.1 Back up cluster data

Full backup backs up all data of a cluster at a specific time point. TiDB supports the following way of full backup:

- Back up cluster snapshots: A snapshot of a TiDB cluster contains transactionally consistent data at a specific time. For details, see Snapshot backup.

Full backup occupies much storage space and contains only cluster data at a specific time point. If you want to choose the restore point as required, that is, to perform point-in-time recovery (PITR), you can use the following two ways of backup at the same time:

- Start log backup. After log backup is started, the task keeps running on all TiKV nodes and backs up TiDB incremental data in small batches to the specified storage periodically.
- Perform snapshot backup regularly. Back up the full cluster data to the backup storage, for example, perform cluster snapshot backup at 0:00 AM every day.

Backup performance and impact on TiDB clusters

- When CPU and I/O resources are sufficient in the cluster, the snapshot backup has a limited impact on the TiDB cluster, generally staying below 20%. With appropriate configuration of the TiDB cluster, this impact can be further minimized to 10% or even less. When CPU and I/O resources are insufficient, you can adjust the TiKV configuration item `backup.num-threads` to change the number of worker threads used by the backup task to reduce the impact of the backup task on the TiDB cluster. The backup speed of a TiKV node is scalable and ranges from 50 MB/s to 100 MB/s. For more information, see Backup performance and impact.
- When there are only log backup tasks, the impact on the cluster is about 5%. Log backup flushes all the changes generated after the last refresh every 3-5 minutes to the backup storage, which can **achieve a Recovery Point Objective (RPO) as short as five minutes**.

8.4.1.3.2 Restore backup data

Corresponding to the backup features, you can perform two types of restore: full restore and PITR.

- Restore a full backup
    - Restore cluster snapshot backup: You can restore snapshot backup data to an empty cluster or a cluster that does not have data conflicts (with the same schema or tables). For details, see Restore snapshot backup. In addition, you can restore specific databases or tables from the backup data and filter out unwanted data. For details, see Restore specific databases or tables from backup data.
- Restore data to any point in time (PITR)

- By running the `br restore point` command, you can restore the latest snapshot backup data before recovery time point and log backup data to a specified time. BR automatically determines the restore scope, accesses backup data, and restores data to the target cluster in turn.

Restore performance and impact on TiDB clusters

- Data restore is performed at a scalable speed. Generally, the speed is 1 GiB/s per TiKV node. For more details, see Restore performance and impact.
- On each TiKV node, PITR can restore log data at 30 GiB/h. For more details, see PITR performance and impact.

8.4.1.4 Backup storage

TiDB supports backing up data to Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, NFS, and other S3-compatible file storage services. For details, see the following documents:

- Specify backup storage in URI
- Configure access privileges to backup storages

8.4.1.5 Compatibility

8.4.1.5.1 Compatibility with other features

Backup and restore might go wrong when some TiDB features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

Feature	Issue	Solution
GBK charset		BR of versions earlier than v5.4.0 does not support restoring `charset = GBK` tables. No version of BR supports recovering `charset = GBK` tables to TiDB clusters earlier than v5.4.0.

Feature	Issue	Solution
Clustered index	#565	Make sure that the value of the `tidb_enable_clustered_index` global variable during restore is consistent with that during backup. Otherwise, data inconsistency might occur, such as `default not found` error and inconsis-

Feature	Issue	Solution
New collation	#352	Make sure that the value of the `new_collation_enabled` variable in the `mysql.tidb` table during restore is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass. For more

Feature	Issue	Solution
Global temporary tables		Make sure that you are using v5.3.0 or a later version of BR to back up and restore data. Otherwise, an error occurs in the definition of the backed global temporary tables.

Feature	Issue	Solution
TiDB Lightning Physical Import		If the upstream database uses the physical import mode of TiDB Lightning, data cannot be backed up in log backup. It is recommended to perform a full backup after the data import. For more information, see When the upstream database imports data

Feature	Issue	Solution
TiCDC		BR v8.2.0 and later: if the target cluster to be restored has a changefeed and the changefeed CheckpointTS is earlier than the BackupTS, BR does not perform the restoration. BR versions before v8.2.0: if the target cluster to be restored has any active TiCDC

Feature	Issue	Solution
Vector search		Make sure that you are using v8.4.0 or a later version of BR to back up and restore data. Restoring tables with vector data types to TiDB clusters earlier than v8.4.0 is not supported.

8.4.1.5.2 Version compatibility

Note:

> It is recommended to use the BR of the same major version as your TiDB cluster for backup and restoration.

Before performing backup and restore, BR compares the TiDB cluster version with its own and checks their compatibility. If the versions are incompatible, BR reports an error and exits. To forcibly skip the version check, you can set `--check-requirements=false`. Note that skipping the version check might introduce incompatibility in data.

Starting from v7.0.0, TiDB gradually supports performing backup and restore operations through SQL statements. Therefore, it is strongly recommended to use the BR tool of the same major version as the TiDB cluster when backing up and restoring cluster data, and avoid performing data backup and restore operations across major versions. This helps ensure smooth execution of restore operations and data consistency. Starting from v7.6.0, BR restores data in some `mysql` system tables by default, that is, the `--with-sys-table` option is set to `true` by default. When restoring data to a TiDB cluster with a different version, if you encounter an error similar to `[BR:Restore:ErrRestoreIncompatibleSys] ↪ incompatible system table` due to different schemas of system tables, you can set `--with-sys-table=false` to skip restoring the system tables and avoid this error.

BR version compatibility matrix before TiDB v6.6.0

The compatibility information for BR before TiDB v6.6.0 is as follows:

Backup version (vertical) / Restore version (horizontal)	Restore to TiDB v6.0	Restore to TiDB v6.1	Restore to TiDB v6.2	Restore to TiDB v6.3, v6.4, or v6.5	Restore to TiDB v6.6
TiDB v6.0, v6.1, v6.2, v6.3, v6.4, or v6.5 snapshot backup	Compatible (known issue #36379: if backup data contains an empty schema, BR might report an error.)	Compatible	Compatible	Compatible	Compatible (BR must be v6.6)
TiDB v6.3, v6.4, v6.5, or v6.6 log backup	Incompatible	Incompatible	Incompatible	Compatible	Compatible

BR version compatibility matrix between TiDB v6.5.0 and v8.5.0

This section introduces the BR compatibility information for all Long-Term Support (LTS) versions between TiDB v6.5.0 and v8.5.0 (including v6.5.0, v7.1.0, v7.5.0, v8.1.0, and v8.5.0):

> **Note:**
>
> Known issue: Starting from version v7.2.0, some system table fields in newly created clusters are case-insensitive. However, for clusters that are **upgraded online** from versions earlier than v7.2.0 to v7.2.0 or later, the corresponding system table fields remain case-sensitive. Backup and restore operations involving system tables between these two types of clusters might fail. For more details, see Issue #43717.

The following table lists the compatibility matrix for full backups. Note that all information in the table applies to newly created clusters. For clusters upgraded from a version earlier than v7.2.0 to v7.2.0 or later, their behavior is consistent with that of backups from v7.1.0.

Backup version	Compatible restore versions	Incompatible restore versions
v6.5.0	v7.1.0	v7.5.0 and later
v7.1.0	-	v7.5.0 and later
v7.5.0	v7.5.0 and later	-
v8.1.0	v8.1.0 and later	-
v8.5.0	v8.5.0 and later	-

The following table lists the compatibility matrix for log backups. Note that all information in the table applies to newly created clusters. For clusters upgraded from a version earlier than v7.2.0 to v7.2.0 or later, their behavior is consistent with that of backups from v7.1.0.

Backup version	Compatible restore versions	Incompatible restore versions
v6.5.0	v7.1.0	v7.5.0 and later
v7.1.0	-	v7.5.0 and later
v7.5.0	v7.5.0 and later	-
v8.1.0	v8.1.0 and later	-
v8.5.0	v8.5.0 and later	-

> **Note:**

- When only data of non-system tables is backed up (full backup or log backup), all versions are compatible with each other.
- In scenarios where restoring the `mysql` system table is incompatible, you can resolve the problem by setting `--with-sys-table=false` to skip restoring all system tables, or use a more fine-grained filter to just skip incompatible system tables, for example: `--filter '*.*' --filter "__TiDB_BR_Temporary_*.*" --filter '!mysql.*' --filter 'mysql.bind_info' --filter 'mysql.user' --filter 'mysql.global_priv' --filter 'mysql.global_grants' --filter 'mysql.default_roles' --filter 'mysql.role_edges' --filter '!sys.*' --filter '!INFORMATION_SCHEMA.*' --filter '!PERFORMANCE_SCHEMA.*' --filter '!METRICS_SCHEMA.*' --filter '!INSPECTION_SCHEMA.*'`.
- `-` means that there are no compatibility restrictions for the corresponding scenario.

8.4.2 Architecture

8.4.2.1 Overview of TiDB Backup & Restore Architecture

As described in TiDB Backup & Restore Overview, TiDB supports backing up and restoring multiple types of cluster data. You can use Backup & Restore (BR) and TiDB Operator to access these features, and create tasks to back up data from TiKV nodes or restore data to TiKV nodes.

For details about the architecture of each backup and restore feature, see the following documents:

- Full data backup and restore
  - Back up snapshot data
  - Restore snapshot backup data
- Data change log backup
  - Log backup: backup of KV data change
- Point-in-time recovery (PITR)
  - PITR

8.4.2.2 TiDB Snapshot Backup and Restore Architecture

This document introduces the architecture and process of TiDB snapshot backup and restore using a Backup & Restore (BR) tool as an example.

8.4.2.2.1 Architecture

The TiDB snapshot backup and restore architecture is as follows:

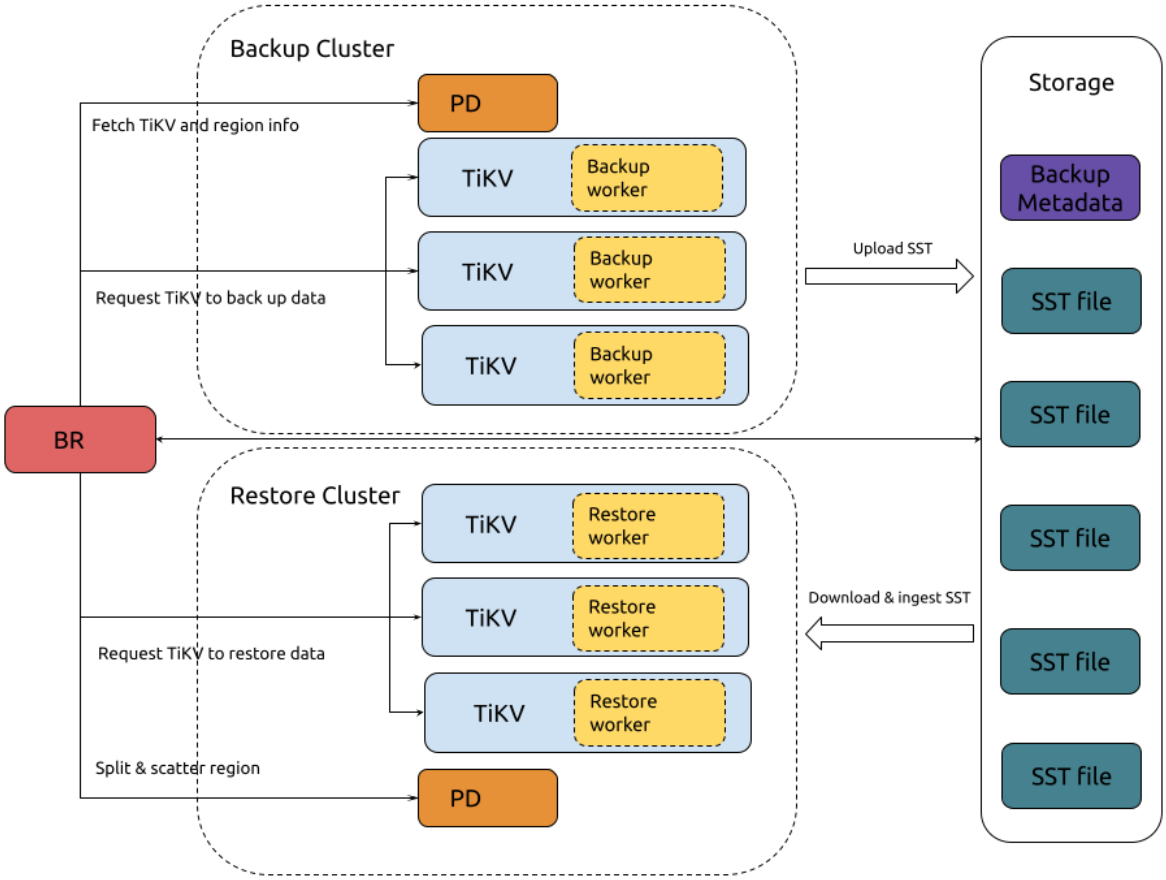

Figure 138: BR snapshot backup and restore architecture

8.4.2.2.2 Process of backup

The process of a cluster snapshot backup is as follows:

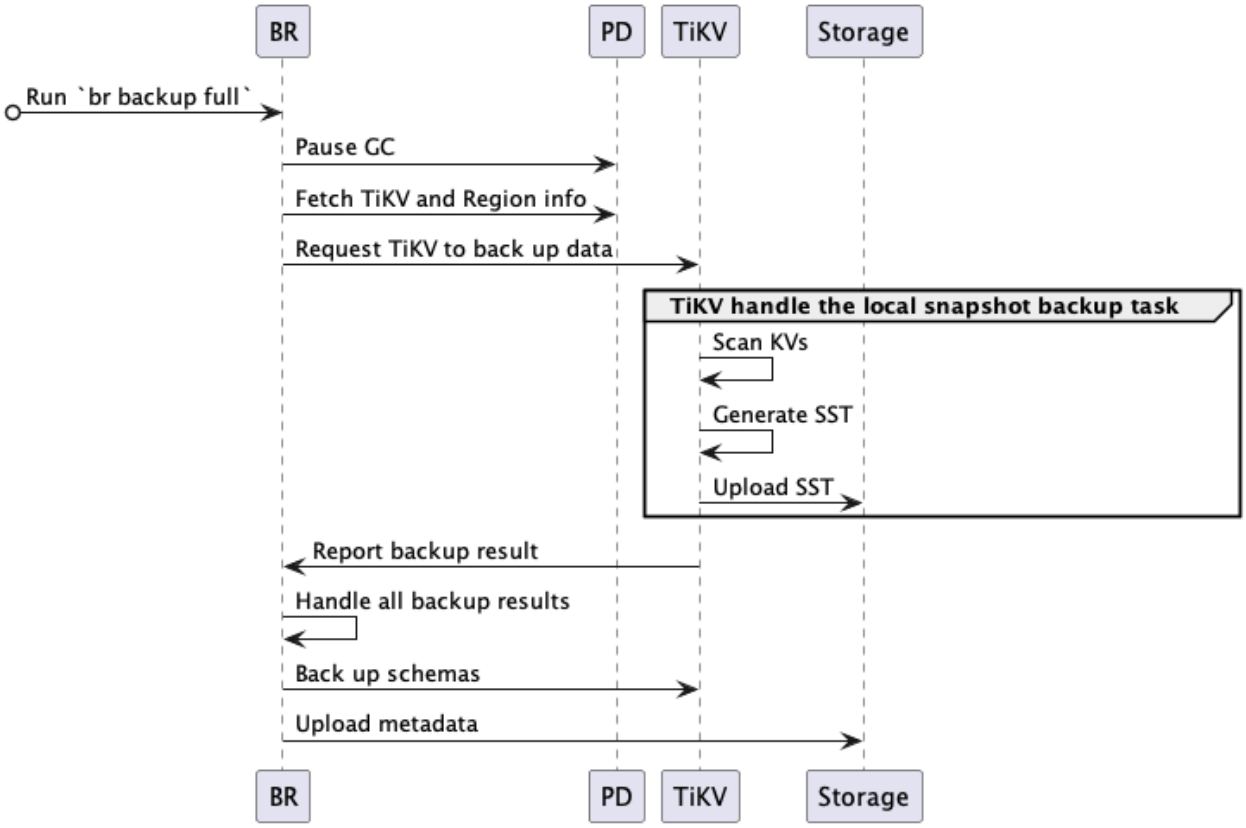

Figure 139: snapshot backup process design

The complete backup process is as follows:

1. BR receives the `br backup full` command.

    - Gets the backup time point and storage path.

2. BR schedules the backup data.

    - **Pause GC**: BR configures the TiDB GC time to prevent the backup data from being cleaned up by TiDB GC mechanism.
    - **Fetch TiKV and Region info**: BR accesses PD to get all TiKV nodes addresses and Region distribution of data.
    - **Request TiKV to back up data**: BR creates a backup request and sends it to all TiKV nodes. The backup request includes the backup time point, Regions to be backed up, and the storage path.

3. TiKV accepts the backup request and initiates a backup worker.

4. TiKV backs up the data.

- **Scan KVs**: the backup worker reads data corresponding to the backup time point from the Region where the leader locates.
- **Generate SST**: the backup worker saves the data to SST files, which are stored in the memory.
- **Upload SST**: the backup worker uploads the SST files to the storage path.

5. BR receives the backup result from each TiKV node.

    - If some data fails to be backed up due to Region changes, for example, a TiKV node is down, BR will retry the backup.
    - If there is any data fails to be backed up and cannot be retried, the backup task fails.
    - After all data is backed up, BR will then back up the metadata.

6. BR backs up the metadata.

    - **Back up schemas**: BR backs up the table schemas and calculates the checksum of the table data.
    - **Upload metadata**: BR generates the backup metadata and uploads it to the storage path. The backup metadata includes the backup timestamp, the table and corresponding backup files, data checksum, and file checksum.

8.4.2.2.3 Process of restore

The process of a cluster snapshot restore is as follows:

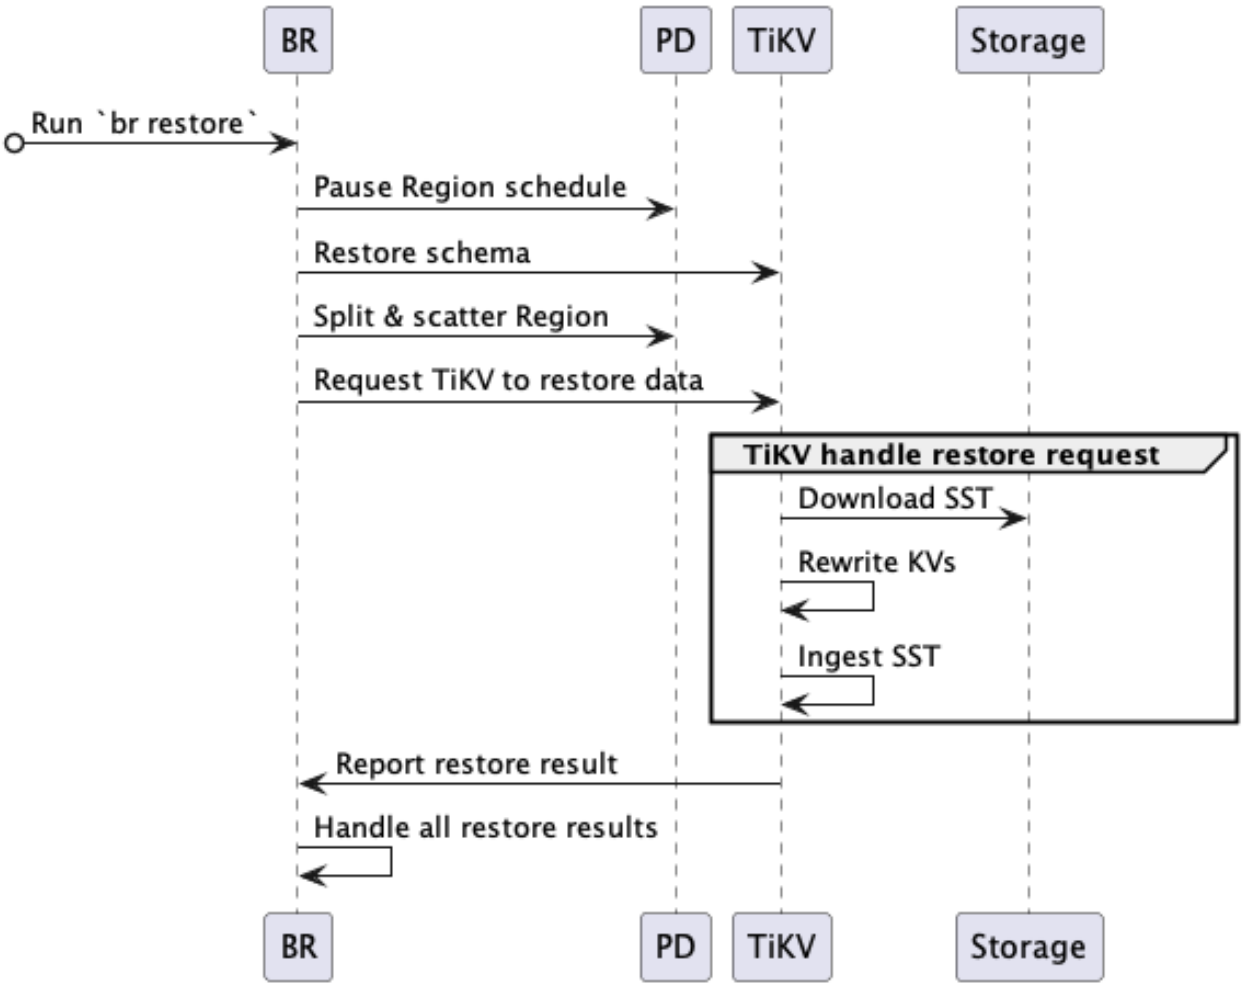

Figure 140: snapshot restore process design

The complete restore process is as follows:

1. BR receives the `br restore` command.

    - Gets the data storage path and the database or table to be restored.
    - Checks whether the table to be restored exists and whether it meets the requirements for restore.

2. BR schedules the restore data.

    - **Pause Region schedule**: BR requests PD to pause the automatic Region scheduling during restore.
    - **Restore schema**: BR gets the schema of the backup data and the database and table to be restored. Note that the ID of a newly created table might be different from that of the backup data.

- **Split & scatter Region**: BR requests PD to allocate Regions (split Region) based on backup data, and schedules Regions to be evenly distributed to storage nodes (scatter Region). Each Region has a specified data range `[start key, end key)`.
- **Request TiKV to restore data**: BR creates a restore request and sends it to the corresponding TiKV nodes according to the result of Region split. The restore request includes the data to be restored and rewrite rules.

3. TiKV accepts the restore request and initiates a restore worker.

    - The restore worker calculates the backup data that needs to be read to restore.

4. TiKV restores the data.

    - **Download SST**: the restore worker downloads corresponding SST files from the storage path to a local directory.
    - **Rewrite KVs**: the restore worker rewrites the KV data according to the new table ID, that is, replace the original table ID in the Key-Value with the new table ID. The restore worker also rewrites the index ID in the same way.
    - **Ingest SST**: the restore worker ingests the processed SST files into RocksDB.
    - **Report restore result**: the restore worker reports the restore result to BR.

5. BR receives the restore result from each TiKV node.

    - If some data fails to be restored due to `RegionNotFound` or `EpochNotMatch`, for example, a TiKV node is down, BR will retry the restore.
    - If there is any data fails to be restored and cannot be retried, the restore task fails.
    - After all data is restored, the restore task succeeds.

8.4.2.2.4 Backup files

Types of backup files

Snapshot backup generates the following types of files:

- `SST` file: stores the data that the TiKV node backs up. The size of an `SST` file equals to that of a Region.
- `backupmeta` file: stores the metadata of a backup task, including the number of all backup files, and the key range, the size, and the Hash (sha256) value of each backup file.
- `backup.lock` file: prevents multiple backup tasks from storing data at the same directory.

Naming format of SST files

When data is backed up to Google Cloud Storage (GCS) or Azure Blob Storage, SST files are named in the format of `storeID_regionID_regionEpoch_keyHash_timestamp_cf`. The fields in the name are explained as follows:

- `storeID` is the TiKV node ID.
- `regionID` is the Region ID.
- `regionEpoch` is the version number of Region.
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a file.
- `timestamp` is the Unix timestamp of an SST file when it is generated by TiKV.
- `cf` indicates the Column Family of RocksDB (only restores data whose `cf` is `default` or `write`).

When data is backed up to Amazon S3 or a network disk, the SST files are named in the format of `regionID_regionEpoch_keyHash_timestamp_cf`. The fields in the name are explained as follows:

- `regionID` is the Region ID.
- `regionEpoch` is the version number of Region.
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a file.
- `timestamp` is the Unix timestamp of an SST file when it is generated by TiKV.
- `cf` indicates the Column Family of RocksDB (only restores data whose `cf` is `default` or `write`).

Storage format of SST files

- For details about the storage format of SST files, see RocksDB BlockBasedTable format.
- For details about the encoding format of backup data in SST files, see mapping of table data to Key-Value.

Structure of backup files

When you back up data to GCS or Azure Blob Storage, the SST files, `backupmeta` files, and `backup.lock` files are stored in the same directory as the following structure:

```
.
└── 20220621
    ├── backupmeta
    |── backup.lock
    ├── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
    ├── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
    ├── {storeID}-{regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
```

When you back up data to Amazon S3 or a network disk, the SST files are stored in sub-directories based on the `storeID`. The structure is as follows:

```
.
├── 20220621
│   ├── backupmeta
│   ├── backup.lock
│   ├── store1
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store100
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store2
│   │   └── {regionID}-{regionEpoch}-{keyHash}-{timestamp}-{cf}.sst
│   ├── store3
│   ├── store4
│   └── store5
```

8.4.2.3 TiDB Log Backup and PITR Architecture

This document introduces the architecture and process of TiDB log backup and point-in-time recovery (PITR) using a Backup & Restore (BR) tool as an example.

8.4.2.3.1 Architecture

The log backup and PITR architecture is as follows:

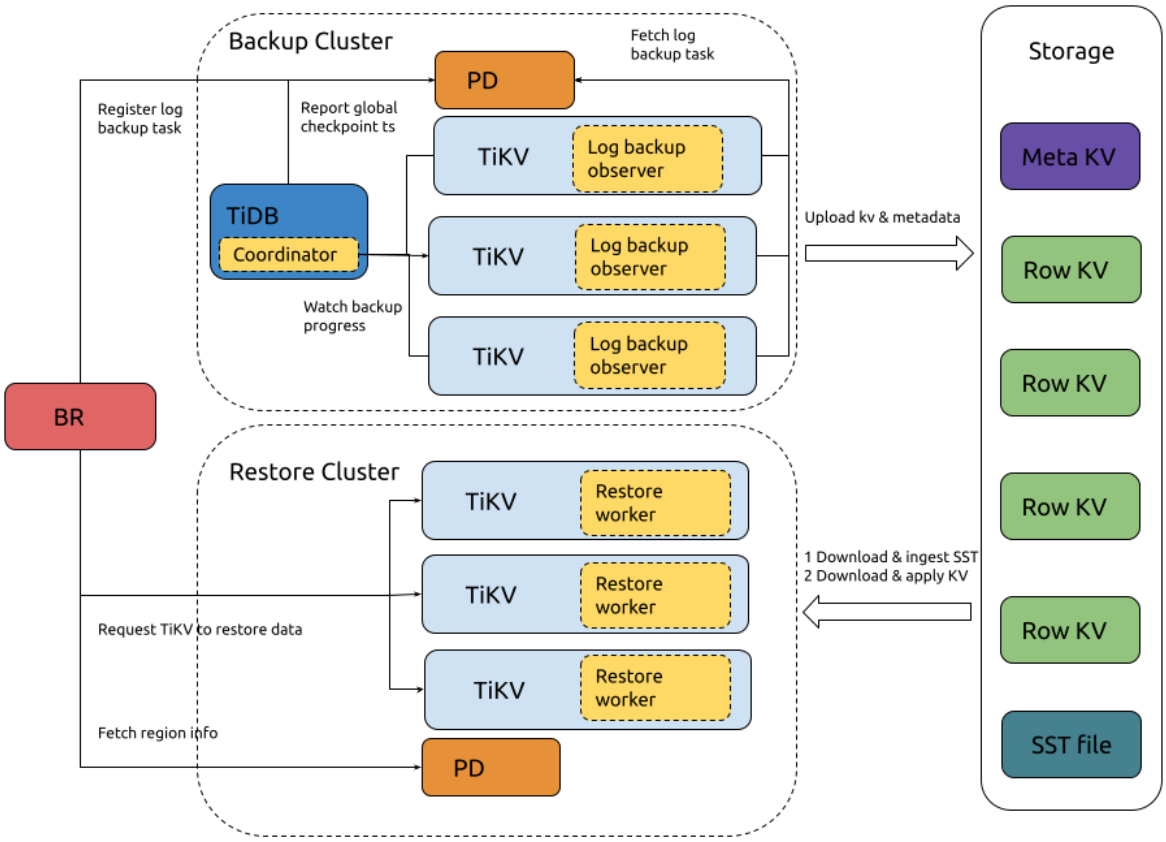

Figure 141: BR log backup and PITR architecture

8.4.2.3.2 Process of log backup

The process of a cluster log backup is as follows:

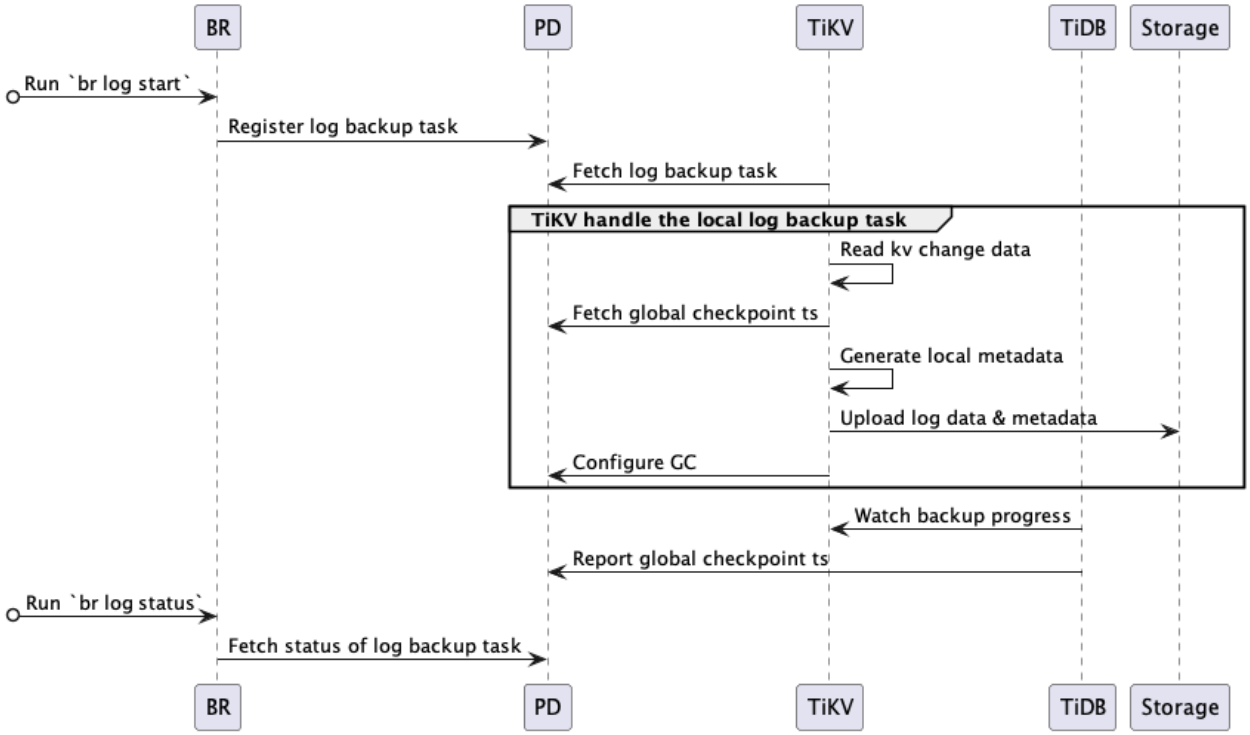

Figure 142: BR log backup process design

System components and key concepts involved in the log backup process:

- **local metadata**: indicates the metadata backed up by a single TiKV node, including local checkpoint ts, global checkpoint ts, and backup file information.
- **local checkpoint ts** (in local metadata): indicates that all logs generated before local checkpoint ts in this TiKV node have been backed up to the target storage.
- **global checkpoint ts**: indicates that all logs generated before global checkpoint ts in all TiKV nodes have been backed up to the target storage. TiDB Coordinator calculates this timestamp by collecting local checkpoint ts of all TiKV node and then reports it to PD.
- **TiDB Coordinator**: a TiDB node is elected as the coordinator, which is responsible for collecting and calculating the progress of the entire log backup task (global checkpoint ts). This component is stateless in design, and after its failure, a new Coordinator is elected from the surviving TiDB nodes.
- **TiKV log backup observer**: runs on each TiKV node in the TiDB cluster, which is responsible for backing up log data. If a TiKV node fails, backing up the data range on it will be taken by other TiKV nodes after region re-election, and these nodes will back up data of the failure range starting from global checkpoint ts.

The complete backup process is as follows:

1. BR receives the `br log start` command.

- BR parses the checkpoint ts (the start time of log backup) and storage path of the backup task.
- **Register log backup task**: BR registers a log backup task in PD.

2. TiKV monitors the creation and update of the log backup task.

- **Fetch log backup task**: The log backup observer of each TiKV node fetches the log backup task from PD and then backs up the log data in the specified range.

3. The log backup observer backs up the KV change logs continuously.

- **Read kv change data**: reads KV change data and then saves the change log to backup files in custom format.
- **Fetch global checkpoint ts**: fetches the global checkpoint ts from PD.
- **Generate local metadata**: generates the local metadata of the backup task, including local checkpoint ts, global checkpoint ts, and backup file information.
- **Upload log data & metadata**: uploads the backup files and local metadata to the target storage periodically.
- **Configure GC**: requests PD to prevent data that have not been backed up (greater than local checkpoint ts) from being recycled by the TiDB GC mechanism.

4. The TiDB Coordinator monitors the progress of the log backup task.

- **Watch backup progress**: gets the backup progress of each Region (Region checkpoint ts) by polling all TiKV nodes.
- **Report global checkpoint ts**: calculates the progress of the entire log backup task (global checkpoint ts) based on the Region checkpoint ts and then reports the global checkpoint ts to PD.

5. PD persists the status of the log backup task, and you can view it using `br log status`.

8.4.2.3.3 Process of PITR

The process of PITR is as follows:

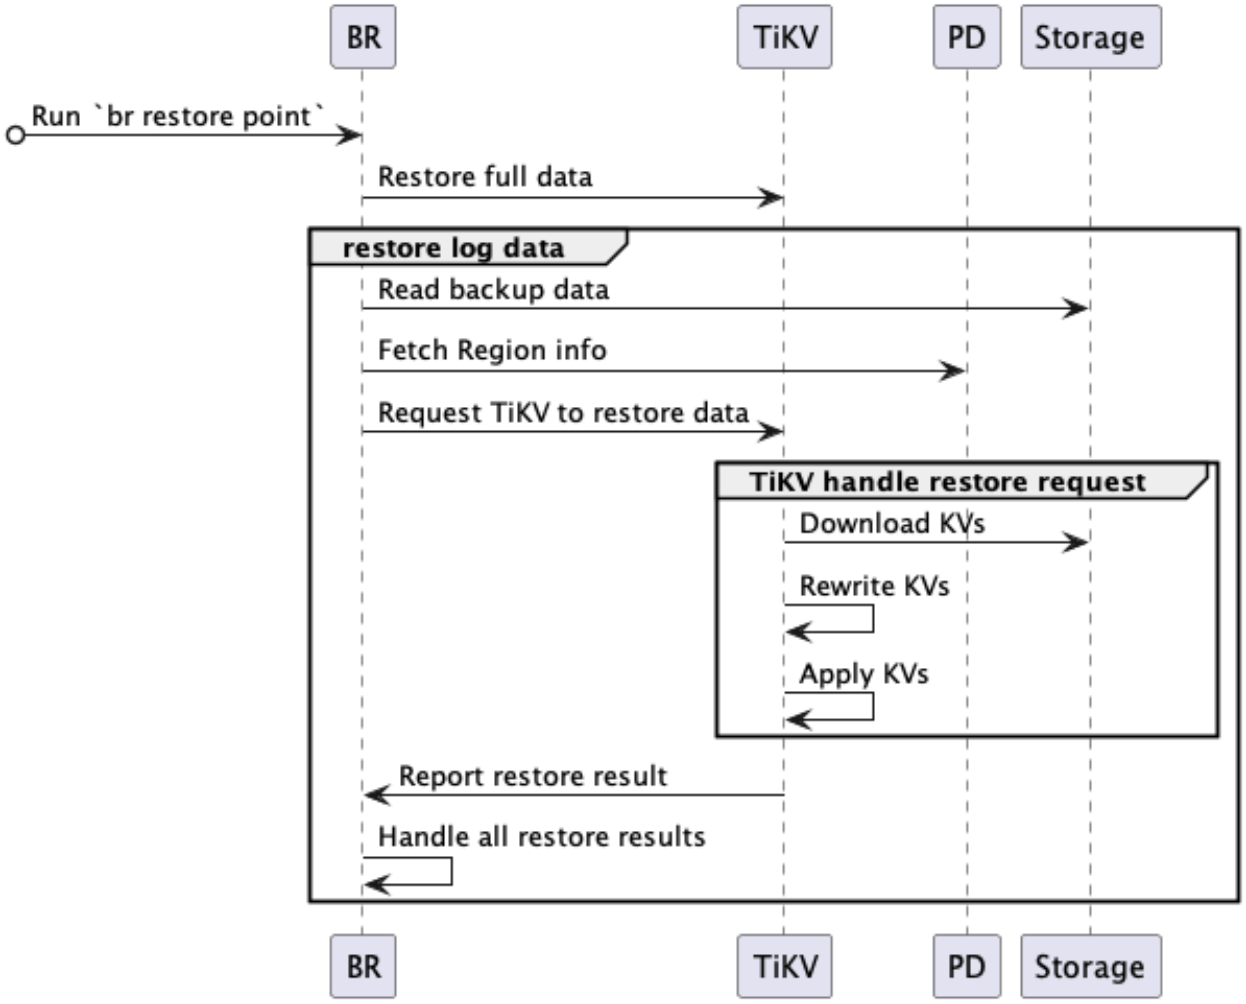

Figure 143: Point-in-time recovery process design

The complete PITR process is as follows:

1. BR receives the `br restore point` command.

- BR parses the full backup data address, log backup data address, and the point-in-time recovery time.
- Queries the restore object (database or table) in the backup data and checks whether the table to be restored exists and meets the restore requirements.

2. BR restores the full backup data.

- Restores full backup data. For more details about the process of snapshot backup data restore, refer to Restore snapshot backup data.

3. BR restores the log backup data.

- **Read backup data**: reads the log backup data and calculates the log backup data that needs to be restored.
- **Fetch Region info**: fetches all Regions distributions by accessing PD.
- **Request TiKV to restore data**: creates a log restore request and sends it to the corresponding TiKV node. The log restore request contains the log backup data information to be restored.

4. TiKV accepts the restore request from BR and initiates a log restore worker.

- The log restore worker gets the log backup data that needs to be restored.

5. TiKV restores the log backup data.

- **Download KVs**: the log restore worker downloads the corresponding backup data from the backup storage to a local directory according to the log restore request.
- **Rewrite KVs**: the log restore worker rewrites the KV data of the backup data according to the table ID of the restore cluster table, that is, replace the original table ID in the Key-Value with the new table ID. The restore worker also rewrites the index ID in the same way.
- **Apply KVs**: the log restore worker writes the processed KV data to the store (RocksDB) through the raft interface.
- **Report restore result**: the log restore worker returns the restore result to BR.

6. BR receives the restore result from each TiKV node.

- If some data fails to be restored due to `RegionNotFound` or `EpochNotMatch`, for example, a TiKV node is down, BR will retry the restore.
- If there is any data fails to be restored and cannot be retried, the restore task fails.
- After all data is restored, the restore task succeeds.

8.4.2.3.4 Log backup files

Log backup generates the following types of files:

- `{resolved_ts}-{uuid}.meta` file: is generated every time each TiKV node uploads the log backup data and stores metadata of all log backup data files uploaded this time. The `{resolved_ts}` is the resolved timestamp of the TiKV node. The latest `resolved_ts` of the log backup task is the minimum resolved timestamp among all TiKV nodes. The `{uuid}` is generated randomly when the file is created.
- `{store_id}.ts` file: is updated with global checkpoint ts every time each TiKV node uploads the log backup data. The `{store_id}` is the store ID of the TiKV node.

- `{min_ts}-{uuid}.log` file: stores the KV change log data of the backup task. The `{min_ts}` is the minimum TSO timestamp of the KV change log data in the file, and the `{uuid}` is generated randomly when the file is created.
- `v1_stream_truncate_safepoint.txt` file: stores the timestamp corresponding to the latest backup data in storage that deleted by `br log truncate`.

Structure of backup files

```
.
├── v1
│   ├── backupmeta
│   │   ├── ...
│   │   └── {resolved_ts}-{uuid}.meta
│   ├── global_checkpoint
│   │   └── {store_id}.ts
│   └── {date}
│       └── {hour}
│           └── {store_id}
│               ├── ...
│               └── {min_ts}-{uuid}.log
└── v1_stream_truncate_safepoint.txt
```

Explanation of the backup file directory structure:

- `backupmeta`: stores backup metadata. The `resolved_ts` in the filename indicates the backup progress, meaning that data before this TSO has been fully backed up. However, note that this TSO only reflects the progress of certain shards.
- `global_checkpoint`: represents the global backup progress. It records the latest point in time to which data can be restored using `br restore point`.
- `{date}/{hour}`: stores backup data for the corresponding date and hour. When cleaning up storage, always use `br log truncate` instead of manually deleting data. This is because the metadata references the data in this directory, and manual deletion might lead to restore failures or data inconsistencies after restore.

The following is an example:

```
.
├── v1
│   ├── backupmeta
│   │   ├── ...
│   │   ├── 435213818858112001-e2569bda-a75a-4411-88de-f469b49d6256.meta

8.4.3 Use BR

8.4.3.1 Usage Overview of TiDB Backup and Restore

This document describes best practices of using TiDB backup and restore features, including how to choose a backup method, how to manage backup data, and how to install and deploy the backup and restore tool.

8.4.3.1.1 Recommended practices

Before using TiDB backup and restore features, it is recommended that you understand the recommended backup and restore solutions.

How to back up data?

TiDB provides two types of backup. Which one should I use? Full backup contains the full data of a cluster at a certain point in time. Log backup contains the data changes written to TiDB. It is recommended to use both types of backup at the same time:

- Start log backup: Run the `tiup br log start` command to start the log backup task. After that, the task keeps running on all TiKV nodes and backs up TiDB data changes to the specified storage in small batches regularly.

- **Perform snapshot (full) backup regularly**: Run the `tiup br backup full` command to back up the snapshot of the cluster to the specified storage. For example, back up the cluster snapshot at 0:00 AM every day.

How to manage backup data?

BR provides only basic backup and restore features, and does not support backup management. Therefore, you need to decide how to manage backup data on your own, which might involve the following questions?

- Which backup storage system should I choose?
- In which directory should I place the backup data during a backup task?
- In what way should I organize the directory of the full backup data and log backup data?
- How to handle the historical backup data in the storage system?

The following sections will answer these questions one by one.

Choose a backup storage system

It is recommended that you store backup data to Amazon S3, Google Cloud Storage (GCS), or Azure Blob Storage. Using these systems, you do not need to worry about the backup capacity and bandwidth allocation.

If the TiDB cluster is deployed in a self-built data center, the following practices are recommended:

- Build MinIO as the backup storage system, and use the S3 protocol to back up data to MinIO.
- Mount Network File System (NFS, such as NAS) disks to br command-line tool and all TiKV instances, and use the POSIX file system interface to write backup data to the corresponding NFS directory.

> **Note:**
>
> If you do not choose NFS or a storage system that supports Amazon S3, GCS, or Azure Blob Storage protocols, the data backed up is generated at each TiKV node. **Note that this is not the recommended way to use BR**, because collecting the backup data might result in data redundancy and operation and maintenance problems.

Organize the backup data directory

- Store the snapshot backup and log backup in the same directory for unified management, for example, `backup-${cluster-id}`.
- Store each snapshot backup in a directory with the backup date included, for example, `backup-${cluster-id}/fullbackup-202209081330`.
- Store the log backup in a fixed directory, for example, `backup-${cluster-id}/` ↪ `logbackup`. The log backup program creates subdirectories under the `logbackup` directory every day to distinguish the data backed up each day.

Handle historical backup data

Assume that you need to set the life cycle for each backup data, for example, 7 days. Such a life cycle is called **backup retention period**, which will also be mentioned in backup tutorials.

- To perform PITR, you need to restore the full backup before the restore point, and the log backup between the full backup and the restore point. Therefore, **It is recommended to only delete the log backup before the full snapshot**. For log backups that exceed the backup retention period, you can use `tiup br log truncate` command to delete the backup before the specified time point.
- For backup data that exceeds the retention period, you can delete or archive the backup directory.

How to restore data?

- To restore only full backup data, you can use `tiup br restore` to perform a full restore of the specified backup.
- If you have started log backup and regularly performed a full backup, you can run the `tiup br restore point` command to restore data to any time point within the backup retention period.

8.4.3.1.2 Deploy and use BR

To deploy BR, ensure that the following requirements are met:

- BR, TiKV nodes, and the backup storage system provide network bandwidth that is greater than the backup speed. If the target cluster is particularly large, the threshold of backup and restore speed is limited by the bandwidth of the backup network.
- The backup storage system provides sufficient read and write performance (IOPS). Otherwise, they might become a performance bottleneck during backup or restore.
- TiKV nodes have at least two additional CPU cores and high performance disks for backups. Otherwise, the backup might have an impact on the services running on the cluster.
- BR runs on a node with more than 8 cores and 16 GiB memory.

You can use backup and restore features in several ways, such as via the command-line tool, by running SQL commands, and using TiDB Operator. The following sections describe these three methods in detail.

Use br command-line tool (recommended)

TiDB supports backup and restore using br command-line tool.

- You can run the `tiup install br` command to install br command-line tool using TiUP online.
- For details about how to use `br` commands to back up and restore data, refer to the following documents:
    - TiDB Snapshot Backup and Restore Guide
    - TiDB Log Backup and PITR Guide
    - TiDB Backup and Restore Use Cases

Use SQL statements

TiDB supports full backup and restore using SQL statements:

- `BACKUP`: backs up full snapshot data.
- `RESTORE`: restores snapshot backup data.
- `SHOW BACKUPS|RESTORES`: views the backup and restore progress.

Use TiDB Operator on Kubernetes

On Kubernetes, you can use TiDB Operator to back up TiDB cluster data to Amazon S3, GCS, or Azure Blob Storage, and restore data from the backup data in such systems. For details, see Back Up and Restore Data Using TiDB Operator.

- TiDB Backup and Restore Overview
- TiDB Backup and Restore Architecture

8.4.3.2 Snapshot Backup and Restore Guide

This document describes how to back up and restore TiDB snapshots using the br command-line tool (hereinafter referred to as `br`). Before backing up and restoring data, you need to install the br command-line tool first.

Snapshot backup is an implementation to back up the entire cluster. It is based on multi-version concurrency control (MVCC) and backs up all data in the specified snapshot to a target storage. The size of the backup data is approximately the size of the compressed single replica in the cluster. After the backup is completed, you can restore the backup data

to an empty cluster or a cluster that does not contain conflict data (with the same schema or same tables), restore the cluster to the time point of the snapshot backup, and restore multiple replicas according to the cluster replica settings.

Besides basic backup and restore, snapshot backup and restore also provides the following features:

- Backup data of a specified time point
- Restore data of a specified database or table

8.4.3.2.1 Back up cluster snapshots

> **Note:**
>
> - The following examples assume that Amazon S3 access keys and secret keys are used to authorize permissions. If IAM roles are used to authorize permissions, you need to set `--send-credentials-to-tikv` to `false`.
> - If other storage systems or authorization methods are used to authorize permissions, adjust the parameter settings according to Backup Storages.

You can back up a TiDB cluster snapshot by running the `tiup br backup full` command. Run `tiup br backup full --help` to see the help information:

```
tiup br backup full --pd "${PD_IP}:2379" \
    --backupts '2022-09-08 13:30:00 +08:00' \
    --storage "s3://backup-101/snapshot-202209081330?access-key=${access-key
        ↪ }&secret-access-key=${secret-access-key}"
```

In the preceding command:

- `--backupts`: The time point of the snapshot. The format can be TSO or timestamp, such as `400036290571534337` or `2018-05-11 01:42:23 +08:00`. If the data of this snapshot is garbage collected, the `tiup br backup` command returns an error and `br` exits. When backing up using a timestamp, it is recommended to specify the time zone as well. Otherwise, `br` uses the local time zone to construct the timestamp by default, which might lead to an incorrect backup time point. If you leave this parameter unspecified, `br` picks the snapshot corresponding to the backup start time.
- `--storage`: The storage address of the backup data. Snapshot backup supports Amazon S3, Google Cloud Storage, and Azure Blob Storage as backup storage. The preceding command uses Amazon S3 as an example. For more details, see URI Formats of External Storage Services.

During backup, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the backup task is completed and statistics such as total backup time, average backup speed, and backup data size are displayed.

```
Full Backup
    ↪ <-------------------------------------------------------------------------->
    ↪  100.00%
Checksum
    ↪ <-------------------------------------------------------------------------->
    ↪  100.00%
*** ["Full Backup success summary"] *** [backup-checksum=3.597416ms] [backup
    ↪ -fast-checksum=2.36975ms] *** [total-take=4.715509333s] [BackupTS
    ↪ =435844546560000000] [total-kv=1131] [total-kv-size=250kB] [average-
    ↪ speed=53.02kB/s] [backup-data-size(after-compressed)=71.33kB] [Size
    ↪ =71330]
```

8.4.3.2.2 Get the backup time point of a snapshot backup

To manage a lot of backups, if you need to get the physical time of a snapshot backup, you can run the following command:

```
tiup br validate decode --field="end-version" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}" | tail -n1
```

The output is as follows, corresponding to the physical time `2022-09-08 13:30:00 ↪ +0800 CST`:

```
435844546560000000
```

8.4.3.2.3 Restore cluster snapshots

Note:

- For BR v7.5.0 and earlier versions, the snapshot restore speed per TiKV node is approximately 100 MiB/s.
- Starting from BR v7.6.0, to address potential restore bottlenecks in scenarios with large-scale Regions, BR supports accelerating restore through the coarse-grained Region scattering algorithm (experimental). You can enable this feature by specifying the command-line parameter `--granularity="coarse-grained"`.

- Starting from BR v8.0.0, the snapshot restore through the coarse-grained Region scattering algorithm is generally available (GA) and enabled by default. BR improves the snapshot restore speed significantly by implementing various optimizations such as adopting the coarse-grained Region scattering algorithm, creating databases and tables in batches, reducing the mutual impact between SST file downloads and ingest operations, and accelerating the restore of table statistics. According to test results from real-world cases, the SST file download speed for snapshot restore is improved by approximately up to 10 times, the data restore speed per TiKV node stabilizes at 1.2 GiB/s, the end-to-end restore speed is improved by approximately 1.5 to 3 times, and 100 TiB of data can be restored within one hour.
- Starting from BR v8.2.0, the command line parameter `--granularity` is deprecated, and the coarse-grained Region scattering algorithm is enabled by default.
- Starting from BR v8.3.0, the snapshot restore task introduces available disk space checks for TiKV and TiFlash: at the beginning of the task, BR verifies whether TiKV and TiFlash have sufficient disk space based on the size of SST files to be restored; for TiKV v8.3.0 or later version, TiKV verifies whether it has sufficient disk space before downloading each SST file. If the space is insufficient according to any of these checks, the restore task fails with an error. You can skip the check at the beginning of the restore task by setting `--check-requirements=false`, but the disk space check before TiKV downloads each SST file cannot be skipped.

You can restore a snapshot backup by running the `tiup br restore full` command. Run `tiup br restore full --help` to see the help information:

The following example restores the preceding backup snapshot to a target cluster:

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

During restore, a progress bar is displayed in the terminal as shown below. When the progress bar advances to 100%, the restore task is completed and statistics such as total restore time, average restore speed, and total data size are displayed.

```
Full Restore
    ↪ <-----------------------
```

Restore a database or a table

BR supports restoring partial data of a specified database or table from backup data. This feature allows you to filter out unwanted data and back up only a specific database or table.

Restore a database

To restore a database to a cluster, run the `tiup br restore db` command. The following example restores the `test` database from the backup data to the target cluster:

```
tiup br restore db \
--pd "${PD_IP}:2379" \
--db "test" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

In the preceding command, `--db` specifies the name of the database to be restored.

Restore a table

To restore a single table to a cluster, run the `tiup br restore table` command. The following example restores the `test.usertable` table from the backup data to the target cluster:

```
tiup br restore table --pd "${PD_IP}:2379" \
--db "test" \
--table "usertable" \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

In the preceding command, `--db` specifies the name of the database to be restored, and `--table` specifies the name of the table to be restored.

Restore multiple tables with table filter

To restore multiple tables with more complex filter rules, run the `tiup br restore ↪ full` command and specify the table filters with `--filter` or `-f`. The following example restores tables that match the `db*.tbl*` filter rule from the backup data to the target cluster:

```
tiup br restore full \
--pd "${PD_IP}:2379" \
--filter 'db*.tbl*' \
--storage "s3://backup-101/snapshot-202209081330?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"
```

Restore tables in the `mysql` schema

- Starting from BR v5.1.0, when you back up snapshots, BR automatically backs up the **system tables** in the `mysql` schema, but does not restore these system tables by default.

- Starting from v6.2.0, BR lets you specify `--with-sys-table` to restore **data in some system tables**.
- Starting from v7.6.0, BR enables `--with-sys-table` by default, which means that BR restores **data in some system tables** by default.

BR can restore data in the following system tables:

```
+---------------------------------+
| mysql.columns_priv              |
| mysql.db                        |
| mysql.default_roles             |
| mysql.global_grants             |
| mysql.global_priv               |
| mysql.role_edges                |
| mysql.tables_priv               |
| mysql.user                      |
| mysql.bind_info                 |
+---------------------------------+
```

BR does not restore the following system tables:

- Statistics tables (`mysql.stat_*`). But statistics can be restored. See Back up statistics.
- System variable tables (`mysql.tidb` and `mysql.global_variables`)
- Other system tables

```
+-----------------------------------------------------+
| capture_plan_baselines_blacklist                    |
| column_stats_usage                                  |
| gc_delete_range                                     |
| gc_delete_range_done                                |
| global_variables                                    |
| stats_buckets                                       |
| stats_extended                                      |
| stats_feedback                                      |
| stats_fm_sketch                                     |
| stats_histograms                                    |
| stats_history                                       |
| stats_meta                                          |
| stats_meta_history                                  |
| stats_table_locked                                  |
| stats_top_n                                         |
| tidb                                                |
+-----------------------------------------------------+
```

When you restore data related to system privilege, note that before restoring data, BR checks whether the system tables in the target cluster are compatible with those in the backup data. "Compatible" means that all the following conditions are met:

- The target cluster has the same system tables as the backup data.
- The **number of columns** in the system privilege table of the target cluster is the same as that in the backup data. The column order is not important.
- The columns in the system privilege table of the target cluster are compatible with that in the backup data. If the data type of the column is a type with a length (such as integer and string), the length in the target cluster must be >= the length in the backup data. If the data type of the column is an `ENUM` type, the number of `ENUM` values in the target cluster must be a superset of that in the backup data.

8.4.3.2.4 Performance and impact

Performance and impact of snapshot backup

The backup feature has some impact on cluster performance (transaction latency and QPS). However, you can mitigate the impact by adjusting the number of backup threads `backup.num-threads` or by adding more clusters.

To illustrate the impact of backup, this document lists the test conclusions of several snapshot backup tests:

- (5.3.0 and earlier) When the backup threads of BR on a TiKV node take up 75% of the total CPU of the node, the QPS is reduced by 35% of the original QPS.
- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 80%, the impact of BR tasks on the cluster (write and read) is 20% at most.
- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 75%, the impact of BR tasks on the cluster (write and read) is 10% at most.
- (5.4.0 and later) When there are no more than `8` threads of BR on a TiKV node and the cluster's total CPU utilization does not exceed 60%, BR tasks have little impact on the cluster (write and read).

You can use the following methods to manually control the impact of backup tasks on cluster performance. However, these two methods also reduce the speed of backup tasks while reducing the impact of backup tasks on the cluster.

- Recommended method: Adjust the TiKV configuration parameter `backup.num-threads`, which controls the number of worker threads used by backup tasks. Because backup is a CPU-intensive operation, tuning this parameter allows you to control TiKV's CPU usage more precisely, enabling better resource isolation and predictability. In most scenarios, simply adjusting `num-threads` is sufficient to limit

the impact of backup on the cluster. Internal testing shows that when the number of threads is set to `8` or fewer, and overall cluster CPU usage remains below 60%, the impact of backup on foreground workloads is negligible.

- Alternative method: If you have already set `backup.num-threads` to a small value (for example, `1`), but still want to further reduce the impact of backup on the cluster, consider using the `--ratelimit` parameter. This option limits the bandwidth used to write backup files to external storage, specified in MiB/s. Note that the actual rate limiting effect depends on the size of the compressed data. You can refer to the `backup data size (after compressed)` field in the logs for more insight. When `--ratelimit` is enabled, BR automatically sets `--concurrency` to `1` to reduce the number of concurrent requests.

Note:

Enabling `--ratelimit` will further reduce backup throughput. In most cases, if you are already performing backups during off-peak hours and have reduced `backup.num-threads` to 1 but still observe backup impact on foreground workloads, it typically indicates that the cluster is approaching its resource limits.

In such situations, you can consider the following alternatives:

- Scale out a cluster to increase available resources.
- Enable `Log Backup` to offload backup pressure and minimize disruption to online workloads.

The impact of backup on cluster performance can be reduced by limiting the backup threads number, but this affects the backup performance. The preceding tests show that the backup speed is proportional to the number of backup threads. When the number of threads is small, the backup speed is about 20 MiB/thread. For example, 5 backup threads on a single TiKV node can reach a backup speed of 100 MiB/s.

Performance and impact of snapshot restore

- During data restore, TiDB tries to fully utilize the TiKV CPU, disk IO, and network bandwidth resources. Therefore, it is recommended to restore the backup data on an empty cluster to avoid affecting the running applications.
- The speed of restoring backup data is much related with the cluster configuration, deployment, and running applications. In internal tests, the restore speed of a single TiKV node can reach 100 MiB/s. The performance and impact of snapshot restore are varied in different user scenarios and should be tested in actual environments.

- BR provides a coarse-grained Region scattering algorithm to accelerate Region restore in large-scale Region scenarios. This algorithm ensures that each TiKV node receives stable and evenly distributed download tasks, thus fully utilizing the resources of each TiKV node and achieving a rapid parallel recovery. In several real-world cases, the snapshot restore speed of the cluster is improved by about 3 times in large-scale Region scenarios.

- Starting from v8.0.0, the `br` command-line tool introduces the `--tikv-max-restore-concurrency` parameter to control the maximum number of files that BR downloads and ingests per TiKV node. By configuring this parameter, you can also control the maximum length of the job queue (the maximum length of the job queue = 32 * the number of TiKV nodes * `--tikv-max-restore-concurrency`), thereby controlling the memory consumption of the BR node.

  In normal cases, `--tikv-max-restore-concurrency` is automatically adjusted based on the cluster configuration, so manual configuration is unnecessary. If the **TiKV-Details** > **Backup & Import** > **Import RPC count** monitoring metric in Grafana shows that the number of files BR downloads remains close to 0 for a long time while the number of files that BR ingests consistently reaches the upper limit, it indicates that ingesting file tasks pile up and the job queue has reached its maximum length. In this case, you can take the following measures to alleviate the task pilling-up issue:

  - Set the `--ratelimit` parameter to limit the download speed, ensuring sufficient resources for ingesting file tasks. For example, if the disk throughput of any TiKV node is `x MiB/s` and the network bandwidth for downloading backup files exceeds `x/2 MiB/s`, you can set the parameter as `--ratelimit x/2`. If the disk throughput of any TiKV node is `x MiB/s` and the network bandwidth for downloading backup files is less than or equal to `x/2 MiB/s`, you can leave the parameter `--ratelimit` unset.
  - Increase the `--tikv-max-restore-concurrency` to increase the maximum length of the job queue.

- TiDB Snapshot Backup and Restore Architecture

8.4.3.3 TiDB Log Backup and PITR Guide

A full backup (snapshot backup) contains the full cluster data at a certain point, while TiDB log backup can back up data written by applications to a specified storage in a timely manner. If you want to choose the restore point as required, that is, to perform point-in-time recovery (PITR), you can start log backup and run full backup regularly.

Before you back up or restore data using the br command-line tool (hereinafter referred to as `br`), you need to install `br` first.

8.4.3.3.1 Back up TiDB cluster

Start log backup

> **Note:**
>
> - The following examples assume that Amazon S3 access keys and secret keys are used to authorize permissions. If IAM roles are used to authorize permissions, you need to set `--send-credentials-to-tikv` to `false`.
> - If other storage systems or authorization methods are used to authorize permissions, adjust the parameter settings according to Backup Storages.

To start a log backup, run `tiup br log start`. A cluster can only run one log backup task each time.

```
tiup br log start --task-name=pitr --pd "${PD_IP}:2379" \
--storage 's3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}'
```

Query the status of the log backup

After the log backup task starts, it runs in the background of the TiDB cluster until you stop it manually. During this process, the TiDB change logs are regularly backed up to the specified storage in small batches. To query the status of the log backup task, run the following command:

```
tiup br log status --task-name=pitr --pd "${PD_IP}:2379"
```

Expected output:

```
  Total 1 Tasks.
> #1 <
            name: pitr
          status:  NORMAL
           start: 2022-05-13 11:09:40.7 +0800
             end: 2035-01-01 00:00:00 +0800
         storage: s3://backup-101/log-backup
    speed(est.): 0.00 ops/s
checkpoint[global]: 2022-05-13 11:31:47.2 +0800; gap=4m53s
```

The fields are explained as follows:

- `name`: the name of the log backup task.

- `status`: the status of the log backup task, including `NORMAL`, `PAUSED`, and `ERROR`.
- `start`: the start timestamp of the log backup task.
- `end`: the end timestamp of the log backup task. Currently, this field does not take effect.
- `storage`: the URI of the external storage for the log backup.
- `speed(est.)`: the current data transfer rate of the log backup. This value is estimated based on traffic samples taken in the past few seconds. For more accurate traffic statistics, you can check the `Log Backup` row in the **TiKV-Details** dashboard at Grafana.
- `checkpoint[global]`: the current progress of the log backup. You can use PITR to restore to a point in time before this timestamp.

If the log backup task is paused, the `log status` command outputs additional fields to display the details of the pause. They are:

- `pause-time`: the time when the pause operation is executed.
- `pause-operator`: the hostname of the machine that executes the pause operation.
- `pause-operator-pid`: the PID of the process that executes the pause operation.
- `pause-payload`: additional information attached when the task is paused.

If the pause is due to an error in TiKV, you might also see additional error reports from TiKV:

- `error[store=*]`: the error code on TiKV.
- `error-happen-at[store=*]`: the time when the error occurs on TiKV.
- `error-message[store=*]`: the error message on TiKV.

Run full backup regularly

The snapshot backup can be used as a method of full backup. You can run `tiup br backup full` to back up the cluster snapshot to the backup storage according to a fixed schedule (for example, every 2 days).

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage 's3://backup-101/snapshot-${date}?access-key=${access-key}&secret-access-key=${secret-access-key}'
```

8.4.3.3.2 Run PITR

To restore the cluster to any point in time within the backup retention period, you can use `tiup br restore point`. When you run this command, you need to specify the **time point you want to restore**, **the latest snapshot backup data before the time point**, and the **log backup data**. BR will automatically determine and read data needed for the restore, and then restore these data to the specified cluster in order.

```
tiup br restore point --pd "${PD_IP}:2379" \
--storage='s3://backup-101/logbackup?access-key=${access-key}&secret-access-
    ↪ key=${secret-access-key}' \
--full-backup-storage='s3://backup-101/snapshot-${date}?access-key=${access-
    ↪ key}&secret-access-key=${secret-access-key}' \
--restored-ts '2022-05-15 18:00:00+0800'
```

During data restore, you can view the progress through the progress bar in the terminal. The restore is divided into two phases, full restore and log restore (restore meta files and restore KV files). After each phase is completed, `br` outputs information such as restore time and data size.

```
Full Restore
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
*** ["Full Restore success summary"] ****** [total-take=xxx.xxxs] [restore-
    ↪ data-size(after-compressed)=xxx.xxx] [Size=xxxx] [BackupTS={TS}] [
    ↪ total-kv=xxx] [total-kv-size=xxx] [average-speed=xxx]
Restore Meta Files
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
Restore KV Files
    ↪ <-------------------------------------------------------------------------
    ↪  100.00%
*** ["restore log success summary"] [total-take=xxx.xx] [restore-from={TS}]
    ↪ [restore-to={TS}] [total-kv-count=xxx] [total-size=xxx]
```

8.4.3.3.3 Clean up outdated data

As described in the Usage Overview of TiDB Backup and Restore:

To perform PITR, you need to restore the full backup before the restore point, and the log backup between the full backup point and the restore point. Therefore, for log backups that exceed the backup retention period, you can use `tiup br log truncate` to delete the backup before the specified time point. **It is recommended to only delete the log backup before the full snapshot**.

The following steps describe how to clean up backup data that exceeds the backup retention period:

1. Get the **last full backup** outside the backup retention period.
2. Use the `validate` command to get the time point corresponding to the backup. Assume that the backup data before 2022/09/01 needs to be cleaned, you should look for the last full backup before this time point and ensure that it will not be cleaned.

```
FULL_BACKUP_TS=`tiup br validate decode --field="end-version" --storage
    ↪  "s3://backup-101/snapshot-${date}?access-key=${access-key}&
    ↪ secret-access-key=${secret-access-key}"| tail -n1`
```

3. Delete log backup data earlier than the snapshot backup `FULL_BACKUP_TS`:

```
tiup br log truncate --until=${FULL_BACKUP_TS} --storage='s3://backup
    ↪ -101/logbackup?access-key=${access-key}&secret-access-key=${
    ↪ secret-access-key}'
```

4. Delete snapshot data earlier than the snapshot backup `FULL_BACKUP_TS`:

```
aws s3 rm --recursive s3://backup-101/snapshot-${date}
```

8.4.3.3.4 Performance capabilities of PITR

- On each TiKV node, PITR can restore snapshot data (full restore) at a speed of 2 TiB/h and log data (including meta files and KV files) at a speed of 30 GiB/h.
- BR deletes outdated log backup data (`tiup br log truncate`) at a speed of 600 GB/h.

Note:

The preceding specifications are based on test results from the following two testing scenarios. The actual data might be different.

- Snapshot data restore speed = Total size of restored snapshot data on all TiKV nodes in the cluster / (duration * the number of TiKV nodes)
- Log data restore speed = Total size of restored log data on all TiKV nodes in the cluster / (duration * the number of TiKV nodes)

External storage only contains KV data of a single replica. Therefore, the data size in external storage does not represent the actual data size restored in the cluster. BR restores all replicas according to the number of replicas configured for the cluster. The more replicas there are, the more data can be actually restored. The default replica number for all clusters in the test is 3. To improve the overall restore performance, you can modify the `import.num-threads` item in the TiKV configuration file and the `pitr-concurrency` option in the BR command.

Testing scenario 1 (on TiDB Cloud) is as follows:

- The number of TiKV nodes (8 core, 16 GB memory): 21
- TiKV configuration item `import.num-threads`: 8
- BR command option `pitr-concurrency`: 128
- The number of Regions: 183,000
- New log data created in the cluster: 10 GB/h
- Write (INSERT/UPDATE/DELETE) QPS: 10,000

Testing scenario 2 (on TiDB Self-Managed) is as follows:

- The number of TiKV nodes (8 core, 64 GB memory): 6
- TiKV configuration item `import.num-threads`: 8
- BR command option `pitr-concurrency`: 128
- The number of Regions: 50,000
- New log data created in the cluster: 10 GB/h
- Write (INSERT/UPDATE/DELETE) QPS: 10,000

8.4.3.3.5 Monitoring and alert

After log backup tasks are distributed, each TiKV node continuously writes data to external storage. You can view the monitoring data for this process in the **TiKV-Details > Backup Log** dashboard.

To receive notifications metrics deviate from normal ranges, see Log backup alerts to configure alert rules.

8.4.3.4 TiDB Backup and Restore Use Cases

TiDB Snapshot Backup and Restore Guide and TiDB Log Backup and PITR Guide introduce the backup and restore solutions provided by TiDB, namely, snapshot (full) backup and restore, log backup and point-in-time recovery (PITR). This document helps you to quickly get started with the backup and restore solutions of TiDB in specific use cases.

Assume that you have deployed a TiDB production cluster on AWS and the business team requests the following requirements:

- Back up the data changes in a timely manner. When the database encounters a disaster, you can quickly recover the application with minimal data loss (only a few minutes of data loss is tolerable).

- Perform business audits every month at no specific time. When an audit request is received, you must provide a database to query the data at a certain time point of the past month as requested.

With PITR, you can satisfy the preceding requirements.

8.4.3.4.1 Deploy the TiDB cluster and BR

To use PITR, you need to deploy a TiDB cluster >= v6.2.0 and update BR to the same version as the TiDB cluster. This document uses v8.5.1 as an example.

The following table shows the recommended hardware resources for using PITR in a TiDB cluster.

Component	CPU	Memory	Disk	AWS instance	Number of instances
TiDB	8 core+	16 GB+	SAS	c5.2xlarge	2
PD	8 core+	16 GB+	SSD	c5.2xlarge	3
TiKV	8 core+	32 GB+	SSD	m5.2xlarge	3
BR	8 core+	16 GB+	SAS	c5.2xlarge	1
Monitor	8 core+	16 GB+	SAS	c5.2xlarge	1

Note:

- When BR runs backup and restore tasks, it needs to access PD and TiKV. Make sure that BR can connect to all PD and TiKV nodes.
- BR and PD servers must use the same time zone.

Deploy or upgrade a TiDB cluster using TiUP:

- To deploy a new TiDB cluster, refer to Deploy a TiDB cluster.
- If the TiDB cluster is earlier than v6.2.0, upgrade it by referring to Upgrade a TiDB cluster.

Install or upgrade BR using TiUP:

- Install:

```
tiup install br:v8.5.1
```

- Upgrade:

```
tiup update br:v8.5.1
```

8.4.3.4.2 Configure backup storage (Amazon S3)

Before you start a backup task, prepare the backup storage, including the following aspects:

1. Prepare the S3 bucket and directory that stores the backup data.
2. Configure the permissions to access the S3 bucket.
3. Plan the subdirectory that stores each backup data.

The detailed steps are as follows:

1. Create a directory in S3 to store the backup data. The directory in this example is `s3://tidb-pitr-bucket/backup-data`.

    1. Create a bucket. You can choose an existing S3 to store the backup data. If there is none, refer to AWS documentation: Creating a bucket and create an S3 bucket. In this example, the bucket name is `tidb-pitr-bucket`.
    2. Create a directory for your backup data. In the bucket (`tidb-pitr-bucket`), create a directory named `backup-data`. For detailed steps, refer to AWS documentation: Organizing objects in the Amazon S3 console using folders.

2. Configure permissions for BR and TiKV to access the S3 directory. It is recommended to grant permissions using the IAM method, which is the most secure way to access the S3 bucket. For detailed steps, refer to AWS documentation: Controlling access to a bucket with user policies. The required permissions are as follows:

    - TiKV and BR in the backup cluster need `s3:ListBucket`, `s3:GetObject`, `s3:DeleteObject`, `s3:PutObject`, and `s3:AbortMultipartUpload` permissions of the `s3://tidb-pitr-bucket/backup-data` directory.
    - TiKV and BR in the restore cluster need `s3:ListBucket` and `s3:GetObject` permissions of the `s3://tidb-pitr-bucket/backup-data` directory.

3. Plan the directory structure that stores the backup data, including the snapshot (full) backup and the log backup.

    - All snapshot backup data are stored in the `s3://tidb-pitr-bucket/backup-data/snapshot-${date}` directory. `${date}` is the start time of the snapshot backup. For example, a snapshot backup starting at 2022/05/12 00:01:30 is stored in `s3://tidb-pitr-bucket/backup-data/snapshot-20220512000130`.
    - Log backup data are stored in the `s3://tidb-pitr-bucket/backup-data/log-backup/` directory.

8.4.3.4.3 Determine the backup policy

To meet the requirements of minimum data loss, quick recovery, and business audits within a month, you can set the backup policy as follows:

- Run the log backup to continuously back up the data change in the database.
- Run a snapshot backup at 00:00 AM every two days.
- Retain the snapshot backup data and log backup data within 30 days and clean up backup data older than 30 days.

8.4.3.4.4 Run log backup

After the log backup task is started, the log backup process runs in the TiKV cluster to continuously send the data change in the database to the S3 storage. To start a log backup task, run the following command:

```
tiup br log start --task-name=pitr --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/log-backup'
```

When the log backup task is running, you can query the backup status:

```
tiup br log status --task-name=pitr --pd="${PD_IP}:2379"

  Total 1 Tasks.
> #1 <
    name: pitr
    status:  NORMAL
    start: 2022-05-13 11:09:40.7 +0800
      end: 2035-01-01 00:00:00 +0800
    storage: s3://tidb-pitr-bucket/backup-data/log-backup
    speed(est.): 0.00 ops/s
checkpoint[global]: 2022-05-13 11:31:47.2 +0800; gap=4m53s
```

8.4.3.4.5 Run snapshot backup

You can run snapshot backup tasks on a regular basis using an automatic tool such as crontab. For example, run a snapshot backup at 00:00 every two days.

The following are two snapshot backup examples:

- Run a snapshot backup at 2022/05/14 00:00:00

  ```
  tiup br backup full --pd="${PD_IP}:2379" \
  --storage='s3://tidb-pitr-bucket/backup-data/snapshot-20220514000000' \
  --backupts='2022/05/14 00:00:00 +08:00'
  ```

- Run a snapshot backup at 2022/05/16 00:00:00

```
tiup br backup full --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/snapshot-20220516000000' \
--backupts='2022/05/16 00:00:00 +08:00'
```

8.4.3.4.6 Run PITR

Assume that you need to query the data at 2022/05/15 18:00:00. You can use PITR to restore a cluster to that time point by restoring a snapshot backup taken at 2022/05/14 and the log backup data between the snapshot and 2022/05/15 18:00:00.

The command is as follows:

```
tiup br restore point --pd="${PD_IP}:2379" \
--storage='s3://tidb-pitr-bucket/backup-data/log-backup' \
--full-backup-storage='s3://tidb-pitr-bucket/backup-data/snapshot
   ↪ -20220514000000' \
--restored-ts '2022-05-15 18:00:00+0800'

Full Restore
   ↪ <-------------------------------------------------------------------------
   ↪  100.00%
[2022/05/29 18:15:39.132 +08:00] [INFO] [collector.go:69] ["Full Restore
   ↪ success summary"] [total-ranges=12] [ranges-succeed=xxx] [ranges-
   ↪ failed=0] [split-region=xxx.xxxµs] [restore-ranges=xxx] [total-take=
   ↪ xxx.xxxs] [restore-data-size(after-compressed)=xxx.xxx] [Size=xxxx] [
   ↪ BackupTS={TS}] [total-kv=xxx] [total-kv-size=xxx] [average-speed=xxx]
Restore Meta Files
   ↪ <-------------------------------------------------------------------------
   ↪  100.00%
Restore KV Files
   ↪ <-------------------------------------------------------------------------
   ↪  100.00%
[2022/05/29 18:15:39.325 +08:00] [INFO] [collector.go:69] ["restore log
   ↪ success summary"] [total-take=xxx.xx] [restore-from={TS}] [restore-to
   ↪ ={TS}] [total-kv-count=xxx] [total-size=xxx]
```

8.4.3.4.7 Clean up outdated data

You can clean up outdated data every two days using an automatic tool such as crontab.

For example, you can run the following commands to clean up outdated data:

- Delete snapshot data earlier than 2022/05/14 00:00:00

```
shell  rm s3://tidb-pitr-bucket/backup-data/snapshot-20220514000000
```

- Delete log backup data earlier than 2022/05/14 00:00:00

```
shell  tiup br log truncate --until='2022-05-14 00:00:00 +0800' --storage
↪ ='s3://tidb-pitr-bucket/backup-data/log-backup'
```

8.4.3.5 Backup Storages

TiDB supports storing backup data to Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, and NFS. Specifically, you can specify the URI of backup storage in the `--storage` or `-s` parameter of `br` commands. This document introduces the URI format and authentication of different external storage services, and server-side encryption.

8.4.3.5.1 Send credentials to TiKV

CLI parameter	Description	Default value
`--send-credentials-to-tikv`	Controls whether to send credentials obtained by BR to TiKV.	`true`

By default, BR sends a credential to each TiKV node when using Amazon S3, GCS, or Azure Blob Storage as the storage system. This behavior simplifies the configuration and is controlled by the parameter `--send-credentials-to-tikv`(or `-c` in short).

Note that this operation is not applicable to cloud environments. If you use IAM Role authorization, each node has its own role and permissions. In this case, you need to configure `--send-credentials-to-tikv=false` (or `-c=0` in short) to disable sending credentials:

```
tiup br backup full -c=0 -u pd-service:2379 --storage 's3://bucket-name/
    ↪ prefix'
```

If you back up or restore data using the `BACKUP` and `RESTORE` statements, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
    ↪ FALSE;
```

8.4.3.5.2 URI format

URI format description

The URI format of the external storage service is as follows:

```
[scheme]://[host]/[path]?[parameters]
```

For more information about the URI format, see URI Formats of External Storage Services.

URI examples

This section provides some URI examples by using `external` as the `host` parameter (`bucket name` or `container name` in the preceding sections).

Back up snapshot data to Amazon S3

```
tiup br backup full -u "${PD_IP}:2379" \
--storage "s3://external/backup-20220915?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"
```

Restore snapshot data from Amazon S3

```
tiup br restore full -u "${PD_IP}:2379" \
--storage "s3://external/backup-20220915?access-key=${access-key}&secret-
    ↪ access-key=${secret-access-key}"
```

Back up snapshot data to GCS

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage "gcs://external/backup-20220915?credentials-file=${credentials-
    ↪ file-path}"
```

Restore snapshot data from GCS

```
tiup br restore full --pd "${PD_IP}:2379" \
--storage "gcs://external/backup-20220915?credentials-file=${credentials-
    ↪ file-path}"
```

Back up snapshot data to Azure Blob Storage

```
tiup br backup full -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915?account-name=${account-name}&
    ↪ account-key=${account-key}"
```

Restore the `test` database from snapshot backup data in Azure Blob Storage

```
tiup br restore db --db test -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915account-name=${account-name}&
    ↪ account-key=${account-key}"
```

8.4.3.5.3 Authentication

When storing backup data in a cloud storage system, you need to configure authentication parameters depending on the specific cloud service provider. This section describes the authentication methods used by Amazon S3, GCS, and Azure Blob Storage, and how to configure the accounts used to access the corresponding storage service.

Before backup, configure the following privileges to access the backup directory on S3.

- Minimum privileges for TiKV and Backup & Restore (BR) to access the backup directories during backup: `s3:ListBucket`, `s3:GetObject`, `s3:DeleteObject`, `s3:PutObject` ↪ , and `s3:AbortMultipartUpload`
- Minimum privileges for TiKV and BR to access the backup directories during restore: `s3:ListBucket` and `s3:GetObject`.

If you have not yet created a backup directory, refer to Create a bucket to create an S3 bucket in the specified region. If necessary, you can also create a folder in the bucket by referring to Create a folder.

> **Note:**
>
> In 2024, AWS changed the default behavior, and newly created instances now only support IMDSv2 by default. For more details, see Set IMDSv2 as default for all new instance launches in your account. Therefore, starting from v8.4.0, BR supports obtaining IAM role permissions on Amazon EC2 instances with only IMDSv2 enabled. When using BR of an earlier version before v8.4.0, you need to configure the instance to support both IMDSv1 and IMDSv2.

It is recommended that you configure access to S3 using either of the following ways:

- Method 1: Specify the access key

  If you specify an access key and a secret access key in the URI, authentication is performed using the specified access key and secret access key. Besides specifying the key in the URI, the following methods are also supported:

  - BR reads the environment variables `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_` ↪ `ACCESS_KEY`.
  - BR reads the environment variables `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY`.
  - BR reads the shared credentials file in the path specified by the environment variable `$AWS_SHARED_CREDENTIALS_FILE`.
  - BR reads the shared credentials file in the `~/.aws/credentials` path.

- Method 2: Access based on the IAM role

  Associate an IAM role that can access S3 with EC2 instances where the TiKV and BR nodes run. After the association, BR can directly access the backup directories in S3 without additional settings.

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage "s3://${host}/${path}"
```

You can configure the account used to access GCS by specifying the access key. If you specify the `credentials-file` parameter, the authentication is performed using the specified `credentials-file`. Besides specifying the key in the URI, the following methods are also supported:

- BR reads the file in the path specified by the environment variable `$GOOGLE_APPLICATION_CREDENTIALS`
- BR reads the file `~/.config/gcloud/application_default_credentials.json`.
- BR obtains the credentials from the metadata server when the cluster is running in GCE or GAE.

- Method 1: Specify the shared access signature

  If you specify `account-name` and `sas-token` in the URI, the authentication is performed using the specified account name and shared access signature (SAS) token. Note that the SAS token contains the `&` character. You need to encode it as `%26` before appending it to the URI. You can also directly encode the entire `sas-token` using percent-encoding.

- Method 2: Specify the access key

  If you specify `account-name` and `account-key` in the URI, the authentication is performed using the specified account name and account key. Besides the method of specifying the key in the URI, BR can also read the key from the environment variable `$AZURE_STORAGE_KEY`.

- Method 3: Use Azure AD for backup and restore

  Configure the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` on the node where BR is running.

  - When the cluster is started using TiUP, TiKV uses the systemd service. The following example shows how to configure the preceding three environment variables for TiKV:

> **Note:**
> If this method is used, you need to restart TiKV in step 3. If your cluster cannot be restarted, use **Method 1: Specify the access key** for backup and restore.

1. Suppose that the TiKV port on this node is 24000, that is, the name of the systemd service is tikv-24000:

```
systemctl edit tikv-24000
```

2. Edit the TiKV configuration file to configure the three environment variables:

```
[Service]
Environment="AZURE_CLIENT_ID=aaaaaaaa-aaaa-aaaa-aaaa-
    ↪ aaaaaaaaaaaa"
Environment="AZURE_TENANT_ID=aaaaaaaa-aaaa-aaaa-aaaa-
    ↪ aaaaaaaaaaaa"
Environment="AZURE_CLIENT_SECRET=
    ↪ aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
```

3. Reload the configuration and restart TiKV:

```
systemctl daemon-reload
systemctl restart tikv-24000
```

- To configure the Azure AD information for TiKV and BR started with command lines, you only need to check whether the environment variables $AZURE_CLIENT ↪ _ID, $AZURE_TENANT_ID, and $AZURE_CLIENT_SECRET are configured in the operating environment by running the following commands:

```
echo $AZURE_CLIENT_ID
echo $AZURE_TENANT_ID
echo $AZURE_CLIENT_SECRET
```

- Use BR to back up data to Azure Blob Storage:

```
tiup br backup full -u "${PD_IP}:2379" \
--storage "azure://external/backup-20220915?account-name=${account-
    ↪ name}"
```

8.4.3.5.4 Server-side encryption

Amazon S3 server-side encryption

BR supports server-side encryption when backing up data to Amazon S3. You can also use an AWS KMS key you create for S3 server-side encryption using BR. For details, see BR S3 server-side encryption.

Azure Blob Storage server-side encryption

BR supports specifying the Azure server-side encryption scope or providing the encryption key when backing up data to Azure Blob Storage. This feature lets you establish a security boundary for different backup data of the same storage account. For details, see BR Azure Blob Storage server-side encryption.

8.4.3.5.5 Other features supported by the storage service

Amazon S3 Object Lock can help prevent backup data from accidental or intentional deletion during a specified retention period, enhancing the security and integrity of data. Starting from v6.3.0, BR supports Amazon S3 Object Lock for snapshot backups, adding an additional layer of security for full backups. Starting from v8.0.0, PITR also supports Amazon S3 Object Lock. Whether for full backups or log data backups, the Object Lock feature ensures more reliable data protection, further strengthening the security of data backup and recovery and meeting regulatory requirements.

BR and PITR automatically detect whether the Amazon S3 Object Lock feature is enabled or disabled. You do not need to perform any additional operations.

> **Warning:**
>
> If the Object Lock feature is enabled during the snapshot backup or PITR log backup process, the snapshot backup or log backup might fail. You need to restart the snapshot backup or PITR log backup task to continue the backup.

8.4.4 BR CLI Manuals

8.4.4.1 br Command-line Manual

This document describes the definition, components, and common options of `br` commands, and how to perform snapshot backup and restore, and log backup and point-in-time recovery (PITR) using `br` commands.

8.4.4.1.1 `br` command-line description

A `br` command consists of sub-commands, options, and parameters. A sub-command is the characters without `-` or `--`. An option is the characters that start with `-` or `--` ↪ . A parameter is the characters that immediately follow behind and are passed to the sub-command or the option.

The following is a complete `br` command:

```
tiup br backup full --pd "${PD_IP}:2379" \
--storage "s3://backup-data/snapshot-202209081330/"
```

Explanations for the preceding command are as follows:

- `backup`: the sub-command of `tiup br`.
- `full`: the sub-command of `tiup br backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored. `"s3://backup-data/snapshot-202209081330/"` is the parameter of `-s`.

- `--pd`: the option that specifies the PD service address. `"${PD_IP}:2379"` is the parameter of `--pd`.

Commands and sub-commands

A `tiup br` command consists of multiple layers of sub-commands. Currently, br command-line tool has the following sub-commands:

- `tiup br backup`: used to back up the data of the TiDB cluster.
- `tiup br log`: used to start and manage log backup tasks.
- `tiup br restore`: used to restore backup data of the TiDB cluster.
- `tiup br debug`: used to parse backup metadata, check backup data, and so on.

`tiup br backup` and `tiup br restore` include the following sub-commands:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore a specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

`tiup br debug` includes the following sub-commands:

- `checksum`: (hidden parameter) used to offline check the integrity of backup data to ensure that all backup files match the CRC64 checksum results calculated by `ADMIN CHECKSUM TABLE`.
- `backupmeta`: used to check whether an intersection exists among backup data files. In normal cases, backup data files do not intersect.
- `decode`: used to parse the `backupmeta` metadata file of a full backup into JSON format. In addition, you can parse specific fields using the `--field` parameter.
- `encode`: used to encode the `backupmeta.json` metadata file of a full backup into the protobuf format that is used during data restore.
- `reset-pd-config-as-default`: (deprecated) used to restore the PD configurations that were changed during the data recovery process to default configurations.
- `search-log-backup`: used to search for specific key information in log backup data.

Common options

- `--pd`: specifies the PD service address. For example, `"${PD_IP}:2379"`.
- `-s` (or `--storage`): specifies the path where the backup files are stored. Amazon S3, Google Cloud Storage (GCS), Azure Blob Storage, and NFS are supported to store backup data. For more details, refer to URI Formats of External Storage Services.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.

- `--status-addr`: specifies the listening address through which `br` provides statistics to Prometheus.
