2 About TiDB **24**

2.1 TiDB Introduction 24

2.1.1 Key features 24

2.1.2 Use cases 25

2.1.3 See also 26

2.2 TiDB 5.1 Release Notes 26

2.2.1 Compatibility changes 27

2.2.2 New features 37

2.2.3 Improvements 39

2.2.4 Bug Fixes 42

2.3 TiDB Features 45

2.3.1 Data types, functions, and operators 45

2.3.2 Indexing and constraints 45

2.3.3 SQL statements 46

2.3.4 Advanced SQL features 46

2.3.5 Data definition language (DDL) 47

2.3.6 Transactions 47

2.3.7 Partitioning 47

2.3.8 Statistics 47

2.3.9 Security · · · · · 48
2.3.10 Data import and export · · · · · 48
2.3.11 Management, observability, and tools · · · · · 48
2.4 TiDB Experimental Features · · · · · 49
2.4.1 Performance · · · · · 49
2.4.2 Stability · · · · · 49
2.4.3 Scheduling · · · · · 49
2.4.4 SQL · · · · · 50
2.4.5 Configuration management · · · · · 50
2.4.6 Data sharing and subscription · · · · · 50
2.4.7 Storage · · · · · 50
2.4.8 Backup and restoration · · · · · 50
2.4.9 Garbage collection · · · · · 50
2.4.10 Diagnostics · · · · · 51
2.5 Benchmarks · · · · · 51
2.5.1 TiDB Sysbench Performance Test Report – v5.1.0 vs. v5.0.2 · · · · · 51
2.5.2 TiDB TPC-C Performance Test Report – v5.1.0 vs. v5.0.2 · · · · · 57
2.5.3 TiDB TPC-H 100GB Performance Test Report – TiDB v5.1 MPP mode vs. Greenplum 6.15.0 and Apache Spark 3.1.1 · · · · · 59
2.6 MySQL Compatibility · · · · · 63
2.6.1 Unsupported features · · · · · 63
2.6.2 Features that are different from MySQL · · · · · 64
2.7 TiDB Limitations · · · · · 69
2.7.1 Limitations on identifier length · · · · · 69
2.7.2 Limitations on the total number of databases, tables, views, and connections · · · · · 69
2.7.3 Limitations on a single database · · · · · 69
2.7.4 Limitations on a single table · · · · · 69
2.7.5 Limitation on a single row · · · · · 70
2.7.6 Limitations on string types · · · · · 70
2.7.7 Limitations on SQL statements · · · · · 70

2.8 Credits · · · · · 71
2.8.1 TiDB developers · · · · · 71
2.8.2 Writers and translators for TiDB documentation · · · · · 72

3 Quick Start **72**
3.1 Quick Start Guide for the TiDB Database Platform · · · · · 72
3.1.1 Deploy a local test cluster · · · · · 73
3.1.2 Simulate production deployment on a single machine · · · · · 77
3.1.3 What's next · · · · · 83
3.2 Explore SQL with TiDB · · · · · 83
3.2.1 Category · · · · · 83
3.2.2 Show, create and drop a database · · · · · 84
3.2.3 Create, show, and drop a table · · · · · 84
3.2.4 Create, show, and drop an index · · · · · 85
3.2.5 Insert, update, and delete data · · · · · 86
3.2.6 Query data · · · · · 86
3.2.7 Create, authorize, and delete a user · · · · · 87
3.3 Import Example Database · · · · · 87
3.3.1 Download all data files · · · · · 87
3.3.2 Load data into TiDB · · · · · 87

4 Deploy **89**
4.1 Software and Hardware Recommendations · · · · · 89
4.1.1 Linux OS version requirements · · · · · 89
4.1.2 Software recommendations · · · · · 90
4.1.3 Server recommendations · · · · · 90
4.1.4 Network requirements · · · · · 92
4.1.5 Web browser requirements · · · · · 99
4.2 TiDB Environment and System Configuration Check · · · · · 99
4.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV · · · · · 99
4.2.2 Check and disable system swap · · · · · 101
4.2.3 Check and stop the firewall service of target machines · · · · · 102

4.2.4 Check and install the NTP service 102
4.2.5 Check and configure the optimal parameters of the operating system .. 105
4.2.6 Manually configure the SSH mutual trust and sudo without password . 111
4.2.7 Install the `numactl` tool 112
4.3 Plan Cluster Topology 113
4.3.1 Minimal Deployment Topology 113
4.3.2 TiFlash Deployment Topology 115
4.3.3 TiCDC Deployment Topology 118
4.3.4 TiDB Binlog Deployment Topology 120
4.3.5 TiSpark Deployment Topology 125
4.3.6 Geo-Distributed Deployment Topology 128
4.3.7 Hybrid Deployment Topology 132
4.4 Install and Start 137
4.4.1 Deploy a TiDB Cluster Using TiUP 137
4.4.2 Deploy a TiDB Cluster in Kubernetes 145
4.5 Check Cluster Status 145
4.5.1 Check the TiDB cluster status 145
4.5.2 Log in to the database and perform simple operations 148
4.6 Test Cluster Performance 150
4.6.1 How to Test TiDB Using Sysbench 150
4.6.2 How to Run TPC-C Test on TiDB 155

5 Migrate **157**

5.1 Migration Overview 157
5.1.1 Migrate from Aurora to TiDB 157
5.1.2 Migrate from MySQL to TiDB 158
5.1.3 Migrate data from files to TiDB 158
5.2 Migrate from MySQL 159
5.2.1 Migrate from Amazon Aurora MySQL Using TiDB Lightning 159
5.2.2 Migrate from MySQL SQL Files Using TiDB Lightning 162
5.2.3 Migrate from Amazon Aurora MySQL Using DM 164

5.3 Migrate from CSV Files 164
5.3.1 TiDB Lightning CSV Support and Restrictions 164
5.3.2 LOAD DATA 169
5.4 Migrate from MySQL SQL Files Using TiDB Lightning 172
5.4.1 Step 1: Deploy TiDB Lightning 172
5.4.2 Step 2: Configure data source of TiDB Lightning 173
5.4.3 Step 3: Run TiDB Lightning to import data 174

6 Maintain **174**
6.1 Upgrade 174
6.1.1 Upgrade TiDB Using TiUP 174
6.1.2 Use TiDB Operator 180
6.2 Scale 180
6.2.1 Scale the TiDB Cluster Using TiUP 180
6.2.2 Use TiDB Operator 191
6.3 Backup and Restore 191
6.3.1 Use BR Tool (Recommended) 191
6.4 Time Zone Support 251
6.5 Daily Check 253
6.5.1 Key indicators of TiDB Dashboard 253
6.6 Maintain a TiFlash Cluster 259
6.6.1 Check the TiFlash version 259
6.6.2 TiFlash critical logs 259
6.6.3 TiFlash system table 260
6.7 TiUP Common Operations 260
6.7.1 View the cluster list 261
6.7.2 Start the cluster 261
6.7.3 View the cluster status 262
6.7.4 Modify the configuration 262
6.7.5 Replace with a hotfix package 263
6.7.6 Rename the cluster 264
6.7.7 Stop the cluster 264
6.7.8 Clean up cluster data 265
6.7.9 Destroy the cluster 265

6.8 Modify Configuration Online 266
6.8.1 Common Operations 266

7 Monitor and Alert 321

7.1 TiDB Monitoring Framework Overview 321
7.1.1 About Prometheus in TiDB 321
7.1.2 About Grafana in TiDB 322
7.2 TiDB Monitoring API 324
7.2.1 Use the state interface 324
7.2.2 Use the metrics interface 325
7.3 Deploy Monitoring Services for the TiDB Cluster 325
7.3.1 Deploy Prometheus and Grafana 326
7.3.2 Configure Grafana 329
7.3.3 View component metrics 330
7.4 Export Grafana Snapshots 332
7.4.1 Usage 332
7.4.2 FAQs 333
7.5 TiDB Cluster Alert Rules 334
7.5.1 TiDB alert rules 336
7.5.2 PD alert rules 340
7.5.3 TiKV alert rules 345
7.5.4 TiDB Binlog alert rules 354
7.5.5 TiCDC Alert rules 354
7.5.6 Node_exporter host alert rules 354
7.5.7 Blackbox_exporter TCP, ICMP, and HTTP alert rules 358
7.6 TiFlash Alert Rules 362
7.6.1 `TiFlash_schema_error` 363
7.6.2 `TiFlash_schema_apply_duration` 363
7.6.3 `TiFlash_raft_read_index_duration` 363
7.6.4 `TiFlash_raft_wait_index_duration` 364

8 Troubleshoot 364

8.1 TiDB Troubleshooting Map · · · · · 364
8.1.1 1. Service Unavailable · · · · · 364
8.1.2 2. Latency increases significantly · · · · · 365
8.1.3 3. TiDB issues · · · · · 365
8.1.4 4. TiKV issues · · · · · 370
8.1.5 5. PD issues · · · · · 374
8.1.6 6. Ecosystem tools · · · · · 376
8.1.7 7. Common log analysis · · · · · 382
8.2 Identify Slow Queries · · · · · 384
8.2.1 Usage example · · · · · 384
8.2.2 Fields description · · · · · 385
8.2.3 Related system variables · · · · · 388
8.2.4 Memory mapping in slow log · · · · · 389
8.2.5 `SLOW_QUERY` / `CLUSTER_SLOW_QUERY` usage examples · · · · · 391
8.2.6 Query slow queries with pseudo `stats` · · · · · 393
8.2.7 Identify problematic SQL statements · · · · · 397
8.3 Analyze Slow Queries · · · · · 402
8.3.1 Identify the performance bottleneck of the query · · · · · 402
8.3.2 Analyze system issues · · · · · 403
8.3.3 Analyze optimizer issues · · · · · 410
8.4 SQL Diagnostics · · · · · 410
8.4.1 Overview · · · · · 411
8.4.2 Cluster information tables · · · · · 411
8.4.3 Cluster monitoring tables · · · · · 412
8.4.4 Automatic diagnostics · · · · · 413
8.5 Identify Expensive Queries · · · · · 413
8.5.1 Expensive query log example · · · · · 413
8.5.2 Fields description · · · · · 414
8.6 Statement Summary Tables · · · · · 415
8.6.1 `statements_summary` · · · · · 415
8.6.2 `statements_summary_history` · · · · · 417
8.6.3 `statements_summary_evicted` · · · · · 417

8.6.4 The `cluster` tables for statement summary 417
8.6.5 Parameter configuration 418
8.6.6 Limitation 420
8.6.7 Troubleshooting examples 421
8.6.8 Fields description 422
8.7 Troubleshoot Hotspot Issues 425
8.7.1 Common hotspots 425
8.7.2 Identify hotspot issues 426
8.7.3 Use `SHARD_ROW_ID_BITS` to process hotspots 430
8.7.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM` 433
8.7.5 Optimization of small table hotspots 436
8.8 Troubleshoot Increased Read and Write Latency 436
8.8.1 Common causes 436
8.8.2 Other causes 440
8.9 TiDB Cluster Troubleshooting Guide 441
8.9.1 Cannot connect to the database 441
8.9.2 Cannot start `tidb-server` 442
8.9.3 Cannot start `tikv-server` 442
8.9.4 Cannot start `pd-server` 443
8.9.5 The TiDB/TiKV/PD process aborts unexpectedly 443
8.9.6 TiDB panic 443
8.9.7 The connection is rejected 443
8.9.8 Open too many files 444
8.9.9 Database access times out and the system load is too high 444
8.10 Troubleshoot High Disk I/O Usage in TiDB 444
8.10.1 Check the current I/O metrics 444
8.10.2 Handle I/O issues 447
8.11 Troubleshoot Lock Conflicts 448
8.11.1 Optimistic transaction mode 448
8.11.2 Pessimistic transaction mode 455

8.12 Troubleshoot a TiFlash Cluster · · · · · 464
8.12.1 TiFlash fails to start · · · · · 464
8.12.2 TiFlash replica is always unavailable · · · · · 465
8.12.3 TiFlash query time is unstable, and the error log prints many `Lock Exception` messages · · · · · 466
8.12.4 Some queries return the `Region Unavailable` error · · · · · 466
8.12.5 Data file corruption · · · · · 466
8.13 Troubleshoot Write Conflicts in Optimistic Transactions · · · · · 466
8.13.1 The reason of write conflicts · · · · · 467
8.13.2 Detect write conflicts · · · · · 467
8.13.3 Resolve write conflicts · · · · · 469

9 Performance Tuning 470
9.1 System Tuning · · · · · 470
9.1.1 Operating System Tuning · · · · · 470
9.2 Software Tuning · · · · · 475
9.2.1 Configuration · · · · · 475
9.2.2 Coprocessor Cache · · · · · 492
9.3 SQL Tuning · · · · · 494
9.3.1 SQL Tuning Overview · · · · · 494
9.3.2 Understanding the Query Execution Plan · · · · · 494
9.3.3 SQL Optimization Process · · · · · 560
9.3.4 Control Execution Plans · · · · · 621

10 Tutorials 652
10.1 Multiple Data Centers in One City Deployment · · · · · 652
10.1.1 Raft protocol · · · · · 652
10.1.2 Three DCs in one city deployment · · · · · 653
10.2 Three Data Centers in Two Cities Deployment · · · · · 658
10.2.1 Overview · · · · · 658
10.2.2 Architecture · · · · · 659
10.2.3 Configuration · · · · · 662

10.3 Read Historical Data 666
10.3.1 Use Stale Read (Recommended) 666
10.3.2 Read Historical Data Using the System Variable `tidb_snapshot` 673
10.4 Best Practices 678
10.4.1 TiDB Best Practices 678
10.4.2 Best Practices for Developing Java Applications with TiDB 686
10.4.3 Best Practices for Using HAProxy in TiDB 698
10.4.4 Highly Concurrent Write Best Practices 710
10.4.5 Best Practices for Monitoring TiDB Using Grafana 721
10.4.6 PD Scheduling Best Practices 732
10.4.7 Best Practices for TiKV Performance Tuning with Massive Regions 741
10.4.8 Best Practices for Three-Node Hybrid Deployment 747
10.4.9 Local Read under Three Data Centers Deployment 752
10.5 Placement Rules 753
10.5.1 Rule system 754
10.5.2 Configure rules 756
10.5.3 Typical usage scenarios 761
10.6 Load Base Split 764
10.6.1 Scenarios 764
10.6.2 Implementation principles 765
10.6.3 Usage 765
10.7 Store Limit 766
10.7.1 Implementation principles 766
10.7.2 Usage 767

11 TiDB Tools **768**

11.1 TiDB Tools Overview 768
11.1.1 Deployment and operation Tools 768
11.1.2 Data management tools 769
11.1.3 OLAP Query tool 771

11.2 TiDB Tools Use Cases · · · · · 771
11.2.1 Deploy and operate TiDB on physical or virtual machines · · · · · 772
11.2.2 Deploy and operate TiDB in Kubernetes · · · · · 772
11.2.3 Import data from CSV to TiDB · · · · · 772
11.2.4 Import full data from MySQL/Aurora · · · · · 772
11.2.5 Migrate data from MySQL/Aurora · · · · · 772
11.2.6 Back up and restore TiDB cluster · · · · · 772
11.2.7 Migrate data to TiDB · · · · · 772
11.2.8 TiDB incremental data subscription · · · · · 773
11.3 Download TiDB Tools · · · · · 773
11.3.1 TiUP · · · · · 773
11.3.2 TiDB Operator · · · · · 773
11.3.3 TiDB Binlog · · · · · 773
11.3.4 TiDB Lightning · · · · · 774
11.3.5 BR (backup and restore) · · · · · 775
11.3.6 TiDB DM (Data Migration) · · · · · 776
11.3.7 Dumpling · · · · · 777
11.3.8 sync-diff-inspector · · · · · 778
11.3.9 TiCDC · · · · · 779
11.4 TiUP · · · · · 779
11.4.1 TiUP Documentation Map · · · · · 779
11.4.2 TiUP Overview · · · · · 779
11.4.3 TiUP Terminology and Concepts · · · · · 783
11.4.4 Manage TiUP Components with TiUP Commands · · · · · 784
11.4.5 TiUP FAQ · · · · · 788
11.4.6 TiUP Troubleshooting Guide · · · · · 789
11.4.7 TiUP Reference · · · · · 791
11.4.8 Topology Configuration File for TiDB Deployment Using TiUP · · · · · 794
11.4.9 TiUP Mirror Reference Guide · · · · · 817
11.4.10 TiUP Components · · · · · 827

11.5 TiDB Operator · · · · · 853
11.6 Backup & Restore (BR) · · · · · 853
11.6.1 BR Tool Overview · · · · · 853
11.6.2 Use BR Command-line for Backup and Restoration · · · · · 868
11.6.3 BR Use Cases · · · · · 881
11.6.4 External Storages · · · · · 901
11.6.5 Backup & Restore FAQ · · · · · 911
11.7 TiDB Binlog · · · · · 914
11.7.1 TiDB Binlog Cluster Overview · · · · · 914
11.7.2 TiDB Binlog Tutorial · · · · · 917
11.7.3 TiDB Binlog Cluster Deployment · · · · · 927
11.7.4 TiDB Binlog Cluster Operations · · · · · 939
11.7.5 TiDB Binlog Configuration File · · · · · 942
11.7.6 Upgrade TiDB Binlog · · · · · 961
11.7.7 TiDB Binlog Monitoring · · · · · 963
11.7.8 Reparo User Guide · · · · · 979
11.7.9 binlogctl · · · · · 983
11.7.10 Binlog Consumer Client User Guide · · · · · 986
11.7.11 TiDB Binlog Relay Log · · · · · 989
11.7.12 Bidirectional Replication between TiDB Clusters · · · · · 991
11.7.13 TiDB Binlog Glossary · · · · · 996
11.7.14 Troubleshoot · · · · · 996
11.7.15 TiDB Binlog FAQ · · · · · 998
11.8 TiDB Lightning · · · · · 1006
11.8.1 TiDB Lightning Overview · · · · · 1006
11.8.2 TiDB Lightning Tutorial · · · · · 1009
11.8.3 TiDB Lightning Deployment · · · · · 1012
11.8.4 TiDB Lightning Configuration · · · · · 1016
11.8.5 Key Features · · · · · 1037
11.8.6 TiDB Lightning Monitoring · · · · · 1067
11.8.7 TiDB Lightning FAQs · · · · · 1085
11.8.8 TiDB Lightning Glossary · · · · · 1095

11.9 TiDB Data Migration 1099
11.9.1 DM versions 1099
11.9.2 Basic features 1100
11.9.3 Advanced features 1101
11.9.4 Usage restrictions 1101
11.10 TiCDC 1102
11.10.1 TiCDC Overview 1102
11.10.2 Deploy TiCDC 1112
11.10.3 Manage TiCDC Cluster and Replication Tasks 1115
11.10.4 Troubleshoot TiCDC 1138
11.10.5 Key Monitoring Metrics of TiCDC 1153
11.10.6 TiCDC Alert Rules 1159
11.10.7 TiCDC Open Protocol 1164
11.10.8 Quick Start Guide on Integrating TiDB with Confluent Platform 1176
11.10.9 TiCDC Glossary 1179
11.11 Use Dumpling to Export Data 1180
11.11.1 Export data from TiDB or MySQL 1181
11.11.2 Option list of Dumpling 1187
11.12 sync-diff-inspector 1192
11.12.1 sync-diff-inspector User Guide 1192
11.12.2 Data Check for Tables with Different Schema or Table Names 1199
11.12.3 Data Check in the Sharding Scenario 1201
11.12.4 Data Check for TiDB Upstream and Downstream Clusters 1207
11.13 TiSpark 1208
11.13.1 TiSpark Quick Start Guide 1208
11.13.2 TiSpark User Guide 1212

12 Reference **1222**

12.1 Cluster Architecture 1222
12.1.1 TiDB Architecture 1222
12.1.2 TiDB Storage 1224
12.1.3 TiDB Computing 1230
12.1.4 TiDB Scheduling 1237

12.2 Storage Engine - TiKV · · · · · 1242
12.2.1 TiKV Overview · · · · · 1242
12.2.2 RocksDB Overview · · · · · 1244
12.2.3 Titan Overview · · · · · 1247
12.2.4 Titan Configuration · · · · · 1255
12.3 Storage Engine - TiFlash · · · · · 1259
12.3.1 TiFlash Overview · · · · · 1259
12.3.2 Use TiFlash · · · · · 1262
12.4 System Variables · · · · · 1278
12.4.1 Variable Reference · · · · · 1279
12.5 Configuration File Parameters · · · · · 1323
12.5.1 TiDB Configuration File · · · · · 1323
12.5.2 TiKV Configuration File · · · · · 1343
12.5.3 Configure TiFlash · · · · · 1380
12.5.4 PD Configuration File · · · · · 1388

2 About TiDB

2.1 TiDB Introduction

TiDB (/'ta di bi:/, "Ti" stands for Titanium) is an open-source NewSQL database that supports Hybrid Transactional and Analytical Processing (HTAP) workloads. It is MySQL compatible and features horizontal scalability, strong consistency, and high availability. The goal of TiDB is to provide users with a one-stop database solution that covers OLTP (Online Transactional Processing), OLAP (Online Analytical Processing), and HTAP services. TiDB is suitable for various use cases that require high availability and strong consistency with large-scale data.

2.1.1 Key features

- **Horizontally scaling out or scaling in easily**

  The TiDB architecture design of separating computing from storage enables you to separately scale out or scale in the computing or storage capacity online as needed. The scaling process is transparent to application operations and maintenance staff.

- **Financial-grade high availability**

  The data is stored in multiple replicas. Data replicas obtain the transaction log using the Multi-Raft protocol. A transaction can be committed only when data has been successfully written into the majority of replicas. This can guarantee strong consistency, and availability when a minority of replicas go down. To meet the requirements of different disaster tolerance levels, you can configure the geographic location and number of replicas as needed.

- **Real-time HTAP**

  TiDB provides two storage engines: TiKV, a row-based storage engine, and TiFlash, a columnar storage engine. TiFlash uses the Multi-Raft Learner protocol to replicate data from TiKV in real time, ensuring that the data between the TiKV row-based storage engine and the TiFlash columnar storage engine are consistent. TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.

- **Cloud-native distributed database**

  TiDB is a distributed database designed for the cloud, providing flexible scalability, reliability and security on the cloud platform. Users can elastically scale TiDB to meet the requirements of their changing workloads. In TiDB, each piece of data has 3 replicas at least, which can be scheduled in different cloud availability zones to tolerate the outage of a whole data center. TiDB Operator helps manage TiDB on Kubernetes

and automates tasks related to operating the TiDB cluster, which makes TiDB easier to deploy on any cloud that provides managed Kubernetes. TiDB Cloud, the fully-managed TiDB service, is the easiest, most economical, and most resilient way to unlock the full power of TiDB in the cloud, allowing you to deploy and run TiDB clusters with just a few clicks.

- **Compatible with the MySQL 5.7 protocol and MySQL ecosystem**

  TiDB is compatible with the MySQL 5.7 protocol, common features of MySQL, and the MySQL ecosystem. To migrate your applications to TiDB, you do not need to change a single line of code in many cases or only need to modify a small amount of code. In addition, TiDB provides a series of data migration tools to help easily migrate application data into TiDB.

2.1.2 Use cases

- **Financial industry scenarios with high requirements for data consistency, reliability, availability, scalability, and disaster tolerance**

  As we all know, the financial industry has high requirements for data consistency, reliability, availability, scalability, and disaster tolerance. The traditional solution is to provide services in two data centers in the same city, and provide data disaster recovery but no services in a third data center located in another city. This solution has the disadvantages of low resource utilization, high maintenance cost, and the fact that RTO (Recovery Time Objective) and RPO (Recovery Point Objective) cannot meet expectations. TiDB uses multiple replicas and the Multi-Raft protocol to schedule data to different data centers, racks, and machines. When some machines fail, the system can automatically switch to ensure that the system RTO 30s and RPO = 0.

- **Massive data and high concurrency scenarios with high requirements for storage capacity, scalability, and concurrency**

  As applications grow rapidly, the data surges. Traditional standalone databases cannot meet the data capacity requirements. The solution is to use sharding middleware or a NewSQL database (like TiDB), and the latter is more cost-effective. TiDB adopts a separate computing and storage architecture, which enables you to scale out or scale in the computing or storage capacity separately. The computing layer supports a maximum of 512 nodes, each node supports a maximum of 1,000 concurrencies, and the maximum cluster capacity is at the PB (petabytes) level.

- **Real-time HTAP scenarios**

  With the fast growth of 5G, Internet of Things, and artificial intelligence, the data generated by a company keeps increasing tremendously, reaching a scale of hundreds of TB (terabytes) or even the PB level. The traditional solution is to process online transactional applications using an OLTP database and use an ETL (Extract, Transform, Load) tool to replicate the data into an OLAP database for data analysis. This solution has multiple disadvantages such as high storage costs and poor real-time performance.

TiDB introduces the TiFlash columnar storage engine in v4.0, which combines with the TiKV row-based storage engine to build TiDB as a true HTAP database. With a small amount of extra storage cost, you can handle both online transactional processing and real-time data analysis in the same system, which greatly saves the cost.

- **Data aggregation and secondary processing scenarios**

  The application data of most companies are scattered in different systems. As the application grows, the decision-making leaders need to understand the business status of the entire company to make decisions in time. In this case, the company needs to aggregate the scattered data into the same system and execute secondary processing to generate a T+0 or T+1 report. The traditional solution is to use ETL and Hadoop, but the Hadoop system is complicated, with high operations and maintenance cost and storage cost. Compared with Hadoop, TiDB is much simpler. You can replicate data into TiDB using ETL tools or data migration tools provided by TiDB. Reports can be directly generated using SQL statements.

2.2 TiDB 5.1 Release Notes

Release date: June 24, 2021

TiDB version: 5.1.0

In v5.1, the key new features or improvements are as follows:

- Support the Common Table Expression (CTE) feature of MySQL 8.0 to improve the readability and execution efficiency of SQL statements.
- Support changing column types online to improve code development flexibility.
- Introduce a new statistics type to improve query stability, which is enabled as an experimental feature by default.
- Support the dynamic privilege feature of MySQL 8.0 to implement more fine-grained control over certain operations.
- Support directly reading data from the local replica using the Stale Read feature to reduce read latency and improve query performance (Experimental).
- Add the Lock View feature to facilitate database administrators (DBAs) to observe transaction locking events and troubleshoot deadlock problems (Experimental).
- Add TiKV write rate limiter for background tasks to ensure that the latency of read and write requests is stable.

2.2.1 Compatibility changes

> **Note:**
>
> When upgrading from an earlier TiDB version to v5.1, if you want to know the compatibility change notes of all intermediate versions, you can check the Release Notes for the corresponding version.

2.2.1.1 System variables

Variable name	Change type	Description
`cte_max_recursion_depth`	Newly added	Controls the maximum recursion depth in Common Table Expressions.
`init_connect`	Newly added	Controls the initial connection to a TiDB server.
`tidb_analyze_version`	Newly added	Controls how TiDB collects statistics. The default value of this variable is 2. This is an experimental feature.

Variable name	Change type	Description
`tidb_enable_enhanced_security` ↪	Newly added	Indicates whether the TiDB server you are connected to has the Security Enhanced Mode (SEM) enabled. This variable setting cannot be changed without restarting the TiDB server.
`tidb_enforce_mpp` ↪	Newly added	Controls whether to ignore the optimizer's cost estimation and to forcibly use the MPP mode for query execution. The data type of this variable is `BOOL` and the default value is `false`.

Variable name	Change type	Description
tidb_partition_prune_mode ↪	Newly added	Specifies whether to enable dynamic pruning mode for partitioned tables. This feature is experimental. The default value of this variable is `static`, which means the dynamic pruning mode for partitioned tables is disabled by default.

2.2.1.2 Configuration file parameters

Configuration file	Configuration item	Change type	Description

Configuration file	Configuration item	Change type	Description
TiDB configuration file	`security.` ↪ `enable-` ↪ `sem`	Newly added	Controls whether to enable the Security Enhanced Mode (SEM). The default value of this configuration item is `false`, which means the SEM is disabled.
TiDB configuration file	`performance` ↪ `.` ↪ `committer` ↪ `-` ↪ `concurrency` ↪	Modified	Controls the concurrency number for requests related to commit operations in the commit phase of a single transaction. The default value is changed from `16` to `128`.

Configuration file	Configuration item	Change type	Description
TiDB configuration file	performance ↪ .tcp-no ↪ -delay	Newly added	Determines whether to enable TCP_NODELAY at the TCP layer. The default value is true, which means TCP_NODELAY is enabled.
TiDB configuration file	performance ↪ . ↪ enforce ↪ -mpp	Newly added	Controls whether TiDB ignores cost estimates of Optimizer at the instance level and enforces the MPP mode. The default value is false. This configuration item controls the initial value of the system variable tidb_enforce_mpp ↪ .

Configuration file	Configuration item	Change type	Description
TiDB configuration file	pessimistic-txn.deadlock-history-capacity	Newly added	Sets the maximum number of deadlock events that can be recorded in the INFORMATION_SCHEMA.DEADLOCKS table of a single TiDB server. The default value is 10.
TiKV configuration file	abort-on-panic	Newly added	Sets whether the abort process allows the system to generate core dump files when TiKV panics. The default value is false, which means it is not allowed to generate core dump files.

Configuration file	Configuration item	Change type	Description
TiKV configuration file	`hibernate-regions`	Modified	The default value is changed from `false` to `true`. If a Region is idle for a long time, it is automatically set as hibernated.
TiKV configuration file	`old-value-cache-memory-quota`	Newly added	Sets the upper limit of memory usage by TiCDC old values. The default value is `512MB`.
TiKV configuration file	`sink-memory-quota`	Newly added	Sets the upper limit of memory usage by TiCDC data change events. The default value is `512MB`.

Configuration file	Configuration item	Change type	Description
TiKV configuration file	`incremental-scan-threads`	Newly added	Sets the number of threads for the task of incrementally scanning historical data. The default value is `4`, which means there are four threads for the task.
TiKV configuration file	`incremental-scan-concurrency`	Newly added	Sets the maximum number of concurrent executions for the tasks of incrementally scanning historical data. The default value is `6`, which means that six tasks can be concurrently executed at most.

Configuration file	Configuration item	Change type	Description
TiKV configuration file	soft-pending-compaction-bytes-limit	Modified	The soft limit on the pending compaction bytes. The default value is changed from "64GB" to "192GB".
TiKV configuration file	storage.io-rate-limit	Newly added	Controls the I/O rate of TiKV writes. The default value of storage.io-rate-limit.max-bytes-per-sec is "0MB".
TiKV configuration file	resolved-ts.enable	Newly added	Determines whether to maintain the resolved-ts for all Region leaders. The default value is true.
TiKV configuration file	resolved-ts.advance-ts-interval	Newly added	The interval at which the resolved-ts is forwarded. The default value is "1s". You can change the value dynamically.

Configuration file	Configuration item	Change type	Description
TiKV configuration file	`resolved-ts.scan-lock-pool-size`	Newly added	The number of threads that TiKV uses to scan the MVCC (multi-version concurrency control) lock data when initializing the `resolved-ts`. The default value is 2.

2.2.1.3 Others

- Before the upgrade, check the value of the TiDB configuration `feedback-probability`. If the value is not 0, the "panic in the recoverable goroutine" error will occur after the upgrade, but this error does not affect the upgrade.
- Upgrade the Go compiler version of TiDB from go1.13.7 to go1.16.4, which improves the TiDB performance. If you are a TiDB developer, upgrade your Go compiler version to ensure a smooth compilation.
- Avoid creating tables with clustered indexes in the cluster that uses TiDB Binlog during the TiDB rolling upgrade.
- Avoid executing statements like `alter table ... modify column` or `alter table ... change column` during the TiDB rolling upgrade.
- Since v5.1, setting the replica of system tables, when building TiFlash replicas for each table, is no longer supported. Before upgrading the cluster, you need to clear the relevant system table replicas; otherwise, the upgrade will fail.
- Deprecate the `--sort-dir` parameter in the `cdc cli changefeed` command of TiCDC. Instead, you can set `--sort-dir` in the `cdc server` command. #1795
- After upgrading to TiDB 5.1, if TiDB returns the "function READ ONLY has only noop implementation" error, you can let TiDB ignore this error by setting the value of `tidb_enable_noop_functions` to `ON`. This is because the `read_only` variable in MySQL does not yet take effect in TiDB (which is a 'noop' behavior in TiDB). Therefore, even if this variable is set in TiDB, you can still write data into the TiDB cluster.

2.2.2 New features

2.2.2.1 SQL

- Support the Common Table Expression (CTE) feature of MySQL 8.0.

  This feature empowers TiDB with the capability of querying hierarchical data recursively or non-recursively and meets the needs of using tree queries to implement application logics in multiple sectors such as human resources, manufacturing, financial markets, and education.

  In TiDB, you can apply the `WITH` statement to use Common Table Expressions. User document, #17472

- Support the dynamic privilege feature of MySQL 8.0.

  Dynamic privileges are used to limit the `SUPER` privilege and provide TiDB with more flexible privilege configuration for more fine-grained access control. For example, you can use dynamic privileges to create a user account that can only perform `BACKUP` and `RESTORE` operations.

  The supported dynamic privileges are as follows:

  - `BACKUP_ADMIN`
  - `RESTORE_ADMIN`
  - `ROLE_ADMIN`
  - `CONNECTION_ADMIN`
  - `SYSTEM_VARIABLES_ADMIN`

  You can also use plugins to add new privileges. To check out all supported privileges, execute the `SHOW PRIVILEGES` statement. User document

- Add a new configuration item for the Security Enhanced Mode (SEM), which divides the TiDB administrator privileges in a finer-grained way.

  The Security Enhanced Mode is disabled by default. To enable it, see the user document.

- Enhance the capability of changing column types online. Support changing the column type online using the `ALTER TABLE` statement, including but not limited to:

  - Changing `VARCHAR` to `BIGINT`
  - Modifying the `DECIMAL` precision
  - Compressing the length of `VARCHAR(10)` to `VARCHAR(5)`

  User document

- Introduce a new SQL syntax `AS OF TIMESTAMP` to perform Stale Read, a new experimental feature used to read historical data from a specified point in time or from a specified time range.

  User document, #21094

  The examples of `AS OF TIMESTAMP` are as follows:

```
SELECT * FROM t AS OF TIMESTAMP '2020-09-06 00:00:00';
START TRANSACTION READ ONLY AS OF TIMESTAMP '2020-09-06 00:00:00';
SET TRANSACTION READ ONLY as of timestamp '2020-09-06 00:00:00';
```

- Introduce a new statistics type `tidb_analyze_version = 2` (Experimental).

  `tidb_analyze_version` is set to `2` by default, which avoids the large errors that might occur in the large data volume caused by hash conflicts in Version 1 and maintains the estimation accuracy in most scenarios.

  User document

2.2.2.2 Transaction

- Support the Lock View feature (Experimental)

  The Lock View feature provides more information about lock conflicts and lock waits of pessimistic locks, which helps DBAs to observe transaction locking conditions and troubleshoot deadlock problems. #24199

  User document:

  - View the pessimistic locks and other locks that currently occur on all TiKV nodes in the clusters: `DATA_LOCK_WAITS`
  - View several deadlock errors that recently occurred on the TiDB nodes: `DEADLOCKS`
  - View the transaction information executed currently on the TiDB nodes: `TIDB_TRX`

2.2.2.3 Performance

- Stale read of data replicas (Experimental)

  Read local replicas data directly to reduce read latency and improve the query performance

  User document, #21094

- Enable the Hibernate Region feature by default.

  If a Region is in an inactive state for a long time, it is automatically set to a silent state, which reduces the system overhead of the heartbeat information between the Leader and the Follower.

  User document, #10266

2.2.2.4 Stability

- Solve the replication stability issue of TiCDC
  - Improve TiCDC memory usage to avoid OOM in the following scenarios
  - If large amounts of data is accumulated during the replication interruption, exceeding 1TB, the re-replication causes OOM problems.
  - Large amounts of data writes cause OOM problems in TiCDC.
  - Reduce the possibility of TiCDC replication interruption in the following scenarios:

    project#11

    * Replication interruption when the network is unstable
    * Replication interruption when some TiKV/PD/TiCDC nodes are down

- TiFlash storage memory control

  Optimize the speed and memory usage of Region snapshot generation and reduce the possibility of OOM

- Add a write rate limiter for TiKV background tasks (TiKV Write Rate Limiter)

  To ensure the duration stability of read and write requests, TiKV Write Rate Limiter smoothes the write traffic of TiKV background tasks such as GC and Compaction. The default value of TiKV background task write rate limiter is "0MB". It is recommended to set this value to the optimal I/O bandwidth of the disk, such as the maximum I/O bandwidth specified by the cloud disk manufacturer.

  User document, #9156

- Solve scheduling stability issues when multiple scaling tasks are performed at the same time

2.2.2.5 Telemetry

TiDB adds the running status of TiDB cluster requests in telemetry, including execution status, failure status, etc.

To learn more about the information and how to disable this behavior, refer to Telemetry.

2.2.3 Improvements

- TiDB
  - Support the built-in function `VITESS_HASH()` #23915
  - Support pushing down data of the enumerated type to TiKV to improve performance when using enumerated types in `WHERE` clauses #23619
  - Support the `RENAME USER` syntax #23648

  - Optimize the calculation of Window Function to solve TiDB OOM problems when paging data with ROW_NUMBER() #23807
  - Optimize the calculation of `UNION ALL` to solve the TiDB OOM problems when using `UNION ALL` to join a large number of `SELECT` statements #21441
  - Optimize the dynamic pruning mode of partitioned tables to improve performance and stability #24150
  - Fix the `Region is Unavailable` issue that occurs in multiple scenarios project#62
  - Fix multiple `Region is Unavailable` issues that might occur in frequent scheduling situations
  - Fix `Region is Unavailable` issue that might occur in some high stress write situations
  - Avoid frequently reading the `mysql.stats_histograms` table if the cached statistics is up-to-date to avoid high CPU usage #24317

- TiKV

  - Use `zstd` to compress Region snapshots, preventing large space differences between nodes in case of heavy scheduling or scaling #10005
  - Solve OOM issues in multiple cases #10183
    * Add memory usage tracking for each module
    * Solve the OOM issue caused by oversized Raft entries cache
    * Solve the OOM issue caused by stacked GC tasks
    * Solve the OOM issue caused by fetching too many Raft entries from the Raft log to memory at one time
  - Split Regions more evenly to mitigate the issue that the growth of Region size exceeds the splitting speed when there are hotspot writes #9785

- TiFlash

  - Support `Union All`, `TopN`, and `Limit` functions
  - Support the Cartesian product including left outer join and semi anti join in MPP mode
  - Optimize lock operations to avoid that running DDL statements and read operations are blocked by each other
  - Optimize cleanup of expired data by TiFlash
  - Support further filtering of query filters on `timestamp` columns at the TiFlash storage level
  - Improve the startup and scalability speed of TiFlash when a large number of tables are in a cluster
  - Improve TiFlash compatibility when running on unknown CPUs

- PD

  - Avoid unexpected statistics after adding the `scatter region` scheduler #3602

  - Solve multiple scheduling issues in the scaling process
    * Optimize the generation process of replica snapshots to solve slow scheduling issues during scaling #3563 #10059 #10001
    * Solve slow scheduling issues caused by heartbeat pressure due to traffic changes #3693 #3739 #3728 #3751
    * Reduce the space discrepancies of large clusters due to scheduling, and optimize the scheduling formula to prevent the bursting issue (which is similar to heterogeneous space clusters) caused by large compression rate discrepancies #3592 #10005

- Tools
  - Backup & Restore (BR)
    * Support backing up and restoring system tables in the `mysql` schema #1143 #1078
    * Support the S3-compatible storage that is based on the virtual-host addressing mode #10243
    * Optimize the format of backupmeta to reduce memory usage #1171
  - TiCDC
    * Improve the descriptions of some log messages to be clearer and more useful for diagnosing problems #1759
    * Support the back pressure feature to allow the TiCDC scanning speed to sense the downstream processing capacity #10151
    * Reduce memory usage when TiCDC performs the initial scan #10133
    * Improve the cache hit rate for the TiCDC Old Value in pessimistic transactions #10089
  - Dumpling
    * Improve the logic of exporting data from TiDB v4.0 to avoid TiDB becoming out of memory (OOM) #273
    * Fix the issue that no error is output when a backup operation fails #280
  - TiDB Lightning
    * Improve data importing speed. The optimization results show that the speed of importing TPC-C data is increased by 30%, and the speed of importing large tables (2TB+) with more indexes (5 indexes) is increased by more than 50%. #753
    * Add a pre-check on the data to be imported and also on the target cluster before importing, and report errors to reject the import process if it does not meet the import requirements #999
    * Optimize the timing of checkpoint updates on the Local backend to improve performance of restarting from breakpoints#1080

2.2.4 Bug Fixes

- TiDB
  - Fix the issue that the execution result of project elimination might be wrong when the projection result is empty #23887
  - Fix the issue of wrong query results when a column contains `NULL` values in some cases #23891
  - Forbid generating MPP plans when the scan contains virtual columns #23886
  - Fix the wrong reuse of `PointGet` and `TableDual` in Plan Cache #23187 #23144 #23304 #23290
  - Fix the error that occurs when the optimizer builds the `IndexMerge` plan for clustered indexes #23906
  - Fix the type inference of the BIT-type errors #23832
  - Fix the issue that some optimizer hints do not take effect when the `PointGet` operator exists #23570
  - Fix the issue that DDL operations might fail when rolling back due to an error #23893
  - Fix the issue that the index range of the binary literal constant is incorrectly built #23672
  - Fix the potential wrong results of the `IN` clause in some cases #23889
  - Fix the wrong results of some string functions #23759
  - Users now need both `INSERT` and `DELETE` privileges on a table to perform `REPLACE` operations #23909
  - Users now need both `INSERT` and `DELETE` privileges on a table to perform `REPLACE` operations #24070
  - Fix the wrong `TableDual` plans caused by incorrectly comparing binaries and bytes#23846
  - Fix the panic issue caused by using the prefix index and index join in some cases #24547 #24716 #24717
  - Fix the issue that the prepared plan cache of `point get` is incorrectly used by the `point get` statement in the transaction #24741
  - Fix the issue of writing the wrong prefix index value when the collation is `ascii_bin` or `latin1_bin` #24569
  - Fix the issue that the ongoing transaction might be interrupted by the GC worker #24591
  - Fix a bug that the point query might get wrong on the clustered index when `new-collation` is enabled but `new-row-format` is disabled #24541
  - Refactor the conversion of partition keys for shuffle hash join #24490
  - Fix the panic issue that occurs when building the plan for queries that contain the `HAVING` clause #24045
  - Fix the issue that the column pruning improvement causes the `Apply` and `Join` operators' results to go wrong #23887
  - Fix a bug that the primary lock fallen back from async commit cannot be resolved #24384

  - Fix a GC issue of statistics that might cause duplicated fm-sketch records #24357
  - Avoid unnecessary pessimistic rollback when the pessimistic locking receives the `ErrKeyExists` error #23799
  - Fix the issue that numeric literals cannot be recognized when the sql_mode contains `ANSI_QUOTES` #24429
  - Forbid statements such as `INSERT INTO table PARTITION (<partitions>)... ON DUPLICATE KEY UPDATE` to read data from non-listed partitions #24746
  - Fix the potential `index out of range` error when a SQL statement contains both `GROUP BY` and `UNION` #24281
  - Fix the issue that the `CONCAT` function incorrectly handles the collation #24296
  - Fix the issue that the `collation_server` global variable does not take effect in new sessions #24156

- TiKV

  - Fix the issue that the coprocessor fails to properly handle the signed or unsigned integer types in the `IN` expression #9821
  - Fix the issue of many empty Regions after batch ingesting SST files #964
  - Fix a bug that TiKV cannot start up after the file dictionary file is damaged #9886
  - Fix a TiCDC OOM issue caused by reading old values #9996 #9981
  - Fix the issue of empty value in the secondary index for the clustered primary key column when collation is `latin1_bin` #24548
  - Add the `abort-on-panic` configuration, which allows TiKV to generate the core dump file when panic occurs. Users still need to correctly configure the environment to enable core dump #10216
  - Fix the performance regression issue of `point get` queries that occurs when TiKV is not busy #10046

- PD

  - Fix the issue that the PD Leader re-election is slow when there are many stores #3697
  - Fix the panic issue that occurs when removing the evict leader scheduler from a non-existent store #3660
  - Fix the issue that the statistics are not updated after offline peers are merged #3611

- TiFlash

  - Fix the issue of incorrect results when casting the time type to the integer type
  - Fix a bug that the `receiver` cannot find corresponding tasks within 10 seconds
  - Fix the issue that there might be invalid iterators in `cancelMPPQuery`
  - Fix a bug that the behavior of the `bitwise` operator is different from that of TiDB

  - Fix the alert issue caused by overlapping ranges when using the `prefix key`
  - Fix the issue of incorrect results when casting the string type to the integer type
  - Fix the issue that consecutive and fast writes might make TiFlash out of memory
  - Fix the potential issue that the exception of null pointer might be raised during the table GC
  - Fix the TiFlash panic issue that occurs when writing data to dropped tables
  - Fix the issue that TiFlash might panic during BR restore
  - Fix the issue of incorrect results when cloning shared delta index concurrently
  - Fix the potential panic that occurs when the Compaction Filter feature is enabled
  - Fix the issue that TiFlash cannot resolve the lock fallen back from async commit
  - Fix the issue of incorrect results returned when the casted result of the `TIMEZONE` type contains the `TIMESTAMP` type
  - Fix the TiFlash panic issue that occurs during Segment Split

- Tools

  - TiDB Lightning

    * Fix the issue of TiDB Lightning panic that occurs when generating KV data #1127
    * Fix a bug that the batch split Region fails due to the total key size exceeding the raft entry limit during the data import #969
    * Fix the issue that when importing CSV files, if the last line of the file does not contain line break characters (`\r\n`), an error will be reported #1133
    * Fix the issue that if a table to be imported includes an auto-increment column of the double type, the auto_increment value becomes abnormal #1178

  - Backup & Restore (BR)

    * Fix the issue of backup interruption caused by the failure of a few TiKV nodes #980

  - TiCDC

    * Fix the concurrency issue in Unified Sorter and filter the unhelpful error messages #1678
    * Fix a bug that the creation of redundant directories might interrupt the replication with MinIO #1463
    * Set the default value of the `explicit_defaults_for_timestamp` session variable to ON to make the MySQL 5.7 downstream keep the same behavior with the upstream TiDB #1585
    * Fix the issue that the incorrect handling of `io.EOF` might cause replication interruption #1633
    * Correct the TiKV CDC endpoint CPU metric in the TiCDC dashboard #1645
    * Increase `defaultBufferChanSize` to avoid replication blocking in some cases #1259
    * Fix the issue that the time zone information is lost in the Avro output #1712
    * Support cleaning up stale temporary files in Unified Sorter and forbid sharing the `sort-dir` directory #1742

* Fix a deadlock bug in the KV client that occurs when many stale Regions exist #1599
* Fix the wrong help information in the `--cert-allowed-cn` flag #1697
* Revert the update for `explicit_defaults_for_timestamp` which requires the SUPER privilege when replicating data to MySQL #1750
* Support the sink flow control to reduce the risk of memory overflow #1840
* Fix a bug that the replication task might stop when moving a table #1828
* Fix the issue that the TiKV GC safe point is blocked due to the stagnation of TiCDC changefeed checkpoint #1759

2.3 TiDB Features

This document lists the features supported in each TiDB version. Note that supports for experimental features might change before the final release.

2.3.1 Data types, functions, and operators

Data types, functions, and operators	5.2	5.1	5.0	4.0
Numeric types	Y	Y	Y	Y
Date and time types	Y	Y	Y	Y
String types	Y	Y	Y	Y
JSON type	Experimental	Experimental	Experimental	Experimental
Control flow functions	Y	Y	Y	Y
String functions	Y	Y	Y	Y
Numeric functions and operators	Y	Y	Y	Y
Date and time functions	Y	Y	Y	Y
Bit functions and operators	Y	Y	Y	Y
Cast functions and operators	Y	Y	Y	Y
Encryption and compression functions	Y	Y	Y	Y
Information functions	Y	Y	Y	Y
JSON functions	Experimental	Experimental	Experimental	Experimental
Aggregation functions	Y	Y	Y	Y
Window functions	Y	Y	Y	Y
Miscellaneous functions	Y	Y	Y	Y
Operators	Y	Y	Y	Y
Character sets and collations [1]	Y	Y	Y	Y

2.3.2 Indexing and constraints

[1] TiDB incorrectly treats latin1 as a subset of utf8. See TiDB #18955 for more details.

Indexing and constraints	5.2	5.1	5.0	4.(
Expression indexes	Experimental	Experimental	Experimental	Experi
Columnar storage (TiFlash)	Y	Y	Y	Y
RocksDB engine	Y	Y	Y	Y
Titan plugin	Y	Y	Y	Y
Invisible indexes	Y	Y	Y	N
Composite `PRIMARY KEY`	Y	Y	Y	Y
Unique indexes	Y	Y	Y	Y
Clustered index on integer `PRIMARY KEY`	Y	Y	Y	Y
Clustered index on composite or non-integer key	Y	Y	Y	N

2.3.3 SQL statements

SQL statements [2]	5.2	5.1	5.0	4.
Basic `SELECT`, `INSERT`, `UPDATE`, `DELETE`, `REPLACE`	Y	Y	Y	Y
`INSERT ON DUPLICATE KEY UPDATE`	Y	Y	Y	Y
`LOAD DATA INFILE`	Y	Y	Y	Y
`SELECT INTO OUTFILE`	Y	Y	Y	Y
`INNER JOIN`, `LEFT|RIGHT [OUTER] JOIN`	Y	Y	Y	Y
`UNION`, `UNION ALL`	Y	Y	Y	Y
`EXCEPT` and `INTERSECT` operators	Y	Y	Y	N
`GROUP BY`, `ORDER BY`	Y	Y	Y	Y
Window Functions	Y	Y	Y	Y
Common Table Expressions (CTE)	Y	Y	N	N
`START TRANSACTION`, `COMMIT`, `ROLLBACK`	Y	Y	Y	Y
`EXPLAIN`	Y	Y	Y	Y
`EXPLAIN ANALYZE`	Y	Y	Y	Y
User-defined variables	Experimental	Experimental	Experimental	Experi
Table Lock		Experimental	Experimental	Experi

2.3.4 Advanced SQL features

Advanced SQL features	5.2	5.1	5.0	4.0
Prepared statement cache	Experimental	Experimental	Experimental	Experimental
SQL plan management (SPM)	Y	Y	Y	Y
Coprocessor cache	Y	Y	Y	Experimental
Stale Read	Y	Y	N	N
Follower reads	Y	Y	Y	Y
Read historical data (tidb_snapshot)	Y	Y	Y	Y
Optimizer hints	Y	Y	Y	Y
MPP Execution Engine	Y	Y	Y	N

Advanced SQL features	5.2	5.1	5.0	4.0
Index Merge Join	Experimental	Experimental	Experimental	Experimental

2.3.5 Data definition language (DDL)

Data definition language (DDL)	5.2	5.1	5.0	4.0
Basic `CREATE`, `DROP`, `ALTER`, `RENAME`, `TRUNCATE`	Y	Y	Y	Y
Generated columns	Experimental	Experimental	Experimental	Experime
Views	Y	Y	Y	Y
Sequences	Y	Y	Y	Y
Auto increment	Y	Y	Y	Y
Auto random	Y	Y	Y	Y
DDL algorithm assertions	Y	Y	Y	Y
Multi-schema change: add columns	Experimental	Experimental	Experimental	Experime
Change column type	Y	Y	N	N

2.3.6 Transactions

Transactions	5.2	5.1	5.0	4.0
Async commit	Y	Y	Y	N
1PC	Y	Y	Y	N
Large transactions (10GB)	Y	Y	Y	Y
Pessimistic transactions	Y	Y	Y	Y
Optimistic transactions	Y	Y	Y	Y
Repeatable-read isolation (snapshot isolation)	Y	Y	Y	Y
Read-committed isolation	Y	Y	Y	Y

2.3.7 Partitioning

Partitioning	5.2	5.1	5.0	4.0
Range partitioning	Y	Y	Y	Y
Hash partitioning	Y	Y	Y	Y
List partitioning	Experimental	Experimental	Experimental	N
List COLUMNS partitioning	Experimental	Experimental	Experimental	N
`EXCHANGE PARTITION`	Experimental	Experimental	Experimental	N
Dynamic Pruning	Experimental	Experimental	N	N

2.3.8 Statistics

Statistics	5.2	5.1	5.0	4.0
CMSketch	Deprecated	Deprecated	Deprecated	Y
Histograms	Y	Y	Y	Y
Extended statistics (multiple columns)	Experimental	Experimental	Experimental	N
Statistics Feedback	Experimental	Experimental	Experimental	Experimental

2.3.9 Security

Security	5.2	5.1	5.0	4.0
Transparent layer security (TLS)	Y	Y	Y	Y
Encryption at rest (TDE)	Y	Y	Y	Y
Role-based authentication (RBAC)	Y	Y	Y	Y
Certificate-based authentication	Y	Y	Y	Y
`caching_sha2_password` authentication	Y	N	N	N
MySQL compatible `GRANT` system	Y	Y	Y	Y
Dynamic Privileges	Y	Y	N	N
Security Enhanced Mode	Y	Y	N	N
Redacted Log Files	Y	Y	Y	N

2.3.10 Data import and export

Data import and export	5.2	5.1	5.0	4.0
Fast Importer (TiDB Lightning)	Y	Y	Y	Y
mydumper logical dumper	Deprecated	Deprecated	Deprecated	Deprecated
Dumpling logical dumper	Y	Y	Y	Y
Transactional `LOAD DATA`	Y	Y	Y	N
Database migration toolkit (DM)	Y	Y	Y	Y
TiDB Binlog	Y	Y	Y	Y
Change data capture (CDC)	Y	Y	Y	Y

2.3.11 Management, observability, and tools

Management, observability, and tools	5.2	5.1	5.0	4.0
TiDB Dashboard	Y	Y	Y	Y
SQL diagnostics	Experimental	Experimental	Experimental	Experimenta
Information schema	Y	Y	Y	Y
Metrics schema	Y	Y	Y	Y
Statements summary tables	Y	Y	Y	Y
Slow query log	Y	Y	Y	Y

Management, observability, and tools	5.2	5.1	5.0	4.0
TiUP deployment	Y	Y	Y	Y
Ansible deployment	N	N	N	Deprecated
Kubernetes operator	Y	Y	Y	Y
Built-in physical backup	Y	Y	Y	Y
Global Kill	Experimental	Experimental	Experimental	Experimenta
Lock View	Y	Experimental	Experimental	Experimenta
`SHOW CONFIG`	Y	Y	Y	Y
`SET CONFIG`	Experimental	Experimental	Experimental	Experimenta

2.4 TiDB Experimental Features

This document introduces the experimental features of TiDB in different versions. It is **NOT** recommended to use these features in the production environment.

2.4.1 Performance

- Randomly sample about 10000 rows of data to quickly build statistics (Introduced in v3.0)

2.4.2 Stability

- Improve the stability of the optimizer's choice of indexes (Introduced in v5.0)
  - Extend the statistics feature by collecting the multi-column order dependency information.
  - Refactor the statistics module, including deleting the `TopN` value from `CMSKetch` and the histogram, and adding NDV information for histogram buckets of each table index. For details, see descriptions about Statistics - `tidb_analyze_version = 2`.

2.4.3 Scheduling

- Cascading Placement Rules feature. It is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader. See Cascading Placement Rules for details. (Introduced in v4.0)
- Elastic scheduling feature. It enables the TiDB cluster to dynamically scale out and in on Kubernetes based on real-time workloads, which effectively reduces the stress during your application's peak hours and saves overheads. See Enable TidbCluster Auto-scaling for details. (Introduced in v4.0)

2.4.4 SQL

- List Partition (Introduced in v5.0)
- List COLUMNS Partition (Introduced in v5.0)
- Dynamic Pruning Mode for Partitioned Tables. (Introduced in v5.1)
- The expression index feature. The expression index is also called the function-based index. When you create an index, the index fields do not have to be a specific column but can be an expression calculated from one or more columns. This feature is useful for quickly accessing the calculation-based tables. See Expression index for details. (Introduced in v4.0)
- Generated Columns.
- User-Defined Variables.
- JSON data type and JSON functions.
- Prepare Plan cache. (Introduced in v4.0)
- Using `ALTER TABLE` to modify multiple columns or indexes (Introduced in v5.0.0)
- Cascades Planner: a cascades framework-based top-down query optimizer (Introduced in v3.0)
- Table Lock (Introduced in v4.0.0)

2.4.5 Configuration management

- Persistently store configuration parameters in PD, and support dynamically modifying configuration items. (Introduced in v4.0)

2.4.6 Data sharing and subscription

- Integrate TiCDC with Kafka Connect (Confluent Platform) (Introduced in v5.0)
- The cyclic replication feature of TiCDC (Introduced in v5.0)

2.4.7 Storage

- Disable Titan.
- Titan Level Merge.

2.4.8 Backup and restoration

- Back up Raw KV.

2.4.9 Garbage collection

- Green GC.

2.4.10 Diagnostics

- SQL diagnostics.
- Cluster diagnostics.

2.5 Benchmarks

2.5.1 TiDB Sysbench Performance Test Report – v5.1.0 vs. v5.0.2

2.5.1.1 Test overview

This test aims at comparing the Sysbench performance of TiDB v5.1.0 and TiDB v5.0.2 in the Online Transactional Processing (OLTP) scenario. The results show that compared with v5.0.2, the Point Select performance of v5.1.0 is improved by 19.4%, and the performance of the Read Write and Update Index is slightly reduced.

2.5.1.2 Test environment (AWS EC2)

2.5.1.2.1 Hardware configuration

Service type	EC2 type	Instance count
PD	m5.xlarge	3
TiKV	i3.4xlarge	3
TiDB	c5.4xlarge	3
Sysbench	c5.9xlarge	1

2.5.1.2.2 Software version

Service type	Software version
PD	v5.0.2 and v5.1.0
TiDB	v5.0.2 and v5.1.0
TiKV	v5.0.2 and v5.1.0
Sysbench	1.0.20

2.5.1.2.3 Parameter configuration

TiDB v5.1.0 and TiDB v5.0.2 use the same configuration.

TiDB parameter configuration

```
log.level: "error"
performance.max-procs: 20
prepared-plan-cache.enabled: true
tikv-client.max-batch-wait-time: 2000000
```

TiKV parameter configuration

```
storage.scheduler-worker-pool-size: 5
raftstore.store-pool-size: 3
raftstore.apply-pool-size: 3
rocksdb.max-background-jobs: 8
raftdb.max-background-jobs: 4
raftdb.allow-concurrent-memtable-write: true
server.grpc-concurrency: 6
readpool.unified.min-thread-count: 5
readpool.unified.max-thread-count: 20
readpool.storage.normal-concurrency: 10
pessimistic-txn.pipelined: true
server.enable-request-batch: false
```

TiDB global variable configuration

```
set global tidb_hashagg_final_concurrency=1;
set global tidb_hashagg_partial_concurrency=1;
set global tidb_enable_async_commit = 1;
set global tidb_enable_1pc = 1;
set global tidb_guarantee_linearizability = 0;
set global tidb_enable_clustered_index = 1;
```

2.5.1.3 Test plan

1. Deploy TiDB v5.1.0 and v5.0.2 using TiUP.
2. Use Sysbench to import 16 tables, each table with 10 million rows of data.
3. Execute the `analyze table` statement on each table.
4. Back up the data used for restore before different concurrency tests, which ensures data consistency for each test.
5. Start the Sysbench client to perform the `point_select`, `read_write`, `update_index`, and `update_non_index` tests. Perform stress tests on TiDB via HAProxy. The test takes 5 minutes.
6. After each type of test is completed, stop the cluster, overwrite the cluster with the backup data in step 4, and restart the cluster.

2.5.1.3.1 Prepare test data

Execute the following command to prepare the test data:

```
sysbench oltp_common \
    --threads=16 \
    --rand-type=uniform \
```

```
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$aws_nlb_host \
    --mysql-port=$aws_nlb_port \
    --mysql-user=root \
    --mysql-password=password \
    prepare --tables=16 --table-size=10000000
```

2.5.1.3.2 Perform the test

Execute the following command to perform the test:

```
sysbench $testname \
    --threads=$threads \
    --time=300 \
    --report-interval=1 \
    --rand-type=uniform \
    --db-driver=mysql \
    --mysql-db=sbtest \
    --mysql-host=$aws_nlb_host \
    --mysql-port=$aws_nlb_port \
    run --tables=16 --table-size=10000000
```

2.5.1.4 Test results

2.5.1.4.1 Point Select performance

Threads	v5.0.2 QPS	v5.0.2 95% latency (ms)	v5.1.0 QPS	v5.1.0 95% latency (ms)	QPS improvement
150	137732.27	1.86	158861.67	2	15.34%
300	201420.58	2.91	238038.44	2.71	18.18%
600	303631.52	3.49	428573.21	2.07	41.15%
900	383628.13	3.55	464863.22	3.89	21.18%
1200	391451.54	5.28	413656.74	13.46	5.67%
1500	410276.93	7.43	471418.78	10.65	14.90%

Compared with v5.0.2, the Point Select performance of v5.1.0 is improved by 19.4%.

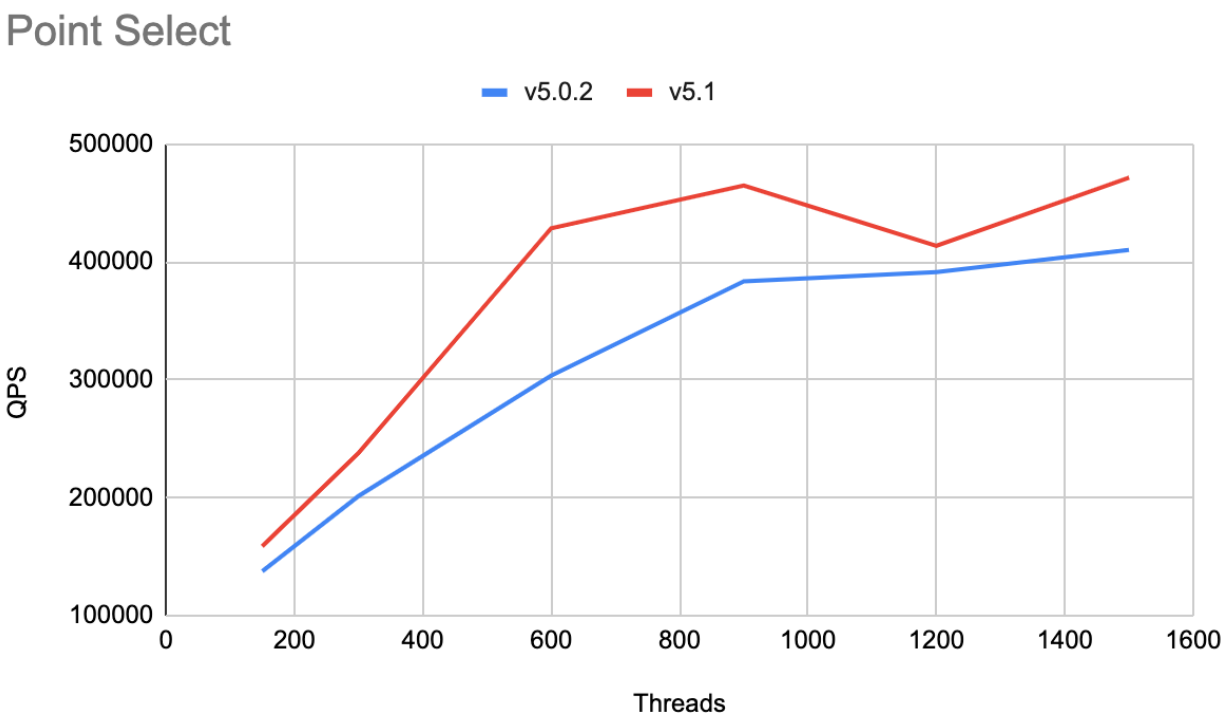

Figure 1: Point Select

2.5.1.4.2 Update Non-index performance

Threads	v5.0.2 QPS	v5.0.2 95% latency (ms)	v5.1.0 QPS	v5.1.0 95% latency (ms)	QPS improvement
150	29248.2	7.17	29362.7	8.13	0.39%
300	40316.09	12.52	39651.52	13.7	-1.65%
600	51011.11	22.28	47047.9	27.66	-7.77%
900	58814.16	27.66	59331.84	28.67	0.88%
1200	65286.52	32.53	67745.39	31.37	3.77%
1500	68300.86	39.65	67899.17	44.17	-0.59%

Compared with v5.0.2, the Update Non-index performance of v5.1.0 is reduced by 0.8%.

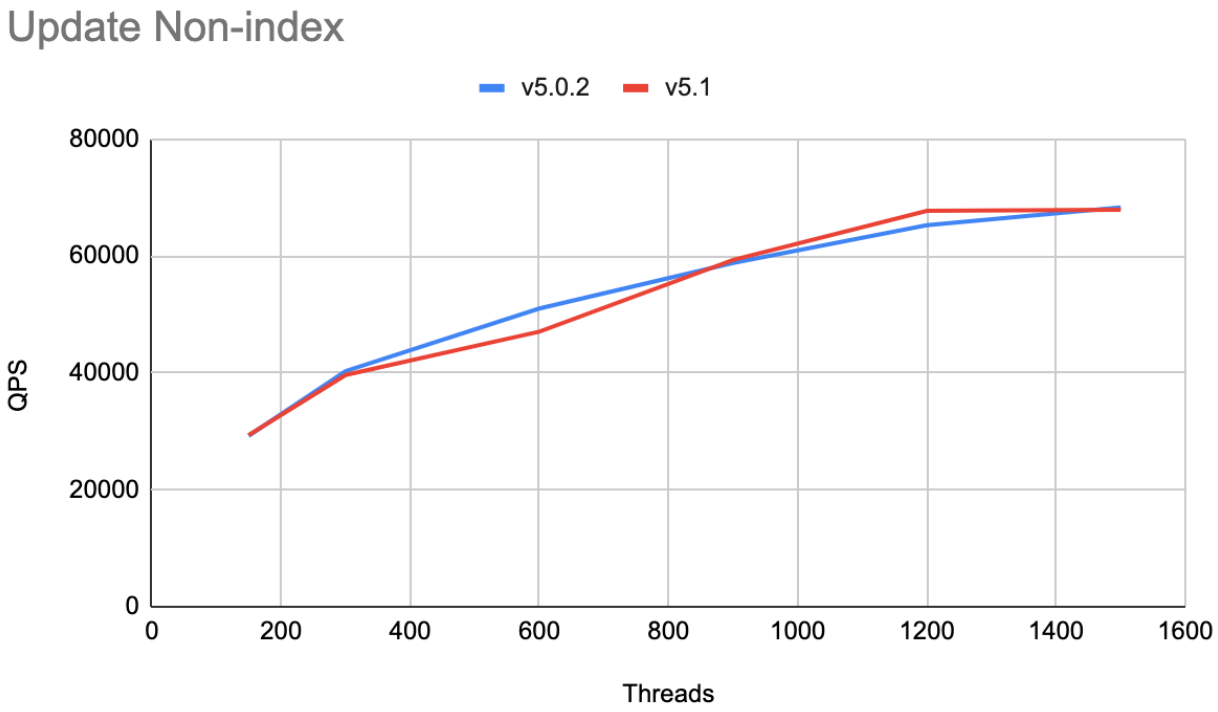

Figure 2: Update Non-index

2.5.1.4.3 Update Index performance

Threads	v5.0.2 QPS	v5.0.2 95% latency (ms)	v5.1.0 QPS	v5.1.0 95% latency (ms)	QPS improvement
150	15066.54	14.73	14829.31	14.73	-1.57%
300	18535.92	24.83	17401.01	29.72	-6.12%
600	22862.73	41.1	21923.78	44.98	-4.11%

1200	27566.18	70.55	27800.62	69.29	0.85%
1500	28184.76	92.42	28679.72	86	1.76%

Compared with v5.0.2, the Update Index performance of v5.1.0 is reduced by 1.8%.

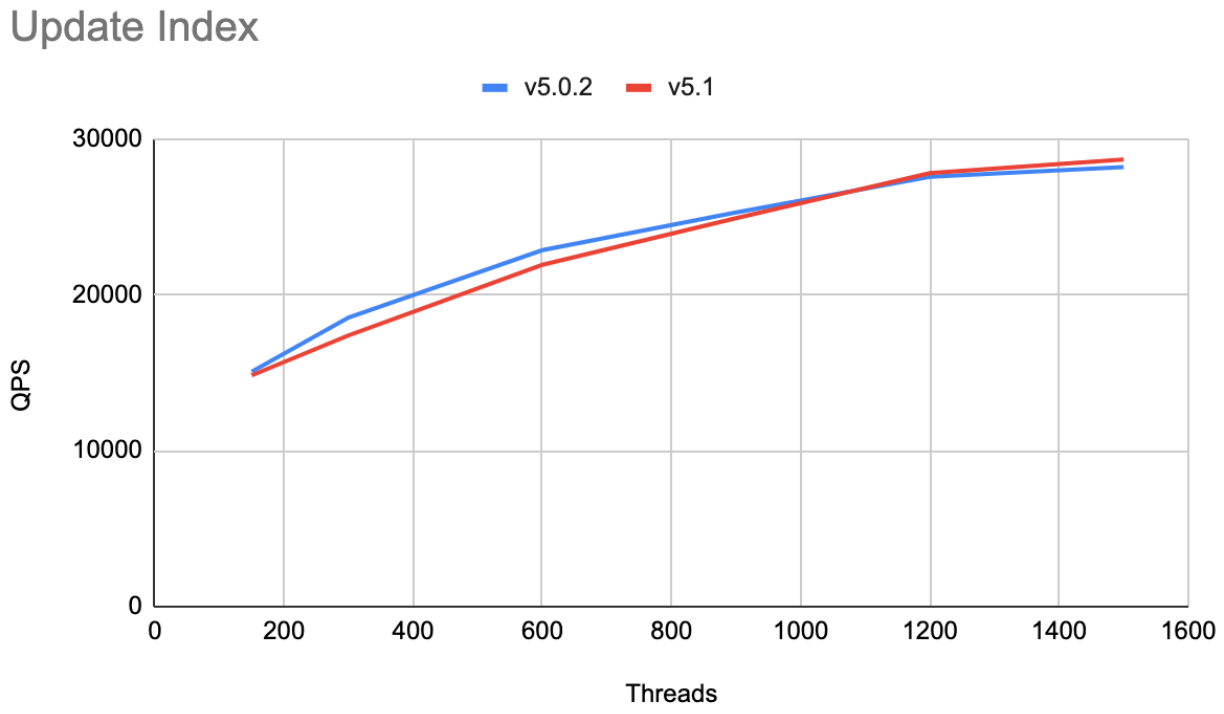

Figure 3: Update Index

2.5.1.4.4 Read Write performance

Threads	v5.0.2 QPS	v5.0.2 95% latency (ms)	v5.1.0 QPS	v5.1.0 95% latency (ms)	QPS improvement
150	66415.33	56.84	66591.49	57.87	0.27%
300	82488.39	97.55	81226.41	101.13	-1.53%
600	99195.36	173.58	97357.86	179.94	-1.85%
900	107382.76	253.35	101665.95	267.41	-5.32%
1200	112389.23	337.94	107426.41	350.33	-4.42%
1500	113548.73	450.77	109805.26	442.73	-3.30%

Compared with v5.0.2, the Read Write performance of v5.1.0 is reduced by 2.7%.

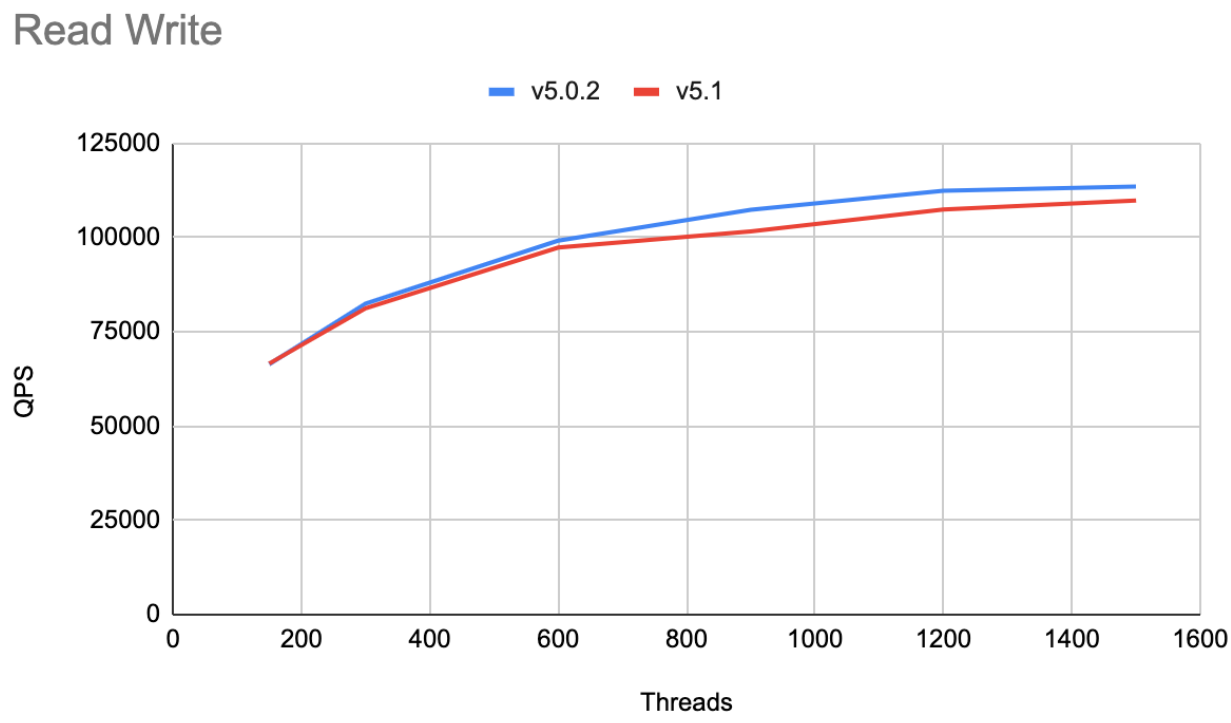

Figure 4: Read Write

2.5.2 TiDB TPC-C Performance Test Report – v5.1.0 vs. v5.0.2

2.5.2.1 Test overview

This test aims to compare the TPC-C performance of TiDB v5.1.0 and TiDB v5.0.2 in the online transactional processing (OLTP) scenario. The results show that compared with v5.0.2, the TPC-C performance of v5.1.0 is improved by 2.8%.

2.5.2.2 Test environment (AWS EC2)

2.5.2.3 Hardware configuration

Service type	EC2 type	Instance count
PD	m5.xlarge	3
TiKV	i3.4xlarge	3
TiDB	c5.4xlarge	3
TPC-C	c5.9xlarge	1

2.5.2.3.1 Software version

Service type	Software version
PD	v5.0.2 and v5.1.0
TiDB	v5.0.2 and v5.1.0
TiKV	v5.0.2 and v5.1.0
TiUP	1.5.1

2.5.2.3.2 Parameter configuration

TiDB v5.1.0 and TiDB v5.0.2 use the same configuration.

TiDB parameter configuration

```
log.level: "error"
performance.max-procs: 20
prepared-plan-cache.enabled: true
tikv-client.max-batch-wait-time: 2000000
```

TiKV parameter configuration

```
pessimistic-txn.pipelined: true
raftdb.allow-concurrent-memtable-write: true
raftdb.max-background-jobs: 4
raftstore.apply-max-batch-size: 2048
raftstore.apply-pool-size: 3
raftstore.store-max-batch-size: 2048
raftstore.store-pool-size: 3
readpool.storage.normal-concurrency: 10
readpool.unified.max-thread-count: 20
readpool.unified.min-thread-count: 5
rocksdb.max-background-jobs: 8
server.grpc-concurrency: 6
storage.scheduler-worker-pool-size: 20
server.enable-request-batch: false
```

TiDB global variable configuration

{

```
set global tidb_hashagg_final_concurrency=1;
set global tidb_hashagg_partial_concurrency=1;
set global tidb_enable_async_commit = 1;
set global tidb_enable_1pc = 1;
set global tidb_guarantee_linearizability = 0;
set global tidb_enable_clustered_index = 1;
```

2.5.2.4 Test plan

1. Deploy TiDB v5.1.0 and v5.0.2 using TiUP.
2. Create a database named `tpcc`: `create database tpcc;`.
3. Use BenchmarkSQL to import the TPC-C 5000 Warehouse data: `tiup bench tpcc prepare --warehouses 5000 --db tpcc -H 127.0.0.1 -P 4000`.
4. Execute the `tiup bench tpcc run -U root --db tpcc --host 127.0.0.1 --port 4000 --time 300s --warehouses 5000 --threads {{thread}}` command to perform stress tests on TiDB via HAProxy.
5. Extract the tpmC data of New Order from the result.

2.5.2.5 Test result

Compared with v5.0.2, the TPC-C performance of v5.1.0 is **improved by 2.8%**.

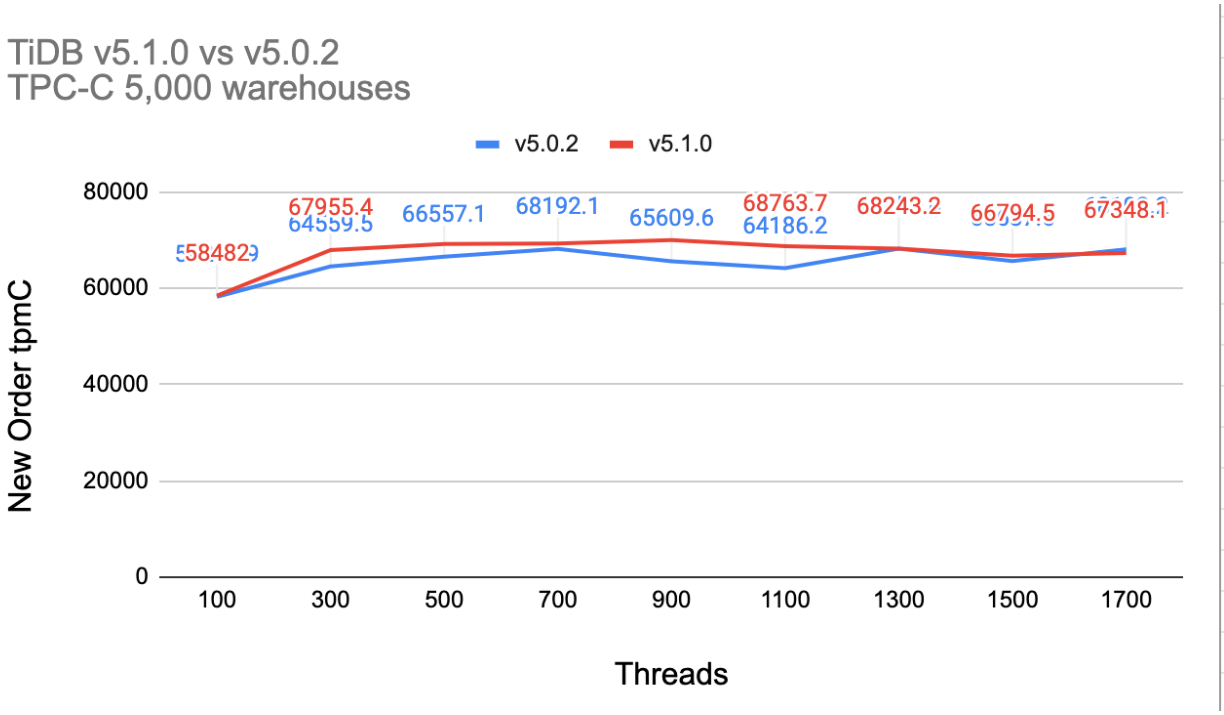

Figure 5: TPC-C

2.5.3 TiDB TPC-H 100GB Performance Test Report – TiDB v5.1 MPP mode vs. Greenplum 6.15.0 and Apache Spark 3.1.1

2.5.3.1 Test overview

This test aims at comparing the TPC-H 100GB performance of TiDB v5.1 in the MPP mode with that of Greenplum and Apache Spark, two mainstream analytics engines, in their

latest versions. The test result shows that the performance of TiDB v5.1 in the MPP mode is two to three times faster than that of the other two solutions under TPC-H workload.

In v5.0, TiDB introduces the MPP mode for TiFlash, which significantly enhances TiDB's Hybrid Transactional and Analytical Processing (HTAP) capabilities. Test objects in this report are as follows:

- TiDB v5.1 columnar storage in the MPP mode
- Greenplum 6.15.0
- Apache Spark 3.1.1 + Parquet

2.5.3.2 Test environment

2.5.3.2.1 Hardware prerequisite

- Node count: 3
- CPU: Intel(R) Xeon(R) CPU E5-2630 v4 @ 2.20GHz, 40 cores
- Memory: 189 GB
- Disks: NVMe 3TB * 2

2.5.3.2.2 Software version

Service type	Software version
TiDB	5.1
Greenplum	6.15.0
Apache Spark	3.1.1

2.5.3.2.3 Parameter configuration

TiDB v5.1

For the v5.1 cluster, TiDB uses the default parameter configuration except for the following configuration items.

In the configuration file `users.toml` of TiFlash, configure `max_memory_usage` as follows:

```
[profiles.default]
max_memory_usage = 10000000000000
```

Set session variables with the following SQL statements:

```
set @@tidb_isolation_read_engines='tiflash';
set @@tidb_allow_mpp=1;
set @@tidb_mem_quota_query = 10 << 30;
```

All TPC-H test tables are replicated to TiFlash in columnar format, with no additional partitions or indexes.

Greenplum

Except for the initial 3 nodes, the Greenplum cluster is deployed using an additional master node. Each segment server contains 8 segments, which means 4 segments per NVMe SSD. So there are 24 segments in total. The storage format is append-only/column-oriented storage and partition keys are used as primary keys.

```
log_statement = all
gp_autostats_mode = none
statement_mem = 2048MB
gp_vmem_protect_limit = 16384
```

Apache Spark

The test of Apache Spark uses Apache Parquet as the storage format and stores the data on HDFS. The HDFS system consists of three nodes. Each node has two assigned NVMe SSD disks as the data disks. The Spark cluster is deployed in standalone mode, using NVMe SSD disks as the local directory of `spark.local.dir` to speed up the shuffle spill, with no additional partitions or indexes.

```
--driver-memory 20G
--total-executor-cores 120
--executor-cores 5
--executor-memory 15G
```

2.5.3.3 Test result

Note:

The following test results are the average data of three tests. All numbers are in seconds.

Query ID	TiDB v5.1	Greenplum 6.15.0	Apache Spark 3.1.1 + Parquet
1	8.08	64.1307	52.64
2	2.53	4.76612	11.83
3	4.84	15.62898	13.39
4	10.94	12.88318	8.54
5	12.27	23.35449	25.23
6	1.32	6.033	2.21
7	5.91	12.31266	25.45

Query ID	TiDB v5.1	Greenplum 6.15.0	Apache Spark 3.1.1 + Parquet
8	6.71	11.82444	23.12
9	44.19	22.40144	35.2
10	7.13	12.51071	12.18
11	2.18	2.6221	10.99
12	2.88	7.97906	6.99
13	6.84	10.15873	12.26
14	1.69	4.79394	3.89
15	3.29	10.48785	9.82
16	5.04	4.64262	6.76
17	11.7	74.65243	44.65
18	12.87	64.87646	30.27
19	4.75	8.08625	4.7
20	8.89	15.47016	8.4
21	24.44	39.08594	34.83
22	1.23	7.67476	4.59

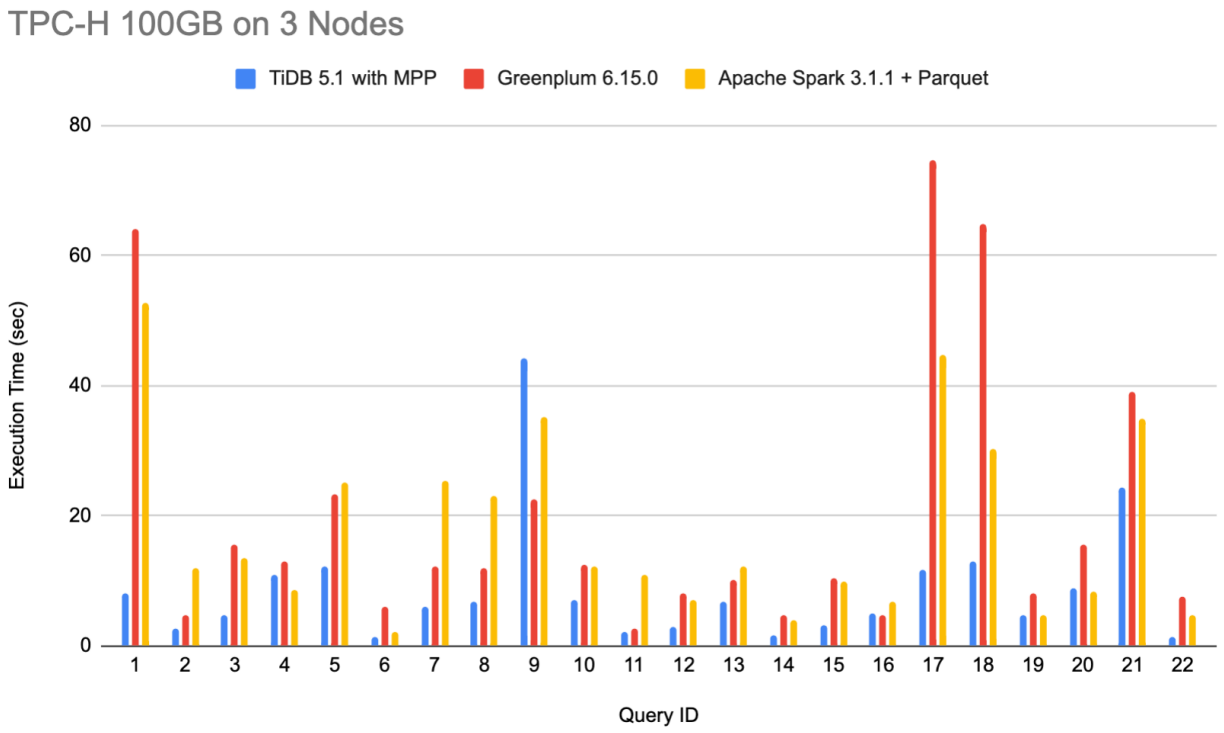

Figure 6: TPC-H

In the performance diagram above:

- Blue lines represent TiDB v5.1;

- Red lines represent Greenplum 6.15.0;
- Yellow lines represent Apache Spark 3.1.1.
- The y-axis represents the execution time of the query. The less the time is, the better the performance is.

2.6 MySQL Compatibility

TiDB is highly compatible with the MySQL 5.7 protocol and the common features and syntax of MySQL 5.7. The ecosystem tools for MySQL 5.7 (PHPMyAdmin, Navicat, MySQL Workbench, mysqldump, and Mydumper/myloader) and the MySQL client can be used for TiDB.

However, some features of MySQL are not supported. This could be because there is now a better way to solve the problem (such as XML functions superseded by JSON), or a lack of current demand versus effort required (such as stored procedures and functions). Some features might also be difficult to implement as a distributed system.

- In addition, TiDB does not support the MySQL replication protocol, but provides specific tools to replicate data with MySQL.
  - Replicate data from MySQL: TiDB Data Migration (DM) is a tool that supports the full data migration and the incremental data replication from MySQL/MariaDB into TiDB.
  - Replicate data to MySQL: TiCDC is a tool for replicating the incremental data of TiDB by pulling TiKV change logs. TiCDC uses the MySQL sink to replicate the incremental data of TiDB to MySQL.

> **Note:**
>
> This page refers to general differences between MySQL and TiDB. Refer to the dedicated pages for Security and Pessimistic Transaction Model compatibility.

2.6.1 Unsupported features

- Stored procedures and functions
- Triggers
- Events
- User-defined functions
- `FOREIGN KEY` constraints #18209
- Temporary tables #1248
- `FULLTEXT` syntax and indexes #1793
- `SPATIAL` (also known as `GIS`/`GEOMETRY`) functions, data types and indexes #6347

- Character sets other than `utf8`, `utf8mb4`, `ascii`, `latin1` and `binary`
- SYS schema
- Optimizer trace
- XML Functions
- X-Protocol #1109
- Savepoints #6840
- Column-level privileges #9766
- `XA` syntax (TiDB uses a two-phase commit internally, but this is not exposed via an SQL interface)
- `CREATE TABLE tblName AS SELECT stmt` syntax #4754
- `CHECK TABLE` syntax #4673
- `CHECKSUM TABLE` syntax #1895
- `GET_LOCK` and `RELEASE_LOCK` functions #14994
- `LOAD DATA` with the `REPLACE` keyword #24515

2.6.2 Features that are different from MySQL

2.6.2.1 Auto-increment ID

- In TiDB, auto-increment columns are only guaranteed to be unique and incremental on a single TiDB server, but they are *not* guaranteed to be incremental among multiple TiDB servers or allocated sequentially. It is recommended that you do not mix default values and custom values. Otherwise, you might encounter the `Duplicated Error` error message.
- You can use the `tidb_allow_remove_auto_inc` system variable to allow or forbid removing the `AUTO_INCREMENT` column attribute. The syntax of removing the column attribute is `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE`.
- TiDB does not support adding the `AUTO_INCREMENT` column attribute, and this attribute cannot be recovered once it is removed.
- See `AUTO_INCREMENT` for more details.

Note:

- If you have not specified the primary key when creating a table, TiDB uses `_tidb_rowid` to identify the row. The allocation of this value shares an allocator with the auto-increment column (if such a column exists). If you specify an auto-increment column as the primary key, TiDB uses this column to identify the row. In this situation, the following situation might happen:

```
mysql> CREATE TABLE t(id INT UNIQUE KEY AUTO_INCREMENT);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(),(),();
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0

mysql> SELECT _tidb_rowid, id FROM t;
+-------------+------+
| _tidb_rowid | id |
+-------------+------+
|           4 |    1 |
|           5 |    2 |
|           6 |    3 |
+-------------+------+
3 rows in set (0.01 sec)
```

2.6.2.2 Performance schema

TiDB uses a combination of Prometheus and Grafana to store and query the performance monitoring metrics. Performance schema tables return empty results in TiDB.

2.6.2.3 Query Execution Plan

The output format, output content, and the privilege setting of Query Execution Plan (`EXPLAIN`/`EXPLAIN FOR`) in TiDB is greatly different from those in MySQL.

The MySQL system variable `optimizer_switch` is read-only in TiDB and has no effect on query plans. You can also use optimizer hints in similar syntax to MySQL, but the available hints and implementation might differ.

See Understand the Query Execution Plan for more details.

2.6.2.4 Built-in functions

TiDB supports most of the MySQL built-in functions, but not all. The statement `SHOW BUILTINS` provides a list of functions that are available.

See also: TiDB SQL Grammar.

2.6.2.5 DDL

In TiDB, all supported DDL changes are performed online. Compared with DDL operations in MySQL, the DDL operations in TiDB have the following major restrictions:

- Multiple operations cannot be completed in a single `ALTER TABLE` statement. For example, it is not possible to add multiple columns or indexes in a single statement. Otherwise, the `Unsupported multi schema change` error might be output.
- `ALTER TABLE` in TiDB does not support the changes of some data types. For example, TiDB does not support the change from the `DECIMAL` type to the `DATE` type. If a data type change is unsupported, TiDB reports the `Unsupported modify column: type %d not match origin %d` error. Refer to ALTER TABLE for more details.
- The `ALGORITHM={INSTANT,INPLACE,COPY}` syntax functions only as an assertion in TiDB, and does not modify the `ALTER` algorithm. See ALTER TABLE for further details.
- Adding/Dropping the primary key of the `CLUSTERED` type is unsupported. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.
- TiDB supports `HASH`, `RANGE`, and `LIST` partitioning types. For an unsupported partition type, TiDB returns `Warning: Unsupported partition type, treat as normal table`.
- Table partitioning supports `ADD`, `DROP`, and `TRUNCATE` operations. Other partition operations are ignored. The following table partition syntaxes are not supported:
  - `PARTITION BY KEY`
  - `SUBPARTITION`
  - `{CHECK|OPTIMIZE|REPAIR|IMPORT|DISCARD|REBUILD|REORGANIZE|COALESCE} PARTITION`

2.6.2.6 Analyze table

Statistics Collection works differently in TiDB than in MySQL, in that it is a relatively lightweight and short-lived operation in MySQL/InnoDB, while in TiDB it completely rebuilds the statistics for a table and can take much longer to complete.

These differences are documented further in ANALYZE TABLE.

2.6.2.7 Limitations of `SELECT` syntax

- The syntax `SELECT ... INTO @variable` is not supported.
- The syntax `SELECT ... GROUP BY ... WITH ROLLUP` is not supported.
- The syntax `SELECT .. GROUP BY expr` does not imply `GROUP BY expr ORDER BY expr` as it does in MySQL 5.7.

For details, see the SELECT statement reference.

2.6.2.8 `UPDATE` statement

See the UPDATE statement reference.

2.6.2.9 Views

Views in TiDB are not updatable. They do not support write operations such as `UPDATE`, `INSERT`, and `DELETE`.

2.6.2.10 Storage engines

For compatibility reasons, TiDB supports the syntax to create tables with alternative storage engines. In implementation, TiDB describes the metadata as the InnoDB storage engine.

TiDB supports storage engine abstraction similar to MySQL, but you need to specify the storage engine using the `--store` option when you start the TiDB server.

2.6.2.11 SQL modes

TiDB supports most SQL modes:

- The compatibility modes, such as `ORACLE` and `POSTGRESQL` are parsed but ignored. Compatibility modes are deprecated in MySQL 5.7 and removed in MySQL 8.0.
- The `ONLY_FULL_GROUP_BY` mode has minor semantic differences from MySQL 5.7.
- The `NO_DIR_IN_CREATE` and `NO_ENGINE_SUBSTITUTION` SQL modes in MySQL are accepted for compatibility, but are not applicable to TiDB.

2.6.2.12 Default differences

- Default character set:
  - The default value in TiDB is `utf8mb4`.
  - The default value in MySQL 5.7 is `latin1`.
  - The default value in MySQL 8.0 is `utf8mb4`.
- Default collation:
  - The default collation of `utf8mb4` in TiDB is `utf8mb4_bin`.
  - The default collation of `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`.
  - The default collation of `utf8mb4` in MySQL 8.0 is `utf8mb4_0900_ai_ci`.
- Default value of `foreign_key_checks`:
  - The default value in TiDB is `OFF` and currently TiDB only supports `OFF`.
  - The default value in MySQL 5.7 is `ON`.
- Default SQL mode:
  - The default SQL mode in TiDB includes these modes: `ONLY_FULL_GROUP_BY,`
    ↪ `STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO`
    ↪ `,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`.
  - The default SQL mode in MySQL:
    * The default SQL mode in MySQL 5.7 is the same as TiDB.
    * The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`
      ↪ `,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_`
      ↪ `,NO_ENGINE_SUBSTITUTION`.

- Default value of `lower_case_table_names`:
  - The default value in TiDB is `2` and currently TiDB only supports `2`.
  - The default value in MySQL:
    * On Linux: `0`
    * On Windows: `1`
    * On macOS: `2`
- Default value of `explicit_defaults_for_timestamp`:
  - The default value in TiDB is `ON` and currently TiDB only supports `ON`.
  - The default value in MySQL:
    * For MySQL 5.7: `OFF`.
    * For MySQL 8.0: `ON`.

2.6.2.13 Date and Time

2.6.2.13.1 Named timezone

- TiDB uses all time zone rules currently installed in the system for calculation (usually the `tzdata` package). You can use all time zone names without importing the time zone table data. You cannot modify the calculation rules by importing the time zone table data.
- MySQL uses the local time zone by default and relies on the current time zone rules built into the system (such as when to start daylight saving time) for calculation; and the time zone cannot be specified by the time zone name without importing the time zone table data.

2.6.2.14 Type system differences

The following column types are supported by MySQL, but **NOT** by TiDB:

- FLOAT4/FLOAT8
- `SQL_TSI_*` (including SQL_TSI_MONTH, SQL_TSI_WEEK, SQL_TSI_DAY, SQL_TSI_HOUR, SQL_TSI_MINUTE and SQL_TSI_SECOND, excluding SQL_TSI_YEAR)

2.6.2.15 Incompatibility caused by deprecated features

TiDB does not implement certain features that have been marked as deprecated in MySQL, including:

- Specifying precision for floating point types. MySQL 8.0 deprecates this feature, and it is recommended to use the `DECIMAL` type instead.
- The `ZEROFILL` attribute. MySQL 8.0 deprecates this feature, and it is recommended to instead pad numeric values in your application.

2.7 TiDB Limitations

This document describes the common usage limitations of TiDB, including the maximum identifier length and the maximum number of supported databases, tables, indexes, partitioned tables, and sequences.

2.7.1 Limitations on identifier length

Identifier type	Maximum length (number of characters allowed)
Database	64
Table	64
Column	64
Index	64
View	64
Sequence	64

2.7.2 Limitations on the total number of databases, tables, views, and connections

Identifier type	Maximum number
Databases	unlimited
Tables	unlimited
Views	unlimited
Connections	unlimited

2.7.3 Limitations on a single database

Type	Upper limit
Tables	unlimited

2.7.4 Limitations on a single table

Type	Upper limit (default value)
Columns	Defaults to 1017 and can be adjusted up to 4096
Indexes	Defaults to 64 and can be adjusted up to 512
Rows	unlimited
Size	unlimited
Partitions	8192

- The upper limit of `Columns` can be modified via `table-column-count-limit`.
- The upper limit of `Indexes` can be modified via `index-limit`.

2.7.5 Limitation on a single row

Type	Upper limit
Size	6 MB by default. You can adjust the size limit via the `txn-entry-size-limit` configuration item.

2.7.6 Limitations on string types

Type	Upper limit
CHAR	256 characters
BINARY	256 characters
VARBINARY	65535 characters
VARCHAR	16383 characters
TEXT	6 MB
BLOB	6 MB

2.7.7 Limitations on SQL statements

Type	Upper limit
The maximum number of SQL statements in a single transaction	When the optimistic transaction is used and the transaction retry is enabled, the default upper limit is 5000, which can be modified using `stmt-count-limit`.

2.8 Credits

Each contributor has played an important role in promoting the robust development of TiDB. We sincerely appreciate all contributors who have submitted code, written and translated documents for TiDB.

2.8.1 TiDB developers

TiDB developers contribute to new feature development, performance improvement, stability guarantee, and bug fixes. The following is the list of contributors in TiDB related repos:

- pingcap/tidb
- tikv/tikv
- pingcap/parser
- tikv/pd
- pingcap/tidb-operator
- pingcap/tiup
- pingcap/br
- pingcap/dm
- pingcap/tidb-binlog
- pingcap/tidb-dashboard
- pingcap/tiflow
- pingcap/tidb-tools
- pingcap/tidb-lightning

- pingcap/tispark
- pingcap/dumpling
- tikv/client-java
- tidb-incubator/TiBigData
- ti-community-infra

2.8.2 Writers and translators for TiDB documentation

Writers and translators write and translate documents for TiDB and the related projects. The following is the list of contributors in TiDB documentation related repos:

- pingcap/docs-cn
- pingcap/docs
- pingcap/docs-tidb-operator
- pingcap/docs-dm
- tikv/website

3 Quick Start

3.1 Quick Start Guide for the TiDB Database Platform

This guide walks you through the quickest way to get started with TiDB. For non-production environments, you can deploy your TiDB database by either of the following methods:

- Deploy a local test cluster (for Mac and Linux)
- Simulate production deployment on a single machine (for Linux only)

Note:

- TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.
- The deployment method provided in this guide is **ONLY FOR** quick start, **NOT FOR** production.
  - To deploy a self-hosted production cluster, see production installation guide.
  - To deploy TiDB in Kubernetes, see Get Started with TiDB in Kubernetes.
  - To manage TiDB in the cloud, see TiDB Cloud Quick Start.

3.1.1 Deploy a local test cluster

- Scenario: Quickly deploy a local TiDB cluster for testing using a single Mac or Linux server. By deploying such a cluster, you can learn the basic architecture of TiDB and the operation of its components, such as TiDB, TiKV, PD, and the monitoring components.

> **Note:**
>
> Currently, some TiDB components do not have a released version that supports the Apple M1 chip. Therefore, the `tiup playground` command currently cannot be executed on the local Mac machine that uses the Apple M1 chip.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Declare the global environment variable:

> **Note:**
>
> After the installation, TiUP displays the absolute path of the corresponding `profile` file. You need to modify the following `source` command according to the path.

```
source .bash_profile
```

3. Start the cluster in the current session:

    - If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

```
tiup playground
```

- If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

```
tiup playground v5.1.5 --db 2 --pd 3 --kv 3 --monitor
```

The command downloads a version cluster to the local machine and starts it, such as v5.1.5. `--monitor` means that the monitoring component is also deployed.

To view the latest version, run `tiup list tidb`.

This command returns the access methods of the cluster:

```
CLUSTER START SUCCESSFULLY, Enjoy it ^-^
To connect TiDB: mysql --host 127.0.0.1 --port 4000 -u root
To connect TiDB: mysql --host 127.0.0.1 --port 4001 -u root
To view the dashboard: http://127.0.0.1:2379/dashboard
To view the monitor: http://127.0.0.1:9090
```

> **Note:**
> For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command. If you want the data to be persisted on storage, run `tiup --tag <your-tag> playground ...`. For details, refer to TiUP Reference Guide.

4. Start a new session to access TiDB:

   - Use the TiUP client to connect to TiDB.

   ```
   tiup client
   ```

   - You can also use the MySQL client to connect to TiDB.

   ```
   mysql --host 127.0.0.1 --port 4000 -u root
   ```

5. Access the Prometheus dashboard of TiDB at http://127.0.0.1:9090.
6. Access the TiDB Dashboard at http://127.0.0.1:2379/dashboard. The default username is `root`, with an empty password.
7. (Optional) Load data to TiFlash for analysis.
8. Clean up the cluster after the test deployment:

   1. Stop the process by pressing `ctrl-c`.
   2. Run the following command:

   ```
   tiup clean --all
   ```

Note:

TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Declare the global environment variable:

Note:

After the installation, TiUP displays the absolute path of the corresponding `profile` file. You need to modify the following `source` command according to the path.

```
source .bash_profile
```

3. Start the cluster in the current session:

   - If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

     ```
     tiup playground
     ```

   - If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

     ```
     tiup playground v5.1.5 --db 2 --pd 3 --kv 3 --monitor
     ```

     The command downloads a version cluster to the local machine and starts it, such as v5.1.5. `--monitor` means that the monitoring component is also deployed.

     To view the latest version, run `tiup list tidb`.

     This command returns the access methods of the cluster:

```
CLUSTER START SUCCESSFULLY, Enjoy it ^-^
To connect TiDB: mysql --host 127.0.0.1 --port 4000 -u root
To connect TiDB: mysql --host 127.0.0.1 --port 4001 -u root
To view the dashboard: http://127.0.0.1:2379/dashboard
To view the monitor: http://127.0.0.1:9090
```

> **Note:**
> For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command. If you want the data to be persisted on storage, run `tiup --tag <your-tag> playground ...`. For details, refer to TiUP Reference Guide.

4. Start a new session to access TiDB:

   - Use the TiUP client to connect to TiDB.

     ```
     tiup client
     ```

   - You can also use the MySQL client to connect to TiDB.

     ```
     mysql --host 127.0.0.1 --port 4000 -u root
     ```

5. Access the Prometheus dashboard of TiDB at http://127.0.0.1:9090.
6. Access the TiDB Dashboard at http://127.0.0.1:2379/dashboard. The default username is `root`, with an empty password.
7. (Optional) Load data to TiFlash for analysis.
8. Clean up the cluster after the test deployment:

   1. Stop the process by pressing `ctrl-c`.
   2. Run the following command:

      ```
      tiup clean --all
      ```

> **Note:**
>
> TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

3.1.2 Simulate production deployment on a single machine

- Scenario: Experience the smallest TiDB cluster with the complete topology and simulate the production deployment steps on a single Linux server.

This section describes how to deploy a TiDB cluster using a YAML file of the smallest topology in TiUP.

3.1.2.1 Prepare

Prepare a target machine that meets the following requirements:

- CentOS 7.3 or a later version is installed
- The Linux OS has access to the Internet, which is required to download TiDB and related software installation packages

The smallest TiDB cluster topology is as follows:

> **Note:**
>
> The IP address of the following instances only serves as an example IP. In your actual deployment, you need to replace the IP with your actual IP.

Instance	Count	IP	Configuration
TiKV	3	10.0.1.1 10.0.1.2 10.0.1.3	Avoid conflict between the port and the directory

Instance	Count	IP	Configuration
TiDB	1	10.0.1.1	The default port Global directory configuration
PD	1	10.0.1.1	The default port Global directory configuration
TiFlash	1	10.0.1.1	The default port Global directory configuration

Instance	Count	IP	Configuration
Monitor	1	10.0.1.1	The default port Global directory configuration

Other requirements for the target machine:

- The `root` user and its password is required
- Stop the firewall service of the target machine, or open the port needed by the TiDB cluster nodes
- Currently, the TiUP cluster supports deploying TiDB on the x86_64 (AMD64) and ARM architectures:
  - It is recommended to use CentOS 7.3 or later versions on AMD64
  - It is recommended to use CentOS 7.6 1810 on ARM

3.1.2.2 Deploy

> **Note:**
>
> You can log in to the target machine as a regular user or the `root` user. The following steps use the `root` user as an example.

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Declare the global environment variable.

> **Note:**
> After the installation, TiUP displays the absolute path of the corresponding `profile` file. You need to modify the following `source` command according to the path.

```
source .bash_profile
```

3. Install the cluster component of TiUP:

```
tiup cluster
```

4. If the TiUP cluster is already installed on the machine, update the software version:

```
tiup update --self && tiup update cluster
```

5. Use the `root` user privilege to increase the connection limit of the `sshd` service. This is because TiUP needs to simulate deployment on multiple machines.

    1. Modify `/etc/ssh/sshd_config`, and set `MaxSessions` to `20`.
    2. Restart the `sshd` service:

    ```
    service sshd restart
    ```

6. Create and start the cluster:

    Edit the configuration file according to the following template, and name it as `topo.yaml`:

```
# # Global variables are applied to all deployments and used as the default value of
# # the deployments if a specific deployment value is missing.
global:
 user: "tidb"
 ssh_port: 22
 deploy_dir: "/tidb-deploy"
 data_dir: "/tidb-data"

# # Monitored variables are applied to all the machines.
monitored:
 node_exporter_port: 9100
 blackbox_exporter_port: 9115
```

```
server_configs:
 tidb:
   log.slow-threshold: 300
 tikv:
   readpool.storage.use-unified-pool: false
   readpool.coprocessor.use-unified-pool: true
 pd:
   replication.enable-placement-rules: true
   replication.location-labels: ["host"]
 tiflash:
   logger.level: "info"

pd_servers:
 - host: 10.0.1.1

tidb_servers:
 - host: 10.0.1.1

tikv_servers:
 - host: 10.0.1.1
   port: 20160
   status_port: 20180
   config:
     server.labels: { host: "logic-host-1" }

 - host: 10.0.1.1
   port: 20161
   status_port: 20181
   config:
     server.labels: { host: "logic-host-2" }

 - host: 10.0.1.1
   port: 20162
   status_port: 20182
   config:
     server.labels: { host: "logic-host-3" }

tiflash_servers:
 - host: 10.0.1.1

monitoring_servers:
 - host: 10.0.1.1

grafana_servers:
 - host: 10.0.1.1
```

- `user: "tidb"`: Use the `tidb` system user (automatically created during deployment) to perform the internal management of the cluster. By default, use port 22 to log in to the target machine via SSH.
- `replication.enable-placement-rules`: This PD parameter is set to ensure that TiFlash runs normally.
- `host`: The IP of the target machine.

7. Execute the cluster deployment command:

```
tiup cluster deploy <cluster-name> <tidb-version> ./topo.yaml --user
    ↪ root -p
```

- `<cluster-name>`: Set the cluster name
- `<tidb-version>`: Set the TiDB cluster version. You can see all the supported TiDB versions by running the `tiup list tidb` command

Enter "y" and the `root` user's password to complete the deployment:

```
Do you want to continue? [y/N]: y
Input SSH password:
```

8. Start the cluster:

```
tiup cluster start <cluster-name>
```

9. Access the cluster:

- Install the MySQL client. If it is already installed, skip this step.

```
yum -y install mysql
```

- Access TiDB. The password is empty:

```
mysql -h 10.0.1.1 -P 4000 -u root
```

- Access the Grafana monitoring dashboard at http://%7Bgrafana-ip%7D:3000. The default username and password are both `admin`.
- Access the TiDB Dashboard at http://%7Bpd-ip%7D:2379/dashboard. The default username is `root`, and the password is empty.
- To view the currently deployed cluster list:

```
tiup cluster list
```

- To view the cluster topology and status:

```
tiup cluster display <cluster-name>
```

3.1.3 What's next

- If you have just deployed a TiDB cluster for the local test environment:
  - Learn Basic SQL operations in TiDB
  - Migrate data to TiDB
- If you are ready to deploy a TiDB cluster for the production environment:
  - Deploy TiDB using TiUP
  - Deploy TiDB on Cloud using TiDB Operator
- If you're looking for analytics solution with TiFlash:
  - Use TiFlash
  - TiFlash Overview

3.2 Explore SQL with TiDB

TiDB is compatible with MySQL, you can use MySQL statements directly in most of the cases. For unsupported features, see Compatibility with MySQL.

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can run TiDB directly in your web browser without installing it. You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML and CRUD operations. For a complete list of TiDB statements, see TiDB SQL Syntax Diagram.

3.2.1 Category

SQL is divided into the following 4 types according to their functions:

- DDL (Data Definition Language): It is used to define database objects, including databases, tables, views, and indexes.
- DML (Data Manipulation Language): It is used to manipulate application related records.
- DQL (Data Query Language): It is used to query the records after conditional filtering.
- DCL (Data Control Language): It is used to define access privileges and security levels.

Common DDL features are creating, modifying, and deleting objects (such as tables and indexes). The corresponding commands are `CREATE`, `ALTER`, and `DROP`.

3.2.2 Show, create and drop a database

A database in TiDB can be considered as a collection of objects such as tables and indexes.

To show the list of databases, use the `SHOW DATABASES` statement:

```
SHOW DATABASES;
```

To use the database named `mysql`, use the following statement:

```
USE mysql;
```

To show all the tables in a database, use the `SHOW TABLES` statement:

```
SHOW TABLES FROM mysql;
```

To create a database, use the `CREATE DATABASE` statement:

```
CREATE DATABASE db_name [options];
```

To create a database named `samp_db`, use the following statement:

```
CREATE DATABASE IF NOT EXISTS samp_db;
```

Add `IF NOT EXISTS` to prevent an error if the database exists.

To delete a database, use the `DROP DATABASE` statement:

```
DROP DATABASE samp_db;
```

3.2.3 Create, show, and drop a table

To create a table, use the `CREATE TABLE` statement:

```
CREATE TABLE table_name column_name data_type constraint;
```

For example, to create a table named `person` which includes fields such as number, name, and birthday, use the following statement:

```
CREATE TABLE person (
    id INT(11),
    name VARCHAR(255),
    birthday DATE
    );
```

To view the statement that creates the table (DDL), use the `SHOW CREATE` statement:

```
SHOW CREATE table person;
```

To delete a table, use the `DROP TABLE` statement:

```
DROP TABLE person;
```

3.2.4 Create, show, and drop an index

Indexes are used to speed up queries on indexed columns. To create an index for the column whose value is not unique, use the `CREATE INDEX` statement:

```
CREATE INDEX person_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD INDEX person_id (id);
```

To create a unique index for the column whose value is unique, use the `CREATE UNIQUE INDEX` statement:

```
CREATE UNIQUE INDEX person_unique_id ON person (id);
```

Or use the `ALTER TABLE` statement:

```
ALTER TABLE person ADD UNIQUE person_unique_id (id);
```

To show all the indexes in a table, use the `SHOW INDEX` statement:

```
SHOW INDEX FROM person;
```

To delete an index, use the `DROP INDEX` or `ALTER TABLE` statement. `DROP INDEX` can be nested in `ALTER TABLE`:

```
DROP INDEX person_id ON person;
```

```
ALTER TABLE person DROP INDEX person_unique_id;
```

> **Note:**
>
> DDL operations are not transactions. You don't need to run a `COMMIT` statement when executing DDL operations.

3.2.5 Insert, update, and delete data

Common DML features are adding, modifying, and deleting table records. The corresponding commands are `INSERT`, `UPDATE`, and `DELETE`.

To insert data into a table, use the `INSERT` statement:

```
INSERT INTO person VALUES(1,'tom','20170912');
```

To insert a record containing data of some fields into a table, use the `INSERT` statement:

```
INSERT INTO person(id,name) VALUES('2','bob');
```

To update some fields of a record in a table, use the `UPDATE` statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

> **Note:**
>
> The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

3.2.6 Query data

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
+------+
| name |
+------+
| tom |
+------+
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person where id<5;
```

3.2.7 Create, authorize, and delete a user

DCL are usually used to create or delete users, and manage user privileges.

To create a user, use the `CREATE USER` statement. The following example creates a user named `tiuser` with the password `123456`:

```
CREATE USER 'tiuser'@'localhost' IDENTIFIED BY '123456';
```

To grant `tiuser` the privilege to retrieve the tables in the `samp_db` database:

```
GRANT SELECT ON samp_db.* TO 'tiuser'@'localhost';
```

To check the privileges of `tiuser`:

```
SHOW GRANTS for tiuser@localhost;
```

To delete `tiuser`:

```
DROP USER 'tiuser'@'localhost';
```

3.3 Import Example Database

Examples used in the TiDB manual use System Data from Capital Bikeshare, released under the Capital Bikeshare Data License Agreement.

3.3.1 Download all data files

The system data is available for download in .zip files organized per year. Downloading and extracting all files requires approximately 3GB of disk space. To download all files for years 2010-2017 using a bash script:

```
mkdir -p bikeshare-data && cd bikeshare-data

curl -L --remote-name-all https://s3.amazonaws.com/capitalbikeshare-data
    ↪ /{2010..2017}-capitalbikeshare-tripdata.zip
unzip \*-tripdata.zip
```

3.3.2 Load data into TiDB

The system data can be imported into TiDB using the following schema:

```
CREATE DATABASE bikeshare;
USE bikeshare;

CREATE TABLE trips (
```

```
 trip_id bigint NOT NULL PRIMARY KEY AUTO_INCREMENT,
 duration integer not null,
 start_date datetime,
 end_date datetime,
 start_station_number integer,
 start_station varchar(255),
 end_station_number integer,
 end_station varchar(255),
 bike_number varchar(255),
 member_type varchar(255)
);
```

You can import files individually using the example `LOAD DATA` command here, or import all files using the bash loop below:

```
SET tidb_dml_batch_size = 20000;
LOAD DATA LOCAL INFILE '2017Q1-capitalbikeshare-tripdata.csv' INTO TABLE
    ↪ trips
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES
(duration, start_date, end_date, start_station_number, start_station,
end_station_number, end_station, bike_number, member_type);
```

3.3.2.1 Import all files

> **Note:**
>
> When you start the MySQL client, use the `--local-infile=1` option.

To import all `*.csv` files into TiDB in a bash loop:

```
for FILE in *.csv; do
 echo "== $FILE =="
 mysql bikeshare --local-infile=1 -e "SET tidb_dml_batch_size = 20000; LOAD
    ↪ DATA LOCAL INFILE '${FILE}' INTO TABLE trips FIELDS TERMINATED BY

```

4 Deploy

4.1 Software and Hardware Recommendations

As an open source distributed NewSQL database with high performance, TiDB can be deployed in the Intel architecture server, ARM architecture server, and major virtualization environments and runs well. TiDB supports most of the major hardware networks and Linux operating systems.

4.1.1 Linux OS version requirements

Linux OS Platform	Version
Red Hat Enterprise Linux	7.3 or later 7.x releases
CentOS	7.3 or later 7.x releases
Oracle Enterprise Linux	7.3 or later 7.x releases
Ubuntu LTS	16.04 or later

Note:

- For Oracle Enterprise Linux, TiDB supports the Red Hat Compatible Kernel (RHCK) and does not support the Unbreakable Enterprise Kernel provided by Oracle Enterprise Linux.
- A large number of TiDB tests have been run on the CentOS 7.3 system, and in our community there are a lot of best practices in which TiDB is deployed on the Linux operating system. Therefore, it is recommended to deploy TiDB on CentOS 7.3 or later.
- The support for the Linux operating systems above includes the deployment and operation in physical servers as well as in major virtualized environments like VMware, KVM and XEN.
- Red Hat Enterprise Linux 8.0, CentOS 8 Stream, and Oracle Enterprise Linux 8.0 are not supported yet as the testing of these platforms is in progress.
- Support for CentOS 8 Linux is not planned because its upstream support ends on December 31, 2021.
- Support for Ubuntu 16.04 will be removed in future versions of TiDB. Upgrading to Ubuntu 18.04 or later is strongly recommended.

Other Linux OS versions such as Debian Linux and Fedora Linux might work but are not officially supported.

4.1.2 Software recommendations

4.1.2.1 Control machine

Software	Version
sshpass	1.06 or later
TiUP	1.5.0 or later

> **Note:**
>
> It is required that you deploy TiUP on the control machine to operate and manage TiDB clusters.

4.1.2.2 Target machines

Software	Version
sshpass	1.06 or later
numa	2.0.12 or later
tar	any

4.1.3 Server recommendations

You can deploy and run TiDB on the 64-bit generic hardware server platform in the Intel x86-64 architecture or on the hardware server platform in the ARM architecture. The requirements and recommendations about server hardware configuration (ignoring the resources occupied by the operating system itself) for development, test, and production environments are as follows:

4.1.3.1 Development and test environments

Component	CPU	Memory	Local Storage	Network	Instance Number (Minimum Requirement)
TiDB	8 core+	16 GB+	No special requirements	Gigabit network card	1 (can be deployed on the same machine with PD)

Component	CPU	Memory	Local Storage	Network	Instance Number (Minimum Requirement)
PD	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1 (can be deployed on the same machine with TiDB)
TiKV	8 core+	32 GB+	SAS, 200 GB+	Gigabit network card	3
TiFlash	32 core+	64 GB+	SSD, 200 GB+	Gigabit network card	1
TiCDC	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the test environment, the TiDB and PD instances can be deployed on the same server.
- For performance-related test, do not use low-performance storage and network hardware configuration, in order to guarantee the correctness of the test result.
- For the TiKV server, it is recommended to use NVMe SSDs to ensure faster reads and writes.
- If you only want to test and verify the features, follow Quick Start Guide for TiDB to deploy TiDB on a single machine.
- The TiDB server uses the disk to store server logs, so there are no special requirements for the disk type and capacity in the test environment.

4.1.3.2 Production environment

Component	CPU	Memory	Hard Disk Type	Network	Instance N
TiDB	16 core+	32 GB+	SAS	10 Gigabit network card (2 preferred)	
PD	4 core+	8 GB+	SSD	10 Gigabit network card (2 preferred)	
TiKV	16 core+	32 GB+	SSD	10 Gigabit network card (2 preferred)	
TiFlash	48 core+	128 GB+	1 or more SSDs	10 Gigabit network card (2 preferred)	
TiCDC	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
Monitor	8 core+	16 GB+	SAS	Gigabit network card	

Component	CPU	Memory	Hard Disk Type	Network	Instance N

Note:

- In the production environment, the TiDB and PD instances can be deployed on the same server. If you have a higher requirement for performance and reliability, try to deploy them separately.
- It is strongly recommended to use higher configuration in the production environment.
- It is recommended to keep the size of TiKV hard disk within 2 TB if you are using PCIe SSDs or within 1.5 TB if you are using regular SSDs.

Before you deploy TiFlash, note the following items:

- TiFlash can be deployed on multiple disks.
- It is recommended to use a high-performance SSD as the first disk of the TiFlash data directory to buffer the real-time replication of TiKV data. The performance of this disk should not be lower than that of TiKV, such as PCI-E SSD. The disk capacity should be no less than 10% of the total capacity; otherwise, it might become the bottleneck of this node. You can deploy ordinary SSDs for other disks, but note that a better PCI-E SSD brings better performance.
- It is recommended to deploy TiFlash on different nodes from TiKV. If you must deploy TiFlash and TiKV on the same node, increase the number of CPU cores and memory, and try to deploy TiFlash and TiKV on different disks to avoid interfering each other.
- The total capacity of the TiFlash disks is calculated in this way: `the data volume of the entire TiKV cluster to be replicated / the number of TiKV replicas * the number of TiFlash replicas`. For example, if the overall planned capacity of TiKV is 1 TB, the number of TiKV replicas is 3, and the number of TiFlash replicas is 2, then the recommended total capacity of TiFlash is `1024 GB / 3 * 2`. You can replicate only the data of some tables. In such case, determine the TiFlash capacity according to the data volume of the tables to be replicated.

Before you deploy TiCDC, note that it is recommended to deploy TiCDC on PCIe-SSD disks larger than 1 TB.

4.1.4 Network requirements

As an open source distributed NewSQL database, TiDB requires the following network port configuration to run. Based on the TiDB deployment in actual environments, the administrator can open relevant ports in the network side and host side.

Component	Default Port	Description
TiDB	4000	the communication port for the application and DBA tools
TiDB	10080	the communication port to report TiDB status
TiKV	20160	the TiKV communication port

Component	Default Port	Description
TiKV	20180	the communication port to report TiKV status
PD	2379	the communication port between TiDB and PD
PD	2380	the internode communication port within the PD cluster

Component	Default Port	Description
TiFlash	9000	the TiFlash TCP service port
TiFlash	8123	the TiFlash HTTP service port
TiFlash	3930	the TiFlash RAFT and Coprocessor service port
TiFlash	20170	the TiFlash Proxy service port

Component	Default Port	Description
TiFlash	20292	the port for Prometheus to pull TiFlash Proxy metrics
TiFlash	8234	the port for Prometheus to pull TiFlash metrics
Pump	8250	the Pump communication port
Drainer	8249	the Drainer communication port
TiCDC	8300	the TiCDC communication port

Component	Default Port	Description
Prometheus	9090	the communication port for the Prometheus service
Node_exporter	9100	the communication port to report the system information of every TiDB cluster node

Component	Default Port	Description
Blackbox_exporter	9115	the Blackbox_exporter communication port, used to monitor the ports in the TiDB cluster
Grafana	3000	the port for the external Web monitoring service and client (Browser) access

Component	Default Port	Description
Alertmanager	9093	the port for the alert web service
Alertmanager	9094	the alert communication port

4.1.5 Web browser requirements

TiDB relies on Grafana to provide visualization of database metrics. A recent version of Internet Explorer, Chrome or Firefox with Javascript enabled is sufficient.

4.2 TiDB Environment and System Configuration Check

This document describes the environment check operations before deploying TiDB. The following steps are ordered by priorities.

4.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV

For production deployments, it is recommended to use NVMe SSD of EXT4 filesystem to store TiKV data. This configuration is the best practice, whose reliability, security, and stability have been proven in a large number of online scenarios.

Log in to the target machines using the `root` user account.

Format your data disks to the ext4 filesystem and add the `nodelalloc` and `noatime` mount options to the filesystem. It is required to add the `nodelalloc` option, or else the TiUP deployment cannot pass the precheck. The `noatime` option is optional.

> **Note:**
>
> If your data disks have been formatted to ext4 and have added the mount options, you can uninstall it by running the `umount /dev/nvme0n1p1` command, skip directly to the fifth step below to edit the `/etc/fstab` file, and add the options again to the filesystem.

Take the `/dev/nvme0n1` data disk as an example:

1. View the data disk.

```
fdisk -l
```

```
Disk /dev/nvme0n1: 1000 GB
```

2. Create the partition.

```
parted -s -a optimal /dev/nvme0n1 mklabel gpt -- mkpart primary ext4 1
    ↪ -1
```

> **Note:**
>
> Use the `lsblk` command to view the device number of the partition: for a NVMe disk, the generated device number is usually `nvme0n1p1`; for a regular disk (for example, `/dev/sdb`), the generated device number is usually `sdb1`.

3. Format the data disk to the ext4 filesystem.

```
mkfs.ext4 /dev/nvme0n1p1
```

4. View the partition UUID of the data disk.

   In this example, the UUID of nvme0n1p1 is `c51eb23b-195c-4061-92a9-3
   ↪ fad812cc12f`.

```
lsblk -f
```

```
NAME   FSTYPE LABEL UUID                                 MOUNTPOINT
sda
 ─sda1 ext4        237b634b-a565-477b-8371-6dff0c41f5ab /boot
 ─sda2 swap        f414c5c0-f823-4bb1-8fdf-e531173a72ed
 ─sda3 ext4        547909c1-398d-4696-94c6-03e43e317b60 /
```

```
sr0
nvme0n1
 ─nvme0n1p1 ext4       c51eb23b-195c-4061-92a9-3fad812cc12f
```

5. Edit the `/etc/fstab` file and add the `nodelalloc` mount options.

```
vi /etc/fstab
```

```
UUID=c51eb23b-195c-4061-92a9-3fad812cc12f /data1 ext4 defaults,
    ↪ nodelalloc,noatime 0 2
```

6. Mount the data disk.

```
mkdir /data1 && \
mount -a
```

7. Check using the following command.

```
mount -t ext4
```

```
/dev/nvme0n1p1 on /data1 type ext4 (rw,noatime,nodelalloc,data=ordered)
```

If the filesystem is ext4 and `nodelalloc` is included in the mount options, you have successfully mount the data disk ext4 filesystem with options on the target machines.

4.2.2 Check and disable system swap

TiDB needs sufficient memory space for operation. When memory is insufficient, using swap as a buffer might degrade performance. Therefore, it is recommended to disable the system swap permanently by executing the following commands:

```
echo "vm.swappiness = 0">> /etc/sysctl.conf
swapoff -a && swapon -a
sysctl -p
```

Note:

- Executing `swapoff -a` and then `swapon -a` is to refresh swap by dumping data to memory and cleaning up swap. If you drop the swappiness change and execute only `swapoff -a`, swap will be enabled again after you restart the system.
- `sysctl -p` is to make the configuration effective without restarting the system.

4.2.3 Check and stop the firewall service of target machines

In TiDB clusters, the access ports between nodes must be open to ensure the transmission of information such as read and write requests and data heartbeats. In common online scenarios, the data interaction between the database and the application service and between the database nodes are all made within a secure network. Therefore, if there are no special security requirements, it is recommended to stop the firewall of the target machine. Otherwise, refer to the port usage and add the needed port information to the allowlist of the firewall service.

The rest of this section describes how to stop the firewall service of a target machine.

1. Check the firewall status. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo firewall-cmd --state
sudo systemctl status firewalld.service
```

2. Stop the firewall service.

```
sudo systemctl stop firewalld.service
```

3. Disable automatic start of the firewall service.

```
sudo systemctl disable firewalld.service
```

4. Check the firewall status.

```
sudo systemctl status firewalld.service
```

4.2.4 Check and install the NTP service

TiDB is a distributed database system that requires clock synchronization between nodes to guarantee linear consistency of transactions in the ACID model.

At present, the common solution to clock synchronization is to use the Network Time Protocol (NTP) services. You can use the `pool.ntp.org` timing service on the Internet, or build your own NTP service in an offline environment.

To check whether the NTP service is installed and whether it synchronizes with the NTP server normally, take the following steps:

1. Run the following command. If it returns `running`, then the NTP service is running.

```
sudo systemctl status ntpd.service
```

```
ntpd.service - Network Time Service
Loaded: loaded (/usr/lib/systemd/system/ntpd.service; disabled; vendor
    ↪ preset: disabled)
Active: active (running) since — 2017-12-18 13:13:19 CST; 3s ago
```

- If it returns `Unit ntpd.service could not be found.`, then try the following command to see whether your system is configured to use `chronyd` instead of `ntpd` to perform clock synchronization with NTP:

  ```
  sudo systemctl status chronyd.service
  ```

  ```
  chronyd.service - NTP client/server
  Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled;
      ↪ vendor preset: enabled)
  Active: active (running) since Mon 2021-04-05 09:55:29 EDT; 3 days
      ↪ ago
  ```

  If the result shows that neither `chronyd` nor `ntpd` is configured, it means that neither of them is installed in your system. You should first install `chronyd` or `ntpd` and ensure that it can be automatically started. By default, `ntpd` is used.

  If your system is configured to use `chronyd`, proceed to step 3.

2. Run the `ntpstat` command to check whether the NTP service synchronizes with the NTP server.

> **Note:**
> For the Ubuntu system, you need to install the `ntpstat` package.

```
ntpstat
```

- If it returns `synchronised to NTP server` (synchronizing with the NTP server), then the synchronization process is normal.

  ```
  synchronised to NTP server (85.199.214.101) at stratum 2
  time correct to within 91 ms
  polling server every 1024 s
  ```

- The following situation indicates the NTP service is not synchronizing normally:

  ```
  unsynchronised
  ```

- The following situation indicates the NTP service is not running normally:

```
Unable to talk to NTP daemon. Is it running?
```

3. Run the `chronyc tracking` command to check wheter the Chrony service synchronizes with the NTP server.

> **Note:**
> This only applies to systems that use Chrony instead of NTPd.

```
chronyc tracking
```

- If the command returns `Leap status     : Normal`, the synchronization process is normal.

```
Reference ID    : 5EC69F0A (ntp1.time.nl)
Stratum         : 2
Ref time (UTC)  : Thu May 20 15:19:08 2021
System time     : 0.000022151 seconds slow of NTP time
Last offset     : -0.000041040 seconds
RMS offset      : 0.000053422 seconds
Frequency       : 2.286 ppm slow
Residual freq   : -0.000 ppm
Skew            : 0.012 ppm
Root delay      : 0.012706812 seconds
Root dispersion : 0.000430042 seconds
Update interval : 1029.8 seconds
Leap status     : Normal
```

- If the command returns the following result, an error occurs in the synchronization:

```
Leap status     : Not synchronised
```

- If the command returns the following result, the `chronyd` service is not running normally:

```
506 Cannot talk to daemon
```

To make the NTP service start synchronizing as soon as possible, run the following command. Replace `pool.ntp.org` with your NTP server.

```
sudo systemctl stop ntpd.service && \
sudo ntpdate pool.ntp.org && \
sudo systemctl start ntpd.service
```

To install the NTP service manually on the CentOS 7 system, run the following command:

```
sudo yum install ntp ntpdate && \
sudo systemctl start ntpd.service && \
sudo systemctl enable ntpd.service
```

4.2.5 Check and configure the optimal parameters of the operating system

For TiDB in the production environment, it is recommended to optimize the operating system configuration in the following ways:

1. Disable THP (Transparent Huge Pages). The memory access pattern of databases tends to be sparse rather than consecutive. If the high-level memory fragmentation is serious, higher latency will occur when THP pages are allocated.
2. Set the I/O Scheduler of the storage media to `noop`. For the high-speed SSD storage media, the kernel's I/O scheduling operations can cause performance loss. After the Scheduler is set to `noop`, the performance is better because the kernel directly sends I/O requests to the hardware without other operations. Also, the noop Scheduler is better applicable.
3. Choose the `performance` mode for the cpufrequ module which controls the CPU frequency. The performance is maximized when the CPU frequency is fixed at its highest supported operating frequency without dynamic adjustment.

Take the following steps to check the current operating system configuration and configure optimal parameters:

1. Execute the following command to see whether THP is enabled or disabled:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
[always] madvise never
```

> **Note:**
>
> If `[always] madvise never` is output, THP is enabled. You need to disable it.

2. Execute the following command to see the I/O Scheduler of the disk where the data directory is located. Assume that you create data directories on both sdb and sdc disks:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
noop [deadline] cfq
noop [deadline] cfq
```

> **Note:**
>
> If `noop [deadline] cfq` is output, the I/O Scheduler for the disk is in the `deadline` mode. You need to change it to `noop`.

3. Execute the following command to see the `ID_SERIAL` of the disk:

```
udevadm info --name=/dev/sdb | grep ID_SERIAL
```

```
E: ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81
E: ID_SERIAL_SHORT=6d0946606d79f90025f3e09a0c1f9e81
```

> **Note:**
>
> If multiple disks are allocated with data directories, you need to execute the above command several times to record the `ID_SERIAL` of each disk.

4. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
```

```
analyzing CPU 0:
current policy: frequency should be within 1.20 GHz and 3.10 GHz.
            The governor "powersave" may decide which speed to use
               ↪ within this range.
```

> **Note:**
>
> If `The governor "powersave"` is output, the power policy of the cpufreq module is `powersave`. You need to modify it to `performance`. If you use a virtual machine or a cloud host, the output is usually `Unable to` ↪ `determine current policy`, and you do not need to change anything.

5. Configure optimal parameters of the operating system:

    - Method one: Use tuned (Recommended)

1. Execute the `tuned-adm list` command to see the tuned profile of the current operating system:

```
tuned-adm list
```

```
Available profiles:
- balanced                  - General non-specialized tuned
    ↪ profile
- desktop                   - Optimize for the desktop use-case
- hpc-compute               - Optimize for HPC compute workloads
- latency-performance       - Optimize for deterministic
    ↪ performance at the cost of increased power consumption
- network-latency           - Optimize for deterministic
    ↪ performance at the cost of increased power consumption,
    ↪ focused on low latency network performance
- network-throughput        - Optimize for streaming network
    ↪ throughput, generally only necessary on older CPUs or 40G
    ↪ + networks
- powersave                 - Optimize for low power consumption
- throughput-performance    - Broadly applicable tuning that
    ↪ provides excellent performance across a variety of common
    ↪  server workloads
- virtual-guest             - Optimize for running inside a
    ↪ virtual guest
- virtual-host              - Optimize for running KVM guests
Current active profile: balanced
```

   The output `Current active profile: balanced` means that the tuned profile of the current operating system is `balanced`. It is recommended to optimize the configuration of the operating system based on the current profile.

2. Create a new tuned profile:

```
mkdir /etc/tuned/balanced-tidb-optimal/
vi /etc/tuned/balanced-tidb-optimal/tuned.conf
```

```
[main]
include=balanced

[cpu]
governor=performance

[vm]
transparent_hugepages=never

[disk]
devices_udev_regex=(ID_SERIAL=36d0946606d79f90025f3e09a0c1fc035
    ↪ )|(ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81)
```

```
elevator=noop
```

The output `include=balanced` means to add the optimization configuration of the operating system to the current `balanced` profile.

3. Apply the new tuned profile:

```
tuned-adm profile balanced-tidb-optimal
```

- Method two: Configure using scripts. Skip this method if you already use method one.

1. Execute the `grubby` command to see the default kernel version:

> **Note:**
> Install the `grubby` package first before you execute `grubby`.

```
grubby --default-kernel
```

```
/boot/vmlinuz-3.10.0-957.el7.x86_64
```

2. Execute `grubby --update-kernel` to modify the kernel configuration:

```
grubby --args="transparent_hugepage=never" --update-kernel /
    ↪ boot/vmlinuz-3.10.0-957.el7.x86_64
```

> **Note:**
> `--update-kernel` is followed by the actual default kernel version.

3. Execute `grubby --info` to see the modified default kernel configuration:

```
grubby --info /boot/vmlinuz-3.10.0-957.el7.x86_64
```

> **Note:**
> `--info` is followed by the actual default kernel version.

```
index=0
kernel=/boot/vmlinuz-3.10.0-957.el7.x86_64
args="ro crashkernel=auto rd.lvm.lv=centos/root rd.lvm.lv=
    ↪ centos/swap rhgb quiet LANG=en_US.UTF-8
    ↪ transparent_hugepage=never"
root=/dev/mapper/centos-root
initrd=/boot/initramfs-3.10.0-957.el7.x86_64.img
title=CentOS Linux (3.10.0-957.el7.x86_64) 7 (Core)
```

4. Modify the current kernel configuration to immediately disable THP:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

5. Configure the I/O Scheduler in the udev script:

```
vi /etc/udev/rules.d/60-tidb-schedulers.rules
```

```
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1fc035", ATTR{queue/scheduler}="
    ↪ noop"
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
    ↪ d0946606d79f90025f3e09a0c1f9e81", ATTR{queue/scheduler}="
    ↪ noop"
```

6. Apply the udev script:

```
udevadm control --reload-rules
udevadm trigger --type=devices --action=change
```

7. Create a service to configure the CPU power policy:

```
cat >> /etc/systemd/system/cpupower.service << EOF
[Unit]
Description=CPU performance
[Service]
Type=oneshot
ExecStart=/usr/bin/cpupower frequency-set --governor
    ↪ performance
[Install]
WantedBy=multi-user.target
EOF
```

8. Apply the CPU power policy configuration service:

```
systemctl daemon-reload
systemctl enable cpupower.service
systemctl start cpupower.service
```

6. Execute the following command to verify the THP status:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
always madvise [never]
```

7. Execute the following command to verify the I/O Scheduler of the disk where the data directory is located:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
[noop] deadline cfq
[noop] deadline cfq
```

8. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
  ```
```

analyzing CPU 0: current policy: frequency should be within 1.20 GHz and 3.10 GHz. The governor "performance" may decide which speed to use within this range. "'

9. Execute the following commands to modify the `sysctl` parameters:

```
echo "fs.file-max = 1000000">> /etc/sysctl.conf
echo "net.core.somaxconn = 32768">> /etc/sysctl.conf
echo "net.ipv4.tcp_tw_recycle = 0">> /etc/sysctl.conf
echo "net.ipv4.tcp_syncookies = 0">> /etc/sysctl.conf
echo "vm.overcommit_memory = 1">> /etc/sysctl.conf
echo "vm.min_free_kbytes = 1048576">> /etc/sysctl.conf
sysctl -p
```

Note:

- `vm.min_free_kbytes` is a Linux kernel parameter that controls the minimum amount of free memory reserved by the system, measured in KiB.
- The setting of `vm.min_free_kbytes` affects the memory reclaim mechanism. Setting it too large reduces the available memory, while setting it too small might cause memory request speeds to exceed background reclaim speeds, leading to memory reclamation and consequent delays in memory allocation.
- It is recommended to set `vm.min_free_kbytes` to `1048576` KiB (1 GiB) at least. If NUMA is installed, it is recommended to set it to `number of NUMA nodes * 1048576` KiB.
- For servers with memory sizes less than 16 GiB, it is recommended to keep the default value of `vm.min_free_kbytes` unchanged.

10. Execute the following command to configure the user's `limits.conf` file:

```
cat << EOF >>/etc/security/limits.conf
tidb           soft    nofile          1000000
tidb           hard    nofile          1000000
```
```

```
tidb          soft    stack         32768
tidb          hard    stack         32768
EOF
```

4.2.6 Manually configure the SSH mutual trust and sudo without password

This section describes how to manually configure the SSH mutual trust and sudo without password. It is recommended to use TiUP for deployment, which automatically configure SSH mutual trust and login without password. If you deploy TiDB clusters using TiUP, ignore this section.

1. Log in to the target machine respectively using the `root` user account, create the `tidb` user and set the login password.

```
useradd tidb && \
passwd tidb
```

2. To configure sudo without password, run the following command, and add `tidb ALL =(ALL)NOPASSWD: ALL` to the end of the file:

```
visudo
```

```
tidb ALL=(ALL) NOPASSWD: ALL
```

3. Use the `tidb` user to log in to the control machine, and run the following command. Replace `10.0.1.1` with the IP of your target machine, and enter the `tidb` user password of the target machine as prompted. After the command is executed, SSH mutual trust is already created. This applies to other machines as well. Newly created `tidb` users do not have the `.ssh` directory. To create such a directory, execute the command that generates the RSA key. To deploy TiDB components on the control machine, configure mutual trust for the control machine and the control machine itself.

```
ssh-keygen -t rsa
ssh-copy-id -i ~/.ssh/id_rsa.pub 10.0.1.1
```

4. Log in to the control machine using the `tidb` user account, and log in to the IP of the target machine using `ssh`. If you do not need to enter the password and can successfully log in, then the SSH mutual trust is successfully configured.

```
ssh 10.0.1.1
```

```
[tidb@10.0.1.1 ~]$
```

5. After you log in to the target machine using the `tidb` user, run the following command. If you do not need to enter the password and can switch to the `root` user, then sudo without password of the `tidb` user is successfully configured.

```
sudo -su root
```

```
[root@10.0.1.1 tidb]#
```

4.2.7 Install the `numactl` tool

This section describes how to install the NUMA tool. In online environments, because the hardware configuration is usually higher than required, to better plan the hardware resources, multiple instances of TiDB or TiKV can be deployed on a single machine. In such scenarios, you can use NUMA tools to prevent the competition for CPU resources which might cause reduced performance.

Note:

- Binding cores using NUMA is a method to isolate CPU resources and is suitable for deploying multiple instances on highly configured physical machines.
- After completing deployment using `tiup cluster deploy`, you can use the `exec` command to perform cluster level management operations.

1. Log in to the target node to install. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo yum -y install numactl
```

2. Run the `exec` command using `tiup cluster` to install in batches.

```
tiup cluster exec --help
```

```
Run shell command on host in the tidb cluster
Usage:
cluster exec <cluster-name> [flags]
Flags:
    --command string the command run on cluster host (default "ls")
-h, --help           help for exec
    --sudo           use root permissions (default false)
```

To use the sudo privilege to execute the installation command for all the target machines in the `tidb-test` cluster, run the following command:

```
tiup cluster exec tidb-test --sudo --command "yum -y install numactl"
```

4.3 Plan Cluster Topology

4.3.1 Minimal Deployment Topology

This document describes the minimal deployment topology of TiDB clusters.

4.3.1.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

4.3.1.1.1 Topology templates

- The simple template for the minimal topology
- The complex template for the minimal topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.2 TiFlash Deployment Topology

This document describes the deployment topology of TiFlash based on the minimal TiDB topology.

TiFlash is a columnar storage engine, and gradually becomes the standard cluster topology. It is suitable for real-time HTAP applications.

4.3.2.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
TiFlash	1	32 VCore 64 GB 2TB (nvme ssd) * 1	10.0.1.10	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default port Global directory configuration

4.3.2.1.1 Topology templates

- The simple template for the TiFlash topology
- The complex template for the TiFlash topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

4.3.2.1.2 Key parameters

- To enable the Placement Rules feature of PD, set the value of `replication.enable-placement-rules` in the configuration template to `true`.
- The instance level `"-host"` configuration in `tiflash_servers` only supports IP, not domain name.
- For detailed TiFlash parameter description, see TiFlash Configuration.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.

- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.3 TiCDC Deployment Topology

Note:

TiCDC is a feature for general availability (GA) since v4.0.6. You can use it in the production environment.

This document describes the deployment topology of TiCDC based on the minimal cluster topology.

TiCDC is a tool for replicating the incremental data of TiDB, introduced in TiDB 4.0. It supports multiple downstream platforms, such as TiDB, MySQL, and MQ. Compared with TiDB Binlog, TiCDC has lower latency and native high availability.

4.3.3.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration
CDC	3	8 VCore 16GB * 1	10.0.1.10 10.0.1.11 10.0.1.12	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

4.3.3.1.1 Topology templates

- The simple template for the TiCDC topology
- The complex template for the TiCDC topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.4 TiDB Binlog Deployment Topology

This document describes the deployment topology of TiDB Binlog based on the minimal TiDB topology.

TiDB Binlog is the widely used component for replicating incremental data. It provides near real-time backup and replication.

4.3.4.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32 GB	10.0.1.1 10.0.1.2 10.0.1.3	Default port configuration; Enable `enable_binlog` ↪ ; Enable `ignore` ↪ - ↪ `error` ↪
PD	3	4 VCore 8 GB	10.0.1.4 10.0.1.5 10.0.1.6	Default port configuration
TiKV	3	16 VCore 32 GB	10.0.1.7 10.0.1.8 10.0.1.9	Default port configuration

Instance	Count	Physical machine configuration	IP	Configuration
Pump	3	8 VCore 16GB	10.0.1.1 10.0.1.7 10.0.1.8	Default port configuration; Set GC time to 7 days

Instance	Count	Physical machine configuration	IP	Configuration
Drainer	1	8 VCore 16GB	10.0.1.12	Default port configuration; Set the default initialization commitTS -1 as the latest timestamp; Configure the downstream target TiDB as `10.0.1.12:4000` ↪

4.3.4.1.1 Topology templates

- The simple template for the TiDB Binlog topology (with `mysql` as the downstream type)
- The simple template for the TiDB Binlog topology (with `file` as the downstream type)
- The complex template for the TiDB Binlog topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

4.3.4.1.2 Key parameters

The key parameters in the topology configuration templates are as follows:

- `server_configs.tidb.binlog.enable: true`
  - Enables the binlog service.
  - Default value: `false`.
- `server_configs.tidb.binlog.ignore-error: true`
  - It is recommended to enable this configuration in high availability scenarios.
  - If set to `true`, when an error occurs, TiDB stops writing data into binlog, and adds `1` to the value of the `tidb_server_critical_error_total` monitoring metric.
  - If set to `false`, when TiDB fails to write data into binlog, the whole TiDB service is stopped.
- `drainer_servers.config.syncer.db-type`

  The downstream type of TiDB Binlog. Currently, `mysql`, `tidb`, `kafka`, and `file` are supported.
- `drainer_servers.config.syncer.to`

  The downstream configuration of TiDB Binlog. Depending on different `db-type`s, you can use this configuration item to configure the connection parameters of the downstream database, the connection parameters of Kafka, and the file save path. For details, refer to TiDB Binlog Configuration File.

Note:

- When editing the configuration file template, if you do not need custom ports or directories, modify the IP only.

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.5 TiSpark Deployment Topology

Warning:

TiSpark support in the TiUP cluster is still an experimental feature. It is **NOT** recommended to use it in the production environment.

This document introduces the TiSpark deployment topology and how to deploy TiSpark based on the minimum cluster topology.

TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer complex OLAP queries. It brings benefits of both the Spark platform and the distributed TiKV cluster to TiDB and makes TiDB a one-stop solution for both online transactions and analytics.

For more information about the TiSpark architecture and how to use it, see TiSpark User Guide.

4.3.5.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global directory configuration
PD	3	4 VCore 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global directory configuration
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default port Global directory configuration

Instance	Count	Physical machine configuration	IP	Configuration
TiSpark	3	8 VCore 16GB * 1	10.0.1.21 (master) 10.0.1.22 (worker) 10.0.1.23 (worker)	Default port Global directory configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.11	Default port Global directory configuration

4.3.5.2 Topology templates

- Simple TiSpark topology template
- Complex TiSpark topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.5.3 Prerequisites

TiSpark is based on the Apache Spark cluster, so before you start the TiDB cluster that contains TiSpark, you must ensure that Java Runtime Environment (JRE) 8 is installed on the server that deploys TiSpark. Otherwise, TiSpark cannot be started.

TiUP does not support installing JRE automatically. You need to install it on your own. For detailed installation instruction, see How to download and install prebuilt OpenJDK packages.

If JRE 8 has already been installed on the deployment server but is not in the path of the system's default package management tool, you can specify the path of the JRE environment to be used by setting the `java_home` parameter in the topology configuration. This parameter corresponds to the `JAVA_HOME` system environment variable.

4.3.6 Geo-Distributed Deployment Topology

This document takes the typical architecture of three data centers (DC) in two cities as an example, and introduces the geo-distributed deployment architecture and the key configuration. The cities used in this example are Shanghai (referred to as `sha`) and Beijing (referred to as `bja` and `bjb`).

4.3.6.1 Topology information

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
TiDB	5	16 VCore 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3 10.0.1.4	10.0.1.5	Default port Global directory configuration
PD	5	4 VCore 8GB * 1	10.0.1.6 10.0.1.7 10.0.1.8 10.0.1.9	10.0.1.10	Default port Global directory configuration
TiKV	5	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.11 10.0.1.12 10.0.1.13 10.0.1.14	10.0.1.15	Default port Global directory configuration

Instance	Count	Physical machine configuration	BJ IP	SH IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.16		Default port Global directory configuration

4.3.6.1.1 Topology templates

- The geo-distributed topology template

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

4.3.6.1.2 Key parameters

This section describes the key parameter configuration of the TiDB geo-distributed deployment.

TiKV parameters

- The gRPC compression format (`none` by default):

  To increase the transmission speed of gRPC packages between geo-distributed target nodes, set this parameter to `gzip`.

```
server.grpc-compression-type: gzip
```

- The label configuration:

  Since TiKV is deployed across different data centers, if the physical machines go down, the Raft Group might lose three of the default five replicas, which causes the cluster

unavailability. To address this issue, you can configure the labels to enable the smart scheduling of PD, which ensures that the Raft Group does not allow three replicas to be located in TiKV instances on the same machine in the same cabinet of the same data center.

- The TiKV configuration:

  The same host-level label information is configured for the same physical machine.

```
config:
  server.labels:
    zone: bj
    dc: bja
    rack: rack1
    host: host2
```

- To prevent remote TiKV nodes from launching unnecessary Raft elections, it is required to increase the minimum and maximum number of ticks that the remote TiKV nodes need to launch an election. The two parameters are set to `0` by default.

```
raftstore.raft-min-election-timeout-ticks: 1000
raftstore.raft-max-election-timeout-ticks: 1020
```

PD parameters

- The PD metadata information records the topology of the TiKV cluster. PD schedules the Raft Group replicas on the following four dimensions:

```
replication.location-labels: ["zone","dc","rack","host"]
```

- To ensure high availability of the cluster, adjust the number of Raft Group replicas to be `5`:

```
replication.max-replicas: 5
```

- Forbid the remote TiKV Raft replica being elected as Leader:

```
label-property:
     reject-leader:
       - key: "dc"
         value: "sha"
```

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

Schedule Replicas by Topology Labels further explains the use of labels and the number of Raft Group replicas.

4.3.7 Hybrid Deployment Topology

This document describes the topology and key parameters of the TiKV and TiDB hybrid deployment.

The hybrid deployment is usually used in the following scenario:

The deployment machine has multiple CPU processors with sufficient memory. To improve the utilization rate of the physical machine resources, multiple instances can be deployed on a single machine, that is, TiDB and TiKV's CPU resources are isolated through NUMA node bindings. PD and Prometheus are deployed together, but their data directories need to use separate file systems.

4.3.7.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	6	32 VCore 64GB	10.0.1.1 10.0.1.2 10.0.1.3	Configure NUMA to bind CPU cores

Instance	Count	Physical machine configuration	IP	Configuration
PD	3	16 VCore 32 GB	10.0.1.4 10.0.1.5 10.0.1.6	Configure the `location_lables` parameter

Instance	Count	Physical machine configuration	IP	Configuration
TiKV	6	32 VCore 64GB	10.0.1.7 10.0.1.8 10.0.1.9	1. Separate the instance-level port and status_port; 2. Configure the global parameters `readpool` ↪ , `storage` ↪ and `raftstore` ↪ ; 3. Configure labels of the instance-level host; 4. Con-

Instance	Count	Physical machine configuration	IP	Configuration
Monitoring & Grafana	1	4 VCore 8GB * 1 500GB (ssd)	10.0.1.10	Default configuration

4.3.7.1.1 Topology templates

- The simple template for the hybrid deployment
- The complex template for the hybrid deployment

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see Topology Configuration File for Deploying TiDB Using TiUP.

4.3.7.1.2 Key parameters

This section introduces the key parameters when you deploy multiple instances on a single machine, which is mainly used in scenarios when multiple instances of TiDB and TiKV are deployed on a single machine. You need to fill in the results into the configuration template according to the calculation methods provided below.

- Optimize the configuration of TiKV
  - To configure `readpool` to be self-adaptive to the thread pool. By configuring the `readpool.unified.max-thread-count` parameter, you can make `readpool.storage` and `readpool.coprocessor` share a unified thread pool, and set the self-adaptive switch respectively.
    * Enable `readpool.storage` and `readpool.coprocessor`:

```
readpool.storage.use-unified-pool: true
readpool.coprocessor.use-unified-pool: true
```

    * The calculation method:

```
readpool.unified.max-thread-count = cores * 0.8 / the number of
    ↪ TiKV instances
```

- To configure the storage CF (all RocksDB column families) to be self-adaptive to memory. By configuring the `storage.block-cache.capacity` parameter, you can make CF automatically balance the memory usage.
  - `storage.block-cache` enables the CF self-adaptation by default. You do not need to modify it.

    ```
    storage.block-cache.shared: true
    ```

  - The calculation method:

    ```
    storage.block-cache.capacity = (MEM_TOTAL * 0.5 / the number of
        ↪ TiKV instances)
    ```

- If multiple TiKV instances are deployed on the same physical disk, add the `capacity` parameter in the TiKV configuration:

```
raftstore.capacity = disk total capacity / the number of TiKV
    ↪ instances
```

- The label scheduling configuration

  Since multiple instances of TiKV are deployed on a single machine, if the physical machines go down, the Raft Group might lose two of the default three replicas, which causes the cluster unavailability. To address this issue, you can use the label to enable the smart scheduling of PD, which ensures that the Raft Group has more than two replicas in multiple TiKV instances on the same machine.

  - The TiKV configuration

    The same host-level label information is configured for the same physical machine:

    ```
    config:
      server.labels:
        host: tikv1
    ```

  - The PD configuration

    To enable PD to identify and scheduling Regions, configure the labels type for PD:

    ```
    pd:
      replication.location-labels: ["host"]
    ```

- `numa_node` core binding

- In the instance parameter module, configure the corresponding `numa_node` parameter and add the number of CPU cores.
- Before using NUMA to bind cores, make sure that the numactl tool is installed, and confirm the information of CPUs in the physical machines. After that, configure the parameters.
- The `numa_node` parameter corresponds to the `numactl --membind` configuration.

Note:

- When editing the configuration file template, modify the required parameter, IP, port, and directory.
- Each component uses the global `<deploy_dir>/<components_name>-<port>` as their `deploy_dir` by default. For example, if TiDB specifies the `4001` port, its `deploy_dir` is `/tidb-deploy/tidb-4001` by default. Therefore, in multi-instance scenarios, when specifying a non-default port, you do not need to specify the directory again.
- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.4 Install and Start

4.4.1 Deploy a TiDB Cluster Using TiUP

TiUP is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides TiUP cluster, a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

TiUP supports deploying TiDB, TiFlash, TiDB Binlog, TiCDC, and the monitoring system. This document introduces how to deploy TiDB clusters of different topologies.

Note:

TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.

4.4.1.1 Step 1: Prerequisites and precheck

Make sure that you have read the following documents:

- Hardware and software requirements
- Environment and system configuration check

4.4.1.2 Step 2: Install TiUP on the control machine

You can install TiUP on the control machine in either of the two ways: online deployment and offline deployment.

4.4.1.2.1 Method 1: Deploy TiUP online

Log in to the control machine using a regular user account (take the `tidb` user as an example). All the following TiUP installation and cluster management operations can be performed by the `tidb` user.

1. Install TiUP by executing the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

2. Set the TiUP environment variables:

   Redeclare the global environment variables:

```
source .bash_profile
```

   Confirm whether TiUP is installed:

```
which tiup
```

3. Install the TiUP cluster component:

```
tiup cluster
```

4. If TiUP is already installed, update the TiUP cluster component to the latest version:

```
tiup update --self && tiup update cluster
```

   Expected output includes "`Update successfully!`".

5. Verify the current version of your TiUP cluster:

```
tiup --binary cluster
```

4.4.1.2.2 Method 2: Deploy TiUP offline

Perform the following steps in this section to deploy a TiDB cluster offline using TiUP:

Step 1: Prepare the TiUP offline component package

To prepare the TiUP offline component package, manually pack an offline component package using `tiup mirror clone`.

1. Install the TiUP package manager online.

    1. Install the TiUP tool:

    ```
    curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.
        ↪ com/install.sh | sh
    ```

    2. Redeclare the global environment variables:

    ```
    source .bash_profile
    ```

    3. Confirm whether TiUP is installed:

    ```
    which tiup
    ```

2. Pull the mirror using TiUP.

    1. Pull the needed components on a machine that has access to the Internet:

    ```
    tiup mirror clone tidb-community-server-${version}-linux-amd64 ${
        ↪ version} --os=linux --arch=amd64
    ```

    The command above creates a directory named `tidb-community-server-` ↪ `${version}-linux-amd64` in the current directory, which contains the component package necessary for starting a cluster.

    2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

    ```
    tar czvf tidb-community-server-${version}-linux-amd64.tar.gz tidb-
        ↪ community-server-${version}-linux-amd64
    ```

    `tidb-community-server-${version}-linux-amd64.tar.gz` is an independent offline environment package.

Step 2: Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following commands:

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz && \
sh tidb-community-server-${version}-linux-amd64/local_install.sh && \
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically executes the `tiup mirror set tidb -community-server-${version}-linux-amd64` command to set the current mirror address to `tidb-community-server-${version}-linux-amd64`.

To switch the mirror to another directory, you can manually execute the `tiup mirror set <mirror-dir>` command. To switch the mirror to the online environment, you can execute the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

4.4.1.3 Step 3: Initialize cluster topology file

According to the intended cluster topology, you need to manually create and edit the cluster initialization configuration file.

To create the cluster initialization configuration file, you can create a YAML-formatted configuration file on the control machine using TiUP:

```
tiup cluster template > topology.yaml
```

> **Note:**
>
> For the hybrid deployment scenarios, you can also execute `tiup cluster template --full > topology.yaml` to create the recommended topology template. For the geo-distributed deployment scenarios, you can execute `tiup cluster template --multi-dc > topology.yaml` to create the recommended topology template.

Execute `vi topology.yaml` to see the configuration file content:

```
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"
server_configs: {}
pd_servers:
  - host: 10.0.1.4
  - host: 10.0.1.5
  - host: 10.0.1.6
tidb_servers:
  - host: 10.0.1.7
  - host: 10.0.1.8
  - host: 10.0.1.9
tikv_servers:
  - host: 10.0.1.1
```

```
  - host: 10.0.1.2
  - host: 10.0.1.3
monitoring_servers:
  - host: 10.0.1.4
grafana_servers:
  - host: 10.0.1.4
alertmanager_servers:
  - host: 10.0.1.4
```

The following examples cover the most common scenarios. You need to modify the configuration file (named `topology.yaml`) according to the topology description and templates in the corresponding links. For other scenarios, edit the configuration template accordingly.

- Minimal deployment topology

  This is the basic cluster topology, including tidb-server, tikv-server, and pd-server. It is suitable for OLTP applications.

- TiFlash deployment topology

  This is to deploy TiFlash along with the minimal cluster topology. TiFlash is a columnar storage engine, and gradually becomes a standard cluster topology. It is suitable for real-time HTAP applications.

- TiCDC deployment topology

  This is to deploy TiCDC along with the minimal cluster topology. TiCDC is a tool for replicating the incremental data of TiDB, introduced in TiDB 4.0. It supports multiple downstream platforms, such as TiDB, MySQL, and MQ. Compared with TiDB Binlog, TiCDC has lower latency and native high availability. After the deployment, start TiCDC and create the replication task using `cdc cli`.

- TiDB Binlog deployment topology

  This is to deploy TiDB Binlog along with the minimal cluster topology. TiDB Binlog is the widely used component for replicating incremental data. It provides near real-time backup and replication.

- TiSpark deployment topology

  This is to deploy TiSpark along with the minimal cluster topology. TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer the OLAP queries. Currently, TiUP cluster's support for TiSpark is still **experimental**.

- Hybrid deployment topology

  This is to deploy multiple instances on a single machine. You need to add extra configurations for the directory, port, resource ratio, and label.

- Geo-distributed deployment topology

  This topology takes the typical architecture of three data centers in two cities as an example. It introduces the geo-distributed deployment architecture and the key configuration that requires attention.

> **Note:**
>
> - For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
> - For parameters that should be effective on a specific node, configure these parameters in the `config` of this node.
> - Use `.` to indicate the subcategory of the configuration, such as `log.slow-threshold`. For more formats, see TiUP configuration template.
> - For more parameter description, see TiDB `config.toml.example`, TiKV `config.toml.example`, PD `config.toml.example`, and TiFlash configuration.

4.4.1.4 Step 4: Execute the deployment command

> **Note:**
>
> You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:
>
> - If you use secret keys, you can specify the path of the keys through `-i` or `--identity_file`;
> - If you use passwords, add the `-p` flag to enter the password interaction window;
> - If password-free login to the target machine has been configured, no authentication is required.
>
> In general, TiUP creates the user and group specified in the `topology.yaml` file on the target machine, with the following exceptions:
>
> - The user name configured in `topology.yaml` already exists on the target machine.
> - You have used the `--skip-create-user` option in the command line to explicitly skip the step of creating the user.

Before you execute the `deploy` command, use the `check` and `check --apply` commands to detect and automatically repair the potential risks in the cluster:

```
tiup cluster check ./topology.yaml --user root [-p] [-i /home/root/.ssh/
    ↪ gcp_rsa]
tiup cluster check ./topology.yaml --apply --user root [-p] [-i /home/root/.
    ↪ ssh/gcp_rsa]
```

Then execute the `deploy` command to deploy the TiDB cluster:

```
tiup cluster deploy tidb-test v5.1.5 ./topology.yaml --user root [-p] [-i /
    ↪ home/root/.ssh/gcp_rsa]
```

In the above command:

- The name of the deployed TiDB cluster is `tidb-test`.
- You can see the latest supported versions by running `tiup list tidb`. This document takes `v5.1.5` as an example.
- The initialization configuration file is `topology.yaml`.
- `--user root`: Log in to the target machine through the `root` key to complete the cluster deployment, or you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]`: optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the `root` user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.
- If you need to specify the user group name to be created on the target machine, see this example.

At the end of the output log, you will see `Deployed cluster` `tidb-test` ↪ `successfully`. This indicates that the deployment is successful.

4.4.1.5 Step 5: Check the clusters managed by TiUP

```
tiup cluster list
```

TiUP supports managing multiple TiDB clusters. The command above outputs information of all the clusters currently managed by TiUP, including the name, deployment user, version, and secret key information:

```
Starting /home/tidb/.tiup/components/cluster/v1.5.0/cluster list
Name            User  Version      Path
    ↪                                                PrivateKey
----            ----  -------      ----
    ↪                                                ----------
```

```
tidb-test       tidb v5.1.5     /home/tidb/.tiup/storage/cluster/clusters/
    ↪ tidb-test /home/tidb/.tiup/storage/cluster/clusters/tidb-test/ssh/
    ↪ id_rsa
```

4.4.1.6 Step 6: Check the status of the deployed TiDB cluster

For example, execute the following command to check the status of the `tidb-test` cluster:

```
tiup cluster display tidb-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down`/`inactive`), and directory information.

4.4.1.7 Step 7: Start the TiDB cluster

```
tiup cluster start tidb-test
```

If the output log includes `Started cluster` `` `tidb-test` `` `successfully`, the start is successful.

4.4.1.8 Step 8: Verify the running status of the TiDB cluster

For the specific operations, see Verify Cluster Status.

4.4.1.9 What's next

If you have deployed TiFlash along with the TiDB cluster, see the following documents:

- Use TiFlash
- Maintain a TiFlash Cluster
- TiFlash Alert Rules and Solutions
- Troubleshoot TiFlash

If you have deployed TiCDC along with the TiDB cluster, see the following documents:

- Manage TiCDC Cluster and Replication Tasks
- Troubleshoot TiCDC

4.4.2 Deploy a TiDB Cluster in Kubernetes

You can use TiDB Operator to deploy TiDB clusters in Kubernetes. TiDB Operator is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB in Kubernetes documentation is independent of the TiDB documentation. For detailed steps on how to deploy TiDB clusters in Kubernetes using TiDB Operator, see TiDB in Kubernetes documentation.

4.5 Check Cluster Status

After a TiDB cluster is deployed, you need to check whether the cluster runs normally. This document introduces how to check the cluster status using TiUP commands, TiDB Dashboard and Grafana, and how to log into the TiDB database to perform simple SQL operations.

4.5.1 Check the TiDB cluster status

This section describes how to check the TiDB cluster status using TiUP commands, TiDB Dashboard, and Grafana.

4.5.1.1 Use TiUP

Use the `tiup cluster display <cluster-name>` command to check the cluster status. For example:

```
tiup cluster display tidb-test
```

Expected output: If the `Status` information of each node is `Up`, the cluster runs normally.

4.5.1.2 Use TiDB Dashboard

1. Log in to TiDB Dashboard at `${pd-ip}:${pd-port}/dashboard`. The username and password is the same as that of the TiDB `root` user. If you have modified the `root` password, enter the modified password. The password is empty by default.

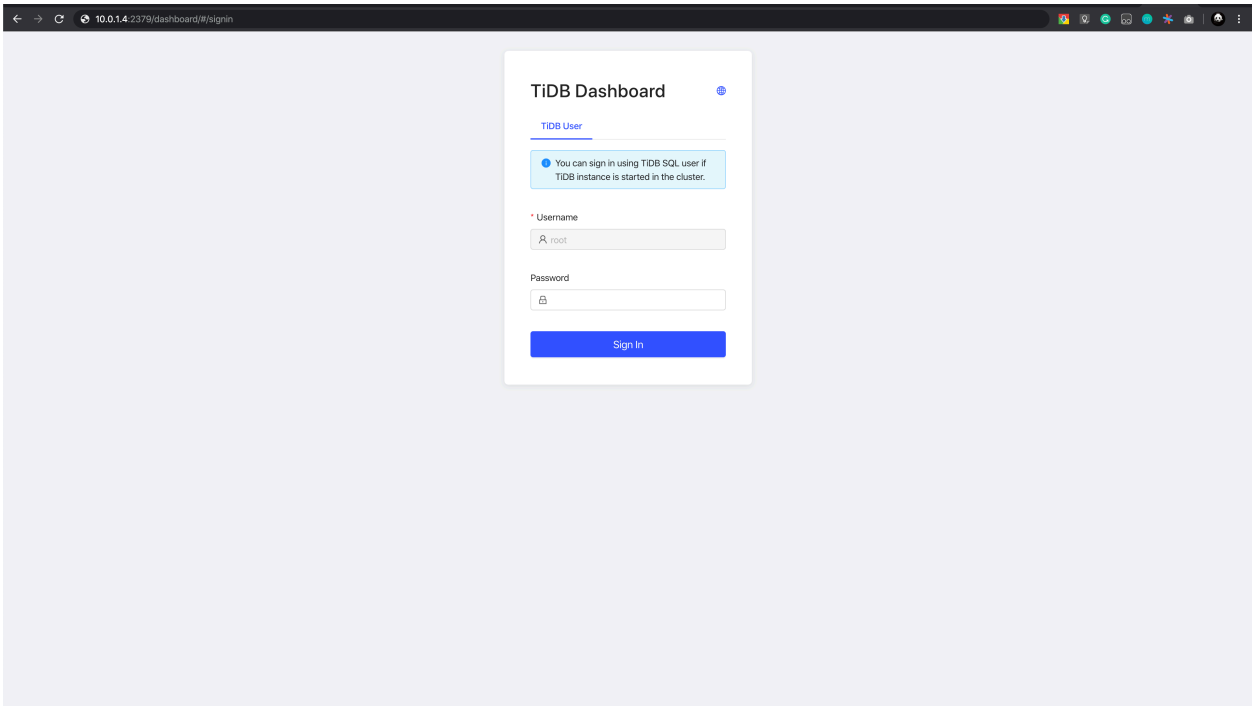

Figure 7: TiDB-Dashboard

2. The home page displays the node information in the TiDB cluster.

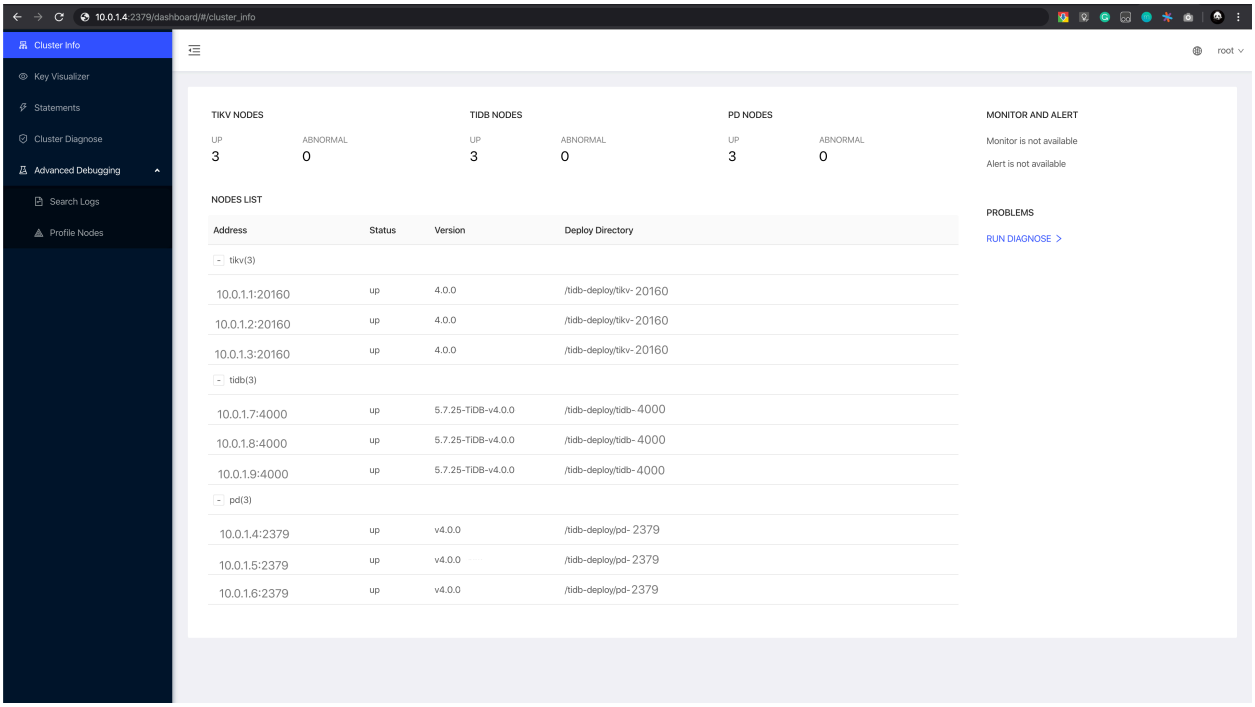

Figure 8: TiDB-Dashboard-status

4.5.1.3 Use Grafana

1. Log in to the Grafana monitoring at `${Grafana-ip}:3000`. The default username and password are both `admin`.

2. To check the TiDB port status and load monitoring information, click **Overview**.

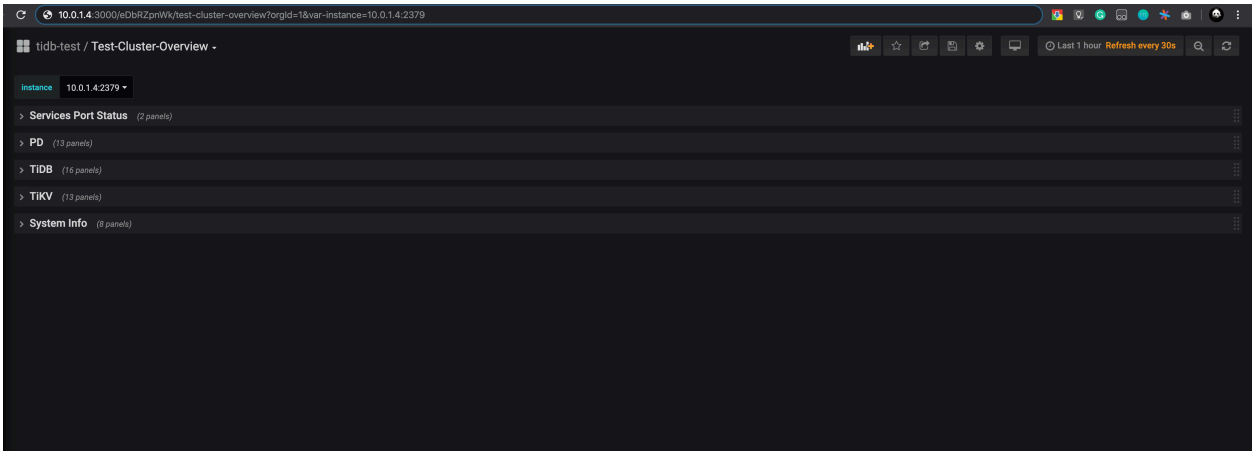

Figure 9: Grafana-overview

4.5.2 Log in to the database and perform simple operations

> **Note:**
>
> Install the MySQL client before you log in to the database.

Log in to the database by running the following command:

```
mysql -u root -h ${tidb_server_host_IP_address} -P 4000
```

`${tidb_server_host_IP_address}` is one of the IP addresses set for `tidb_servers` when you initialize the cluster topology file, such as `10.0.1.7`.

The following information indicates successful login:

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.7.25-TiDB-v5.0.0 TiDB Server (Apache License 2.0)
    ↪ Community Edition, MySQL 5.7 compatible
Copyright (c) 2000, 2015, Oracle and/or its affiliates. All rights reserved
    ↪ .
Oracle is a registered trademark of Oracle Corporation and/or its
affiliates. Other names may be trademarks of their respective
owners.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
    ↪ statement.
```

4.5.2.1 Database operations

- Check the version of TiDB:

  ```
  select tidb_version()\G
  ```

  Expected output:

  ```
  *************************** 1. row ***************************
  tidb_version(): Release Version: v5.0.0
  Edition: Community
  Git Commit Hash: 689a6b6439ae7835947fcaccf329a3fc303986cb
  Git Branch: HEAD
  UTC Build Time: 2020-05-28 11:09:45
  GoVersion: go1.13.4
  ```

```
Race Enabled: false
TiKV Min Version: v3.0.0-60965b006877ca7234adaced7890d7b029ed1306
Check Table Before Drop: false
1 row in set (0.00 sec)
```

- Create a database named `pingcap`:

```
create database pingcap;
```

Expected output:

```
Query OK, 0 rows affected (0.10 sec)
```

Switch to the `pingcap` database:

```
use pingcap;
```

Expected output:

```
Database changed
```

- Create a table named `tab_tidb`:

```
CREATE TABLE `tab_tidb` (
`id` int(11) NOT NULL AUTO_INCREMENT,
`name` varchar(20) NOT NULL DEFAULT '',
`age` int(11) NOT NULL DEFAULT 0,
`version` varchar(20) NOT NULL DEFAULT '',
PRIMARY KEY (`id`),
KEY `idx_age` (`age`));
```

Expected output:

```
Query OK, 0 rows affected (0.11 sec)
```

- Insert data:

```
insert into `tab_tidb` values (1,'TiDB',5,'TiDB-v5.0.0');
```

Expected output:

```
Query OK, 1 row affected (0.03 sec)
```

- View the entries in `tab_tidb`:

```
select * from tab_tidb;
```

Expected output:

```
+----+------+-----+-------------+
| id | name | age | version |
+----+------+-----+-------------+
|  1 | TiDB |  5 | TiDB-v5.0.0 |
+----+------+-----+-------------+
1 row in set (0.00 sec)
```

- View the store state, `store_id`, capacity, and uptime of TiKV:

```
select STORE_ID,ADDRESS,STORE_STATE,STORE_STATE_NAME,CAPACITY,AVAILABLE
    ↪ ,UPTIME from INFORMATION_SCHEMA.TIKV_STORE_STATUS;
```

Expected output:

```
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
| STORE_ID | ADDRESS         | STORE_STATE | STORE_STATE_NAME | CAPACITY
    ↪  | AVAILABLE | UPTIME    |
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
|        1 | 10.0.1.1:20160 |        0 | Up              | 49.98GiB | 46.3
    ↪ GiB | 5h21m52.474864026s |
|        4 | 10.0.1.2:20160 |        0 | Up              | 49.98GiB |
    ↪ 46.32GiB | 5h21m52.522669177s |
|        5 | 10.0.1.3:20160 |        0 | Up              | 49.98GiB |
    ↪ 45.44GiB | 5h21m52.713660541s |
+--
    ↪ --------+-------------------+-------------+-----------------+----------+-
    ↪
3 rows in set (0.00 sec)
```

- Exit TiDB:

```
exit
```

Expected output:

```
Bye
```

4.6 Test Cluster Performance

4.6.1 How to Test TiDB Using Sysbench

It is recommended to use Sysbench 1.0 or later, which can be downloaded here.

4.6.1.1 Test plan

4.6.1.1.1 TiDB configuration

Higher log level means fewer logs to be printed and thus positively influences TiDB performance. Enable `prepared plan cache` in the TiDB configuration to lower the cost of optimizing execution plan. Specifically, you can add the following command in the TiUP configuration file:

```
server_configs:
  tidb:
    log.level: "error"
    prepared-plan-cache.enabled: true
```

4.6.1.1.2 TiKV configuration

Higher log level also means better performance for TiKV.

There are multiple Column Families on TiKV cluster which are mainly used to store different types of data, including Default CF, Write CF, and Lock CF. For the Sysbench test, you only need to focus on Default CF and Write CF. The Column Family that is used to import data has a constant proportion among TiDB clusters:

Default CF : Write CF = 4 : 1

Configuring the block cache of RocksDB on TiKV should be based on the machine's memory size, in order to make full use of the memory. To deploy a TiKV cluster on a 40GB virtual machine, it is recommended to configure the block cache as follows:

```
server_configs:
  tikv:
    log-level: "error"
    rocksdb.defaultcf.block-cache-size: "24GB"
    rocksdb.writecf.block-cache-size: "6GB"
```

You can also configure TiKV to share block cache:

```
server_configs:
  tikv:
    storage.block-cache.capacity: "30GB"
```

For more detailed information on TiKV performance tuning, see Tune TiKV Performance.

4.6.1.2 Test process

Note:

The test in this document was performed without load balancing tools such as HAproxy. We run the Sysbench test on individual TiDB node and added the results up. The load balancing tools and the parameters of different versions might also impact the performance.

4.6.1.2.1 Sysbench configuration

This is an example of the Sysbench configuration file:

```
mysql-host={TIDB_HOST}
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads={8, 16, 32, 64, 128, 256}
report-interval=10
db-driver=mysql
```

The above parameters can be adjusted according to actual needs. Among them, `TIDB_HOST` is the IP address of the TiDB server (because we cannot include multiple addresses in the configuration file), `threads` is the number of concurrent connections in the test, which can be adjusted in "8, 16, 32, 64, 128, 256". When importing data, it is recommended to set threads = 8 or 16. After adjusting `threads`, save the file named **config**.

See the following as a sample **config** file:

```
mysql-host=172.16.30.33
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads=16
report-interval=10
db-driver=mysql
```

4.6.1.2.2 Data import

> **Note:**
>
> If you enable the optimistic transaction model (TiDB uses the pessimistic transaction model by default), TiDB rolls back transactions when a concurrency conflict is found. Setting `tidb_disable_txn_auto_retry` to `off` turns on the automatic retry mechanism after meeting a transaction conflict, which can prevent Sysbench from quitting because of the transaction conflict error.

Before importing the data, it is necessary to make some settings to TiDB. Execute the following command in MySQL client:

```
set global tidb_disable_txn_auto_retry = off;
```

Then exit the client.

Restart MySQL client and execute the following SQL statement to create a database `sbtest`:

```
create database sbtest;
```

Adjust the order in which Sysbench scripts create indexes. Sysbench imports data in the order of "Build Table -> Insert Data -> Create Index", which takes more time for TiDB to import data. Users can adjust the order to speed up the import of data. Suppose that you use the Sysbench version 1.0.14. You can adjust the order in either of the following two ways:

- Download the modified oltp_common.lua file for TiDB and overwrite the `/usr/share/sysbench/oltp_common.lua` file with it.
- In `/usr/share/sysbench/oltp_common.lua`, move the lines 235-240 to be right behind the line 198.

> **Note:**
>
> This operation is optional and is only to save the time consumed by data import.

At the command line, enter the following command to start importing data. The config file is the one configured in the previous step:

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 prepare
```

4.6.1.2.3 Warming data and collecting statistics

To warm data, we load data from disk into the block cache of memory. The warmed data has significantly improved the overall performance of the system. It is recommended to warm data once after restarting the cluster.

Sysbench 1.0.14 does not provide data warming, so it must be done manually. If you are using a later version of Sysbench, you can use the data warming feature included in the tool itself.

Take a table sbtest7 in Sysbench as an example. Execute the following SQL to warming up data:

```
SELECT COUNT(pad) FROM sbtest7 USE INDEX (k_7);
```

Collecting statistics helps the optimizer choose a more accurate execution plan. The `analyze` command can be used to collect statistics on the table sbtest. Each table needs statistics.

```
ANALYZE TABLE sbtest7;
```

4.6.1.2.4 Point select test command

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size
    ↪ =10000000 run
```

4.6.1.2.5 Update index test command

```
sysbench --config-file=config oltp_update_index --tables=32 --table-size
    ↪ =10000000 run
```

4.6.1.2.6 Read-only test command

```
sysbench --config-file=config oltp_read_only --tables=32 --table-size
    ↪ =10000000 run
```

4.6.1.3 Common issues

4.6.1.3.1 TiDB and TiKV are both properly configured under high concurrency, why is the overall performance still low?

This issue often has things to do with the use of a proxy. You can add pressure on single TiDB server, sum each result up and compare the summed result with the result with proxy.

Take HAproxy as an example. The parameter `nbproc` can increase the number of processes it can start at most. Later versions of HAproxy also support `nbthread` and `cpu-map`. All of these can mitigate the negative impact of proxy use on performance.

4.6.1.3.2 Under high concurrency, why is the CPU utilization rate of TiKV still low?

Although the overall CPU utilization rate is low for TiKV, the CPU utilization rate of some modules in the cluster might be high.

The maximum concurrency limits for other modules on TiKV, such as storage readpool, coprocessor, and gRPC, can be adjusted through the TiKV configuration file.

The actual CPU usage can be observed through Grafana's TiKV Thread CPU monitor panel. If there is a bottleneck on the modules, it can be adjusted by increasing the concurrency of the modules.

4.6.1.3.3 Given that TiKV has not yet reached the CPU usage bottleneck under high concurrency, why is TiDB's CPU utilization rate still low?

CPU of NUMA architecture is used on some high-end equipment where cross-CPU access to remote memory will greatly reduce performance. By default, TiDB will use all CPUs of the server, and goroutine scheduling will inevitably lead to cross-CPU memory access.

Therefore, it is recommended to deploy n TiDBs (n is the number of NUMA CPUs) on the server of NUMA architecture, and meanwhile set the TiDB parameter `max-procs` to a value that is the same as the number of NUMA CPU cores.

4.6.2 How to Run TPC-C Test on TiDB

This document describes how to test TiDB using TPC-C.

TPC-C is an online transaction processing (OLTP) benchmark. It tests the OLTP system by using a commodity sales model that involves the following five transactions of different types:

- NewOrder
- Payment
- OrderStatus
- Delivery
- StockLevel

4.6.2.1 Prepare

Before testing, TPC-C Benchmark specifies the initial state of the database, which is the rule for data generation in the database. The `ITEM` table contains a fixed number of 100,000 items, while the number of warehouses can be adjusted. If there are W records in the `WAREHOUSE` table, then:

- The `STOCK` table has W * 100,000 records (Each warehouse corresponds to the stock data of 100,000 items)

- The `DISTRICT` table has W * 10 records (Each warehouse provides services to 10 districts)
- The `CUSTOMER` table has W * 10 * 3,000 records (Each district has 3,000 customers)
- The `HISTORY` table has W * 10 * 3,000 records (Each customer has one transaction history)
- The `ORDER` table has W * 10 * 3,000 records (Each district has 3,000 orders and the last 900 orders generated are added to the `NEW-ORDER` table. Each order randomly generates 5 ~ 15 ORDER-LINE records.

In this document, the testing uses 1,000 warehouses as an example to test TiDB.

TPC-C uses tpmC (transactions per minute) to measure the maximum qualified throughput (MQTh, Max Qualified Throughput). The transactions are the NewOrder transactions and the final unit of measure is the number of new orders processed per minute.

The test in this document is implemented based on go-tpc. You can download the test program using TiUP commands.

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see TiUP Bench.

4.6.2.2 Load data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test. This section provides the following command to load data.

Execute the following TiUP command in Shell:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 prepare
```

Based on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller `WAREHOUSE` value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

4.6.2.3 Run the test

Execute the following command to run the test:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 run
```

During the test, test results are continuously printed on the console:

```
[Current] NEW_ORDER - Takes(s): 4.6, Count: 5, TPM: 65.5, Sum(ms): 4604, Avg
    ↪ (ms): 920, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms): 1500
[Current] ORDER_STATUS - Takes(s): 1.4, Count: 1, TPM: 42.2, Sum(ms): 256,
    ↪ Avg(ms): 256, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
```

```
[Current] PAYMENT - Takes(s): 6.9, Count: 5, TPM: 43.7, Sum(ms): 2208, Avg(
    ↪ ms): 441, 90th(ms): 512, 99th(ms): 512, 99.9th(ms): 512
[Current] STOCK_LEVEL - Takes(s): 4.4, Count: 1, TPM: 13.8, Sum(ms): 224,
    ↪ Avg(ms): 224, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
...
```

After the test is finished, the test summary results are printed:

```
[Summary] DELIVERY - Takes(s): 455.2, Count: 32, TPM: 4.2, Sum(ms): 44376,
    ↪ Avg(ms): 1386, 90th(ms): 2000, 99th(ms): 4000, 99.9th(ms): 4000
[Summary] DELIVERY_ERR - Takes(s): 455.2, Count: 1, TPM: 0.1, Sum(ms): 953,
    ↪ Avg(ms): 953, 90th(ms): 1000, 99th(ms): 1000, 99.9th(ms): 1000
[Summary] NEW_ORDER - Takes(s): 487.8, Count: 314, TPM: 38.6, Sum(ms):
    ↪ 282377, Avg(ms): 899, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms):
    ↪ 1500
[Summary] ORDER_STATUS - Takes(s): 484.6, Count: 29, TPM: 3.6, Sum(ms):
    ↪ 8423, Avg(ms): 290, 90th(ms): 512, 99th(ms): 1500, 99.9th(ms): 1500
[Summary] PAYMENT - Takes(s): 490.1, Count: 321, TPM: 39.3, Sum(ms): 144708,
    ↪  Avg(ms): 450, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1500
[Summary] STOCK_LEVEL - Takes(s): 487.6, Count: 41, TPM: 5.0, Sum(ms): 9318,
    ↪  Avg(ms): 227, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1000
```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

4.6.2.4 Clean up test data

Execute the following command to clean up the test data:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 cleanup
```

5 Migrate

5.1 Migration Overview

This document describes how to migrate data to TiDB, including migrating data from MySQL and from CSV/SQL files.

5.1.1 Migrate from Aurora to TiDB

In a cloud environment, you can directly migrate full data to TiDB by exporting snapshot from Aurora. For details, see Migrate from Amazon Aurora MySQL Using TiDB Lightning.

5.1.2 Migrate from MySQL to TiDB

To migrate data from MySQL to TiDB, it is recommended to use one of the following methods:

- Use Dumpling and TiDB Lightning to migrate full data.
- Use TiDB Data Migration (DM) to migrate full and incremental data.

5.1.2.1 Use Dumpling and TiDB Lightning (full data)

5.1.2.1.1 Scenarios

You can use Dumpling and TiDB Lightning to migrate full data when the data size is greater than 1 TB. If you need to replicate incremental data, it is recommended to use DM to create an incremental replication task.

5.1.2.1.2 Migration method

1. Use Dumpling to export the full MySQL data.
2. Use TiDB Lightning to import the full data to TiDB. For details, refer to Migrate data using Dumpling and TiDB Lightning.

5.1.2.2 Use DM

5.1.2.2.1 Scenarios

You can use DM to migrate full MySQL data and to replicate incremental data. It is suggested that the size of the full data is less than 1 TB. Otherwise, it is recommended to use Dumpling and TiDB Lightning to import the full data, and then use DM to replicate the incremental data.

5.1.2.2.2 Migration method

For details, refer to Migrate from MySQL (Amazon Aurora).

5.1.3 Migrate data from files to TiDB

You can migrate data from CSV/SQL files to TiDB.

5.1.3.1 Migrate data from CSV files to TiDB

5.1.3.1.1 Scenarios

You can migrate data from heterogeneous databases that are not compatible with the MySQL protocol to TiDB.

5.1.3.1.2 Migration method

1. Export full data to CSV files.
2. Import CSV files to TiDB using one of the following methods:

    - Use TiDB Lightning.

      Its import speed is fast. It is recommended to use TiDB Lightning in the case of large amounts of data in CSV files. For details, refer to TiDB Lightning CSV Support.
    - Use the `LOAD DATA` statement.

      Execute the `LOAD DATA` statement in TiDB to import CSV files. This is more convenient, but if an error or interruption occurs during the import, manual intervention is required to check the consistency and integrity of the data. Therefore, it is **not recommended** to use this method in the production environment. For details, refer to LOAD DATA.

5.1.3.2 Migrate data from SQL files to TiDB

Use Mydumper and TiDB Lightning to migrate data from SQL files to TiDB. For details, refer to Use Dumpling and TiDB Lightning.

5.2 Migrate from MySQL

5.2.1 Migrate from Amazon Aurora MySQL Using TiDB Lightning

This document introduces how to migrate full data from Amazon Aurora MySQL to TiDB using TiDB Lightning.

5.2.1.1 Step 1: Export full data from Aurora to Amazon S3

Refer to AWS Documentation - Exporting DB snapshot data to Amazon S3 to export the snapshot data of Aurora to Amazon S3.

5.2.1.2 Step 2: Deploy TiDB Lightning

For detailed deployment methods, see Deploy TiDB Lightning.

5.2.1.3 Step 3: Configure the data source of TiDB Lightning

Based on different deployment methods, edit the `tidb-lighting.toml` configuration file as follows:

1. Configure `data-source-dir` under `[mydumper]` as the S3 Bucket path of exported data in step 1.

```
[mydumper]
# Data source directory
data-source-dir = "s3://bucket-name/data-path"
```

2. Configure the target TiDB cluster as follows:

```
[tidb]
# The target cluster information. Fill in one address of tidb-server.
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
# The PD address of the cluster.
pd-addr = "127.0.0.1:2379"
```

3. Configure the backend mode:

```
[tikv-importer]
# Uses Local-backend.
backend = "local"
# The storage path of local temporary files. Ensure that the
    ↪ corresponding directory does not exist or is empty and that the
    ↪ disk capacity is greater than the size of the dataset to be
    ↪ imported.
sorted-kv-dir = "/path/to/local-temp-dir"
```

4. Configure the file routing.

```
[mydumper]
no-schema = true

[[mydumper.files]]
# Uses single quoted strings to avoid escaping.
pattern = '(?i)^(?:[^/]*/)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[^/]*/)*(?:[a-
    ↪ z0-9\-_.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'
```

Note:

- The above example uses the Local-backend for best performance. You can also choose TiDB-backend or Importer-backend according to your need. For detailed introduction of the three backend modes, see TiDB Lightning Backends.
- Because the path for exporting snapshot data from Aurora is different from the default file naming format supported by TiDB Lightning, you need to set additional file routing configuration.
- If TLS is enabled in the target TiDB cluster, you also need to configure TLS.

For other configurations, see TiDB Lightning Configuration.

5.2.1.4 Step 4: Create table schema

Because the snapshot data exported from Aurora to S3 does not contain the SQL statement file used to create database tables, you need to manually export and import the table creation statements corresponding to the database tables into TiDB. You can use Dumpling and TiDB Lightning to create all table schemas:

1. Use Dumpling to export table schema files:

```
./dumpling --host database-1.cedtft9htlae.us-west-2.rds.amazonaws.com
    ↪ --port 3306 --user root --password password --consistency none --
    ↪ no-data --output ./schema --filter "mydb.*"
```

Note:

- Set the parameters of the data source address and the path of output files according to your actual situation. For example, `database-1.cedtft9htlae.us-west-2.rds.amazonaws.com` is the address of Aurora MySQL.
- If you need to export all database tables, you do not need to set the `--filter` parameter. If you only need to export some of the database tables, configure `--filter` according to table-filter.

2. Use TiDB Lightning to create table schemas:

```
./tidb-lightning -config tidb-lightning.toml -d ./schema -no-schema=
    ↪ false
```

In this example, TiDB Lightning is only used to create table schemas, so you need to execute the above command quickly. At a regular speed, ten table creation statements can be executed in one second.

Note:

If the number of database tables to create is relatively small, you can manually create the corresponding databases and tables in TiDB directly, or use other tools such as mysqldump to export the schema and then import it into TiDB.

5.2.1.5 Step 5: Run TiDB Lightning to import data

Run TiDB Lightning to start the import operation. If you start TiDB Lightning by using `nohup` directly in the command line, the program might exit because of the `SIGHUP` signal. Therefore, it is recommended to write `nohup` in a script. For example:

```
### !/bin/bash
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

When the import operation is started, view the progress by the following two ways:

- `grep` the keyword `progress` in logs, which is updated every 5 minutes by default.
- Access the monitoring dashboard. See Monitor TiDB Lightning for details.

5.2.2 Migrate from MySQL SQL Files Using TiDB Lightning

This document describes how to migrate data from MySQL SQL files to TiDB using TiDB Lightning. For details on how to generate MySQL SQL files, refer to Dumpling.

The data migration process described in this document uses TiDB Lightning. The steps are as follows.

5.2.2.1 Step 1: Deploy TiDB Lightning

Before you start the migration, deploy TiDB Lightning.

Note:

- If you choose the Local-backend to import data, the TiDB cluster cannot provide services during the import process. This mode imports data quickly, which is suitable for importing a large amount of data (above the TB level).

- If you choose the TiDB-backend, the cluster can provide services normally during the import, at a slower import speed.
- For detailed differences between the two backend modes, see TiDB Lightning Backends.

5.2.2.2 Step 2: Configure data source of TiDB Lightning

This document takes the TiDB-backend as an example. Create the `tidb-lightning.toml` configuration file and add the following major configurations in the file:

1. Set the `data-source-dir` under `[mydumper]` to the path of the MySQL SQL file.

```
[mydumper]
# Data source directory
data-source-dir = "/data/export"
```

> **Note:**
>
> If a corresponding schema already exists in the downstream, set `no-schema=true` to skip the creation of the schema.

2. Add the configuration of the target TiDB cluster.

```
[tidb]
# The target cluster information. Fill in one address of tidb-server.
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
```

3. Add the necessary parameter for the backend. This document uses the TiDB-backend mode. Here, "backend" can also be set to "local" or "importer" according to your actual application scenario. For details, refer to Backend Mode.

```
[tikv-importer]
backend = "tidb"
```

4. Add necessary parameters for importing the TiDB cluster.

```
[tidb]
host = "{{tidb-host}}"
port = {{tidb-port}}
user = "{{tidb-user}}"
password = "{{tidb-password}}"
```

For other configurations, see TiDB Lightning Configuration.

5.2.2.3 Step 3: Run TiDB Lightning to import data

Run TiDB Lightning to start the import operation. If you start TiDB Lightning by using `nohup` directly in the command line, the program might exit because of the `SIGHUP` signal. Therefore, it is recommended to write `nohup` in a script. For example:

```
### !/bin/bash
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

When the import operation is started, view the progress by the following two ways:

- `grep` the keyword `progress` in logs, which is updated every 5 minutes by default.
- Access the monitoring dashboard. See Monitor TiDB Lightning for details.

5.2.3 Migrate from Amazon Aurora MySQL Using DM

To migrate data from MySQL (Amazon Aurora) to TiDB, refer to Migrate from MySQL (Amazon Aurora).

5.3 Migrate from CSV Files

5.3.1 TiDB Lightning CSV Support and Restrictions

This document describes how to migrate data from CSV files to TiDB using TiDB Lightning. For information about how to generate CSV files from MySQL, see Export to CSV files using Dumpling.

TiDB Lightning supports reading CSV (comma-separated values) data source, as well as other delimited format such as TSV (tab-separated values).

5.3.1.1 File name

A CSV file representing a whole table must be named as `db_name.table_name.csv`. This will be restored as a table `table_name` inside the database `db_name`.

If a table spans multiple CSV files, they should be named like `db_name.table_name` ↪ `.003.csv`. The number part do not need to be continuous, but must be increasing and zero-padded.

The file extension must be `*.csv`, even if the content is not separated by commas.

5.3.1.2 Schema

CSV files are schema-less. To import them into TiDB, a table schema must be provided. This could be done either by:

- Providing a file named `db_name.table_name-schema.sql` containing the `CREATE TABLE` DDL statement, and also a file named `db_name-schema-create.sql` containing the `CREATE DATABASE` DDL statement.
- Creating the empty tables directly in TiDB in the first place, and then setting `[mydumper] no-schema = true` in `tidb-lightning.toml`.

5.3.1.3 Configuration

The CSV format can be configured in `tidb-lightning.toml` under the `[mydumper.csv]` section. Most settings have a corresponding option in the MySQL `LOAD DATA` statement.

```
[mydumper.csv]
### Separator between fields. Must not be empty. It is not recommended to
    ↪ use the default ','. It is recommended to use '\|+\|' or other
    ↪ uncommon character combinations.
separator = ','
### Quoting delimiter. Empty value means no quoting.
delimiter = '"'
### Whether the CSV files contain a header.
### If `header` is true, the first line will be skipped.
header = true
### Whether the CSV contains any NULL value.
### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
### When `not-null` is false (that is, CSV can contain NULL),
### fields equal to this value will be treated as NULL.
null = '\N'
### Whether to interpret backslash escapes inside fields.
backslash-escape = true
### If a line ends with a separator, remove it.
trim-last-separator = false
```

In all string fields such as `separator` and `delimiter`, if the input involves special characters, you can use backslash escape sequence to represent them in a *double-quoted* string (`"⋯"`). For example, `separator = "\u001f"` means using the ASCII character 0x1F as separator.

Additionally, you can use *single-quoted* strings (`'⋯'`) to suppress backslash escaping. For example, `separator = '\t'` means using the two-character string: a backslash followed by the letter "t", as the separator.

See the TOML v1.0.0 specification for details.

5.3.1.3.1 `separator`

- Defines the field separator.
- Can be multiple characters, but must not be empty.
- Common values:
  - `','` for CSV (comma-separated values)
  - `"\t"` for TSV (tab-separated values)
  - `"\u0001"` to use the ASCII character 0x01 as separator
- Corresponds to the `FIELDS TERMINATED BY` option in the LOAD DATA statement.

5.3.1.3.2 `delimiter`

- Defines the delimiter used for quoting.
- If `delimiter` is empty, all fields are unquoted.
- Common values:
  - `'"'` quote fields with double-quote, same as RFC 4180
  - `''` disable quoting
- Corresponds to the `FIELDS ENCLOSED BY` option in the `LOAD DATA` statement.

5.3.1.3.3 `header`

- Whether *all* CSV files contain a header row.
- If `header` is true, the first row will be used as the *column names*. If `header` is false, the first row is not special and treated as an ordinary data row.

5.3.1.3.4 `not-null` and `null`

- The `not-null` setting controls whether all fields are non-nullable.
- If `not-null` is false, the string specified by `null` will be transformed to the SQL NULL instead of a concrete value.
- Quoting will not affect whether a field is null.

  For example, with the CSV file:

```
A,B,C
\N,"\N",
```

  In the default settings (`not-null = false; null = '\N'`), the columns `A` and `B` are both converted to NULL after importing to TiDB. The column `C` is simply the empty string `''` but not NULL.

5.3.1.3.5 `backslash-escape`

- Whether to interpret backslash escapes inside fields.
- If `backslash-escape` is true, the following sequences are recognized and transformed:

Sequence	Converted to
`\0`	Null character (U+0000)
`\b`	Backspace (U+0008)
`\n`	Line feed (U+000A)
`\r`	Carriage return (U+000D)
`\t`	Tab (U+0009)
`\Z`	Windows EOF (U+001A)

  In all other cases (for example, `\"`) the backslash is simply stripped, leaving the next character (`"`) in the field. The character left has no special roles (for example, delimiters) and is just an ordinary character.

- Quoting will not affect whether backslash escapes are interpreted.
- Corresponds to the `FIELDS ESCAPED BY '\'` option in the `LOAD DATA` statement.

5.3.1.3.6 `trim-last-separator`

- Treats the field `separator` as a terminator, and removes all trailing separators.

  For example, with the CSV file:

```
A,,B,,
```

- When `trim-last-separator = false`, this is interpreted as a row of 5 fields `('A', '', 'B', '', '')`.
- When `trim-last-separator = true`, this is interpreted as a row of 3 fields `('A', '', 'B')`.

5.3.1.3.7 Non-configurable options

TiDB Lightning does not support every option supported by the `LOAD DATA` statement. Some examples:

- The line terminator must only be CR (`\r`), LF (`\n`) or CRLF (`\r\n`), which means `LINES TERMINATED BY` is not customizable.
- There cannot be line prefixes (`LINES STARTING BY`).
- The header cannot be simply skipped (`IGNORE n LINES`). It must be valid column names if present.

5.3.1.4 Strict format

Lightning works the best when the input files have uniform size around 256 MB. When the input is a single huge CSV file, Lightning can only use one thread to process it, which slows down import speed a lot.

This can be fixed by splitting the CSV into multiple files first. For the generic CSV format, there is no way to quickly identify when a row starts and ends without reading the whole file. Therefore, Lightning by default does *not* automatically split a CSV file. However, if you are certain that the CSV input adheres to certain restrictions, you can enable the `strict-format` setting to allow Lightning to split the file into multiple 256 MB-sized chunks for parallel processing.

```
[mydumper]
strict-format = true
```

Currently, a strict CSV file means every field occupies only a single line. In other words, one of the following must be true:

- Delimiter is empty, or
- Every field does not contain CR (`\r`) or LF (`\n`).

If a CSV file is not strict, but `strict-format` was wrongly set to `true`, a field spanning multiple lines may be cut in half into two chunks, causing parse failure, or even worse, quietly importing corrupted data.

5.3.1.5 Common configurations

5.3.1.5.1 CSV

The default setting is already tuned for CSV following RFC 4180.

```
[mydumper.csv]
separator = ',' # It is not recommended to use the default ',' . It is
    ↪ recommended to use '\|+\|' or other uncommon character combinations
    ↪ .
delimiter = '"'
header = true
not-null = false
null = '\N'
backslash-escape = true
trim-last-separator = false
```

Example content:

```
ID,Region,Count
1,"East",32
2,"South",\N
3,"West",10
4,"North",39
```

5.3.1.5.2 TSV

```
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
trim-last-separator = false
```

Example content:

```
ID    Region    Count
1     East      32
2     South     NULL
3     West      10
4     North     39
```

5.3.1.5.3 TPC-H DBGEN

```
[mydumper.csv]
separator = '|'
delimiter = ''
header = false
not-null = true
backslash-escape = false
trim-last-separator = true
```

Example content:

```
1|East|32|
2|South|0|
3|West|10|
4|North|39|
```

5.3.2 LOAD DATA

The `LOAD DATA` statement batch loads data into a TiDB table.

5.3.2.1 Synopsis

```
LoadDataStmt ::=
    'LOAD' 'DATA' LocalOpt 'INFILE' stringLit DuplicateOpt 'INTO' 'TABLE'
        ↪ TableName CharsetOpt Fields Lines IgnoreLines
        ↪ ColumnNameOrUserVarListOptWithBrackets LoadDataSetSpecOpt
```

5.3.2.2 Parameters

5.3.2.2.1 `LocalOpt`

You can specify that the imported data file is located on the client or on the server by configuring the `LocalOpt` parameter. Currently, TiDB only supports data import from the client. Therefore, when importing data, set the value of `LocalOpt` to `Local`.

5.3.2.2.2 `Fields` and `Lines`

You can specify how to process the data format by configuring the `Fields` and `Lines` parameters.

- `FIELDS TERMINATED BY`: Specifies the separating character of each data.
- `FIELDS ENCLOSED BY`: Specifies the enclosing character of each data.
- `LINES TERMINATED BY`: Specifies the line terminator, if you want to end a line with a certain character.

Take the following data format as an example:

```
"bob","20","street 1"\r\n
"alice","33","street 1"\r\n
```

If you want to extract `bob`, `20`, and `street 1`, specify the separating character as `','`, and the enclosing character as `'\"'`:

```
FIELDS TERMINATED BY ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n'
```

If you do not specify the parameters above, the imported data is processed in the following way by default:

```
FIELDS TERMINATED BY '\t' ENCLOSED BY ''
LINES TERMINATED BY '\n'
```

5.3.2.2.3 `IGNORE number LINES`

You can ignore the first `number` lines of a file by configuring the `IGNORE number LINES` parameter. For example, if you configure `IGNORE 1 LINES`, the first line of a file is ignored.

In addition, TiDB currently only supports parsing the syntax of the `DuplicateOpt`, `CharsetOpt`, and `LoadDataSetSpecOpt` parameters.

5.3.2.3 Examples

```
CREATE TABLE trips (
    trip_id bigint NOT NULL PRIMARY KEY AUTO_INCREMENT,
    duration integer not null,
    start_date datetime,
    end_date datetime,
    start_station_number integer,
    start_station varchar(255),
    end_station_number integer,
    end_station varchar(255),
    bike_number varchar(255),
    member_type varchar(255)
    );
```

```
Query OK, 0 rows affected (0.14 sec)
```

The following example imports data using `LOAD DATA`. Comma is specified as the separating character. The double quotation marks that enclose the data is ignored. The first line of the file is ignored.

If you see the error message `ERROR 1148 (42000): the used command is not allowed with this TiDB version`, refer to ERROR 1148 (42000): the used command is not allowed with this TiDB version.

```
LOAD DATA LOCAL INFILE '/mnt/evo970/data-sets/bikeshare-data/2017Q4-
    ↪ capitalbikeshare-tripdata.csv' INTO TABLE trips FIELDS TERMINATED BY
    ↪ ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n' IGNORE 1 LINES (
    ↪ duration, start_date, end_date, start_station_number, start_station,
    ↪ end_station_number, end_station, bike_number, member_type);
```

```
Query OK, 815264 rows affected (39.63 sec)
Records: 815264 Deleted: 0 Skipped: 0 Warnings: 0
```

`LOAD DATA` also supports using hexadecimal ASCII character expressions or binary ASCII character expressions as the parameters for `FIELDS ENCLOSED BY` and `FIELDS TERMINATED BY`. See the following example:

```
LOAD DATA LOCAL INFILE '/mnt/evo970/data-sets/bikeshare-data/2017Q4-
    ↪ capitalbikeshare-tripdata.csv' INTO TABLE trips FIELDS TERMINATED BY
    ↪ x'2c' ENCLOSED BY b'100010' LINES TERMINATED BY '\r\n' IGNORE 1 LINES
    ↪  (duration, start_date, end_date, start_station_number, start_station
    ↪ , end_station_number, end_station, bike_number, member_type);
```

In the above example, `x'2c'` is the hexadecimal representation of the `,` character and `b'100010'` is the binary representation of the `"` character.

5.3.2.4 MySQL compatibility

The syntax of this statement is compatible with MySQL except for the `LOAD DATA... ↪ REPLACE INTO` syntax #24515. Any other syntax compatibility differences should be reported via an issue on GitHub.

Note:

- For versions earlier than TiDB v4.0.0, `LOAD DATA` committed every 20000 rows. By default, TiDB now commits all rows in one transaction. This can result in the error `ERROR 8004 (HY000)at line 1: Transaction ↪ is too large, size: 100000058` after upgrading from TiDB 4.0 or earlier versions. The recommended way to resolve this error is to increase the `txn-total-size-limit` value in your `tidb.toml` file. If you are unable to increase this limit, you can also restore the previous behavior by setting `tidb_dml_batch_size` to 20000.
- No matter how many rows are committed in a transaction, `LOAD DATA` is not rolled back by the `ROLLBACK` statement in an explicit transaction.
- The `LOAD DATA` statement is always executed in optimistic transaction mode, regardless of the TiDB transaction mode configuration.

5.4 Migrate from MySQL SQL Files Using TiDB Lightning

This document describes how to migrate data from MySQL SQL files to TiDB using TiDB Lightning. For details on how to generate MySQL SQL files, refer to Dumpling.

The data migration process described in this document uses TiDB Lightning. The steps are as follows.

5.4.1 Step 1: Deploy TiDB Lightning

Before you start the migration, deploy TiDB Lightning.

Note:

- If you choose the Local-backend to import data, the TiDB cluster cannot provide services during the import process. This mode imports data quickly, which is suitable for importing a large amount of data (above the TB level).
- If you choose the TiDB-backend, the cluster can provide services normally during the import, at a slower import speed.
- For detailed differences between the two backend modes, see TiDB Lightning Backends.

5.4.2 Step 2: Configure data source of TiDB Lightning

This document takes the TiDB-backend as an example. Create the `tidb-lightning.toml` configuration file and add the following major configurations in the file:

1. Set the `data-source-dir` under `[mydumper]` to the path of the MySQL SQL file.

```
[mydumper]
# Data source directory
data-source-dir = "/data/export"
```

Note:

If a corresponding schema already exists in the downstream, set `no-schema=true` to skip the creation of the schema.

2. Add the configuration of the target TiDB cluster.

```
[tidb]
# The target cluster information. Fill in one address of tidb-server.
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
```

3. Add the necessary parameter for the backend. This document uses the TiDB-backend mode. Here, "backend" can also be set to "local" or "importer" according to your actual application scenario. For details, refer to Backend Mode.

```
[tikv-importer]
backend = "tidb"
```

4. Add necessary parameters for importing the TiDB cluster.

```
[tidb]
host = "{{tidb-host}}"
port = {{tidb-port}}
user = "{{tidb-user}}"
password = "{{tidb-password}}"
```

For other configurations, see TiDB Lightning Configuration.

5.4.3 Step 3: Run TiDB Lightning to import data

Run TiDB Lightning to start the import operation. If you start TiDB Lightning by using `nohup` directly in the command line, the program might exit because of the `SIGHUP` signal. Therefore, it is recommended to write `nohup` in a script. For example:

```
## !/bin/bash
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

When the import operation is started, view the progress by the following two ways:

- `grep` the keyword `progress` in logs, which is updated every 5 minutes by default.
- Access the monitoring dashboard. See Monitor TiDB Lightning for details.

6 Maintain

6.1 Upgrade

6.1.1 Upgrade TiDB Using TiUP

This document is targeted for the following upgrade paths:

- Upgrade from TiDB 4.0 versions to TiDB 5.1 versions.
- Upgrade from TiDB 5.0 versions to TiDB 5.1 versions.

> **Note:**
>
> If your cluster to be upgraded is v3.1 or an earlier version (v3.0 or v2.1), the direct upgrade to v5.1 or its patch versions is not supported. You need to upgrade your cluster first to v4.0 and then to v5.1.

6.1.1.1 Upgrade caveat

- TiDB currently does not support version downgrade or rolling back to an earlier version after the upgrade.
- For the v4.0 cluster managed using TiDB Ansible, you need to import the cluster to TiUP (`tiup cluster`) for new management according to Upgrade TiDB Using TiUP (v4.0). Then you can upgrade the cluster to v5.1 or its patch versions according to this document.
- To update versions earlier than 3.0 to 5.1:
  1. Update this version to 3.0 using TiDB Ansible.
  2. Use TiUP (`tiup cluster`) to import the TiDB Ansible configuration.
  3. Update the 3.0 version to 4.0 according to Upgrade TiDB Using TiUP (v4.0).
  4. Upgrade the cluster to v5.1 according to this document.
- Support upgrading the versions of TiDB Binlog, TiCDC, TiFlash, and other components.
- For detailed compatibility changes of different versions, see the Release Notes of each version. Modify your cluster configuration according to the "Compatibility Changes" section of the corresponding release notes.

> **Note:**
>
> Do not execute any DDL request during the upgrade, otherwise an undefined behavior issue might occur.

6.1.1.2 Preparations

This section introduces the preparation works needed before upgrading your TiDB cluster, including upgrading TiUP and the TiUP Cluster component.

6.1.1.2.1 Step 1: Upgrade TiUP or TiUP offline mirror

Before upgrading your TiDB cluster, you first need to upgrade TiUP or TiUP mirror.

Upgrade TiUP and TiUP Cluster

> **Note:**
>
> If the control machine of the cluster to upgrade cannot access `https://tiup-mirrors.pingcap.com`, skip this section and see Upgrade TiUP offline mirror.

1. Upgrade the TiUP version. It is recommended that the TiUP version is `1.5.0` or later.

```
tiup update --self
tiup --version
```

2. Upgrade the TiUP Cluster version. It is recommended that the TiUP Cluster version is `1.5.0` or later.

```
tiup update cluster
tiup cluster --version
```

Upgrade TiUP offline mirror

> **Note:**
>
> If the cluster to upgrade was deployed not using the offline method, skip this step.

Refer to Deploy a TiDB Cluster Using TiUP - Deploy TiUP offline to download the TiUP mirror of the new version and upload it to the control machine. After executing `local_install.sh`, TiUP will complete the overwrite upgrade.

```
tar xzvf tidb-community-server-${version}-linux-amd64.tar.gz
sh tidb-community-server-${version}-linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

After the overwrite upgrade, execute the following command to upgrade the TiUP Cluster component.

```
tiup update cluster
```

Now, the offline mirror has been upgraded successfully. If an error occurs during TiUP operation after the overwriting, it might be that the `manifest` is not updated. You can try `rm -rf ~/.tiup/manifests/*` before running TiUP again.

6.1.1.2.2 Step 2: Edit TiUP topology configuration file

> **Note:**
>
> Skip this step if one of the following situations applies:

- You have not modified the configuration parameters of the original cluster. Or you have modified the configuration parameters using `tiup cluster` but no more modification is needed.
- After the upgrade, you want to use v5.1's default parameter values for the unmodified configuration items.

1. Enter the `vi` editing mode to edit the topology file:

```
tiup cluster edit-config <cluster-name>
```

2. Refer to the format of topology configuration template and fill the parameters you want to modify in the `server_configs` section of the topology file.

3. After the modification, enter : + w + q to save the change and exit the editing mode. Enter Y to confirm the change.

Note:

Before you upgrade the cluster to v5.1, make sure that the parameters you have modified in v4.0 are compatible in v5.1. For details, see TiKV Configuration File.

6.1.1.2.3 Step 3: Check the health status of the current cluster

To avoid the undefined behaviors or other issues during the upgrade, it is recommended to check the health status of Regions of the current cluster before the upgrade. To do that, you can use the `check` sub-command.

```
tiup cluster check <cluster-name> --cluster
```

After the command is executed, the "Region status" check result will be output.

- If the result is "All Regions are healthy", all Regions in the current cluster are healthy and you can continue the upgrade.
- If the result is "Regions are not fully healthy: m miss-peer, n pending-peer" with the "Please fix unhealthy regions before other operations." prompt, some Regions in the current cluster are abnormal. You need to troubleshoot the anomalies until the check result becomes "All Regions are healthy". Then you can continue the upgrade.

6.1.1.3 Perform a rolling upgrade to the TiDB cluster

This section describes how to perform a rolling upgrade to the TiDB cluster and how to verify the version after the upgrade.

6.1.1.3.1 Upgrade the TiDB cluster to a specified version

You can upgrade your cluster in one of the two ways: online upgrade and offline upgrade.

By default, TiUP Cluster upgrades the TiDB cluster using the online method, which means that the TiDB cluster can still provide services during the upgrade process. With the online method, the leaders are migrated one by one on each node before the upgrade and restart. Therefore, for a large-scale cluster, it takes a long time to complete the entire upgrade operation.

If your application has a maintenance window for the database to be stopped for maintenance, you can use the offline upgrade method to quickly perform the upgrade operation.

Online upgrade

```
tiup cluster upgrade <cluster-name> <version>
```

For example, if you want to upgrade the cluster to v5.1.5:

```
tiup cluster upgrade <cluster-name> v5.1.5
```

Note:

- Performing a rolling upgrade to the cluster will upgrade all components one by one. During the upgrade of TiKV, all leaders in a TiKV instance are evicted before stopping the instance. The default timeout time is 5 minutes (300 seconds). The instance is directly stopped after this timeout time.
- To perform the upgrade immediately without evicting the leader, specify `--force` in the command above. This method causes performance jitter but not data loss.
- To keep a stable performance, make sure that all leaders in a TiKV instance are evicted before stopping the instance. You can set `--transfer-timeout` to a larger value, for example, `--transfer-timeout 3600` (unit: second).

Offline upgrade

1. Before the offline upgrade, you first need to stop the entire cluster.

```
tiup cluster stop <cluster-name>
```

2. Use the `upgrade` command with the `--offline` option to perform the offline upgrade.

```
tiup cluster upgrade <cluster-name> <version> --offline
```

3. After the upgrade, the cluster will not be automatically restarted. You need to use the `start` command to restart it.

```
tiup cluster start <cluster-name>
```

6.1.1.3.2 Verify the cluster version

Execute the `display` command to view the latest cluster version `TiDB Version`:

```
tiup cluster display <cluster-name>
```

```
Cluster type:     tidb
Cluster name:     <cluster-name>
Cluster version:  v5.1.5
```

> **Note:**
>
> By default, TiUP and TiDB share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.

6.1.1.4 FAQ

This section describes common problems encountered when updating the TiDB cluster using TiUP.

6.1.1.4.1 If an error occurs and the upgrade is interrupted, how to resume the upgrade after fixing this error?

Re-execute the `tiup cluster upgrade` command to resume the upgrade. The upgrade operation restarts the nodes that have been previously upgraded. If you do not want the upgraded nodes to be restarted, use the `replay` sub-command to retry the operation:

1. Execute `tiup cluster audit` to see the operation records:

```
tiup cluster audit
```

Find the failed upgrade operation record and keep the ID of this operation record. The ID is the `<audit-id>` value in the next step.

2. Execute `tiup cluster replay <audit-id>` to retry the corresponding operation:

```
tiup cluster replay <audit-id>
```

6.1.1.4.2 The evict leader has waited too long during the upgrade. How to skip this step for a quick upgrade?

You can specify `--force`. Then the processes of transferring PD leader and evicting TiKV leader are skipped during the upgrade. The cluster is directly restarted to update the version, which has a great impact on the cluster that runs online. Here is the command:

```
tiup cluster upgrade <cluster-name> <version> --force
```

6.1.1.4.3 How to update the version of tools such as pd-ctl after upgrading the TiDB cluster?

You can upgrade the tool version by using TiUP to install the `ctl` component of the corresponding version:

```
tiup install ctl:v5.1.5
```

6.1.1.5 TiDB 5.1 compatibility changes

- See TiDB 5.1 Release Notes for the compatibility changes.
- Try to avoid creating a new clustered index table when you apply rolling updates to the clusters using TiDB-Binlog.

6.1.2 Use TiDB Operator

6.2 Scale

6.2.1 Scale the TiDB Cluster Using TiUP

The capacity of a TiDB cluster can be increased or decreased without interrupting the online services.

This document describes how to scale the TiDB, TiKV, PD, TiCDC, or TiFlash cluster using TiUP. If you have not installed TiUP, refer to the steps in Install TiUP on the control machine.

To view the current cluster name list, run `tiup cluster list`.

For example, if the original topology of the cluster is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.1.1 Scale out a TiDB/PD/TiKV cluster

If you want to add a TiDB node to the `10.0.1.5` host, take the following steps.

> **Note:**
>
> You can take similar steps to add the PD node. Before you add the TiKV node, it is recommended that you adjust the PD scheduling parameters in advance according to the cluster load.

1. Configure the scale-out topology:

> **Note:**
>
> - The port and directory information is not required by default.
> - If multiple instances are deployed on a single machine, you need to allocate different ports and directories for them. If the ports or directories have conflicts, you will receive a notification during deployment or scaling.
> - Since TiUP v1.0.0, the scale-out configuration will inherit the global configuration of the original cluster.

Add the scale-out topology configuration in the `scale-out.yaml` file:

```
vi scale-out.yaml
```

```
tidb_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 4000
  status_port: 10080
  deploy_dir: /data/deploy/install/deploy/tidb-4000
  log_dir: /data/deploy/install/log/tidb-4000
```

Here is a TiKV configuration file template:

```
tikv_servers:
- host: 10.0.1.5
  ssh_port: 22
  port: 20160
  status_port: 20180
  deploy_dir: /data/deploy/install/deploy/tikv-20160
  data_dir: /data/deploy/install/data/tikv-20160
  log_dir: /data/deploy/install/log/tikv-20160
```

Here is a PD configuration file template:

```
pd_servers:
- host: 10.0.1.5
  ssh_port: 22
  name: pd-1
  client_port: 2379
  peer_port: 2380
  deploy_dir: /data/deploy/install/deploy/pd-2379
  data_dir: /data/deploy/install/data/pd-2379
  log_dir: /data/deploy/install/log/pd-2379
```

To view the configuration of the current cluster, run `tiup cluster edit-config <cluster-name>`. Because the parameter configuration of `global` and `server_configs` is inherited by `scale-out.yaml` and thus also takes effect in `scale-out.yaml`.

After the configuration, the current topology of the cluster is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	**TiDB** + TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yaml
```

Note:

The command above is based on the assumption that the mutual trust has been configured for the user to execute the command and the new

machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

If you see the `Scaled cluster <cluster-name> out successfully`, the scale-out operation is successfully completed.

3. Check the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser to monitor the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	**TiDB** + TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.1.2 Scale out a TiFlash cluster

If you want to add a TiFlash node to the `10.0.1.4` host, take the following steps.

Note:

When adding a TiFlash node to an existing TiDB cluster, you need to note the following things:

1. Confirm that the current TiDB version supports using TiFlash. Otherwise, upgrade your TiDB cluster to v5.0 or later versions.
2. Execute the `tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> config set enable-placement-rules true` command to enable the Placement Rules feature. Or execute the corresponding command in pd-ctl.

1. Add the node information to the `scale-out.yaml` file:

Create the `scale-out.yaml` file to add the TiFlash node information.

```
tiflash_servers:
  - host: 10.0.1.4
```

Currently, you can only add IP but not domain name.

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yaml
```

> **Note:**
> The command above is based on the assumption that the mutual trust has been configured for the user to execute the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD + **TiFlash**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.1.3 Scale out a TiCDC cluster

If you want to add two TiCDC nodes to the `10.0.1.3` and `10.0.1.4` hosts, take the following steps.

1. Add the node information to the `scale-out.yaml` file:

Create the `scale-out.yaml` file to add the TiCDC node information.

```
cdc_servers:
```

```
  - host: 10.0.1.3
    gc-ttl: 86400
    data_dir: /data/deploy/install/data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /data/deploy/install/data/cdc-8300
```

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yaml
```

> **Note:**
>
> The command above is based on the assumption that the mutual trust has been configured for the user to execute the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + **TiCDC**
10.0.1.4	TiDB + PD + TiFlash + **TiCDC**
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.1.4 Scale in a TiDB/PD/TiKV cluster

If you want to remove a TiKV node from the `10.0.1.5` host, take the following steps.

> **Note:**

- You can take similar steps to remove the TiDB and PD node.
- Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously and the stopping process takes a long time, TiUP takes them offline in different methods. For details, see Particular handling of components' offline process.

Note:

The PD Client in TiKV caches the list of PD nodes. The current version of TiKV has a mechanism to automatically and regularly update PD nodes, which can help mitigate the issue of an expired list of PD nodes cached by TiKV. However, after scaling out PD, you should try to avoid directly removing all PD nodes at once that exist before the scaling. If necessary, before making all the previously existing PD nodes offline, make sure to switch the PD leader to a newly added PD node.

1. View the node ID information:

```
tiup cluster display <cluster-name>
```

```
Starting /root/.tiup/components/cluster/v1.5.0/cluster display <cluster
    ↪ -name>
TiDB Cluster: <cluster-name>
TiDB Version: v5.1.5
ID            Role        Host       Ports                            Status
    ↪  Data Dir             Deploy Dir
--            ----        ----       -----                            ------
    ↪  --------             ----------
10.0.1.3:8300 cdc         10.0.1.3   8300                             Up
    ↪      data/cdc-8300        deploy/cdc-8300
10.0.1.4:8300 cdc         10.0.1.4   8300                             Up
    ↪      data/cdc-8300        deploy/cdc-8300
10.0.1.4:2379 pd          10.0.1.4   2379/2380
    ↪ Healthy data/pd-2379        deploy/pd-2379
10.0.1.1:20160 tikv       10.0.1.1   20160/20180                      Up
    ↪      data/tikv-20160      deploy/tikv-20160
10.0.1.2:20160 tikv       10.0.1.2   20160/20180                      Up
    ↪      data/tikv-20160      deploy/tikv-20160
10.0.1.5:20160 tikv       10.0.1.5   20160/20180                      Up
    ↪      data/tikv-20160      deploy/tikv-20160
```

```
10.0.1.3:4000 tidb       10.0.1.3   4000/10080                   Up
   ↪     -                    deploy/tidb-4000
10.0.1.4:4000 tidb       10.0.1.4   4000/10080                   Up
   ↪     -                    deploy/tidb-4000
10.0.1.5:4000 tidb       10.0.1.5   4000/10080                   Up
   ↪     -                    deploy/tidb-4000
10.0.1.3:9000 tiflash    10.0.1.3   9000/8123/3930/20170/20292/8234 Up
   ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.4:9000 tiflash    10.0.1.4   9000/8123/3930/20170/20292/8234 Up
   ↪  data/tiflash-9000    deploy/tiflash-9000
10.0.1.5:9090 prometheus 10.0.1.5   9090                         Up
   ↪     data/prometheus-9090 deploy/prometheus-9090
10.0.1.5:3000 grafana    10.0.1.5   3000                         Up
   ↪     -                    deploy/grafana-3000
10.0.1.5:9093 alertmanager 10.0.1.5 9093/9294                   Up
   ↪     data/alertmanager-9093 deploy/alertmanager-9093
```

2. Run the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.5:20160
```

   The `--node` parameter is the ID of the node to be taken offline.

   If you see the `Scaled cluster <cluster-name> in successfully`, the scale-in operation is successfully completed.

3. Check the cluster status:

   The scale-in process takes some time. If the status of the node to be scaled in becomes `Tombstone`, that means the scale-in operation is successful.

   To check the scale-in status, run the following command:

```
tiup cluster display <cluster-name>
```

   Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiFlash + TiCDC
10.0.1.5	TiDB + Monitor **(TiKV is deleted)**
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.1.5 Scale in a TiFlash cluster

If you want to remove a TiFlash node from the `10.0.1.4` host, take the following steps.

6.2.1.5.1 1. Adjust the number of replicas of the tables according to the number of remaining TiFlash nodes

Before the node goes down, make sure that the number of remaining nodes in the TiFlash cluster is no smaller than the maximum number of replicas of all tables. Otherwise, modify the number of TiFlash replicas of the related tables.

1. For all tables whose replicas are greater than the number of remaining TiFlash nodes in the cluster, execute the following command in the TiDB client:

```
alter table <db-name>.<table-name> set tiflash replica 0;
```

2. Wait for the TiFlash replicas of the related tables to be deleted. Check table replication progress and the replicas are deleted if the replication information of the related tables is not found.

6.2.1.5.2 2. Perform the scale-in operation

Next, perform the scale-in operation with one of the following solutions.

Solution 1: Use TiUP to remove a TiFlash node

1. First, confirm the name of the node to be taken down:

```
tiup cluster display <cluster-name>
```

2. Remove the TiFlash node (assume that the node name is `10.0.1.4:9000` from Step 1):

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:9000
```

Solution 2: Manually remove a TiFlash node

In special cases (such as when a node needs to be forcibly taken down), or if the TiUP scale-in operation fails, you can manually remove a TiFlash node with the following steps.

1. Use the store command of pd-ctl to view the store ID corresponding to this TiFlash node.

    - Enter the store command in pd-ctl (the binary file is under `resources/bin` in the tidb-ansible directory).

- If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:<cluster-version > pd`:

```
tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store
```

> **Note:**
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

2. Remove the TiFlash node in pd-ctl:

   - Enter `store delete <store_id>` in pd-ctl (`<store_id>` is the store ID of the TiFlash node found in the previous step.
   - If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:<cluster-version > pd`:

```
tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store
    ↪ delete <store_id>
```

> **Note:**
> If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

3. Wait for the store of the TiFlash node to disappear or for the `state_name` to become `Tombstone` before you stop the TiFlash process.
4. Manually delete TiFlash data files (whose location can be found in the `data_dir` directory under the TiFlash configuration of the cluster topology file).
5. Manually update TiUP's cluster configuration file (delete the information of the TiFlash node that goes down in edit mode).

```
tiup cluster edit-config <cluster-name>
```

> **Note:**
>
> Before all TiFlash nodes in the cluster stop running, if not all tables replicated to TiFlash are canceled, you need to manually clean up the replication rules in PD, or the TiFlash node cannot be taken down successfully.

The steps to manually clean up the replication rules in PD are below:

1. View all data replication rules related to TiFlash in the current PD instance:

```
curl http://<pd_ip>:<pd_port>/pd/api/v1/config/rules/group/tiflash
```

```
[
  {
    "group_id": "tiflash",
    "id": "table-45-r",
    "override": true,
    "start_key": "7480000000000000FF2D5F720000000000FA",
    "end_key": "7480000000000000FF2E00000000000000F8",
    "role": "learner",
    "count": 1,
    "label_constraints": [
      {
        "key": "engine",
        "op": "in",
        "values": [
          "tiflash"
        ]
      }
    ]
  }
]
```

2. Remove all data replication rules related to TiFlash. Take the rule whose `id` is `table -45-r` as an example. Delete it by the following command:

```
curl -v -X DELETE http://<pd_ip>:<pd_port>/pd/api/v1/config/rule/
    ↪ tiflash/table-45-r
```

6.2.1.6 Scale in a TiCDC cluster

If you want to remove the TiCDC node from the `10.0.1.4` host, take the following steps:

1. Take the node offline:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

2. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at http://10.0.1.5:3000 using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + **(TiCDC is deleted)**
10.0.1.5	TiDB + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.2.2 Use TiDB Operator

6.3 Backup and Restore

6.3.1 Use BR Tool (Recommended)

6.3.1.1 BR Tool Overview

BR (Backup & Restore) is a command-line tool for distributed backup and restoration of the TiDB cluster data.

Compared with Dumpling, BR is more suitable to scenarios involving huge data volumes.

In addition to regular backup and restoration, you can also use BR for large-scale data migration as long as compatibility is ensured.

This document describes BR's implementation principles, recommended deployment configuration, usage restrictions and several methods to use BR.

6.3.1.1.1 Implementation principles

BR sends the backup or restoration commands to each TiKV node. After receiving these commands, TiKV performs the corresponding backup or restoration operations.

Each TiKV node has a path in which the backup files generated in the backup operation are stored and from which the stored backup files are read during the restoration.

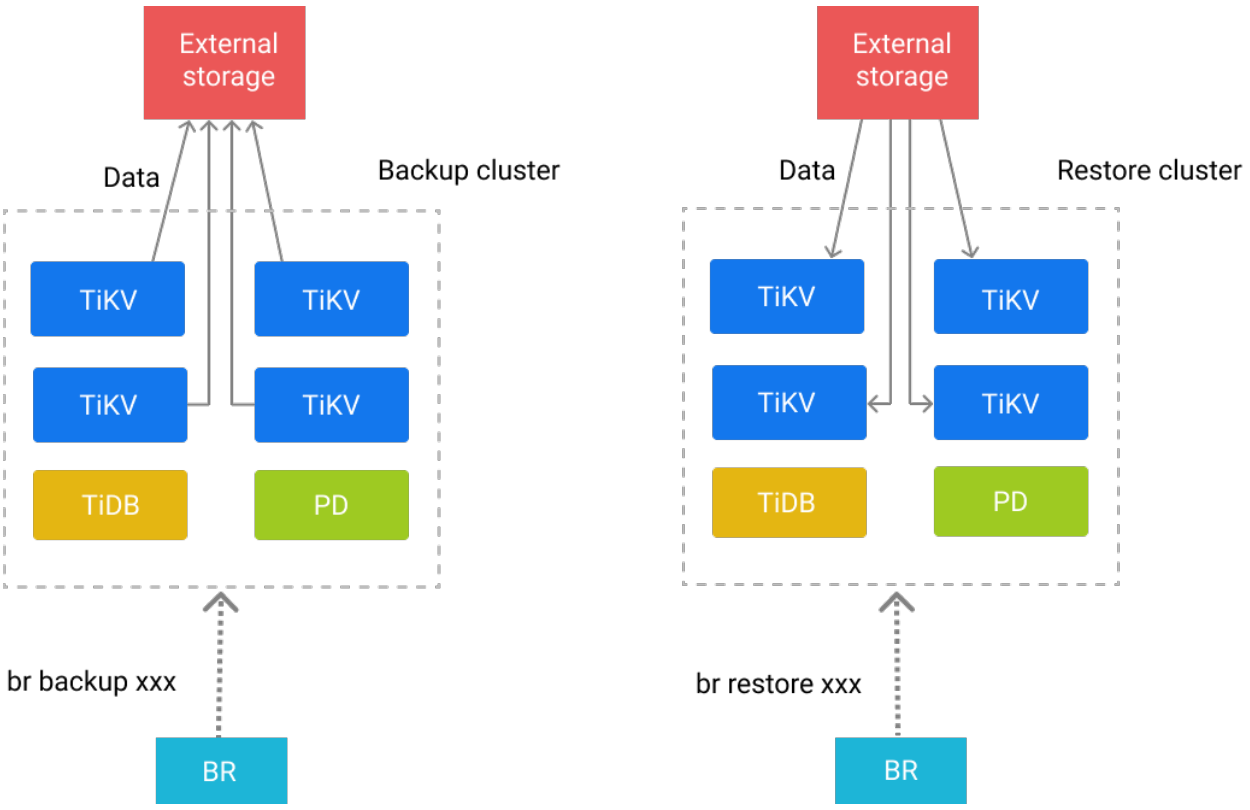

Figure 10: br-arch

Backup principle

When BR performs a backup operation, it first obtains the following information from PD:

- The current TS (timestamp) as the time of the backup snapshot
- The TiKV node information of the current cluster

According to these information, BR starts a TiDB instance internally to obtain the database or table information corresponding to the TS, and filters out the system databases (`information_schema`, `performance_schema`, `mysql`) at the same time.

According to the backup sub-command, BR adopts the following two types of backup logic:

- Full backup: BR traverses all the tables and constructs the KV range to be backed up according to each table.
- Single table backup: BR constructs the KV range to be backed up according a single table.

Finally, BR collects the KV range to be backed up and sends the complete backup request to the TiKV node of the cluster.

The structure of the request:

```
BackupRequest{
    ClusterId,    // The cluster ID.
    StartKey,     // The starting key of the backup (backed up).
    EndKey,       // The ending key of the backup (not backed up).
    StartVersion, // The version of the last backup snapshot, used for the
        ↪ incremental backup.
    EndVersion,   // The backup snapshot time.
    StorageBackend, // The path where backup files are stored.
    RateLimit,    // Backup speed (MB/s).
}
```

After receiving the backup request, the TiKV node traverses all Region leaders on the node to find the Regions that overlap with the KV ranges in this request. The TiKV node backs up some or all of the data within the range, and generates the corresponding SST file.

After finishing backing up the data of the corresponding Region, the TiKV node returns the metadata to BR. BR collects the metadata and stores it in the `backupmeta` file which is used for restoration.

If `StartVersion` is not `0`, the backup is seen as an incremental backup. In addition to KVs, BR also collects DDLs between `[StartVersion, EndVersion)`. During data restoration, these DDLs are restored first.

If checksum is enabled when you execute the backup command, BR calculates the checksum of each backed up table for data check.

Types of backup files

Two types of backup files are generated in the path where backup files are stored:

- **The SST file**: stores the data that the TiKV node backed up.
- **The `backupmeta` file**: stores the metadata of this backup operation, including the number, the key range, the size, and the Hash (sha256) value of the backup files.
- **The `backup.lock` file**: prevents multiple backup operations from storing data to the same directory.

The format of the SST file name

The SST file is named in the format of `storeID_regionID_regionEpoch_keyHash_cf`, where

- `storeID` is the TiKV node ID;
- `regionID` is the Region ID;
- `regionEpoch` is the version number of the Region;

- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a key;
- `cf` indicates the Column Family of RocksDB (`default` or `write` by default).

Restoration principle

During the data restoration process, BR performs the following tasks in order:

1. It parses the `backupmeta` file in the backup path, and then starts a TiDB instance internally to create the corresponding databases and tables based on the parsed information.
2. It aggregates the parsed SST files according to the tables.
3. It pre-splits Regions according to the key range of the SST file so that every Region corresponds to at least one SST file.
4. It traverses each table to be restored and the SST file corresponding to each tables.
5. It finds the Region corresponding to the SST file and sends a request to the corresponding TiKV node for downloading the file. Then it sends a request for loading the file after the file is successfully downloaded.

After TiKV receives the request to load the SST file, TiKV uses the Raft mechanism to ensure the strong consistency of the SST data. After the downloaded SST file is loaded successfully, the file is deleted asynchronously.

After the restoration operation is completed, BR performs a checksum calculation on the restored data to compare the stored data with the backed up data.

6.3.1.1.2 Deploy and use BR

Recommended deployment configuration

- It is recommended that you deploy BR on the PD node.
- It is recommended that you mount a high-performance SSD to BR nodes and all TiKV nodes. A 10-gigabit network card is recommended. Otherwise, bandwidth is likely to be the performance bottleneck during the backup and restore process.

Note:

- If you do not mount a network disk or use other shared storage, the data backed up by BR will be generated on each TiKV node. Because BR only backs up leader replicas, you should estimate the space reserved for each node based on the leader size.

- Because TiDB uses leader count for load balancing by default, leaders can greatly differ in size. This might resulting in uneven distribution of backup data on each node.

Usage restrictions

The following are the limitations of using BR for backup and restoration:

- When BR restores data to the upstream cluster of TiCDC/Drainer, TiCDC/Drainer cannot replicate the restored data to the downstream.
- BR supports operations only between clusters with the same `new_collations_enabled_on_first_bo` ↪ value because BR only backs up KV data. If the cluster to be backed up and the cluster to be restored use different collations, the data validation fails. Therefore, before restoring a cluster, make sure that the switch value from the query result of the `select VARIABLE_VALUE from mysql.tidb where VARIABLE_NAME='` ↪ `new_collation_enabled';` statement is consistent with that during the backup process.

Compatibility

The compatibility issues of BR and the TiDB cluster are divided into the following categories:

- Some versions of BR are not compatible with the interface of the TiDB cluster.
- The KV format might change when some features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

These features are as follows:

Features	Related issues	Solutions

Features	Related issues	Solutions
Clustered index	#565	Make sure that the value of the `tidb_enable_clustered_index` global variable during restore is consistent with that during backup. Otherwise, data inconsistency might occur, such as `default not found` and inconsistent

Features	Related issues	Solutions
New collation	#352	Make sure that the value of the `new_collations_enabled_on_first_bootstrap` variable is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass.

Features	Related issues	Solutions
TiCDC enabled on the restore cluster	#364	Currently, TiKV cannot push down the BR-ingested SST files to TiCDC. Therefore, you need to disable TiCDC when using BR to restore data.

However, even after you have ensured that the above features are consistently enabled or disabled during backup and restore, compatibility issues might still occur due to the inconsistent internal versions or inconsistent interfaces between BR and TiKV/TiDB/PD. To avoid such cases, BR has the built-in version check.

Version check

Before performing backup and restore, BR compares and checks the TiDB cluster version and the BR version. If there is a major-version mismatch (for example, BR v4.x and TiDB v5.x), BR prompts a reminder to exit. To forcibly skip the version check, you can set `--check-requirements=false`.

Note that skipping the version check might introduce incompatibility. The version compatibility information between BR and TiDB versions are as follows:

Backup version (vertical)			
Restore version (horizontal)	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR nightly to back up TiDB nightly			(If a table with the primary key of the non-integer clustered index type is restored to a TiDB v4.0 cluster, BR will cause data error without warning.)

Backup version (vertical)	Restore version (horizontal)		
	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR v5.0 to back up TiDB v5.0			(If a table with the primary key of the non-integer clustered index type is restored to a TiDB v4.0 cluster, BR will cause data error without warning.)

Backup version (vertical)	Restore version (horizontal)		
	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR v4.0 to back up TiDB v4.0			(If TiKV >= v4.0.0-rc.1, and if BR contains the #233 bug fix and TiKV does not contain the #7241 bug fix, BR will cause the TiKV node to restart.)

Backup version (vertical)	Restore version (horizontal)	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR nightly or v5.0 to back up TiDB v4.0		(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)	(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)	(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)

Back up and restore table data in the `mysql` system schema (experimental feature)

> **Warning:**
>
> This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default.

If you want the data of a system table (for example, `mysql.usertable1`) to be restored to the system schema `mysql`, you can set the `filter` parameter to filter the table name (`-f "mysql.usertable1"`). After the setting, the system table is first restored to the temporary schema, and then to the system schema through renaming.

It should be noted that the following system tables cannot be restored correctly due to technical reasons. Even if `-f "mysql.*"` is specified, these tables will not be restored:

- Tables related to statistics: "stats_buckets", "stats_extended", "stats_feedback", "stats_fm_sketch", "stats_histograms", "stats_meta", "stats_top_n"
- Tables related to privileges or the system: "tidb", "global_variables", "columns_priv", "db", "default_roles", "global_grants", "global_priv", "role_edges", "tables_priv", "user", "gc_delete_range", "Gc_delete_range_done", "schema_index_usage"

Minimum machine configuration required for running BR

The minimum machine configuration required for running BR is as follows:

CPU	Memory	Hard Disk Type	Network
1 core	4 GB	HDD	Gigabit network card

In general scenarios (less than 1000 tables for backup and restore), the CPU consumption of BR at runtime does not exceed 200%, and the memory consumption does not exceed 4 GB. However, when backing up and restoring a large number of tables, BR might consume more than 4 GB of memory. In a test of backing up 24000 tables, BR consumes about 2.7 GB of memory, and the CPU consumption remains below 100%.

Best practices

The following are some recommended operations for using BR for backup and restoration:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- BR supports restore on clusters of different topologies. However, the online applications will be greatly impacted during the restore operation. It is recommended that you perform restore during the off-peak hours or use `rate-limit` to limit the rate.
- It is recommended that you execute multiple backup operations serially. Running different backup operations in parallel reduces backup performance and also affects the online application.
- It is recommended that you execute multiple restore operations serially. Running different restore operations in parallel increases Region conflicts and also reduces restore performance.
- It is recommended that you mount a shared storage (for example, NFS) on the backup path specified by `-s`, to make it easier to collect and manage backup files.
- It is recommended that you use a storage hardware with high throughput, because the throughput of a storage hardware limits the backup and restoration speed.

How to use BR

Currently, the following methods are supported to run the BR tool:

- Use SQL statements
- Use the command-line tool
- Use BR In the Kubernetes environment

Use SQL statements

TiDB supports both `BACKUP` and `RESTORE` SQL statements. The progress of these operations can be monitored with the statement `SHOW BACKUPS|RESTORES`.

Use the command-line tool

The `br` command-line utility is available as a separate download. For details, see Use BR Command-line for Backup and Restoration.

In the Kubernetes environment

In the Kubernetes environment, you can use the BR tool to back up TiDB cluster data to S3-compatible storage, Google Cloud Storage (GCS) and persistent volumes (PV), and restore them:

> **Note:**
>
> For Amazon S3 and Google Cloud Storage parameter descriptions, see the External Storages document.

- Back up Data to S3-Compatible Storage Using BR
- Restore Data from S3-Compatible Storage Using BR
- Back up Data to GCS Using BR
- Restore Data from GCS Using BR
- Back up Data to PV Using BR
- Restore Data from PV Using BR

6.3.1.1.3 Other documents about BR

- Use BR Command-line
- BR Use Cases
- BR FAQ
- External Storages

6.3.1.2 Use BR Command-line for Backup and Restoration

This document describes how to back up and restore TiDB cluster data using the BR command line.

Make sure you have read BR Tool Overview, especially Usage Restrictions and Best Practices.

6.3.1.2.1 BR command-line description

A `br` command consists of sub-commands, options, and parameters.

- Sub-command: the characters without `-` or `--`.
- Option: the characters that start with `-` or `--`.
- Parameter: the characters that immediately follow behind and are passed to the sub-command or the option.

This is a complete `br` command:

```
br backup full --pd "${PDIP}:2379" -s "local:///tmp/backup"
```

Explanations for the above command are as follows:

- `backup`: the sub-command of `br`.
- `full`: the sub-command of `backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored.
- `"local:///tmp/backup"`: the parameter of `-s`. `/tmp/backup` is the path in the local disk where the backed up files of each TiKV node are stored.
- `--pd`: the option that specifies the Placement Driver (PD) service address.
- `"${PDIP}:2379"`: the parameter of `--pd`.

Note:

- When the `local` storage is used, the backup data are scattered in the local file system of each node.
- It is **not recommended** to back up to a local disk in the production environment because you **have to** manually aggregate these data to complete the data restoration. For more information, see Restore Cluster Data.
- Aggregating these backup data might cause redundancy and bring troubles to operation and maintenance. Even worse, if restoring data without aggregating these data, you can receive a rather confusing error message `SST file not found`.
- It is recommended to mount the NFS disk on each node, or back up to the `S3` object storage.

Sub-commands

A `br` command consists of multiple layers of sub-commands. Currently, BR has the following three sub-commands:

- `br backup`: used to back up the data of the TiDB cluster.
- `br restore`: used to restore the data of the TiDB cluster.

Each of the above three sub-commands might still include the following three sub-commands to specify the scope of an operation:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore the specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

Common options

- `--pd`: used for connection, specifying the PD server address. For example, `"${PDIP}:2379"`.
- `-h` (or `--help`): used to get help on all sub-commands. For example, `br backup --help`.
- `-V` (or `--version`): used to check the version of BR.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.
- `--status-addr`: specifies the listening address through which BR provides statistics to Prometheus.

6.3.1.2.2 Use BR command-line to back up cluster data

To back up the cluster data, use the `br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster or a single table.

Back up all the cluster data

To back up all the cluster data, execute the `br backup full` command. To get help on this command, execute `br backup full -h` or `br backup full --help`.

Usage example:

Back up all the cluster data to the `/tmp/backup` path of each TiKV node and write the `backupmeta` file to this path.

Note:

- If the backup disk and the service disk are different, it has been tested that online backup reduces QPS of the read-only online service by about 15%-25% in case of full-speed backup. If you want to reduce the impact on QPS, use `--ratelimit` to limit the rate.
- If the backup disk and the service disk are the same, the backup competes with the service for I/O resources. This might decrease the QPS of the read-only online service by more than half. Therefore, it is **highly not recommended** to back up the online service data to the TiKV data disk.

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a backup operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `backupfull.log` file.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety. The progress bar is displayed as follows:

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
Full Backup <---------/.....................................................>
    ↪ 17.12%.
```

Back up a database

To back up a database in the cluster, execute the `br backup db` command. To get help on this command, execute `br backup db -h` or `br backup db --help`.

Usage example:

Back up the data of the `test` database to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup db \
    --pd "${PDIP}:2379" \
    --db test \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backuptable.log
```

In the above command, `--db` specifies the name of the database to be backed up. For descriptions of other options, see Back up all the cluster data.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

Back up a table

To back up the data of a single table in the cluster, execute the `br backup table` command. To get help on this command, execute `br backup table -h` or `br backup table --help`.

Usage example:

Back up the data of the `test.usertable` table to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup table \
    --pd "${PDIP}:2379" \
    --db test \
    --table usertable \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backuptable.log
```

The `table` sub-command has two options:

- `--db`: specifies the database name
- `--table`: specifies the table name.

For descriptions of other options, see Back up all cluster data.

A progress bar is displayed in the terminal during the backup operation. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

Back up with table filter

To back up multiple tables with more complex criteria, execute the `br backup full` command and specify the table filters with `--filter` or `-f`.

Usage example:

The following command backs up the data of all tables in the form `db*.tbl*` to the `/tmp/backup` path on each TiKV node and writes the `backupmeta` file to this path.

```
br backup full \
    --pd "${PDIP}:2379" \
    --filter 'db*.tbl*' \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
```

Back up data to Amazon S3 backend

If you back up the data to the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

You can refer to the AWS Official Document to create an S3 `Bucket` in the specified `Region`. You can also refer to another AWS Official Document to create a `Folder` in the `Bucket`.

> **Note:**
>
> To complete one backup, TiKV and BR usually require the minimum privileges of `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When backing up using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "s3://${Bucket}/${Folder}" \
    --s3.region "${region}" \
    --send-credentials-to-tikv=true \
    --ratelimit 128 \
    --log-file backuptable.log
```

Back up incremental data

This feature is currently experimental and is not recommended for use in the production environment.

If you want to back up incrementally, you only need to specify the **last backup timestamp** `--lastbackupts`.

The incremental backup has two limitations:

- The incremental backup needs to be under a different path from the previous full backup.
- GC (Garbage Collection) safepoint must be before the `lastbackupts`.

To back up the incremental data between `(LAST_BACKUP_TS, current PD timestamp]`, execute the following command:

```
br backup full\
    --pd ${PDIP}:2379 \
    --ratelimit 128 \
    -s local:///home/tidb/backupdata/incr \
    --lastbackupts ${LAST_BACKUP_TS}
```

To get the timestamp of the last backup, execute the `validate` command. For example:

```
LAST_BACKUP_TS=`br validate decode --field="end-version" -s local:///home/
    ↪ tidb/backupdata | tail -n1`
```

In the above example, for the incremental backup data, BR records the data changes and the DDL operations during `(LAST_BACKUP_TS, current PD timestamp]`. When restoring data, BR first restores DDL operations and then the data.

Point-in-time recovery (experimental feature)

Point-in-time recovery (PITR) allows you to restore data to a point in time of your choice.

An example scenario would be to take a full backup every day and take incremental backups every 6 hours and then use TiCDC for PITR. Assume that on one day, the full backup was performed at 00:00 and the first incremental backup was performed at 06:00. If you want to restore the database to the state of 07:16, you can first restore the full backup (taken at 00:00) and the incremental backup (taken at 06:00), and then restore TiCDC logs that fill in the gap between 06:00 and 07:16.

To peform the PITR, you can take the following steps:

1. Restore a full backup using `br restore full`.
2. (optional) Restore incremental backup(s).

3. Use `br restore cdclog` to restore the transactions that happened after the last incremental backup. The complete command to execute is as follows:

```
br restore cdclog --storage local:///data/cdclog --start-ts $START_TS
    ↪ --end-ts $END_TS
```

In the command above:

- `local:///data/cdclog` is the location of the TiCDC logs. This might be on the local filesystem or on the external storage like S3.
- `$START_TS` is the end position of the restore from the last restored backup (either a full backup or an incremental backup).
- `$END_TS` is the point to which you want to restore your data.

Back up Raw KV (experimental feature)

> **Warning:**
>
> This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

In some scenarios, TiKV might run independently of TiDB. Given that, BR also supports bypassing the TiDB layer and backing up data in TiKV.

For example, you can execute the following command to back up all keys between `[0x31 ↪ , 0x3130303030303030)` in the default CF to `$BACKUP_DIR`:

```
br backup raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
    --ratelimit 128 \
    --end 3130303030303030 \
    --format hex \
    --cf default
```

Here, the parameters of `--start` and `--end` are decoded using the method specified by `--format` before being sent to TiKV. Currently, the following methods are available:

- "raw": The input string is directly encoded as a key in binary format.
- "hex": The default encoding method. The input string is treated as a hexadecimal number.
- "escape": First escape the input string, and then encode it into binary format.

6.3.1.2.3 Use BR command-line to restore cluster data

To restore the cluster data, use the `br restore` command. You can add the `full`, `db` or `table` sub-command to specify the scope of your restoration: the whole cluster, a database or a single table.

> **Note:**
>
> If you use the local storage, you **must** copy all back up SST files to every TiKV node in the path specified by `--storage`.
>
> Even if each TiKV node eventually only need to read a part of the all SST files, they all need full access to the complete archive because:
>
> - Data are replicated into multiple peers. When ingesting SSTs, these files have to be present on *all* peers. This is unlike back up where reading from a single node is enough.
> - Where each peer is scattered to during restore is random. We don't know in advance which node will read which file.
>
> These can be avoided using shared storage, for example mounting an NFS on the local path, or using S3. With network storage, every node can automatically read every SST file, so these caveats no longer apply.

Restore all the backup data

To restore all the backup data to the cluster, execute the `br restore full` command. To get help on this command, execute `br restore full -h` or `br restore full --help`.

Usage example:

Restore all the backup data in the `/tmp/backup` path to the cluster.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file restorefull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a restoration operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `restorefull.log` file.

A progress bar is displayed in the terminal during the restoration. When the progress bar advances to 100%, the restoration is complete. Then the BR also checks the backup data to ensure data safety.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file restorefull.log
Full Restore <---------/.....................................................>
    ↪ 17.12%.
```

Restore a database

To restore a database to the cluster, execute the `br restore db` command. To get help on this command, execute `br restore db -h` or `br restore db --help`.

Usage example:

Restore a database backed up in the `/tmp/backup` path to the cluster.

```
br restore db \
    --pd "${PDIP}:2379" \
    --db "test" \
    --ratelimit 128 \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

In the above command, `--db` specifies the name of the database to be restored. For descriptions of other options, see Restore all backup data).

> **Note:**
>
> When you restore the backup data, the name of the database specified by `--db` ↪ must be the same as the one specified by `-- db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

Restore a table

To restore a single table to the cluster, execute the `br restore table` command. To get help on this command, execute `br restore table -h` or `br restore table --help`.

Usage example:

Restore a table backed up in the `/tmp/backup` path to the cluster.

```
br restore table \
    --pd "${PDIP}:2379" \
    --db "test" \
    --table "usertable" \
    --ratelimit 128 \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see Restore all backup data and Restore a database.

Restore with table filter

To restore multiple tables with more complex criteria, execute the `br restore full` command and specify the table filters with `--filter` or `-f`.

Usage example:

The following command restores a subset of tables backed up in the `/tmp/backup` path to the cluster.

```
br restore full \
    --pd "${PDIP}:2379" \
    --filter 'db*.tbl*' \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

Restore data from Amazon S3 backend

If you restore data from the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

> **Note:**
>
> To complete one restore, TiKV and BR usually require the minimum privileges of `s3:ListBucket` and `s3:GetObject`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When restoring data using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

`Bucket` and `Folder` in the `--storage` parameter represent the S3 bucket and the folder where the data to be restored is located.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "s3://${Bucket}/${Folder}" \
    --s3.region "${region}" \
    --ratelimit 128 \
    --send-credentials-to-tikv=true \
    --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see Restore a database.

Restore incremental data

This feature is currently experimental and is not recommended for use in the production environment.

Restoring incremental data is similar to restoring full data using BR. Note that when restoring incremental data, make sure that all the data backed up before `last backup ts` has been restored to the target cluster.

Restore tables created in the `mysql` schema (experimental feature)

BR backs up tables created in the `mysql` schema by default.

When you restore data using BR, the tables created in the `mysql` schema are not restored by default. If you need to restore these tables, you can explicitly include them using the table filter. The following example restores `mysql.usertable` created in `mysql` schema. The command restores `mysql.usertable` along with other data.

```
br restore full -f '*.*' -f '!mysql.*' -f 'mysql.usertable' -s
    ↪ $external_storage_url --ratelimit 128
```

In the above command, `-f '*.*'` is used to override the default rules and `-f '!mysql.*'` instructs BR not to restore tables in `mysql` unless otherwise stated. `-f 'mysql.usertable'` indicates that `mysql.usertable` is required for restore. For detailed implementation, refer to the table filter document.

If you only need to restore `mysql.usertable`, use the following command:

```
br restore full -f 'mysql.usertable' -s $external_storage_url --ratelimit
    ↪ 128
```

Warning:

Although you can back up and restore system tables (such as `mysql.tidb` ↪) using the BR tool, some unexpected situations might occur after the restoration, including:

- the statistical information tables (`mysql.stat_*`) cannot be restored.
- the system variable tables (`mysql.tidb,mysql.global_variables`) cannot be restored.
- the user information tables (such as `mysql.user` and `mysql.` ↪ `columns_priv`) cannot be restored.
- GC data cannot be restored.

Restoring system tables might cause more compatibility issues. To avoid unexpected problems, **DO NOT** restore system tables in the production environment.

Restore Raw KV (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Similar to backing up Raw KV, you can execute the following command to restore Raw KV:

```
br restore raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
    --end 3130303030303030 \
    --ratelimit 128 \
    --format hex \
    --cf default
```

In the above example, all the backed up keys in the range `[0x31, 0x3130303030303030` ↪ `)` are restored to the TiKV cluster. The coding methods of these keys are identical to that of keys during the backup process

Online restore (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It also relies on the unstable `Placement Rules` feature of PD. It is highly **not recommended** to use this feature in the production environment.

During data restoration, writing too much data affects the performance of the online cluster. To avoid this effect as much as possible, BR supports Placement rules to isolate resources. In this case, downloading and importing SST are only performed on a few specified nodes (or "restore nodes" for short). To complete the online restore, take the following steps.

1. Configure PD, and start Placement rules:

```
echo "config set enable-placement-rules true" | pd-ctl
```

2. Edit the configuration file of the "restore node" in TiKV, and specify "restore" to the `server` configuration item:

```
[server]
labels = { exclusive = "restore" }
```

3. Start TiKV of the "restore node" and restore the backed up files using BR. Compared with the offline restore, you only need to add the `--online` flag:

```
br restore full \
    -s "local://$BACKUP_DIR" \
    --ratelimit 128 \
    --pd $PD_ADDR \
    --online
```

6.3.1.3 BR Use Cases

BR is a tool for distributed backup and restoration of the TiDB cluster data.

This document describes how to run BR in the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

This document aims to help you achieve the following goals:

- Back up and restore data using a network disk or local disk correctly.
- Get the status of a backup or restoration operation through monitoring metrics.
- Learn how to tune performance during the operation.
- Troubleshoot the possible anomalies during the backup operation.

6.3.1.3.1 Audience

You are expected to have a basic understanding of TiDB and TiKV.

Before reading on, make sure you have read BR Tool Overview, especially Usage Restrictions and Best Practices.

6.3.1.3.2 Prerequisites

This section introduces the recommended method of deploying TiDB, cluster versions, the hardware information of the TiKV cluster, and the cluster configuration for the use case demonstrations.

You can estimate the performance of your backup or restoration operation based on your own hardware and configuration.

Deployment method

It is recommended that you deploy the TiDB cluster using TiUP and get BR by downloading TiDB Toolkit.

Cluster versions

- TiDB: v5.1.5
- TiKV: v5.1.5
- PD: v5.1.5
- BR: v5.1.5

> **Note:**
>
> It is recommended that you use the latest version of TiDB/TiKV/PD/BR and make sure that the BR version is **consistent with** the TiDB version.

TiKV hardware information

- Operating system: CentOS Linux release 7.6.1810 (Core)
- CPU: 16-Core Common KVM processor
- RAM: 32GB
- Disk: 500G SSD * 2
- NIC: 10 Gigabit network card

Cluster configuration

BR directly sends commands to the TiKV cluster and are not dependent on the TiDB server, so you do not need to configure the TiDB server when using BR.

- TiKV: default configuration
- PD: default configuration

6.3.1.3.3 Use cases

This document describes the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

It is recommended that you use a network disk to back up and restore data. This spares you from collecting backup files and greatly improves the backup efficiency especially when the TiKV cluster is in a large scale.

Before the backup or restoration operations, you need to do some preparations:

- Preparation for backup
- Preparation for restoration

Preparation for backup

The BR tool already supports self-adapting to GC. It automatically registers `backupTS` ↪ (the latest PD timestamp by default) to PD's `safePoint` to ensure that TiDB's GC Safe Point does not move forward during the backup, thus avoiding manually setting GC configurations.

For the detailed usage of the `br backup` command, refer to Use BR Command-line for Backup and Restoration.

1. Before executing the `br backup` command, ensure that no DDL is running on the TiDB cluster.
2. Ensure that the storage device where the backup will be created has sufficient space.

Preparation for restoration

Before executing the `br restore` command, check the new cluster to make sure that the table in the cluster does not have a duplicate name.

Back up a single table to a network disk (recommended in production environment)

Use the `br backup` command to back up the single table data `--db batchmark --table` ↪ `order_line` to the specified path `local:///br_data` in the network disk.

Backup prerequisites

- Preparation for backup
- Configure a high-performance SSD hard disk host as the NFS server to store data, and all BR nodes, TiKV nodes, and TiFlash nodes as NFS clients. Mount the same path (for example, `/br_data`) to the NFS server for NFS clients to access the server.
- The total transfer rate between the NFS server and all NFS clients must reach at least `the number of TiKV instances * 150MB/s`. Otherwise the network I/O might become the performance bottleneck.

Note:

- During data backup, because only the data of leader replicas are backed up, even if there is a TiFlash replica in the cluster, BR can complete the backup without mounting TiFlash nodes.
- When restoring data, BR will restore the data of all replicas. Also, TiFlash nodes need access to the backup data for BR to complete the restore. Therefore, before the restore, you must mount TiFlash nodes to the NFS server.

Topology

The following diagram shows the typology of BR:

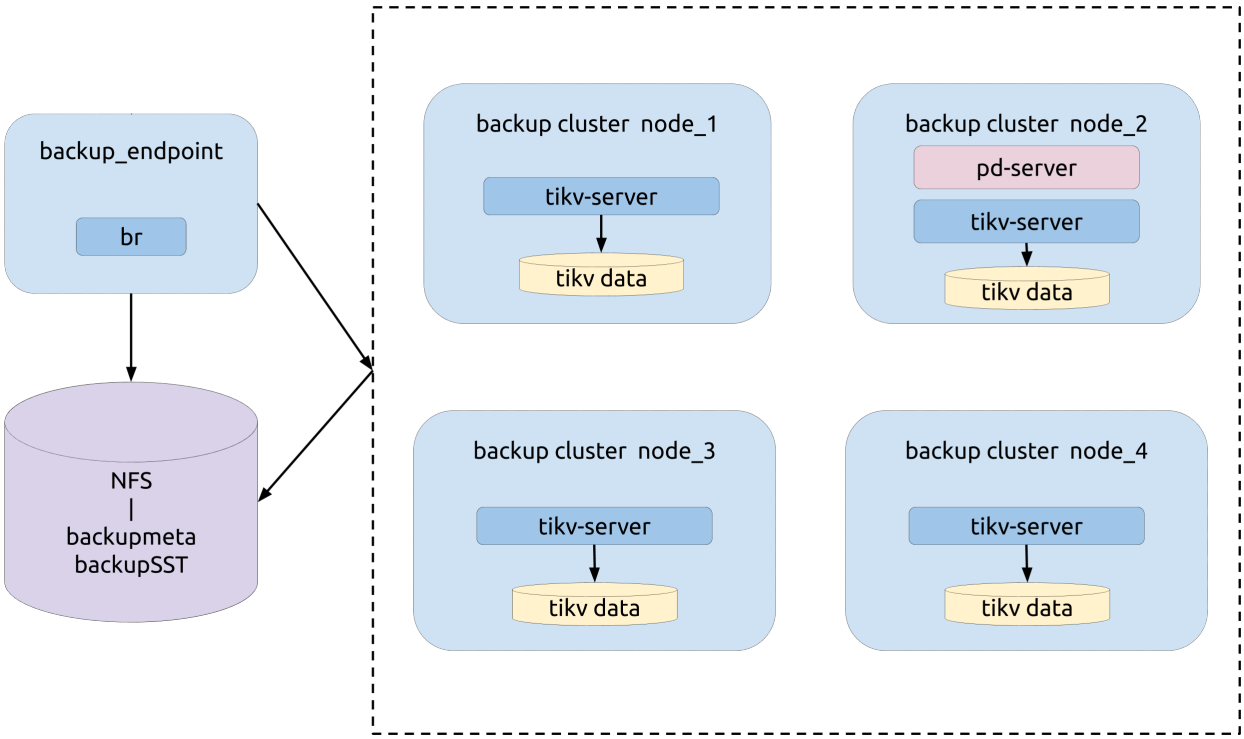

Figure 11: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark --table order_line`). The following image shows an example of this information:

```
+-----------+------------+---------------------+------------+--------------+
| Db_name   | Table_name | Checksum_crc64_xor  | Total_kvs  | Total_bytes  |
+-----------+------------+---------------------+------------+--------------+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----------+------------+---------------------+------------+--------------+
1 row in set (5 min 47.59 sec)
```

Figure 12: img

Execute the `br backup` command:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///br_data \
```

```
    --pd ${PD_ADDR}:2379 \
    --log-file backup-nfs.log
```

Monitoring metrics for the backup

During the backup process, pay attention to the following metrics on the monitoring panels to get the status of the backup process.

Backup CPU Utilization: the CPU usage rate of each working TiKV node in the backup operation (for example, backup-worker and backup-endpoint).

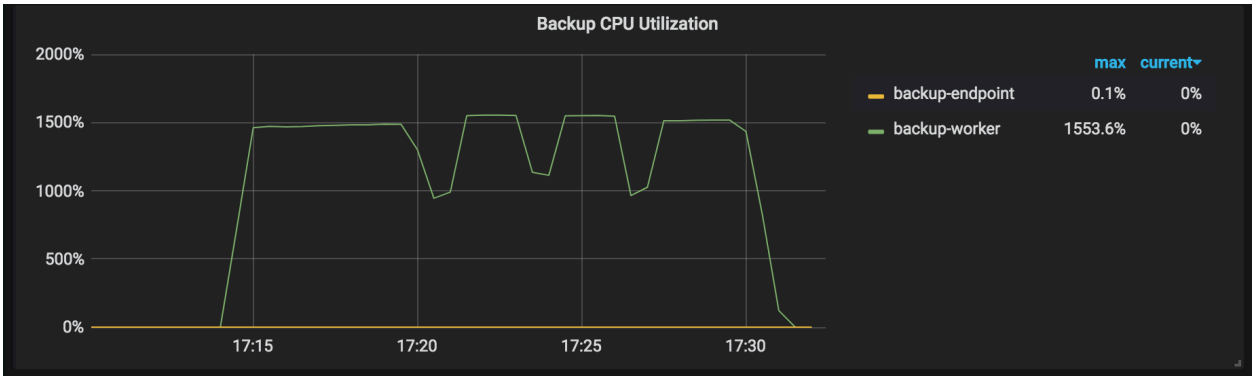

Figure 13: img

IO Utilization: the I/O usage rate of each working TiKV node in the backup operation.

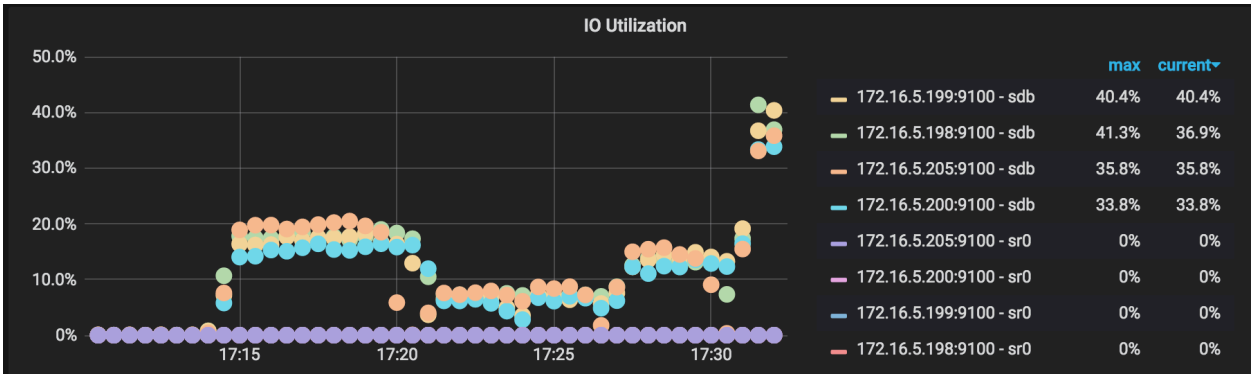

Figure 14: img

BackupSST Generation Throughput: the backupSST generation throughput of each working TiKV node in the backup operation, which is normally around 150MB/s.

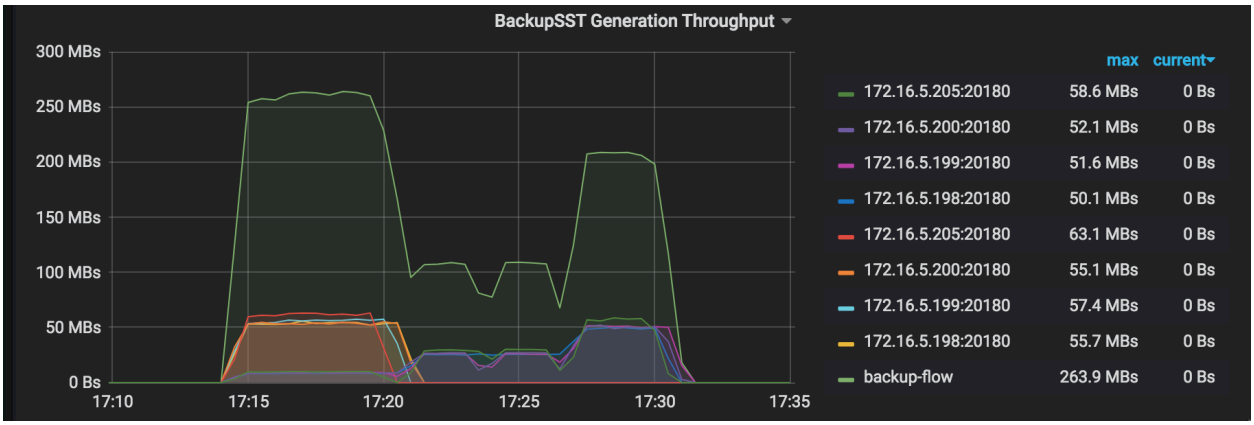

Figure 15: img

One Backup Range Duration: the duration of backing up a range, which is the total time cost of scanning KVs and storing the range as the backupSST file.

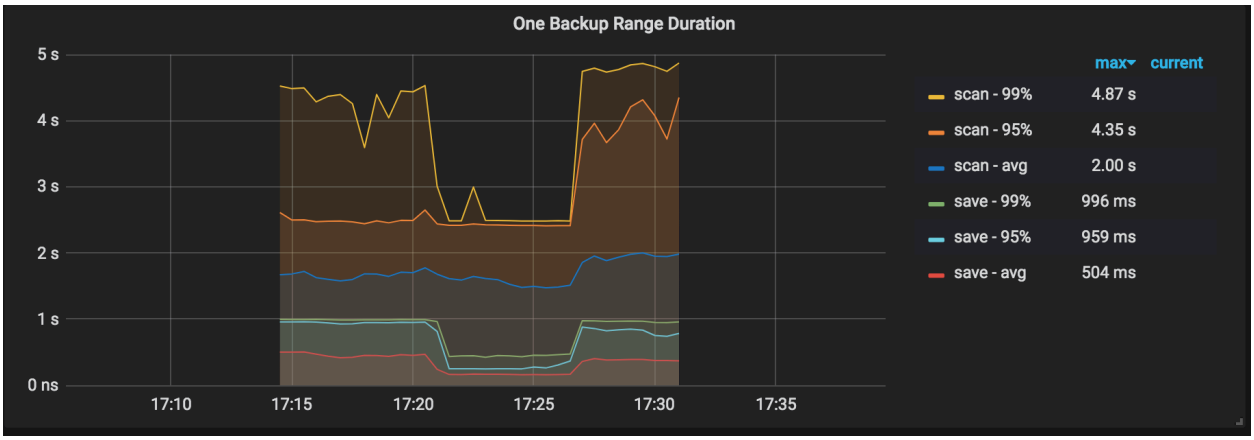

Figure 16: img

One Backup Subtask Duration: the duration of each sub-task into which a backup task is divided.

Note:

- In this task, the single table to be backed up has three indexes and the task is normally divided into four sub-tasks.
- The panel in the following image has thirteen points on it, which means nine (namely, 13-4) retries. Region scheduling might occur during the backup process, so a few retries is normal.

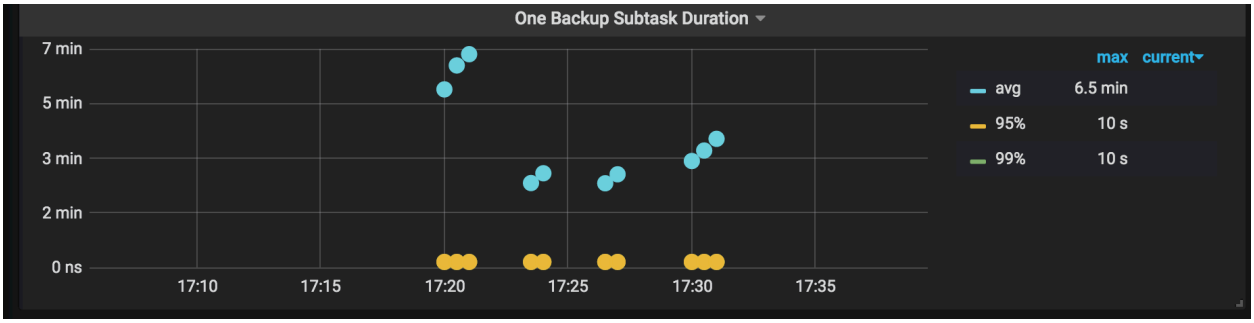

Figure 17: img

Backup Errors: the errors occurred during the backup process. No error occurs in normal situations. Even if a few errors occur, the backup operation has the retry mechanism which might increase the backup time but does not affect the operation correctness.

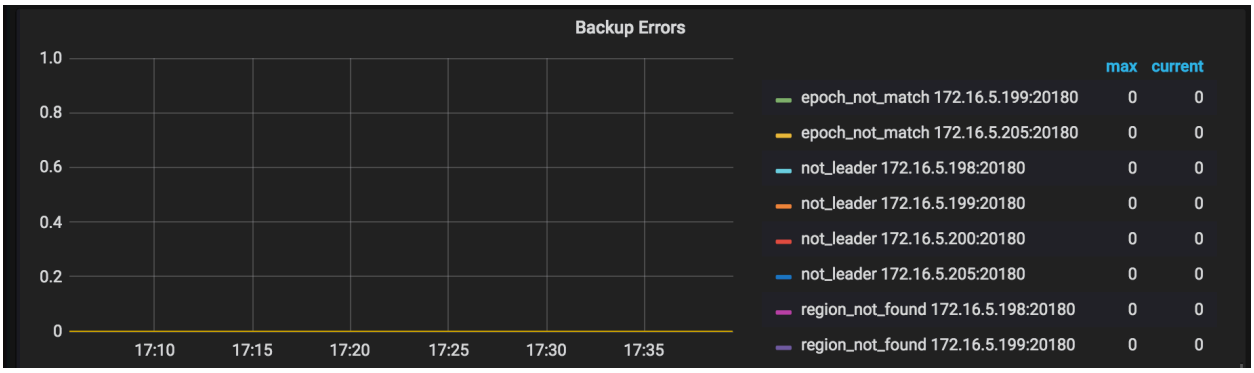

Figure 18: img

Checksum Request Duration: the duration of the admin checksum request in the backup cluster.

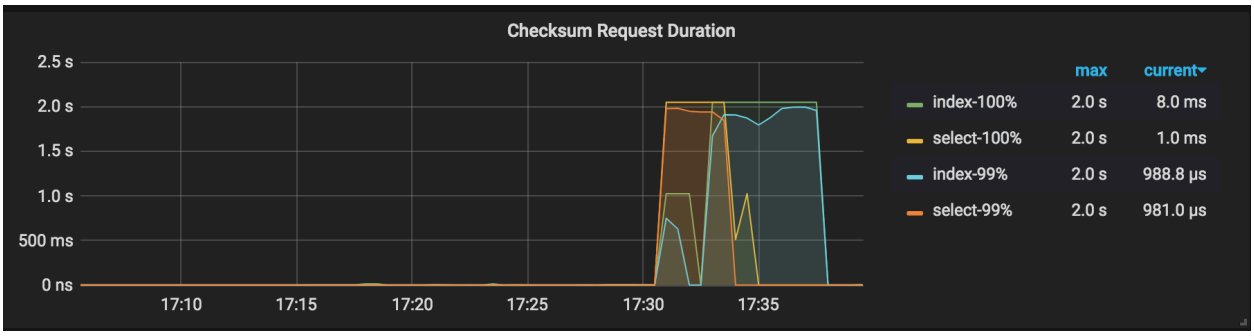

Figure 19: img

Backup results explanation

When finishing the backup, BR outputs the backup summary to the console.

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search "summary" in this log, you can see the following information:

```
["Full backup Success summary:
    total backup ranges: 2,
    total success: 2,
    total failed: 0,
    total take(Full backup time): 31.802912166s,
    total take(real time): 49.799662427s,
    total size(MB): 5997.49,
    avg speed(MB/s): 188.58,
    total kv: 120000000"]
    ["backup checksum"=17.907153678s]
    ["backup fast checksum"=349.333µs]
    ["backup total regions"=43]
    [BackupTS=422618409346269185]
    [Size=826765915]
```

The above log includes the following information:

- Backup duration: `total take(Full backup time): 31.802912166s`
- Total runtime of the application: `total take(real time): 49.799662427s`
- Backup data size: `total size(MB): 5997.49`
- Backup throughput: `avg speed(MB/s): 188.58`
- Number of backed-up KV pairs: `total kv: 120000000`
- Backup checksum duration: `["backup checksum"=17.907153678s]`
- Total duration of calculating the checksum, KV pairs, and bytes of each table: `["backup fast checksum"=349.333µs]`
- Total number of backup Regions: `["backup total regions"=43]`
- The actual size of the backup data in the disk after compression: `[Size=826765915]`
- Snapshot timestamp of the backup data: `[BackupTS=422618409346269185]`

From the above information, the throughput of a single TiKV instance can be calculated: `avg speed(MB/s)/tikv_count` = 62.86.

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the backup process (for example, in the Monitoring metrics for the backup, the highest CPU usage rate of backup-worker is around 1500% and the overall I/O usage rate is below 30%), you can try to increase the value of `--concurrency` (4 by default) to tune the performance. But this performance tuning method is not suitable for the use cases of many small tables. See the following example:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///br_data/ \
    --pd ${PD_ADDR}:2379 \
    --log-file backup-nfs.log \
    --concurrency 16
```

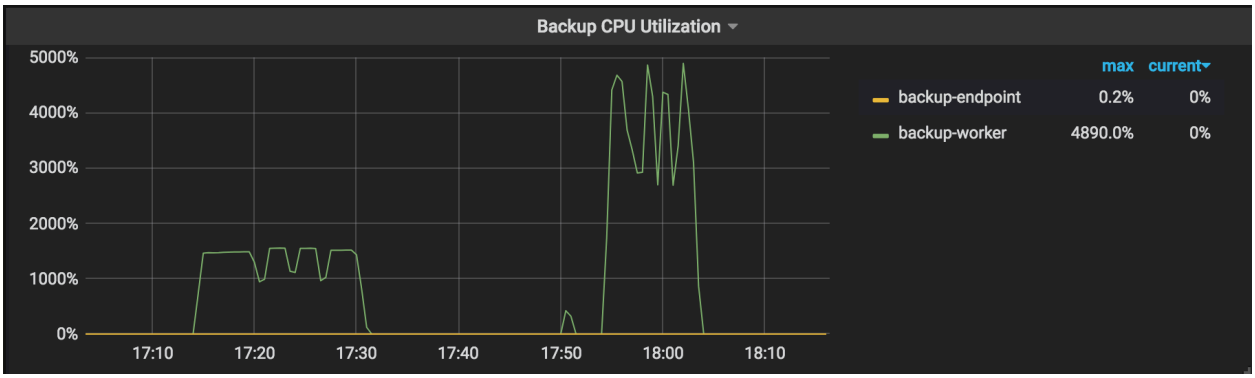

Figure 20: img

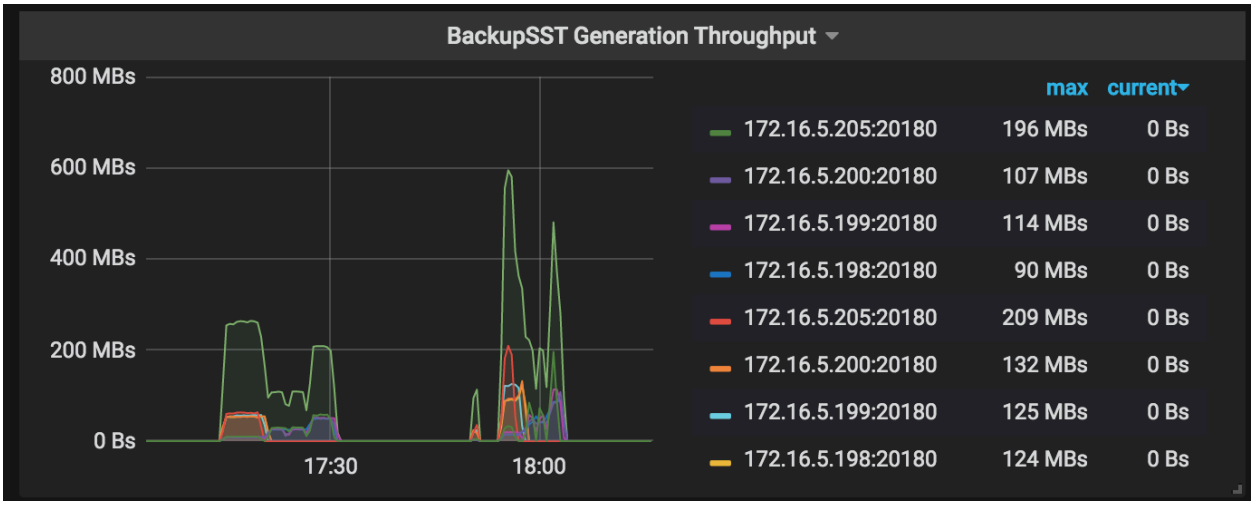

Figure 21: img

The tuned performance results are as follows (with the same data size):

- Backup duration: `total take(s)` reduced from `986.43` to `535.53`
- Backup throughput: `avg speed(MB/s)` increased from `358.09` to `659.59`

- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from `89` to `164.89`

Restore data from a network disk (recommended in production environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- Preparation for restoration

Topology

The following diagram shows the typology of BR:

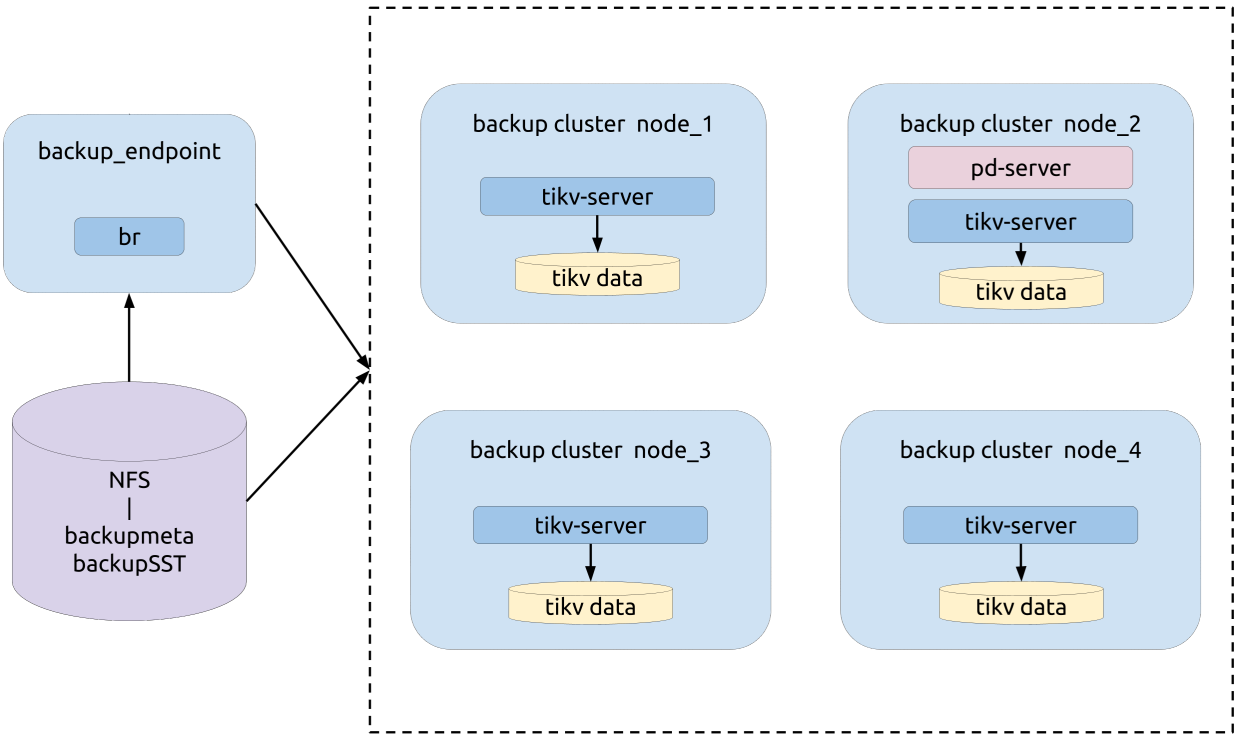

Figure 22: img

Restoration operation

Before the restoration, refer to Preparation for restoration for the preparation.

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data
    ↪ --pd 172.16.5.198:2379 --log-file restore-nfs.log
```

Monitoring metrics for the restoration

During the restoration process, pay attention to the following metrics on the monitoring panels to get the status of the restoration process.

CPU Utilization: the CPU usage rate of each working TiKV node in the restoration operation.

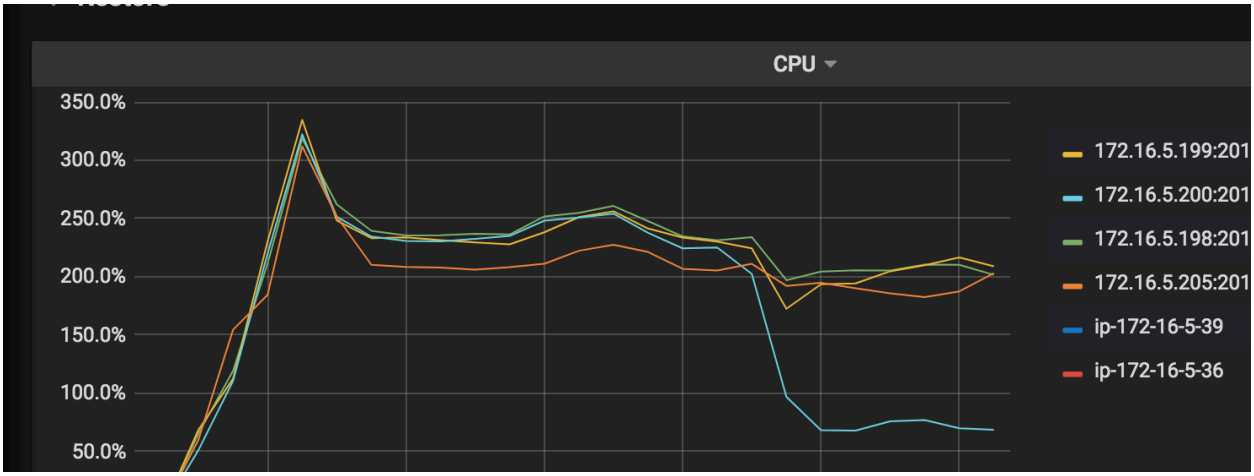

Figure 23: img

IO Utilization: the I/O usage rate of each working TiKV node in the restoration operation.

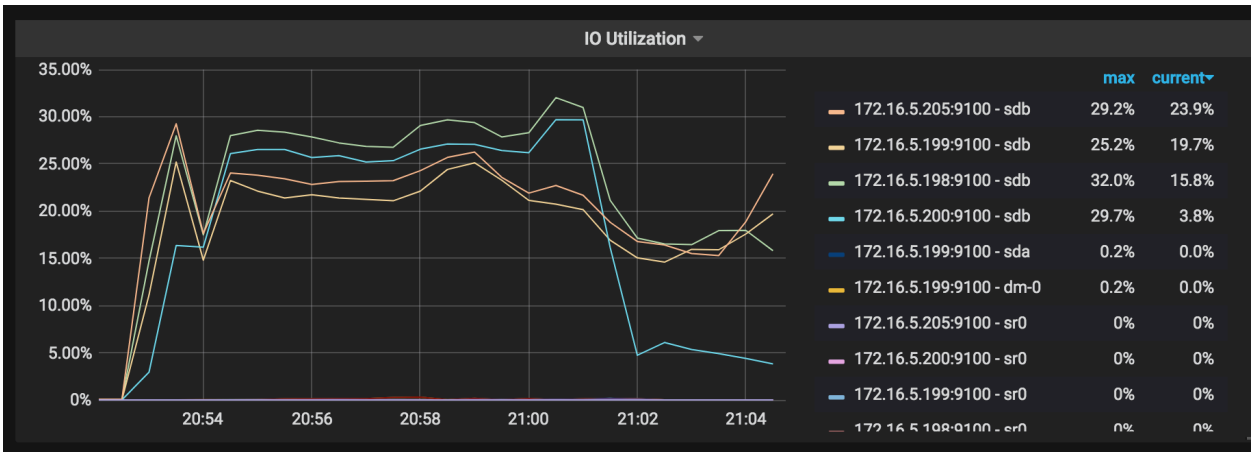

Figure 24: img

Region: the Region distribution. The more even Regions are distributed, the better the restoration resources are used.

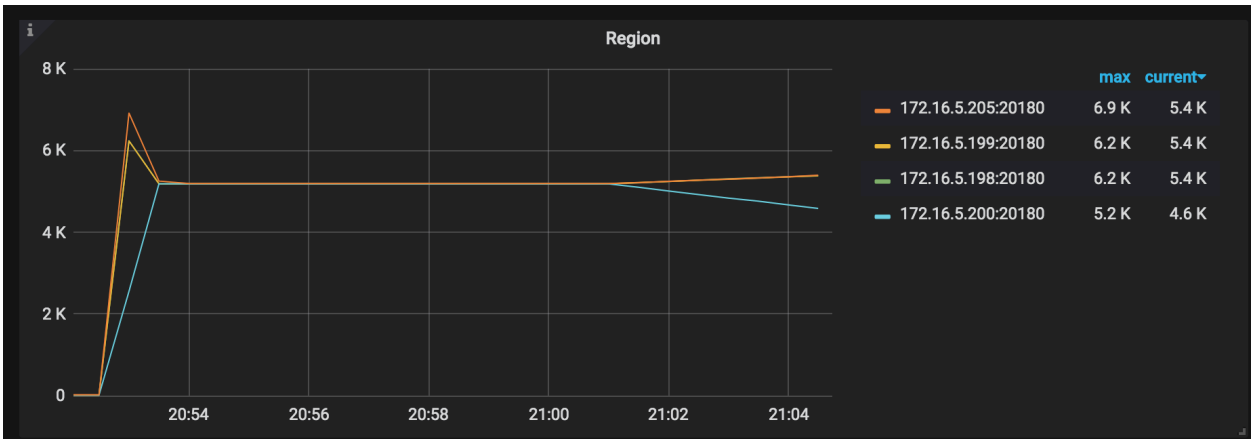

Figure 25: img

Process SST Duration: the delay of processing the SST files. When restoring a table, if `tableID` is changed, you need to rewrite `tableID`. Otherwise, `tableID` is renamed. Generally, the delay of rewriting is longer than that of renaming.

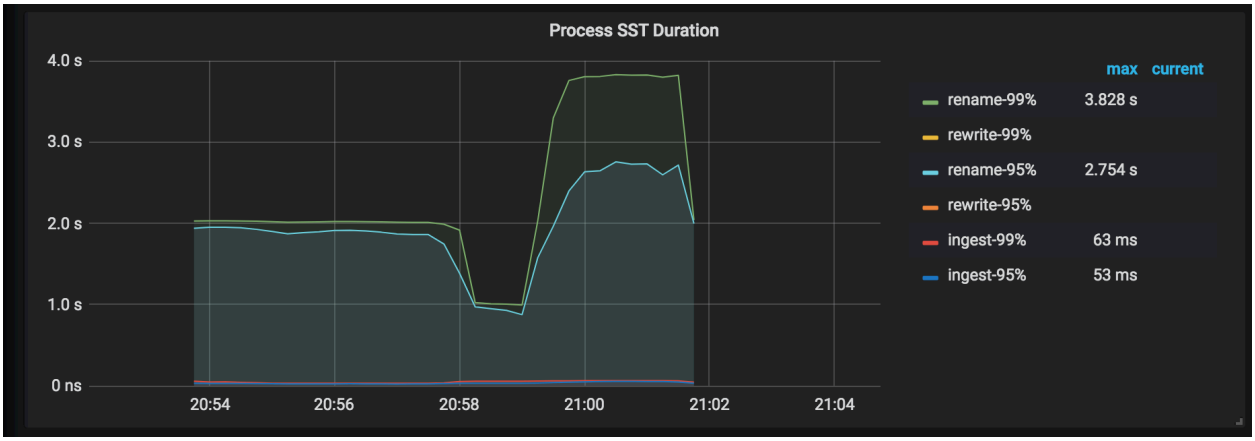

Figure 26: img

DownLoad SST Throughput: the throughput of downloading SST files from External Storage.

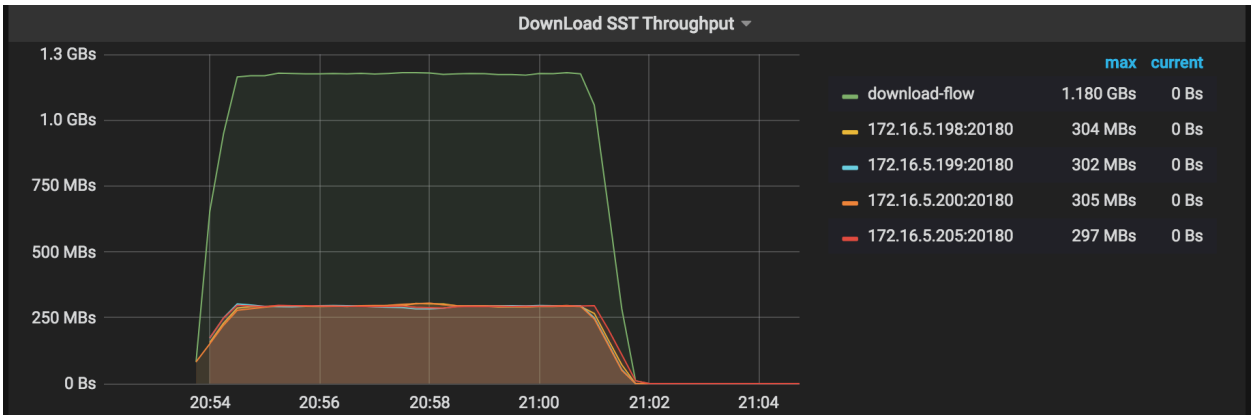

Figure 27: img

Restore Errors: the errors occurred during the restoration process.

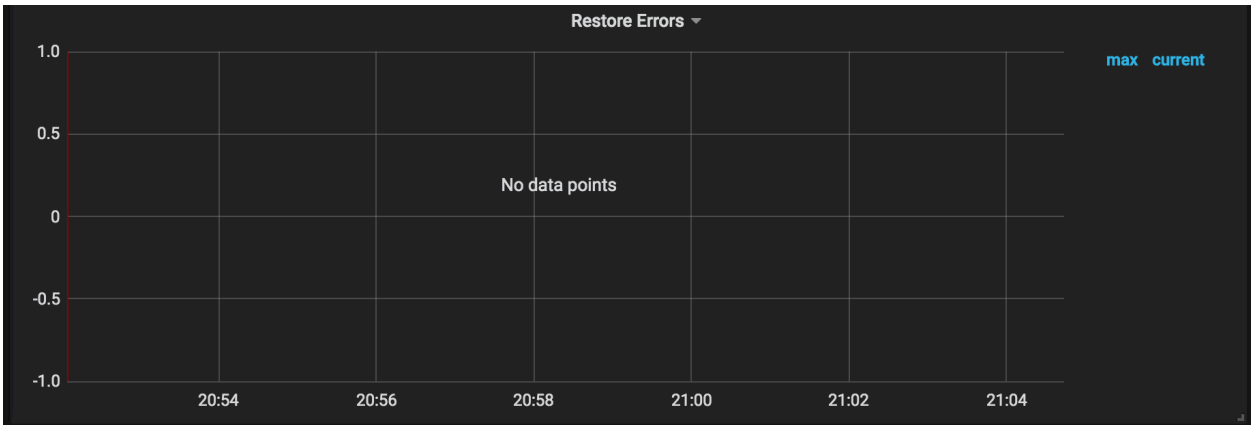

Figure 28: img

Checksum Request duration: the duration of the admin checksum request. This duration for the restoration is longer than that for the backup.

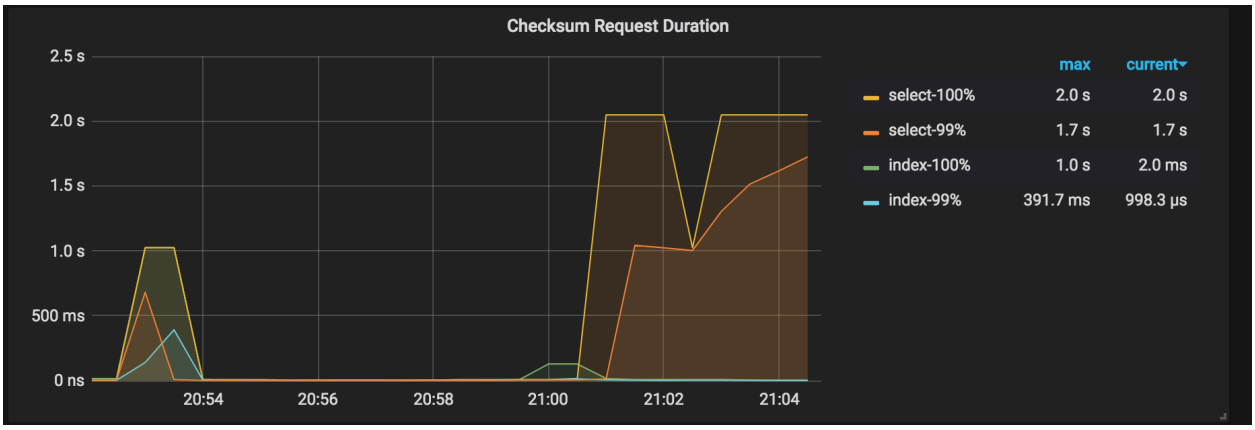

Figure 29: img

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search "summary" in this log, you can see the following information:

```
["Table Restore summary:
   total restore tables: 1,
   total success: 1,
   total failed: 0,
   total take(Full restore time): 17m1.001611365s,
   total take(real time): 16m1.371611365s,
   total kv: 5659888624,
   total size(MB): 353227.18,
   avg speed(MB/s): 367.42"]
   ["restore files"=9263]
   ["restore ranges"=6888]
   ["split region"=49.049182743s]
   ["restore checksum"=6m34.879439498s]
   [Size=48693068713]
```

The above log includes the following information:

- Restore duration: `total take(Full restore time): 17m1.001611365s`
- Total runtime of the application: `total take(real time): 16m1.371611365s`
- Restore data size: `total size(MB): 353227.18`
- Restore KV pair number: `total kv: 5659888624`
- Restore throughput: `avg speed(MB/s): 367.42`
- `Region Split` duration: `take=49.049182743s`
- Restore checksum duration: `restore checksum=6m34.879439498s`

- The actual size of the restored data in the disk: `[Size=48693068713]`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` = `91.8`
- The average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` = `87.4`

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the restore process, you can try to increase the value of `--concurrency` which is `128` by default. See the following example:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data/
    ↪ --pd 172.16.5.198:2379 --log-file restore-concurrency.log --
    ↪ concurrency 1024
```

The tuned performance results are as follows (with the same data size):

- Restore duration: `total take(s)` reduced from `961.37` to `443.49`
- Restore throughput: `avg speed(MB/s)` increased from `367.42` to `796.47`
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from `91.8` to `199.1`
- Average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` increased from `87.4` to `162.3`

Back up a single table to a local disk (recommended in testing environment)

Use the `br backup` command to back up the single table `--db batchmark --table order_line` to the specified path `local:///home/tidb/backup_local` in the local disk.

Backup prerequisites

- Preparation for backup
- Each TiKV node has a separate disk to store the backupSST file.
- The `backup_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `backup_endpoint` node must have the same directory for the backup (for example, `/home/tidb/backup_local`).

Topology

The following diagram shows the typology of BR:

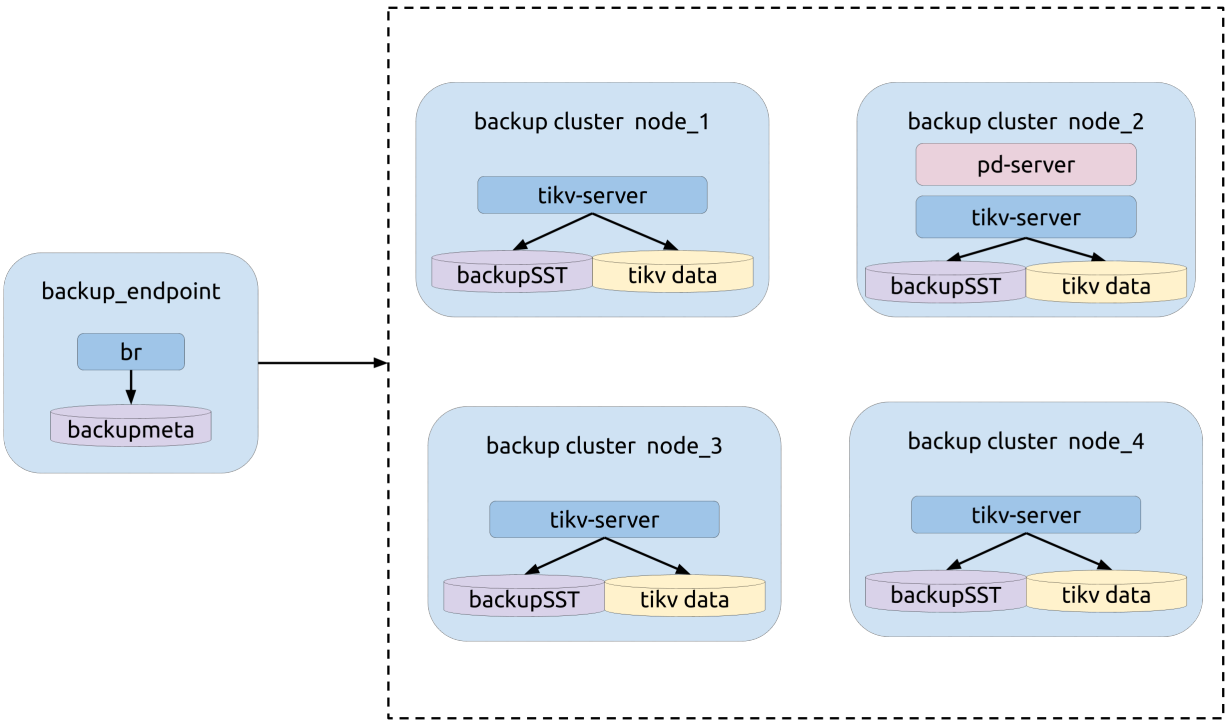

Figure 30: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark --table order_line`). The following image shows an example of this information:

```
+----------+------------+---------------------+------------+--------------+
| Db_name  | Table_name | Checksum_crc64_xor  | Total_kvs  | Total_bytes  |
+----------+------------+---------------------+------------+--------------+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+----------+------------+---------------------+------------+--------------+
1 row in set (5 min 47.59 sec)
```

Figure 31: img

Execute the `br backup` command:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///home/tidb/backup_local/ \
```

```
    --pd ${PD_ADDR}:2379 \
    --log-file backup_local.log
```

During the backup process, pay attention to the metrics on the monitoring panels to get the status of the backup process. See Monitoring metrics for the backup for details.

Backup results explanation

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search "summary" in this log, you can see the following information:

```
["Table backup summary: total backup ranges: 4, total success: 4, total
    ↪ failed: 0, total take(s): 551.31, total kv: 5659888624, total size(MB
    ↪ ): 353227.18, avg speed(MB/s): 640.71"] ["backup total regions"=6795]
    ↪  ["backup checksum"=6m33.962719217s] ["backup fast checksum
    ↪ "=22.995552ms]
```

The information from the above log includes:

- Backup duration: `total take(s): 551.31`
- Data size: `total size(MB): 353227.18`
- Backup throughput: `avg speed(MB/s): 640.71`
- Backup checksum duration: `take=6m33.962719217s`

From the above information, the throughput of a single TiKV instance can be calculated: `avg speed(MB/s)/tikv_count` = 160.

Restore data from a local disk (recommended in testing environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- Preparation for restoration
- The TiKV cluster and the backup data do not have a duplicate database or table. Currently, BR does not support table route.
- Each TiKV node has a separate disk to store the backupSST file.
- The `restore_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `restore_endpoint` node must have the same directory for the restoration (for example, `/home/tidb/backup_local/`).

Before the restoration, follow these steps:

1. Collect all backupSST files into the same directory.
2. Copy the collected backupSST files to all TiKV nodes of the cluster.

3. Copy the `backupmeta` file to the `restore endpoint` node.

Topology

The following diagram shows the typology of BR:

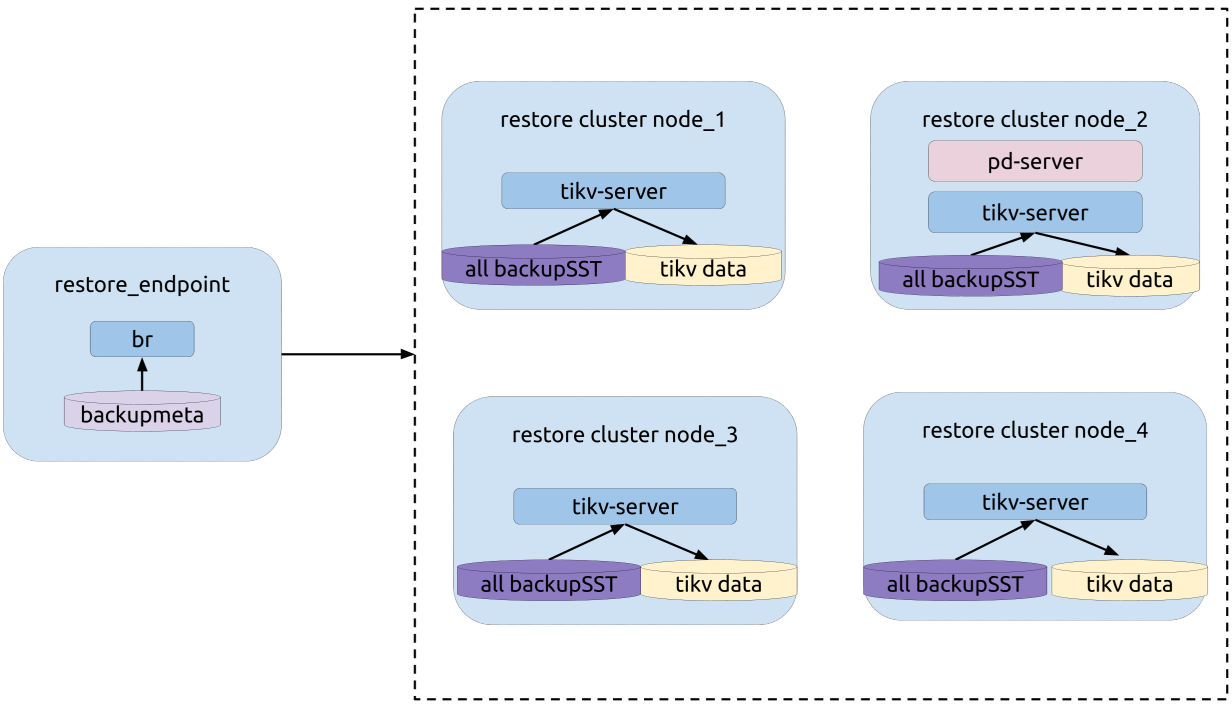

Figure 32: img

Restoration operation

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///home/tidb
    ↪ /backup_local/ --pd 172.16.5.198:2379 --log-file restore_local.log
```

During the restoration process, pay attention to the metrics on the monitoring panels to get the status of the restoration process. See Monitoring metrics for the restoration for details.

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search “summary” in this log, you can see the following information:

```
["Table Restore summary: total restore tables: 1, total success: 1, total
    ↪ failed: 0, total take(s): 908.42, total kv: 5659888624, total size(MB
    ↪ ): 353227.18, avg speed(MB/s): 388.84"] ["restore files"=9263] ["
    ↪ restore ranges"=6888] ["split region"=58.7885518s] ["restore checksum
    ↪ "=6m19.349067937s]
```

The above log includes the following information:

- Restoration duration: `total take(s): 908.42`
- Data size: `total size(MB): 353227.18`
- Restoration throughput: `avg speed(MB/s): 388.84`
- `Region Split` duration: `take=58.7885518s`
- Restoration checksum duration: `take=6m19.349067937s`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` = 97.2
- The average restoration speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` = 92.4

6.3.1.3.4 Error handling during backup

This section introduces the common errors occurred during the backup process.

`key locked Error` in the backup log

Error message in the log: `log - ["backup occur kv error"][error="{\"KvError
↪ \":{\"locked\":`

If a key is locked during the backup process, BR tries to resolve the lock. A small number of these errors do not affect the correctness of the backup.

Backup failure

Error message in the log: `log - Error: msg:"Io(Custom { kind: AlreadyExists,
↪ error: \"[5_5359_42_123_default.sst] is already exists in /dir/backup_local
↪ /\" })"`

If the backup operation fails and the above message occurs, perform one of the following operations and then start the backup operation again:

- Change the directory for the backup. For example, change `/dir/backup-2020-01-01/` to `/dir/backup_local/`.
- Delete the backup directory of all TiKV nodes and BR nodes.

6.3.1.4 External Storages

Backup & Restore (BR), TiDB Lighting, and Dumpling support reading and writing data on the local filesystem and on Amazon S3. BR also supports reading and writing data on the Google Cloud Storage (GCS). These are distinguished by the URL scheme in the `--storage` parameter passed into BR, in the `-d` parameter passed into TiDB Lightning, and in the `--output` (`-o`) parameter passed into Dumpling.

6.3.1.4.1 Schemes

The following services are supported:

Service	Schemes	Example URL
Local filesystem, distributed on every node	local	`local:///path/to/dest/`
Amazon S3 and compatible services	s3	`s3://bucket-name/prefix/of/dest/`
Google Cloud Storage (GCS)	gcs, gs	`gcs://bucket-name/prefix/of/dest/`
Write to nowhere (for benchmarking only)	noop	`noop://`

6.3.1.4.2 URL parameters

Cloud storages such as S3 and GCS sometimes require additional configuration for connection. You can specify parameters for such configuration. For example:

- Use Dumpling to export data to S3:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
   -o 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
   ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
   -d 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3 (using the path style in the request mode):

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
   ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
   -d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
      ↪ ://10.154.10.132:8088'
```

- Use BR to back up data to GCS:

```
./br backup full -u 127.0.0.1:2379 \
   -s 'gcs://bucket-name/prefix'
```

S3 URL parameters

URL parameter	Description
`access-key`	The access key
`secret-access-key`	The secret access key
`region`	Service Region for Amazon S3 (default to `us-east-1`)
`use-accelerate-endpoint`	Whether to use the accelerate endpoint on Amazon S3 (default to `false`)
`endpoint`	URL of custom endpoint for S3-compatible services (for example, `https://s3.example.com/`)

URL parameter	Description
`force-path-style`	Use path style access rather than virtual hosted style access (default to `false`)
`storage-class`	Storage class of the uploaded objects (for example, `STANDARD`, `STANDARD_IA`)
`sse`	Server-side encryption algorithm used to encrypt the upload (empty, `AES256` or `aws:kms`)
`sse-kms-key-id`	If `sse` is set to `aws:kms`, specifies the KMS ID

URL parameter	Description
`acl`	Canned ACL of the uploaded objects (for example, `private`, `authenticated-read`)

Note:

It is not recommended to pass in the access key and secret access key directly in the storage URL, because these keys are logged in plain text. The migration tools try to infer these keys from the environment in the following order:

1. `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables
2. `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables
3. Shared credentials file on the tool node at the path specified by the `$AWS_SHARED_CREDENTIALS_FILE` environment variable
4. Shared credentials file on the tool node at `~/.aws/credentials`
5. Current IAM role of the Amazon EC2 container
6. Current IAM role of the Amazon ECS task

GCS URL parameters

URL parameter	Description
`credentials-file`	The path to the credentials JSON file on the tool node

URL parameter	Description
`storage-class`	Storage class of the uploaded objects (for example, `STANDARD`, `COLDLINE`)
`predefined-acl`	Predefined ACL of the uploaded objects (for example, `private`, `project-private`)

When `credentials-file` is not specified, the migration tool will try to infer the credentials from the environment, in the following order:

1. Content of the file on the tool node at the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS` environment variable
2. Content of the file on the tool node at `~/.config/gcloud/application_default_credentials.json`
3. When running in GCE or GAE, the credentials fetched from the metadata server.

6.3.1.4.3 Command-line parameters

In addition to the URL parameters, BR and Dumpling also support specifying these configurations using command-line parameters. For example:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
    -o 's3://my-bucket/sql-backup' \
    --s3.region 'us-west-2'
```

If you have specified URL parameters and command-line parameters at the same time, the URL parameters are overwritten by the command-line parameters.

S3 command-line parameters

Command-line parameter	Description
`--s3.region`	Amazon S3's service region, which defaults to `us-east-1`.
`--s3.endpoint`	The URL of custom endpoint for S3-compatible services. For example, `https://s3.example.com/`.

Command-line parameter	Description
`--s3.storage-class`	The storage class of the upload object. For example, `STANDARD` and `STANDARD_IA`.
`--s3.sse`	The server-side encryption algorithm used to encrypt the upload. The value options are empty, `AES256` and `aws:kms`.

Command-line parameter	Description
`--s3.sse-kms-key-id`	If `--s3.sse` is configured as `aws:kms`, this parameter is used to specify the KMS ID.
`--s3.acl`	The canned ACL of the upload object. For example, `private` and `authenticated-read`.

Command-line parameter	Description
`--s3.provider`	The type of the S3-compatible service. The supported types are `aws`, `alibaba`, `ceph`, `netease` and `other`.

GCS command-line parameters

Command-line parameter	Description
`--gcs.credentials-file`	The path of the JSON-formatted credential on the tool node.
`--gcs.storage-class`	The storage type of the upload object, such as `STANDARD` and `COLDLINE`.

Command-line parameter	Description
`--gcs.predefined-acl`	The predefined ACL of the upload object, such as `private` and `project-private`.

6.3.1.4.4 BR sending credentials to TiKV

By default, when using S3 and GCS destinations, BR will send the credentials to every TiKV nodes to reduce setup complexity.

However, this is unsuitable on cloud environment, where every node has their own role and permission. In such cases, you need to disable credentials sending with `--send-credentials-to-tikv=false` (or the short form `-c=0`):

```
./br backup full -c=0 -u pd-service:2379 -s 's3://bucket-name/prefix'
```

When using SQL statements to back up and restore data, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
    FALSE;
```

This option is not supported in TiDB Lightning and Dumpling, because the two applications are currently standalone.

6.3.1.5 Backup & Restore FAQ

This document lists the frequently asked questions (FAQs) and the solutions about Backup & Restore (BR).

6.3.1.5.1 What should I do if the error message `could not read local://...:download sst failed` is returned during data restoration?

When you restore data, each node must have access to **all** backup files (SST files). By default, if `local` storage is used, you cannot restore data because the backup files are

scattered among different nodes. Therefore, you have to copy the backup file of each TiKV node to the other TiKV nodes.

It is recommended to mount an NFS disk as a backup disk during backup. For details, see Back up a single table to a network disk.

6.3.1.5.2 How much does it affect the cluster during backup using BR?

When you use the `oltp_read_only` scenario of `sysbench` to back up to a disk (make sure the backup disk and the service disk are different) at full rate, the cluster QPS is decreased by 15%-25%. The impact on the cluster depends on the table schema.

To reduce the impact on the cluster, you can use the `--ratelimit` parameter to limit the backup rate.

6.3.1.5.3 Does BR back up system tables? During data restoration, do they raise conflict?

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default. For more details, refer to the Back up and restore table data in the `mysql` system schema (experimental feature).

6.3.1.5.4 What should I do to handle the `Permission denied` or `No such file or directory` error, even if I have tried to run BR using root in vain?

You need to confirm whether TiKV has access to the backup directory. To back up data, confirm whether TiKV has the write permission. To restore data, confirm whether it has the read permission.

During the backup operation, if the storage medium is the local disk or a network file system (NFS), make sure that the user to start BR and the user to start TiKV are consistent (if BR and TiKV are on different machines, the users' UIDs must be consistent). Otherwise, the `Permission denied` issue might occur.

Running BR with the root access might fail due to the disk permission, because the backup files (SST files) are saved by TiKV.

> **Note:**
>
> You might encounter the same problem during data restoration. When the SST files are read for the first time, the read permission is verified. The execution duration of DDL suggests that there might be a long interval between checking the permission and running BR. You might receive the error message `Permission denied` after waiting for a long time.
>
> Therefore, It is recommended to check the permission before data restoration.

6.3.1.5.5 What should I do to handle the `Io(Os...)` error?

Almost all of these problems are system call errors that occur when TiKV writes data to the disk. For example, if you encounter error messages such as `Io(Os {code: 13, kind: PermissionDenied...})` or `Io(Os {code: 2, kind: NotFound...})`, you can first check the mounting method and the file system of the backup directory, and try to back up data to another folder or another hard disk.

For example, you might encounter the `Code: 22(invalid argument)` error when backing up data to the network disk built by `samba`.

6.3.1.5.6 What should I do to handle the `rpc error: code = Unavailable desc =...` error occurred in BR?

This error might occur when the capacity of the cluster to restore (using BR) is insufficient. You can further confirm the cause by checking the monitoring metrics of this cluster or the TiKV log.

To handle this issue, you can try to scale out the cluster resources, reduce the concurrency during restore, and enable the `RATE_LIMIT` option.

6.3.1.5.7 Where are the backed up files stored when I use `local` storage?

When you use `local` storage, `backupmeta` is generated on the node where BR is running, and backup files are generated on the Leader nodes of each Region.

6.3.1.5.8 How about the size of the backup data? Are there replicas of the backup?

During data backup, backup files are generated on the Leader nodes of each Region. The size of the backup is equal to the data size, with no redundant replicas. Therefore, the total data size is approximately the total number of TiKV data divided by the number of replicas.

However, if you want to restore data from local storage, the number of replicas is equal to that of the TiKV nodes, because each TiKV must have access to all backup files.

6.3.1.5.9 What should I do when BR restores data to the upstream cluster of TiCDC/Drainer?

- **The data restored using BR cannot be replicated to the downstream**. This is because BR directly imports SST files but the downstream cluster currently cannot obtain these files from the upstream.
- Before v4.0.3, DDL jobs generated during the BR restore might cause unexpected DDL executions in TiCDC/Drainer. Therefore, if you need to perform restore on the upstream cluster of TiCDC/Drainer, add all tables restored using BR to the TiCDC/Drainer block list.

You can use `filter.rules` to configure the block list for TiCDC and use `syncer.ignore -table` to configure the block list for Drainer.

6.3.1.5.10 Does BR back up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table? Does the restored table have multiple Regions?

Yes. BR backs up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table. The data of the restored table is also split into multiple Regions.

6.3.1.5.11 Why is the `region is unavailable` error reported for a SQL query after I use BR to restore the backup data?

If the cluster backed up using BR has TiFlash, `TableInfo` stores the TiFlash information when BR restores the backup data. If the cluster to be restored does not have TiFlash, the `region is unavailable` error is reported.

6.3.1.5.12 Does BR support in-place full recovery of some historical backup?

No. BR does not support in-place full recovery of some historical backup.

6.3.1.5.13 How can I use BR for incremental backup in the Kubernetes environment?

To get the `commitTs` field of the last BR backup, run the `kubectl -n ${namespace} get bk ${name}` command using kubectl. You can use the content of this field as `--lastbackupts`.

6.3.1.5.14 How can I convert BR backupTS to Unix time?

BR `backupTS` defaults to the latest timestamp obtained from PD before the backup starts. You can use `pd-ctl tso timestamp` to parse the timestamp to obtain an accurate value, or use `backupTS >> 18` to quickly obtain an estimated value.

6.3.1.5.15 After BR restores the backup data, do I need to execute the `ANALYZE` statement on the table to update the statistics of TiDB on the tables and indexes?

BR does not back up statistics (except in v4.0.9). Therefore, after restoring the backup data, you need to manually execute `ANALYZE TABLE` or wait for TiDB to automatically execute `ANALYZE`.

In v4.0.9, BR backs up statistics by default, which consumes too much memory. To ensure that the backup process goes well, the backup for statistics is disabled by default starting from v4.0.10.

If you do not execute `ANALYZE` on the table, TiDB will fail to select the optimized execution plan due to inaccurate statistics. If query performance is not a key concern, you can ignore `ANALYZE`.

6.4 Time Zone Support

The time zone in TiDB is decided by the global `time_zone` system variable and the session `time_zone` system variable. The default value of `time_zone` is `SYSTEM`. The actual time zone corresponding to `System` is configured when the TiDB cluster bootstrap is initialized. The detailed logic is as follows:

- Prioritize the use of the `TZ` environment variable.
- If the `TZ` environment variable fails, extract the time zone from the actual soft link address of `/etc/localtime`.
- If both of the above methods fail, use `UTC` as the system time zone.

You can use the following statement to set the global server `time_zone` value at runtime:

```
SET GLOBAL time_zone = timezone;
```

Each client has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

You can use the following statement to view the current values of the global and client-specific time zones:

```
SELECT @@global.time_zone, @@session.time_zone;
```

To set the format of the value of the `time_zone`:

- The value 'SYSTEM' indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as '+10:00' or '-6:00'.
- The value can be given as a named time zone, such as 'Europe/Helsinki', 'US/Eastern', or 'MET'.

The current session time zone setting affects the display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`.

Note:

Only the values of the Timestamp data type is affected by time zone. This is because the Timestamp data type uses the literal value + time zone information. Other data types, such as Datetime/Date/Time, do not have time zone information, thus their values are not affected by the changes of time zone.

```
create table t (ts timestamp, dt datetime);
```

```
Query OK, 0 rows affected (0.02 sec)
```

```
set @@time_zone = 'UTC';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
insert into t values ('2017-09-30 11:11:11', '2017-09-30 11:11:11');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
set @@time_zone = '+8:00';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+---------------------|---------------------+
| ts                  | dt                  |
+---------------------|---------------------+
| 2017-09-30 19:11:11 | 2017-09-30 11:11:11 |
+---------------------|---------------------+
1 row in set (0.00 sec)
```

In this example, no matter how you adjust the value of the time zone, the value of the Datetime data type is not affected. But the displayed value of the Timestamp data type changes if the time zone information changes. In fact, the value that is stored in the storage does not change, it's just displayed differently according to different time zone setting.

Note:

- Time zone is involved during the conversion of the value of Timestamp and Datetime, which is handled based on the current `time_zone` of the session.
- For data migration, you need to pay special attention to the time zone setting of the primary database and the secondary database.

6.5 Daily Check

As a distributed database, TiDB is more complicated than the stand-alone database in terms of the mechanism, and monitoring items. To help operate and maintain TiDB in a more convenient way, this document introduces some key performance indicators.

6.5.1 Key indicators of TiDB Dashboard

Starting from v4.0, TiDB provides a new operation and maintenance management tool, TiDB Dashboard. This tool is integrated into the PD component. You can access TiDB Dashboard at the default address `http://${pd-ip}:${pd_port}/dashboard`.

TiDB Dashboard simplifies the operation and maintenance of the TiDB database. You can view the running status of the entire TiDB cluster through one interface. The following are descriptions of some performance indicators.

6.5.1.1 Instance panel

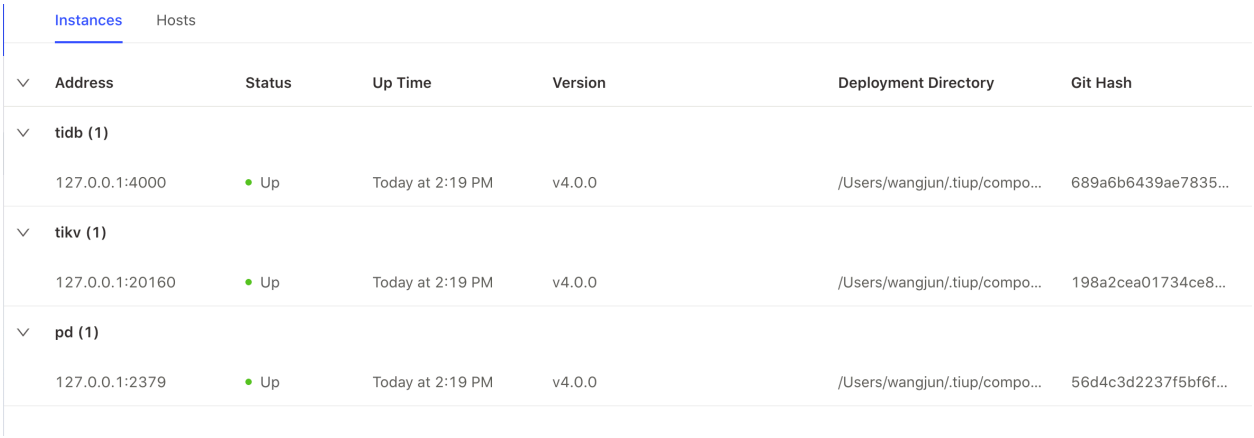

Figure 33: Instance panel

- **Status**: This indicator is used to check whether the status is normal. For an online node, this can be ignored.

- **Up Time**: The key indicator. If you find that the `Up Time` is changed, you need to locate the reason why the component is restarted.
- **Version**, **Deployment Directory**, **Git Hash**: These indicators need to be checked to avoid inconsistent or even incorrect version/deployment directory.

6.5.1.2 Host panel

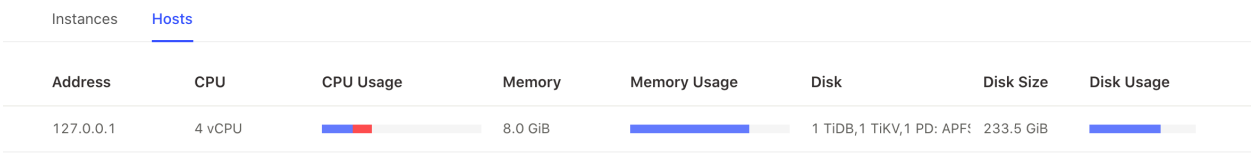

Figure 34: Host panel

You can view the usage of CPU, memory, and disk. When the usage of any resource exceeds 80%, it is recommended to scale out the capacity accordingly.

6.5.1.3 SQL analysis panel

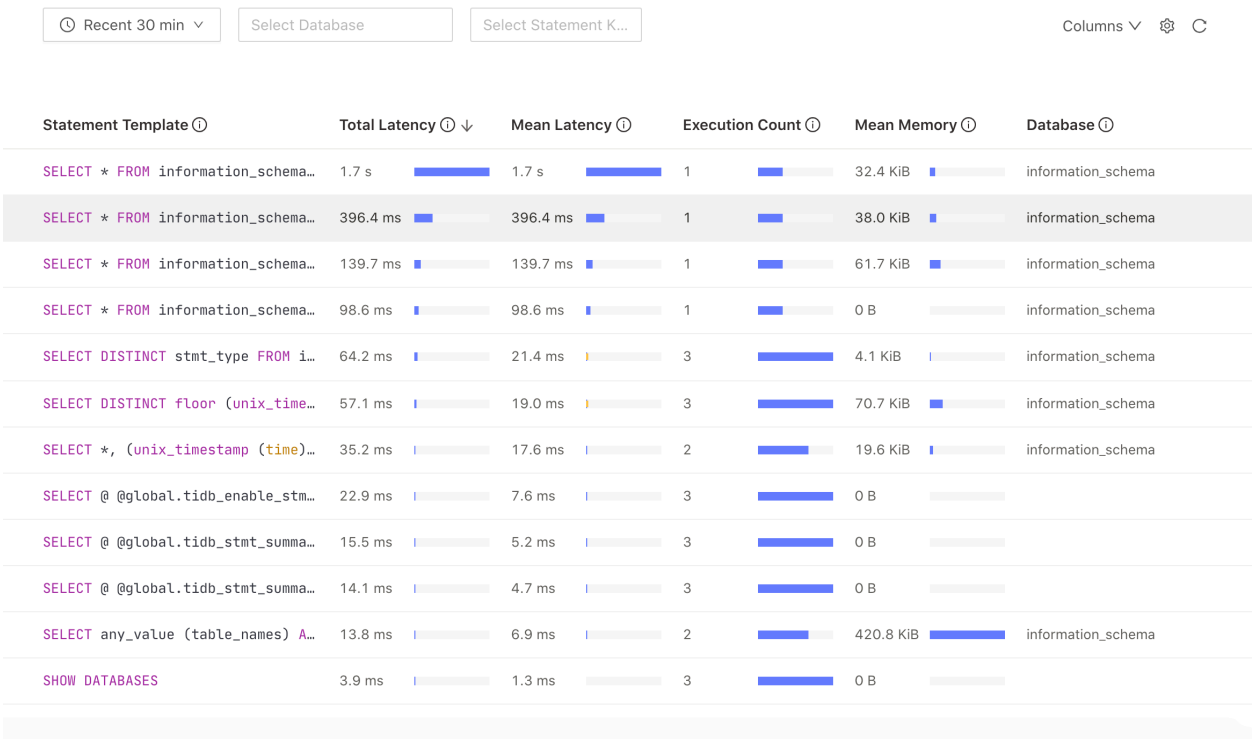

Figure 35: SQL analysis panel

You can locate the slow SQL statement executed in the cluster. Then you can optimize the specific SQL statement.

6.5.1.4 Region panel

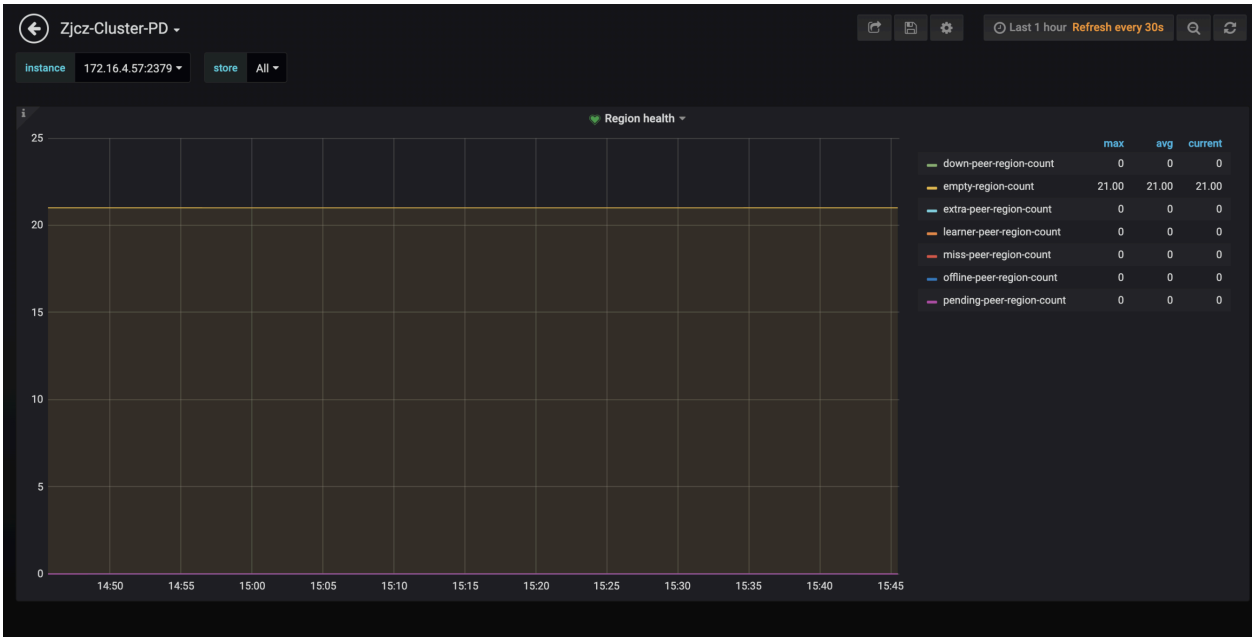

Figure 36: Region panel

- `miss-peer-region-count`: The number of Regions without enough replicas. This value is not always greater than `0`.
- `extra-peer-region-count`: The number of Regions with extra replicas. These Regions are generated during the scheduling process.
- `empty-region-count`: The number of empty Regions, generated by executing the `TRUNCATE TABLE/DROP TABLE` statement. If this number is large, you can consider enabling `Region Merge` to merge Regions across tables.
- `pending-peer-region-count`: The number of Regions with outdated Raft logs. It is normal that a few pending peers are generated in the scheduling process. However, it is not normal if this value is large for a period of time.
- `down-peer-region-count`: The number of Regions with an unresponsive peer reported by the Raft leader.
- `offline-peer-region-count`: The number of Regions during the offline process.

Generally, it is normal that these values are not `0`. However, it is not normal that they are not `0` for quite a long time.

6.5.1.5 KV Request Duration

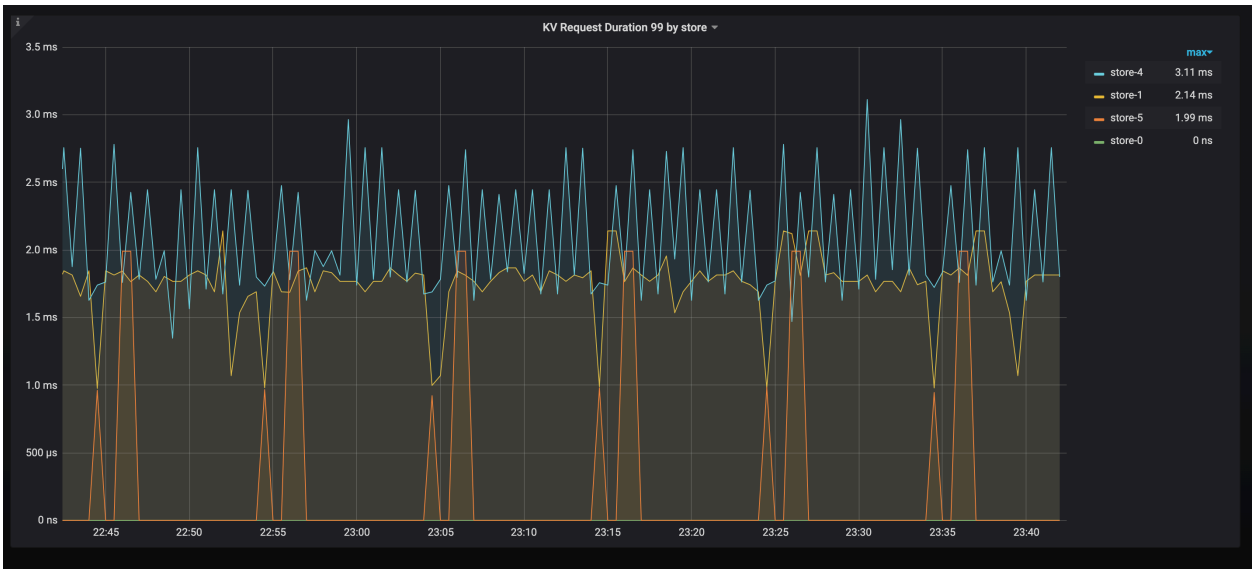

Figure 37: TiKV request duration

The KV request duration 99 in TiKV. If you find nodes with a long duration, check whether there are hot spots, or whether there are nodes with poor performance.

6.5.1.6 PD TSO Wait Duration

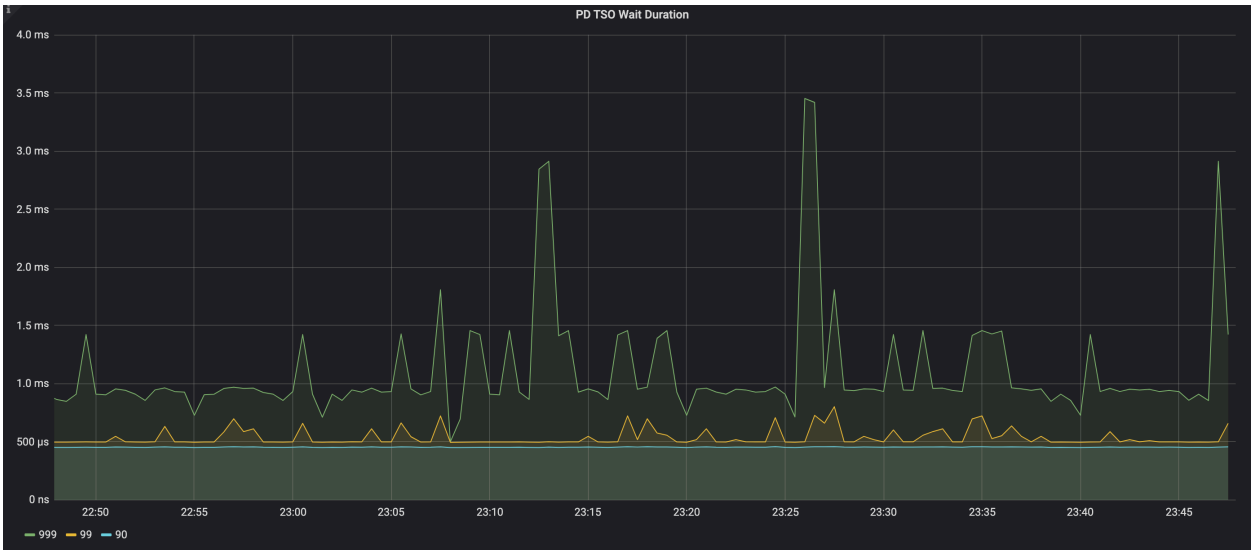

Figure 38: TiDB TSO Wait Duration

The time it takes for TiDB to obtain TSO from PD. The following are reasons for the long wait duration:

- High network latency from TiDB to PD. You can manually execute the ping command to test the network latency.
- High load for the TiDB server.
- High load for the PD server.

6.5.1.7 Overview panel

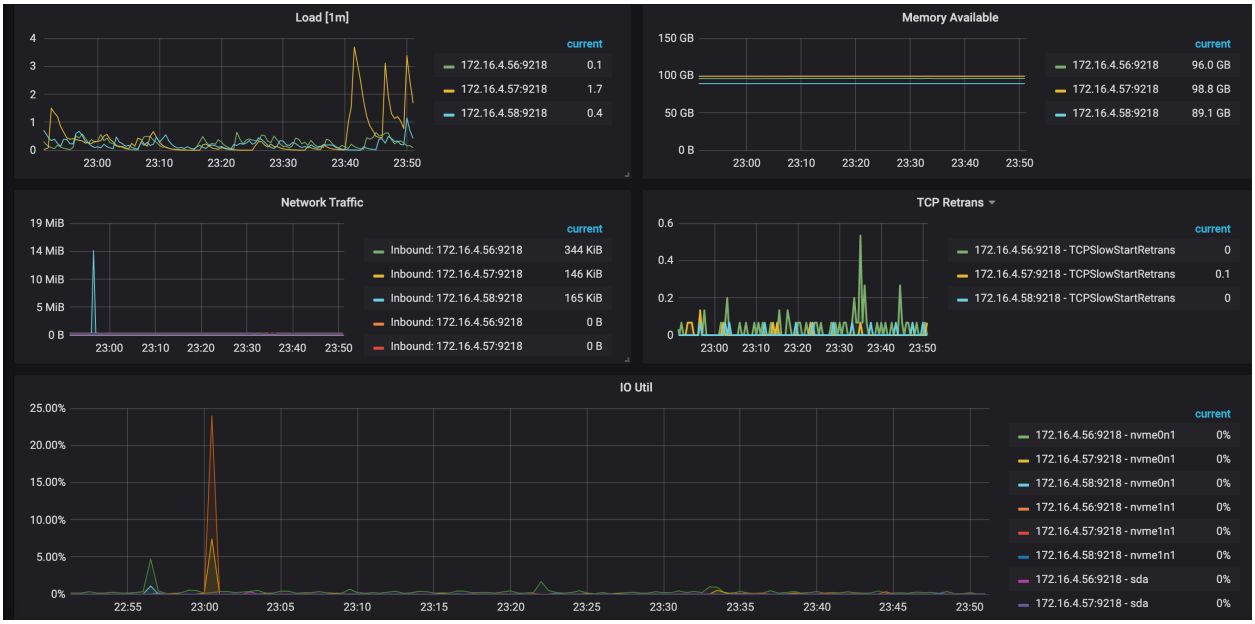

Figure 39: Overview panel

You can view the load, memory available, network traffic, and I/O utilities. When a bottleneck is found, it is recommended to scale out the capacity, or to optimize the cluster topology, SQL, cluster parameters, etc.

6.5.1.8 Exceptions

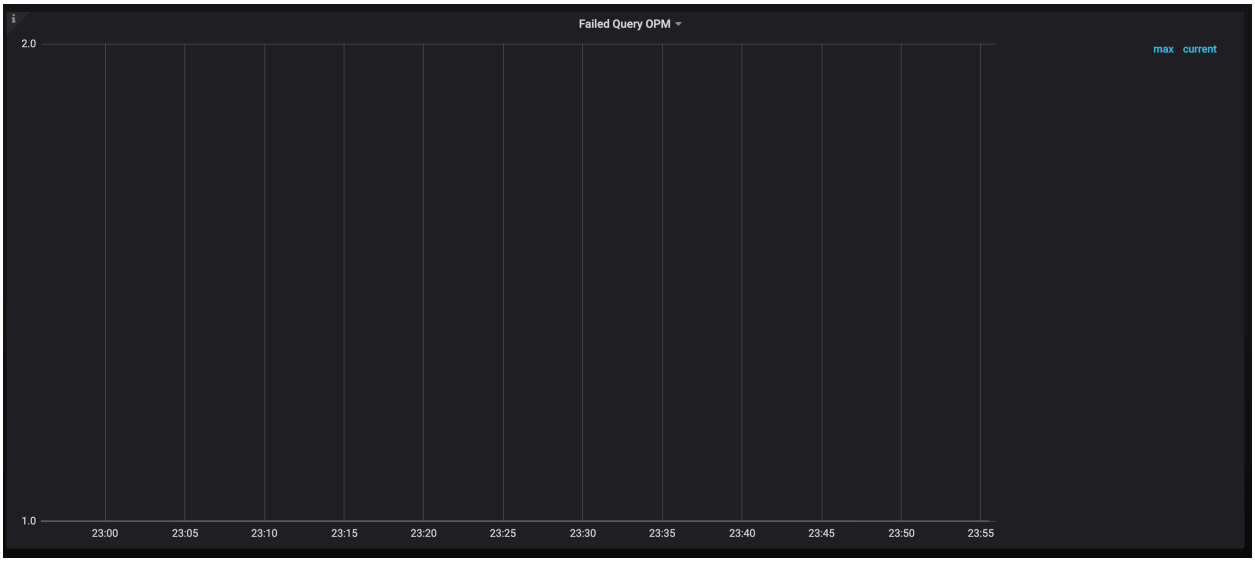

Figure 40: Exceptions

You can view the errors triggered by the execution of SQL statements on each TiDB instance. These include syntax error, primary key conflicts, etc.

6.5.1.9 GC status

```
(root@127.0.0.1) [(none)]>select * from mysql.tidb;
+-----------------------+------------------------------------------------------------------------------------------------------+-----------------------------------------------------------------------------------------------------------
```

6.6 Maintain a TiFlash Cluster

This document describes how to perform common operations when you maintain a TiFlash cluster, including checking the TiFlash version. This document also introduces critical logs and a system table of TiFlash.

6.6.1 Check the TiFlash version

There are two ways to check the TiFlash version:

- If the binary file name of TiFlash is `tiflash`, you can check the version by executing the `./tiflash version` command.

  However, to execute the above command, you need to add the directory path which includes the `libtiflash_proxy.so` dynamic library to the `LD_LIBRARY_PATH` environment variable. This is because the running of TiFlash relies on the `libtiflash_proxy.so` dynamic library.

  For example, when `tiflash` and `libtiflash_proxy.so` are in the same directory, you can first switch to this directory, and then use the following command to check the TiFlash version:

```
LD_LIBRARY_PATH=./ ./tiflash version
```

- Check the TiFlash version by referring to the TiFlash log. For the log path, see the `[logger]` part in the `tiflash.toml` file. For example:

```
<information>: TiFlash version: TiFlash 0.2.0 master-375035282451103999
    ↪ f3863c691e2fc2
```

6.6.2 TiFlash critical logs

Log Information	Log Description
[INFO] [<unknown>] ["KVStore: Start to persist [region 47, applied: term 6 index 10]"] [thread_id=23]	Data starts to be replicated (the number in the square brackets at the start of the log refers to the thread ID

Log Information	Log Description
[DEBUG] [<unknown>] ["CoprocessorHandler: grpc::Status DB::CoprocessorHandler::execute(): Handling DAG request"] [thread_id=30]	Handling DAG request, that is, TiFlash starts to handle a Coprocessor request
[DEBUG] [<unknown>] ["CoprocessorHandler: grpc::Status DB::CoprocessorHandler::execute(): Handle DAG request done"] [thread_id=30]	Handling DAG request done, that is, TiFlash finishes handling a Coprocessor request

You can find the beginning or the end of a Coprocessor request, and then locate the related logs of the Coprocessor request through the thread ID printed at the start of the log.

6.6.3 TiFlash system table

The column names and their descriptions of the `information_schema.tiflash_replica` system table are as follows:

Column Name	Description
TABLE_SCHEMA	database name
TABLE_NAME	table name
TABLE_ID	table ID
REPLICA_COUNT	number of TiFlash replicas
AVAILABLE	available or not (0/1)
PROGRESS	replication progress [0.0~1.0]

6.7 TiUP Common Operations

This document describes the following common operations when you operate and maintain a TiDB cluster using TiUP.

- View the cluster list

- Start the cluster
- View the cluster status
- Modify the configuration
- Stop the cluster
- Destroy the cluster

6.7.1 View the cluster list

You can manage multiple TiDB clusters using the TiUP cluster component. When a TiDB cluster is deployed, the cluster appears in the TiUP cluster list.

To view the list, run the following command:

```
tiup cluster list
```

6.7.2 Start the cluster

The components in the TiDB cluster are started in the following order:

PD > TiKV > Pump > TiDB > TiFlash > Drainer > TiCDC > Prometheus > Grafana > Alertmanager

To start the cluster, run the following command:

```
tiup cluster start ${cluster-name}
```

> **Note:**
>
> Replace `${cluster-name}` with the name of your cluster. If you forget the cluster name, check it by running `tiup cluster list`.

You can start only some of the components by adding the `-R` or `-N` parameters in the command. For example:

- This command starts only the PD component:

  ```
  tiup cluster start ${cluster-name} -R pd
  ```

- This command starts only the PD components on the `1.2.3.4` and `1.2.3.5` hosts:

  ```
  tiup cluster start ${cluster-name} -N 1.2.3.4:2379,1.2.3.5:2379
  ```

Note:

If you start the specified component by using the `-R` or `-N` parameters, make sure the starting order is correct. For example, start the PD component before the TiKV component. Otherwise, the start might fail.

6.7.3 View the cluster status

After starting the cluster, check the status of each component to ensure that they work normally. TiUP provides the `display` command, so you do not have to log in to every machine to view the component status.

```
tiup cluster display ${cluster-name}
```

6.7.4 Modify the configuration

When the cluster is in operation, if you need to modify the parameters of a component, run the `edit-config` command. The detailed steps are as follows:

1. Open the configuration file of the cluster in the editing mode:

   ```
   tiup cluster edit-config ${cluster-name}
   ```

2. Configure the parameters:

   - If the configuration is globally effective for a component, edit `server_configs`:

     ```
     server_configs:
       tidb:
         log.slow-threshold: 300
     ```

   - If the configuration takes effect on a specific node, edit the configuration in `config` of the node:

     ```
     tidb_servers:
     - host: 10.0.1.11
         port: 4000
         config:
             log.slow-threshold: 300
     ```

For the parameter format, see the TiUP parameter template.

Use . to represent the hierarchy of the configuration items.

For more information on the configuration parameters of components, refer to TiDB `config.toml.example`, TiKV `config.toml.example`, and PD `config.toml.example` ↪ .

3. Rolling update the configuration and restart the corresponding components by running the `reload` command:

```
tiup cluster reload ${cluster-name} [-N <nodes>] [-R <roles>]
```

6.7.4.1 Example

If you want to set the transaction size limit parameter (`txn-total-size-limit` in the performance module) to `1G` in tidb-server, edit the configuration as follows:

```
server_configs:
  tidb:
    performance.txn-total-size-limit: 1073741824
```

Then, run the `tiup cluster reload ${cluster-name} -R tidb` command to rolling restart the TiDB component.

6.7.5 Replace with a hotfix package

For normal upgrade, see Upgrade TiDB Using TiUP. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 300)
```

```
Global Flags:

      --native-ssh      Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

6.7.6 Rename the cluster

After deploying and starting the cluster, you can rename the cluster using the `tiup ↪ cluster rename` command:

```
tiup cluster rename ${cluster-name} ${new-name}
```

Note:

- The operation of renaming a cluster restarts the monitoring system (Prometheus and Grafana).
- After a cluster is renamed, some panels with the old cluster name might remain on Grafana. You need to delete them manually.

6.7.7 Stop the cluster

The components in the TiDB cluster are stopped in the following order (The monitoring component is also stopped):

Alertmanager > Grafana > Prometheus > TiCDC > Drainer > TiFlash > TiDB > Pump > TiKV > PD

To stop the cluster, run the following command:

```
tiup cluster stop ${cluster-name}
```

Similar to the `start` command, the `stop` command supports stopping some of the components by adding the `-R` or `-N` parameters. For example:

- This command stops only the TiDB component:

```
tiup cluster stop ${cluster-name} -R tidb
```

- This command stops only the TiDB components on the `1.2.3.4` and `1.2.3.5` hosts:

```
tiup cluster stop ${cluster-name} -N 1.2.3.4:4000,1.2.3.5:4000
```

6.7.8 Clean up cluster data

The operation of cleaning up cluster data stops all the services and cleans up the data directory or/and log directory. The operation cannot be reverted, so proceed **with caution**.

- Clean up the data of all services in the cluster, but keep the logs:

```
tiup cluster clean ${cluster-name} --data
```

- Clean up the logs of all services in the cluster, but keep the data:

```
tiup cluster clean ${cluster-name} --log
```

- Clean up the data and logs of all services in the cluster:

```
tiup cluster clean ${cluster-name} --all
```

- Clean up the logs and data of all services except Prometheus:

```
tiup cluster clean ${cluster-name} --all --ignore-role prometheus
```

- Clean up the logs and data of all services except the `172.16.13.11:9000` instance:

```
tiup cluster clean ${cluster-name} --all --ignore-node
    ↪ 172.16.13.11:9000
```

- Clean up the logs and data of all services except the `172.16.13.12` node:

```
tiup cluster clean ${cluster-name} --all --ignore-node 172.16.13.12
```

6.7.9 Destroy the cluster

The destroy operation stops the services and clears the data directory and deployment directory. The operation cannot be reverted, so proceed **with caution**.

```
tiup cluster destroy ${cluster-name}
```

6.8 Modify Configuration Online

This document describes how to modify the cluster configuration online.

> **Note:**
>
> This feature is experimental. It is **NOT** recommended to use this feature in the production environment.

You can update the configuration of components (including TiDB, TiKV, and PD) online using SQL statements, without restarting the cluster components. Currently, the method of changing TiDB instance configuration is different from that of changing configuration of other components (such TiKV and PD).

6.8.1 Common Operations

This section describes the common operations of modifying configuration online.

6.8.1.1 View instance configuration

To view the configuration of all instances in the cluster, use the `show config` statement. The result is as follows:

```
show config;
```

```
+--
   ↪ ----+-----------------+-----------------------------------------------------------
   ↪
| Type | Instance     | Name                                                          |
   ↪  Value
   ↪
   ↪ |
+--
   ↪ ----+-----------------+-----------------------------------------------------------
   ↪
| tidb | 127.0.0.1:4001 | advertise-address                                           |
   ↪  127.0.0.1
   ↪
   ↪ |
| tidb | 127.0.0.1:4001 | binlog.binlog-socket                                        |
   ↪
   ↪
   ↪ |
```

```
| tidb | 127.0.0.1:4001 | binlog.enable                                                |
    ↪  false
    ↪
    ↪ |
| tidb | 127.0.0.1:4001 | binlog.ignore-error                                          |
    ↪  false
    ↪
    ↪ |
| tidb | 127.0.0.1:4001 | binlog.strategy                                              |
    ↪  range
    ↪
    ↪ |
| tidb | 127.0.0.1:4001 | binlog.write-timeout                                         |
    ↪  15s
    ↪
    ↪ |
| tidb | 127.0.0.1:4001 | check-mb4-value-in-utf8                                      |
    ↪  true
    ↪
    ↪ |

...
```

You can filter the result by fields. For example:

```
show config where type='tidb'
show config where instance in (...)
show config where name like '%log%'
show config where type='tikv' and name='log-level'
```

6.8.1.2 Modify TiKV configuration online

Note:

- After changing TiKV configuration items online, the TiKV configuration file is automatically updated. However, you also need to modify the corresponding configuration items by executing `tiup edit-config`; otherwise, operations such as `upgrade` and `reload` will overwrite your changes. For details of modifying configuration items, refer to Modify configuration using TiUP.
- After executing `tiup edit-config`, you do not need to execute `tiup ↪ reload`.

When using the `set config` statement, you can modify the configuration of a single instance or of all instances according to the instance address or the component type.

- Modify the configuration of all TiKV instances:

> **Note:**
>
> It is recommended to wrap variable names in backticks.

```
set config tikv `split.qps-threshold`=1000;
```

- Modify the configuration of a single TiKV instance:

```
set config "127.0.0.1:20180" `split.qps-threshold`=1000;
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If an error occurs during the batch modification, a warning is returned:

```
set config tikv `log-level`='warn';
```

```
Query OK, 0 rows affected, 1 warning (0.04 sec)
```

```
show warnings;
```

```
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Level   | Code | Message
    ↪
    ↪ |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
| Warning | 1105 | bad request to http://127.0.0.1:20180/config: fail to
    ↪ update, error: "config log-level can not be changed" |
+--
    ↪ -------+------+-----------------------------------------------------------------
    ↪
1 row in set (0.00 sec)
```

The batch modification does not guarantee atomicity. The modification might succeed on some instances, while failing on others. If you modify the configuration of the entire TiKV cluster using `set tikv key=val`, your modification might fail on some instances. You can use `show warnings` to check the result.

If some modifications fail, you need to re-execute the corresponding statement or modify each failed instance. If some TiKV instances cannot be accessed due to network issues or machine failure, modify these instances after they are recovered.

If a configuration item is successfully modified, the result is persisted in the configuration file, which will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words, such as `limit` and `key`. For these configuration items, use backtick ` to enclose them. For example, `` `raftstore.raft-log-gc-size-limit` ``.

The following TiKV configuration items can be modified online:

Configuration item	Description
`raftstore.raft-max-entry-size`	The maximum size of a single log
`raftstore.raft-log-gc-tick-interval`	The time interval at which the polling task of deleting obsolete Raft logs is scheduled

Configuration item	Description
`raftstore.raft-log-gc-threshold`	The soft limit on the maximum allowable number of residual Raft logs
`raftstore.raft-log-gc-count-limit`	The hard limit on the allowable number of residual Raft logs

Configuration item	Description
`raftstore.raft-log-gc-size-limit`	The hard limit on the allowable size of residual Raft logs
`raftstore.raft-entry-cache-life-time`	The maximum remaining time allowed for the log cache in memory

Configuration item	Description
`raftstore.raft-max-leader-lease`	Determines the maximum duration that the leader can be sure of its validity. If the duration exceeds the value of this configuration item, there might be a new leader in the cluster. During the transfer of leaders, TiKV does a conservative judgment: it sets the duration to the value of `raftstore.raft-election-timeout-ticks` to avoid unavailable status.
`raftstore.split-region-check-tick-interval`	The time interval for checking whether the Region split is needed

Configuration item	Description
`raftstore.region-split-check-diff`	The maximum value by which the Region data is allowed to exceed before Region split
`raftstore.region-compact-check-interval`	The time interval to check whether it is necessary to manually trigger RocksDB compaction

Configuration item	Description
`raftstore.region-compact-check-step`	The number of Region checked at one time for each round of manual compaction
`raftstore.region-compact-min-tombstones`	The number of tombstones required to trigger RocksDB compaction

Configuration item	Description
`raftstore.region-compact-tombstones-percent`	The proportion of tombstones to the total number of entries in the RocksDB compaction
`raftstore.pd-heartbeat-tick-interval`	The time interval which a Region's heartbeat to PD is triggered

Configuration item	Description
`raftstore.pd-heartbeat-tick-interval`	The time interval at which a Region's heartbeat to PD is triggered
`raftstore.snap-mgr-gc-tick-interval`	The time interval at which the recycle of expired snapshot files is triggered
`raftstore.snap-gc-timeout`	The longest time for which a snapshot file is saved

Configuration item	Description
`raftstore.lock-cf-compact-interval`	The time interval at which TiKV triggers a manual compaction for the Lock Column Family
`raftstore.lock-cf-compact-bytes-threshold`	The size at which TiKV triggers a manual compaction for the Lock Column Family

Configuration item	Description
`raftstore.max-messages-per-tick`	The maximum number of messages processed per batch
`raftstore.max-peer-down-duration`	The longest inactive duration allowed for a peer

Configuration item	Description
`raftstore.max-leader-missing-duration`	The longest duration for a peer to be without a leader. If this value is exceeded, the peer verifies with PD whether it has been deleted.

Configuration item	Description
raftstore.abnormal-leader-missing-duration	The normal duration allowed for a peer to be without a leader. If this value is exceeded, the peer is seen as abnormal and marked in metrics and logs.

Configuration item	Description
raftstore.peer-stale-state-check-interval	The time interval to check whether a peer is valid
raftstore.consistency-check-interval	The time interval to check consistency
raftstore.raft-store-max-leader-lease	The longest trusted period of a Raft leader lease

Configuration item	Description
`raftstore.allow-remove-leader`	Determines whether to allow to remove the main switch
`raftstore.merge-check-tick-interval`	The time interval for the merge check
`raftstore.cleanup-import-sst-interval`	The time interval for checking expired SST files

Configuration item	Description
`raftstore.local-read-batch-size`	The maximum number of read requests processed in one batch

Configuration item	Description
`raftstore.hibernate-timeout`	The shortest wait duration before entering hibernation upon start. Within this duration, TiKV does not hibernate (not released).
`coprocessor.split-region-on-table`	Enables to split Region by table

Configuration item	Description
`coprocessor.batch-split-limit`	The threshold of Region split batches
`coprocessor.region-max-size`	The maximum size of a Region
`coprocessor.region-split-size`	The size of the newly split Region
`coprocessor.region-max-keys`	The maximum number of keys allowed in a Region

Configuration item	Description
coprocessor.region-split-keys	The number of keys in the newly split Region
pessimistic-txn.wait-for-lock-timeout	The longest duration that a pessimistic transaction waits for the lock
pessimistic-txn.wake-up-delay-duration	The duration after which a pessimistic transaction is woken up

Configuration item	Description
`pessimistic-txn.pipelined`	Whether to enable the pipelined pessimistic locking process
`gc.ratio-threshold`	The threshold which Region GC is skipped (the number of GC versions/the number of keys)

Configuration item	Description
gc.batch-keys	The number of keys processed in one batch
gc.max-write-bytes-per-sec	The maximum bytes that can be written into RocksDB per second
gc.enable-compaction-filter	Whether to enable compaction filter

Configuration item	Description
gc. ↪ compaction ↪ - skip ↪ filter ↪ - clus- ↪ skip ter ↪ - ver- ↪ version sion ↪ - check ↪ check of	Whether to com- paction filter (not re- leased)
{db- ↪ name ↪ }. ↪ max size ↪ - of ↪ total total ↪ - WAL ↪ wal ↪ - ↪ size ↪	The maxi- mum
{db- ↪ name num- ↪ }. ↪ max of ↪ - back- ↪ background ground ↪ - threads ↪ jobs in ↪	The ber RocksDB

Configuration item	Description
{db-name}.max-open-files	The total number of files that RocksDB can open
{db-name}.compaction-readahead-size	The size of compaction readahead reading
{db-name}.bytes-per-sync	The rate at which OS incrementally synchronizes files to disk while these files are being written asynchronously

Configuration item	Description
{db-name}.wal-bytes-per-sync	The rate at which OS incrementally synchronizes WAL files to disk while the WAL files are being written
{db-name}.writable-file-max-buffer-size	The maximum buffer size used in WritableFileWriter buffer size

Configuration item	Description
{db-name}.{cf-name}.block-cache-size	The size of a block cache
{db-name}.{cf-name}.write-buffer-size	The size of a memtable
{db-name}.{cf-name}.max-write-buffer-number	The maximum number of memtables

Configuration item	Description
`{db-name}.{cf-name}.max-bytes-for-level-base`	The maximum number of bytes at base level (L1) for the level base
`{db-name}.{cf-name}.target-file-size-base`	The size of the target file at base level

Configuration item	Description
{db-name}.{cf-name}.{level-0-file-num-compaction-trigger}	The maximum number of files at L0 that trigger compaction
{db-name}.{cf-name}.{level-0-slowdown-writes-trigger}	The maximum number of files at L0 that trigger write stall

Configuration item	Description
{db-name}.{cf-name}.level0-stop-writes-trigger	The maximum number of files at L0 that completely block write
{db-name}.{cf-name}.max-compaction-bytes	The maximum number of bytes written by one compaction

Configuration item	Description
`{db-name}.{cf-name}.max-bytes-for-level-multiplier`	The default amplification multiple for each layer
`{db-name}.{cf-name}.disable-auto-compactions`	Enables or disables automatic compaction

Configuration item	Description
{db-name}.{cf-name}.soft-pending-compaction-bytes-limit	The soft limit on the pending compaction bytes
{db-name}.{cf-name}.hard-pending-compaction-bytes-limit	The hard limit on the pending compaction bytes

Configuration item	Description
`{db-name}.{cf-name}.titan.blob_run_mode`	The mode of processing blob files
`server.snap-max-write-bytes-per-sec`	Sets the maximum allowable disk bandwidth when processing snapshots

Configuration item	Description
`server.concurrent-send-snapshot-limit`	Sets the maximum number of snapshots sent at the same time
`server.concurrent-recv-snapshot-limit`	Sets the maximum number of snapshots received at the same time
`storage.block-cache.capacity`	The size of shared block cache (supported since v4.0.3)

Configuration item	Description
`backup.num-threads`	The number of backup threads (supported since v4.0.3)

Configuration item	Description
`split-qps-threshold`	The threshold to execute `load-base-split` on a Region. If the QPS of read requests for a Region exceeds `qps-threshold` for a consecutive period of time, this Region should be split.

Configuration item	Description
`split.byte-threshold`	The threshold to execute `split` on a Region. If the traffic of read requests for a Region exceeds the `byte-threshold` for a consecutive period of time, this Region should be split.

Configuration item	Description
`split.split-balance-score`	The parameter of `balance-load` split checker is to control the threshold at which Region split is triggered. The smaller the value is, the more balanced the load is. But setting it too small might cause split failure. The default value is `0.25`, and the corresponding threshold is `2000`.
`split.qps-threshold`	The number of queries per second to write/read one Region over the threshold continuously for more than 10 seconds will trigger the split. The default value of this configuration item is `3000`. When you manually lower the value, it is recommended to not lower it to less than `1000`, to avoid too many unnecessary splits.
`split.byte-threshold`	The byte number per second to write/read one Region over the threshold continuously for more than 10 seconds will trigger the split. The default value of this configuration item is `30MiB`. When you manually lower the value, it is recommended to not lower it to less than `20MiB`, to avoid too many unnecessary splits.
`split.region-cpu-overload-threshold-ratio`	The threshold ratio to determine whether a Region is overloaded. If the CPU usage of a Region exceeds the threshold ratio of the CPU usage of all Regions, the Region might be split. The default value is `0.25`. During traffic peaks, you can modify the parameter dynamically to make it effective immediately.
`split.detect-times`	The duration for which the access exceeds the threshold. If this duration is exceeded, a Region split is performed. The default value is `10s`. During traffic peaks, you can modify the parameter dynamically to make it effective immediately.
`split.split-balance-score`	The parameter of `balance-load` split checker is to control how balanced load you want the split Regions to be. The smaller the value is, the more balanced the load is. But setting it too small might cause split

Configuration item	Description
`split.split-score`	The parameter of load-based split. The smaller the value, the fewer cross-Region visits after Region split.
`cdc.min-ts-interval`	The time interval at which Resolved TS is forwarded

Configuration item	Description
`cdc.old-value.memory.quota`	The upper limit of memory occupied by the TiCDC Old Value entries
`cdc.sink.memory.quota`	The upper limit of memory occupied by TiCDC data change events

Configuration item	Description
`cdc.incremental-scan-speed-limit`	The rate limit on the speed of incremental scanning for historical data
`cdc.incremental-scan-concurrency`	The maximum number of concurrent incremental scanning tasks for historical data

In the table above, the five `cdc.*` parameters are supported since v5.1.2.

In the table above, parameters with the `{db-name}` or `{db-name}.{cf-name}` prefix are

configurations related to RocksDB. The optional values of `db-name` are `rocksdb` and `raftdb`.

- When `db-name` is `rocksdb`, the optional values of `cf-name` are `defaultcf`, `writecf`, `lockcf`, and `raftcf`.
- When `db-name` is `raftdb`, the value of `cf-name` can be `defaultcf`.

For detailed parameter description, refer to TiKV Configuration File.

6.8.1.3 Modify PD configuration online

Currently, PD does not support the separate configuration for each instance. All PD instances share the same configuration.

You can modify the PD configurations using the following statement:

```
set config pd `log.level`='info';
```

If the modification is successful, `Query OK` is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If a configuration item is successfully modified, the result is persisted in etcd instead of in the configuration file; the configuration in etcd will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words. For these configuration items, use backtick ` to enclose them. For example, `` `schedule.leader-schedule-limit` ``.

The following PD configuration items can be modified online:

Configuration item	Description
`log.level`	The log level
`cluster-version`	The cluster version

Configuration item	Description
`schedule-max-merge-region-size`	Controls the size limit of Region Merge (in MB)
`schedule-max-merge-region-keys`	Specifies the maximum numbers of the Region Merge keys
`schedule-patrol-region-interval`	Determines the frequency which replicaChecker checks the health state of a Region

Configuration item	Description
`schedule-interval`	Determines the time interval of performing split and merge operations on the same Region
`schedule-max-snapshot-count`	Determines the maximum number of snapshots that a single store can send or receive at the same time

Configuration item	Description
`schedule-max-pending-peer-count`	Determines the maximum number of pending peers in a single store
`schedule-max-store-down-time`	The down-time after which PD judges that the disconnected store can not be recovered
`schedule-leader-schedule-policy`	Determines the policy of leader scheduling

Configuration item	Description
`schedule-limit`	The number of leader schedule tasks performed at the same time
`schedule-limit`	The number of Region schedule tasks performed at the same time

Configuration item	Description
`schedule-replica-schedule-limit`	The number of Replica scheduling tasks performed at the same time
`schedule-merge-schedule-limit`	The number of Region Merge scheduling tasks performed at the same time

Configuration item	Description
`schedule-hot-region-schedule-limit`	The number of hot Region schedule scheduling tasks performed at the same time
`schedule-hot-region-cache-hits-threshold`	Determines the threshold which a Region is considered a hot spot

Configuration item	Description
`schedule.high-space-ratio`	The threshold ratio below which the capacity of the store is sufficient
`schedule.low-space-ratio`	The threshold ratio above which the capacity of the store is insufficient
`schedule.tolerant-size-ratio`	Controls the balance buffer size

Configuration item	Description
`schedule-enable-remove-down-replica`	Determines whether to enable the feature that automatically removes `DownReplica`
`schedule-enable-replace-offline-replica`	Determines whether to enable the feature that migrates `OfflineReplica`

Configuration item	Description
`schedule-limit`	Determines whether to enable the feature that automatically supplements replicas
`schedule-limit`	Determines whether to enable the feature that removes extra replicas
`schedule-limit`	Determines whether to enable location replacement check

Configuration item	Description
`schedule.enable-cross-table-merge`	Determines whether to enable cross-table merge
`schedule.enable-one-way-merge`	Enables one-way merge, which only allows merging with the next adjacent Region
`replication.max-replicas`	Sets the maximum number of replicas

Configuration item	Description
`replication.location-labels`	The topology information of a TiKV cluster
`replication.enable-placement-rules`	Enables Placement Rules
`replication.strictly-match-label`	Enables the label check
`pd-server.use-region-storage`	Enables independent Region storage

Configuration item	Description
pd-server.max-gap-reset-ts	Sets the maximum interval of resetting timestamp (BR)
pd-server.key-type	Sets the cluster key type
pd-server.metric-storage	Sets the storage address of the cluster metrics
pd-server.dashboard-address	Sets the dashboard address

Configuration item	Description
`replication.s` ↪ `-` ↪ `mode` ↪ `.` ↪ `replication` ↪ `-` ↪ `mode` ↪	Sets the backup mode

For detailed parameter description, refer to PD Configuration File.

6.8.1.4 Modify TiDB configuration online

Currently, the method of changing TiDB configuration is different from that of changing TiKV and PD configurations. You can modify TiDB configuration by using system variables.

The following example shows how to modify `slow-threshold` online by using the `tidb_slow_log_threshold` variable.

The default value of `slow-threshold` is 300 ms. You can set it to 200 ms by using `tidb_slow_log_threshold`.

```
set tidb_slow_log_threshold = 200;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_slow_log_threshold;
```

```
+-----------------------------+
| @@tidb_slow_log_threshold |
+-----------------------------+
| 200                       |
+-----------------------------+
1 row in set (0.00 sec)
```

The following TiDB configuration items can be modified online:

Configuration item	SQL variable
`mem-quota-query`	`tidb_mem_quota_query`
`log.enable-slow-log`	`tidb_enable_slow_log`
`log.slow-threshold`	`tidb_slow_log_threshold`
`log.expensive-threshold`	`tidb_expensive_query_time_threshold`

7 Monitor and Alert

7.1 TiDB Monitoring Framework Overview

The TiDB monitoring framework adopts two open source projects: Prometheus and Grafana. TiDB uses Prometheus to store the monitoring and performance metrics and Grafana to visualize these metrics.

7.1.1 About Prometheus in TiDB

As a time series database, Prometheus has a multi-dimensional data model and flexible query language. As one of the most popular open source projects, Prometheus has been adopted by many companies and organizations and has a very active community. PingCAP is one of the active developers and adopters of Prometheus for monitoring and alerting in TiDB, TiKV and PD.

Prometheus consists of multiple components. Currently, TiDB uses the following of them:

- The Prometheus Server to scrape and store time series data
- The client libraries to customize necessary metrics in the application
- An Alertmanager for the alerting mechanism

The diagram is as follows:

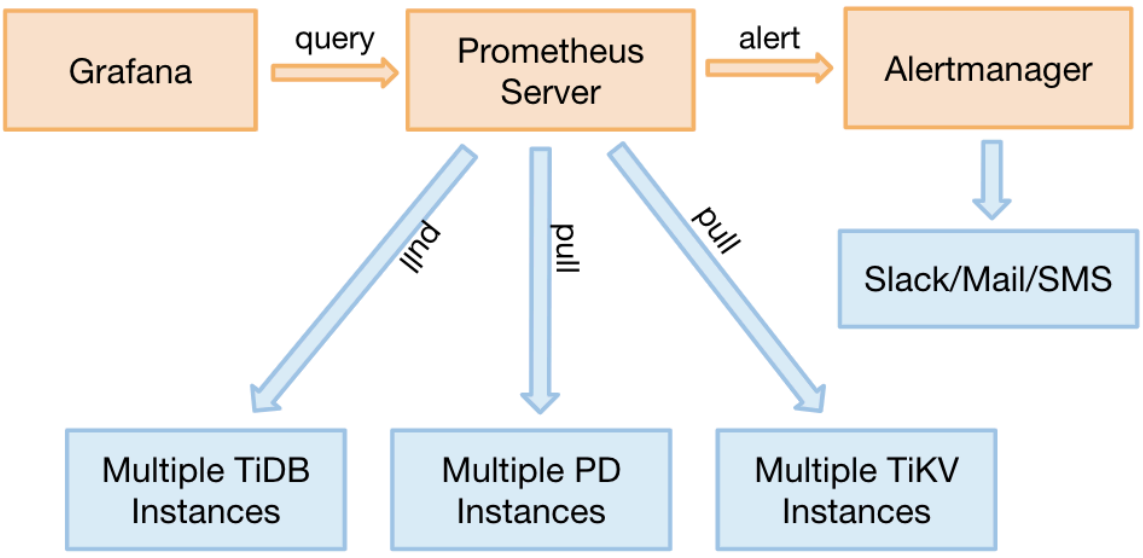

Figure 42: diagram

7.1.2 About Grafana in TiDB

Grafana is an open source project for analyzing and visualizing metrics. TiDB uses Grafana to display the performance metrics as follows:

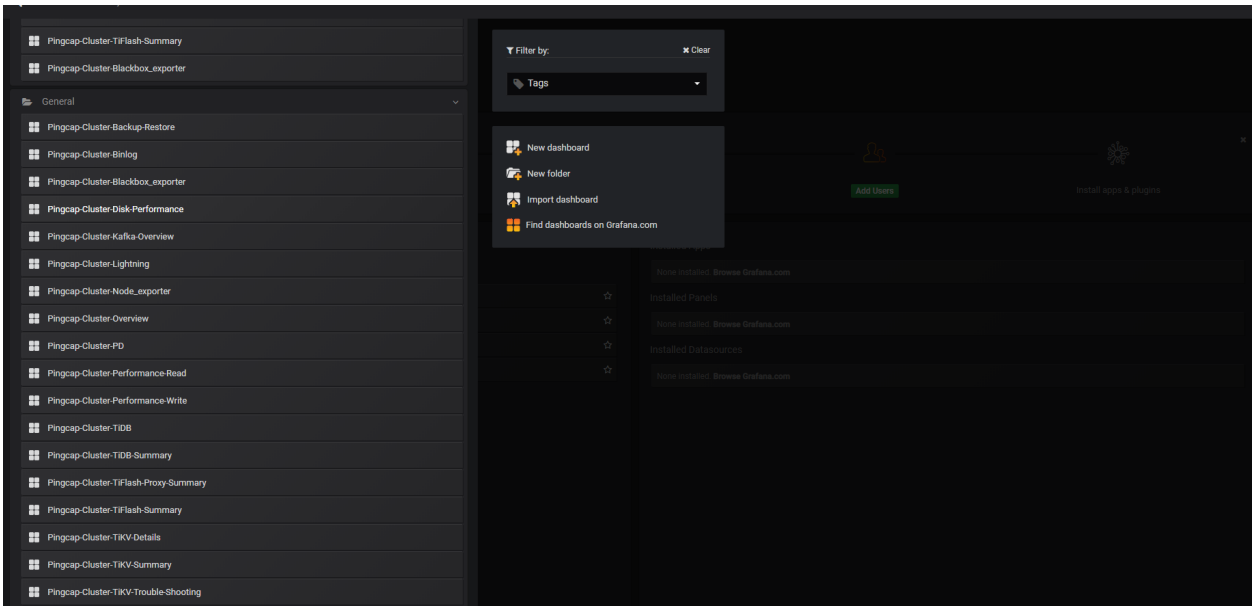

Figure 43: Grafana monitored_groups

- {TiDB_Cluster_name}-Backup-Restore: Monitoring metrics related to backup and restore.
- {TiDB_Cluster_name}-Binlog: Monitoring metrics related to TiDB Binlog.
- {TiDB_Cluster_name}-Blackbox_exporter: Monitoring metrics related to network probe.
- {TiDB_Cluster_name}-Disk-Performance: Monitoring metrics related to disk performance.
- {TiDB_Cluster_name}-Kafka-Overview: Monitoring metrics related to Kafka.
- {TiDB_Cluster_name}-Lightning: Monitoring metrics related to TiDB Lightning.
- {TiDB_Cluster_name}-Node_exporter: Monitoring metrics related to the operating system.
- {TiDB_Cluster_name}-Overview: Monitoring overview related to important components.
- {TiDB_Cluster_name}-PD: Monitoring metrics related to the PD server.
- {TiDB_Cluster_name}-Performance-Read: Monitoring metrics related to read performance.
- {TiDB_Cluster_name}-Performance-Write: Monitoring metrics related to write performance.
- {TiDB_Cluster_name}-TiDB: Detailed monitoring metrics related to the TiDB server.

- {TiDB_Cluster_name}-TiDB-Summary: Monitoring overview related to TiDB.
- {TiDB_Cluster_name}-TiFlash-Proxy-Summary: Monitoring overview of the proxy server that is used to replicate data to TiFlash.
- {TiDB_Cluster_name}-TiFlash-Summary: Monitoring overview related to TiFlash.
- {TiDB_Cluster_name}-TiKV-Details: Detailed monitoring metrics related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Summary: Monitoring overview related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Trouble-Shooting: Monitoring metrics related to the TiKV error diagnostics.
- {TiDB_Cluster_name}-TiCDC: Detailed monitoring metrics related to TiCDC.

Each group has multiple panel labels of monitoring metrics, and each panel contains detailed information of multiple monitoring metrics. For example, the **Overview** monitoring group has five panel labels, and each labels corresponds to a monitoring panel. See the following UI:

Figure 44: Grafana Overview

7.2 TiDB Monitoring API

You can use the following two types of interfaces to monitor the TiDB cluster state:

- The state interface: this interface uses the HTTP interface to get the component information.
- The metrics interface: this interface uses Prometheus to record the detailed information of the various operations in components and views these metrics using Grafana.

7.2.1 Use the state interface

The state interface monitors the basic information of a specific component in the TiDB cluster. It can also act as the monitor interface for Keepalive messages. In addition, the state interface for the Placement Driver (PD) can get the details of the entire TiKV cluster.

7.2.1.1 TiDB server

- TiDB API address: `http://${host}:${port}`
- Default port: `10080`

The following example uses `http://${host}:${port}/status` to get the current state of the TiDB server and to determine whether the server is alive. The result is returned in JSON format.

```
curl http://127.0.0.1:10080/status
{
    connections: 0, # The current number of clients connected to the TiDB
        ↪ server.
    version: "5.7.25-TiDB-v3.0.0-beta-250-g778c3f4a5", # The TiDB version
        ↪ number.
    git_hash: "778c3f4a5a716880bcd1d71b257c8165685f0d70" # The Git Hash of
        ↪ the current TiDB code.
}
```

7.2.1.2 PD server

- PD API address: `http://${host}:${port}/pd/api/v1/${api_name}`
- Default port: `2379`
- Details about API names: see PD API doc

The PD interface provides the state of all the TiKV servers and the information about load balancing. See the following example for the information about a single-node TiKV cluster:

```
curl http://127.0.0.1:2379/pd/api/v1/stores
{
  "count": 1, # The number of TiKV nodes.
  "stores": [ # The list of TiKV nodes.
    # The details about the single TiKV node.
    {
      "store": {
        "id": 1,
        "address": "127.0.0.1:20160",
        "version": "3.0.0-beta",
        "state_name": "Up"
      },
      "status": {
        "capacity": "20 GiB", # The total capacity.
        "available": "16 GiB", # The available capacity.
        "leader_count": 17,
        "leader_weight": 1,
        "leader_score": 17,
        "leader_size": 17,
        "region_count": 17,
        "region_weight": 1,
        "region_score": 17,
        "region_size": 17,
        "start_ts": "2019-03-21T14:09:32+08:00", # The starting timestamp.
        "last_heartbeat_ts": "2019-03-21T14:14:22.961171958+08:00", # The
            ↪ timestamp of the last heartbeat.
        "uptime": "4m50.961171958s"
      }
    }
  ]
```

7.2.2 Use the metrics interface

The metrics interface monitors the state and performance of the entire TiDB cluster.

- If you use other deployment ways, deploy Prometheus and Grafana before using this interface.

After Prometheus and Grafana are successfully deployed, configure Grafana.

7.3 Deploy Monitoring Services for the TiDB Cluster

This document is intended for users who want to manually deploy TiDB monitoring and alert services.

If you deploy the TiDB cluster using TiUP, the monitoring and alert services are automatically deployed, and no manual deployment is needed.

7.3.1 Deploy Prometheus and Grafana

Assume that the TiDB cluster topology is as follows:

Name	Host IP	Services
Node1	192.168.199.113	PD1, TiDB, node_export, Prometheus, Grafana
Node2	192.168.199.114	PD2, node_export
Node3	192.168.199.115	PD3, node_export
Node4	192.168.199.116	TiKV1, node_export
Node5	192.168.199.117	TiKV2, node_export
Node6	192.168.199.118	TiKV3, node_export

7.3.1.1 Step 1: Download the binary package

```
## Downloads the package.
wget https://download.pingcap.org/prometheus-2.8.1.linux-amd64.tar.gz
wget https://download.pingcap.org/node_exporter-0.17.0.linux-amd64.tar.gz
wget https://download.pingcap.org/grafana-6.1.6.linux-amd64.tar.gz
```

```
## Extracts the package.
tar -xzf prometheus-2.8.1.linux-amd64.tar.gz
tar -xzf node_exporter-0.17.0.linux-amd64.tar.gz
tar -xzf grafana-6.1.6.linux-amd64.tar.gz
```

7.3.1.2 Step 2: Start `node_exporter` on Node1, Node2, Node3, and Node4

```
cd node_exporter-0.17.0.linux-amd64

## Starts the node_exporter service.
$ ./node_exporter --web.listen-address=":9100" \
    --log.level="info" &
```

7.3.1.3 Step 3: Start Prometheus on Node1

Edit the Prometheus configuration file:

```
cd prometheus-2.8.1.linux-amd64 &&
vi prometheus.yml
```

```
...

global:
  scrape_interval:  15s # By default, scrape targets every 15 seconds.
  evaluation_interval: 15s # By default, scrape targets every 15 seconds.
  # scrape_timeout is set to the global default value (10s).
  external_labels:
    cluster: 'test-cluster'
    monitor: "prometheus"

scrape_configs:
  - job_name: 'overwritten-nodes'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:9100'
      - '192.168.199.114:9100'
      - '192.168.199.115:9100'
      - '192.168.199.116:9100'
      - '192.168.199.117:9100'
      - '192.168.199.118:9100'

  - job_name: 'tidb'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:10080'

  - job_name: 'pd'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.113:2379'
      - '192.168.199.114:2379'
      - '192.168.199.115:2379'

  - job_name: 'tikv'
    honor_labels: true # Do not overwrite job & instance labels.
    static_configs:
    - targets:
      - '192.168.199.116:20180'
      - '192.168.199.117:20180'
      - '192.168.199.118:20180'
```

```
...
```

Start the Prometheus service:

```
$ ./prometheus \
    --config.file="./prometheus.yml" \
    --web.listen-address=":9090" \
    --web.external-url="http://192.168.199.113:9090/" \
    --web.enable-admin-api \
    --log.level="info" \
    --storage.tsdb.path="./data.metrics" \
    --storage.tsdb.retention="15d" &
```

7.3.1.4 Step 4: Start Grafana on Node1

Edit the Grafana configuration file:

```
cd grafana-6.1.6 &&
vi conf/grafana.ini

...

[paths]
data = ./data
logs = ./data/log
plugins = ./data/plugins
[server]
http_port = 3000
domain = 192.168.199.113
[database]
[session]
[analytics]
check_for_updates = true
[security]
admin_user = admin
admin_password = admin
[snapshots]
[users]
[auth.anonymous]
[auth.basic]
[auth.ldap]
[smtp]
[emails]
[log]
mode = file
```

```
[log.console]
[log.file]
level = info
format = text
[log.syslog]
[event_publisher]
[dashboards.json]
enabled = false
path = ./data/dashboards
[metrics]
[grafana_net]
url = https://grafana.net

...
```

Start the Grafana service:

```
$ ./bin/grafana-server \
    --config="./conf/grafana.ini" &
```

7.3.2 Configure Grafana

This section describes how to configure Grafana.

7.3.2.1 Step 1: Add a Prometheus data source

1. Log in to the Grafana Web interface.

    - Default address: http://localhost:3000
    - Default account: admin
    - Default password: admin

    Note:
    For the **Change Password** step, you can choose **Skip**.

2. In the Grafana sidebar menu, click **Data Source** within the **Configuration**.
3. Click **Add data source**.
4. Specify the data source information.

    - Specify a **Name** for the data source.
    - For **Type**, select **Prometheus**.

- For **URL**, specify the Prometheus address.
- Specify other fields as needed.

5. Click **Add** to save the new data source.

7.3.2.2 Step 2: Import a Grafana dashboard

To import a Grafana dashboard for the PD server, the TiKV server, and the TiDB server, take the following steps respectively:

1. Click the Grafana logo to open the sidebar menu.
2. In the sidebar menu, click **Dashboards** -> **Import** to open the **Import Dashboard** window.
3. Click **Upload .json File** to upload a JSON file (Download TiDB Grafana configuration file).

> **Note:**
> For the TiKV, PD, and TiDB dashboards, the corresponding JSON files are `tikv_summary.json`, `tikv_details.json`, `tikv_trouble_shooting .json`, `pd.json`, `tidb.json`, and `tidb_summary.json`.

4. Click **Load**.
5. Select a Prometheus data source.
6. Click **Import**. A Prometheus dashboard is imported.

7.3.3 View component metrics

Click **New dashboard** in the top menu and choose the dashboard you want to view.

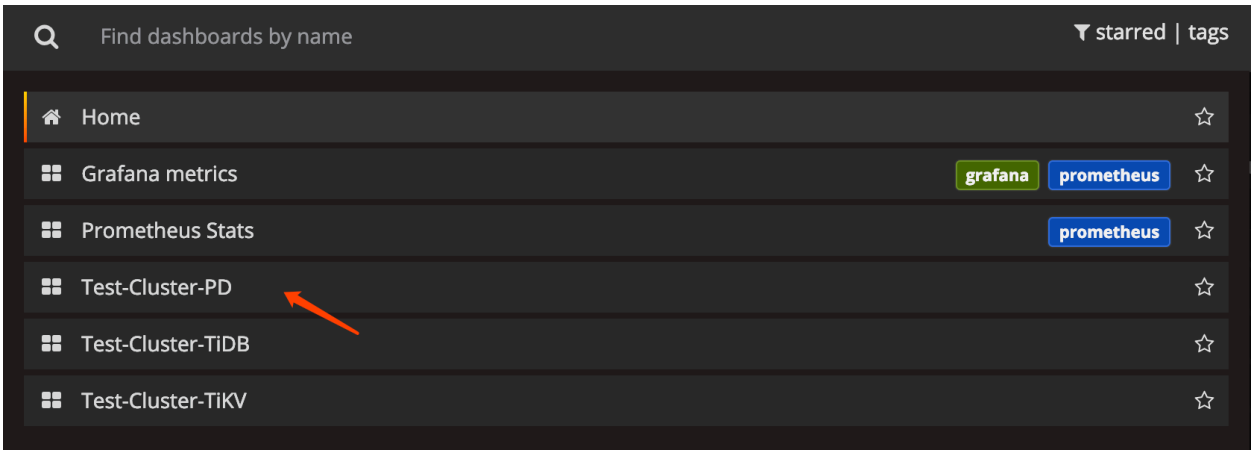

Figure 45: view dashboard

You can get the following metrics for cluster components:

- **TiDB server:**
  - Query processing time to monitor the latency and throughput
  - The DDL process monitoring
  - TiKV client related monitoring
  - PD client related monitoring
- **PD server:**
  - The total number of times that the command executes
  - The total number of times that a certain command fails
  - The duration that a command succeeds
  - The duration that a command fails
  - The duration that a command finishes and returns result
- **TiKV server:**
  - Garbage Collection (GC) monitoring
  - The total number of times that the TiKV command executes
  - The duration that Scheduler executes commands
  - The total number of times of the Raft propose command
  - The duration that Raft executes commands
  - The total number of times that Raft commands fail
  - The total number of times that Raft processes the ready state

7.4 Export Grafana Snapshots

Metrics data is important in troubleshooting. When you request remote assistance, sometimes the support staff need to view the Grafana dashboards to diagnose problems. MetricsTool can help export snapshots of Grafana dashboards as local files and visualize these snapshots. You can share these snapshots with outsiders and allow them to accurately read out the graphs, without giving out access to other sensitive information on the Grafana server.

7.4.1 Usage

MetricsTool can be accessed from https://metricstool.pingcap.net/. It consists of three sets of tools:

- **Export**: A user script running on the browser's Developer Tool, allowing you to download a snapshot of all visible panels in the current dashboard on any Grafana v6.x.x server.

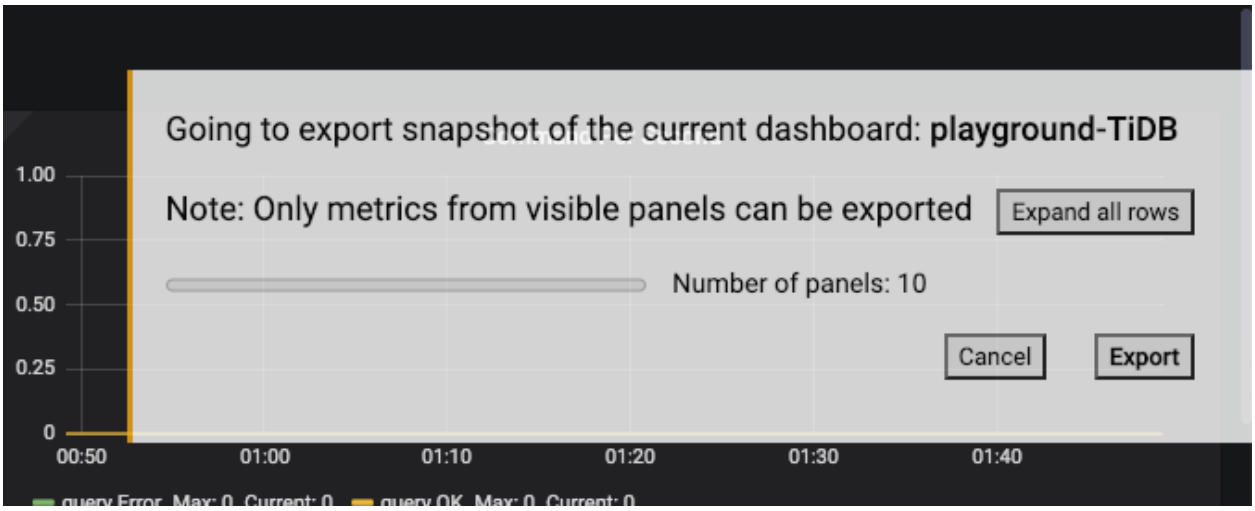

Figure 46: Screenshot of MetricsTool Exporter after running the user script

- **Visualize**: A web page visualizing the exported snapshot files. The visualized snapshots can be operated in the same way as live Grafana dashboards.

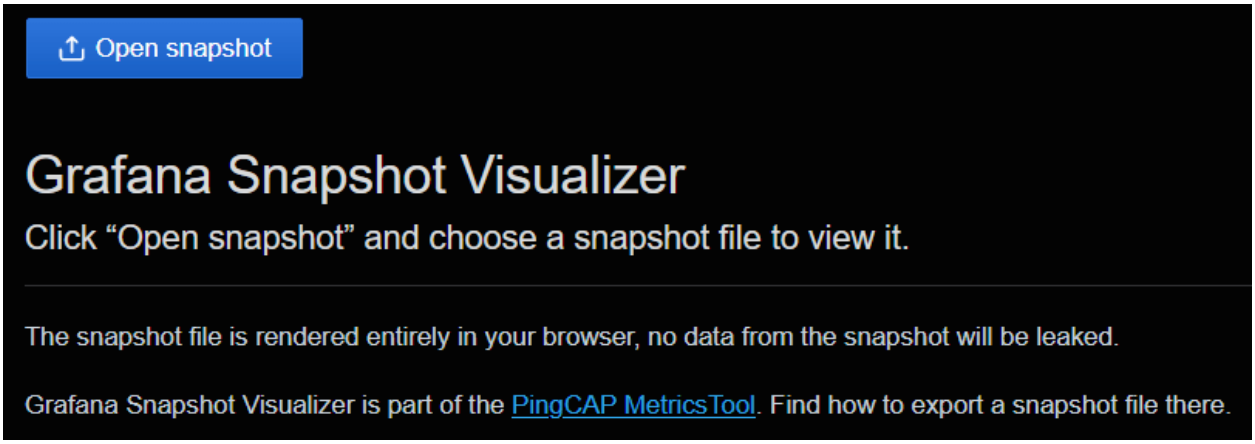

Figure 47: Screenshot of MetricsTool Visualizer

- **Import**: Instructions to import the exported snapshot back into an actual Grafana instance.

7.4.2 FAQs

7.4.2.1 What is the advantage of this tool compared with screenshot or PDF printing?

The snapshot files exported by MetricsTool contain the actual values when they are taken. And the Visualizer allows you to interact with the rendered graphs as if it is a live Grafana dashboard, supporting operations like toggling series, zooming into a smaller time range, and checking the precise value at a given time. This makes MetricsTool much more powerful than images or PDFs.

7.4.2.2 What are included in the snapshot file?

The snapshot file contains the values of all graphs and panels in the selected time range. It does not save the original metrics from the data sources (and thus you cannot edit the query expression in the Visualizer).

7.4.2.3 Will the Visualizer save the uploaded snapshot files in PingCAP's servers?

No, the Visualizer parses the snapshot files entirely inside your browser. Nothing will be sent to PingCAP. You are free to view snapshot files received from sensitive sources, and no need to worry about these leaking to third parties through the Visualizer.

7.4.2.4 Can it export metrics besides Grafana?

No, we only support Grafana v6.x.x at the moment.

7.4.2.5 Will there be problems to execute the script before all metrics are loaded?

No, the script UI will notify you to wait for all metrics to be loaded. However, you can manually skip waiting and export the snapshot in case of some metrics loading for too long.

7.4.2.6 Can we share a link to a visualized snapshot?

No, but you can share the snapshot file, with instruction on how to use the Visualizer to view it. If you truly need a world-readable URL, you may also try the public `snapshot.raintank.io` service built into Grafana, but make sure all privacy concerns are cleared before doing so.

7.5 TiDB Cluster Alert Rules

This document describes the alert rules for different components in a TiDB cluster, including the rule descriptions and solutions of the alert items in TiDB, TiKV, PD, TiFlash, TiDB Binlog, TiCDC, Node_exporter and Blackbox_exporter.

According to the severity level, alert rules are divided into three categories (from high to low): emergency-level, critical-level, and warning-level. This division of severity levels applies to all alert items of each component below.

Severity level	Description
Emergency-level	The highest severity level at which the service is unavailable. Emergency-level alerts are often caused by a service or node failure. **Manual intervention is required immediately**.

Severity level	Description
Critical-level	Decreased service availability. For the critical-level alerts, a close watch on the abnormal metrics is required.
Warning-level	Warning-level alerts are a reminder for an issue or error.

7.5.1 TiDB alert rules

This section gives the alert rules for the TiDB component.

7.5.1.1 Emergency-level alerts

7.5.1.1.1 `TiDB_schema_error`

- Alert rule:

```
increase(tidb_session_schema_lease_error_total{type="outdated"}[15m])>
↪ 0
```

- Description:

The latest schema information is not reloaded in TiDB within one lease. When TiDB fails to continue providing services, an alert is triggered.

- Solution:

  It is often caused by an unavailable Region or a TiKV timeout. You need to locate the issue by checking the TiKV monitoring items.

7.5.1.1.2 TiDB_tikvclient_region_err_total

- Alert rule:

  `increase(tidb_tikvclient_region_err_total[10m])> 6000`

- Description:

  When TiDB accesses TiKV, a Region error occurs. When the error is reported over 6000 times in 10 minutes, an alert is triggered.

- Solution:

  View the monitoring status of TiKV.

7.5.1.1.3 TiDB_domain_load_schema_total

- Alert rule:

  `increase(tidb_domain_load_schema_total{type="failed"}[10m])> 10`

- Description:

  The total number of failures to reload the latest schema information in TiDB. If the reloading failure occurs over 10 times in 10 minutes, an alert is triggered.

- Solution:

  Same as TiDB_schema_error.

7.5.1.1.4 TiDB_monitor_keep_alive

- Alert rule:

  `increase(tidb_monitor_keep_alive_total[10m])< 100`

- Description:

  Indicates whether the TiDB process still exists. If the number of times for `tidb_monitor_keep_alive_total` increases less than 100 in 10 minutes, the TiDB process might already exit and an alert is triggered.

- Solution:

  - Check whether the TiDB process is out of memory.
  - Check whether the machine has restarted.

7.5.1.2 Critical-level alerts

7.5.1.2.1 TiDB_server_panic_total

- Alert rule:

  `increase(tidb_server_panic_total[10m])> 0`

- Description:

  The number of panicked TiDB threads. When a panic occurs, an alert is triggered. The thread is often recovered, otherwise, TiDB will frequently restart.

- Solution:

  Collect the panic logs to locate the issue.

7.5.1.3 Warning-level alerts

7.5.1.3.1 TiDB_memory_abnormal

- Alert rule:

  `go_memstats_heap_inuse_bytes{job="tidb"} > 1e+10`

- Description:

  The monitoring on the TiDB memory usage. If the usage exceeds 10 G, an alert is triggered.

- Solution:

  Use the HTTP API to troubleshoot the goroutine leak issue.

7.5.1.3.2 TiDB_query_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tidb_server_handle_query_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 1
  ```

- Description:

  The latency of handling a request in TiDB. If the ninety-ninth percentile latency exceeds 1 second, an alert is triggered.

- Solution:

  View TiDB logs and search for the `SLOW_QUERY` and `TIME_COP_PROCESS` keywords to locate the slow SQL queries.

7.5.1.3.3 TiDB_server_event_error

- Alert rule:

  ```
  increase(tidb_server_event_total{type=~"server_start|server_hang"}[15m
  ↪ ])> 0
  ```

- Description:

  The number of events that happen in the TiDB service. An alert is triggered when the following events happen:

  1. start: The TiDB service starts.
  2. hang: When a critical-level event (currently there is only one scenario: TiDB cannot write binlog) happens, TiDB enters the `hang` mode and waits to be killed manually.

- Solution:

  - Restart TiDB to recover the service.
  - Check whether the TiDB Binlog service is normal.

7.5.1.3.4 TiDB_tikvclient_backoff_seconds_count

- Alert rule:

  ```
  increase(tidb_tikvclient_backoff_seconds_count[10m])> 10
  ```

- Description:

  The number of retries when TiDB fails to access TiKV. When the retry times is over 10 in 10 minutes, an alert is triggered.

- Solution:

  View the monitoring status of TiKV.

7.5.1.3.5 TiDB_monitor_time_jump_back_error

- Alert rule:

  ```
  increase(tidb_monitor_time_jump_back_total[10m])> 0
  ```

- Description:

  When the time of the machine that holds TiDB rewinds, an alert is triggered.

- Solution:

  Troubleshoot the NTP configurations.

7.5.1.3.6 TiDB_ddl_waiting_jobs

- Alert rule:

  `sum(tidb_ddl_waiting_jobs)> 5`

- Description:

  When the number of DDL tasks pending for execution in TiDB exceeds 5, an alert is triggered.

- Solution:

  Check whether there is any time-consuming `add index` operation that is being executed by running `admin show ddl`.

7.5.2 PD alert rules

This section gives the alert rules for the PD component.

7.5.2.1 Emergency-level alerts

7.5.2.1.1 PD_cluster_down_store_nums

- Alert rule:

  ```
  (sum(pd_cluster_status{type="store_down_count"})by (instance)> 0)and (
  ↪ sum(etcd_server_is_leader)by (instance)> 0)
  ```

- Description:

  PD has not received a TiKV/TiFlash heartbeat for a long time (the default configuration is 30 minutes).

- Solution:

  - Check whether the TiKV/TiFlash process is normal, the network is isolated or the load is too high, and recover the service as much as possible.
  - If the TiKV/TiFlash instance cannot be recovered, you can make it offline.

7.5.2.2 Critical-level alerts

7.5.2.2.1 PD_etcd_write_disk_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_disk_wal_fsync_duration_seconds_bucket
↪ [1m]))by (instance, job, le))> 1
```

- Description:

  If the latency of the fsync operation exceeds 1 second, it indicates that etcd writes data to disk at a lower speed than normal. It might lead to PD leader timeout or failure to store TSO on disk in time, which will shut down the service of the entire cluster.

- Solution:

  - Find the cause of slow writes. It might be other services that overload the system. You can check whether PD itself occupies a large amount of CPU or I/O resources.
  - Try to restart PD or manually transfer leader to another PD to recover the service.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.2.2 PD_miss_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="miss-peer-region-count"})by (instance)>
↪ 100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  The number of Region replicas is smaller than the value of `max-replicas`. When a TiKV machine is down and its downtime exceeds `max-down-time`, it usually leads to missing replicas for some Regions during a period of time.

- Solution:

  - Find the cause of the issue by checking whether there is any TiKV machine that is down or being made offline.
  - Watch the Region health panel and see whether `miss-peer-region-count` is continuously decreasing.

7.5.2.3 Warning-level alerts

7.5.2.3.1 PD_cluster_lost_connect_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_disconnected_count"})by (instance)>
↪ 0)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  PD does not receive a TiKV/TiFlash heartbeat within 20 seconds. Normally a TiKV/TiFlash heartbeat comes in every 10 seconds.

- Solution:

  - Check whether the TiKV/TiFlash instance is being restarted.
  - Check whether the TiKV/TiFlash process is normal, the network is isolated, and the load is too high, and recover the service as much as possible.
  - If you confirm that the TiKV/TiFlash instance cannot be recovered, you can make it offline.
  - If you confirm that the TiKV/TiFlash instance can be recovered, but not in the short term, you can consider increasing the value of `max-down-time`. It will prevent the TiKV/TiFlash instance from being considered as irrecoverable and the data from being removed from the TiKV/TiFlash.

7.5.2.3.2 PD_cluster_low_space

- Alert rule:

```
(sum(pd_cluster_status{type="store_low_space_count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  Indicates that there is no sufficient space on the TiKV/TiFlash node.

- Solution:

  - Check whether the space in the cluster is generally insufficient. If so, increase its capacity.
  - Check whether there is any issue with Region balance scheduling. If so, it will lead to uneven data distribution.
  - Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, core dump, etc.
  - Lower the Region weight of the node to reduce the data volume.
  - When it is not possible to release the space, consider proactively making the node offline. This prevents insufficient disk space that leads to downtime.

7.5.2.3.3 PD_etcd_network_peer_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_network_peer_round_trip_time_seconds_bucket
↪ [1m]))by (To, instance, job, le))> 1
```

- Description:

  The network latency between PD nodes is high. It might lead to the leader timeout and TSO disk storage timeout, which impacts the service of the cluster.

- Solution:

  - Check the network and system load status.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.4 PD_tidb_handle_requests_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(pd_client_request_handle_requests_duration_second
↪ {type="tso"}[1m]))by (instance, job, le))> 0.1
```

- Description:

  It takes a longer time for PD to handle the TSO request. It is often caused by a high load.

- Solution:

  - Check the load status of the server.
  - Use pprof to analyze the CPU profile of PD.
  - Manually switch the PD leader.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.5 PD_down_peer_region_nums

- Alert rule:

```
(sum(pd_regions_status{type="down-peer-region-count"})by (instance)> 0)
↪ and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  The number of Regions with an unresponsive peer reported by the Raft leader.

- Solution:

- Check whether there is any TiKV that is down, or that was just restarted, or that is busy.
- Watch the Region health panel and see whether `down_peer_region_count` is continuously decreasing.
- Check the network between TiKV servers.

7.5.2.3.6 `PD_pending_peer_region_count`

- Alert rule:

```
(sum(pd_regions_status{type="pending-peer-region-count"})by (instance)>
↪  100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

  There are too many Regions that have lagged Raft logs. It is normal that scheduling leads to a small number of pending peers, but if the number remains high, there might be an issue.

- Solution:

  - Watch the Region health panel and see whether `pending_peer_region_count` is continuously decreasing.
  - Check the network between TiKV servers, especially whether there is enough bandwidth.

7.5.2.3.7 `PD_leader_change`

- Alert rule:

```
count(changes(pd_tso_events{type="save"}[10m])> 0)>= 2
```

- Description:

  The PD leader is recently switched.

- Solution:

  - Exclude the human factors, such as restarting PD, manually transferring leader, adjusting leader priority, etc.
  - Check the network and system load status.
  - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.8 TiKV_space_used_more_than_80%

- Alert rule:

```
sum(pd_cluster_status{type="storage_size"})/ sum(pd_cluster_status{type
↪ ="storage_capacity"})* 100 > 80
```

- Description:

  Over 80% of the cluster space is occupied.

- Solution:

  - Check whether it is needed to increase capacity.
  - Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, core dump, etc.

7.5.2.3.9 PD_system_time_slow

- Alert rule:

```
changes(pd_tso_events{type="system_time_slow"}[10m])>= 1
```

- Description:

  The system time rewind might happen.

- Solution:

  Check whether the system time is configured correctly.

7.5.2.3.10 PD_no_store_for_making_replica

- Alert rule:

```
increase(pd_checker_event_count{type="replica_checker", name="no_target_store
↪ "}[1m])> 0
```

- Description:

  There is no appropriate store for additional replicas.

- Solution:

  - Check whether there is enough space in the store.
  - Check whether there is any store for additional replicas according to the label configuration if it is configured.

7.5.3 TiKV alert rules

This section gives the alert rules for the TiKV component.

7.5.3.1 Emergency-level alerts

7.5.3.1.1 TiKV_memory_used_too_fast

- Alert rule:

```
process_resident_memory_bytes{job=~"tikv",instance=~".*"} - (process_resident_memor
↪ {job=~"tikv",instance=~".*"} offset 5m)> 5*1024*1024*1024
```

- Description:

  Currently, there are no TiKV monitoring items about memory. You can monitor the memory usage of the machines in the cluster by Node_exporter. The above rule indicates that when the memory usage exceeds 5 GB within 5 minutes (the memory is occupied too fast in TiKV), an alert is triggered.

- Solution:

  Adjust the `block-cache-size` value of both `rockdb.defaultcf` and `rocksdb.writecf` ↪ .

7.5.3.1.2 TiKV_GC_can_not_work

- Alert rule:

```
sum(increase(tikv_gcworker_gc_tasks_vec{task="gc"}[1d]))< 1 and sum(
↪ increase(tikv_gc_compaction_filter_perform[1d]))< 1
```

- Description:

  GC is not performed successfully on a TiKV instance within 24 hours, which indicates that GC is not working properly. If GC does not run in a short term, it will not cause much trouble; but if GC keeps down, more and more versions are retained, which slows down the query.

- Solution:

  1. Perform `SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME = ↪ "tikv_gc_leader_desc"` to locate the `tidb-server` corresponding to the GC leader;
  2. View the log of the `tidb-server`, and grep gc_worker tidb.log;
  3. If you find that the GC worker has been resolving locks (the last log is "start resolve locks") or deleting ranges (the last log is "start delete {number} ranges") during this time, it means the GC process is running normally. Otherwise, contact support@pingcap.com to resolve this issue.

7.5.3.2 Critical-level alerts

7.5.3.2.1 TiKV_server_report_failure_msg_total

- Alert rule:

```
sum(rate(tikv_server_report_failure_msg_total{type="unreachable"}[10m])
↪ )BY (store_id)> 10
```

- Description:

  Indicates that the remote TiKV cannot be connected.

- Solution:

  1. Check whether the network is clear.
  2. Check whether the remote TiKV is down.
  3. If the remote TiKV is not down, check whether the pressure is too high. Refer to the solution in TiKV_channel_full_total.

7.5.3.2.2 TiKV_channel_full_total

- Alert rule:

```
sum(rate(tikv_channel_full_total[10m]))BY (type, instance)> 0
```

- Description:

  This issue is often caused by the stuck Raftstore thread and high pressure on TiKV.

- Solution:

  1. Watch the Raft Propose monitor, and see whether the alerted TiKV node has a much higher Raft propose than other TiKV nodes. If so, it means that there are one or more hot spots on this TiKV. You need to check whether the hot spot scheduling can work properly.
  2. Watch the Raft I/O monitor, and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk. One feasible but unsafe solution is setting `sync-log` to `false`.
  3. Watch the Raft Process monitor, and see whether the tick duration is high. If so, you need to add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

7.5.3.2.3 TiKV_write_stall

- Alert rule:

```
delta(tikv_engine_write_stall[10m])> 0
```

- Description:

  The write pressure on RocksDB is too high, and a stall occurs.

- Solution:

    1. View the disk monitor, and troubleshoot the disk issues;
    2. Check whether there is any write hot spot on the TiKV;
    3. Set `max-sub-compactions` to a larger value under the `[rocksdb]` and `[raftdb]` configurations.

7.5.3.2.4 TiKV_raft_log_lag

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_log_lag_bucket[1m]))by
↪  (le, instance))> 5000
```

- Description:

    If this value is relatively large, it means Follower has lagged far behind Leader, and Raft cannot be replicated normally. It is possibly because the TiKV machine where Follower is located is stuck or down.

7.5.3.2.5 TiKV_async_request_snapshot_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_second
↪ {type="snapshot"}[1m]))by (le, instance, type))> 1
```

- Description:

    If this value is relatively large, it means the load pressure on Raftstore is too high, and it might be stuck already.

- Solution:

    Refer to the solution in TiKV_channel_full_total.

7.5.3.2.6 TiKV_async_request_write_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_second
↪ {type="write"}[1m]))by (le, instance, type))> 1
```

- Description:

    If this value is relatively large, it means the Raft write takes a long time.

- Solution:

    1. Check the pressure on Raftstore. See the solution in TiKV_channel_full_total.
    2. Check the pressure on the apply worker thread.

7.5.3.2.7 TiKV_coprocessor_request_wait_seconds

- Alert rule:

```
histogram_quantile(0.9999, sum(rate(tikv_coprocessor_request_wait_seconds_bucket
↪ [1m]))by (le, instance, req))> 10
```

- Description:

  If this value is relatively large, it means the pressure on the Coprocessor worker is high. There might be a slow task that makes the Coprocessor thread stuck.

- Solution:

  1. View the slow query log from the TiDB log to see whether the index or full table scan is used in a query, or see whether it is needed to analyze;
  2. Check whether there is a hot spot;
  3. View the Coprocessor monitor and see whether `total` and `process` in `coprocessor table/index scan` match. If they differ a lot, it indicates too many invalid queries are performed. You can see whether there is `over seek bound`. If so, there are too many versions that GC does not handle in time. Then you need to increase the number of parallel GC threads.

7.5.3.2.8 TiKV_raftstore_thread_cpu_seconds_total

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"raftstore_.*"}[1m]))by (
↪ instance, name)> 1.6
```

- Description:

  The pressure on the Raftstore thread is too high.

- Solution:

  Refer to the solution in TiKV_channel_full_total.

7.5.3.2.9 TiKV_raft_append_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_append_log_duration_seconds_bucket
↪ [1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of appending Raft log. If it is high, it usually means I/O is too busy.

7.5.3.2.10 TiKV_raft_apply_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_apply_log_duration_seconds_bucket
↪ [1m]))by (le, instance))> 1
```

- Description:

  Indicates the time cost of applying Raft log. If it is high, it usually means I/O is too busy.

7.5.3.2.11 TiKV_scheduler_latch_wait_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_latch_wait_duration_seconds_bucket
↪ [1m]))by (le, instance, type))> 1
```

- Description:

  The waiting time for the write operations to obtain the memory lock in Scheduler. If it is high, there might be many write conflicts, or that some operations that lead to conflicts take a long time to finish and block other operations that wait for the same lock.

- Solution:

  1. View the scheduler command duration in the Scheduler-All monitor and see which command is most time-consuming;
  2. View the scheduler scan details in the Scheduler-All monitor and see whether `total` and `process` match. If they differ a lot, there are many invalid scans. You can also see whether there is `over seek bound`. If there is too much, it indicates GC does not work in time;
  3. View the storage async snapshot/write duration in the Storage monitor and see whether the Raft operation is performed in time.

7.5.3.2.12 TiKV_thread_apply_worker_cpu_seconds

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name="apply_worker"}[1m]))by (
↪ instance)> 1.8
```

- Description:

  The pressure on the apply Raft log thread is too high. It is often caused by a burst of writes.

7.5.3.3 Warning-level alerts

7.5.3.3.1 TiKV_leader_drops

- Alert rule:

  ```
  delta(tikv_pd_heartbeat_tick_total{type="leader"}[30s])< -10
  ```

- Description:

  It is often caused by a stuck Raftstore thread.

- Solution:

  1. Refer to TiKV_channel_full_total.
  2. It there is low pressure on TiKV, consider whether the PD scheduling is too frequent. You can view the Operator Create panel on the PD page, and check the types and number of the PD scheduling.

7.5.3.3.2 TiKV_raft_process_ready_duration_secs

- Alert rule:

  ```
  histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket
  ↪ {type='ready'}[1m]))by (le, instance, type))> 2
  ```

- Description:

  Indicates the time cost of handling Raft ready. If this value is large, it is often caused by the stuck appending log task.

7.5.3.3.3 TiKV_raft_process_tick_duration_secs

- Alert rule:

  ```
  histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket
  ↪ {type='tick'}[1m]))by (le, instance, type))> 2
  ```

- Description:

  Indicates the time cost of handling Raft tick. If this value is large, it is often caused by too many Regions.

- Solution:

  1. Consider using a higher-level log such as `warn` or `error`.
  2. Add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

7.5.3.3.4 TiKV_scheduler_context_total

- Alert rule:

  ```
  abs(delta( tikv_scheduler_context_total[5m]))> 1000
  ```

- Description:

  The number of write commands that are being executed by Scheduler. If this value is large, it means the task is not finished timely.

- Solution:

  Refer to TiKV_scheduler_latch_wait_duration_seconds.

7.5.3.3.5 TiKV_scheduler_command_duration_seconds

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tikv_scheduler_command_duration_seconds_bucket
  ↪ [1m]))by (le, instance, type))> 1
  ```

- Description:

  Indicates the time cost of executing the Scheduler command.

- Solution:

  Refer to TiKV_scheduler_latch_wait_duration_seconds.

7.5.3.3.6 TiKV_coprocessor_outdated_request_wait_seconds

- Alert rule:

  ```
  delta(tikv_coprocessor_outdated_request_wait_seconds_count[10m])> 0
  ```

- Description:

  The waiting time of the expired requests by Coprocessor. If this value is large, it means there is high pressure on Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

7.5.3.3.7 TiKV_coprocessor_pending_request

- Alert rule:

```
delta(tikv_coprocessor_pending_request[10m])> 5000
```

- Description:

  The queuing requests of Coprocessor.

- Solution:

  Refer to TiKV_coprocessor_request_wait_seconds.

7.5.3.3.8 TiKV_batch_request_snapshot_nums

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"cop_.*"}[1m]))by (instance
↪ )/ (count(tikv_thread_cpu_seconds_total{name=~"cop_.*"})* 0.9)/
↪ count(count(tikv_thread_cpu_seconds_total)by (instance))> 0
```

- Description:

  The Coprocessor CPU usage of a TiKV machine exceeds 90%.

7.5.3.3.9 TiKV_pending_task

- Alert rule:

```
sum(tikv_worker_pending_task_total)BY (instance,name)> 1000
```

- Description:

  The number of pending tasks of TiKV.

- Solution:

  Check which kind of tasks has a higher value. You can normally find a solution to the Coprocessor and apply worker tasks from other metrics.

7.5.3.3.10 TiKV_low_space

- Alert rule:

```
sum(tikv_store_size_bytes{type="available"})by (instance)/ sum(tikv_store_size_byte
↪ {type="capacity"})by (instance)< 0.2
```

- Description:

  The data volume of TiKV exceeds 80% of the configured node capacity or the disk capacity of the machine.

- Solution:
  - Check the balance condition of node space.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.3.3.11 `TiKV_approximate_region_size`

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_region_size_bucket[1m
↪ ]))by (le))> 1073741824
```

- Description:

  The maximum Region approximate size that is scanned by the TiKV split checker is continually larger than 1 GB within one minute.

- Solution:

  The speed of splitting Regions is slower than the write speed. To alleviate this issue, you'd better update TiDB to a version that supports batch-split (>= 2.1.0-rc1). If it is not possible to update temporarily, you can use `pd-ctl operator add split-region <region_id> --policy=approximate` to manually split Regions.

7.5.4 TiDB Binlog alert rules

For the detailed descriptions of TiDB Binlog alert rules, see TiDB Binlog monitoring document.

7.5.5 TiCDC Alert rules

For the detailed descriptions of TiCDC alert rules, see TiCDC Alert Rules.

7.5.6 Node_exporter host alert rules

This section gives the alert rules for the Node_exporter host.

7.5.6.1 Emergency-level alerts

7.5.6.1.1 `NODE_disk_used_more_than_80%`

- Alert rule:

```
node_filesystem_avail_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/boot"}
↪  / node_filesystem_size_bytes{fstype=~"(ext.|xfs)", mountpoint!~"/
↪ boot"} * 100 <= 20
```

- Description:

  The disk space usage of the machine exceeds 80%.

- Solution:

  - Log in to the machine, run the `df -h` command to check the disk space usage.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.6.1.2 NODE_disk_inode_more_than_80%

- Alert rule:

```
node_filesystem_files_free{fstype=~"(ext.|xfs)"} / node_filesystem_files
↪ {fstype=~"(ext.|xfs)"} * 100 < 20
```

- Description:

  The inode usage of the filesystem on the machine exceeds 80%.

- Solution:

  - Log in to the machine and run the `df -i` command to view the node usage of the filesystem.
  - Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.6.1.3 NODE_disk_readonly

- Alert rule:

```
node_filesystem_readonly{fstype=~"(ext.|xfs)"} == 1
```

- Description:

  The filesystem is read-only and data cannot be written in it. It is often caused by disk failure or filesystem corruption.

- Solution:

  - Log in to the machine and create a file to test whether it is normal.
  - Check whether the disk LED is normal. If not, replace the disk and repair the filesystem of the machine.

7.5.6.2 Critical-level alerts

7.5.6.2.1 NODE_memory_used_more_than_80%

- Alert rule:

  ```
  (((node_memory_MemTotal_bytes-node_memory_MemFree_bytes-node_memory_Cached_bytes
  ↪ )/(node_memory_MemTotal_bytes)*100))>= 80
  ```

- Description:

  The memory usage of the machine exceeds 80%.

- Solution:

  - View the Memory panel of the host in the Grafana Node Exporter dashboard, and see whether Used memory is too high and Available memory is too low.
  - Log in to the machine and run the `free -m` command to view the memory usage. You can run `top` to check whether there is any abnormal process that has an overly high memory usage.

7.5.6.3 Warning-level alerts

7.5.6.3.1 NODE_node_overload

- Alert rule:

  ```
  (node_load5 / count without (cpu, mode)(node_cpu_seconds_total{mode="
  ↪ system"}))> 1
  ```

- Description:

  The CPU load on the machine is relatively high.

- Solution:

  - View the CPU Usage and Load Average of the host in the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the load average and the CPU usage, and see whether there is any abnormal process that has an overly high CPU usage.

7.5.6.3.2 NODE_cpu_used_more_than_80%

- Alert rule:

  ```
  avg(irate(node_cpu_seconds_total{mode="idle"}[5m]))by(instance)* 100 <=
  ↪ 20
  ```

- Description:

  The CPU usage of the machine exceeds 80%.

- Solution:

  - View the CPU Usage and Load Average of the host on the Grafana Node Exporter dashboard to check whether they are too high.
  - Log in to the machine and run `top` to check the Load Average and the CPU Usage, and see whether there is any abnormal process that has an overly high CPU usage.

7.5.6.3.3 NODE_tcp_estab_num_more_than_50000

- Alert rule:

  ```
  node_netstat_Tcp_CurrEstab > 50000
  ```

- Description:

  There are more than 50,000 TCP links in the "establish" status on the machine.

- Solution:

  - Log in to the machine and run `ss -s` to check the number of TCP links in the "estab" status in the current system.
  - Run `netstat` to check whether there is any abnormal link.

7.5.6.3.4 NODE_disk_read_latency_more_than_32ms

- Alert rule:

  ```
  ((rate(node_disk_read_time_seconds_total{device=~".+"}[5m])/ rate(
  ↪ node_disk_reads_completed_total{device=~".+"}[5m]))or (irate(node_disk_read_time
  ↪ {device=~".+"}[5m])/ irate(node_disk_reads_completed_total{device
  ↪ =~".+"}[5m])))* 1000 > 32
  ```

- Description:

  The read latency of the disk exceeds 32 ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the read latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

7.5.6.3.5 NODE_disk_write_latency_more_than_16ms

- Alert rule:

```
((rate(node_disk_write_time_seconds_total{device=~".+"}[5m])/ rate
↪ (node_disk_writes_completed_total{device=~".+"}[5m]))or (irate(
↪ node_disk_write_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_writes_co
↪ {device=~".+"}[5m])))> 16
```

- Description:

  The write latency of the disk exceeds 16ms.

- Solution:

  - Check the disk status by viewing the Grafana Disk Performance dashboard.
  - Check the write latency of the disk by viewing the Disk Latency panel.
  - Check the I/O usage by viewing the Disk I/O Utilization panel.

7.5.7 Blackbox_exporter TCP, ICMP, and HTTP alert rules

This section gives the alert rules for the Blackbox_exporter TCP, ICMP, and HTTP.

7.5.7.1 Emergency-level alerts

7.5.7.1.1 TiDB_server_is_down

- Alert rule:

```
probe_success{group="tidb"} == 0
```

- Description:

  Failure to probe the TiDB service port.

- Solution:

  - Check whether the machine that provides the TiDB service is down.
  - Check whether the TiDB process exists.
  - Check whether the network between the monitoring machine and the TiDB machine is normal.

7.5.7.1.2 Pump_server_is_down

- Alert rule:

  ```
  probe_success{group="pump"} == 0
  ```

- Description:

  Failure to probe the pump service port.

- Solution:

  - Check whether the machine that provides the pump service is down.
  - Check whether the pump process exists.
  - Check whether the network between the monitoring machine and the pump machine is normal.

7.5.7.1.3 Drainer_server_is_down

- Alert rule:

  ```
  probe_success{group="drainer"} == 0
  ```

- Description:

  Failure to probe the Drainer service port.

- Solution:

  - Check whether the machine that provides the Drainer service is down.
  - Check whether the Drainer process exists.
  - Check whether the network between the monitoring machine and the Drainer machine is normal.

7.5.7.1.4 TiKV_server_is_down

- Alert rule:

  ```
  probe_success{group="tikv"} == 0
  ```

- Description:

  Failure to probe the TiKV service port.

- Solution:

  - Check whether the machine that provides the TiKV service is down.
  - Check whether the TiKV process exists.
  - Check whether the network between the monitoring machine and the TiKV machine is normal.

7.5.7.1.5 PD_server_is_down

- Alert rule:

  ```
  probe_success{group="pd"} == 0
  ```

- Description:

  Failure to probe the PD service port.

- Solution:

  - Check whether the machine that provides the PD service is down.
  - Check whether the PD process exists.
  - Check whether the network between the monitoring machine and the PD machine is normal.

7.5.7.1.6 Node_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="node_exporter"} == 0
  ```

- Description:

  Failure to probe the Node_exporter service port.

- Solution:

  - Check whether the machine that provides the Node_exporter service is down.
  - Check whether the Node_exporter process exists.
  - Check whether the network between the monitoring machine and the Node_exporter machine is normal.

7.5.7.1.7 Blackbox_exporter_server_is_down

- Alert rule:

  ```
  probe_success{group="blackbox_exporter"} == 0
  ```

- Description:

  Failure to probe the Blackbox_Exporter service port.

- Solution:

  - Check whether the machine that provides the Blackbox_Exporter service is down.
  - Check whether the Blackbox_Exporter process exists.
  - Check whether the network between the monitoring machine and the Blackbox_Exporter machine is normal.

7.5.7.1.8 Grafana_server_is_down

- Alert rule:

  `probe_success{group="grafana"} == 0`

- Description:

  Failure to probe the Grafana service port.

- Solution:

  - Check whether the machine that provides the Grafana service is down.
  - Check whether the Grafana process exists.
  - Check whether the network between the monitoring machine and the Grafana machine is normal.

7.5.7.1.9 Pushgateway_server_is_down

- Alert rule:

  `probe_success{group="pushgateway"} == 0`

- Description:

  Failure to probe the Pushgateway service port.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

7.5.7.1.10 Kafka_exporter_is_down

- Alert rule:

  `probe_success{group="kafka_exporter"} == 0`

- Description:

  Failure to probe the Kafka_Exporter service port.

- Solution:

  - Check whether the machine that provides the Kafka_Exporter service is down.
  - Check whether the Kafka_Exporter process exists.
  - Check whether the network between the monitoring machine and the Kafka_Exporter machine is normal.

7.5.7.1.11 Pushgateway_metrics_interface

- Alert rule:

  ```
  probe_success{job="blackbox_exporter_http"} == 0
  ```

- Description:

  Failure to probe the Pushgateway service http interface.

- Solution:

  - Check whether the machine that provides the Pushgateway service is down.
  - Check whether the Pushgateway process exists.
  - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

7.5.7.2 Warning-level alerts

7.5.7.2.1 BLACKER_ping_latency_more_than_1s

- Alert rule:

  ```
  max_over_time(probe_duration_seconds{job=~"blackbox_exporter.*_icmp"}[1
  ↪ m])> 1
  ```

- Description:

  The ping latency exceeds 1 second.

- Solution:

  - View the ping latency between the two nodes on the Grafana Blackbox Exporter page to check whether it is too high.
  - Check the TCP panel on the Grafana Node Exporter page to check whether there is any packet loss.

7.6 TiFlash Alert Rules

This document introduces the alert rules of the TiFlash cluster.

7.6.1 TiFlash_schema_error

- Alert rule:

  ```
  increase(tiflash_schema_apply_count{type="failed"}[15m])> 0
  ```

- Description:

  When the schema apply error occurs, an alert is triggered.

- Solution:

  The error might be caused by some wrong logic. Contact TiFlash R&D for support.

7.6.2 TiFlash_schema_apply_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_schema_apply_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 20
  ```

- Description:

  When the probability that the apply duration exceeds 20 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by the internal problems of the TiFlash TMT engine. Contact TiFlash R&D for support.

7.6.3 TiFlash_raft_read_index_duration

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_raft_read_index_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 3
  ```

- Description:

  When the probability that the read index duration exceeds 3 seconds is over 99%, an alert is triggered.

> **Note:**
>
> `read index` is the kvproto request sent to the TiKV leader. TiKV region retries, busy store, or network problems might lead to long request time of `read index`.

- Solution:

  The frequent retries might be caused by frequent splitting or migration of the TiKV cluster. You can check the TiKV cluster status to identify the retry reason.

7.6.4 `TiFlash_raft_wait_index_duration`

- Alert rule:

  ```
  histogram_quantile(0.99, sum(rate(tiflash_raft_wait_index_duration_seconds_bucket
  ↪ [1m]))BY (le, instance))> 2
  ```

- Description:

  When the probability that the waiting time for Region Raft Index in TiFlash exceeds 2 seconds is over 99%, an alert is triggered.

- Solution:

  It might be caused by a communication error between TiKV and the proxy. Contact TiFlash R&D for support.

8 Troubleshoot

8.1 TiDB Troubleshooting Map

This document summarizes common issues in TiDB and other components. You can use this map to diagnose and solve issues when you encounter related problems.

8.1.1 1. Service Unavailable

8.1.1.1 1.1 The client reports `Region is Unavailable` error

- 1.1.1 The `Region is Unavailable` error is usually because a Region is not available for a period of time. You might encounter `TiKV server is busy`, or the request to TiKV fails due to `not leader` or `epoch not match`, or the request to TiKV time out. In such cases, TiDB performs a `backoff` retry mechanism. When the `backoff` exceeds a threshold (20s by default), the error will be sent to the client. Within the `backoff` threshold, this error is not visible to the client.

- 1.1.2 Multiple TiKV instances are OOM at the same time, which causes no Leader in a Region for a period of time. See case-991 in Chinese.

- 1.1.3 TiKV reports `TiKV server is busy`, and exceeds the `backoff` time. For more details, refer to 4.3. `TiKV server is busy` is a result of the internal flow control mechanism and should not be counted in the `backoff` time. This issue will be fixed.

- 1.1.4 Multiple TiKV instances failed to start, which causes no Leader in a Region. When multiple TiKV instances are deployed in a physical machine, the failure of the physical machine can cause no Leader in a Region if the label is not properly configured. See case-228 in Chinese.

- 1.1.5 When a Follower apply is lagged in a previous epoch, after the Follower becomes a Leader, it rejects the request with `epoch not match`. See case-958 in Chinese (TiKV needs to optimize its mechanism).

8.1.1.2 1.2 PD errors cause service unavailable

Refer to 5 PD issues.

8.1.2 2. Latency increases significantly

8.1.2.1 2.1 Transient increase

- 2.1.1 Wrong TiDB execution plan causes latency increase. Refer to 3.3.
- 2.1.2 PD Leader election issue or OOM. Refer to 5.2 and 5.3.
- 2.1.3 A significant number of Leader drops in some TiKV instances. Refer to 4.4.

8.1.2.2 2.2 Persistent and significant increase

- 2.2.1 TiKV single thread bottleneck
  - Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana -> TiKV-details -> Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue. See case-612 in Chinese.
  - For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana -> TiKV-details -> Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.
- 2.2.2 CPU load increases.
- 2.2.3 TiKV slow write. Refer to 4.5.
- 2.2.4 TiDB wrong execution plan. Refer to 3.3.

8.1.3 3. TiDB issues

8.1.3.1 3.1 DDL

- 3.1.1 An error `ERROR 1105 (HY000): unsupported modify decimal column precision` is reported when you modify the length of the `decimal` field. TiDB does not support changing the length of the `decimal` field.
- 3.1.2 TiDB DDL job hangs or executes slowly (use `admin show ddl jobs` to check DDL progress)

- Cause 1: Network issue with other components (PD/TiKV).
- Cause 2: Early versions of TiDB (earlier than v3.0.8) have heavy internal load because of a lot of goroutine at high concurrency.
- Cause 3: In early versions (v2.1.15 & versions < v3.0.0-rc1), PD instances fail to delete TiDB keys, which causes every DDL change to wait for two leases.
- For other unknown causes, report a bug.
- Solution:
  * For cause 1, check the network connection between TiDB and TiKV/PD.
  * For cause 2 and 3, the issues are already fixed in later versions. You can upgrade TiDB to a later version.
  * For other causes, you can use the following solution of migrating the DDL owner.
- DDL owner migration:
  * If you can connect to the TiDB server, execute the owner election command again: `curl -X POST http://{TiDBIP}:10080/ddl/owner/resign`
  * If you cannot connect to the TiDB server, use `tidb-ctl` to delete the DDL owner from the etcd of the PD cluster to trigger re-election: `tidb-ctl etcd delowner [LeaseID] [flags] + ownerKey`

- 3.1.3 TiDB reports `information schema is changed` error in log
  - Cause 1: The DML operation touches a table that is under DDL. You can use `admin show ddl job` to check the DDLs that are currently in progress.
  - Cause 2: The current DML operation is executed too long. During the time, many DDL operations are executed, which causes `schema version` changes to be more than 1024. The new version `lock table` might also cause schema version changes.
  - Cause 3: The TiDB instance that is currently executing DML statements cannot load the new `schema information` (maybe caused by network issues with PD or TiKV). During this time, many DDL statements are executed (including `lock table`), which causes `schema version` changes to be more than 1024.
  - Solution: The first two causes do not impact the application, as the related DML operations retry after failure. For cause 3, you need to check the network between TiDB and TiKV/PD.
  - Background: The increased number of `schema version` is consistent with the number of `schema state` of each DDL change operation. For example, the `create table` operation has 1 version change, and the `add column` operation has 4 version changes. Therefore, too many column change operations might cause `schema version` to increase fast. For details, refer to online schema change.

- 3.1.4 TiDB reports `information schema is out of date` in log

- Cause 1: The TiDB server that is executing the DML statement is stopped by `graceful kill` and prepares to exit. The execution time of the transaction that contains the DML statement exceeds one DDL lease. An error is reported when the transaction is committed.
- Cause 2: The TiDB server cannot connect to PD or TiKV when it is executing the DML statement, which causes the following problems:
  * The TiDB server did not load the new schema within one DDL lease (`45s` by default); or
  * The TiDB server disconnects from PD with the `keep alive` setting.
- Cause 3: TiKV has high load or network timed out. Check the node loads in **Grafana** -> **TiDB** and **TiKV**.
- Solution:
  * For cause 1, retry the DML operation when TiDB is started.
  * For cause 2, check the network between the TiDB server and PD/TiKV.
  * For cause 3, investigate why TiKV is busy. Refer to 4 TiKV issues.

8.1.3.2 3.2 OOM issues

- 3.2.1 Symptom
  - Client: The client reports the error `ERROR 2013 (HY000): Lost connection to MySQL server during query`.
  - Check the log
    * Execute `dmesg -T | grep tidb-server`. The result shows the OOM-killer log around the time point when the error occurs.
    * Grep the "Welcome to TiDB" log in `tidb.log` around the time point after the error occurs (namely, the time when tidb-server restarts).
    * Grep `fatal error: runtime: out of memory` or `cannot allocate memory` in `tidb_stderr.log`.
    * In v2.1.8 or earlier versions, you can grep `fatal error: stack overflow` in the `tidb_stderr.log`.
  - Monitor: The memory usage of tidb-server instances increases sharply in a short period of time.
- 3.2.2 Locate the SQL statement that causes OOM. (Currently all versions of TiDB cannot locate SQL accurately. You still need to analyze whether OOM is caused by the SQL statement after you locate one.)
  - For versions >= v3.0.0, grep "expensive_query" in `tidb.log`. That log message records SQL queries that timed out or exceed memory quota.

- For versions < v3.0.0, grep "memory exceeds quota" in `tidb.log` to locate SQL queries that exceed memory quota.

> **Note:**
>
> The default threshold for a single SQL memory usage is `1GB` (in bytes, scope:`SESSION`). You can set this parameter by configuring `tidb_mem_quota_query`. You can also modify the `mem-quota-query` item (in bytes) in the configuration file by hot loading the configuration items.

- 3.2.3 Mitigate OOM issues
  - By enabling `SWAP`, you can mitigate the OOM issue caused by overuse of memory by large queries. When the memory is insufficient, this method can have impact on the performance of large queries due to the I/O overhead. The degree to which the performance is affected depends on the remaining memory space and the disk I/O speed.
- 3.2.4 Typical reasons for OOM
  - The SQL query has `join`. If you view the SQL statement by using `explain`, you can find that the `join` operation selects the `HashJoin` algorithm and the `inner` table is large.
  - The data volume of a single `UPDATE/DELETE` query is too large. See case-882 in Chinese.
  - The SQL contains multiple sub-queries connected by `Union`. See case-1828 in Chinese.

8.1.3.3 3.3 Wrong execution plan

- 3.3.1 Symptom
  - SQL query execution time is much longer compared with that of previous executions, or the execution plan suddenly changes. If the execution plan is logged in the slow log, you can directly compare the execution plans.
  - SQL query execution time is much longer compared with that of other databases such as MySQL. Compare the execution plan with other databases to see the differences, such as `Join Order`.
  - In slow log, the number of SQL execution time `Scan Keys` is large.
- 3.3.2 Investigate the execution plan

  - `explain analyze {SQL}`. When the execution time is acceptable, compare `count` in the result of `explain analyze` and the number of `row` in `execution info`. If a large difference is found in the `TableScan/IndexScan` row, it is likely that the statistics is incorrect. If a large difference is found in other rows, the problem might not be in the statistics.
  - `select count(*)`. When the execution plan contains a `join` operation, `explain analyze` might take a long time. You can check whether the problem is in the statistics by executing `select count(*)` for the conditions on `TableScan/IndexScan` and comparing the `row count` information in the `explain` result.

- 3.3.3 Mitigation

  - For v3.0 and later versions, use the `SQL Bind` feature to bind the execution plan.
  - Update the statistics. If you are roughly sure that the problem is caused by the statistics, dump the statistics. If the cause is outdated statistics, such as the `modify count/row count` in `show stats_meta` is greater than a certain value (for example, 0.3), or the table has an index of time column, you can try recovering by using `analyze table`. If `auto analyze` is configured, check whether the `tidb_auto_analyze_ratio` system variable is too large (for example, greater than 0.3), and whether the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.
  - For other situations, report a bug.

8.1.3.4 3.4 SQL execution error

- 3.4.1 The client reports the `ERROR 1265(01000)Data Truncated` error. This is because the way TiDB internally calculates the precision of `Decimal` type is incompatible with that of MySQL. This issue has been fixed in v3.0.10 (#14438).

  - Cause:

    In MySQL, if two large-precision `Decimal` are divided and the result exceeds the maximum decimal precision (`30`), only `30` digits are reserved and no error is reported;

    In TiDB, the calculation result is the same as in MySQL, but inside the data structure that represents `Decimal`, a field for decimal precision still retains the actual precision.

    Take `(0.1^30)/ 10` as an example. The results in TiDB and MySQL are both `0`, because the precision is `30` at most. However, in TiDB, the field for decimal precision is still `31`.

    After multiple `Decimal` divisions, even though the result is correct, this precision field could grow larger and larger, and eventually exceeds the threshold in TiDB (`72`), and the `Data Truncated` error is reported.

    The multiplication of `Decimal` does not have this issue, because the out-of-bounds is bypassed, and the precision is set to the maximum precision limit.

- Solution: You can bypass this issue by manually adding `Cast(xx as decimal(a , b))`, in which `a` and `b` are the target precisions.

8.1.4 4. TiKV issues

8.1.4.1 4.1 TiKV panics and fails to start

- 4.1.1 `sync-log = false`. The `unexpected raft log index: last_index X < applied_index Y` error is returned after the machine is powered off.

  This issue is expected. You can restore the Region using `tikv-ctl`.

- 4.1.2 If TiKV is deployed on a virtual machine, when the virtual machine is killed or the physical machine is powered off, the `entries[X, Y] is unavailable from storage` error is reported.

  This issue is expected. The `fsync` of virtual machines is not reliable, so you need to restore the Region using `tikv-ctl`.

- 4.1.3 For other unexpected causes, report a bug.

8.1.4.2 4.2 TiKV OOM

- 4.2.1 If the `block-cache` configuration is too large, it might cause OOM.

  To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana -> TiKV-details**.

  Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"` parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- 4.2.2 Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM.

  To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana -> TiKV-details -> coprocessor overview**.

- 4.2.3 Other components occupy too much memory.

  This issue is unexpected. You can report a bug.

8.1.4.3 4.3 The client reports the `server is busy` error

Check the specific cause for busy by viewing the monitor **Grafana -> TiKV -> errors**. `server is busy` is caused by the flow control mechanism of TiKV, which informs `tidb/ti` ↪ `-client` that TiKV is currently under too much pressure and will retry later.

- 4.3.1 TiKV RocksDB encounters `write stall`.

  A TiKV instance has two RocksDB instances, one in `data/raft` to save the Raft log, another in `data/db` to save the real data. You can check the specific cause for stall by running `grep "Stalling" RocksDB` in the log. The RocksDB log is a file starting with `LOG`, and `LOG` is the current log.

  - Too many `level0 sst` causes stall. You can add the `[rocksdb] max-sub-` ↪ `compactions = 2` (or 3) parameter to speed up `level0 sst` compaction. The compaction task from level0 to level1 is divided into several subtasks (the max number of subtasks is the value of `max-sub-compactions`) to be executed concurrently. See case-815 in Chinese.
  - Too many `pending compaction bytes` causes stall. The disk I/O fails to keep up with the write operations in business peaks. You can mitigate this problem by increasing the `soft-pending-compaction-bytes-limit` and `hard-pending-` ↪ `compaction-bytes-limit` of the corresponding CF.
    * The default value of `[rocksdb.defaultcf] soft-pending-compaction` ↪ `-bytes-limit` is `64GB`. If the pending compaction bytes reaches the threshold, RocksDB slows down the write speed. You can set `[rocksdb.` ↪ `defaultcf] soft-pending-compaction-bytes-limit` to `128GB`.
    * The default value of `hard-pending-compaction-bytes-limit` is `256GB`. If the pending compaction bytes reaches the threshold (this is not likely to happen, because RocksDB slows down the write after the pending compaction bytes reaches `soft-pending-compaction-bytes-limit`), RocksDB stops the write operation. You can set `hard-pending-compaction-bytes-limit` to `512GB`.
    * If the disk I/O capacity fails to keep up with the write for a long time, it is recommended to scale up your disk. If the disk throughput reaches the upper limit and causes write stall (for example, the SATA SSD is much lower than NVME SSD), while the CPU resources is sufficient, you may apply a compression algorithm of higher compression ratio. This way, the CPU resources is traded for disk resources, and the pressure on the disk is eased.
    * If the default CF compaction sees a high pressure, change the `[rocksdb.` ↪ `defaultcf] compression-per-level` parameter from `["no", "no", "` ↪ `lz4", "lz4", "lz4", "zstd", "zstd"]` to `["no", "no", "zstd", "` ↪ `zstd", "zstd", "zstd", "zstd"]`.
  - Too many memtables causes stall. This usually occurs when the amount of instant writes is large and the memtables flush to the disk slowly. If the disk write speed

cannot be improved, and this issue only occurs during business peaks, you can mitigate it by increasing the `max-write-buffer-number` of the corresponding CF.

  * For example, set `[rocksdb.defaultcf] max-write-buffer-number` to `8` (`5` by default). Note that this might cause more memory usage in the peak, because more memtables might be in the memory.

- 4.3.2 `scheduler too busy`

  - Serious write conflict. `latch wait duration` is high. You can view `latch wait duration` in the monitor **Grafana -> TiKV-details -> scheduler prewrite/scheduler commit**. When the write tasks pile up in the scheduler, the pending write tasks exceed the threshold set in `[storage] scheduler-pending-write-threshold` (100MB). You can verify the cause by viewing the metric corresponding to `MVCC_CONFLICT_COUNTER`.
  - Slow write causes write tasks to pile up. The data being written to TiKV exceeds the threshold set by `[storage] scheduler-pending-write-threshold` (100MB). Refer to 4.5.

- 4.3.3 `raftstore is busy`. The processing of messages is slower than the receiving of messages. The short-term `channel full` status does not affect the service, but if the error persists for a long time, it might cause Leader switch.

  - `append log` encounters stall. Refer to 4.3.1.
  - `append log duration` is high, which causes slow processing of messages. You can refer to 4.5 to analyze why `append log duration` is high.
  - raftstore receives a large batch of messages in an instant (check in the TiKV Raft messages dashboard), and fails to process them. Usually the short-term `channel full` status does not affect the service.

- 4.3.4 TiKV coprocessor is in a queue. The number of piled up tasks exceeds `coprocessor threads * readpool.coprocessor.max-tasks-per-worker-[normal|low|high]`. Too many large queries leads to the tasks piling up in coprocessor. You need to check whether a execution plan change causes a large number of table scan operations. Refer to 3.3.

8.1.4.4 4.4 Some TiKV nodes drop Leader frequently

- 4.4.1 Re-election because TiKV is restarted

  - After TiKV panics, it is pulled up by systemd and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.
  - TiKV is stopped or killed by a third party and then pulled up by systemd. Check the cause by viewing `dmesg` and the TiKV log.

  - TiKV is OOM, which causes restart. Refer to 4.2.
  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage). See case case-500 in Chinese.

- 4.4.2 TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`. Refer to 4.3.1.

- 4.4.3 Re-election because of network isolation.

8.1.4.5 4.5 TiKV write is slow

- 4.5.1 Check whether the TiKV write is low by viewing the `prewrite/commit/raw-put` duration of TiKV gRPC (only for raw KV clusters). Generally, you can locate the slow phase according to the performance-map. Some common situations are listed as follows.

- 4.5.2 The scheduler CPU is busy (only for transaction kv).

  The `scheduler command duration` of prewrite/commit is longer than the sum of `scheduler latch wait duration` and `storage async write duration`. The scheduler worker has a high CPU demand, such as over 80% of `scheduler-worker-pool-size` * 100%, or the CPU resources of the entire machine are relatively limited. If the write workload is large, check if `[storage] scheduler-worker-pool-size` is set too small.

  For other situations, report a bug.

- 4.5.3 Append log is slow.

  The **Raft IO**/`append log duration` in TiKV Grafana is high, usually because the disk write operation is slow. You can verify the cause by checking the `WAL Sync Duration max` value of RocksDB - raft.

  For other situations, report a bug.

- 4.5.4 The raftstore thread is busy.

  The **Raft Propose**/`propose wait duration` is significantly larger than the append log duration in TiKV Grafana. Take the following methods:

  - Check whether the `[raftstore] store-pool-size` configuration value is too small. It is recommended to set the value between `1` and `5` and not too large.
  - Check whether the CPU resources on the machine are insufficient.

- 4.5.5 Apply is slow.

  The **Raft IO**/`apply log duration` in TiKV Grafana is high, which usually comes with a high **Raft Propose**/`apply wait duration`. The possible causes are as follows:

- `[raftstore] apply-pool-size` is too small (it is recommended to set the value between `1` and `5` and not too large), and the **Thread CPU**/`apply CPU` is large.
- The CPU resources on the machine are insufficient.
- Region write hot spot. A single apply thread has high CPU usage. Currently, we cannot properly address the hot spot problem on a single Region, which is being improved. To view the CPU usage of each thread, modify the Grafana expression and add `by (instance, name)`.
- RocksDB write is slow. **RocksDB kv**/`max write duration` is high. A single Raft log might contain multiple KVs. When writing into RocksDB, 128 KVs are written into RocksDB in a write batch. Therefore, an apply log might be associated with multiple writes in RocksDB.
- For other situations, report a bug.

- 4.5.6 Raft commit log is slow.

  The **Raft IO**/`commit log duration` in TiKV Grafana is high (this metric is only supported in Grafana after v4.x). Every Region corresponds to an independent Raft group. Raft has a flow control mechanism, similar to the sliding window mechanism of TCP. You can control the size of the sliding window by configuring the `[raftstore]` ↪ `raft-max-inflight-msgs = 256` parameter. If there is a write hot spot and the `commit log duration` is high, you can adjust the parameter, such as increasing it to `1024`.

- 4.5.7 For other situations, refer to the write path on performance-map and analyze the cause.

8.1.5 5. PD issues

8.1.5.1 5.1 PD scheduling

- 5.1.1 Merge
  - Empty Regions across tables cannot be merged. You need to modify the `[` ↪ `coprocessor] split-region-on-table` parameter in TiKV, which is set to `false` in v4.x by default. See case-896 in Chinese.
  - Region merge is slow. You can check whether the merged operator is generated by accessing the monitor dashboard in **Grafana** -> **PD** -> **operator**. To accelerate the merge, increase the value of `merge-schedule-limit`.

- 5.1.2 Add replicas or take replicas online/offline
  - The TiKV disk uses 80% of the capacity, and PD does not add replicas. In this situation, the number of miss peers increases, so TiKV needs to be scaled out. See case-801 in Chinese.

  - When a TiKV node is taken offline, some Region cannot be migrated to other nodes. This issue has been fixed in v3.0.4 (#5526). See case-870 in Chinese.

- 5.1.3 Balance

  - The Leader/Region count is not evenly distributed. See case-394 and case-759 in Chinese. The major cause is that the balance performs scheduling based on the size of Region/Leader, so this might result in the uneven distribution of the count. In TiDB 4.0, the `[leader-schedule-policy]` parameter is introduced, which enables you to set the scheduling policy of Leader to be `count`-based or `size`-based.

8.1.5.2 5.2 PD election

- 5.2.1 PD switches Leader.

  - Cause 1: Disk. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana -> disk performance -> latency/load**. You can also use the FIO tool to run a check on the disk if necessary. See case-292 in Chinese.
  - Cause 2: Network. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana -> PD -> etcd**. See case-177 in Chinese.
  - Cause 3: High system load. The log shows `server is likely overloaded`. See case-214 in Chinese.

- 5.2.2 PD cannot elect a Leader or the election is slow.

  - PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19. See case-875 in Chinese.
  - The election is slow: The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region -storage` to `true`, which significantly reduce the Region loading duration. See case-429 in Chinese.

- 5.2.3 PD timed out when TiDB executes SQL statements.

  - PD doesn't have a Leader or switches Leader. Refer to 5.2.1 and 5.2.2.
  - Network issue. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> blackbox_exporter -> ping latency**.

  - PD panics. Report a bug.
  - PD is OOM. Refer to 5.3.
  - If the issue has other causes, get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

- 5.2.4 Other issues

  - PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040). For details, see case-947 in Chinese.
  - For other situations, report a bug.

8.1.5.3 5.3 PD OOM

- 5.3.1 When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- 5.3.2 PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that TCP InSegs is relatively large. This issue has been fixed in v3.0.6 (#1952).

8.1.5.4 5.4 Grafana display

- 5.4.1 The monitor in **Grafana** -> **PD** -> **cluster** -> **role** displays follower. The Grafana expression issue has been fixed in v3.0.8 (#1065). For details, see case-1022.

8.1.6 6. Ecosystem tools

8.1.6.1 6.1 TiDB Binlog

- 6.1.1 TiDB Binlog is a tool that collects changes from TiDB and provides backup and replication to downstream TiDB or MySQL platforms. For details, see TiDB Binlog on GitHub.
- 6.1.2 The `Update Time` in Pump/Drainer Status is updated normally, and no anomaly shows in the log, but no data is written to the downstream.

  - Binlog is not enabled in the TiDB configuration. Modify the `[binlog]` configuration in TiDB.

- 6.1.3 `sarama` in Drainer reports the `EOF` error.

  - The Kafka client version in Drainer is inconsistent with the version of Kafka. You need to modify the `[syncer.to] kafka-version` configuration.

- 6.1.4 Drainer fails to write to Kafka and panics, and Kafka reports the `Message was too large` error.

  - The binlog data is too large, so the single message written to Kafka is too large. You need to modify the following configuration of Kafka:

    ```
    message.max.bytes=1073741824
    replica.fetch.max.bytes=1073741824
    fetch.message.max.bytes=1073741824
    ```

    For details, see case-789 in Chinese.

- 6.1.5 Inconsistent data in upstream and downstream

  - Some TiDB nodes do not enable binlog. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the http://127.0.0.1:10080/info/all interface. For versions earlier than v3.0.6, you can check the binlog status by viewing the configuration file.
  - Some TiDB nodes go into the `ignore binlog` status. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the http://127.0.0.1:10080/info/all interface. For versions earlier than v3.0.6, check the TiDB log to see whether it contains the `ignore binlog` keyword.
  - The value of the timestamp column is inconsistent in upstream and downstream.
    * This is caused by different time zones. You need to ensure that Drainer is in the same time zone as the upstream and downstream databases. Drainer obtains its time zone from `/etc/localtime` and does not support the `TZ` environment variable. See case-826 in Chinese.
    * In TiDB, the default value of timestamp is `null`, but the same default value in MySQL 5.7 (not including MySQL 8) is the current time. Therefore, when the timestamp in upstream TiDB is `null` and the downstream is MySQL 5.7, the data in the timestamp column is inconsistent. You need to run `set @@global.explicit_defaults_for_timestamp=on;` in the upstream before enabling binlog.
  - For other situations, report a bug.

- 6.1.6 Slow replication

  - The downstream is TiDB/MySQL, and the upstream performs frequent DDL operations. See case-1023 in Chinese.
  - The downstream is TiDB/MySQL, and the table to be replicated has no primary key and no unique index, which causes reduced performance in binlog. It is recommended to add the primary key or unique index.
  - If the downstream outputs to files, check whether the output disk or network disk is slow.

  - For other situations, report a bug.

- 6.1.7 Pump cannot write binlog and reports the `no space left on device` error.

  - The local disk space is insufficient for Pump to write binlog data normally. You need to clean up the disk space and then restart Pump.

- 6.1.8 Pump reports the `fail to notify all living drainer` error when it is started.

  - Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.
  - Solution: Use the binlogctl tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the binlogctl tool to change its state and then restart Pump. See the case fail-to-notify-all-living-drainer.

- 6.1.9 Drainer reports the `gen update sqls failed: table xxx: row data is corruption []` error.

  - Trigger: The upstream performs DML operations on this table while performing `DROP COLUMN` DDL. This issue has been fixed in v3.0.6. See case-820 in Chinese.

- 6.1.10 Drainer replication is hung. The process remains active but the checkpoint is not updated.

  - This issues has been fixed in v3.0.4. See case-741 in Chinese.

- 6.1.11 Any component panics.

  - Report a bug.

8.1.6.2 6.2 Data Migration

- 6.2.1 TiDB Data Migration (DM) is a migration tool that supports data migration from MySQL/MariaDB into TiDB. For details, see DM on GitHub.

- 6.2.2 `Access denied for user 'root'@'172.31.43.27' (using password: YES)` shows when you run `query status` or check the log.

  - The database related passwords in all the DM configuration files should be encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt the password. Cleartext passwords can be used since v1.0.6.

  - During DM operation, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also prechecks the corresponding privileges automatically while starting the data replication task.
  - To deploy different versions of DM-worker/DM-master/dmctl in a DM cluster, see the case study on AskTUG in Chinese.

- 6.2.3 A replication task is interrupted with the `driver: bad connection` error returned.

  - The `driver: bad connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart and so on), and that the data of the current request has not yet been sent to TiDB.
    * For versions earlier than DM 1.0.0 GA, stop the task by running `stop-task` and then restart the task by running `start-task`.
    * For DM 1.0.0 GA or later versions, an automatic retry mechanism for this type of error is added. See #265.

- 6.2.4 A replication task is interrupted with the `invalid connection` error.

  - The `invalid connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, TiKV busy and so on), and that a part of the data for the current request has been sent to TiDB. Because DM has the feature of concurrently replicating data to the downstream in replication tasks, several errors might occur when a task is interrupted. You can check these errors by running `query-status` or `query-error`.
    * If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.
    * If DM does not retry or fails to retry automatically because of version problems (automatic retry is introduced in v1.0.0-rc.1), use `stop-task` to stop the task and then use `start-task` to restart the task.

- 6.2.5 The relay unit reports the error `event from * in * diff from passed-in` ↪ `event *`, or a replication task is interrupted with an error that fails to get or parse binlog, such as `get binlog error ERROR 1236 (HY000)and binlog checksum` ↪ `mismatch, data may be corrupted returned`

  - During the process that DM pulls relay log or the incremental replication, this two errors might occur if the size of the upstream binlog file exceeds 4 GB.
  - Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the binlog file size, and store the replicated binlog positions as checkpoints. However, the official MySQL uses uint32 to store binlog positions, which means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.

  - Solution:
    * For relay processing units, manually recover replication.
    * For binlog replication processing units, manually recover replication.

- 6.2.6 The DM replication is interrupted, and the log returns `ERROR 1236 (HY000) ↪ The slave is connecting using CHANGE MASTER TO MASTER_AUTO_POSITION ↪ = 1, but the master has purged binary logs containing GTIDs that the ↪ slave requires.`

  - Check whether the master binlog is purged.
  - Check the position information recorded in `relay.meta`.
    * `relay.meta` has recorded the empty GTID information. DM-worker saves the GTID information in memory to `relay.meta` when it exits or in every 30s. When DM-worker does not obtain the upstream GTID information, it saves the empty GTID information to `relay.meta`. See case-772 in Chinese.
    * The binlog event recorded in `relay.meta` triggers the incomplete recover process and records the wrong GTID information. This issue is fixed in v1.0.2, and might occur in earlier versions.

- 6.2.7 The DM replication process returns an error `Error 1366: incorrect utf8 ↪ value eda0bdedb29d(\ufffd\ufffd\ufffd\ufffd\ufffd\ufffd)`.

  - This value cannot be successfully written into MySQL 8.0 or TiDB, but can be written into MySQL 5.7. You can skip the data format check by enabling the `tidb_skip_utf8_check` parameter.

8.1.6.3 6.3 TiDB Lightning

- 6.3.1 TiDB Lightning is a tool for fast full import of large amounts of data into a TiDB cluster. See TiDB Lightning on GitHub.

- 6.3.2 Import speed is too slow.

  - `region-concurrency` is set too high, which causes thread contention and reduces performance. Three ways to troubleshoot:
    * The setting can be found from the start of the log by searching `region- ↪ concurrency`.
    * If TiDB Lightning shares a server with other services (for example, Importer), you must manually set `region-concurrency` to 75% of the total number of CPU cores on that server.
    * If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning might not be able to read this out. In this case, `region- ↪ concurrency` must also be manually reduced.

  - Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Mydumper output. If the indices are negligible, you may first remove them from the schema, and add them back via `CREATE INDEX` after the import is complete.
  - The version of TiDB Lightning is old. Try the latest version, which might improve the import speed.

- 6.3.3 `checksum failed: checksum mismatched remote vs local`.

  - Cause 1: The table might already have data. These old data can affect the final checksum.
  - Cause 2: If the checksum of the target database is 0, which means nothing is imported, it is possible that the cluster is too hot and fails to take in any data.
  - Cause 3: If the data source is generated by the machine and not backed up by Mydumper, ensure it respects the constrains of the table. For example:
    * `AUTO_INCREMENT` columns need to be positive, and do not contain the value "0".
    * UNIQUE and PRIMARY KEYs must not have duplicate entries.
  - Solution: See Troubleshooting Solution.

- 6.3.4 `Checkpoint for ⋯ has invalid status:(error code)`

  - Cause: Checkpoint is enabled, and Lightning/Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed. The error code is an integer less than 25, with possible values as `0, 3, 6, 9, 12, 14, 15, 17, 18, 20 and 21`. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later the exit occurs.
  - Solution: See Troubleshooting Solution.

- 6.3.5 `ResourceTemporarilyUnavailable("Too many open engines ⋯: 8")`

  - Cause: The number of concurrent engine files exceeds the limit specified by tikv-importer. This could be caused by misconfiguration. In addition, even when the configuration is correct, if tidb-lightning has exited abnormally before, an engine file might be left at a dangling open state, which could cause this error as well.
  - Solution: See Troubleshooting Solution.

- 6.3.6 `cannot guess encoding for input file, please convert to UTF-8 manually`

  - Cause: TiDB Lightning only supports the UTF-8 and GB-18030 encodings. This error means the file is not in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical ALTER TABLE executions.
  - Solution: See Troubleshooting Solution.

- 6.3.7 `[sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 0 45 0 0}'`

  - Cause: A timestamp type entry has a time value that does not exist. This is either because of DST changes or because the time value has exceeded the supported range (from Jan 1, 1970 to Jan 19, 2038).
  - Solution: See Troubleshooting Solution.

8.1.7 7. Common log analysis

8.1.7.1 7.1 TiDB

- 7.1.1 `GC life time is shorter than transaction duration`.

  The transaction duration exceeds the GC lifetime (10 minutes by default).

  You can increase the GC lifetime by modifying the `tidb_gc_life_time` system variable. Generally, it is not recommended to modify this parameter, because changing it might cause many old versions to pile up if this transaction has a large number of `UPDATE` and `DELETE` statements.

- 7.1.2 `txn takes too much time`.

  This error is returned when you commit a transaction that has not been committed for a long time (over 590 seconds).

  If your application needs to execute a transaction of such a long time, you can increase the `[tikv-client] max-txn-time-use = 590` parameter and the GC lifetime to avoid this issue. It is recommended to check whether your application needs such a long transaction time.

- 7.1.3 `coprocessor.go` reports `request outdated`.

  This error is returned when the coprocessor request sent to TiKV waits in a queue at TiKV for over 60 seconds.

  You need to investigate why the TiKV coprocessor is in a long queue.

- 7.1.4 `region_cache.go` reports a large number of `switch region peer to next due to send request fail`, and the error message is `context deadline exceeded`.

  The request for TiKV timed out and triggers the region cache to switch the request to other nodes. You can continue to run the `grep "<addr> cancelled` command on the `addr` field in the log and take the following steps according to the `grep` results:

  - `send request is cancelled`: The request timed out during the sending phase. You can investigate the monitoring **Grafana** -> **TiDB** -> **Batch Client**/`Pending Request Count by TiKV` and see whether the Pending Request Count is greater than 128:
    * If the value is greater than 128, the sending goes beyond the processing capacity of KV, so the sending piles up.
    * If the value is not greater than 128, check the log to see if the report is caused by the operation and maintenance changes of the corresponding KV; otherwise, this error is unexpected, and you need to report a bug.
  - `wait response is cancelled`: The request timed out after it is sent to TiKV. You need to check the response time of the corresponding TiKV address and the Region logs in PD and KV at that time.

- 7.1.5 `distsql.go` reports `inconsistent index`.

  The data index seems to be inconsistent. Run the `admin check table <TableName>` command on the table where the reported index is. If the check fails, disable garbage collection by running the following command, and report a bug:

```
SET GLOBAL tidb_gc_enable = 0;
```

8.1.7.2 7.2 TiKV

- 7.2.1 `key is locked`.

  The read and write have conflict. The read request encounters data that has not been committed and needs to wait until the data is committed.

  A small number of this error has no impact on the business, but a large number of this error indicates that the read-write conflict is severe in your business.

- 7.2.2 `write conflict`.

  This is the write-write conflict in optimistic transactions. If multiple transactions modify the same key, only one transaction succeed and other transactions automatically obtain the timestamp again and retry the operation, with no impact on the business.

  If the conflict is severe, it might cause transaction failure after multiple retries. In this case, it is recommended to use the pessimistic lock.

- 7.2.3 `TxnLockNotFound`.

  This transaction commit is too slow, which is rolled back by other transactions after TTL (3 seconds for a small transaction by default). This transaction will automatically retry, so the business is usually not affected.

- 7.2.4 `PessimisticLockNotFound`.

  Similar to `TxnLockNotFound`. The pessimistic transaction commit is too slow and thus rolled back by other transactions.

- 7.2.5 `stale_epoch`.

  The request epoch is outdated, so TiDB re-sends the request after updating the routing. The business is not affected. Epoch changes when Region has a split/merge operation or a replica is migrated.

- 7.2.6 `peer is not leader`.

  The request is sent to a replica that is not Leader. If the error response indicates which replica is the latest Leader, TiDB updates the local routing according the error and sends a new request to the latest Leader. Usually, the business is not affected.

  In v3.0 and later versions, TiDB tries other peers if the request to the previous Leader fails, which might lead to frequent `peer is not leader` in TiKV log. You can check the `switch region peer to next due to send request fail` log of the corresponding Region in TiDB to determine the root cause of the sending failure. For details, refer to 7.1.4.

  This error might also be returned if a Region has no Leader due to other reasons. For details, see 4.4.

8.2 Identify Slow Queries

To help users identify slow queries, analyze and improve the performance of SQL execution, TiDB outputs the statements whose execution time exceeds slow-threshold (The default value is 300 milliseconds) to slow-query-file (The default value is "tidb-slow.log").

TiDB enables the slow query log by default. You can enable or disable the feature by modifying the configuration `enable-slow-log`.

8.2.1 Usage example

```
## Time: 2019-08-14T09:26:59.487776265+08:00

8.2.2 Fields description

> **Note:**
>
> The unit of all the following time fields in the slow query log is **"second"**.

Slow query basics:

- `Time`: The print time of log.
- `Query_time`: The execution time of a statement.

- `Parse_time`: The parsing time for the statement.
- `Compile_time`: The duration of the query optimization.
- `Query`: A SQL statement. `Query` is not printed in the slow log, but the corresponding field is called `Query` after the slow log is mapped to the memory table.
- `Digest`: The fingerprint of the SQL statement.
- `Txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `Is_internal`: Whether a SQL statement is TiDB internal. `true` indicates that a SQL statement is executed internally in TiDB and `false` indicates that a SQL statement is executed by the user.
- `Index_ids`: The IDs of the indexes involved in a statement.
- `Succ`: Whether a statement is executed successfully.
- `Backoff_time`: The waiting time before retry when a statement encounters errors that require a retry. The common errors as such include: `lock occurs`, `Region split`, and `tikv server is busy`.
- `Plan`: The execution plan of the statement. Use the `select tidb_decode_plan('xxx ...')` statement to parse the specific execution plan.
- `Prepared`: Whether this statement is a `Prepare` or `Execute` request or not.
- `Plan_from_cache`: Whether this statement hits the execution plan cache.
- `Rewrite_time`: The time consumed for rewriting the query of this statement.
- `Preproc_subqueries`: The number of subqueries (in the statement) that are executed in advance. For example, the `where id in (select if from t)` subquery might be executed in advance.
- `Preproc_subqueries_time`: The time consumed for executing the subquery of this statement in advance.
- `Exec_retry_count`: The retry times of this statement. This field is usually for pessimistic transactions in which the statement is retried when the lock is failed.
- `Exec_retry_time`: The execution retry duration of this statement. For example, if a statement has been executed three times in total (failed for the first two times), `Exec_retry_time` means the total duration of the first two executions. The duration of the last execution is `Query_time` minus `Exec_retry_time`.

The following fields are related to transaction execution:

- `Prewrite_time`: The duration of the first phase (prewrite) of the two-phase transaction commit.
- `Commit_time`: The duration of the second phase (commit) of the two-phase transaction commit.
- `Get_commit_ts_time`: The time spent on getting `commit_ts` during the second phase (commit) of the two-phase transaction commit.
- `Local_latch_wait_time`: The time that TiDB spends on waiting for the lock before the second phase (commit) of the two-phase transaction commit.
- `Write_keys`: The count of keys that the transaction writes to the Write CF in TiKV.
- `Write_size`: The total size of the keys or values to be written when the transaction commits.

- `Prewrite_region`: The number of TiKV Regions involved in the first phase (prewrite) of the two-phase transaction commit. Each Region triggers a remote procedure call.

Memory usage fields:

- `Mem_max`: The maximum memory space used during the execution period of a SQL statement (the unit is byte).

Hard disk fields:

- `Disk_max`: The maximum disk space used during the execution period of a SQL statement (the unit is byte).

User fields:

- `User`: The name of the user who executes this statement.
- `Conn_ID`: The Connection ID (session ID). For example, you can use the keyword `con:3` to search for the log whose session ID is `3`.
- `DB`: The current database.

TiKV Coprocessor Task fields:

- `Request_count`: The number of Coprocessor requests that a statement sends.
- `Total_keys`: The number of keys that Coprocessor has scanned.
- `Process_time`: The total processing time of a SQL statement in TiKV. Because data is sent to TiKV concurrently, this value might exceed `Query_time`.
- `Wait_time`: The total waiting time of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `Process_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `Cop_proc_avg`: The average execution time of cop-tasks.
- `Cop_proc_p90`: The P90 execution time of cop-tasks.
- `Cop_proc_max`: The maximum execution time of cop-tasks.
- `Cop_proc_addr`: The address of the cop-task with the longest execution time.
- `Cop_wait_avg`: The average waiting time of cop-tasks.
- `Cop_wait_p90`: The P90 waiting time of cop-tasks.
- `Cop_wait_max`: The maximum waiting time of cop-tasks.
- `Cop_wait_addr`: The address of the cop-task whose waiting time is the longest.

- `Cop_backoff_{backoff-type}_total_times`: The total times of backoff caused by an error.
- `Cop_backoff_{backoff-type}_total_time`: The total time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_time`: The longest time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_max_addr`: The address of the cop-task that has the longest backoff time caused by an error.
- `Cop_backoff_{backoff-type}_avg_time`: The average time of backoff caused by an error.
- `Cop_backoff_{backoff-type}_p90_time`: The P90 percentile backoff time caused by an error.

8.2.3 Related system variables

- `tidb_slow_log_threshold`: Sets the threshold for the slow log. The SQL statement whose execution time exceeds this threshold is recorded in the slow log. The default value is 300 (ms).

- `tidb_query_log_max_len`: Sets the maximum length of the SQL statement recorded in the slow log. The default value is 4096 (byte).

- tidb_redact_log: Determines whether to desensitize user data using `?` in the SQL statement recorded in the slow log. The default value is `0`, which means to disable the feature.

- `tidb_enable_collect_execution_info`: Determines whether to record the physical execution information of each operator in the execution plan. The default value is `1`. This feature impacts the performance by approximately 3%. After enabling this feature, you can view the `Plan` information as follows:

```
> select tidb_decode_plan('
    ↪ jAOIMAk1XzE3CTAJMQlmdW5jczpjb3VudChDb2x1bW4jNyktPkMJC/

    ↪
```

If you are conducting a performance test, you can disable the feature of automatically collecting the execution information of operators:

```
set @@tidb_enable_collect_execution_info=0;
```

The returned result of the `Plan` field has roughly the same format with that of `EXPLAIN` or `EXPLAIN ANALYZE`. For more details of the execution plan, see `EXPLAIN` or `EXPLAIN ANALYZE`.

For more information, see TiDB specific variables and syntax.

8.2.4 Memory mapping in slow log

You can query the content of the slow query log by querying the `INFORMATION_SCHEMA.` ↪ `SLOW_QUERY` table. Each column name in the table corresponds to one field name in the slow log. For table structure, see the introduction to the `SLOW_QUERY` table in Information Schema.

> **Note:**
>
> Every time you query the `SLOW_QUERY` table, TiDB reads and parses the current slow query log.

For TiDB 4.0, `SLOW_QUERY` supports querying the slow log of any period of time, including the rotated slow log file. You need to specify the `TIME` range to locate the slow log files that need to be parsed. If you don't specify the `TIME` range, TiDB only parses the current slow log file. For example:

- If you don't specify the time range, TiDB only parses the slow query data that TiDB is writing to the slow log file:

```
select count(*),
     min(time),
     max(time)
from slow_query;
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 122492   | 2020-03-11 23:35:20.908574 | 2020-03-25 19:16:38.229035 |
+----------+----------------------------+----------------------------+
```

- If you specify the time range, for example, from `2020-03-10 00:00:00` to `2020-03-11 00:00:00`, TiDB first locates the slow log files of the specified time range, and then parses the slow query information:

```
select count(*),
     min(time),
     max(time)
from slow_query
where time > '2020-03-10 00:00:00'
  and time < '2020-03-11 00:00:00';
```

```
+----------+----------------------------+----------------------------+
| count(*) | min(time)                  | max(time)                  |
+----------+----------------------------+----------------------------+
| 2618049 | 2020-03-10 00:00:00.427138 | 2020-03-10 23:00:22.716728 |
+----------+----------------------------+----------------------------+
```

Note:

If the slow log files of the specified time range are removed, or there is no slow query, the query returns NULL.

TiDB 4.0 adds the CLUSTER_SLOW_QUERY system table to query the slow query information of all TiDB nodes. The table schema of the CLUSTER_SLOW_QUERY table differs from that of the SLOW_QUERY table in that an INSTANCE column is added to CLUSTER_SLOW_QUERY. The INSTANCE column represents the TiDB node address of the row information on the slow query. You can use CLUSTER_SLOW_QUERY the way you do with SLOW_QUERY.

When you query the CLUSTER_SLOW_QUERY table, TiDB pushes the computation and the judgment down to other nodes, instead of retrieving all slow query information from other nodes and executing the operations on one TiDB node.

8.2.5 SLOW_QUERY / CLUSTER_SLOW_QUERY usage examples

8.2.5.1 Top-N slow queries

Query the Top 2 slow queries of users. Is_internal=false means excluding slow queries inside TiDB and only querying slow queries of users.

```
select query_time, query
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 2;
```

Output example:

```
+-------------+-----------------------------------------------------------------+
    ↪
| query_time | query                                                            |
+-------------+-----------------------------------------------------------------+
    ↪
| 12.77583857 | select * from t_slim, t_wide where t_slim.c0=t_wide.c0; |
|  0.734982725 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=
    ↪ t1.c0; |
+-------------+-----------------------------------------------------------------+
    ↪
```

8.2.5.2 Query the Top-N slow queries of the test user

In the following example, the slow queries executed by the test user are queried, and the first two results are displayed in reverse order of execution time.

```
select query_time, query, user
from information_schema.slow_query
where is_internal = false
  and user = "test"
order by query_time desc
limit 2;
```

Output example:

```
+------------+-------------------------------------------------------------------------+------
   ↪
| Query_time | query                                                                   |
   ↪ user         |
+------------+-------------------------------------------------------------------------+------
   ↪
| 0.676408014 | select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1
   ↪ .c1; | test |
+------------+-------------------------------------------------------------------------+------
   ↪
```

8.2.5.3 Query similar slow queries with the same SQL fingerprints

After querying the Top-N SQL statements, continue to query similar slow queries using the same fingerprints.

1. Acquire Top-N slow queries and the corresponding SQL fingerprints.

```
select query_time, query, digest
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 1;
```

Output example:

```
+------------+----------------------------+-----------------------------------
   ↪
| query_time | query                      | digest
   ↪                                                          |
+------------+----------------------------+-----------------------------------
   ↪
| 0.302558006 | select * from t1 where a=1; | 4751
   ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa |
+------------+----------------------------+-----------------------------------
   ↪
```

2. Query similar slow queries with the fingerprints.

```
select query, query_time
from information_schema.slow_query
where digest = "4751
   ↪ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa";
```

Output example:

```
+----------------------------+-------------+
| query                      | query_time |
+----------------------------+-------------+
| select * from t1 where a=1; | 0.302558006 |
| select * from t1 where a=2; | 0.401313532 |
+----------------------------+-------------+
```

8.2.6 Query slow queries with pseudo stats

```
select query, query_time, stats
from information_schema.slow_query
where is_internal = false
  and stats like '%pseudo%';
```

Output example:

```
+----------------------------+-------------+--------------------------------+
   ↪
| query                      | query_time | stats                          |
+----------------------------+-------------+--------------------------------+
   ↪
| select * from t1 where a=1; | 0.302558006 | t1:pseudo                      |
| select * from t1 where a=2; | 0.401313532 | t1:pseudo                      |
| select * from t1 where a>2; | 0.602011247 | t1:pseudo                      |
| select * from t1 where a>3; | 0.50077719 | t1:pseudo                       |
| select * from t1 join t2; | 0.931260518 | t1:407872303825682445,t2:pseudo
   ↪ |
+----------------------------+-------------+--------------------------------+
   ↪
```

8.2.6.1 Query slow queries whose execution plan is changed

When the execution plan of SQL statements of the same category is changed, the execution slows down, because the statistics is outdated, or the statistics is not accurate enough to reflect the real data distribution. You can use the following SQL statement to query SQL statements with different execution plans.

```
select count(distinct plan_digest) as count,
       digest,
       min(query)
from cluster_slow_query
group by digest
having count > 1
```

```
limit 3\G
```

Output example:

```
***************************[ 1. row ]***************************
count     | 2
digest    | 17b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94
min(query) | SELECT DISTINCT c FROM sbtest25 WHERE id BETWEEN ? AND ? ORDER
    ↪ BY c [arguments: (291638, 291737)];
***************************[ 2. row ]***************************
count     | 2
digest    | 9337865f3e2ee71c1c2e740e773b6dd85f23ad00f8fa1f11a795e62e15fc9b23
min(query) | SELECT DISTINCT c FROM sbtest22 WHERE id BETWEEN ? AND ? ORDER
    ↪ BY c [arguments: (215420, 215519)];
***************************[ 3. row ]***************************
count     | 2
digest    | db705c89ca2dfc1d39d10e0f30f285cbbadec7e24da4f15af461b148d8ffb020
min(query) | SELECT DISTINCT c FROM sbtest11 WHERE id BETWEEN ? AND ? ORDER
    ↪ BY c [arguments: (303359, 303458)];
```

Then you can query the different plans using the SQL fingerprint in the query result above:

```
select min(plan),
       plan_digest
from cluster_slow_query
where digest='17
    ↪ b4518fde82e32021877878bec2bb309619d384fca944106fcaf9c93b536e94'
group by plan_digest\G
```

Output example:

```
*************************** 1. row ***************************
  min(plan):  Sort_6                root    100.00131380758702   sbtest.
     ↪ sbtest25.c:asc
        ─HashAgg_10          root    100.00131380758702   group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          ─TableReader_15    root    100.00131380758702   data:
            ↪ TableRangeScan_14
            ─TableScan_14    cop     100.00131380758702   table:sbtest25,
              ↪ range:[502791,502890], keep order:false
plan_digest: 6
    ↪ afbbd21f60ca6c6fdf3d3cd94f7c7a49dd93c00fcf8774646da492e50e204ee
*************************** 2. row ***************************
  min(plan):  Sort_6                root    1                    sbtest.
     ↪ sbtest25.c:asc
```

```
        └─HashAgg_12          root    1                    group by:sbtest.
          ↪ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
          ↪ .c
          └─TableReader_13    root    1                    data:HashAgg_8
            └─HashAgg_8       cop     1                    group by:sbtest.
              ↪ sbtest25.c,
              └─TableScan_11  cop     1.2440069558121831   table:sbtest25,
                ↪ range:[472745,472844], keep order:false
```

8.2.6.2 Query the number of slow queries for each TiDB node in a cluster

```
select instance, count(*) from information_schema.cluster_slow_query where
   ↪ time >= "2020-03-06 00:00:00" and time < now() group by instance;
```

Output example:

```
+---------------+----------+
| instance      | count(*) |
+---------------+----------+
| 0.0.0.0:10081 | 124      |
| 0.0.0.0:10080 | 119771   |
+---------------+----------+
```

8.2.6.3 Query slow logs occurring only in abnormal time period

If you find problems such as decreased QPS or increased latency for the time period from `2020-03-10 13:24:00` to `2020-03-10 13:27:00`, the reason might be that a large query crops up. Run the following SQL statement to query slow logs that occur only in abnormal time period. The time range from `2020-03-10 13:20:00` to `2020-03-10 13:23:00` refers to the normal time period.

```
SELECT * FROM
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ count(*),
        min(time),
        sum(query_time) AS sum_query_time,
        sum(Process_time) AS sum_process_time,
        sum(Wait_time) AS sum_wait_time,
        sum(Commit_time),
        sum(Request_count),
        sum(process_keys),
        sum(Write_keys),
        max(Cop_proc_max),
        min(query),min(prev_stmt),
        digest
    FROM information_schema.CLUSTER_SLOW_QUERY
```

```
    WHERE time >= '2020-03-10 13:24:00'
           AND time < '2020-03-10 13:27:00'
           AND Is_internal = false
    GROUP BY digest) AS t1
WHERE t1.digest NOT IN
    (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ digest
    FROM information_schema.CLUSTER_SLOW_QUERY
    WHERE time >= '2020-03-10 13:20:00'
           AND time < '2020-03-10 13:23:00'
    GROUP BY digest)
ORDER BY t1.sum_query_time DESC limit 10\G
```

Output example:

```
***************************[ 1. row ]***************************
count(*)          | 200
min(time)         | 2020-03-10 13:24:27.216186
sum_query_time    | 50.114126194
sum_process_time | 268.351
sum_wait_time     | 8.476
sum(Commit_time) | 1.044304306
sum(Request_count) | 6077
sum(process_keys) | 202871950
sum(Write_keys)  | 319500
max(Cop_proc_max) | 0.263
min(query)        | delete from test.tcs2 limit 5000;
min(prev_stmt)    |
digest            | 24
    ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df
```

8.2.6.4 Parse other TiDB slow log files

TiDB uses the session variable `tidb_slow_query_file` to control the files to be read and parsed when querying `INFORMATION_SCHEMA.SLOW_QUERY`. You can query the content of other slow query log files by modifying the value of the session variable.

```
set tidb_slow_query_file = "/path-to-log/tidb-slow.log"
```

8.2.6.5 Parse TiDB slow logs with `pt-query-digest`

Use `pt-query-digest` to parse TiDB slow logs.

> **Note:**
>
> It is recommended to use `pt-query-digest` 3.0.13 or later versions.

For example:

```
pt-query-digest --report tidb-slow.log
```

Output example:

```
## 320ms user time, 20ms system time, 27.00M rss, 221.32M vsz
## Current date: Mon Mar 18 13:18:51 2019

8.2.7 Identify problematic SQL statements

Not all of the `SLOW_QUERY` statements are problematic. Only those whose `process_time` is very large increase the pressure on the entire cluster.

The statements whose `wait_time` is very large and `process_time` is very small are usually not problematic. This is because the statement is blocked by real problematic statements and it has to wait in the execution queue, which leads to a much longer response time.

8.2.7.1 `admin show slow` command

In addition to the TiDB log file, you can identify slow queries by running the `admin show slow` command:

```
admin show slow recent N
admin show slow top [internal | all] N
```

`recent N` shows the recent N slow query records, for example:

```
admin show slow recent 10
```

`top N` shows the slowest N query records recently (within a few days). If the `internal` option is provided, the returned results would be the inner SQL executed by the system; If the `all` option is provided, the returned results would be the user's SQL combinated with inner SQL; Otherwise, this command would only return the slow query records from the user's SQL.

```
admin show slow top 3
admin show slow top internal 3
admin show slow top all 5
```

TiDB stores only a limited number of slow query records because of the limited memory. If the value of `N` in the query command is greater than the records count, the number of returned records is smaller than `N`.

The following table shows output details:

Column name	Description
start	The starting time of the SQL execution
duration	The duration of the SQL execution

Column name	Description
details	The details of the SQL execution
succ	Whether the SQL statement is executed successfully. `1` means success and `0` means failure.
conn_id	The connection ID for the session
transcation_ts	The `commit ts` for a transaction commit

Column name	Description
user	The user name for the execution of the statement
db	The database involved when the statement is executed
table_ids	The ID of the table involved when the SQL statement is executed

Column name	Description
index_ids	The ID of the index involved when the SQL statement is executed
internal	This is a TiDB internal SQL statement
digest	The fingerprint of the SQL statement
sql	The SQL statement that is being executed or has been executed

8.3 Analyze Slow Queries

To address the issue of slow queries, you need to take the following two steps:

1. Among many queries, identify which type of queries are slow.
2. Analyze why this type of queries are slow.

You can easily perform step 1 using the slow query log and the statement summary table features. It is recommended to use TiDB Dashboard, which integrates the two features and directly displays the slow queries in your browser.

This document focuses on how to perform step 2 - analyze why this type of queries are slow.

Generally, slow queries have the following major causes:

- Optimizer issues, such as wrong index selected, wrong join type or sequence selected.
- System issues. All issues not caused by the optimizer are system issues. For example, a busy TiKV instance processes requests slowly; outdated Region information causes slow queries.

In actual situations, optimizer issues might cause system issues. For example, for a certain type of queries, the optimizer uses a full table scan instead of the index. As a result, the SQL queries consume many resources, which causes the CPU usage of some TiKV instances to soar. This seems like a system issue, but in essence, it is an optimizer issue.

To identify system issues is relatively simple. To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. Therefore, it is recommended to analyze slow queries by following these procedures:

1. Identify the performance bottleneck of the query, that is, the time-consuming part of the query process.
2. Analyze the system issues: analyze the possible causes according to the query bottleneck and the monitoring/log information of that time.
3. Analyze the optimizer issues: analyze whether there is a better execution plan.

The procedures above are explained in the following sections.

8.3.1 Identify the performance bottleneck of the query

First, you need to have a general understanding of the query process. The key stages of the query execution process in TiDB are illustrated in TiDB performance map.

You can get the duration information using the following methods:

- Slow log. It is recommended to view the slow log in TiDB Dashboard.
- `EXPLAIN ANALYZE` statement.

The methods above are different in the following aspects:

- The slow log records the duration of almost all stages of a SQL execution, from parsing to returning results, and is relatively comprehensive (you can query and analyze the slow log in TiDB Dashboard in an intuitive way).
- By executing `EXPLAIN ANALYZE`, you can learn the time consumption of each operator in an actual SQL execution. The results have more detailed statistics of the execution duration.

In summary, the slow log and `EXPLAIN ANALYZE` statements help you determine the SQL query is slow in which component (TiDB or TiKV) at which stage of the execution. Therefore, you can accurately identify the performance bottleneck of the query.

In addition, since v4.0.3, the `Plan` field in the slow log also includes the SQL execution information, which is the result of `EXPLAIN ANALYZE`. So you can find all information of SQL duration in the slow log.

8.3.2 Analyze system issues

System issues can be divided into the following types according to different execution stages of a SQL statement:

1. TiKV is slow in data processing. For example, the TiKV coprocessor processes data slowly.
2. TiDB is slow in execution. For example, a `Join` operator processes data slowly.
3. Other key stages are slow. For example, getting the timestamp takes a long time.

For each slow query, first determine to which type the query belongs, and then analyze it in detail.

8.3.2.1 TiKV is slow in data processing

If TiKV is slow in data processing, you can easily identify it in the result of `EXPLAIN ANALYZE`. In the following example, `StreamAgg_8` and `TableFullScan_15`, two `tikv-tasks` (as indicated by `cop[tikv]` in the `task` column), take `170ms` to execute. After subtracting `170ms`, the execution time of TiDB operators account for a very small proportion of the total execution time. This indicates that the bottleneck is in TiKV.

```
+--
    ↪ ------------------------+---------+---------+-----------+-----------------+-----
    ↪
```

```
| id                    | estRows | actRows | task   | access object |
    ↪ execution info                                                  |
    ↪ operator info               | memory   | disk |
+--
    ↪ ----------------------+---------+---------+----------+---------------+-----
    ↪
| StreamAgg_16            | 1.00    | 1       | root     |               | time
    ↪ :170.08572ms, loops:2                                             |
    ↪ funcs:count(Column#5)->Column#3 | 372 Bytes | N/A |
|  ─TableReader_17        | 1.00    | 1       | root     |               | time
    ↪ :170.080369ms, loops:2, rpc num: 1, rpc time:17.023347ms, proc keys
    ↪ :28672 | data:StreamAgg_8  | 202 Bytes | N/A |
|    ─StreamAgg_8         | 1.00    | 1       | cop[tikv] |              | time
    ↪ :170ms, loops:29                                                  |
    ↪ funcs:count(1)->Column#5    | N/A      | N/A |
|      ─TableFullScan_15  | 7.00    | 28672   | cop[tikv] | table:t    | time
    ↪ :170ms, loops:29                                                  |
    ↪ keep order:false, stats:pseudo | N/A   | N/A |
+--
    ↪ ----------------------+---------+---------+----------+---------------+-----
    ↪
```

In addition, the `Cop_process` and `Cop_wait` fields in the slow log can also help your analysis. In the following example, the total duration of the query is around `180.85ms`, and the largest `coptask` takes `171ms`. This indicates that the bottleneck of this query is on the TiKV side.

For the description of each field in the slow log, see fields description.

```
## Query_time: 0.18085
...
## Num_cop_tasks: 1
## Cop_process: Avg_time: 170ms P90_time: 170ms Max_time: 170ms Max_addr:
    ↪ 10.6.131.78
## Cop_wait: Avg_time: 1ms P90_time: 1ms Max_time: 1ms Max_Addr: 10.6.131.78
```

After identifying that TiKV is the bottleneck, you can find out the cause as described in the following sections.

8.3.2.1.1 TiKV instance is busy

During the execution of a SQL statement, TiDB might fetch data from multiple TiKV instances. If one TiKV instance responds slowly, the overall SQL execution speed is slowed down.

The `Cop_wait` field in the slow log can help you determine this cause.

```
## Cop_wait: Avg_time: 1ms P90_time: 2ms Max_time: 110ms Max_Addr:
   ↪ 10.6.131.78
```

The log above shows that a `cop-task` sent to the `10.6.131.78` instance waits `110ms` ↪ before being executed. It indicates that this instance is busy. You can check the CPU monitoring of that time to confirm the cause.

8.3.2.1.2 Too many outdated keys

A TiKV instance has much outdated data, which needs to be cleaned up for data scan. This impacts the processing speed.

Check `Total_keys` and `Processed_keys`. If they are greatly different, the TiKV instance has too many keys of the older versions.

```
...
## Total_keys: 2215187529 Processed_keys: 1108056368
...
```

8.3.2.2 Other key stages are slow

8.3.2.2.1 Slow in getting timestamps

You can compare `Wait_TS` and `Query_time` in the slow log. The timestamps are prefetched, so generally `Wait_TS` should be low.

```
## Query_time: 0.0300000
...
## Wait_TS: 0.02500000
```

8.3.2.2.2 Outdated Region information

Region information on the TiDB side might be outdated. In this situation, TiKV might return the `regionMiss` error. Then TiDB gets the Region information from PD again, which is reflected in the `Cop_backoff` information. Both the failed times and the total duration are recorded.

```
## Cop_backoff_regionMiss_total_times: 200 Cop_backoff_regionMiss_total_time
   ↪ : 0.2 Cop_backoff_regionMiss_max_time: 0.2
   ↪ Cop_backoff_regionMiss_max_addr: 127.0.0.1
   ↪ Cop_backoff_regionMiss_avg_time: 0.2 Cop_backoff_regionMiss_p90_time:
   ↪  0.2
## Cop_backoff_rpcPD_total_times: 200 Cop_backoff_rpcPD_total_time: 0.2
   ↪ Cop_backoff_rpcPD_max_time: 0.2 Cop_backoff_rpcPD_max_addr: 127.0.0.1
   ↪  Cop_backoff_rpcPD_avg_time: 0.2 Cop_backoff_rpcPD_p90_time: 0.2
```

8.3.2.2.3 Subqueries are executed in advance

For statements with non-correlated subqueries, the subquery part might be executed in advance. For example, in `select * from t1 where a = (select max(a)from t2)`, the `select max(a)from t2` part might be executed in advance in the optimization stage. The result of `EXPLAIN ANALYZE` does not show the duration of this type of subqueries.

```
mysql> explain analyze select count(*) from t where a=(select max(t1.a)
    ↪ from t t1, t t2 where t1.a=t2.a);
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
| id                          | estRows | actRows | task    | access object |
    ↪ execution info      | operator info                 | memory   | disk |
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
| StreamAgg_59                | 1.00    | 1       | root      |               | time
    ↪ :4.69267ms, loops:2 | funcs:count(Column#10)->Column#8 | 372 Bytes |
    ↪ N/A |
| └─TableReader_60            | 1.00    | 1       | root      |               |
    ↪ time:4.690428ms, loops:2 | data:StreamAgg_48          | 141 Bytes | N/A
    ↪  |
|   └─StreamAgg_48            | 1.00    |         | cop[tikv] |               |
    ↪ time:0ns, loops:0     | funcs:count(1)->Column#10    | N/A      | N/A
    ↪ |
|     └─Selection_58          | 16384.00 |       | cop[tikv] |               |
    ↪ time:0ns, loops:0     | eq(test.t.a, 1)              | N/A      | N/A
    ↪ |
|       └─TableFullScan_57    | 16384.00 | -1    | cop[tikv] | table:t       |
    ↪ time:0s, loops:0      | keep order:false             | N/A      | N/A
    ↪ |
+--
    ↪ ---------------------------+----------+---------+-----------+---------------+--
    ↪
5 rows in set (7.77 sec)
```

But you can identify this type of subquery execution in the slow log:

```
## Query_time: 7.770634843
...
## Rewrite_time: 7.765673663 Preproc_subqueries: 1 Preproc_subqueries_time:
    ↪ 7.765231874
```

From log record above, you can see that a subquery is executed in advance and takes `7.76s`.

8.3.2.3 TiDB is slow in execution

Assume that the execution plan in TiDB is correct but the execution is slow. To solve this type of issue, you can adjust parameters or use the hint according to the result of `EXPLAIN ANALYZE` for the SQL statement.

If the execution plan is incorrect, see the Analyze optimizer issues section.

8.3.2.3.1 Low concurrency

If the bottleneck is in the operator with concurrency, speed up the execution by adjusting the concurrency. For example:

```
mysql> explain analyze select sum(t1.a) from t t1, t t2 where t1.a=t2.a;
+--
   ↪ ------------------------------+-------------+----------+----------+-------
   ↪
| id                            | estRows     | actRows  | task     | access
   ↪ object | execution info
   ↪                                                                  | operator
   ↪ info                                | memory         | disk   |
+--
   ↪ ------------------------------+-------------+----------+----------+-------
   ↪
| HashAgg_11                    | 1.00        | 1        | root     |
   ↪             | time:9.666832189s, loops:2, PartialConcurrency:4,
   ↪ FinalConcurrency:4     | funcs:sum(Column#6)->Column#5            |
   ↪ 322.125 KB     | N/A    |
|  ─Projection_24               | 268435456.00 | 268435456 | root |
   ↪             | time:9.098644711s, loops:262145, Concurrency:4
   ↪                               | cast(test.t.a, decimal(65,0) BINARY)->
   ↪ Column#6 | 199 KB   | N/A    |
|    ─HashJoin_14               | 268435456.00 | 268435456 | root |
   ↪             | time:6.616773501s, loops:262145, Concurrency:5, probe
   ↪ collision:0, build:881.404µs | inner join, equal:[eq(test.t.a, test.t
   ↪ .a)] | 131.75 KB | 0 Bytes |

   ↪             | time:6.553717ms, loops:17
   ↪                                                  | data:Selection_20
   ↪                          | 33.6318359375 KB | N/A  |
|        ─Selection_20          | 16384.00    |          | cop[tikv] |
   ↪           | time:0ns, loops:0
   ↪                                                             | not(isnull(
   ↪ test.t.a))                      | N/A            | N/A    |
|          ─TableFullScan_19    | 16384.00    | -1       | cop[tikv] | table:
   ↪ t2   | time:0s, loops:0
   ↪                                                              | keep order:
```

```
    ↪ false                          | N/A            | N/A    |
|     └─TableReader_18(Probe)   | 16384.00   | 16384    | root     |
    ↪              | time:6.880923ms, loops:17
    ↪                                                  | data:Selection_17
    ↪                          | 33.6318359375 KB | N/A  |
|       └─Selection_17          | 16384.00   |          | cop[tikv] |
    ↪            | time:0ns, loops:0
    ↪                                                        | not(isnull(
    ↪ test.t.a))                     | N/A            | N/A    |
|         └─TableFullScan_16    | 16384.00   | -1       | cop[tikv] | table:
    ↪ t1   | time:0s, loops:0
    ↪                                                         | keep order:
    ↪ false                          | N/A            | N/A    |
+--
    ↪ ------------------------------+--------------+----------+----------+--------
    ↪
9 rows in set (9.67 sec)
```

As shown above, `HashJoin_14` and `Projection_24` consume much of the execution time. Consider increasing their concurrency using SQL variables to speed up execution.

All system variables are documented in system-variables. To increase the concurrency of `HashJoin_14`, you can modify the `tidb_hash_join_concurrency` system variable.

8.3.2.3.2 Data is spilled to disk

Another cause of slow execution is disk spill that occurs during execution if the memory limit is reached. You can find out this cause in the execution plan and the slow log:

```
+--
    ↪ ----------------------+----------+---------+----------+--------------+------
    ↪
| id                    | estRows  | actRows | task    | access object |
    ↪ execution info          | operator info     | memory             |
    ↪ disk         |
+--
    ↪ ----------------------+----------+---------+----------+--------------+------
    ↪
| Sort_4                | 462144.00 | 462144 | root   |              | time
    ↪ :2.02848898s, loops:453 | test.t.a       | 149.68795776367188 MB |
    ↪ 219.3203125 MB |
|  └─TableReader_8      | 462144.00 | 462144 | root   |              | time
    ↪ :616.211272ms, loops:453 | data:TableFullScan_7 | 197.49601364135742
    ↪ MB | N/A |

    ↪ s, loops:0          | keep order:false  | N/A                | N/A
```

```
    ↪          |
+--
    ↪ ----------------------+----------+--------+----------+-------------+------
    ↪
```

```
...
## Disk_max: 229974016
...
```

8.3.2.3.3 Join operations with Cartesian product

Join operations with Cartesian product generate data volume as large as `left child row count * right child row count`. This is inefficient and should be avoided.

This type of join operations is marked `CARTESIAN` in the execution plan. For example:

```
mysql> explain select * from t t1, t t2 where t1.a>t2.a;
+--
    ↪ --------------------------+------------+----------+-------------+--------
    ↪
| id                          | estRows    | task     | access object | operator
    ↪  info                                  |
+--
    ↪ --------------------------+------------+----------+-------------+--------
    ↪
| HashJoin_8                  | 99800100.00 | root   |             | CARTESIAN
    ↪ inner join, other cond:gt(test.t.a, test.t.a) |
|  ─TableReader_15(Build)   | 9990.00    | root     |             | data:
    ↪ Selection_14                                 |
|    ─Selection_14          | 9990.00    | cop[tikv] |            | not(
    ↪ isnull(test.t.a))                             |

```

8.3.3 Analyze optimizer issues

To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. You need to have some understanding of the optimization process and each operator.

For the following examples, assume that the table schema is `create table t (id int , a int, b int, c int, primary key(id), key(a), key(b, c))`.

1. `select * from t`: There is no filter condition and a full table scan is performed. So the `TableFullScan` operator is used to read data.
2. `select a from t where a=2`: There is a filter condition and only the index columns are read, so the `IndexReader` operator is used to read data.
3. `select * from t where a=2`: There is a filter condition for `a` but the `a` index cannot fully cover the data to be read, so the `IndexLookup` operator is used.
4. `select b from t where c=3`: Without the prefix condition, the multi-column index cannot be used. So the `IndexFullScan` is used.
5. …

The examples above are operators used for data reads. For more operators, see Understand TiDB Execution Plan.

In addition, reading SQL Tuning Overview helps you better understand the TiDB optimizer and determine whether the execution plan is reasonable or not.

Most optimizer issues are explained in SQL Tuning Overview. For the solutions, see the following documents:

1. Wrong Index Solution
2. Wrong join order
3. Expressions are not pushed down

8.4 SQL Diagnostics

> **Warning:**
>
> SQL diagnostics is still an experimental feature. It is **NOT** recommended that you use it in the production environment.

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

8.4.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table**: The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query these information using SQL statements.
- **Cluster monitoring table**: The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

8.4.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.

- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the sysctl information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

8.4.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.` ↪ `metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

8.4.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

8.5 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `mem-quota-query` (1 GB by default) to the tidb-server log file ("tidb.log" by default).

> **Note:**
>
> The expensive query log differs from the slow query log in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

8.5.1 Expensive query log example

```
[2020/02/05 15:32:25.096 +08:00] [WARN] [expensivequery.go:167] [
    ↪ expensive_query] [cost_time=60.008338935s] [wait_time=0s] [
    ↪ request_count=1] [total_keys=70] [process_keys=65] [num_cop_tasks=1]
    ↪ [process_avg_time=0s] [process_p90_time=0s] [process_max_time=0s] [
    ↪ process_max_addr=10.0.1.9:20160] [wait_avg_time=0.002s] [
    ↪ wait_p90_time=0.002s] [wait_max_time=0.002s] [wait_max_addr
    ↪ =10.0.1.9:20160] [stats=t:pseudo] [conn_id=60026] [user=root] [
```

```
↪ database=test] [table_ids="[122]"] [txn_start_ts=414420273735139329]
↪ [mem_max="1035 Bytes (1.0107421875 KB)"] [sql="insert into t select
↪ sleep(1) from t"]
```

8.5.2 Fields description

Basic fields:

- `cost_time`: The execution time of a statement when the log is printed.
- `stats`: The version of statistics used by the tables or indexes involved in a statement. If the value is `pseudo`, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- `table_ids`: The IDs of the tables involved in a statement.
- `txn_start_ts`: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- `sql`: The sql statement.

Memory usage related fields:

- `mem_max`: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is `60026`.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.
- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.

- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

8.6 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided statement summary tables in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` in terms of features.

- `statements_summary`
- `statements_summary_history`
- `cluster_statements_summary`
- `cluster_statements_summary_history`
- `statements_summary_evicted`

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

8.6.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the SQL digest and the plan digest, and provides statistics for each SQL category.

The "SQL digest" here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
    ↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The "plan digest" here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
  SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
    SUMMARY_END_TIME: 2020-01-02 11:30:00
           STMT_TYPE: Select
         SCHEMA_NAME: test
              DIGEST: 0611
                  ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
                  ↪
         DIGEST_TEXT: select * from employee where id = ?
         TABLE_NAMES: test.employee
         INDEX_NAMES: NULL
         SAMPLE_USER: root
          EXEC_COUNT: 3
         SUM_LATENCY: 1035161
         MAX_LATENCY: 399594
         MIN_LATENCY: 301353
         AVG_LATENCY: 345053
   AVG_PARSE_LATENCY: 57000
   MAX_PARSE_LATENCY: 57000
AVG_COMPILE_LATENCY: 175458
MAX_COMPILE_LATENCY: 175458
....................
             AVG_MEM: 103
             MAX_MEM: 103
            AVG_DISK: 65535
            MAX_DISK: 65535
  AVG_AFFECTED_ROWS: 0
```

```
        FIRST_SEEN: 2020-01-02 11:12:54
         LAST_SEEN: 2020-01-02 11:25:24
QUERY_SAMPLE_TEXT: select * from employee where id=3100
 PREV_SAMPLE_TEXT:
      PLAN_DIGEST:
          ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
          ↪
             PLAN: Point_Get_1   root   1      table:employee, handle:3100
```

Note:

In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).

8.6.2 `statements_summary_history`

The table schema of `statements_summary_history` is identical to that of `statements_summary` ↪ . `statements_summary_history` saves the historical data of a time range. By checking historical data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

8.6.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` variable controls the maximum number of statements that the `statement_summary` table stores in memory. The `statement_summary` ↪ table uses the LRU algorithm. Once the number of SQL statements exceeds the `tidb_stmt_summary_max_stmt_count` value, the longest unused record is evicted from the table. The number of evicted SQL statements during each period is recorded in the `statements_summary_evicted` table.

The `statements_summary_evicted` table is updated only when a SQL record is evicted from the `statement_summary` table. The `statements_summary_evicted` only records the period during which the eviction occurs and the number of evicted SQL statements.

8.6.4 The `cluster` tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` ↪ tables only show the statement summary of a single TiDB server. To query

the data of the entire cluster, you need to query the `cluster_statements_summary` ↪ , `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` ↪ data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as those in `statements_summary`.

8.6.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. `1` represents `enable`, and `0` means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.
- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` ↪ table is refreshed. The time unit is second (s). The default value is `1800`.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statement_summary_evicted` table. The default value is `24`.
- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL statements that can be stored in statement summary tables. Before v5.1.1, the default value is `200`. Since v5.1.1, the default value is `3000`. If the limit is exceeded, those SQL statements that recently remain unused are cleared. These cleared SQL statements are recorded in the `statement_summary_evicted` table.
- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is `4096`.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. `1` means to count, and `0` means not to count. The default value is `0`.

> **Note:**
>
> When a category of SQL statement needs to be removed because the `tidb_stmt_summary_max_stmt_count` limit is exceeded, TiDB removes the data of that SQL statement category of all time ranges from the `statement_summary_history` table. Therefore, even if the number of SQL statement categories in a certain time range does not reach the limit, the

number of SQL statements stored in the `statement_summary_history` table is less than the actual number of SQL statements. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the configuration above takes effect, every 30 minutes the `statements_summary` table is cleared. The `statements_summary_history` table stores data generated over the recent 12 hours.

The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` table is updated every 30 minutes.

The system variables above have two scopes: global and session. These scopes work differently from other system variables:

- After setting the global variable, your setting applies to the whole cluster immediately.
- After setting the session variable, your setting applies to the current TiDB server immediately. This is useful when you debug on a single TiDB server instance.
- The session variable has a higher read priority. The global variable is read only when no session variable is set.
- If you set the session variable to a blank string, the global variable is re-read.

Note:

The `tidb_stmt_summary_history_size`, `tidb_stmt_summary_max_stmt_count`, and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs. It is not recommended to set them too large values.

8.6.5.1 Set a proper size for statement summary

After the system has run for a period of time, you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----------------------------------------+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----------------------------------------+
| 3000                                    |
+-----------------------------------------+
1 row in set (0.001 sec)

+----------+
| count(*) |
+----------+
|     3001 |
+----------+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+---------------------+---------------------+--------------+
| BEGIN_TIME          | END_TIME            | EVICTED_COUNT |
+---------------------+---------------------+--------------+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 |     59 |
+---------------------+---------------------+--------------+
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 |     45 |
+---------------------+---------------------+--------------+
2 row in set (0.001 sec)
```

From the preceding result, you can see that a maximum of 59 SQL categories are evicted. In this case, it is recommended that you increase the size of the `statement_summary` table by at least 59 records, which means increasing the size to at least 3059 records.

8.6.6 Limitation

The statement summary tables have the following limitation:

All data of the statement summary tables above will be lost when the TiDB server is restarted. This is because statement summary tables are all memory tables, and the data is cached in memory instead of being persisted on storage.

8.6.7 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

8.6.7.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary
    WHERE digest_text LIKE 'select * from employee%';
```

`1ms` and `0.3ms` are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-------------+-----------+-----------------------------------------+
| avg_latency | exec_count | query_sample_text                      |
+-------------+-----------+-----------------------------------------+
|     1042040 |         2 | select * from employee where name='eric' |
|      345053 |         3 | select * from employee where id=3100 |
+-------------+-----------+-----------------------------------------+
2 rows in set (0.00 sec)
```

8.6.7.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
    FROM information_schema.statements_summary_history
    WHERE summary_begin_time='2020-01-02 10:00:00'
    ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
| sum_latency | avg_latency | exec_count | query_sample_text
    ↪                                        |
+--
    ↪ -----------+-------------+-----------+-----------------------------------
    ↪
```

```
|    7855660 |   1122237 |       7 | select avg(salary) from employee
    ↪ where company_id=2013      |
|    7241960 |   1448392 |       5 | select * from employee join company
    ↪ on employee.company_id=company.id |
|    2084081 |   1042040 |       2 | select * from employee where name='
    ↪ eric'                     |
+--
    ↪ ----------+-------------+-----------+-----------------------------------
    ↪
3 rows in set (0.00 sec)
```

8.6.8 Fields description

8.6.8.1 `statements_summary` fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.
- `INDEX_NAMES`: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- `SAMPLE_USER`: The users who execute SQL statements of this category. Only one user is taken.
- `PLAN_DIGEST`: The digest of the execution plan.
- `PLAN`: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- `PLAN_CACHE_HITS`: The total number of times that SQL statements of this category hit the plan cache.
- `PLAN_IN_CACHE`: Indicates whether the previous execution of SQL statements of this category hit the plan cache.

Fields related to execution time:

- `SUMMARY_BEGIN_TIME`: The beginning time of the current summary period.
- `SUMMARY_END_TIME`: The ending time of the current summary period.

- `FIRST_SEEN`: The time when SQL statements of this category are seen for the first time.
- `LAST_SEEN`: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- `EXEC_COUNT`: Total execution times of SQL statements of this category.
- `SUM_ERRORS`: The sum of errors occurred during execution.
- `SUM_WARNINGS`: The sum of warnings occurred during execution.
- `SUM_LATENCY`: The total execution latency of SQL statements of this category.
- `MAX_LATENCY`: The maximum execution latency of SQL statements of this category.
- `MIN_LATENCY`: The minimum execution latency of SQL statements of this category.
- `AVG_LATENCY`: The average execution latency of SQL statements of this category.
- `AVG_PARSE_LATENCY`: The average latency of the parser.
- `MAX_PARSE_LATENCY`: The maximum latency of the parser.
- `AVG_COMPILE_LATENCY`: The average latency of the compiler.
- `MAX_COMPILE_LATENCY`: The maximum latency of the compiler.
- `AVG_MEM`: The average memory (byte) used.
- `MAX_MEM`: The maximum memory (byte) used.
- `AVG_DISK`: The average disk space (byte) used.
- `MAX_DISK`: The maximum disk space (byte) used.

Fields related to TiKV Coprocessor task:

- `SUM_COP_TASK_NUM`: The total number of Coprocessor requests sent.
- `MAX_COP_PROCESS_TIME`: The maximum execution time of Coprocessor tasks.
- `MAX_COP_PROCESS_ADDRESS`: The address of the Coprocessor task with the maximum execution time.
- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.
- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.

- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.
- `AVG_TXN_RETRY`: The average number of transaction retries.
- `MAX_TXN_RETRY`: The maximum number of transaction retries.
- `SUM_BACKOFF_TIMES`: The sum of retries when SQL statements of this category encounter errors that require a retry.
- `BACKOFF_TYPES`: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- `AVG_AFFECTED_ROWS`: The average number of rows affected.
- `PREV_SAMPLE_TEXT`: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

8.6.8.2 `statements_summary_evicted` fields description

- `BEGIN_TIME`: Records the starting time.

- `END_TIME`: Records the ending time.
- `EVICTED_COUNT`: The number of SQL categories that are evicted during the record period.

8.7 Troubleshoot Hotspot Issues

This document describes how to locate and resolve the problem of read and write hotspots.

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency.

8.7.1 Common hotspots

This section describes TiDB encoding rules, table hotspots, and index hotspots.

8.7.1.1 TiDB encoding rules

TiDB assigns a TableID to each table, an IndexID to each index, and a RowID to each row. By default, if the table uses an integer primary key, the value of the primary key is treated as the RowID. Among these IDs, TableID is unique in the entire cluster, while IndexID and RowID are unique in the table. The type of all these IDs is int64.

Each row of data is encoded as a key-value pair according to the following rule:

```
Key: tablePrefix{tableID}_recordPrefixSep{rowID}
Value: [col1, col2, col3, col4]
```

The `tablePrefix` and `recordPrefixSep` of the key are specific string constants, used to distinguish from other data in the KV space.

For Index data, the key-value pair is encoded according to the following rule:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: rowID
```

Index data has two types: the unique index and the non-unique index.

- For unique indexes, you can follow the coding rules above.

- For non-unique indexes, a unique key cannot be constructed through this encoding, because the `tablePrefix{tableID}_indexPrefixSep{indexID}` of the same index is the same and the `ColumnsValue` of multiple rows might be the same. The encoding rule for non-unique indexes is as follows:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}
    ↪ _indexedColumnsValue_rowID
Value: null
```

8.7.1.2 Table hotspots

According to TiDB coding rules, the data of the same table is in a range prefixed by the beginning of the TableID, and the data is arranged in the order of RowID values. When RowID values are incremented during table inserting, the inserted line can only be appended to the end. The Region will split after it reaches a certain size, and then it still can only be appended to the end of the range. The `INSERT` operation can only be executed on one Region, forming a hotspot.

The common auto-increment primary key is sequentially increasing. When the primary key is of the integer type, the value of the primary key is used as the RowID by default. At this time, the RowID is sequentially increasing, and a write hotspot of the table forms when a large number of `INSERT` operations exist.

Meanwhile, the RowID in TiDB is also sequentially auto-incremental by default. When the primary key is not an integer type, you might also encounter the problem of write hotspots.

8.7.1.3 Index hotspots

Index hotspots are similar to table hotspots. Common index hotspots appear in fields that are monotonously increasing in time order, or `INSERT` scenarios with a large number of repeated values.

8.7.2 Identify hotspot issues

Performance problems are not necessarily caused by hotspots and might be caused by multiple factors. Before troubleshooting issues, confirm whether it is related to hotspots.

- To judge write hotspots, open **Hot Write** in the **TiKV-Trouble-Shooting** monitoring panel to check whether the Raftstore CPU metric value of any TiKV node is significantly higher than that of other nodes.
- To judge read hotspots, open **Thread_CPU** in the **TiKV-Details** monitoring panel to check whether the coprocessor CPU metric value of any TiKV node is particularly high.

8.7.2.1 Use TiDB Dashboard to locate hotspot tables

The **Key Visualizer** feature in TiDB Dashboard helps users narrow down hotspot troubleshooting scope to the table level. The following is an example of the thermal diagram shown by **Key Visualizer**. The horizontal axis of the graph is time, and the vertical axis are various tables and indexes. The brighter the color, the greater the load. You can switch the read or write flow in the toolbar.

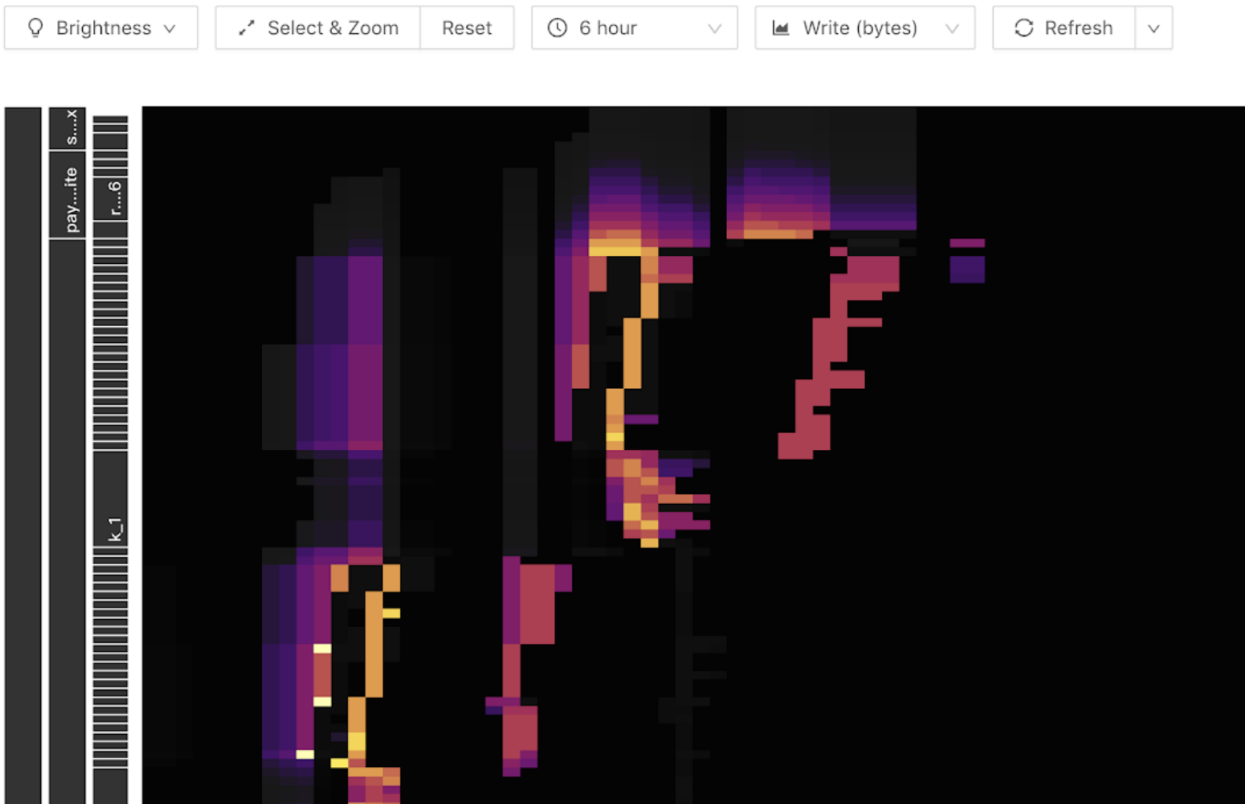

Figure 48: Dashboard Example 1

The following bright diagonal lines (oblique upward or downward) can appear in the write flow graph. Because the write only appears at the end, as the number of table Regions becomes larger, it appears as a ladder. This indicates that a write hotspot shows in this table:

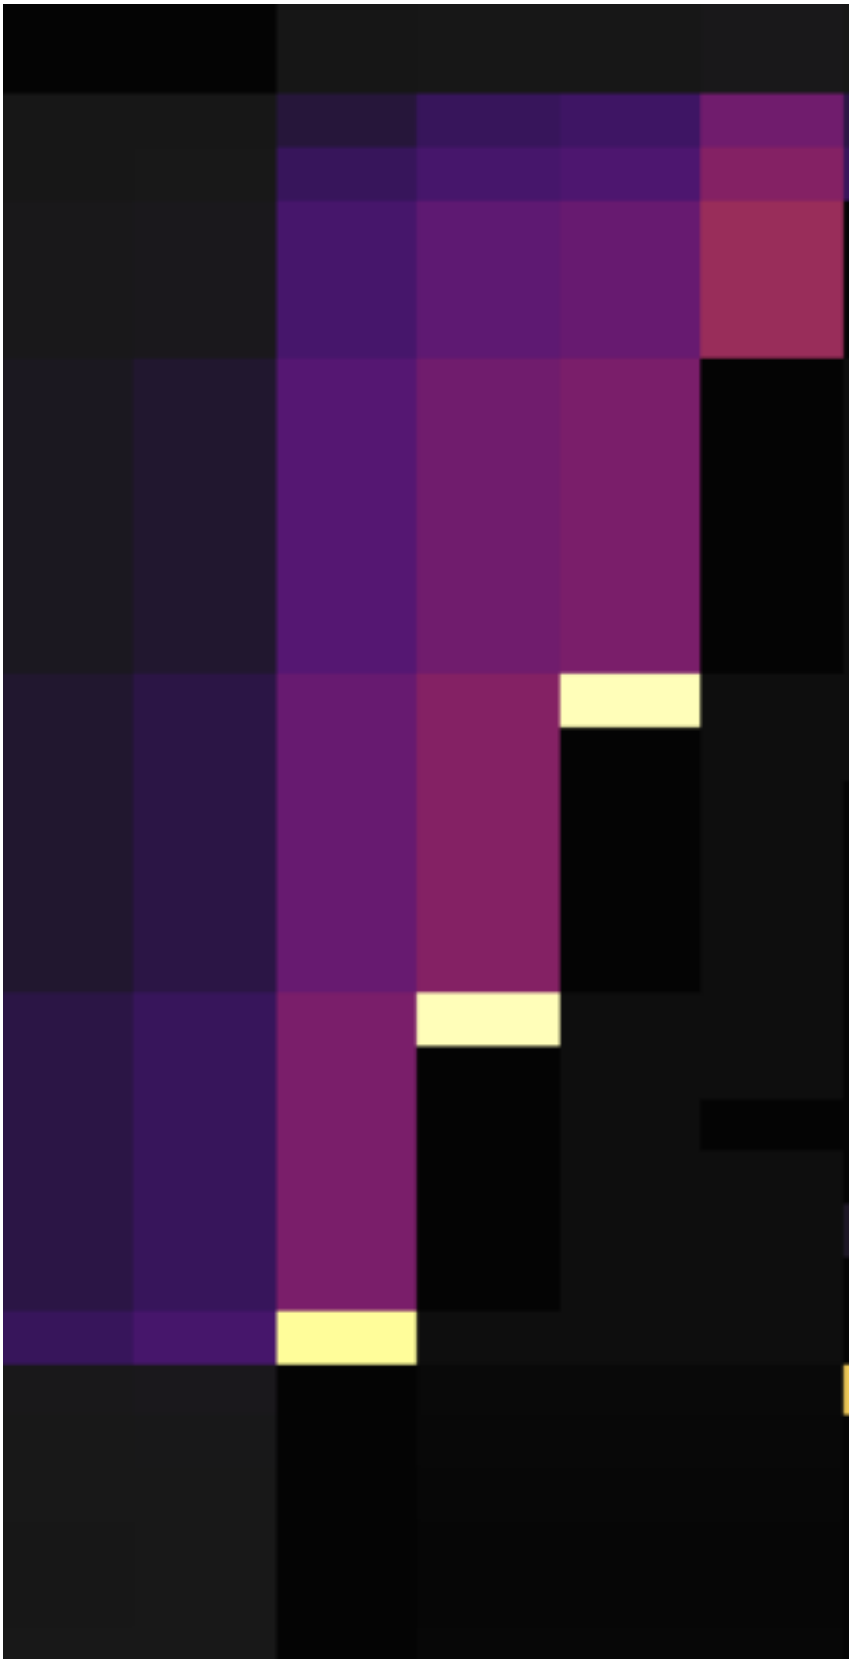

Figure 49: Dashboard Example 2

For read hotspots, a bright horizontal line is generally shown in the thermal diagram. Usually these are caused by small tables with a large number of accesses, shown as follows:

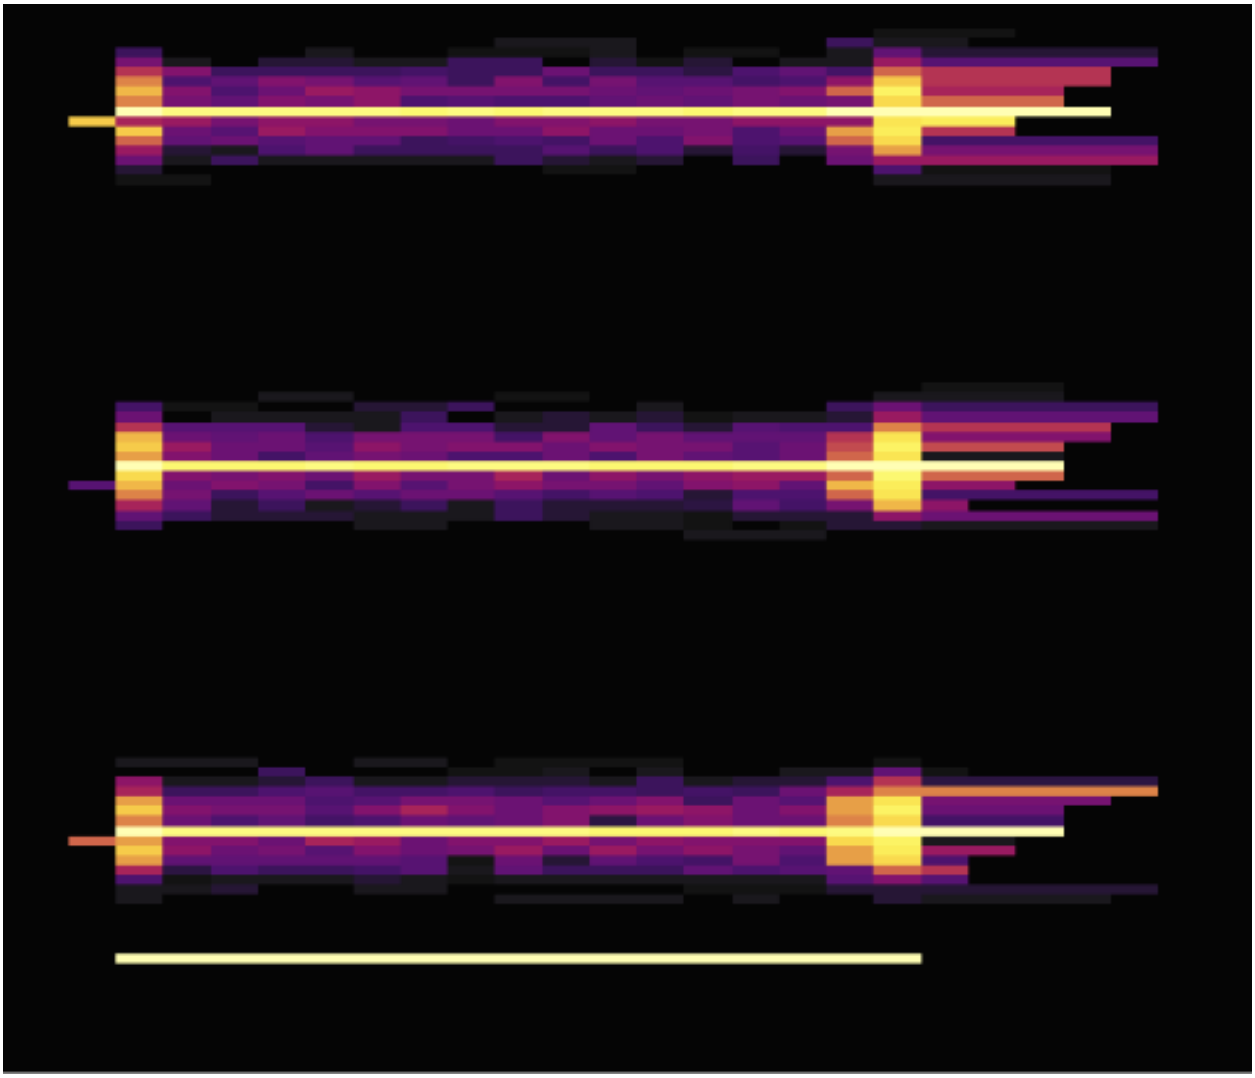

Figure 50: Dashboard Example 3

Hover over the bright block, you can see what table or index has a heavy load. For example:

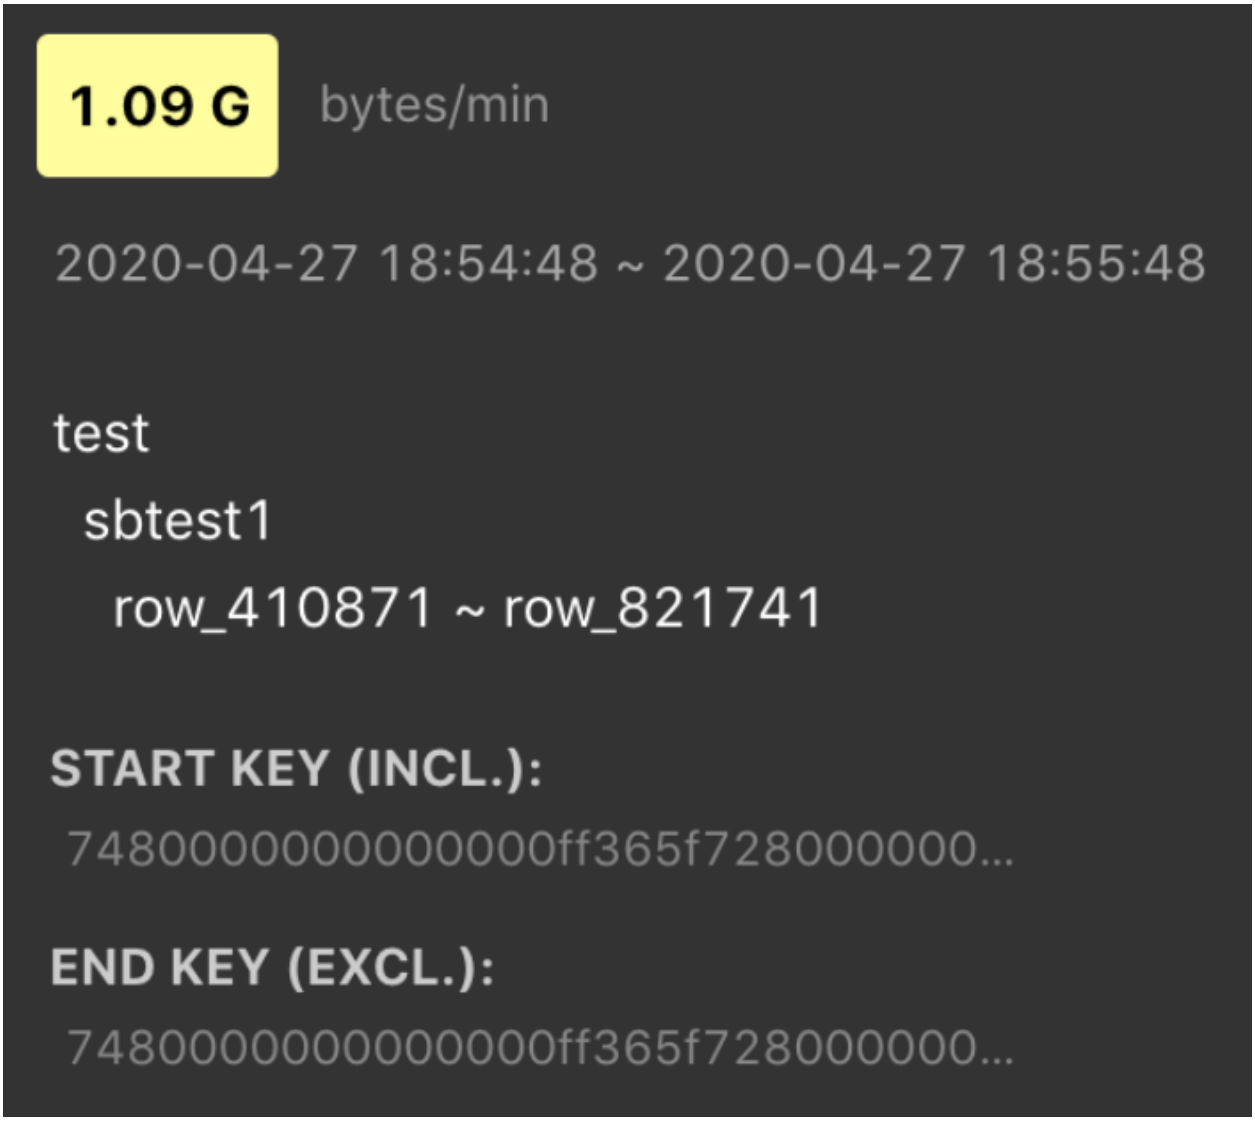

Figure 51: Dashboard Example 4

8.7.3 Use `SHARD_ROW_ID_BITS` to process hotspots

For a non-integer primary key or a table without a primary key or a joint primary key, TiDB uses an implicit auto-increment RowID. When a large number of `INSERT` operations exist, the data is written into a single Region, resulting in a write hotspot.

By setting `SHARD_ROW_ID_BITS`, RowID are scattered and written into multiple Regions, which can alleviates the write hotspot issue. However, if you set `SHARD_ROW_ID_BITS` to an over large value, the number of RPC requests will be enlarged, increasing CPU and network overhead.

```
SHARD_ROW_ID_BITS = 4 # Represents 16 shards.
SHARD_ROW_ID_BITS = 6 # Represents 64 shards.
```

```
SHARD_ROW_ID_BITS = 0 # Represents the default 1 shard.
```

Statement example:

```
CREATE TABLE: CREATE TABLE t (c int) SHARD_ROW_ID_BITS = 4;
ALTER TABLE: ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

The value of `SHARD_ROW_ID_BITS` can be dynamically modified. The modified value only takes effect for newly written data.

For the table with a primary key of the `CLUSTERED` type, TiDB uses the primary key of the table as the RowID. At this time, the `SHARD_ROW_ID_BITS` option cannot be used because it changes the RowID generation rules. For the table with the primary key of the `NONCLUSTERED` type, TiDB uses an automatically allocated 64-bit integer as the RowID. In this case, you can use the `SHARD_ROW_ID_BITS` feature. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

The following two load diagrams shows the case where two tables without primary keys use `SHARD_ROW_ID_BITS` to scatter hotspots. The first diagram shows the situation before scattering hotspots, while the second one shows the situation after scattering hotspots.

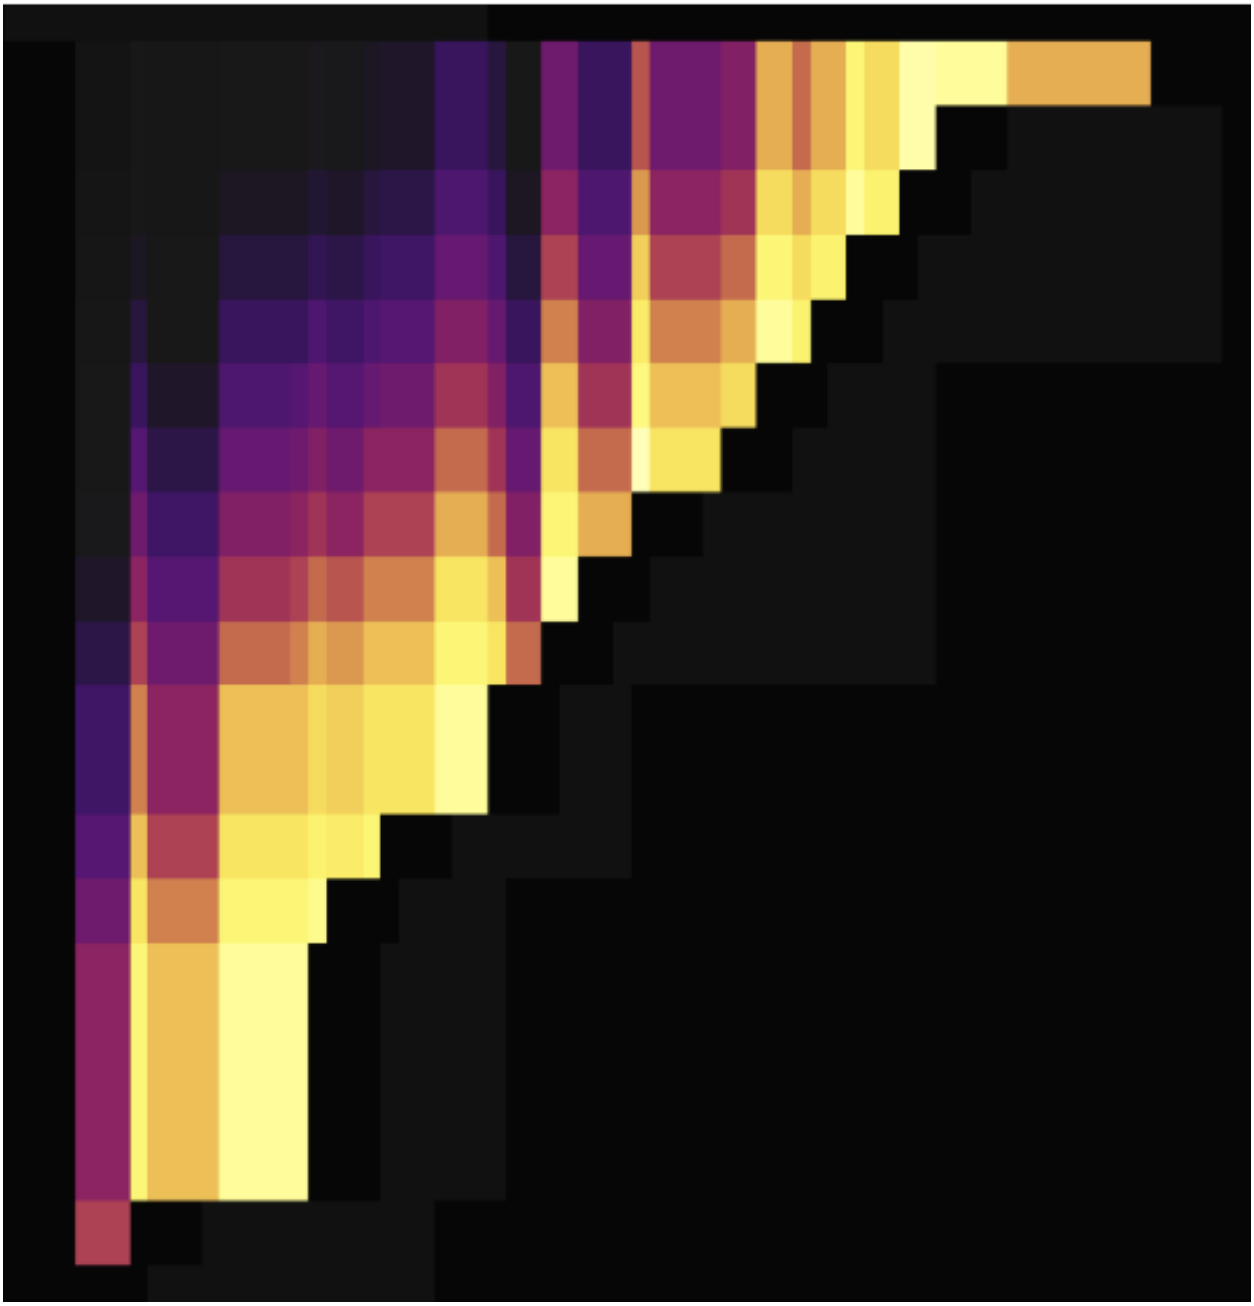

Figure 52: Dashboard Example 5

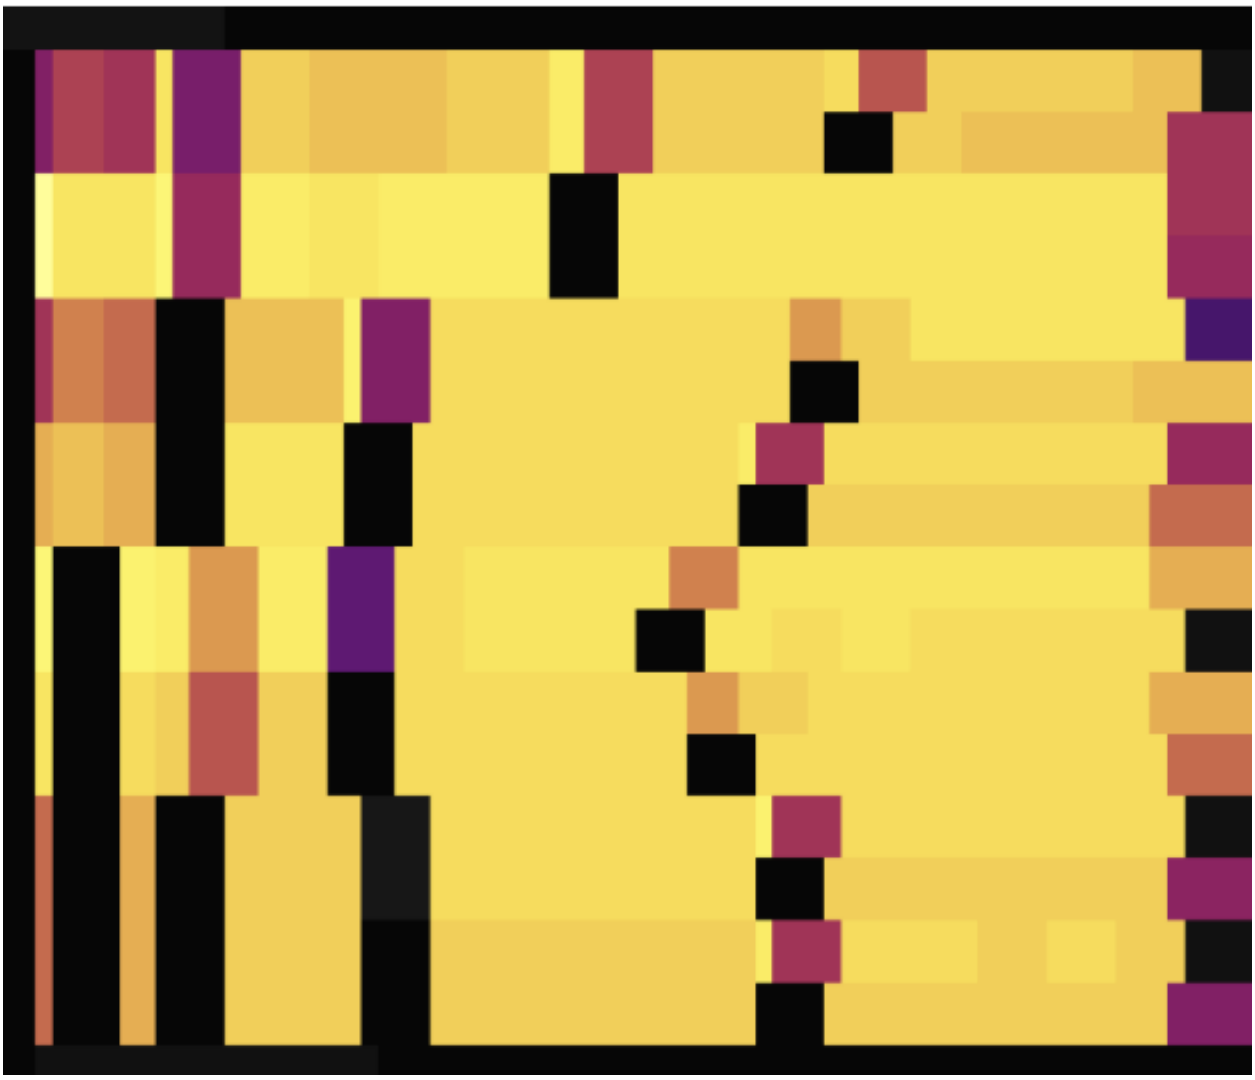

Figure 53: Dashboard Example 6

As shown in the load diagrams above, before setting `SHARD_ROW_ID_BITS`, load hotspots are concentrated on a single Region. After setting `SHARD_ROW_ID_BITS`, load hotspots become scattered.

8.7.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM`

To resolve the write hotspots brought by auto-increment primary keys, use `AUTO_RANDOM` to handle hotspot tables that have auto-increment primary keys.

If this feature is enabled, TiDB generates randomly distributed and non-repeated (before the space is used up) primary keys to achieve the purpose of scattering write hotspots.

Note that the primary keys generated by TiDB are no longer auto-increment primary keys and you can use `LAST_INSERT_ID()` to obtain the primary key value assigned last time.

To use this feature, modify `AUTO_INCREMENT` to `AUTO_RANDOM` in the `CREATE TABLE` statement. This feature is suitable for non-application scenarios where the primary keys only need to guarantee uniqueness.

For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b varchar(255));
INSERT INTO t (b) VALUES ("foo");
SELECT * FROM t;
```

```
+------------+---+
| a          | b |
+------------+---+
| 1073741825 | b |
+------------+---+
```

```
SELECT LAST_INSERT_ID();
```

```
+------------------+
| LAST_INSERT_ID() |
+------------------+
| 1073741825       |
+------------------+
```

The following two load diagrams shows the situations both before and after modifying `AUTO_INCREMENT` to `AUTO_RANDOM` to scatter hotspots. The first one uses `AUTO_INCREMENT`, while the second one uses `AUTO_RANDOM`.

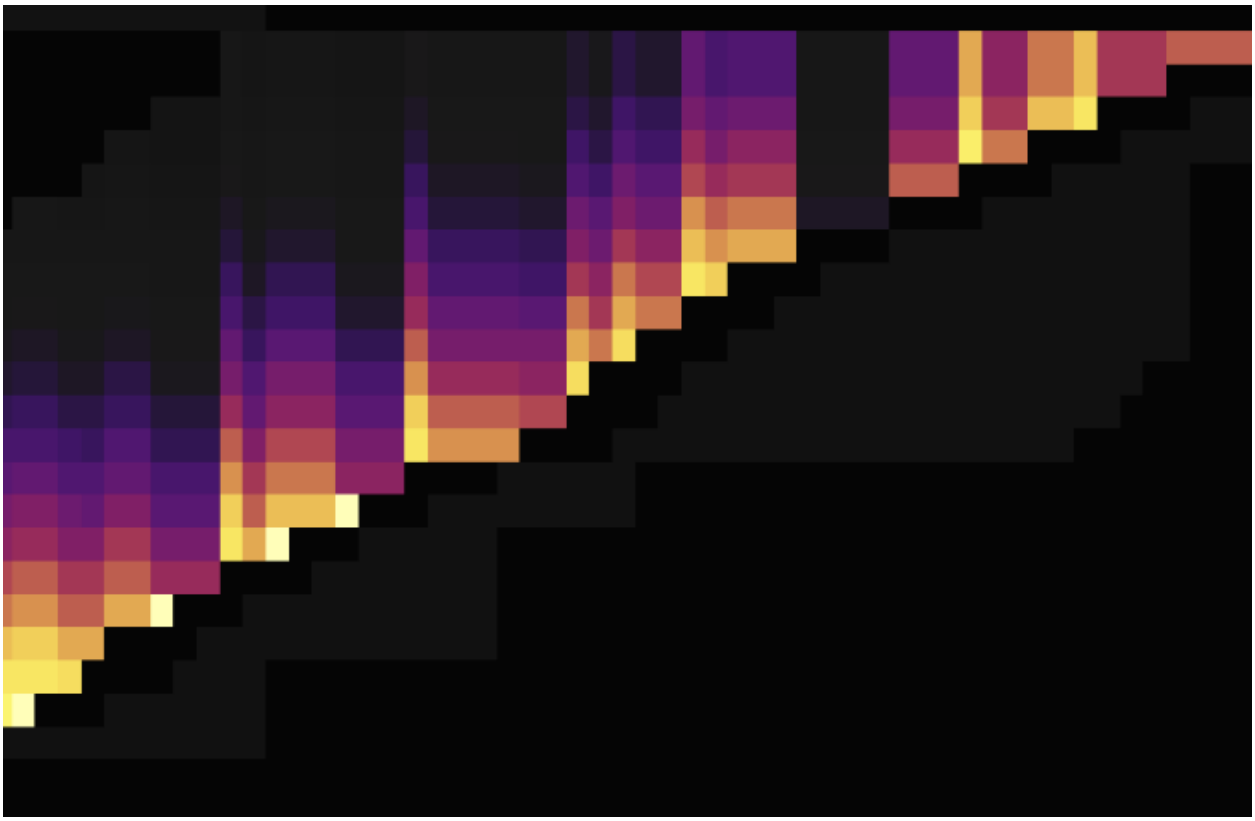

Figure 54: Dashboard Example 7

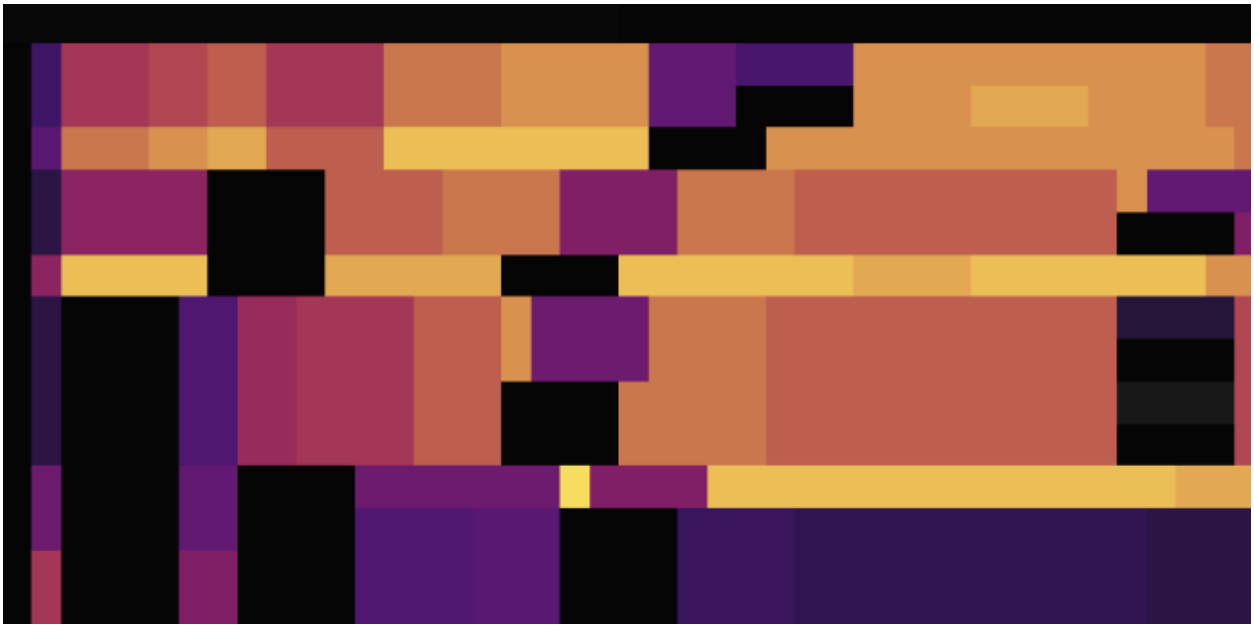

Figure 55: Dashboard Example 8

As shown in the load diagrams above, using `AUTO_RANDOM` to replace `AUTO_INCREMENT` can well scatter hotspots.

For more details, see AUTO_RANDOM.

8.7.5 Optimization of small table hotspots

The Coprocessor Cache feature of TiDB supports pushing down computing result caches. After this feature is enabled, TiDB caches the computing results that will be pushed down to TiKV. This feature works well for read hotspots of small tables.

For more details, see Coprocessor Cache.

8.8 Troubleshoot Increased Read and Write Latency

This document introduces the possible causes of read and write latency and jitters, and how to troubleshoot these issues.

8.8.1 Common causes

8.8.1.1 Incorrect TiDB execution plan

The execution plan of queries is unstable and might select the incorrect index, which causes higher latency.

8.8.1.1.1 Phenomenon

- If the query execution plan is output in the slow log, you can directly view the plan. Execute the `select tidb_decode_plan('xxx...')` statement to parse the detailed execution plan.
- The number of scanned keys in the monitor abnormally increases; in the slow log, the number of `Scan Keys` are large.
- The SQL execution duration in TiDB is greatly different than that in other databases such as MySQL. You can compare the execution plan of other databases (for example, whether `Join Order` is different).

8.8.1.1.2 Possible reason

The statistics is inaccurate.

8.8.1.1.3 Troubleshooting methods

- Update the statistical information
  - Execute `analyze table` manually and execute `analyze` periodically with the `crontab` command to keep the statistics accurate.
  - Execute `auto analyze` automatically. Lower the threshold value of `analyze ratio`, increase the frequency of information collection, and set the start and end time of the execution. See the following examples:
    * `set global tidb_auto_analyze_ratio=0.2;`
    * `set global tidb_auto_analyze_start_time='00:00 +0800';`
    * `set global tidb_auto_analyze_end_time='06:00 +0800';`
- Bind the execution plan
  - Modify the application SQL statements and execute `use index` to consistently use the index of the column.
  - In 3.0 versions, you do not need to modify the application SQL statements. Use `create global binding` to create the binding SQL statement of `force index`.
  - In 4.0 versions, SQL Plan Management is supported, which avoids the performance decrease caused by unstable execution plans.

8.8.1.2 PD anomalies

8.8.1.2.1 Phenomenon

There is an abnormal increase of the `wait duration` metric for the PD TSO. This metric represents the duration of waiting for PD to return requests.

8.8.1.2.2 Possible reasons

- Disk issue. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana -> disk performance -> latency/load**. You can also use the FIO tool to run a check on the disk if necessary.
- Network issues between PD peers. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana -> PD -> etcd**.
- High server load. The log shows `server is likely overloaded`.
- PD cannot elect a Leader: The PD log shows `lease is not expired`. This issue has been fixed in v3.0.x and v2.1.19.

- The leader election is slow. The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region-storage` to `true`, which significantly reduce the Region loading duration.
- The network issue between TiDB and PD. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana -> black-box_exporter -> ping latency**.
- PD reports the `FATAL` error, and the log shows `range failed to find revision pair`. This issue has been fixed in v3.0.8 (#2040).
- When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 (#1986).
- PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that `TCP InSegs` is relatively large. This issue has been fixed in v3.0.6 (#1952).
- PD panics. Report a bug.
- Other causes. Get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and report a bug.

8.8.1.3 TiKV anomalies

8.8.1.3.1 Phenomenon

The `KV Cmd Duration` metric in the monitor increases abnormally. This metric represents the duration between the time that TiDB sends a request to TiKV and the time that TiDB receives the response.

8.8.1.3.2 Possible reasons

- Check the `gRPC duration` metric. This metric represents the total duration of a gRPC request in TiKV. You can find out the potential network issue by comparing `gRPC duration` of TiKV and `KV duration` of TiDB. For example, the gRPC duration is short but the KV duration of TiDB is long, which indicates that the network latency between TiDB and TiKV might be high, or that the NIC bandwidth between TiDB and TiKV is fully occupied.
- Re-election because TiKV is restarted.
  - After TiKV panics, it is pulled up by `systemd` and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, report a bug if it happens.

  - TiKV is stopped or killed by a third party and then pulled up by `systemd`. Check the cause by viewing `dmesg` and the TiKV log.
  - TiKV is OOM, which causes restart.
  - TiKV is hung because of dynamically adjusting `THP` (Transparent Hugepage).

- Check monitor: TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows `server is busy`.

- Re-election because of network isolation.

- If the `block-cache` configuration is too large, it might cause TiKV OOM. To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**. Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"`parameter is set properly. By default, TiKV's `block-cache` is set to `45%` of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM. To verify the cause, you can check whether `response size` exceeds the `network outbound` traffic by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

8.8.1.4 Bottleneck of a single TiKV thread

There are some single threads in TiKV that might become the bottleneck.

- Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana** -> **TiKV-details** -> **Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue.
- For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana** -> **TiKV-details** -> **Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed `80%`), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

8.8.1.5 CPU load increases

8.8.1.5.1 Phenomenon

The usage of CPU resources becomes the bottleneck.

8.8.1.5.2 Possible reasons

- Hotspot issue
- High overall load. Check the slow queries and expensive queries of TiDB. Optimize the executing queries by adding indexes or executing queries in batches. Another solution is to scale out the cluster.

8.8.2 Other causes

8.8.2.1 Cluster maintenance

Most of each online cluster has three or five nodes. If the machine to be maintained has the PD component, you need to determine whether the node is the leader or the follower. Disabling a follower has no impact on the cluster operation. Before disabling a leader, you need to switch the leadership. During the leadership change, performance jitter of about 3 seconds will occur.

8.8.2.2 Minority of replicas are offline

By default, each TiDB cluster has three replicas, so each Region has three replicas in the cluster. These Regions elect the leader and replicate data through the Raft protocol. The Raft protocol ensures that TiDB can still provide services without data loss even when the nodes (that are fewer than half of replicas) fail or are isolated. For the cluster with three replicas, the failure of one node might cause performance jitter but the usability and correctness in theory are not affected.

8.8.2.3 New indexes

Creating indexes consumes a huge amount of resources when TiDB scans tables and backfills indexes. Index creation might even conflict with the frequently updated fields, which affects the application. Creating indexes on a large table often takes a long time, so you must try to balance the index creation time and the cluster performance (for example, creating indexes at the off-peak time).

Parameter adjustment:

Currently, you can use `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` ↪ to dynamically adjust the speed of index creation. Usually, the smaller the values, the smaller the impact on the system, with longer execution time though.

In general cases, you can first keep their default values (`4` and `256`), observe the resource usage and response speed of the cluster, and then increase the value of `tidb_ddl_reorg_worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor, increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

8.8.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

8.9 TiDB Cluster Troubleshooting Guide

You can use this guide to help you diagnose and solve basic problems while using TiDB. If your problem is not resolved, please collect the following information and create an issue:

- The exact error message and the operations while the error occurs
- The state of all the components
- The `error/fatal/panic` information in the log of the component that reports the error
- The configuration and deployment topology
- The TiDB component related issue in `dmesg`

For other information, see Frequently Asked Questions (FAQ).

8.9.1 Cannot connect to the database

1. Make sure all the services are started, including `tidb-server`, `pd-server`, and `tikv-server`.

2. Use the `ps` command to check if all the processes are running.

    - If a certain process is not running, see the following corresponding sections to diagnose and solve the issue.
    - If all the processes are running, check the `tidb-server` log to see if the following messages are displayed:

  - InformationSchema is out of date: This message is displayed if the `tikv-server` cannot be connected. Check the state and log of `pd-server` and `tikv-server`.
  - panic: This message is displayed if there is an issue with the program. Please provide the detailed panic log and create an issue.

3. If the data is cleared and the services are re-deployed, make sure that:

   - All the data in `tikv-server` and `pd-server` are cleared. The specific data is stored in `tikv-server` and the metadata is stored in `pd-server`. If only one of the two servers is cleared, the data will be inconsistent.
   - After the data in `pd-server` and `tikv-server` are cleared and the `pd-server` and `tikv-server` are restarted, the `tidb-server` must be restarted too. The cluster ID is randomly allocated when the `pd-server` is initialized. So when the cluster is re-deployed, the cluster ID changes and you need to restart the `tidb-server` to get the new cluster ID.

8.9.2 Cannot start `tidb-server`

See the following for the situations when the `tidb-server` cannot be started:

- Error in the startup parameters.

  See the TiDB configuration and options.

- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tidb-server` is not occupied.

- Cannot connect to `pd-server`.

  - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
  - If there is no issue with the network, check the state and log of the `pd-server` process.

8.9.3 Cannot start `tikv-server`

See the following for the situations when the `tikv-server` cannot be started:

- Error in the startup parameters: See the TiKV configuration and options.
- The port is occupied: Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tikv-server` is not occupied.

- Cannot connect to `pd-server`.
  - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
  - If there is no issue with the network, check the state and log of the `pd-server` process.
- The file is occupied.

  Do not open two TiKV files on one database file directory.

8.9.4 Cannot start `pd-server`

See the following for the situations when the `pd-server` cannot be started:

- Error in the startup parameters.

  See the PD configuration and options.
- The port is occupied.

  Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `pd-server` is not occupied.

8.9.5 The TiDB/TiKV/PD process aborts unexpectedly

- Is the process started on the foreground? The process might exit because the client aborts.
- Is `nohup+&` run in the command line? This might cause the process to abort because it receives the hup signal. It is recommended to write and run the startup command in a script.

8.9.6 TiDB panic

Please provide the panic log and create an issue.

8.9.7 The connection is rejected

Make sure the network parameters of the operating system are correct, including but not limited to:

- The port in the connection string is consistent with the `tidb-server` starting port.
- The firewall is configured correctly.

8.9.8 Open too many files

Before starting the process, make sure the result of `ulimit -n` is large enough. It is recommended to set the value to `unlimited` or larger than `1000000`.

8.9.9 Database access times out and the system load is too high

First, check the slow query log and see if it is because of some inappropriate SQL statement.

If you failed to solve the problem, provide the following information:

- The deployment topology
  - How many `tidb-server`/`pd-server`/`tikv-server` instances are deployed?
  - How are these instances distributed in the machines?
- The hardware configuration of the machines where these instances are deployed:
  - The number of CPU cores
  - The size of the memory
  - The type of the disk (SSD or Hard Drive Disk)
  - Are they physical machines or virtual machines?
- Are there other services besides the TiDB cluster?
- Are the `pd-server`s and `tikv-server`s deployed separately?
- What is the current operation?
- Check the CPU thread name using the `top -H` command.
- Are there any exceptions in the network or IO monitoring data recently?

8.10 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

8.10.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

8.10.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

8.10.1.1.1 The first type of monitoring panels

In **Overview> System Info> IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as `Disk Latency` and `Disk Load` to determine whether any anomaly exists. If necessary, use the fio tool to check the disk.

8.10.1.1.2 The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details** > **Raft IO**, you can see the metrics related to disk writes of these two instances:

- `Append log duration`: This metric indicates the response time of writes into RockDB that stores Raft logs. The `.99` response time should be within 50 ms.
- `Apply log duration`: This metric indicates the response time of writes into RockDB that stores real data. The `.99` response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

8.10.1.1.3 The third type of monitoring panels

In **TiKV-Details** > **Storage**, there are monitoring metrics related to storage:

- `Storage command total`: Indicates the number of different commands received.
- `Storage async write duration`: Includes monitoring metrics such as `disk sync` ↪ `duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

8.10.1.1.4 Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the prewrite/commit/raw-put (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append log`. Otherwise, you might need to report a bug.
- The `raftstore` thread is busy. In TiKV Grafana, `Raft Propose/propose wait duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:
  - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
  - Whether the CPU resource of the machine is insufficient.
- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose/apply wait duration`. The possible causes are as follows:
  - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU/apply cpu` is also relatively high.
  - Insufficient CPU resources on the machine.
  - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).
  - Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply` log might involve multiple RocksDB writes.
  - For other causes, report them as bugs.
- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as `1024`.

8.10.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

  You can check the monitoring panel (**Grafana** -> **TiKV** -> **errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

  It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

  If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

  For example, when the pressure of `default cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd" , "zstd"]` to `compression-per-level = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

8.10.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- TiKV_write_stall
- TiKV_raft_log_lag
- TiKV_async_request_snapshot_duration_seconds
- TiKV_async_request_write_duration_seconds
- TiKV_raft_append_log_duration_secs
- TiKV_raft_apply_log_duration_secs

8.10.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.

- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

8.11 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document introduces how to troubleshoot and resolve lock conflicts in TiDB.

8.11.1 Optimistic transaction mode

Transactions in TiDB use two-phase commit (2PC) that includes the Prewrite phase and the Commit phase. The procedure is as follows:

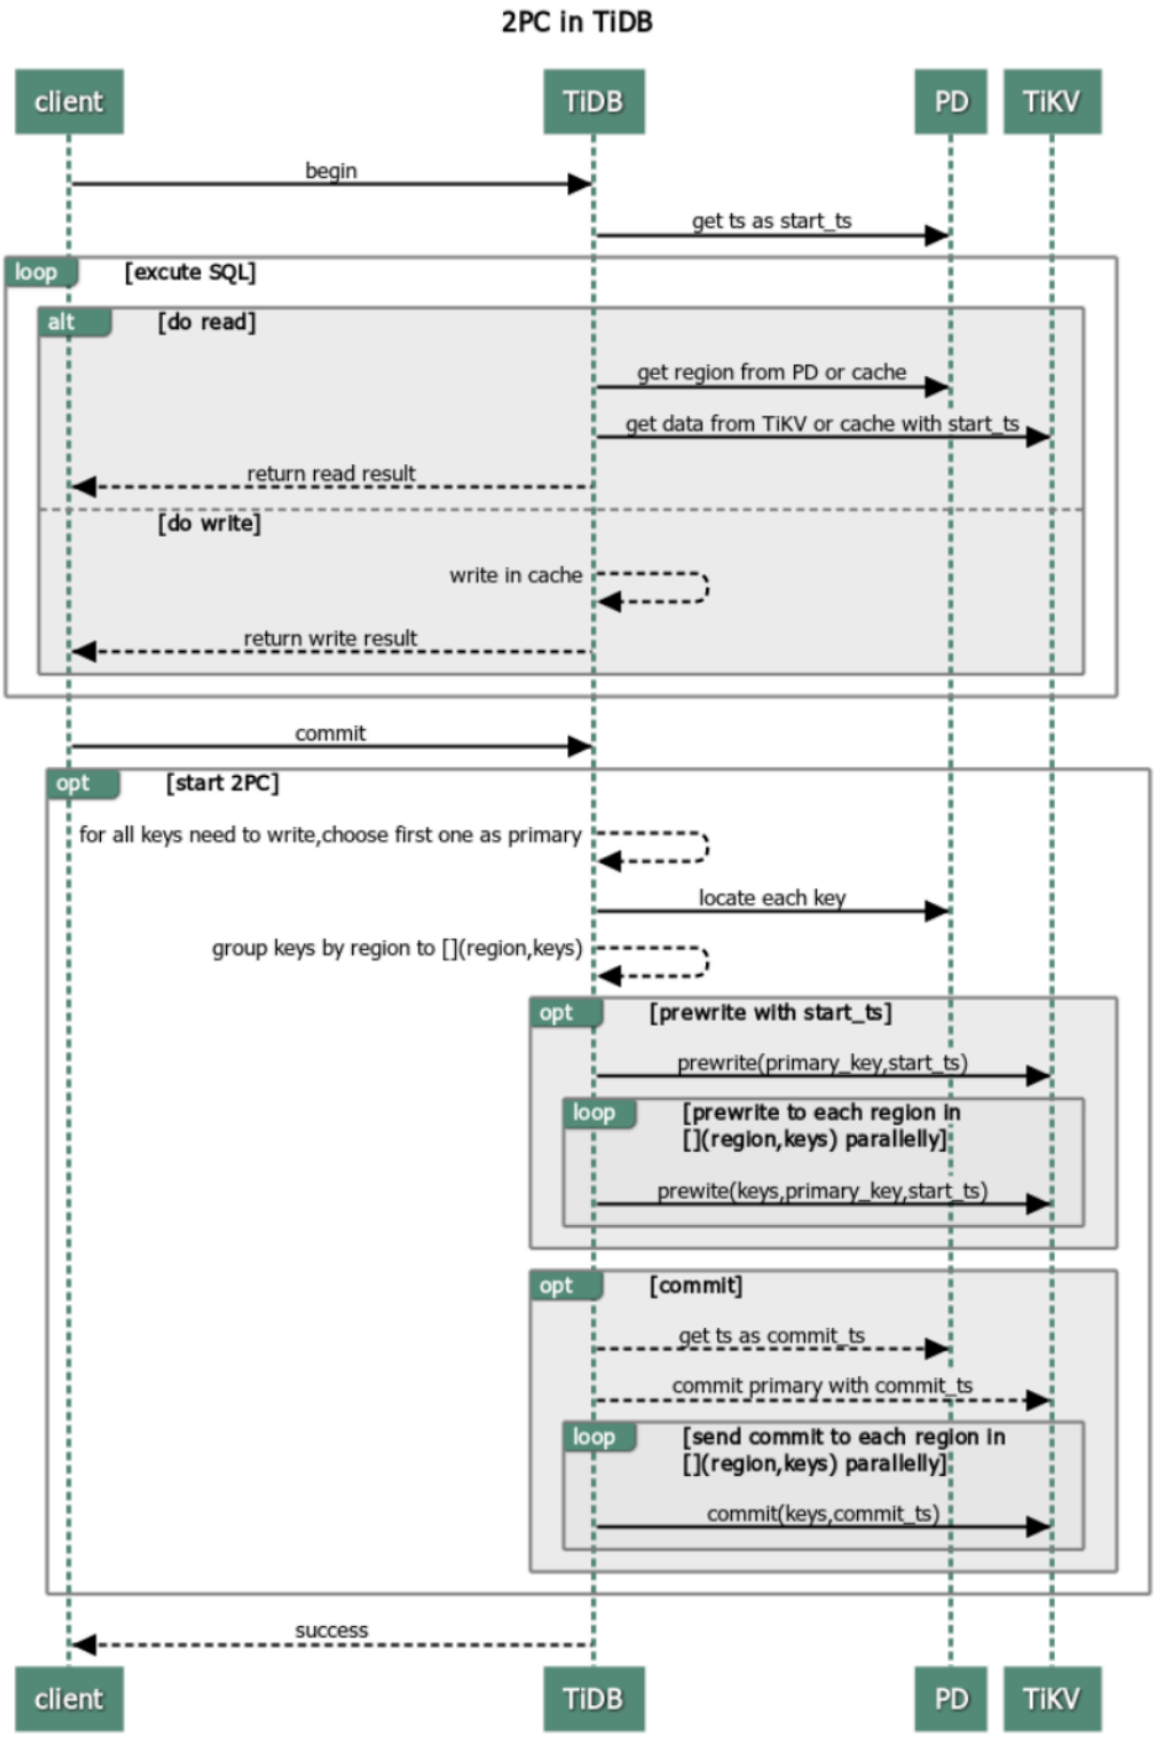

Figure 56: two-phase commit in the optimistic transaction mode

For details of Percolator and TiDB's algorithm of the transactions, see Google's Percolator.

8.11.1.1 Prewrite phase (optimistic)

In the Prewrite phase, TiDB adds a primary lock and a secondary lock to target keys. If there are lots of requests for adding locks to the same target key, TiDB prints an error such as write conflict or `keyislocked` to the log and reports it to the client. Specifically, the following errors related to locks might occur in the Prewrite phase.

8.11.1.1.1 Read-write conflict (optimistic)

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the start_ts of the current transaction. The transaction needs to read the latest data before start_ts, that is, the target key of the latest commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

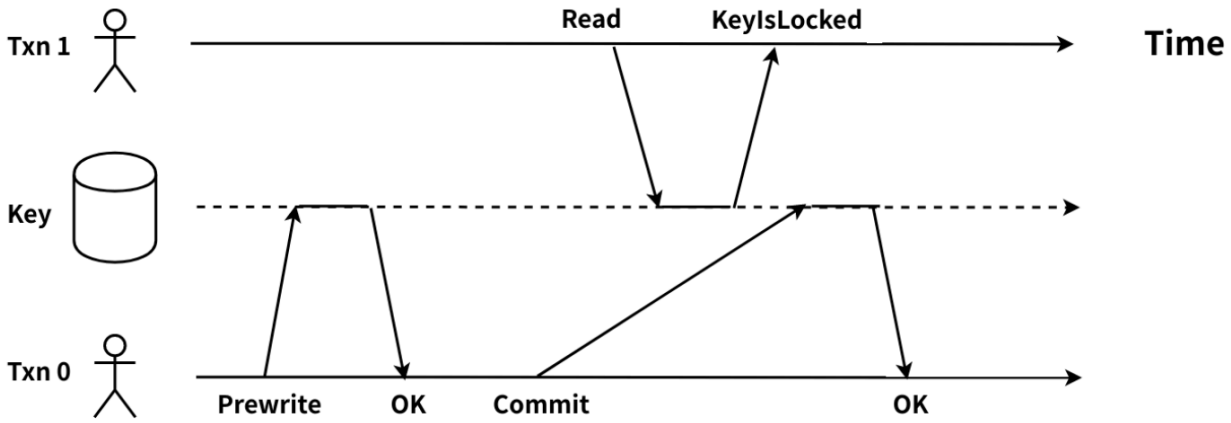

Figure 57: read-write conflict

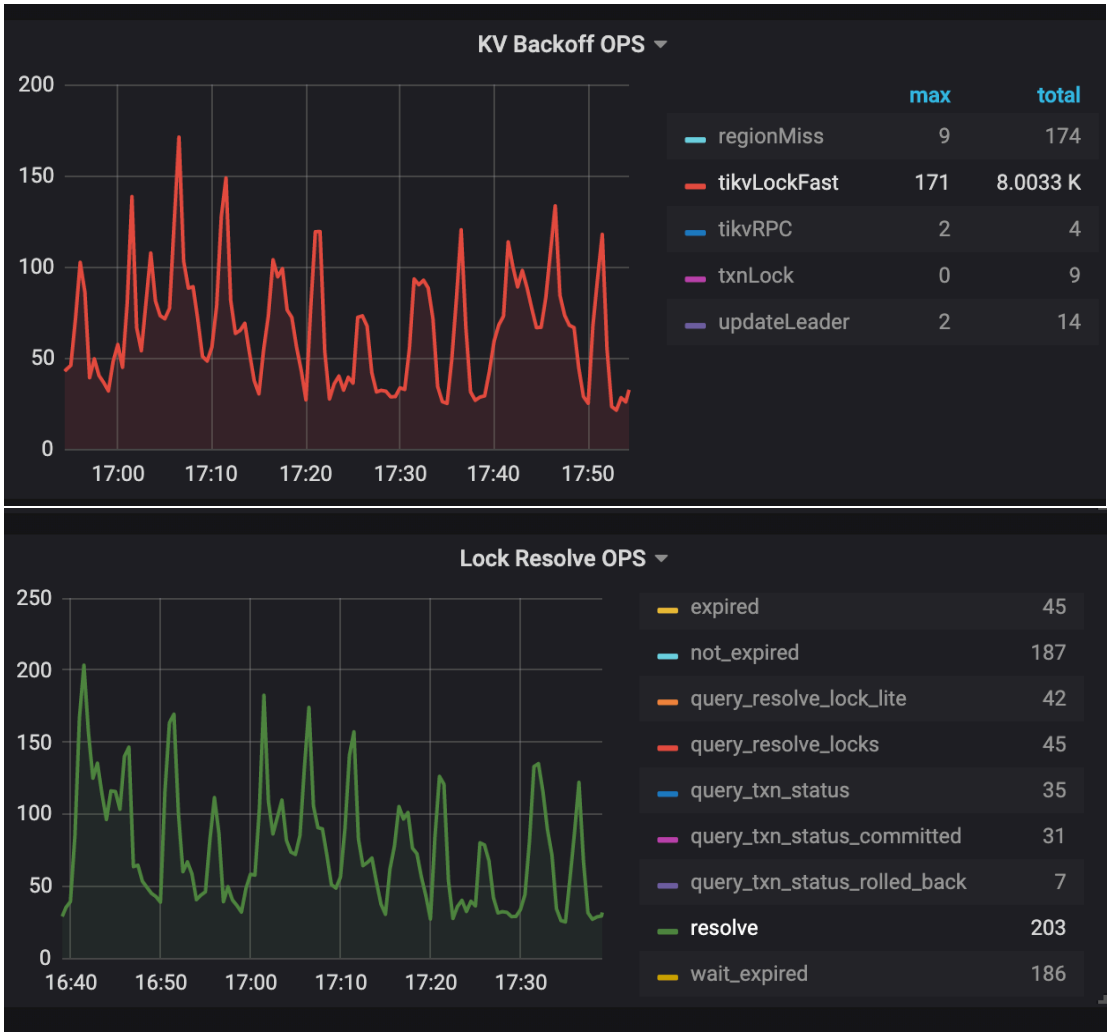


Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.

You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

- Monitoring data through Grafana

  On the `KV Errors` panel in the TiDB dashboard, there are two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check read-write conflicts in the transactions. If the values of both `not_expired` and `resolve` ↪ under `Lock Resolve OPS` increase, there might be many read-write conflicts. The `not_expired` item means that the transaction's lock has not timed out. The `resolve` item means that the other transaction tries to clean up the locks. If the value of another `txnLockFast` item under `KV Backoff OPS` increases, there might also be read-write conflicts.

- Logs of the TiDB server

  If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
    ↪ :406.038899ms txnStartTS:416643508703592451 region_id:8297
    ↪ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
    ↪ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
    ↪ :0 scan_processed_write:0 scan_total_data:0
```

```
    ↪ scan_processed_data:0 scan_total_lock:0 scan_processed_lock
    ↪ :0"]
```

- txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, `416643508703592451` is the start_ts.
- backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is `TxnLockFast`.
- backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255 milliseconds in the backoff and retry.
- region_id: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

   If there is any read-write conflict, you can see the following message in the TiKV log:

```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
    ↪ :7480000000000004
    ↪ D35F698000000000000010380000000004C788E0380000000004C0748
    ↪ lock_version: 411402933858205712 key: 7480000000000004
    ↪ D35F7280000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

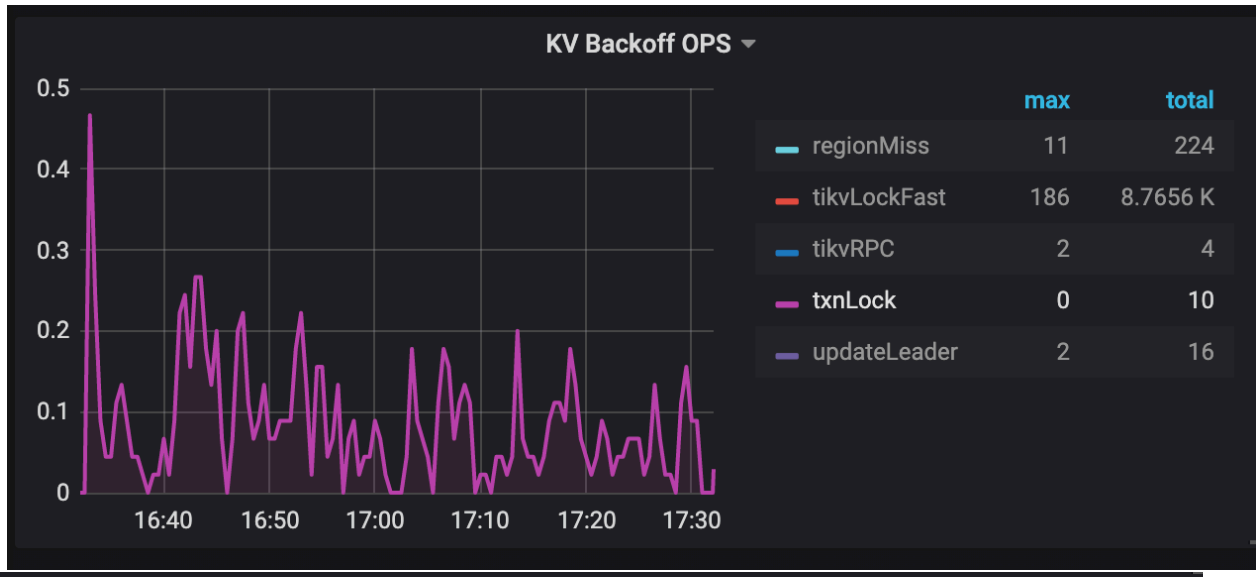
   This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

   - primary_lock: Indicates that the target key is locked by the primary lock.
   - lock_version: The start_ts of the transaction that owns the lock.
   - key: The target key that is locked.
   - lock_ttl: The lock's TTL (Time To Live)
   - txn_size: The number of keys that are in the Region of the transaction that owns the lock.

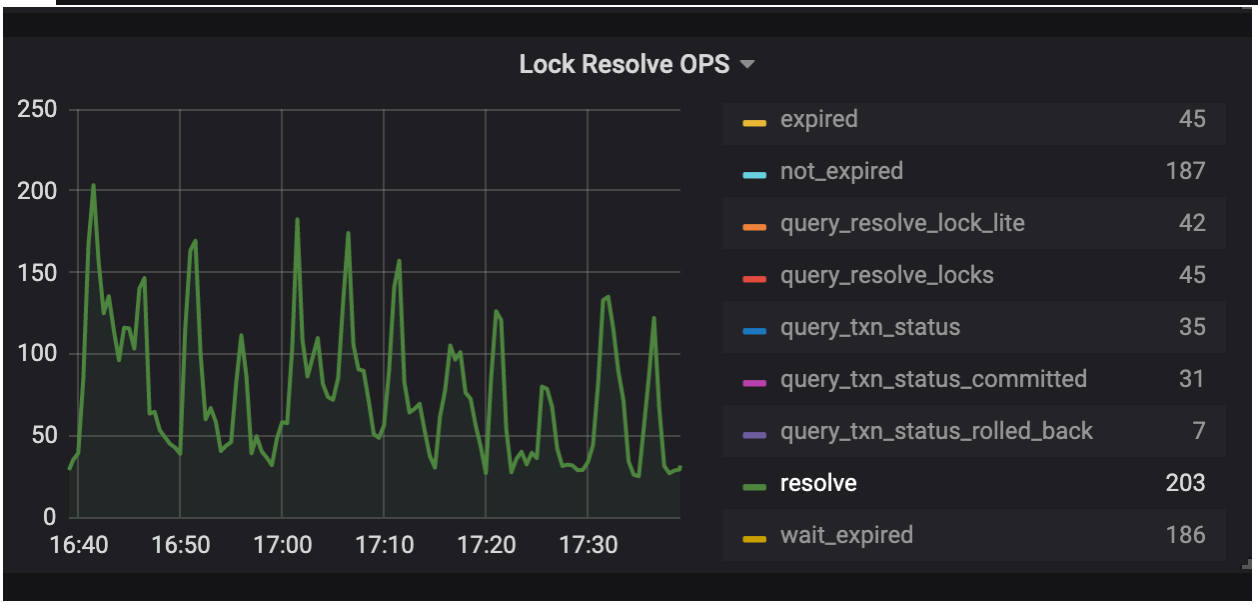
Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 100 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.
- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:

```
./tidb-ctl decoder -f table_row -k "t\x00\x00\x00\x00\x00\x00\x00\x1c_r
    ↪ \x00\x00\x00\x00\x00\x00\x00\xfa"



table_id: -9223372036854775780
row_id: -9223372036854775558
```



8.11.1.1.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a "KeyIsLocked" error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when "KeyIsLocked" occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The `KV Errors` panel in the TiDB dashboard has two monitoring metrics `Lock Resolve OPS` and `KV Backoff OPS` which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under `Lock Resolve OPS` and the `txnLock` item under `KV Backoff OPS` have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.

Solutions:

- If there is a small amount of txnLock in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 200 ms and the maximum time is 3000 ms for a single retry.
- If there are too many "txnLock" operations in the `KV Backoff OPS`, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

8.11.1.2 Commit phase (optimistic)

After the Prewrite phase completes, the client obtains commit_ts, and then the transaction is going to the next phase of 2PC - the Commit phase.

8.11.1.2.1 LockNotFound error

The error log of "TxnLockNotFound" means that transaction commit time is longer than the the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to tidb_retry_limit. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any "LockNotFound" error in the following ways:

1. View the logs of the TiDB server

   If a "TxnLockNotFound" error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
   ↪ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
   ↪ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
   ↪ 412720515987275779, commit_ts: 412720519984971777, key: [116,
   ↪ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 0, 2]
   ↪ })) [try again later]"]
```

   - start_ts: The start_ts of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the start_ts.
   - commit_ts: The commit_ts of the transaction that outputs the `TxnLockNotFound` ↪ error. In the above log, `412720519984971777` is the commit_ts.

2. View the logs of the TiKV server

   If a "TxnLockNotFound" error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
    ↪ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
    ↪ err=RemoteStoped]
```

Solutions:

- By checking the time interval between start_ts and commit_ts, you can confirm whether the commit time exceeds the TTL time.

  Checking the time interval using the PD control tool:

```
./pd-ctl tso [start_ts]
./pd-ctl tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

8.11.2 Pessimistic transaction mode

Before v3.0.8, TiDB uses the optimistic transaction mode by default. In this mode, if there is a transaction conflict, the latest transaction will fail to commit. Therefore, the application needs to support retrying transactions. The pessimistic transaction mode resolves this issue, and the application does not need to modify any logic for the workaround.

The commit phase of the pessimistic transaction mode and the optimistic transaction mode in TiDB has the same logic, and both commits are in the 2PC mode. The important adaptation of pessimistic transactions is DML execution.

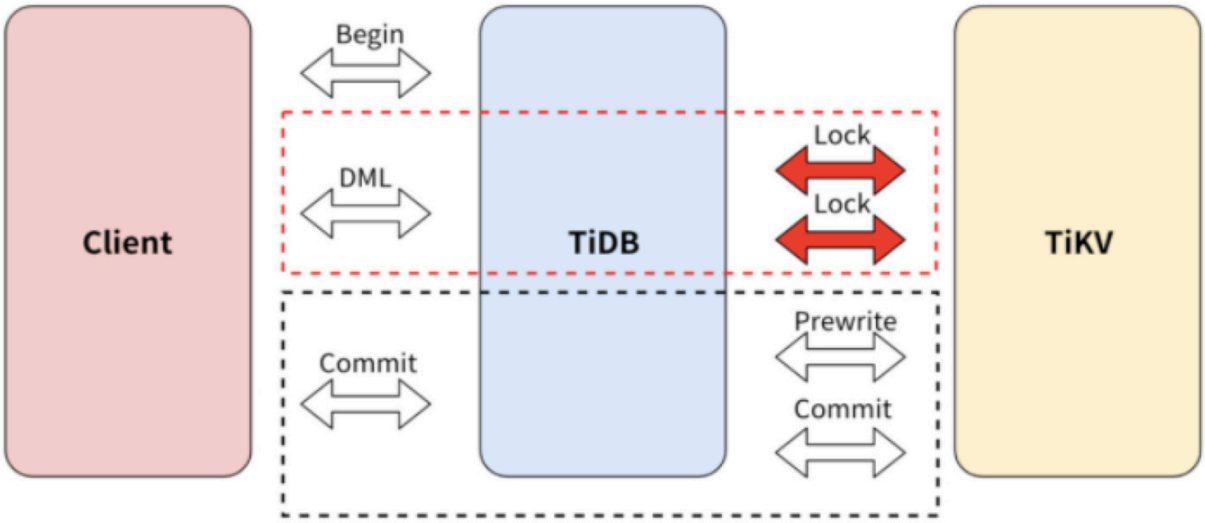


Figure 58: TiDB pessimistic transaction commit logic

The pessimistic transaction adds an `Acquire Pessimistic Lock` phase before 2PC. This phase includes the following steps:

1. (same as the optimistic transaction mode) Receive the `begin` request from the client, and the current timestamp is this transaction's start_ts.
2. When the TiDB server receives an `update` request from the client, the TiDB server initiates a pessimistic lock request to the TiKV server, and the lock is persisted to the TiKV server.
3. (same as the optimistic transaction mode) When the client sends the commit request, TiDB starts to perform the 2PC similar to the optimistic transaction mode.

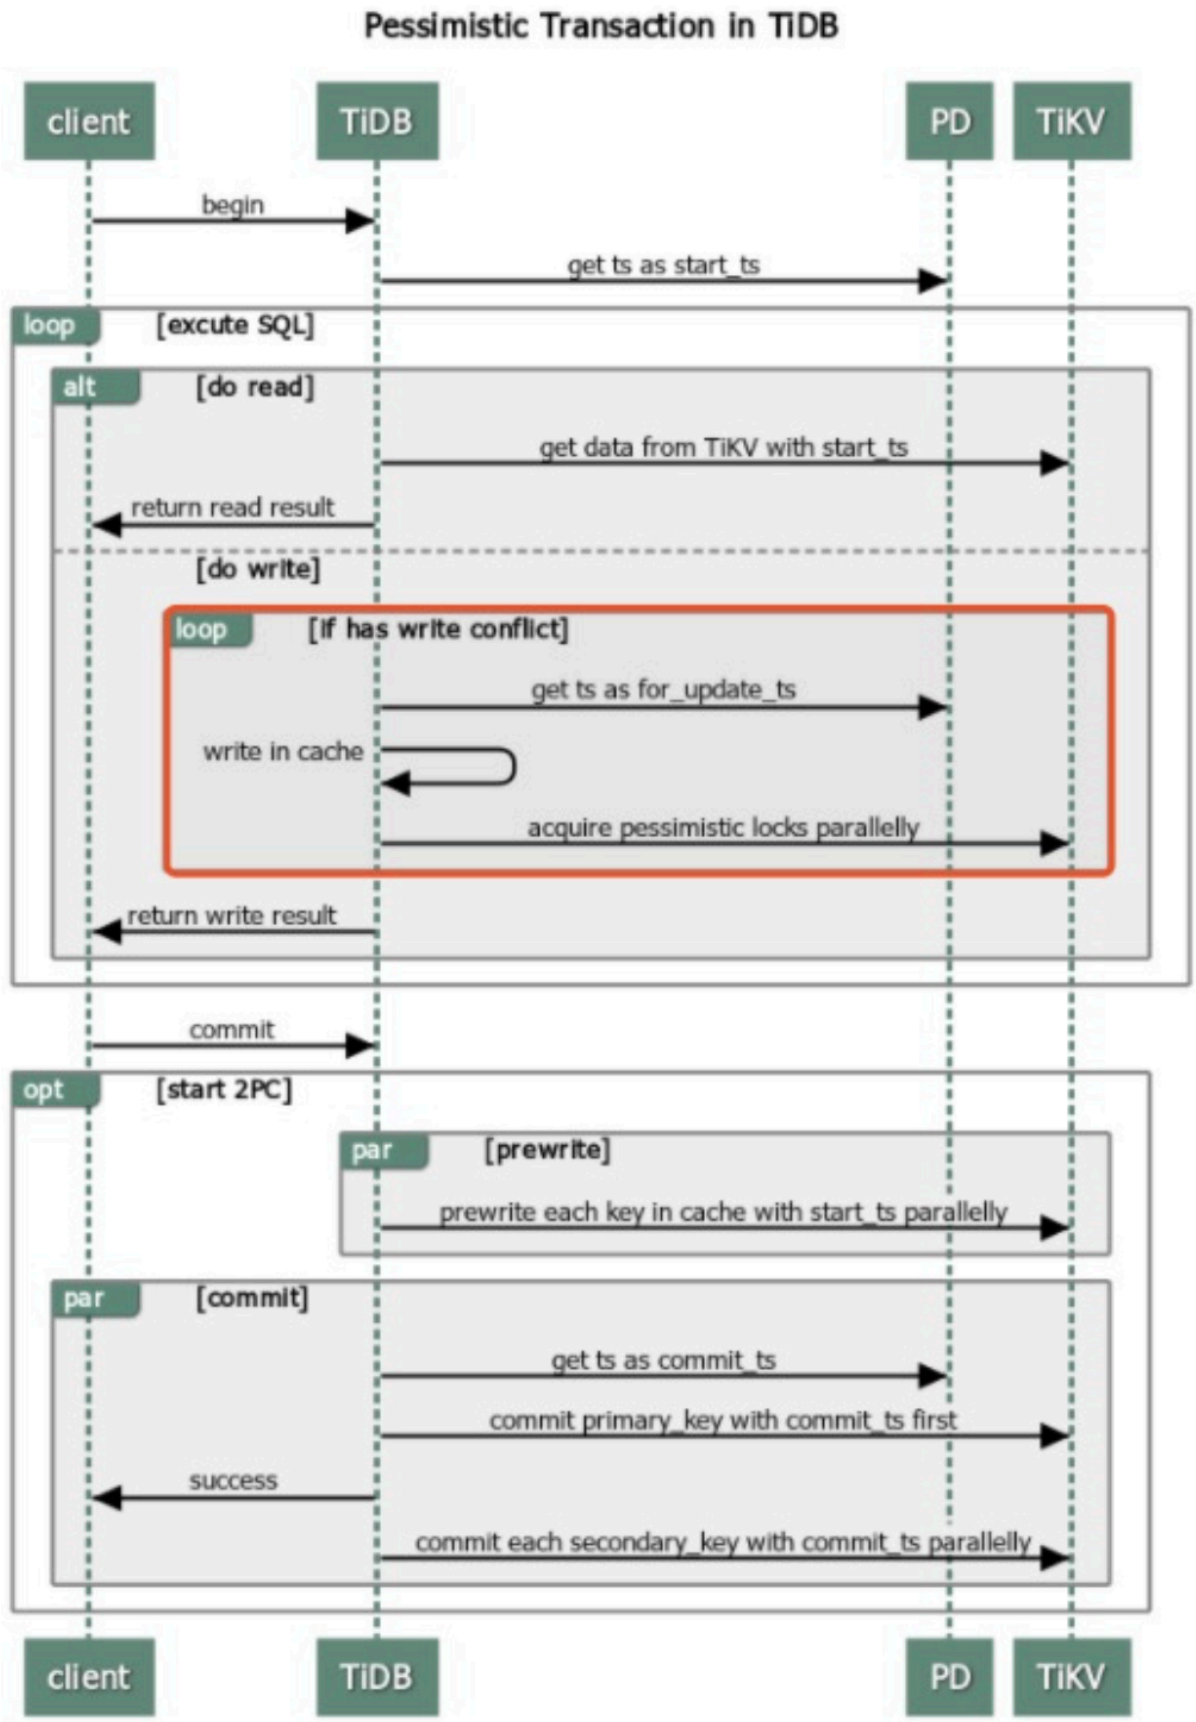

Figure 59: Pessimistic transactions in TiDB

For details, see Pessimistic transaction mode.

8.11.2.1 Prewrite phase (pessimistic)

In the transaction pessimistic mode, the commit phase is the same as the 2PC. Therefore, the read-write conflict also exists as in the optimistic transaction mode.

8.11.2.1.1 Read-write conflict (pessimistic)

Same as Read-write conflict (optimistic).

8.11.2.2 Commit phase (pessimistic)

In the pessimistic transaction mode, there will be no `TxnLockNotFound` error. Instead, the pessimistic lock will automatically update the TTL of the transaction through `txnheartbeat` to ensure that the second transaction does not clear the lock of the first transaction.

8.11.2.3 Other errors related to locks

8.11.2.3.1 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by pessimistic-txn.max-retry-count.

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.

8.11.2.3.2 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the innodb_lock_wait_timeout parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

8.11.2.3.3 TTL manager has timed out

The transaction execution time can not exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter performance.max-txn-ttl.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or
    ↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

8.11.2.3.4 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
    ↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the Deadlock errors section and the `DEADLOCKS` table document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

8.11.2.4 Use Lock View to troubleshoot issues related to pessimistic locks

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the pessimistic lock conflicts and pessimistic lock waitings. For the detailed introduction of these tables, see the following documents:

- `TIDB_TRX` and `CLUSTER_TIDB_TRX`: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.
- `DATA_LOCK_WAITS`: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- `DEADLOCKS` and `CLUSTER_DEADLOCKS`: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

> **Warning:**
>
> Currently, this is an experimental feature. The definition and behavior of the table structure might have major changes in future releases.

The following sections show the examples of troubleshooting some issues using these tables.

8.11.2.4.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table. For example:

```
select * from information_schema.deadlocks;
```

```
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
| DEADLOCK_ID | OCCUR_TIME                 | RETRYABLE | TRY_LOCK_TRX_ID |
    ↪ CURRENT_SQL_DIGEST                                    | KEY
    ↪                                  | TRX_HOLDING_LOCK |
+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪

+--
    ↪ ----------+----------------------------+----------+-------------------+------
    ↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the digest of the SQL statement currently being executed in each transaction, and the key on which the conflict occurs.

You can get the text of the normalized SQL statement corresponding to the digest of the SQL statements executed recently from the `STATEMENTS_SUMMARY` or `STATEMENTS_SUMMARY_HISTORY` table. For details, see STATEMENTS_SUMMARY and STATEMENTS_SUMMARY_HISTORY tables. You can also join the obtained results directly with the `DEADLOCKS` table. Note that the `STATEMENTS_SUMMARY` table might not contain the information of all SQL statements, so left join is used in the following example:

```
select l.deadlock_id, l.occur_time, l.try_lock_trx_id, l.trx_holding_lock,
    ↪ s.digest_text from information_schema.deadlocks as l left join
    ↪ information_schema.statements_summary as s on l.current_sql_digest =
    ↪ s.digest;
```

```
+--
    ↪ ----------+----------------------------+------------------+------------------
    ↪
| deadlock_id | occur_time                 | try_lock_trx_id  | trx_holding_lock |
    ↪  digest_text                           |
```

```
+--

8.11.2.4.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
    ↪ group by `key` order by `count` desc;
```

```
+----------------------------------------+-------+
| key                                    | count |
+----------------------------------------+-------+
| 7480000000000000415f728000000000000001 | 2 |
| 7480000000000000415f728000000000000002 | 1 |
+----------------------------------------+-------+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter out transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select trx.* from information_schema.data_lock_waits as l left join
    ↪ information_schema.tidb_trx as trx on l.trx_id = trx.id where l.key =
    ↪  "7480000000000000415f728000000000000001"\G
```

```

8.11.2.4.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```
select l.key, trx.* from information_schema.data_lock_waits as l join
    ↪ information_schema.tidb_trx as trx on l.current_holding_trx_id = trx.
    ↪ id where l.trx_id = 425497223886536705\G
```

```
*************************** 1. row ***************************

1 row in set (0.01 sec)
```

If the `start_ts` of the current transaction is unknown, you can try to find it out from the information in the `TIDB_TRX` / `CLUSTER_TIDB_TRX` table or in the `PROCESSLIST` / `CLUSTER_PROCESSLIST` table.

8.12 Troubleshoot a TiFlash Cluster

This section describes some commonly encountered issues when using TiFlash, the reasons, and the solutions.

8.12.1 TiFlash fails to start

The issue might occur due to different reasons. It is recommended that you troubleshoot it following the steps below:

1. Check whether your system is CentOS8.

   CentOS8 does not have the `libnsl.so` system library. You can manually install it via the following command:

   ```
   shell dnf install libnsl
   ```

2. Check your system's `ulimit` parameter setting.

   ```
   shell ulimit -n 1000000
   ```

3. Use the PD Control tool to check whether there is any TiFlash instance that failed to go offline on the node (same IP and Port) and force the instance(s) to go offline. For detailed steps, refer to Scale in a TiFlash cluster.

If the above methods cannot resolve your issue, save the TiFlash log files and email to info@pingcap.com for more information.

8.12.2 TiFlash replica is always unavailable

This is because TiFlash is in an abnormal state caused by configuration errors or environment issues. Take the following steps to identify the faulty component:

1. Check whether PD enables the `Placement Rules` feature:

   ```
   echo 'config show replication' | /path/to/pd-ctl -u http://<pd-ip>:<pd-
   ↪ port>
   ```

   The expected result is `"enable-placement-rules": "true"`. If not enabled, enable the Placement Rules feature.

2. Check whether the TiFlash process is working correctly by viewing `UpTime` on the TiFlash-Summary monitoring panel.

3. Check whether the TiFlash proxy status is normal through `pd-ctl`.

   ```
   echo "store" | /path/to/pd-ctl -u http://<pd-ip>:<pd-port>
   ```

   The TiFlash proxy's `store.labels` includes information such as `{"key": "engine ↪ ", "value": "tiflash"}`. You can check this information to confirm a TiFlash proxy.

4. Check whether `pd buddy` can correctly print the logs (the log path is the value of `log` in the [flash.flash_cluster] configuration item; the default log path is under the `tmp` directory configured in the TiFlash configuration file).

5. Check whether the number of configured replicas is less than or equal to the number of TiKV nodes in the cluster. If not, PD cannot replicate data to TiFlash:

   ```
   echo 'config placement-rules show' | /path/to/pd-ctl -u http://<pd-ip
   ↪ >:<pd-port>
   ```

   Reconfirm the value of `default: count`.

> **Note:**
>
> After the placement rules feature is enabled, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to placement rules.

6. Check whether the remaining disk space of the machine (where `store` of the TiFlash node is) is sufficient. By default, when the remaining disk space is less than 20% of the `store` capacity (which is controlled by the `low-space-ratio` parameter), PD cannot schedule data to this TiFlash node.

8.12.3 TiFlash query time is unstable, and the error log prints many `Lock Exception` messages

This is because large amounts of data are written to the cluster, which causes that the TiFlash query encounters a lock and requires query retry.

You can set the query timestamp to one second earlier in TiDB. For example, if the current time is '2020-04-08 20:15:01', you can execute `set @@tidb_snapshot='2020-04-08 20:15:00';` before you execute the query. This makes less TiFlash queries encounter a lock and mitigates the risk of unstable query time.

8.12.4 Some queries return the `Region Unavailable` error

If the load pressure on TiFlash is too heavy and it causes that TiFlash data replication falls behind, some queries might return the `Region Unavailable` error.

In this case, you can balance the load pressure by adding more TiFlash nodes.

8.12.5 Data file corruption

Take the following steps to handle the data file corruption:

1. Refer to Take a TiFlash node down to take the corresponding TiFlash node down.
2. Delete the related data of the TiFlash node.
3. Redeploy the TiFlash node in the cluster.

8.13 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the

transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

8.13.1 The reason of write conflicts

TiDB implements its transactions by using the Percolator transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see TiDB Optimistic Transaction Model.

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.
2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts` > `txn.start_ts`), a write conflict occurs.

8.13.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

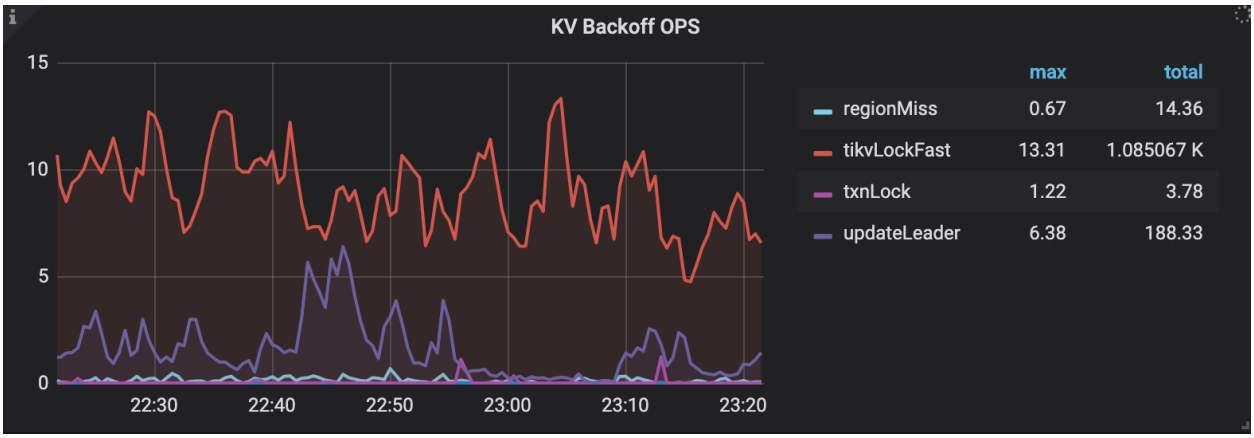

Figure 60: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

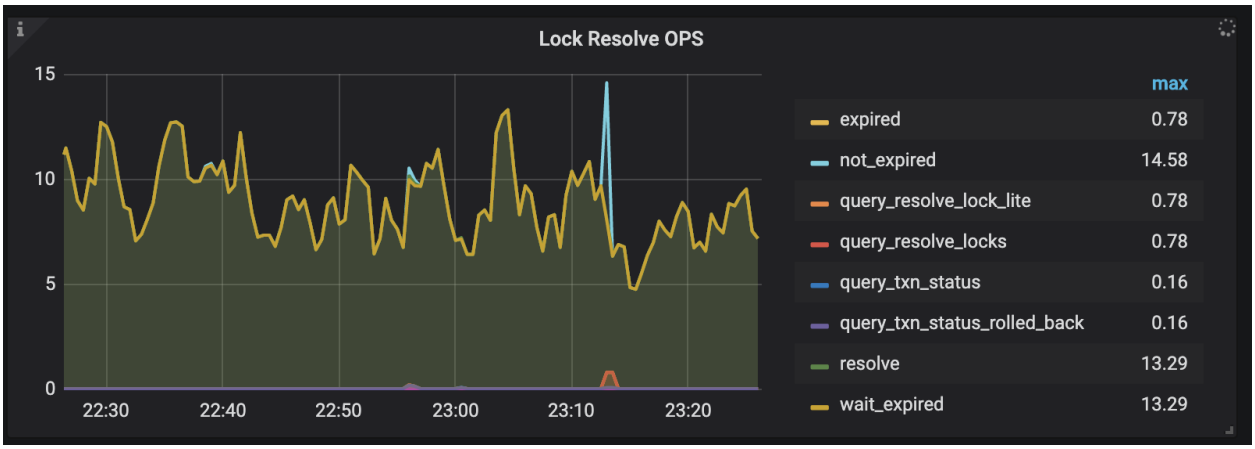

Figure 61: lock-resolve-ops

  - `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
  - `wait_expired` indicates that the transaction needs to wait the lock to expire.
  - `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

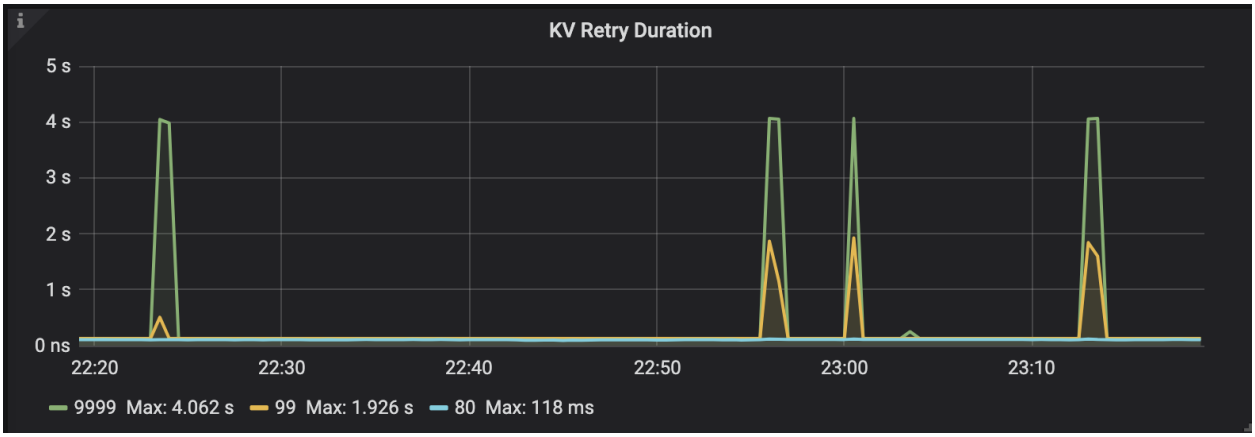

Figure 62: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the key word to search in the TiDB log. The key word also indicates the write conflict exists in the cluster.

8.13.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts. When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
    ↪ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
    ↪ conflict, txnStartTS=416617006551793665, conflictStartTS
    ↪ =416617018650001409, conflictCommitTS=416617023093080065, key={
    ↪ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
    ↪ indexID=1, indexValues={string, }} [try again later]"]
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.
- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`,

indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.

- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
./pd-ctl -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}
    ↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default model. The pessimistic transaction model can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

9 Performance Tuning

9.1 System Tuning

9.1.1 Operating System Tuning

This document introduces how to tune each subsystem of CentOS 7.

Note:

- The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affects other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
- Fully test all the changes in the test environment before applying them to the production environment.

9.1.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

9.1.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`
- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

9.1.1.1.2 perf

perf is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see perf Examples.

9.1.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in In 60 seconds. Compared with perf/ftrace, BPF provides programmability and smaller performance overhead. Compared with kprobe, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see BPF Compiler Collection (BCC).

9.1.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

9.1.1.2.1 CPU—frequency scaling

cpufreq is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

9.1.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:
  - Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.
  - For other devices, check the chip manual to see whether these devices support distributing interrupts.
    * If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
    * If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the kernel document.

9.1.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see tune network.

9.1.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

9.1.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

9.1.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to noop.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

9.1.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.

- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see CPU—frequency scaling, CPU—interrupt affinity, and NUMA CPU binding. If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the kernel document.

- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.

- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.

- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.

- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC

to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.

- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog` ↪ . Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core.` ↪ `netdev_max_backlog` value.

- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is `1000`, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.

- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

9.2 Software Tuning

9.2.1 Configuration

9.2.1.1 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. In the TiDB configuration file, you can configure the options as below to control TiDB behaviors when the memory quota exceeds the threshold value:

```
#### Valid options: ["log", "cancel"]
oom-action = "cancel"
```

- If the configuration item above uses “log”, when the memory quota of a single SQL query exceeds the threshold value which is controlled by the `tidb_mem_quota_query` variable, TiDB prints an entry of log. Then the SQL query continues to be executed. If OOM occurs, you can find the corresponding SQL query in the log.
- If the configuration item above uses “cancel”, when the memory quota of a single SQL query exceeds the threshold value, TiDB stops executing the SQL query immediately and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes much memory in the SQL execution process.

9.2.1.1.1 Configure the memory quota of a query

In the configuration file, you can set the default Memory Quota for each Query. The following example sets it to 32GB:

```
mem-quota-query = 34359738368
```

In addition, you can control the memory quota of a query using the following session variables. Generally, you only need to configure `tidb_mem_quota_query`. Other variables are used for advanced configuration which most users do not need to care about.

Variable Name	Description	Unit	Default Value
tidb_mem_quota_query	Control the memory quota of a query	Byte	1 << 30 (1 GB)
tidb_mem_quota_hashjoin	Control the memory quota of "HashJoinExec"	Byte	32 << 30
tidb_mem_quota_mergejoin	Control the memory quota of "MergeJoinExec"	Byte	32 << 30
tidb_mem_quota_sort	Control the memory quota of "SortExec"	Byte	32 << 30
tidb_mem_quota_topn	Control the memory quota of "TopNExec"	Byte	32 << 30
tidb_mem_quota_indexlookupreader	Control the memory quota of "IndexLookUpExecutor"	Byte	32 << 30
tidb_mem_quota_indexlookupjoin	Control the memory quota of "IndexLookUpJoin"	Byte	32 << 30
tidb_mem_quota_nestedloopapply	Control the memory quota of "NestedLoopApplyExec"	Byte	32 << 30

Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:
set @@tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:
set @@tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:
set @@tidb_mem_quota_query = 8 << 10;
```

9.2.1.1.2 Configure the memory usage threshold of a tidb-server instance

In the TiDB configuration file, you can set the memory usage threshold of a tidb-server instance by configuring `server-memory-quota`.

The following example sets the total memory usage of a tidb-server instance to 32 GB:

```
[performance]
server-memory-quota = 34359738368
```

In this configuration, when the memory usage of a tidb-server instance reaches 32 GB, the instance starts to kill running SQL statements randomly until the memory usage drops below 32 GB. SQL operations that are forced to terminate return an `Out Of Global Memory Limit!` error message to the client.

Warning:

- `server-memory-quota` is still an experimental feature. It is **NOT** recommended that you use it in a production environment.
- The default value of `server-memory-quota` is `0`, which means no memory limit.

9.2.1.1.3 Trigger the alarm of excessive memory usage

In the default configuration, a tidb-server instance prints an alarm log and records associated status files when the machine memory usage reaches 80% of its total memory. You can set the memory usage ratio threshold by configuring `memory-usage-alarm-ratio`. For detailed alarm rules, refer to the description of `memory-usage-alarm-ratio`.

Note that after the alarm is triggered once, it will be triggered again only if the memory usage rate has been below the threshold for more than ten seconds and reaches the threshold again. In addition, to avoid storing excessive status files generated by alarms, currently, TiDB only retains the status files generated during the recent five alarms.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set `memory-usage-alarm-ratio` to `0.8`:

   ```
   mem-quota-query = 34359738368 // Increases the memory limit of each
       ↪ query to construct SQL statements that take up larger memory.
   [performance]
   memory-usage-alarm-ratio = 0.8
   ```

2. Execute `CREATE TABLE t(a int);` and insert 1000 rows of data.

3. Execute `select * from t t1 join t t1 join t t3 order by t1.a`. This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.

4. Check the `tidb.log` file which records the total system memory, current system memory usage, memory usage of the tidb-server instance, and the directory of status files.

```
[2020/11/30 15:25:17.252 +08:00] [WARN] [memory_usage_alarm.go:141] ["
    ↪ tidb-server has the risk of OOM. Running SQLs and heap profile
    ↪ will be recorded in record path"] ["is server-memory-quota set"=
    ↪ false] ["system memory total"=33682427904] ["system memory usage
    ↪ "=27142864896] ["tidb-server memory usage"=22417922896] [memory-
    ↪ usage-alarm-ratio=0.8] ["record path"="/tmp/1000_tidb/
    ↪ MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA=/tmp-storage/record"]
```

   The fields of the example log file above are described as follows:

   - `is server-memory-quota set` indicates whether `server-memory-quota` is set.
   - `system memory total` indicates the total memory of the current system.
   - `system memory usage` indicates the current system memory usage.
   - `tidb-server memory usage` indicates the memory usage of the tidb-server instance.
   - `memory-usage-alarm-ratio` indicates the value of `memory-usage-alarm-ratio`.
   - `record path` indicates the directory of status files.

5. You can see a set of files in the directory of status files (In the above example, the directory is `/tmp/1000_tidb/MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA=/tmp-storage ↪ /record`), including `goroutinue`, `heap`, and `running_sql`. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the format of log content in `running_sql`, refer to `expensive-queries`.

9.2.1.2 Tune TiKV Thread Pool Performance

This document introduces TiKV internal thread pools and how to tune their performance.

9.2.1.2.1 Thread pool introduction

The TiKV thread pool is mainly composed of gRPC, Scheduler, UnifyReadPool, Raftstore, Apply, RocksDB, and some scheduled tasks and detection components that do not consume much CPU. This document mainly introduces a few CPU-intensive thread pools that affect the performance of read and write requests.

- The gRPC thread pool: it handles all network requests and forwards requests of different task types to different thread pools.
- The Scheduler thread pool: it detects write transaction conflicts, converts requests like the two-phase commit, pessimistic locking, and transaction rollbacks into key-value pair arrays, and then sends them to the Raftstore thread for Raft log replication.

- The Raftstore thread pool: it processes all Raft messages and the proposal to add a new log, and writing the log to a disk. When the logs in the majority of replicas are consistent, this thread pool sends the log to the Apply thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.
- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and `Compact` operation, refer to RocksDB: A Persistent Key-Value Store for Flash and RAM Storage.
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

9.2.1.2.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage.use-unified-pool` to `true`.

9.2.1.2.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

  The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is `5`. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

  - If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to `2`.

  - If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` ↪ , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than `80% * server.grpc-concurrency`).

- The Scheduler thread pool.

  When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is `8`; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is `4`.

  This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation**.

  - If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
  - If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

  Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is `8`, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler` ↪ `worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

  The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) is `2`. All write requests are written into RocksDB in the way of `fsync` from the Raftstore thread.

  Due to I/O, Raftstore threads cannot reach 100% CPU usage theoretically. To reduce disk writes as much as possible, you can put together multiple write requests and write them to RocksDB. It is recommended to keep the overall CPU usage below 60% (If the default number of threads is `2`, it is recommended to keep `TiKV-Details.Thread` ↪ `CPU.Raft store CPU` on Grafana within 120%). Do not increase the size of the Raftstore thread pool to improve write performance without thinking, because this might increase the disk burden and degrade performance.

- The UnifyReadPool thread pool.

  The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default

thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified.max-thread-count` to `10`. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

- The RocksDB thread pool.

  The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

  - If the machine has a small number of CPU cores, set both `rocksdb.max-background-jobs` and `raftdb.max-background-jobs` to `4`.
  - If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not `0`.
    * If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to `2` or `3`. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is `3` in TiKV 4.0 and `1` in TiKV 3.0.
    * If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (`5` by default).
    * If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to `64` or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

9.2.1.3 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance.

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements `Column Families` (CF) from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.

  - The `default` CF stores the actual data. The corresponding parameters are in `[rocksdb.defaultcf]`.
  - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in `[rocksdb.writecf]`.
  - The `lock` CF stores the lock information. The system uses the default parameters.

- The Raft RocksDB (RaftDB) instance stores Raft logs.

  - The `default` CF stores the Raft log. The corresponding parameters are in `[raftdb.defaultcf]`.

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under `[storage.block-cache]`. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied. To use a separate block cache instance for each CF, set `shared=false` under `[storage.block-cache]`, and configure individual block cache size for each CF. For example, you can configure the size of `write` CF by setting the `block-cache-size` parameter under `[rocksdb.writecf]`.

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

9.2.1.3.1 Parameter specification

```
#### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
#### Set listening address
#### addr = "127.0.0.1:20160"

#### Size of thread pool for gRPC
#### grpc-concurrency = 4
#### The number of gRPC connections between each TiKV instance
#### grpc-raft-conn-num = 10

#### Most read requests from TiDB are sent to the coprocessor of TiKV. This
   ↪ parameter is used to set the number of threads
#### of the coprocessor. If many read requests exist, add the number of
   ↪ threads and keep the number within that of the
#### system CPU cores. For example, for a 32-core machine deployed with TiKV
   ↪ , you can even set this parameter to 30 in
```

```
#### repeatable read scenarios. If this parameter is not set, TiKV
   ↪ automatically sets it to CPU cores * 0.8.
#### end-point-concurrency = 8

#### Tag the TiKV instances to schedule replicas.
#### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
#### The data directory
#### data-dir = "/tmp/tikv/store"

#### In most cases, you can use the default value. When importing data, it
   ↪ is recommended to set the parameter to 1024000.
#### scheduler-concurrency = 102400
#### This parameter controls the number of write threads. When write
   ↪ operations occur frequently, set this parameter value
#### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker
   ↪ -pool` are busy, set the value of parameter
#### `scheduler-worker-pool-size` higher and increase the number of write
   ↪ threads.
#### scheduler-worker-pool-size = 4

[storage.block-cache]
##### Whether to create a shared block cache for all RocksDB column families
   ↪ .
##### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
   ↪ block cache can speed up read.
##### It is recommended to turn on shared block cache. Since only the total
   ↪ cache size need to be
##### set, it is easier to configure. In most cases, it should be able to
   ↪ auto-balance cache usage
##### between column families with standard LRU algorithm.
##### ## The rest of config in the storage.block-cache session is effective
   ↪ only when shared block cache
##### is on.
#### shared = true

##### Size of the shared block cache. Normally it should be tuned to 30%-50%
   ↪  of system's total memory.
##### When the config is not set, it is decided by the sum of the following
   ↪ fields or their default
##### value:
#####  * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
#####  * rocksdb.writecf.block-cache-size or 15% of system's total memory
#####  * rocksdb.lockcf.block-cache-size or 2% of system's total memory
```

```
#####  * raftdb.defaultcf.block-cache-size or 2% of system's total memory
##### ## To deploy multiple TiKV nodes on a single physical machine,
   ↪ configure this parameter explicitly.
##### Otherwise, the OOM problem might occur in TiKV.
#### capacity = "1GB"

[pd]
#### PD address
#### endpoints = ["127.0.0.1:2379","127.0.0.2:2379","127.0.0.3:2379"]

[metric]
#### The interval of pushing metrics to Prometheus Pushgateway
interval = "15s"
#### Prometheus Pushgateway address
address = ""
job = "tikv"

[raftstore]
#### Raft RocksDB directory. The default value is Raft subdirectory of [
   ↪ storage.data-dir].
#### If there are multiple disks on the machine, store the data of Raft
   ↪ RocksDB on different disks to improve TiKV performance.
#### raftdb-path = "/tmp/tikv/store/raft"

region-max-size = "384MB"
#### The threshold value of Region split
region-split-size = "256MB"
#### When the data size change in a Region is larger than the threshold
   ↪ value, TiKV checks whether this Region needs split.
#### To reduce the costs of scanning data in the checking process, set the
   ↪ value to 32MB during checking and set it to
#### the default value in normal operation.
region-split-check-diff = "32MB"

[rocksdb]
#### The maximum number of threads of RocksDB background tasks. The
   ↪ background tasks include compaction and flush.
#### For detailed information why RocksDB needs to implement compaction, see
   ↪  RocksDB-related materials. When write
#### traffic (like the importing data size) is big, it is recommended to
   ↪ enable more threads. But set the number of the enabled
#### threads smaller than that of CPU cores. For example, when importing
   ↪ data, for a machine with a 32-core CPU,
#### set the value to 28.
#### max-background-jobs = 8
```

```
#### The maximum number of file handles RocksDB can open
#### max-open-files = 40960

#### The file size limit of RocksDB MANIFEST. For more details, see https://
   ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MB"

#### The directory of RocksDB write-ahead logs. If there are two disks on
   ↪ the machine, store the RocksDB data and WAL logs
#### on different disks to improve TiKV performance.
#### wal-dir = "/tmp/tikv/store"

#### Use the following two parameters to deal with RocksDB archiving WAL.
#### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
   ↪ persist-in-memory-RocksDB-database%3F
#### wal-ttl-seconds = 0
#### wal-size-limit = 0

#### In most cases, set the maximum total size of RocksDB WAL logs to the
   ↪ default value.
#### max-total-wal-size = "4GB"

#### Use this parameter to enable or disable the statistics of RocksDB.
#### enable-statistics = true

#### Use this parameter to enable the readahead feature during RocksDB
   ↪ compaction. If you are using mechanical disks, it is recommended to
   ↪ set the value to 2MB at least.
#### compaction-readahead-size = "2MB"

[rocksdb.defaultcf]
#### The data block size. RocksDB compresses data based on the unit of block
   ↪ .
#### Similar to page in other databases, block is the smallest unit cached
   ↪ in block-cache.
block-size = "64KB"

#### The compaction mode of each layer of RocksDB data. The optional values
   ↪ include no, snappy, zlib,
#### bzip2, lz4, lz4hc, and zstd.
#### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of
   ↪ level0 and level1; lz4 compaction algorithm is used
#### from level2 to level4; zstd compaction algorithm is used from level5 to
   ↪  level6.
```

```
#### "no" means no compaction. "lz4" is a compaction algorithm with moderate
   ↪  speed and compaction ratio. The
#### compaction ratio of zlib is high. It is friendly to the storage space,
   ↪ but its compaction speed is slow. This
#### compaction occupies many CPU resources. Different machines deploy
   ↪ compaction modes according to CPU and I/O resources.
#### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
   ↪ zstd" and find much I/O pressure of the
#### system (run the iostat command to find %util lasts 100%, or run the top
   ↪  command to find many iowaits) when writing
#### (importing) a lot of data while the CPU resources are adequate, you can
   ↪  compress level0 and level1 and exchange CPU
#### resources for I/O resources. If you use the compaction mode of "no:no:
   ↪ lz4:lz4:lz4:zstd:zstd" and you find the I/O
#### pressure of the system is not big when writing a lot of data, but CPU
   ↪ resources are inadequate. Then run the top
#### command and choose the -H option. If you find a lot of bg threads (
   ↪ namely the compaction thread of RocksDB) are
#### running, you can exchange I/O resources for CPU resources and change
   ↪ the compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
#### In a word, it aims at making full use of the existing resources of the
   ↪ system and improving TiKV performance
#### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

#### The RocksDB memtable size
write-buffer-size = "128MB"

#### The maximum number of the memtables. The data written into RocksDB is
   ↪ first recorded in the WAL log, and then inserted
#### into memtables. When the memtable reaches the size limit of `write-
   ↪ buffer-size`, it turns into read only and generates
#### a new memtable receiving new write operations. The flush threads of
   ↪ RocksDB will flush the read only memtable to the
#### disks to become an sst file of level0. `max-background-flushes`
   ↪ controls the maximum number of flush threads. When the
#### flush threads are busy, resulting in the number of the memtables
   ↪ waiting to be flushed to the disks reaching the limit
#### of `max-write-buffer-number`, RocksDB stalls the new operation.
#### "Stall" is a flow control mechanism of RocksDB. When importing data,
   ↪ you can set the `max-write-buffer-number` value
#### higher, like 10.
max-write-buffer-number = 5

#### When the number of sst files of level0 reaches the limit of `level0-
```

```
    ↪ slowdown-writes-trigger`, RocksDB
#### tries to slow down the write operation, because too many sst files of
    ↪ level0 can cause higher read pressure of
#### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
    ↪ trigger` are for the flow control of RocksDB.
#### When the number of sst files of level0 reaches 4 (the default value),
    ↪ the sst files of level0 and the sst files
#### of level1 which overlap those of level0 implement compaction to relieve
    ↪  the read pressure.
level0-slowdown-writes-trigger = 20

#### When the number of sst files of level0 reaches the limit of `level0-
    ↪ stop-writes-trigger`, RocksDB stalls the new
#### write operation.
level0-stop-writes-trigger = 36

#### When the level1 data size reaches the limit value of `max-bytes-for-
    ↪ level-base`, the sst files of level1
#### and their overlap sst files of level2 implement compaction. The golden
    ↪ rule: the first reference principle
#### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
    ↪ bytes-for-level-base` value is roughly equal to the
#### data volume of level0. Thus unnecessary compaction is reduced. For
    ↪ example, if the compaction mode is
#### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
    ↪ write-buffer-size * 4, because there is no
#### compaction of level0 and level1 and the trigger condition of compaction
    ↪  for level0 is that the number of the
#### sst files reaches 4 (the default value). When both level0 and level1
    ↪ adopt compaction, it is necessary to analyze
#### RocksDB logs to know the size of an sst file compressed from an
    ↪ mentable. For example, if the file size is 32MB,
#### the proposed value of `max-bytes-for-level-base` is 32MB * 4 = 128MB.
max-bytes-for-level-base = "512MB"

#### The sst file size. The sst file size of level0 is influenced by the
    ↪ compaction algorithm of `write-buffer-size`
#### and level0. `target-file-size-base` is used to control the size of a
    ↪ single sst file of level1-level6.
target-file-size-base = "32MB"

[rocksdb.writecf]
#### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]
```

```
#### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

#### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"

[raftdb]
#### The maximum number of the file handles RaftDB can open
#### max-open-files = 40960

#### Configure this parameter to enable or disable the RaftDB statistics
   ↪ information.
#### enable-statistics = true

#### Enable the readahead feature in RaftDB compaction. If you are using
   ↪ mechanical disks, it is recommended to set
#### this value to 2MB at least.
#### compaction-readahead-size = "2MB"

[raftdb.defaultcf]
#### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

#### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

#### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"
```

9.2.1.3.2 TiKV memory usage

Besides `block cache` and `write buffer` which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.
- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

9.2.1.3.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GB.
- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

9.2.1.4 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

9.2.1.4.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

> **Note:**
>
> To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

9.2.1.4.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` session variable:

```
set @@tidb_replica_read = '<target value>';
```

Scope: SESSION

Default: leader

This variable is used to set the data read mode expected by the current session.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its original behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations.

9.2.1.4.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

9.2.1.5 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash, including planning machine resources and tuning TiDB parameters.

9.2.1.5.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

9.2.1.5.2 Tune TiDB parameters

1. For the TiDB node dedicated to OLAP/TiFlash, it is recommended that you increase the value of the `tidb_distsql_scan_concurrency` configuration item for this node to `80`:

```
set @@tidb_distsql_scan_concurrency = 80;
```

2. Enable the super batch feature:

   You can use the `tidb_allow_batch_cop` variable to set whether to merge Region requests when reading from TiFlash.

   When the number of Regions involved in the query is relatively large, try to set this variable to `1` (effective for coprocessor requests with `aggregation` operators that are pushed down to TiFlash), or set this variable to `2` (effective for all coprocessor requests that are pushed down to TiFlash).

```
set @@tidb_allow_batch_cop = 1;
```

3. Enable the optimization of pushing down aggregate functions before TiDB operators such as `JOIN` or `UNION`:

   You can use the `tidb_opt_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations are quite slow in the query, try to set this variable to `1`.

```
set @@tidb_opt_agg_push_down = 1;
```

4. Enable the optimization of pushing down aggregate functions with `Distinct` before TiDB operators such as `JOIN` or `UNION`:

   You can use the `tidb_opt_distinct_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations with `Distinct` are quite slow in the query, try to set this variable to `1`.

```
set @@tidb_opt_distinct_agg_push_down = 1;
```

9.2.2 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

9.2.2.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see TiDB Configuration File.

9.2.2.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.
- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.
- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
  - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.

    In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
  - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.

    In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
  - The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

    In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.
- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

9.2.2.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

9.2.2.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in Operators for accessing tables by using the `EXPLAIN ANALYZE` statement. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);
+--
   ↪ ----------------------------+----------+---------+----------+---------------
   ↪
| id                          | estRows  | actRows | task    | access object
   ↪       | execution info
   ↪
   ↪ | operator info               | memory             | disk |
+--
   ↪ ----------------------------+----------+---------+----------+---------------
   ↪
| IndexLookUp_6               | 262400.00 | 262400 | root    |
   ↪                      | time:620.513742ms, loops:258, cop_task: {num:
   ↪ 4, max: 5.530817ms, min: 1.51829ms, avg: 2.70883ms, p95: 5.530817ms,
   ↪ max_proc_keys: 2480, p95_proc_keys: 2480, tot_proc: 1ms, tot_wait: 1
   ↪ ms, rpc_num: 4, rpc_time: 10.816328ms, copr_cache_hit_rate: 0.75} | |
   ↪  6.685169219970703 MB | N/A |
|  ─IndexFullScan_4(Build)   | 262400.00 | 262400 | cop[tikv] | table:t,
   ↪ index:a(a, c) | proc max:93ms, min:1ms, p80:93ms, p95:93ms, iters
   ↪ :275, tasks:4
   ↪
   ↪ | keep order:false, stats:pseudo | 1.7549400329589844 MB | N/A |
|  ─TableRowIDScan_5(Probe)  | 262400.00 | 0     | cop[tikv] | table:t
   ↪           | time:0ns, loops:0
   ↪
   ↪ | keep order:false, stats:pseudo | N/A            | N/A |
+--
   ↪ ----------------------------+----------+---------+----------+---------------
   ↪
3 rows in set (0.62 sec)
```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The `0.75` in the above example means that the hit rate is about 75%.

9.2.2.3.2 View the Grafana monitoring panel

In Grafana, you can see the **copr-cache** panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

9.3 SQL Tuning

9.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- Understanding the Query Execution Plan introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- SQL Optimization Process introduces what optimizations TiDB is capable of using to improve query execution performance.
- Control Execution Plans introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.

9.3.2 Understanding the Query Execution Plan

9.3.2.1 `EXPLAIN` Overview

> **Note:**
>
> When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less -S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow → button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible

ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
    ↪  pad1 VARCHAR(255), INDEX(a));
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)

Query OK, 2 rows affected (0.02 sec)
Records: 2 Duplicates: 0 Warnings: 0

+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| id                          | estRows | task     | access object     |
    ↪ operator info                                |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
| IndexLookUp_10              | 10.00   | root     |                   |
    ↪                                             |
|  ─IndexRangeScan_8(Build)   | 10.00   | cop[tikv] | table:t, index:a(a) |
    ↪ range:[1,1], keep order:false, stats:pseudo |
|  ─TableRowIDScan_9(Probe)   | 10.00   | cop[tikv] | table:t          | keep
    ↪ order:false, stats:pseudo         |
+--
    ↪ ----------------------------+---------+----------+-------------------+------
    ↪
3 rows in set (0.00 sec)
```

`EXPLAIN` does not execute the actual query. `EXPLAIN ANALYZE` can be used to execute the query and show `EXPLAIN` information. This can be useful in diagnosing cases where the execution plan selected is suboptimal. For additional examples of using `EXPLAIN`, see the following documents:

- Indexes
- Joins
- Subqueries

- Aggregation
- Views
- Partitions

9.3.2.1.1 Understand EXPLAIN output

The following describes the output of the `EXPLAIN` statement above:

- `id` describes the name of an operator, or sub-task that is required to execute the SQL statement. See Operator overview for additional details.
- `estRows` shows an estimate of the number of rows TiDB expects to process. This number might be based on dictionary information, such as when the access method is based on a primary or unique key, or it could be based on statistics such as a CMSketch or histogram.
- `task` shows where an operator is performing the work. See Task overview for additional details.
- `access object` shows the table, partition and index that is being accessed. The parts of the index are also shown, as in the case above that the column `a` from the index was used. This can be useful in cases where you have composite indexes.
- `operator info` shows additional details about the access. See Operator info overview for additional details.

Operator overview

An operator is a particular step that is executed as part of returning query results. The operators that perform table scans (of the disk or the TiKV Block Cache) are listed as follows:

- **TableFullScan**: Full table scan
- **TableRangeScan**: Table scans with the specified range
- **TableRowIDScan**: Scans the table data based on the RowID. Usually follows an index read operation to retrieve the matching data rows.
- **IndexFullScan**: Similar to a "full table scan", except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.

- **IndexLookUp**: First aggregates the RowID (in TiKV) scanned by the `Build` side. Then at the `Probe` side, accurately reads the data from TiKV based on these RowIDs. At the `Build` side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the `Probe` side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookUp`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many `Build`s and one `Probe`. The execution process of `IndexMerge` the same as that of `IndexLookUp`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism, so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `└─IndexRangeScan_8(Build)` operator finds the internal `RowID` for rows that match the `a(a)` index. The `└─TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE/HAVING/ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column)< 1992` can not use an index, but `date_column < '1992-01-01` can.
- It is recommended to compare data of the same type and character set and collation. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index `(a, b, c)`:
  - When `a` is an equivalent query, continue to figure out the query range of `b`; when `b` is also an equivalent query, continue to figure out the query range of `c`.
  - Otherwise, if `a` is a non-equivalent query, you can only figure out the range of `a`.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans. However, all `Join` operations can only be performed as root tasks in TiDB.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see Optimizer Hints.

9.3.2.2 `EXPLAIN` Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the `EXPLAIN` statement to learn the current execution plan.

The following statement from the bikeshare example database counts how many trips were taken on the July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
    ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ---------------------------+----------+-----------+---------------+-----------
    ↪
```

```
| id                          | estRows | task     | access object | operator
    ↪ info
    ↪
    ↪ |
+--
    ↪ ----------------------------+---------+----------+---------------+-----------
    ↪
| StreamAgg_20                | 1.00    | root     |               | funcs:count(
    ↪ Column#13)->Column#11
    ↪
    ↪ |
|  ─TableReader_21            | 1.00    | root     |               | data:
    ↪ StreamAgg_9
    ↪
    ↪ |
|    ─StreamAgg_9             | 1.00    | cop[tikv] |              | funcs:count
    ↪ (1)->Column#13
    ↪
    ↪ |
|      ─Selection_19          | 250.00  | cop[tikv] |              | ge(
    ↪ bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(bikeshare
    ↪ .trips.start_date, 2017-07-01 23:59:59.000000) |
|        ─TableFullScan_18    | 10000.00 | cop[tikv] | table:trips | keep
    ↪ order:false, stats:pseudo
    ↪
    ↪ |
+--
    ↪ ----------------------------+---------+----------+---------------+-----------
    ↪
5 rows in set (0.00 sec)
```

From the child operator `─TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` operator. Approximately `250` rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `─TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV

(`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.

4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is `1`, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see `EXPLAIN ANALYZE`.
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `—TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

> **Note:**
>
> For a general view of the Regions that a table contains, execute `SHOW TABLE ↪ REGIONS`.

9.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ----------------------------+---------+---------+-----------+---------------+-
    ↪
| id                          | estRows | actRows | task      | access object |
    ↪ execution info
    ↪
    ↪ | operator info
    ↪
    ↪ | memory   | disk |
+--
    ↪ ----------------------------+---------+---------+-----------+---------------+-
    ↪
| StreamAgg_20                | 1.00    | 1       | root      |               |
    ↪ time:1.031417203s, loops:2
    ↪
    ↪ | funcs:count(Column#13)->Column#11
    ↪
    ↪ | 632 Bytes | N/A |
```

```
|  └─TableReader_21          | 1.00    | 56      | root     |                |
   ↪ time:1.031408123s, loops:2, cop_task: {num: 56, max: 782.147269ms,
   ↪ min: 5.759953ms, avg: 252.005927ms, p95: 609.294603ms, max_proc_keys:
   ↪  910371, p95_proc_keys: 704775, tot_proc: 11.524s, tot_wait: 580ms,
   ↪ rpc_num: 56, rpc_time: 14.111932641s} | data:StreamAgg_9
   ↪                                                                | 328 Bytes |
   ↪ N/A |

5 rows in set (1.03 sec)
```

The example query above takes 1.03 seconds to execute, which is an ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the `operator info` (`stats:pseudo`) of `└─TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
   ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
Query OK, 0 rows affected (10.22 sec)

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `TableFullScan_18` operator is accurate and the estimate for `Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a background operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```
+----------+-----------+----------------+---------+
| Db_name  | Table_name | Partition_name | Healthy |
+----------+-----------+----------------+---------+
| bikeshare | trips   |                |     100 |
+----------+-----------+----------------+---------+
1 row in set (0.00 sec)
```

9.3.2.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.
- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
*************************** 1. row ***************************
       Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint(20) NOT NULL AUTO_INCREMENT,
```

```
  `duration` int(11) NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int(11) DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int(11) DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
   ↪ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

> **Note:**
>
> You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL ↪ JOBS` command. The defaults in TiDB are carefully chosen so that adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of 10240 and worker count of 32 can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in `EXPLAIN`. In the following output, you can see that a new execution plan is chosen, and the `TableFullScan` and `Selection` operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
   ↪ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
   ↪ ------------------------+---------+-----------+-----------------------------
   ↪
```

```
| id                          | estRows | task    | access object
    ↪                           | operator info
    ↪                                                 |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
| StreamAgg_17                | 1.00    | root      |
    ↪                                                 | funcs:count(Column#13)->Column
    ↪ #11                                |
|  ─IndexReader_18            | 1.00    | root      |
    ↪                                                 | index:StreamAgg_9
    ↪                                                   |
|    ─StreamAgg_9             | 1.00    | cop[tikv] |
    ↪                                                     | funcs:count(1)->Column#13
    ↪                                       |
|      ─IndexRangeScan_16     | 8471.88 | cop[tikv] | table:trips, index:
    ↪ start_date(start_date) | range:[2017-07-01 00:00:00,2017-07-01
    ↪ 23:59:59], keep order:false |
+--
    ↪ ----------------------------+---------+-----------+-------------------------
    ↪
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use EXPLAIN ANALYZE:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
    ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
    ↪ ----------------------------+---------+---------+-----------+-----------------
    ↪
| id                          | estRows | actRows | task  | access object
    ↪                           | execution info
    ↪
    ↪ | operator info                                                | memory
    ↪   | disk |
+--
    ↪ ----------------------------+---------+---------+-----------+-----------------
    ↪

    ↪                                                 | time:4.516728ms, loops:2
    ↪
    ↪ | funcs:count(Column#13)->Column#11                            | 372
    ↪ Bytes | N/A |
|  ─IndexReader_18            | 1.00    | 1       | root      |
```

```
    ↪                                          | time:4.514278ms, loops:2,
    ↪ cop_task: {num: 1, max:4.462288ms, proc_keys: 11409, rpc_num: 1,
    ↪ rpc_time: 4.457148ms} | index:StreamAgg_9                          |
    ↪ 238 Bytes | N/A |
|    ─StreamAgg_9          | 1.00    | 1       | cop[tikv] |
    ↪                                        | time:4ms, loops:12
    ↪
    ↪ | funcs:count(1)->Column#13                                  | N/A
    ↪      | N/A |
|      ─IndexRangeScan_16  | 8471.88 | 11409 | cop[tikv] | table:trips,
    ↪ index:start_date(start_date) | time:4ms, loops:12
    ↪
    ↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
    ↪  N/A | N/A |
+--
    ↪ ---------------------------+---------+---------+-----------+-------------------
    ↪
4 rows in set (0.00 sec)
```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

> **Note:**
>
> Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the coprocessor cache. When it is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive `TableFullScan` and `Selection` operators.

9.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- IndexLookup
- IndexReader
- Point_Get and Batch_Point_Get
- IndexFullScan

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 intkey INT NOT NULL,
 pad1 VARBINARY(1024),
 INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
    ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
    ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

9.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

```

The `IndexLookup` operator has two child nodes:

- The `─IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal `RowID` (for this table, the primary key).
- The `─TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on statistics in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪      |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| TableReader_7         | 898.50 | root     |               | data:Selection_6
   ↪     |
|  ─Selection_6         | 898.50 | cop[tikv] |              | gt(test.t1.intkey
   ↪ , 100) |
|    ─TableFullScan_5   | 1010.00 | cop[tikv] | table:t1 | keep order:false
   ↪     |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

The IndexLookup operator can also be used to efficiently optimize LIMIT on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| id                           | estRows | task     | access object
   ↪              | operator info                    |
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
| IndexLookUp_21               | 10.00  | root     |
   ↪                              | limit embedded(offset:0, count:10) |
|  ─Limit_20(Build)            | 10.00  | cop[tikv] |
   ↪                              | offset:0, count:10             |
|    ─IndexFullScan_18         | 10.00  | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true, desc    |
|  ─TableRowIDScan_19(Probe)  | 10.00  | cop[tikv] | table:t1
   ↪                  | keep order:false, stats:pseudo |
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
```

```
4 rows in set (0.00 sec)
```

In the above example, the last 20 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

9.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;
```

```
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task    | access object
   ↪              | operator info                  |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
| IndexLookUp_10              | 1.00    | root     |
   ↪                               |                                |
|  ─IndexRangeScan_8(Build)  | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | range:[123,123], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 1.00    | cop[tikv] | table:t1
   ↪                  | keep order:false               |
+--
   ↪ ----------------------------+---------+----------+-------------------------
   ↪
3 rows in set (0.00 sec)

+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| id                    | estRows | task    | access object               |
   ↪ operator info                 |
+--
   ↪ ----------------------+---------+----------+-----------------------------+
   ↪
| Projection_4          | 1.00    | root     |                             |
   ↪ test.t1.id                    |
|  ─IndexReader_6        | 1.00    | root     |                              |
   ↪ index:IndexRangeScan_5        |
```

```
|   └─IndexRangeScan_5   | 1.00   | cop[tikv] | table:t1, index:intkey(
    ↪ intkey) | range:[123,123], keep order:false |
+--
    ↪ ----------------------+---------+-----------+--------------------------------+
    ↪
3 rows in set (0.00 sec)
```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `└─IndexRangeScan_5`, the value of the `RowID` can be returned directly.

9.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```
EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);
```

```
+-------------+---------+------+--------------+---------------+
| id          | estRows | task | access object | operator info |
+-------------+---------+------+--------------+---------------+

    ↪ operator info            |
+--
    ↪ ----------------+---------+------+-------------------------------------+----
    ↪
| Batch_Point_Get_1 | 2.00 | root | table:t1, index:unique_key(unique_key)
    ↪ | keep order:false, desc:false |
+--
    ↪ ----------------+---------+------+-------------------------------------+----
    ↪
1 row in set (0.00 sec)
```

9.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task     | access object
   ↪ | operator info                    |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| StreamAgg_12                | 1.00    | root     |
   ↪ | funcs:min(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
   ↪                               | offset:0, count:1                |
|    ─IndexReader_29          | 1.00    | root     |
   ↪                               | index:Limit_28                   |
|      ─Limit_28              | 1.00    | cop[tikv] |
   ↪                              | offset:0, count:1                |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true           |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
5 rows in set (0.00 sec)

+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| id                          | estRows | task     | access object
   ↪ | operator info                    |
+--
   ↪ ---------------------------+---------+----------+-------------------------
   ↪
| StreamAgg_12                | 1.00    | root     |
   ↪ | funcs:max(test.t1.intkey)->Column#4 |
|  ─Limit_16                  | 1.00    | root     |
   ↪                               | offset:0, count:1                |
|    ─IndexReader_29          | 1.00    | root     |
   ↪                               | index:Limit_28                   |
|      ─Limit_28              | 1.00    | cop[tikv] |
   ↪                              | offset:0, count:1                |
|        ─IndexFullScan_27    | 1.00    | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:true, desc     |
```

```
+--
    ↪ ---------------------------+---------+----------+-------------------------
    ↪
5 rows in set (0.00 sec)
```

In the above statements, an `IndexFullScan` task is performed on each TiKV Region. Despite the name `FullScan`, only the first row needs to be read (`-Limit_28`). Each TiKV Region returns its `MIN` or `MAX` value to TiDB, which then performs Stream Aggregation to filter for a single row. Stream Aggregation with the aggregation function `MAX` or `MIN` also ensures that `NULL` is returned if the table is empty.

By contrast, executing the `MIN` function on an unindexed value will result in `TableFullScan`. The query will require all rows to be scanned in TiKV, but a `TopN` calculation is performed to ensure each TiKV Region only returns one row to TiDB. Although `TopN` prevents excessive rows from being transferred between TiKV and TiDB, this statement is still considered far less efficient than the above example where `MIN` is able to make use of an index.

```
EXPLAIN SELECT MIN(pad1) FROM t1;
```

```
+--
    ↪ ----------------------------+---------+----------+--------------+----------
    ↪
| id                          | estRows | task    | access object | operator

+--
   ↪ -------------------------+---------+-----------+----------------------------
   ↪
4 rows in set (0.00 sec)

+--
   ↪ -------------------------+---------+-----------+----------------------------
   ↪
| id                        | estRows | task    | access object               |
   ↪ operator info                                                 |
+--
   ↪ -------------------------+---------+-----------+----------------------------
   ↪
| StreamAgg_20              | 1.00    | root      |                             |
   ↪ funcs:avg(Column#7, Column#8)->Column#4                       |
|  ─IndexReader_21          | 1.00    | root      |                              |
   ↪  index:StreamAgg_8                                            |
|    ─StreamAgg_8           | 1.00    | cop[tikv] |                              |
   ↪  funcs:count(test.t1.intkey)->Column#7, funcs:sum(test.t1.intkey)->
   ↪ Column#8 |
|      ─IndexFullScan_19    | 1010.00 | cop[tikv] | table:t1, index:intkey(
   ↪ intkey) | keep order:false                                     |
+--
```

```
    ↪ ------------------------+--------+----------+-------------------------------
    ↪
4 rows in set (0.00 sec)
```

In the above examples, `IndexFullScan` is more efficient than `TableFullScan` because the width of the value in the `(intkey + RowID)` index is less than the width of the full row.

The following statement does not support using an `IndexFullScan` operator because additional columns are required from the table:

```
EXPLAIN SELECT AVG(intkey), ANY_VALUE(pad1) FROM t1;
```

```
+--

    ↪ ---------------------------+--------+----------+-------------+-----------
    ↪
5 rows in set (0.00 sec)
```

9.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),

```

9.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `└─TableReader_28(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

```
EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
    ↪ t2.t1_id;
```

```

   ↪
6 rows in set (0.00 sec)
```

Index join is efficient in memory usage, but might be slower to execute than other join methods when a large number of probe operations are required. Consider also the following query:

```
SELECT * FROM t1 INNER JOIN t2 ON t1.id=t2.t1_id WHERE t1.pad1 = 'value'
   ↪ and t2.pad1='value';
```

In an inner join operation, TiDB implements join reordering and might access either `t1` or `t2` first. Assume that TiDB selects `t1` as the first table to apply the `build` step, and then TiDB is able to filter on the predicate `t1.col = 'value'` before probing the table `t2`. The filter for the predicate `t2.col='value'` will be applied on each probe of table `t2`, which might be less efficient than other join methods.

Index join is effective if the build side is small and the probe side is pre-indexed and large. Consider the following query where an index join performs worse than a hash join and is not chosen by the SQL Optimizer:

```
-- DROP previously added index
ALTER TABLE t2 DROP INDEX t1_id;

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
   ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
   ↪ .int_col = 1;
```

```
Query OK, 0 rows affected (0.29 sec)

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from `0.61 sec` to `0.14 sec`, as the following result shows:

```
-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
    ↪ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
    ↪ .int_col = 1;
```

```
Query OK, 0 rows affected (3.65 sec)

Note:

In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an NP-complete problem, and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use SQL Plan Management to bind a hint to a query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint `INL_JOIN` creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on the outer table using the hint `INL_HASH_JOIN`. Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- tidb_index_join_batch_size (default value: 25000) - the batch size of index lookup join operations.
- tidb_index_lookup_join_concurrency (default value: 4) - the number of concurrent index lookup tasks.

9.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the Build side of the join in a hash table, and then reads the data on the Probe side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```

   ↪ false                              |
+--
   ↪ ---------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of HashJoin_27, TiDB performs the following operations in order:

1. Cache the data of the Build side in memory.
2. Construct a Hash Table on the Build side based on the cached data.
3. Read the data at the Probe side.

4. Use the data of the `Probe` side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1GB) is exceeded, TiDB will attempt to use temporary storage on condition that the `oom-use-tmp-storage` value is `true` (default). This means that the `Build` operator used as part of the hash join might be created on disk. Runtime statistics such as memory usage are visible in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1GB (default) `tidb_mem_quota_query` quota, and a 500MB quota. At 500MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
    ↪  t2.id;
```

```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the `Build` operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: `5`) - the number of concurrent hash join tasks.

9.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the `Build` and the `Probe` sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```
+--
   ↪ -------------------------+----------+----------+---------------+-----------

| MergeJoin_7               | 142020.00 | root    |               | inner join,
   ↪ left key:test.t1.id, right key:test.t2.id |
|  ─TableReader_12(Build)  | 180000.00 | root    |               | data:
   ↪ TableFullScan_11                          |
|    ─TableFullScan_11     | 180000.00 | cop[tikv] | table:t2 | keep order:
   ↪ true                                      |
|  ─TableReader_10(Probe)  | 142020.00 | root    |               | data:
   ↪ TableFullScan_9                           |
|    ─TableFullScan_9      | 142020.00 | cop[tikv] | table:t1 | keep order:
   ↪ true                                      |
+--
   ↪ -------------------------+----------+----------+---------------+-----------
   ↪
5 rows in set (0.00 sec)
```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the `Build` side into the memory.
2. Read the data of the `Probe` side.
3. Compare whether each row of data on the `Probe` side matches a complete Join Group on the `Build` side. Apart from equivalent conditions, there are non-equivalent conditions. Here "match" mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

9.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the MPP mode to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on TiFlash.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id int, value int);
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;
```

```
SET tidb_allow_mpp = 1;
```

9.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

9.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSenderare` two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ----------------------------------+---------+------------------+--------------
   ↪
| id                                | estRows | task              | access object |
   ↪  operator info                                  |
+--
   ↪ ----------------------------------+---------+------------------+--------------
   ↪
| TableReader_31                    | 2.00    | root              |               |
   ↪ data:ExchangeSender_30                          |
|  ─ExchangeSender_30               | 2.00    | batchCop[tiflash] |               |
   ↪ ExchangeType: PassThrough                       |
|    ─Projection_26                 | 2.00    | batchCop[tiflash] |               |
   ↪ Column#4                                        |
|      ─HashAgg_27                  | 2.00    | batchCop[tiflash] |               |
   ↪ group by:test.t1.id, funcs:sum(Column#7)->Column#4 |
|        ─ExchangeReceiver_29       | 2.00    | batchCop[tiflash] |               |
   ↪                                                 |
|          ─ExchangeSender_28       | 2.00    | batchCop[tiflash] |               |
   ↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
```

```
|           └─HashAgg_9            | 2.00   | batchCop[tiflash] |           |
   ↪ group by:test.t1.id, funcs:count(1)->Column#7 |
|             └─TableFullScan_25   | 3.00   | batchCop[tiflash] | table:t1  |
   ↪ keep order:false                             |
+--
   ↪ ---------------------------------+---------+-------------------+-------------
   ↪
```

The above execution plan contains two query fragments:

- The first is `[TableFullScan_25, HashAgg_9, ExchangeSender_28]`, which is mainly responsible for the first-stage aggregation.
- The second is `[ExchangeReceiver_29, HashAgg_27, Projection_26, ExchangeSender_30 ↪ ]`, which is mainly responsible for the second-stage aggregation.

The `operator info` column of the `ExchangeSender` operator shows the exchange type information. Currently, there are three exchange types. See the following:

- HashPartition: The `ExchangeSender` operator firstly partitions data according to the Hash values and then distributes data to the `ExchangeReceiver` operator of upstream MPP tasks. This exchange type is often used for Hash Aggregation and Shuffle Hash Join algorithms.
- Broadcast: The `ExchangeSender` operator distributes data to upstream MPP tasks through broadcast. This exchange type is often used for Broadcast Join.
- PassThrough: The `ExchangeSender` operator sends data to the only upstream MPP task, which is different from the Broadcast type. This exchange type is often used when returning data to TiDB.

In the example execution plan, the exchange type of the operator `ExchangeSender_28` is HashPartition, meaning that it performs the Hash Aggregation algorithm. The exchange type of the operator `ExchangeSender_30` is PassThrough, meaning that it is used to return data to TiDB.

MPP is also often applied to join operations. The MPP mode in TiDB supports the following two join algorithms:

- Shuffle Hash Join: Shuffle the data input from the join operation using the HashPartition exchange type. Then, upstream MPP tasks join data within the same partition.
- Broadcast Join: Broadcast data of the small table in the join operation to each node, after which each node joins the data separately.

The following is a typical execution plan for Shuffle Hash Join:

```
SET tidb_opt_broadcast_join=0;
SET tidb_broadcast_join_threshold_count=0;
SET tidb_broadcast_join_threshold_size=0;
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```

   ↪ not(isnull(test.t1.id))                      |
|              ─TableFullScan_20      | 6.00   | cop[tiflash] | table:b      |
   ↪ keep order:false                             |
+--
   ↪ ------------------------------------+--------+-------------+--------------+
   ↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment `[TableFullScan_20, Selection_21, ExchangeSender_22]` reads data from table b and shuffles data to upstream MPP tasks.
- The query fragment `[TableFullScan_16, Selection_17, ExchangeSender_18]` reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment `[ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_44 ↪ , ExchangeSender_47]` joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```
+--
   ↪ ----------------------------------+---------+-------------+---------------+

| id                                | estRows | task      | access object |
   ↪ operator info                          |
+--
   ↪ ----------------------------------+---------+-------------+---------------+
   ↪
| StreamAgg_15                      | 1.00    | root        |               |
   ↪ funcs:count(1)->Column#7               |
|  TableReader_47                   | 9.00    | root        |               |
   ↪ data:ExchangeSender_46                 |
|    ExchangeSender_46              | 9.00    | cop[tiflash] |              |
   ↪ ExchangeType: PassThrough              |
|      HashJoin_43                  | 9.00    | cop[tiflash] |              |
   ↪ inner join, equal:[eq(test.t1.id, test.t1.id)] |
|        ExchangeReceiver_20(Build) | 6.00    | cop[tiflash] |              |
   ↪                                        |
|          ExchangeSender_19        | 6.00    | cop[tiflash] |              |
   ↪ ExchangeType: Broadcast                |
|            Selection_18           | 6.00    | cop[tiflash] |              |
   ↪ not(isnull(test.t1.id))                |
|              TableFullScan_17     | 6.00    | cop[tiflash] | table:a      |
   ↪ keep order:false                       |
|        Selection_22(Probe)        | 6.00    | cop[tiflash] |              |
   ↪ not(isnull(test.t1.id))                |
|          TableFullScan_21         | 6.00    | cop[tiflash] | table:b      |
   ↪ keep order:false                       |
+--
   ↪ ----------------------------------+---------+-------------+---------------+
   ↪
```

In the above execution plan:

- The query fragment `[TableFullScan_17, Selection_18, ExchangeSender_19]` reads data from the small table (table a) and broadcasts the data to each node that contains data from the large table (table b).
- The query fragment `[TableFullScan_21, Selection_22, ExchangeReceiver_20, ↪ HashJoin_43, ExchangeSender_46]` joins all data and returns it to TiDB.

9.3.2.5.3 `EXPLAIN ANALYZE` statements in the MPP mode

The `EXPLAIN ANALYZE` statement is similar to `EXPLAIN`, but it also outputs some runtime information.

The following is the output of a simple `EXPLAIN ANALYZE` example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
   ↪ ----------------------------------+---------+---------+-------------------+-----
   ↪

```

Compared to the output of `EXPLAIN`, the `operator info` column of the operator `ExchangeSender` also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

9.3.2.6 Explain Statements That Use Subqueries

TiDB performs several optimizations to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of `EXPLAIN`.

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
    ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
    ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
 id INT NOT NULL PRIMARY KEY auto_increment,
 t1_id INT NOT NULL,
 UNIQUE (t1_id)
);

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
    ↪  LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
ANALYZE TABLE t1, t2, t3;
```

9.3.2.6.1 Inner join (non-unique subquery)

In the following example, the `IN` subquery searches for a list of IDs from the table `t2` ↪ . For semantic correctness, TiDB needs to guarantee that the column `t1_id` is unique. Using `EXPLAIN`, you can see the execution plan used to remove duplicates and perform an `INNER JOIN` operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```

   ↪ PRIMARY(id) | range: decided by [eq(test.t1.id, test.t2.t1_id)], keep
   ↪  order:false                                    |
|    ─TableRowIDScan_12(Probe) | 1.00    | cop[tikv] | table:t1
   ↪                | keep order:false
```

```
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+----------+----------------------
    ↪
8 rows in set (0.00 sec)
```

The result above shows that TiDB performs an index join operation that starts by reading the index on `t2.t1_id`. The values of `t1_id` are deduplicated inside TiKV first as a part of the `─HashAgg_31` operator task, and then deduplicated again in TiDB as a part of the `─HashAgg_38(Build)` operator task. The deduplication is performed by the aggregation function `firstrow(test.t2.t1_id)`. The result is then joined against the `t1` table's `PRIMARY KEY`.

9.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```
+--
    ↪ ------------------------------+---------+----------+----------------------
    ↪
| id                            | estRows | task    | access object
    ↪           | operator info
    ↪
    ↪ |
+--
    ↪ ------------------------------+---------+----------+----------------------
    ↪
| IndexJoin_17                  | 1978.13 | root    |
    ↪                           | inner join, inner:IndexLookUp_16, outer key
    ↪ :test.t3.t1_id, inner key:test.t1.id, equal cond:eq(test.t3.t1_id,
    ↪ test.t1.id) |
|  ─TableReader_44(Build)       | 1978.00 | root    |
    ↪                           | data:TableFullScan_43
    ↪
    ↪ |
|    ─TableFullScan_43          | 1978.00 | cop[tikv] | table:t3
    ↪              | keep order:false
    ↪
    ↪ |
|  ─IndexLookUp_16(Probe)       | 1.00    | root      |
    ↪                           |
```

```
    ↪
    ↪ |
|    └─IndexRangeScan_14(Build) | 1.00    | cop[tikv] | table:t1, index:
    ↪ PRIMARY(id) | range: decided by [eq(test.t1.id, test.t3.t1_id)], keep
    ↪  order:false                                    |
|    └─TableRowIDScan_15(Probe) | 1.00    | cop[tikv] | table:t1
    ↪                | keep order:false
    ↪
    ↪ |
+--
    ↪ ---------------------------------+---------+-----------+-----------------------
    ↪
6 rows in set (0.01 sec)
```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

9.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `HashAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
    ↪ t1.int_col);
```

```
+--
    ↪ ---------------------------+-----------+-----------+-----------------------
    ↪
| id                          | estRows  | task      | access object            |
    ↪  operator info
    ↪
    ↪ |
+--
    ↪ ---------------------------+-----------+-----------+-----------------------
    ↪
| MergeJoin_9                 | 45446.40 | root      |                          |
    ↪  semi join, left key:test.t1.id, right key:test.t2.t1_id, other cond:
    ↪ ne(test.t2.t1_id, test.t1.int_col) |
|  └─IndexReader_24(Build)  | 180000.00 | root    |
    ↪ | index:IndexFullScan_23
    ↪                                                                    |
|    └─IndexFullScan_23     | 180000.00 | cop[tikv] | table:t2, index:t1_id(
    ↪ t1_id) | keep order:true
    ↪                                                                   |
```

```
|  └─TableReader_22(Probe)  | 56808.00 | root    |
   ↪ | data:Selection_21
   ↪
   ↪ |
|    └─Selection_21         | 56808.00 | cop[tikv] |
   ↪ | ne(test.t1.id, test.t1.int_col)
   ↪                                                                 |
|      └─TableFullScan_20   | 71010.00 | cop[tikv] | table:t1
   ↪ | keep order:true
   ↪
   ↪ |
+--
   ↪ --------------------------+----------+----------+--------------------------
   ↪
6 rows in set (0.00 sec)
```

From the result above, you can see that TiDB uses a `Semi Join` algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the subquery decorrelation optimization has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `└─Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

9.3.2.6.4 Anti semi join (`NOT IN` subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```
EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE
   ↪ int_col < 100);
```

```
+--
   ↪ --------------------------+---------+----------+--------------+--------------
   ↪
| id                        | estRows | task    | access object | operator
   ↪ info                                                          |
+--
   ↪ --------------------------+---------+----------+--------------+--------------
   ↪
```

```
| IndexMergeJoin_20       | 1598.40 | root    |              | anti semi join
   ↪ , inner:TableReader_15, outer key:test.t3.t1_id, inner key:test.t1.id
   ↪  |
|  ─TableReader_28(Build)  | 1998.00 | root    |              | data:
   ↪ TableFullScan_27                                                    |
|    ─TableFullScan_27     | 1998.00 | cop[tikv] | table:t3 | keep order:
   ↪ false                                                                |
|  ─TableReader_15(Probe)  | 1.00    | root    |              | data:
   ↪ Selection_14                                                        |
|    ─Selection_14         | 1.00    | cop[tikv] |              | lt(test.t1.
   ↪ int_col, 100)                                                        |
|      ─TableRangeScan_13  | 1.00    | cop[tikv] | table:t1 | range:
   ↪ decided by [test.t3.t1_id], keep order:true                          |
+--
   ↪ --------------------------+---------+-----------+---------------+-------------
   ↪
6 rows in set (0.00 sec)
```

This query starts by reading the table `t3` and then probes the table `t1` based on the `PRIMARY KEY`. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (`NOT IN`) and semi-join because only the first row needs to match before the join is rejected.

9.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```
CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
   ↪ pad2 BLOB, pad3 BLOB);
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
    ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

From the output of SHOW TABLE REGIONS, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```
+--
    ↪ ---------+--------------+--------------+-----------+-----------------+-------+--
    ↪
| REGION_ID | START_KEY | END_KEY    | LEADER_ID | LEADER_STORE_ID | PEERS |

    ↪ 63211 |
+--
    ↪ ---------+--------------+--------------+----------+-----------------+-------+--
    ↪
4 rows in set (0.00 sec)
```

Using `EXPLAIN` with the following aggregation statement, you can see that `StreamAgg_8` is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in `StreamAgg_16`:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| id                         | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
| StreamAgg_16               | 1.00     | root     |               | funcs:count(
    ↪ Column#7)->Column#5 |
| ─TableReader_17            | 1.00     | root     |               | data:
    ↪ StreamAgg_8            |
|   ─StreamAgg_8             | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#7    |
|     ─TableFullScan_15      | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ -------------------------+----------+----------+--------------+-----------
    ↪
4 rows in set (0.00 sec)
```

This is easiest to observe in `EXPLAIN ANALYZE`, where the `actRows` matches the number of Regions from `SHOW TABLE REGIONS` because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```
+--
    ↪ -------------------------+----------+---------+----------+---------------+---
    ↪
| id                         | estRows  | actRows | task     | access object |
    ↪ execution info
```

```
    ↪

    ↪
4 rows in set (0.01 sec)
```

9.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the `HashAgg` operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```
+--
    ↪ ----------------------+----------+----------+--------------+--------------
    ↪
| id                    | estRows  | task     | access object | operator
    ↪ info             |
+--
    ↪ ----------------------+----------+----------+--------------+--------------
    ↪
```

```
| HashAgg_9              | 1.00     | root     |              | funcs:count(
    ↪ Column#6)->Column#5 |
|  ─TableReader_10       | 1.00     | root     |              | data:
    ↪ HashAgg_5              |
|    ─HashAgg_5          | 1.00     | cop[tikv] |              | funcs:count
    ↪ (1)->Column#6    |
|      ─TableFullScan_8  | 242020.00 | cop[tikv] | table:t1 | keep order:
    ↪ false            |
+--
    ↪ ----------------------+----------+----------+--------------+------------
    ↪
4 rows in set (0.00 sec)
```

The `operator info` shows that the hashing function used to aggregate the data is `funcs:count(1)->Column#6`.

9.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```
CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.11 sec)

Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

+--
    ↪ ---------------------------+----------+----------+--------------+----------
    ↪
| id                         | estRows | task     | access object | operator
    ↪ info
    ↪ |
+--
    ↪ ---------------------------+----------+----------+--------------+----------
    ↪
| Projection_4               | 8000.00 | root     |              | test.t2.col1
    ↪ , Column#3                                                              |
|  ─StreamAgg_8              | 8000.00 | root     |              | group by:
    ↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
    ↪ ->test.t2.col1 |
```

```
|   └─Sort_13               | 10000.00 | root    |              | test.t2.
    ↪ col1
    ↪                                                                    |
|     └─TableReader_12      | 10000.00 | root    |              | data:
    ↪ TableFullScan_11
    ↪                                                                      |
|       └─TableFullScan_11  | 10000.00 | cop[tikv] | table:t2 | keep order:
    ↪ false, stats:pseudo
    ↪ |
+--
    ↪ ---------------------------+----------+-----------+---------------+-----------
    ↪
5 rows in set (0.00 sec)
```

In this example, the `└─Sort_13` operator can be eliminated by adding an index on `col1` ↪ . Once the index is added, the data can be read in order and the `└─Sort_13` operator is eliminated:

```
ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;
```

```
Query OK, 0 rows affected (0.28 sec)

    ↪ ) | keep order:true, stats:pseudo
    ↪                                                                 |
+--
    ↪ ---------------------------+--------+----------+-------------------------+
    ↪
5 rows in set (0.00 sec)
```

9.3.2.8 EXPLAIN Statements Using Views

EXPLAIN displays the tables and indexes that a view references, not the name of the view itself. This is because views are only virtual tables and do not store any data themselves. The definition of the view and the rest of the statement are merged together during SQL optimization.

From the bikeshare example database, you can see that the following two queries are executed in a similar manner:

```
ALTER TABLE trips ADD INDEX (duration);
CREATE OR REPLACE VIEW long_trips AS SELECT * FROM trips WHERE duration >
    ↪ 3600;
EXPLAIN SELECT * FROM long_trips;
EXPLAIN SELECT * FROM trips WHERE duration > 3600;
```

```
Query OK, 0 rows affected (2 min 10.11 sec)

Query OK, 0 rows affected (0.13 sec)

+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
| id                           | estRows   | task     | access object
    ↪                     | operator info                    |
+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
| IndexLookUp_12               | 6372547.67 | root    |
    ↪                                  |                                  |
|  ─IndexRangeScan_10(Build)  | 6372547.67 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_11(Probe)  | 6372547.67 | cop[tikv] | table:trips
    ↪                     | keep order:false                 |
+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
```

```
3 rows in set (0.00 sec)

+--
    ↪ ----------------------------+----------+----------+-----------------------
    ↪
| id                          | estRows  | task     | access object
    ↪                     | operator info                   |
+--
    ↪ ----------------------------+----------+----------+-----------------------
    ↪
| IndexLookUp_10              | 833219.37 | root    |
    ↪                                  |                                  |
|  ─IndexRangeScan_8(Build)  | 833219.37 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false |
|  ─TableRowIDScan_9(Probe)  | 833219.37 | cop[tikv] | table:trips
    ↪                    | keep order:false                |
+--
    ↪ ----------------------------+----------+----------+-----------------------
    ↪
3 rows in set (0.00 sec)
```

Similarly, predicates from the view are pushed down to the base table:

```
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| id                          | estRows | task    | access object
    ↪                     | operator info                                |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
| IndexLookUp_14              | 3.33    | root     |
    ↪                                   |
    ↪                                          |
|  ─IndexRangeScan_11(Build) | 3333.33 | cop[tikv] | table:trips, index:
    ↪ duration(duration) | range:(3600,+inf], keep order:false, stats:
    ↪ pseudo |
|  ─Selection_13(Probe)      | 3.33    | cop[tikv] |
    ↪                                  | eq(bikeshare.trips.bike_number, "
    ↪ W00950")   |
|    ─TableRowIDScan_12      | 3333.33 | cop[tikv] | table:trips
    ↪                     | keep order:false, stats:pseudo              |
```

```
+--
   ↪ ----------------------------+---------+----------+-----------------------
   ↪
4 rows in set (0.00 sec)

+--
   ↪ ----------------------+------------+----------+--------------+------------
   ↪
| id                    | estRows    | task     | access object | operator
   ↪ info                       |
+--
   ↪ ----------------------+------------+----------+--------------+------------
   ↪
| TableReader_7         | 43.00      | root     |               | data:
   ↪ Selection_6                      |
|  ─Selection_6         | 43.00      | cop[tikv] |              | eq(bikeshare.
   ↪ trips.bike_number, "W00950") |
|    ─TableFullScan_5   | 19117643.00 | cop[tikv] | table:trips | keep order
   ↪ :false                   |
+--
   ↪ ----------------------+------------+----------+--------------+------------
   ↪
3 rows in set (0.00 sec)
```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself. Consider the following composite index:

```
ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';
```

```
Query OK, 0 rows affected (2 min 31.20 sec)

+--

    ↪ order:false |
|  ─TableRowIDScan_9(Probe)  | 19117.64 | cop[tikv] | table:trips
    ↪                                    | keep order:false
    ↪                           |
+--
    ↪ ----------------------------+---------+----------+-----------------------
    ↪
3 rows in set (0.00 sec)
```

In the first statement, TiDB is able to use both parts of the composite index (`bike_number, duration`). In the second statement, only the first part which is `bike_number` of the index (`bike_number, duration`) is used.

9.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to

execute a query. Because of partition pruning, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
 id BIGINT NOT NULL auto_increment,
 d date NOT NULL,
 pad1 BLOB,
 pad2 BLOB,
 pad3 BLOB,
 PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
 PARTITION p2016 VALUES LESS THAN (2017),
 PARTITION p2017 VALUES LESS THAN (2018),
 PARTITION p2018 VALUES LESS THAN (2019),
 PARTITION p2019 VALUES LESS THAN (2020),
 PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
 ('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
 ('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
   ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```
SELECT SLEEP(1);
ANALYZE TABLE t1;
```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```
+--

+--
   ↪ ---------------------------+---------+----------+-------------------------+-
   ↪
5 rows in set (0.01 sec)
```

Starting from the inner-most (`─TableFullScan_19`) operator and working back towards the root operator (`StreamAgg_21`):

- TiDB successfully identified that only one partition (`p2017`) needed to be accessed. This is noted under `access object`.
- The partition itself was scanned in the operator `─TableFullScan_19` and then `─Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `─Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `─TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

    ↪                     | eq(year(test.t1.d), 2017)    |
|           ─TableFullScan_110  | 11116.00 | cop[tikv] | table:t1,
    ↪ partition:pmax | keep order:false       |
+--
    ↪ ----------------------------------+----------+----------+----------------------
    ↪
27 rows in set (0.00 sec)
```

From the output above:

- TiDB believes that it needs to access all of the partitions (`p2016..pMax`). This is because the predicate `YEAR(d)= 2017` is considered non-sargable. This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.
- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `─PartitionUnion_21` unions the results from accessing each partition.

9.3.2.10 Explain Statements Using Index Merge

`IndexMerge` is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

```
mysql> EXPLAIN SELECT * from t where a = 1 or b = 1;
```

```
+--
   ↪ ---------------------+---------+----------+--------------+-----------------
   ↪
| id                    | estRows | task     | access object | operator info

mysql> explain select * from t use index(idx_a, idx_b) where a > 1 or b >
   ↪ 1;
+--
   ↪ ----------------------------+--------+----------+----------------------+-
   ↪
| id                           | estRows | task    | access object        |
   ↪ operator info                                |
+--
   ↪ ----------------------------+--------+----------+----------------------+-
   ↪
| IndexMerge_16                | 6666.67 | root    |                      |
   ↪                                             |
|  ─IndexRangeScan_13(Build)  | 3333.33 | cop[tikv] | table:t, index:idx_a(a
   ↪ ) | range:(1,+inf], keep order:false, stats:pseudo |
|  ─IndexRangeScan_14(Build)  | 3333.33 | cop[tikv] | table:t, index:idx_b(b
   ↪ ) | range:(1,+inf], keep order:false, stats:pseudo |
|  ─TableRowIDScan_15(Probe)  | 6666.67 | cop[tikv] | table:t           |
   ↪ keep order:false, stats:pseudo           |
+--
   ↪ ----------------------------+--------+----------+----------------------+-
   ↪
```

In the above query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without `IndexMerge`, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, `IndexMerge` is introduced in TiDB to access tables.

`IndexMerge` allows the optimizer to use multiple indexes per table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the figure above. Here the `IndexMerge_16` operator has three child nodes, among which `IndexRangeScan_13` and `IndexRangeScan_14` get all the `RowID`s that meet the conditions based on the result of range scan, and then the `TableRowIDScan_15` operator accurately reads all the data that meets the conditions according to these `RowID`s.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan`/`TableRangeScan`, the `operator info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan`/`TableFullScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_13` operator indicates that the operator scans the data from 1 to positive infinity.

> **Note:**
>
> At present, the `IndexMerge` feature is disabled by default in TiDB 4.0.0-rc.1. In addition, the currently supported scenarios of `IndexMerge` in TiDB 4.0 are limited to the disjunctive normal form (expressions connected by `or`). The conjunctive normal form (expressions connected by `and`) will be supported in later versions. Enable the `IndexMerge` in one of two ways:
>
> - Set `tidb_enable_index_merge=1`;
> - Use the SQL Hint `USE_INDEX_MERGE` in the query.
>
> SQL Hint has a higher priority than system variables.

9.3.3 SQL Optimization Process

9.3.3.1 SQL Optimization Process

In TiDB, the process from inputting a query to getting the execution result according to the final execution plan is illustrated as follows:

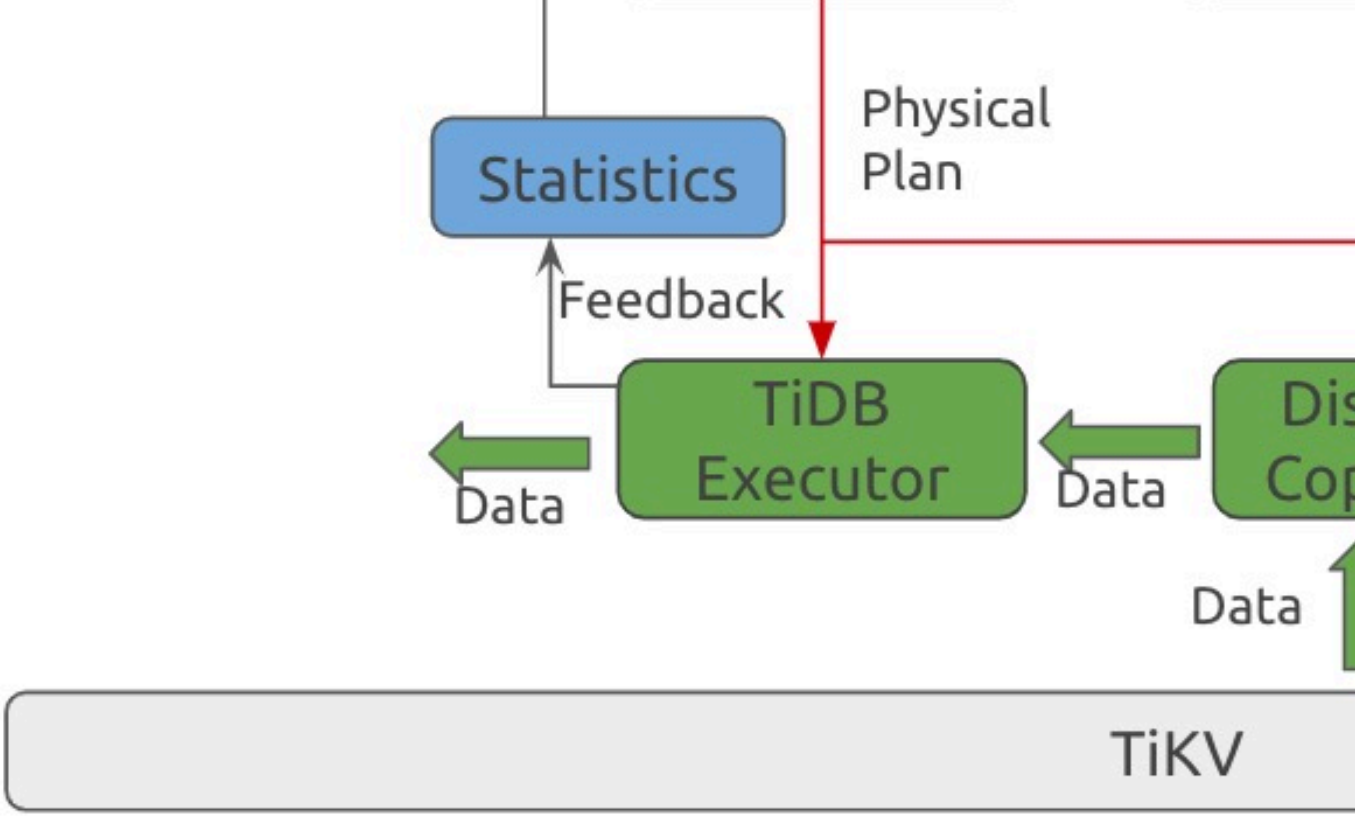

Figure 63: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see SQL Logical Optimization.

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see SQL Physical Optimization.

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see Execution Plan Cache.

9.3.3.2 Logic Optimization

9.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- Subquery Related Optimizations
- Column Pruning
- Decorrelation of Correlated Subquery
- Eliminate Max/Min
- Predicates Push Down
- Partition Pruning
- TopN and Limit Operator Push Down
- Join Reorder

9.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ..)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a "correlated subquery", and the externally introduced column is called a "correlated column". For optimizations about correlated subquery, see Decorrelation of correlated subquery. This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in Understanding TiDB Execution Plan as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

`... < ALL (SELECT ... FROM ...)` or `... > ANY (SELECT ... FROM ...)`

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is NULL. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id)and if(sum(s.id is null)!= 0, null, true)`
- `t.id < any (select s.id from s)` is rewritten as `t.id < max(s.id)or if(sum(s.id is null)!= 0, null, false)`

`... != ANY (SELECT ... FROM ...)`

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s)where (t.id != s.id or cnt_distinct > 1)`

`... = ALL (SELECT ... FROM ...)`

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct from s )where (t.id = s.id and cnt_distinct <= 1)`

`... IN (SELECT ... FROM ...)`

In this case, the subquery of `IN` is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of `JOIN`.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2.a`. The form of `DISTINCT` attribute here can be eliminated automatically if `t2.a` has the `UNIQUE` attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```

+--
   ↪ ---------------------------+---------+----------+-----------------------+----
   ↪
```

This rewrite gets better performance when the `IN` subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with t2 as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable tidb_opt_insubq_to_join_and_agg is used to control this optimization. When this optimization is not suitable, you can manually disable it.

`EXISTS` subquery and `... >/>=/</<=/=/!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the `EXISTS` subquery is evaluated to `TRUE` in the optimization stage in advance, so it does not show in the final execution result.

```
create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);
```

```
+--

```

9.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b> 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called "Column Pruning", corresponding to the `columnPruner` rule. If you want to disable this rule, refer to The Blocklist of Optimization Rules and Expression Pushdown.

9.3.3.2.4 Decorrelation of Correlated Subquery

Subquery related optimizations describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a)from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a)sum_a from t2 group by b)t2 where t1.b = t2.b and t1.a < t2.sum_a;`. In this way, a correlated subquery is rewritten into `JOIN`.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, because it may bring better execution performance. At present, this optimization can be disabled by setting `subquery decorrelation` optimization rules in blocklist of optimization rules and expression pushdown.

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

|        ─Selection_22            | 9990.00 | cop[tikv] |             | not(
    ↪ isnull(test.t2.b))
    ↪                                                       |
|          ─TableFullScan_21      | 10000.00 | cop[tikv] | table:t2 | keep
    ↪ order:false, stats:pseudo
    ↪                                                     |
|  ─TableReader_15(Probe)         | 9990.00 | root     |              | data:
    ↪ Selection_14
    ↪                                                                  |
|    ─Selection_14                | 9990.00 | cop[tikv] |             | not(
    ↪ isnull(test.t1.b))
    ↪                                                       |
|      ─TableFullScan_13          | 10000.00 | cop[tikv] | table:t1 | keep
    ↪ order:false, stats:pseudo
```

```
    ↪                                                  |
+--
    ↪ --------------------------------+---------+----------+--------------+-------
    ↪
```

The above is an example where the optimization takes effect. `HashJoin_11` is a normal `inner join`.

Then, turn off the subquery decorrelation rules:

```
insert into mysql.opt_rule_blacklist values("decorrelate");
admin reload opt_rule_blacklist;
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
    ↪ = t1.b);
```

```

    ↪                     | funcs:sum(Column#10)->Column#7
    ↪                                          |
|        ─IndexLookUp_28               | 1.00    | root     |
    ↪                     |
    ↪                                                                    |
```

```
|         ─IndexRangeScan_25(Build) | 10.00   | cop[tikv] | table:t2, index
    ↪ :idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep order:
    ↪ false, stats:pseudo |
|         ─HashAgg_17(Probe)         | 1.00    | cop[tikv] |
    ↪                     | funcs:sum(test.t2.a)->Column#10
    ↪                                       |
|           ─TableRowIDScan_26       | 10.00   | cop[tikv] | table:t2
    ↪           | keep order:false, stats:pseudo
    ↪                                        |
+--
    ↪ ------------------------------------+---------+----------+-----------------
    ↪
```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(` ↪ `test.t2.b, test.t1.b)]` in `operator info` of `IndexRangeScan_25(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

9.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert the `max/min` aggregate functions to the TopN operator by applying the `max/min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max/min` functions in the `select` statement:

- The statement with only one `max/min` function
- The statement with multiple `max/min` functions

One `max/min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
    ↪ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
| id                          | estRows | task     | access object         |
   ↪ operator info                    |
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
| StreamAgg_13                | 1.00    | root     |                       |
   ↪ funcs:max(test.t.a)->Column#4   |
| └─Limit_17                  | 1.00    | root     |                       |
   ↪ offset:0, count:1                |
|   └─IndexReader_27          | 1.00    | root     |                       |
   ↪ index:Limit_26                   |
|     └─Limit_26              | 1.00    | cop[tikv] |                       |
   ↪ offset:0, count:1                |
|       └─IndexFullScan_25    | 1.00    | cop[tikv] | table:t, index:idx_a(a) |
   ↪  keep order:true, desc, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+-----------------------+---
   ↪
5 rows in set (0.00 sec)
```

Multiple `max`/`min` functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max`/`min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
    (select max(a) as max_a from t) t1,
    (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max` ↪ `/min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
    (select max(a) as max_a from (select a from t where a is not null order
       ↪  by a desc limit 1) t) t1,
    (select min(a) as min_a from (select a from t where a is not null order
       ↪  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+--
   ↪ ----------------------------------+---------+-----------+----------------------
   ↪

9.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```
create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪            |
+--
   ↪ ----------------------+----------+-----------+---------------+----------------
   ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
   ↪            |
|  └─Selection_6         | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
   ↪            |
```

```
|   └─TableFullScan_5   | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
3 rows in set (0.00 sec)
```

In this query, pushing down the predicate `a < 1` to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```
create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
| id                    | estRows | task    | access object | operator info
    ↪            |
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
| TableReader_7         | 3323.33 | root    |               | data:Selection_6
    ↪           |
|  └─Selection_6        | 3323.33 | cop[tikv] |             | lt(test.t.a, 1)
    ↪             |
|    └─TableFullScan_5  | 10000.00 | cop[tikv] | table:t  | keep order:false
    ↪ , stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+--------------+----------------
    ↪
```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate `a < substring('123', 1, 1)` are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate `a < 1`. After that, TiDB can push `a < 1` down to TiKV.

Case 3: push predicates below join operator

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
    ↪ --------------------------+----------+-----------+--------------+-----------
    ↪
| id                        | estRows | task    | access object | operator
    ↪ info                       |
```

```
+--
   ↪ --------------------------+---------+----------+--------------+-----------
   ↪
| HashJoin_8                | 4154.17 | root     |              | inner join,
   ↪ equal:[eq(test.t.a, test.s.a)] |
| ─TableReader_15(Build)    | 3323.33 | root     |              | data:
   ↪ Selection_14                     |
|   ─Selection_14           | 3323.33 | cop[tikv] |             | lt(test.s.a
   ↪ , 1)                       |
|     ─TableFullScan_13     | 10000.00 | cop[tikv] | table:s    | keep order:
   ↪ false, stats:pseudo        |
| ─TableReader_12(Probe)    | 3323.33 | root     |              | data:
   ↪ Selection_11                     |
|   ─Selection_11           | 3323.33 | cop[tikv] |             | lt(test.t.a
   ↪ , 1)                       |
|     ─TableFullScan_10     | 10000.00 | cop[tikv] | table:t    | keep order:
   ↪ false, stats:pseudo        |
+--
   ↪ --------------------------+---------+----------+--------------+-----------
   ↪
7 rows in set (0.00 sec)
```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the `ON` condition is `t.a = s.a`. The predicate `s.a <1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```
create table t(id int primary key, a int not null);
desc select * from t where substring('123', a, 1) = '1';
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪                     |
+--
   ↪ ----------------------+---------+----------+-------------+-----------------
   ↪
| Selection_7           | 2.00    | root     |             | eq(substring("123
   ↪ ", test.t.a, 1), "1") |
| ─TableReader_6        | 2.00    | root     |             | data:
   ↪ TableFullScan_5             |
```

```
|   └─TableFullScan_5   | 2.00   | cop[tikv] | table:t    | keep order:false,
    ↪  stats:pseudo    |
+--
    ↪ ----------------------+---------+-----------+--------------+-----------------
    ↪
```

In this query, there is a predicate `substring('123', a, 1)= '1'`.

From the `explain` results, we can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `substring`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
    ↪ ----------------------------+----------+-----------+--------------+----------
    ↪
| id                          | estRows | task    | access object | operator
    ↪ info                           |
+--
    ↪ ----------------------------+----------+-----------+--------------+----------
    ↪
| Selection_7                 | 10000.00 | root    |               | isnull(test
    ↪ .s.a)                          |
|  └─HashJoin_8               | 12500.00 | root    |               | left outer
    ↪  join, equal:[eq(test.t.a, test.s.a)] |
|    ├─TableReader_13(Build)  | 10000.00 | root    |               | data:
    ↪ TableFullScan_12                    |
|    │ └─TableFullScan_12     | 10000.00 | cop[tikv] | table:s   | keep order:
    ↪ false, stats:pseudo            |
|    └─TableReader_11(Probe)  | 10000.00 | root    |               | data:
    ↪ TableFullScan_10                    |
|      └─TableFullScan_10     | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo            |
+--
    ↪ ----------------------------+----------+-----------+--------------+----------
    ↪
6 rows in set (0.00 sec)
```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with `NULL` values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If

it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```
create table t(id int primary key, a char);
set @a = 1;
explain select * from t where a < @a;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info
   ↪            |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| Selection_5           | 8000.00 | root     |               | lt(test.t.a,
   ↪ getvar("a"))  |
| └─TableReader_7       | 10000.00 | root    |               | data:
   ↪ TableFullScan_6       |
|   └─TableFullScan_6   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo |
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.00 sec)
```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with `1`, and does not push down it to TiKV.

An example to help you understand is as follows:

```
create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+----+------+----------+
| id | a    | @a:=@a+1 |
+----+------+----------+
|  1 |    1 | 2        |
|  2 |    2 | 3        |
+----+------+----------+
2 rows in set (0.00 sec)
```

As you can see from this query, the value of `@a` will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

9.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
 id INT NOT NULL PRIMARY KEY,
 pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
 PARTITION p0 VALUES LESS THAN (100),
 PARTITION p1 VALUES LESS THAN (200),
 PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| id                        | estRows | task    | access object       |
   ↪ operator info                              |
+--
   ↪ -------------------------+---------+-----------+----------------------+------
   ↪
| PartitionUnion_8          | 80.00   | root    |                      |
   ↪                                          |
|  ─TableReader_10          | 40.00   | root    |                      | data:
   ↪ TableRangeScan_9                        |
|    ─TableRangeScan_9      | 40.00   | cop[tikv] | table:t1, partition:p0 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
|  ─TableReader_12          | 40.00   | root    |                      | data:
   ↪ TableRangeScan_11                       |
|    ─TableRangeScan_11     | 40.00   | cop[tikv] | table:t1, partition:p1 |
   ↪ range:[80,120], keep order:false, stats:pseudo |
+--
   ↪ -------------------------+---------+-----------+----------------------+------
```

```
    ↪
5 rows in set (0.00 sec)
```

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
    ↪ ----------------------+----------+-----------+-----------------------+---------
    ↪
| id                    | estRows | task    | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+----------+-----------+-----------------------+---------
    ↪
| TableReader_8         | 10.00   | root    |                       | data:
    ↪ Selection_7           |
|  ─Selection_7         | 10.00   | cop[tikv] |                     | eq(test.t
    ↪ .x, 1)             |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+----------+-----------+-----------------------+---------
    ↪
```

In the SQL statement above, it can be known from the condition `x = 1` that all results fall in one partition. The value `1` can be confirmed to be in the `p1` partition after passing through the Hash partition. Therefore, only the `p1` partition needs to be scanned, and there is no need to access the `p2`, `p3`, and `p4` partitions that will not have matching results. From the execution plan, only one `TableFullScan` operator appears and the `p1` partition is specified in `access object`, so it can be confirmed that `partition pruning` takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
   ↪ ---------------------------+---------+----------+----------------------+----
   ↪
| id                          | estRows | task     | access object        |
   ↪ operator info               |
+--
   ↪ ---------------------------+---------+----------+----------------------+----
   ↪
| Union_10                    | 13333.33 | root    |                      |
   ↪                             |
|  ─TableReader_13            | 3333.33 | root     |                      | data
   ↪ :Selection_12             |
|    ─Selection_12            | 3333.33 | cop[tikv] |                     | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_11      | 10000.00 | cop[tikv] | table:t, partition:p0
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_16            | 3333.33 | root     |                      | data
   ↪ :Selection_15             |
|    ─Selection_15            | 3333.33 | cop[tikv] |                     | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_14      | 10000.00 | cop[tikv] | table:t, partition:p1
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_19            | 3333.33 | root     |                      | data
   ↪ :Selection_18             |
|    ─Selection_18            | 3333.33 | cop[tikv] |                     | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_17      | 10000.00 | cop[tikv] | table:t, partition:p2
   ↪ | keep order:false, stats:pseudo |
|  ─TableReader_22            | 3333.33 | root     |                      | data
   ↪ :Selection_21             |
|    ─Selection_21            | 3333.33 | cop[tikv] |                     | gt(
   ↪ test.t.x, 2)              |
|      ─TableFullScan_20      | 10000.00 | cop[tikv] | table:t, partition:p3
   ↪ | keep order:false, stats:pseudo |
+--
   ↪ ---------------------------+---------+----------+----------------------+----
   ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the `x > 2` condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
    ↪ t2.x < 2);
```

```

|    ─TableReader_18(Build)         | 9990.00 | root    |
    ↪                       | data:Selection_17                            |
|      ─Selection_17                | 9990.00 | cop[tikv] |
    ↪                     | not(isnull(test.t2.x))                       |
|        ─TableFullScan_16          | 10000.00 | cop[tikv] | table:t2
    ↪           | keep order:false, stats:pseudo               |
|    ─Selection_19(Probe)           | 0.80    | root    |
    ↪                       | not(isnull(test.t1.x))                       |
|      ─MaxOneRow_20                | 1.00    | root    |
    ↪                       |                                              |
|        ─Union_21                  | 2.00    | root    |
    ↪                       |                                              |
|          ─TableReader_24          | 2.00    | root    |
    ↪                       | data:Selection_23                            |
|            ─Selection_23          | 2.00    | cop[tikv] |
    ↪                     | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2)   |
|              ─TableFullScan_22    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p0 | keep order:false, stats:pseudo    |
|          ─TableReader_27          | 2.00    | root    |
    ↪                       | data:Selection_26                            |
|            ─Selection_26          | 2.00    | cop[tikv] |
    ↪                     | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2)   |
```

```
|            └─TableFullScan_25    | 2500.00 | cop[tikv] | table:t1,
    ↪ partition:p1 | keep order:false, stats:pseudo    |
+--
    ↪ ----------------------------------+---------+----------+-------------------
    ↪
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x = 3;
```

```
+--

    ↪
| id                    | estRows | task     | access object       | operator
    ↪ info               |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
| TableReader_8         | 10.00   | root     |                      | data:
    ↪ Selection_7           |
|  └─Selection_7        | 10.00   | cop[tikv] |                      | eq(test.t
    ↪ .x, 3)             |
|    └─TableFullScan_6  | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪ keep order:false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+----------------------+--------
    ↪
```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x in(1,13);
```

```

|    ─Selection_10            | 20.00   | cop[tikv] |                     | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_9       | 10000.00 | cop[tikv] | table:t, partition:p0 |
    ↪  keep order:false, stats:pseudo |
|  ─TableReader_14            | 20.00   | root     |                      | data:
    ↪ Selection_13              |
|    ─Selection_13            | 20.00   | cop[tikv] |                     | in(
    ↪ test.t.x, 1, 13)          |
|      ─TableFullScan_12      | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ --------------------------+---------+----------+----------------------+-----
    ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
```

```
    partition p0 values less than (5),
    partition p1 values less than (10),
    partition p2 values less than (15)
    );
explain select * from t where x between 7 and 14;
```

```

|      ─TableFullScan_12    | 10000.00 | cop[tikv] | table:t, partition:p2 |
    ↪  keep order:false, stats:pseudo |
+--
    ↪ -------------------------+---------+----------+--------------------+-----
    ↪
```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of `fn(col)`, the query condition is one of `>`, `<`, `=`, `>=`, and `<=`, and the `fn` function is monotonous.

If the `fn` function is monotonous, for any `x` and `y`, if `x > y`, then `fn(x) > fn(y)`. Then this `fn` function can be called strictly monotonous. For any `x` and `y`, if `x > y`, then `fn` ↪ `(x) >= fn(y)`. In this case, `fn` could also be called "monotonous". Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

```
unix_timestamp
to_days
```

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
   partition p0 values less than (to_days('2020-04-01')),
   partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```

   ↪ Selection_7                     |
|  ─Selection_7         | 3333.33 | cop[tikv] |                      | gt(test.t
   ↪ .id, 2020-04-18 00:00:00.000000) |
|    ─TableFullScan_6   | 10000.00 | cop[tikv] | table:t, partition:p1 |
   ↪ keep order:false, stats:pseudo |
+--
   ↪ ----------------------+----------+----------+----------------------+---------
   ↪
```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
   partition p0 values less than (5),
   partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
   ↪ t2.x < 2);
```

```

|          └─TableReader_24        | 2.00    | root    |
   ↪                     | data:Selection_23
   ↪                                       |
|            └─Selection_23        | 2.00    | cop[tikv] |
   ↪                   | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|              └─TableFullScan_22  | 2.50    | cop[tikv] | table:t1,
   ↪ partition:p0 | keep order:false, stats:pseudo                |
|          └─TableReader_27        | 2.00    | root    |
   ↪                     | data:Selection_26
   ↪                                       |
|            └─Selection_26        | 2.00    | cop[tikv] |
   ↪                   | lt(test.t2.x, 2), lt(test.t2.x, test.t1.x)
   ↪         |
|              └─TableFullScan_25  | 2.50    | cop[tikv] | table:t1,
   ↪ partition:p1 | keep order:false, stats:pseudo                |
+--
   ↪ ---------------------------------+----------+-----------+--------------------
   ↪
14 rows in set (0.00 sec)
```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table.

Theoretically, the `t1.x> val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

9.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to Optimization Rules and Blocklist for Expression Pushdown.

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```
+--------------------------+---------+-----------+--------------+--------------------
    ↪
| id                       | estRows | task      | access object | operator
    ↪ info            |
+--------------------------+---------+-----------+--------------+--------------------
    ↪
| TopN_7                   | 10.00   | root      |              | test.t.a,
    ↪ offset:0, count:10 |
|  ─TableReader_15         | 10.00   | root      |              | data:TopN_14
    ↪                |
|    ─TopN_14              | 10.00   | cop[tikv] |              | test.t.a,
    ↪ offset:0, count:10 |
|      ─TableFullScan_13   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
+--------------------------+---------+-----------+--------------+--------------------
    ↪
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| id                              | estRows | task      | access object |
   ↪ operator info                                |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
| TopN_12                         | 10.00    | root      |               | test.t.a,
   ↪  offset:0, count:10                  |
|  ─HashJoin_17                   | 12.50    | root      |               | left
   ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
|    ─TopN_18(Build)              | 10.00    | root      |               | test.t.a
   ↪ , offset:0, count:10                 |
|      ─TableReader_26            | 10.00    | root      |               | data:
   ↪ TopN_25                              |
|        ─TopN_25                 | 10.00    | cop[tikv] |               | test.t.a
   ↪ , offset:0, count:10                 |
|          ─TableFullScan_24      | 10000.00 | cop[tikv] | table:t       | keep
   ↪ order:false, stats:pseudo            |
|    ─TableReader_30(Probe)       | 10000.00 | root      |               | data:
   ↪ TableFullScan_29                     |
|      ─TableFullScan_29          | 10000.00 | cop[tikv] | table:s       | keep
   ↪ order:false, stats:pseudo            |
+---------------------------------+----------+-----------+---------------+-------------
   ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+-------------------------------+----------+-----------+---------------+---------------
   ↪
```

```
| id                           | estRows | task    | access object | operator
   ↪ info                         |
+------------------------------+---------+---------+---------------+---------------
   ↪
| TopN_12                      | 10.00   | root    |               | test.t.id,
   ↪ offset:0, count:10           |
|  ─HashJoin_16                | 12500.00 | root   |               | inner join,
   ↪  equal:[eq(test.t.a, test.s.a)] |
|    ─TableReader_21(Build)    | 10000.00 | root   |               | data:
   ↪ TableFullScan_20             |
|      ─TableFullScan_20       | 10000.00 | cop[tikv] | table:s     | keep order:
   ↪ false, stats:pseudo          |
|    ─TableReader_19(Probe)    | 10000.00 | root   |               | data:
   ↪ TableFullScan_18             |
|      ─TableFullScan_18       | 10000.00 | cop[tikv] | table:t     | keep order:
   ↪ false, stats:pseudo          |
+------------------------------+---------+---------+---------------+---------------
   ↪
6 rows in set (0.00 sec)
```

TopN cannot be pushed down before `Inner Join`. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;
```

```
+--------------------------------+---------+----------+--------------+-------------
   ↪
| id                             | estRows | task     | access object |

```

```
|   └─Limit_21(Build)           | 10.00   | root     |             | offset
   ↪ :0, count:10                          |
|     └─TableReader_31          | 10.00   | root     |             | data:
   ↪ Limit_30                              |
|       └─Limit_30              | 10.00   | cop[tikv] |            | offset
   ↪ :0, count:10                          |
|         └─TableFullScan_29    | 10.00   | cop[tikv] | table:t    | keep
   ↪ order:true, stats:pseudo              |
|   └─TableReader_35(Probe)     | 10000.00 | root    |             | data:
   ↪ TableFullScan_34                      |
|     └─TableFullScan_34        | 10000.00 | cop[tikv] | table:s   | keep
   ↪ order:false, stats:pseudo             |
+-------------------------------+----------+-----------+-------------+-------------
   ↪
8 rows in set (0.00 sec)
```

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t ↪ .id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

9.3.3.2.9 Introduction to Join Reorder

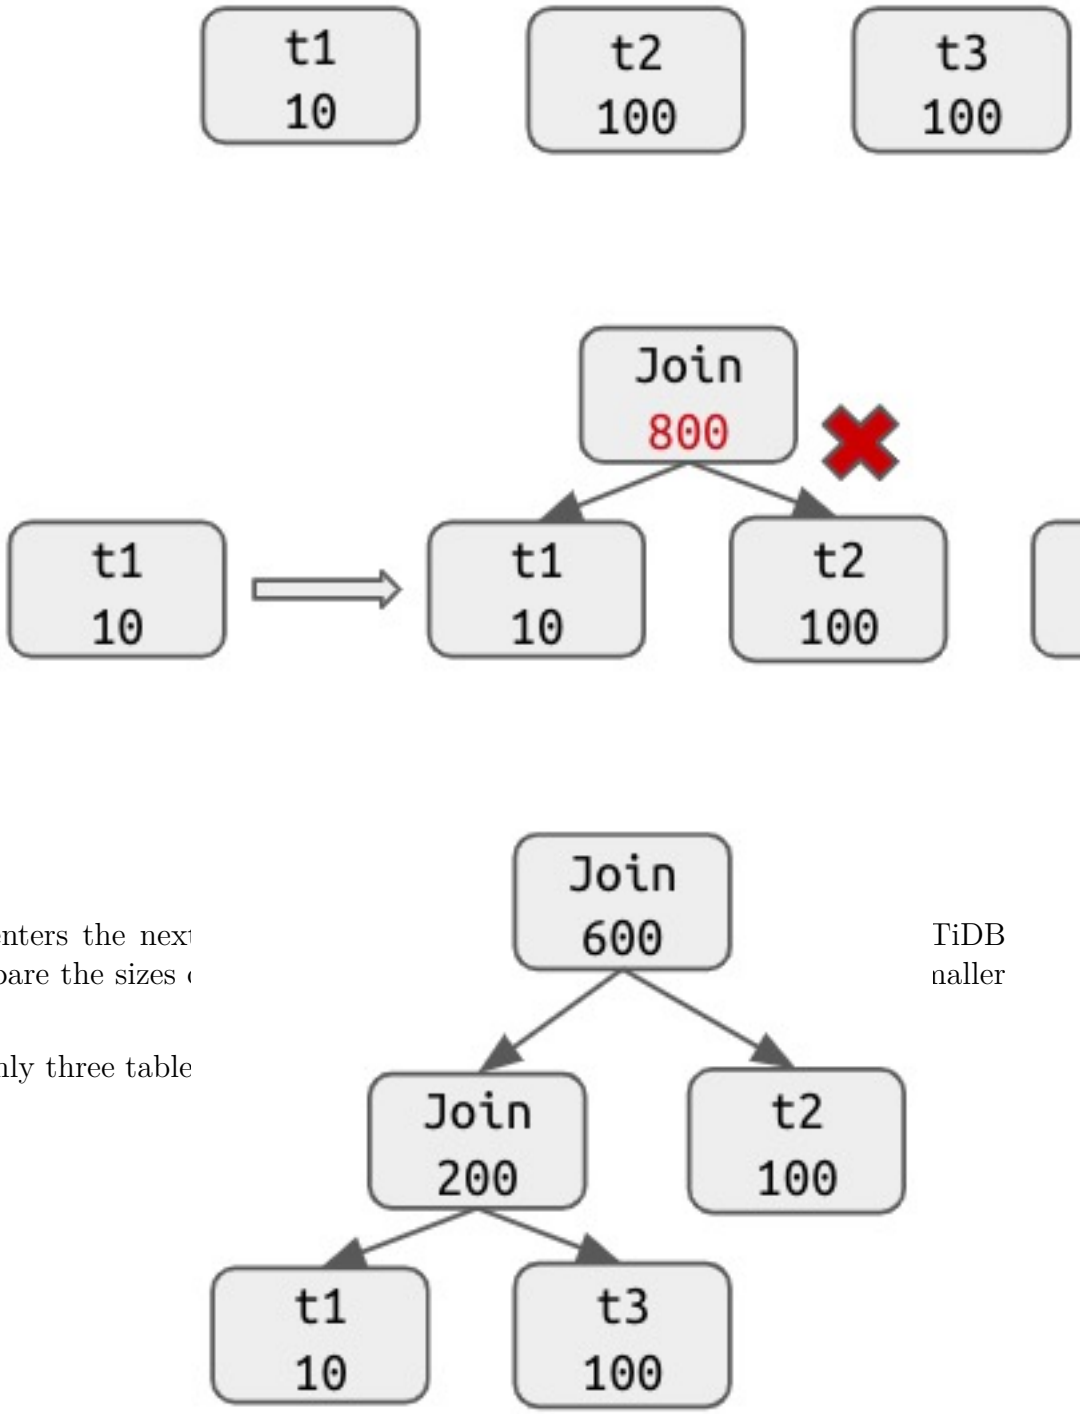
In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1



As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, TiDB uses the Join Reorder algorithm, also known as the greedy algorithm.

Instance of Join Reorder algorithm

Take the three tables above (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

After that, respectively. By smaller result se

Then TiDB enters the nex continues to compare the sizes result set.

In this case only three table

TiDB naller

Figure 66: join-reorder-3

The above process is the Join Reorder algorithm currently used in TiDB.

Limitations of Join Reorder algorithm

The current Join Reorder algorithm has the following limitations:

- The Join Reorder for Outer Join is not supported

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to Description of the syntax elements.

9.3.3.3 Physical Optimization

9.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

Understand the Query Execution Plan has introduced some physical operators. This chapter focuses on the following aspects:

- In Index Selection, you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In Introduction to Statistics, you will learn what statistics TiDB collects to obtain the data distribution of a table.
- Wrong Index Solution introduces how to use the right index when you find the index is selected wrongly.
- Distinct Optimization introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.

9.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / BatchPointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the `_tidb_rowid` column, or if there are no other operators for accessing tables to

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	Tiflash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookUpReader	A table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the index does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection

of an operator for accessing tables.

Index selection rules

TiDB provides a heuristic rule named skyline-pruning based on the cost estimation of each operator for accessing tables. It can reduce the probability of wrong index selection caused by wrong estimation.

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes. To judge an index, the following three dimensions are needed:

- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or IndexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do.
- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.
- How many access conditions are covered by the indexed columns. An "access condition" is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.

For these three dimensions, if an index named idx_a is not worse than the index named idx_b in all three dimensions and one of the dimensions is better than idx_b, then idx_a is preferred.

Selection based on cost estimation

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

   This is usually due to stale or inaccurate statistics. You can re-execute the `analyze table` statement or modify the parameters of the `analyze table` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

   At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

   In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through Optimizer Hints.

- `USE_INDEX` / `IGNORE_INDEX` can force the optimizer to use / not use certain indexes.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

9.3.3.3.3 Introduction to Statistics

TiDB uses statistics to decide which index to choose. The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`. The default value of this variable in each version of v5.1.x is as follows:

Version	Default value
v5.1.0 - v5.1.3	2, which serves as an experimental feature
v5.1.4 and later v5.1.x versions	1

Note:

When `tidb_analyze_version = 2`, if memory overflow occurs after `ANALYZE` is executed, you need to set `tidb_analyze_version = 1` and perform one of the following operations:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
sql   select distinct(concat('ANALYZE ',table_schema, '.',
↪  table_name,';'))from information_schema.tables, mysql
↪ .stats_histograms where stats_ver = 2 and table_id =
↪ tidb_table_id ;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
sql   select distinct(concat('DROP STATS ',table_schema,
↪  '.', table_name,';'))from information_schema.tables,
↪ mysql.stats_histograms where stats_ver = 2 and table_id =
↪  tidb_table_id ;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
sql   SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt'; mysql -h
↪  XXX -u user -P 4000 ... < '/tmp/sql.txt';
```

These two versions include different information in TiDB:

Information	Version 1	Version 2
The total number of rows in the table	√	√
Column Count-Min Sketch	√	×

Information	Version 1	Version 2
Index Count-Min Sketch	√	×
Column Top-N	√	√ (Maintenance methods and precision are improved)
Index Top-N	√ (Insufficient maintenance precision might cause inaccuracy)	√ (Maintenance methods and precision are improved)

Information	Version 1	Version 2
Column histogram	√	√ (The histogram does not include Top-N values.)

Information	Version 1	Version 2
Index histogram	√	√ (The histogram buckets record the number of different values in each bucket, and the histogram does not include Top-N values.)
The number of `NULL` ↪ s in the column	√	√

Information	Version 1	Version 2
The number of `NULL` ↪ s in the index	√	√
The average length of columns	√	√
The average length of indexes	√	√

Compared to Version 1, Version 2 statistics avoids the potential inaccuracy caused by hash collision when the data volume is huge. It also maintains the estimate precision in most scenarios.

This document briefly introduces the histogram, Count-Min Sketch, and Top-N, and details the collection and maintenance of statistics.

Histogram

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here "equal-depth" means that the number of values falling into each bucket is as equal as possible. For example, for a given set {1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5}, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains

four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

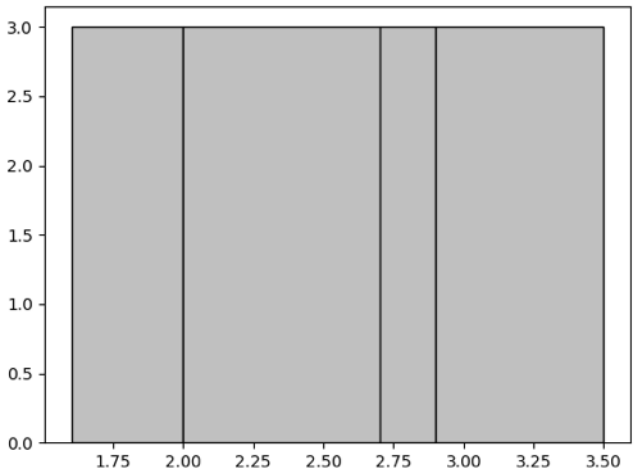


Figure 67: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to Manual Collection. When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

Count-Min Sketch is a hash structure. When an equivalence query contains `a = 1` or `IN` query (for example, `a in (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see Full Collection.
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the

default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see Full Collection.

Top-N values

Top-N values are values with the top N occurrences in a column or index. TiDB records the values and occurrences of Top-N values.

Collect statistics

Manual collection

You can run the `ANALYZE` statement to collect statistics.

Note:

The execution time of `ANALYZE TABLE` in TiDB is longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while in TiDB a comprehensive set of statistics is completely rebuilt. Scripts that were written for MySQL may naively expect `ANALYZE TABLE` will be a short-lived operation.

For quicker analysis, you can set `tidb_enable_fast_analyze` to `1` to enable the Quick Analysis feature. The default value for this parameter is `0`.

After Quick Analysis is enabled, TiDB randomly samples approximately 10,000 rows of data to build statistics. Therefore, in the case of uneven data distribution or a relatively small amount of data, the accuracy of statistical information is relatively poor. It might lead to poor execution plans, such as choosing the wrong index. If the execution time of the normal `ANALYZE` statement is acceptable, it is recommended to disable the Quick Analysis feature.

`tidb_enable_fast_analyze` is an experimental feature, which currently **does not match exactly** with the statistical information of `tidb_analyze_version=2`. Therefore, you need to set the value of `tidb_analyze_version` to `1` when `tidb_enable_fast_analyze` is enabled.

Full collection

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|
    ↪ CMSKETCH WIDTH|SAMPLES];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated `TOPN`s.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- To collect statistics of the index columns on all `IndexNameList`s in `TableName`:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
    ↪ CMSKETCH DEPTH|CMSKETCH WIDTH|SAMPLES];
```

The statement collects statistics of all index columns when `IndexNameList` is empty.

- To collect statistics of partition in all `PartitionNameList`s in `TableName`:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
    ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH|SAMPLES];
```

- To collect statistics of index columns for the partitions in all `PartitionNameList`s in `TableName`:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH|SAMPLES];
```

Note:

To ensure that the statistical information before and after the collection is consistent, when you set `tidb_analyze_version=2`, `ANALYZE TABLE TableName INDEX` will also collect statistics of the whole table instead of the given index.

Incremental collection

To improve the speed of analysis after full collection, incremental collection could be used to analyze the newly added sections in monotonically non-decreasing columns such as time columns.

Note:

- Currently, the incremental collection is only provided for index.
- When using the incremental collection, you must ensure that only `INSERT` operations exist on the table, and that the newly inserted value on the index column is monotonically non-decreasing. Otherwise, the statistical information might be inaccurate, affecting the TiDB optimizer to select an appropriate execution plan.

You can perform incremental collection using the following syntax.

- To incrementally collect statistics for index columns in all `IndexNameLists` in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName INDEX [IndexNameList] [WITH NUM
    ↪ BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH|SAMPLES];
```

- To incrementally collect statistics of index columns for partitions in all `PartitionNameLists` ↪ in `TableName`:

```
ANALYZE INCREMENTAL TABLE TableName PARTITION PartitionNameList INDEX [
    ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
    ↪ WIDTH|SAMPLES];
```

Automatic update

For the `INSERT`, `DELETE`, or `UPDATE` statements, TiDB automatically updates the number of rows and updated rows. TiDB persists this information regularly and the update cycle is 20 * `stats-lease`. The default value of `stats-lease` is `3s`. If you specify the value as `0`, it does not update automatically.

Three system variables related to automatic update of statistics are as follows:

System Variable	Default Value	Description
tidb_auto_analyze_ratio	0.5	The threshold value of automatic update
tidb_auto_analyze_start_time	00:00 +0000	The start time in a day when TiDB can perform automatic update
tidb_auto_analyze_end_time	23:59 +0000	The end time in a day when TiDB can perform automatic update

When the ratio of the number of modified rows to the total number of rows of `tbl` ↪ in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics of this table.

Before v5.0, when the query is executed, TiDB collects feedback with the probability of `feedback-probability` and uses it to update the histogram and Count-Min Sketch. **In the current version, this feature is experimental and disabled by default, and it is not recommended to enable this feature in the production environment.**

Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using the following parameters, to control its effect on the system.

`tidb_build_stats_concurrency`

Currently, when you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on one column or index. You can use the `tidb_build_stats_concurrency` parameter to control the number of simultaneous tasks. The default value is `4`.

`tidb_distsql_scan_concurrency`

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` parameter to control the number of Region to be read at one time. The default value is `15`.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency` ↪ parameter to control the number of Region to be read at one time. The default value is `1`.

View `ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using the following SQL statement:

```
SHOW ANALYZE STATUS [ShowLikeOrWhere]
```

This statement returns the state of `ANALYZE`. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW ANALYZE STATUS` statement returns the following 7 columns:

Syntax Element	Description
table_schema	The database name
table_name	The table name
partition_name	The partition name

Syntax Element	Description
job_info	The task information. The element includes index names when index analysis is performed.
row_count	The number of rows that have been analyzed
start_time	The time at which the task starts
state	The state of a task, including `pending`, `running`, `finished`, and `failed`

View statistics

You can view the statistics status using the following statements.

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

The syntax of `ShowLikeOrWhereOpt` is as follows:

```
SHOW STATS_META [ShowLikeOrWhere]
```

Currently, the `SHOW STATS_META` statement returns the following 6 columns:

Syntax Element	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`update_time`	The time of the update
`modify_count`	The number of modified rows
`row_count`	The total number of rows

Note:

When TiDB automatically updates the total number of rows and the number of modified rows according to DML statements, `update_time` is also updated. Therefore, `update_time` does not necessarily indicate the last time when the `ANALYZE` statement is executed.

Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count >= row_count`, the health state is 0; when `modify_count < row_count`, the health state is (1 - `modify_count` ↪ `/row_count`) * 100.

The synopsis of `SHOW STATS_HEALTHY` is:

Figure 68: ShowStatsHealthy

and the synopsis of the `ShowLikeOrWhereOpt` part is:

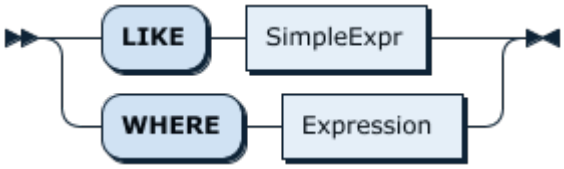

Figure 69: ShowLikeOrWhereOpt

Currently, the `SHOW STATS_HEALTHY` statement returns the following 4 columns:

Syntax Element	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`healthy`	The health state of tables

Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Syntax as follows:

```
SHOW STATS_HISTOGRAMS [ShowLikeOrWhere]
```

This statement returns the number of different values and the number of `NULL` in all the columns. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_HISTOGRAMS` statement returns the following 10 columns:

Syntax Element	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`update_time`	The time of the update
`distinct_count`	The number of different values
`null_count`	The number of `NULL`
`avg_col_size`	The average length of columns
correlation	The Pearson correlation coefficient of the column and the integer primary key, which indicates the degree of association between the two columns

Syntax Element	Description

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

The syntax is as follows:

```
SHOW STATS_BUCKETS [ShowLikeOrWhere]
```

The diagram is as follows:

Figure 70: SHOW STATS_BUCKETS

This statement returns information about all the buckets. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_BUCKETS` statement returns the following 11 columns:

Syntax Element	Description
`db_name`	The database name
`table_name`	The table name
`partition_name`	The partition name
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`bucket_id`	The ID of a bucket
`count`	The number of all the values that falls on the bucket and the previous buckets

Syntax Element	Description
`repeats`	The occurrence number of the maximum value
`lower_bound` ↪	The minimum value
`upper_bound` ↪	The maximum value
`ndv`	The number of different values in the bucket. When `tidb_analyze_version` ↪ `= 1`, `ndv` is always `0`, which has no actual meaning.

Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

The syntax is as follows:

```
SHOW STATS_TOPN [ShowLikeOrWhere];
```

Currently, the `SHOW STATS_TOPN` statement returns the following 7 columns:

Syntax Element	Description
`db_name` ↪	The database name
`table_name` ↪	The table name
`partition_name` ↪	The partition name

Syntax Element	Description
`column_name`	The column name (when `is_index` is `0`) or the index name (when `is_index` is `1`)
`is_index`	Whether it is an index column or not
`value`	The value of this column
`count`	How many times the value appears

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

Syntax as follows:

```
DROP STATS TableName
```

The statement deletes statistics of all the tables in `TableName`.

Import and export statistics

Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${
    ↪ db_name}/${table_name}
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${
    ↪ db_name}/${table_name}/${yyyyMMddHHmmss}
```

Import statistics

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Syntax:

```
LOAD STATS 'file_name'
```

`file_name` is the file name of the statistics to be imported.

See also

- DROP STATS

9.3.3.3.4 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

You can first view the health state of tables in the statistics, and then solve this issue according to the different health states.

Low health state

The low health state means TiDB has not performed the`ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be Count-Min Sketch. You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimzer hint (see USE_INDEX for details). Also, you can change the query behavior by using SQL Plan Management in a non-intrusive way.

Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

9.3.3.3.5 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+--
   ↪ ----------------------+---------+-----------+---------------+----------------
   ↪
| id                    | estRows | task    | access object | operator info
   ↪                               |
+--
   ↪ ----------------------+---------+-----------+---------------+----------------
   ↪
| HashAgg_6             | 2.40    | root      |               | group by:test.t.a
   ↪ , funcs:firstrow(test.t.a)->test.t.a |
| └─TableReader_11      | 3.00    | root      |               | data:

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The `tidb_opt_distinct_agg_push_down` system variable or the `distinct-agg-push-down` configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV/TiFlash Coprocessor.

Take the following queries as an example of this optimization. `tidb_opt_distinct_agg_push_down` is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to `1`, the `distinct a` part of `count(distinct a)` is pushed to TiKV/TiFlash Coprocessor: there is a HashAgg_5 to remove the duplicated values on column a in the TiKV Coprocessor. It might reduce the computation overhead of `HashAgg_8` in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+--
   ↪ ----------------------+---------+----------+--------------+----------------
   ↪
| id                    | estRows | task     | access object | operator info

9.3.3.4 SQL Prepare Execution Plan Cache

> **Warning:**
>
> This feature is still experimental. It is not recommended to use it in the production environment.

TiDB supports execution plan caching for `Prepare` and `Execute` queries. This includes both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

In the current version of TiDB, when the `Prepare` statement meets any of the following conditions, the query cannot use the execution plan cache:

- The query contains variables other than `?` (including system variables or user-defined variables);
- The query contains sub-queries;
- The query contains functions that cannot be cached, such as `current_user()`, `database()`, and `last_insert_id()`;
- The `Order By` statement of the query contains `?`;
- The `Group By` statement of the query contains `?`;
- The `Limit [Offset]` statement of the query contains `?`;
- The window frame definition of the `Window` function contains `?`;
- Partition tables are involved in the query.

The LRU linked list is designed as a session-level cache because `Prepare` / `Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed;
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword;
- The current schema version, which is updated after every successfully executed DDL statement;
- The SQL mode when executing `Execute`;
- The current time zone, which is the value of the `time_zone` system variable.

Any change in the above information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode / `time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are two points worth noting about execution plan caching and query performance:

- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are `2` and `1` respectively. Considering that these two parameters maybe be `1` and `2` in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;

- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also result in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is `1`, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes `10000`, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Currently, the execution plan cache is disabled by default. You can enable this feature by enabling the `prepare-plan-cache` in the TiDB configuration file.

> **Note:**
>
> The execution plan cache feature applies only for `Prepare` / `Execute` queries and does not take effect for normal queries.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous `Execute` statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
   ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
```

```
-- The second execution hits the cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 1                      |
+------------------------+
1 row in set (0.00 sec)
```

If you find that a certain set of `Prepare` / `Execute` has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the above statement as an example:

```
MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
    ↪  where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+------------------------+
| @@last_plan_from_cache |
+------------------------+
| 0                      |
+------------------------+
1 row in set (0.00 sec)
```

9.3.4 Control Execution Plans

9.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB's execution

plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In Optimizer Hints, you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In SQL Plan Management, you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background to alleviate the execution plan instability caused by reasons such as version upgrades, which degrades cluster performance.
- Finally, you will learn how to use the blocklist in Blocklist of Optimization Rules and Expression Pushdown.

9.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

> **Note:**
>
> MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the `Hint` syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

9.3.4.2.1 Syntax

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `UPDATE` or `DELETE` keyword in a SQL statement. Optimizer hints are not currently supported for `INSERT` statements.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```
SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM t t1, t t2 WHERE t1.a = t2.b;
```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

> **Note:**
>
> If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

9.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
    ↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.
- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

> **Note:**
>
> You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

QB_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
    ↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

> **Note:**
>
> In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

MERGE_JOIN(t1_name [, tl_name ...])

The `MERGE_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

> **Note:**
>
> `TIDB_SMJ` is the alias for `MERGE_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_SMJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_SMJ` and `MERGE_JOIN` are both valid names for the hint, but `MERGE_JOIN` is recommended.

INL_JOIN(t1_name [, tl_name …])

The `INL_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the `WHERE` condition, it is recommended to use this hint. For example:

```
select /*+ INL_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

The parameter(s) given in `INL_JOIN()` is the candidate table for the inner table when you create the query plan. For example, `INL_JOIN(t1)` means that TiDB only considers using `t1` as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in `INL_JOIN()`; if it does not has an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/ * from t t1, t t2 where t1.a = t2.b;` query, you must use the `t` table's alias `t1` or `t2` rather than `t` as `INL_JOIN()`'s parameter.

> **Note:**
>
> `TIDB_INLJ` is the alias for `INL_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_INLJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_INLJ` and `INL_JOIN` are both valid names for the hint, but `INL_JOIN` is recommended.

INL_HASH_JOIN

The `INL_HASH_JOIN(t1_name [, tl_name])` hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that `INL_JOIN` creates a hash table on the joined inner table, but `INL_HASH_JOIN` creates a hash table on the joined outer table. `INL_HASH_JOIN` has a fixed

limit on memory usage, while the memory used by `INL_JOIN` depends on the number of rows matched in the inner table.

HASH_JOIN(t1_name [, tl_name ...])

The `HASH_JOIN(t1_name [, tl_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

Note:

`TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name [, tl_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

HASH_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.
    ↪ id;
```

STREAM_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1
    ↪ .id;
```

USE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to use only the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, idx2);` statement.

```
SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;
```

> **Note:**
>
> If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])

The `IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to ignore the given index(es) for a specified `t1_name` table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

AGG_TO_COP()

The `AGG_TO_COP()` hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

LIMIT_TO_COP()

The `LIMIT_TO_COP()` hint tells the optimizer to push down the `Limit` and `TopN` operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c
    ↪ LIMIT 1;
```

READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])

The `READ_FROM_STORAGE(TIFLASH[t1_name [, tl_name ...]], TIKV[t2_name [, tl_name ...]])` hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - `TIKV` and `TIFLASH`. If a table has an alias, use the alias as the parameter of `READ_FROM_STORAGE()`; if the table does not has an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
    ↪ t2 where t1.a = t2.a;
```

Note:

If you want the optimizer to use a table from another schema, you need to explicitly specify the schema name. For example:

```
SELECT /*+ READ_FROM_STORAGE(TIFLASH[test1.t1,test2.t2]) */ t1
    ↪ .a FROM test1.t t1, test2.t t2 WHERE t1.a = t2.a;
```

USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. The given list of indexes are optional parameters. If you explicitly specify the list, TiDB selects indexes from the list to build index merge; if you do not give the list of indexes, TiDB selects indexes from all available indexes to build index merge. For example:

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
    ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

Note:

The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

This hint takes effect on strict conditions, including:

- If the query can select a single index scan in addition to full table scan, the optimizer does not select index merge.
- If the query is in an explicit transaction, and if the statements before this query has already written data, the optimizer does not select index merge.

9.3.4.2.3 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

> **Note:**
>
> This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

NO_INDEX_MERGE()

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

> **Note:**
>
> `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.

USE_TOJA(boolean_value)

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a
    ↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

MAX_EXECUTION_TIME(N)

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id
    ↪  = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

MEMORY_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

READ_CONSISTENT_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to `'
↪ follower'` or `'leader'` also controls whether to enable this feature.

IGNORE_PLAN_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when prepare-plan-cache is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id =
    ↪ ?';
```

NTH_PLAN(N)

The `NTH_PLAN(N)` hint reminds the optimizer to select the `N`th physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

> **Note:**
>
> `NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

9.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

9.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The Optimizer Hints document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

Create a binding

```
CREATE [GLOBAL | SESSION] BINDING FOR BindableStmt USING BindableStmt
```

This statement binds SQL execution plans at the GLOBAL or SESSION level. Currently, supported bindable SQL statements (BindableStmt) in TiDB include `SELECT`, `DELETE`, `UPDATE`, and `INSERT` / `REPLACE` with `SELECT` subqueries.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `join`
   ↪  keyword and not specifying the associated columns with the `using`
   ↪ keyword.
create global binding for
    select * from t t1 join t t2
using
    select * from t t1 join t t2;

-- Type two: `DELETE` statements that contain the `using` keyword.
```

```
create global binding for
    delete from t1 using t1 join t2 on t1.a = t2.a
using
    delete from t1 using t1 join t2 on t1.a = t2.a;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- First rewrite of type one statements: Add a `using` clause for the `
    ↪ join` keyword.
create global binding for
    select * from t t1 join t t2 using (a)
using
    select * from t t1 join t t2 using (a);

-- Second rewrite of type one statements: Delete the `join` keyword.
create global binding for
    select * from t t1, t t2
using
    select * from t t1, t t2;

-- Rewrite of type two statements: Remove the `using` keyword from the `
    ↪ delete` statement.
create global binding for
    delete t1 from t1 join t2 on t1.a = t2.a
using
    delete t1 from t1 join t2 on t1.a = t2.a;
```

Note:

When creating execution plan bindings for `INSERT` / `REPLACE` statements with `SELECT` subqueries, you need to specify the optimizer hints you want to bind in the `SELECT` subquery, not after the `INSERT` / `REPLACE` keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
create global binding for
    insert into t1 select * from t2 where a > 1 and b = 1
using
    insert into t1 select /*+ use_index(@sel_1 t2, a) */ * from t2 where a
        ↪ > 1 and b = 1;
```

```
-- The hint cannot take effect in the following statement.
create global binding for
    insert into t1 select * from t2 where a > 1 and b = 1
using
    insert /*+ use_index(@sel_1 t2, a) */ into t1 select * from t2 where a
        ↪ > 1 and b = 1;
```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

`Normalization` is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```
select * from t where a > 1
-- After normalization, the above statement is as follows:
select * from test . t where a > ?
```

Note:

Multiple constants joined by commas `,` are normalized as `...` instead of `?`.

For example:

```
select * from t limit 10
select * from t limit 10, 20
select * from t where a in (1)
select * from t where a in (1,2,3)
-- After normalization, the above statements are as follows:
select * from test . t limit ?
select * from test . t limit ...
select * from test . t where a in ( ? )
select * from test . t where a in ( ... )
```

When bindings are created, TiDB treats SQL statements that contain a single constant and SQL statements that contain multiple constants joined by commas differently. Therefore, you need to create bindings for the two SQL types separately.

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```
-- Creates a GLOBAL binding and specifies using `sort merge join` in this
   ↪ binding.
create global binding for
   select * from t1, t2 where t1.id = t2.id
using
   select /*+ merge_join(t1, t2) */ * from t1, t2 where t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
   ↪ specified in the GLOBAL binding.
explain select * from t1, t2 where t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
   ↪  binding.
create binding for
   select * from t1, t2 where t1.id = t2.id
using
   select /*+ hash_join(t1, t2) */ * from t1, t2 where t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
   ↪ SESSION binding is used, instead of `sort merge join` specified in
   ↪ the GLOBAL binding.
explain select * from t1, t2 where t1.id = t2.id;
```

When the first `select` statement is being executed, the optimizer adds the `sm_join(` ↪ `t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is MergeJoin. When the second `select` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is HashJoin.

Each standardized SQL statement can have only one binding created using `CREATE` ↪ `BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use ${` ↪ `database}` is executed.

The original SQL statement and the bound statement must have the same text after

normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `select * from test . t where a > ?`

  ```
  sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM
  ↪ t use index (idx)WHERE a > 2
  ```

- This binding will fail because the original SQL statement is processed as `select * from test . t where a > ?`, while the bound SQL statement is processed differently as `select * from test . t where b > ?`.

  ```
  sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM
  ↪ t use index(idx)WHERE b > 2
  ```

> **Note:**
>
> For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

Remove binding

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in create binding in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.
drop session binding for select * from t1, t2 where t1.id = t2.id;

-- Views the SQL execution plan again.
explain select * from t1,t2 where t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint

to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

View binding

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the GLOBAL or SESSION level. The default scope is SESSION. Currently `SHOW BINDINGS` outputs eight columns, as shown below:

Column Name	Note
original_sql	Original SQL statement after parameterization
bind_sql	Bound SQL statement with hints
default_db	Default database
status	Status including `using`, `deleted`, `invalid`, `rejected`, and `pending` ↪ `verify`
create_time	Creating time
update_time	Updating time
charset	Character set
collation	Ordering rule

Column Name	Note
source	The way in which a binding is created, including `manual` (created by the `create [global] binding` SQL statement), `capture` (captured automatically by TiDB), and `evolve` (evolved automatically by TiDB)

9.3.4.3.2 Baseline capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

> **Note:**
>
> Because the automatic binding creation function relies on Statement Summary, make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.

- SQL statements that are bound to a manually created execution plan.

For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

> **Note:**
>
> Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

9.3.4.3.3 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
set global tidb_evolve_plan_baselines = on;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

> **Note:**
>
> The feature baseline evolution is not generally available for now. It is **NOT RECOMMENDED** to use it in the production environment.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is `3s`) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than 2/3 that of the binding

execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
create table t(a int, b int, key(a), key(b));
```

Perform the following query on table `t`:

```
select * from t where a < 100 and b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
create global binding for select * from t where a < 100 and b < 100 using
    ↪ select * from t use index(a) where a < 100 and b < 100;
```

When the query above is executed again, the optimizer selects index `a` (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table `t`, an increasing number of rows meet the `a < 100` condition and a decreasing number of rows meet the `b < 100` condition. At this time, using index `a` under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index `b`. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index `a`, index `b` is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index `b` and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is `600s`. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (`00:00 +0000` by default) and `tidb_evolve_plan_task_e`
  ↪ (`23:59 +0000` by default) to limit the time window.

Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.
- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
`memory_quota`	The maximum memory that can be used for a query.
`use_toja`	Whether the optimizer transforms sub-queries to Join.
`use_cascades`	Whether to use the cascades optimizer.
`no_index_merge`	Whether the optimizer uses Index Merge as an option for reading tables.
`read_consistent_replica`	Whether to forcibly enable Follower Read when reading tables.
`max_execution_time`	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads, when the isolation condition changes, this hint has a great influence on the evolved

execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

9.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

9.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Rule Name	Description
Column pruning	column_prune	Prune operator will prune the column if it is not needed by the upper executor.

Optimization Rule	Rule Name	Description
Decorrelate sub-query	decorrelate	Tries to rewrite the correlated sub-query to non-correlated join or aggregation.
Aggregation elimination	aggregation_elim	Tries to remove unnecessary aggregation operators from the execution plan.

Optimization Rule	Rule Name	Description
Projection elimination	projection_eliminate	Remove unnecessary projection operators from the execution plan.
Max/Min elimination	max_min_eliminate	Remove some max/min functions in aggregation to the `order by` + `limit 1` form.

Optimization Rule	Rule Name	Description
Predicate push-down	predicate_push_down	Tries to push predicates down to the operator that is closer to the data source.
Outer join elimination	outer_join_eliminate	Tries to remove the unnecessary left join or right join from the execution plan.

Optimization Rule	Rule Name	Description
Partition pruning	partition_processor	Prunes partitions which are rejected by the predicates and rewrite partitioned table query to the `UnionAll` ↪ ↪ `+` ↪ ↪ `Partition` ↪ ↪ `Datasource` ↪ form.
Aggregation push-down	aggregation_push_down	Tries to push aggregations down to their children.

Optimization Rule	Rule Name	Description
TopN push-down	topn_push_down	This is to push the TopN operator to the place closer to the data source.
Join reorder	join_reorder	Decides the order of multi-table joins.

Disable optimization rules

You can use the blocklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

> **Note:**
>
> All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table Important Optimization Rules.

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("
    ↪ topn_push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

> **Note:**
>
> `admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
    ↪ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

9.3.4.4.2 The blocklist of expression pushdown

The blocklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions which are supported to be pushed down

Expression Classification	Concrete Operations
Logical operations	AND (&&), OR (||), NOT (!)
Comparison functions and operators	<, <=, =, != (<>), >, >=, <=>, IN(), IS NULL, LIKE, IS TRUE, IS FALSE, COALESCE()
Numeric functions and operators	+, -, *, /, ABS(), CEIL(), CEILING(), FLOOR()
Control flow functions	CASE, IF(), IFNULL()

Expression Classification	Concrete Operations
JSON functions	JSON_TYPE(json_val), JSON_EXTRACT(json_doc, path[, path] ...), JSON_UNQUOTE(json_val), JSON_OBJECT(key, val[, key, val] ...), JSON_ARRAY([val[, val] ...]), JSON_MERGE(json_doc, json_doc[, json_doc] ...), JSON_SET(json_doc, path, val[, path, val] ...), JSON_INSERT(json_doc, path, val[, path, val] ...), JSON_REPLACE(json_doc, path, val[, path, val] ...), JSON_REMOVE(json_doc, path[, path] ...)
Date and time functions	DATE_FORMAT()

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blocklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```
+------------+-------------+------+------+-------------------+-------+
| Field      | Type        | Null | Key  | Default           | Extra |
+------------+-------------+------+------+-------------------+-------+
| name       | char(100)   | NO   |      | NULL              |       |
| store_type | char(100)   | NO   |      | tikv,tiflash,tidb |       |
| reason     | varchar(200)| YES  |      | NULL              |       |
+------------+-------------+------+------+-------------------+-------+
3 rows in set (0.00 sec)
```

Here is the description of each field above:

- `name`: The name of the function that is disabled to be pushed down.
- `store_type`: To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.

  - When `store_type` is `tidb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
  - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
  - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- `reason`: To record the reason why this function is added to the blocklist.

Usage

This section describes how to use the blocklist of expression pushdown.

Add to the blocklist

To add one or more expressions (functions or operators) to the blocklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

Remove from the blocklist

To remove one or more expressions from the blocklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

> **Note:**
>
> `admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

9.3.4.4.3 Expression blocklist usage example

In the following example, the `<` and `>` operators are added to the blocklist, and then the `>` operator is removed from the blocklist.

To judge whether the blocklist takes effect, observe the results of `EXPLAIN` (See Optimize SQL statements using `EXPLAIN`).

1. The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| id                    | estRows | task     | access object | operator
    ↪ info                |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
| TableReader_7         | 0.00    | root     |               | data:
    ↪ Selection_6               |
| ─Selection_6          | 0.00    | cop[tikv] |               | gt(ssb_1.t.
    ↪ a, 2), lt(ssb_1.t.a, 2) |
|   ─TableFullScan_5    | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
3 rows in set (0.00 sec)
```

2. Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
    ↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

3. Observe the execution plan again and you will find that both the `<` and `>` operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
    ↪ ----------------------+---------+----------+---------------+-----------
    ↪
```

```
| id                    | estRows | task     | access object | operator
    ↪ info                |
+--
    ↪ ----------------------+---------+----------+---------------+----------
    ↪
| Selection_7           | 10000.00 | root    |               | gt(ssb_1.t.a
    ↪ , 2), lt(ssb_1.t.a, 2) |
|  ─TableReader_6       | 10000.00 | root    |               | data:
    ↪ TableFullScan_5           |
|    ─TableFullScan_5   | 10000.00 | cop[tikv] | table:t   | keep order:
    ↪ false, stats:pseudo |
+--
    ↪ ----------------------+---------+----------+---------------+----------
    ↪
3 rows in set (0.00 sec)
```

4. Remove one expression (here is >) from the blocklist and execute `admin reload ↪ expr_pushdown_blacklist`.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

5. Observe the execution plan again and you will find that < is not pushed down while > is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
    ↪ ------------------------+---------+----------+---------------+----------
    ↪

10 Tutorials

10.1 Multiple Data Centers in One City Deployment

As a NewSQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across data centers (DC). This document introduces the deployment of multiple DCs in one city.

10.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is implemented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three DCs in case one DC fails.
- Deploy TiDB in at least three cities in case data safety issue occurs in one city.

The native Raft protocol does not have a good support for an even number of replicas. Considering the impact of cross-city network latency, three DCs in the same city might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

10.1.2 Three DCs in one city deployment

TiDB clusters can be deployed in three DCs in the same city. In this solution, data replication across the three DCs is implemented using the Raft protocol within the cluster. These three DCs can provide read and write services at the same time. Data consistency is not affected even if one DC fails.

10.1.2.1 Simple architecture

TiDB, TiKV and PD are distributed among three DCs, which is the most common deployment with the highest availability.

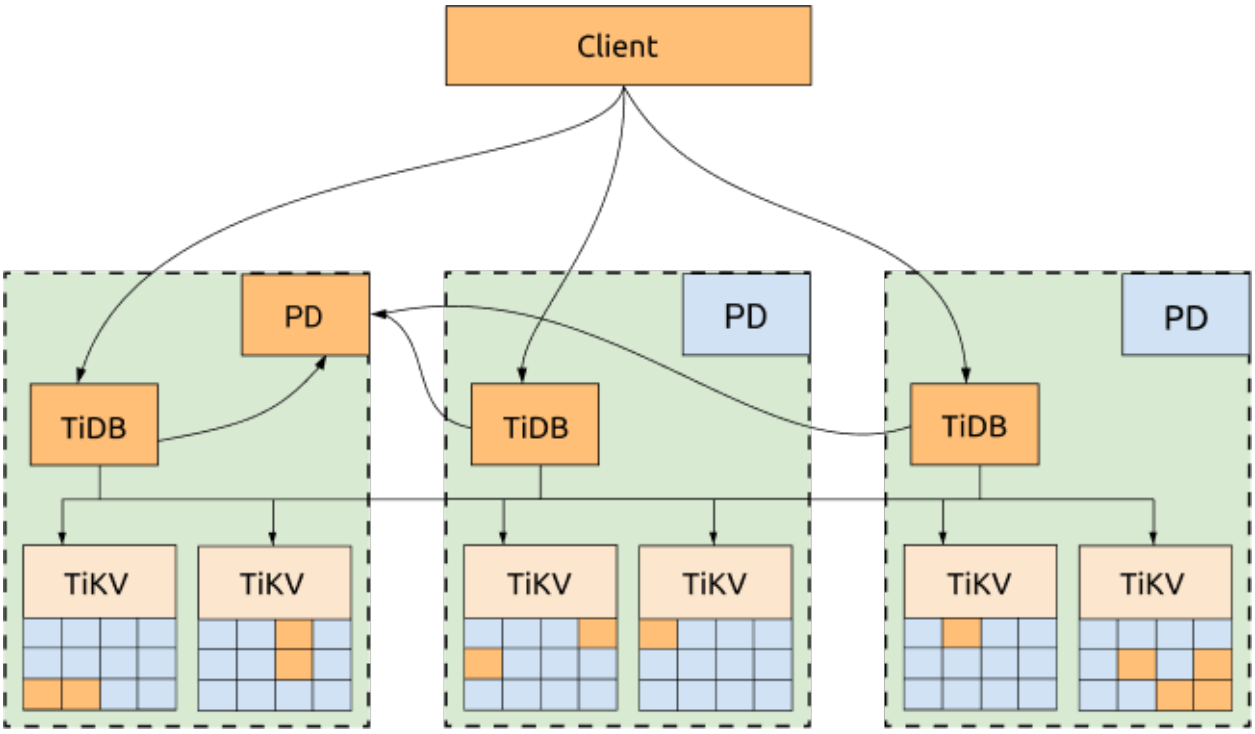

Figure 71: 3-DC Deployment Architecture

Advantages:

- All replicas are distributed among three DCs, with high availability and disaster recovery capability.
- No data will be lost if one DC is down (RPO = 0).
- Even if one DC is down, the other two DCs will automatically start leader election and automatically resume services within a reasonable amount of time (within 20 seconds in most cases). See the following diagram for more information:

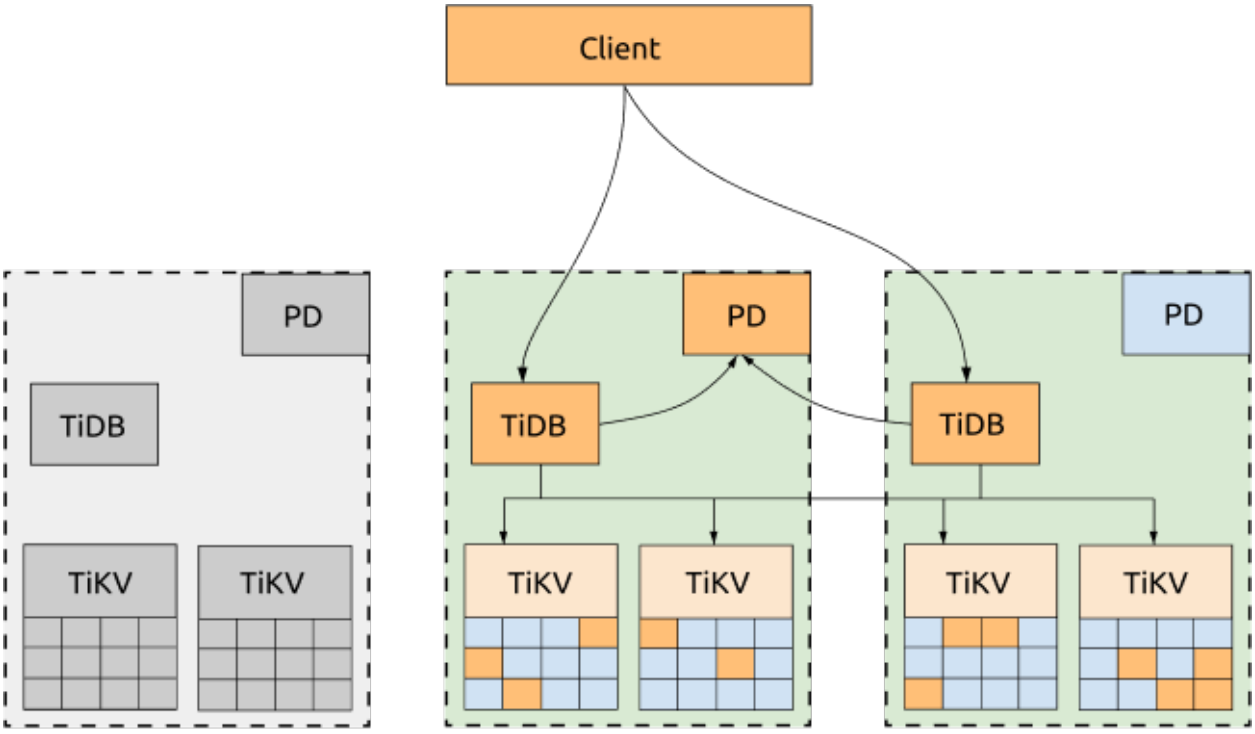

Figure 72: Disaster Recovery for 3-DC Deployment

Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least 2 DCs. Because TiDB uses 2-phase commit for writes, the write latency is at least twice the latency of the network between two DCs.
- The read performance will also be affected by the network latency if the leader is not in the same DC with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same DC, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

10.1.2.2 Optimized architecture

If not all of the three DCs need to provide services to the applications, you can dispatch all the requests to one DC and configure the scheduling policy to migrate all the TiKV Region leader and PD leader to the same DC. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across DCs. If this DC is down, the PD leader and TiKV Region leader will be automatically elected in other surviving DCs, and you just need to switch the requests to the DCs that are still alive.

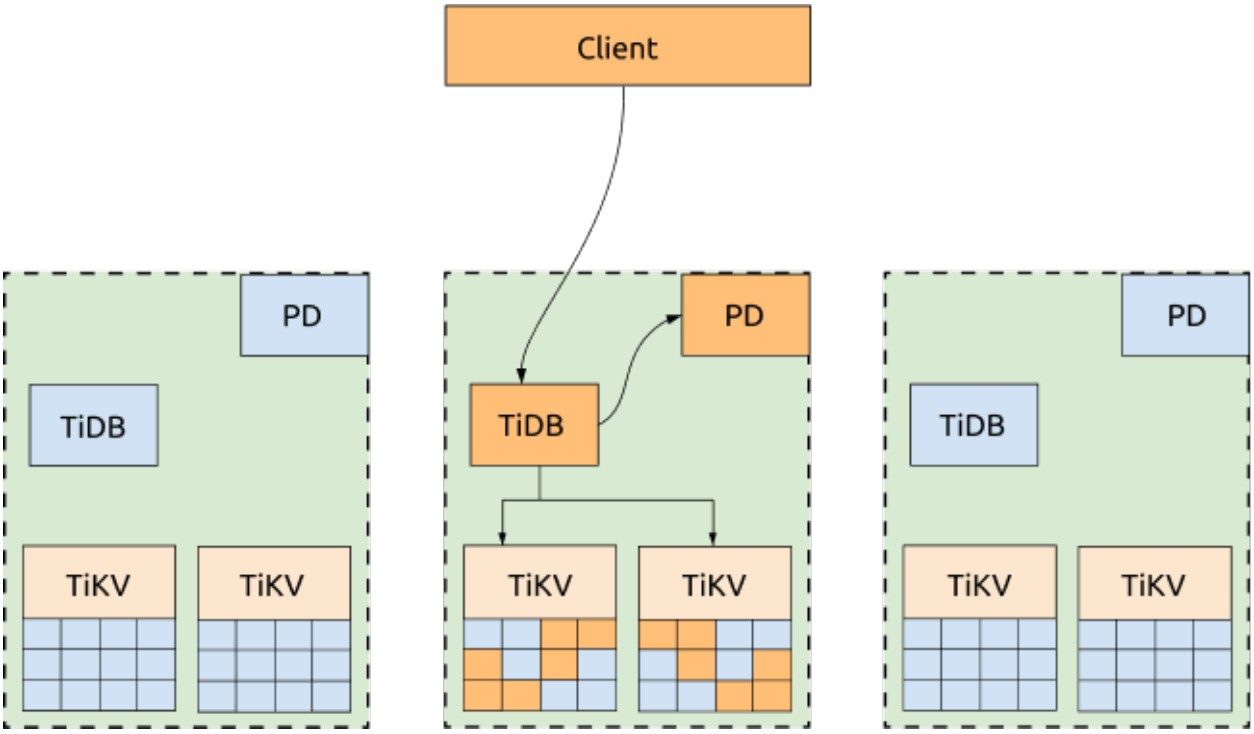

Figure 73: Read Performance Optimized 3-DC Deployment

Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other DCs to the DC that provides services to the
   ↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

Disadvantages:

- Write scenarios are still affected by network latency across DCs. This is because Raft follows the majority protocol and all written data must be replicated to at least two DCs.
- The TiDB server that provides services is only in one DC.
- All application traffic is processed by one DC and the performance is limited by the network bandwidth pressure of that DC.

- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the DC that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

10.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

10.1.2.3.1 Topology example

The following example assumes that three DCs (IDC1, IDC2, and IDC3) are located in one city; each IDC has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three DCs in one city is as follows:

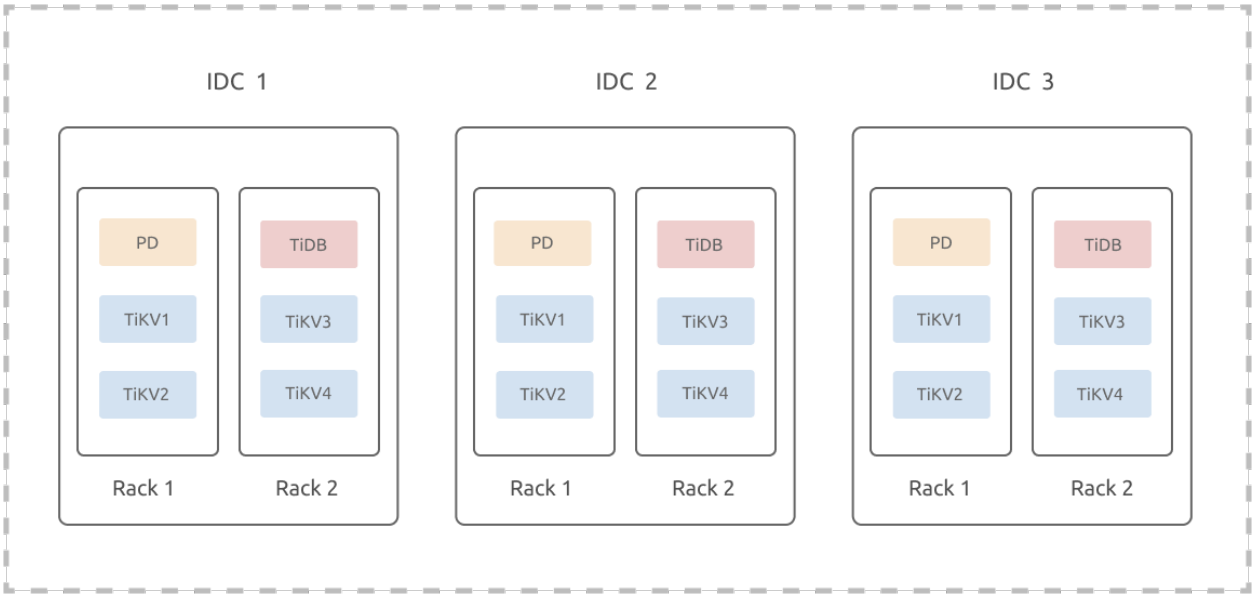

Figure 74: 3-DC in One City

10.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the limitation described above, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

10.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to configure in the cluster initialization configuration file according to the planned topology:

```
server_configs:
  pd:
    replication.location-labels: ["zone","dc","rack","host"]

tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { zone: "z1", dc: "d1", rack: "r1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { zone: "z1", dc: "d1", rack: "r1", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { zone: "z1", dc: "d1", rack: "r2", host: "32" }
  - host: 10.63.10.33
    config:
      server.labels: { zone: "z1", dc: "d1", rack: "r2", host: "33" }
  - host: 10.63.10.34
    config:
      server.labels: { zone: "z2", dc: "d1", rack: "r1", host: "34" }
  - host: 10.63.10.35
    config:
      server.labels: { zone: "z2", dc: "d1", rack: "r1", host: "35" }
  - host: 10.63.10.36
```

```
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r2", host: "36" }
- host: 10.63.10.37
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r2", host: "37" }
- host: 10.63.10.38
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r1", host: "38" }
- host: 10.63.10.39
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r1", host: "39" }
- host: 10.63.10.40
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r2", host: "40" }
- host: 10.63.10.41
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r2", host: "41" }
```

In the example above, `zone` is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the DC might be scaled out in the future, the three-layer label structure (`dc`, `rack`, `host`) is not directly adopted. Assuming that `d2`, `d3`, and `d4` are to be scaled out, you only need to scale out the DCs in the corresponding availability zone and scale out the racks in the corresponding DC.

If this three-layer label structure is directly adopted, after scaling out a DC, you might need to apply new labels and the data in TiKV needs to be rebalanced.

10.1.2.4 High availability and disaster recovery analysis

The multiple DCs in one city deployment can guarantee that if one DC fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when failure occurs, these policies prioritize availability over performance.

10.2 Three Data Centers in Two Cities Deployment

This document introduces the architecture and configuration of the three data centers (DC) in two cities deployment.

10.2.1 Overview

The architecture of three DCs in two cities is a highly available and disaster tolerant deployment solution that provides a production data center, a disaster recovery center in

the same city, and a disaster recovery centers in another city. In this mode, the three DCs in two cities are interconnected. If one DC fails or suffers from a disaster, other DCs can still operate well and take over the the key applications or all applications. Compared with the the multi-DC in one city deployment, this solution has the advantage of cross-city high availability and can survive city-level natural disasters.

The distributed database TiDB natively supports the three-DC-in-two-city architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across DCs in the same city is relatively low, the application traffic can be dispatched to two DCs in the same city, and the traffic load can be shared by these two DCs by controlling the distribution of TiKV Region leaders and PD leaders.

10.2.2 Architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three DCs in two cities for the distributed database of TiDB.

In this example, two DCs (IDC1 and IDC2) are located in Seattle and another DC (IDC3) is located in San Francisco. The network latency between IDC1 and IDC2 is lower than 3 milliseconds. The network latency between IDC3 and IDC1/IDC2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three DCs in two cities: IDC1 in Seattle, IDC2 in Seattle, and IDC3 in San Francisco.
- The cluster has five replicas, two in IDC1, two in IDC2, and one in IDC3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

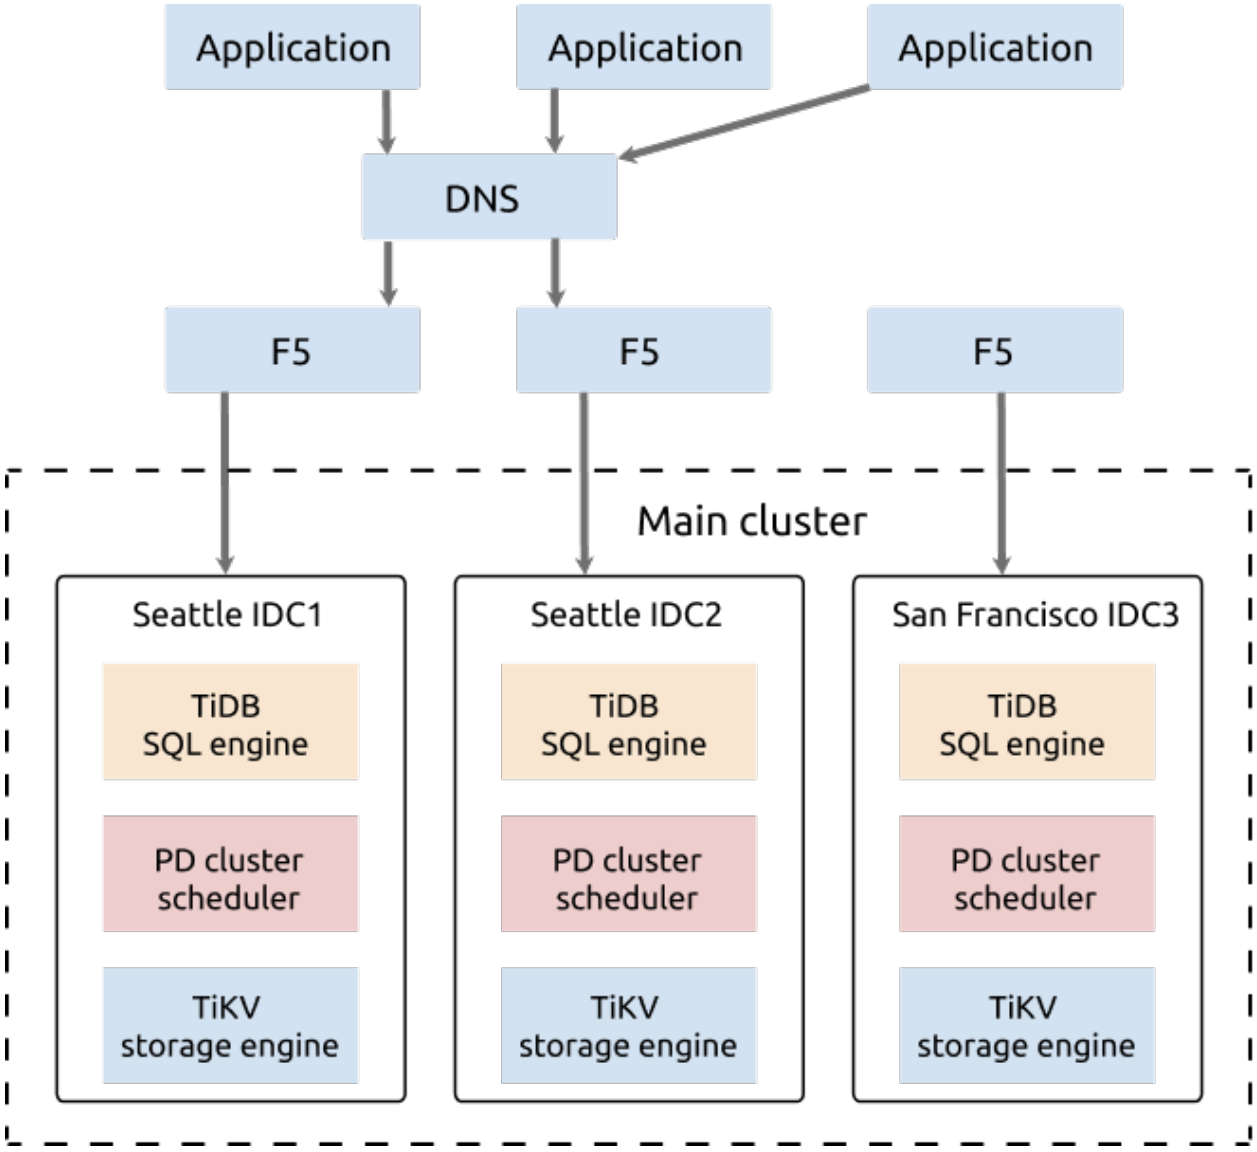

Figure 75: 3-DC-in-2-city architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two DCs (IDC1 and IDC2) that are in the same city (Seattle). Compared with the three-DC solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**
  - Region leaders are in DCs of the same city with low latency, so the write is faster.
  - The two DCs can provide services at the same time, so the resources usage rate is higher.
  - If one DC fails, services are still available and data safety is ensured.

- **Disadvantages**
  - Because the data consistency is achieved by the Raft algorithm, when two DCs in the same city fail at the same time, only one surviving replica remains in the disaster recovery DC in another city (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
  - Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
  - Five replicas are configured in three DCs in two cities, data redundancy increases, which brings a higher storage cost.

10.2.2.1 Deployment details

The configuration of the three DCs in two cities (Seattle and San Francisco) deployment plan is illustrated as follows:

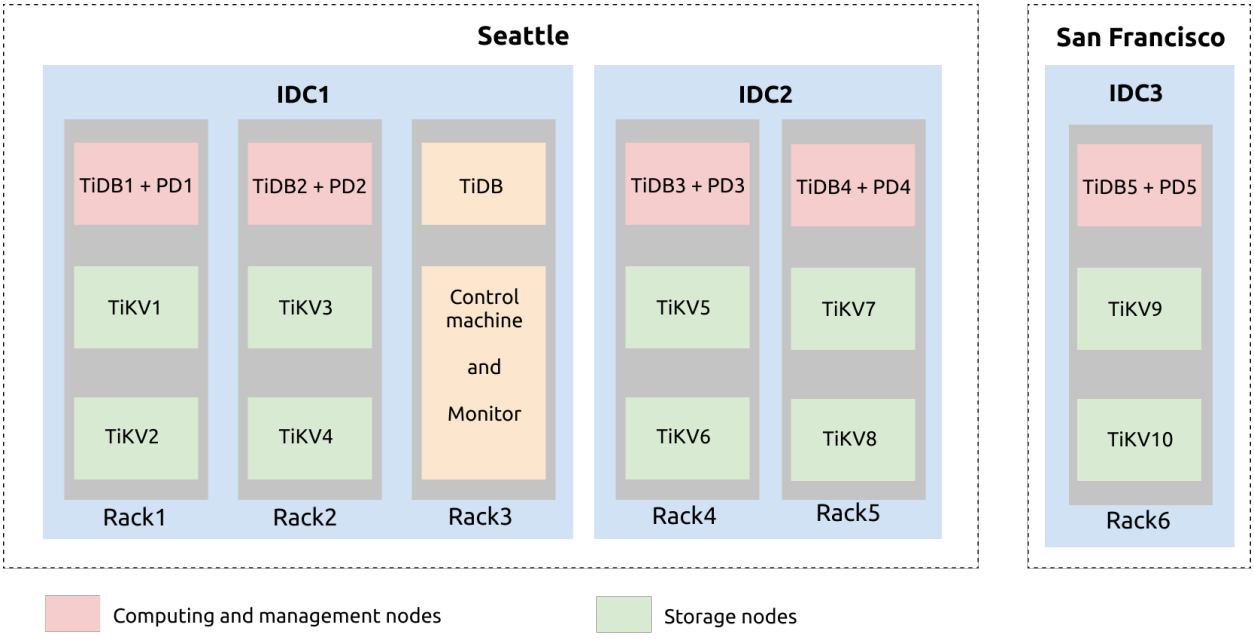

Figure 76: 3-DC-2-city

- From the illustration above, you can see that Seattle has two DCs: IDC1 and IDC2. IDC1 has three sets of racks: RAC1, RAC2, and RAC3. IDC2 has two racks: RAC4 and RAC5. The IDC3 DC in San Francisco has the RAC6 rack.
- From the RAC1 rack illustrated above, TiDB and PD services are deployed on the same server. Each of the two TiKV servers are deployed with two TiKV instances (tikv-server). This is similar to RAC2, RAC4, RAC5, and RAC6.

- The TiDB server, the control machine, and the monitoring server are on RAC3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.
- Another backup server can be added to deploy Drainer. Drainer saves binlog data to a specified location by outputting files, to achieve incremental backup.

10.2.3 Configuration

10.2.3.1 Example

See the following `tiup topology.yaml` yaml file for example:

```
## # Global variables are applied to all deployments and used as the default
   ↪ value of
## # the deployments if a specific deployment value is missing.
global
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["dc","rack","zone","host"]

pd_servers:
  - host: 10.63.10.10
    name: "pd-10"
  - host: 10.63.10.11
    name: "pd-11"
  - host: 10.63.10.12
    name: "pd-12"
  - host: 10.63.10.13
    name: "pd-13"
  - host: 10.63.10.14
    name: "pd-14"

tidb_servers:
  - host: 10.63.10.10
  - host: 10.63.10.11
  - host: 10.63.10.12
  - host: 10.63.10.13
  - host: 10.63.10.14
```

```
tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { dc: "1", zone: "1", rack: "1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { dc: "1", zone: "2", rack: "2", host: "31" }
  - host: 10.63.10.32
    config:
      server.labels: { dc: "2", zone: "3", rack: "3", host: "32" }
  - host: 10.63.10.33
    config:
      server.labels: { dc: "2", zone: "4", rack: "4", host: "33" }
  - host: 10.63.10.34
    config:
      server.labels: { dc: "3", zone: "5", rack: "5", host: "34" }
      raftstore.raft-min-election-timeout-ticks: 1000
      raftstore.raft-max-election-timeout-ticks: 1200

monitoring_servers:
  - host: 10.63.10.60

grafana_servers:
  - host: 10.63.10.60

alertmanager_servers:
  - host: 10.63.10.60
```

10.2.3.2 Labels design

In the deployment of three DCs in two cities, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`dc`, `zone`, `rack`, `host`) based on the physical structure of the deployment.

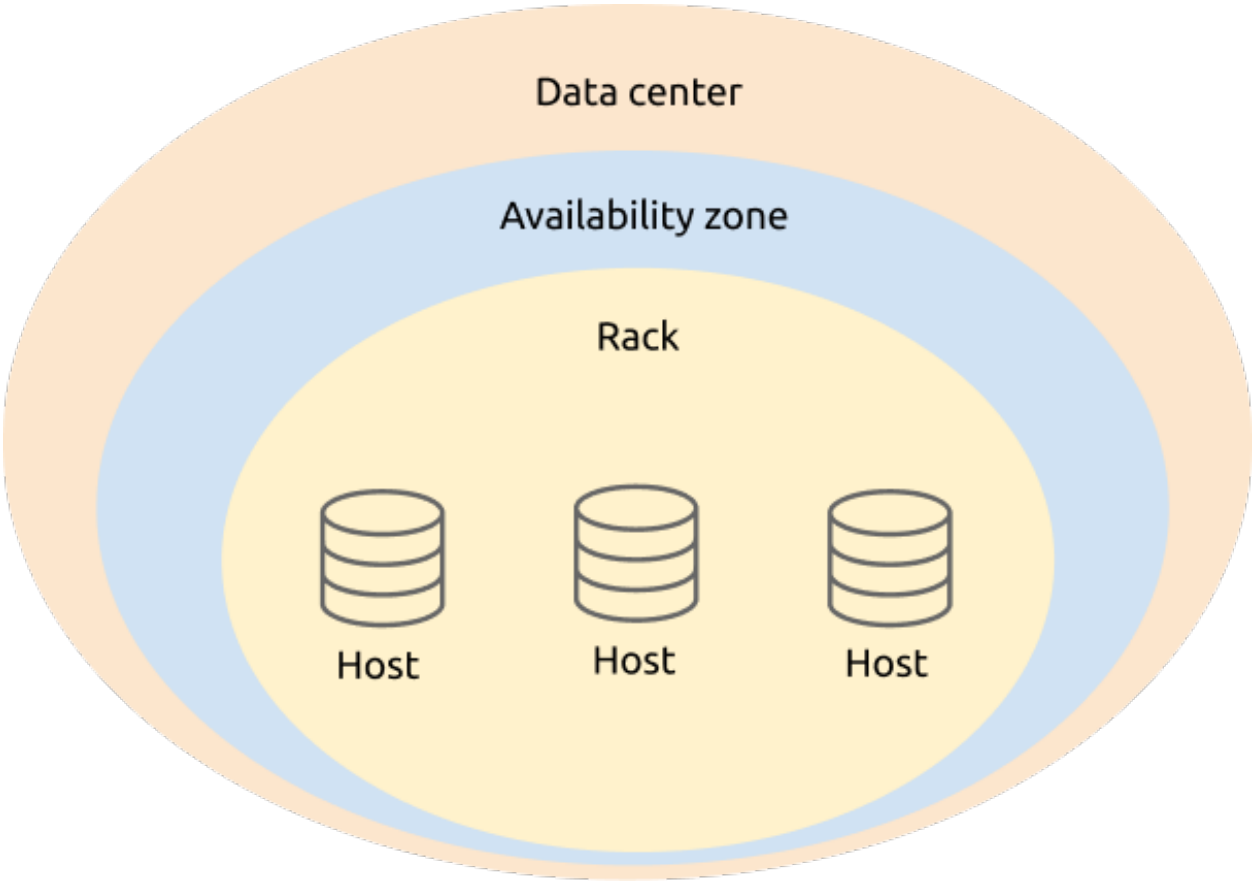

Figure 77: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
  pd:
    replication.location-labels: ["dc","zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
  - host: 10.63.10.30
    config:
      server.labels: { dc: "1", zone: "1", rack: "1", host: "30" }
  - host: 10.63.10.31
    config:
      server.labels: { dc: "1", zone: "2", rack: "2", host: "31" }
  - host: 10.63.10.32
    config:
```

```
    server.labels: { dc: "2", zone: "3", rack: "3", host: "32" }
- host: 10.63.10.33
  config:
    server.labels: { dc: "2", zone: "4", rack: "4", host: "33" }
- host: 10.63.10.34
  config:
    server.labels: { dc: "3", zone: "5", rack: "5", host: "34" }
```

10.2.3.3 Optimize parameter configuration

In the deployment of three DCs in two cities, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another city (San Francisco). Modify the following TiKV parameters for IDC3 (alone) in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 1000
raftstore.raft-max-election-timeout-ticks: 1200
```

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:<cluster-version> pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to IDC3. Scheduling the Raft leader to in another city (IDC3) causes unnecessary network overhead between IDC1/IDC2 in Seattle and IDC3 in San Francisco. The network bandwidth and latency also affect performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

- Configure the priority of PD. To avoid the situation where the PD leader is in another city (IDC3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another city (San Francisco). The larger the number, the higher the priority.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

10.3 Read Historical Data

10.3.1 Use Stale Read (Recommended)

10.3.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

> **Note:**
>
> Since v5.1.1, Stale Read is a feature for general availability (GA).

10.3.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `Readindex` from different data centers for

verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see Local Read under Three Data Centers Deployment.

10.3.1.1.2 Usages

In TiDB, you can specify either an exact point in time or a time range when performing stale reads:

- Specifying an exact point in time (recommended): If you need TiDB to read data that follows the global transaction consistency from a specific point in time without damaging the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see `AS OF TIMESTAMP` Clause.
- Specifying a time range: If you need TiDB to read data as new as possible within a time range without damaging the isolation level, you can specify the time range in the query statement. Then, TiDB selects a suitable timestamp within the specified time range to read the corresponding data. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. For detailed usage, refer to the introduction of the `AS OF TIMESTAMP` clause and the `TIDB_BOUNDED_STALENESS` function.

10.3.1.2 Read Historical Data Using the `AS OF TIMESTAMP` Clause

This document describes how to perform the Stale Read feature using the `AS OF TIMESTAMP` clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

> **Warning:**
>
> Currently, you cannot use Stale Read together with TiFlash. If your SQL query contains the `AS OF TIMESTAMP` clause and TiDB might read data from TiFlash replicas, you might encounter an error with a message like `ERROR 1105 (HY000): stale requests require tikv backend`.
>
> To fix the problem, disable TiFlash replicas for your Stale Read query. To do that, perform one of the following operations:
>
> - Use the `set session tidb_isolation_read_engines='tidb,tikv'` variable.
> - Use the hint to enforce TiDB to read data from TiKV.

TiDB supports reading historical data through a standard SQL interface, which is the `AS OF TIMESTAMP` SQL clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

> **Note:**
>
> When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

10.3.1.2.1 Syntax

You can use the `AS OF TIMESTAMP` clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the `AS OF TIMESTAMP` clause. The format of datetime is like "2016-10-08 16:45:26.999", with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as "2016-10-08 16:45:26". You can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW() - INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. "Suitable" means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW()- INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.

- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW()- INTERVAL 20 SECOND, NOW() ↪ )`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

> **Note:**
>
> In addition to specifying a timestamp, the most common use of the `AS OF ↪ TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.
>
> You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.
>
> Before v5.1.1, the `Prepare` statement and the `AS OF TIMESTAMP` syntax are not perfectly compatible. It is not recommended to use them together. Since v5.1.1, the `Prepare` statement and the `AS OF TIMESTAMP` syntax are fully compatible, and you can use them together.

10.3.1.2.2 Usage examples

This section describes different ways to use the `AS OF TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to use `AS OF TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+---------------------+
| now()               |
+---------------------+
| 2021-05-26 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

Read historical data using the `SELECT` statement

You can use the `SELECT ... FROM ... AS OF TIMESTAMP` statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> When reading multiple tables using one `SELECT` statement, you need to make sure that the format of TIMESTAMP EXPRESSIONs is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, c as of timestamp NOW()- INTERVAL 2 SECOND;`. In addition, you must specify the `AS OF` information for the relevant table in the `SELECT` statement; otherwise, the `SELECT` statement reads the latest data by default.

Read historical data using the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `START TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|    2 |
```

```
|    3 |
+------+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
>
> If you start a transaction with the statement `SET TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

10.3.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

> **Note:**
>
> You can also use the Stale Read feature to read historical data, which is more recommended.

10.3.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

> **Note:**
>
> - Even when data is updated or removed, its history versions can be read using the SQL interface.
> - When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

10.3.2.2 How TiDB reads data from history versions

The `tidb_snapshot` system variable is introduced to support reading history data. About the `tidb_snapshot` variable:

- The variable is valid in the `SESSION` scope.
- Its value can be modified using the `SET` statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is "2016-10-08 16:45:26.999". Generally, the datetime can be set using second precision, for example "2016-10-08 16:45:26".
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the `SELECT` operations will read data from this Snapshot.

> **Note:**
>
> Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the `tidb_snapshot` variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the `SET` statement to set the value of the `tidb_snapshot` variable to "" (empty string).

10.3.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see TiDB Garbage Collection (GC)

Pay special attention to the following:

- `tidb_gc_life_time`: This system variable is used to configure the retention time of earlier modifications (default: `10m0s`).
- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point ↪ '`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

10.3.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+---------------------+
| now()               |
```

```
+---------------------+
| 2016-10-08 16:45:26 |
+---------------------+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

6. Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

> **Note:**
> In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

Result: The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|    2 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

7. Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+------+
| c    |
+------+
|    1 |
|   22 |
|    3 |
+------+
3 rows in set (0.00 sec)
```

> **Note:**
> You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

10.3.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

Note:

Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO LOCAL OUTFLE` and use `LOAD DATA` to import the data later on.
- Use Dumpling to export a historical snapshot. Dumpling performs well in exporting larger sets of data.

10.4 Best Practices

10.4.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- TiDB Internal (I) - Data Storage
- TiDB Internal (II) - Computing
- TiDB Internal (III) - Scheduling

10.4.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

10.4.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to PingCAP blog posts.

10.4.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

10.4.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of Google Percolator. This document introduces the following features:

- Optimistic transaction model

  TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

  Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction model

  In TiDB, the pessimistic transaction model has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

  However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

  As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

  - A transaction is limited to 5,000 SQL statements (by default)
  - Each Key-Value entry is no more than 6 MB (by default)
  - The total size of Key-Value entries is no more than 10 GB.

  You can find similar limits in Google Cloud Spanner.

10.4.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval, `[StartKey, EndKey ↪ )`. When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

10.4.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

10.4.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see TiDB Internal (II) - Computing.

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

10.4.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

  Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index, there will be one more Key-Value when inserting a piece of data. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

  In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

  As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

  - For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
  - If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

  For example, if a commonly used query is `select * from t where c1 = 10 and c2 = 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

  TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

  If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

  The following two conditions do not have the problem of two accesses:

  - Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where c > 10;`. At this time, all needed data can be obtained if you access the index. This situation is called `Covering Index`. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10;` as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.
  - The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

  As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

  - `tidb_distsql_scan_concurrency`:

    The concurrency of scanning data, including scanning the table and index data.
  - `tidb_index_lookup_size`:

    If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.
  - `tidb_index_lookup_concurrency`:

If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

  You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

  TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

10.4.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

10.4.1.3.1 Deployment

Before deployment, read Software and Hardware Requirements.

It is recommended to deploy the TiDB cluster using TiUP. This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

10.4.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in Tune TiKV Memory Parameter Performance.

10.4.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

> **Note:**
>
> When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are `INSERT`, `UPDATE` or `DELETE` statements.

When deleting a large amount of data, it is recommended to use `Delete from t where xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following `DELETE` statement. If possible, it is recommended to refine the `WHERE` condition. Assume that you need to delete all data on `2017-05-26`, you can use the following statements:

```
for i from 0 to 23:
    while affected_rows > 0:
        delete from t where insert_time >= i:00:00 and insert_time < (i+1)
            ↪ :00:00 limit 5000;
        affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier `Delete` statements do not affect the later ones.

10.4.1.3.4 Query

For query requirements and specific statements, refer to System Variables.

You can control the concurrency of SQL execution through the `SET` statement and the selection of the `Join` operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index hint`.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

10.4.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses Grafana + Prometheus to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate `overview` panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, tidb-server, tikv-server, and pd-server, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides TiDB Dashboard UI to improve usability. You can access TiDB Dashboard by visiting http://$%7BPD_IP%7D:$%7BPD_PORT%7D/dashboard in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

10.4.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from FAQ and TiDB Cluster Troubleshooting Guide. You can also search the issue list or create an issue in TiDB repository on GitHub.

TiDB also has many useful ecosystem tools. See Ecosystem Tool Overview for details.

For more articles on the technical details of TiDB, see the PingCAP official blog site.

10.4.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot

- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

10.4.2 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

10.4.2.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard MySQL protocol.
- JDBC API and JDBC drivers: Java applications usually use the standard JDBC (Java Database Connectivity) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include MySQL Connector/J and MariaDB Connector/J.
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC DataSource defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as MyBatis and Hibernate to further simplify and manage the database access operations.
- Application implementation: The application logic controls when to send what commands to the database. Some applications use Spring Transaction aspects to manage transactions' start and commit logics.

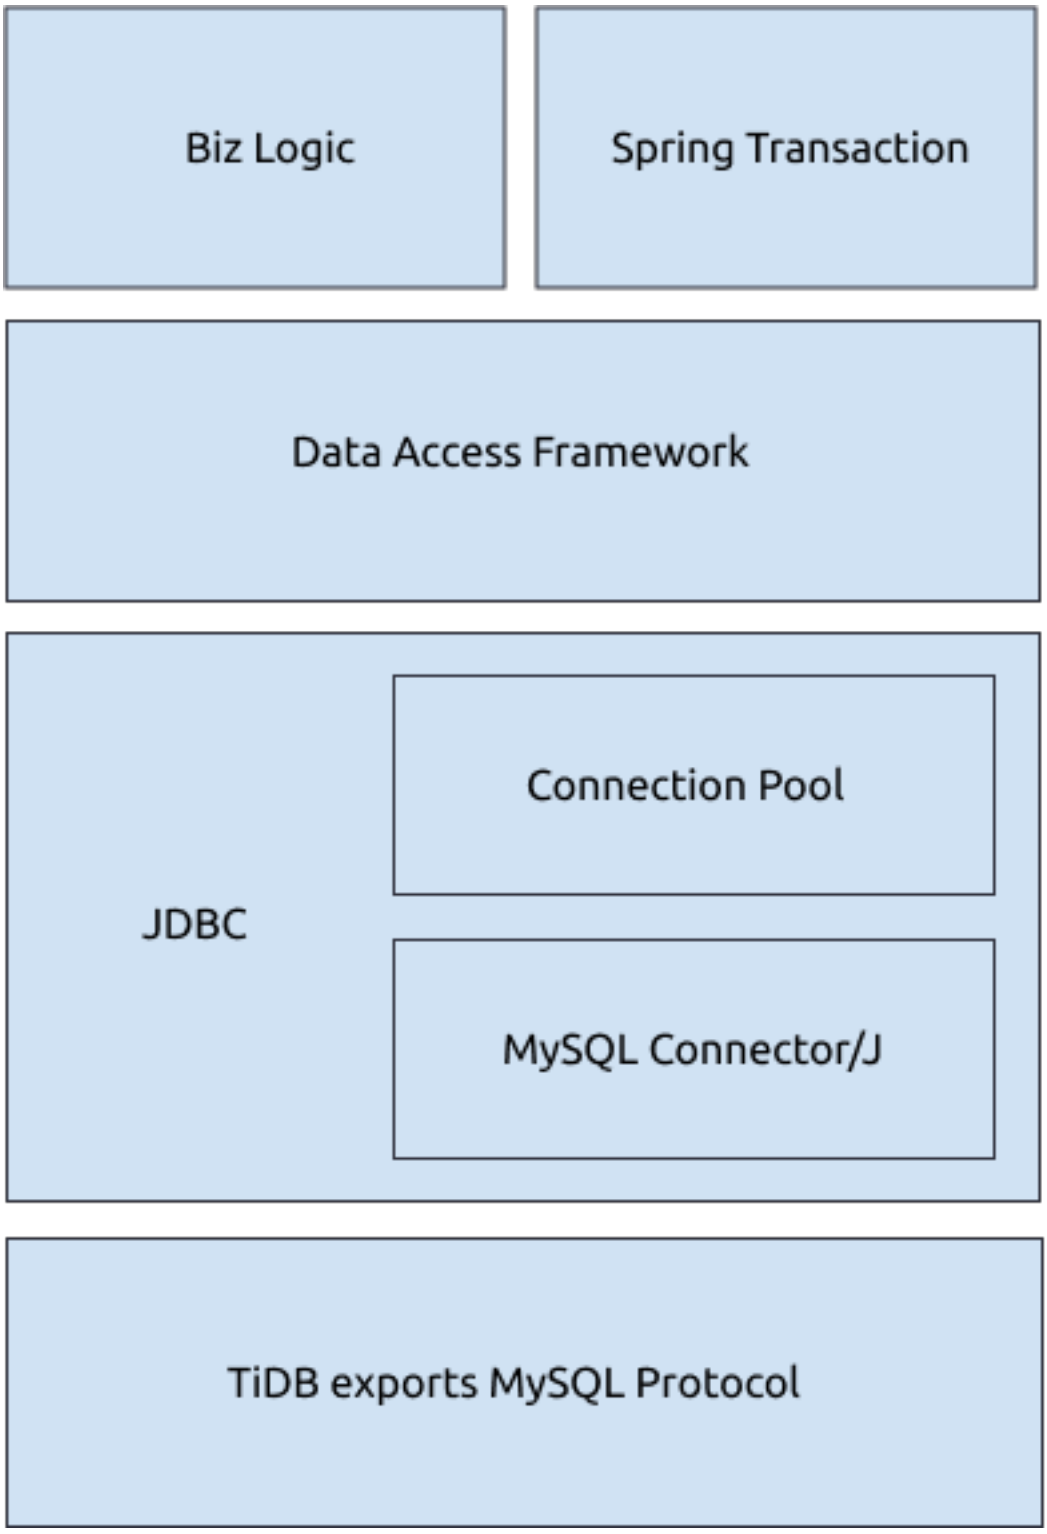

Figure 78: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

10.4.2.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

10.4.2.2.1 JDBC API

For JDBC API usage, see JDBC official tutorial. This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use Prepared Statements instead of regular execution from a text file and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see MySQL JDBC parameters.

Use Batch API

For batch inserts, you can use the `addBatch/executeBatch` API. The `addBatch()` method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

Note:

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see Batch-related parameters.

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

Usually, there are two kinds of processing methods in JDBC:

- Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.
- To use Cursor Fetch, first set `FetchSize` as a positive integer and configure `useCursorFetch=true` in the JDBC URL.

TiDB supports both methods, but it is preferred that you use the first method, because it is a simpler implementation and has a better execution efficiency.

10.4.2.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces MySQL Connector/J's parameter configurations (If you use MariaDB, see MariaDB's parameter configurations). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to `Prepare`.

`useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the "prepare" operation will be done only on the client. To avoid the parsing overhead of the

server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

`cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the "prepare" operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

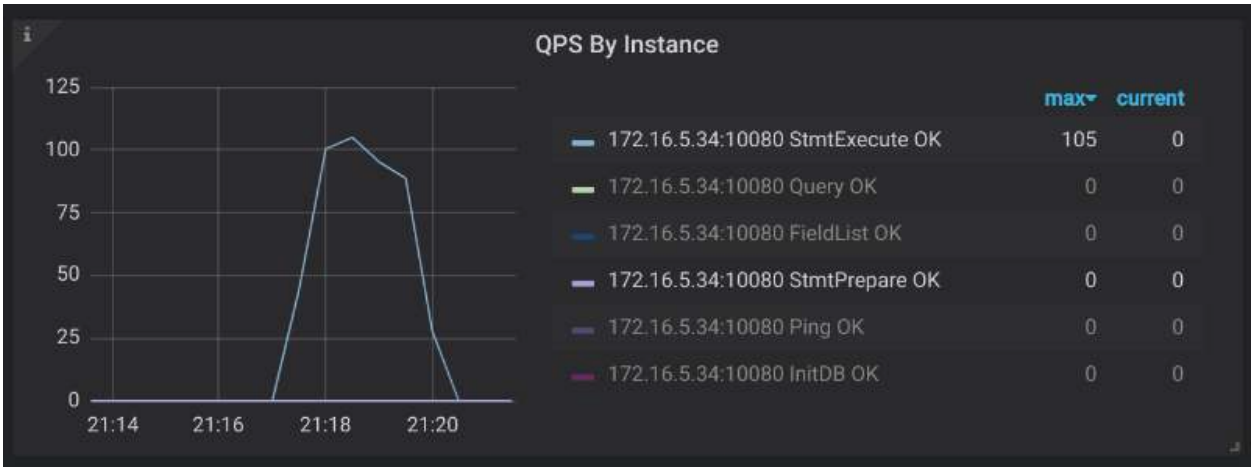

Figure 79: QPS By Instance

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

`prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is `256`). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

`prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is `25`). If your application requires "preparing" many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare( "insert into t (a) values(?)" );
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple "values" keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
    ↪ values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
    ↪ t set a = 12 where id = 3;
```

In addition, because of a client bug, if you want to configure `rewriteBatchedStatements` ↪ `=true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Check parameters before execution

Through monitoring, you might notice that although the application only performs `INSERT` operations to the TiDB cluster, there are a lot of redundant `SELECT` statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` configuration includes a group of configurations:

```
cacheServerConfiguration=true
useLocalSessionState=true
```

```
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
```

After it is configured, you can check the monitoring to see a decreased number of `SELECT` statements.

10.4.2.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

Java has many connection pool implementations such as HikariCP, tomcat-jdbc, durid, c3p0, and dbcp. TiDB does not limit which connection pool you use, so you can choose whichever you like for your application.

10.4.2.3.1 Configure the number of connections

It is a common practice that the connection pool size is well adjusted according to the application's own needs. Take HikariCP as an example:

- `maximumPoolSize`: The maximum number of connections in the connection pool. If this value is too large, TiDB consumes resources to maintain useless connections. If this value is too small, the application gets slow connections. So configure this value for your own good. For details, see About Pool Sizing.
- `minimumIdle`: The minimum number of idle connections in the connection pool. It is mainly used to reserve some connections to respond to sudden requests when the application is idle. You can also configure it according to your application needs.

The application needs to return the connection after finishing using it. It is also recommended that the application use the corresponding connection pool monitoring (such as `metricRegistry`) to locate the connection pool issue in time.

10.4.2.3.2 Probe configuration

The connection pool maintains persistent connections to TiDB. TiDB does not proactively close client connections by default (unless an error is reported), but generally there will be network proxies such as LVS or HAProxy between the client and TiDB. Usually, these proxies will proactively clean up connections that are idle for a certain period of time. In addition to paying attention to the idle configuration of the proxies, the connection pool also needs to keep alive or probe connections.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
    ↪ . The driver has not received any packets from the server. com.mysql.
    ↪ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
    ↪ failure
```

If `n` in `n milliseconds ago` is `0` or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as `3600000` in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

10.4.2.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

10.4.2.4.1 MyBatis

MyBatis is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t where id =?` as a Prepared Statement and be "prepared", and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.
- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for "preparing" the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

Dynamic SQL Batch

Dynamic SQL - foreach

To support the automatic rewriting of multiple `INSERT` statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements =true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
  insert into test
   (id, v1, v2)
  values
  <foreach item="item" index="index" collection="list" separator=",">
  (
   #{item.id}, #{item.v1}, #{item.v2}
  )
  </foreach>
  on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of `(?,?,?)` following "values" is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

Streaming result

A previous section introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping's `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
  select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer.MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

10.4.2.4.2 ExecutorType

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`
- Batch: Each update operation (`INSERT`/`DELETE`/`UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

10.4.2.5 Spring Transaction

In the real world, applications might use Spring Transaction and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the Propagation configuration. Because TiDB does not support savepoint, nested transactions are not supported yet.

10.4.2.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

10.4.2.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

jstack

jstack is similar to pprof/goroutine in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using jstack multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using Batch ExecutorType in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or Java swiss knife are common methods to view the thread ID. Also, to locate the issue of "a thread occupies a lot of CPU resources and I don't know what it is executing", do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the jstack output to find the stack information of the corresponding thread.

jmap & mat

Unlike pprof/heap in Go, jmap dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool mat.

Through mat, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use mat to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that mat only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust mat configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

trace

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using btrace or arthas trace is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see Java Flame Graphs Introduction: Fire For Everyone!.

10.4.2.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

Join us at TiDB Community slack channel, and share with broad TiDB user group about your experience or problems when you develop Java applications with TiDB.

10.4.3 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of HAProxy in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

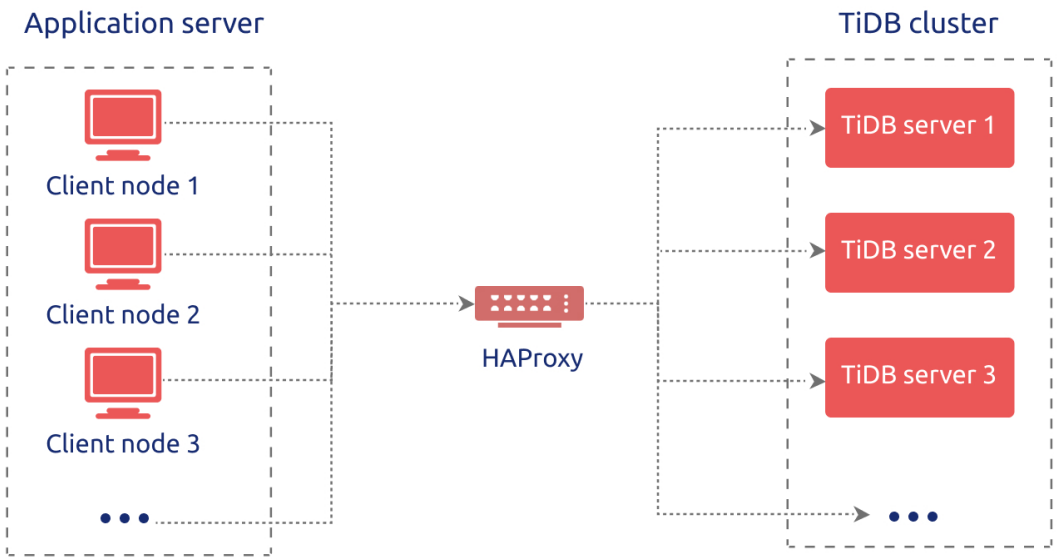

Figure 80: HAProxy Best Practices in TiDB

10.4.3.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. The latest stable version 2.0.0 was released on August 16, 2019, bringing more excellent features.

10.4.3.2 Basic features

- High Availability: HAProxy provides high availability with support for a graceful shutdown and a seamless switchover;
- Load Balancing: Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- Health Check: HAProxy periodically checks the status of HTTP or TCP mode of the server;
- Sticky Session: HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- SSL: HTTPS communication and resolution are supported;
- Monitoring and Statistics: Through the web page, you can monitor the service state and traffic flow in real time.

10.4.3.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

10.4.3.3.1 Hardware requirements

For your server, it is recommended to meet the following hardware requirements. You can also improve server specifications according to the load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	16 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

10.4.3.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Operating system version	Architecture
Linux 2.4	x86, x86_64, Alpha, SPARC, MIPS, and PA-RISC
Linux 2.6 or 3.x	x86, x86_64, ARM, SPARC, and PPC64
Solaris 8 or 9	UltraSPARC II and III
Solaris 10	Opteron and UltraSPARC
FreeBSD 4.10 ~ 10	x86
OpenBSD 3.1 or later versions	i386, AMD64, macppc, Alpha, and SPARC64
AIX 5.1 ~ 5.3	Power™

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

10.4.3.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the configuration file based on your actual scenario.

10.4.3.4.1 Install HAProxy

1. Use yum to install HAProxy:

   ```
   yum -y install haproxy
   ```

2. Check whether the installation is successful:

   ```
   which haproxy
   ```

   ```
   /usr/sbin/haproxy
   ```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
`-v`	Reports the version and build date.
`-vv`	Displays the version, build options, libraries versions and usable pollers.
`-d`	Enables debug mode.
`-db`	Disables background mode and multi-process mode.
`-dM [< ↪ byte ↪ >]`	Forces memory poisoning, which means that each and every memory region allocated with malloc() or pool_alloc2() will be filled with `<byte>` before being passed to the caller.

Option	Description
`-V`	Enables verbose mode (disables quiet mode).
`-D`	Starts as a daemon.
`-C <dir>`	Changes to directory `<dir>` before loading configuration files.
`-W`	Master-worker mode.
`-q`	Sets "quiet" mode: This disables some messages during the configuration parsing and during startup.
`-c`	Only performs a check of the configuration files and exits before trying to bind.
`-n <` ↪ `limit` ↪ `>`	Limits the per-process connection limit to `<limit>`.

Option	Description
`-m <limit>`	Limits the total allocatable memory to `<limit>` megabytes across all processes.
`-N <limit>`	Sets the default per-proxy maxconn to `<limit>` instead of the builtin default value (usually 2000).
`-L <name>`	Changes the local peer name to `<name>`, which defaults to the local hostname.
`-p <file>`	Writes all processes' PIDs into `<file>` during startup.

Option	Description
`-de`	Disables the use of epoll(7). epoll(7) is available only on Linux 2.6 and some custom Linux 2.4 systems.
`-dp`	Disables the use of poll(2). select(2) might be used instead.
`-dS`	Disables the use of splice(2), which is broken on older kernels.
`-dR`	Disables SO_REUSEPORT usage.
`-dr`	Ignores server address resolution failures.
`-dV`	Disables SSL verify on the server side.

Option	Description
`-sf <pidlist>`	Sends the "finish" signal to the PIDs in pidlist after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
`-st <pidlist>`	Sends the "terminate" signal to the PIDs in pidlist after startup. The processes which receive this signal terminate immediately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
`-x <unix_socket>`	Connects to the specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
`-S <bind>[,<bind_options>...]`	In master-worker mode, creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to Management Guide of HAProxy and General Commands Manual of HAProxy.

10.4.3.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global                                  # Global configuration.
   log         127.0.0.1 local2         # Global syslog servers (up to two).
   chroot      /var/lib/haproxy         # Changes the current directory and
      ↪ sets superuser privileges for the startup process to improve
      ↪ security.
   pidfile     /var/run/haproxy.pid     # Writes the PIDs of HAProxy processes
      ↪  into this file.
   maxconn     4000                     # The maximum number of concurrent
      ↪ connections for a single HAProxy process.
   user        haproxy                  # Same with the UID parameter.
   group       haproxy                  # Same with the GID parameter. A
      ↪ dedicated user group is recommended.
   nbproc      40                       # The number of processes created when
      ↪  going daemon. When starting multiple processes to forward requests
      ↪ , make sure the value is large enough so that HAProxy does not
      ↪ block processes.
   daemon                               # Makes the process fork into
      ↪ background. It is equivalent to the command line "-D" argument. It
      ↪ can be disabled by the command line "-db" argument.
   stats socket /var/lib/haproxy/stats # The directory where statistics
      ↪ output is saved.

defaults                                # Default configuration.
   log global                           # Inherits the settings of the global
      ↪ configuration.
   retries 2                            # The maximum number of retries to
      ↪ connect to an upstream server. If the number of connection attempts
      ↪  exceeds the value, the backend server is considered unavailable.
   timeout connect 2s                   # The maximum time to wait for a
      ↪ connection attempt to a backend server to succeed. It should be set
      ↪  to a shorter time if the server is located on the same LAN as
      ↪ HAProxy.
   timeout client 30000s                # The maximum inactivity time on the
      ↪ client side.
   timeout server 30000s                # The maximum inactivity time on the
      ↪ server side.

listen admin_stats                      # The name of the Stats page reporting
   ↪  information from frontend and backend. You can customize the name
   ↪ according to your needs.
   bind 0.0.0.0:8080                    # The listening port.
   mode http                            # The monitoring mode.

    ↪ if it is detected as failed three times, the server is considered
    ↪ unavailable.
  server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
  server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

10.4.3.4.3 Start HAProxy

There are two methods to start HAProxy.

Method 1: Execute `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

Method 2: Use `systemd` to start HAProxy.

```
systemctl start haproxy.service
```

10.4.3.4.4 Stop HAProxy

There are two methods to stop HAProxy.

Method 1: Use `kill -9`.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

Method 2: Use `systemd`.

```
systemctl stop haproxy.service
```

10.4.4 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

10.4.4.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and TiDB Best Practices:

- Data Storage
- Computing
- Scheduling

10.4.4.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing, settlement and so on. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

10.4.4.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to Scheduling for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports Follower-Read) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

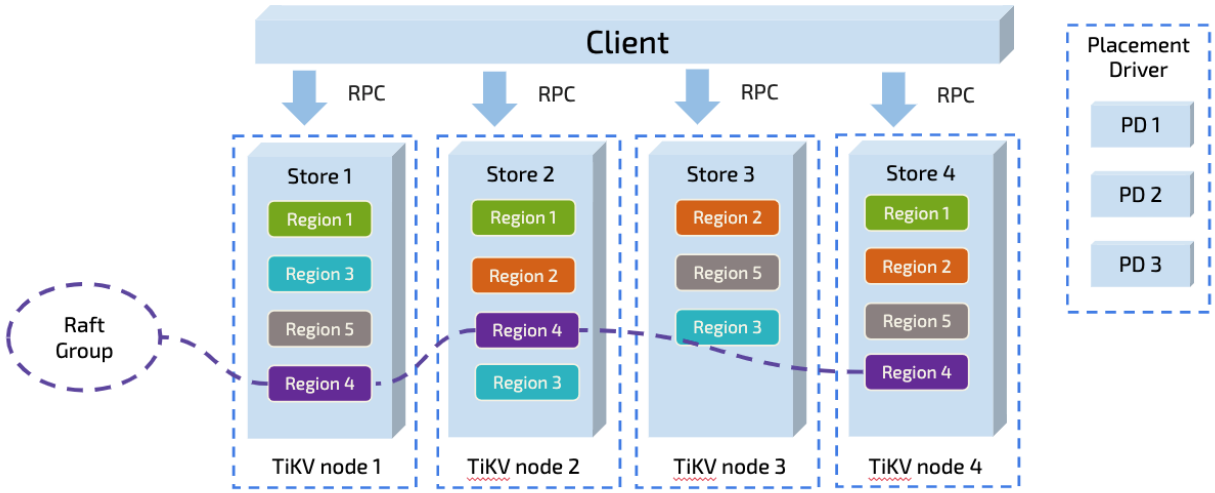

Figure 81: TiDB Data Overview

In theory, by the virtue of this architecture, TiDB can linearly scale its read and write capacities and make full use of the distributed resources so long as there is no `AUTO_INCREMENT` primary key in the write scenario, or there is no monotonically increasing index. From this point of view, TiDB is especially suitable for the highly-concurrent and write-intensive scenario. However, the actual situation often differs from the theoretical assumption.

> **Note:**
>
> No `AUTO_INCREMENT` primary key in the write scenario or no monotonically increasing index means no write hotspot in the application.

10.4.4.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(
    id        BIGINT PRIMARY KEY,
    age       INT,
    user_name VARCHAR(32),
    email     VARCHAR(128)
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
INSERT INTO TEST_HOTSPOT(id, age, user_name, email) values(%v, %v, '%v', '%
    ↪ v');
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

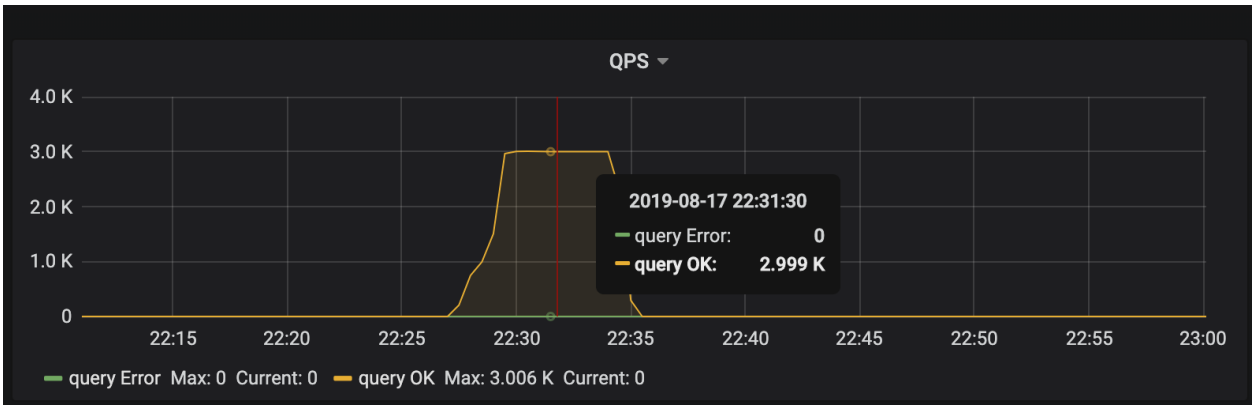

Figure 82: QPS1

The client starts "intensive" write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

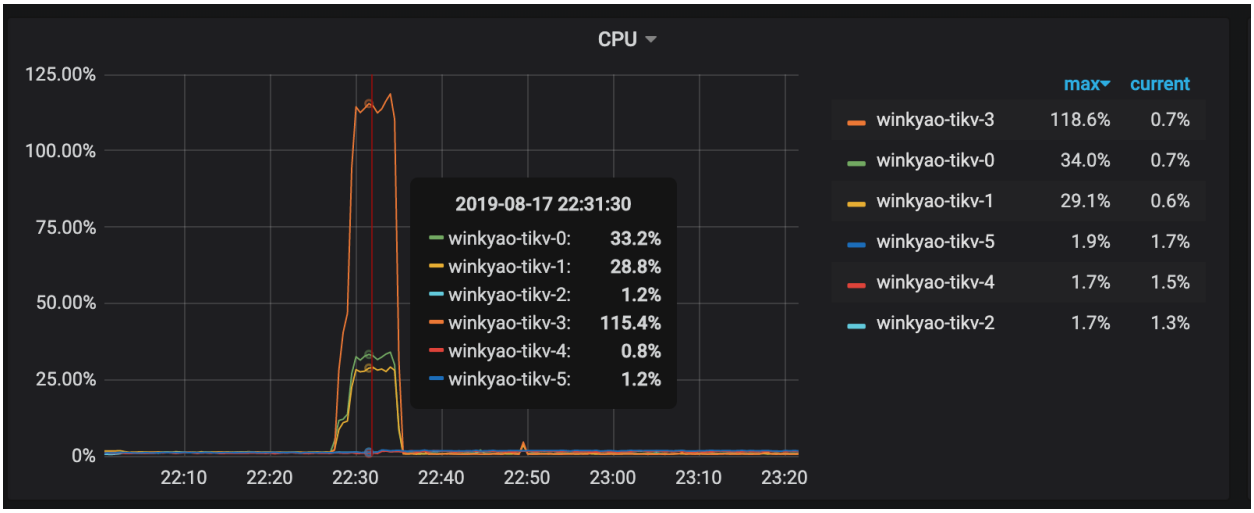

Figure 83: QPS2

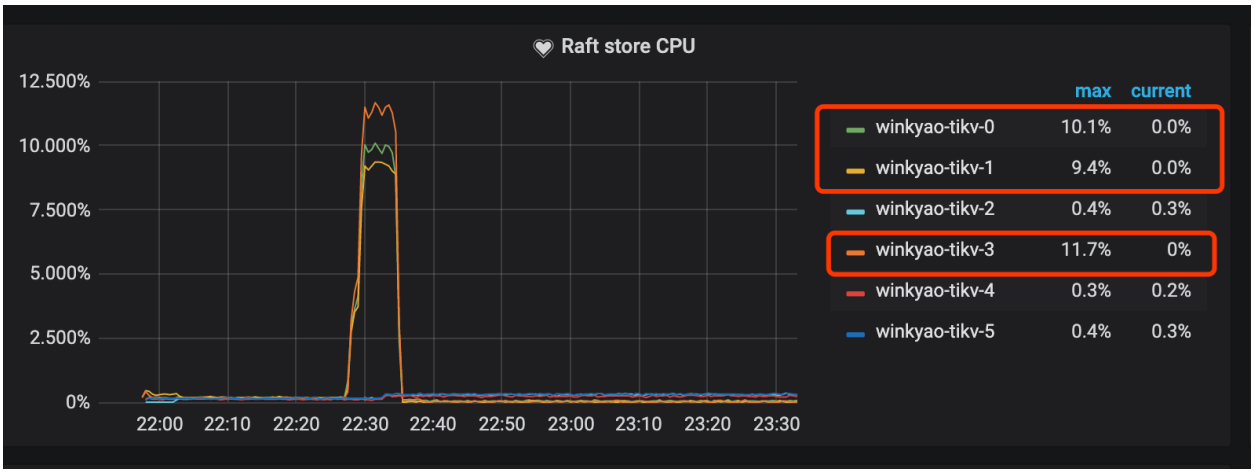

Figure 84: QPS3

Raft store CPU is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

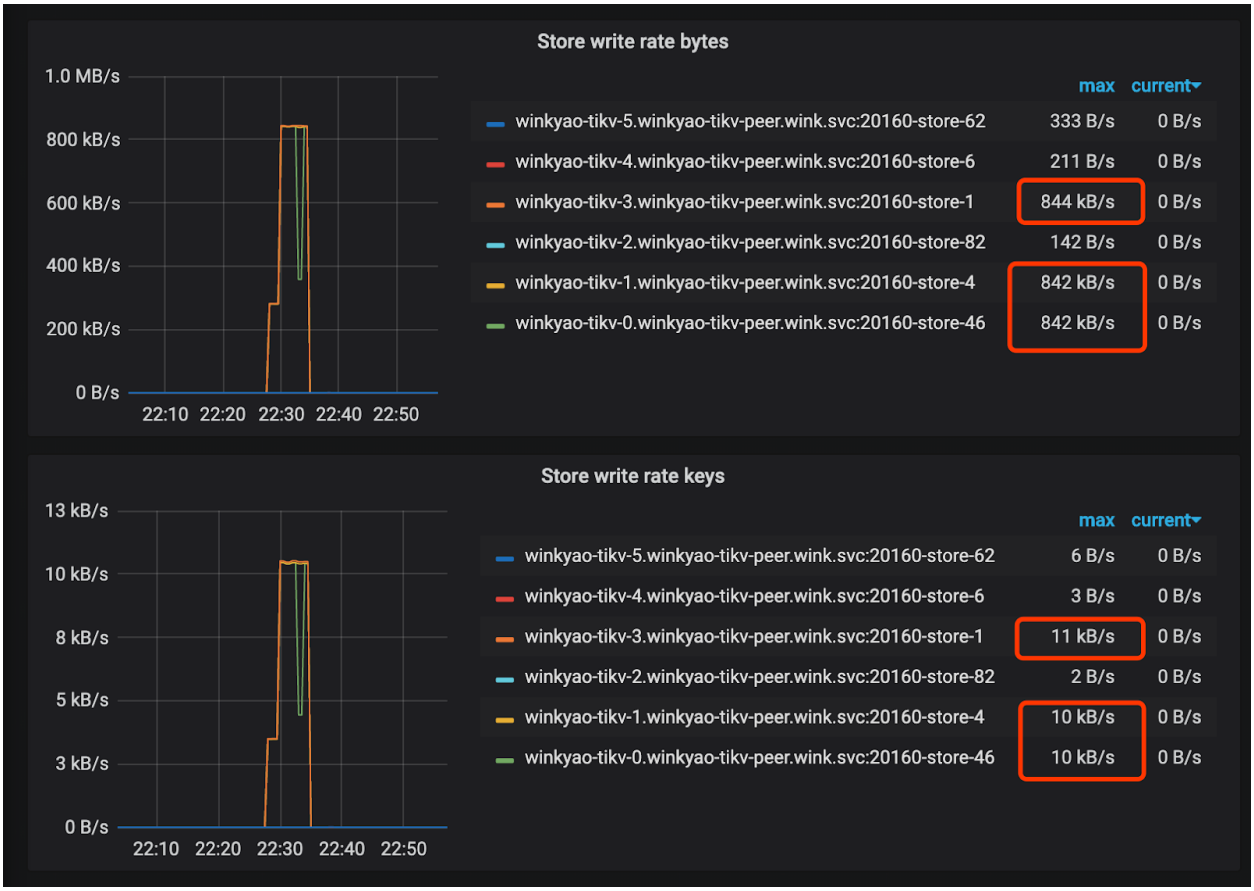

Figure 85: QPS4

10.4.4.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

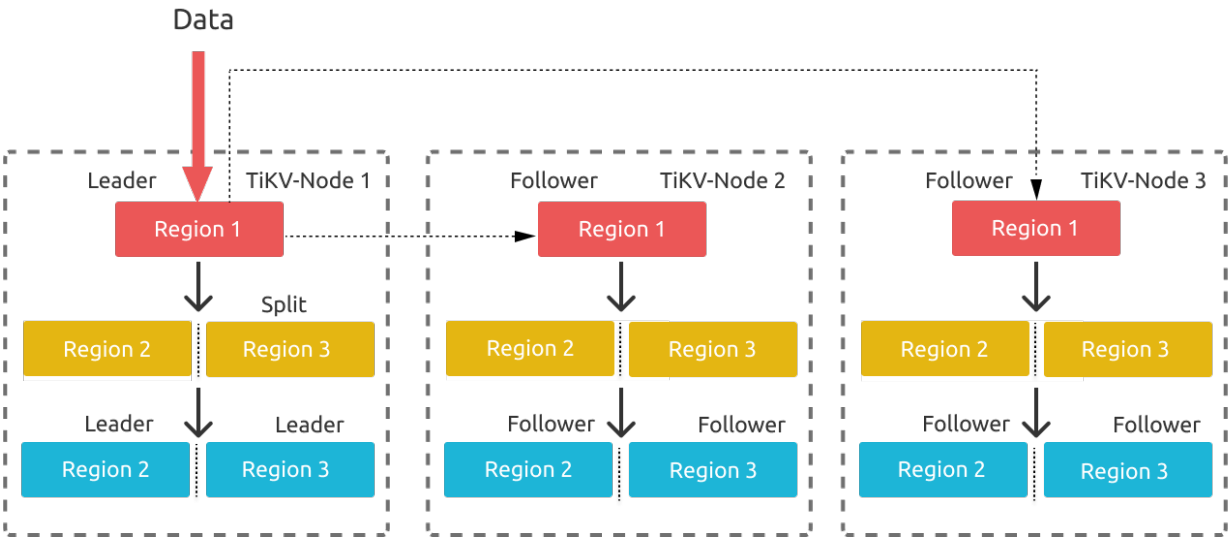

Figure 86: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

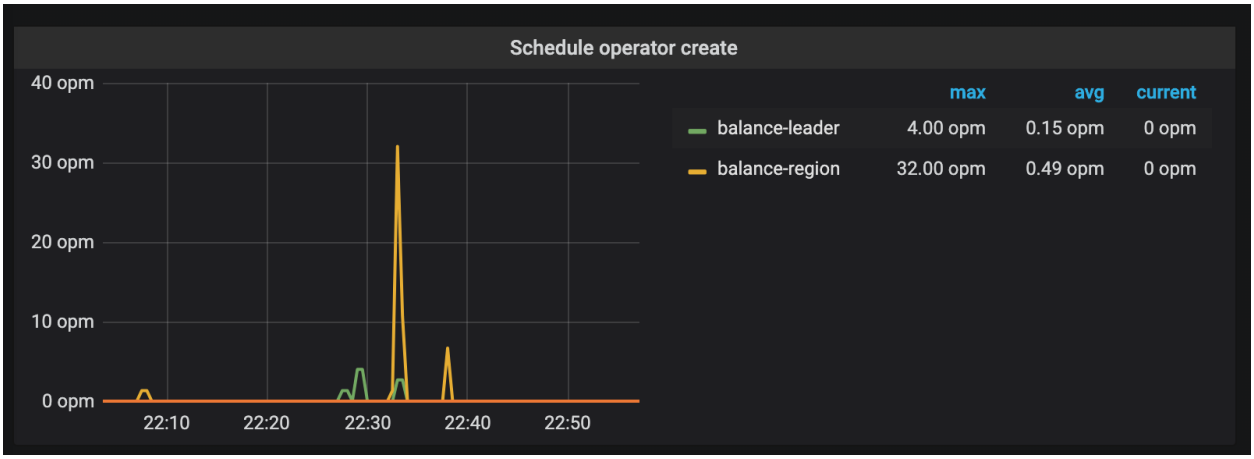

Figure 87: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

10.4.4.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called Split Region. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (
    ↪ upper_value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

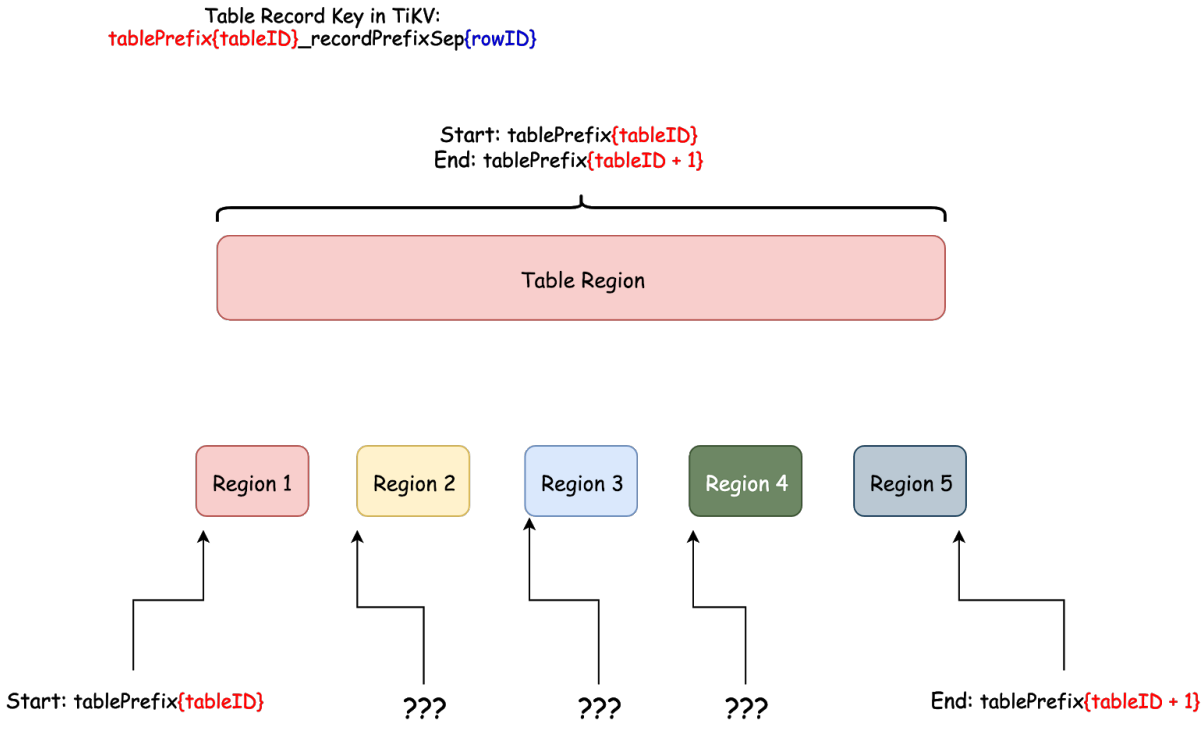

Figure 88: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all `0`, the scheduling is successful.

You can also check the Region distribution using the table-regions.py script. Currently, the Region distribution is relatively even:

```
[root@172.16.4.4 scripts]# python table-regions.py --host 172.16.4.3 --port
    ↪ 31453 test test_hotspot
[RECORD - test.test_hotspot] - Leaders Distribution:
  total leader count: 127
  store: 1, num_leaders: 21, percentage: 16.54%
  store: 4, num_leaders: 20, percentage: 15.75%
  store: 6, num_leaders: 21, percentage: 16.54%
  store: 46, num_leaders: 21, percentage: 16.54%
  store: 82, num_leaders: 23, percentage: 18.11%
  store: 62, num_leaders: 21, percentage: 16.54%
```

Then operate the write load again:

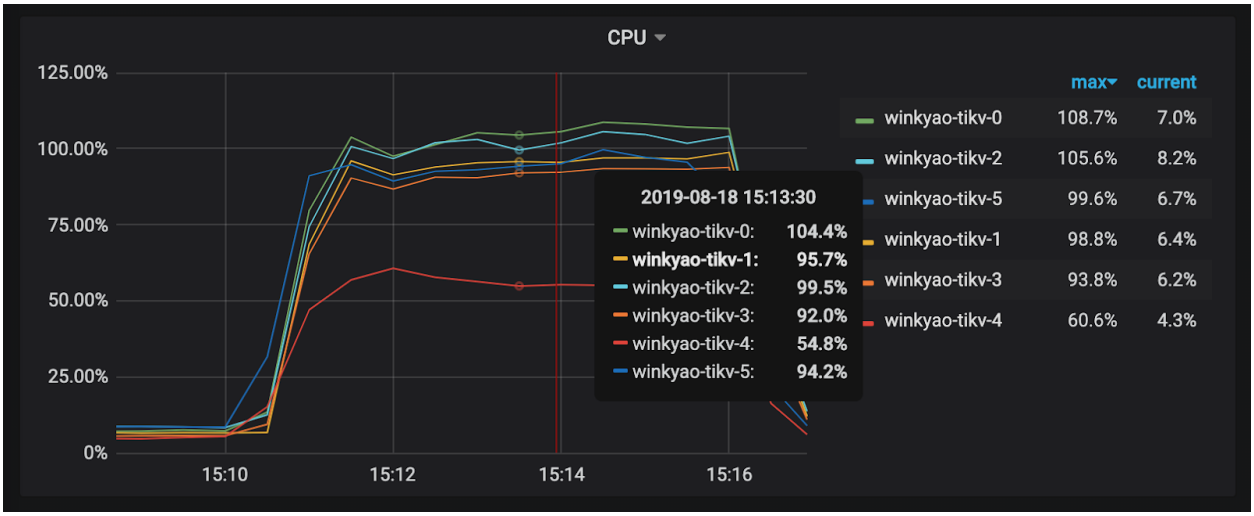

Figure 89: QPS6

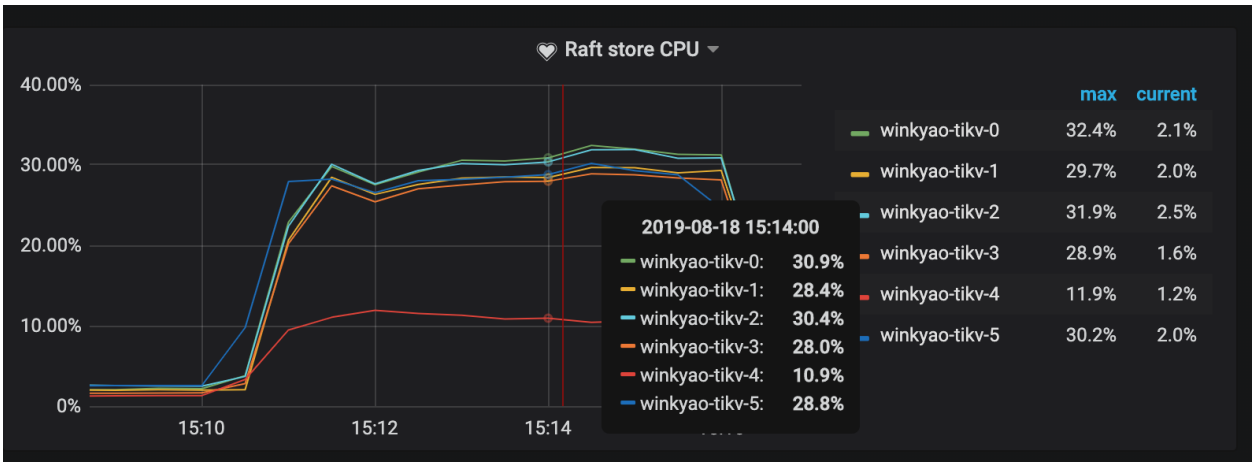

Figure 90: QPS7

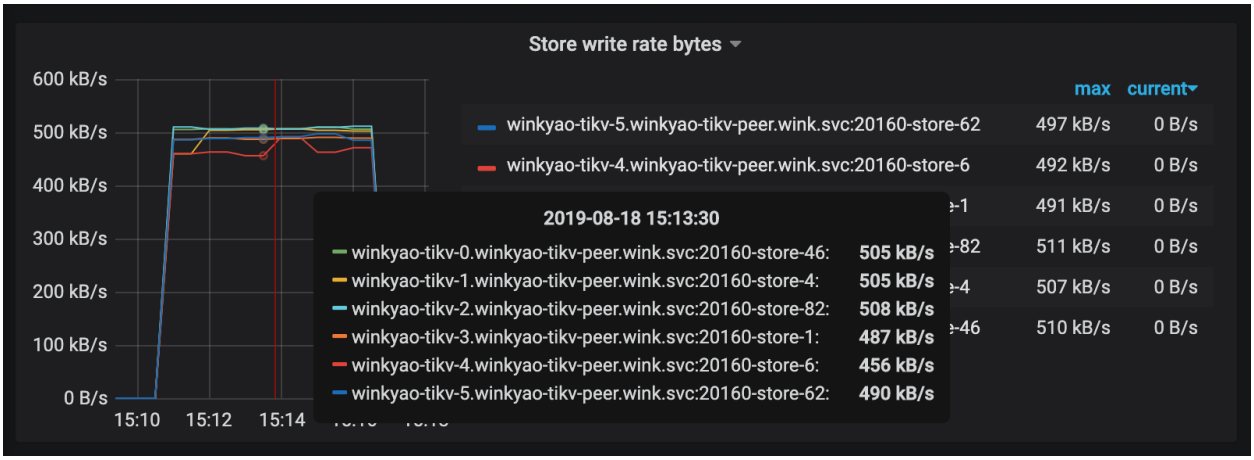

Figure 91: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to Split Region.

10.4.4.7 Complex hotspot problems

Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to `SHARD_ROW_ID_BITS` for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to Pre-split Regions.

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

> **Note:**
>
> The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 (16=2^4) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 (2^3) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

> **Note:**
>
> The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.
>
> This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to `1`, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

10.4.4.8 Parameter configuration

In v2.1, the latch mechanism is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

10.4.5 Best Practices for Monitoring TiDB Using Grafana

When you deploy a TiDB cluster using TiUP and have added Grafana and Prometheus in the topology configuration, a set of Grafana + Prometheus monitoring platform is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

10.4.5.1 Monitoring architecture

Prometheus is a time series database with a multi-dimensional data model and a flexible query language. Grafana is an open source monitoring system for analyzing and visualizing metrics.

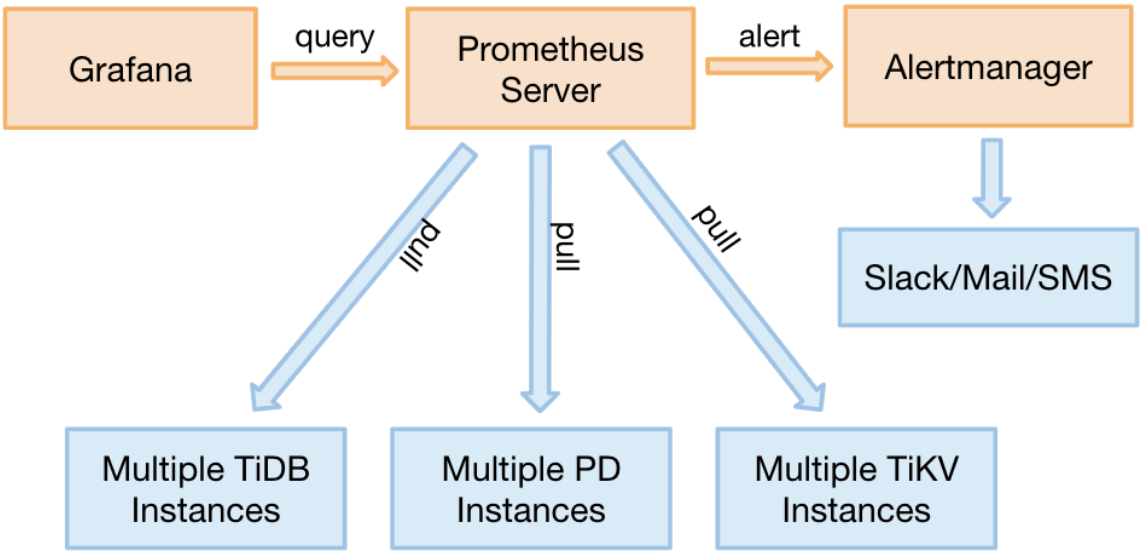

Figure 92: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

10.4.5.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20181
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
### Check the real-time QPS of different types of SQL statements. The
    ↪ numbers below are the cumulative values of counter type (scientific
    ↪ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

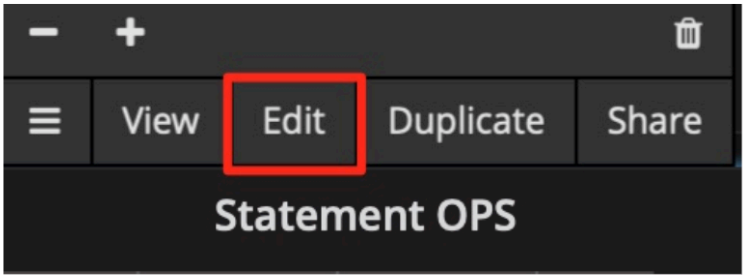

Figure 93: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_t` ↪ metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- `rate[1m]`: The growth rate in one minute. It can only be used for the data of counter type.
- `sum`: The sum of values.
- `by type`: The summed data is grouped by type in the original metric value.
- `Legend format`: The format of the metric name.
- `Resolution`: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 94: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to Prometheus official website.

10.4.5.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

10.4.5.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the source and display of monitoring data section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the `Legend format` field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (`instance`, `job` and `type`):

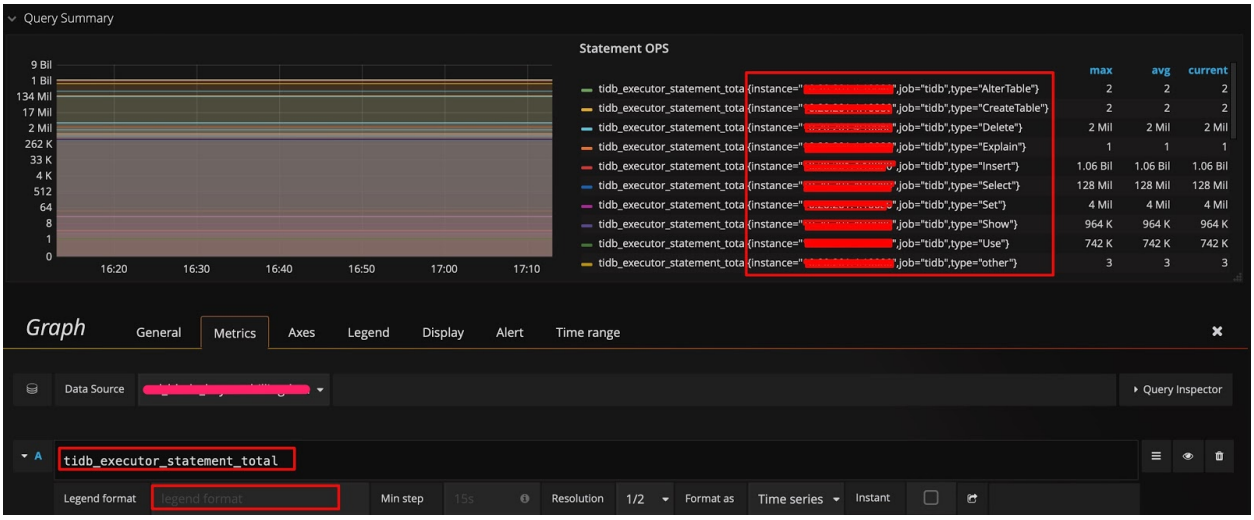

Figure 95: Edit query expression and check all dimensions

Then you can modify the query expression by adding the `instance` dimension after `type`, and adding `{{instance}}` to the `Legend format` field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

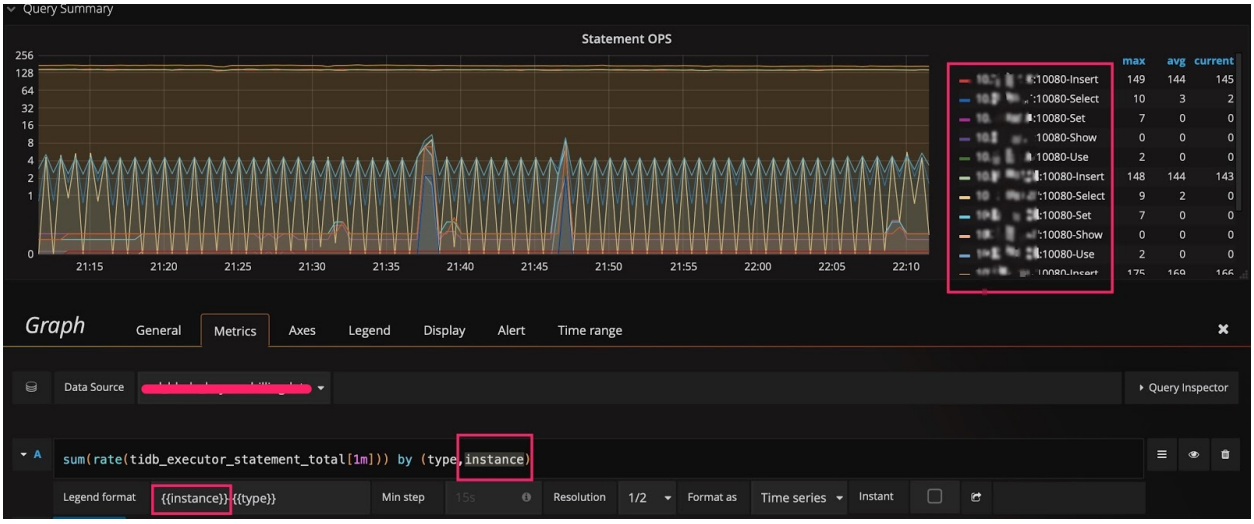

Figure 96: Add an instance dimension to the query expression

10.4.5.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale (log2n), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

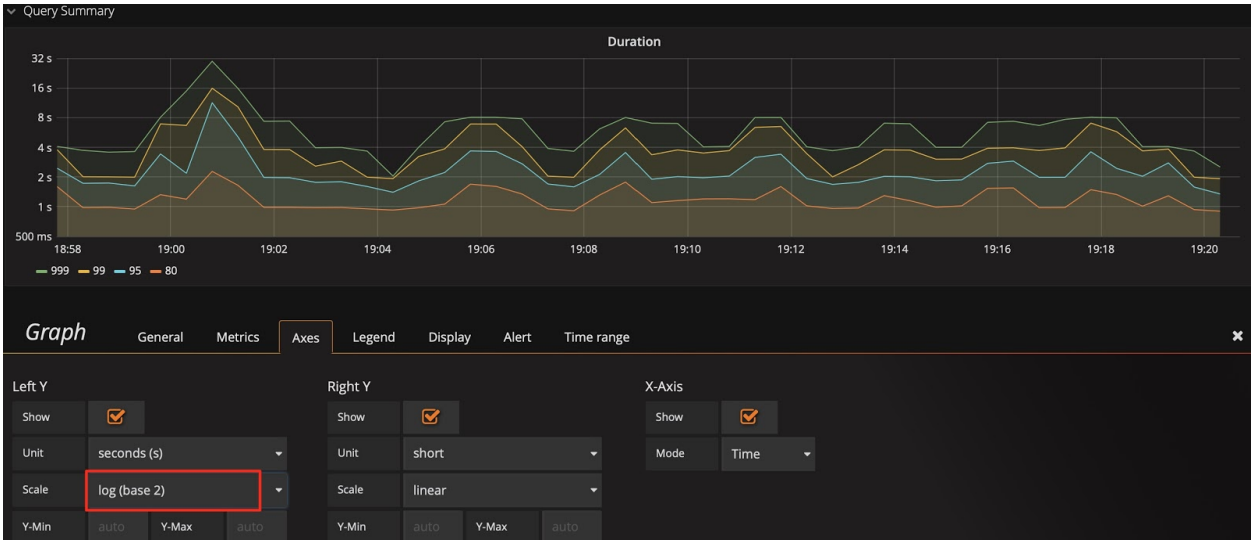

Figure 97: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

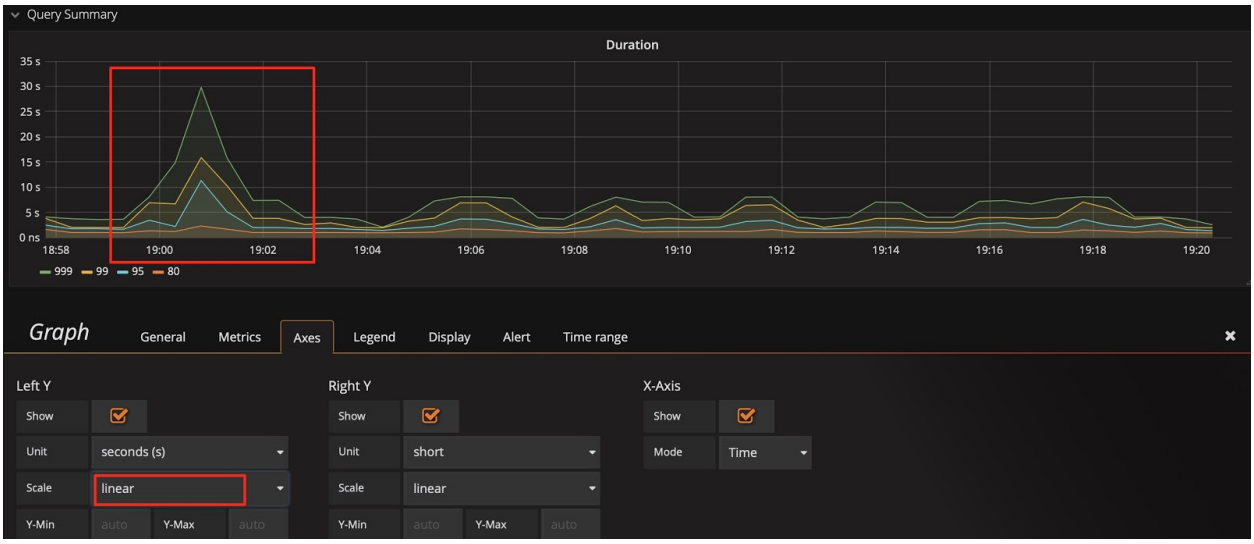

Figure 98: Switch to a linear scale

Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

10.4.5.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from `0` to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to `0`:

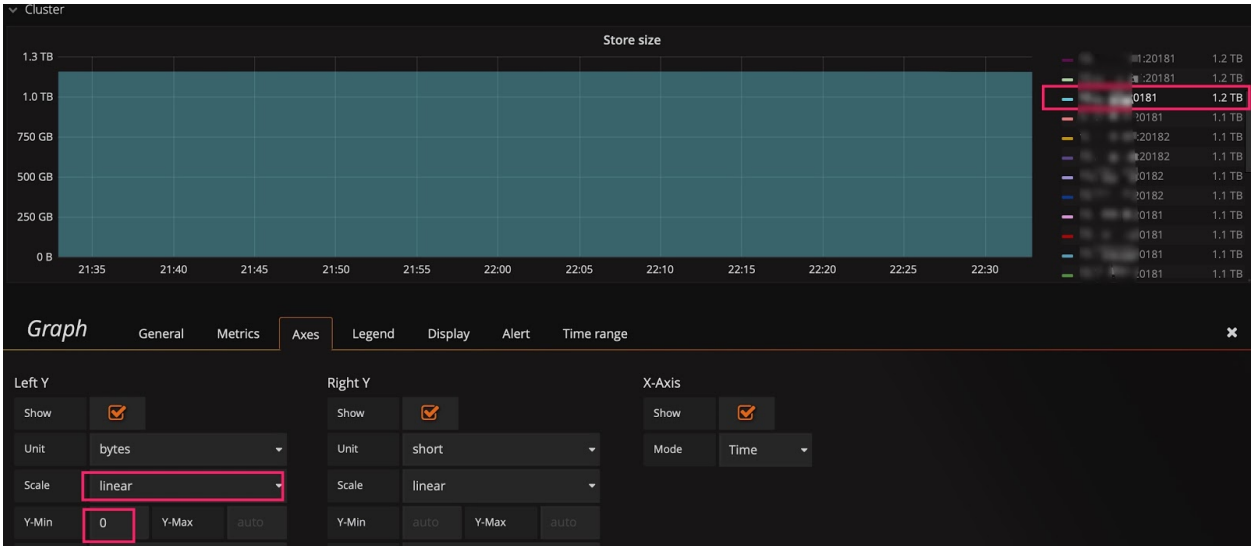

Figure 99: Baseline defaults to 0

Change the baseline to `auto`:

Figure 100: Change the baseline to auto

10.4.5.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

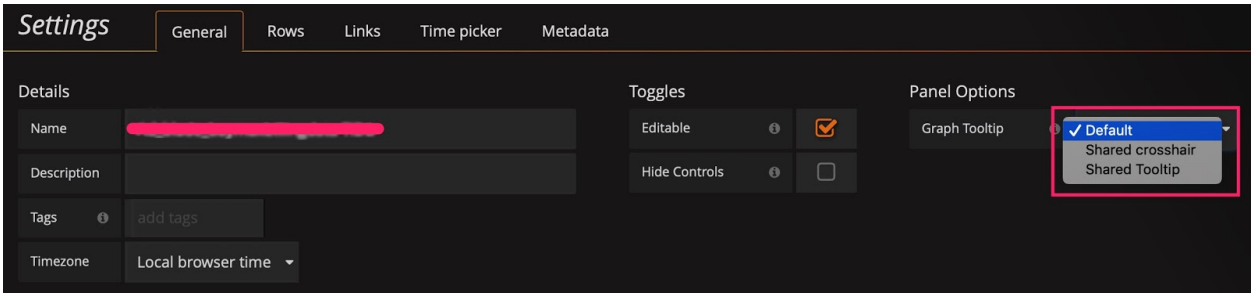

Figure 101: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

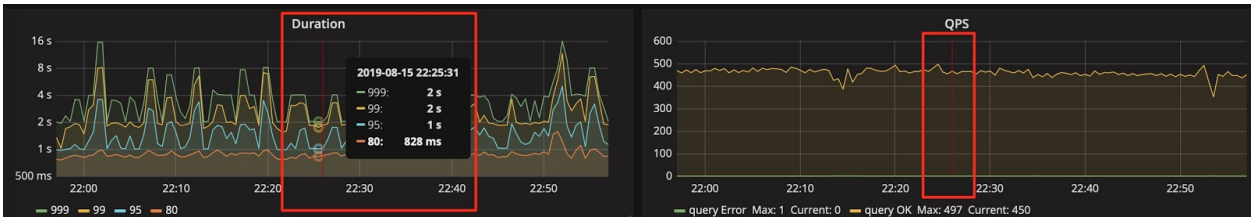

Figure 102: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

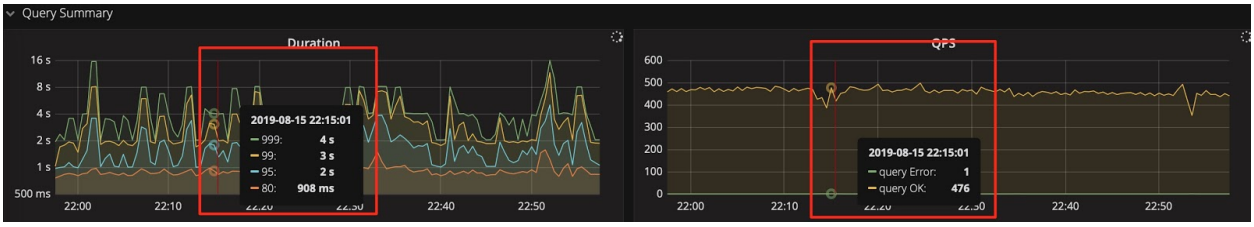

Figure 103: Set the graphic presentation tool to Shared Tooltip

10.4.5.3.5 Tip 5: Enter `IP address:port number` to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the `instance` field, you can manually enter `IP address:2379` to check the data of the leader.

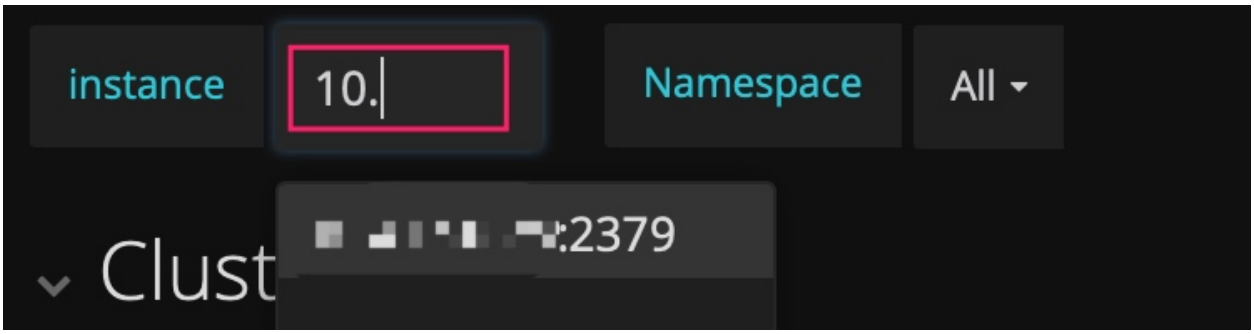

Figure 104: Check the metrics in history

10.4.5.3.6 Tip 6: Use the `Avg` function

Generally, only `Max` and `Current` functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the `Avg` function to the legend to check the overall trend for the duration of time.

Add summary functions such as the `Avg` function:

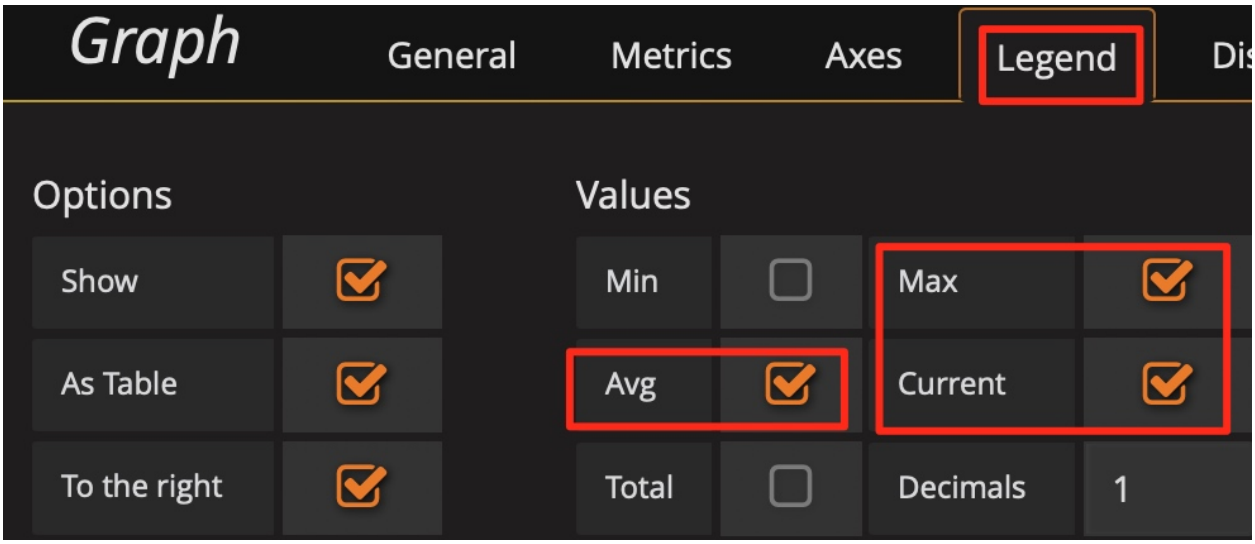

Figure 105: Add summary functions such as Avg

Then check the overall trend:

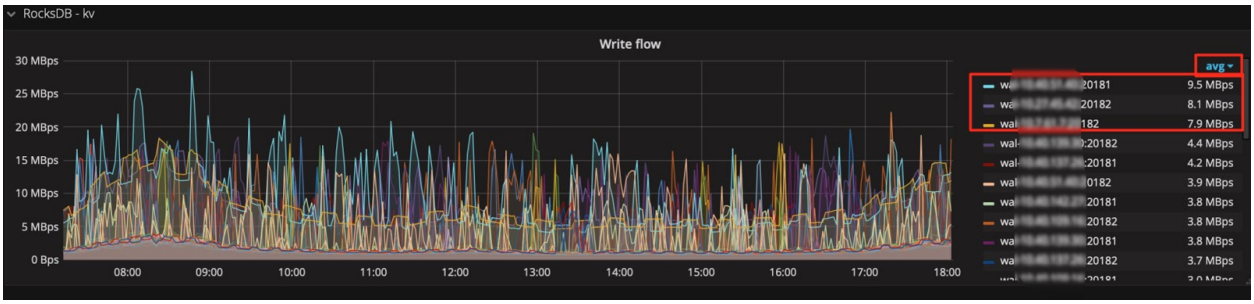

Figure 106: Add Avg function to check the overall trend

10.4.5.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

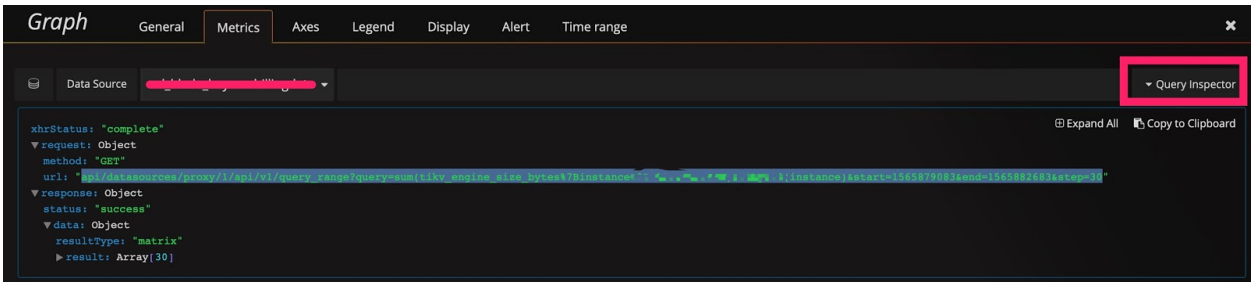

Figure 107: The API of Prometheus

```
curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
    ↪ /query_range?query=sum(tikv_engine_size_bytes%7
    ↪ Binstancexxxxxxxxx20181%22%7D)%20by%20(instance)&start=1565879269&end
    ↪ =1565882869&step=30' |python -m json.tool
```

```
{
    "data": {
```

```
        "result": [
            {
                "metric": {
                    "instance": "xxxxxxxxxx:20181"
                },
                "values": [
                    [
                        1565879269,
                        "1006046235280"
                    ],
                    [
                        1565879299,
                        "1006057877794"
                    ],
                    [
                        1565879329,
                        "1006021550039"
                    ],
                    [
                        1565879359,
                        "1006021550039"
                    ],
                    [
                        1565882869,
                        "1006132630123"
                    ]
                ]
            }
        ],
        "resultType": "matrix"
    },
    "status": "success"
}
```

10.4.5.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

10.4.6 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

> **Note:**
>
> This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

10.4.6.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

10.4.6.1.1 Scheduling process

The scheduling process generally has three steps:

1. Collect information

   Each TiKV node periodically reports two types of heartbeats to PD:

   - `StoreHeartbeat`: Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
   - `RegionHeartbeat`: Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

   PD collects and restores this information for scheduling decisions.

2. Generate operators

   Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

3. Execute operators

   To execute the operators, the general procedure is:

   1. The generated operator first joins a queue managed by `OperatorController`.
   2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
   3. The operator is marked as "finish" or "timeout" and removed from the queue.

10.4.6.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively ("1" by default for both). For example, when the `leader-weight` of a store is set to "2", the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to "0.5", the number of leaders on the node is about half as many as that of other nodes.

10.4.6.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

10.4.6.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient, and so on.

10.4.6.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as "offline" using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker` ↪ finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

10.4.6.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (`1h` by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size` (20 MiB by default)
- The number of keys in this Region is smaller than the value of `max-merge-region-keys` (200,000 by default).

10.4.6.2 Query scheduling status

You can check the status of scheduling system through metrics, pd-ctl and logs. This section briefly introduces the methods of metrics and pd-ctl. Refer to PD Monitoring Metrics and PD Control for details.

10.4.6.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using pd-ctl with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

10.4.6.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of pd-ctl to query balance status of each store.

10.4.6.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using pd-ctl with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

10.4.6.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using pd-ctl with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

10.4.6.3 Control scheduling strategy

You can use pd-ctl to adjust the scheduling strategy from the following three aspects. Refer to PD Control for more details.

10.4.6.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through pd-ctl. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

10.4.6.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through pd-ctl. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

10.4.6.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in pd-ctl, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

10.4.6.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

10.4.6.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on hot regions scheduling.
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a region merge scheduling.

- Hardware and software environment varies among stores. You can adjust the values of `leader-weight` and `region-weight` accordingly to control the distribution of leader/region.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
  - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
  - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
  - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, etc., which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
  - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit it set to "0".
  - Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
  - Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

10.4.6.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger value.s Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in Leaders/regions are not evenly distributed.
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to "0".
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

10.4.6.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to Leaders/regions are not evenly distributed for troubleshooting.

10.4.6.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

  Solution: adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

  Solutions: Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to TiDB HTTP API for more details.

10.4.6.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to `10ms`. This makes region scanning faster at the cost of more CPU consumption.
- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:
  - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
  - PD
    * Set `key-type` to `"txn"` or `"raw"`. You can modify the parameter dynamically.
    * Or keep `key-type` as `table` and set `enable-cross-table-merge` to `true`. You can modify the parameter dynamically.

> **Note:**
> After placement rules are enabled, properly switch the value of `key-type` between `txn` and `raw` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

10.4.6.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

10.4.7 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of or even tens of millions of Regions are created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

10.4.7.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

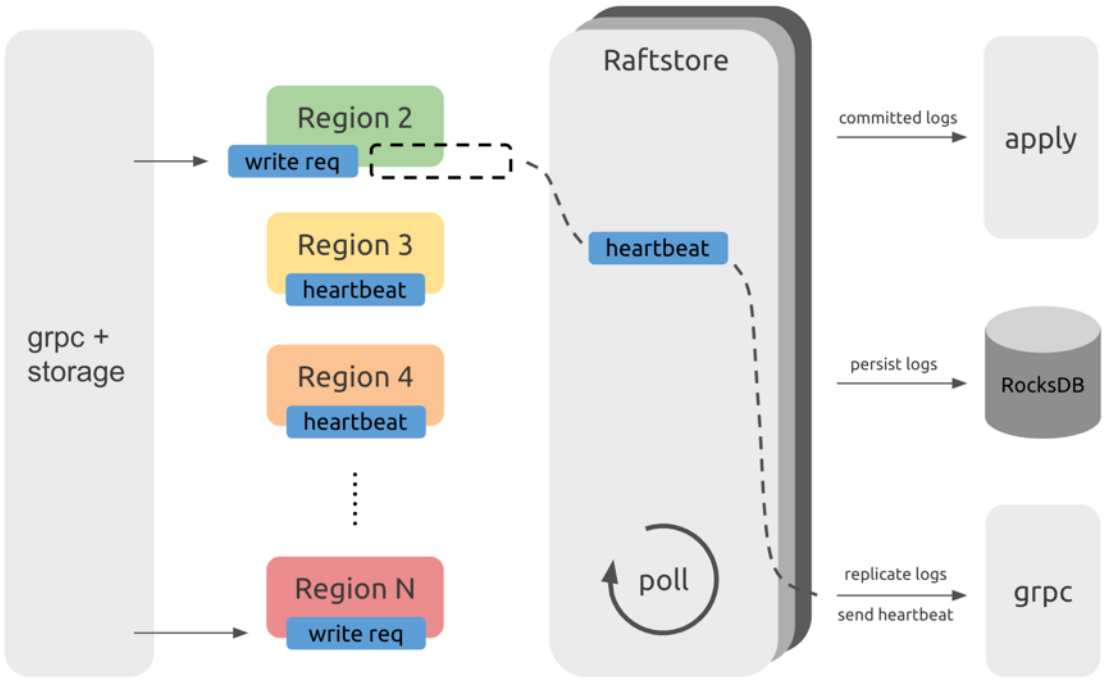

Figure 108: Raftstore Workflow

> **Note:**
>
> This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

10.4.7.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the

Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, `propose wait duration` can be as high as hundreds of milliseconds.

Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

10.4.7.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- `Raft store CPU` in the **Thread-CPU** panel

  Reference value: lower than `raftstore.store-pool-size * 85%`.

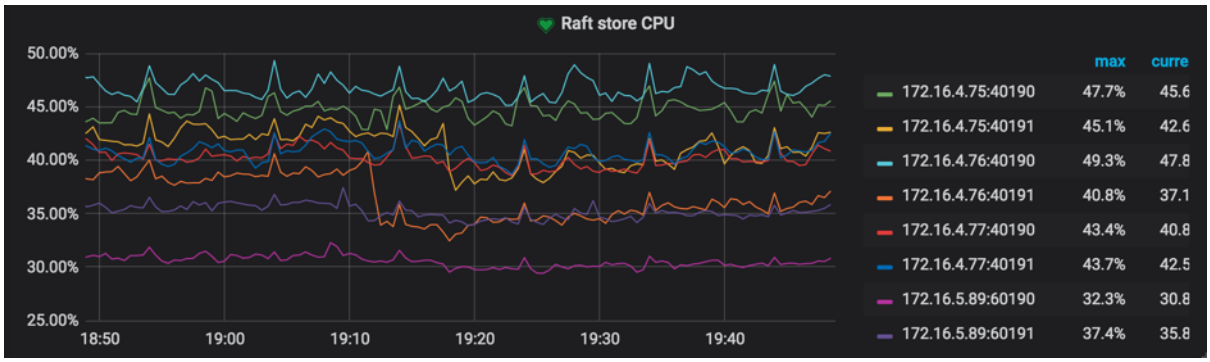

Figure 109: Check Raftstore CPU

- `Propose wait duration` in the **Raft Propose** panel

  `Propose wait duration` is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

  Reference value: lower than 50~100 ms according to the cluster size

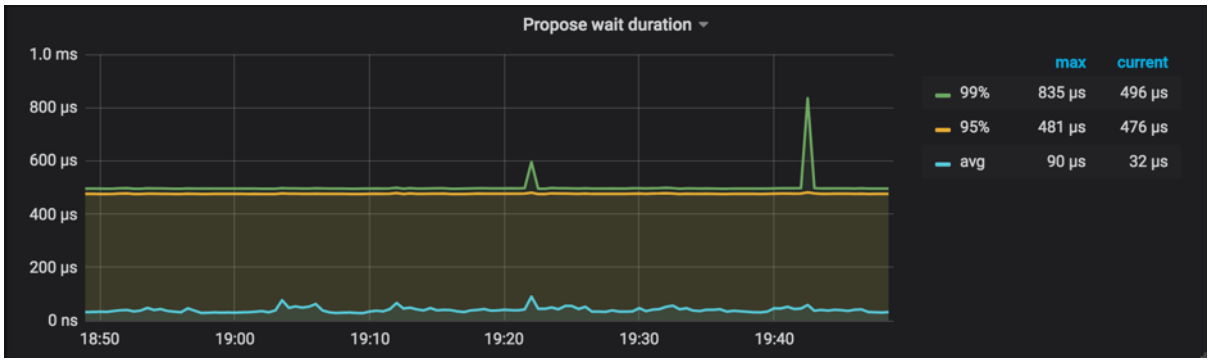

Figure 110: Check Propose wait duration

10.4.7.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

10.4.7.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to `2` in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

10.4.7.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore doesn't send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in TiKV master. You can configure this feature according to your needs. For details, refer to Configure Hibernate Region.

10.4.7.3.3 Method 3: Enable `Region Merge`

Note:

`Region Merge` is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling `Region Merge`. Contrary to `Region Split`, `Region Merge` is the process of merging adjacent small Regions through scheduling. After dropping data or executing the `Drop Table` or `Truncate Table` statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable `Region Merge` by configuring the following parameters:

```
>> pd-ctl config set max-merge-region-size 20
>> pd-ctl config set max-merge-region-keys 200000
>> pd-ctl config set merge-schedule-limit 8
```

Refer to Region Merge and the following three configuration parameters in the PD configuration file for more details:

- `max-merge-region-size`
- `max-merge-region-keys`
- `merge-schedule-limit`

The default configuration of the `Region Merge` parameters is rather conservative. You can speed up the `Region Merge` process by referring to the method provided in PD Scheduling Best Practices.

10.4.7.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

10.4.7.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between `election timeout` and `heartbeat`. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
    ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

10.4.7.4 Other problems and solutions

This section describes some other problems and solutions.

10.4.7.4.1 Switching PD Leader is slow

PD needs to persist Region Meta information on etcd to ensure that PD can quickly resume to provide Region routing services after switching the PD Leader node. As the number of Regions increases, the performance problem of etcd appears, making it slower for PD to get Region Meta information from etcd when PD is switching the Leader. With millions of Regions, it might take more than ten seconds or even tens of seconds to get the meta information from etcd.

To address this problem, `use-region-storage` is enabled by default in PD since TiDB v3.0. With this feature enabled, PD stores Region Meta information on local LevelDB and synchronizes the information among PD nodes through other mechanisms.

10.4.7.4.2 PD routing information is not updated in time

In TiKV, pd-worker regularly reports Region Meta information to PD. When TiKV is restarted or switches the Region leader, PD needs to recalculate Region's `approximate ↪ size / keys` through statistics. Therefore, with a large number of Regions, the single-threaded pd-worker might become the bottleneck, causing tasks to be piled up and not processed in time. In this situation, PD cannot obtain certain Region Meta information in time so that the routing information is not updated in time. This problem does not affect the actual reads and writes, but might cause inaccurate PD scheduling and require several round trips when TiDB updates Region cache.

You can check **Worker pending tasks** under **Task** in the **TiKV Grafana** panel to determine whether pd-worker has tasks piled up. Generally, `pending tasks` should be kept at a relatively low value.

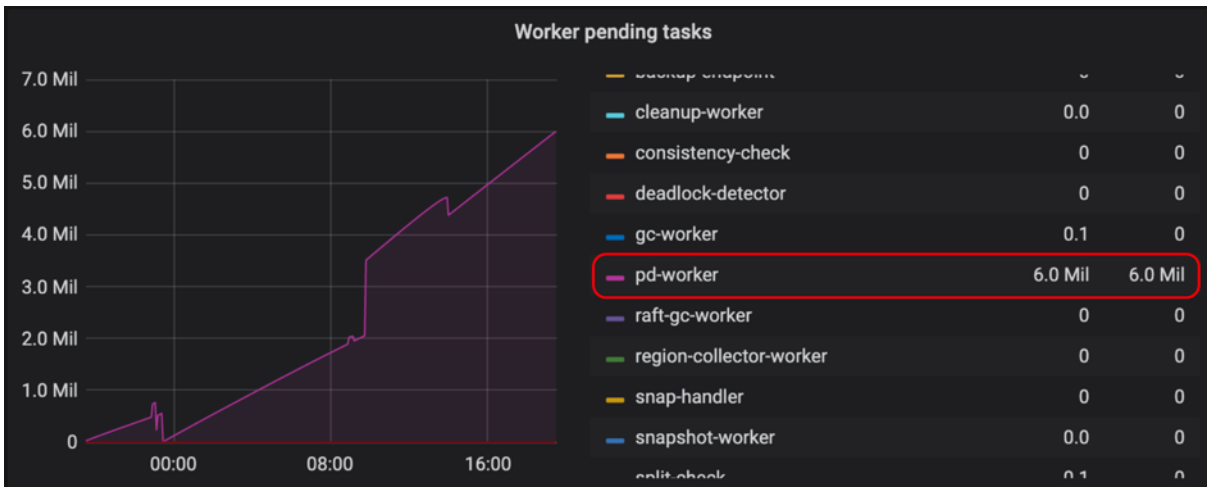

Figure 111: Check pd-worker

pd-worker has been optimized for better performance since v3.0.5. If you encounter a similar problem, it is recommended to upgrade to the latest version.

10.4.7.4.3 Prometheus is slow to query metrics

In a large-scale cluster, as the number of TiKV instances increases, Prometheus has greater pressure to query metrics, making it slower for Grafana to display these metrics. To ease this problem, metrics pre-calculation is configured since v3.0.

10.4.8 Best Practices for Three-Node Hybrid Deployment

For a TiDB cluster, if you have no requirements on high performance but need to control the cost, you can deploy the TiDB, TiKV, and PD components on three machines in a hybrid way.

This document offers an example of three-node hybrid deployment and a TPC-C test against the deployed cluster. Based on this example, this document offers best practices for the deployment scenario and its parameter adjustment.

10.4.8.1 Prerequisites for deployment and the test method

In this example, three physical machines are used for deployment, each with 16 CPU cores and 32 GB of memory. On each machine (node), one TiDB instance, one TiKV instance, and one PD instance are deployed in a hybrid way.

Because PD and TiKV both store information on the disk, the read and write latency of disk directly affects the latency of the PD and TiKV services. To avoid the situation that

PD and TiKV compete for disk resources and affect each other, it is recommended to use different disks for PD and TiKV.

In this example, the TPC-C 5000 Warehouse data is used in TiUP bench and the test lasts 12 hours with the `terminals` parameter set to `128` (concurrency). Close attention is paid to metrics related to performance stability of the cluster.

The image below shows the QPS monitor of the cluster within 12 hours with the default parameter configuration. From the image, you can see an obvious performance jitter.

Figure 112: QPS with default config

After the parameter adjustment, the performance is improved.

Figure 113: QPS with modified config

10.4.8.2 Parameter adjustment

Performance jitter occurs in the image above, because the default thread pool configuration and the resource allocation to background tasks are for machines with sufficient resources. In the hybrid deployment scenario, the resources are shared among multiple components, so you need to limit the resource consumption via configuration parameters.

The final cluster configuration for this test is as follows:

```
tikv:
    readpool.unified.max-thread-count: 6
    server.grpc-concurrency: 2
    storage.scheduler-worker-pool-size: 2
    gc.max-write-bytes-per-sec: 300K
    rocksdb.max-background-jobs: 3
```

```
    rocksdb.max-sub-compactions: 1
    rocksdb.rate-bytes-per-sec:  “200M”

  tidb:
    performance.committer-concurrency: 4
    performance.max-procs: 8
```

The following sections introduce the meanings and the adjustment methods of these parameters.

10.4.8.2.1 Configuration of TiKV thread pool size

This section offers best practices for adjusting parameters that relate to the resource allocation of thread pools for foreground applications. Reducing these thread pool sizes will compromise performance, but in the hybrid deployment scenario with limited resources, the cluster itself is hard to achieve high performance. In this scenario, the overall stability of the cluster is preferred over performance.

If you conduct an actual load test, you can first use the default configuration and observe the actual resource usage of each thread pool. Then you can adjust the corresponding configuration items and reduce the sizes of the thread pools that have lower usage.

`readpool.unified.max-thread-count`

The default value of this parameter is 80% of the number of machine threads. In a hybrid deployment scenario, you need to manually calculate and specify this value. You can first set it to 80% of the expected number of CPU threads used by TiKV.

`server.grpc-concurrency`

This parameter defaults to `4`. Because in the existing deployment plan, the CPU resources are limited and the actual requests are few. You can observe the monitoring panel, lower the value of this parameter, and keep the usage rate below 80%.

In this test, the value of this parameter is set to `2`. Observe the **gRPC poll CPU** panel and you can see that the usage rate is just around 80%.

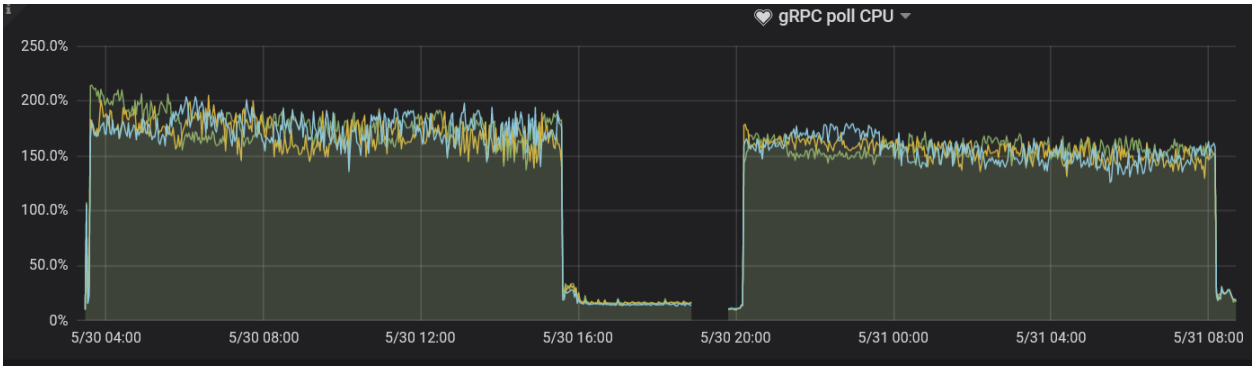

Figure 114: gRPC Pool CPU

`storage.scheduler-worker-pool-size`

When TiKV detects that the CPU core number of the machine is greater than or equal to `16`, this parameter value defaults to `8`. When the CPU core number is smaller than `16`, the parameter value defaults to `4`. This parameter is used when TiKV converts complex transaction requests to simple key-value reads or writes, but the scheduler thread pool does not performs any writes.

Ideally, the usage rate of the scheduler thread pool is kept between 50% and 75%. Similar to the gRPC thread pool, the `storage.scheduler-worker-pool-size` parameter defaults to a larger value during the hybrid deployment, which makes resource usage insufficient. In this test, the value of this parameter is set to `2`, which is in line with the best practices, a conclusion drawn by observing the corresponding metrics in the **Scheduler worker CPU** panel.

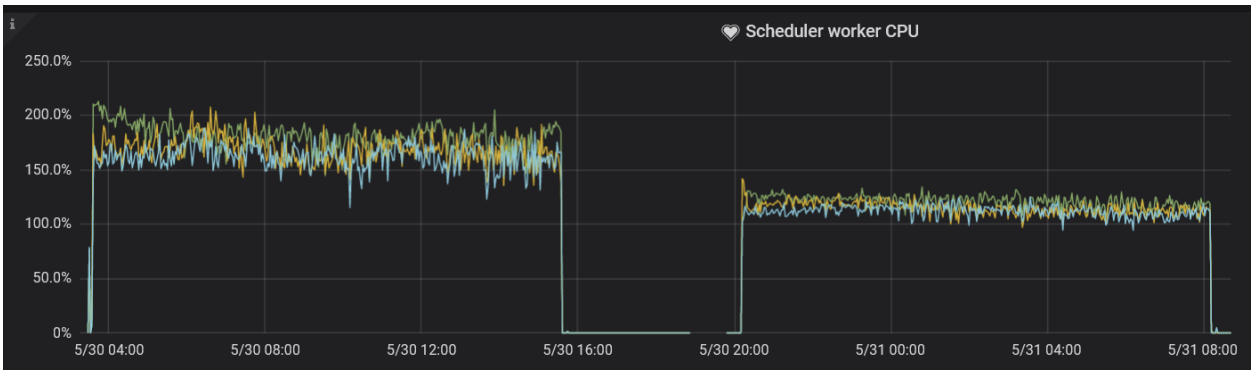

Figure 115: Scheduler Worker CPU

10.4.8.2.2 Resource configuration for TiKV background tasks

In addition to foreground tasks, TiKV regularly sorts data and cleans outdated data in background tasks. The default configuration allocates sufficient resources to these tasks for the scenario of high-traffic writes.

However, in the hybrid deployment scenario, this default configuration is not in line with the best practices. You need to limit the resource usage of background tasks by adjusting the following parameters.

`rocksdb.max-background-jobs` and `rocksdb.max-sub-compactions`

The RocksDB thread pool is used to perform compaction and flush jobs. The default value of `rocksdb.max-background-jobs` is `8`, which obviously exceeds the resource that is in need. Therefore, the value should be adjusted to limit the resource usage.

`rocksdb.max-sub-compactions` indicates the number of concurrent sub-tasks allowed for a single compaction job, which defaults to `3`. You can lower this value when the write traffic is not high.

In the test, the `rocksdb.max-background-jobs` value is set to `3` and the `rocksdb.max-sub-compactions` value is set to `1`. No write stall occurs during the 12-hour test with the TPC-C load. When optimizing the two parameter values according to the actual load, you can lower the values gradually based on monitoring metrics:

- If write stall occurs, increase the value of `rocksdb.max-background-jobs`.
- If the write stall persists, set the value of `rocksdb.max-sub-compactions` to `2` or `3`.

`rocksdb.rate-bytes-per-sec`

This parameter is used to limit the disk traffic for the background compaction jobs. The default configuration has no limit for this parameter. To avoid the situation that compaction jobs occupy the resources of foreground services, you can adjust this parameter value according to the sequential read and write speed of the disk, which reserves enough disk bandwidth for foreground services.

The method of optimizing the RocksDB thread pool is similar to that of optimizing the compaction thread pool. You can determine whether the value you have adjusted is suitable according to whether write stall occurs.

`gc.max_write_bytes_per_sec`

Because TiDB uses the multi-version concurrency control (MVCC) model, TiKV periodically cleans old version data in the background. When the available resources are limited, this operation causes periodical performance jitter. You can use the `gc.max_write_bytes_per_sec` parameter to limit the resource usage of such an operation.

Figure 116: GC Impact

In addition to setting this parameter value in the configuration file, you can also dynamically adjust this value in tikv-ctl.

```
tiup ctl:<cluster-version> tikv --host=${ip:port} modify-tikv-config -n gc.
    ↪ max_write_bytes_per_sec -v ${limit}
```

> **Note:**
>
> In application scenarios with frequent updates, limiting GC traffic might cause the MVCC versions to pile up and affect read performance. Currently, to achieve a balance between performance jitter and performance decrease, you might need to try multiple times to adjust the value of this parameter.

10.4.8.2.3 TiDB parameter adjustment

Generally, you can adjust the TiDB parameters of execution operators using system variables such as `tidb_hash_join_concurrency` and `tidb_index_lookup_join_concurrency`.

In this test, these parameters are not adjusted. In the load test of your actual application, if the execution operators consume an excessive amount of CPU resources, you can limit the resource usage of specific operators according to your application scenario. For more details, see TiDB system variables.

`performance.max-procs`

This parameter is used to control how many CPU cores an entire Go process can use. By default, the value is equal to the number of CPU cores of the current machine or cgroups.

When Go is running, a proportion of threads is used for background tasks such as GC. If you do not limit the value of the `performance.max-procs` parameter, these background tasks will consume too much CPU.

10.4.9 Local Read under Three Data Centers Deployment

In the model of three data centers, a Region has three replicas which are isolated in each data center. However, due to the requirement of strongly consistent read, TiDB must access the Leader replica of the corresponding data for every query. If the query is generated in a data center different from that of the Leader replica, TiDB needs to read data from another data center, thus causing the access latency to increase.

This document describes how to use the Stale Read feature to avoid cross-center access and reduce the access latency at the expense of real-time data availability.

10.4.9.1 Deploy a TiDB cluster of three data centers

For the three-data-center deployment method, refer to Multiple Data Centers in One City Deployment.

Note that if both the TiKV and TiDB nodes have the configuration item `labels` configured, the TiKV and TiDB nodes in the same data center must have the same value for the `zone` label. For example, if a TiKV node and a TiDB node are both in the data center `dc-1`, then the two nodes need to be configured with the following label:

```
[labels]
zone=dc-1
```

10.4.9.2 Perform local read using Stale Read

Stale Read is a mechanism that TiDB provides for the users to read historical data. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes. When using Stale Read in some scenarios of geo-distributed deployment, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query process.

When TiDB receives a Stale Read query, if the `zone` label of that TiDB node is configured, then TiDB sends the request to the TiKV node with the same `zone` label where the corresponding data replica resides.

For how to perform Stale Read, see Perform Stale Read using the `AS OF TIMESTAMP` clause.

10.5 Placement Rules

> **Warning:**
>
> In the scenario of using TiFlash, the Placement Rules feature has been extensively tested and can be used in the production environment. Except for the scenario where TiFlash is used, using Placement Rules alone has not been extensively tested, so it is not recommended to enable this feature separately in the production environment.

Placement Rules is an experimental feature of the Placement Driver (PD) introduced in v4.0. It is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the

attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader.

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules.

10.5.1 Rule system

The configuration of the whole rule system consists of multiple rules. Each rule can specify attributes such as the number of replicas, the Raft role, the placement location, and the key range in which this rule takes effect. When PD is performing schedule, it first finds the rule corresponding to the Region in the rule system according to the key range of the Region, and then generates the corresponding schedule to make the distribution of the Region replica comply with the rule.

The key ranges of multiple rules can have overlapping parts, which means that a Region can match multiple rules. In this case, PD decides whether the rules overwrite each other or take effect at the same time according to the attributes of rules. If multiple rules take effect at the same time, PD will generate schedules in sequence according to the stacking order of the rules for rule matching.

In addition, to meet the requirement that rules from different sources are isolated from each other, these rules can be organized in a more flexible way. Therefore, the concept of "Group" is introduced. Generally, users can place rules in different groups according to different sources.

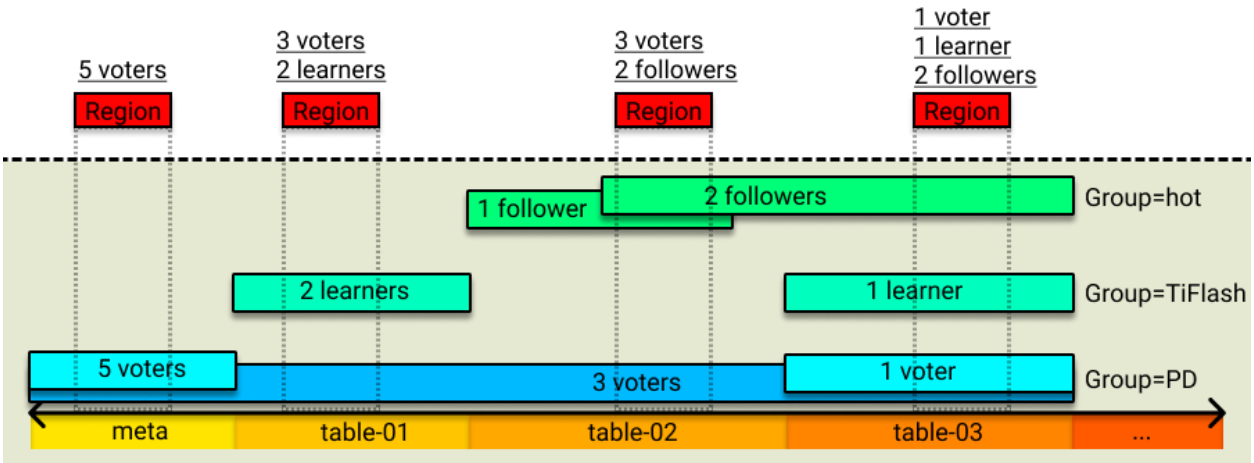

Figure 117: Placement rules overview

10.5.1.1 Rule fields

The following table shows the meaning of each field in a rule:

Field name	Type and restriction	Description
GroupID	string	The group ID that marks the source of the rule.
ID	string	The unique ID of a rule in a group.
Index	int	The stacking sequence of rules in a group.
Override	true/false	Whether to overwrite rules with smaller index (in a g
StartKey	string, in hexadecimal form	Applies to the starting key of a range.
EndKey	string, in hexadecimal form	Applies to the ending key of a range.
Role	string	Replica roles, including voter/leader/follower/learner.
Count	int, positive integer	The number of replicas.
LabelConstraint	[]Constraint	Filters nodes based on the label.
LocationLabels	[]string	Used for physical isolation.
IsolationLevel	string	Used to set the minimum physical isolation level

`LabelConstraint` is similar to the function in Kubernetes that filters labels based on these four primitives: `in`, `notIn`, `exists`, and `notExists`. The meanings of these four primitives are as follows:

- `in`: the label value of the given key is included in the given list.
- `notIn`: the label value of the given key is not included in the given list.
- `exists`: includes the given label key.
- `notExists`: does not include the given label key.

The meaning and function of `LocationLabels` are the same with those earlier than v4.0. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology: the cluster has multiple zones (Availability Zones), each zone has multiple racks, and each rack has multiple hosts. When performing schedule, PD first tries to place the Region's peers in different zones. If this try fails (such as there are three replicas but only two zones in total), PD guarantees to place these replicas in different racks. If the number of racks is not enough to guarantee isolation, then PD tries the host-level isolation.

The meaning and function of `IsolationLevel` is elaborated in Cluster topology configuration. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology with `LocationLabels` and set `IsolationLevel` to `zone`, then PD ensures that all peers of each Region are placed in different zones during the scheduling. If the minimum isolation level restriction on `IsolationLevel` cannot be met (for example, 3 replicas are configured but there are only 2 data zones in total), PD will not try to make up to meet this restriction. The default value of `IsolationLevel` is an empty string, which means that it is disabled.

10.5.1.2 Fields of the rule group

The following table shows the description of each field in a rule group:

Field name	Type and restriction	Description
`ID`	`string`	The group ID that marks the source of the rule.
`Index`	`int`	The stacking sequence of different groups.
`Override`	`true/false`	Whether to override groups with smaller indexes.

10.5.2 Configure rules

The operations in this section are based on pd-ctl, and the commands involved in the operations also support calls via HTTP API.

10.5.2.1 Enable Placement Rules

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to Disable Placement Rules. To enable this feature after it has been disabled, you can modify the PD configuration file as follows before initializing the cluster:

```
[replication]
enable-placement-rules = true
```

In this way, PD enables this feature after the cluster is successfully bootstrapped and generates corresponding rules according to the `max-replicas` and `location-labels` configurations:

```
{
  "group_id": "pd",
  "id": "default",
  "start_key": "",
  "end_key": "",
  "role": "voter",
  "count": 3,
  "location_labels": ["zone", "rack", "host"],
  "isolation_level": ""
}
```

For a bootstrapped cluster, you can also enable Placement Rules online through pd-ctl:

```
pd-ctl config placement-rules enable
```

PD also generates default rules based on the `max-replicas` and `location-labels` configurations.

Note:

After enabling Placement Rules, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.

10.5.2.2 Disable Placement Rules

You can use pd-ctl to disable the Placement Rules feature and switch to the previous scheduling strategy.

```
pd-ctl config placement-rules disable
```

Note:

After disabling Placement Rules, PD uses the original `max-replicas` and `location-labels` configurations. The modification of rules (when Placement Rules is enabled) will not update these two configurations in real time. In addition, all the rules that have been configured remain in PD and will be used the next time you enable Placement Rules.

10.5.2.3 Set rules using pd-ctl

Note:

The change of rules affects the PD scheduling in real time. Improper rule setting might result in fewer replicas and affect the high availability of the system.

pd-ctl supports using the following methods to view rules in the system, and the output is a JSON-format rule or a rule list.

- To view the list of all rules:

  ```
  pd-ctl config placement-rules show
  ```

- To view the list of all rules in a PD Group:

  ```
  pd-ctl config placement-rules show --group=pd
  ```

- To view the rule of a specific ID in a Group:

```
pd-ctl config placement-rules show --group=pd --id=default
```

- To view the rule list that matches a Region:

```
pd-ctl config placement-rules show --region=2
```

  In the above example, `2` is the Region ID.

Adding rules and editing rules are similar. You need to write the corresponding rules into a file and then use the `save` command to save the rules to PD:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule1",
        "role": "voter",
        "count": 3,
        "location_labels": ["zone", "rack", "host"]
    },
    {
        "group_id": "pd",
        "id": "rule2",
        "role": "voter",
        "count": 2,
        "location_labels": ["zone", "rack", "host"]
    }
]
EOF
pd-ctl config placement save --in=rules.json
```

The above operation writes `rule1` and `rule2` to PD. If a rule with the same `GroupID` + `ID` already exists in the system, this rule is overwritten.

To delete a rule, you only need to set the `count` of the rule to `0`, and the rule with the same `GroupID` + `ID` will be deleted. The following command deletes the `pd / rule2` rule:

```
cat > rules.json <<EOF
[
    {
        "group_id": "pd",
        "id": "rule2"
    }
]
EOF
pd-ctl config placement save --in=rules.json
```

10.5.2.4 Use pd-ctl to configure rule groups

- To view the list of all rule groups:

```
pd-ctl config placement-rules rule-group show
```

- To view the rule group of a specific ID:

```
pd-ctl config placement-rules rule-group show pd
```

- To set the `index` and `override` attributes of the rule group:

```
pd-ctl config placement-rules rule-group set pd 100 true
```

- To delete the configuration of a rule group (use the default group configuration if there is any rule in the group):

```
pd-ctl config placement-rules rule-group delete pd
```

10.5.2.5 Use pd-ctl to batch update groups and rules in groups

To view and modify the rule groups and all rules in the groups at the same time, execute the `rule-bundle` subcommand.

In this subcommand, `get {group_id}` is used to query a group, and the output result shows the rule group and rules of the group in a nested form:

```
pd-ctl config placement-rules rule-bundle get pd
```

The output of the above command:

```
{
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
    {
      "group_id": "pd",
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
}
```

To write the output to a file, add the `--out` argument to the `rule-bundle get` subcommand, which is convenient for subsequent modification and saving.

```
pd-ctl config placement-rules rule-bundle get pd --out="group.json"
```

After the modification is finished, you can use the `rule-bundle set` subcommand to save the configuration in the file to the PD server. Unlike the `save` command described in Set rules using pd-ctl, this command replaces all the rules of this group on the server side.

```
pd-ctl config placement-rules rule-bundle set pd --in="group.json"
```

10.5.2.6 Use pd-ctl to view and modify all configurations

You can also view and modify all configuration using pd-ctl. To do that, save all configuration to a file, edit the configuration file, and then save the file to the PD server to overwrite the previous configuration. This operation also uses the `rule-bundle` subcommand.

For example, to save all configuration to the `rules.json` file, execute the following command:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

After editing the file, execute the following command to save the configuration to the PD server:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

10.5.2.7 Use tidb-ctl to query the table-related key range

If you need special configuration for metadata or a specific table, you can execute the `keyrange` command in tidb-ctl to query related keys. Remember to add `--encode` at the end of the command.

```
tidb-ctl keyrange --database test --table ttt --encode
```

```
global ranges:
  meta: (6d00000000000000f8, 6e00000000000000f8)
  table: (7400000000000000f8, 7500000000000000f8)
table ttt ranges: (NOTE: key range might be changed after DDL)
  table: (748000000000000ff2d00000000000000f8, 7480000000000000
    ↪ ff2e00000000000000f8)
  table indexes: (748000000000000ff2d5f690000000000fa, 7480000000000000
    ↪ ff2d5f720000000000fa)
    index c2: (748000000000000ff2d5f698000000000ff0000010000000000fa,
      ↪ 748000000000000ff2d5f698000000000ff0000020000000000fa)
    index c3: (748000000000000ff2d5f698000000000ff0000020000000000fa,
      ↪ 748000000000000ff2d5f698000000000ff0000030000000000fa)
```

```
    index c4: (7480000000000000ff2d5f698000000000ff0000030000000000fa,
        ↪ 7480000000000000ff2d5f698000000000ff0000040000000000fa)
  table rows: (7480000000000000ff2d5f720000000000fa, 7480000000000000
      ↪ ff2e000000000000f8)
```

> **Note:**
>
> DDL and other operations can cause table ID changes, so you need to update the corresponding rules at the same time.

10.5.3 Typical usage scenarios

This section introduces the typical usage scenarios of Placement Rules.

10.5.3.1 Scenario 1: Use three replicas for normal tables and five replicas for the metadata to improve cluster disaster tolerance

You only need to add a rule that limits the key range to the range of metadata, and set the value of `count` to `5`. Here is an example of this rule:

```
{
  "group_id": "pd",
  "id": "meta",
  "index": 1,
  "override": true,
  "start_key": "6d000000000000000f8",
  "end_key": "6e000000000000000f8",
  "role": "voter",
  "count": 5,
  "location_labels": ["zone", "rack", "host"]
}
```

10.5.3.2 Scenario 2: Place five replicas in three data centers in the proportion of 2:2:1, and the Leader should not be in the third data center

Create three rules. Set the number of replicas to `2`, `2`, and `1` respectively. Limit the replicas to the corresponding data centers through `label_constraints` in each rule. In addition, change `role` to `follower` for the data center that does not need a Leader.

```
[
    {
        "group_id": "pd",
```

```
        "id": "zone1",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 2,
        "label_constraints": [
            {"key": "zone", "op": "in", "values": ["zone1"]}
        ],
        "location_labels": ["rack", "host"]
    },
    {
        "group_id": "pd",
        "id": "zone2",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 2,
        "label_constraints": [
            {"key": "zone", "op": "in", "values": ["zone2"]}
        ],
        "location_labels": ["rack", "host"]
    },
    {
        "group_id": "pd",
        "id": "zone3",
        "start_key": "",
        "end_key": "",
        "role": "follower",
        "count": 1,
        "label_constraints": [
            {"key": "zone", "op": "in", "values": ["zone3"]}
        ],
        "location_labels": ["rack", "host"]
    }
]
```

10.5.3.3 Scenario 3: Add two TiFlash replicas for a table

Add a separate rule for the row key of the table and limit `count` to `2`. Use `label_constraints` to ensure that the replicas are generated on the node of `engine = tiflash`. Note that a separate `group_id` is used here to ensure that this rule does not overlap or conflict with rules from other sources in the system.

```
{
  "group_id": "tiflash",
```

```
  "id": "learner-replica-table-ttt",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
  "role": "learner",
  "count": 2,
  "label_constraints": [
    {"key": "engine", "op": "in", "values": ["tiflash"]}
  ],
  "location_labels": ["host"]
}
```

10.5.3.4 Scenario 4: Add two follower replicas for a table in the Beijing node with high-performance disks

The following example shows a more complicated `label_constraints` configuration. In this rule, the replicas must be placed in the `bj1` or `bj2` machine room, and the disk type must not be `hdd`.

```
{
  "group_id": "follower-read",
  "id": "follower-read-table-ttt",
  "start_key": "7480000000000000ff2d000000000000000f8",
  "end_key": "7480000000000000ff2e000000000000000f8",
  "role": "follower",
  "count": 2,
  "label_constraints": [
    {"key": "zone", "op": "in", "values": ["bj1", "bj2"]},
    {"key": "disk", "op": "notIn", "values": ["hdd"]}
  ],
  "location_labels": ["host"]
}
```

10.5.3.5 Scenario 5: Migrate a table to the nodes with SSD disks

Different from scenario 3, this scenario is not to add new replica(s) on the basis of the existing configuration, but to forcibly override the other configuration of a data range. So you need to specify an `index` value large enough and set `override` to `true` in the rule group configuration to override the existing rule.

The rule:

```
{
  "group_id": "ssd-override",
  "id": "ssd-table-45",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e00000000000000f8",
```

```
  "role": "voter",
  "count": 3,
  "label_constraints": [
    {"key": "disk", "op": "in", "values": ["ssd"]}
  ],
  "location_labels": ["rack", "host"]
}
```

The rule group:

```
{
  "id": "ssd-override",
  "index": 1024,
  "override": true,
}
```

10.6 Load Base Split

Load Base Split is a new feature introduced in TiDB 4.0. It aims to solve the hotspot issue caused by unbalanced access between Regions, such as full table scans for small tables.

10.6.1 Scenarios

In TiDB, it is easy to generate hotspots when the load is concentrated on certain nodes. PD tries to schedule the hot Regions so that they are distributed as evenly as possible across all nodes for better performance.

However, the minimum unit for PD scheduling is Region. If the number of hotspots in a cluster is smaller than the number of nodes, or if a few hotspots have far more load than other Regions, PD can only move the hotspot from one node to another, but not make the entire cluster share the load.

This scenario is especially common with workloads that are mostly read requests, such as full table scans and index lookups for small tables, or frequent access to some fields.

Previously, the solution to this problem was to manually execute a command to split one or more hotspot Regions, but this approach has two problems:

- Evenly splitting a Region is not always the best choice, because requests might be concentrated on a few keys. In such cases, hotspots might still be on one of the Regions after evenly splitting, and it might take multiple even splits to realize the goal.
- Human intervention is not timely or simple.

10.6.2 Implementation principles

Load Base Split automatically splits the Region based on statistics. It identifies the Regions whose read load consistently exceeds the threshold for 10 seconds, and splits these Regions at a proper position. When choosing the split position, Load Base Split tries to balance the access load of both Regions after the split and avoid access across Regions.

The Region split by Load Base Split will not be merged quickly. On the one hand, PD's `MergeChecker` skips the hot Regions; on the other hand, PD also determines whether to merge two Regions according to `QPS` in the heartbeat information, to avoid the merging of two Regions with high `QPS`.

10.6.3 Usage

The Load Base Split feature is currently controlled by the `split.qps-threshold` parameter (QPS threshold) and `split.byte-threshold` parameter (traffic threshold). If the sum of all types of read requests per second for a Region exceeds the QPS threshold or traffic threshold for 10 consecutive seconds, PD splits the Region.

Load Base Split is enabled by default, but the parameter is set to a rather high value. `split.qps-threshold` defaults to `3000` and `split.byte-threshold` defaults to 30MB/s. If you want to disable this feature, set the two thresholds high enough at the same time.

To modify the parameter, take either of the following two methods:

- Use a SQL statement:

```
# Set the QPS threshold to 1500
SET config tikv split.qps-threshold=1500;
# Set the byte threshold to 15 MiB (15 * 1024 * 1024)
SET config tikv split.byte-threshold=15728640;
```

- Use TiKV:

```
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.qps-threshold":"1500"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
    ↪ json" -d '{"split.byte-threshold":"15728640"}'
```

Accordingly, you can view the configuration by either of the following two methods:

- Use a SQL statement:

```
show config where type='tikv' and name like '%split.qps-threshold%';
```

- Use TiKV:

```
curl "http://ip:status_port/config"
```

Note:

Starting from v4.0.0-rc.2, you can modify and view the configuration using SQL statements.

10.7 Store Limit

Store Limit is a feature of PD, introduced in TiDB 3.0. It is designed to control the scheduling speed in a finer manner for better performance in different scenarios.

10.7.1 Implementation principles

PD performs scheduling at the unit of operator. An operator might contain several scheduling operations. For example:

```
"replace-down-replica {mv peer: store [2] to [3]} (kind:region,replica,
    ↪ region:10(4,5), createAt:2020-05-18 06:40:25.775636418 +0000 UTC m
    ↪ =+2168762.679540369, startAt:2020-05-18 06:40:25.775684648 +0000 UTC
    ↪ m=+2168762.679588599, currentStep:0, steps:[add learner peer 20 on
    ↪ store 3, promote learner peer 20 on store 3 to voter, remove peer on
    ↪ store 2])"
```

In this above example, the `replace-down-replica` operator contains the following specific operations:

1. Add a learner peer with the ID 20 to `store 3`.
2. Promote the learner peer with the ID 20 on `store 3` to a voter.
3. Delete the peer on `store 2`.

Store Limit achieves the store-level speed limit by maintaining a mapping from store IDs to token buckets in memory. The different operations here correspond to different token buckets. Currently, Store Limit only supports limiting the speed of two operations: adding learners/peers and deleting peers. That is, each store has two types of token buckets.

Every time an operator is generated, it checks whether enough tokens exist in the token buckets for its operations. If yes, the operator is added to the scheduling queue, and the corresponding token is taken from the token bucket. Otherwise, the operator is abandoned. Because the token bucket replenishes tokens at a fixed rate, the speed limit is thus achieved.

Store Limit is different from other limit-related parameters in PD (such as `region-schedule-limit` and `leader-schedule-limit`) in that it mainly limits the consuming speed of operators, while other parameters limits the generating speed of operators. Before introducing the Store Limit feature, the speed limit of scheduling is mostly at the global scope. Therefore, even if the global speed is limited, it is still possible that the scheduling operations are concentrated on some stores, affecting the performance of the cluster. By limiting the speed at a finer level, Store Limit can better control the scheduling behavior.

10.7.2 Usage

The parameters of Store Limit can be configured using `pd-ctl`.

10.7.2.1 View setting of the current store

To view the limit setting of the current store, run the following commands:

```
store limit                     // Shows the speed limit of adding and deleting peers in all stores.
store limit add-peer            // Shows the speed limit of adding peers in all stores.
store limit remove-peer         // Shows the speed limit of deleting peers in all stores.
```

10.7.2.2 Set limit for all stores

To set the speed limit for all stores, run the following commands:

```
store limit all 5               // All stores can at most add and delete 5 peers per minute.
store limit all 5 add-peer      // All stores can at most add 5 peers per minute.
store limit all 5 remove-peer   // All stores can at most delete 5 peers per minute.
```

10.7.2.3 Set limit for a single store

To set the speed limit for a single store, run the following commands:

```
store limit 1 5                 // store 1 can at most add and delete 5 peers per minute.
store limit 1 5 add-peer        // store 1 can at most add 5 peers per minute.
store limit 1 5 remove-peer     // store 1 can at most delete 5 peers per minute.
```

11 TiDB Tools

11.1 TiDB Tools Overview

TiDB provides a rich set of tools to help you with deployment operations, data management (such as import and export, data migration, backup & recovery), and complex OLAP queries. You can select the applicable tools according to your needs.

11.1.1 Deployment and operation Tools

To meet your deployment and operation needs in different system environments, TiDB provides two deployment and Operation tools, TiUP and TiDB Operator.

11.1.1.1 Deploy and operate TiDB on physical or virtual machines

TiUP is a TiDB package manager on physical or virtual machines. TiUP can manage multiple TiDB components such as TiDB, PD, TiKV. To start any component in the TiDB ecosystem, you just need to execute a single TiUP command.

TiUP provides TiUP cluster, a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

The following are the basics of TiUP:

- Terminology and Concepts
- Deploy a TiDB Cluster Using TiUP
- Manage TiUP Components with TiUP Commands
- Applicable TiDB versions: v4.0 and above

11.1.1.2 Deploy and operate TiDB in Kubernetes

TiDB Operator is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

The following are the basics of TiDB Operator:

- TiDB Operator Architecture
- Get Started with TiDB Operator in Kubernetes
- Applicable TiDB versions: v2.1 and above

11.1.2 Data management tools

TiDB provides multiple data management tools, such as import and export, backup and restore, data replication, data migration, incremental synchronization, and data validation.

11.1.2.1 Full data export

Dumpling is a tool for the logical full data export from MySQL or TiDB.

The following are the basics of Dumpling:

- Input: MySQL/TiDB cluster
- Output: SQL/CSV file
- Supported TiDB versions: all versions
- Kubernetes support: No

> **Note:**
>
> PingCAP previously maintained a fork of the mydumper project with enhancements specific to TiDB. Starting from v7.5.0, Mydumper is deprecated and most of its features have been replaced by Dumpling. It is strongly recommended that you use Dumpling instead of Mydumper.

11.1.2.2 Full data import

TiDB Lightning (Lightning) is a tool used for the full import of large amounts of data into a TiDB cluster. Currently, TiDB Lightning supports reading SQL dump exported via Dumpling or CSV data source.

TiDB Lightning supports three modes:

- `local`: TiDB Lightning parses data into ordered key-value pairs and directly imports them into TiKV. This mode is usually for importing a large amount of data (at the TB level) to a new cluster. During the import, the cluster cannot provide services.
- `importer`: This mode is similar to the `local` mode. To use this mode, you need to deploy an additional component `tikv-importer` to help import key-value pairs. If the target cluster is in v4.0 or later versions, it is recommended to use the `local` mode.
- `tidb`: This mode uses TiDB/MySQL as the backend, which is slower than the `local` mode and `importer` mode but can be performed online. It also supports importing data to MySQL.

The following are the basics of TiDB Lightning:

- Input data source:
  - The output file of Dumpling
  - Other compatible CSV file
- Supported TiDB versions: v2.1 or later
- Kubernetes support: Yes. See Quickly restore data into a TiDB cluster in Kubernetes using TiDB Lightning for details.

> **Note:**
>
> The Loader tool is no longer maintained. For scenarios related to Loader, it is recommended that you use the `tidb` mode of TiDB Lighting instead. For details, see TiDB Lightning TiDB backends.

11.1.2.3 Backup and restore

Backup & Restore (BR) is a command-line tool for distributed backup and restore of the TiDB cluster data. BR can effectively back up and restore TiDB clusters of huge data volume.

The following are the basics of BR:

- Input and output data source: SST + `backupmeta` file
- Supported TiDB versions: v3.1 and v4.0
- Kubernetes support: Yes. See Back up Data to S3-Compatible Storage Using BR and Restore Data from S3-Compatible Storage Using BR for details.

11.1.2.4 Incremental data replication

TiDB Binlog is a tool that collects binlog for TiDB clusters and provides near real-time sync and backup. It can be used for incremental data replication between TiDB clusters, such as making a TiDB cluster the secondary cluster of the primary TiDB cluster.

The following are the basics of TiDB Binlog:

- Input/Output:
  - Input: TiDB cluster
  - Output: TiDB cluster, MySQL, Kafka or incremental backup files
- Supported TiDB versions: v2.1 or later
- Kubernetes support: Yes. See TiDB Binlog Cluster Operations and TiDB Binlog Drainer Configurations in Kubernetes for details.

11.1.2.5 Data migration

TiDB Data Migration (DM) is an integrated data replication task management platform that supports the full data migration and the incremental data replication from MySQL/-MariaDB to TiDB.

The following are the basics of DM:

- Input: MySQL/MariaDB
- Output: TiDB cluster
- Supported TiDB versions: all versions
- Kubernetes support: No, under development

If the data volume is below the TB level, it is recommended to migrate data from MySQL/MariaDB to TiDB directly using DM. The migration process includes the full data import and export and the incremental data replication.

If the data volume is at the TB level, take the following steps:

1. Use Dumpling to export the full data from MySQL/MariaDB.
2. Use TiDB Lightning to import the data exported in Step 1 to the TiDB cluster.
3. Use DM to replicate the incremental data from MySQL/MariaDB to TiDB.

> **Note:**
>
> The Syncer tool is no longer maintained. For scenarios related to Syncer, it is recommended that you use DM's incremental task mode instead.

11.1.3 OLAP Query tool

TiDB provides the OLAP query tool TiSpark, which allows you to query TiDB tables as if you were using native Spark.

11.1.3.1 Query TiKV data source using Spark

TiSpark is a thin layer built for running Apache Spark on top of TiKV to answer the complex OLAP queries. It takes advantages of both the Spark platform and the distributed TiKV cluster and seamlessly glues to TiDB, and provides a one-stop Hybrid Transactional and Analytical Processing (HTAP) solution.

11.2 TiDB Tools Use Cases

This document introduces the common use cases of TiDB tools and how to choose the right tool for your scenario.

11.2.1 Deploy and operate TiDB on physical or virtual machines

If you need to deploy and operate TiDB on physical or virtual machines, you can install TiUP, and then use TiUP to manage TiDB components such as TiDB, PD, and TiKV.

11.2.2 Deploy and operate TiDB in Kubernetes

If you need to deploy and operate TiDB in Kubernetes, you can deploy a Kubernetes cluster, and then deploy TiDB Operator. After that, you can use TiDB Operator to deploy and operate a TiDB cluster.

11.2.3 Import data from CSV to TiDB

If you need to import the compatible CSV files exported by other tools to TiDB, use TiDB Lightning.

11.2.4 Import full data from MySQL/Aurora

If you need to import full data from MySQL/Aurora, use Dumpling first to export data as SQL dump files, and then use TiDB Lightning to import data into the TiDB cluster.

11.2.5 Migrate data from MySQL/Aurora

If you need to migrate both full data and incremental data from MySQL/Aurora, use TiDB Data Migration (DM) to perform the full and incremental data migration.

If the full data volume is large (at the TB level), you can first use Dumpling and TiDB Lightning to perform the full data migration, and then use DM to perform the incremental data migration.

11.2.6 Back up and restore TiDB cluster

If you need to back up a TiDB cluster or restore backed up data to the cluster, use BR (Backup & Restore).

In addition, BR can also be used to perform incremental backup and incremental restore of TiDB cluster data.

11.2.7 Migrate data to TiDB

If you need to migrate data from a TiDB cluster to another TiDB cluster, use Dumpling to export full data from TiDB as SQL dump files, and then use TiDB Lightning to import data to another TiDB cluster.

If you also need to migrate incremental data, use TiDB Binlog.

11.2.8 TiDB incremental data subscription

If you need to subscribe to TiDB's incremental changes, use TiDB Binlog.

11.3 Download TiDB Tools

This document collects the available downloads for most officially maintained versions of TiDB tools.

11.3.1 TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems. For more information, see Install TiUP.

11.3.2 TiDB Operator

TiDB Operator runs in Kubernetes. After deploying the Kubernetes cluster, you can choose to deploy TiDB Operator either online or offline. For more information, see Deploying TiDB Operator in Kubernetes.

11.3.3 TiDB Binlog

If you want to download the latest version of TiDB Binlog, directly download the TiDB package, because TiDB Binlog is included in the TiDB package.

Package name	OS	Architecture	SHA256 checksum
`https://download.pingcap.org/tidb-{version}-linux-amd64.tar.gz` (TiDB Binlog)	Linux	amd64	`https://download.pingcap.org/tidb-{version}-linux-amd64.tar.sha256`

Note:

`{version}` in the above download link indicates the version number of TiDB. For example, the download link for `v5.1.5` is `https://download.pingcap.org/tidb-v5.1.5-linux-amd64.tar.gz`.

11.3.4 TiDB Lightning

Download TiDB Lightning by using the download link in the following table:

Package name	OS	Architecture	SHA256 checksum
`https://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.tar.gz`	Linux	amd64	`https://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.sha256`

Note:

`{version}` in the above download link indicates the version number of TiDB Lightning. For example, the download link for `v5.1.5` is `https://download.pingcap.org/tidb-toolkit-v5.1.5-linux-amd64.tar.gz`.

11.3.5 BR (backup and restore)

Download BR by using the download link in the following table:

Package name	OS	Architecture	SHA256 checksum
`http ↪ ://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.tar.gz ↪`	Linux	amd64	`http ↪ ://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.tar.sha256 ↪`

Note:

`{version}` in the above download link indicates the version number of BR. For example, the download link for `v5.1.5` is `http://download.pingcap.org/tidb-toolkit-v5.1.5-linux-amd64.tar.gz`.

11.3.6 TiDB DM (Data Migration)

Download DM by using the download link in the following table:

Package name	OS	Architecture	SHA256 checksum
`https://download.pingcap.org/dm-{version}-linux-amd64.tar.gz`	Linux	amd64	`https://download.pingcap.org/dm-{version}-linux-amd64.sha256`

Note:

`{version}` in the above download link indicates the version number of DM. For example, the download link for `v2.0.4` is `https://download.pingcap.org/dm-v2.0.4-linux-amd64.tar.gz`. You can check the published DM versions in the DM Release page.

11.3.7 Dumpling

Download Dumpling from the links below:

Installation package	Operating system	Architecture	SHA256 checksum
`https://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.tar.gz`	Linux	amd64	`https://download.pingcap.org/tidb-toolkit-{version}-linux-amd64.sha256`

Note:

The `{version}` in the download link is the version number of Dumpling. For example, the link for downloading the `v5.1.5` version of Dumpling is `https://download.pingcap.org/tidb-toolkit-v5.1.5-linux-amd64.tar.gz`. You can view the currently released versions in Dumpling Releases.

Dumpling supports arm64 linux. You can replace `amd64` in the download link with `arm64`, which means the `arm64` version of Dumpling.

11.3.8 sync-diff-inspector

Download sync-diff-inspector from the links below:

Package name	OS	Architecture	SHA256 checksum
tidb-enterprise-tools-nightly-linux-amd64.tar.gz	Linux	amd64	tidb-enterprise-tools-nightly-linux-amd64.sha256

11.3.9 TiCDC

To download TiCDC, refer to Deploy TiCDC.

11.4 TiUP

11.4.1 TiUP Documentation Map

11.4.1.1 User guide

- TiUP Overview: Gives an overall introduction to TiUP, for example, how to install and use TiUP, and the related terminologies.
- TiUP Terminology and Concepts: Explains the terms that you might bump into when using TiUP, and help you understand the key concepts of TiUP
- TiUP Component Management: Introduces all TiUP commands in detail, and how to use TiUP to download, update and delete components
- TiUP FAQ: Introduces common issues when you use TiUP, including FAQs of the third-party components of TiUP
- TiUP Troubleshooting Guide: Introduces the troubleshooting methods and solutions if you encounter issues when using TiUP
- TiUP Reference Guide: Introduces detailed references, including commands, components, and mirrors.

11.4.1.2 TiUP resources

- TiUP Issues: Lists TiUP GitHub issues

11.4.2 TiUP Overview

Starting with TiDB 4.0, TiUP, as the package manager, makes it far easier to manage different cluster components in the TiDB ecosystem. Now you can run any component with only a single line of TiUP commands.

11.4.2.1 Install TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/
    ↪ install.sh | sh
```

This command installs TiUP in the `$HOME/.tiup` folder. The installed components and the data generated by their operation are also placed in this folder. This command also automatically adds `$HOME/.tiup/bin` to the `PATH` environment variable in the Shell `.profile` file, so you can use TiUP directly.

After installation, you can check the version of TiUP:

```
tiup --version
```

> **Note:**
>
> By default, TiUP shares usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see Telemetry.

11.4.2.2 TiUP ecosystem introduction

TiUP is not only a package manager in the TiDB ecosystem. Its ultimate mission is to enable everyone to use TiDB ecosystem tools **easier than ever before** by building its own ecosystem. This requires introducing additional packages to enrich the TiUP ecosystem.

This series of TiUP documents introduce what these packages do and how you can use them.

In the TiUP ecosystem, you can get help information by adding `--help` to any command, such as the following command to get help information for TiUP itself:

```
tiup --help
```

```
TiUP is a command-line component management tool that can help to download
    ↪ and install
TiDB platform components to the local system. You can run a specific version
    ↪  of a component via
"tiup <component>[:version]". If no version number is specified, the latest
    ↪ version installed
locally will be used. If the specified component does not have any version
    ↪ installed locally,
the latest stable version will be downloaded from the repository.
```

```
Usage:
  tiup [flags] <command> [args...]
  tiup [flags] <component> [args...]

Available Commands:
  install    Install a specific version of a component
  list       List the available TiDB components or versions
  uninstall  Uninstall components or versions of a component
  update     Update tiup components to the latest version
  status     List the status of instantiated components
  clean      Clean the data of instantiated components
  mirror     Manage a repository mirror for TiUP components
  help       Help about any command or component

Components Manifest:
  use "tiup list" to fetch the latest components manifest

Flags:
  -B, --binary <component>[:version] Print binary path of a specific version
     ↪  of a component <component>[:version]
                                     and the latest version installed will be
                                        ↪ selected if no version specified
      --binpath string               Specify the binary path of component
         ↪ instance
  -h, --help                         help for tiup
      --skip-version-check           Skip the strict version check, by default
         ↪  a version must be a valid SemVer string
  -T, --tag string                   Specify a tag for component instance
  -v, --version                      version for tiup

Component instances with the same "tag" will share a data directory (
   ↪ $TIUP_HOME/data/$tag):
  $ tiup --tag mycluster playground

Examples:
  $ tiup playground                  # Quick start
  $ tiup playground nightly          # Start a playground with the latest
     ↪ nightly version
  $ tiup install <component>[:version] # Install a component of specific
     ↪ version
  $ tiup update --all                # Update all installed components to the
     ↪ latest version
  $ tiup update --nightly            # Update all installed components to the
     ↪ nightly version
```

```
  $ tiup update --self            # Update the "tiup" to the latest version
  $ tiup list                     # Fetch the latest supported components
     ↪ list
  $ tiup status                   # Display all running/terminated
     ↪ instances
  $ tiup clean <name>             # Clean the data of running/terminated
     ↪ instance (Kill process if it's running)
  $ tiup clean --all              # Clean the data of all running/
     ↪ terminated instances

Use "tiup [command] --help" for more information about a command.
```

The output is long but you can focus on only two parts:

- Available commands
  - install: used to install components
  - list: used to view the list of available components
  - uninstall: used to uninstall components
  - update: used to update the component version
  - status: used to view the running history of components
  - clean: used to clear the running log of components
  - mirror: used to clone a private mirror from the official mirror
  - help: used to print out help information
- Available components
  - playground: used to start a TiDB cluster locally
  - client: used to connect to a TiDB cluster in a local machine
  - cluster: used to deploy a TiDB cluster for production environments
  - bench: used to stress test the database

Note:

- The number of available components will continue to grow. To check the latest supported components, execute the `tiup list` command.
- The list of available versions of components will also continue to grow. To check the latest supported component versions, execute the `tiup ↪ list <component>` command.

TiUP commands are implemented in TiUP's internal code and used for package management operations, while TiUP components are independent component packages installed by TiUP commands.

For example, if you run the `tiup list` command, TiUP directly runs its own internal code; if you run the `tiup playground` command, TiUP first checks whether there is a local package named "playground", and if not, TiUP downloads the package from the mirror, and then run it.

11.4.3 TiUP Terminology and Concepts

This document explains important terms and concepts of TiUP.

11.4.3.1 TiUP components

The TiUP program contains only a few commands for downloading, updating, and uninstalling components. TiUP expands its functions with various components. A **component** is a program or script that can be run. When running a component through `tiup <component>`, TiUP adds a set of environment variables, creates the data directory for the program, and then runs the program.

By running the `tiup <component>` command, you can run a component supported by TiUP. The running logic is:

- If you specify a version of a component through `tiup <component>[:version]`:
  - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
  - If the component has one or more versions installed locally, but there is no version specified by you, TiUP downloads the specified version from the mirror server.
  - If the specified version of the component is installed locally, TiUP sets the environment variable to run the installed version.
- If you run a component through `tiup <component>` and specify no version:
  - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
  - If one or more versions have been installed locally, TiUP sets the environment variable to run the latest installed version.

11.4.3.2 TiUP mirrors

All components of TiUP are downloaded from the TiUP mirrors. TiUP mirrors contain the TAR package of each component and the corresponding meta information (version, entry startup file, checksum). TiUP uses PingCAP's official mirrors by default. You can customize the mirror source through the `TIUP_MIRRORS` environment variable.

TiUP mirrors can be a local file directory or an online HTTP server:

- `TIUP_MIRRORS=/path/to/local tiup list`
- `TIUP_MIRRORS=https://private-mirrors.example.com tiup list`

11.4.4 Manage TiUP Components with TiUP Commands

You can use the following TiUP commands to manage components in the TiUP ecosystem:

- list: Queries the component list. By using this TiUP command, you can see all the optional components to install and all the optional versions of each component.
- install: Installs the specific version of a component.
- update: Updates a component to the latest version.
- uninstall: Uninstalls a component.
- status: Checks the status of a running component.
- clean: Cleans up the instance on which a component is deployed.
- help: Prints the help information. If you append another TiUP command to this command, the usage of the appended command is printed.

This document introduces the common component management operations and the corresponding TiUP commands.

11.4.4.1 Query the component list

You can use the `tiup list` command to query the component list. This usage of this command is as follows:

- `tiup list`: checks which components can be installed.
- `tiup list ${component}`: checks which versions of a specific component can be installed.

You can also use the following flags in the above commands:

- `--installed`: checks which components or which version of a specific component has been installed locally. `---all`: views all components, including the hidden ones `---verbose`: views all columns (including installed versions and supported platforms)

Example 1: View all currently installed components.

```
tiup list --installed
```

Example 2: Get a list of the TiKV component of all installable versions from the server.

```
tiup list tikv
```

11.4.4.2 Install components

You can use the `tiup install` command to query the component list. This usage of this command is as follows:

- `tiup install <component>`: installs the latest stable version of a specified component.
- `tiup install <component>:[version]`: installs the specified version of a specified component.

Example 1: Use TiUP to install the latest stable version of TiDB.

```
tiup install tidb
```

Example 2: Use TiUP to install the nightly version of TiDB.

```
tiup install tidb:nightly
```

Example 3: Use TiUP to install TiKV v5.1.5.

```
tiup install tikv:v5.1.5
```

11.4.4.3 Upgrade components

After a new version of a component is published, you can use the `tiup update` command to upgrade this component. The usage of this command is basically the same as that of `tiup install`, except for the following flags:

- `--all`: Upgrades all components.
- `--nightly`: Upgrades to the nightly version.
- `--self`: Upgrades TiUP itself to the latest version.
- `--force`: Forcibly upgrades to the latest version.

Example 1: Upgrade all components to the latest versions.

```
tiup update --all
```

Example 2: Upgrade all components to the nightly version.

```
tiup update --all --nightly
```

Example 3: Upgrade TiUP to the latest version.

```
tiup update --self
```

11.4.4.4 Operate components

After the installation is complete, you can use the `tiup <component>` command to start the corresponding component:

```
tiup [flags] <component>[:version] [args...]

Flags:
  -T, --tag string                Specifies the tag for the component
      ↪ instance.
```

To use this command, you need to specify the component name and the optional version. If no version is specified, the latest stable version (installed) of this component is used.

Before the component is started, TiUP creates a directory for it, and then puts this component into the directory for operation. The component generates all the data in this directory, and the name of this directory is the tag name specified when the component operates. If no tag is specified, a tag name is randomly generated. This working directory will be *automatically deleted* when the instance is terminated.

If you want to start the same component multiple times and reuse the previous working directory, you can use `--tag` to specify the same name when the component is started. After the tag is specified, the working directory will *not be automatically deleted* when the instance is terminated, which makes it convenient to reuse the working directory.

Example 1: Operate TiDB v5.1.5.

```
tiup tidb:v5.1.5
```

Example 2: Specify the tag with which TiKV operates.

```
tiup --tag=experiment tikv
```

11.4.4.4.1 Query the operating status of a component

You can use the `tiup status` command to check the operating status of a component:

```
tiup status
```

By executing this command, you will get a list of instances, one instance per line. The list contains the following columns:

- `Name`: The tag name of the instance.
- `Component`: The component name of the instance.
- `PID`: The process ID of the operating instance.
- `Status`: The instance status. `RUNNING` means that the instance is operating. `TERM` means that the instance is terminated.
- `Created Time`: The starting time of the instance.

- `Directory`: The working directory of the instance, which can be specified using `--tag`.
- `Binary`: The executable program of the instance, which can be specified using `--binpath`.
- `Args`: The arguments of the operating instance.

11.4.4.4.2 Clean component instance

You can use the `tiup clean` command to clean up component instances and delete the working directory. If the instance is still operating before the cleaning, the related process is killed first. The command usage is as follows:

```
tiup clean [tag] [flags]
```

The following flag is supported:

- `--all`: Cleans up all instance information.

In the above command, `tag` is the instance tag to be cleaned. If `--all` is used, no tag is passed.

Example 1: Clean up the component instance with the `experiment` tag name.

```
tiup clean experiment
```

Example 2: Clean up all component instances.

```
tiup clean --all
```

11.4.4.4.3 Uninstall components

The components installed using TiUP take up local disk space. If you do not want to keep too many components of old versions, you can check which versions of a component are currently installed, and then uninstall this component.

You can use the `tiup uninstall` command to uninstall all versions or specific versions of a component. This command also supports uninstalling all components. The command usage is as follows:

```
tiup uninstall [component][:version] [flags]
```

The following flags are supported in this command:

- `--all`: Uninstalls all components or versions.
- `--self`: Uninstalls TiUP itself.

`component` is the component to be uninstalled. `version` is the version to be uninstalled. Both `component` and `version` can be ignored in the `tiup uninstall` command. If you ignore either one of these two, you need to add the `--all` flag.

- If the version is ignored, adding `--all` means to uninstall all versions of this component.
- If the version and the component are both ignored, adding `--all` means to uninstall all components of all versions.

Example 1: Uninstall TiDB v5.1.5.

```
tiup uninstall tidb:v5.1.5
```

Example 2: Uninstall TiKV of all versions.

```
tiup uninstall tikv --all
```

Example 3: Uninstall all installed components.

```
tiup uninstall --all
```

11.4.5 TiUP FAQ

11.4.5.1 Can TiUP not use the official mirror source?

TiUP supports specifying the mirror source through the `TIUP_MIRRORS` environment variable. The address of the mirror source can be a local directory or an HTTP server address. If your environment cannot access the network, you can create your own offline mirror source to use TiUP.

After using an unofficial mirror, if you want the official mirror back and use it, take one of the following measures:

- Set the `TIUP_MIRRORS` variable to the official mirror address: `https://tiup-mirrors.pingcap.com`.
- Make sure that the `TIUP_MIRRORS` variable is not set, and then execute the `tiup mirror set https://tiup-mirrors.pingcap.com` command.

11.4.5.2 How do I put my own component into the TiUP mirrors?

TiUP does not support third-party components for the time being, but the TiUP Team has developed the TiUP component development specifications and is developing the tiup-publish component. After everything is ready, a contributor can publish their own components to TiUP's official mirrors by using the `tiup publish <comp> <version>` command.

11.4.5.3 What is the difference between the TiUP playground and TiUP cluster components?

The TiUP playground component is mainly used to build a stand-alone development environment on Linux or macOS operating systems. It helps you get started quickly and run a specified version of the TiUP cluster easily. The TiUP cluster component is mainly used to deploy and maintain a production environment cluster, which is usually a large-scale cluster.

11.4.5.4 How do I write the topology file for the TiUP cluster component?

Refer to these templates to write the topology file. The templates include:

- Multi-DC deployment topology
- Minimal deployment topology
- Complete topology file

You can edit your topology file based on the templates and your needs.

11.4.5.5 Can multiple instances be deployed on the same host?

You can use the TiUP cluster component to deploy multiple instances on the same host, but with different ports and directories configured; otherwise, directory and port conflicts might occur.

11.4.5.6 Are port and directory conflicts detected within the same cluster?

Port and directory conflicts in the same cluster are detected during deployment and scaling. If there is any directory or port conflict, the deployment or scaling process is interrupted.

11.4.5.7 Are port and directory conflicts detected among different clusters?

If multiple different clusters are deployed by the same TiUP control machine, the port and directory conflicts among these clusters are detected during deployment and scaling. If the clusters are deployed by different TiUP control machines, conflict detection is not supported currently.

11.4.5.8 During cluster deployment, TiUP received an `ssh: handshake failed: read tcp 10.10.10.34:38980 -> 10.10.10.34:3600: read: connection reset by peer` error

The error might occur because the default number of concurrent threads of TiUP exceeds the default maximum number of SSH connections. To solve the issue, you can increase the default number of SSH connections, and then restart the sshd service:

```
vi /etc/ssh/sshd_config
```

```
MaxSessions 1000
MaxStartups 1000
```

11.4.6 TiUP Troubleshooting Guide

This document introduces some common issues when you use TiUP and the troubleshooting methods. If this document does not include the issues you bump into, file a new issue in the Github TiUP repository.

11.4.6.1 Troubleshoot TiUP commands

11.4.6.1.1 Can't see the latest component list using `tiup list`

TiUP does not update the latest component list from the mirror server every time. You can forcibly refresh the component list by running `tiup list`.

11.4.6.1.2 Can't see the latest version information of a component using `tiup list <component>`

Same as the previous issue, the component version information is only obtained from the mirror server when there is no local cache. You can refresh the component list by running `tiup list <component>`.

11.4.6.1.3 Component downloading process is interrupted

Unstable network might result in an interrupted component downloading process. You can try to download the component again. If you cannot download it after trying multiple times, it might be caused by the CDN server and you can report the issue here.

11.4.6.1.4 A checksum error occurs during component downloading process

Because the CDN server has a short cache time, the new checksum file might not match the component package. Try to download again after 5 minutes. If the new checksum file still does not match the component package, report the issue here.

11.4.6.2 Troubleshoot TiUP cluster component

11.4.6.2.1 `unable to authenticate, attempted methods [none publickey]` is prompted during deployment

During deployment, component packages are uploaded to the remote host and the initialization is performed. This process requires connecting to the remote host. This error is caused by the failure to find the SSH private key to connect to the remote host.

To solve this issue, confirm whether you have specified the private key by running `tiup cluster deploy -i identity_file`:

- If the `-i` flag is not specified, it might be that TiUP does not automatically find the private key path. It is recommended to explicitly specify the private key path using `-i`.
- If the `-i` flag is specified, it might be that TiUP cannot log in to the remote host using the specified private key. You can verify it by manually executing the `ssh -i identity_file user@remote` command.
- If a password is used to log in to the remote host, make sure that you have specified the `-p` flag and entered the correct login password.

11.4.6.2.2 The process of upgrading the cluster using the TiUP cluster component is interrupted

To avoid misuse cases, the TiUP cluster component does not support the upgrade of specified nodes, so after the upgrade fails, you need to perform the upgrade operations again, including idempotent operations during the upgrade process.

The upgrade process can be divided into the following steps:

1. Back up the old version of components on all nodes
2. Distribute new components to remote
3. Perform a rolling restart to all components

If the upgrade is interrupted during a rolling restart, instead of repeating the `tiup cluster upgrade` operation, you can use `tiup cluster restart -N <node1> -N <node2>` to restart the nodes that have not completed the restart.

If the number of un-restarted nodes of the same component is relatively large, you can also restart a certain type of component by running `tiup cluster restart -R <component>`.

11.4.6.2.3 During the upgrade, you find that `node_exporter-9100.service/blackbox_expor` does not exist

If you previously migrated your cluster from TiDB Ansible and the exporter was not deployed in TiDB Ansible, this situation might happen. To solve it, you can manually copy the missing files from other nodes to the new node for the time being. The TiUP team will complete the missing components during the migration process.

11.4.7 TiUP Reference

TiUP serves as the package manager of the TiDB ecosystem. It manages components in the TiDB ecosystem, such as TiDB, PD, and TiKV.

11.4.7.1 Syntax

```
tiup [flags] <command> [args...]   # Executes a command
### or
tiup [flags] <component> [args...] # Runs a component
```

You can use the `help` command to get the information of a specific command. The summary of each command shows its parameters and their usage. Mandatory parameters are shown in angle brackets, and optional parameters are shown in square brackets.

`<command>` represents the command name. For the list of supported commands, see the Command list below. `<component>` represents the component name. For the list of supported components, see the Component list below.

11.4.7.2 Options

11.4.7.2.1 -B, –binary

- If you enable this option, the specified binary file path is printed.
  - Executing `tiup -B/--binary <component>` will have the path of the latest stable installed `<component>` component printed. If `<component>` is not installed, an error is returned.
  - Executing `tiup -B/--binary <component>:<version>` will have the path of the installed `<component>` component's `<version>` printed. If this `<version>` is not printed, an error is returned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

11.4.7.2.2 –binpath

> **Note:**
>
> This option can only be used in commands of the `tiup [flags] <component > [args...]` format.

- Specifies the path of the component to be executed. When a component is executed, if you do not want to use the binary file in the TiUP mirror, you can add this option to specify using the binary file in a custom path.
- Data type: `STRING`

11.4.7.2.3 –skip-version-check

Note:

This option is deprecated since v1.3.0.

- Skips the validity check for version numbers. By default, the specified version number can only be the semantic version.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

11.4.7.2.4 -T, –tag

- Specifies a tag for the component to be started. Some components need to use disk storage during the execution, and TiUP allocates a temporary storage directory for this execution. If you want TiUP to allocate a fixed directory, you can use `-T/--tag` to specify the name of the directory, so that the same batch of files can be read and written in multiple executions with the same tag.
- Data type: `STRING`

11.4.7.2.5 -v, –version

Prints the TiUP version.

11.4.7.2.6 –help

Prints the help information.

11.4.7.3 Command list

TiUP has multiple commands, and these commands have multiple sub-commands. For the specific commands and their detailed descriptions, click the corresponding links in the list below:

- install: Installs a component.
- list: Shows the component list.
- uninstall: Uninstalls a component.
- update: Updates the installed component.
- status: Shows the running status of a component.
- clean: Cleans the data directory of a component.
- mirror: Manages the mirror.

- telemetry: Enables or disables the telemetry.
- completion: Completes the TiUP command.
- env: Shows the TiUP-related environment variables.
- help: Shows the help information of a command or component.

11.4.7.4 Component list

- cluster: Manages the TiDB cluster in a production environment.
- dm: Manages the TiDB Data Migration (DM) cluster in a production environment.

11.4.8 Topology Configuration File for TiDB Deployment Using TiUP

To deploy or scale TiDB using TiUP, you need to provide a topology file (sample) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

11.4.8.1 File structure

A topology configuration file for TiDB deployment using TiUP might contain the following sections:

- global: The cluster's global configuration. Some of the configuration items use the default values and you can configure them separately in each instance.
- monitored: Configuration for monitoring services, namely, the blackbox_exporter and the `node_exporter`. On each machine, a `node_exporter` and a `blackbox_exporter` are deployed.
- server_configs: Components' global configuration. You can configure each component separately. If an instance has a configuration item with the same name, the instance's configuration item will take effect.
- pd_servers: The configuration of the PD instance. This configuration specifies the machines to which the PD component is deployed.
- tidb_servers: The configuration of the TiDB instance. This configuration specifies the machines to which the TiDB component is deployed.
- tikv_servers: The configuration of the TiKV instance. This configuration specifies the machines to which the TiKV component is deployed.
- tiflash_servers: The configuration of the TiFlash instance. This configuration specifies the machines to which the TiFlash component is deployed.
- pump_servers: The configuration of the Pump instance. This configuration specifies the machines to which the Pump component is deployed.
- drainer_servers: The configuration of the Drainer instance. This configuration specifies the machines to which the Drainer component is deployed.

- cdc_servers: The configuration of the TiCDC instance. This configuration specifies the machines to which the TiCDC component is deployed.
- tispark_masters: The configuration of the TiSpark master instance. This configuration specifies the machines to which the TiSpark master component is deployed. Only one node of TiSpark master can be deployed.
- tispark_workers: The configuration of the TiSpark worker instance. This configuration specifies the machines to which the TiSpark worker component is deployed.
- monitoring_servers: Specifies the machines to which Prometheus is deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- grafana_servers: The configuration of the Grafana instance. This configuration specifies the machines to which Grafana is deployed.
- alertmanager_servers: The configuration of the Alertmanager instance. This configuration specifies the machines to which Alertmanager is deployed.

11.4.8.1.1 `global`

The `global` section corresponds to the cluster's global configuration and has the following fields:

- `user`: The user used to start the deployed cluster. The default value is `"tidb"`. If the user specified in the `<user>` field does not exist on the target machine, this user is automatically created.
- `group`: The user group to which a user belongs. It is specified when the user is created. The value defaults to that of the `<user>` field. If the specified group does not exist, it is automatically created.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. The default value is `22`.
- `enable_tls`: Specifies whether to enable TLS for the cluster. After TLS is enabled, the generated TLS certificate must be used for connections between components or between the client and the component. The default value is `false`.
- `deploy_dir`: The deployment directory of each component. The default value is `"deployed"`. Its application rules are as follows:
  - If the absolute path of `deploy_dir` is configured at the instance level, the actual deployment directory is `deploy_dir` configured for the instance.
  - For each instance, if you do not configure `deploy_dir`, its default value is the relative path `<component-name>-<component-port>`.
  - If `global.deploy_dir` is an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
  - If `global.deploy_dir` is a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.

- `data_dir`: The data directory. Default value: `"data"`. Its application rules are as follows:
  - If the absolute path of `data_dir` is configured at the instance level, the actual deployment directory is `data_dir` configured for the instance.
  - For each instance, if you do not configure `data_dir`, its default value is `<global.data_dir>`.
  - If `data_dir` is a relative path, the component data is placed in `<deploy_dir>/<data_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.
- `log_dir`: The data directory. Default value: `"log"`. Its application rules are as follows:
  - If the absolute path `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
  - For each instance, if you not configure `log_dir`, its default value is `<global.log_dir>`.
  - If `log_dir` is a relative path, the component log is placed in `<deploy_dir>/<log_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.
- `os`: The operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is "linux".
- `arch`: The CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are "amd64" and "arm64". The default value is "amd64".
- `resource_control`: Runtime resource control. All configurations in this field are written into the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
  - `memory_limit`: Limits the maximum runtime memory. For example, "2G" means that the maximum memory of 2 GB can be used.
  - `cpu_quota`: Limits the maximum CPU usage at runtime. For example, "200%".
  - `io_read_bandwidth_max`: Limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.
  - `io_write_bandwidth_max`: Limits maximum I/O bandwidth for disk writes. For example, `/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M`.
  - `limit_core`: Controls the size of core dump.

A `global` configuration example is as follows:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the above configuration, the `tidb` user is used to start the cluster. At the same time, each component is restricted to a maximum of 2 GB of memory when it is running.

11.4.8.1.2 `monitored`

`monitored` is used to configure the monitoring service on the target machine: `node_exporter` and `blackbox_exporter`. The following fields are included:

- `node_exporter_port`: The service port of `node_exporter`. The default value is `9100`.
- `blackbox_exporter_port`: The service port of `blackbox_exporter`. The default value is `9115`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

A `monitored` configuration example is as follows:

```
monitored:
  node_exporter_port: 9100
  blackbox_exporter_port: 9115
```

The above configuration specifies that `node_exporter` uses the `9100` port and `blackbox_exporter` uses the `9115` port.

11.4.8.1.3 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configuration of this section can be overwritten by the configurations with the same names in an instance. `server_configs` mainly includes the following fields:

- `tidb`: TiDB service-related configuration. For the complete configuration, see TiDB configuration file.
- `tikv`: TiKV service-related configuration. For the complete configuration, see TiKV configuration file.
- `pd`: PD service-related configuration. For the complete configuration, see PD configuration file.
- `tiflash`: TiFlash service-related configuration. For the complete configuration, see TiFlash configuration file.
- `tiflash_learner`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `pump`: Pump service-related configuration. For the complete configuration, see TiDB Binlog configuration file.
- `drainer`: Drainer service-related configuration. For the complete configuration, see TiDB Binlog configuration file.
- `cdc`: TiCDC service-related configuration. For the complete configuration, see Deploy TiCDC.

A `server_configs` configuration example is as follows:

```
server_configs:
  tidb:
    run-ddl: true
    lease: "45s"
    split-table: true
    token-limit: 1000
  tikv:
    log-level: "info"
    readpool.unified.min-thread-count: 1
```

The above configuration specifies the global configuration of TiDB and TiKV.

11.4.8.1.4 `pd_servers`

`pd_servers` specifies the machines to which PD services are deployed. It also specifies the service configuration on each machine. `pd_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the PD services are deployed. The field value is an IP address and is mandatory.

- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `name`: Specifies the name of the PD instance. Different instances must have unique names; otherwise, instances cannot be deployed.
- `client_port`: Specifies the port that PD uses to connect to the client. The default value is 2379.
- `peer_port`: Specifies the port for communication between PDs. The default value is 2380.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `pd` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pd` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- host
- listen_host
- name
- client_port
- peer_port
- deploy_dir
- data_dir
- log_dir
- arch
- os

A pd_servers configuration example is as follows:

```
pd_servers:
  - host: 10.0.1.11
    config:
      schedule.max-merge-region-size: 20
      schedule.max-merge-region-keys: 200000
  - host: 10.0.1.12
```

The above configuration specifies that PD will be deployed on 10.0.1.11 and 10.0.1.12, and makes specific configurations for the PD of 10.0.1.11.

11.4.8.1.5 tidb_servers

tidb_servers specifies the machines to which TiDB services are deployed. It also specifies the service configuration on each machine. tidb_servers is an array, and each element of the array contains the following fields:

- host: Specifies the machine to which the TiDB services are deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: The listening port of TiDB services, which is used to provide connection to the MySQL client. The default value is 4000.
- status_port: The listening port of the TiDB status service, which is used to view the status of the TiDB services from the external via HTTP requests. The default value is 10080.

- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tidb` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tidb` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`
- `log_dir`
- `arch`
- `os`

A `tidb_servers` configuration example is as follows:

```
tidb_servers:
  - host: 10.0.1.14
    config:
      log.level: warn
```

```
    log.slow-query-file: tidb-slow-overwrited.log
  - host: 10.0.1.15
```

11.4.8.1.6 `tikv_servers`

`tikv_servers` specifies the machines to which TiKV services are deployed. It also specifies the service configuration on each machine. `tikv_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiKV services are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the TiKV services. The default value is `20160`.
- `status_port`: The listening port of the TiKV status service. The default value is `20180`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tikv` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tikv` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.

- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `tikv_servers` configuration example is as follows:

```
tikv_servers:
  - host: 10.0.1.14
    config:
      server.labels: { zone: "zone1", host: "host1" }
  - host: 10.0.1.15
    config:
      server.labels: { zone: "zone1", host: "host2" }
```

11.4.8.1.7 `tiflash_servers`

`tiflash_servers` specifies the machines to which TiFlash services are deployed. It also specifies the service configuration on each machine. This section is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiFlash services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `tcp_port`: The port of the TiFlash TCP service. The default value is `9000`.

- `http_port`: The port of the TiFlash HTTP service. The default value is `8123`.
- `flash_service_port`: The port via which TiFlash provides services. TiDB reads data from TiFlash via this port. The default value is `3930`.
- `metrics_port`: TiFlash's status port, which is used to output metric data. The default value is `8234`.
- `flash_proxy_port`: The port of the built-in TiKV. The default value is `20170`.
- `flash_proxy_status_port`: The status port of the built-in TiKV. The default value is `20292`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`. TiFlash supports multiple `data_dir` directories separated by commas.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `tmp_path`: The storage path of TiFlash temporary files. The default value is [`path` or the first directory of `storage.latest.dir`] + "/tmp".
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `tiflash` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiflash` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `learner_config`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

After the deployment, for the fields above, you can only add directories to `data_dir`; for the fields below, you cannot modified these fields:

- `host`
- `tcp_port`
- `http_port`
- `flash_service_port`
- `flash_proxy_port`
- `flash_proxy_status_port`
- `metrics_port`
- `deploy_dir`
- `log_dir`
- `tmp_path`
- `arch`
- `os`

A `tiflash_servers` configuration example is as follows:

```
tiflash_servers:
  - host: 10.0.1.21
  - host: 10.0.1.22
```

11.4.8.1.8 `pump_servers`

`pump_servers` specifies the machines to which the Pump services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `pump_servers` is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the Pump services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Pump services. The default value is `8250`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.

- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `pump` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pump` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pump_servers` configuration example is as follows:

```
pump_servers:
  - host: 10.0.1.21
    config:
      gc: 7
  - host: 10.0.1.22
```

11.4.8.1.9 `drainer_servers`

`drainer_servers` specifies the machines to which the Drainer services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `drainer_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Drainer services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of Drainer services. The default value is `8249`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `commit_ts`: When Drainer starts, it reads the checkpoint. If Drainer cannot read the checkpoint, it uses this field as the replication time point for the initial startup. This field defaults to `-1` (Drainer always gets the latest timestamp from the PD as the commit_ts).
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The configuration rule of this field is the same as the `drainer` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `drainer` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `commit_ts`
- `arch`
- `os`

A `drainer_servers` configuration example is as follows:

```
drainer_servers:
  - host: 10.0.1.21
    config:
      syncer.db-type: "mysql"
      syncer.to.host: "127.0.0.1"
      syncer.to.user: "root"
      syncer.to.password: ""
      syncer.to.port: 3306
      syncer.ignore-table:
        - db-name: test
          tbl-name: log
        - db-name: test
          tbl-name: audit
```

11.4.8.1.10 `cdc_servers`

`cdc_servers` specifies the machines to which the TiCDC services are deployed. It also specifies the service configuration on each machine. `cdc_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiCDC services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.

- `port`: The listening port of the TiCDC services. The default value is `8300`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir:` Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `gc-ttl`: The Time To Live (TTL) duration of the service level GC safepoint set by TiCDC in PD, in seconds. The default value is `86400`, which is 24 hours.
- `tz`: The time zone that the TiCDC services use. TiCDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `config`: The field content is merged with the `cdc` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`

- log_dir
- arch
- os

A cdc_servers configuration example is as follows:

```
cdc_servers:
  - host: 10.0.1.20
    gc-ttl: 86400
    data_dir: "/cdc-data"
  - host: 10.0.1.21
    gc-ttl: 86400
    data_dir: "/cdc-data"
```

11.4.8.1.11 tispark_masters

tispark_masters specifies the machines to which the master node of TiSpark is deployed. It also specifies the service configuration on each machine. tispark_masters is an array. Each array element contains the following fields:

- host: Specifies the machine to which the TiSpark master is deployed. The field value is an IP address and is mandatory.
- listen_host: When the machine has multiple IP addresses, listen_host specifies the listening IP address of the service. The default value is 0.0.0.0.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- port: Spark's listening port, used for communication before the node. The default value is 7077.
- web_port: Spark's web port, which provides web services and the task status. The default value is 8080.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- java_home: Specifies the path of the JRE environment to be used. This parameter corresponds to the JAVA_HOME system environment variable.
- spark_config: Configures to configure the TiSpark services. Then, a configuration file is generated and sent to the machine specified in host.
- spark_env: Configures the environment variables when Spark starts.

- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_masters` configuration example is as follows:

```
tispark_masters:
  - host: 10.0.1.21
    spark_config:
      spark.driver.memory: "2g"
      spark.eventLog.enabled: "False"
      spark.tispark.grpc.framesize: 2147483647
      spark.tispark.grpc.timeout_in_sec: 100
      spark.tispark.meta.reload_period_in_sec: 60
      spark.tispark.request.command.priority: "Low"
      spark.tispark.table.scan_concurrency: 256
    spark_env:
      SPARK_EXECUTOR_CORES: 5
      SPARK_EXECUTOR_MEMORY: "10g"
      SPARK_WORKER_CORES: 5
      SPARK_WORKER_MEMORY: "10g"
  - host: 10.0.1.22
```

11.4.8.1.12 `tispark_workers`

`tispark_workers` specifies the machines to which the worker nodes of TiSpark are deployed. It also specifies the service configuration on each machine. `tispark_workers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark workers are deployed. The field value is an IP address and is mandatory.

- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path in which the JRE environment to be used is located. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_workers` configuration example is as follows:

```
tispark_workers:
  - host: 10.0.1.22
  - host: 10.0.1.23
```

11.4.8.1.13 `monitoring_servers`

`monitoring_servers` specifies the machines to which the Prometheus services are deployed. It also specifies the service configuration on each machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the monitoring services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Prometheus services. The default value is `9090`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as "0,1".
- `storage_retention`: The retention time of the Prometheus monitoring data. The default value is `"30d"`.
- `rule_dir`: Specifies a local directory that should contain complete `*.rules.yml` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the rules for Prometheus.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
  - `remote_write`: See the Prometheus document `<remote_write>`.
  - `remote_read`: See the Prometheus document `<remote_read>`.
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:
  - host: 10.0.1.11
    rule_dir: /local/rule/dir
    remote_config:
      remote_write:
      - queue_config:
          batch_send_deadline: 5m
          capacity: 100000
          max_samples_per_send: 10000
          max_shards: 300
        url: http://127.0.0.1:8003/write
      remote_read:
      - url: http://127.0.0.1:8003/read
      external_alertmanagers:
      - host: 10.1.1.1
        web_port: 9093
      - host: 10.1.1.2
        web_port: 9094
```

11.4.8.1.14 `grafana_servers`

`grafana_servers` specifies the machines to which the Grafana services are deployed. It also specifies the service configuration on each machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the Grafana services are deployed. The field value is an IP address and is mandatory.

- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: The listening port of the Grafana services. The default value is `3000`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `username`: The user name on the Grafana login interface.
- `password`: The password corresponding to Grafana.
- `dashboard_dir`: Specifies a local directory that should contain complete `dashboard (*.json)` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the dashboards for Grafana.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

Note:

If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. For the `*.json` files in the local dashboards directory, update the value of the `datasource` field to the new cluster name (because `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`

- deploy_dir
- arch
- os

A grafana_servers configuration example is as follows:

```
grafana_servers:
  - host: 10.0.1.11
    dashboard_dir: /local/dashboard/dir
```

11.4.8.1.15 alertmanager_servers

alertmanager_servers specifies the machines to which the Alertmanager services are deployed. It also specifies the service configuration on each machine. alertmanager_servers is an array. Each array element contains the following fields:

- host: Specifies the machine to which the Alertmanager services are deployed. The field value is an IP address and is mandatory.
- ssh_port: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the ssh_port of the global section is used.
- web_port: Specifies the port used that Alertmanager uses to provide web services. The default value is 9093.
- cluster_port: Specifies the communication port between one Alertmanger and other Alertmanager. The default value is 9094.
- deploy_dir: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the deploy_dir directory configured in global.
- data_dir: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the data_dir directory configured in global.
- log_dir: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the log_dir directory configured in global.
- numa_node: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has numactl installed. If this field is specified, cpubind and membind policies are allocated using numactl. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- config_file: Specifies a local file that is transferred to the target machine during the initialization phase of the cluster configuration as the configuration of Alertmanager.

- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
  - host: 10.0.1.11
    config_file: /local/config/file
  - host: 10.0.1.12
    config_file: /local/config/file
```

11.4.9 TiUP Mirror Reference Guide

TiUP mirrors are TiUP's component warehouse, which stores components and their metadata. TiUP mirrors take the following two forms:

- Directory on the local disk: serves the local TiUP client, which is called a local mirror in this document.
- HTTP mirror started based on the remote disk directory: serves the remote TiUP client, which is called a remote mirror in this document.

11.4.9.1 Create and update mirror

You can create a TiUP mirror using one of the following two methods:

- Execute `tiup mirror init` to create a mirror from scratch.
- Execute `tiup mirror clone` to clone from an existing mirror.

After the mirror is created, you can add components to or delete components from the mirror using the `tiup mirror` commands. TiUP updates a mirror by adding files and assigning a new version number to it, rather than deleting any files from the mirror.

11.4.9.2 Mirror structure

A typical mirror structure is as follows:

```
+ <mirror-dir>                                  # Mirror's root directory
|-- root.json                                   # Mirror's root certificate
|-- {2..N}.root.json                            # Mirror's root certificate
|-- {1..N}.index.json                           # Component/user index
|-- {1..N}.{component}.json                     # Component metadata
|-- {component}-{version}-{os}-{arch}.tar.gz # Component binary package
|-- snapshot.json                               # Mirror's latest snapshot
|-- timestamp.json                              # Mirror's latest timestamp
|--+ commits                                    # Mirror's update log (deletable)
   |--+ commit-{ts1..tsN}
      |-- {N}.root.json
      |-- {N}.{component}.json
      |-- {N}.index.json
      |-- {component}-{version}-{os}-{arch}.tar.gz
      |-- snapshot.json
      |-- timestamp.json
|--+ keys                                       # Mirror's private key (can be
   ↪ moved to other locations)
   |-- {hash1..hashN}-root.json                 # Private key of the root
      ↪ certificate
   |-- {hash}-index.json                        # Private key of the indexes
   |-- {hash}-snapshot.json                     # Private key of the snapshots
   |-- {hash}-timestamp.json                    # Private key of the timestamps
```

Note:

- The `commits` directory stores the logs generated in the process of mirror update and is used to roll back the mirror. You can delete the old log directories regularly when the disk space is insufficient.

- The private key stored in the `keys` directory is sensitive. It is recommended to keep it separately.

11.4.9.2.1 Root directory

In a TiUP mirror, the root certificate is used to store the public key of other metadata files. Each time any metadata file (`*.json`) is obtained, TiUP client needs to find the corresponding public key in the installed `root.json` based on the metadata file type (root, index, snapshot, timestamp). Then TiUP client uses the public key to verify whether the signature is valid.

The root certificate's format is as follows:

```
{
    "signatures": [                                         # Each metadata file
        ↪  has some signatures which are signed by several private keys
        ↪ corresponding to the file.
        {
            "keyid": "{id-of-root-key-1}",                  # The ID of the
                ↪ first private key that participates in the signature. This
                ↪ ID is obtained by hashing the content of the public key
                ↪ that corresponds to the private key.
            "sig": "{signature-by-root-key-1}"              # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {                                             # The signed part.
        "_type": "root",                                    # The type of this
            ↪ file. root.json's type is root.
        "expires": "{expiration-date-of-this-file}",        # The expiration
            ↪ time of the file. If the file expires, the client rejects the
            ↪ file.
        "roles": {                                          # Records the keys
            ↪ used to sign each metadata file.
            "{role:index,root,snapshot,timestamp}": {       # Each involved
                ↪ metadata file includes index, root, snapshot, and timestamp
                ↪ .
```

```
            "keys": {                                   # Only the key's
                ↪ signature recorded in `keys` is valid.
                "{id-of-the-key-1}": {                  # The ID of the
                    ↪ first key used to sign {role}.
                    "keytype": "rsa",                   # The key's type.
                        ↪ Currently, the key type is fixed as rsa.
                    "keyval": {                         # The key's payload.
                        "public": "{public-key-content}" # The public key's
                            ↪  content.
                    },
                    "scheme": "rsassa-pss-sha256"       # Currently, the
                        ↪ scheme is fixed as rsassa-pss-sha256.
                },
                "{id-of-the-key-N}": {                  # The ID of the Nth
                    ↪ key used to sign {role}.
                    "keytype": "rsa",
                    "keyval": {
                        "public": "{public-key-content}"
                    },
                    "scheme": "rsassa-pss-sha256"
                }
            },
            "threshold": {N},                           # Indicates that the
                ↪  metadata file needs at least N key signatures.
            "url": "/{role}.json"                       # The address from
                ↪ which the file can be obtained. For index files, prefix
                ↪  it with the version number (for example, /{N}.index.
                ↪ json).
        }
    },
    "spec_version": "0.1.0",                            # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": {N}                                      # The version number
        ↪  of this file. You need to create a new {N+1}.root.json every
        ↪ time you update the file, and set its version to N + 1.
  }
}
```

11.4.9.2.2 Index

The index file records all the components in the mirror and the owner information of the components.

The index file's format is as follows:

```
{
    "signatures": [                                         # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "index",                                   # The file type.
        "components": {                                     # The component list
            ↪ .
            "{component1}": {                               # The name of the
                ↪ first component.
                "hidden": {bool},                           # Whether it is a
                    ↪ hidden component.
                "owner": "{owner-id}",                      # The component
                    ↪ owner's ID.
                "standalone": {bool},                       # Whether it is a
                    ↪ standalone component.
                "url": "/{component}.json",                 # The address from
                    ↪ which the component can be obtained. You need to prefix
                    ↪  it with the version number (for example, /{N}.{
                    ↪ component}.json).
                "yanked": {bool}                            # Indicates whether
                    ↪ the component is marked as deleted.
            },
            ...
            "{componentN}": {                               # The name of the
                ↪ Nth component.
                ...
            },
        },
        "default_components": ["{component1}".."{componentN}"], # The default
```

```
    ↪  component that a mirror must contain. Currently, this field
    ↪ defaults to empty (disabled).
"expires": "{expiration-date-of-this-file}",     # The expiration
    ↪ time of the file. If the file expires, the client rejects the
    ↪ file.
"owners": {
    "{owner1}": {                                # The ID of the
       ↪ first owner.
        "keys": {                                # Only the key's
           ↪ signature recorded in `keys` is valid.
            "{id-of-the-key-1}": {               # The first key of
               ↪ the owner.
                "keytype": "rsa",                # The key's type.
                   ↪ Currently, the key type is fixed as rsa.
                "keyval": {                      # The key's payload.
                    "public": "{public-key-content}" # The public key's
                       ↪  content.
                },
                "scheme": "rsassa-pss-sha256"    # Currently, the
                   ↪ scheme is fixed as rsassa-pss-sha256.
            },
            ...
            "{id-of-the-key-N}": {               # The Nth key of the
               ↪  owner.
                ...
            }
        },
        "name": "{owner-name}",                  # The name of the
           ↪ owner.
        "threshod": {N}                          # Indicates that the
           ↪  components owned by the owner must have at least N
           ↪ valid signatures.
    },
    ...
    "{ownerN}": {                                # The ID of the Nth
       ↪ owner.
        ...
    }
}
"spec_version": "0.1.0",                         # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
"version": {N}                                   # The version number
    ↪  of this file. You need to create a new {N+1}.index.json every
```

```
            ↪  time you update the file, and set its version to N + 1.
    }
}
```

11.4.9.2.3 Component

The component's metadata file records information of the component-specific platform and the version.

The component metadata file's format is as follows:

```
{
    "signatures": [                                     # The file's
       ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",             # The ID of the
               ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",        # The signed part of
               ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",              # The ID of the Nth
               ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"          # The signed part of
               ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "component",                           # The file type.
        "description": "{description-of-the-component}", # The description of
           ↪  the component.
        "expires": "{expiration-date-of-this-file}",    # The expiration
           ↪ time of the file. If the file expires, the client rejects the
           ↪ file.
        "id": "{component-id}",                         # The globally
           ↪ unique ID of the component.
        "nightly": "{nightly-cursor}",                  # The nightly cursor
           ↪ , and the value is the latest nightly version number (for
           ↪ example, v5.0.0-nightly-20201209).
        "platforms": {                                  # The component's
           ↪ supported platforms (such as darwin/amd64, linux/arm64).
            "{platform-pair-1}": {
                "{version-1}": {                        # The semantic
                   ↪ version number (for example, v1.0.0).
```

```
                "dependencies": null,                   # Specifies the
                    ↪ dependency relationship between components. The
                    ↪ field is not used yet and is fixed as null.
                "entry": "{entry}",                     # The relative path
                    ↪ of the entry binary file in the tar package.
                "hashs": {                              # The checksum of
                    ↪ the tar package. sha256 and sha512 are used.
                    "sha256": "{sum-of-sha256}",
                    "sha512": "{sum-of-sha512}",
                },
                "length": {length-of-tar},              # The length of the
                    ↪ tar package.
                "released": "{release-time}",           # The release date
                    ↪ of the version.
                "url": "{url-of-tar}",                  # The download
                    ↪ address of the tar package.
                "yanked": {bool}                        # Indicates whether
                    ↪ this version is disabled.
            }
        },
        ...
        "{platform-pair-N}": {
            ...
        }
    },
    "spec_version": "0.1.0",                            # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": {N}                                      # The version number
        ↪  of this file. You need to create a new {N+1}.{component}.json
        ↪  every time you update the file, and set its version to N + 1.
}
```

11.4.9.2.4 Snapshot

The snapshot file records the version number of each metadata file:

The snapshot file's structure is as follows:

```
{
    "signatures": [                                     # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",             # The ID of the
                ↪ first private key that participates in the signature.
```

```
        "sig": "{signature-by-index-key-1}",          # The signed part of
            ↪  this file by this private key.
    },
    ...
    {
        "keyid": "{id-of-root-key-N}",                # The ID of the Nth
            ↪ private key that participates in the signature.
        "sig": "{signature-by-root-key-N}"            # The signed part of
            ↪  this file by this private key.
    }
],
"signed": {
    "_type": "snapshot",                              # The file type.
    "expires": "{expiration-date-of-this-file}",      # The expiration
        ↪ time of the file. If the file expires, the client rejects the
        ↪ file.
    "meta": {                                         # Other metadata
        ↪ files' information.
        "/root.json": {
            "length": {length-of-json-file},          # The length of root
                ↪ .json
            "version": {version-of-json-file}         # The version of
                ↪ root.json
        },
        "/index.json": {
            "length": {length-of-json-file},
            "version": {version-of-json-file}
        },
        "/{component-1}.json": {
            "length": {length-of-json-file},
            "version": {version-of-json-file}
        },
        ...
        "/{component-N}.json": {
            ...
        }
    },
    "spec_version": "0.1.0",                          # The specified
        ↪ version followed by this file. If the file structure is
        ↪ changed in the future, the version number needs to be upgraded
        ↪ . The current version number is 0.1.0.
    "version": 0                                      # The version number
        ↪  of this file, which is fixed as 0.
}
```

11.4.9.2.5 Timestamp

The timestamp file records the checksum of the current snapshot.

The timestamp file's format is as follows:

```
{
    "signatures": [                                         # The file's
        ↪ signature.
        {
            "keyid": "{id-of-index-key-1}",                 # The ID of the
                ↪ first private key that participates in the signature.
            "sig": "{signature-by-index-key-1}",            # The signed part of
                ↪  this file by this private key.
        },
        ...
        {
            "keyid": "{id-of-root-key-N}",                  # The ID of the Nth
                ↪ private key that participates in the signature.
            "sig": "{signature-by-root-key-N}"              # The signed part of
                ↪  this file by this private key.
        }
    ],
    "signed": {
        "_type": "timestamp",                               # The file type.
        "expires": "{expiration-date-of-this-file}",        # The expiration
            ↪ time of the file. If the file expires, the client rejects the
            ↪ file.
        "meta": {                                           # The information of
            ↪  snapshot.json.
            "/snapshot.json": {
                "hashes": {
                    "sha256": "{sum-of-sha256}"             # snapshot.json's
                        ↪ sha256.
                },
                "length": {length-of-json-file}             # The length of
                    ↪ snapshot.json.
            }
        },
        "spec_version": "0.1.0",                            # The specified
            ↪ version followed by this file. If the file structure is
            ↪ changed in the future, the version number needs to be upgraded
            ↪ . The current version number is 0.1.0.
        "version": {N}                                      # The version number
            ↪  of this file. You need to overwrite timestamp.json every time
            ↪  you update the file, and set its version to N + 1.
```

11.4.9.3 Client workflow

The client uses the following logic to ensure that the files downloaded from the mirror are safe:

- A `root.json` file is included with the binary when the client is installed.
- The running client performs the following tasks based on the existing `root.json`:
    1. Obtain the version from `root.json` and mark it as `N`.
    2. Request `{N+1}.root.json` from the mirror. If the request is successful, use the public key recorded in `root.json` to verify whether the file is valid.
    3. Request `timestamp.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    4. Check whether the checksum of `snapshot.json` recorded in `timestamp.json` matches the checksum of the local `snapshot.json`. If the two do not match, request the latest `snapshot.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
    5. Obtain the version number `N` of the `index.json` file from `snapshot.json` and request `{N}.index.json` from the mirror. Then use the public key recorded in `root.json` to verify whether the file is valid.
    6. For components such as `tidb.json` and `tikv.json`, the client obtains the version numbers `N` of the components from `snapshot.json` and requests `{N}.{component}.json` from the mirror. Then the client uses the public key recorded in `index.json` to verify whether the file is valid.
    7. For component's tar files, the client obtains the URLs and checksums of the files from `{component}.json` and request the URLs for the tar packages. Then the client verifies whether the checksum is correct.

11.4.10 TiUP Components

11.4.10.1 Quickly Deploy a Local TiDB Cluster

The TiDB cluster is a distributed system that consists of multiple components. A typical TiDB cluster consists of at least three PD nodes, three TiKV nodes, and two TiDB nodes. If you want to have a quick experience on TiDB, you might find it time-consuming and complicated to manually deploy so many components. This document introduces the playground component of TiUP and how to use it to quickly build a local TiDB test environment.

11.4.10.1.1 TiUP playground overview

The basic usage of the playground component is shown as follows:

```
tiup playground ${version} [flags]
```

If you directly execute the `tiup playground` command, TiUP uses the locally installed TiDB, TiKV, and PD components or installs the stable version of these components to start a TiDB cluster that consists of one TiKV instance, one TiDB instance, and one PD instance.

This command actually performs the following operations:

- Because this command does not specify the version of the playground component, TiUP first checks the latest version of the installed playground component. Assume that the latest version is v1.5.0, then this command works the same as `tiup playground:v1.5.0`.
- If you have not used TiUP playground to install the TiDB, TiKV, and PD components, the playground component installs the latest stable version of these components, and then start these instances.
- Because this command does not specify the version of the TiDB, PD, and TiKV component, TiUP playground uses the latest version of each component by default. Assume that the latest version is v5.1.5, then this command works the same as `tiup playground:v1.5.0 v5.1.5`.
- Because this command does not specify the number of each component, TiUP playground, by default, starts a smallest cluster that consists of one TiDB instance, one TiKV instance, and one PD instance.
- After starting each TiDB component, TiUP playground reminds you that the cluster is successfully started and provides you some useful information, such as how to connect to the TiDB cluster through the MySQL client and how to access the TiDB Dashboard.

The command-line flags of the playground component are described as follows:

```
Flags:
      --db int                TiDB instance number (default 1)
      --db.binpath string     TiDB instance binary path
      --db.config string      TiDB instance configuration file
      --db.host host          Set the listening address of TiDB
      --drainer int           Set the Drainer data of the cluster
      --drainer.binpath string Specify the location of the Drainer binary
         ↪ files (optional, for debugging)
      --drainer.config string Specify the Drainer configuration file
  -h, --help                  help for tiup
      --host string           Playground cluster host (default "127.0.0.1")
      --kv int                TiKV instance number (default 1)
      --kv.binpath string     TiKV instance binary path
      --kv.config string      TiKV instance configuration file
      --monitor               Start prometheus component
      --pd int                PD instance number (default 1)
      --pd.binpath string     PD instance binary path
      --pd.config string      PD instance configuration file
      --pump int              Specify the number of Pump nodes in the cluster
         ↪ . If the value is not "0", TiDB Binlog is enabled.
      --pump.binpath string   Specify the location of the Pump binary files (
         ↪ optional, for debugging)
      --pump.config string    Specify the Pump configuration file (optional,
         ↪ for debugging)
```

```
      --tiflash int           TiFlash instance number
      --tiflash.binpath string TiFlash instance binary path
      --tiflash.config string TiFlash instance configuration file
```

11.4.10.1.2 Examples

Check available TiDB versions

```
tiup list tidb
```

Start a TiDB cluster of a specific version

```
tiup playground ${version}
```

Replace `${version}` with the target version number.

Start a TiDB cluster of the nightly version

```
tiup playground nightly
```

In the command above, `nightly` indicates the latest development version of TiDB.

Override PD's default configuration

First, you need to copy the PD configuration template. Assume you place the copied file to `~/config/pd.toml` and make some changes according to your need, then you can execute the following command to override PD's default configuration:

```
tiup playground --pd.config ~/config/pd.toml
```

Replace the default binary files

By default, when playground is started, each component is started using the binary files from the official mirror. If you want to put a temporarily compiled local binary file into the cluster for testing, you can use the `--{comp}.binpath` flag for replacement. For example, execute the following command to replace the binary file of TiDB:

```
tiup playground --db.binpath /xx/tidb-server
```

Start multiple component instances

By default, only one instance is started for each TiDB, TiKV, and PD component. To start multiple instances for each component, add the following flag:

```
tiup playground --db 3 --pd 3 --kv 3
```

11.4.10.1.3 Quickly connect to the TiDB cluster started by playground

TiUP provides the `client` component, which is used to automatically find and connect to a local TiDB cluster started by playground. The usage is as follows:

```
tiup client
```

This command provides a list of TiDB clusters that are started by playground on the current machine on the console. Select the TiDB cluster to be connected. After clicking Enter, a built-in MySQL client is opened to connect to TiDB.

11.4.10.1.4 View information of the started cluster

```
tiup playground display
```

The command above returns the following results:

```
Pid   Role    Uptime
---   ----    ------
84518 pd      35m22.929404512s
84519 tikv    35m22.927757153s
84520 pump    35m22.92618275s
86189 tidb    exited
86526 tidb    34m28.293148663s
86190 drainer 35m19.91349249s
```

11.4.10.1.5 Scale out a cluster

The command-line parameter for scaling out a cluster is similar to that for starting a cluster. You can scale out two TiDB instances by executing the following command:

```
tiup playground scale-out --db 2
```

11.4.10.1.6 Scale in clusters

You can specify a `pid` in the `tiup playground scale-in` command to scale in the corresponding instance. To view the `pid`, execute `tiup playground display`.

```
tiup playground scale-in --pid 86526
```

11.4.10.2 Deploy and Maintain an Online TiDB Cluster Using TiUP

This document focuses on how to use the TiUP cluster component. For the complete steps of online deployment, refer to Deploy a TiDB Cluster Using TiUP.

Similar to the TiUP playground component used for a local test deployment, the TiUP cluster component quickly deploys TiDB for production environment. Compared with playground, the cluster component provides more powerful production cluster management features, including upgrading, scaling, and even operation and auditing.

For the help information of the cluster component, run the following command:

```
tiup cluster
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.5.2/
    ↪ cluster
Deploy a TiDB cluster for production

Usage:
  cluster [flags]
  cluster [command]

Available Commands:
  check       Perform preflight checks for the cluster
  deploy      Deploy a cluster for production
  start       Start a TiDB cluster
  stop        Stop a TiDB cluster
  restart     Restart a TiDB cluster
  scale-in    Scale in a TiDB cluster
  scale-out   Scale out a TiDB cluster
  clean       Clean up cluster data
  destroy     Destroy a specified cluster
  upgrade     Upgrade a specified TiDB cluster
  exec        Run shell command on host in the tidb cluster
  display     Display information of a TiDB cluster
  list        List all clusters
  audit       Show audit log of cluster operation
  import      Import an exist TiDB cluster from TiDB Ansible
  edit-config Edit TiDB cluster config
  reload      Reload a TiDB cluster's config and restart if needed
  patch       Replace the remote package with a specified package and restart
     ↪  the service
  help        Help about any command

Flags:
  -h, --help              help for cluster
      --native-ssh        Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes               Skip all confirmations and assumes 'yes'
```

11.4.10.2.1 Deploy the cluster

To deploy the cluster, run the `tiup cluster deploy` command. The usage of the command is as follows:

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

This command requires you to provide the cluster name, the TiDB cluster version, and a topology file of the cluster.

To write a topology file, refer to the example. The following file is an example of the simplest topology:

> **Note:**
>
> The topology file used by the TiUP cluster component for deployment and scaling is written using yaml syntax, so make sure that the indentation is correct.

```
---

pd_servers:
  - host: 172.16.5.134
    name: pd-134
  - host: 172.16.5.139
    name: pd-139
  - host: 172.16.5.140
    name: pd-140

tidb_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

grafana_servers:
  - host: 172.16.5.134

monitoring_servers:
  - host: 172.16.5.134
```

By default, TiUP is deployed as the binary files running on the amd64 architecture. If the target machine is the arm64 architecture, you can configure it in the topology file:

```
global:
  arch: "arm64"        # Configures all machines to use the binary files of
     ↪ the arm64 architecture by default

tidb_servers:
  - host: 172.16.5.134
    arch: "amd64"      # Configures this machine to use the binary files of
       ↪ the amd64 architecture
  - host: 172.16.5.139
    arch: "arm64"      # Configures this machine to use the binary files of
       ↪ the arm64 architecture
  - host: 172.16.5.140 # Machines that are not configured with the arch
     ↪ field use the default value in the global field, which is arm64 in
     ↪ this case.

...
```

Save the file as `/tmp/topology.yaml`. If you want to use TiDB v5.1.5 and your cluster name is `prod-cluster`, run the following command:

```
tiup cluster deploy -p prod-cluster v5.1.5 /tmp/topology.yaml
```

During the execution, TiUP asks you to confirm your topology again and requires the root password of the target machine (the `-p` flag means inputting password):

```
Please confirm your topology:
TiDB Cluster: prod-cluster
TiDB Version: v5.1.5
Type       Host         Ports       Directories
----       ----         -----       -----------
pd         172.16.5.134 2379/2380  deploy/pd-2379,data/pd-2379
pd         172.16.5.139 2379/2380  deploy/pd-2379,data/pd-2379

tidb       172.16.5.139 4000/10080 deploy/tidb-4000
tidb       172.16.5.140 4000/10080 deploy/tidb-4000
prometheus 172.16.5.134 9090      deploy/prometheus-9090,data/prometheus
   ↪ -9090
grafana    172.16.5.134 3000      deploy/grafana-3000
Attention:
```

```
   1. If the topology is not what you expected, check your yaml file.
   2. Please confirm there is no port/directory conflicts in same host.
Do you want to continue? [y/N]:
```

After you enter the password, TiUP cluster downloads the required components and deploy them on the corresponding machines. When you see the following message, the deployment is successful:

```
Deployed cluster `prod-cluster` successfully
```

11.4.10.2.2 View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup cluster list
```

```
Starting /root/.tiup/components/cluster/v1.5.2/cluster list
Name         User Version   Path
   ↪ PrivateKey
----         ---- -------   ----
   ↪ ----------
prod-cluster tidb v5.1.4  /root/.tiup/storage/cluster/clusters/prod-cluster
   ↪  /root/.tiup/storage/cluster/clusters/prod-cluster/ssh/id_rsa
```

11.4.10.2.3 Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup cluster start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup cluster ↪ list`.

11.4.10.2.4 Check the cluster status

TiUP provides the `tiup cluster display` command to view the status of each component in the cluster. With this command, you don't have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.5.2/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v5.1.5
```

```

172.16.5.139:20160 tikv     172.16.5.139 20160/20180 Up       data/tikv
    ↪ -20160     deploy/tikv-20160
172.16.5.140:20160 tikv     172.16.5.140 20160/20180 Up       data/tikv
    ↪ -20160     deploy/tikv-20160
```

The `Status` column uses `Up` or `Down` to indicate whether the service is running normally.

For the PD component, `|L` or `|UI` might be appended to `Up` or `Down`. `|L` indicates that the PD node is a Leader, and `|UI` indicates that TiDB Dashboard is running on the PD node.

11.4.10.2.5 Scale in a cluster

> **Note:**
>
> This section describes only the syntax of the scale-in command. For detailed steps of online scaling, refer to Scale the TiDB Cluster Using TiUP.

Scaling in a cluster means making some node(s) offline. This operation removes the specific node(s) from the cluster and deletes the remaining files.

Because the offline process of the TiKV and TiDB Binlog components is asynchronous (which requires removing the node through API), and the process takes a long time (which requires continuous observation on whether the node is successfully taken offline), special treatment is given to the TiKV and TiDB Binlog components.

- For TiKV and Binlog:
  - TiUP cluster takes the node offline through API and directly exits without waiting for the process to be completed.
  - Afterwards, when a command related to the cluster operation is executed, TiUP cluster examines whether there is a TiKV/Binlog node that has been taken offline. If not, TiUP cluster continues with the specified operation; If there is, TiUP cluster takes the following steps:
    1. Stop the service of the node that has been taken offline.
    2. Clean up the data files related to the node.
    3. Remove the node from the cluster topology.
- For other components:
  - When taking the PD component down, TiUP cluster quickly deletes the specified node from the cluster through API, stops the service of the specified PD node, and deletes the related data files.
  - When taking other components down, TiUP cluster directly stops the node service and deletes the related data files.

The basic usage of the scale-in command:

```
tiup cluster scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two flags: the cluster name and the node ID. The node ID can be obtained by using the `tiup cluster display` command in the previous section.

For example, to make the TiKV node on `172.16.5.140` offline, run the following command:

```
tiup cluster scale-in prod-cluster -N 172.16.5.140:20160
```

By running `tiup cluster display`, you can see that the TiKV node is marked `Offline`:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.5.2/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v5.1.4
```

```
ID                  Role        Host          Ports       Status    Data Dir
    ↪               Deploy Dir
--                  ----        ----          -----       ------    --------
    ↪               ----------
172.16.5.134:3000 grafana   172.16.5.134 3000       Up        -
    ↪                     deploy/grafana-3000
172.16.5.134:2379 pd        172.16.5.134 2379/2380  Up|L      data/pd-2379
    ↪         deploy/pd-2379
172.16.5.139:2379 pd        172.16.5.139 2379/2380  Up|UI     data/pd-2379
    ↪         deploy/pd-2379
172.16.5.140:2379 pd        172.16.5.140 2379/2380  Up        data/pd-2379
    ↪         deploy/pd-2379
172.16.5.134:9090 prometheus 172.16.5.134 9090      Up        data/
    ↪ prometheus-9090 deploy/prometheus-9090
172.16.5.134:4000 tidb      172.16.5.134 4000/10080 Up        -
    ↪                     deploy/tidb-4000
172.16.5.139:4000 tidb      172.16.5.139 4000/10080 Up        -
    ↪                     deploy/tidb-4000
172.16.5.140:4000 tidb      172.16.5.140 4000/10080 Up        -
    ↪                     deploy/tidb-4000
172.16.5.134:20160 tikv     172.16.5.134 20160/20180 Up       data/tikv
    ↪ -20160    deploy/tikv-20160
172.16.5.139:20160 tikv     172.16.5.139 20160/20180 Up       data/tikv
    ↪ -20160    deploy/tikv-20160
172.16.5.140:20160 tikv     172.16.5.140 20160/20180 Offline data/tikv
    ↪ -20160    deploy/tikv-20160
```

After PD schedules the data on the node to other TiKV nodes, this node will be deleted automatically.

11.4.10.2.6 Scale out a cluster

> **Note:**
>
> This section describes only the syntax of the scale-out command. For detailed steps of online scaling, refer to Scale the TiDB Cluster Using TiUP.

The scale-out operation has an inner logic similar to that of deployment: the TiUP cluster component firstly ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

When you scale out PD, the node is added to the cluster by `join`, and the configurations of services associated with PD are updated. When you scale out other services, the service

is started directly and added to the cluster.

All services conduct correctness validation when they are scaled out. The validation results show whether the scaling-out is successful.

To add a TiKV node and a PD node in the `tidb-test` cluster, take the following steps:

1. Create a `scale.yaml` file, and add IPs of the new TiKV and PD nodes:

> **Note:**
> You need to create a topology file, which includes only the description of the new nodes, not the existing nodes.

```
---

pd_servers:
  - ip: 172.16.5.140

tikv_servers:
  - ip: 172.16.5.140
```

2. Perform the scale-out operation. TiUP cluster adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup cluster scale-out tidb-test scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup cluster display tidb-test`.

11.4.10.2.7 Rolling upgrade

> **Note:**
> This section describes only the syntax of the upgrade command. For detailed steps of online upgrade, refer to Upgrade TiDB Using TiUP.

The rolling upgrade feature leverages the distributed capabilities of TiDB. The upgrade process is made as transparent as possible to the application, and does not affect the business.

Before the upgrade, TiUP cluster checks whether the configuration file of each component is rational. If so, the components are upgraded node by node; if not, TiUP reports an error and exits. The operations vary with different nodes.

Operations for different nodes

- Upgrade the PD node
  - First, upgrade non-Leader nodes.
  - After all the non-Leader nodes are upgraded, upgrade the Leader node.
    * The upgrade tool sends a command to PD that migrates Leader to an already upgraded node.
    * After the Leader role is switched to another node, upgrade the previous Leader node.
  - During the upgrade, if any unhealthy node is detected, the tool stops this upgrade operation and exits. You need to manually analyze the cause, fix the issue and run the upgrade again.
- Upgrade the TiKV node
  - First, add a scheduling operation in PD that migrates the Region Leader of this TiKV node. This ensures that the upgrade process does not affect the business.
  - After the Leader is migrated, upgrade this TiKV node.
  - After the upgraded TiKV is started normally, remove the scheduling of the Leader.
- Upgrade other services
  - Stop the service normally and update the node.

Upgrade command

The flags for the upgrade command is as follows:

```
Usage:
  cluster upgrade <cluster-name> <version> [flags]

Flags:
      --force               Force upgrade won't transfer leader
  -h, --help                help for upgrade
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 300)

Global Flags:
      --native-ssh     Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes            Skip all confirmations and assumes 'yes'
```

For example, the following command upgrades the cluster to v5.1.5:

```
tiup cluster upgrade tidb-test v5.1.5
```

11.4.10.2.8 Update configuration

If you want to dynamically update the component configurations, the TiUP cluster component saves a current configuration for each cluster. To edit this configuration, execute the `tiup cluster edit-config <cluster-name>` command. For example:

```
tiup cluster edit-config prod-cluster
```

TiUP cluster opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano`.

After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup cluster reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

> **Note:**
>
> For monitoring components, customize the configuration by executing the `tiup cluster edit-config` command to add a custom configuration path on the corresponding instance. For example:

```
---

grafana_servers:
  - host: 172.16.5.134
    dashboard_dir: /path/to/local/dashboards/dir

monitoring_servers:
  - host: 172.16.5.134
    rule_dir: /path/to/local/rules/dir

alertmanager_servers:
  - host: 172.16.5.134
    config_file: /path/to/local/alertmanager.yml
```

The content and format requirements for files under the specified path are as follows:

- The folder specified in the `dashboard_dir` field of `grafana_servers` must contain full `*.json` files.
- The folder specified in the `rule_dir` field of `monitoring_servers` must contain full `*.rules.yml` files.
- For the format of files specified in the `config_file` field of `alertmanager_servers`, refer to the Alertmanager configuration template.

When you execute `tiup reload`, TiUP first deletes all old configuration files in the target machine and then uploads the corresponding configuration from the control machine to the corresponding configuration directory of the target machine. Therefore, if you want to modify a particular configuration file, make sure that all configuration files (including the unmodified ones) are in the same directory. For example, to modify Grafana's `tidb.json` file, you need to first copy all the `*.json` files from Grafana's `dashboards` directory to your local directory. Otherwise, other JSON files will be missing from the target machine.

Note:

If you have configured the `dashboard_dir` field of `grafana_servers`, after executing the `tiup cluster rename` command to rename the cluster, you need to complete the following operations:

1. In the local `dashboards` directory, change the cluster name to the new cluster name.
2. In the local `dashboards` directory, change `datasource` to the new cluster name, because `datasource` is named after the cluster name.
3. Execute the `tiup cluster reload -R grafana` command.

11.4.10.2.9 Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service

Usage:
  cluster patch <cluster-name> <package-path> [flags]

Flags:
  -h, --help                help for patch
  -N, --node strings        Specify the nodes
```

```
      --overwrite           Use this package in the future scale-out
          ↪ operations
  -R, --role strings        Specify the role
      --transfer-timeout int Timeout in seconds when transferring PD and
          ↪ TiKV store leaders (default 300)

Global Flags:
      --native-ssh      Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

11.4.10.2.10 Import TiDB Ansible cluster

> **Note:**
>
> Currently, TiUP cluster's support for TiSpark is still **experimental**. It is not supported to import a TiDB cluster with TiSpark enabled.

Before TiUP is released, TiDB Ansible is often used to deploy TiDB clusters. To enable TiUP to take over the cluster deployed by TiDB Ansible, use the `import` command.

The usage of the `import` command is as follows:

```
tiup cluster import --help
```

```
Import an exist TiDB cluster from TiDB-Ansible

Usage:
  cluster import [flags]

Flags:
  -d, --dir string      The path to TiDB-Ansible directory
```

```
  -h, --help            help for import
      --inventory string The name of inventory file (default "inventory.ini
         ↪ ")
      --no-backup       Don't backup ansible dir, useful when there're
         ↪ multiple inventory files
  -r, --rename NAME     Rename the imported cluster to NAME

Global Flags:
      --native-ssh     Use the system's native SSH client
      --wait-timeout int Timeout of waiting the operation
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
         ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

You can use either of the following commands to import a TiDB Ansible cluster:

```
cd tidb-ansible
tiup cluster import
```

```
tiup cluster import --dir=/path/to/tidb-ansible
```

11.4.10.2.11 View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
  tiup cluster audit [audit-id] [flags]

Flags:
  -h, --help help for audit
```

If the `[audit-id]` flag is not specified, the command shows a list of commands that have been executed. For example:

```
tiup cluster audit
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.5.2/
   ↪ cluster audit
ID     Time                      Command
--     ----                      -------
4BLhr0 2022-03-01T13:25:09+08:00 /home/tidb/.tiup/components/cluster/v1.5.2/
   ↪ cluster deploy test v5.1.5 /tmp/topology.yaml
4BKWjF 2022-02-28T23:36:57+08:00 /home/tidb/.tiup/components/cluster/v1.5.2/
   ↪ cluster deploy test v5.1.5 /tmp/topology.yaml
```

```
4BKVwH 2022-02-28T23:02:08+08:00 /home/tidb/.tiup/components/cluster/v1.5.2/
    ↪ cluster deploy test v5.1.5 /tmp/topology.yaml
4BKKH1 2022-02-28T16:39:04+08:00 /home/tidb/.tiup/components/cluster/v1.5.2/
    ↪ cluster destroy test
4BKKDx 2022-02-28T16:36:57+08:00 /home/tidb/.tiup/components/cluster/v1.5.2/
    ↪ cluster deploy test v5.1.5 /tmp/topology.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` of a command as the flag as follows:

```
tiup cluster audit 4BLhr0
```

11.4.10.2.12 Run commands on a host in the TiDB cluster

To run command on a host in the TiDB cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
  cluster exec <cluster-name> [flags]

Flags:
      --command string the command run on cluster host (default "ls")
  -h, --help           help for exec
  -N, --node strings   Only exec on host with specified nodes
  -R, --role strings   Only exec on host with specified roles
      --sudo           use root permissions (default false)

Global Flags:
      --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
          ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes             Skip all confirmations and assumes 'yes'
```

For example, to execute `ls /tmp` on all TiDB nodes, run the following command:

```
tiup cluster exec test-cluster --command='ls /tmp'
```

11.4.10.2.13 Cluster controllers

Before TiUP is released, you can control the cluster using `tidb-ctl`, `tikv-ctl`, `pd-ctl`, and other tools. To make the tools easier to download and use, TiUP integrates them into an all-in-one component, `ctl`.

```
Usage:
  tiup ctl:<cluster-version> {tidb/pd/tikv/binlog/etcd} [flags]

Flags:
  -h, --help help for tiup
```

This command has a corresponding relationship with those of the previous tools:

```
tidb-ctl [args] = tiup ctl tidb [args]
pd-ctl [args] = tiup ctl pd [args]
tikv-ctl [args] = tiup ctl tikv [args]
binlogctl [args] = tiup ctl bindlog [args]
etcdctl [args] = tiup ctl etcd [args]
```

For example, if you previously view the store by running `pd-ctl -u http://127.0.0.1:2379 store`, now you can run the following command in TiUP:

```
tiup ctl:<cluster-version> pd -u http://127.0.0.1:2379 store
```

11.4.10.2.14 Environment checks for target machines

You can use the `check` command to perform a series of checks on the environment of the target machine and output the check results. By executing the `check` command, you can find common unreasonable configurations or unsupported situations. The command flag list is as follows:

```
Usage:
  tiup cluster check <topology.yml | cluster-name> [flags]
Flags:
      --apply               Try to fix failed checks
      --cluster             Check existing cluster, the input is a cluster
         ↪ name.
      --enable-cpu          Enable CPU thread count check
      --enable-disk         Enable disk IO (fio) check
      --enable-mem          Enable memory size check
  -h, --help                help for check
  -i, --identity_file string The path of the SSH identity file. If specified
     ↪ , public key authentication will be used.
  -p, --password            Use password of target hosts. If specified,
     ↪ password authentication will be used.
      --user string         The user name to login via SSH. The user must
         ↪ has root (or sudo) privilege.
```

By default, this command is used to check the environment before deployment. By specifying the `--cluster` flag to switch the mode, you can also check the target machines of an existing cluster, for example:

```
#### check deployed servers before deployment
tiup cluster check topology.yml --user tidb -p
#### check deployed servers of an existing cluster
tiup cluster check <cluster-name> --cluster
```

The CPU thread count check, memory size check, and disk performance check are disabled by default. For the production environment, it is recommended that you enable the three checks and make sure they pass to obtain the best performance.

- CPU: If the number of threads is greater than or equal to 16, the check is passed.
- Memory: If the total size of physical memory is greater than or equal to 32 GB, the check is passed.
- Disk: Execute `fio` test on the partitions of `data_dir` and record the results.

When running the checks, if the `--apply` flag is specified, the program automatically repairs the failed items. Automatic repair is limited to some items that can be adjusted by modifying the configuration or system parameters. Other unrepaired items need to be handled manually according to the actual situation.

Environment checks are not necessary for deploying a cluster. For the production environment, it is recommended to perform environment checks and pass all check items before deployment. If not all the check items are passed, the cluster might be deployed and run normally, but the best performance might not be obtained.

11.4.10.2.15 Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--native-ssh` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup cluster deploy <cluster-name> <version> <topo> --native-ssh`
- Start a cluster: `tiup cluster start <cluster-name> --native-ssh`
- Upgrade a cluster: `tiup cluster upgrade ... --native-ssh`

You can add `--native-ssh` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
#### or
export TIUP_NATIVE_SSH=1
#### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--native-ssh` at the same time, `--native-ssh` has higher priority.

> **Note:**
>
> During the process of cluster deployment, if you need to use a password for connection (`-p`) or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

11.4.10.2.16 Migrate control machine and back up TiUP data

The TiUP data is stored in the `.tiup` directory in the user's home directory. To migrate the control machine, you can take the following steps to copy the `.tiup` directory to the corresponding target machine:

1. Execute `tar czvf tiup.tar.gz .tiup` in the home directory of the original machine.
2. Copy `tiup.tar.gz` to the home directory of the target machine.
3. Execute `tar xzvf tiup.tar.gz` in the home directory of the target machine.
4. Add the `.tiup` directory to the `PATH` environment variable.

   If you use `bash` and you are a `tidb` user, you can add `export PATH=/home/tidb/.tiup/bin:$PATH` in `~/.bashrc` and execute `source ~/.bashrc`. Then make corresponding adjustments according to the shell and the user you use.

> **Note:**
>
> It is recommended that you back up the `.tiup` directory regularly to avoid the loss of TiUP data caused by abnormal conditions, such as disk damage of the control machine.

11.4.10.3 Create a Private Mirror

When creating a private cloud, usually, you need to use an isolated network environment, where the official mirror of TiUP is not accessible. Therefore, you can create a private mirror, which is mainly implemented by the `mirror` command. You can also use the `mirror` command for offline deployment.

11.4.10.3.1 TiUP `mirror` overview

Execute the following command to get the help information of the `mirror` command:

```
tiup mirror --help
```

```
The 'mirror' command is used to manage a component repository for TiUP, you
    ↪  can use
it to create a private repository, or to add new component to an existing
    ↪ repository.
The repository can be used either online or offline.
It also provides some useful utilities to help managing keys, users and
    ↪ versions
of components or the repository itself.
Usage:
  tiup mirror <command> [flags]
Available Commands:
  init       Initialize an empty repository
  sign       Add signatures to a manifest file
  genkey     Generate a new key pair
  clone      Clone a local mirror from remote mirror and download all
      ↪ selected components
  publish    Publish a component
Flags:
  -h, --help       help for mirror
      --repo string Path to the repository
Global Flags:
      --skip-version-check Skip the strict version check, by default a
          ↪ version must be a valid SemVer string
Use "tiup mirror [command] --help" for more information about a command.
```

The `tiup mirror clone` command is used to build a local mirror. The basic usage is as follows:

```
tiup mirror clone <target-dir> [global-version] [flags]
```

- `target-dir`: used to specify the directory in which cloned data is stored.
- `global-version`: used to quickly set a global version for all components.

The `tiup mirror clone` command provides many optional flags (might provide more in the future). These flags can be divided into the following categories according to their intended usages:

- Determines whether to use prefix matching to match the version when cloning

  If the `--prefix` flag is specified, the version number is matched by prefix for the clone. For example, if you specify `--prefix` as "v5.0.0", then "v5.0.0-rc", and "v5.0.0" are matched.

- Determines whether to use the full clone

  If you specify the `--full` flag, you can clone the official mirror fully.

> **Note:**
> If `--full`, `global-version` flags, and the component versions are not specified, only some meta information is cloned.

- Determines whether to clone packages from the specific platform

  If you want to clone packages only for a specific platform, use `-os` and `-arch` to specify the platform. For example:

  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux` command to clone for linux.
  - Execute the `tiup mirror clone <target-dir> [global-version] --arch=amd64` command to clone for amd64.
  - Execute the `tiup mirror clone <target-dir> [global-version] --os=linux --arch=amd64` command to clone for linux/amd64.

- Determines whether to clone a specific version of a package

  If you want to clone only one version (not all versions) of a component, use `--<component>=<version>` to specify this version. For example:

  - Execute the `tiup mirror clone <target-dir> --tidb v5.1.5` command to clone the v5.1.5 version of the TiDB component.
  - Execute the `tiup mirror clone <target-dir> --tidb v5.1.5 --tikv all` command to clone the v5.1.5 version of the TiDB component and all versions of the TiKV component.
  - Execute the `tiup mirror clone <target-dir> v5.1.5` command to clone the v5.1.5 version of all components in a cluster.

11.4.10.3.2 Usage examples

This section introduces the usage examples of the `mirror` command.

The repository that is cloned using `tiup mirror clone` can be shared among hosts either by sharing the files via SCP, NFS or by making the repository available over the HTTP or HTTPS protocol. Use `tiup mirror set <location>` to specify the location of the repository.

Refer to Deploy a TiDB Cluster Using TiUP to install the TiUP offline mirror, deploy a TiDB cluster, and start it.

11.4.10.4 Stress Test TiDB Using TiUP Bench Component

When you test the performance of a database, it is often required to stress test the database. To facilitate this, TiUP has integrated the bench component, which provides two workloads for stress testing: TPC-C and TPC-H. The commands and flags are as follows:

```
tiup bench
```

```
Starting component `bench`: /home/tidb/.tiup/components/bench/v1.5.0/bench
Benchmark database with different workloads

Usage:
  tiup bench [command]

Available Commands:
  help       Help about any command
  tpcc
  tpch

Flags:
      --count int         Total execution count, 0 means infinite
  -D, --db string         Database name (default "test")
  -d, --driver string     Database driver: mysql
      --dropdata          Cleanup data before prepare
  -h, --help              help for /Users/joshua/.tiup/components/bench/v0
     ↪ .0.1/bench
  -H, --host string       Database host (default "127.0.0.1")
      --ignore-error      Ignore error when running workload
      --interval duration Output interval time (default 10s)
      --isolation int     Isolation Level 0: Default, 1: ReadUncommitted,
                          2: ReadCommitted, 3: WriteCommitted, 4:
                             ↪ RepeatableRead,
                          5: Snapshot, 6: Serializable, 7: Linerizable
      --max-procs int     runtime.GOMAXPROCS
  -p, --password string   Database password
```

```
  -P, --port int          Database port (default 4000)
      --pprof string      Address of pprof endpoint
      --silence           Don't print error when running workload
      --summary           Print summary TPM only, or also print current TPM
          ↪ when running workload
  -T, --threads int       Thread concurrency (default 16)
      --time duration     Total execution time (default 2562047h47m16
          ↪ .854775807s)
  -U, --user string       Database user (default "root")
```

The following sections describe how to run TPC-C and TPC-H tests using TiUP.

11.4.10.4.1 Run TPC-C test using TiUP

The TiUP bench component supports the following commands and flags to run the TPC-C test:

```
Available Commands:
  check      Check data consistency for the workload
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload

Flags:
      --check-all      Run all consistency checks
  -h, --help           help for tpcc
      --parts int      Number to partition warehouses (default 1)
      --warehouses int Number of warehouses (default 10)
```

Test procedures

1. Create 4 warehouses using 4 partitions via hash:

   ```
   tiup bench tpcc --warehouses 4 --parts 4 prepare
   ```

2. Run the TPC-C test:

   ```
   tiup bench tpcc --warehouses 4 run
   ```

3. Clean up data:

   ```
   tiup bench tpcc --warehouses 4 cleanup
   ```

4. Check the consistency:

   ```
   tiup bench tpcc --warehouses 4 check
   ```

5. Generate the CSV file:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv
```

6. Generate the CSV file for the specified table:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=
    ↪ csv --tables history,orders
```

11.4.10.4.2 Run TPC-H test using TiUP

The TiUP bench component supports the following commands and parameters to run the TPC-H test:

```
Available Commands:
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload

Flags:
      --check          Check output data, only when the scale factor equals 1
  -h, --help           help for tpch
      --queries string All queries (default "q1,q2,q3,q4,q5,q6,q7,q8,q9,q10,
          ↪ q11,q12,q13,q14,q15,q16,q17,q18,q19,q20,q21,q22")
      --sf int         scale factor
```

Test procedures

1. Prepare data:

```
tiup bench tpch --sf=1 prepare
```

2. Run the TPC-H test by executing one of the following commands:

   - If you check the result, run this command:

   ```
   tiup bench tpch --sf=1 --check=true run
   ```

   - If you do not check the result, run this command:

   ```
   tiup bench tpch --sf=1 run
   ```

3. Clean up data:

```
tiup bench tpch cleanup
```

11.5 TiDB Operator

TiDB Operator is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB Operator documentation (also named as TiDB in Kubernetes documentation) is independent of the TiDB documentation. To access the documentation, click the following link:

- TiDB in Kubernetes documentation

11.6 Backup & Restore (BR)

11.6.1 BR Tool Overview

BR (Backup & Restore) is a command-line tool for distributed backup and restoration of the TiDB cluster data.

Compared with Dumpling, BR is more suitable to scenarios involving huge data volumes.

In addition to regular backup and restoration, you can also use BR for large-scale data migration as long as compatibility is ensured.

This document describes BR's implementation principles, recommended deployment configuration, usage restrictions and several methods to use BR.

11.6.1.1 Implementation principles

BR sends the backup or restoration commands to each TiKV node. After receiving these commands, TiKV performs the corresponding backup or restoration operations.

Each TiKV node has a path in which the backup files generated in the backup operation are stored and from which the stored backup files are read during the restoration.

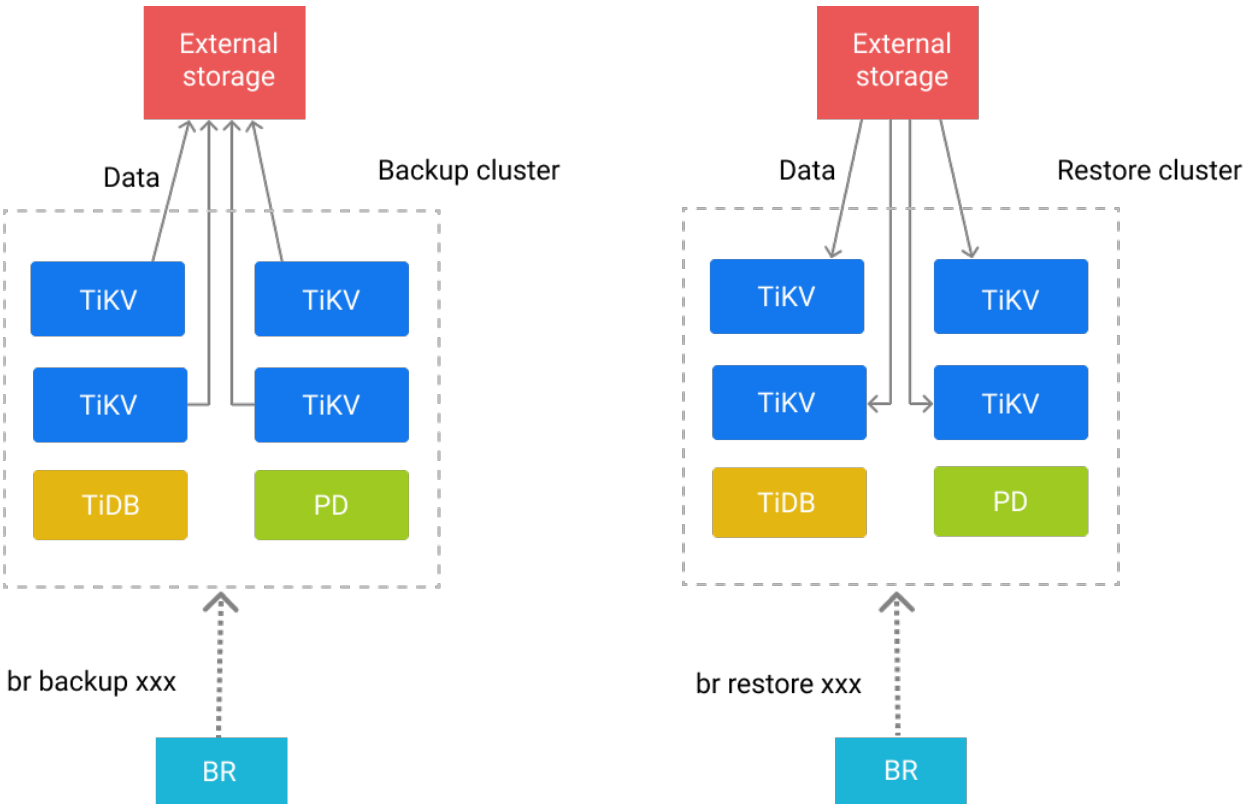

Figure 118: br-arch

Backup principle

When BR performs a backup operation, it first obtains the following information from PD:

- The current TS (timestamp) as the time of the backup snapshot
- The TiKV node information of the current cluster

According to these information, BR starts a TiDB instance internally to obtain the database or table information corresponding to the TS, and filters out the system databases (`information_schema`, `performance_schema`, `mysql`) at the same time.

According to the backup sub-command, BR adopts the following two types of backup logic:

- Full backup: BR traverses all the tables and constructs the KV range to be backed up according to each table.
- Single table backup: BR constructs the KV range to be backed up according a single table.

Finally, BR collects the KV range to be backed up and sends the complete backup request to the TiKV node of the cluster.

The structure of the request:

```
BackupRequest{
    ClusterId,    // The cluster ID.
    StartKey,     // The starting key of the backup (backed up).
    EndKey,       // The ending key of the backup (not backed up).
    StartVersion, // The version of the last backup snapshot, used for the
        ↪ incremental backup.
    EndVersion,   // The backup snapshot time.
    StorageBackend, // The path where backup files are stored.
    RateLimit,    // Backup speed (MB/s).
}
```

After receiving the backup request, the TiKV node traverses all Region leaders on the node to find the Regions that overlap with the KV ranges in this request. The TiKV node backs up some or all of the data within the range, and generates the corresponding SST file.

After finishing backing up the data of the corresponding Region, the TiKV node returns the metadata to BR. BR collects the metadata and stores it in the `backupmeta` file which is used for restoration.

If `StartVersion` is not `0`, the backup is seen as an incremental backup. In addition to KVs, BR also collects DDLs between `[StartVersion, EndVersion)`. During data restoration, these DDLs are restored first.

If checksum is enabled when you execute the backup command, BR calculates the checksum of each backed up table for data check.

11.6.1.1.1 Types of backup files

Two types of backup files are generated in the path where backup files are stored:

- **The SST file**: stores the data that the TiKV node backed up.
- **The `backupmeta` file**: stores the metadata of this backup operation, including the number, the key range, the size, and the Hash (sha256) value of the backup files.
- **The `backup.lock` file**: prevents multiple backup operations from storing data to the same directory.

11.6.1.1.2 The format of the SST file name

The SST file is named in the format of `storeID_regionID_regionEpoch_keyHash_cf`, where

- `storeID` is the TiKV node ID;
- `regionID` is the Region ID;

- `regionEpoch` is the version number of the Region;
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a key;
- `cf` indicates the Column Family of RocksDB (`default` or `write` by default).

Restoration principle

During the data restoration process, BR performs the following tasks in order:

1. It parses the `backupmeta` file in the backup path, and then starts a TiDB instance internally to create the corresponding databases and tables based on the parsed information.
2. It aggregates the parsed SST files according to the tables.
3. It pre-splits Regions according to the key range of the SST file so that every Region corresponds to at least one SST file.
4. It traverses each table to be restored and the SST file corresponding to each tables.
5. It finds the Region corresponding to the SST file and sends a request to the corresponding TiKV node for downloading the file. Then it sends a request for loading the file after the file is successfully downloaded.

After TiKV receives the request to load the SST file, TiKV uses the Raft mechanism to ensure the strong consistency of the SST data. After the downloaded SST file is loaded successfully, the file is deleted asynchronously.

After the restoration operation is completed, BR performs a checksum calculation on the restored data to compare the stored data with the backed up data.

11.6.1.2 Deploy and use BR

11.6.1.2.1 Recommended deployment configuration

- It is recommended that you deploy BR on the PD node.
- It is recommended that you mount a high-performance SSD to BR nodes and all TiKV nodes. A 10-gigabit network card is recommended. Otherwise, bandwidth is likely to be the performance bottleneck during the backup and restore process.

Note:

- If you do not mount a network disk or use other shared storage, the data backed up by BR will be generated on each TiKV node. Because BR only backs up leader replicas, you should estimate the space reserved for each node based on the leader size.
- Because TiDB uses leader count for load balancing by default, leaders can greatly differ in size. This might resulting in uneven distribution of backup data on each node.

11.6.1.2.2 Usage restrictions

The following are the limitations of using BR for backup and restoration:

- When BR restores data to the upstream cluster of TiCDC/Drainer, TiCDC/Drainer cannot replicate the restored data to the downstream.
- BR supports operations only between clusters with the same `new_collations_enabled_on_first_bo` ↪ value because BR only backs up KV data. If the cluster to be backed up and the cluster to be restored use different collations, the data validation fails. Therefore, before restoring a cluster, make sure that the switch value from the query result of the `select VARIABLE_VALUE from mysql.tidb where VARIABLE_NAME='` ↪ `new_collation_enabled';` statement is consistent with that during the backup process.

11.6.1.2.3 Compatibility

The compatibility issues of BR and the TiDB cluster are divided into the following categories:

- Some versions of BR are not compatible with the interface of the TiDB cluster.
- The KV format might change when some features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

These features are as follows:

Features	Related issues	Solutions

Features	Related issues	Solutions
Clustered index	#565	Make sure that the value of the `tidb_enable_clustered_index` global variable during restore is consistent with that during backup. Otherwise, data inconsistency might occur, such as `default not found` and inconsistent

Features	Related issues	Solutions
New collation	#352	Make sure that the value of the `new_collations_enabled_on_first_bootstrap` variable is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass.

Features	Related issues	Solutions
TiCDC enabled on the restore cluster	#364	Currently, TiKV cannot push down the BR-ingested SST files to TiCDC. Therefore, you need to disable TiCDC when using BR to restore data.

However, even after you have ensured that the above features are consistently enabled or disabled during backup and restore, compatibility issues might still occur due to the inconsistent internal versions or inconsistent interfaces between BR and TiKV/TiDB/PD. To avoid such cases, BR has the built-in version check.

Version check

Before performing backup and restore, BR compares and checks the TiDB cluster version and the BR version. If there is a major-version mismatch (for example, BR v4.x and TiDB v5.x), BR prompts a reminder to exit. To forcibly skip the version check, you can set `--check-requirements=false`.

Note that skipping the version check might introduce incompatibility. The version compatibility information between BR and TiDB versions are as follows:

Backup version (vertical)			
Restore version (horizontal)	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR nightly to back up TiDB nightly			(If a table with the primary key of the non-integer clustered index type is restored to a TiDB v4.0 cluster, BR will cause data error without warning.)

Backup version (vertical)	Restore version (horizontal)	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR v5.0 to back up TiDB v5.0				(If a table with the primary key of the non-integer clustered index type is restored to a TiDB v4.0 cluster, BR will cause data error without warning.)

Backup version (vertical)	Restore version (horizontal)		
	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR v4.0 to back up TiDB v4.0			(If TiKV >= v4.0.0-rc.1, and if BR contains the #233 bug fix and TiKV does not contain the #7241 bug fix, BR will cause the TiKV node to restart.)

Backup version (vertical)	Restore version (horizontal)	Use BR nightly to restore TiDB nightly	Use BR v5.0 to restore TiDB v5.0	Use BR v4.0 to restore TiDB v4.0
Use BR nightly or v5.0 to back up TiDB v4.0		(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)	(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)	(If the TiDB version is earlier than v4.0.9, the #609 issue might occur.)

11.6.1.2.4 Back up and restore table data in the `mysql` system schema (experimental feature)

> **Warning:**
>
> This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default.

If you want the data of a system table (for example, `mysql.usertable1`) to be restored to the system schema `mysql`, you can set the `filter` parameter to filter the table name (`-f "mysql.usertable1"`). After the setting, the system table is first restored to the temporary schema, and then to the system schema through renaming.

It should be noted that the following system tables cannot be restored correctly due to technical reasons. Even if `-f "mysql.*"` is specified, these tables will not be restored:

- Tables related to statistics: "stats_buckets", "stats_extended", "stats_feedback", "stats_fm_sketch", "stats_histograms", "stats_meta", "stats_top_n"
- Tables related to privileges or the system: "tidb", "global_variables", "columns_priv", "db", "default_roles", "global_grants", "global_priv", "role_edges", "tables_priv", "user", "gc_delete_range", "Gc_delete_range_done", "schema_index_usage"

11.6.1.2.5 Minimum machine configuration required for running BR

The minimum machine configuration required for running BR is as follows:

CPU	Memory	Hard Disk Type	Network
1 core	4 GB	HDD	Gigabit network card

In general scenarios (less than 1000 tables for backup and restore), the CPU consumption of BR at runtime does not exceed 200%, and the memory consumption does not exceed 4 GB. However, when backing up and restoring a large number of tables, BR might consume more than 4 GB of memory. In a test of backing up 24000 tables, BR consumes about 2.7 GB of memory, and the CPU consumption remains below 100%.

11.6.1.2.6 Best practices

The following are some recommended operations for using BR for backup and restoration:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- BR supports restore on clusters of different topologies. However, the online applications will be greatly impacted during the restore operation. It is recommended that you perform restore during the off-peak hours or use `rate-limit` to limit the rate.
- It is recommended that you execute multiple backup operations serially. Running different backup operations in parallel reduces backup performance and also affects the online application.
- It is recommended that you execute multiple restore operations serially. Running different restore operations in parallel increases Region conflicts and also reduces restore performance.
- It is recommended that you mount a shared storage (for example, NFS) on the backup path specified by `-s`, to make it easier to collect and manage backup files.

- It is recommended that you use a storage hardware with high throughput, because the throughput of a storage hardware limits the backup and restoration speed.

11.6.1.2.7 How to use BR

Currently, the following methods are supported to run the BR tool:

- Use SQL statements
- Use the command-line tool
- Use BR In the Kubernetes environment

Use SQL statements

TiDB supports both `BACKUP` and `RESTORE` SQL statements. The progress of these operations can be monitored with the statement `SHOW BACKUPS|RESTORES`.

Use the command-line tool

The `br` command-line utility is available as a separate download. For details, see Use BR Command-line for Backup and Restoration.

In the Kubernetes environment

In the Kubernetes environment, you can use the BR tool to back up TiDB cluster data to S3-compatible storage, Google Cloud Storage (GCS) and persistent volumes (PV), and restore them:

> **Note:**
>
> For Amazon S3 and Google Cloud Storage parameter descriptions, see the External Storages document.

- Back up Data to S3-Compatible Storage Using BR
- Restore Data from S3-Compatible Storage Using BR
- Back up Data to GCS Using BR
- Restore Data from GCS Using BR
- Back up Data to PV Using BR
- Restore Data from PV Using BR

- BR FAQ
- External Storages

11.6.2 Use BR Command-line for Backup and Restoration

This document describes how to back up and restore TiDB cluster data using the BR command line.

Make sure you have read BR Tool Overview, especially Usage Restrictions and Best Practices.

11.6.2.1 BR command-line description

A `br` command consists of sub-commands, options, and parameters.

- Sub-command: the characters without `-` or `--`.
- Option: the characters that start with `-` or `--`.
- Parameter: the characters that immediately follow behind and are passed to the sub-command or the option.

This is a complete `br` command:

```
br backup full --pd "${PDIP}:2379" -s "local:///tmp/backup"
```

Explanations for the above command are as follows:

- `backup`: the sub-command of `br`.
- `full`: the sub-command of `backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored.
- `"local:///tmp/backup"`: the parameter of `-s`. `/tmp/backup` is the path in the local disk where the backed up files of each TiKV node are stored.
- `--pd`: the option that specifies the Placement Driver (PD) service address.
- `"${PDIP}:2379"`: the parameter of `--pd`.

Note:

- When the `local` storage is used, the backup data are scattered in the local file system of each node.
- It is **not recommended** to back up to a local disk in the production environment because you **have to** manually aggregate these data to complete the data restoration. For more information, see Restore Cluster Data.
- Aggregating these backup data might cause redundancy and bring troubles to operation and maintenance. Even worse, if restoring data without aggregating these data, you can receive a rather confusing error message `SST file not found`.
- It is recommended to mount the NFS disk on each node, or back up to the `S3` object storage.

11.6.2.1.1 Sub-commands

A `br` command consists of multiple layers of sub-commands. Currently, BR has the following three sub-commands:

- `br backup`: used to back up the data of the TiDB cluster.
- `br restore`: used to restore the data of the TiDB cluster.

Each of the above three sub-commands might still include the following three sub-commands to specify the scope of an operation:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore the specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

11.6.2.1.2 Common options

- `--pd`: used for connection, specifying the PD server address. For example, `"${PDIP}:2379"`.
- `-h` (or `--help`): used to get help on all sub-commands. For example, `br backup --help`.
- `-V` (or `--version`): used to check the version of BR.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.
- `--status-addr`: specifies the listening address through which BR provides statistics to Prometheus.

11.6.2.2 Use BR command-line to back up cluster data

To back up the cluster data, use the `br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster or a single table.

11.6.2.2.1 Back up all the cluster data

To back up all the cluster data, execute the `br backup full` command. To get help on this command, execute `br backup full -h` or `br backup full --help`.

Usage example:

Back up all the cluster data to the `/tmp/backup` path of each TiKV node and write the `backupmeta` file to this path.

Note:

- If the backup disk and the service disk are different, it has been tested that online backup reduces QPS of the read-only online service by about 15%-25% in case of full-speed backup. If you want to reduce the impact on QPS, use `--ratelimit` to limit the rate.
- If the backup disk and the service disk are the same, the backup competes with the service for I/O resources. This might decrease the QPS of the read-only online service by more than half. Therefore, it is **highly not recommended** to back up the online service data to the TiKV data disk.

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a backup operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `backupfull.log` file.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety. The progress bar is displayed as follows:

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
Full Backup <---------/.....................................................>
    ↪ 17.12%.
```

11.6.2.2.2 Back up a database

To back up a database in the cluster, execute the `br backup db` command. To get help on this command, execute `br backup db -h` or `br backup db --help`.

Usage example:

Back up the data of the `test` database to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup db \
    --pd "${PDIP}:2379" \
    --db test \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backuptable.log
```

In the above command, `--db` specifies the name of the database to be backed up. For descriptions of other options, see Back up all the cluster data.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

11.6.2.2.3 Back up a table

To back up the data of a single table in the cluster, execute the `br backup table` command. To get help on this command, execute `br backup table -h` or `br backup table --help`.

Usage example:

Back up the data of the `test.usertable` table to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup table \
    --pd "${PDIP}:2379" \
    --db test \
    --table usertable \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backuptable.log
```

The `table` sub-command has two options:

- `--db`: specifies the database name
- `--table`: specifies the table name.

For descriptions of other options, see Back up all cluster data.

A progress bar is displayed in the terminal during the backup operation. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

11.6.2.2.4 Back up with table filter

To back up multiple tables with more complex criteria, execute the `br backup full` command and specify the table filters with `--filter` or `-f`.

Usage example:

The following command backs up the data of all tables in the form `db*.tbl*` to the `/tmp/backup` path on each TiKV node and writes the `backupmeta` file to this path.

```
br backup full \
    --pd "${PDIP}:2379" \
    --filter 'db*.tbl*' \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file backupfull.log
```

11.6.2.2.5 Back up data to Amazon S3 backend

If you back up the data to the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

You can refer to the AWS Official Document to create an S3 `Bucket` in the specified `Region`. You can also refer to another AWS Official Document to create a `Folder` in the `Bucket`.

> **Note:**
>
> To complete one backup, TiKV and BR usually require the minimum privileges of `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When backing up using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

```
br backup full \
    --pd "${PDIP}:2379" \
    --storage "s3://${Bucket}/${Folder}" \
```

```
    --s3.region "${region}" \
    --send-credentials-to-tikv=true \
    --ratelimit 128 \
    --log-file backuptable.log
```

11.6.2.2.6 Back up incremental data

This feature is currently experimental and is not recommended for use in the production environment.

If you want to back up incrementally, you only need to specify the **last backup timestamp** `--lastbackupts`.

The incremental backup has two limitations:

- The incremental backup needs to be under a different path from the previous full backup.
- GC (Garbage Collection) safepoint must be before the `lastbackupts`.

To back up the incremental data between `(LAST_BACKUP_TS, current PD timestamp]`, execute the following command:

```
br backup full\
    --pd ${PDIP}:2379 \
    --ratelimit 128 \
    -s local:///home/tidb/backupdata/incr \
    --lastbackupts ${LAST_BACKUP_TS}
```

To get the timestamp of the last backup, execute the `validate` command. For example:

```
LAST_BACKUP_TS=`br validate decode --field="end-version" -s local:///home/
    ↪ tidb/backupdata | tail -n1`
```

In the above example, for the incremental backup data, BR records the data changes and the DDL operations during `(LAST_BACKUP_TS, current PD timestamp]`. When restoring data, BR first restores DDL operations and then the data.

11.6.2.2.7 Point-in-time recovery (experimental feature)

Point-in-time recovery (PITR) allows you to restore data to a point in time of your choice.

An example scenario would be to take a full backup every day and take incremental backups every 6 hours and then use TiCDC for PITR. Assume that on one day, the full backup was performed at 00:00 and the first incremental backup was performed at 06:00. If you want to restore the database to the state of 07:16, you can first restore the full backup

(taken at 00:00) and the incremental backup (taken at 06:00), and then restore TiCDC logs that fill in the gap between 06:00 and 07:16.

To peform the PITR, you can take the following steps:

1. Restore a full backup using `br restore full`.
2. (optional) Restore incremental backup(s).
3. Use `br restore cdclog` to restore the transactions that happened after the last incremental backup. The complete command to execute is as follows:

```
br restore cdclog --storage local:///data/cdclog --start-ts $START_TS
    ↪ --end-ts $END_TS
```

In the command above:

- `local:///data/cdclog` is the location of the TiCDC logs. This might be on the local filesystem or on the external storage like S3.
- `$START_TS` is the end position of the restore from the last restored backup (either a full backup or an incremental backup).
- `$END_TS` is the point to which you want to restore your data.

11.6.2.2.8 Back up Raw KV (experimental feature)

> **Warning:**
>
> This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

In some scenarios, TiKV might run independently of TiDB. Given that, BR also supports bypassing the TiDB layer and backing up data in TiKV.

For example, you can execute the following command to back up all keys between `[0x31 ↪ , 0x3130303030303030)` in the default CF to `$BACKUP_DIR`:

```
br backup raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
    --ratelimit 128 \
    --end 3130303030303030 \
    --format hex \
    --cf default
```

Here, the parameters of `--start` and `--end` are decoded using the method specified by `--format` before being sent to TiKV. Currently, the following methods are available:

- "raw": The input string is directly encoded as a key in binary format.
- "hex": The default encoding method. The input string is treated as a hexadecimal number.
- "escape": First escape the input string, and then encode it into binary format.

11.6.2.3 Use BR command-line to restore cluster data

To restore the cluster data, use the `br restore` command. You can add the `full`, `db` or `table` sub-command to specify the scope of your restoration: the whole cluster, a database or a single table.

> **Note:**
>
> If you use the local storage, you **must** copy all back up SST files to every TiKV node in the path specified by `--storage`.
>
> Even if each TiKV node eventually only need to read a part of the all SST files, they all need full access to the complete archive because:
>
> - Data are replicated into multiple peers. When ingesting SSTs, these files have to be present on *all* peers. This is unlike back up where reading from a single node is enough.
> - Where each peer is scattered to during restore is random. We don't know in advance which node will read which file.
>
> These can be avoided using shared storage, for example mounting an NFS on the local path, or using S3. With network storage, every node can automatically read every SST file, so these caveats no longer apply.

11.6.2.3.1 Restore all the backup data

To restore all the backup data to the cluster, execute the `br restore full` command. To get help on this command, execute `br restore full -h` or `br restore full --help`.

Usage example:

Restore all the backup data in the `/tmp/backup` path to the cluster.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file restorefull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a restoration operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `restorefull.log` file.

A progress bar is displayed in the terminal during the restoration. When the progress bar advances to 100%, the restoration is complete. Then the BR also checks the backup data to ensure data safety.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "local:///tmp/backup" \
    --ratelimit 128 \
    --log-file restorefull.log
Full Restore <---------/.....................................................>
    ↪ 17.12%.
```

11.6.2.3.2 Restore a database

To restore a database to the cluster, execute the `br restore db` command. To get help on this command, execute `br restore db -h` or `br restore db --help`.

Usage example:

Restore a database backed up in the `/tmp/backup` path to the cluster.

```
br restore db \
    --pd "${PDIP}:2379" \
    --db "test" \
    --ratelimit 128 \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

In the above command, `--db` specifies the name of the database to be restored. For descriptions of other options, see Restore all backup data).

Note:

When you restore the backup data, the name of the database specified by `--db` ↪ must be the same as the one specified by `-- db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

11.6.2.3.3 Restore a table

To restore a single table to the cluster, execute the `br restore table` command. To get help on this command, execute `br restore table -h` or `br restore table --help`.

Usage example:

Restore a table backed up in the `/tmp/backup` path to the cluster.

```
br restore table \
    --pd "${PDIP}:2379" \
    --db "test" \
    --table "usertable" \
    --ratelimit 128 \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see Restore all backup data and Restore a database.

11.6.2.3.4 Restore with table filter

To restore multiple tables with more complex criteria, execute the `br restore full` command and specify the table filters with `--filter` or `-f`.

Usage example:

The following command restores a subset of tables backed up in the `/tmp/backup` path to the cluster.

```
br restore full \
    --pd "${PDIP}:2379" \
    --filter 'db*.tbl*' \
    --storage "local:///tmp/backup" \
    --log-file restorefull.log
```

11.6.2.3.5 Restore data from Amazon S3 backend

If you restore data from the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

> **Note:**
>
> To complete one restore, TiKV and BR usually require the minimum privileges of `s3:ListBucket` and `s3:GetObject`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When restoring data using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

`Bucket` and `Folder` in the `--storage` parameter represent the S3 bucket and the folder where the data to be restored is located.

```
br restore full \
    --pd "${PDIP}:2379" \
    --storage "s3://${Bucket}/${Folder}" \
    --s3.region "${region}" \
    --ratelimit 128 \
    --send-credentials-to-tikv=true \
    --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see Restore a database.

11.6.2.3.6 Restore incremental data

This feature is currently experimental and is not recommended for use in the production environment.

Restoring incremental data is similar to restoring full data using BR. Note that when restoring incremental data, make sure that all the data backed up before `last backup ts` has been restored to the target cluster.

11.6.2.3.7 Restore tables created in the `mysql` schema (experimental feature)

BR backs up tables created in the `mysql` schema by default.

When you restore data using BR, the tables created in the `mysql` schema are not restored by default. If you need to restore these tables, you can explicitly include them using the table filter. The following example restores `mysql.usertable` created in `mysql` schema. The command restores `mysql.usertable` along with other data.

```
br restore full -f '*.*' -f '!mysql.*' -f 'mysql.usertable' -s
    ↪ $external_storage_url --ratelimit 128
```

In the above command, `-f '*.*'` is used to override the default rules and `-f '!mysql.*'` instructs BR not to restore tables in `mysql` unless otherwise stated. `-f 'mysql.usertable'` indicates that `mysql.usertable` is required for restore. For detailed implementation, refer to the table filter document.

If you only need to restore `mysql.usertable`, use the following command:

```
br restore full -f 'mysql.usertable' -s $external_storage_url --ratelimit 128
```

> **Warning:**
>
> Although you can back up and restore system tables (such as `mysql.tidb`) using the BR tool, some unexpected situations might occur after the restoration, including:
>
> - the statistical information tables (`mysql.stat_*`) cannot be restored.
> - the system variable tables (`mysql.tidb,mysql.global_variables`) cannot be restored.
> - the user information tables (such as `mysql.user` and `mysql.columns_priv`) cannot be restored.
> - GC data cannot be restored.
>
> Restoring system tables might cause more compatibility issues. To avoid unexpected problems, **DO NOT** restore system tables in the production environment.

11.6.2.3.8 Restore Raw KV (experimental feature)

> **Warning:**
>
> This feature is in the experiment, without being thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Similar to backing up Raw KV, you can execute the following command to restore Raw KV:

```
br restore raw --pd $PD_ADDR \
    -s "local://$BACKUP_DIR" \
    --start 31 \
```

```
    --end 3130303030303030 \
    --ratelimit 128 \
    --format hex \
    --cf default
```

In the above example, all the backed up keys in the range `[0x31, 0x3130303030303030 ↪ )` are restored to the TiKV cluster. The coding methods of these keys are identical to that of keys during the backup process

11.6.2.3.9 Online restore (experimental feature)

> **Warning:**
>
> This feature is in the experiment, without being thoroughly tested. It also relies on the unstable `Placement Rules` feature of PD. It is highly **not recommended** to use this feature in the production environment.

During data restoration, writing too much data affects the performance of the online cluster. To avoid this effect as much as possible, BR supports Placement rules to isolate resources. In this case, downloading and importing SST are only performed on a few specified nodes (or "restore nodes" for short). To complete the online restore, take the following steps.

1. Configure PD, and start Placement rules:

```
echo "config set enable-placement-rules true" | pd-ctl
```

2. Edit the configuration file of the "restore node" in TiKV, and specify "restore" to the `server` configuration item:

```
[server]
labels = { exclusive = "restore" }
```

3. Start TiKV of the "restore node" and restore the backed up files using BR. Compared with the offline restore, you only need to add the `--online` flag:

```
br restore full \
    -s "local://$BACKUP_DIR" \
    --ratelimit 128 \
    --pd $PD_ADDR \
    --online
```

11.6.3 BR Use Cases

BR is a tool for distributed backup and restoration of the TiDB cluster data.

This document describes how to run BR in the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

This document aims to help you achieve the following goals:

- Back up and restore data using a network disk or local disk correctly.
- Get the status of a backup or restoration operation through monitoring metrics.
- Learn how to tune performance during the operation.
- Troubleshoot the possible anomalies during the backup operation.

11.6.3.1 Audience

You are expected to have a basic understanding of TiDB and TiKV.

Before reading on, make sure you have read BR Tool Overview, especially Usage Restrictions and Best Practices.

11.6.3.2 Prerequisites

This section introduces the recommended method of deploying TiDB, cluster versions, the hardware information of the TiKV cluster, and the cluster configuration for the use case demonstrations.

You can estimate the performance of your backup or restoration operation based on your own hardware and configuration.

11.6.3.2.1 Deployment method

It is recommended that you deploy the TiDB cluster using TiUP and get BR by downloading TiDB Toolkit.

11.6.3.2.2 Cluster versions

- TiDB: v5.1.5
- TiKV: v5.1.5
- PD: v5.1.5
- BR: v5.1.5

Note:

It is recommended that you use the latest version of TiDB/TiKV/PD/BR and make sure that the BR version is **consistent with** the TiDB version.

11.6.3.2.3 TiKV hardware information

- Operating system: CentOS Linux release 7.6.1810 (Core)
- CPU: 16-Core Common KVM processor
- RAM: 32GB
- Disk: 500G SSD * 2
- NIC: 10 Gigabit network card

11.6.3.2.4 Cluster configuration

BR directly sends commands to the TiKV cluster and are not dependent on the TiDB server, so you do not need to configure the TiDB server when using BR.

- TiKV: default configuration
- PD: default configuration

11.6.3.3 Use cases

This document describes the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

It is recommended that you use a network disk to back up and restore data. This spares you from collecting backup files and greatly improves the backup efficiency especially when the TiKV cluster is in a large scale.

Before the backup or restoration operations, you need to do some preparations:

- Preparation for backup
- Preparation for restoration

11.6.3.3.1 Preparation for backup

The BR tool already supports self-adapting to GC. It automatically registers `backupTS` ↪ (the latest PD timestamp by default) to PD's `safePoint` to ensure that TiDB's GC Safe Point does not move forward during the backup, thus avoiding manually setting GC configurations.

For the detailed usage of the `br backup` command, refer to Use BR Command-line for Backup and Restoration.

1. Before executing the `br backup` command, ensure that no DDL is running on the TiDB cluster.
2. Ensure that the storage device where the backup will be created has sufficient space.

11.6.3.3.2 Preparation for restoration

Before executing the `br restore` command, check the new cluster to make sure that the table in the cluster does not have a duplicate name.

11.6.3.3.3 Back up a single table to a network disk (recommended in production environment)

Use the `br backup` command to back up the single table data `--db batchmark --table` ↪ `order_line` to the specified path `local:///br_data` in the network disk.

Backup prerequisites

- Preparation for backup
- Configure a high-performance SSD hard disk host as the NFS server to store data, and all BR nodes, TiKV nodes, and TiFlash nodes as NFS clients. Mount the same path (for example, `/br_data`) to the NFS server for NFS clients to access the server.
- The total transfer rate between the NFS server and all NFS clients must reach at least `the number of TiKV instances * 150MB/s`. Otherwise the network I/O might become the performance bottleneck.

Note:

- During data backup, because only the data of leader replicas are backed up, even if there is a TiFlash replica in the cluster, BR can complete the backup without mounting TiFlash nodes.
- When restoring data, BR will restore the data of all replicas. Also, TiFlash nodes need access to the backup data for BR to complete the restore. Therefore, before the restore, you must mount TiFlash nodes to the NFS server.

Topology

The following diagram shows the typology of BR:

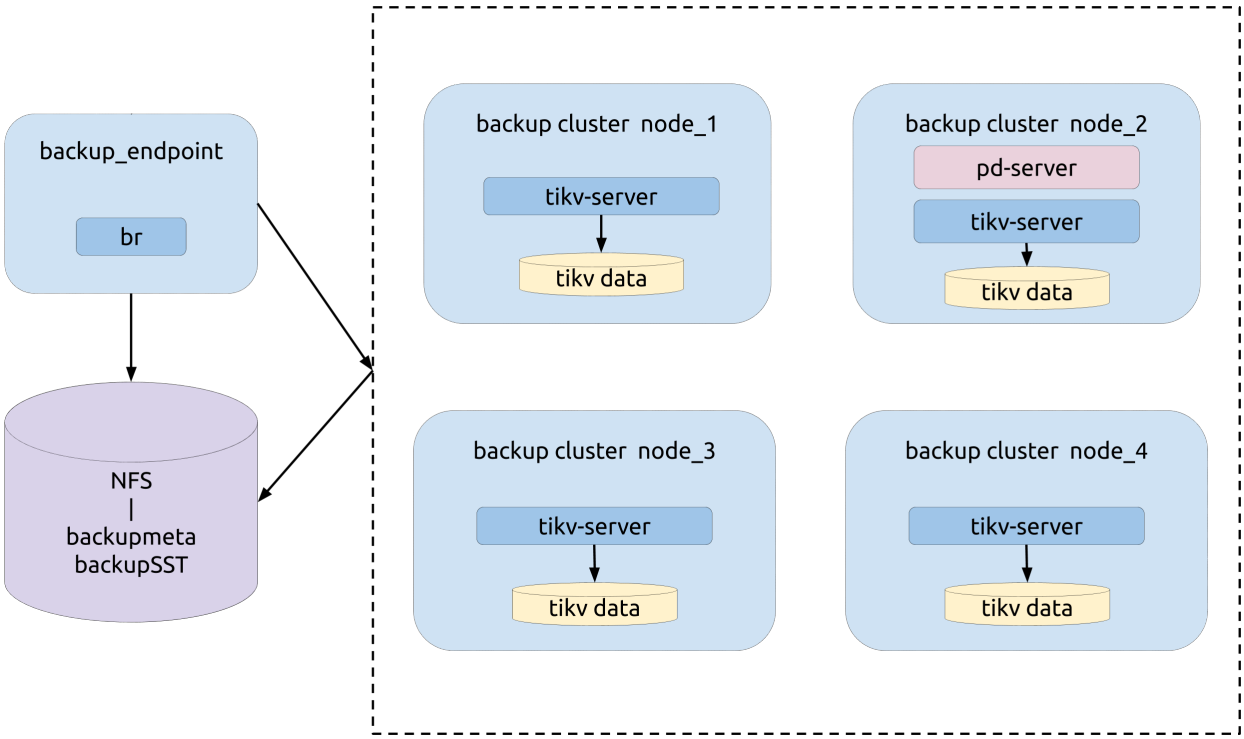

Figure 119: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark --table order_line`). The following image shows an example of this information:

```
+-----------+------------+---------------------+-----------+--------------+
| Db_name   | Table_name | Checksum_crc64_xor  | Total_kvs | Total_bytes  |
+-----------+------------+---------------------+-----------+--------------+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----------+------------+---------------------+-----------+--------------+
1 row in set (5 min 47.59 sec)
```

Figure 120: img

Execute the `br backup` command:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///br_data \
    --pd ${PD_ADDR}:2379 \
    --log-file backup-nfs.log
```

Monitoring metrics for the backup

During the backup process, pay attention to the following metrics on the monitoring panels to get the status of the backup process.

Backup CPU Utilization: the CPU usage rate of each working TiKV node in the backup operation (for example, backup-worker and backup-endpoint).

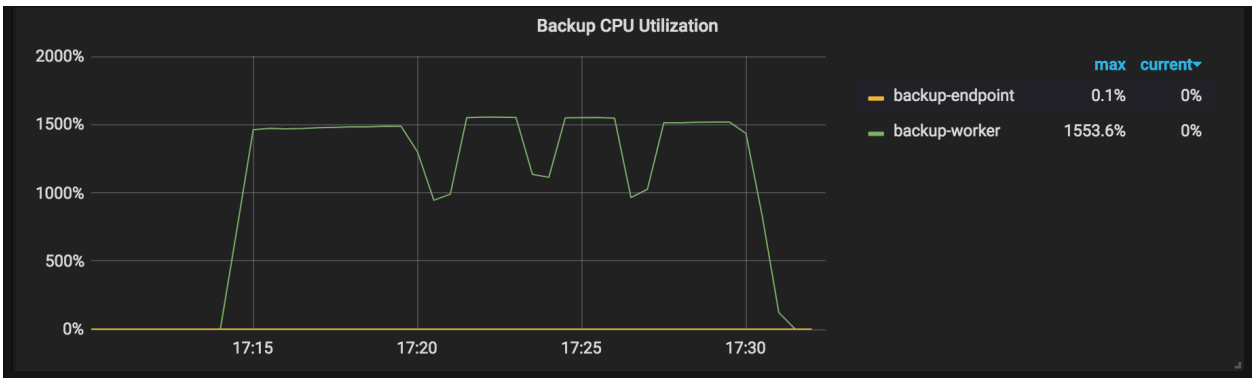

Figure 121: img

IO Utilization: the I/O usage rate of each working TiKV node in the backup operation.

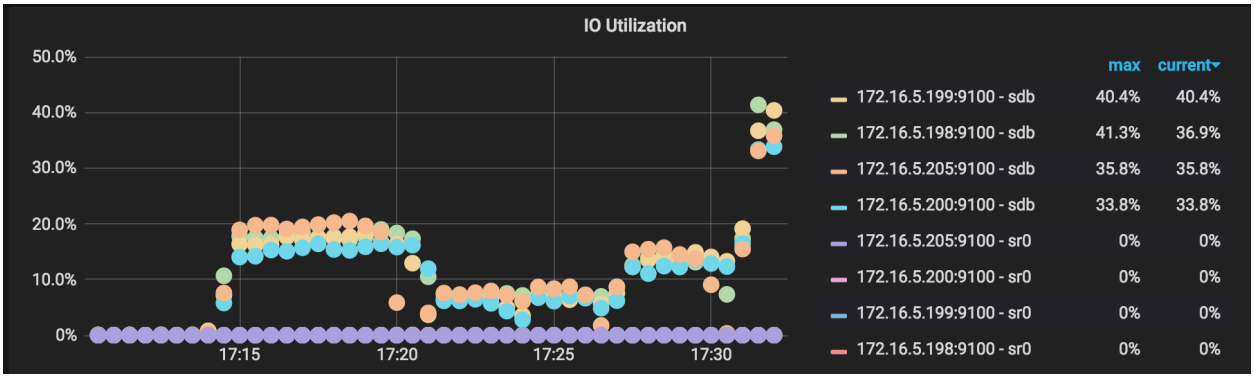

Figure 122: img

BackupSST Generation Throughput: the backupSST generation throughput of each working TiKV node in the backup operation, which is normally around 150MB/s.

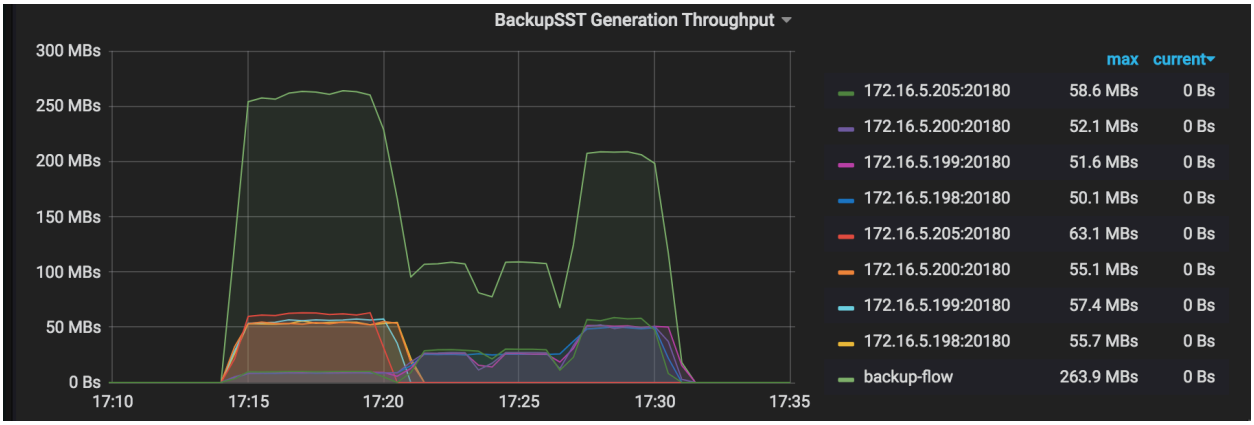

Figure 123: img

One Backup Range Duration: the duration of backing up a range, which is the total time cost of scanning KVs and storing the range as the backupSST file.

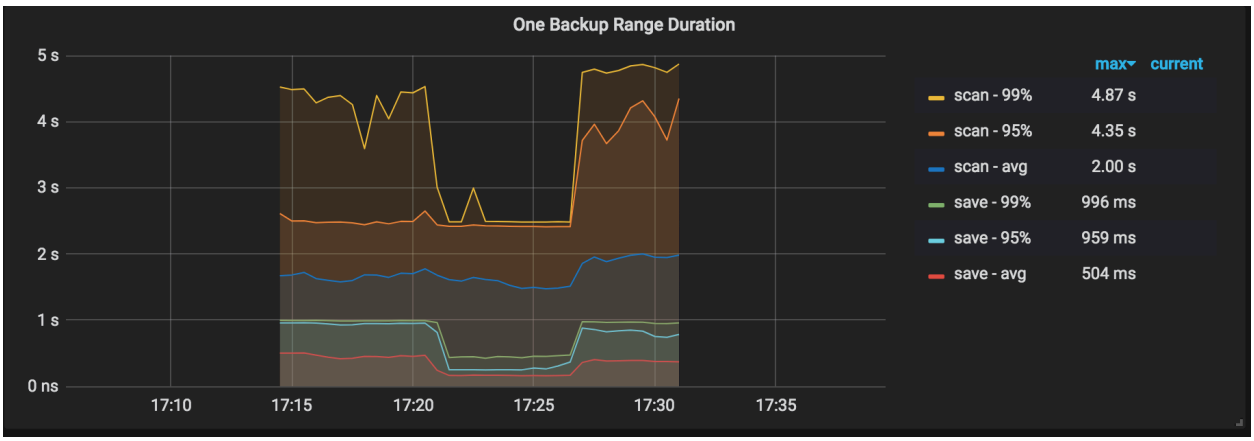

Figure 124: img

One Backup Subtask Duration: the duration of each sub-task into which a backup task is divided.

Note:

- In this task, the single table to be backed up has three indexes and the task is normally divided into four sub-tasks.

- The panel in the following image has thirteen points on it, which means nine (namely, 13-4) retries. Region scheduling might occur during the backup process, so a few retries is normal.

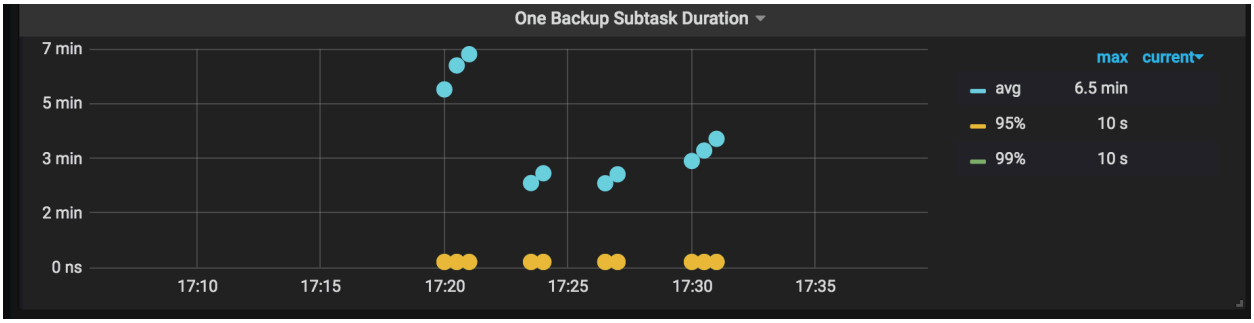

Figure 125: img

Backup Errors: the errors occurred during the backup process. No error occurs in normal situations. Even if a few errors occur, the backup operation has the retry mechanism which might increase the backup time but does not affect the operation correctness.

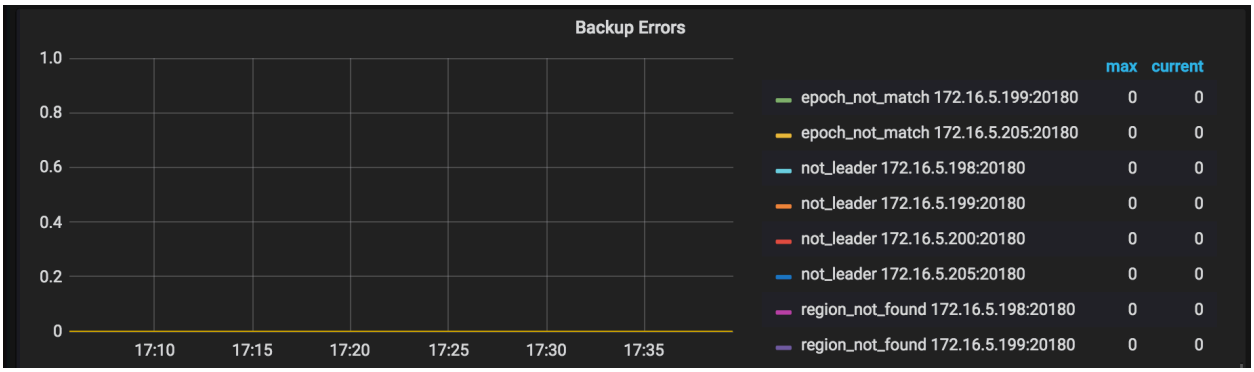

Figure 126: img

Checksum Request Duration: the duration of the admin checksum request in the backup cluster.

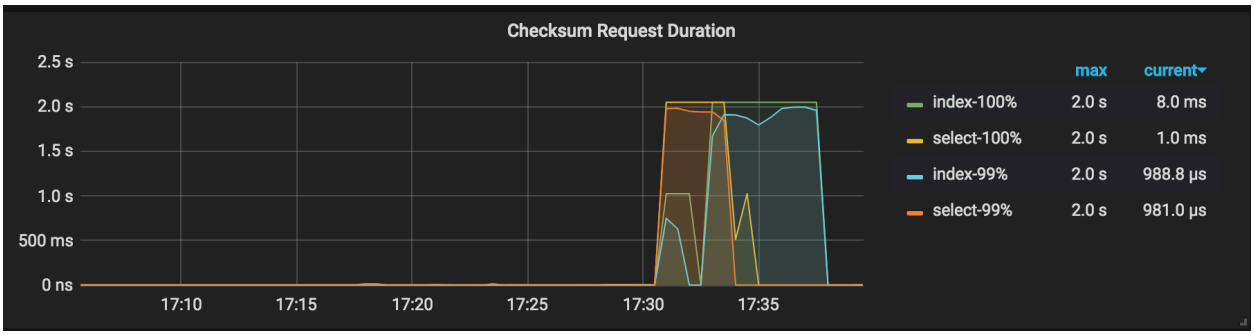

Figure 127: img

Backup results explanation

When finishing the backup, BR outputs the backup summary to the console.

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search "summary" in this log, you can see the following information:

```
["Full backup Success summary:
    total backup ranges: 2,
    total success: 2,
    total failed: 0,
    total take(Full backup time): 31.802912166s,
    total take(real time): 49.799662427s,
    total size(MB): 5997.49,
    avg speed(MB/s): 188.58,
    total kv: 120000000"]
    ["backup checksum"=17.907153678s]
    ["backup fast checksum"=349.333µs]
    ["backup total regions"=43]
    [BackupTS=422618409346269185]
    [Size=826765915]
```

The above log includes the following information:

- Backup duration: `total take(Full backup time): 31.802912166s`
- Total runtime of the application: `total take(real time): 49.799662427s`
- Backup data size: `total size(MB): 5997.49`
- Backup throughput: `avg speed(MB/s): 188.58`
- Number of backed-up KV pairs: `total kv: 120000000`
- Backup checksum duration: `["backup checksum"=17.907153678s]`
- Total duration of calculating the checksum, KV pairs, and bytes of each table: `["backup fast checksum"=349.333µs]`

- Total number of backup Regions: `["backup total regions"=43]`
- The actual size of the backup data in the disk after compression: `[Size=826765915]`
- Snapshot timestamp of the backup data: `[BackupTS=422618409346269185]`

From the above information, the throughput of a single TiKV instance can be calculated: `avg speed(MB/s)/tikv_count` = `62.86`.

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the backup process (for example, in the Monitoring metrics for the backup, the highest CPU usage rate of backup-worker is around `1500%` and the overall I/O usage rate is below `30%`), you can try to increase the value of `--concurrency` (`4` by default) to tune the performance. But this performance tuning method is not suitable for the use cases of many small tables. See the following example:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///br_data/ \
    --pd ${PD_ADDR}:2379 \
    --log-file backup-nfs.log \
    --concurrency 16
```

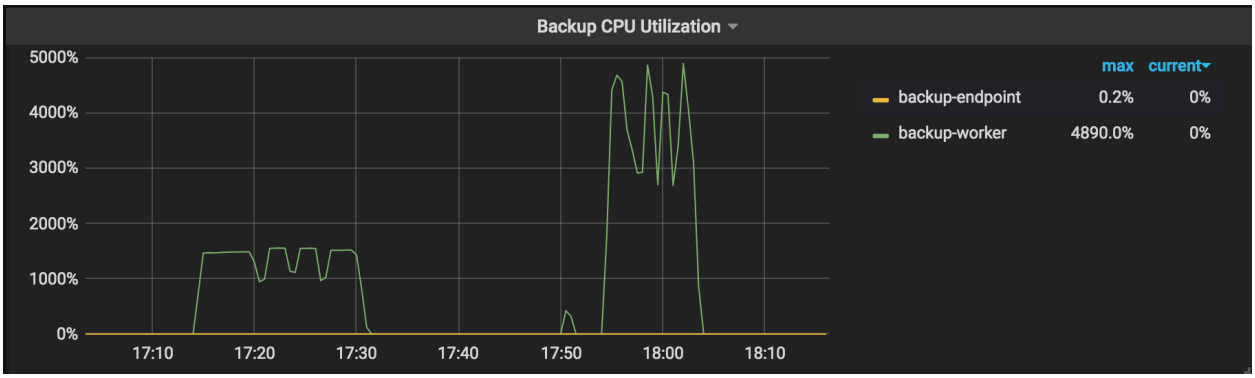

Figure 128: img

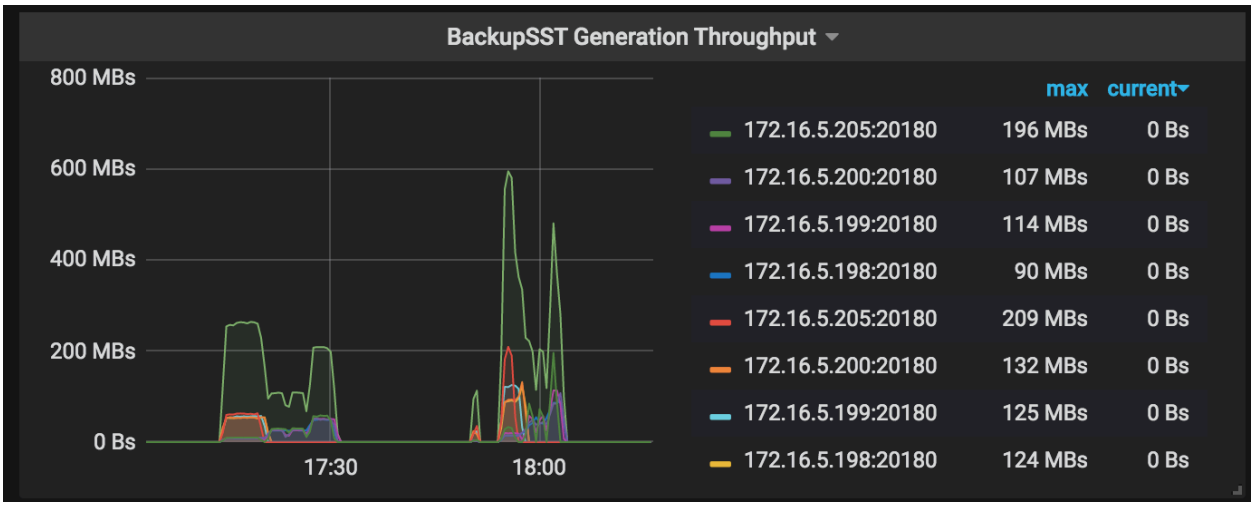

Figure 129: img

The tuned performance results are as follows (with the same data size):

- Backup duration: `total take(s)` reduced from `986.43` to `535.53`
- Backup throughput: `avg speed(MB/s)` increased from `358.09` to `659.59`
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from `89` to `164.89`

11.6.3.3.4 Restore data from a network disk (recommended in production environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- Preparation for restoration

Topology

The following diagram shows the typology of BR:

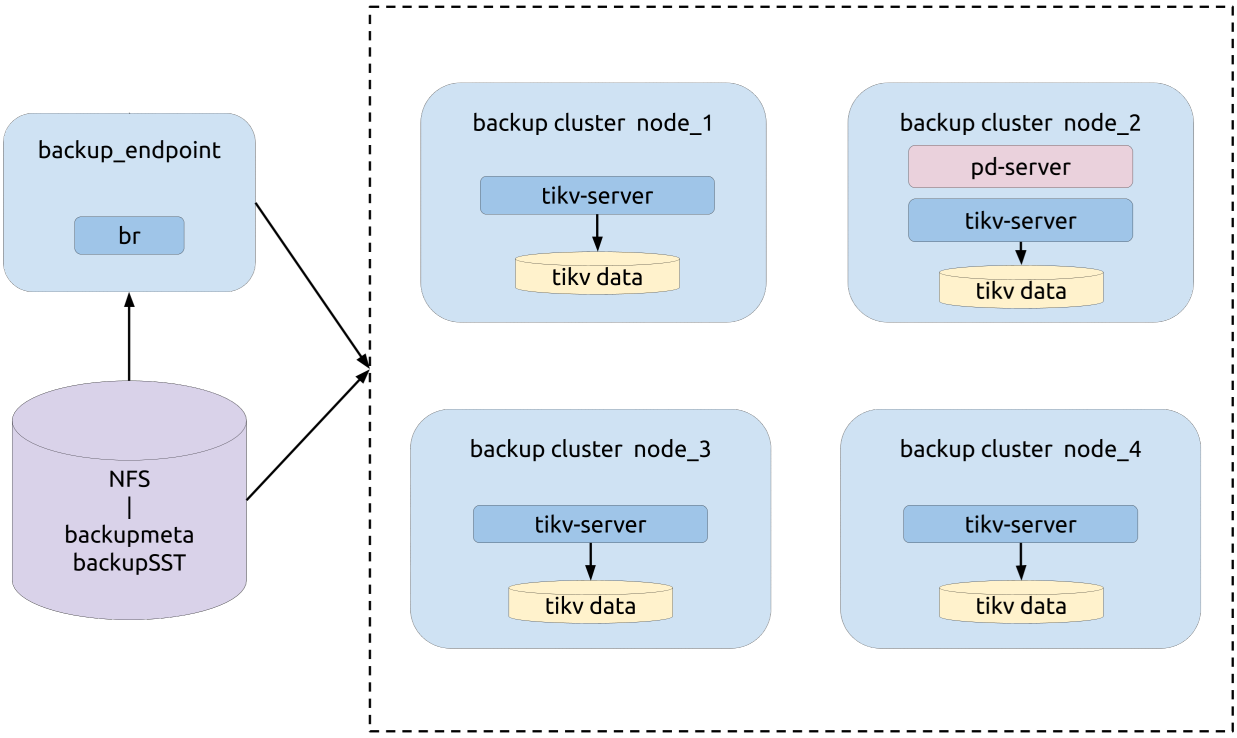

Figure 130: img

Restoration operation

Before the restoration, refer to Preparation for restoration for the preparation.

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data
    ↪ --pd 172.16.5.198:2379 --log-file restore-nfs.log
```

Monitoring metrics for the restoration

During the restoration process, pay attention to the following metrics on the monitoring panels to get the status of the restoration process.

CPU Utilization: the CPU usage rate of each working TiKV node in the restoration operation.

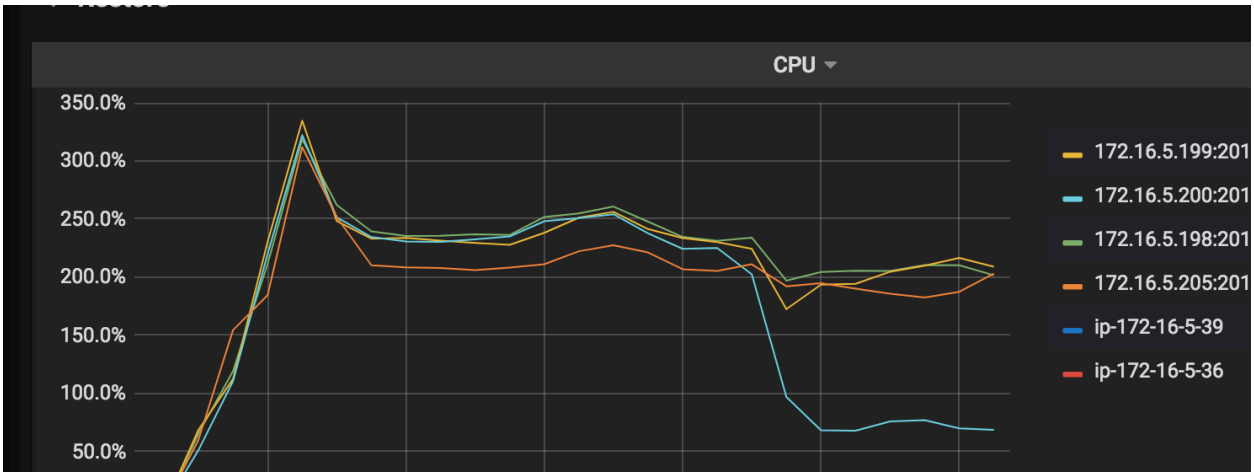

Figure 131: img

IO Utilization: the I/O usage rate of each working TiKV node in the restoration operation.

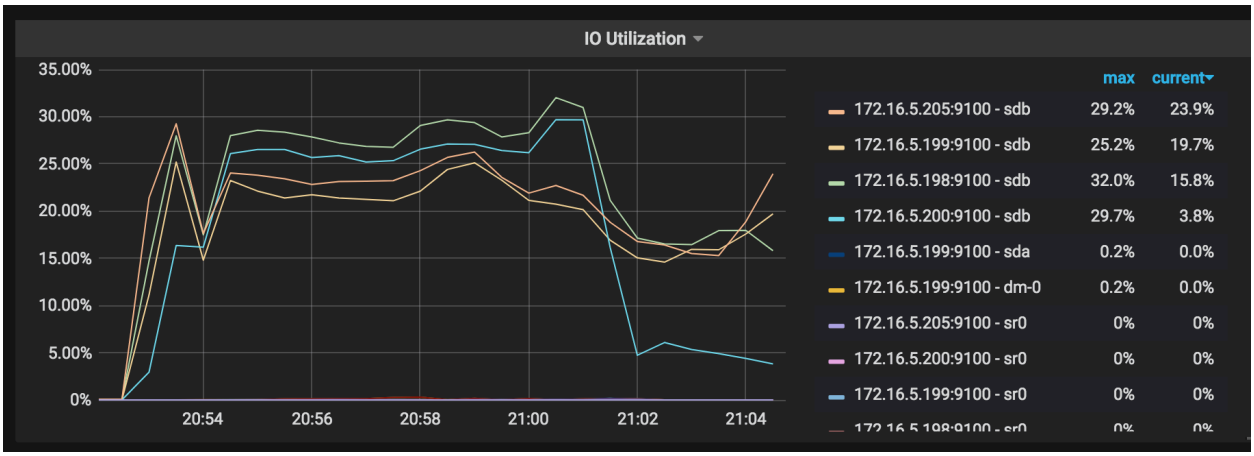

Figure 132: img

Region: the Region distribution. The more even Regions are distributed, the better the restoration resources are used.

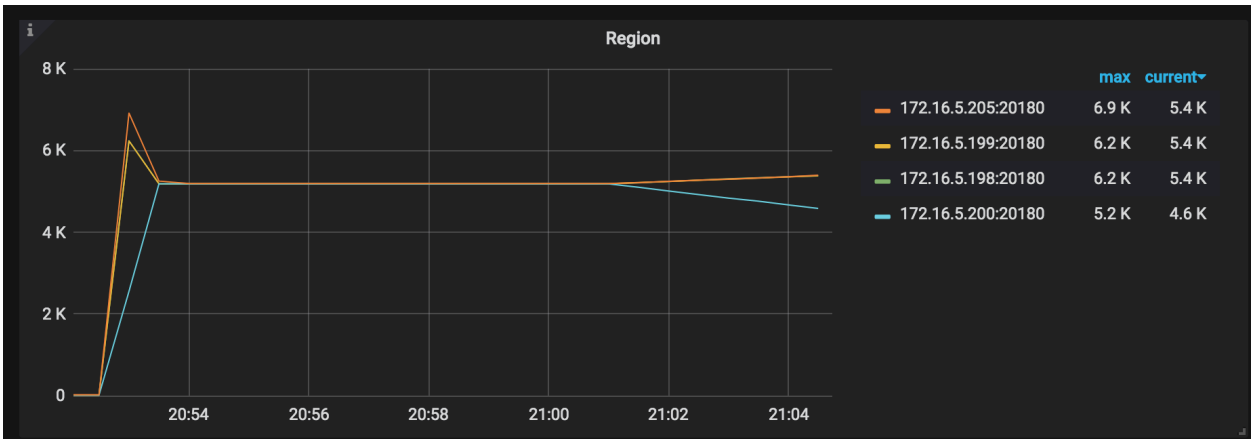

Figure 133: img

Process SST Duration: the delay of processing the SST files. When restoring a table, if `tableID` is changed, you need to rewrite `tableID`. Otherwise, `tableID` is renamed. Generally, the delay of rewriting is longer than that of renaming.

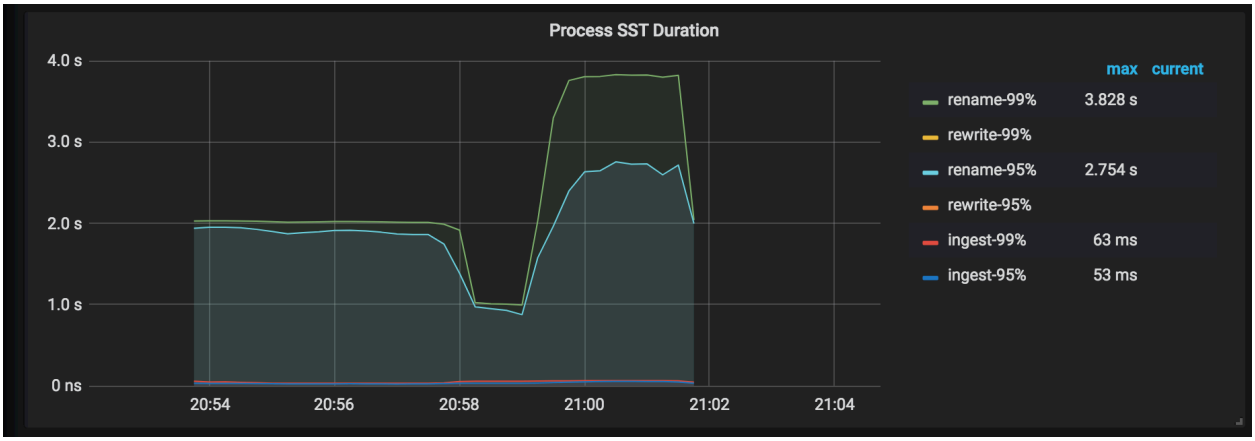

Figure 134: img

DownLoad SST Throughput: the throughput of downloading SST files from External Storage.

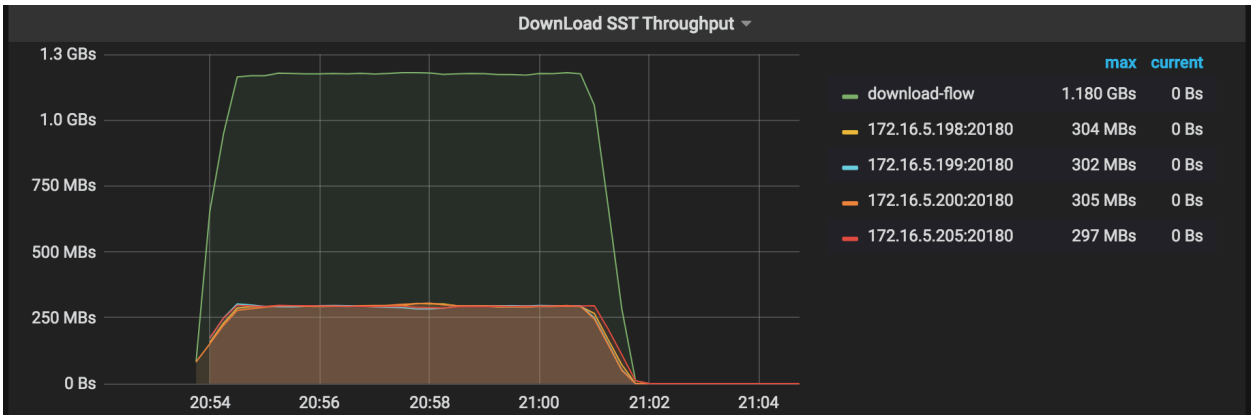

Figure 135: img

Restore Errors: the errors occurred during the restoration process.

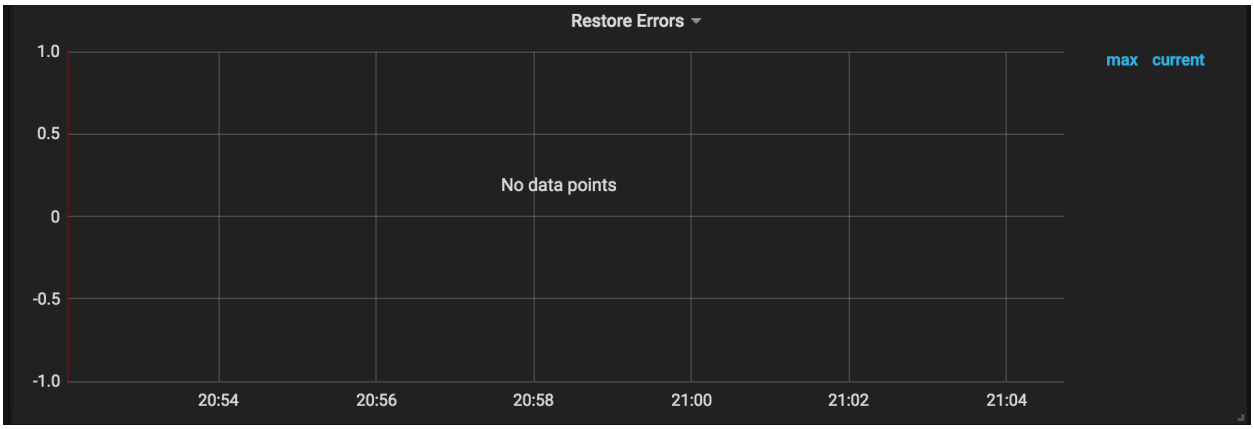

Figure 136: img

Checksum Request duration: the duration of the admin checksum request. This duration for the restoration is longer than that for the backup.

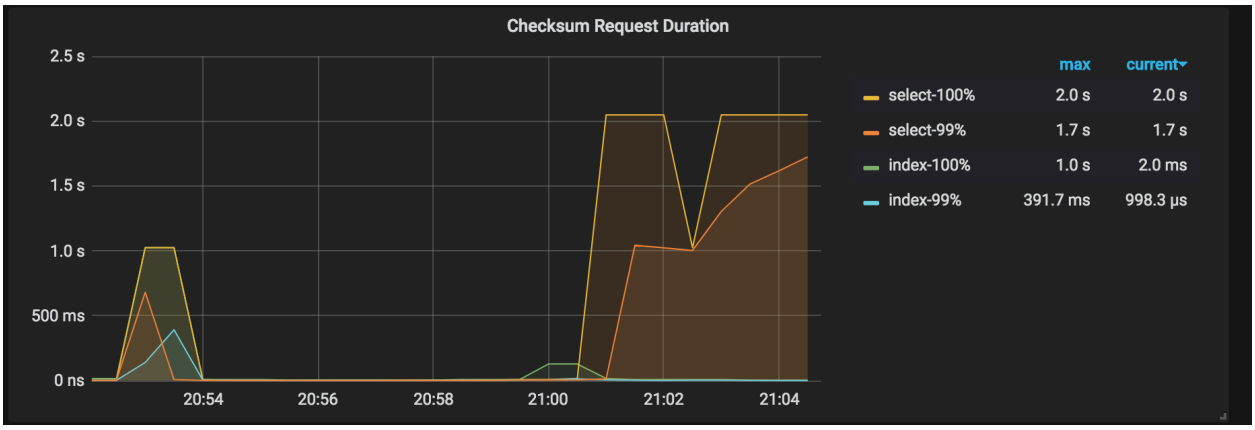

Figure 137: img

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search "summary" in this log, you can see the following information:

```
["Table Restore summary:
   total restore tables: 1,
   total success: 1,
   total failed: 0,
   total take(Full restore time): 17m1.001611365s,
   total take(real time): 16m1.371611365s,
   total kv: 5659888624,
   total size(MB): 353227.18,
   avg speed(MB/s): 367.42"]
   ["restore files"=9263]
   ["restore ranges"=6888]
   ["split region"=49.049182743s]
   ["restore checksum"=6m34.879439498s]
   [Size=48693068713]
```

The above log includes the following information:

- Restore duration: `total take(Full restore time): 17m1.001611365s`
- Total runtime of the application: `total take(real time): 16m1.371611365s`
- Restore data size: `total size(MB): 353227.18`
- Restore KV pair number: `total kv: 5659888624`
- Restore throughput: `avg speed(MB/s): 367.42`
- `Region Split` duration: `take=49.049182743s`
- Restore checksum duration: `restore checksum=6m34.879439498s`

- The actual size of the restored data in the disk: `[Size=48693068713]`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` = `91.8`
- The average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` = `87.4`

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the restore process, you can try to increase the value of `--concurrency` which is `128` by default. See the following example:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data/
    ↪ --pd 172.16.5.198:2379 --log-file restore-concurrency.log --
    ↪ concurrency 1024
```

The tuned performance results are as follows (with the same data size):

- Restore duration: `total take(s)` reduced from `961.37` to `443.49`
- Restore throughput: `avg speed(MB/s)` increased from `367.42` to `796.47`
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from `91.8` to `199.1`
- Average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` increased from `87.4` to `162.3`

11.6.3.3.5 Back up a single table to a local disk (recommended in testing environment)

Use the `br backup` command to back up the single table `--db batchmark --table order_line` to the specified path `local:///home/tidb/backup_local` in the local disk.

Backup prerequisites

- Preparation for backup
- Each TiKV node has a separate disk to store the backupSST file.
- The `backup_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `backup_endpoint` node must have the same directory for the backup (for example, `/home/tidb/backup_local`).

Topology

The following diagram shows the typology of BR:

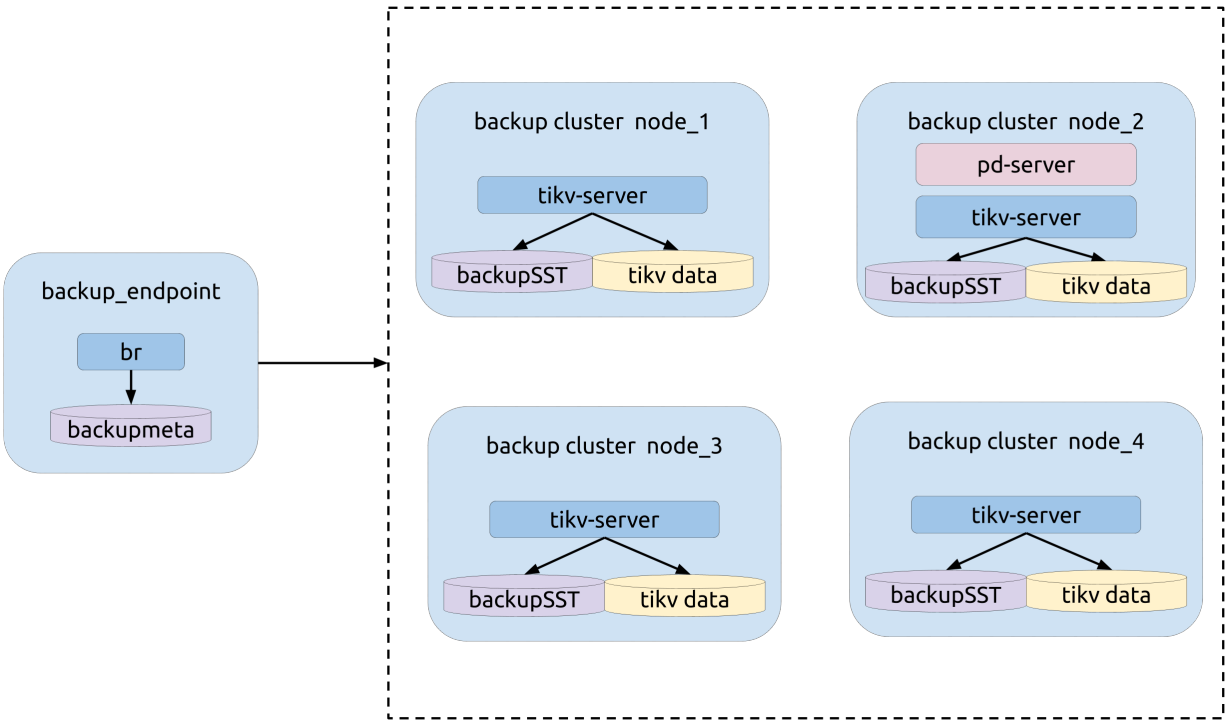

Figure 138: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark --table order_line`). The following image shows an example of this information:

```
+----------+------------+---------------------+-----------+--------------+
| Db_name  | Table_name | Checksum_crc64_xor  | Total_kvs | Total_bytes  |
+----------+------------+---------------------+-----------+--------------+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+----------+------------+---------------------+-----------+--------------+
1 row in set (5 min 47.59 sec)
```

Figure 139: img

Execute the `br backup` command:

```
bin/br backup table \
    --db batchmark \
    --table order_line \
    -s local:///home/tidb/backup_local/ \
```

```
    --pd ${PD_ADDR}:2379 \
    --log-file backup_local.log
```

During the backup process, pay attention to the metrics on the monitoring panels to get the status of the backup process. See Monitoring metrics for the backup for details.

Backup results explanation

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search "summary" in this log, you can see the following information:

```
["Table backup summary: total backup ranges: 4, total success: 4, total
    ↪ failed: 0, total take(s): 551.31, total kv: 5659888624, total size(MB
    ↪ ): 353227.18, avg speed(MB/s): 640.71"] ["backup total regions"=6795]
    ↪  ["backup checksum"=6m33.962719217s] ["backup fast checksum
    ↪ "=22.995552ms]
```

The information from the above log includes:

- Backup duration: `total take(s): 551.31`
- Data size: `total size(MB): 353227.18`
- Backup throughput: `avg speed(MB/s): 640.71`
- Backup checksum duration: `take=6m33.962719217s`

From the above information, the throughput of a single TiKV instance can be calculated: `avg speed(MB/s)/tikv_count` = 160.

11.6.3.3.6 Restore data from a local disk (recommended in testing environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- Preparation for restoration
- The TiKV cluster and the backup data do not have a duplicate database or table. Currently, BR does not support table route.
- Each TiKV node has a separate disk to store the backupSST file.
- The `restore_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `restore_endpoint` node must have the same directory for the restoration (for example, `/home/tidb/backup_local/`).

Before the restoration, follow these steps:

1. Collect all backupSST files into the same directory.
2. Copy the collected backupSST files to all TiKV nodes of the cluster.
3. Copy the `backupmeta` file to the `restore endpoint` node.

Topology

The following diagram shows the typology of BR:

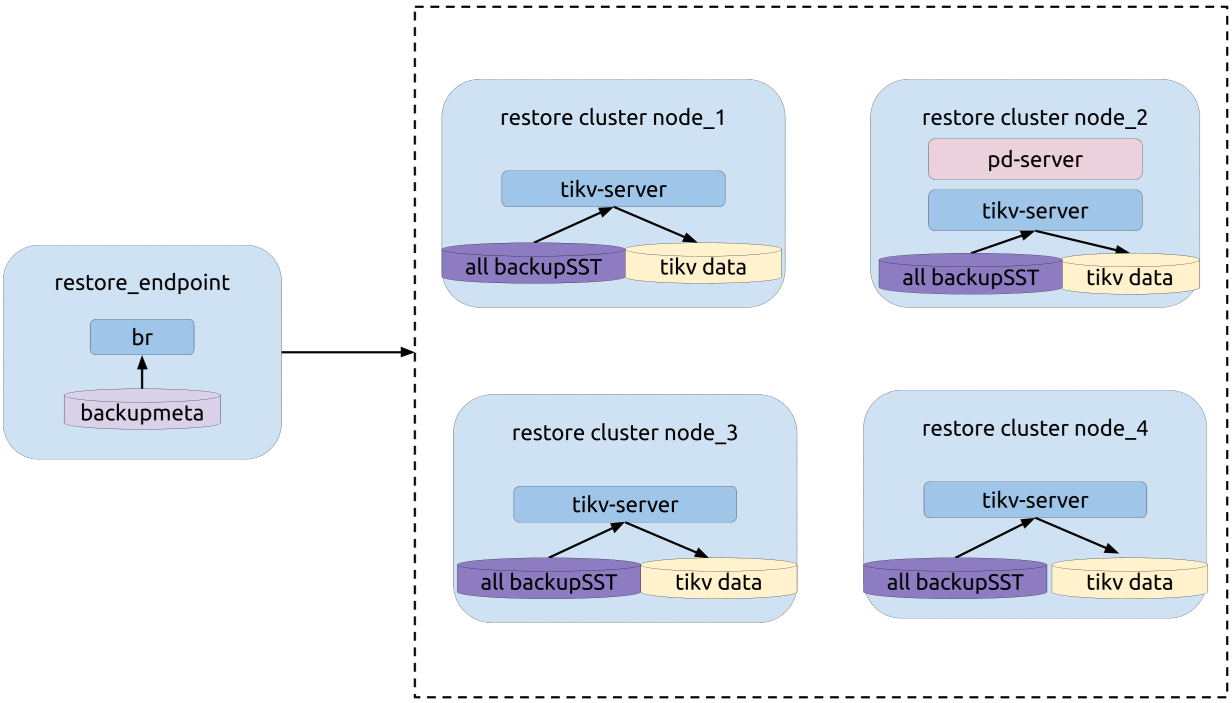

Figure 140: img

Restoration operation

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///home/tidb
    ↪ /backup_local/ --pd 172.16.5.198:2379 --log-file restore_local.log
```

During the restoration process, pay attention to the metrics on the monitoring panels to get the status of the restoration process. See Monitoring metrics for the restoration for details.

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search "summary" in this log, you can see the following information:

```
["Table Restore summary: total restore tables: 1, total success: 1, total
    ↪ failed: 0, total take(s): 908.42, total kv: 5659888624, total size(MB
    ↪ ): 353227.18, avg speed(MB/s): 388.84"] ["restore files"=9263] ["
    ↪ restore ranges"=6888] ["split region"=58.7885518s] ["restore checksum
    ↪ "=6m19.349067937s]
```

The above log includes the following information:

- Restoration duration: `total take(s): 908.42`
- Data size: `total size(MB): 353227.18`
- Restoration throughput: `avg speed(MB/s): 388.84`
- `Region Split` duration: `take=58.7885518s`
- Restoration checksum duration: `take=6m19.349067937s`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` = 97.2
- The average restoration speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` = 92.4

11.6.3.4 Error handling during backup

This section introduces the common errors occurred during the backup process.

11.6.3.4.1 `key locked Error` in the backup log

Error message in the log: `log - ["backup occur kv error"][error="{\"KvError
↪ \":{\"locked\":`

If a key is locked during the backup process, BR tries to resolve the lock. A small number of these errors do not affect the correctness of the backup.

11.6.3.4.2 Backup failure

Error message in the log: `log - Error: msg:"Io(Custom { kind: AlreadyExists,
↪ error: \"[5_5359_42_123_default.sst] is already exists in /dir/backup_local
↪ /\" })"`

If the backup operation fails and the above message occurs, perform one of the following operations and then start the backup operation again:

- Change the directory for the backup. For example, change `/dir/backup-2020-01-01/` to `/dir/backup_local/`.
- Delete the backup directory of all TiKV nodes and BR nodes.

11.6.4 External Storages

Backup & Restore (BR), TiDB Lighting, and Dumpling support reading and writing data on the local filesystem and on Amazon S3. BR also supports reading and writing data on the Google Cloud Storage (GCS). These are distinguished by the URL scheme in the `--storage` parameter passed into BR, in the `-d` parameter passed into TiDB Lightning, and in the `--output` (`-o`) parameter passed into Dumpling.

11.6.4.1 Schemes

The following services are supported:

Service	Schemes	Example URL
Local filesystem, distributed on every node	local	`local:///path/to/dest/`
Amazon S3 and compatible services	s3	`s3://bucket-name/prefix/of/dest/`
Google Cloud Storage (GCS)	gcs, gs	`gcs://bucket-name/prefix/of/dest/`
Write to nowhere (for benchmarking only)	noop	`noop://`

11.6.4.2 URL parameters

Cloud storages such as S3 and GCS sometimes require additional configuration for connection. You can specify parameters for such configuration. For example:

- Use Dumpling to export data to S3:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
   -o 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
   ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
   -d 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3 (using the path style in the request mode):

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
   ↪ local --sorted-kv-dir=/tmp/sorted-kvs \
   -d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
      ↪ ://10.154.10.132:8088'
```

- Use BR to back up data to GCS:

```
./br backup full -u 127.0.0.1:2379 \
   -s 'gcs://bucket-name/prefix'
```

11.6.4.2.1 S3 URL parameters

URL parameter	Description
`access-key`	The access key
`secret-access-key`	The secret access key
`region`	Service Region for Amazon S3 (default to `us-east-1`)
`use-accelerate-endpoint`	Whether to use the accelerate endpoint on Amazon S3 (default to `false`)
`endpoint`	URL of custom endpoint for S3-compatible services (for example, `https://s3.example.com/`)

URL parameter	Description
`force-path-style`	Use path style access rather than virtual hosted style access (default to `false`)
`storage-class`	Storage class of the uploaded objects (for example, `STANDARD`, `STANDARD_IA`)
`sse`	Server-side encryption algorithm used to encrypt the upload (empty, `AES256` or `aws:kms`)
`sse-kms-key-id`	If `sse` is set to `aws:kms`, specifies the KMS ID

URL parameter	Description
`acl`	Canned ACL of the uploaded objects (for example, `private`, `authenticated-read`)

Note:

It is not recommended to pass in the access key and secret access key directly in the storage URL, because these keys are logged in plain text. The migration tools try to infer these keys from the environment in the following order:

1. `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables
2. `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables
3. Shared credentials file on the tool node at the path specified by the `$AWS_SHARED_CREDENTIALS_FILE` environment variable
4. Shared credentials file on the tool node at `~/.aws/credentials`
5. Current IAM role of the Amazon EC2 container
6. Current IAM role of the Amazon ECS task

11.6.4.2.2 GCS URL parameters

URL parameter	Description
`credentials-file`	The path to the credentials JSON file on the tool node

URL parameter	Description
`storage-class`	Storage class of the uploaded objects (for example, `STANDARD`, `COLDLINE`)
`predefined-acl`	Predefined ACL of the uploaded objects (for example, `private`, `project-private`)

When `credentials-file` is not specified, the migration tool will try to infer the credentials from the environment, in the following order:

1. Content of the file on the tool node at the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS` environment variable
2. Content of the file on the tool node at `~/.config/gcloud/application_default_credentials.json`
3. When running in GCE or GAE, the credentials fetched from the metadata server.

11.6.4.3 Command-line parameters

In addition to the URL parameters, BR and Dumpling also support specifying these configurations using command-line parameters. For example:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
    -o 's3://my-bucket/sql-backup' \
    --s3.region 'us-west-2'
```

If you have specified URL parameters and command-line parameters at the same time, the URL parameters are overwritten by the command-line parameters.

11.6.4.3.1 S3 command-line parameters

Command-line parameter	Description
`--s3.region`	Amazon S3's service region, which defaults to `us-east-1`.
`--s3.endpoint`	The URL of custom endpoint for S3-compatible services. For example, `https://s3.example.com/`.

Command-line parameter	Description
`--s3.storage-class`	The storage class of the upload object. For example, `STANDARD` and `STANDARD_IA`.
`--s3.sse`	The server-side encryption algorithm used to encrypt the upload. The value options are empty, `AES256` and `aws:kms`.

Command-line parameter	Description
`--s3.sse-kms-key-id`	If `--s3.sse` is configured as `aws:kms`, this parameter is used to specify the KMS ID.
`--s3.acl`	The canned ACL of the upload object. For example, `private` and `authenticated-read`.

Command-line parameter	Description
`--s3.provider`	The type of the S3-compatible service. The supported types are `aws`, `alibaba`, `ceph`, `netease` and `other`.

11.6.4.3.2 GCS command-line parameters

Command-line parameter	Description
`--gcs.credentials-file`	The path of the JSON-formatted credential on the tool node.

Command-line parameter	Description
`--gcs.storage-class`	The storage type of the upload object, such as `STANDARD` and `COLDLINE`.
`--gcs.predefined-acl`	The predefined ACL of the upload object, such as `private` and `project-private`.

11.6.4.4 BR sending credentials to TiKV

By default, when using S3 and GCS destinations, BR will send the credentials to every TiKV nodes to reduce setup complexity.

However, this is unsuitable on cloud environment, where every node has their own role and permission. In such cases, you need to disable credentials sending with `--send-credentials-to-tikv=false` (or the short form `-c=0`):

```
./br backup full -c=0 -u pd-service:2379 -s 's3://bucket-name/prefix'
```

When using SQL statements to back up and restore data, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
    FALSE;
```

This option is not supported in TiDB Lightning and Dumpling, because the two applications are currently standalone.

11.6.5 Backup & Restore FAQ

This document lists the frequently asked questions (FAQs) and the solutions about Backup & Restore (BR).

11.6.5.1 What should I do if the error message `could not read local://...:download sst failed` is returned during data restoration?

When you restore data, each node must have access to **all** backup files (SST files). By default, if `local` storage is used, you cannot restore data because the backup files are scattered among different nodes. Therefore, you have to copy the backup file of each TiKV node to the other TiKV nodes.

It is recommended to mount an NFS disk as a backup disk during backup. For details, see Back up a single table to a network disk.

11.6.5.2 How much does it affect the cluster during backup using BR?

When you use the `oltp_read_only` scenario of `sysbench` to back up to a disk (make sure the backup disk and the service disk are different) at full rate, the cluster QPS is decreased by 15%-25%. The impact on the cluster depends on the table schema.

To reduce the impact on the cluster, you can use the `--ratelimit` parameter to limit the backup rate.

11.6.5.3 Does BR back up system tables? During data restoration, do they raise conflict?

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default. For more details, refer to the Back up and restore table data in the `mysql` system schema (experimental feature).

11.6.5.4 What should I do to handle the `Permission denied` or `No such file or directory` error, even if I have tried to run BR using root in vain?

You need to confirm whether TiKV has access to the backup directory. To back up data, confirm whether TiKV has the write permission. To restore data, confirm whether it has the read permission.

During the backup operation, if the storage medium is the local disk or a network file system (NFS), make sure that the user to start BR and the user to start TiKV are consistent (if BR and TiKV are on different machines, the users' UIDs must be consistent). Otherwise, the `Permission denied` issue might occur.

Running BR with the root access might fail due to the disk permission, because the backup files (SST files) are saved by TiKV.

Note:

You might encounter the same problem during data restoration. When the SST files are read for the first time, the read permission is verified. The execution duration of DDL suggests that there might be a long interval between checking the permission and running BR. You might receive the error message `Permission denied` after waiting for a long time.

Therefore, It is recommended to check the permission before data restoration.

11.6.5.5 What should I do to handle the `Io(Os...)` error?

Almost all of these problems are system call errors that occur when TiKV writes data to the disk. For example, if you encounter error messages such as `Io(Os {code: 13, kind: PermissionDenied...})` or `Io(Os {code: 2, kind: NotFound...})`, you can first check the mounting method and the file system of the backup directory, and try to back up data to another folder or another hard disk.

For example, you might encounter the `Code: 22(invalid argument)` error when backing up data to the network disk built by `samba`.

11.6.5.6 What should I do to handle the `rpc error: code = Unavailable desc =...` error occurred in BR?

This error might occur when the capacity of the cluster to restore (using BR) is insufficient. You can further confirm the cause by checking the monitoring metrics of this cluster or the TiKV log.

To handle this issue, you can try to scale out the cluster resources, reduce the concurrency during restore, and enable the `RATE_LIMIT` option.

11.6.5.7 Where are the backed up files stored when I use `local` storage?

When you use `local` storage, `backupmeta` is generated on the node where BR is running, and backup files are generated on the Leader nodes of each Region.

11.6.5.8 How about the size of the backup data? Are there replicas of the backup?

During data backup, backup files are generated on the Leader nodes of each Region. The size of the backup is equal to the data size, with no redundant replicas. Therefore, the total data size is approximately the total number of TiKV data divided by the number of replicas.

However, if you want to restore data from local storage, the number of replicas is equal to that of the TiKV nodes, because each TiKV must have access to all backup files.

11.6.5.9 What should I do when BR restores data to the upstream cluster of TiCDC/Drainer?

- **The data restored using BR cannot be replicated to the downstream**. This is because BR directly imports SST files but the downstream cluster currently cannot obtain these files from the upstream.
- Before v4.0.3, DDL jobs generated during the BR restore might cause unexpected DDL executions in TiCDC/Drainer. Therefore, if you need to perform restore on the upstream cluster of TiCDC/Drainer, add all tables restored using BR to the TiCDC/Drainer block list.

You can use `filter.rules` to configure the block list for TiCDC and use `syncer.ignore-table` to configure the block list for Drainer.

11.6.5.10 Does BR back up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table? Does the restored table have multiple Regions?

Yes. BR backs up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table. The data of the restored table is also split into multiple Regions.

11.6.5.11 Why is the `region is unavailable` error reported for a SQL query after I use BR to restore the backup data?

If the cluster backed up using BR has TiFlash, `TableInfo` stores the TiFlash information when BR restores the backup data. If the cluster to be restored does not have TiFlash, the `region is unavailable` error is reported.

11.6.5.12 Does BR support in-place full recovery of some historical backup?

No. BR does not support in-place full recovery of some historical backup.

11.6.5.13 How can I use BR for incremental backup in the Kubernetes environment?

To get the `commitTs` field of the last BR backup, run the `kubectl -n ${namespace} get bk ${name}` command using kubectl. You can use the content of this field as `--lastbackupts`.

11.6.5.14 How can I convert BR backupTS to Unix time?

BR `backupTS` defaults to the latest timestamp obtained from PD before the backup starts. You can use `pd-ctl tso timestamp` to parse the timestamp to obtain an accurate value, or use `backupTS >> 18` to quickly obtain an estimated value.

11.6.5.15 After BR restores the backup data, do I need to execute the `ANALYZE` statement on the table to update the statistics of TiDB on the tables and indexes?

BR does not back up statistics (except in v4.0.9). Therefore, after restoring the backup data, you need to manually execute `ANALYZE TABLE` or wait for TiDB to automatically execute `ANALYZE`.

In v4.0.9, BR backs up statistics by default, which consumes too much memory. To ensure that the backup process goes well, the backup for statistics is disabled by default starting from v4.0.10.

If you do not execute `ANALYZE` on the table, TiDB will fail to select the optimized execution plan due to inaccurate statistics. If query performance is not a key concern, you can ignore `ANALYZE`.

11.7 TiDB Binlog

11.7.1 TiDB Binlog Cluster Overview

This document introduces the architecture and the deployment of the cluster version of TiDB Binlog.

TiDB Binlog is a tool used to collect binlog data from TiDB and provide near real-time backup and replication to downstream platforms.

TiDB Binlog has the following features:

- **Data replication:** replicate the data in the TiDB cluster to other databases
- **Real-time backup and restoration:** back up the data in the TiDB cluster and restore the TiDB cluster when the cluster fails

> **Note:**
>
> TiDB Binlog is not compatible with some features introduced in TiDB v5.0 and they cannot be used together. For details, see Notes. It is recommended to use TiCDC instead of TiDB Binlog.

11.7.1.1 TiDB Binlog architecture

The TiDB Binlog architecture is as follows:

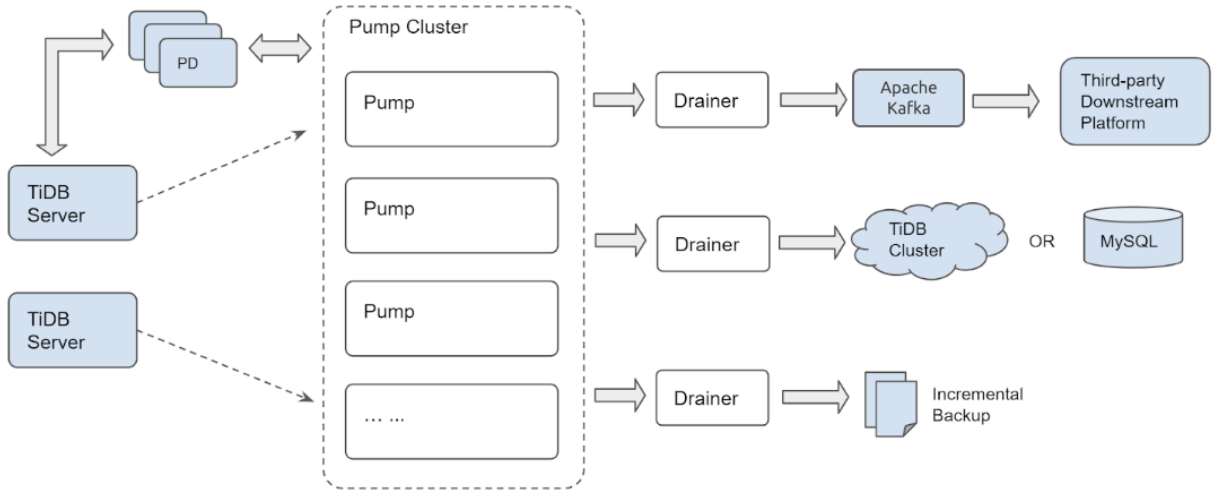

Figure 141: TiDB Binlog architecture

The TiDB Binlog cluster is composed of Pump and Drainer.

11.7.1.1.1 Pump

Pump is used to record the binlogs generated in TiDB, sort the binlogs based on the commit time of the transaction, and send binlogs to Drainer for consumption.

11.7.1.1.2 Drainer

Drainer collects and merges binlogs from each Pump, converts the binlog to SQL or data of a specific format, and replicates the data to a specific downstream platform.

11.7.1.1.3 `binlogctl` guide

`binlogctl` is an operations tool for TiDB Binlog with the following features:

- Obtaining the current `tso` of TiDB cluster
- Checking the Pump/Drainer state
- Modifying the Pump/Drainer state
- Pausing or closing Pump/Drainer

11.7.1.2 Main features

- Multiple Pumps form a cluster which can scale out horizontally
- TiDB uses the built-in Pump Client to send the binlog to each Pump
- Pump stores binlogs and sends the binlogs to Drainer in order

- Drainer reads binlogs of each Pump, merges and sorts the binlogs, and sends the binlogs downstream
- Drainer supports relay log. By the relay log, Drainer ensures that the downstream clusters are in a consistent state.

11.7.1.3 Notes

- In v5.1, the incompatibility between the clustered index feature introduced in v5.0 and TiDB Binlog has been resolved. After you upgrade TiDB Binlog and TiDB Server to v5.1 and enable TiDB Binlog, TiDB will support creating tables with clustered indexes; data insertion, deletion, and update on the created tables with clustered indexes will be replicated to the downstream via TiDB Binlog. When you use TiDB Binlog to replicate the tables with clustered indexes, pay attention to the following:
  - If you have upgraded the cluster to v5.1 from v5.0 by manually controlling the upgrade sequence, make sure that TiDB binlog is upgraded to v5.1 before upgrading the TiDB server to v5.1.
  - It is recommended to configure the system variable `tidb_enable_clustered_index` ↪ to a same value to ensure that the structure of TiDB clustered index tables between the upstream and downstream is consistent.

- TiDB Binlog is incompatible with the following features introduced in TiDB v5.0 and they cannot be used together.
  - TiDB Clustered Index: After TiDB Binlog is enabled, TiDB does not allow creating clustered indexes with non-single integer columns as primary keys; data insertion, deletion, and update of the created clustered index tables will not be replicated downstream via TiDB Binlog. If you need to replicate tables with clustered indexes, upgrade your cluster to v5.1 or use TiCDC instead.
  - TiDB system variable tidb_enable_async_commit: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use TiCDC instead of TiDB Binlog.
  - TiDB system variable tidb_enable_1pc: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use TiCDC instead of TiDB Binlog.

- TiDB Binlog is incompatible with the following feature introduced in TiDB v4.0.7 and they cannot be used together:
  - TiDB system variable tidb_enable_amend_pessimistic_txn: The two features have compatibility issues. Using them together might cause the issue that TiDB Binlog replicates data inconsistently.

- Drainer supports replicating binlogs to MySQL, TiDB, Kafka or local files. If you need to replicate binlogs to other Drainer unsuppored destinations, you can set Drainer to

replicate the binlog to Kafka and read the data in Kafka for customized processing according to binlog consumer protocol. See Binlog Consumer Client User Guide.

- To use TiDB Binlog for recovering incremental data, set the config `db-type` to `file` ↪ (local files in the proto buffer format). Drainer converts the binlog to data in the specified proto buffer format and writes the data to local files. In this way, you can use Reparo to recover data incrementally.

  Pay attention to the value of `db-type`:

  - If your TiDB version is earlier than 2.1.9, set `db-type="pb"`.
  - If your TiDB version is 2.1.9 or later, set `db-type="file"` or `db-type="pb"`.

- If the downstream is MySQL, MariaDB, or another TiDB cluster, you can use sync-diff-inspector to verify the data after data replication.

11.7.2 TiDB Binlog Tutorial

This tutorial starts with a simple TiDB Binlog deployment with a single node of each component (Placement Driver, TiKV Server, TiDB Server, Pump, and Drainer), set up to push data into a MariaDB Server instance.

This tutorial is targeted toward users who have some familiarity with the TiDB Architecture, who may have already set up a TiDB cluster (not mandatory), and who wants to gain hands-on experience with TiDB Binlog. This tutorial is a good way to "kick the tires" of TiDB Binlog and to familiarize yourself with the concepts of its architecture.

> **Warning:**
>
> The instructions to deploy TiDB in this tutorial should **not** be used to deploy TiDB in a production or development setting.

This tutorial assumes you're using a modern Linux distribution on x86-64. A minimal CentOS 7 installation running in VMware is used in this tutorial for the examples. It's recommended that you start from a clean install, so that you aren't impacted by quirks of your existing environment. If you don't want to use local virtualization, you can easily start a CentOS 7 VM using your cloud service.

11.7.2.1 TiDB Binlog Overview

TiDB Binlog is a solution to collect binary log data from TiDB and provide real-time data backup and replication. It pushes incremental data updates from a TiDB Server cluster into downstream platforms.

You can use TiDB Binlog for incremental backups, to replicate data from one TiDB cluster to another, or to send TiDB updates through Kafka to a downstream platform of your choice.

TiDB Binlog is particularly useful when you migrate data from MySQL or MariaDB to TiDB, in which case you may use the TiDB DM (Data Migration) platform to get data from a MySQL/MariaDB cluster into TiDB, and then use TiDB Binlog to keep a separate, downstream MySQL/MariaDB instance/cluster in sync with your TiDB cluster. TiDB Binlog enables application traffic to TiDB to be pushed to a downstream MySQL or MariaDB instance/cluster, which reduces the risk of a migration to TiDB because you can easily revert the application to MySQL or MariaDB without downtime or data loss.

See TiDB Binlog Cluster User Guide for more information.

11.7.2.2 Architecture

TiDB Binlog comprises two components: the **Pump** and the **Drainer**. Several Pump nodes make up a pump cluster. Each Pump node connects to TiDB Server instances and receives updates made to each of the TiDB Server instances in a cluster. A Drainer connects to the Pump cluster and transforms the received updates into the correct format for a particular downstream destination, for example, Kafka, another TiDB Cluster or a MySQL/MariaDB server.

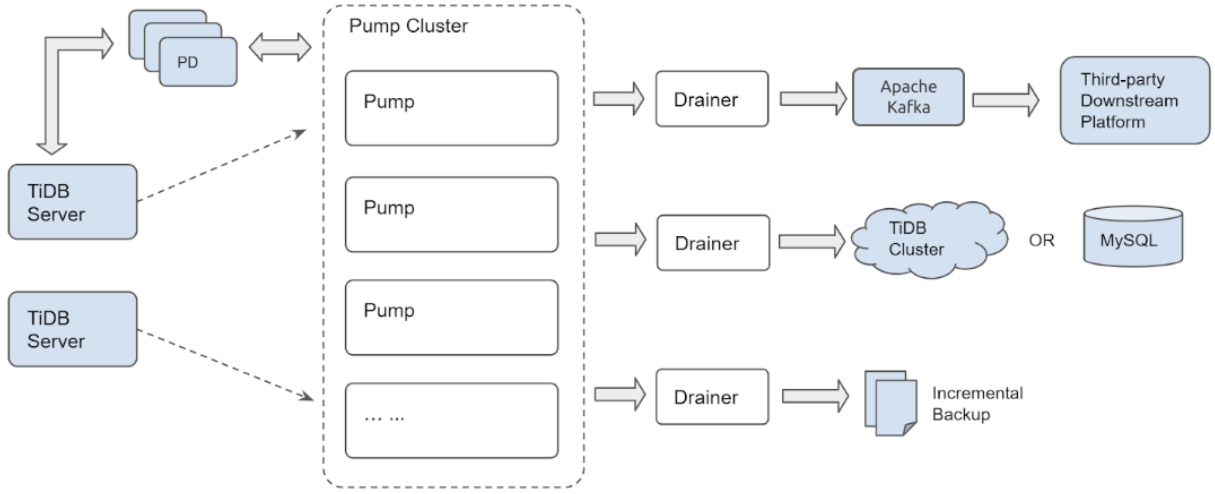

Figure 142: TiDB-Binlog architecture

The clustered architecture of Pump ensures that updates won't be lost as new TiDB Server instances join or leave the TiDB Cluster or Pump nodes join or leave the Pump cluster.

11.7.2.3 Installation

We're using MariaDB Server in this case instead of MySQL Server because RHEL/CentOS 7 includes MariaDB Server in their default package repositories. We'll need the client as well as the server for later use. Let's install them now:

```
sudo yum install -y mariadb-server
```

```
curl -L https://download.pingcap.org/tidb-latest-linux-amd64.tar.gz | tar
    ↪ xzf -
cd tidb-latest-linux-amd64
```

Expected output:

```
[kolbe@localhost ~]$ curl -LO https://download.pingcap.org/tidb-latest-linux
    ↪ -amd64.tar.gz | tar xzf -
  % Total    % Received % Xferd Average Speed Time  Time    Time Current
                                Dload Upload  Total  Spent   Left Speed
100  368M 100  368M   0     0  8394k     0  0:00:44 0:00:44 --:--:-- 11.1M
[kolbe@localhost ~]$ cd tidb-latest-linux-amd64
[kolbe@localhost tidb-latest-linux-amd64]$
```

11.7.2.4 Configuration

Now we'll start a simple TiDB cluster, with a single instance for each of `pd-server`, `tikv-server`, and `tidb-server`.

Populate the config files using:

```
printf > pd.toml %s\\n 'log-file="pd.log"' 'data-dir="pd.data"'
printf > tikv.toml %s\\n 'log-file="tikv.log"' '[storage]' 'data-dir="tikv.
    ↪ data"' '[pd]' 'endpoints=["127.0.0.1:2379"]' '[rocksdb]' max-open-
    ↪ files=1024 '[raftdb]' max-open-files=1024
printf > pump.toml %s\\n 'log-file="pump.log"' 'data-dir="pump.data"' 'addr
    ↪ ="127.0.0.1:8250"' 'advertise-addr="127.0.0.1:8250"' 'pd-urls="http
    ↪ ://127.0.0.1:2379"'
printf > tidb.toml %s\\n 'store="tikv"' 'path="127.0.0.1:2379"' '[log.file
    ↪ ]' 'filename="tidb.log"' '[binlog]' 'enable=true'
printf > drainer.toml %s\\n 'log-file="drainer.log"' '[syncer]' 'db-type="
    ↪ mysql"' '[syncer.to]' 'host="127.0.0.1"' 'user="root"' 'password=""'
    ↪ 'port=3306'
```

Use the following commands to see the configuration details:

```
for f in *.toml; do echo "$f:"; cat "$f"; echo; done
```

Expected output:

```
drainer.toml:
log-file="drainer.log"
[syncer]
db-type="mysql"
[syncer.to]
host="127.0.0.1"
user="root"
password=""
port=3306

pd.toml:
log-file="pd.log"
data-dir="pd.data"

pump.toml:
log-file="pump.log"
data-dir="pump.data"
addr="127.0.0.1:8250"
advertise-addr="127.0.0.1:8250"
pd-urls="http://127.0.0.1:2379"

tidb.toml:
store="tikv"
path="127.0.0.1:2379"
[log.file]
filename="tidb.log"
[binlog]
enable=true

tikv.toml:
log-file="tikv.log"
[storage]
data-dir="tikv.data"
[pd]
endpoints=["127.0.0.1:2379"]
[rocksdb]
max-open-files=1024
[raftdb]
max-open-files=1024
```

11.7.2.5 Bootstrapping

Now we can start each component. This is best done in a specific order - firstly the Placement Driver (PD), then TiKV Server, then Pump (because TiDB must connect to the

Pump service to send the binary log), and finally the TiDB Server.

Start all the services using:

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./bin/pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/pd-server --config=pd.toml
   ↪ &>pd.out &
[1] 20935
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/tikv-server --config=tikv.
   ↪ toml &>tikv.out &
[2] 20944
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/pump --config=pump.toml &>
   ↪ pump.out &
[3] 21050
[kolbe@localhost tidb-latest-linux-amd64]$ sleep 3
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/tidb-server --config=tidb.
   ↪ toml &>tidb.out &
[4] 21058
```

If you execute `jobs`, you should see a list of running daemons:

```
[kolbe@localhost tidb-latest-linux-amd64]$ jobs
[1]   Running                 ./bin/pd-server --config=pd.toml &>pd.out &
[2]   Running                 ./bin/tikv-server --config=tikv.toml &>tikv.out &
[3]-  Running                 ./bin/pump --config=pump.toml &>pump.out &
[4]+  Running                 ./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If one of the services has failed to start (if you see "`Exit 1`" instead of "`Running`", for example), try to restart that individual service.

11.7.2.6 Connecting

You should have all 4 components of our TiDB Cluster running now, and you can now connect to the TiDB Server on port 4000 using the MariaDB/MySQL command-line client:

```
mysql -h 127.0.0.1 -P 4000 -u root -e 'select tidb_version()\G'
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ mysql -h 127.0.0.1 -P 4000 -u
   ↪ root -e 'select tidb_version()\G'
```

```
*************************** 1. row ***************************
tidb_version(): Release Version: v3.0.0-beta.1-154-gd5afff70c
Git Commit Hash: d5afff70cdd825d5fab125c8e52e686cc5fb9a6e
Git Branch: master
UTC Build Time: 2019-04-24 03:10:00
GoVersion: go version go1.12 linux/amd64
Race Enabled: false
TiKV Min Version: 2.1.0-alpha.1-ff3dd160846b7d1aed9079c389fc188f7f5ea13e
Check Table Before Drop: false
```

At this point we have a TiDB Cluster running, and we have `pump` reading binary logs from the cluster and storing them as relay logs in its data directory. The next step is to start a MariaDB server that `drainer` can write to.

Start `drainer` using:

```
sudo systemctl start mariadb
./bin/drainer --config=drainer.toml &>drainer.out &
```

If you are using an operating system that makes it easier to install MySQL server, that's also OK. Just make sure it's listening on port 3306 and that you can either connect to it as user "root" with an empty password, or adjust drainer.toml as necessary.

```
mysql -h 127.0.0.1 -P 3306 -u root
```

```
show databases;
```

Expected output:

```
[kolbe@localhost ~]$ mysql -h 127.0.0.1 -P 3306 -u root
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 20
Server version: 5.5.60-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
   ↪ statement.

MariaDB [(none)]> show databases;
+--------------------+
| Database           |
+--------------------+
| information_schema |
| mysql              |
| performance_schema |
| test               |
```

```
| tidb_binlog     |
+-----------------+
5 rows in set (0.01 sec)
```

Here we can already see the `tidb_binlog` database, which contains the `checkpoint` table used by `drainer` to record up to what point binary logs from the TiDB cluster have been applied.

```
MariaDB [tidb_binlog]> use tidb_binlog;
Database changed
MariaDB [tidb_binlog]> select * from checkpoint;
+--------------------+-------------------------------------------+
| clusterID          | checkPoint                                |
+--------------------+-------------------------------------------+
| 6678715361817107733 | {"commitTS":407637466476445697,"ts-map":{}} |
+--------------------+-------------------------------------------+
1 row in set (0.00 sec)
```

Now, let's open another client connection to the TiDB server, so that we can create a table and insert some rows into it. (It's recommended that you do this under a GNU screen so you can keep multiple clients open at the same time.)

```
mysql -h 127.0.0.1 -P 4000 --prompt='TiDB [\d]> ' -u root
```

```
create database tidbtest;
use tidbtest;
create table t1 (id int unsigned not null AUTO_INCREMENT primary key);
insert into t1 () values (),(),(),(),();
select * from t1;
```

Expected output:

```
TiDB [(none)]> create database tidbtest;
Query OK, 0 rows affected (0.12 sec)

TiDB [(none)]> use tidbtest;
Database changed
TiDB [tidbtest]> create table t1 (id int unsigned not null AUTO_INCREMENT
    ↪ primary key);
Query OK, 0 rows affected (0.11 sec)

TiDB [tidbtest]> insert into t1 () values (),(),(),(),();
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

TiDB [tidbtest]> select * from t1;
```

```
+----+
| id |
+----+
|  1 |
|  2 |
|  3 |
|  4 |
|  5 |
+----+
5 rows in set (0.00 sec)
```

Switching back to the MariaDB client, we should find the new database, new table, and the newly inserted rows:

```
use tidbtest;
show tables;
select * from t1;
```

Expected output:

```
MariaDB [(none)]> use tidbtest;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
MariaDB [tidbtest]> show tables;
+--------------------+
| Tables_in_tidbtest |
+--------------------+
| t1                 |
+--------------------+
1 row in set (0.00 sec)

MariaDB [tidbtest]> select * from t1;
+----+
| id |
+----+
|  1 |
|  2 |
|  3 |
|  4 |
|  5 |
+----+
5 rows in set (0.00 sec)
```

You should see the same rows that you inserted into TiDB when querying the MariaDB server. Congratulations! You've just set up TiDB Binlog!

11.7.2.7 binlogctl

Information about Pumps and Drainers that have joined the cluster is stored in PD. You can use the binlogctl tool query and manipulate information about their states. See binlogctl guide for more information.

Use `binlogctl` to get a view of the current status of Pumps and Drainers in the cluster:

```
./bin/binlogctl -cmd drainers
./bin/binlogctl -cmd pumps
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd drainers
[2019/04/11 17:44:10.861 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
   ↪ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
   ↪ 192.168.236.128:8249, State: online, MaxCommitTS: 407638907719778305,
   ↪  UpdateTime: 2019-04-11 17:44:10 -0400 EDT}"]

[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd pumps
[2019/04/11 17:44:13.904 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
   ↪ pump] [node="{NodeID: localhost.localdomain:8250, Addr:
   ↪ 192.168.236.128:8250, State: online, MaxCommitTS: 407638914024079361,
   ↪  UpdateTime: 2019-04-11 17:44:13 -0400 EDT}"]
```

If you kill a Drainer, the cluster puts it in the "paused" state, which means that the cluster expects it to rejoin:

```
pkill drainer
./bin/binlogctl -cmd drainers
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ pkill drainer
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd drainers
[2019/04/11 17:44:22.640 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
   ↪ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
   ↪ 192.168.236.128:8249, State: paused, MaxCommitTS: 407638915597467649,
   ↪  UpdateTime: 2019-04-11 17:44:18 -0400 EDT}"]
```

You can use "NodeIDs" with `binlogctl` to control individual nodes. In this case, the NodeID of the drainer is "localhost.localdomain:8249" and the NodeID of the Pump is "localhost.localdomain:8250".

The main use of `binlogctl` in this tutorial is likely to be in the event of a cluster restart. If you end all processes in the TiDB cluster and try to restart them (not including

the downstream MySQL/MariaDB server or Drainer), Pump will refuse to start because it cannot contact Drainer and believe that Drainer is still "online".

There are 3 solutions to this issue:

- Stop Drainer using `binlogctl` instead of killing the process:

```
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=drainers
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=offline-drainer
   ↪ --node-id=localhost.localdomain:8249
```

- Start Drainer *before* starting Pump.
- Use `binlogctl` after starting PD (but before starting Drainer and Pump) to update the state of the paused Drainer:

```
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=update-drainer --
   ↪ node-id=localhost.localdomain:8249 --state=offline
```

11.7.2.8 Cleanup

To stop the TiDB cluster and TiDB Binlog processes, you can execute `pkill -P $$` in the shell where you started all the processes that form the cluster (pd-server, tikv-server, pump, tidb-server, drainer). To give each component enough time to shut down cleanly, it's helpful to stop them in a particular order:

```
for p in tidb-server drainer pump tikv-server pd-server; do pkill "$p";
   ↪ sleep 1; done
```

Expected output:

```
kolbe@localhost tidb-latest-linux-amd64]$ for p in tidb-server drainer pump
   ↪ tikv-server pd-server; do pkill "$p"; sleep 1; done
[4]- Done                    ./bin/tidb-server --config=tidb.toml &>tidb.out
[5]+ Done                    ./bin/drainer --config=drainer.toml &>drainer.out
[3]+ Done                    ./bin/pump --config=pump.toml &>pump.out
[2]+ Done                    ./bin/tikv-server --config=tikv.toml &>tikv.out
[1]+ Done                    ./bin/pd-server --config=pd.toml &>pd.out
```

If you wish to restart the cluster after all services exit, use the same commands you ran originally to start the services. As discussed in the binlogctl section above, you'll need to start `drainer` before `pump`, and `pump` before `tidb-server`.

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./bin/drainer --config=drainer.toml &>drainer.out &
sleep 3
```

```
./bin/pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If any of the components fail to start, try to restart the failed individual component(s).

11.7.2.9 Conclusion

In this tutorial, we've set up TiDB Binlog to replicate from a TiDB cluster to a downstream MariaDB server, using a cluster with a single Pump and a single Drainer. As we've seen, TiDB Binlog is a comprehensive platform for capturing and processing changes to a TiDB cluster.

In a more robust development, testing, or production deployment, you'd have multiple TiDB servers for high availability and scaling purposes, and you'd use multiple Pump instances to ensure that application traffic to TiDB server instances is unaffected by problems in the Pump cluster. You may also use additional Drainer instances to push updates to different downstream platforms or to implement incremental backups.

11.7.3 TiDB Binlog Cluster Deployment

This document describes how to deploy TiDB Binlog using a Binary package.

11.7.3.1 Hardware requirements

Pump and Drainer are deployed and operate on 64-bit universal hardware server platforms with Intel x86-64 architecture.

In environments of development, testing and production, the requirements on server hardware are as follows:

Service	The Number of Servers	CPU	Disk	Memory
Pump	3	8 core+	SSD, 200 GB+	16G
Drainer	1	8 core+	SAS, 100 GB+ (If binlogs are output as local files, the disk size depends on how long these files are retained.)	16G

11.7.3.2 Deploy TiDB Binlog using TiUP

It is recommended to deploy TiDB Binlog using TiUP. To do that, when deploying TiDB using TiUP, you need to add the node information of `drainer` and `pump` of TiDB Binlog in TiDB Binlog Deployment Topology. For detailed deployment information, refer to Deploy a TiDB Cluster Using TiUP.

11.7.3.3 Deploy TiDB Binlog using a Binary package

11.7.3.3.1 Download the official Binary package

Run the following commands to download the packages:

```
version="latest" for nightly builds &&
wget https://download.pingcap.org/tidb-latest-linux-amd64.{tar.gz,sha256}
```

Check the file integrity. If the result is OK, the file is correct.

```
sha256sum -c tidb-latest-linux-amd64.sha256
```

For TiDB v2.1.0 GA or later versions, Pump and Drainer are already included in the TiDB download package. For other TiDB versions, you need to download Pump and Drainer separately using the following command:

```
wget https://download.pingcap.org/tidb-binlog-$version-linux-amd64.{tar.gz,
    ↪ sha256}
```

Check the file integrity. If the result is OK, the file is correct.

```
sha256sum -c tidb-binlog-$version-linux-amd64.sha256
```

11.7.3.3.2 The usage example

Assuming that you have three PD nodes, one TiDB node, two Pump nodes, and one Drainer node, the information of each node is as follows:

Node	IP
TiDB	192.168.0.10
PD1	192.168.0.16
PD2	192.168.0.15
PD3	192.168.0.14
Pump	192.168.0.11
Pump	192.168.0.12
Drainer	192.168.0.13

The following part shows how to use Pump and Drainer based on the nodes above.

1. Deploy Pump using the binary.

    - To view the command line parameters of Pump, execute `./bin/pump -help`:

```
Usage of Pump:
-L string
    the output information level of logs: debug, info, warn, error,
        ↪  fatal ("info" by default)
-V
    the print version information
-addr string
    the RPC address through which Pump provides the service (-addr=
        ↪ "192.168.0.11:8250")
-advertise-addr string
    the RPC address through which Pump provides the external
        ↪ service (-advertise-addr="192.168.0.11:8250")
-config string
    the path of the configuration file. If you specify the
        ↪ configuration file, Pump reads the configuration in the
        ↪ configuration file first. If the corresponding
        ↪ configuration also exits in the command line parameters,
        ↪ Pump uses the configuration of the command line
        ↪ parameters to cover that of the configuration file.
-data-dir string
    the path where the Pump data is stored
-gc int
    the number of days to retain the data in Pump ("7" by default)
-heartbeat-interval int
    the interval of the heartbeats Pump sends to PD (in seconds)
-log-file string
    the file path of logs
-log-rotate string
    the switch frequency of logs (hour/day)
-metrics-addr string
    the Prometheus Pushgateway address. If not set, it is forbidden
        ↪  to report the monitoring metrics.
-metrics-interval int
    the report frequency of the monitoring metrics ("15" by default
        ↪ , in seconds)
-node-id string
    the unique ID of a Pump node. If you do not specify this ID,
        ↪ the system automatically generates an ID based on the
        ↪ host name and listening port.
-pd-urls string
    the address of the PD cluster nodes (-pd-urls="http
        ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
```

```
      ↪ ://192.168.0.14:2379")
-fake-binlog-interval int
   the frequency at which a Pump node generates fake binlog ("3"
      ↪ by default, in seconds)
```

- Taking deploying Pump on "192.168.0.11" as an example, the Pump configuration file is as follows:

```
# Pump Configuration

# the bound address of Pump
addr = "192.168.0.11:8250"

# the address through which Pump provides the service
advertise-addr = "192.168.0.11:8250"

# the number of days to retain the data in Pump ("7" by default)
gc = 7

# the directory where the Pump data is stored
data-dir = "data.pump"

# the interval of the heartbeats Pump sends to PD (in seconds)
heartbeat-interval = 2

# the address of the PD cluster nodes (each separated by a comma
   ↪ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
   ↪ ://192.168.0.14:2379"

# [security]
# This section is generally commented out if no special security
   ↪ settings are required.
# The file path containing a list of trusted SSL CAs connected to
   ↪ the cluster.
# ssl-ca = "/path/to/ca.pem"
# The path to the X509 certificate in PEM format that is connected
   ↪ to the cluster.
# ssl-cert = "/path/to/drainer.pem"
# The path to the X509 key in PEM format that is connected to the
   ↪ cluster.
# ssl-key = "/path/to/drainer-key.pem"

# [storage]
# Set to true (by default) to guarantee reliability by ensuring
```

```
    ↪ binlog data is flushed to the disk
# sync-log = true

# When the available disk capacity is less than the set value, Pump
    ↪  stops writing data.
# 42 MB -> 42000000, 42 mib -> 44040192
# default: 10 gib
# stop-write-at-available-space = "10 gib"
# The LSM DB settings embedded in Pump. Unless you know this part
    ↪ well, it is usually commented out.
# [storage.kv]
# block-cache-capacity = 8388608
# block-restart-interval = 16
# block-size = 4096
# compaction-L0-trigger = 8
# compaction-table-size = 67108864
# compaction-total-size = 536870912
# compaction-total-size-multiplier = 8.0
# write-buffer = 67108864
# write-L0-pause-trigger = 24
# write-L0-slowdown-trigger = 17
```

- The example of starting Pump:

```
./bin/pump -config pump.toml
```

  If the command line parameters is the same with the configuration file parameters, the values of command line parameters are used.

2. Deploy Drainer using binary.

- To view the command line parameters of Drainer, execute `./bin/drainer -help`:

```
Usage of Drainer:
-L string
    the output information level of logs: debug, info, warn, error,
        ↪  fatal ("info" by default)
-V
    the print version information
-addr string
    the address through which Drainer provides the service (-addr="
        ↪ 192.168.0.13:8249")
-c int
    the number of the concurrency of the downstream for replication
        ↪ . The bigger the value, the better throughput performance
        ↪  of the concurrency ("1" by default).
```

```
-cache-binlog-count int
    the limit on the number of binlog items in the cache ("8" by
        ↪ default)
    If a large single binlog item in the upstream causes OOM in
        ↪ Drainer, try to lower the value of this parameter to
        ↪ reduce memory usage.
-config string
    the directory of the configuration file. Drainer reads the
        ↪ configuration file first.
    If the corresponding configuration exists in the command line
        ↪ parameters, Drainer uses the configuration of the command
        ↪  line parameters to cover that of the configuration file.
-data-dir string
    the directory where the Drainer data is stored ("data.drainer"
        ↪ by default)
-dest-db-type string
    the downstream service type of Drainer
    The value can be "mysql", "tidb", "kafka", and "file". ("mysql"
        ↪  by default)
-detect-interval int
    the interval of checking the online Pump in PD ("10" by default
        ↪ , in seconds)
-disable-detect
    whether to disable the conflict monitoring
-disable-dispatch
    whether to disable the SQL feature of splitting a single binlog
        ↪  file. If it is set to "true", each binlog file is
        ↪ restored to a single transaction for replication based on
        ↪  the order of binlogs.
    It is set to "False", when the downstream is MySQL.
-ignore-schemas string
    the db filter list ("INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,
        ↪ mysql,test" by default)
    It does not support the Rename DDL operation on tables of `
        ↪ ignore schemas`.
-initial-commit-ts
    If Drainer does not have the related breakpoint information,
        ↪ you can configure the related breakpoint information
        ↪ using this parameter. ("-1" by default)
    If the value of this parameter is `-1`, Drainer automatically
        ↪ obtains the latest timestamp from PD.
-log-file string
    the path of the log file
-log-rotate string
    the switch frequency of log files, hour/day
```

```
-metrics-addr string
    the Prometheus Pushgateway address
    It it is not set, the monitoring metrics are not reported.
-metrics-interval int
    the report frequency of the monitoring metrics ("15" by default
        ↪ , in seconds)
-node-id string
    the unique ID of a Drainer node. If you do not specify this ID,
        ↪  the system automatically generates an ID based on the
        ↪ host name and listening port.
-pd-urls string
    the address of the PD cluster nodes (-pd-urls="http
        ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
        ↪ ://192.168.0.14:2379")
-safe-mode
    Whether to enable safe mode so that data can be written into
        ↪ the downstream MySQL/TiDB repeatedly.
    This mode replaces the `INSERT` statement with the `REPLACE`
        ↪ statement and splits the `UPDATE` statement into `DELETE`
        ↪  plus `REPLACE`.
-txn-batch int
    the number of SQL statements of a transaction which are output
        ↪ to the downstream database ("1" by default)
```

- Taking deploying Drainer on "192.168.0.13" as an example, the Drainer configuration file is as follows:

```
# Drainer Configuration.

# the address through which Drainer provides the service
    ↪ ("192.168.0.13:8249")
addr = "192.168.0.13:8249"

# the address through which Drainer provides the external service
advertise-addr = "192.168.0.13:8249"

# the interval of checking the online Pump in PD ("10" by default,
    ↪ in seconds)
detect-interval = 10

# the directory where the Drainer data is stored "data.drainer" by
    ↪ default)
data-dir = "data.drainer"

# the address of the PD cluster nodes (each separated by a comma
```

```
   ↪ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
   ↪ ://192.168.0.14:2379"

# the directory of the log file
log-file = "drainer.log"

# Drainer compresses the data when it gets the binlog from Pump.
   ↪ The value can be "gzip". If it is not configured, it will
   ↪ not be compressed
# compressor = "gzip"

# [security]
# This section is generally commented out if no special security
   ↪ settings are required.
# The file path containing a list of trusted SSL CAs connected to
   ↪ the cluster.
# ssl-ca = "/path/to/ca.pem"
# The path to the X509 certificate in PEM format that is connected
   ↪ to the cluster.
# ssl-cert = "/path/to/pump.pem"
# The path to the X509 key in PEM format that is connected to the
   ↪ cluster.
# ssl-key = "/path/to/pump-key.pem"

# Syncer Configuration
[syncer]
# If the item is set, the sql-mode will be used to parse the DDL
   ↪ statement.
# If the downstream database is MySQL or TiDB, then the downstream
   ↪ sql-mode
# is also set to this value.
# sql-mode = "STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION"

# the number of SQL statements of a transaction that are output to
   ↪ the downstream database ("20" by default)
txn-batch = 20

# the number of the concurrency of the downstream for replication.
   ↪ The bigger the value,
# the better throughput performance of the concurrency ("16" by
   ↪ default)
worker-count = 16

# whether to disable the SQL feature of splitting a single binlog
```

```
   ↪ file. If it is set to "true",
# each binlog file is restored to a single transaction for
   ↪ replication based on the order of binlogs.
# If the downstream service is MySQL, set it to "False".

# The maximum size of a broker request (unit: byte). The default
    ↪ value is 1 GiB and the maximum value is 2 GiB.
# kafka-max-message-size = 1073741824

# the topic name of the Kafka cluster that saves the binlog data.
    ↪ The default value is <cluster-id>_obinlog.
# To run multiple Drainers to replicate data to the same Kafka
    ↪ cluster, you need to set different `topic-name`s for each
    ↪ Drainer.
# topic-name = ""
```

- Starting Drainer:

> **Note:**
> If the downstream is MySQL/TiDB, to guarantee the data integrity, you need to obtain the `initial-commit-ts` value and make a full backup of the data and restore the data before the initial start of Drainer.

When Drainer is started for the first time, use the `initial-commit-ts` parameter.

```
./bin/drainer -config drainer.toml -initial-commit-ts {initial-
    ↪ commit-ts}
```

If the command line parameter and the configuration file parameter are the same, the parameter value in the command line is used.

3. Starting TiDB server:

    - After starting Pump and Drainer, start TiDB server with binlog enabled by adding this section to your config file for TiDB server:

    ```
    [binlog]
    enable=true
    ```

    - TiDB server will obtain the addresses of registered Pumps from PD and will stream data to all of them. If there are no registered Pump instances, TiDB server will refuse to start or will block starting until a Pump instance comes online.

Note:

- When TiDB is running, you need to guarantee that at least one Pump is running normally.
- To enable the TiDB Binlog service in TiDB server, use the `-enable-binlog` startup parameter in TiDB, or add enable=true to the binlog section of the TiDB server configuration file.
- Make sure that the TiDB Binlog service is enabled in all TiDB instances in a same cluster, otherwise upstream and downstream data inconsistency might occur during data replication. If you want to temporarily run a TiDB instance where the TiDB Binlog service is not enabled, set `run_ddl=false` in the TiDB configuration file.
- Drainer does not support the `rename` DDL operation on the table of `ignore schemas` (the schemas in the filter list).
- If you want to start Drainer in an existing TiDB cluster, generally you need to make a full backup of the cluster data, obtain **snapshot timestamp**, import the data to the target database, and then start Drainer to replicate the incremental data from the corresponding **snapshot timestamp**.
- When the downstream database is TiDB or MySQL, ensure that the `sql_mode` in the upstream and downstream databases are consistent. In other words, the `sql_mode` should be the same when each SQL statement is executed in the upstream and replicated to the downstream. You can execute the `select @@sql_mode;` statement in the upstream and downstream respectively to compare `sql_mode`.
- When a DDL statement is supported in the upstream but incompatible with the downstream, Drainer fails to replicate data. An example is to

replicate the `CREATE TABLE t1(a INT)ROW_FORMAT=FIXED;` statement when the downstream database MySQL uses the InnoDB engine. In this case, you can configure skipping transactions in Drainer, and manually execute compatible statements in the downstream database.

11.7.4 TiDB Binlog Cluster Operations

This document introduces the following TiDB Binlog cluster operations:

- The state of a Pump and Drainer nodes
- Starting or exiting a Pump or Drainer process
- Managing the TiDB Binlog cluster by using the binlogctl tool or by directly performing SQL operations in TiDB

11.7.4.1 Pump or Drainer state

Pump or Drainer state description:

- `online`: running normally
- `pausing`: in the pausing process
- `paused`: has been stopped
- `closing`: in the offline process
- `offline`: has been offline

Note:

The state information of a Pump or Drainer node is maintained by the service itself and is regularly updated to the Placement Driver (PD).

11.7.4.2 Starting and exiting a Pump or Drainer process

11.7.4.2.1 Pump

- Starting: When started, the Pump node notifies all Drainer nodes in the `online` state. If the notification is successful, the Pump node sets its state to `online`. Otherwise, the Pump node reports an error, sets its state to `paused` and exits the process.
- Exiting: The Pump node enters the `paused` or `offline` state before the process is exited normally; if the process is exited abnormally (caused by the `kill -9` command, process panic, crash), the node is still in the `online` state.

- Pause: You can pause a Pump process by using the `kill` command (not `kill -9` ↪), pressing Ctrl+C or using the `pause-pump` command in the binlogctl tool. After receiving the pause instruction, the Pump node sets its state to `pausing`, stops receiving binlog write requests and stops providing binlog data to Drainer nodes. After all threads are safely exited, the Pump node updates its state to `paused` and exits the process.
- Offline: You can close a Pump process only by using the `offline-pump` command in the binlogctl tool. After receiving the offline instruction, the Pump node sets its state to `closing` and stops receiving the binlog write requests. The Pump node continues providing binlog to Drainer nodes until all binlog data is consumed by Drainer nodes. Then, the Pump node sets its state to `offline` and exits the process.

11.7.4.2.2 Drainer

- Starting: When started, the Drainer node sets its state to `online` and tries to pull binlogs from all Pump nodes which are not in the `offline` state. If it fails to get the binlogs, it keeps trying.
- Exiting: The Drainer node enters the `paused` or `offline` state before the process is exited normally; if the process is exited abnormally (caused by `kill -9`, process panic, crash), the Drainer node is still in the `online` state.
  - Pause: You can pause a Drainer process by using the `kill` command (not `kill` ↪ `-9`), pressing Ctrl+C or using the `pause-drainer` command in the binlogctl tool. After receiving the pause instruction, the Drainer node sets its state to `pausing` and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node sets its state to `paused` and exits the process.
  - Offline: You can close a Drainer process only by using the `offline-drainer` command in the binlogctl tool. After receiving the offline instruction, the Drainer node sets its state to `closing` and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node updates its state to `offline` and exits the process.

For how to pause, close, check, and modify the state of Drainer, see the binlogctl guide.

11.7.4.3 Use `binlogctl` to manage Pump/Drainer

`binlogctl` is an operations tool for TiDB Binlog with the following features:

- Checking the state of Pump or Drainer
- Pausing or closing Pump or Drainer
- Handling the abnormal state of Pump or Drainer

For detailed usage of `binlogctl`, refer to binlogctl overview.

11.7.4.4 Use SQL statements to manage Pump or Drainer

To view or modify binlog related states, execute corresponding SQL statements in TiDB.

- Check whether binlog is enabled:

```
show variables like "log_bin";
```

```
+---------------+-------+
| Variable_name | Value |
+---------------+-------+
| log_bin       | 0     |
+---------------+-------+
```

When the Value is `0`, binlog is enabled. When the Value is `1`, binlog is disabled.

- Check the status of all the Pump or Drainer nodes:

```
show pump status;
```

```
+--------|----------------|--------|--------------------|--------------------|
   ↪
| NodeID |   Address    | State |   Max_Commit_Ts  |    Update_Time     |
+--------|----------------|--------|--------------------|--------------------|
   ↪
| pump1 | 127.0.0.1:8250 | Online | 408553768673342237 | 2019-05-01
   ↪ 00:00:01 |
+--------|----------------|--------|--------------------|--------------------|
   ↪
| pump2 | 127.0.0.2:8250 | Online | 408553768673342335 | 2019-05-01
   ↪ 00:00:02 |
+--------|----------------|--------|--------------------|--------------------|
   ↪
```

```
show drainer status;
```

```
+----------|----------------|--------|--------------------|--------------------|
   ↪
|  NodeID |     Address    | State |   Max_Commit_Ts  |    Update_Time     |
+----------|----------------|--------|--------------------|--------------------|
   ↪
| drainer1 | 127.0.0.3:8249 | Online | 408553768673342532 | 2019-05-01
   ↪ 00:00:03 |
+----------|----------------|--------|--------------------|--------------------|
   ↪
| drainer2 | 127.0.0.4:8249 | Online | 408553768673345531 | 2019-05-01
   ↪ 00:00:04 |
```

```
+----------|---------------|--------|--------------------|-----------------------|
    ↪
```

- Modify the state of a Pump or Drainer node in abnormal situations

```
change pump to node_state ='paused' for node_id 'pump1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
change drainer to node_state ='paused' for node_id 'drainer1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

Executing the above SQL statements works the same as the `update-pump` or `update -drainer` commands in binlogctl. Use the above SQL statements **only** when the Pump or Drainer node is in abnormal situations.

Note:

- Checking whether binlog is enabled and the running status of Pump or Drainer is supported in TiDB v2.1.7 and later versions.
- Modifying the status of Pump or Drainer is supported in TiDB v3.0.0-rc.1 and later versions. This feature only supports modifying the status of Pump or Drainer nodes stored in PD. To pause or close the node, use the `binlogctl` tool.

11.7.5 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

11.7.5.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see Pump Configuration.

11.7.5.1.1 addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

11.7.5.1.2 advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

11.7.5.1.3 socket

- The Unix socket address that HTTP API listens to.
- Default value: ""

11.7.5.1.4 pd-urls

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

11.7.5.1.5 data-dir

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

11.7.5.1.6 heartbeat-interval

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: `2`

11.7.5.1.7 gen-binlog-interval

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: `3`

11.7.5.1.8 gc

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: `7`

11.7.5.1.9 log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

11.7.5.1.10 log-level

- Specifies the log level.
- Default value: `info`

11.7.5.1.11 node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

11.7.5.1.12 security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

ssl-cert

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: “”

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

11.7.5.1.13 storage

This section introduces configuration items related to storage.

sync-log

- Specifies whether to use `fsync` after each **batch** write to binlog to ensure data safety.
- Default value: `true`

kv_chan_cap

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: `1048576` (that is, 2 to the power of 20)

slow_write_threshold

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and `"take a long time to write binlog"` is output in the log.
- Default value: `1`

stop-write-at-available-space

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as `900 MB`, `5 GB`, and `12 GiB` to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: `10 GiB`

kv

Currently the storage of Pump is implemented based on GoLevelDB. Under `storage` there is also a `kv` subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- block-cache-capacity
- block-restart-interval
- block-size
- compaction-L0-trigger
- compaction-table-size
- compaction-total-size
- compaction-total-size-multiplier
- write-buffer
- write-L0-pause-trigger
- write-L0-slowdown-trigger

For the detailed description of the above items, see GoLevelDB Document.

11.7.5.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see Drainer Configuration

11.7.5.2.1 addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8249`

11.7.5.2.2 advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

11.7.5.2.3 log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: ""

11.7.5.2.4 log-level

- Specifies the log level.
- Default value: `info`

11.7.5.2.5 node-id

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

11.7.5.2.6 data-dir

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

11.7.5.2.7 detect-interval

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: `5`

11.7.5.2.8 pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

11.7.5.2.9 initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- commit ts (commit timestamp) is a specific point in time for transaction commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
  - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (backupmeta).
  - If Dumpling is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumpling (metadata),
  - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

11.7.5.2.10 synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: `5`

11.7.5.2.11 compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: "", which means no compression.

11.7.5.2.12 security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

ssl-cert

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainer.pem`.
- Default value: “”

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

11.7.5.2.13 syncer

The `syncer` section includes configuration items related to the downstream.

db-type

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

sql-mode

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: “”

ignore-txn-commit-ts

- Specifies the commit timestamp at which the binlog is ignored, such as `[416815754209656834, 421349811963822081]`.
- Default value: `[]`

ignore-schemas

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: `INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql`

ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the `toml` file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: `[]`

replicate-do-db

- Specifies the database to be replicated. For example, `[db1, db2]`.
- Default value: `[]`

replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name ="test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name ="test"
tbl-name = "~^a.*"
```

Default value: `[]`

txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: `20`

worker-count

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: `16`

disable-dispatch

- Disables the concurrency and forcibly set `worker-count` to `1`.
- Default value: `false`

safe-mode

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete` plus `Replace Into`

Default value: `false`

11.7.5.2.14 syncer.to

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

mysql/tidb

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is `3306` by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.
- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is `""` by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is `1m`. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

file

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

kafka

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addrs`
- `kafka-addrs`
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

11.7.5.2.15 syncer.to.checkpoint

This section introduces a configuration item related to `syncer.to.checkpoint`.

11.7.5.2.16 type

- Specifies in what way the replication progress is saved.
- Available options: `mysql` and `tidb`.
- Default value: The same as the downstream type. For example, when the downstream is `file`, the progress is saved in the local file system; when the downstream is `mysql`, the progress is saved in the downstream database. If you explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:
  - `schema`: `tidb_binlog` by default.

> **Note:**
> When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

  - `host`
  - `user`
  - `password`
  - `port`

11.7.5.3 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

11.7.5.3.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see Pump Configuration.

addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

socket

- The Unix socket address that HTTP API listens to.
- Default value: “”

pd-urls

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

data-dir

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

heartbeat-interval

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: `2`

gen-binlog-interval

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: `3`

gc

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: `7`

log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

log-level

- Specifies the log level.
- Default value: `info`

node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

ssl-cert

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: “”

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

storage

This section introduces configuration items related to storage.

sync-log

- Specifies whether to use `fsync` after each **batch** write to binlog to ensure data safety.
- Default value: `true`

kv_chan_cap

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: `1048576` (that is, 2 to the power of 20)

slow_write_threshold

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and `"take a long time to write binlog"` is output in the log.
- Default value: `1`

stop-write-at-available-space

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as `900 MB`, `5 GB`, and `12 GiB` to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: `10 GiB`

kv

Currently the storage of Pump is implemented based on GoLevelDB. Under `storage` there is also a `kv` subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- block-cache-capacity
- block-restart-interval
- block-size

- compaction-L0-trigger
- compaction-table-size
- compaction-total-size
- compaction-total-size-multiplier
- write-buffer
- write-L0-pause-trigger
- write-L0-slowdown-trigger

For the detailed description of the above items, see GoLevelDB Document.

11.7.5.3.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see Drainer Configuration

addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8249`

advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

log-level

- Specifies the log level.
- Default value: `info`

node-id

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

data-dir

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

detect-interval

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: `5`

pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- commit ts (commit timestamp) is a specific point in time for transaction commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
  - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (backupmeta).
  - If Dumpling is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumpling (metadata),
  - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: `5`

compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: "", which means no compression.

security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: ""

ssl-cert

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainer.pem`.
- Default value: ""

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: ""

syncer

The `syncer` section includes configuration items related to the downstream.

db-type

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

sql-mode

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: ""

ignore-txn-commit-ts

- Specifies the commit timestamp at which the binlog is ignored, such as `[416815754209656834, 421349811963822081]`.
- Default value: `[]`

ignore-schemas

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: `INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql`

ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the `toml` file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: `[]`

replicate-do-db

- Specifies the database to be replicated. For example, `[db1, db2]`.
- Default value: `[]`

replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name ="test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name ="test"
tbl-name = "~^a.*"
```

Default value: `[]`

txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: `20`

worker-count

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: `16`

disable-dispatch

- Disables the concurrency and forcibly set `worker-count` to `1`.
- Default value: `false`

safe-mode

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete` plus `Replace Into`

Default value: `false`

syncer.to

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

mysql/tidb

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is `3306` by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.
- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is `""` by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is `1m`. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

file

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

kafka

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addrs`
- `kafka-addrs`
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

syncer.to.checkpoint

This section introduces a configuration item related to `syncer.to.checkpoint`.

type

- Specifies in what way the replication progress is saved.
- Available options: `mysql` and `tidb`.
- Default value: The same as the downstream type. For example, when the downstream is `file`, the progress is saved in the local file system; when the downstream is `mysql`, the progress is saved in the downstream database. If you explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:
  - `schema`: `tidb_binlog` by default.

> **Note:**
> When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

- `host`
- `user`
- `password`
- `port`

11.7.6 Upgrade TiDB Binlog

This document introduces how to upgrade TiDB Binlog that is deployed manually to the latest cluster version. There is also a section on how to upgrade TiDB Binlog from an earlier incompatible version (Kafka/Local version) to the latest version.

11.7.6.1 Upgrade TiDB Binlog deployed manually

Follow the steps in this section if you deploy TiDB Binlog manually.

11.7.6.1.1 Upgrade Pump

First, upgrade each Pump instance in the cluster one by one. This ensures that there are always Pump instances in the cluster that can receive binlogs from TiDB. The steps are as below:

1. Replace the original file with the new version of `pump`.
2. Restart the Pump process.

11.7.6.1.2 Upgrade Drainer

Second, upgrade the Drainer component:

1. Replace the original file with the new version of `drainer`.
2. Restart the Drainer process.

11.7.6.2 Upgrade TiDB Binlog from Kafka/Local version to the cluster version

The new TiDB versions (v2.0.8-binlog, v2.1.0-rc.5 or later) are not compatible with the Kafka version or Local version of TiDB Binlog. If TiDB is upgraded to one of the new versions, it is required to use the cluster version of TiDB Binlog. If the Kafka or local

version of TiDB Binlog is used before upgrading, you need to upgrade your TiDB Binlog to the cluster version.

The corresponding relationship between TiDB Binlog versions and TiDB versions is shown in the following table:

TiDB Binlog version	TiDB version	Note
Local	TiDB 1.0 or earlier	
Kafka	TiDB 1.0 ~ TiDB 2.1 RC5	TiDB 1.0 supports both the local and Kafka versions of TiDB Binlog.
Cluster	TiDB v2.0.8-binlog, TiDB 2.1 RC5 or later	TiDB v2.0.8-binlog is a special 2.0 version supporting the cluster version of TiDB Binlog.

11.7.6.2.1 Upgrade process

> **Note:**
>
> If importing the full data is acceptable, you can abandon the old version and deploy TiDB Binlog following TiDB Binlog Cluster Deployment.

If you want to resume replication from the original checkpoint, perform the following steps to upgrade TiDB Binlog:

1. Deploy the new version of Pump.
2. Stop the TiDB cluster service.
3. Upgrade TiDB and the configuration, and write the binlog data to the new Pump cluster.
4. Reconnect the TiDB cluster to the service.
5. Make sure that the old version of Drainer has replicated the data in the old version of Pump to the downstream completely;

   Query the `status` interface of Drainer, command as below:

```
curl 'http://172.16.10.49:8249/status'
```

```
{"PumpPos":{"172.16.10.49:8250":{"offset":32686}},"Synced": true ,"
    ↪ DepositWindow":{"Upper":398907800202772481,"Lower
    ↪ ":398907799455662081}}
```

If the return value of `Synced` is True, it means Drainer has replicated the data in the old version of Pump to the downstream completely.

6. Start the new version of Drainer.
7. Close the Pump and Drainer of the old versions and the dependent Kafka and ZooKeeper.

11.7.7 TiDB Binlog Monitoring

After you have deployed TiDB Binlog successfully, you can go to the Grafana Web (default address: http://grafana_ip:3000, default account: admin, password: admin) to check the state of Pump and Drainer.

11.7.7.1 Monitoring metrics

TiDB Binlog consists of two components: Pump and Drainer. This section shows the monitoring metrics of Pump and Drainer.

11.7.7.1.1 Pump monitoring metrics

To understand the Pump monitoring metrics, check the following table:

Pump monitoring metrics	Description
Storage Size	Records the total disk space (capacity) and the available disk space (available)

Pump monitoring metrics	Description
Metadata	Records the biggest TSO (`gc_tso` ↪) of the binlog that each Pump node can delete, and the biggest commit TSO (`max_commit_tso` ↪) of the saved binlog

Pump monitoring metrics	Description
Write Binlog QPS by Instance	Shows QPS of writing binlog requests received by each Pump node
Write Binlog Latency	Records the latency time of each Pump node writing binlog

Pump monitoring metrics	Description
Storage Write Binlog Size	Shows the size of the binlog data written by Pump
Storage Write Binlog Latency	Records the latency time of the Pump storage module writing binlog

Pump monitoring metrics	Description
Pump Storage Error By Type	Records the number of errors encountered by Pump, counted based on the type of error
Query TiKV	The number of times that Pump queries the transaction status through TiKV

11.7.7.1.2 Drainer monitoring metrics

To understand the Drainer monitoring metrics, check the following table:

Drainer monitoring metrics	Description
Drainer monitoring metrics	Description
Checkpoint TSO	Shows the biggest TSO time of the binlog that Drainer has already replicated into the downstream. You can get the lag by using the current time to subtract the bin-

Drainer monitoring metrics	Description
Pump Handle TSO	Records the biggest TSO time among the binlog files that Drainer obtains from each Pump node
Pull Binlog QPS by Pump NodeID	Shows the QPS when Drainer obtains binlog from each Pump node

Drainer monitoring metrics	Description
95% Binlog Reach Duration By Pump	Records the delay from the time when binlog is written into Pump to the time when the binlog is obtained by Drainer

Drainer monitoring metrics	Description
Error By Type	Shows the number of errors encountered by Drainer, counted based on the type of error
SQL Query Time	Records the time it takes Drainer to execute the SQL statement in the downstream

Drainer monitoring metrics	Description
DrainerEvent	Shows the number of various types of events, including “ddl”, “insert”, “delete”, “update”, “flush”, and “savepoint”

Drainer monitoring metrics	Description
Execute Time	Records the time it takes to write binlog into the downstream syncing module
95% Binlog Size	Shows the size of the binlog data that Drainer obtains from each Pump node

Drainer monitoring metrics	Description
DDL Job Count	Records the number of DDL statements handled by Drainer
Queue Size	Records the work queue size in Drainer

11.7.7.2 Alert rules

This section gives the alert rules for TiDB Binlog. According to the severity level, TiDB Binlog alert rules are divided into three categories (from high to low): emergency-level, critical-level and warning-level.

11.7.7.2.1 Emergency-level alerts

Emergency-level alerts are often caused by a service or node failure. Manual intervention is required immediately.

`binlog_pump_storage_error_count`

- Alert rule:

  `changes(binlog_pump_storage_error_count[1m])> 0`

- Description:

  Pump fails to write the binlog data to the local storage.

- Solution:

  Check whether an error exists in the `pump_storage_error` monitoring and check the Pump log to find the causes.

11.7.7.2.2 Critical-level alerts

For the critical-level alerts, a close watch on the abnormal metrics is required.

`binlog_drainer_checkpoint_high_delay`

- Alert rule:

  `(time()- binlog_drainer_checkpoint_tso / 1000)> 3600`

- Description:

  The delay of Drainer replication exceeds one hour.

- Solution:

  - Check whether it is too slow to obtain the data from Pump:

    You can check `handle tso` of Pump to get the time for the latest message of each Pump. Check whether a high latency exists for Pump and make sure the corresponding Pump is running normally.
  - Check whether it is too slow to replicate data in the downstream based on Drainer `event` and Drainer `execute latency`:
    * If Drainer `execute time` is too large, check the network bandwidth and latency between the machine with Drainer deployed and the machine with the target database deployed, and the state of the target database.
    * If Drainer `execute time` is not too large and Drainer `event` is too small, add `work count` and `batch` and retry.
  - If the two solutions above cannot work, contact support@pingcap.com.

11.7.7.2.3 Warning-level alerts

Warning-level alerts are a reminder for an issue or error.

`binlog_pump_write_binlog_rpc_duration_seconds_bucket`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(binlog_pump_rpc_duration_seconds_bucket{
  ↪ method="WriteBinlog"}[5m]))> 1
  ```

- Description:

  It takes too much time for Pump to handle the TiDB request of writing binlog.

- Solution:

  - Verify the disk performance pressure and check the disk performance monitoring via `node exported`.
  - If both `disk latency` and `util` are low, contact support@pingcap.com.

`binlog_pump_storage_write_binlog_duration_time_bucket`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(binlog_pump_storage_write_binlog_duration_time_bucket
  ↪ {type="batch"}[5m]))> 1
  ```

- Description:

  The time it takes for Pump to write the local binlog to the local disk.

- Solution:

  Check the state of the local disk of Pump and fix the problem.

`binlog_pump_storage_available_size_less_than_20G`

- Alert rule:

  ```
  binlog_pump_storage_storage_size_bytes{type="available"} < 20 * 1024 *
  ↪ 1024 * 1024
  ```

- Description:

  The available disk space of Pump is less than 20 GB.

- Solution:

  Check whether Pump `gc_tso` is normal. If not, adjust the GC time configuration of Pump or get the corresponding Pump offline.

`binlog_drainer_checkpoint_tso_no_change_for_1m`

- Alert rule:

  ```
  changes(binlog_drainer_checkpoint_tso[1m])< 1
  ```

- Description:

  Drainer `checkpoint` has not been updated for one minute.

- Solution:

  Check whether all the Pumps that are not offline are running normally.

`binlog_drainer_execute_duration_time_more_than_10s`

- Alert rule:

  ```
  histogram_quantile(0.9, rate(binlog_drainer_execute_duration_time_bucket
  ↪ [1m]))> 10
  ```

- Description:

  The transaction time it takes Drainer to replicate data to TiDB. If it is too large, the Drainer replication of data is affected.

- Solution:

  - Check the TiDB cluster state.
  - Check the Drainer log or monitor. If a DDL operation causes this problem, you can ignore it.

11.7.8 Reparo User Guide

Reparo is a TiDB Binlog tool, used to recover the incremental data. To back up the incremental data, you can use Drainer of TiDB Binlog to output the binlog data in the protobuf format to files. To restore the incremental data, you can use Reparo to parse the binlog data in the files and apply the binlog in TiDB/MySQL.

Download Reparo via tidb-binlog-cluster-latest-linux-amd64.tar.gz

11.7.8.1 Reparo usage

11.7.8.1.1 Description of command line parameters

```
Usage of Reparo:
-L string
    The level of the output information of logs
    Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)
-V Prints the version.
-c int
    The number of concurrencies in the downstream for the replication
       ↪ process (`16` by default). A higher value indicates a better
       ↪ throughput for the replication.
-config string
    The path of the configuration file
    If the configuration file is specified, Reparo reads the configuration
       ↪ data in this file.
    If the configuration data also exists in the command line parameters,
       ↪ Reparo uses the configuration data in the command line parameters
       ↪ to cover that in the configuration file.
-data-dir string
```

```
    The storage directory for the binlog file in the protobuf format that
       ↪ Drainer outputs ("data.drainer" by default)
-dest-type string
    The downstream service type
    Value: "print"/"mysql" ("print" by default)
    If it is set to "print", the data is parsed and printed to standard
       ↪ output while the SQL statement is not executed.
    If it is set to "mysql", you need to configure the "host", "port", "user
       ↪ " and "password" information in the configuration file.
-log-file string
    The path of the log file
-log-rotate string
    The switch frequency of log files
    Value: "hour"/"day"
-start-datetime string
    Specifies the time point for starting recovery.
    Format: "2006-01-02 15:04:05"
    If it is not set, the recovery process starts from the earliest binlog
       ↪ file.
-stop-datetime string
    Specifies the time point of finishing the recovery process.
    Format: "2006-01-02 15:04:05"
    If it is not set, the recovery process ends up with the last binlog file
       ↪ .
-safe-mode bool
    Specifies whether to enable safe mode. When enabled, it supports
       ↪ repeated replication.
-txn-batch int
    The number of SQL statements in a transaction that is output to the
       ↪ downstream database (`20` by default).
```

11.7.8.1.2 Description of the configuration file

```
### The storage directory for the binlog file in the protobuf format that
    ↪ Drainer outputs
data-dir = "./data.drainer"

### The level of the output information of logs
### Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)
log-level = "info"

### Uses `start-datetime` and `stop-datetime` to specify the time range in
    ↪ which
### the binlog files are to be recovered.
```

```
### Format: "2006-01-02 15:04:05"
### start-datetime = ""
### stop-datetime = ""

### Correspond to `start-datetime` and `stop-datetime` respectively.
### They are used to specify the time range in which the binlog files are to
    ↪  be recovered.
### If `start-datetime` and `stop-datetime` are set, there is no need to set
    ↪  `start-tso` and `stop-tso`.
### start-tso = 0
### stop-tso = 0

### The downstream service type
### Value: "print"/"mysql" ("print" by default)
### If it is set to "print", the data is parsed and printed to standard
    ↪ output
### while the SQL statement is not executed.
### If it is set to "mysql", you need to configure `host`, `port`, `user`
    ↪ and `password` in [dest-db].
dest-type = "mysql"

### The number of SQL statements in a transaction that is output to the
    ↪ downstream database (`20` by default).
txn-batch = 20

### The number of concurrencies in the downstream for the replication
    ↪ process (`16` by default). A higher value indicates a better
    ↪ throughput for the replication.
worker-count = 16

### Safe-mode configuration
### Value: "true"/"false" ("false" by default)
### If it is set to "true", Reparo splits the `UPDATE` statement into a `
    ↪ DELETE` statement plus a `REPLACE` statement.
safe-mode = false

### `replicate-do-db` and `replicate-do-table` specify the database and
    ↪ table to be recovered.
### `replicate-do-db` has priority over `replicate-do-table`.
### You can use a regular expression for configuration. The regular
    ↪ expression should start with "~".
### The configuration method for `replicate-do-db` and `replicate-do-table`
    ↪ is
### the same with that for `replicate-do-db` and `replicate-do-table` of
    ↪ Drainer.
```

```
### replicate-do-db = ["~^b.*","s1"]
### [[replicate-do-table]]
### db-name ="test"
### tbl-name = "log"
### [[replicate-do-table]]
### db-name ="test"
### tbl-name = "~^a.*"

### If `dest-type` is set to `mysql`, `dest-db` needs to be configured.
[dest-db]
host = "127.0.0.1"
port = 3309
user = "root"
password = ""
```

11.7.8.1.3 Start example

```
./bin/reparo -config reparo.toml
```

Note:

- `data-dir` specifies the directory for the binlog file that Drainer outputs.
- Both `start-datatime` and `start-tso` are used to specify the time point for starting recovery, but they are different in the time format. If they are not set, the recovery process starts from the earliest binlog file by default.
- Both `stop-datetime` and `stop-tso` are used to specify the time point for finishing recovery, but they are different in the time format. If they are not set, the recovery process ends up with the last binlog file by default.
- `dest-type` specifies the destination type. Its value can be "mysql" and "print."
  - When it is set to `mysql`, the data can be recovered to MySQL or TiDB that uses or is compatible with the MySQL protocol. In this case, you need to specify the database information in `[dest-db]` of the configuration information.
  - When it is set to `print`, only the binlog information is printed. It is generally used for debugging and checking the binlog information. In this case, there is no need to specify `[dest-db]`.

- `replicate-do-db` specifies the database for recovery. If it is not set, all the databases are to be recovered.
- `replicate-do-table` specifies the table for recovery. If it is not set, all the tables are to be recovered.

11.7.9 binlogctl

Binlog Control (`binlogctl` for short) is a command line tool for TiDB Binlog. You can use `binlogctl` to manage TiDB Binlog clusters.

You can use `binlogctl` to:

- Check the state of Pump or Drainer
- Pause or close Pump or Drainer
- Handle the abnormal state of Pump or Drainer

The following are its usage scenarios:

- An error occurs during data replication or you need to check the running state of Pump or Drainer.
- You need to pause or close Pump or Drainer when maintaining the cluster.
- A Pump or Drainer process exits abnormally, while the node state is not updated or is unexpected. This affects the data replication task.

11.7.9.1 Download `binlogctl`

Note:

It is recommended that the version of the Control tool you use is consistent with the version of the cluster.

```
wget https://download.pingcap.org/tidb-{version}-linux-amd64.tar.gz &&
wget https://download.pingcap.org/tidb-{version}-linux-amd64.sha256
```

To check the file integrity, execute the following command. If the result is OK, the file is correct.

```
sha256sum -c tidb-{version}-linux-amd64.sha256
```

To check the file integrity, execute the following command. If the result is OK, the file is correct.

```
sha256sum -c tidb-enterprise-tools-latest-linux-amd64.sha256
```

11.7.9.2 Descriptions

Command line parameters:

```
Usage of binlogctl:
  -V   prints version and exit
  -cmd string
       operator: "generate_meta", "pumps", "drainers", "update-pump", "
          ↪ update-drainer", "pause-pump", "pause-drainer", "offline-pump
          ↪ ", "offline-drainer", "encrypt" (default "pumps")
  -data-dir string
       meta directory path (default "binlog_position")
  -node-id string
       id of node, used to update some nodes with operations update-pump,
          ↪ update-drainer, pause-pump, pause-drainer, offline-pump and
          ↪ offline-drainer
  -pd-urls string
       a comma separated list of PD endpoints (default "http
          ↪ ://127.0.0.1:2379")
  -show-offline-nodes
       include offline nodes when querying pumps/drainers
  -ssl-ca string
       Path of file that contains list of trusted SSL CAs for connection
          ↪ with cluster components.
  -ssl-cert string
       Path of file that contains X509 certificate in PEM format for
          ↪ connection with cluster components.
  -ssl-key string
       Path of file that contains X509 key in PEM format for connection with
          ↪  cluster components.
  -state string
       set node's state, can be set to online, pausing, paused, closing or
          ↪ offline.
  -text string
       text to be encrypted when using encrypt command
  -time-zone Asia/Shanghai
       set time zone if you want to save time info in savepoint file; for
          ↪ example, Asia/Shanghai for CST time, `Local` for local time
```

Command examples:

- Check the state of all the Pump or Drainer nodes.

  Set `cmd` to `pumps` or `drainers`. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd pumps
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node"] [
    ↪ type=pump] [node="{NodeID: 1.1.1.1:8250, Addr: pump:8250, State:
    ↪ online, MaxCommitTS: 408012403141509121, UpdateTime: 2019-04-28
    ↪ 09:29:57 +0000 UTC}"]
```

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd drainers
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node"] [
    ↪ type=drainer] [node="{NodeID: 1.1.1.1:8249, Addr: 1.1.1.1:8249,
    ↪ State: online, MaxCommitTS: 408012403141509121, UpdateTime:
    ↪ 2019-04-28 09:29:57 +0000 UTC}"]
```

- Pause or close Pump or Drainer.

  You can use the following commands to pause or close services:

Command	Description	Example
pause-pump	Pause Pump	`bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-pump -node-id ip-127-0-0-1:8250`
pause-drainer	Pause Drainer	`bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-drainer -node-id ip-127-0-0-1:8249`
offline-pump	Close Pump	`bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-pump -node-id ip-127-0-0-1:8250`
offline-drainer	Close Drainer	`bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-drainer -node-id ip-127-0-0-1:8249`

  `binlogctl` sends the HTTP request to the Pump or Drainer node. After receiving the request, the node executes the exiting procedures accordingly.

- Modify the state of a Pump or Drainer node in abnormal states.

  When a Pump or Drainer node runs normally or when it is paused or closed in the normal process, it is in the normal state. In abnormal states, the Pump or Drainer node cannot correctly maintain its state. This affects data replication tasks. In this case, use `binlogctl` to repair the state information.

  To update the state of a Pump or Drainer node, set `cmd` to `update-pump` or `update-drainer`. The state can be `paused` or `offline`. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd update-pump -node-id
    ↪ ip-127-0-0-1:8250 -state paused
```

Note:

When a Pump or Drainer node runs normally, it regularly updates its state to PD. The above command directly modifies the Pump or Drainer state saved in PD; therefore, do not use the command when the Pump or Drainer node runs normally. For more information, refer to TiDB Binlog FAQ.

11.7.10 Binlog Consumer Client User Guide

Binlog Consumer Client is used to consume TiDB secondary binlog data from Kafka and output the data in a specific format. Currently, Drainer supports multiple kinds of down streaming, including MySQL, TiDB, file and Kafka. But sometimes users have customized requirements for outputting data to other formats, for example, Elasticsearch and Hive, so this feature is introduced.

11.7.10.1 Configure Drainer

Modify the configuration file of Drainer and set it to output the data to Kafka:

```
[syncer]
db-type = "kafka"

[syncer.to]
### the Kafka address
kafka-addrs = "127.0.0.1:9092"
### the Kafka version
kafka-version = "0.8.2.0"
```

11.7.10.2 Customized development

11.7.10.2.1 Data format

Firstly, you need to obtain the format information of the data which is output to Kafka by Drainer:

```
// `Column` stores the column data in the corresponding variable based on
   ↪ the data type.
message Column {
  // Indicates whether the data is null
  optional bool is_null = 1 [ default = false ];
  // Stores `int` data
  optional int64 int64_value = 2;
  // Stores `uint`, `enum`, and `set` data
```

```
  optional uint64 uint64_value = 3;
  // Stores `float` and `double` data
  optional double double_value = 4;
  // Stores `bit`, `blob`, `binary` and `json` data
  optional bytes bytes_value = 5;
  // Stores `date`, `time`, `decimal`, `text`, `char` data
  optional string string_value = 6;
}

// `ColumnInfo` stores the column information, including the column name,
   ↪ type, and whether it is the primary key.
message ColumnInfo {
  optional string name = 1 [ (gogoproto.nullable) = false ];
  // the lower case column field type in MySQL
  // https://dev.mysql.com/doc/refman/8.0/en/data-types.html
  // for the `numeric` type: int bigint smallint tinyint float double
     ↪ decimal bit
  // for the `string` type: text longtext mediumtext char tinytext varchar
  // blob longblob mediumblob binary tinyblob varbinary
  // enum set
  // for the `json` type: json
  optional string mysql_type = 2 [ (gogoproto.nullable) = false ];
  optional bool is_primary_key = 3 [ (gogoproto.nullable) = false ];
}

// `Row` stores the actual data of a row.
message Row { repeated Column columns = 1; }

// `MutationType` indicates the DML type.
enum MutationType {
  Insert = 0;
  Update = 1;
  Delete = 2;
}

// `Table` contains mutations in a table.
message Table {
  optional string schema_name = 1;
  optional string table_name = 2;
  repeated ColumnInfo column_info = 3;
  repeated TableMutation mutations = 4;
}

// `TableMutation` stores mutations of a row.
message TableMutation {
```

```
  required MutationType type = 1;
  // data after modification
  required Row row = 2;
  // data before modification. It only takes effect for `Update MutationType
     ↪ `.
  optional Row change_row = 3;
}

// `DMLData` stores all the mutations caused by DML in a transaction.
message DMLData {
  // `tables` contains all the table changes in the transaction.
  repeated Table tables = 1;
}

// `DDLData` stores the DDL information.
message DDLData {
  // the database used currently
  optional string schema_name = 1;
  // the relates table
  optional string table_name = 2;
  // `ddl_query` is the original DDL statement query.
  optional bytes ddl_query = 3;
}

// `BinlogType` indicates the binlog type, including DML and DDL.
enum BinlogType {
  DML = 0; // Has `dml_data`
  DDL = 1; // Has `ddl_query`
}

// `Binlog` stores all the changes in a transaction. Kafka stores the
   ↪ serialized result of the structure data.
message Binlog {
  optional BinlogType type = 1 [ (gogoproto.nullable) = false ];
  optional int64 commit_ts = 2 [ (gogoproto.nullable) = false ];
  optional DMLData dml_data = 3;
  optional DDLData ddl_data = 4;
}
```

For the definition of the data format, see binlog.proto.

11.7.10.2.2 Driver

The TiDB-Tools project provides Driver, which is used to read the binlog data in Kafka. It has the following features:

- Read the Kafka data.
- Locate the binlog stored in Kafka based on `commit ts`.

You need to configure the following information when using Driver:

- `KafkaAddr`: the address of the Kafka cluster
- `CommitTS`: from which `commit ts` to start reading the binlog
- `Offset`: from which Kafka `offset` to start reading data. If `CommitTS` is set, you needn't configure this parameter.
- `ClusterID`: the cluster ID of the TiDB cluster
- `Topic`: the topic name of Kafka. If Topic is empty, use the default name in Drainer `<ClusterID>_obinlog`.

You can use Driver by quoting the Driver code in package and refer to the example code provided by Driver to learn how to use Driver and parse the binlog data.

Currently, two examples are provided:

- Using Driver to replicate data to MySQL. This example shows how to convert a binlog to SQL
- Using Driver to print data

Note:

- The example code only shows how to use Driver. If you want to use Driver in the production environment, you need to optimize the code.
- Currently, only the Golang version of Driver and example code are available. If you want to use other languages, you need to generate the code file in the corresponding language based on the binlog proto file and develop an application to read the binlog data in Kafka, parse the data, and output the data to the downstream. You are also welcome to optimize the example code and submit the example code of other languages to TiDB-Tools.

11.7.11 TiDB Binlog Relay Log

When replicating binlogs, Drainer splits transactions from the upstream and replicates the split transactions concurrently to the downstream.

In extreme cases where the upstream clusters are not available and Drainer exits abnormally, the downstream clusters (MySQL or TiDB) might be in the intermediate states with inconsistent data. In such cases, Drainer can use the relay log to ensure that the downstream clusters are in a consistent state.

11.7.11.1 Consistent state during Drainer replication

The downstream clusters reaching a consistent state means the data of the downstream clusters are the same as the snapshot of the upstream which sets `tidb_snapshot = ts`.

The checkpoint consistency means Drainer checkpoint saves the consistent state of replication in `consistent`. When Drainer runs, `consistent` is `false`. After Drainer exits normally, `consistent` is set to `true`.

You can query the downstream checkpoint table as follows:

```
select * from tidb_binlog.checkpoint;
```

```
+--------------------+-------------------------------------------------------------------+
   ↪
| clusterID        | checkPoint
   ↪                                                  |
+--------------------+-------------------------------------------------------------------+
   ↪
| 6791641053252586769 | {"consistent":false,"commitTS":414529105591271429,"
   ↪ ts-map":{}} |
+--------------------+-------------------------------------------------------------------+
   ↪
```

11.7.11.2 Implementation principles

After Drainer enables the relay log, it first writes the binlog events to the disks and then replicates the events to the downstream clusters.

If the upstream clusters are not available, Drainer can restore the downstream clusters to a consistent state by reading the relay log.

> **Note:**
>
> If the relay log data is lost at the same time, this method does not work, but its incidence is very low. In addition, you can use the Network File System to ensure data safety of the relay log.

11.7.11.2.1 Trigger scenarios where Drainer consumes binlogs from the relay log

When Drainer is started, if it fails to connect to the Placement Driver (PD) of the upstream clusters, and it detects that `consistent = false` in the checkpoint, Drainer will try to read the relay log, and restore the downstream clusters to a consistent state. After that, the Drainer process sets the checkpoint `consistent` to `true` and then exits.

11.7.11.2.2 GC mechanism of relay log

Before data is replicated to the downstream, Drainer writes data to the relay log file. If the size of a relay log file reaches 10 MB (by default) and the binlog data of the current transaction is completely written, Drainer starts to write data to the next relay log file. After Drainer successfully replicates data to the downstream, it automatically cleans up the relay log files whose data has been replicated. The relay log into which data is currently being written will not be cleaned up.

11.7.11.3 Configuration

To enable the relay log, add the following configuration in Drainer:

```
[syncer.relay]
### It saves the directory of the relay log. The relay log is not enabled if
    ↪ the value is empty.
### The configuration only comes to effect if the downstream is TiDB or
    ↪ MySQL.
log-dir = "/dir/to/save/log"
### The size limit of a single relay log file (unit: byte).
### When the size of a relay log file reaches this limit, data is written to
    ↪ the next relay log file.
max-file-size = 10485760
```

11.7.12 Bidirectional Replication between TiDB Clusters

> **Warning:**
>
> Currently, bidirectional replication is still an experimental feature. It is **NOT** recommended to use it in the production environment.

This document describes the bidirectional replication between two TiDB clusters, how the replication works, how to enable it, and how to replicate DDL operations.

11.7.12.1 User scenario

If you want two TiDB clusters to exchange data changes with each other, TiDB Binlog allows you to do that. For example, you want cluster A and cluster B to replicate data with each other.

Note:

The data written to these two clusters must be conflict-free, that is, in the two clusters, the same primary key or the rows with the unique index of the tables must not be modified.

The user scenario is shown as below:

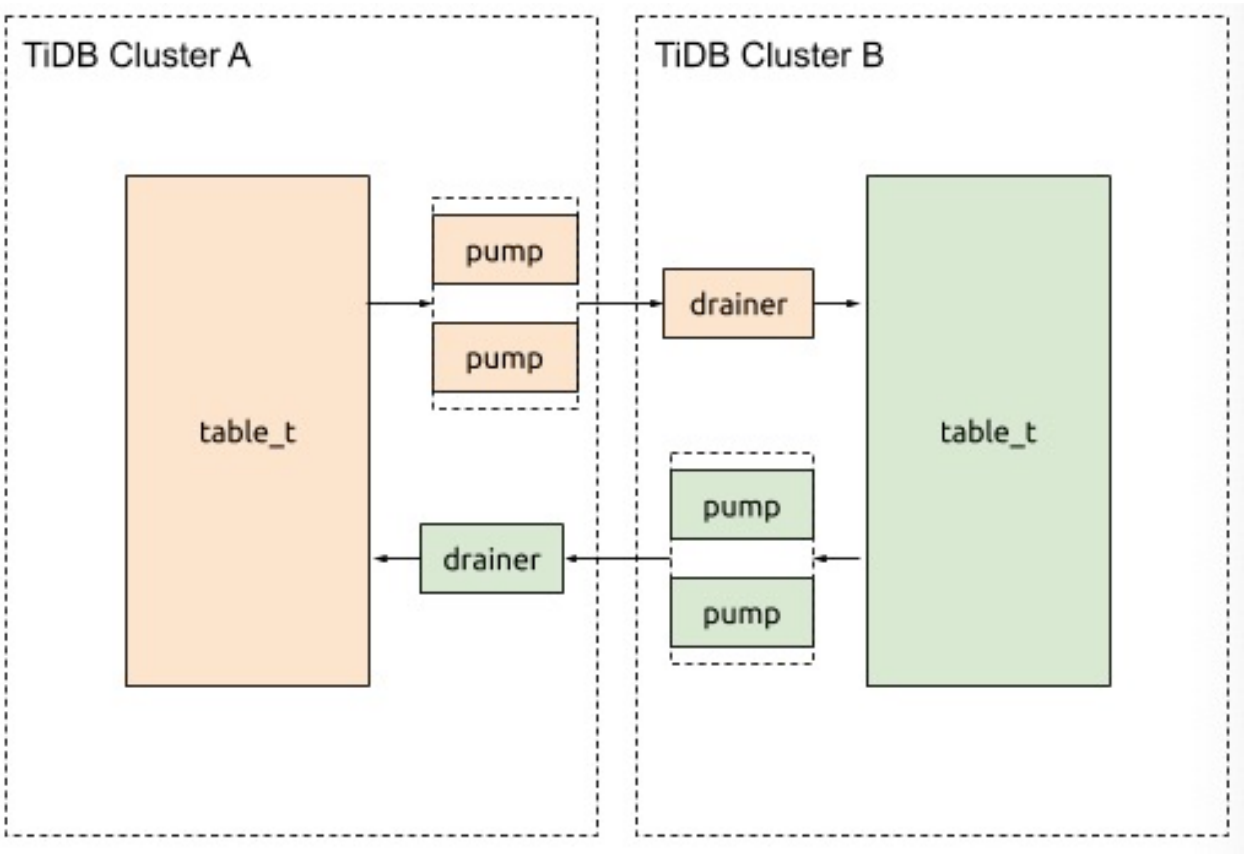

Figure 143: Architect

11.7.12.2 Implementation details

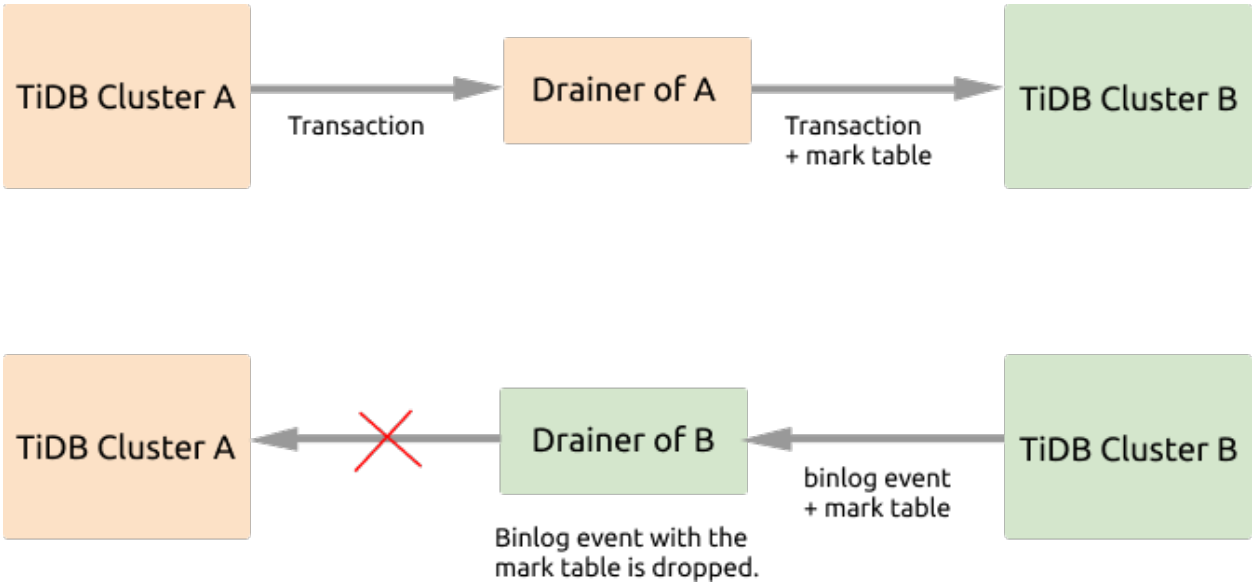

Figure 144: Mark Table

If the bidirectional replication is enabled between cluster A and cluster B, the data written to cluster A will be replicated to cluster B, and then these data changes will be replicated back to cluster A, which causes an infinite loop of replication. From the figure above, you can see that during the data replication, Drainer marks the binlog events, and filters out the marked events to avoid such a replication loop.

The detailed implementation is described as follows:

1. Start the TiDB Binlog replication program for each of the two clusters.
2. When the transaction to be replicated passes through the Drainer of cluster A, this Drainer adds the `_drainer_repl_mark` table to the transaction, writes this DML event update to the mark table, and replicate this transaction to cluster B.
3. Cluster B returns binlog events with the `_drainer_repl_mark` mark table to cluster A. The Drainer of cluster B identifies the mark table with the DML event when parsing the binlog event, and gives up replicating this binlog event to cluster A.

The replication process from cluster B to cluster A is the same as above. The two clusters can be upstream and downstream of each other.

Note:

- When updating the `_drainer_repl_mark` mark table, data changes are required to generate binlogs.

- DDL operations are not transactional, so you need to use the one-way replication method to replicate DDL operations. See Replicate DDL operations for details.

Drainer can use a unique ID for each connection to downstream to avoid conflicts. `channel_id` is used to indicate a channel for bidirectional replication. The two clusters should have the same `channel_id` configuration (with the same value).

If you add or delete columns in the upstream, there might be extra or missing columns of the data to be replicated to the downstream. Drainer allows this situation by ignoring the extra columns or by inserting default values to the missing columns.

11.7.12.3 Mark table

The `_drainer_repl_mark` mark table has the following structure:

```
CREATE TABLE `_drainer_repl_mark` (
  `id` bigint(20) NOT NULL,
  `channel_id` bigint(20) NOT NULL DEFAULT '0',
  `val` bigint(20) DEFAULT '0',
  `channel_info` varchar(64) DEFAULT NULL,
  PRIMARY KEY (`id`,`channel_id`)
);
```

Drainer uses the following SQL statement to update `_drainer_repl_mark`, which ensures data change and the generation of binlog:

```
update drainer_repl_mark set val = val + 1 where id = ? && channel_id = ?;
```

11.7.12.4 Replicate DDL operations

Because Drainer cannot add the mark table to DDL operations, you can only use the one-way replication method to replicate DDL operations.

For example, if DDL replication is enabled from cluster A to cluster B, then the replication is disabled from cluster B to cluster A. This means that all DDL operations are performed on cluster A.

Note:

DDL operations cannot be executed on two clusters at the same time. When a DDL operation is executed, if any DML operation is being executed at the same time or any DML binlog is being replicated, the upstream and downstream table structures of the DML replication might be inconsistent.

11.7.12.5 Configure and enable bidirectional replication

For bidirectional replication between cluster A and cluster B, assume that all DDL operations are executed on cluster A. On the replication path from cluster A to cluster B, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = true # Enables it if you need to perform DDL replication.

[syncer.to]
### 1 means SyncFullColumn and 2 means SyncPartialColumn.
### If set to SyncPartialColumn, Drainer allows the downstream table
### structure to have more or fewer columns than the data to be replicated
### And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
   ↪ columns, and insert zero values to the downstream.
sync-mode = 2

### Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

On the replication path from cluster B to cluster A, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = false # Disables it if you do not need to perform DDL replication
   ↪ .

[syncer.to]
### 1 means SyncFullColumn and 2 means SyncPartialColumn.
### If set to SyncPartialColumn, Drainer allows the downstream table
### structure to have more or fewer columns than the data to be replicated
### And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
   ↪ columns, and insert zero values to the downstream.
sync-mode = 2

### Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

11.7.13 TiDB Binlog Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Binlog.

11.7.13.1 Binlog

In TiDB Binlog, binlogs refer to the binary log data from TiDB. They also refer to the binary log data that Drainer writes to Kafka or files. The former and the latter are in different formats. In addition, binlogs in TiDB and binlogs in MySQL are also in different formats.

11.7.13.2 Binlog event

The DML binlogs from TiDB have three types of event: `INSERT`, `UPDATE`, and `DELETE`. In the monitoring dashboard of Drainer, you can see the number of different events that correspond to the replication data.

11.7.13.3 Checkpoint

A checkpoint indicates the position from which a replication task is paused and resumed, or is stopped and restarted. It records the commit-ts that Drainer replicates to the downstream. When restarted, Drainer reads the checkpoint and starts replicating data from the corresponding commit-ts.

11.7.13.4 Safe mode

Safe mode refers to the mode that supports the idempotent import of DML when a primary key or unique index exists in the table schema in the incremental replication task.

In this mode, the `INSERT` statement is re-written as `REPLACE`, and the `UPDATE` statement is re-written as `DELETE` and `REPLACE`. Then the re-written statement is executed to the downstream. Safe mode is automatically enabled within 5 minutes after Drainer is started. You can manually enable the mode by modifying the `safe-mode` parameter in the configuration file, but this configuration is valid only when the downstream is MySQL or TiDB.

11.7.14 Troubleshoot

11.7.14.1 TiDB Binlog Troubleshooting

This document describes how to troubleshoot TiDB Binlog to find the problem.

If you encounter errors while running TiDB Binlog, take the following steps to troubleshoot:

1. Check whether each monitoring metric is normal or not. Refer to TiDB Binlog Monitoring for details.

2. Use the binlogctl tool to check whether the state of each Pump or Drainer node is normal or not.

3. Check whether `ERROR` or `WARN` exists in the Pump log or Drainer log.

After finding out the problem by the above steps, refer to FAQ and TiDB Binlog Error Handling for the solution. If you fail to find the solution or the solution provided does not help, submit an issue for help.

11.7.14.2 TiDB Binlog Error Handling

This document introduces common errors that you might encounter and solutions to these errors when you use TiDB Binlog.

11.7.14.2.1 `kafka server: Message was too large, server rejected it to avoid allocation error` is returned when Drainer replicates data to Kafka

Cause: Executing a large transaction in TiDB generates binlog data of a large size, which might exceed Kafka's limit on the message size.

Solution: Adjust the configuration parameters of Kafka as shown below:

```
message.max.bytes=1073741824
replica.fetch.max.bytes=1073741824
fetch.message.max.bytes=1073741824
```

11.7.14.2.2 Pump returns `no space left on device` error

Cause: The local disk space is insufficient for Pump to write binlog data normally.

Solution: Clean up the disk space and then restart Pump.

11.7.14.2.3 `fail to notify all living drainer` is returned when Pump is started

Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.

Solution: Use the binlogctl tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes that are in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the binlogctl tool to change its state and then restart Pump.

11.7.14.2.4 Data loss occurs during the TiDB Binlog replication

You need to confirm that TiDB Binlog is enabled on all TiDB instances and runs normally. If the cluster version is later than v3.0, use the `curl {TiDB_IP}:{STATUS_PORT}/` ↪ `info/all` command to confirm the TiDB Binlog status on all TiDB instances.

11.7.14.2.5 When the upstream transaction is large, Pump reports an error `rpc error: code = ResourceExhausted desc = trying to send message larger than max (2191430008 vs. 2147483647)`

This error occurs because the gRPC message sent by TiDB to Pump exceeds the size limit. You can adjust the maximum size of a gRPC message that Pump allows by specifying `max-message-size` when starting Pump.

11.7.14.2.6 Is there any cleaning mechanism for the incremental data of the file format output by Drainer? Will the data be deleted?

- In Drainer v3.0.x, there is no cleaning mechanism for incremental data of the file format.
- In the v4.0.x version, there is a time-based data cleaning mechanism. For details, refer to Drainer's `retention-time` configuration item.

11.7.15 TiDB Binlog FAQ

This document collects the frequently asked questions (FAQs) about TiDB Binlog.

11.7.15.1 What is the impact of enabling TiDB Binlog on the performance of TiDB?

- There is no impact on the query.
- There is a slight performance impact on `INSERT`, `DELETE` and `UPDATE` transactions. In latency, a p-binlog is written concurrently in the TiKV prewrite stage before the transactions are committed. Generally, writing binlog is faster than TiKV prewrite, so it does not increase latency. You can check the response time of writing binlog in Pump's monitoring panel.

11.7.15.2 How high is the replication latency of TiDB Binlog?

The latency of TiDB Binlog replication is measured in seconds, which is generally about 3 seconds during off-peak hours.

11.7.15.3 What privileges does Drainer need to replicate data to the downstream MySQL or TiDB cluster?

To replicate data to the downstream MySQL or TiDB cluster, Drainer must have the following privileges:

- Insert
- Update

- Delete
- Create
- Drop
- Alter
- Execute
- Index
- Select
- Create View

11.7.15.4 What can I do if the Pump disk is almost full?

1. Check whether Pump's GC works well:

    - Check whether the **gc_tso** time in Pump's monitoring panel is identical with that of the configuration file.

2. If GC works well, perform the following steps to reduce the amount of space required for a single Pump:

    - Modify the **GC** parameter of Pump to reduce the number of days to retain data.
    - Add pump instances.

11.7.15.5 What can I do if Drainer replication is interrupted?

Execute the following command to check whether the status of Pump is normal and whether all the Pump instances that are not in the `offline` state are running.

```
binlogctl -cmd pumps
```

Then, check whether the Drainer monitor or log outputs corresponding errors. If so, resolve them accordingly.

11.7.15.6 What can I do if Drainer is slow to replicate data to the downstream MySQL or TiDB cluster?

Check the following monitoring items:

- For the **Drainer Event** monitoring metric, check the speed of Drainer replicating `INSERT`, `UPDATE` and `DELETE` transactions to the downstream per second.
- For the **SQL Query Time** monitoring metric, check the time Drainer takes to execute SQL statements in the downstream.

Possible causes and solutions for slow replication:

- If the replicated database contains a table without a primary key or unique index, add a primary key to the table.
- If the latency between Drainer and the downstream is high, increase the value of the `worker-count` parameter of Drainer. For cross-datacenter replication, it is recommended to deploy Drainer in the downstream.
- If the load in the downstream is not high, increase the value of the `worker-count` parameter of Drainer.

11.7.15.7 What can I do if a Pump instance crashes?

If a Pump instance crashes, Drainer cannot replicate data to the downstream because it cannot obtain the data of this instance. If this Pump instance can recover to the normal state, Drainer resumes replication; if not, perform the following steps:

1. Use binlogctl to change the state of this Pump instance to `offline` to discard the data of this Pump instance.
2. Because Drainer cannot obtain the data of this pump instance, the data in the downstream and upstream is inconsistent. In this situation, perform full and incremental backups again. The steps are as follows:
    1. Stop the Drainer.
    2. Perform a full backup in the upstream.
    3. Clear the data in the downstream including the `tidb_binlog.checkpoint` table.
    4. Restore the full backup to the downstream.
    5. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

11.7.15.8 What is checkpoint?

Checkpoint records the `commit-ts` that Drainer replicates to the downstream. When Drainer restarts, it reads the checkpoint and then replicates data to the downstream starting from the corresponding `commit-ts`. The `["write save point"] [ts =411222863322546177]` Drainer log means saving the checkpoint with the corresponding timestamp.

Checkpoint is saved in different ways for different types of downstream platforms:

- For MySQL/TiDB, it is saved in the `tidb_binlog.checkpoint` table.
- For Kafka/file, it is saved in the file of the corresponding configuration directory.

The data of kafka/file contains `commit-ts`, so if the checkpoint is lost, you can check the latest `commit-ts` of the downstream data by consuming the latest data in the downstream .

Drainer reads the checkpoint when it starts. If Drainer cannot read the checkpoint, it uses the configured `initialCommitTs` as the start point of the initial replication.

11.7.15.9 How to redeploy Drainer on the new machine when Drainer fails and the data in the downstream remains?

If the data in the downstream is not affected, you can redeploy Drainer on the new machine as long as the data can be replicated from the corresponding checkpoint.

- If the checkpoint is not lost, perform the following steps:
    1. Deploy and start a new Drainer (Drainer can read checkpoint and resumes replication).
    2. Use binlogctl to change the state of the old Drainer to `offline`.
- If the checkpoint is lost, perform the following steps:
    1. To deploy a new Drainer, obtain the `commit-ts` of the old Drainer as the `initialCommitTs` of the new Drainer.
    2. Use binlogctl to change the state of the old Drainer to `offline`.

11.7.15.10 How to restore the data of a cluster using a full backup and a binlog backup file?

1. Clean up the cluster and restore a full backup.
2. To restore the latest data of the backup file, use Reparo to set `start-tso` = {snapshot timestamp of the full backup + 1} and `end-ts` = 0 (or you can specify a point in time).

11.7.15.11 How to redeploy Drainer when enabling `ignore-error` in Primary-Secondary replication triggers a critical error?

If a critical error is triggered when TiDB fails to write binlog after enabling `ignore-error`, TiDB stops writing binlog and binlog data loss occurs. To resume replication, perform the following steps:

1. Stop the Drainer instance.
2. Restart the `tidb-server` instance that triggers critical error and resume writing binlog (TiDB does not write binlog to Pump after critical error is triggered).
3. Perform a full backup in the upstream.
4. Clear the data in the downstream including the `tidb_binlog.checkpoint` table.
5. Restore the full backup to the downstream.
6. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

11.7.15.12 When can I pause or close a Pump or Drainer node?

Refer to TiDB Binlog Cluster Operations to learn the description of the Pump or Drainer state and how to start and exit the process.

Pause a Pump or Drainer node when you need to temporarily stop the service. For example:

- Version upgrade

Use the new binary to restart the service after the process is stopped.

- Server maintenance

When the server needs a downtime maintenance, exit the process and restart the service after the maintenance is finished.

Close a Pump or Drainer node when you no longer need the service. For example:

- Pump scale-in

If you do not need too many Pump services, close some of them.

- Cancelling replication tasks

If you no longer need to replicate data to a downstream database, close the corresponding Drainer node.

- Service migration

If you need to migrate the service to another server, close the service and re-deploy it on the new server.

11.7.15.13 How can I pause a Pump or Drainer process?

- Directly kill the process.

> **Note:**
> Do not use the `kill -9` command. Otherwise, the Pump or Drainer node cannot process signals.

- If the Pump or Drainer node runs in the foreground, pause it by pressing Ctrl+C.
- Use the `pause-pump` or `pause-drainer` command in binlogctl.

11.7.15.14 Can I use the `update-pump` or `update-drainer` command in binlogctl to pause the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands can interrupt data replication and might even cause data loss.

11.7.15.15 Can I use the `update-pump` or `update-drainer` command in binlogctl to close the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands interrupts data replication and might even cause data inconsistency. For example:

- When a Pump node runs normally or is in the `paused` state, if you use the `update-pump` command to set the Pump state to `offline`, the Drainer node stops pulling the binlog data from the `offline` Pump. In this situation, the newest binlog cannot be replicated to the Drainer node, causing data inconsistency between upstream and downstream.
- When a Drainer node runs normally, if you use the `update-drainer` command to set the Drainer state to `offline`, the newly started Pump node only notifies Drainer nodes in the `online` state. In this situation, the `offline` Drainer fails to pull the binlog data from the Pump node in time, causing data inconsistency between upstream and downstream.

11.7.15.16 When can I use the `update-pump` command in binlogctl to set the Pump state to `paused`?

In some abnormal situations, Pump fails to correctly maintain its state. Then, use the `update-pump` command to modify the state.

For example, when a Pump process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Pump state information saved in PD is still `online`. In this situation, if you do not need to restart Pump to recover the service at the moment, use the `update-pump` command to update the Pump state to `paused`. Then, interruptions can be avoided when TiDB writes binlogs and Drainer pulls binlogs.

11.7.15.17 When can I use the `update-drainer` command in binlogctl to set the Drainer state to `paused`?

In some abnormal situations, the Drainer node fails to correctly maintain its state, which has influenced the replication task. Then, use the `update-drainer` command to modify the state.

For example, when a Drainer process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Drainer state information saved in PD is still `online`. When a Pump node is started, it fails to notify the exited Drainer node (the `notify drainer ...` error), which cause the Pump node failure. In this situation, use the `update-drainer` command to update the Drainer state to `paused` and restart the Pump node.

11.7.15.18 How can I close a Pump or Drainer node?

Currently, you can only use the `offline-pump` or `offline-drainer` command in binlogctl to close a Pump or Drainer node.

11.7.15.19 When can I use the `update-pump` command in binlogctl to set the Pump state to `offline`?

You can use the `update-pump` command to set the Pump state to `offline` in the following situations:

- When a Pump process is exited abnormally and the service cannot be recovered, the replication task is interrupted. If you want to recover the replication and accept some losses of binlog data, use the `update-pump` command to set the Pump state to `offline` ↪ . Then, the Drainer node stops pulling binlog from the Pump node and continues replicating data.
- Some stale Pump nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-pump` command to set their state to `offline`.

For other situations, use the `offline-pump` command to close the Pump service, which is the regular process.

> **Warning:**
>
> Do not use the `update-pump` command unless you can tolerate binlog data loss and data inconsistency between upstream and downstream, or you no longer need the binlog data stored in the Pump node.

11.7.15.20 Can I use the `update-pump` command in binlogctl to set the Pump state to `offline` if I want to close a Pump node that is exited and set to `paused`?

When a Pump process is exited and the node is in the `paused` state, not all the binlog data in the node is consumed in its downstream Drainer node. Therefore, doing so might risk data inconsistency between upstream and downstream. In this situation, restart the Pump and use the `offline-pump` command to close the Pump node.

11.7.15.21 When can I use the `update-drainer` command in binlogctl to set the Drainer state to `offline`?

Some stale Drainer nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-drainer` command to set their state to `offline`.

11.7.15.22 Can I use SQL operations such as `change pump` and `change drainer` to pause or close the Pump or Drainer service?

No. For more details on these SQL operations, refer to Use SQL statements to manage Pump or Drainer.

These SQL operations directly modifies the state information saved in PD and are functionally equivalent to the `update-pump` and `update-drainer` commands in binlogctl. To pause or close the Pump or Drainer service, use the binlogctl tool.

11.7.15.23 What can I do when some DDL statements supported by the upstream database cause error when executed in the downstream database?

To solve the problem, follow these steps:

1. Check `drainer.log`. Search `exec failed` for the last failed DDL operation before the Drainer process is exited.
2. Change the DDL version to the one compatible to the downstream. Perform this step manually in the downstream database.
3. Check `drainer.log`. Search for the failed DDL operation and find the `commit-ts` of this operation. For example:

```
[2020/05/21 09:51:58.019 +08:00] [INFO] [syncer.go:398] ["add ddl item
    ↪ to syncer, you can add this commit ts to `ignore-txn-commit-ts`
    ↪ to skip this ddl if needed"] [sql="ALTER TABLE `test` ADD INDEX
    ↪ (`index1`)"] ["commit ts"=416815754209656834]。
```

4. Modify the `drainer.toml` configuration file. Add the `commit-ts` in the `ignore-txn-commit-ts` item and restart the Drainer node.

11.7.15.24 TiDB fails to write to binlog and gets stuck, and `listener stopped, waiting for manual stop` appears in the log

In TiDB v3.0.12 and earlier versions, the binlog write failure causes TiDB to report the fatal error. TiDB does not automatically exit but only stops the service, which seems like getting stuck. You can see the `listener stopped, waiting for manual stop` error in the log.

You need to determine the specific causes of the binlog write failure. If the failure occurs because binlog is slowly written into the downstream, you can consider scaling out Pump or increasing the timeout time for writing binlog.

Since v3.0.13, the error-reporting logic is optimized. The binlog write failure causes transaction execution to fail and TiDB Binlog will return an error but will not get TiDB stuck.

11.7.15.25 TiDB writes duplicate binlogs to Pump

This issue does not affect the downstream and replication logic.

When the binlog write fails or becomes timeout, TiDB retries writing binlog to the next available Pump node until the write succeeds. Therefore, if the binlog write to a Pump node is slow and causes TiDB timeout (default 15s), then TiDB determines that the write fails and tries to write to the next Pump node. If binlog is actually successfully written to the timeout-causing Pump node, the same binlog is written to multiple Pump nodes. When Drainer processes the binlog, it automatically de-duplicates binlogs with the same TSO, so this duplicate write does not affect the downstream and replication logic.

11.7.15.26 Reparo is interrupted during the full and incremental restore process. Can I use the last TSO in the log to resume replication?

Yes. Reparo does not automatically enable the safe-mode when you start it. You need to perform the following steps manually:

1. After Reparo is interrupted, record the last TSO in the log as `checkpoint-tso`.
2. Modify the Reparo configuration file, set the configuration item `start-tso` to `checkpoint-tso + 1`, set `stop-tso` to `checkpoint-tso + 80,000,000,000` (approximately five minutes after the `checkpoint-tso`), and set `safe-mode` to `true`. Start Reparo, and Reparo replicates data to `stop-tso` and then stops automatically.
3. After Reparo stops automatically, set `start-tso` to `checkpoint tso + 80,000,000,001` ↪ , set `stop-tso` to `0`, and set `safe-mode` to `false`. Start Reparo to resume replication.

11.8 TiDB Lightning

11.8.1 TiDB Lightning Overview

TiDB Lightning is a tool used for fast full import of large amounts of data into a TiDB

cluster. You can download TiDB Lightning from here.

Currently, TiDB Lightning can mainly be used in the following two scenarios:

- Importing **large amounts** of **new** data **quickly**
- Restore all backup data

Currently, TiDB Lightning supports:

- The data source of the Dumpling, CSV or Amazon Aurora Parquet exported formats.
- Reading data from a local disk or from the Amazon S3 storage. For details, see External Storages.

11.8.1.1 TiDB Lightning architecture

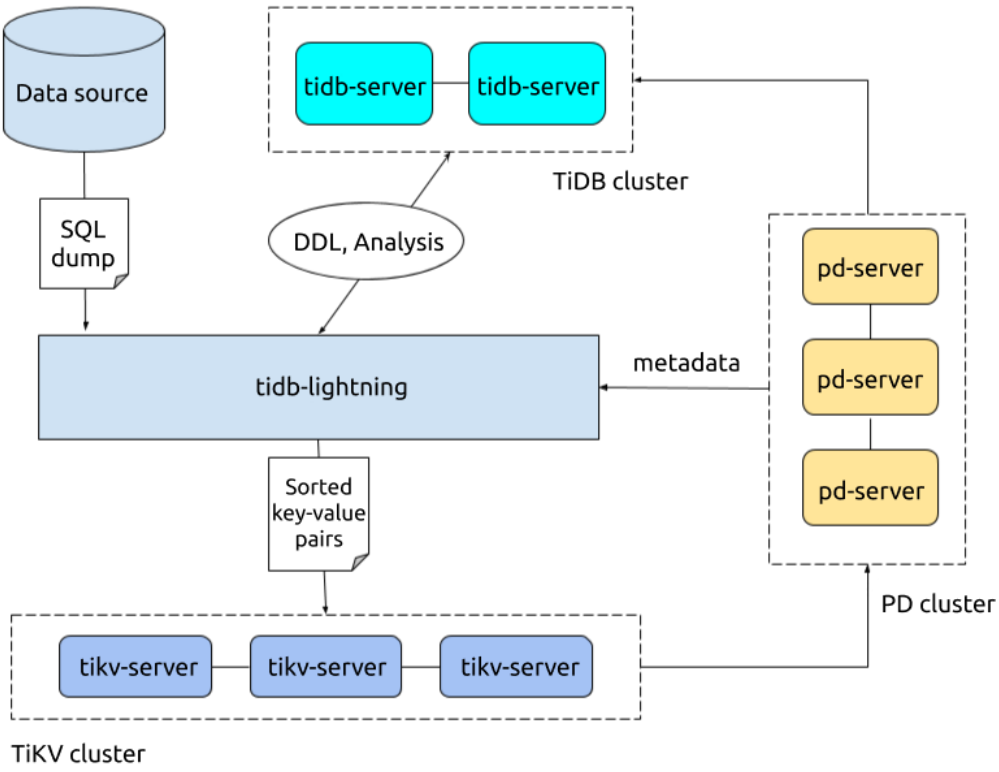

Figure 145: Architecture of TiDB Lightning tool set

The complete import process is as follows:

1. Before importing, `tidb-lightning` switches the TiKV cluster to "import mode", which optimizes the cluster for writing and disables automatic compaction.

2. `tidb-lightning` creates the skeleton of all tables from the data source.

3. Each table is split into multiple continuous *batches*, so that data from a huge table (200 GB+) can be imported incrementally and concurrently.

4. For each batch, `tidb-lightning` creates an *engine file* to store KV pairs. `tidb-lightning` then reads the data source in parallel, transforms each row into KV pairs according to the TiDB rules, and writes these KV pairs into the local files for temporary storage.

5. Once a complete engine file is written, `tidb-lightning` divides and schedules these data and imports them into the target TiKV cluster.

   There are two kinds of engine files: *data engines* and *index engines*, each corresponding to two kinds of KV pairs: the row data and secondary indices. Normally, the row data are entirely sorted in the data source, while the secondary indices are out of order. Because of this, the data engines are uploaded as soon as a batch is completed, while the index engines are imported only after all batches of the entire table are encoded.

6. After all engines associated to a table are imported, `tidb-lightning` performs a checksum comparison between the local data source and those calculated from the cluster, to ensure there is no data corruption in the process; tells TiDB to `ANALYZE` all imported tables, to prepare for optimal query planning; and adjusts the `AUTO_INCREMENT` value so future insertions will not cause conflict.

   The auto-increment ID of a table is computed by the estimated *upper bound* of the number of rows, which is proportional to the total file size of the data files of the table. Therefore, the final auto-increment ID is often much larger than the actual number of rows. This is expected since in TiDB auto-increment is not necessarily allocated sequentially.

7. Finally, `tidb-lightning` switches the TiKV cluster back to "normal mode", so the cluster resumes normal services.

If the target cluster of data import is v3.x or earlier versions, you need to use the Importer-backend to import data. In this mode, `tidb-lightning` sends the parsed KV pairs to `tikv-importer` via gRPC and `tikv-importer` imports the data.

TiDB Lightning also supports using TiDB-backend for data import. In this mode, `tidb-lightning` transforms data into `INSERT` SQL statements and directly executes them on the target cluster. See TiDB Lightning Backends for details.

11.8.1.2 Restrictions

If you use TiDB Lightning together with TiFlash:

No matter a table has TiFlash replica(s) or not, you can import data to that table using TiDB Lightning. Note that this might slow the TiDB Lightning procedure, which depends on the NIC bandwidth on the lightning host, the CPU and disk load of the TiFlash node, and the number of TiFlash replicas.

11.8.2 TiDB Lightning Tutorial

TiDB Lightning is a tool used for fast full import of large amounts of data into a TiDB cluster. Currently, TiDB Lightning supports reading SQL dump exported via SQL or CSV data source. You can use it in the following two scenarios:

- Import **large amounts** of **new** data **quickly**
- Back up and restore all the data

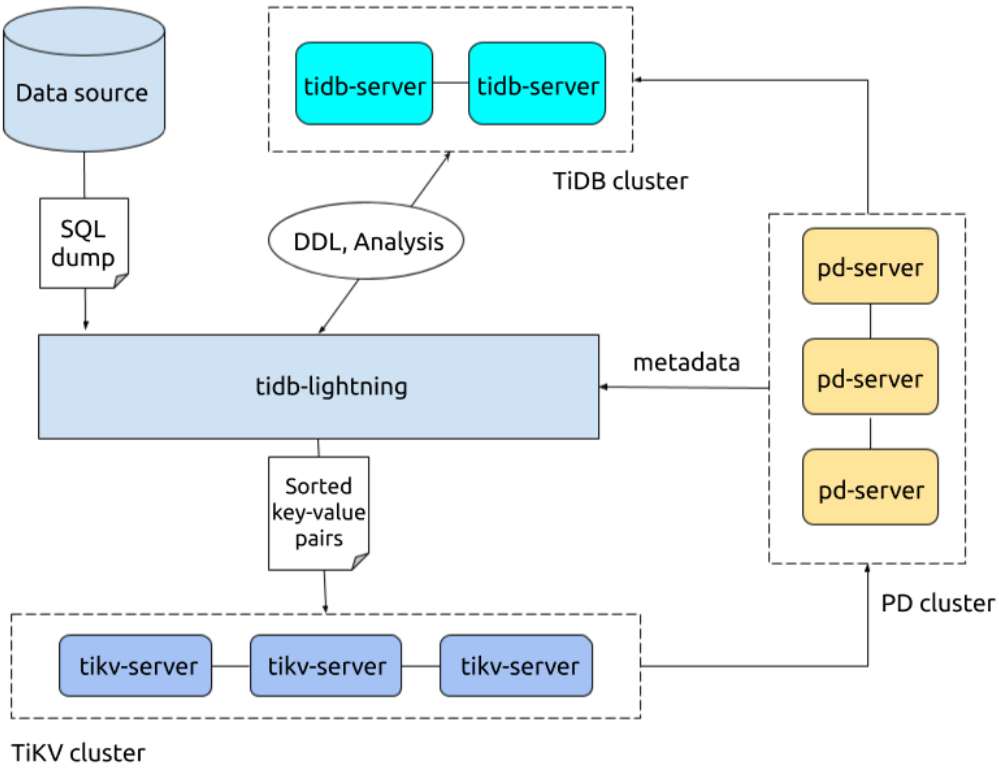

Figure 146: Architecture of TiDB Lightning tool set

11.8.2.1 Prerequisites

This tutorial assumes you use several new and clean CentOS 7 instances. You can use VMware, VirtualBox or other tools to deploy a virtual machine locally or a small cloud virtual machine on a vendor-supplied platform. Because TiDB Lightning consumes a large amount of computer resources, it is recommended that you allocate at least 16 GB memory and CPU of 32 cores for running it with the best performance.

> **Warning:**
>
> The deployment method in this tutorial is only recommended for test and trial. **Do not apply it in the production or development environment.**

11.8.2.2 Prepare full backup data

First, use dumpling to export data from MySQL:

```
./bin/dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f 'test
    ↪ .t[12]' -o /data/my_database/
```

In the above command:

- `-B test`: means the data is exported from the `test` database.
- `-f test.t[12]`: means only the `test.t1` and `test.t2` tables are exported.
- `-t 16`: means 16 threads are used to export the data.
- `-F 256MB`: means a table is partitioned into chunks and one chunk is 256 MB.

After executing this command, the full backup data is exported to the `/data/my_database` directory.

11.8.2.3 Deploy TiDB Lightning

11.8.2.3.1 Step 1: Deploy TiDB cluster

Before the data import, you need to deploy a TiDB cluster. In this tutorial, TiDB v5.0.0 is used as an example. For the deployment method, refer to Deploy a TiDB Cluster Using TiUP.

11.8.2.3.2 Step 2: Download TiDB Lightning installation package

Download the TiDB Lightning installation package from the following link:

- **v5.0.0**: tidb-toolkit-v5.0.0-linux-amd64.tar.gz

> **Note:**
>
> TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

11.8.2.3.3 Step 3: Start `tidb-lightning`

1. Upload `bin/tidb-lightning` and `bin/tidb-lightning-ctl` in the package to the server where TiDB Lightning is deployed.
2. Upload the prepared data source to the server.
3. Configure `tidb-lightning.toml` as follows:

```
[lightning]
# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# Uses the Local-backend
backend = "local"
# Sets the directory for temporarily storing the sorted key-value pairs
    ↪ .
# The target directory must be empty.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
# Local source data directory
data-source-dir = "/data/my_datasource/"

# Configures the wildcard rule. By default, all tables in the mysql,
    ↪ sys, INFORMATION_SCHEMA, PERFORMANCE_SCHEMA, METRICS_SCHEMA, and
    ↪ INSPECTION_SCHEMA system databases are filtered.
# If this item is not configured, the "cannot find schema" error occurs
    ↪  when system tables are imported.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
    ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA
    ↪ .*']
```

```
[tidb]
# Information of the target cluster
host = "172.16.31.2"
port = 4000
user = "root"
password = "rootroot"
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
# The PD address of the cluster
pd-addr = "172.16.31.3:2379"
```

4. After configuring the parameters properly, use a `nohup` command to start the `tidb -lightning` process. If you directly run the command in the command-line, the process might exit because of the SIGHUP signal received. Instead, it's preferable to run a bash script that contains the `nohup` command:

```
#!/bin/bash
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

11.8.2.3.4 Step 4: Check data integrity

After the import is completed, TiDB Lightning exits automatically. If the import is successful, you can find `tidb lightning exit` in the last line of the log file.

If any error occurs, refer to TiDB Lightning FAQs.

11.8.2.4 Summary

This tutorial briefly introduces what TiDB Lightning is and how to quickly deploy a TiDB Lightning cluster to import full backup data to the TiDB cluster.

For detailed features and usage about TiDB Lightning, refer to TiDB Lightning Overview.

11.8.3 TiDB Lightning Deployment

This document describes the hardware requirements of TiDB Lightning using the Local-backend, and how to deploy it manually.

If Local-backend is used for data import, during the import process, **the cluster cannot provide services**. If you do not want the TiDB services to be impacted, perform the data import according to TiDB Lightning TiDB-backend.

11.8.3.1 Notes

Before starting TiDB Lightning, note that:

- If `tidb-lightning` crashes, the cluster is left in "import mode". Forgetting to switch back to "normal mode" can lead to a high amount of uncompacted data on the TiKV cluster, and cause abnormally high CPU usage and stall. You can manually switch the cluster back to "normal mode" via the `tidb-lightning-ctl` tool:

```
bin/tidb-lightning-ctl --switch-mode=normal
```

- TiDB Lightning is required to have the following privileges in the downstream TiDB:

Privilege	Scope
SELECT	Tables
INSERT	Tables
UPDATE	Tables
DELETE	Tables
CREATE	Databases, tables
DROP	Databases, tables
ALTER	Tables

  If the `checksum` configuration item of TiDB Lightning is set to `true`, then the admin user privileges in the downstream TiDB need to be granted to TiDB Lightning.

11.8.3.2 Hardware requirements

`tidb-lightning` is a resource-intensive program. It is recommended to deploy it as follows.

- 32+ logical cores CPU
- 20GB+ memory
- An SSD large enough to store the entire data source, preferring higher read speed
- 10 Gigabit network card (capable of transferring at 1 GB/s)
- `tidb-lightning` fully consumes all CPU cores when running, and deploying on a dedicated machine is highly recommended. If not possible, `tidb-lightning` could be deployed together with other components like `tidb-server`, and the CPU usage could be limited via the `region-concurrency` setting.

Note:

- `tidb-lightning` is a CPU intensive program. In an environment with mixed components, the resources allocated to `tidb-lightning` must be limited. Otherwise, other components might not be able to run. It is recommended to set the `region-concurrency` to 75% of CPU logical cores. For instance, if the CPU has 32 logical cores, you can set the `region-concurrency` to 24.

Additionally, the target TiKV cluster should have enough space to absorb the new data. Besides the standard requirements, the total free space of the target TiKV cluster should be larger than **Size of data source** × **Number of replicas** × **2**.

With the default replica count of 3, this means the total free space should be at least 6 times the size of data source.

11.8.3.3 Export data

Use the `dumpling` tool to export data from MySQL by using the following command:

```
./bin/dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f 'test
    ↪ .t[12]' -o /data/my_database/
```

In this command,

- `-B test`: means the data is exported from the `test` database.
- `-f test.t[12]`: means only the `test.t1` and `test.t2` tables are exported.
- `-t 16`: means 16 threads are used to export the data.
- `-F 256MB`: means a table is partitioned into chunks and one chunk is 256 MB.

If the data source consists of CSV files, see CSV support for configuration.

11.8.3.4 Deploy TiDB Lightning

This section describes how to deploy TiDB Lightning manually.

11.8.3.4.1 Deploy TiDB Lightning manually

Step 1: Deploy a TiDB cluster

Before importing data, you need to have a deployed TiDB cluster. It is highly recommended to use the latest stable version.

You can find deployment instructions in TiDB Quick Start Guide.

Step 2: Download the TiDB Lightning installation package

Refer to the TiDB enterprise tools download page to download the TiDB Lightning package.

> **Note:**
>
> TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

Step 3: Start `tidb-lightning`

1. Upload `bin/tidb-lightning` and `bin/tidb-lightning-ctl` from the tool set.
2. Mount the data source onto the same machine.
3. Configure `tidb-lightning.toml`. For configurations that do not appear in the template below, TiDB Lightning writes a configuration error to the log file and exits.

   `sorted-kv-dir` sets the temporary storage directory for the sorted Key-Value files. The directory must be empty, and the storage space **must be greater than the size of the dataset to be imported**.

```
[lightning]
# The concurrency number of data. It is set to the number of logical
   ↪ CPU
# cores by default. When deploying together with other components, you
   ↪ can
# set it to 75% of the size of logical CPU cores to limit the CPU usage
   ↪ .
# region-concurrency =

# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# Sets the backend to the "local" mode.
backend = "local"
# Sets the directory of temporary local storage.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
# Local source data directory
data-source-dir = "/data/my_database"

[tidb]
# Configuration of any TiDB server from the cluster
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
# An address of pd-server.
pd-addr = "172.16.31.4:2379"
```

The above only shows the essential settings. See the Configuration section for the full list of settings.

4. Run `tidb-lightning`.

```
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

11.8.3.5 Upgrading TiDB Lightning

You can upgrade TiDB Lightning by replacing the binaries alone. No further configuration is needed. See FAQ for the detailed instructions of restarting TiDB Lightning.

If an import task is running, we recommend you to wait until it finishes before upgrading TiDB Lightning. Otherwise, there might be chances that you need to reimport from scratch, because there is no guarantee that checkpoints work across versions.

11.8.4 TiDB Lightning Configuration

This document provides samples for global configuration, task configuration, and TiKV Importer configuration in TiDB Lightning, and describes the usage of command-line parameters.

11.8.4.1 Configuration files

TiDB Lightning has two configuration classes: "global" and "task", and they have compatible structures. Their distinction arises only when the server mode is enabled. When server mode is disabled (the default), TiDB Lightning will only execute one task, and the same configuration file is used for both global and task configurations.

11.8.4.1.1 TiDB Lightning (Global)

```
##### tidb-lightning global configuration

[lightning]
### The HTTP port for displaying the web interface, pulling Prometheus
    ↪ metrics, exposing debug data, and submitting import tasks (in server
    ↪ mode). Setting it to 0 disables the port.
status-addr = ':8289'

### Server mode. Defaults to false, which means an import task starts
    ↪ immediately after you execute the command.
### If this value is set to true, after you execute the command, TiDB
    ↪ Lightning waits until you submit an import task in the web interface.
### See the "TiDB Lightning Web Interface" section for details.
server-mode = false
```

```
### Logging
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14
```

11.8.4.1.2 TiDB Lightning (Task)

```
##### tidb-lightning task configuration

[lightning]
### Checks whether the cluster satisfies the minimum requirement before
   ↪ starting the task, and check whether TiKV has more than 10% free
   ↪ space left during running time.
#check-requirements = true

### The maximum number of engines to be opened concurrently.
### Each table is split into one "index engine" to store indices, and
   ↪ multiple
### "data engines" to store row data. These settings control the maximum
### concurrent number for each type of engines.
### These values affect the memory and disk usage of tikv-importer.
### The sum of these two values must not exceed the max-open-engines setting
### for tikv-importer.
index-concurrency = 2
table-concurrency = 6

### The concurrency number of data. It is set to the number of logical CPU
### cores by default. When deploying together with other components, you can
### set it to 75% of the size of logical CPU cores to limit the CPU usage.
#region-concurrency =

### The maximum I/O concurrency. Excessive I/O concurrency causes an
   ↪ increase in
### I/O latency because the disk's internal buffer is frequently refreshed,
### which causes the cache miss and slows down the read speed. Depending on
   ↪ the storage
### medium, this value might need to be adjusted for optimal performance.
io-concurrency = 5

[security]
### Specifies certificates and keys for TLS connections within the cluster.
### Public certificate of the CA. Leave empty to disable TLS.
```

```
### ca-path = "/path/to/ca.pem"
### Public certificate of this service.
### cert-path = "/path/to/lightning.pem"
### Private key of this service.
### key-path = "/path/to/lightning.key"

[checkpoint]
### Whether to enable checkpoints.
### While importing data, TiDB Lightning records which tables have been
    ↪ imported, so
### even if TiDB Lightning or another component crashes, you can start from
    ↪ a known
### good state instead of restarting from scratch.
enable = true
### The schema name (database name) to store the checkpoints.
schema = "tidb_lightning_checkpoint"
### Where to store the checkpoints.
###  - file: store as a local file.
###  - mysql: store into a remote MySQL-compatible database
driver = "file"
### The data source name (DSN) indicating the location of the checkpoint
    ↪ storage.
### For the "file" driver, the DSN is a path. If the path is not specified,
    ↪ TiDB Lightning would
### default to "/tmp/CHECKPOINT_SCHEMA.pb".
### For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp(
    ↪ HOST:PORT)/".
### If the URL is not specified, the TiDB server from the [tidb] section is
    ↪ used to
### store the checkpoints. You should specify a different MySQL-compatible
### database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"
### Whether to keep the checkpoints after all data are imported. If false,
    ↪ the
### checkpoints will be deleted. Keeping the checkpoints can aid debugging
    ↪ but
### will leak metadata about the data source.
#keep-after-success = false

[tikv-importer]
### Delivery backend, can be "importer", "local", or "tidb".
### backend = "importer"
### The listening address of tikv-importer when backend is "importer".
    ↪ Change it to the actual address.
addr = "172.16.31.10:8287"
```

```
### Action to do when trying to insert a duplicated entry in the "tidb"
    ↪ backend.
###  - replace: use new entry to replace the existing entry
###  - ignore: keep the existing entry, and ignore the new entry
###  - error: report error and quit the program
### on-duplicate = "replace"
### The size limit of generated SST files in the "local" backend. It is
    ↪ better
### to be the same as the Region size of TiKV (96 MB by default).
### region-split-size = 100_663_296
### The number of KV pairs sent in one request in the "local" backend.
### send-kv-pairs = 32768
### The directory of local KV sorting in the "local" backend. If the disk
### performance is low (such as in HDD), it is recommended to set the
    ↪ directory
### on a different disk from `data-source-dir` to improve import speed.
### sorted-kv-dir = ""
### The concurrency that TiKV writes KV data in the "local" backend.
### When the network transmission speed between TiDB Lightning and TiKV
### exceeds 10 Gigabit, you can increase this value accordingly.
### range-concurrency = 16

[mydumper]
### Block size for file reading. Keep it longer than the longest string of
    ↪ the data source.
read-block-size = "64KiB" # default value

### Minimum size (in terms of source data file) of each batch of import.
### TiDB Lightning splits a large table into multiple data engine files
    ↪ according to this size.
### batch-size = 107_374_182_400 # Byte (default = 100 GB)

### The engine file needs to be imported sequentially. Due to parallel
    ↪ processing,
### multiple data engines will be imported at nearly the same time, and this
### creates a queue and wastes resources. Therefore, TiDB Lightning slightly
### increases the size of the first few batches to properly distribute
### resources. The scale up factor is controlled by this parameter, which
### expresses the ratio of duration between the "import" and "write" steps
### with full concurrency. This can be calculated by using the ratio
### (import duration/write duration) of a single table of size around 1 GiB.
### The exact timing can be found in the log. If "import" is faster, the
    ↪ batch
### size variance is smaller, and a ratio of zero means a uniform batch size
    ↪ .
```

```
### This value should be in the range (0 <= batch-import-ratio < 1).
batch-import-ratio = 0.75

### Local source data directory or the URL of the external storage.
data-source-dir = "/data/my_database"
### If no-schema is set to true, tidb-lightning assumes that the table
    ↪ skeletons
### already exist on the target TiDB cluster, and will not execute the `
    ↪ CREATE
### TABLE` statements.
no-schema = false
### The character set of the schema files, containing CREATE TABLE
    ↪ statements;
### only supports one of:
###  - utf8mb4: the schema files must be encoded as UTF-8; otherwise, an
    ↪ error is reported.
###  - gb18030: the schema files must be encoded as GB-18030; otherwise,
###             an error is reported
###  - auto:    (default) automatically detects whether the schema is UTF-8 or
###             GB-18030. An error is reported if the encoding is neither.
###  - binary: do not try to decode the schema files
### Note that the *data* files are always parsed as binary regardless of
### schema encoding.
character-set = "auto"

### the input data in a "strict" format speeds up processing.
### "strict-format = true" requires that:
### in CSV, every value cannot contain literal new lines (U+000A and U+000D,
    ↪  or \r and \n) even
### when quoted, which means new lines are strictly used to separate rows.
### "Strict" format allows TiDB Lightning to quickly locate split positions
    ↪ of a large file for parallel processing.
### However, if the input data is not "strict", it may split a valid data in
    ↪  half and
### corrupt the result.
### The default value is false for safety instead of speed.
strict-format = false

### If strict-format is true, TiDB Lightning splits large CSV files into
    ↪ multiple chunks to process in
### parallel. max-region-size is the maximum size of each chunk after
    ↪ splitting.
### max-region-size = "256MiB" # default value

### Only import tables if these wildcard rules are matched. See the
```

```
    ↪ corresponding section for details.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
    ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA.*']

### Configures how CSV files are parsed.
[mydumper.csv]
### Separator between fields. Must not be empty.
separator = ','
### Quoting delimiter. Empty value means no quoting.
delimiter = '"'
### Whether the CSV files contain a header.
### If `header` is true, the first line will be skipped.
header = true
### Whether the CSV contains any NULL value.
### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
### When `not-null` is false (that is, CSV can contain NULL),
### fields equal to this value will be treated as NULL.
null = '\N'
### Whether to interpret backslash escapes inside fields.
backslash-escape = true
### If a line ends with a separator, remove it.
trim-last-separator = false

[tidb]
### Configuration of any TiDB server from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
### Table schema information is fetched from TiDB via this status-port.
status-port = 10080
### Address of any PD server from the cluster.
pd-addr = "172.16.31.4:2379"
### tidb-lightning imports TiDB as a library and generates some logs itself.
### This setting controls the log level of the TiDB library.
log-level = "error"

### Sets the TiDB session variable to speed up the Checksum and Analyze
    ↪ operations.
### See https://pingcap.com/docs/dev/reference/performance/statistics/#
    ↪ control-analyze-concurrency
### for the meaning of each setting
build-stats-concurrency = 20
distsql-scan-concurrency = 100
```

```
index-serial-scan-concurrency = 20
checksum-table-concurrency = 16

### The default SQL mode used to parse and execute the SQL statements.
sql-mode = "ONLY_FULL_GROUP_BY,NO_ENGINE_SUBSTITUTION"
### Sets maximum packet size allowed for SQL connections.
### Set this to 0 to automatically fetch the `max_allowed_packet` variable
   ↪ from server on every connection.
max-allowed-packet = 67_108_864

### Whether to use TLS for SQL connections. Valid values are:
### - "": if configuration items in the [tidb.security] section are
   ↪ configured, TiDB Lightning requires TLS for SQL connections (same
   ↪ behavior as "cluster"). Otherwise, it uses an unencrypted connection.
### - "false": same behavior as "".
### - "cluster": requires TLS and verifies the server's certificate with
   ↪ the CA specified in the [tidb.security] section.
### - "skip-verify": requires TLS but does not verify the server's
   ↪ certificate (insecure). If the server does not support TLS, the
   ↪ connection falls back to an unencrypted state.
### - "preferred": same behavior as "skip-verify".
### tls = ""

### Specifies certificates and keys for TLS-enabled MySQL connections.
### Defaults to a copy of the [security] section.
### [tidb.security]
### Public certificate of the CA. Set to empty string to disable TLS for SQL
   ↪ .
### ca-path = "/path/to/ca.pem"
### Public certificate of this service. Default to copy of `security.cert-
   ↪ path`
### cert-path = "/path/to/lightning.pem"
### Private key of this service. Default to copy of `security.key-path`
### key-path = "/path/to/lightning.key"

### In the local backend mode, when data import is completed, TiDB Lightning
### can automatically perform the Checksum and Analyze operations. It is
### recommended to leave these as true in the production environment.
### The execution order: Checksum -> Analyze
### Note that these two operations are not needed for the tidb backend mode,
### so they are skipped in operation.
[post-restore]
### Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
   ↪ table to verify data integrity after importing.
### The following options are available:
```

```
### - "required" (default value): Perform admin checksum. If checksum fails,
    ↪  TiDB Lightning will exit with failure.
### - "optional": Perform admin checksum. If checksum fails, TiDB Lightning
    ↪ will report a WARN log but ignore any error.
### - "off": Do not perform checksum.
### Note that since v4.0.8, the default value has changed from "true" to "
    ↪ required".
### Note:
### 1. Checksum failure usually means import exception (data loss or
    ↪ inconsistency). It is recommended to always enable checksum.
### 2. For backward compatibility, bool values "true" and "false" are also
    ↪ allowed for this field.
### "true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"
### Specifies whether to perform `ANALYZE TABLE <table>` for each table
    ↪ after checksum is done.
### Options available for this field are the same as `checksum`. However,
    ↪ the default value for this field is "optional".
analyze = "optional"

### Configures the background periodic actions.
### Supported units: h (hour), m (minute), s (second).
[cron]
### Duration between which TiDB Lightning automatically refreshes the import
    ↪  mode
### status. Should be shorter than the corresponding TiKV setting.
switch-mode = "5m"
### Duration between which an import progress is printed to the log.
log-progress = "5m"

### Split Regions into this size according to the importing data.
#region-split-size = "512MB"
### Stream channel window size. The stream will be blocked on channel full.
#stream-channel-window = 128
### Maximum number of open engines.
max-open-engines = 8
### Maximum upload speed (bytes per second) from Importer to TiKV.
### upload-speed-limit = "512MB"
### Minimum ratio of available space on the target store: `
   ↪ store_available_space`/`store_capacity`.
### Importer pauses uploading SST if the availability ratio of the target
   ↪ store is less than this
### value, to allow enough time for PD to balance Regions.
min-available-ratio = 0.05
```

11.8.4.2 Command line parameters

11.8.4.2.1 Usage of `tidb-lightning`

Parameter	Explanation	Corresponding setting
–config *file*	Reads global configuration from *file*. If not specified, the default configuration would be used.	
-V	Prints program version	
-d *directory*	Directory or external storage URL of the data dump to read from	`mydumper` ↪ `.` ↪ `data` ↪ `-` ↪ `source` ↪ `-` ↪ `dir` ↪

Parameter	Explanation	Corresponding setting
-L *level*	Log level: debug, info, warn, error, fatal (default = info)	`lightning.log.level`
-f *rule*	Table filter rules (can be specified multiple times)	`mydumper.filter`
--backend *backend*	Delivery backend (`local`, `importer`, or `tidb`)	`tikv-importer.backend`

Parameter	Explanation	Corresponding setting
–log-file *file*	Log file path. By default, it is `/tmp/lightning.log.{timestamp}`. If set to '-', it means that the log files will be output to stdout.	`lightning.log-file`
–status-addr *ip:port*	Listening address of the TiDB Lightning server	`lightning.status-port`
–importer *host:port*	Address of TiKV Importer	`tikv-importer.addr`

Parameter	Explanation	Corresponding setting
–pd-urls *host:port*	PD endpoint address	`tidb.pd.addr`
–tidb-host *host*	TiDB server host	`tidb.host`
–tidb-port *port*	TiDB server port (default = 4000)	`tidb.port`
–tidb-status *port*	TiDB status port (default = 10080)	`tidb.status.port`
–tidb-user *user*	User name to connect to TiDB	`tidb.user`
–tidb-password *password*	Password to connect to TiDB	`tidb.password`

Parameter	Explanation	Corresponding setting
–no-schema	Ignore schema files, get schema directly from TiDB	`mydumper.no-schema`
–enable-checkpoint *bool*	Whether to enable checkpoints (default = true)	`checkpoint.enable`
–analyze *level*	Analyze tables after importing. Available values are “required”, “optional” (default value), and “off”	`post-restore.analyze`

Parameter	Explanation	Corresponding setting
–checksum-level	Compare checksum after importing. Available values are “required” (default value), “optional”, and “off”	`post-restore.checksum`

Parameter	Explanation	Corresponding setting
–check-requirements *bool*	Check cluster version compatibility before starting the task, and check whether TiKV has more than 10% free space left during running time. (default = true)	`lightning.check-requirements`

Parameter	Explanation	Corresponding setting
–ca *file*	CA certificate path for TLS connection	`security.ca-path`
–cert *file*	Certificate path for TLS connection	`security.cert-path`
–key *file*	Private key path for TLS connection	`security.key-path`
–server-mode	Start TiDB Lightning in server mode	`lightning.server-mode`

If a command line parameter and the corresponding setting in the configuration file are both provided, the command line parameter will be used. For example, running `./tidb-lightning -L debug --config cfg.toml` would always set the log level to "debug" regardless of the content of `cfg.toml`.

11.8.4.3 Usage of `tidb-lightning-ctl`

This tool can execute various actions given one of the following parameters:

Parameter	Explanation
–compact	Performs a full compaction
–switch-mode *mode*	Switches every TiKV store to the given mode: normal, import
–fetch-mode	Prints the current mode of every TiKV store
–import-engine *uuid*	Imports the closed engine file from TiKV Importer into the TiKV cluster

Parameter	Explanation
–cleanup-engine *uuid*	Deletes the engine file from TiKV Importer
–checkpoint-dump *folder*	Dumps current checkpoint as CSVs into the folder
–checkpoint-error-destroy *table-name*	Removes the checkpoint and drops the table if it caused error
–checkpoint-error-ignore *table-name*	Ignores any error recorded in the checkpoint involving the given table

Parameter	Explanation
–checkpoint-remove *table-name*	Unconditionally removes the checkpoint of the table

The *tablename* must either be a qualified table name in the form `` `db`.`tbl` `` (including the backquotes), or the keyword "all".

Additionally, all parameters of `tidb-lightning` described in the section above are valid in `tidb-lightning-ctl`.

11.8.4.4 Usage of `tikv-importer`

Parameter	Explanation	Corresponding setting
-C, –config *file*	Reads configuration from *file*. If not specified, the default configuration would be used.	
-V, –version	Prints program version	

Parameter	Explanation	Corresponding setting
-A, –addr *ip:port*	Listening address of the TiKV Importer server	`server.addr`
–status-server *ip:port*	Listening address of the status server	`status.address`
–import-dir *dir*	Stores engine files in this directory	`import.dir`
–log-level *level*	Log level: trace, debug, info, warn, error, off	`log.level`
–log-file *file*	Log file path	`log.file`

11.8.5 Key Features

11.8.5.1 TiDB Lightning Checkpoints

Importing a large database usually takes hours or days, and if such long running processes spuriously crashes, it can be very time-wasting to redo the previously completed tasks. To solve this, TiDB Lightning uses *checkpoints* to store the import progress, so that `tidb-lightning` continues importing from where it lefts off after restarting.

This document describes how to enable, configure, store, and control *checkpoints*.

11.8.5.1.1 Enable and configure checkpoints

```
[checkpoint]
#### Whether to enable checkpoints.
#### While importing data, TiDB Lightning records which tables have been
   ↪ imported, so
#### even if TiDB Lightning or some other component crashes, you can start
   ↪ from a known
#### good state instead of restarting from scratch.
enable = true

#### Where to store the checkpoints.
#### - file: store as a local file (requires v2.1.1 or later)
#### - mysql: store into a remote MySQL-compatible database
driver = "file"

#### The schema name (database name) to store the checkpoints
#### Enabled only when `driver = "mysql"`.
#### schema = "tidb_lightning_checkpoint"

#### The data source name (DSN) indicating the location of the checkpoint
   ↪ storage.
#### # For the "file" driver, the DSN is a path. If the path is not
   ↪ specified, Lightning would
#### default to "/tmp/CHECKPOINT_SCHEMA.pb".
#### # For the "mysql" driver, the DSN is a URL in the form of "USER:
   ↪ PASS@tcp(HOST:PORT)/".
#### If the URL is not specified, the TiDB server from the [tidb] section is
   ↪  used to
#### store the checkpoints. You should specify a different MySQL-compatible
#### database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"

#### Whether to keep the checkpoints after all data are imported. If false,
   ↪ the
#### checkpoints are deleted. Keeping the checkpoints can aid debugging but
#### might leak metadata about the data source.
#### keep-after-success = false
```

11.8.5.1.2 Checkpoints storage

TiDB Lightning supports two kinds of checkpoint storage: a local file or a remote MySQL-compatible database.

- With `driver = "file"`, checkpoints are stored in a local file at the path given by the `dsn` setting. Checkpoints are updated rapidly, so we highly recommend placing the checkpoint file on a drive with very high write endurance, such as a RAM disk.
- With `driver = "mysql"`, checkpoints can be saved in any databases compatible with MySQL 5.7 or later, including MariaDB and TiDB. By default, the checkpoints are saved in the target database.

While using the target database as the checkpoints storage, Lightning is importing large amounts of data at the same time. This puts extra stress on the target database and sometimes leads to communication timeout. Therefore, **it is strongly recommended to install a temporary MySQL server to store these checkpoints**. This server can be installed on the same host as `tidb-lightning` and can be uninstalled after the importer progress is completed.

11.8.5.1.3 Checkpoints control

If `tidb-lightning` exits abnormally due to unrecoverable errors (for example, data corruption), it refuses to reuse the checkpoints until the errors are resolved. This is to prevent worsening the situation. The checkpoint errors can be resolved using the `tidb-lightning-ctl` program.

`--checkpoint-error-destroy`

```
tidb-lightning-ctl --checkpoint-error-destroy='`schema`.`table`'
```

This option allows you to restart importing the table from scratch. The schema and table names must be quoted with backquotes and are case-sensitive.

- If importing the table `` `schema`.`table` `` failed previously, this option executes the following operations:
    1. DROPs the table `` `schema`.`table` `` from the target database, which means removing all imported data.
    2. Resets the checkpoints record of this table to be "not yet started".
- If there is no errors involving the table `` `schema`.`table` ``, this operation does nothing.

It is the same as applying the above on every table. This is the most convenient, safe and conservative solution to fix the checkpoint error problem:

```
tidb-lightning-ctl --checkpoint-error-destroy=all
```

`--checkpoint-error-ignore`

```
tidb-lightning-ctl --checkpoint-error-ignore='`schema`.`table`'
tidb-lightning-ctl --checkpoint-error-ignore=all
```

If importing the table `` `schema`.`table` `` failed previously, this clears the error status as if nothing ever happened. The `all` variant applies this operation to all tables.

> **Note:**
>
> Use this option only when you are sure that the error can indeed be ignored. If not, some imported data can be lost. The only safety net is the final "checksum" check, and thus you need to keep the "checksum" option always enabled when using `--checkpoint-error-ignore`.

`--checkpoint-remove`

```
tidb-lightning-ctl --checkpoint-remove='`schema`.`table`'
tidb-lightning-ctl --checkpoint-remove=all
```

This option simply removes all checkpoint information about one table or all tables, regardless of their status.

`--checkpoint-dump`

```
tidb-lightning-ctl --checkpoint-dump=output/directory
```

This option dumps the content of the checkpoint into the given directory, which is mainly used for debugging by the technical staff. This option is only enabled when `driver = "mysql"`.

11.8.5.2 Table Filter

The TiDB ecosystem tools operate on all the databases by default, but oftentimes only a subset is needed. For example, you only want to work with the schemas in the form of `foo*` and `bar*` and nothing else.

Since TiDB 4.0, all TiDB ecosystem tools share a common filter syntax to define subsets. This document describes how to use the table filter feature.

11.8.5.2.1 Usage

CLI

Table filters can be applied to the tools using multiple `-f` or `--filter` command line parameters. Each filter is in the form of `db.table`, where each part can be a wildcard (further explained in the next section). The following lists the example usage in each tool.

- BR:

```
./br backup full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

```
./br restore full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

- Dumpling:

```
./dumpling -f 'foo*.*' -f 'bar*.*' -P 3306 -o /tmp/data/
```

- TiDB Lightning:

```
./tidb-lightning -f 'foo*.*' -f 'bar*.*' -d /tmp/data/ --backend tidb
```

TOML configuration files

Table filters in TOML files are specified as array of strings. The following lists the example usage in each tool.

- TiDB Lightning:

```
[mydumper]
filter = ['foo*.*', 'bar*.*']
```

- TiCDC:

```
[filter]
rules = ['foo*.*', 'bar*.*']

[[sink.dispatchers]]
matcher = ['db1.*', 'db2.*', 'db3.*']
dispatcher = 'ts'
```

11.8.5.2.2 Syntax

Plain table names

Each table filter rule consists of a "schema pattern" and a "table pattern", separated by a dot (`.`). Tables whose fully-qualified name matches the rules are accepted.

```
db1.tbl1
db2.tbl2
db3.tbl3
```

A plain name must only consist of valid identifier characters, such as:

- digits (`0` to `9`)

- letters (`a` to `z`, `A` to `Z`)
- `$`
- `_`
- non ASCII characters (U+0080 to U+10FFFF)

All other ASCII characters are reserved. Some punctuations have special meanings, as described in the next section.

Wildcards

Each part of the name can be a wildcard symbol described in fnmatch(3):

- `*` — matches zero or more characters
- `?` — matches one character
- `[a-z]` — matches one character between "a" and "z" inclusively
- `[!a-z]` — matches one character except "a" to "z".

```
db[0-9].tbl[0-9a-f][0-9a-f]
data.*
*.backup_*
```

"Character" here means a Unicode code point, such as:

- U+00E9 (é) is 1 character.
- U+0065 U+0301 (é) are 2 characters.
- U+1F926 U+1F3FF U+200D U+2640 U+FE0F (🤦🏿‍♀️) are 5 characters.

File import

To import a file as the filter rule, include an `@` at the beginning of the rule to specify the file name. The table filter parser treats each line of the imported file as additional filter rules.

For example, if a file `config/filter.txt` has the following content:

```
employees.*
*.WorkOrder
```

the following two invocations are equivalent:

```
./dumpling -f '@config/filter.txt'
./dumpling -f 'employees.*' -f '*.WorkOrder'
```

A filter file cannot further import another file.

Comments and blank lines

Inside a filter file, leading and trailing white-spaces of every line are trimmed. Furthermore, blank lines (empty strings) are ignored.

A leading `#` marks a comment and is ignored. `#` not at start of line is considered syntax error.

```
#### this line is a comment
db.table  # but this part is not comment and may cause error
```

Exclusion

An `!` at the beginning of the rule means the pattern after it is used to exclude tables from being processed. This effectively turns the filter into a block list.

```
*.*
#^ note: must add the *.* to include all tables first
!*.Password
!employees.salaries
```

Escape character

To turn a special character into an identifier character, precede it with a backslash `\`.

```
db\.with\.dots.*
```

For simplicity and future compatibility, the following sequences are prohibited:

- `\` at the end of the line after trimming whitespaces (use `[ ]` to match a literal whitespace at the end).
- `\` followed by any ASCII alphanumeric character (`[0-9a-zA-Z]`). In particular, C-like escape sequences like `\0`, `\r`, `\n` and `\t` currently are meaningless.

Quoted identifier

Besides `\`, special characters can also be suppressed by quoting using `"` or `` ` ``.

```
"db.with.dots"."tbl\1"
`db.with.dots`.`tbl\2`
```

The quotation mark can be included within an identifier by doubling itself.

```
"foo""bar".`foo``bar`
#### equivalent to:
foo\"bar.foo\`bar
```

Quoted identifiers cannot span multiple lines.

It is invalid to partially quote an identifier:

```
"this is "invalid*.*
```

Regular expression

In case very complex rules are needed, each pattern can be written as a regular expression delimited with `/`:

```
/^db\d{2,}$/./^tbl\d{2,}$/
```

These regular expressions use the Go dialect. The pattern is matched if the identifier contains a substring matching the regular expression. For instance, `/b/` matches `db01`.

> **Note:**
>
> Every `/` in the regular expression must be escaped as `\/`, including inside `[···]`. You cannot place an unescaped `/` between `\Q···\E`.

11.8.5.2.3 Multiple rules

When a table name matches none of the rules in the filter list, the default behavior is to ignore such unmatched tables.

To build a block list, an explicit `*.*` must be used as the first rule, otherwise all tables will be excluded.

```
#### every table will be filtered out
./dumpling -f '!*.Password'

#### only the "Password" table is filtered out, the rest are included.
./dumpling -f '*.*' -f '!*.Password'
```

In a filter list, if a table name matches multiple patterns, the last match decides the outcome. For instance:

```
#### rule 1
employees.*
#### rule 2
!*.dep*
#### rule 3
*.departments
```

The filtered outcome is as follows:

Table name	Rule 1	Rule 2	Rule 3	Outcome
irrelevant.table				Default (reject)
employees.employees				Rule 1 (accept)
employees.dept_emp				Rule 2 (reject)
employees.departments				Rule 3 (accept)
else.departments				Rule 3 (accept)

Note:

In TiDB tools, the system schemas are always excluded in the default configuration. The system schemas are:

- `INFORMATION_SCHEMA`
- `PERFORMANCE_SCHEMA`
- `METRICS_SCHEMA`
- `INSPECTION_SCHEMA`
- `mysql`
- `sys`

11.8.5.3 TiDB Lightning CSV Support and Restrictions

This document describes how to migrate data from CSV files to TiDB using TiDB Lightning. For information about how to generate CSV files from MySQL, see Export to CSV files using Dumpling.

TiDB Lightning supports reading CSV (comma-separated values) data source, as well as other delimited format such as TSV (tab-separated values).

11.8.5.3.1 File name

A CSV file representing a whole table must be named as `db_name.table_name.csv`. This will be restored as a table `table_name` inside the database `db_name`.

If a table spans multiple CSV files, they should be named like `db_name.table_name.003.csv`. The number part do not need to be continuous, but must be increasing and zero-padded.

The file extension must be `*.csv`, even if the content is not separated by commas.

11.8.5.3.2 Schema

CSV files are schema-less. To import them into TiDB, a table schema must be provided. This could be done either by:

- Providing a file named `db_name.table_name-schema.sql` containing the `CREATE TABLE` DDL statement, and also a file named `db_name-schema-create.sql` containing the `CREATE DATABASE` DDL statement.
- Creating the empty tables directly in TiDB in the first place, and then setting `[mydumper] no-schema = true` in `tidb-lightning.toml`.

11.8.5.3.3 Configuration

The CSV format can be configured in `tidb-lightning.toml` under the `[mydumper.csv]` section. Most settings have a corresponding option in the MySQL `LOAD DATA` statement.

```
[mydumper.csv]
#### Separator between fields. Must not be empty. It is not recommended to
   ↪ use the default ','. It is recommended to use '\|+\|' or other
   ↪ uncommon character combinations.
separator = ','
#### Quoting delimiter. Empty value means no quoting.
delimiter = '"'
#### Whether the CSV files contain a header.
#### If `header` is true, the first line will be skipped.
header = true
#### Whether the CSV contains any NULL value.
#### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
#### When `not-null` is false (that is, CSV can contain NULL),
#### fields equal to this value will be treated as NULL.
null = '\N'
#### Whether to interpret backslash escapes inside fields.
backslash-escape = true
#### If a line ends with a separator, remove it.
trim-last-separator = false
```

In all string fields such as `separator` and `delimiter`, if the input involves special characters, you can use backslash escape sequence to represent them in a *double-quoted* string (`"⋯"`). For example, `separator = "\u001f"` means using the ASCII character 0x1F as separator.

Additionally, you can use *single-quoted* strings (`'⋯'`) to suppress backslash escaping. For example, `separator = '\t'` means using the two-character string: a backslash followed by the letter "t", as the separator.

See the TOML v1.0.0 specification for details.

`separator`

- Defines the field separator.
- Can be multiple characters, but must not be empty.
- Common values:
  - `','` for CSV (comma-separated values)
  - `"\t"` for TSV (tab-separated values)
  - `"\u0001"` to use the ASCII character 0x01 as separator

- Corresponds to the `FIELDS TERMINATED BY` option in the LOAD DATA statement.

`delimiter`

- Defines the delimiter used for quoting.
- If `delimiter` is empty, all fields are unquoted.
- Common values:
  - `'"'` quote fields with double-quote, same as RFC 4180
  - `''` disable quoting
- Corresponds to the `FIELDS ENCLOSED BY` option in the `LOAD DATA` statement.

`header`

- Whether *all* CSV files contain a header row.
- If `header` is true, the first row will be used as the *column names*. If `header` is false, the first row is not special and treated as an ordinary data row.

`not-null` and `null`

- The `not-null` setting controls whether all fields are non-nullable.
- If `not-null` is false, the string specified by `null` will be transformed to the SQL NULL instead of a concrete value.
- Quoting will not affect whether a field is null.

  For example, with the CSV file:

```
A,B,C
\N,"\N",
```

  In the default settings (`not-null = false; null = '\N'`), the columns `A` and `B` are both converted to NULL after importing to TiDB. The column `C` is simply the empty string `''` but not NULL.

`backslash-escape`

- Whether to interpret backslash escapes inside fields.
- If `backslash-escape` is true, the following sequences are recognized and transformed:

Sequence	Converted to
\0	Null character (U+0000)
\b	Backspace (U+0008)
\n	Line feed (U+000A)
\r	Carriage return (U+000D)
\t	Tab (U+0009)
\Z	Windows EOF (U+001A)

In all other cases (for example, \") the backslash is simply stripped, leaving the next character (") in the field. The character left has no special roles (for example, delimiters) and is just an ordinary character.

- Quoting will not affect whether backslash escapes are interpreted.
- Corresponds to the `FIELDS ESCAPED BY '\'` option in the `LOAD DATA` statement.

`trim-last-separator`

- Treats the field `separator` as a terminator, and removes all trailing separators.

  For example, with the CSV file:

```
A,,B,,
```

- When `trim-last-separator = false`, this is interpreted as a row of 5 fields `('A', '', 'B', '', '')`.
- When `trim-last-separator = true`, this is interpreted as a row of 3 fields `('A', '', 'B')`.

Non-configurable options

TiDB Lightning does not support every option supported by the `LOAD DATA` statement. Some examples:

- The line terminator must only be CR (\r), LF (\n) or CRLF (\r\n), which means `LINES TERMINATED BY` is not customizable.
- There cannot be line prefixes (`LINES STARTING BY`).
- The header cannot be simply skipped (`IGNORE n LINES`). It must be valid column names if present.

11.8.5.3.4 Strict format

Lightning works the best when the input files have uniform size around 256 MB. When the input is a single huge CSV file, Lightning can only use one thread to process it, which slows down import speed a lot.

This can be fixed by splitting the CSV into multiple files first. For the generic CSV format, there is no way to quickly identify when a row starts and ends without reading the whole file. Therefore, Lightning by default does *not* automatically split a CSV file. However, if you are certain that the CSV input adheres to certain restrictions, you can enable the `strict-format` setting to allow Lightning to split the file into multiple 256 MB-sized chunks for parallel processing.

```
[mydumper]
strict-format = true
```

Currently, a strict CSV file means every field occupies only a single line. In other words, one of the following must be true:

- Delimiter is empty, or
- Every field does not contain CR (`\r`) or LF (`\n`).

If a CSV file is not strict, but `strict-format` was wrongly set to `true`, a field spanning multiple lines may be cut in half into two chunks, causing parse failure, or even worse, quietly importing corrupted data.

11.8.5.3.5 Common configurations

CSV

The default setting is already tuned for CSV following RFC 4180.

```
[mydumper.csv]
separator = ',' # It is not recommended to use the default ',' . It is
    ↪ recommended to use '\|+\|' or other uncommon character combinations
    ↪ .
delimiter = '"'
header = true
not-null = false
null = '\N'
backslash-escape = true
trim-last-separator = false
```

Example content:

```
ID,Region,Count
1,"East",32
2,"South",\N
```

```
3,"West",10
4,"North",39
```

TSV

```
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
trim-last-separator = false
```

Example content:

```
ID    Region    Count
1     East      32
2     South     NULL
3     West      10
4     North     39
```

TPC-H DBGEN

```
[mydumper.csv]
separator = '|'
delimiter = ''
header = false
not-null = true
backslash-escape = false
trim-last-separator = true
```

Example content:

```
1|East|32|
2|South|0|
3|West|10|
4|North|39|
```

11.8.5.4 TiDB Lightning Backends

The backend determines how TiDB Lightning imports data into the target cluster.

TiDB Lightning supports the following backends:

- Importer-backend (default)
- Local-backend

- TiDB-backend

The **Importer-backend** (default): `tidb-lightning` first encodes the SQL or CSV data into KV pairs, and relies on the external `tikv-importer` program to sort these KV pairs and ingest directly into the TiKV nodes.

The **Local-backend**: `tidb-lightning` first encodes data into key-value pairs, sorts and stores them in a local temporary directory, and *upload* these key-value pairs to each TiKV node *as SST files*. Then, TiKV ingests these *SST files* into the cluster. The implementation of Local-backend is the same with that of Importer-backend but does not rely on the external `tikv-importer` component.

The **TiDB-backend**: `tidb-lightning` first encodes these data into SQL `INSERT` statements, and has these statements executed directly on the TiDB node.

Backend	Local-backend	Importer-backend	TiDB-backend
Speed	Fast (~500 GB/hr)	Fast (~300 GB/hr)	Slow (~50 GB/hr)
Resource usage	High	High	Low
Network bandwidth usage	High	Medium	Low
ACID respected while importing	No	No	Yes
Target tables	Must be empty	Must be empty	Can be populated
Additional component required	No	`tikv-importer`	No
TiDB versions supported	>= v4.0.0	All	All
TiDB services impacted	Yes	Yes	No

11.8.5.4.1 How to choose the backend modes

- If the target cluster of data import is v4.0 or later versions, consider using the Local-backend mode first, which is easier to use and has higher performance than that of the other two modes.
- If the target cluster of data import is v3.x or earlier versions, it is recommended to use the Importer-backend mode.
- If the target cluster of data import is in the online production environment, or if the target table of data import already has data on it, it is recommended to use the TiDB-backend mode.

11.8.5.4.2 TiDB Lightning Local-backend

The Local-backend feature is introduced to TiDB Lightning since TiDB v4.0.3. You can use this feature to import data to TiDB clusters of v4.0.0 or above.

Deployment for Local-backend

To deploy TiDB Lightning in the Local-backend mode, see TiDB Lightning Deployment.

11.8.5.4.3 TiDB Lightning TiDB-backend

> **Note:**
>
> Since TiDB v4.0, PingCAP no longer maintains the Loader tool. Since v5.0, the Loader documentation is no longer available. Loader's functionality has been completely replaced by the TiDB-backend of TiDB Lightning, so it is highly recommended to switch to TiDB Lightning.

Deployment for TiDB-backend

When using the TiDB-backend, deploying `tikv-importer` is not necessary. Compared with the standard deployment procedure, the TiDB-backend deployment has the following two differences:

- All steps involving `tikv-importer` can be skipped.
- The configuration must be changed to declare that the TiDB-backend is used.

Hardware requirements

The speed of TiDB Lightning using TiDB-backend is limited by the SQL processing speed of TiDB. Therefore, even a lower-end machine may max out the possible performance. The recommended hardware configuration is:

- 16 logical cores CPU
- An SSD large enough to store the entire data source, preferring higher read speed
- 1 Gigabit network card

Manual deployment

You do not need to download and configure `tikv-importer`. You can download TiDB Lightning from here.

Before running `tidb-lightning`, add the following lines into the configuration file:

```
[tikv-importer]
backend = "tidb"
```

or supplying the `--backend tidb` arguments when executing `tidb-lightning`.

Configuration description and samples

This section provides the samples for task configuration in TiDB Lightning.

```
#### tidb-lightning task configuration

[lightning]
#### Checks whether the cluster satisfies the minimum requirement before
   ↪ starting.
check-requirements = true

#### Each table is split into one "index engine" to store indices, and
   ↪ multiple
#### "data engines" to store row data. These settings control the maximum
#### concurrent number for each type of engines.
#### Controls the maximum number of tables that can be imported in parallel.
   ↪  For TiDB-backend, the default value is the number of CPU cores.
index-concurrency = 40

#### Controls the maximum number of "data engines" allowed to be imported in
   ↪  parallel. The default value is the number of CPU cores. The value
   ↪ should be no less than the value of index-concurrency.
table-concurrency = 40

#### The number of concurrent SQL statements executed. It is set to the
   ↪ number of logical CPU cores by default. The bottleneck of TiDB-
   ↪ backend is usually not the CPU. You can increase this value based on
   ↪ the actual load of the downstream cluster to optimize the write speed
   ↪ . At the same time, when adjusting this configuration, it is
   ↪ recommended to adjust the index-concurrency and table-concurrency to
   ↪ the same value.
region-concurrency = 40

#### Logging
level = "info"
#### The directory to which the log is output. If it is empty (default), the
   ↪  file is saved to /tmp/lightning.log.{timestamp}. If you want the
   ↪ logs to be written to the system standard output, set it to "-".
file = "tidb-lightning.log"

[checkpoint]
#### Whether to enable checkpoints.
#### While importing data, TiDB Lightning records which tables have been
   ↪ imported, so
#### even if TiDB Lightning or some other component crashes, you can start
   ↪ from a known
#### good state instead of restarting from scratch.
enable = true
```

```
#### Where to store the checkpoints.
#### - file (default): store as a local file (requires v2.1.1 or later)
#### - mysql: store into a remote MySQL-compatible database
driver = "file"

#### The schema name (database name) to store the checkpoints
#### Enabled only when `driver = "mysql"`.
#### schema = "tidb_lightning_checkpoint"

#### The data source name (DSN) indicating the location of the checkpoint
   ↪ storage.
#### # For the "file" driver, the DSN is a path. If the path is not
   ↪ specified, Lightning would
#### default to "/tmp/CHECKPOINT_SCHEMA.pb".
#### # For the "mysql" driver, the DSN is a URL in the form of "USER:
   ↪ PASS@tcp(HOST:PORT)/".
#### If the URL is not specified, the TiDB server from the [tidb] section is
   ↪  used to
#### store the checkpoints. You should specify a different MySQL-compatible
#### database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"

#### Whether to keep the checkpoints after all data are imported. If false,
   ↪ the
#### checkpoints are deleted. Keeping the checkpoints can aid debugging but
#### might leak metadata about the data source.
#### keep-after-success = false

[tikv-importer]
#### use the TiDB-backend.
backend = "tidb"

#### Action to do when trying to insert a duplicated entry in the "tidb"
   ↪ backend.
#### - replace: use new entry to replace the existing entry
#### - ignore: keep the existing entry, and ignore the new entry
#### - error: report error and quit the program
#### on-duplicate = "replace"

[mydumper]
#### Block size for file reading. Keep it longer than the longest string of
#### the data source.
#### read-block-size = "64KiB"
```

```
#### Minimum size (in terms of source data file) of each batch of import.
#### TiDB Lightning splits a large table into multiple data engine files
   ↪ according to this size.
#### batch-size = 107_374_182_400 # Byte (default = 100 GB)

#### Local source data directory or the URL of the external storage.
data-source-dir = "/data/my_database"

#### the input data in a "strict" format speeds up processing.
#### "strict-format = true" requires that:
#### in CSV, every value cannot contain literal new lines (U+000A and U+000D
   ↪ , or \r and \n) even
#### when quoted, which means new lines are strictly used to separate rows.
#### "Strict" format allows TiDB Lightning to quickly locate split positions
   ↪  of a large file for parallel processing.
#### However, if the input data is not "strict", it may split a valid data
   ↪ in half and
#### corrupt the result.
#### The default value is false for safety instead of speed.
strict-format = false

#### If strict-format is true, TiDB Lightning splits large CSV files into
   ↪ multiple chunks to process in
#### parallel. max-region-size is the maximum size of each chunk after
   ↪ splitting.
#### max-region-size = 268_435_456 # Byte (default = 256 MB)

#### Only import tables if these wildcard rules are matched. See the
   ↪ corresponding section for details.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
   ↪ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA.*']

#### Configures how CSV files are parsed.
[mydumper.csv]
#### Separator between fields, should be an ASCII character.
separator = ','
#### Quoting delimiter, can either be an ASCII character or empty string.
delimiter = '"'
#### Whether the CSV files contain a header.
#### If `header` is true, the first line will be skipped.
header = true
#### Whether the CSV contains any NULL value.
#### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
#### When `not-null` is false (that is, CSV can contain NULL),
```

```
#### fields equal to this value will be treated as NULL.
null = '\N'
#### Whether to interpret backslash escapes inside fields.
backslash-escape = true
#### If a line ends with a separator, remove it.
trim-last-separator = false

[tidb]
#### Configuration of any TiDB server from the cluster.
host = "172.16.31.1"
port = 4000
user = "root"
password = ""

#### The default SQL mode used to parse and execute the SQL statements.
sql-mode = "ONLY_FULL_GROUP_BY,NO_ENGINE_SUBSTITUTION"

#### Whether to use TLS for SQL connections. Valid values are:
#### * ""          - force TLS (same as "cluster") if [tidb.security]
   ↪ section is populated, otherwise same as "false"
#### * "false"     - disable TLS
#### * "cluster"   - force TLS and verify the server's certificate with the
   ↪  CA specified in the [tidb.security] section
#### * "skip-verify" - force TLS but do not verify the server's certificate
   ↪  (insecure!)
#### * "preferred" - same as "skip-verify", but if the server does not
   ↪ support TLS, fallback to unencrypted connection
#### tls = ""

#### Specifies certificates and keys for TLS-enabled MySQL connections.
#### [tidb.security]

#### Public certificate of the CA. Set to empty string to disable TLS for
   ↪ SQL.
#### ca-path = "/path/to/ca.pem"

#### Public certificate of this service. Default to copy of `security.cert-
   ↪ path`
#### cert-path = "/path/to/lightning.pem"

#### Private key of this service. Default to copy of `security.key-path`
#### key-path = "/path/to/lightning.key"

#### Configures the background periodic actions.
#### Supported units: h (hour), m (minute), s (second).
```

```
[cron]

#### Duration between which an import progress is printed to the log.
log-progress = "5m"
```

For detailed descriptions of the configuration items, see TiDB Lightning Configuration.

Conflict resolution

The TiDB-backend supports importing to an already-populated table. However, the new data might cause a unique key conflict with the old data. You can control how to resolve the conflict by using this task configuration.

```
[tikv-importer]
backend = "tidb"
on-duplicate = "replace" # or "error" or "ignore"
```

Setting	Behavior on conflict	Equivalent SQL statement
replace	New entries replace old ones	`REPLACE INTO ...`
ignore	Keep old entries and ignore new ones	`INSERT IGNORE INTO ...`
error	Abort import	`INSERT INTO ...`

Migrating from Loader to TiDB Lightning TiDB-backend

If you need to import data into a TiDB cluster, TiDB Lightning using the TiDB-backend can completely replace the functionalities of Loader. The following list shows how to translate Loader configurations into TiDB Lightning configurations.

Loader

TiDB Lightning

```

#### log level
log-level = "info"

#### The directory to which the log is output
log-file = "loader.log"

#### Prometheus
status-addr = ":8272"

#### concurrency
pool-size = 16
```

```
[lightning]
#### log level
```

```
level = "info"

#### The directory to which the log is output. If this directory is not
    ↪ specified, it defaults to the directory where the command is executed
    ↪ .
file = "tidb-lightning.log"

#### Prometheus
pprof-port = 8289

#### concurrency (better left as default)
#region-concurrency = 16
```

```
#### checkpoint database
checkpoint-schema = "tidb_loader"
```

```
[checkpoint]
#### checkpoint storage
enable = true
schema = "tidb_lightning_checkpoint"
#### by default the checkpoint is stored in
#### a local file, which is more efficient.
#### but you could still choose to store the
#### checkpoints in the target database with
#### this setting:
#driver = "mysql"
```

```
[tikv-importer]
#### use the TiDB-backend
backend = "tidb"
```

```

#### data source directory
dir = "/data/export/"
```

```
[mydumper]
#### data source directory
data-source-dir = "/data/export"
```

```
[db]
#### TiDB connection parameters
host = "127.0.0.1"
port = 4000
```

```
user = "root"
password = ""

#sql-mode = ""
```

```
[tidb]
#### TiDB connection parameters
host = "127.0.0.1"
port = 4000

#### In the TiDB-backend mode, this parameter is optional.
#### status-port = 10080
user = "root"
password = ""

#sql-mode = ""
```

```
#### [[route-rules]]
#### Table routes
#### schema-pattern = "shard_db_*"
#### table-pattern = "shard_table_*"
#### target-schema = "shard_db"
#### target-table = "shard_table"
```

```
#### [[routes]]
#### schema-pattern = "shard_db_*"
#### table-pattern = "shard_table_*"
#### target-schema = "shard_db"
#### target-table = "shard_table"
```

11.8.5.4.4 TiDB Lightning Importer-backend

Deployment for Importer-backend mode

This section describes how to deploy TiDB Lightning manually in the Importer-backend mode:

Hardware requirements

`tidb-lightning` and `tikv-importer` are both resource-intensive programs. It is recommended to deploy them into two separate machines.

To achieve the best performance, it is recommended to use the following hardware configuration:

- `tidb-lightning`:

  - 32+ logical cores CPU
  - An SSD large enough to store the entire data source, preferring higher read speed
  - 10 Gigabit network card (capable of transferring at 300 MB/s)
  - `tidb-lightning` fully consumes all CPU cores when running, and deploying on a dedicated machine is highly recommended. If not possible, `tidb-lightning` could be deployed together with other components like `tidb-server`, and the CPU usage could be limited via the `region-concurrency` setting.

- `tikv-importer`:

  - 32+ logical cores CPU
  - 40 GB+ memory
  - 1 TB+ SSD, preferring higher IOPS (8000 is recommended)
    * The disk should be larger than the total size of the top N tables, where `N = max(index-concurrency, table-concurrency)`.
  - 10 Gigabit network card (capable of transferring at 300 MB/s)
  - `tikv-importer` fully consumes all CPU, disk I/O and network bandwidth when running, and deploying on a dedicated machine is strongly recommended.

If you have sufficient machines, you can deploy multiple `tidb lightning + tikv importer` servers, with each working on a distinct set of tables, to import the data in parallel.

Deploy TiDB Lightning manually

Step 1: Deploy a TiDB cluster

Before importing data, you need to have a deployed TiDB cluster, with the cluster version 2.0.9 or above. It is highly recommended to use the latest version.

You can find deployment instructions in TiDB Quick Start Guide.

Step 2: Download the TiDB Lightning installation package

Refer to the TiDB enterprise tools download page to download the TiDB Lightning package (choose the same version as that of the TiDB cluster).

Step 3: Start `tikv-importer`

1. Upload `bin/tikv-importer` from the installation package.
2. Configure `tikv-importer.toml`.

```
# TiKV Importer configuration file template

# Log file
log-file = "tikv-importer.log"
# Log level: trace, debug, info, warn, error, off.
log-level = "info"
```

```
# Listening address of the status server.
status-server-address = "0.0.0.0:8286"

[server]
# The listening address of tikv-importer. tidb-lightning needs to
    ↪ connect to
# this address to write data.
addr = "0.0.0.0:8287"

[import]
# The directory to store engine files.
import-dir = "/mnt/ssd/data.import/"
```

The above only shows the essential settings. See the Configuration section for the full list of settings.

3. Run `tikv-importer`.

```
nohup ./tikv-importer -C tikv-importer.toml > nohup.out &
```

Step 4: Start `tidb-lightning`

1. Upload `bin/tidb-lightning` and `bin/tidb-lightning-ctl` from the tool set.
2. Mount the data source onto the same machine.
3. Configure `tidb-lightning.toml`. For configurations that do not appear in the template below, TiDB Lightning writes a configuration error to the log file and exits.

```
[lightning]
# The concurrency number of data. It is set to the number of logical
    ↪ CPU
# cores by default. When deploying together with other components, you
    ↪ can
# set it to 75% of the size of logical CPU cores to limit the CPU usage
    ↪ .
# region-concurrency =

# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# The listening address of tikv-importer. Change it to the actual
    ↪ address.
```

```
addr = "172.16.31.10:8287"

[mydumper]
# mydumper local source data directory
data-source-dir = "/data/my_database"

[tidb]
# Configuration of any TiDB server from the cluster
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
```

The above only shows the essential settings. See the Configuration section for the full list of settings.

4. Run `tidb-lightning`. If you directly run the command in the command-line, the process might exit because of the SIGHUP signal received. Instead, it's preferable to run a bash script that contains the `nohup` command:

```
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

11.8.5.5 TiDB Lightning Web Interface

TiDB Lightning provides a webpage for viewing the import progress and performing some simple task management. This is called the *server mode*.

To enable server mode, either start `tidb-lightning` with the `--server-mode` flag

```
./tidb-lightning --server-mode --status-addr :8289
```

or set the `lightning.server-mode` setting in the configuration file.

```
[lightning]
server-mode = true
status-addr = ':8289'
```

After TiDB Lightning is launched, visit `http://127.0.0.1:8289` to control the program (the actual URL depends on the `status-addr` setting).

In server mode, TiDB Lightning does not start running immediately. Rather, users submit (multiple) *tasks* via the web interface to import data.

11.8.5.5.1 Front page

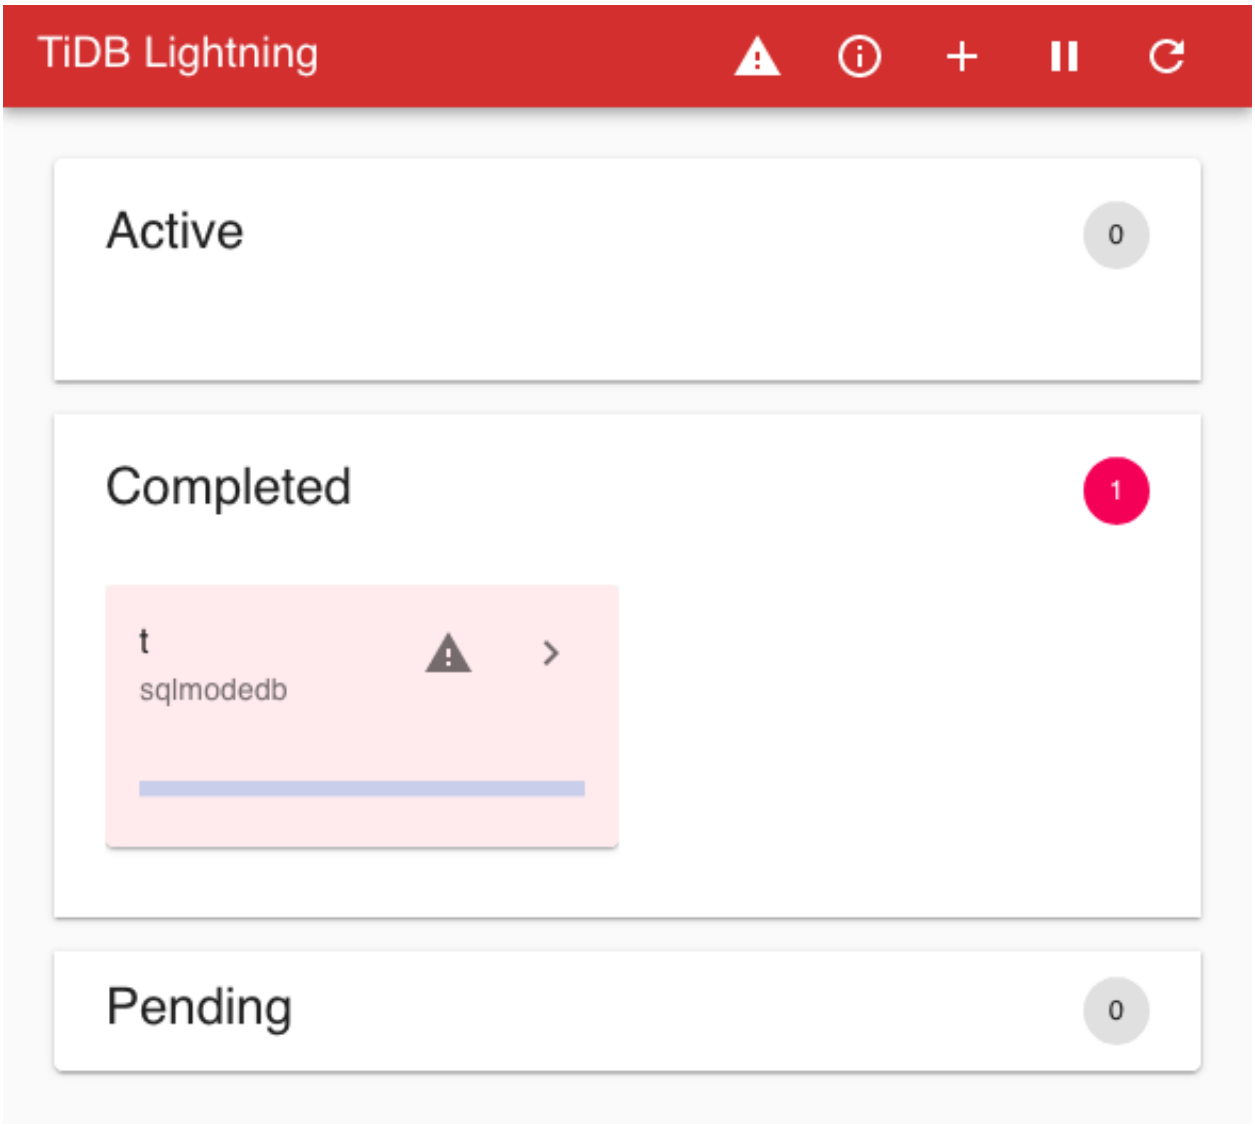

Figure 147: Front page of the web interface

Functions of the title bar, from left to right:

Icon	Function
"TiDB Lightning"	Click to go back to the front page

Icon	Function
	Display any error message from *previous* task
	List current and queued tasks; a badge may appear here to indicate number of queued tasks
+	Submit a task
/	Pause/resume current execution
	Configure auto-refresh of the web page

Three panels below the title bar show all tables in different states:

- Active: these tables are currently being imported
- Completed: these tables have been imported successfully or failed
- Pending: these tables are not yet processed

Each panel contains cards describing the status of the table.

11.8.5.5.2 Submit task

Click the + button on the title bar to submit a task.

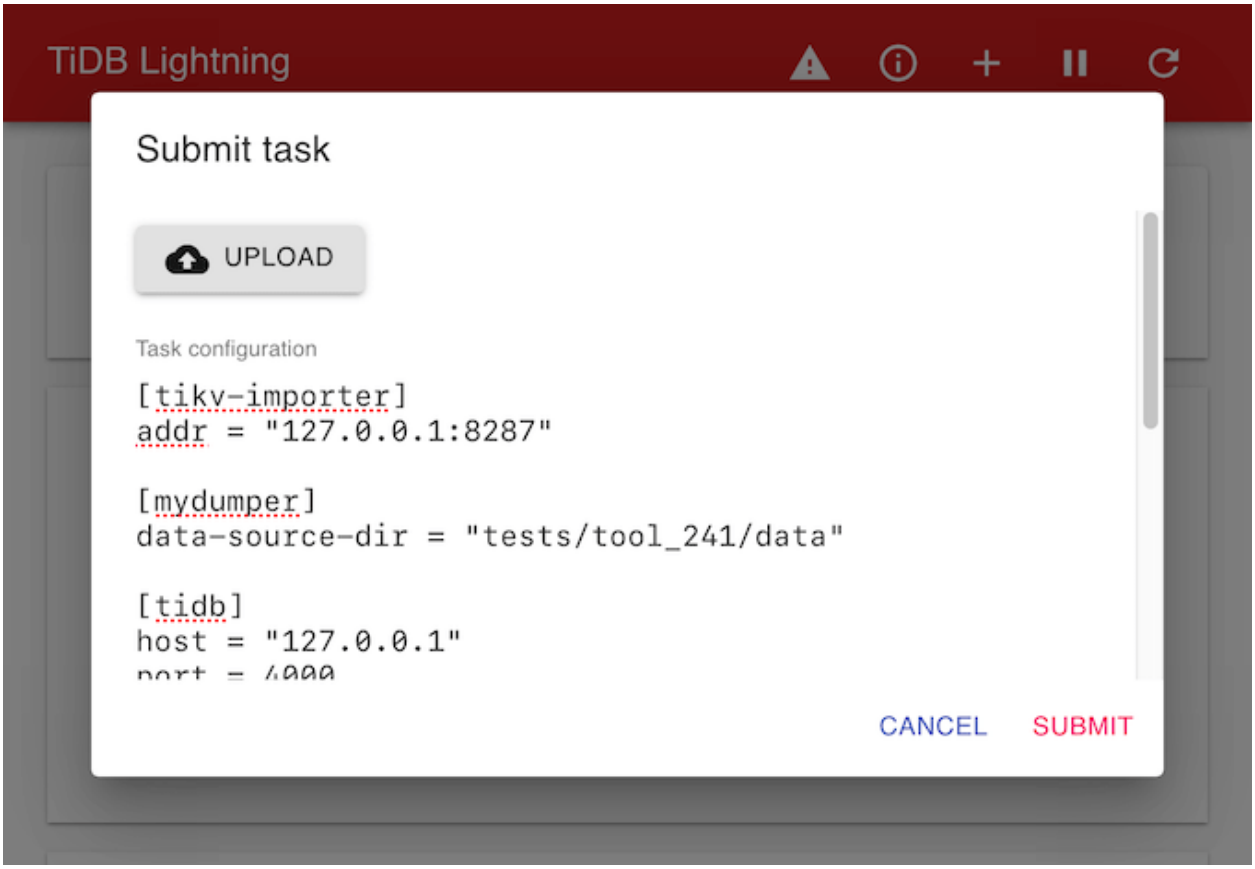

Figure 148: Submit task dialog

Tasks are TOML files described as task configurations. One could also open a local TOML file by clicking **UPLOAD**.

Click **SUBMIT** to run the task. If a task is already running, the new task will be queued and executed after the current task succeeds.

11.8.5.5.3 Table progress

Click the > button of a table card on the front page to view the detailed progress of a table.

Figure 149: Table progress

The page shows the import progress of every engine and data files associated with the table.

Click **TiDB Lightning** on the title bar to go back to the front page.

11.8.5.5.4 Task management

Click the button on the title bar to manage the current and queued tasks.

Figure 150: Task management page

Each task is labeled by the time it was submitted. Clicking the task would show the configuration formatted as JSON.

Manage tasks by clicking the button next to a task. You can stop a task immediately, or reorder queued tasks.

11.8.6 TiDB Lightning Monitoring

`tidb-lightning` supports metrics collection via Prometheus. This document introduces the monitor configuration and monitoring metrics of TiDB Lightning.

11.8.6.1 Monitor configuration

If TiDB Lightning is manually installed, follow the instructions below.

The metrics of `tidb-lightning` can be gathered directly by Prometheus as long as it is discovered. You can set the metrics port in `tidb-lightning.toml`:

```
[lightning]
### HTTP port for debugging and Prometheus metrics pulling (0 to disable)
pprof-port = 8289
```

```
...
```

and in `tikv-importer.toml`:

```
### Listening address of the status server.
status-server-address = '0.0.0.0:8286'
```

You need to configure Prometheus to make it discover the servers. For instance, you can directly add the server address to the `scrape_configs` section:

```
...
scrape_configs:
  - job_name: 'tidb-lightning'
    static_configs:
      - targets: ['192.168.20.10:8289']
  - job_name: 'tikv-importer'
    static_configs:
      - targets: ['192.168.20.9:8286']
```

11.8.6.2 Grafana dashboard

Grafana is a web interface to visualize Prometheus metrics as dashboards.

11.8.6.2.1 Row 1: Speed

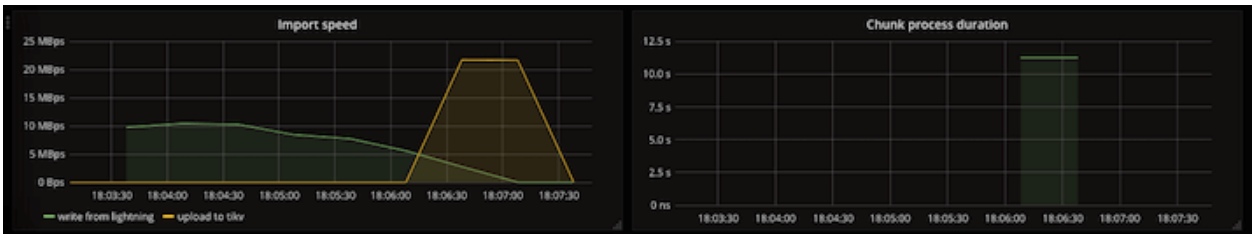

Figure 151: Panels in first row

Panel	Series	Description
Import speed	write from TiDB Lightning	Speed of sending KVs from TiDB Lightning to TiKV Importer, which depends on each table's complexity
Import speed	upload to tikv	Total upload speed from TiKV Importer to all TiKV replicas
Chunk process duration		Average time needed to completely encode one single data file

Sometimes the import speed will drop to zero allowing other parts to catch up. This is

normal.

11.8.6.2.2 Row 2: Progress

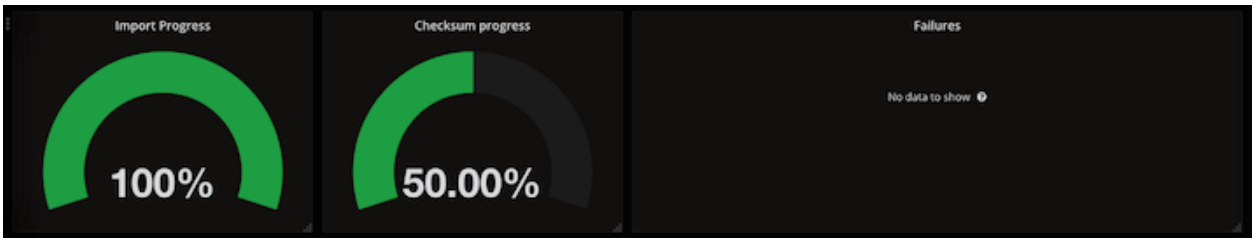

Figure 152: Panels in second row

Panel	Description
Import progress	Percentage of data files encoded so far
Checksum progress	Percentage of tables are verified to be imported successfully
Failures	Number of failed tables and their point of failure, normally empty

11.8.6.2.3 Row 3: Resource

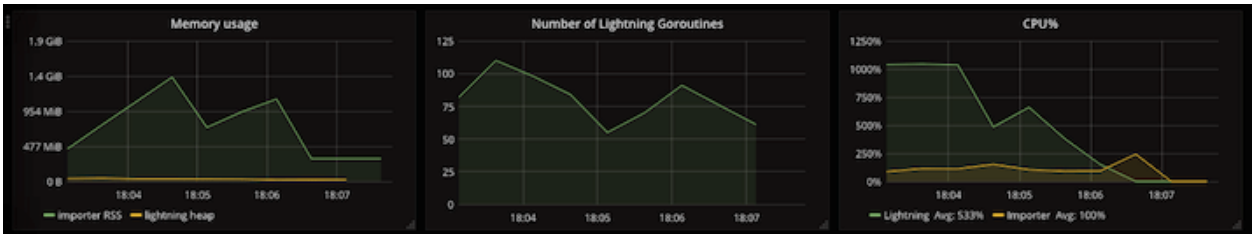

Figure 153: Panels in third row

Panel	Description
Memory usage	Amount of memory occupied by each service

Panel	Description
Number of TiDB Lightning Goroutines	Number of running goroutines used by TiDB Lightning
CPU%	Number of logical CPU cores utilized by each service

11.8.6.2.4 Row 4: Quota

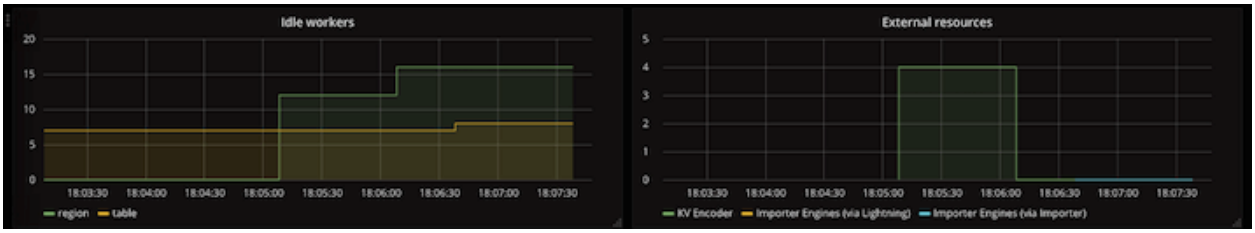

Figure 154: Panels in fourth row

Panel	Series	Description
Idle workers	io	Number of unused `io-concurrency`, normally close to configured value (default 5), and close to 0 means the disk is too slow

Panel	Series	Description
Idle workers	closed-engine	Number of engines which is closed but not yet cleaned up, normally close to index + table-concurrency (default 8), and close to 0 means TiDB Lightning is faster than TiKV Importer, which will cause TiDB Lightning to stall

Panel	Series	Description
Idle workers	table	Number of unused `table-concurrency`, normally 0 until the end of process
Idle workers	index	Number of unused `index-concurrency`, normally 0 until the end of process
Idle workers	region	Number of unused `region-concurrency`, normally 0 until the end of process

Panel	Series	Description
External resources	KV Encoder	Counts active KV encoders, normally the same as `region` ↪ `-` ↪ `concurrency` ↪ until the end of process
External resources	Importer Engines	Counts opened engine files, should never exceed the `max-` ↪ `open` ↪ `-` ↪ `engines` ↪ setting

11.8.6.2.5 Row 5: Read speed

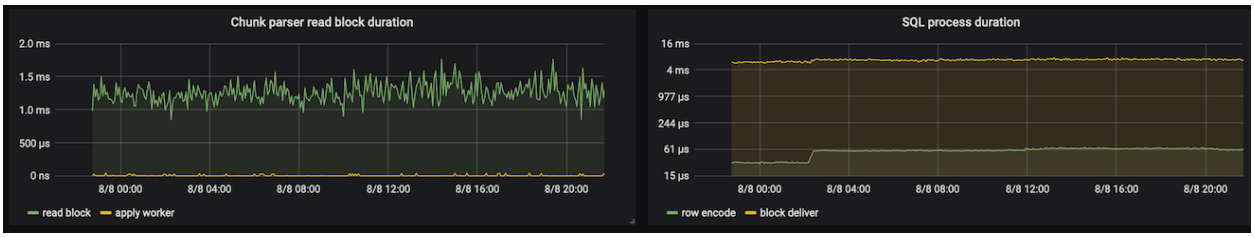

Figure 155: Panels in fifth row

Panel	Series	Description
Chunk parser read block duration	read block	Time taken to read one block of bytes to prepare for parsing
Chunk parser read block duration	apply worker	Time elapsed to wait for an idle io-concurrency
SQL process duration	row encode	Time taken to parse and encode a single row
SQL process duration	block deliver	Time taken to send a block of KV pairs to TiKV Importer

If any of the duration is too high, it indicates that the disk used by TiDB Lightning is too slow or busy with I/O.

11.8.6.2.6 Row 6: Storage

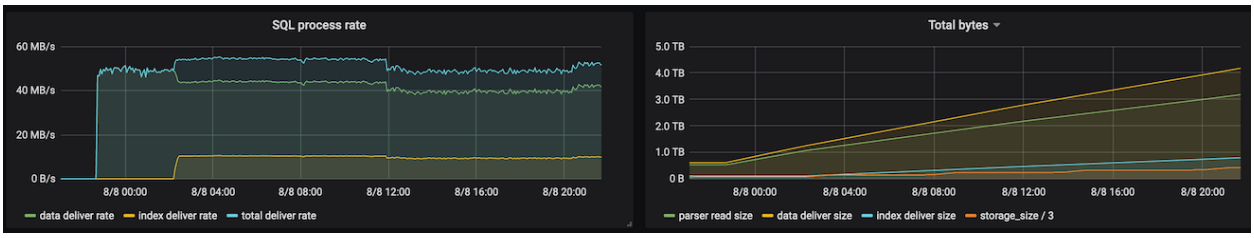

Figure 156: Panels in sixth row

Panel	Series	Description
SQL process rate	data deliver rate	Speed of delivery of data KV pairs to TiKV Importer
SQL process rate	index deliver rate	Speed of delivery of index KV pairs to TiKV Importer
SQL process rate	total deliver rate	The sum of two rates above

Panel	Series	Description
Total bytes	parser read size	Number of bytes being read by TiDB Lightning
Total bytes	data deliver size	Number of bytes of data KV pairs already delivered to TiKV Importer
Total bytes	index deliver size	Number of bytes of index KV pairs already delivered to TiKV Importer

Panel	Series	Description
Total bytes	storage_size / 3	Total size occupied by the TiKV cluster, divided by 3 (the default number of replicas)

11.8.6.2.7 Row 7: Import speed

Figure 157: Panels in seventh row

Panel	Series	Description
Delivery duration	Range delivery	Time taken to upload a range of KV pairs to the TiKV cluster

Panel	Series	Description
Delivery duration	SST delivery	Time taken to upload an SST file to the TiKV cluster
SST process duration	Split SST	Time taken to split the stream of KV pairs into SST files
SST process duration	SST upload	Time taken to upload an SST file
SST process duration	SST ingest	Time taken to ingest an uploaded SST file
SST process duration	SST size	File size of an SST file

11.8.6.3 Monitoring metrics

This section explains the monitoring metrics of `tikv-importer` and `tidb-lightning`, if you need to monitor other metrics not covered by the default Grafana dashboard.

11.8.6.3.1 `tikv-importer`

Metrics provided by `tikv-importer` are listed under the namespace `tikv_import_*`.

- **`tikv_import_rpc_duration`** (Histogram)

  Bucketed histogram for the duration of an RPC action. Labels:

  - **request**: what kind of RPC is executed
    * `switch_mode` — switched a TiKV node to import/normal mode
    * `open_engine` — opened an engine file
    * `write_engine` — received data and written into an engine
    * `close_engine` — closed an engine file
    * `import_engine` — imported an engine file into the TiKV cluster
    * `cleanup_engine` — deleted an engine file
    * `compact_cluster` — explicitly compacted the TiKV cluster
    * `upload` — uploaded an SST file
    * `ingest` — ingested an SST file
    * `compact` — explicitly compacted a TiKV node
  - **result**: the execution result of the RPC
    * `ok`
    * `error`

- **`tikv_import_write_chunk_bytes`** (Histogram)

  Bucketed histogram for the uncompressed size of a block of KV pairs received from TiDB Lightning.

- **`tikv_import_write_chunk_duration`** (Histogram)

  Bucketed histogram for the time needed to receive a block of KV pairs from TiDB Lightning.

- **`tikv_import_upload_chunk_bytes`** (Histogram)

  Bucketed histogram for the compressed size of a chunk of SST file uploaded to TiKV.

- **`tikv_import_upload_chunk_duration`** (Histogram)

  Bucketed histogram for the time needed to upload a chunk of SST file to TiKV.

- **`tikv_import_range_delivery_duration`** (Histogram)

  Bucketed histogram for the time needed to deliver a range of KV pairs into a `dispatch ↪ -job`.

- **`tikv_import_split_sst_duration`** (Histogram)

  Bucketed histogram for the time needed to split off a range from the engine file into a single SST file.

- **`tikv_import_sst_delivery_duration`** (Histogram)

  Bucketed histogram for the time needed to deliver an SST file from a `dispatch-job` to an `ImportSSTJob`.

- **`tikv_import_sst_recv_duration`** (Histogram)

  Bucketed histogram for the time needed to receive an SST file from a `dispatch-job` in an `ImportSSTJob`.

- **`tikv_import_sst_upload_duration`** (Histogram)

  Bucketed histogram for the time needed to upload an SST file from an `ImportSSTJob` to a TiKV node.

- **`tikv_import_sst_chunk_bytes`** (Histogram)

  Bucketed histogram for the compressed size of the SST file uploaded to a TiKV node.

- **`tikv_import_sst_ingest_duration`** (Histogram)

  Bucketed histogram for the time needed to ingest an SST file into TiKV.

- **`tikv_import_each_phase`** (Gauge)

  Indicates the running phase. Possible values are 1, meaning running inside the phase, and 0, meaning outside the phase. Labels:

  - **phase**: `prepare/import`

- **`tikv_import_wait_store_available_count`** (Counter)

  Counts the number of times a TiKV node is found to have insufficient space when uploading SST files. Labels:

  - **store_id**: The TiKV store ID.

11.8.6.3.2 `tidb-lightning`

Metrics provided by `tidb-lightning` are listed under the namespace `lightning_*`.

- **`lightning_importer_engine`** (Counter)

  Counts open and closed engine files. Labels:

  - **type**:
    * `open`
    * `closed`

- **`lightning_idle_workers`** (Gauge)

  Counts idle workers. Labels:

  - **name**:
    * `table` — the remainder of `table-concurrency`, normally 0 until the end of the process
    * `index` — the remainder of `index-concurrency`, normally 0 until the end of the process
    * `region` — the remainder of `region-concurrency`, normally 0 until the end of the process
    * `io` — the remainder of `io-concurrency`, normally close to configured value (default 5), and close to 0 means the disk is too slow
    * `closed-engine` — number of engines which have been closed but not yet cleaned up, normally close to index + table-concurrency (default 8). A value close to 0 means TiDB Lightning is faster than TiKV Importer, which might cause TiDB Lightning to stall

- **`lightning_kv_encoder`** (Counter)

  Counts open and closed KV encoders. KV encoders are in-memory TiDB instances that convert SQL `INSERT` statements into KV pairs. The net values need to be bounded in a healthy situation. Labels:

  - **type**:
    * `open`
    * `closed`

- **`lightning_tables`** (Counter)

  Counts processed tables and their statuses. Labels:

  - **state**: the status of the table, indicating which phase should be completed
    * `pending` — not yet processed
    * `written` — all data encoded and sent
    * `closed` — all corresponding engine files closed
    * `imported` — all engine files have been imported into the target cluster
    * `altered_auto_inc` — AUTO_INCREMENT ID altered
    * `checksum` — checksum performed
    * `analyzed` — statistics analysis performed
    * `completed` — the table has been fully imported and verified
  - **result**: the result of the current phase
    * `success` — the phase completed successfully
    * `failure` — the phase failed (did not complete)

- **`lightning_engines`** (Counter)

  Counts number of engine files processed and their status. Labels:

  - **state**: the status of the engine, indicating which phase should be completed

    * `pending` — not yet processed
    * `written` — all data encoded and sent
    * `closed` — engine file closed
    * `imported` — the engine file has been imported into the target cluster
    * `completed` — the engine has been fully imported
  - **result**: the result of the current phase
    * `success` — the phase completed successfully
    * `failure` — the phase failed (did not complete)

- **`lightning_chunks`** (Counter)

  Counts number of chunks processed and their status. Labels:

  - **state**: a chunk's status, indicating which phase the chunk is in
    * `estimated` — (not a state) this value gives total number of chunks in current task
    * `pending` — loaded but not yet processed
    * `running` — data are being encoded and sent
    * `finished` — the entire chunk has been processed
    * `failed` — errors happened during processing

- **`lightning_import_seconds`** (Histogram)

  Bucketed histogram for the time needed to import a table.

- **`lightning_row_read_bytes`** (Histogram)

  Bucketed histogram for the size of a single SQL row.

- **`lightning_row_encode_seconds`** (Histogram)

  Bucketed histogram for the time needed to encode a single SQL row into KV pairs.

- **`lightning_row_kv_deliver_seconds`** (Histogram)

  Bucketed histogram for the time needed to deliver a set of KV pairs corresponding to one single SQL row.

- **`lightning_block_deliver_seconds`** (Histogram)

  Bucketed histogram for the time needed to deliver a block of KV pairs to Importer.

- **`lightning_block_deliver_bytes`** (Histogram)

  Bucketed histogram for the uncompressed size of a block of KV pairs delivered to Importer.

- **`lightning_chunk_parser_read_block_seconds`** (Histogram)

  Bucketed histogram for the time needed by the data file parser to read a block.

- **`lightning_checksum_seconds`** (Histogram)

  Bucketed histogram for the time needed to compute the checksum of a table.

- **`lightning_apply_worker_seconds`** (Histogram)

  Bucketed histogram for the time needed to acquire an idle worker (see also the `lightning_idle_workers` gauge). Labels:

  - **name**:
    * `table`
    * `index`
    * `region`
    * `io`
    * `closed-engine`

11.8.7 TiDB Lightning FAQs

11.8.7.1 What is the minimum TiDB/TiKV/PD cluster version supported by TiDB Lightning?

The version of TiDB Lightning should be the same as the cluster. If you use the Local-backend mode, the earliest available version is 4.0.0. If you use the Importer-backend mode or the TiDB-backend mode, the earliest available version is 2.0.9, but it is recommended to use the 3.0 stable version.

11.8.7.2 Does TiDB Lightning support importing multiple schemas (databases)?

Yes.

11.8.7.3 What is the privilege requirements for the target database?

TiDB Lightning requires the following privileges:

- SELECT
- UPDATE
- ALTER
- CREATE
- DROP

If the TiDB-backend is chosen, or the target database is used to store checkpoints, it additionally requires these privileges:

- INSERT
- DELETE

The Local-backend and Importer-backend do not require these two privileges because data is ingested into TiKV directly, which bypasses the entire TiDB privilege system. This is secure as long as the ports of TiKV, TiKV Importer and TiDB Lightning are not reachable outside the cluster.

If the `checksum` configuration of TiDB Lightning is set to `true`, then the admin user privileges in the downstream TiDB need to be granted to TiDB Lightning.

11.8.7.4 TiDB Lightning encountered an error when importing one table. Will it affect other tables? Will the process be terminated?

If only one table has an error encountered, the rest will still be processed normally.

11.8.7.5 How to properly restart TiDB Lightning?

If you are using Importer-backend, depending on the status of `tikv-importer`, the basic sequence of restarting TiDB Lightning is like this:

If `tikv-importer` is still running:

1. Stop `tidb-lightning`.
2. Perform the intended modifications, such as fixing the source data, changing settings, replacing hardware etc.
3. If the modification previously has changed any table, remove the corresponding checkpoint too.
4. Start `tidb-lightning`.

If `tikv-importer` needs to be restarted:

1. Stop `tidb-lightning`.
2. Stop `tikv-importer`.
3. Perform the intended modifications, such as fixing the source data, changing settings, replacing hardware etc.
4. Start `tikv-importer`.
5. Start `tidb-lightning` *and wait until the program fails with CHECKSUM error, if any.*
    - Restarting `tikv-importer` would destroy all engine files still being written, but `tidb-lightning` did not know about it. As of v3.0 the simplest way is to let `tidb-lightning` go on and retry.
6. Destroy the failed tables and checkpoints
7. Start `tidb-lightning` again.

If you are using Local-backend or TiDB-backend, the operations are the same as those of using Importer-backend when the `tikv-importer` is still running.

11.8.7.6 How to ensure the integrity of the imported data?

TiDB Lightning by default performs checksum on the local data source and the imported tables. If there is checksum mismatch, the process would be aborted. These checksum information can be read from the log.

You could also execute the `ADMIN CHECKSUM TABLE` SQL command on the target table to recompute the checksum of the imported data.

```
ADMIN CHECKSUM TABLE `schema`.`table`;
```

```
+---------+------------+--------------------+-----------+-------------+
| Db_name | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+---------+------------+--------------------+-----------+-------------+
| schema | table     | 5505282386844578743 |     3 |         96 |
+---------+------------+--------------------+-----------+-------------+
1 row in set (0.01 sec)
```

11.8.7.7 What kinds of data source formats are supported by TiDB Lightning?

TiDB Lightning supports:

- Importing files exported by Dumpling, CSV files, and Apache Parquet files generated by Amazon Aurora
- Reading data from a local disk or from the Amazon S3 storage. For details, see External Storages

11.8.7.8 Could TiDB Lightning skip creating schema and tables?

Yes. If you have already created the tables in the target database, you could set `no-schema = true` in the `[mydumper]` section in `tidb-lightning.toml`. This makes TiDB Lightning skip the `CREATE TABLE` invocations and fetch the metadata directly from the target database. TiDB Lightning will exit with error if a table is actually missing.

11.8.7.9 Can the Strict SQL Mode be disabled to allow importing invalid data?

Yes. By default, the `sql_mode` used by TiDB Lightning is `"STRICT_TRANS_TABLES, NO_ENGINE_SUBSTITUTION"`, which disallows invalid data such as the date `1970-00-00`. The mode can be changed by modifying the `sql-mode` setting in the `[tidb]` section in `tidb-lightning.toml`.

```
...
[tidb]
sql-mode = ""
...
```

11.8.7.10 Can one `tikv-importer` serve multiple `tidb-lightning` instances?

Yes, as long as every `tidb-lightning` instance operates on different tables.

11.8.7.11 How to stop the `tikv-importer` process?

To stop the `tikv-importer` process, you can choose the corresponding operation according to your deployment method.

- For manual deployment: if `tikv-importer` is running in foreground, press Ctrl+C to exit. Otherwise, obtain the process ID using the `ps aux | grep tikv-importer` command and then terminate the process using the `kill «pid»` command.

11.8.7.12 How to stop the `tidb-lightning` process?

To stop the `tidb-lightning` process, you can choose the corresponding operation according to your deployment method.

- For manual deployment: if `tidb-lightning` is running in foreground, press Ctrl+C to exit. Otherwise, obtain the process ID using the `ps aux | grep tidb-lighting` command and then terminate the process using the `kill -2 «pid»` command.

11.8.7.13 Why the `tidb-lightning` process suddenly quits while running in background?

It is potentially caused by starting `tidb-lightning` incorrectly, which causes the system to send a SIGHUP signal to stop the `tidb-lightning` process. In this situation, `tidb-lightning.log` usually outputs the following log:

```
[2018/08/10 07:29:08.310 +08:00] [INFO] [main.go:41] ["got signal to exit"]
    [signal=hangup]
```

It is not recommended to directly use `nohup` in the command line to start `tidb-lightning`. You can start `tidb-lightning` by executing a script.

In addition, if the last log of TiDB Lightning shows that the error is "Context canceled", you need to search for the first "ERROR" level log. This "ERROR" level log is usually followed by "got signal to exit", which indicates that TiDB Lightning received an interrupt signal and then exited.

11.8.7.14 Why my TiDB cluster is using lots of CPU resources and running very slowly after using TiDB Lightning?

If `tidb-lightning` abnormally exited, the cluster might be stuck in the "import mode", which is not suitable for production. The current mode can be retrieved using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

You can force the cluster back to "normal mode" using the following command:

```
tidb-lightning-ctl --config tidb-lightning.toml --fetch-mode
```

11.8.7.15 Can TiDB Lightning be used with 1-Gigabit network card?

The TiDB Lightning toolset is best used with a 10-Gigabit network card. 1-Gigabit network cards are *not recommended*, especially for `tikv-importer`.

1-Gigabit network cards can only provide a total bandwidth of 120 MB/s, which has to be shared among all target TiKV stores. TiDB Lightning can easily saturate all bandwidth of the 1-Gigabit network and bring down the cluster because PD is unable to be contacted anymore. To avoid this, set an *upload speed limit* in Importer's configuration:

```
[import]
### Restricts the total upload speed to TiKV to 100 MB/s or less
upload-speed-limit = "100MB"
```

11.8.7.16 Why TiDB Lightning requires so much free space in the target TiKV cluster?

With the default settings of 3 replicas, the space requirement of the target TiKV cluster is 6 times the size of data source. The extra multiple of "2" is a conservative estimation because the following factors are not reflected in the data source:

- The space occupied by indices
- Space amplification in RocksDB

11.8.7.17 Can TiKV Importer be restarted while TiDB Lightning is running?

No. TiKV Importer stores some information of engines in memory. If `tikv-importer` is restarted, `tidb-lightning` will be stopped due to lost connection. At this point, you need to destroy the failed checkpoints as those TiKV Importer-specific information is lost. You can restart TiDB Lightning afterwards.

See also How to properly restart TiDB Lightning? for the correct sequence.

11.8.7.18 How to completely destroy all intermediate data associated with TiDB Lightning?

1. Delete the checkpoint file.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-
    ↪ remove=all
```

If, for some reason, you cannot run this command, try manually deleting the file `/tmp/tidb_lightning_checkpoint.pb`.

2. If you are using Local-backend, delete the `sorted-kv-dir` directory in the configuration. If you are using Importer-backend, delete the entire `import` directory on the machine hosting `tikv-importer`.

3. Delete all tables and databases created on the TiDB cluster, if needed.

11.8.7.19 Why does TiDB Lightning report the `could not find first pair, this shouldn't happen` error?

This error occurs possibly because the number of files opened by TiDB Lightning exceeds the system limit when TiDB Lightning reads the sorted local files. In the Linux system, you can use the `ulimit -n` command to confirm whether the value of this system limit is too small. It is recommended that you adjust this value to `1000000` (`ulimit -n 1000000`) during the import.

11.8.7.20 Import speed is too slow

Normally it takes TiDB Lightning 2 minutes per thread to import a 256 MB data file. If the speed is much slower than this, there is an error. You can check the time taken for each data file from the log mentioning `restore chunk ⋯ takes`. This can also be observed from metrics on Grafana.

There are several reasons why TiDB Lightning becomes slow:

Cause 1: `region-concurrency` is set too high, which causes thread contention and reduces performance.

1. The setting can be found from the start of the log by searching `region-concurrency`.
2. If TiDB Lightning shares the same machine with other services (for example, TiKV Importer), `region-concurrency` must be **manually** set to 75% of the total number of CPU cores.
3. If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning may not be able to read this out. In this case, `region-concurrency` must also be **manually** reduced.

Cause 2: The table schema is too complex.

Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the Dumpling output. If the indices are negligible, you may first remove them from the schema, and add them back using `CREATE INDEX` after the import is complete.

Cause 3: Each file is too large.

TiDB Lightning works the best when the data source is broken down into multiple files of size around 256 MB so that the data can be processed in parallel. If each file is too large, TiDB Lightning might not respond.

If the data source is CSV, and all CSV files have no fields containing newline control characters (U+000A and U+000D), you can turn on "strict format" to let TiDB Lightning automatically split the large files.

```
[mydumper]
strict-format = true
```

Cause 4: TiDB Lightning is too old.

Try the latest version! Maybe there is new speed improvement.

11.8.7.21 `checksum failed: checksum mismatched remote vs local`

Cause: The checksum of a table in the local data source and the remote imported database differ. This error has several deeper reasons. You can further locate the reason by checking the log that contains `checksum mismatched`.

The lines that contain `checksum mismatched` provide the information `total_kvs: x vs y`, where `x` indicates the number of key-value pairs (KV pairs) calculated by the target cluster after the import is completed, and `y` indicates the number of key-value pairs generated by the local data source.

- If `x` is greater, it means that there are more KV pairs in the target cluster.
  - It is possible that this table is not empty before the import and therefore affects the data checksum. It is also possible that TiDB Lightning has previously failed and shut down, but did not restart correctly.
- If `y` is greater, it means that there are more KV pairs in the local data source.
  - If the checksum of the target database is all 0, it means that no import has occurred. It is possible that the cluster is too busy to receive any data.
  - It is possible that the exported data contains duplicate data, such as the UNIQUE and PRIMARY KEYs with duplicate values, or that the downstream table structure is case-insensitive while the data is case-sensitive.
- Other possible reasons
  - If the data source is machine-generated and not backed up by Dumpling, make sure the data conforms to the table limits. For example, the AUTO_INCREMENT column needs to be positive and not 0.

Solutions:

1. Delete the corrupted data using `tidb-lightning-ctl`, check the table structure and the data, and restart TiDB Lightning to import the affected tables again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error
    ↪ -destroy=all
```

2. Consider using an external database to store the checkpoints (change `[checkpoint]` ↪ `dsn`) to reduce the target database's load.

3. If TiDB Lightning was improperly restarted, see also the "How to properly restart TiDB Lightning" section in the FAQ.

11.8.7.22 `Checkpoint for … has invalid status:` (error code)

Cause: Checkpoint is enabled, and TiDB Lightning or TiKV Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed.

The error code is an integer smaller than 25, with possible values of 0, 3, 6, 9, 12, 14, 15, 17, 18, 20, and 21. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later step the exit occurs at.

Solutions:

If the error was caused by invalid data source, delete the imported data using `tidb-` ↪ `lightning-ctl` and start Lightning again.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error-
    ↪ destroy=all
```

See the Checkpoints control section for other options.

11.8.7.23 `ResourceTemporarilyUnavailable("Too many open engines …: …")`

Cause: The number of concurrent engine files exceeds the limit specified by `tikv-` ↪ `importer`. This could be caused by misconfiguration. Additionally, if `tidb-lightning` exited abnormally, an engine file might be left at a dangling open state, which could cause this error as well.

Solutions:

1. Increase the value of `max-open-engines` setting in `tikv-importer.toml`. This value is typically dictated by the available memory. This could be calculated by using:

   Max Memory Usage ≈ `max-open-engines` × `write-buffer-size` × `max-write-` ↪ `buffer-number`

2. Decrease the value of `table-concurrency` + `index-concurrency` so it is less than `max-open-engines`.

3. Restart `tikv-importer` to forcefully remove all engine files (default to `./data.import/`). This also removes all partially imported tables, which requires TiDB Lightning to clear the outdated checkpoints.

```
tidb-lightning-ctl --config conf/tidb-lightning.toml --checkpoint-error-destroy=all
```

11.8.7.24 `cannot guess encoding for input file, please convert to UTF-8 manually`

Cause: TiDB Lightning only recognizes the UTF-8 and GB-18030 encodings for the table schemas. This error is emitted if the file isn't in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical `ALTER TABLE` executions.

Solutions:

1. Fix the schema so that the file is entirely in either UTF-8 or GB-18030.
2. Manually `CREATE` the affected tables in the target database, and then set `[mydumper] no-schema = true` to skip automatic table creation.
3. Set `[mydumper] character-set = "binary"` to skip the check. Note that this might introduce mojibake into the target database.

11.8.7.25 `[sql2kv] sql encode error = [types:1292]invalid time format: '{1970 1 1 …}'`

Cause: A table contains a column with the `timestamp` type, but the time value itself does not exist. This is either because of DST changes or the time value has exceeded the supported range (Jan 1, 1970 to Jan 19, 2038).

Solutions:

1. Ensure TiDB Lightning and the source database are using the same time zone.

   When executing TiDB Lightning directly, the time zone can be forced using the `$TZ` environment variable.

```
# Manual deployment, and force Asia/Shanghai.
TZ='Asia/Shanghai' bin/tidb-lightning -config tidb-lightning.toml
```

2. When exporting data using Mydumper, make sure to include the `--skip-tz-utc` flag.
3. Ensure the entire cluster is using the same and latest version of `tzdata` (version 2018i or above).

   On CentOS, run `yum info tzdata` to check the installed version and whether there is an update. Run `yum upgrade tzdata` to upgrade the package.

11.8.7.26 `[Error 8025: entry too large, the max entry size is 6291456]`

Cause: A single row of key-value pairs generated by TiDB Lightning exceeds the limit set by TiDB.

Solution:

To bypass this limit, modify the TiDB configuration item `txn-entry-size-limit` and the TiKV configuration item `raft-entry-max-size` to a value larger than the data to be imported and then retry.

11.8.7.27 Encounter `rpc error: code = Unimplemented ...` when TiDB Lightning switches the mode

Cause: Some node(s) in the cluster does not support `switch-mode`. For example, if the TiFlash version is earlier than `v4.0.0-rc.2`, `switch-mode` is not supported.

Solutions:

- If there are TiFlash nodes in the cluster, you can update the cluster to `v4.0.0-rc.2` or higher versions.
- Temporarily disable TiFlash if you do not want to upgrade the cluster.

11.8.7.28 `tidb lightning encountered error: TiDB version too old, expected '>=4.0.0', found '3.0.18'`

TiDB Lightning Local-backend only supports importing data to TiDB clusters of v4.0.0 and later versions. If you try to use Local-backend to import data to a v2.x or v3.x cluster, the above error is reported. At this time, you can modify the configuration to use Importer-backend or TiDB-backend for data import.

Some `nightly` versions might be similar to v4.0.0-beta.2. These `nightly` versions of TiDB Lightning actually support Local-backend. If you encounter this error when using a `nightly` version, you can skip the version check by setting the configuration `check-requirements = false`. Before setting this parameter, make sure that the configuration of TiDB Lightning supports the corresponding version; otherwise, the import might fail.

11.8.7.29 `restore table test.district failed: unknown columns in header [...]`

This error occurs usually because the CSV data file does not contain a header (the first row is not column names but data). Therefore, you need to add the following configuration to the TiDB Lightning configuration file:

```
[mydumper.csv]
header = false
```

11.8.8 TiDB Lightning Glossary

This page explains the special terms used in TiDB Lightning's logs, monitoring, configurations, and documentation.

11.8.8.1 A

11.8.8.1.1 Analyze

An operation to rebuild the statistics information of a TiDB table, which is running the `ANALYZE TABLE` statement.

Because TiDB Lightning imports data without going through TiDB, the statistics information is not automatically updated. Therefore, TiDB Lightning explicitly analyzes every table after importing. This step can be omitted by setting the `post-restore.analyze` configuration to `false`.

11.8.8.1.2 `AUTO_INCREMENT_ID`

Every table has an associated `AUTO_INCREMENT_ID` counter to provide the default value of an auto-incrementing column. In TiDB, this counter is additionally used to assign row IDs.

Because TiDB Lightning imports data without going through TiDB, the `AUTO_INCREMENT_ID` ↪ counter is not automatically updated. Therefore, TiDB Lightning explicitly alters `AUTO_INCREMENT_ID` to a valid value. This step is always performed, even if the table has no `AUTO_INCREMENT` columns.

11.8.8.2 B

11.8.8.2.1 Back end

Back end is the destination where TiDB Lightning sends the parsed result. Also spelled as "backend".

See TiDB Lightning Backends for details.

11.8.8.3 C

11.8.8.3.1 Checkpoint

TiDB Lightning continuously saves its progress into a local file or a remote database while importing. This allows it to resume from an intermediate state should it crashes in the process. See the Checkpoints section for details.

11.8.8.3.2 Checksum

In TiDB Lightning, the checksum of a table is a set of 3 numbers calculated from the content of each KV pair in that table. These numbers are respectively:

- the number of KV pairs,
- total length of all KV pairs, and
- the bitwise-XOR of CRC-64-ECMA value each pair.

TiDB Lightning validates the imported data by comparing the local and remote checksums of every table. The program would stop if any pair does not match. You can skip this check by setting the `post-restore.checksum` configuration to `false`.

See also the FAQs for how to properly handle checksum mismatch.

11.8.8.3.3 Chunk

A continuous range of source data, normally equivalent to a single file in the data source.

When a file is too large, TiDB Lightning might split a file into multiple chunks.

11.8.8.3.4 Compaction

An operation that merges multiple small SST files into one large SST file, and cleans up the deleted entries. TiKV automatically compacts data in background while TiDB Lightning is importing.

> **Note:**
>
> For legacy reasons, you can still configure TiDB Lightning to explicitly trigger a compaction every time a table is imported. However, this is not recommended and the corresponding settings are disabled by default.

See RocksDB's wiki page on Compaction for its technical details.

11.8.8.4 D

11.8.8.4.1 Data engine

An engine for sorting actual row data.

When a table is very large, its data is placed into multiple data engines to improve task pipelining and save space of TiKV Importer. By default, a new data engine is opened for

every 100 GB of SQL data, which can be configured through the `mydumper.batch-size` setting.

TiDB Lightning processes multiple data engines concurrently. This is controlled by the `lightning.table-concurrency` setting.

11.8.8.5 E

11.8.8.5.1 Engine

In TiKV Importer, an engine is a RocksDB instance for sorting KV pairs.

TiDB Lightning transfers data to TiKV Importer through engines. It first opens an engine, sends KV pairs to it (with no particular order), and finally closes the engine. The engine sorts the received KV pairs after it is closed. These closed engines can then be further uploaded to the TiKV stores for ingestion.

Engines use TiKV Importer's `import-dir` as temporary storage, which are sometimes referred to as "engine files".

See also data engine and index engine.

11.8.8.6 F

11.8.8.6.1 Filter

A configuration list that specifies which tables to be imported or excluded.

See Table Filter for details.

11.8.8.7 I

11.8.8.7.1 Import mode

A configuration that optimizes TiKV for writing at the cost of degraded read speed and space usage.

TiDB Lightning automatically switches to and off the import mode while running. However, if TiKV gets stuck in import mode, you can use `tidb-lightning-ctl` to force revert to normal mode.

11.8.8.7.2 Index engine

An engine for sorting indices.

Regardless of number of indices, every table is associated with exactly one index engine.

TiDB Lightning processes multiple index engines concurrently. This is controlled by the `lightning.index-concurrency` setting. Since every table has exactly one index engine, this also configures the maximum number of tables to process at the same time.

11.8.8.7.3 Ingest

An operation which inserts the entire content of an SST file into the RocksDB (TiKV) store.

Ingestion is a very fast operation compared with inserting KV pairs one by one. This operation is the determinant factor for the performance of TiDB Lightning.

See RocksDB's wiki page on Creating and Ingesting SST files for its technical details.

11.8.8.8 K

11.8.8.8.1 KV pair

Abbreviation of "key-value pair".

11.8.8.8.2 KV encoder

A routine which parses SQL or CSV rows to KV pairs. Multiple KV encoders run in parallel to speed up processing.

11.8.8.9 L

11.8.8.9.1 Local checksum

The checksum of a table calculated by TiDB Lightning itself before sending the KV pairs to TiKV Importer.

11.8.8.10 N

11.8.8.10.1 Normal mode

The mode where import mode is disabled.

11.8.8.11 P

11.8.8.11.1 Post-processing

The period of time after the entire data source is parsed and sent to TiKV Importer. TiDB Lightning is waiting for TiKV Importer to upload and ingest the SST files.

11.8.8.12 R

11.8.8.12.1 Remote checksum

The checksum of a table calculated by TiDB after it has been imported.

11.8.8.13 S

11.8.8.13.1 Scattering

An operation that randomly reassigns the leader and the peers of a Region. Scattering ensures that the imported data are distributed evenly among TiKV stores. This reduces stress on PD.

11.8.8.13.2 Splitting

An engine is typically very large (around 100 GB), which is not friendly to TiKV if treated as a single region. TiKV Importer splits an engine into multiple small SST files (configurable by TiKV Importer's `import.region-split-size` setting) before uploading.

11.8.8.13.3 SST file

SST is the abbreviation of "sorted string table". An SST file is RocksDB's (and thus TiKV's) native storage format of a collection of KV pairs.

TiKV Importer produces SST files from a closed engine. These SST files are uploaded and then ingested into TiKV stores.

11.9 TiDB Data Migration

TiDB Data Migration (DM) is an integrated data migration task management platform, which supports the full data migration and the incremental data replication from MySQL-compatible databases (such as MySQL, MariaDB, and Aurora MySQL) into TiDB. DM can help simplify the data migration process and reduce the operation cost of data migration.

11.9.1 DM versions

The stable versions of DM include v1.0, v2.0, and v5.3. It is recommended to use DM v5.3 (the latest stable version of DM) and not recommended to use v1.0 (the earliest stable version of DM).

Currently, the DM documentation is independent of the TiDB documentation. To access the DM documentation, click one of the following links:

- DM v5.3 documentation
- DM v2.0 documentation
- DM v1.0 documentation

Note:

- Since October 2021, DM's GitHub repository has been moved to pingcap/tiflow. If you see any issues with DM, submit your issue to the `pingcap/tiflow` repository for feedback.
- In earlier versions (v1.0 and v2.0), DM uses version numbers that are independent of TiDB. Since v5.3, DM uses the same version number as TiDB. The next version of DM v2.0 is DM v5.3. There are no compatibility changes from DM v2.0 to v5.3, and the upgrade process is no different from a normal upgrade, only an increase in version number.

11.9.2 Basic features

This section describes the basic data migration features provided by DM.

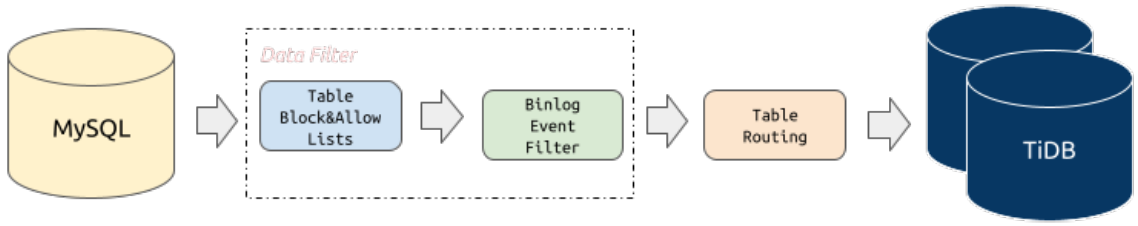

Figure 158: DM Core Features

11.9.2.1 Block and allow lists migration at the schema and table levels

The block and allow lists filtering rule is similar to the `replication-rules-db` ↪ `/replication-rules-table` feature of MySQL, which can be used to filter or replicate all operations of some databases only or some tables only.

11.9.2.2 Binlog event filtering

The binlog event filtering feature means that DM can filter certain types of SQL statements from certain tables in the source database. For example, you can filter all `INSERT` statements in the table `test.sbtest` or filter all `TRUNCATE TABLE` statements in the schema `test`.

11.9.2.3 Schema and table routing

The schema and table routing feature means that DM can migrate a certain table of the source database to the specified table in the downstream. For example, you can migrate the table structure and data from the table `test.sbtest1` in the source database to the table `test.sbtest2` in TiDB. This is also a core feature for merging and migrating sharded databases and tables.

11.9.3 Advanced features

11.9.3.1 Shard merge and migration

DM supports merging and migrating the original sharded instances and tables from the source databases into TiDB, but with some restrictions. For details, see Sharding DDL usage restrictions in the pessimistic mode and Sharding DDL usage restrictions in the optimistic mode.

11.9.3.2 Optimization for third-party online-schema-change tools in the migration process

In the MySQL ecosystem, tools such as `gh-ost` and `pt-osc` are widely used. DM provides support for these tools to avoid migrating unnecessary intermediate data. For details, see Online DDL Tools

11.9.3.3 Filter certain row changes using SQL expressions

In the phase of incremental replication, DM supports the configuration of SQL expressions to filter out certain row changes, which lets you replicate the data with a greater granularity. For more information, refer to Filter Certain Row Changes Using SQL Expressions.

11.9.4 Usage restrictions

Before using the DM tool, note the following restrictions:

- Database version requirements
  - MySQL version > 5.5
  - MariaDB version >= 10.1.2

> **Note:**
>
> If there is a primary-secondary migration structure between the upstream MySQL/MariaDB servers, then choose the following version.
>
> - MySQL version > 5.7.1
> - MariaDB version >= 10.1.3

> **Warning:**
>
> Migrating data from MySQL 8.0 to TiDB using DM is an experimental feature (introduced since DM v2.0). It is **NOT** recommended that you use it in a production environment.

- DDL syntax compatibility
  - Currently, TiDB is not compatible with all the DDL statements that MySQL supports. Because DM uses the TiDB parser to process DDL statements, it only supports the DDL syntax supported by the TiDB parser. For details, see MySQL Compatibility.
  - DM reports an error when it encounters an incompatible DDL statement. To solve this error, you need to manually handle it using dmctl, either skipping this DDL statement or replacing it with a specified DDL statement(s). For details, see Skip or replace abnormal SQL statements.
- Sharding merge with conflicts
  - If conflict exists between sharded tables, solve the conflict by referring to handling conflicts of auto-increment primary key. Otherwise, data migration is not supported. Conflicting data can cover each other and cause data loss.
  - For other sharding DDL migration restrictions, see Sharding DDL usage restrictions in the pessimistic mode and Sharding DDL usage restrictions in the optimistic mode.
- Switch of MySQL instances for data sources

  When DM-worker connects the upstream MySQL instance via a virtual IP (VIP), if you switch the VIP connection to another MySQL instance, DM might connect to the new and old MySQL instances at the same time in different connections. In this situation, the binlog migrated to DM is not consistent with other upstream status that DM receives, causing unpredictable anomalies and even data damage. To make necessary changes to DM manually, see Switch DM-worker connection via virtual IP.

11.10 TiCDC

11.10.1 TiCDC Overview

> **Note:**
>
> TiCDC is a feature for general availability (GA) since v4.0.6. You can use it in the production environment.

TiCDC is a tool for replicating the incremental data of TiDB. This tool is implemented by pulling TiKV change logs. It can restore data to a consistent state with any upstream TSO, and provides TiCDC Open Protocol to support other systems to subscribe to data changes.

11.10.1.1 TiCDC Architecture

When TiCDC is running, it is a stateless node that achieves high availability through etcd in PD. The TiCDC cluster supports creating multiple replication tasks to replicate data to multiple different downstream platforms.

The architecture of TiCDC is shown in the following figure:

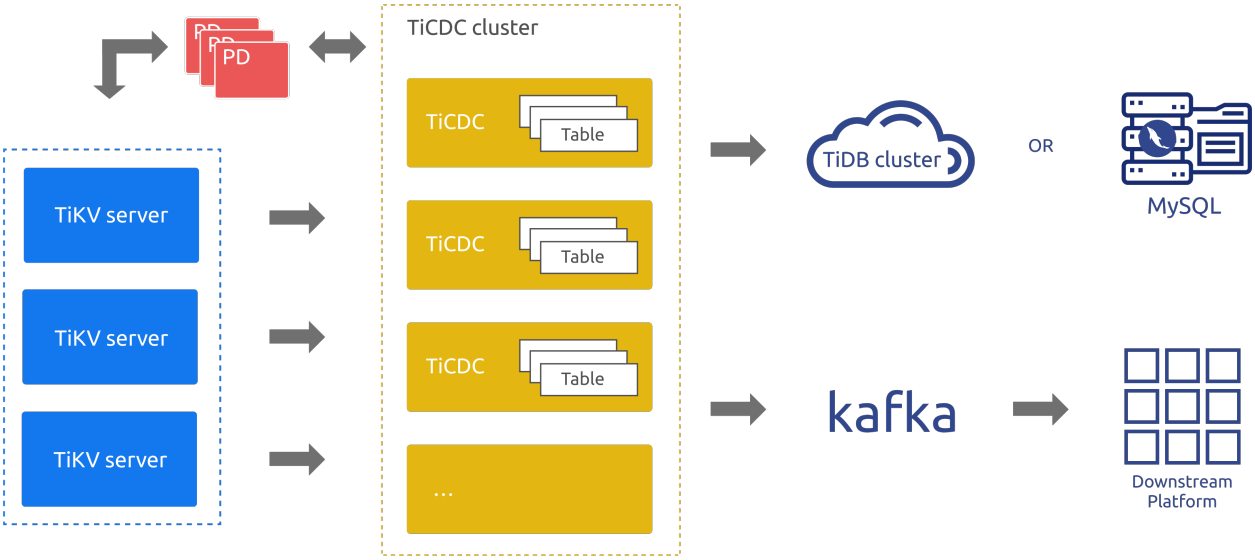

Figure 159: TiCDC architecture

11.10.1.1.1 System roles

- TiKV CDC component: Only outputs key-value (KV) change logs.
  - Assembles KV change logs in the internal logic.
  - Provides the interface to output KV change logs. The data sent includes real-time change logs and incremental scan change logs.
- `capture`: The operating process of TiCDC. Multiple `captures` form a TiCDC cluster that replicates KV change logs.
  - Each `capture` pulls a part of KV change logs.
  - Sorts the pulled KV change log(s).
  - Restores the transaction to downstream or outputs the log based on the TiCDC open protocol.

11.10.1.2 Replication features

This section introduces the replication features of TiCDC.

11.10.1.2.1 Sink support

Currently, the TiCDC sink component supports replicating data to the following downstream platforms:

- Databases compatible with MySQL protocol. The sink component provides the final consistency support.
- Kafka based on the TiCDC Open Protocol. The sink component ensures the row-level order, final consistency or strict transactional consistency.
- `cdclog` (experimental): Files written on the local filesystem or on the Amazon S3-compatible storage.
- Apache Pulsar (experimental)

11.10.1.2.2 Ensure replication order and consistency

Replication order

- For all DDL or DML statements, TiCDC outputs them **at least once**.
- When the TiKV or TiCDC cluster encounters failure, TiCDC might send the same DDL/DML statement repeatedly. For duplicated DDL/DML statements:
  - MySQL sink can execute DDL statements repeatedly. For DDL statements that can be executed repeatedly in the downstream, such as `truncate table`, the statement is executed successfully. For those that cannot be executed repeatedly, such as `create table`, the execution fails, and TiCDC ignores the error and continues the replication.
  - Kafka sink sends messages repeatedly, but the duplicate messages do not affect the constraints of `Resolved Ts`. Users can filter the duplicated messages from Kafka consumers.

Replication consistency

- MySQL sink
  - TiCDC does not split single-table transactions and **ensures** the atomicity of single-table transactions.
  - TiCDC does **not ensure** that the execution order of downstream transactions is the same as that of upstream transactions.
  - TiCDC splits cross-table transactions in the unit of table and does **not ensure** the atomicity of cross-table transactions.

  - TiCDC **ensures** that the order of single-row updates is consistent with that in the upstream.

- Kafka sink

  - TiCDC provides different strategies for data distribution. You can distribute data to different Kafka partitions based on the table, primary key, or timestamp.
  - For different distribution strategies, the different consumer implementations can achieve different levels of consistency, including row-level consistency, eventual consistency, or cross-table transactional consistency.
  - TiCDC does not have an implementation of Kafka consumers, but only provides TiCDC Open Protocol. You can implement the Kafka consumer according to this protocol.

11.10.1.3 Restrictions

TiCDC only replicates the table that has at least one **valid index**. A **valid index** is defined as follows:

- The primary key (`PRIMARY KEY`) is a valid index.
- The unique index (`UNIQUE INDEX`) that meets the following conditions at the same time is a valid index:
  - Every column of the index is explicitly defined as non-nullable (`NOT NULL`).
  - The index does not have the virtual generated column (`VIRTUAL GENERATED COLUMNS`).

Since v4.0.8, TiCDC supports replicating tables **without a valid index** by modifying the task configuration. However, this compromises the guarantee of data consistency to some extent. For more details, see Replicate tables without a valid index.

11.10.1.3.1 Unsupported scenarios

Currently, The following scenarios are not supported:

- The TiKV cluster that uses RawKV alone.
- The DDL operation `CREATE SEQUENCE` and the SEQUENCE function in TiDB. When the upstream TiDB uses `SEQUENCE`, TiCDC ignores `SEQUENCE` DDL operations/functions performed upstream. However, DML operations using `SEQUENCE` functions can be correctly replicated.

TiCDC only provides partial support for scenarios of large transactions in the upstream. For details, refer to FAQ: Does TiCDC support replicating large transactions? Is there any risk?.

11.10.1.4 Notice for compatibility issues

11.10.1.4.1 Incompatibility issue caused by using the TiCDC v5.0.0-rc `cdc cli` tool to operate a v4.0.x cluster

When using the `cdc cli` tool of TiCDC v5.0.0-rc to operate a v4.0.x TiCDC cluster, you might encounter the following abnormal situations:

- If the TiCDC cluster is v4.0.8 or an earlier version, using the v5.0.0-rc `cdc cli` tool to create a replication task might cause cluster anomalies and get the replication task stuck.
- If the TiCDC cluster is v4.0.9 or a later version, using the v5.0.0-rc `cdc cli` tool to create a replication task will cause the old value and unified sorter features to be unexpectedly enabled by default.

Solutions: Use the `cdc` executable file corresponding to the TiCDC cluster version to perform the following operations:

1. Delete the changefeed created using the v5.0.0-rc `cdc cli` tool. For example, run the `tiup cdc:v4.0.9 cli changefeed remove -c xxxx --pd=xxxxx --force` command.
2. If the replication task is stuck, restart the TiCDC cluster. For example, run the `tiup cluster restart <cluster_name> -R cdc` command.
3. Re-create the changefeed. For example, run the `tiup cdc:v4.0.9 cli changefeed create --sink-uri=xxxx --pd=xxx` command.

> **Note:**
>
> The above issue exists only when `cdc cli` is v5.0.0-rc. Other v5.0.x `cdc cli` tool can be compatible with v4.0.x clusters.

11.10.1.5 Install and deploy TiCDC

You can either deploy TiCDC along with a new TiDB cluster or add the TiCDC component to an existing TiDB cluster. For details, see Deploy TiCDC.

11.10.1.6 Manage TiCDC Cluster and Replication Tasks

Currently, you can use the `cdc cli` tool to manage the status of a TiCDC cluster and data replication tasks. For details, see:

- Use `cdc cli` to manage cluster status and data replication task
- Use HTTP interface to manage cluster status and data replication task

11.10.1.7 Troubleshoot TiCDC

For details, refer to Troubleshoot TiCDC.

11.10.1.8 TiCDC Open Protocol

TiCDC Open Protocol is a row-level data change notification protocol that provides data sources for monitoring, caching, full-text indexing, analysis engines, and primary-secondary replication between different databases. TiCDC complies with TiCDC Open Protocol and replicates data changes of TiDB to third-party data medium such as MQ (Message Queue). For more information, see TiCDC Open Protocol.

11.10.1.9 Compatibility notes for `sort-dir` and `data-dir`

The `sort-dir` configuration is used to specify the temporary file directory for the TiCDC sorter. Its functionalities might vary in different versions. The following table lists `sort-dir`'s compatibility changes across versions.

	sort ↪ - ↪ engine ↪ function- ality	Note	Recommendation
Version			
	sort ↪ - ↪ engine ↪ function- ality	Note	Recommendation
v4.0.11 or an earlier v4.0 version, v5.0.0-rc	It is a changefeed configuration item and specifies temporary file directory for the file sorter and unified ↪ sorter.	In these versions, file ↪ sorter and unified ↪ sorter are **experimental features** and **NOT** recommended for the production environment.	It is not recommended to use unified ↪ sorter in the production environment. If mul-

	`sort` ↪ `-` ↪ `engine` ↪ functionality

Version	sort - engine function- ality	Note	Recommendation

11.10.2 Deploy TiCDC

This document describes how to deploy a TiCDC cluster and the hardware and software recommendations for deploying and running it. You can either deploy TiCDC along with a new TiDB cluster or add the TiCDC component to an existing TiDB cluster. Generally, it is recommended that you deploy TiCDC using TiUP. In addition, you can also deploy it using binary as needed.

11.10.2.1 Software and hardware recommendations

In production environments, the recommendations of software and hardware for TiCDC are as follows:

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later versions
CentOS	7.3 or later versions

CPU	Memory	Disk type	Network	Number of TiCDC cluster instances (minimum requirements for production environment)
16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	2

For more information, see Software and Hardware Recommendations.

11.10.2.2 Deploy a new TiDB cluster that includes TiCDC using TiUP

When you deploy a new TiDB cluster using TiUP, you can also deploy TiCDC at the same time. You only need to add the `cdc_servers` section in the initialization configuration file that TiUP uses to start the TiDB cluster. For detailed operations, see Edit the initialization configuration file. For detailed configurable fields, see Configure `cdc_servers` using TiUP.

11.10.2.3 Add TiCDC to an existing TiDB cluster using TiUP

You can also use TiUP to add the TiCDC component to an existing TiDB cluster. Take the following procedures:

1. Make sure that the current TiDB version supports TiCDC; otherwise, you need to upgrade the TiDB cluster to `v4.0.0-rc.1` or later versions. Since v4.0.6, TiCDC has become a feature for general availability (GA). It is recommended that you use v4.0.6 or later versions.
2. To deploy TiCDC, refer to Scale out a TiCDC cluster.

11.10.2.4 Add TiCDC to an existing TiDB cluster using binary (not recommended)

Suppose that the PD cluster has a PD node (the client URL is `10.0.10.25:2379`) that can provide services. If you want to deploy three TiCDC nodes, start the TiCDC cluster by executing the following commands. You only need to specify the same PD address, and the newly started nodes automatically join the TiCDC cluster.

```
cdc server --pd=http://10.0.10.25:2379 --log-file=ticdc_1.log --addr
    ↪ =0.0.0.0:8301 --advertise-addr=127.0.0.1:8301
cdc server --pd=http://10.0.10.25:2379 --log-file=ticdc_2.log --addr
    ↪ =0.0.0.0:8302 --advertise-addr=127.0.0.1:8302
cdc server --pd=http://10.0.10.25:2379 --log-file=ticdc_3.log --addr
    ↪ =0.0.0.0:8303 --advertise-addr=127.0.0.1:8303
```

11.10.2.5 Description of TiCDC `cdc server` command-line parameters

The following are descriptions of options available in the `cdc server` command:

- `gc-ttl`: The TTL (Time To Live) of the service level `GC safepoint` in PD set by TiCDC, and the duration that the replication task can suspend, in seconds. The default value is `86400`, which means 24 hours. Note: Suspending of the TiCDC replication task affects the progress of TiCDC GC safepoint, which means that it affects the progress of upstream TiDB GC, as detailed in Complete Behavior of TiCDC GC safepoint.
- `pd`: The URL of the PD client.
- `addr`: The listening address of TiCDC, the HTTP API address, and the Prometheus address of the service.
- `advertise-addr`: The access address of TiCDC to the outside world.
- `tz`: Time zone used by the TiCDC service. TiCDC uses this time zone when it internally converts time data types such as `TIMESTAMP` or when it replicates data to the downstream. The default is the local time zone in which the process runs. If you specify `time-zone` (in `sink-uri`) and `tz` at the time, the internal TiCDC processes use the time zone specified by `tz`, and the sink uses the time zone specified by `time-zone` for replicating data to the downstream.

- `log-file`: The address of the running log of the TiCDC process. The default is `cdc.log`.
- `log-level`: The log level when the TiCDC process is running. The default is `info`.
- `ca`: The path of the CA certificate file used by TiCDC, in the PEM format (optional).
- `cert`: The path of the certificate file used by TiCDC, in the PEM format (optional).
- `key`: The path of the certificate key file used by TiCDC, in the PEM format (optional).
- `config`: The address of the configuration file that TiCDC uses (optional). This option is supported since TiCDC v5.0.0. This option can be used in the TiCDC deployment since TiUP v1.4.0.
- `data-dir`: Specifies the directory that TiCDC uses when it needs to use disk to store files. Unified Sorter uses this directory to store temporary files. Make sure there is enough space available on the device where this directory is located. If you are using TiUP, you can configure `data_dir` in the `cdc_servers` section, or directly use the default `data_dir` path in `global`.**This option is supported since TiDB v4.0.14, v5.0.3. and later versions.**
- `sort-dir`: Specifies the temporary file directory used by the sorting engine. **Note that this option is not supported since TiDB v4.0.14, v5.0.3 and v5.1.0. Do not use it any more**.

11.10.3 Manage TiCDC Cluster and Replication Tasks

This document describes how to upgrade TiCDC cluster and modify the configuration of TiCDC cluster using TiUP, and how to manage the TiCDC cluster and replication tasks using the command-line tool `cdc cli` and the HTTP interface.

11.10.3.1 Upgrade TiCDC using TiUP

This section introduces how to upgrade the TiCDC cluster using TiUP. In the following example, assume that you need to upgrade TiCDC and the entire TiDB cluster to v5.1.4.

```
tiup update --self && \
tiup update --all && \
tiup cluster upgrade <cluster-name> v5.1.4
```

11.10.3.1.1 Notes for upgrade

- The `changefeed` configuration has changed in TiCDC v4.0.2. See Compatibility notes for the configuration file for details.
- If you encounter any issues, see Upgrade TiDB using TiUP - FAQ.

11.10.3.2 Modify TiCDC configuration using TiUP

This section introduces how to modify the configuration of TiCDC cluster using the `tiup cluster edit-config` command of TiUP. The following example changes the value of `gc-ttl` from the default `86400` to `3600`, namely, one hour.

First, execute the following command. You need to replace `<cluster-name>` with your actual cluster name.

```
tiup cluster edit-config <cluster-name>
```

Then, enter the vi editor page and modify the `cdc` configuraion under `server-configs`. The configuration is shown below:

```
server_configs:
 tidb: {}
 tikv: {}
 pd: {}
 tiflash: {}
 tiflash-learner: {}
 pump: {}
 drainer: {}
 cdc:
   gc-ttl: 3600
```

After the modification, execute the `tiup cluster reload -R cdc` command to reload the configuration.

11.10.3.3 Use TLS

For details about using encrypted data transmission (TLS), see Enable TLS Between TiDB Components.

11.10.3.4 Use `cdc cli` to manage cluster status and data replication task

This section introduces how to use `cdc cli` to manage a TiCDC cluster and data replication tasks. `cdc cli` is the `cli` sub-command executed using the `cdc` binary. The following interface description assumes that:

- `cli` commands are executed directly using the `cdc` binary;
- PD listens on `10.0.10.25` and the port is `2379`.

> **Note:**
>
> The IP address and port that PD listens on correspond to the `advertise-client-urls` parameter specified during the `pd-server` startup. Multiple `pd-servers` have multiple `advertise-client-urls` parameters and you can specify one or multiple parameters. For example, `--pd=http://10.0.10.25:2379` or `--pd=http://10.0.10.25:2379,http://10.0.10.26:2379,http://10.0.10.27:2379`.

If you deploy TiCDC using TiUP, replace `cdc cli` in the following commands with `tiup ctl:<cluster-version> cdc`.

11.10.3.4.1 Manage TiCDC service progress (`capture`)

- Query the `capture` list:

```
cdc cli capture list --pd=http://10.0.10.25:2379
```

```
[
  {
    "id": "806e3a1b-0e31-477f-9dd6-f3f2c570abdd",
    "is-owner": true,
    "address": "127.0.0.1:8300"
  },
  {
    "id": "ea2a4203-56fe-43a6-b442-7b295f458ebc",
    "is-owner": false,
    "address": "127.0.0.1:8301"
  }
]
```

  - `id`: The ID of the service process.
  - `is-owner`: Indicates whether the service process is the owner node.
  - `address`: The address via which the service process provides interface to the outside.

11.10.3.4.2 Manage replication tasks (`changefeed`)

State transfer of replication tasks

The state of a replication task represents the running status of the replication task. During the running of TiCDC, replication tasks might fail with errors, be manually paused, resumed, or reach the specified `TargetTs`. These behaviors can lead to the change of the replication task state. This section describes the states of TiCDC replication tasks and the transfer relationships between states.

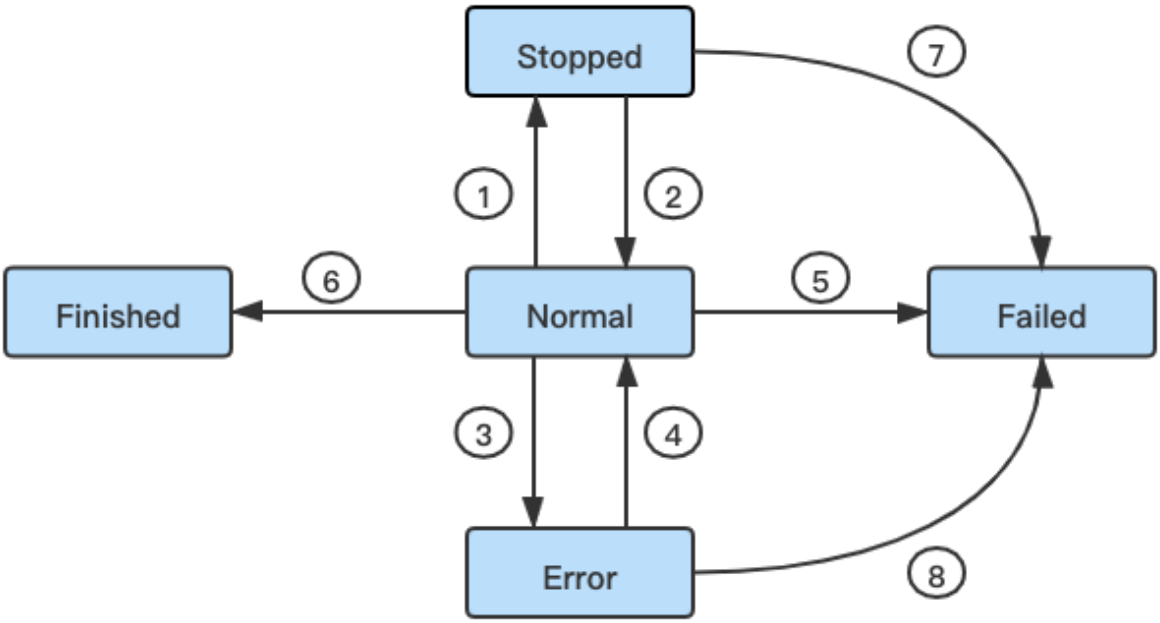

Figure 160: TiCDC state transfer

The states in the above state transfer diagram are described as follows:

- `Normal`: The replication task runs normally and the checkpoint-ts proceeds normally.
- `Stopped`: The replication task is stopped, because the user manually pauses the changefeed. The changefeed in this state blocks GC operations.
- `Error`: The replication task returns an error. The replication cannot continue due to some recoverable errors. The changefeed in this state keeps trying to resume until the state transfers to `Normal`. The changefeed in this state blocks GC operations.
- `Finished`: The replication task is finished and has reached the preset `TargetTs`. The changefeed in this state does not block GC operations.
- `Failed`: The replication task fails. Due to some unrecoverable errors, the replication task cannot resume and cannot be recovered. The changefeed in this state does not block GC operations.

The numbers in the above state transfer diagram are described as follows.

- Execute the `changefeed pause` command
- Execute the `changefeed resume` command to resume the replication task
- Recoverable errors occur during the `changefeed` operation, and the operation is resumed automatically.
- Execute the `changefeed resume` command to resume the replication task

- Unrecoverable errors occur during the `changefeed` operation
- `changefeed` has reached the preset `TargetTs`, and the replication is automatically stopped.
- `changefeed` suspended longer than the duration specified by `gc-ttl`, and cannot be resumed.
- `changefeed` experienced an unrecoverable error when trying to execute automatic recovery.

Create a replication task

Execute the following commands to create a replication task:

```
cdc cli changefeed create --pd=http://10.0.10.25:2379 --sink-uri="mysql://
    ↪ root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-task
    ↪ " --sort-engine="unified"
```

```
Create changefeed successfully!
ID: simple-replication-task
Info: {"sink-uri":"mysql://root:123456@127.0.0.1:3306/","opts":{},"create-
    ↪ time":"2020-03-12T22:04:08.103600025+08:00","start-ts
    ↪ ":415241823337054209,"target-ts":0,"admin-job-type":0,"sort-engine":"
    ↪ unified","sort-dir":".","config":{"case-sensitive":true,"filter":{"
    ↪ rules":["*.*"],"ignore-txn-start-ts":null,"ddl-allow-list":null},"
    ↪ mounter":{"worker-num":16},"sink":{"dispatchers":null,"protocol":"
    ↪ default"},"cyclic-replication":{"enable":false,"replica-id":0,"filter
    ↪ -replica-ids":null,"id-buckets":0,"sync-ddl":false},"scheduler":{"
    ↪ type":"table-number","polling-time":-1}},"state":"normal","history":
    ↪ null,"error":null}
```

- `--changefeed-id`: The ID of the replication task. The format must match the `^[ ↪ a-zA-Z0-9]+(\-[a-zA-Z0-9]+)*$` regular expression. If this ID is not specified, TiCDC automatically generates a UUID (the version 4 format) as the ID.

- `--sink-uri`: The downstream address of the replication task. Configure `--sink-uri` according to the following format. Currently, the scheme supports `mysql/tidb/kafka ↪ /pulsar/s3/local`.

  ```
  [scheme]://[userinfo@][host]:[port][/path]?[query_parameters]
  ```

  When a URI contains special characters, you need to process these special characters using URL encoding.

- `--start-ts`: Specifies the starting TSO of the `changefeed`. From this TSO, the TiCDC cluster starts pulling data. The default value is the current time.

- `--target-ts`: Specifies the ending TSO of the `changefeed`. To this TSO, the TiCDC cluster stops pulling data. The default value is empty, which means that TiCDC does not automatically stop pulling data.
- `--sort-engine`: Specifies the sorting engine for the `changefeed`. Because TiDB and TiKV adopt distributed architectures, TiCDC must sort the data changes before writing them to the sink. This option supports `unified` (by default)/`memory`/`file`.
  - `unified`: When `unified` is used, TiCDC prefers data sorting in memory. If the memory is insufficient, TiCDC automatically uses the disk to store the temporary data. This is the default value of `--sort-engine`.
  - `memory`: Sorts data changes in memory. It is **NOT recommended** to use this sorting engine, because OOM is easily triggered when you replicate a large amount of data.
  - `file`: Entirely uses the disk to store the temporary data. This feature is **deprecated**. It is **NOT recommended** to use it in **any** situation.
- `--config`: Specifies the configuration file of the `changefeed`.
- `sort-dir`: Specifies the temporary file directory used by the sorting engine. **Note that this option is not supported since TiDB v4.0.13, v5.0.3 and v5.1.0. Do not use it any more**.

Configure sink URI with `mysql/tidb`

Sample configuration:

```
--sink-uri="mysql://root:123456@127.0.0.1:3306/?worker-count=16&max-txn-row
    ↪ =5000"
```

The following are descriptions of parameters and parameter values that can be configured for the sink URI with `mysql/tidb`:

Parameter/Parameter Value	Description
`root`	The username of the downstream database
`123456`	The password of the downstream database
`127.0.0.1`	The IP address of the downstream database
`3306`	The port for the downstream data
`worker-count`	The number of SQL statements that can be concurrently executed to the downstream (optional, `16` by default)
`max-txn-row`	The size of a transaction batch that can be executed to the downstream (optional, `256` by default)
`ssl-ca`	The path of the CA certificate file needed to connect to the downstream MySQL instance (optional)

Parameter/Parameter Value	Description
`ssl-cert`	The path of the certificate file needed to connect to the downstream MySQL instance (optional)
`ssl-key`	The path of the certificate key file needed to connect to the downstream MySQL instance (optional)
`time-zone`	The time zone used when connecting to the downstream MySQL instance, which is effective since v4.0.8. This is an optional parameter. If this parameter is not specified, the time zone of TiCDC service processes is used. If this parameter is set to an empty value, no time zone is specified when TiCDC connects to the downstream MySQL instance and the default time zone of the downstream is used.

Configure sink URI with `kafka`

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&partition-
    ↪ num=6&max-message-bytes=67108864&replication-factor=1"
```

The following are descriptions of parameters and parameter values that can be configured for the sink URI with `kafka`:

Parameter/Parameter Value	Description
`127.0.0.1`	The IP address of the downstream Kafka services
`9092`	The port for the downstream Kafka
`topic-name`	Variable. The name of the Kafka topic
`kafka-version`	The version of the downstream Kafka. Optional, `2.4.0` by default. Currently, the earliest supported Kafka version is `0.11.0.2` and the latest one is `2.7.0`. This value needs to be consistent with the actual version of the downstream Kafka.
`kafka-client-id`	Specifies the Kafka client ID of the replication task. Optional. `TiCDC_sarama_producer_replication ID` by default.
`partition-num`	The number of the downstream Kafka partitions. Optional. The value must be **no greater than** the actual number of partitions. If you do not configure this parameter, the partition number is obtained automatically.
`max-message-bytes`	The maximum size of data that is sent to Kafka broker each time (optional, `10MB` by default)
`replication-` ↪ `factor`	The number of Kafka message replicas that can be saved (optional, `1` by default)

Parameter/Parameter Value	Description
`compression`	The compression algorithm used when sending messages (value options are `none`, `lz4`, `gzip`, `snappy`, and `zstd`; `none` by default).
`protocol`	The protocol with which messages are output to Kafka. The value options are `default`, `canal`, `avro`, and `maxwell` (`default` by default)
`auto-create-topic`	Determines whether TiCDC creates the topic automatically when the `topic-name` passed in does not exist in the Kafka cluster (optional, `true` by default)
`max-batch-size`	New in v4.0.9. If the message protocol supports outputting multiple data changes to one Kafka message, this parameter specifies the maximum number of data changes in one Kafka message. It currently takes effect only when Kafka's `protocol` is `default`. It's optional and `16` by default.
`ca`	The path of the CA certificate file needed to connect to the downstream Kafka instance (optional)
`cert`	The path of the certificate file needed to connect to the downstream Kafka instance (optional)
`key`	The path of the certificate key file needed to connect to the downstream Kafka instance (optional)
`sasl-user`	The identity (authcid) of SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional)
`sasl-password`	The password of SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional)
`sasl-mechanism`	The name of SASL/SCRAM authentication needed to connect to the downstream Kafka instance (optional)

Note:

When `protocol` is `default`, TiCDC tries to avoid generating messages that exceed `max-message-bytes` in length. However, if a row is so large that a single change alone exceeds `max-message-bytes` in length , to avoid silent failure, TiCDC tries to output this message and prints a warning in the log.

Integrate TiCDC with Kafka Connect (Confluent Platform)

Warning:

> This is still an experimental feature. Do **NOT** use it in a production environment.

Sample configuration:

```
--sink-uri="kafka://127.0.0.1:9092/topic-name?kafka-version=2.4.0&protocol=
    ↪ avro&partition-num=6&max-message-bytes=67108864&replication-factor=1"
--opts registry="http://127.0.0.1:8081"
```

To use the data connectors provided by Confluent to stream data to relational or non-relational databases, you should use the `avro` protocol and provide a URL for Confluent Schema Registry in `opts`. Note that the `avro` protocol and Confluent integration are **experimental**.

For detailed integration guide, see Quick Start Guide on Integrating TiDB with Confluent Platform.

Configure sink URI with `pulsar`

Sample configuration:

```
--sink-uri="pulsar://127.0.0.1:6650/topic-name?connectionTimeout=2s"
```

The following are descriptions of parameters that can be configured for the sink URI with `pulsar`:

Parameter	Description
`connectionTimeout`	The timeout for establishing a connection to the downstream Pulsar, which is optional and defaults to 30 (seconds)
`operationTimeout`	The timeout for performing an operation on the downstream Pulsar, which is optional and defaults to 30 (seconds)
`tlsTrustCertsFilePath` ↪	The path of the CA certificate file needed to connect to the downstream Pulsar instance (optional)
`tlsAllowInsecureConnection` ↪	Determines whether to allow unencrypted connection after TLS is enabled (optional)
`tlsValidateHostname` ↪	Determines whether to verify the host name of the certificate from the downstream Pulsar (optional)
`maxConnectionsPerBroker` ↪	The maximum number of connections allowed to a single downstream Pulsar broker, which is optional and defaults to 1
`auth.tls`	Uses the TLS mode to verify the downstream Pulsar (optional). For example, `auth=tls&auth.tlsCertFile=/path/to/cert&` ↪ `auth.tlsKeyFile=/path/to/key`.
`auth.token`	Uses the token mode to verify the downstream Pulsar (optional). For example, `auth=token&auth.token=secret-token` or `auth=token&auth.file=path/to/secret-token-file`.

Parameter	Description
`name`	The name of Pulsar producer in TiCDC (optional)
`maxPendingMessages` ↪	Sets the maximum size of the pending message queue, which is optional and defaults to 1000. For example, pending for the confirmation message from Pulsar.
`disableBatching`	Disables automatically sending messages in batches (optional)
`batchingMaxPublishDelay` ↪	Sets the duration within which the messages sent are batched (default: 10ms)
`compressionType`	Sets the compression algorithm used for sending messages (optional). The value options are `NONE`,`LZ4`, `ZLIB`, and `ZSTD`. (`NONE` by default)
`hashingScheme`	The hash algorithm used for choosing the partition to which a message is sent (optional). The value options are `JavaStringHash` (default) and `Murmur3`.
`properties.*`	The customized properties added to the Pulsar producer in TiCDC (optional). For example, `properties.location=Hangzhou`.

For more parameters of Pulsar, see pulsar-client-go ClientOptions and pulsar-client-go ProducerOptions.

Use the task configuration file

For more replication configuration (for example, specify replicating a single table), see Task configuration file.

You can use a configuration file to create a replication task in the following way:

```
cdc cli changefeed create --pd=http://10.0.10.25:2379 --sink-uri="mysql://
    ↪ root:123456@127.0.0.1:3306/" --config changefeed.toml
```

In the command above, `changefeed.toml` is the configuration file for the replication task.

Query the replication task list

Execute the following command to query the replication task list:

```
cdc cli changefeed list --pd=http://10.0.10.25:2379
```

```
[{
    "id": "simple-replication-task",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
```

```
}]
```

- `checkpoint` indicates that TiCDC has already replicated data before this time point to the downstream.
- `state` indicates the state of the replication task.
  - `normal`: The replication task runs normally.
  - `stopped`: The replication task is stopped (manually paused).
  - `error`: The replication task is stopped (by an error).
  - `removed`: The replication task is removed. Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, execute the `changefeed query` command.
  - `finished`: The replication task is finished (data is replicated to the `target-ts`). Tasks of this state are displayed only when you have specified the `--all` option. To see these tasks when this option is not specified, execute the `changefeed query` command.

Query a specific replication task

To query a specific replication task, execute the `changefeed query` command. The query result includes the task information and the task state. You can specify the `--simple` or `-s` argument to simplify the query result that will only include the basic replication state and the checkpoint information. If you do not specify this argument, detailed task configuration, replication states, and replication table information are output.

```
cdc cli changefeed query -s --pd=http://10.0.10.25:2379 --changefeed-id=
    ↪ simple-replication-task
```

```
{
 "state": "normal",
 "tso": 419035700154597378,
 "checkpoint": "2020-08-27 10:12:19.579",
 "error": null
}
```

In the command and result above:

- `state` is the replication state of the current `changefeed`. Each state must be consistent with the state in `changefeed list`.
- `tso` represents the largest transaction TSO in the current `changefeed` that has been successfully replicated to the downstream.
- `checkpoint` represents the corresponding time of the largest transaction TSO in the current `changefeed` that has been successfully replicated to the downstream.
- `error` records whether an error has occurred in the current `changefeed`.

```
cdc cli changefeed query --pd=http://10.0.10.25:2379 --changefeed-id=simple-
    ↪ replication-task
```

```
{
  "info": {
    "sink-uri": "mysql://127.0.0.1:3306/?max-txn-row=20\u0026worker-number
        ↪ =4",
    "opts": {},
    "create-time": "2020-08-27T10:33:41.687983832+08:00",
    "start-ts": 419036036249681921,
    "target-ts": 0,
    "admin-job-type": 0,
    "sort-engine": "unified",
    "sort-dir": ".",
    "config": {
      "case-sensitive": true,
      "enable-old-value": false,
      "filter": {
        "rules": [
          "*.*"
        ],
        "ignore-txn-start-ts": null,
        "ddl-allow-list": null
      },
      "mounter": {
        "worker-num": 16
      },
      "sink": {
        "dispatchers": null,
        "protocol": "default"
      },
      "cyclic-replication": {
        "enable": false,
        "replica-id": 0,
        "filter-replica-ids": null,

        "sync-ddl": false
      },
      "scheduler": {
        "type": "table-number",
        "polling-time": -1
      }
    },
    "state": "normal",
```

```
    "history": null,
    "error": null
  },
  "status": {
    "resolved-ts": 419036036249681921,
    "checkpoint-ts": 419036036249681921,
    "admin-job-type": 0
  },
  "count": 0,
  "task-status": [
    {
      "capture-id": "97173367-75dc-490c-ae2d-4e990f90da0f",
      "status": {
        "tables": {
          "47": {
            "start-ts": 419036036249681921,
            "mark-table-id": 0
          }
        },
        "operation": null,
        "admin-job-type": 0
      }
    }
  ]
}
```

In the command and result above:

- `info` is the replication configuration of the queried `changefeed`.
- `status` is the replication state of the queried `changefeed`.
  - `resolved-ts`: The largest transaction `TS` in the current `changefeed`. Note that this `TS` has been successfully sent from TiKV to TiCDC.
  - `checkpoint-ts`: The largest transaction `TS` in the current `changefeed`. Note that this `TS` has been successfully written to the downstream.
  - `admin-job-type`: The status of a `changefeed`:
    * `0`: The state is normal.
    * `1`: The task is paused. When the task is paused, all replicated `processors` exit. The configuration and the replication status of the task are retained, so you can resume the task from `checkpiont-ts`.
    * `2`: The task is resumed. The replication task resumes from `checkpoint-ts`.
    * `3`: The task is removed. When the task is removed, all replicated `processors` are ended, and the configuration information of the replication task is cleared up. Only the replication status is retained for later queries.

- `task-status` indicates the state of each replication sub-task in the queried `changefeed` ↪ .

Pause a replication task

Execute the following command to pause a replication task:

```
cdc cli changefeed pause --pd=http://10.0.10.25:2379 --changefeed-id simple-
    ↪ replication-task
```

In the above command:

- `--changefeed-id=uuid` represents the ID of the `changefeed` that corresponds to the replication task you want to pause.

Resume a replication task

Execute the following command to resume a paused replication task:

```
cdc cli changefeed resume --pd=http://10.0.10.25:2379 --changefeed-id simple
    ↪ -replication-task
```

In the above command:

- `--changefeed-id=uuid` represents the ID of the `changefeed` that corresponds to the replication task you want to resume.

Remove a replication task

Execute the following command to remove a replication task:

```
cdc cli changefeed remove --pd=http://10.0.10.25:2379 --changefeed-id simple
    ↪ -replication-task
```

In the above command:

- `--changefeed-id=uuid` represents the ID of the `changefeed` that corresponds to the replication task you want to remove.

11.10.3.4.3 Update task configuration

Starting from v4.0.4, TiCDC supports modifying the configuration of the replication task (not dynamically). To modify the `changefeed` configuration, pause the task, modify the configuration, and then resume the task.

```
cdc cli changefeed pause -c test-cf --pd=http://10.0.10.25:2379
cdc cli changefeed update -c test-cf --pd=http://10.0.10.25:2379 --sink-uri
    ↪ ="mysql://127.0.0.1:3306/?max-txn-row=20&worker-number=8" --config=
    ↪ changefeed.toml
cdc cli changefeed resume -c test-cf --pd=http://10.0.10.25:2379
```

Currently, you can modify the following configuration items:

- `sink-uri` of the `changefeed`.
- The `changefeed` configuration file and all configuration items in the file.
- Whether to use the file sorting feature and the sorting directory.
- The `target-ts` of the `changefeed`.

11.10.3.4.4 Manage processing units of replication sub-tasks (`processor`)

- Query the `processor` list:

```
cdc cli processor list --pd=http://10.0.10.25:2379
```

```
[
        {
                "id": "9f84ff74-abf9-407f-a6e2-56aa35b33888",
                "capture-id": "b293999a-4168-4988-a4f4-35d9589b226b",
                "changefeed-id": "simple-replication-task"
        }
]
```

- Query a specific `changefeed` which corresponds to the status of a specific replication task:

```
cdc cli processor query --pd=http://10.0.10.25:2379 --changefeed-id=
    ↪ simple-replication-task --capture-id=b293999a-4168-4988-a4f4-35
    ↪ d9589b226b
```

```
{
  "status": {
    "tables": {
      "56": {   # ID of the replication table, corresponding to
          ↪ tidb_table_id of a table in TiDB
        "start-ts": 417474117955485702,
        "mark-table-id": 0 # ID of mark tables in the cyclic replication
          ↪ , corresponding to tidb_table_id of mark tables in TiDB
      }
    },
```

```
    "operation": null,
    "admin-job-type": 0
  },
  "position": {
    "checkpoint-ts": 417474143881789441,
    "resolved-ts": 417474143881789441,
    "count": 0
  }
}
```

In the command above:

- `status.tables`: Each key number represents the ID of the replication table, corresponding to `tidb_table_id` of a table in TiDB.
- `mark-table-id`: The ID of mark tables in the cyclic replication, corresponding to `tidb_table_id` of mark tables in TiDB.
- `resolved-ts`: The largest TSO among the sorted data in the current processor.
- `checkpoint-ts`: The largest TSO that has been successfully written to the downstream in the current processor.

11.10.3.5 Use HTTP interface to manage cluster status and data replication task

Currently, the HTTP interface provides some basic features for query and maintenance.

In the following examples, suppose that the TiCDC server listens on `127.0.0.1`, and the port is `8300` (you can specify the IP and port in `--addr=ip:port` when starting the TiCDC server).

11.10.3.5.1 Get the TiCDC server status

Use the following command to get the TiCDC server status:

```
curl http://127.0.0.1:8300/status
```

```
{
"version": "0.0.1",
"git_hash": "863f8ea889b144244ff53593a45c47ad22d37396",
"id": "6d92386a-73fc-43f3-89de-4e337a42b766", # capture id
"pid": 12102  # cdc server pid
}
```

11.10.3.5.2 Evict the owner node

```
curl -X POST http://127.0.0.1:8300/capture/owner/resign
```

The above command takes effect only for requesting on the **owner node**.

```
{
 "status": true,
 "message": ""
}
```

```
curl -X POST http://127.0.0.1:8301/capture/owner/resign
```

For nodes other than owner nodes, executing the above command will return the following error.

```
election: not leader
```

11.10.3.5.3 Manually schedule a table to other node

```
curl -X POST http://127.0.0.1:8300/capture/owner/move_table -d 'cf-id=
    ↪ cf060953-036c-4f31-899f-5afa0ad0c2f9&target-cp-id=6f19a6d9-0f8c-4dc9-
    ↪ b299-3ba7c0f216f5&table-id=49'
```

Parameter description:

Parameter name	Description
`cf-id`	The ID of the `changefeed` to be scheduled
`target-cp-id`	The ID of the target `capture`
`table-id`	The ID of the table to be scheduled

For nodes other than owner nodes, executing the above command will return the following error.

```
{
 "status": true,
 "message": ""
}
```

11.10.3.5.4 Dynamically change the log level of TiCDC server

```
curl -X POST -d '"debug"' http://127.0.0.1:8301/admin/log
```

In the command above, the `POST` parameter indicates the new log level. The zap-provided log level options are supported: “debug”, “info”, “warn”, “error”, “dpanic”, “panic”, and “fatal”. This interface parameter is JSON-encoded and you need to pay attention to the use of quotation marks. For example: `'"debug"'`.

11.10.3.6 Task configuration file

This section introduces the configuration of a replication task.

```
### Specifies whether the database names and tables in the configuration
    ↪ file are case-sensitive.
### The default value is true.
### This configuration item affects configurations related to filter and
    ↪ sink.
case-sensitive = true

### Specifies whether to output the old value. New in v4.0.5. Since v5.0,
    ↪ the default value is `true`.
enable-old-value = true

[filter]
### Ignores the transaction of specified start_ts.
ignore-txn-start-ts = [1, 2]

### Filter rules.
### Filter syntax: https://docs.pingcap.com/tidb/stable/table-filter#syntax.
rules = ['*.*', '!test.*']

[mounter]
### mounter thread counts, which is used to decode the TiKV output data.
worker-num = 16

[sink]
### For the sink of MQ type, you can use dispatchers to configure the event
    ↪ dispatcher.
### Supports four dispatchers: default, ts, rowid, and table.
### The dispatcher rules are as follows:
### - default: When multiple unique indexes (including the primary key)
    ↪ exist or the Old Value feature is enabled, events are dispatched in
    ↪ the table mode. When only one unique index (or the primary key)
    ↪ exists, events are dispatched in the rowid mode.
### - ts: Use the commitTs of the row change to create Hash and dispatch
    ↪ events.
### - index-value: Use the value of the primary key or the unique index of
    ↪ the table to create Hash and dispatch events.
### - table: Use the schema name of the table and the table name to create
    ↪ Hash and dispatch events.
### The matching syntax of matcher is the same as the filter rule syntax.
dispatchers = [
    {matcher = ['test1.*', 'test2.*'], dispatcher = "ts"},
    {matcher = ['test3.*', 'test4.*'], dispatcher = "rowid"},
```

```
]
### For the sink of MQ type, you can specify the protocol format of the
    ↪ message.
### Currently four protocols are supported: default, canal, avro, and
    ↪ maxwell. The default protocol is TiCDC Open Protocol.
protocol = "default"

[cyclic-replication]
### Whether to enable cyclic replication.
enable = false
### The replica ID of the current TiCDC.
replica-id = 1
### The replica ID to be filtered.
filter-replica-ids = [2,3]
### Whether to replicate DDL statements.
sync-ddl = true
```

11.10.3.6.1 Notes for compatibility

- In TiCDC v4.0.0, `ignore-txn-commit-ts` is removed and `ignore-txn-start-ts` is added, which uses start_ts to filter transactions.
- In TiCDC v4.0.2, `db-dbs/db-tables/ignore-dbs/ignore-tables` are removed and `rules` is added, which uses new filter rules for databases and tables. For detailed filter syntax, see Table Filter.

11.10.3.7 Cyclic replication

> **Warning:**
>
> Currently (v4.0.2), cyclic replication is still an experimental feature. It is **NOT** recommended to use it in the production environment.

The cyclic replication feature supports replicating data across multiple independent TiDB clusters. For example, TiDB clusters A, cluster B, and cluster C all have a table named `test.user_data` and write data into this table respectively. With the cyclic replication feature, the data written into `test.user_data` in one cluster can be replicated to the other two clusters, so that the `test.user_data` table in the three clusters is consistent with each other.

11.10.3.7.1 Usage example

Enable cyclic replication in the three clusters of A, B, and C. Two TiCDC clusters are used for the replication from cluster A to cluster B. Among the three clusters, DDL statements enters cluster A first.

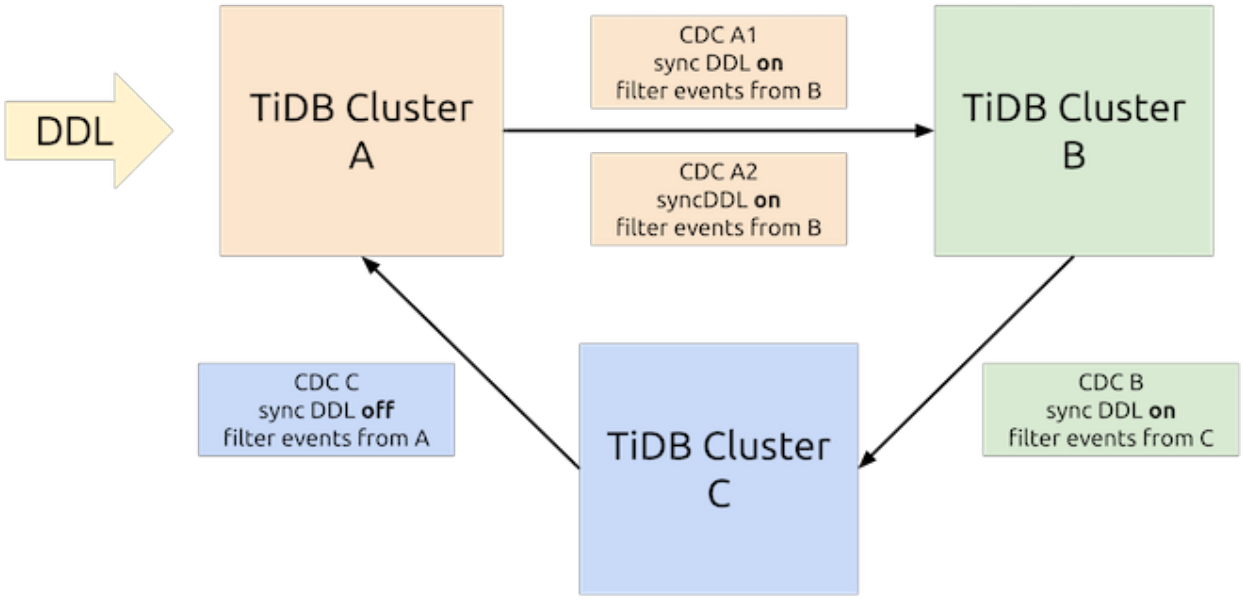

Figure 161: TiCDC cyclic replication

To use the cyclic replication feature, you need to configure the following parameters for the replication task upon the task creation.

- `--cyclic-replica-id`: Specifies the data source (to be written) ID of the upstream cluster. Each cluster ID must be unique.
- `--cyclic-filter-replica-ids`: Specifies the data source ID to be filtered, which is usually the downstream cluster ID.
- `--cyclic-sync-ddl`: Determines whether to replicate DDL statements to the downstream.

To create a cyclic replication task, take the following steps:

1. Enable the TiCDC component in TiDB cluster A, cluster B, and cluster C.

```
# Enables TiCDC in cluster A.
cdc server \
    --pd="http://${PD_A_HOST}:${PD_A_PORT}" \
    --log-file=ticdc_1.log \
    --addr=0.0.0.0:8301 \
```

```
    --advertise-addr=127.0.0.1:8301
# Enables TiCDC in cluster B.
cdc server \
    --pd="http://${PD_B_HOST}:${PD_B_PORT}" \
    --log-file=ticdc_2.log \
    --addr=0.0.0.0:8301 \
    --advertise-addr=127.0.0.1:8301
# Enables TiCDC in cluster C.
cdc server \
    --pd="http://${PD_C_HOST}:${PD_C_PORT}" \
    --log-file=ticdc_3.log \
    --addr=0.0.0.0:8301 \
    --advertise-addr=127.0.0.1:8301
```

2. Create the mark tables used for the cyclic replication in cluster A, cluster B, and cluster C.

```
# Creates mark tables in cluster A.
cdc cli changefeed cyclic create-marktables \
    --cyclic-upstream-dsn="root@tcp(${TIDB_A_HOST}:${TIDB_A_PORT})/" \
    --pd="http://${PD_A_HOST}:${PD_A_PORT}"
# Creates mark tables in cluster B.
cdc cli changefeed cyclic create-marktables \
    --cyclic-upstream-dsn="root@tcp(${TIDB_B_HOST}:${TIDB_B_PORT})/" \
    --pd="http://${PD_B_HOST}:${PD_B_PORT}"
# Creates mark tables in cluster C.
cdc cli changefeed cyclic create-marktables \
    --cyclic-upstream-dsn="root@tcp(${TIDB_C_HOST}:${TIDB_C_PORT})/" \
    --pd="http://${PD_C_HOST}:${PD_C_PORT}"
```

3. Create the cyclic replication task in cluster A, cluster B, and cluster C.

```
# Creates the cyclic replication task in cluster A.
cdc cli changefeed create \
    --sink-uri="mysql://root@${TiDB_B_HOST}/" \
    --pd="http://${PD_A_HOST}:${PD_A_PORT}" \
    --cyclic-replica-id 1 \
    --cyclic-filter-replica-ids 2 \
    --cyclic-sync-ddl true
# Creates the cyclic replication task in cluster B.
cdc cli changefeed create \
    --sink-uri="mysql://root@${TiDB_C_HOST}/" \
    --pd="http://${PD_B_HOST}:${PD_B_PORT}" \
    --cyclic-replica-id 2 \
    --cyclic-filter-replica-ids 3 \
```

```
    --cyclic-sync-ddl true
# Creates the cyclic replication task in cluster C.
cdc cli changefeed create \
    --sink-uri="mysql://root@${TiDB_A_HOST}/" \
    --pd="http://${PD_C_HOST}:${PD_C_PORT}" \
    --cyclic-replica-id 3 \
    --cyclic-filter-replica-ids 1 \
    --cyclic-sync-ddl false
```

11.10.3.7.2 Usage notes

- Before creating the cyclic replication task, you must execute `cdc cli changefeed cyclic create-marktables` to create the mark tables for the cyclic replication.
- The name of the table with cyclic replication enabled must match the `^[a-zA-Z0-9_]+$` regular expression.
- Before creating the cyclic replication task, the tables for the task must be created.
- After enabling the cyclic replication, you cannot create a table that will be replicated by the cyclic replication task.
- To avoid causing errors, do not execute DDL statements such as `ADD COLUMN/DROP COLUMN` when data is written into multiple clusters at the same time.
- To perform online DDL operations, ensure the following requirements are met:
  - The application is compatible with the table schema before and after executing the DDL operations.
  - The TiCDC components of multiple clusters form a one-way DDL replication chain, which is not cyclic. For example, in the example above, only the TiCDC component of cluster C disables `sync-ddl`.
  - DDL operations must be performed on the cluster that is the starting point of the one-way DDL replication chain, such as cluster A in the example above.

11.10.3.8 Output the historical value of a Row Changed Event New in v4.0.5

In the default configuration, the Row Changed Event of TiCDC Open Protocol output in a replication task only contains the changed value, not the value before the change. Therefore, the output value cannot be used by the consumer ends of TiCDC Open Protocol as the historical value of a Row Changed Event.

Starting from v4.0.5, TiCDC supports outputting the historical value of a Row Changed Event. To enable this feature, specify the following configuration in the `changefeed` configuration file at the root level:

```
enable-old-value = true
```

This feature is enabled by default since v5.0. To learn the output format of the TiCDC Open Protocol after this feature is enabled, see TiCDC Open Protocol - Row Changed Event.

11.10.3.9 Replicate tables with the new framework for collations enabled

Starting from v4.0.15, v5.0.4, v5.1.1 and v5.2.0, TiCDC supports tables that have enabled new framework for collations.

11.10.3.10 Replicate tables without a valid index

Since v4.0.8, TiCDC supports replicating tables that have no valid index by modifying the task configuration. To enable this feature, configure in the `changefeed` configuration file as follows:

```
enable-old-value = true
force-replicate = true
```

> **Warning:**
>
> For tables without a valid index, operations such as `INSERT` and `REPLACE` are not reentrant, so there is a risk of data redundancy. TiCDC guarantees that data is distributed only at least once during the replication process. Therefore, enabling this feature to replicate tables without a valid index will definitely cause data redundancy. If you do not accept data redundancy, it is recommended to add an effective index, such as adding a primary key column with the `AUTO RANDOM` attribute.

11.10.3.11 Unified Sorter

Unified sorter is the sorting engine in TiCDC. It can mitigate OOM problems caused by the following scenarios:

- The data replication task in TiCDC is paused for a long time, during which a large amount of incremental data is accumulated and needs to be replicated.
- The data replication task is started from an early timestamp so it becomes necessary to replicate a large amount of incremental data.

For the changefeeds created using `cdc cli` after v4.0.13, Unified Sorter is enabled by default; for the changefeeds that have existed before v4.0.13, the previous configuration is used.

To check whether or not the Unified Sorter feature is enabled on a changefeed, you can execute the following example command (assuming the IP address of the PD instance is `http://10.0.10.25:2379`):

```
cdc cli --pd="http://10.0.10.25:2379" changefeed query --changefeed-id=
    ↪ simple-replication-task | grep 'sort-engine'
```

In the output of the above command, if the value of `sort-engine` is "unified", it means that Unified Sorter is enabled on the changefeed.

Note:

- If your servers use mechanical hard drives or other storage devices that have high latency or limited bandwidth, use the unified sorter with caution.
- By default, Unified Sorter uses `data_dir` to store temporary files. It is recommended to ensure that the free disk space is greater than or equal to 500 GiB. For production environments, it is recommended to ensure that the free disk space on each node is greater than (the maximum `checkpoint-ts` delay allowed by the business) * (upstream write traffic at business peak hours). In addition, if you plan to replicate a large amount of historical data after `changefeed` is created, make sure that the free space on each node is greater than the amount of replicated data.
- Unified sorter is enabled by default. If your servers do not match the above requirements and you want to disable the unified sorter, you need to manually set `sort-engine` to `memory` for the changefeed.
- To enable Unified Sorter on an existing changefeed that uses `memory` to sort, see the methods provided in How do I handle the OOM that occurs after TiCDC is restarted after a task interruption?.

11.10.4 Troubleshoot TiCDC

This document introduces the common issues and errors that you might encounter when using TiCDC, and the corresponding maintenance and troubleshooting methods.

Note:

In this document, the PD address specified in `cdc cli` commands is `--pd =http://10.0.10.25:2379`. When you use the command, replace the address with your actual PD address.

11.10.4.1 How do I choose `start-ts` when creating a task in TiCDC?

The `start-ts` of a replication task corresponds to a Timestamp Oracle (TSO) in the upstream TiDB cluster. TiCDC requests data from this TSO in a replication task. Therefore, the `start-ts` of the replication task must meet the following requirements:

- The value of `start-ts` is larger than the `tikv_gc_safe_point` value of the current TiDB cluster. Otherwise, an error occurs when you create a task.
- Before starting a task, ensure that the downstream has all data before `start-ts`. For scenarios such as replicating data to message queues, if the data consistency between upstream and downstream is not required, you can relax this requirement according to your application need.

If you do not specify `start-ts`, or specify `start-ts` as `0`, when a replication task is started, TiCDC gets a current TSO and starts the task from this TSO.

11.10.4.2 Why can't some tables be replicated when I create a task in TiCDC?

When you execute `cdc cli changefeed create` to create a replication task, TiCDC checks whether the upstream tables meet the replication restrictions. If some tables do not meet the restrictions, `some tables are not eligible to replicate` is returned with a list of ineligible tables. You can choose `Y` or `y` to continue creating the task, and all updates on these tables are automatically ignored during the replication. If you choose an input other than `Y` or `y`, the replication task is not created.

11.10.4.3 How do I view the state of TiCDC replication tasks?

To view the status of TiCDC replication tasks, use `cdc cli`. For example:

```
cdc cli changefeed list --pd=http://10.0.10.25:2379
```

The expected output is as follows:

```
[{
    "id": "4e24dde6-53c1-40b6-badf-63620e4940dc",
    "summary": {
      "state": "normal",
      "tso": 417886179132964865,
      "checkpoint": "2020-07-07 16:07:44.881",
      "error": null
    }
}]
```

- `checkpoint`: TiCDC has replicated all data before this timestamp to downstream.
- `state`: The state of this replication task:
  - `normal`: The task runs normally.
  - `stopped`: The task is stopped manually or encounters an error.
  - `removed`: The task is removed.

Note:

This feature is introduced in TiCDC 4.0.3.

11.10.4.4 TiCDC replication interruptions

11.10.4.4.1 How do I know whether a TiCDC replication task is interrupted?

- Check the `changefeed checkpoint` monitoring metric of the replication task (choose the right `changefeed id`) in the Grafana dashboard. If the metric value stays unchanged, or the `checkpoint lag` metric keeps increasing, the replication task might be interrupted.
- Check the `exit error count` monitoring metric. If the metric value is greater than `0`, an error has occurred in the replication task.
- Execute `cdc cli changefeed list` and `cdc cli changefeed query` to check the status of the replication task. `stopped` means the task has stopped, and the `error` item provides the detailed error message. After the error occurs, you can search `error on running processor` in the TiCDC server log to see the error stack for troubleshooting.
- In some extreme cases, the TiCDC service is restarted. You can search the `FATAL` level log in the TiCDC server log for troubleshooting.

11.10.4.4.2 How do I know whether the replication task is stopped manually?

You can know whether the replication task is stopped manually by executing `cdc cli`. For example:

```
cdc cli changefeed query --pd=http://10.0.10.25:2379 --changefeed-id 28
    ↪ c43ffc-2316-4f4f-a70b-d1a7c59ba79f
```

In the output of the above command, `admin-job-type` shows the state of this replication task:

- `0`: In progress, which means that the task is not stopped manually.
- `1`: Paused. When the task is paused, all replicated `processor`s exit. The configuration and the replication status of the task are retained, so you can resume the task from `checkpiont-ts`.
- `2`: Resumed. The replication task resumes from `checkpoint-ts`.
- `3`: Removed. When the task is removed, all replicated `processor`s are ended, and the configuration information of the replication task is cleared up. The replication status is retained only for later queries.

11.10.4.4.3 How do I handle replication interruptions?

A replication task might be interrupted in the following known scenarios:

- The downstream continues to be abnormal, and TiCDC still fails after many retries.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
  - Handling method: You can resume the replication task via the HTTP interface after the downstream is back to normal.
- Replication cannot continue because of incompatible SQL statement(s) in the downstream.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
  - Handling procedures:
    1. Query the status information of the replication task using the `cdc cli changefeed query` command and record the value of `checkpoint-ts`.
    2. Use the new task configuration file and add the `ignore-txn-start-ts` parameter to skip the transaction corresponding to the specified `start-ts`.
    3. Stop the old replication task via HTTP API. Execute `cdc cli changefeed create` to create a new task and specify the new task configuration file. Specify `checkpoint-ts` recorded in step 1 as the `start-ts` and start a new task to resume the replication.
- In TiCDC v4.0.13 and earlier versions, when TiCDC replicates the partitioned table, it might encounter an error that leads to replication interruption.
  - In this scenario, TiCDC saves the task information. Because TiCDC has set the service GC safepoint in PD, the data after the task checkpoint is not cleaned by TiKV GC within the valid period of `gc-ttl`.
  - Handling procedures:
    1. Pause the replication task by executing `cdc cli changefeed pause -c <changefeed-id>`.
    2. Wait for about one munite, and then resume the replication task by executing `cdc cli changefeed resume -c <changefeed-id>`.

11.10.4.4.4 What should I do to handle the OOM that occurs after TiCDC is restarted after a task interruption?

- Update your TiDB cluster and TiCDC cluster to the latest versions. The OOM problem has already been resolved in **v4.0.14 and later v4.0 versions, v5.0.2 and later v5.0 versions, and the latest versions**.

- In the above updated versions, you can enable the Unified Sorter to help you sort data in the disk when the system memory is insufficient. To enable this function, you can pass `--sort-engine=unified` to the `cdc cli` command when creating a replication task. For example:

```
cdc cli changefeed update -c <changefeed-id> --sort-engine="unified" --pd=
    ↪ http://10.0.10.25:2379
```

If you fail to update your cluster to the above new versions, you can still enable Unified Sorter in **previous versions**. You can pass `--sort-engine=unified` and `--sort-dir=/ ↪ path/to/sort_dir` to the `cdc cli` command when creating a replication task. For example:

```
cdc cli changefeed update -c <changefeed-id> --sort-engine="unified" --sort-
    ↪ dir="/data/cdc/sort" --pd=http://10.0.10.25:2379
```

Note:

- Since v4.0.9, TiCDC supports the unified sorter engine.
- TiCDC (the 4.0 version) does not support dynamically modifying the sorting engine yet. Make sure that the changefeed has stopped before modifying the sorter settings.
- `sort-dir` has different behaviors in different versions. Refer to compatibility notes for`sort-dir` and `data-dir`, and configure it with caution.
- Currently, the unified sorter is an experimental feature. When the number of tables is too large (>=100), the unified sorter might cause performance issues and affect replication throughput. Therefore, it is not recommended to use it in a production environment. Before you enable the unified sorter, make sure that the machine of each TiCDC node has enough disk capacity. If the total size of unprocessed data changes might exceed 1 TB, it is not recommend to use TiCDC for replication.

11.10.4.5 What is `gc-ttl` in TiCDC?

Since v4.0.0-rc.1, PD supports external services in setting the service-level GC safepoint. Any service can register and update its GC safepoint. PD ensures that the key-value data later than this GC safepoint is not cleaned by GC.

When the replication task is unavailable or interrupted, this feature ensures that the data to be consumed by TiCDC is retained in TiKV without being cleaned by GC.

When starting the TiCDC server, you can specify the Time To Live (TTL) duration of GC safepoint by configuring `gc-ttl`. You can also use TiUP to modify `gc-ttl`. The default value is 24 hours. In TiCDC, this value means:

- The maximum time the GC safepoint is retained at the PD after the TiCDC service is stopped.
- The maximum time a replication task can be suspended after the task is interrupted or manually stopped. If the time for a suspended replication task is longer than the value set by `gc-ttl`, the replication task enters the `failed` status, cannot be resumed, and cannot continue to affect the progress of the GC safepoint.

The second behavior above is introduced in TiCDC v4.0.13 and later versions. The purpose is to prevent a replication task in TiCDC from suspending for too long, causing the GC safepoint of the upstream TiKV cluster not to continue for a long time and retaining too many outdated data versions, thus affecting the performance of the upstream cluster.

> **Note:**
>
> In some scenarios, for example, when you use TiCDC for incremental replication after full replication with Dumpling/BR, the default 24 hours of `gc-ttl` may not be sufficient. You need to specify an appropriate value for `gc-ttl` when you start the TiCDC server.

11.10.4.6 What is the complete behavior of TiCDC garbage collection (GC) safepoint?

If a replication task starts after the TiCDC service starts, the TiCDC owner updates the PD service GC safepoint with the smallest value of `checkpoint-ts` among all replication tasks. The service GC safepoint ensures that TiCDC does not delete data generated at that time and after that time. If the replication task is interrupted, or manually stopped, the `checkpoint-ts` of this task does not change. Meanwhile, PD's corresponding service GC safepoint is not updated either.

If the replication task is suspended longer than the time specified by `gc-ttl`, the replication task enters the `failed` status and cannot be resumed. The PD corresponding service GC safepoint will continue.

The Time-To-Live (TTL) that TiCDC sets for a service GC safepoint is 24 hours, which means that the GC mechanism does not delete any data if the TiCDC service can be recovered within 24 hours after it is interrupted.

11.10.4.7 How do I handle the `Error 1298: Unknown or incorrect time zone: 'UTC'` error when creating the replication task or replicating data to MySQL?

This error is returned when the downstream MySQL does not load the time zone. You can load the time zone by running `mysql_tzinfo_to_sql`. After loading the time zone, you can create tasks and replicate data normally.

```
mysql_tzinfo_to_sql /usr/share/zoneinfo | mysql -u root mysql -p
```

If the output of the command above is similar to the following one, the import is successful:

```
Enter password:
Warning: Unable to load '/usr/share/zoneinfo/iso3166.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/leap-seconds.list' as time zone
    ↪ . Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone.tab' as time zone.
    ↪ Skipping it.
Warning: Unable to load '/usr/share/zoneinfo/zone1970.tab' as time zone.
    ↪ Skipping it.
```

If the downstream is a special MySQL environment (a public cloud RDS or some MySQL derivative versions) and importing the time zone using the above method fails, you need to specify the MySQL time zone of the downstream using the `time-zone` parameter in `sink-uri`. You can first query the time zone used by MySQL:

1. Query the time zone used by MySQL:

```
show variables like '%time_zone%';
```

```
+------------------+--------+
| Variable_name  | Value |
+------------------+--------+
| system_time_zone | CST |
| time_zone      | SYSTEM |
+------------------+--------+
```

2. Specify the time zone when you create the replication task and create the TiCDC service:

```
cdc cli changefeed create --sink-uri="mysql://root@127.0.0.1:3306/?time
    ↪ -zone=CST" --pd=http://10.0.10.25:2379
```

Note:

CST might be an abbreviation for the following four different time zones:

- Central Standard Time (USA) UT-6:00
- Central Standard Time (Australia) UT+9:30
- China Standard Time UT+8:00
- Cuba Standard Time UT-4:00

In China, CST usually stands for China Standard Time.

11.10.4.8 How to understand the relationship between the TiCDC time zone and the time zones of the upstream/downstream databases?

	Upstream time zone	TiCDC time zone	Downstream time zone
Configuration method	Time Zone Support	Configured using the `--tz` parameter when you start the TiCDC server	Configured using the `time-zone` parameter in `sink-uri`

	Upstream time zone	TiCDC time zone	Downstream time zone
Description	The time zone of the upstream TiDB, which affects DML operations of the timestamp type and DDL operations related to timestamp type columns.	TiCDC assumes that the upstream TiDB's time zone is the same as the TiCDC time zone configuration, and performs related operations on the timestamp column.	The downstream MySQL processes the timestamp in the DML and DDL operations according to the downstream time zone setting.

Note:

Be careful when you set the time zone of the TiCDC server, because this time zone is used for converting the time type. Keep the upstream time zone, TiCDC time zone, and the downstream time zone consistent. The TiCDC server chooses its time zone in the following priority:

- TiCDC first uses the time zone specified using `--tz`.
- When `--tz` is not available, TiCDC tries to read the time zone set using the `TZ` environment variable.
- When the `TZ` environment variable is not available, TiCDC uses the default time zone of the machine.

11.10.4.9 What is the default behavior of TiCDC if I create a replication task without specifying the configuration file in `--config`?

If you use the `cdc cli changefeed create` command without specifying the `-config` parameter, TiCDC creates the replication task in the following default behaviors:

- Replicates all tables except system tables
- Enables the Old Value feature
- Skips replicating tables that do not contain valid indexes

11.10.4.10 How do I handle the incompatibility issue of configuration files caused by TiCDC upgrade?

Refer to Notes for compatibility.

11.10.4.11 Does TiCDC support outputting data changes in the Canal format?

Yes. To enable Canal output, specify the protocol as `canal` in the `--sink-uri` parameter. For example:

```
cdc cli changefeed create --pd=http://10.0.10.25:2379 --sink-uri="kafka
    ↪ ://127.0.0.1:9092/cdc-test?kafka-version=2.4.0&protocol=canal" --
    ↪ config changefeed.toml
```

Note:

- This feature is introduced in TiCDC 4.0.2.
- TiCDC currently supports outputting data changes in the Canal format only to MQ sinks such as Kafka and Pulsar.

For more information, refer to Create a replication task.

11.10.4.12 Why does the latency from TiCDC to Kafka become higher and higher?

- Check how do I view the state of TiCDC replication tasks.
- Adjust the following parameters of Kafka:
  - Increase the `message.max.bytes` value in `server.properties` to `1073741824` (1 GB).
  - Increase the `replica.fetch.max.bytes` value in `server.properties` to `1073741824` (1 GB).
  - Increase the `fetch.message.max.bytes` value in `consumer.properties` to make it larger than the `message.max.bytes` value.

11.10.4.13 When TiCDC replicates data to Kafka, does it write all the changes in a transaction into one message? If not, on what basis does it divide the changes?

No. According to the different distribution strategies configured, TiCDC divides the changes on different bases, including `default`, `row id`, `table`, and `ts`.

For more information, refer to Replication task configuration file.

11.10.4.14 When TiCDC replicates data to Kafka, can I control the maximum size of a single message in TiDB?

Yes. You can set the `max-message-bytes` parameter to control the maximum size of data sent to the Kafka broker each time (optional, `10MB` by default). You can also set `max-batch-size` to specify the maximum number of change records in each Kafka message. Currently, the setting only takes effect when Kafka's `protocol` is `default` (optional, `16` by default).

11.10.4.15 When TiCDC replicates data to Kafka, does a message contain multiple types of data changes?

Yes. A single message might contain multiple `updates` or `deletes`, and `update` and `delete` might co-exist.

11.10.4.16 When TiCDC replicates data to Kafka, how do I view the timestamp, table name, and schema name in the output of TiCDC Open Protocol?

The information is included in the key of Kafka messages. For example:

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
}
```

For more information, refer to TiCDC Open Protocol event format.

11.10.4.17 When TiCDC replicates data to Kafka, how do I know the timestamp of the data changes in a message?

You can get the unix timestamp by moving `ts` in the key of the Kafka message by 18 bits to the right.

11.10.4.18 How does TiCDC Open Protocol represent `null`?

In TiCDC Open Protocol, the type code `6` represents `null`.

Type	Code	Output Example	Note
Null	6	`{"t":6,"v":null}`	

For more information, refer to TiCDC Open Protocol column type code.

11.10.4.19 The `start-ts` timestamp of the TiCDC task is quite different from the current time. During the execution of this task, replication is interrupted and an error `[CDC:ErrBufferReachLimit]` occurs

Since v4.0.9, you can try to enable the unified sorter feature in your replication task, or use the BR tool for an incremental backup and restore, and then start the TiCDC replication task from a new time.

11.10.4.20 How can I tell if a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event?

If the Old Value feature is not enabled, you cannot tell whether a Row Changed Event of TiCDC Open Protocol is an `INSERT` event or an `UPDATE` event. If the feature is enabled, you can determine the event type by the fields it contains:

- `UPDATE` event contains both `"p"` and `"u"` fields
- `INSERT` event only contains the `"u"` field
- `DELETE` event only contains the `"d"` field

For more information, refer to Open protocol Row Changed Event format.

11.10.4.21 How much PD storage does TiCDC use?

TiCDC uses etcd in PD to store and regularly update the metadata. Because the time interval between the MVCC of etcd and PD's default compaction is one hour, the amount of PD storage that TiCDC uses is proportional to the amount of metadata versions generated within this hour. However, in v4.0.5, v4.0.6, and v4.0.7, TiCDC has a problem of frequent writing, so if there are 1000 tables created or scheduled in an hour, it then takes up all the etcd storage and returns the `etcdserver: mvcc: database space exceeded` error. You need to clean up the etcd storage after getting this error. See etcd maintaince space-quota for details. It is recommended to upgrade your cluster to v4.0.9 or later versions.

11.10.4.22 Does TiCDC support replicating large transactions? Is there any risk?

TiCDC provides partial support for large transactions (more than 5 GB in size). Depending on different scenarios, the following risks might exist:

- When TiCDC's internal processing capacity is insufficient, the replication task error `ErrBufferReachLimit` might occur.
- When TiCDC's internal processing capacity is insufficient or the throughput capacity of TiCDC's downstream is insufficient, out of memory (OOM) might occur.

If you encounter an error above, it is recommended to use BR to restore the incremental data of large transactions. The detailed operations are as follows:

1. Record the `checkpoint-ts` of the changefeed that is terminated due to large transactions, use this TSO as the `--lastbackupts` of the BR incremental backup, and execute incremental data backup.
2. After backing up the incremental data, you can find a log record similar to `["Full backup Failed summary : total backup ranges: 0, total success: 0, total failed: 0"] [BackupTS=421758868510212097]` in the BR log output. Record the `BackupTS` in this log.
3. Restore the incremental data.
4. Create a new changefeed and start the replication task from `BackupTS`.
5. Delete the old changefeed.

11.10.4.23 When the downstream of a changefeed is a database similar to MySQL and TiCDC executes a time-consuming DDL statement, all other changefeeds are blocked. How should I handle the issue?

1. Pause the execution of the changefeed that contains the time-consuming DDL statement. Then you can see that other changefeeds are no longer blocked.
2. Search for the `apply job` field in the TiCDC log and confirm the `start-ts` of the time-consuming DDL statement.

3. Manually execute the DDL statement in the downstream. After the execution finishes, go on performing the following operations.
4. Modify the changefeed configuration and add the above `start-ts` to the `ignore-txn-start-ts` configuration item.
5. Resume the paused changefeed.

11.10.4.24 After I upgrade the TiCDC cluster to v4.0.8, the `[CDC:ErrKafkaInvalidConfig]Canal requires old value to be enabled` error is reported when I execute a changefeed

Since v4.0.8, if the `canal` or `maxwell` protocol is used for output in a changefeed, TiCDC enables the old value feature automatically. However, if you have upgraded TiCDC from an earlier version to v4.0.8 or later, when the changefeed uses the `canal` or `maxwell` protocol and the old value feature is disabled, this error is reported.

To fix the error, take the following steps:

1. Set the value of `enable-old-value` in the changefeed configuration file to `true`.
2. Execute `cdc cli changefeed pause` to pause the replication task.

```
cdc cli changefeed pause -c test-cf --pd=http://10.0.10.25:2379
```

3. Execute `cdc cli changefeed update` to update the original changefeed configuration.

```
cdc cli changefeed update -c test-cf --pd=http://10.0.10.25:2379 --sink-uri="mysql://127.0.0.1:3306/?max-txn-row=20&worker-number=8" --config=changefeed.toml
```

4. Execute `cdc cli changfeed resume` to resume the replication task.

```
cdc cli changefeed resume -c test-cf --pd=http://10.0.10.25:2379
```

11.10.4.25 The `[tikv:9006]GC life time is shorter than transaction duration, transaction starts at xx, GC safe point is yy` error is reported when I use TiCDC to create a changefeed

Solution: You need to execute the `pd-ctl service-gc-safepoint --pd <pd-addrs>` command to query the current GC safepoint and service GC safepoint. If the GC safepoint is smaller than the `start-ts` of the TiCDC replication task (changefeed), you can directly add the `--disable-gc-check` option to the `cdc cli create changefeed` command to create a changefeed.

If the result of `pd-ctl service-gc-safepoint --pd <pd-addrs>` does not have `gc_worker service_id`:

- If your PD version is v4.0.8 or earlier, refer to PD issue #3128 for details.
- If your PD is upgraded from v4.0.8 or an earlier version to a later version, refer to PD issue #3366 for details.

11.10.4.26 `enable-old-value` is set to `true` when I create a TiCDC replication task, but `INSERT/UPDATE` statements from the upstream become `REPLACE INTO` after being replicated to the downstream

When a changefeed is created in TiCDC, the `safe-mode` setting defaults to `true`, which generates the `REPLACE INTO` statement to execute for the upstream `INSERT/UPDATE` statements.

Currently, users cannot modify the `safe-mode` setting, so this issue currently has no solution.

11.10.4.27 When I use TiCDC to replicate messages to Kafka, Kafka returns the `Message was too large` error

For TiCDC v4.0.8 or earlier versions, you cannot effectively control the size of the message output to Kafka only by configuring the `max-message-bytes` setting for Kafka in the Sink URI. To control the message size, you also need to increase the limit on the bytes of messages to be received by Kafka. To add such a limit, add the following configuration to the Kafka server configuration.

```
### The maximum byte number of a message that the broker receives
message.max.bytes=2147483648
### The maximum byte number of a message that the broker copies
replica.fetch.max.bytes=2147483648
### The maximum message byte number that the consumer side reads
fetch.message.max.bytes=2147483648
```

11.10.4.28 How can I find out whether a DDL statement fails to execute in downstream during TiCDC replication? How to resume the replication?

If a DDL statement fails to execute, the replication task (changefeed) automatically stops. The checkpoint-ts is the DDL statement's finish-ts minus one. If you want TiCDC to retry executing this statement in the downstream, use `cdc cli changefeed resume` to resume the replication task. For example:

```
cdc cli changefeed resume -c test-cf --pd=http://10.0.10.25:2379
```

If you want to skip this DDL statement that goes wrong, set the start-ts of the changefeed to the checkpoint-ts (the timestamp at which the DDL statement goes wrong) plus one. For example, if the checkpoint-ts at which the DDL statement goes wrong is `415241823337054209`, execute the following commands to skip this DDL statement:

```
cdc cli changefeed update -c test-cf --pd=http://10.0.10.25:2379 --start-ts
    ↪ 415241823337054210
cdc cli changefeed resume -c test-cf --pd=http://10.0.10.25:2379
```

11.10.4.29 The default value of the time type field is inconsistent when replicating a DDL statement to the downstream MySQL 5.7. What can I do?

Suppose that the `create table test (id int primary key, ts timestamp)` statement is executed in the upstream TiDB. When TiCDC replicates this statement to the downstream MySQL 5.7, MySQL uses the default configuration. The table schema after the replication is as follows. The default value of the `timestamp` field becomes `CURRENT_TIMESTAMP`:

```
mysql root@127.0.0.1:test> show create table test;
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| Table | Create Table
   ↪                                                                    |
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
| test | CREATE TABLE `test` (
   ↪                                                        |
|      |   `id` int(11) NOT NULL,
   ↪                                                    |
|      |   `ts` timestamp NOT NULL DEFAULT CURRENT_TIMESTAMP ON UPDATE
   ↪ CURRENT_TIMESTAMP, |
|      |   PRIMARY KEY (`id`)
   ↪                                                      |
|      | ) ENGINE=InnoDB DEFAULT CHARSET=latin1
   ↪                                  |
+--
   ↪ -----+-----------------------------------------------------------------------
   ↪
1 row in set
```

From the result, you can see that the table schema before and after the replication is inconsistent. This is because the default value of `explicit_defaults_for_timestamp` in TiDB is different from that in MySQL. See MySQL Compatibility for details.

Since v5.0.1 or v4.0.13, for each replication to MySQL, TiCDC automatically sets `explicit_defaults_for_timestamp = ON` to ensure that the time type is consistent between the upstream and downstream. For versions earlier than v5.0.1 or v4.0.13, pay attention to the compatibility issue caused by the inconsistent `explicit_defaults_for_timestamp` ↪ value when using TiCDC to replicate the time type data.

11.10.5 Key Monitoring Metrics of TiCDC

If you use TiUP to deploy the TiDB cluster, you can see a sub-dashboard for TiCDC in the monitoring system which is deployed at the same time. You can get an overview of

TiCDC's current status from the TiCDC dashboard, where the key metrics are displayed. This document provides a detailed description of these key metrics.

The metric description in this document is based on the following replication task example, which replicates data to MySQL using the default configuration.

```
cdc cli changefeed create --pd=http://10.0.10.25:2379 --sink-uri="mysql://
    ↪ root:123456@127.0.0.1:3306/" --changefeed-id="simple-replication-task
    ↪ "
```

The TiCDC dashboard contains four monitoring panels. See the following screenshot:

Figure 162: TiCDC Dashboard - Overview

The description of each panel is as follows:

- **Server**: The summary information of TiKV nodes and TiCDC nodes in the TiDB cluster
- **Changefeed**: The detailed information of TiCDC replication tasks
- **Events**: The detail information about the data flow within the TiCDC cluster
- **TiKV**: TiKV information related to TiCDC

11.10.5.1 Server

The following is an example of the **Server** panel:

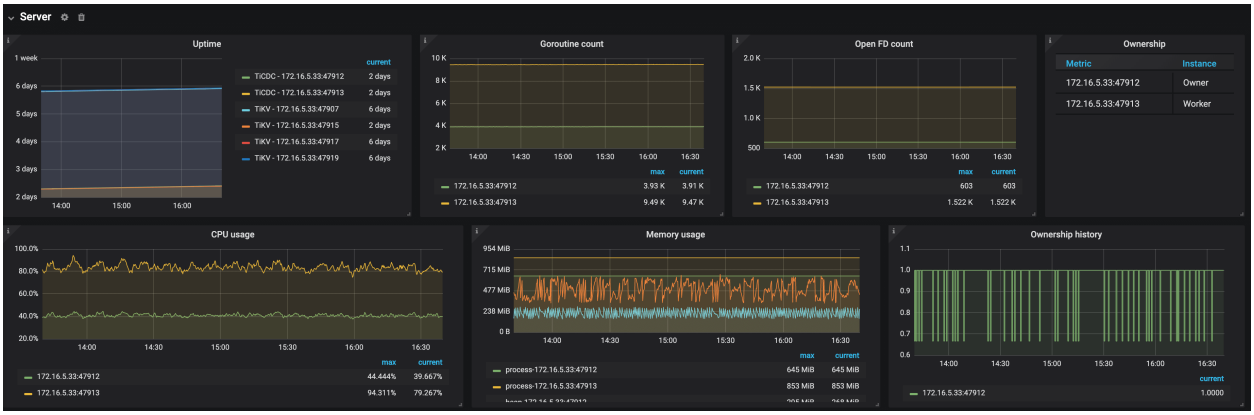

Figure 163: TiCDC Dashboard - Server metrics

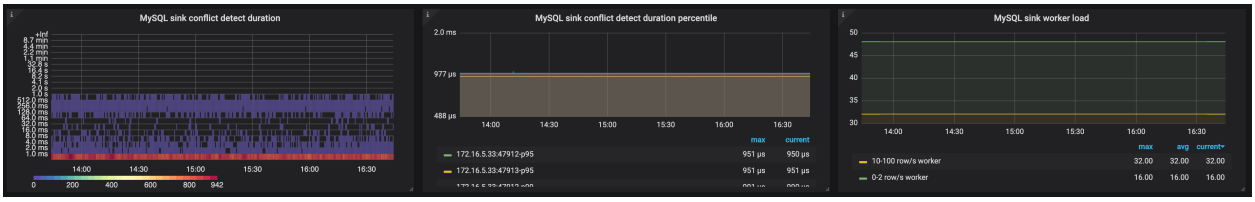


The description of each metric in the **Server** panel is as follows:

- Uptime: The time for which TiKV nodes and TiCDC nodes have been running
- Goroutine count: The number of goroutines of a TiCDC node
- Open FD count: The number of file handles opened by TiCDC nodes
- Ownership: The current status of nodes in the TiCDC cluster
- Ownership history: The ownership history of the TiCDC cluster
- CPU usage: The CPU usage of TiCDC nodes
- Memory usage: The memory usage of TiCDC nodes

11.10.5.2 Changefeed

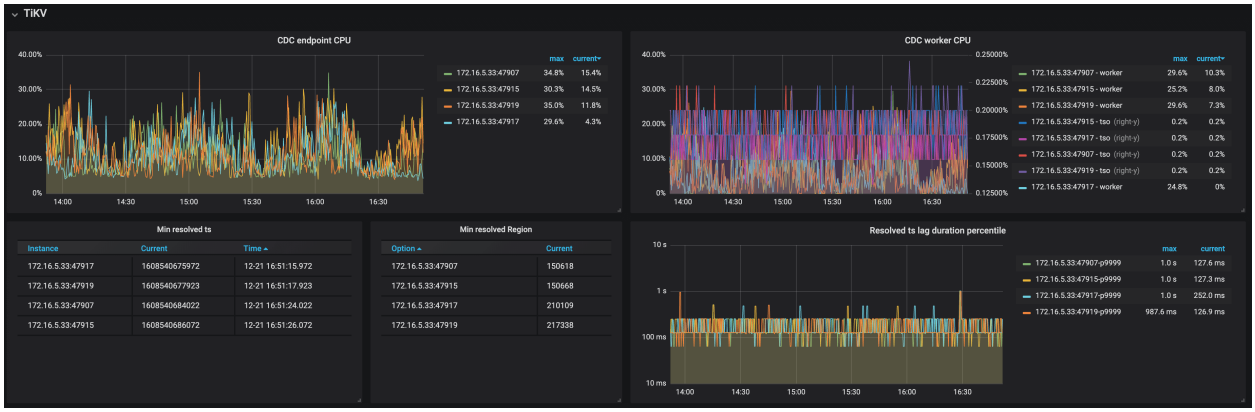
The following is an example of the **Changefeed** panel:

The description of each metric in the **Changefeed** panel is as follows:

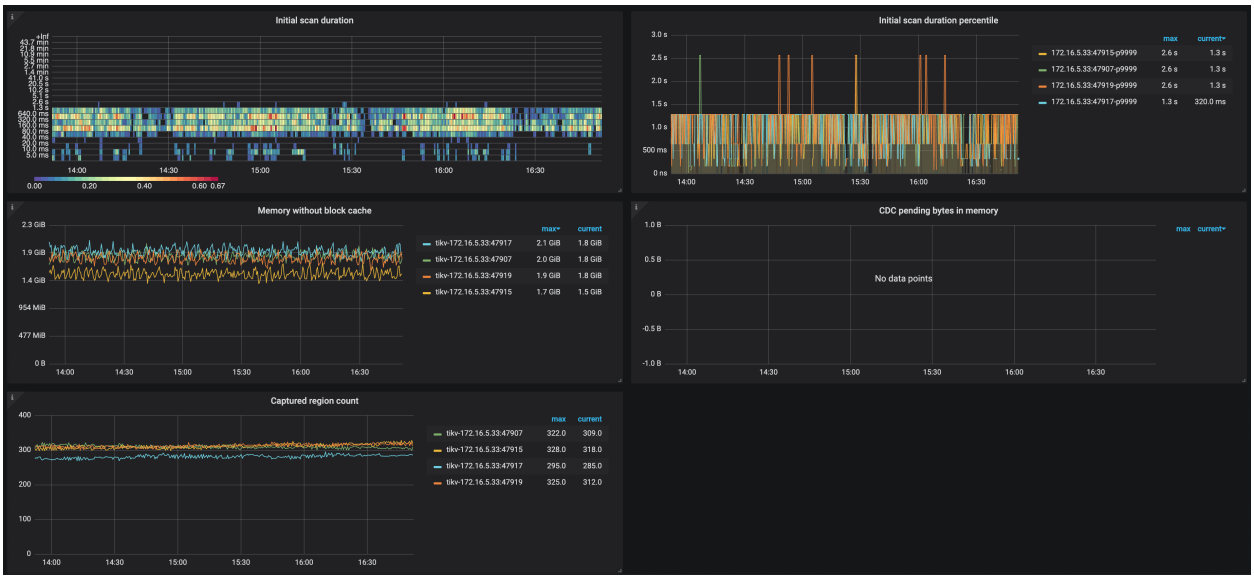
- Changefeed table count: The number of tables that each TiCDC node needs to replicate in the replication task
- Processor resolved ts: The timestamps that have been resolved in the TiCDC cluster
- Table resolved ts: The replication progress of each table in the replication task
- Changefeed checkpoint: The progress of replicating data to the downstream. Normally, the green bars are connected to the yellow line
- PD etcd requests/s: The number of requests that a TiCDC node sends to PD per second
- Exit error count: The number of errors that interrupt the replication task per minute
- Changefeed checkpoint lag: The progress lag of data replication (the unit is second) between the upstream and the downstream
- Changefeed resolved ts lag: The progress lag of data replication (the unit is second) between the upstream and TiCDC nodes
- Flush sink duration: The histogram of the time spent by TiCDC asynchronously flushing data to the downstream
- Flush sink duration percentile: The time (P95, P99, and P999) spent by TiCDC asynchronously flushing data to the downstream within one second
- Sink write duration: The histogram of the time spent by TiCDC writing a transaction change to the downstream
- Sink write duration percentile: The time (P95, P99, and P999) spent by TiCDC writing a transaction change to the downstream within one second
- MySQL sink conflict detect duration: The histogram of the time spent on detecting MySQL sink conflicts
- MySQL sink conflict detect duration percentile: The time (P95, P99, and P999) spent on detecting MySQL sink conflicts within one second
- MySQL sink worker load: The workload of MySQL sink workers of TiCDC nodes

11.10.5.3 Events

The following is an example of the **Events** panel:



The description of each metric in the **Events** panel is as follows:



- Eventfeed count: The number of Eventfeed RPC requests of TiCDC nodes
- Event size percentile: The event size (P95, P99, and P999) which TiCDC receives from TiKV within one second
- Eventfeed error/m: The number of errors reported by Eventfeed RPC requests of TiCDC nodes per minute
- KV client receive events/s: The number of events that the KV client module of TiCDC nodes receives from TiKV per second

- Puller receive events/s: The number of events that the Puller module of TiCDC nodes receives from the KV client per second
- Puller output events/s: The number of events that the Puller module of TiCDC nodes sends to the Sorter module per second
- Sink flush rows/s: The number of events that TiCDC nodes write to the downstream per second
- Puller buffer size: The number of events that TiCDC nodes cache in the Puller module
- Entry sorter buffer size: The number of events that TiCDC nodes cache in the Sorter module
- Processor/Mounter buffer size: The number of events that TiCDC nodes cache in the Processor module and the Mounter module
- Sink row buffer size: The number of events that TiCDC nodes cache in the Sink module
- Entry sorter sort duration: The histogram of the time spent by TiCDC nodes sorting events
- Entry sorter sort duration percentile: The time (P95, P99, and P999) spent by TiCDC sorting events within one second
- Entry sorter merge duration: The histogram of the time spent by TiCDC nodes merging sorted events
- Entry sorter merge duration percentile: The time (P95, P99, and P999) spent by TiCDC merging sorted events within one second
- Mounter unmarshal duration: The histogram of the time spent by TiCDC nodes unmarshaling events
- Mounter unmarshal duration percentile: The time (P95, P99, and P999) spent by TiCDC unmarshaling events within one second
- KV client dispatch events/s: The number of events that the KV client module dispatches among the TiCDC nodes
- KV client batch resolved size: The batch size of resolved timestamp messages that TiKV sends to TiCDC

11.10.5.4 TiKV

The following is an example of the **TiKV** panel:

The description of each metric in the **TiKV** panel is as follows:

- CDC endpoint CPU: The CPU usage of the CDC endpoint threads on TiKV nodes
- CDC worker CPU: The CPU usage of the CDC worker threads on TiKV nodes
- Min resolved ts: The minimum resolved timestamp on TiKV nodes
- Min resolved region: The Region ID of the minimum resolved timestamp on TiKV nodes
- Resolved ts lag duration percentile: The lag between the minimum resolved timestamp on TiKV nodes and the current time
- Initial scan duration: The histogram of the time spent on incremental scan when TiKV nodes connect to TiCDC nodes
- Initial scan duration percentile: The time (P95, P99, and P999) spent on the incremental scan of TiKV nodes within one second
- Memory without block cache: The memory usage of TiKV nodes excluding the RocksDB block cache
- CDC pending bytes in memory: The memory usage of CDC module on TiKV nodes
- Captured region count: The number of event-capturing Regions on TiKV nodes

11.10.6 TiCDC Alert Rules

This document describes the TiCDC alert rules and the corresponding solutions. In descending order, the severity levels are: **Critical**, **Warning**.

11.10.6.1 Critical alerts

This section introduces critical alerts and solutions.

11.10.6.1.1 `cdc_checkpoint_high_delay`

For critical alerts, you need to pay close attention to abnormal monitoring metrics.

- Alert rule:
  (time() - ticdc_processor_checkpoint_ts / 1000) > 600
- Description:
  A replication task is delayed more than 10 minutes.
- Solution:
  See TiCDC Handle Replication Interruption.

11.10.6.2 `cdc_resolvedts_high_delay`

- Alert rule:
  (time() - ticdc_processor_resolved_ts / 1000) > 300
- Description:
  The Resolved TS of a replication task is delayed more than 5 minutes.
- Solution:
  See TiCDC Handle Replication Interruption.

11.10.6.2.1 `ticdc_processor_exit_with_error_count`

- Alert rule:
  `changes(ticdc_processor_exit_with_error_count[1m])> 0`
- Description:
  A replication task reports an error and exits.
- Solution:
  See TiCDC Handle Replication Interruption.

11.10.6.3 Warning alerts

Warning alerts are a reminder for an issue or error.

11.10.6.3.1 `cdc_multiple_owners`

- Alert rule:
  `sum(rate(ticdc_owner_ownership_counter[30s]))>= 2`
- Description:
  There are multiple owners in the TiCDC cluster.
- Solution:
  Collect TiCDC logs to locate the root cause.

11.10.6.3.2 ticdc_mounter_unmarshal_and_mount_time_more_than_1s

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_mounter_unmarshal_and_mount_bucket[1m
↪ ]))* 1000 > 1000
```

- Description:

  It takes a replication task more than 1 second to unmarshal the data changes.

- Solution:

  Collect TiCDC logs to locate the root cause.

11.10.6.3.3 cdc_sink_execute_duration_time_more_than_10s

- Alert rule:

  ```
  histogram_quantile(0.9, rate(ticdc_sink_txn_exec_duration_bucket[1m]))>
  ↪  10
  ```

- Description:

  It takes a replication task more than 10 seconds to write data to the downstream database.

- Solution:

  Check whether there are problems in the downstream database.

11.10.6.3.4 cdc_processor_checkpoint_tso_no_change_for_1m

- Alert rule:

  ```
  changes(ticdc_processor_checkpoint_ts[1m])< 1
  ```

- Description:

  A replication task has not advanced for more than 1 minute.

- Solution:

  See TiCDC Handle Replication Interruption.

11.10.6.3.5 ticdc_puller_entry_sorter_sort_bucket

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_sort_bucket{}[1m
↪ ]))> 1
```

- Description:

  The delay of TiCDC puller entry sorter is too high.

- Solution:

  Collect TiCDC logs to locate the root cause.

11.10.6.3.6 ticdc_puller_entry_sorter_merge_bucket

- Alert rule:

```
histogram_quantile(0.9, rate(ticdc_puller_entry_sorter_merge_bucket{}[1
↪ m]))> 1
```

- Description:

  The delay of TiCDC puller entry sorter merge is too high.

- Solution:

  Collect TiCDC logs to locate the root cause.

11.10.6.3.7 tikv_cdc_min_resolved_ts_no_change_for_1m

- Alert rule:

```
changes(tikv_cdc_min_resolved_ts[1m])< 1 and ON (instance)tikv_cdc_region_resolve_s
↪ {status="resolved"} > 0
```

- Description:

  The minimum Resolved TS 1 of TiKV CDC has not advanced for 1 minute.

- Solution:

  Collect TiKV logs to locate the root cause.

11.10.6.3.8 tikv_cdc_scan_duration_seconds_more_than_10min

- Alert rule:

  ```
  histogram_quantile(0.9, rate(tikv_cdc_scan_duration_seconds_bucket{}[1m
  ↪ ]))> 600
  ```

- Description:

  The TiKV CDC module has scanned for incremental replication for more than 10 minutes.

- Solution:

  Collect TiCDC monitoring metrics and TiKV logs to locate the root cause.

11.10.6.3.9 ticdc_sink_mysql_execution_error

- Alert rule:

  ```
  changes(ticdc_sink_mysql_execution_error[1m])> 0
  ```

- Description:

  An error occurs when a replication task writes data to the downstream MySQL.

- Solution:

  There are many possible root causes. See Troubleshoot TiCDC.

11.10.6.3.10 ticdc_memory_abnormal

- Alert rule:

  ```
  go_memstats_heap_alloc_bytes{job="ticdc"} > 1e+10
  ```

- Description:

  The TiCDC heap memory usage exceeds 10 GiB.

- Solution:

  Collect TiCDC logs to locate the root cause.

11.10.7 TiCDC Open Protocol

TiCDC Open Protocol is a row-level data change notification protocol that provides data sources for monitoring, caching, full-text indexing, analysis engines, and primary-secondary replication between different databases. TiCDC complies with TiCDC Open Protocol and replicates data changes of TiDB to third-party data medium such as MQ (Message Queue).

TiCDC Open Protocol uses Event as the basic unit to replicate data change events to the downstream. The Event is divided into three categories:

- Row Changed Event: Represents the data change in a row. When a row is changed, this Event is sent and contains information about the changed row.
- DDL Event: Represents the DDL change. This Event is sent after a DDL statement is successfully executed in the upstream. The DDL Event is broadcasted to every MQ Partition.
- Resolved Event: Represents a special time point before which the Event received is complete.

11.10.7.1 Restrictions

- In most cases, the Row Changed Event of a version is sent only once, but in special situations such as node failure and network partition, the Row Changed Event of the same version might be sent multiple times.
- On the same table, the Row Changed Events of each version which is first sent are incremented in the order of timestamps (TS) in the Event stream.
- Resolved Events are periodically broadcasted to each MQ Partition. The Resolved Event means that any Event with a TS earlier than Resolved Event TS has been sent to the downstream.
- DDL Events are broadcasted to each MQ Partition.
- Multiple Row Changed Events of a row are sent to the same MQ Partition.

11.10.7.2 Message format

A Message contains one or more Events, arranged in the following format:

Key:

Offset(Byte)	0~7	8~15	16~(15+length1)	...	...
Parameter	Protocol version	Length1	Event Key1	LengthN	Event KeyN

Value:

Offset(Byte)	0~7	8~(7+length1)	...	...
Parameter	Length1	Event Value1	LengthN	Event ValueN

- `LengthN` represents the length of the `N`th key/value.
- The length and protocol version are the big-endian `int64` type.
- The version of the current protocol is `1`.

11.10.7.3 Event format

This section introduces the formats of Row Changed Event, DDL Event, and Resolved Event.

11.10.7.3.1 Row Changed Event

- **Key:**

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":1
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that causes the row change.
Schema Name	String	The name of the schema where the row is in.
Table Name	String	The name of the table where the row is in.

- **Value:**

`Insert` event. The newly added row data is output.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

`Update` event. The newly added row data ("u") and the row data before the update ("p") are output. The latter ("p") is output only when the old value feature is enabled.

```
{
    "u":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    },
    "p":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

`Delete` event. The deleted row data is output. When the old value feature is enabled, the `Delete` event includes all the columns of the deleted row data; when this feature is disabled, the `Delete` event only includes the HandleKey column.

```
{
    "d":{
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
```

```
            "v":<Column Value>
        },
        <Column Name>:{
            "t":<Column Type>,
            "h":<Where Handle>,
            "f":<Flag>,
            "v":<Column Value>
        }
    }
}
```

Parameter	Type	Description
Column Name	String	The column name.
Column Type	Number	The column type. For details, see Column Type Code.
Where Handle	Boolean	Determines whether this column can be the filter condition of the `Where` clause. When this column is unique on the table, `Where Handle` is `true`.
Flag	Number	The bit flags of columns. For details, see Bit flags of columns.
Column Value	Any	The Column value.

11.10.7.3.2 DDL Event

- **Key:**

```
{
    "ts":<TS>,
    "scm":<Schema Name>,
    "tbl":<Table Name>,
    "t":2
}
```

Parameter	Type	Description
TS	Number	The timestamp of the transaction that performs the DDL change.
Schema Name	String	The schema name of the DDL change, which might be an empty string.
Table Name	String	The table name of the DDL change, which might be am empty string.

- **Value:**

```
{
    "q":<DDL Query>,
    "t":<DDL Type>
}
```

Parameter	Type	Description
DDL Query	String	DDL Query SQL
DDL Type	String	The DDL type. For details, see DDL Type Code.

11.10.7.3.3 Resolved Event

- **Key:**

```
{
    "ts":<TS>,
    "t":3
}
```

Parameter	Type	Description
TS	Number	The Resolved timestamp. Any TS earlier than this Event has been sent.

- **Value:** None

11.10.7.4 Examples of the Event stream output

This section shows and displays the output logs of the Event stream.

Suppose that you execute the following SQL statement in the upstream and the MQ Partition number is 2:

```
CREATE TABLE test.t1(id int primary key, val varchar(16));
```

From the following Log 1 and Log 3, you can see that the DDL Event is broadcasted to all MQ Partitions, and that the Resolved Event is periodically broadcasted to each MQ Partition.

```
1. [partition=0] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
2. [partition=0] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
3. [partition=1] [key="{\"ts\":415508856908021766,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":2}"] [value="{\"q\":\"CREATE TABLE test.t1(id int
   ↪ primary key, val varchar(16))\",\"t\":3}"]
4. [partition=1] [key="{\"ts\":415508856908021766,\"t\":3}"] [value=]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
INSERT INTO test.t1(id, val) VALUES (1, 'aa');
INSERT INTO test.t1(id, val) VALUES (2, 'aa');
UPDATE test.t1 SET val = 'bb' WHERE id = 2;
INSERT INTO test.t1(id, val) VALUES (3, 'cc');
COMMIT;
```

- From the following Log 5 and Log 6, you can see that Row Changed Events on the same table might be sent to different partitions based on the primary key, but changes to the same row are sent to the same partition so that the downstream can easily process the Event concurrently.
- From Log 6, multiple changes to the same row in a transaction are only sent in one Row Changed Event.
- Log 8 is a repeated event of Log 7. Row Changed Event might be repeated, but the first Event of each version is sent orderly.

```
5. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":1},\"val\":{\"t\":15,\"v\":\"YWE=\"}}}"]
6. [partition=1] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":2},\"val\":{\"t\":15,\"v\":\"YmI=\"}}}"]
7. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"Y2M=\"}}}"]
8. [partition=0] [key="{\"ts\":415508878783938562,\"scm\":\"test\",\"tbl
   ↪ \":\"t1\",\"t\":1}"] [value="{\"u\":{\"id\":{\"t\":3,\"h\":true,\"v
   ↪ \":3},\"val\":{\"t\":15,\"v\":\"Y2M=\"}}}"]
```

Execute the following SQL statements in the upstream:

```
BEGIN;
DELETE FROM test.t1 WHERE id = 1;
UPDATE test.t1 SET val = 'dd' WHERE id = 3;
UPDATE test.t1 SET id = 4, val = 'ee' WHERE id = 2;
COMMIT;
```

- Log 9 is the Row Changed Event of the `Delete` type. This type of Event only contains primary key columns or unique index columns.
- Log 13 and Log 14 are Resolved Events. The Resolved Event means that in this Partition, any events smaller than the Resolved TS (including Row Changed Event and DDL Event) have been sent.

```

11.10.7.5 Protocol parsing for consumers

Currently, TiCDC does not provide the standard parsing library for TiCDC Open Protocol, but the Golang version and Java version of parsing demonstrations are provided. You can refer to the data format provided in this document and the following demonstrations to implement the protocol parsing for consumers.

- Golang demo
- Java demo

11.10.7.6 Column type code

`Column Type Code` represents the column data type of the Row Changed Event.

Type	Code	Output Example	Description
TINYINT/BOOLEAN	1	{“t”:1,“v”:1}	
SMALLINT	2	{“t”:2,“v”:1}	
INT	3	{“t”:3,“v”:123}	
FLOAT	4	{“t”:4,“v”:153.123}	
DOUBLE	5	{“t”:5,“v”:153.123}	
NULL	6	{“t”:6,“v”:null}	
TIMESTAMP	7	{“t”:7,“v”:“1973-12-30 15:30:00”}	
BIGINT	8	{“t”:8,“v”:123}	
MEDIUMINT	9	{“t”:9,“v”:123}	
DATE	10/14	{“t”:10,“v”:“2000-01-01”}	
TIME	11	{“t”:11,“v”:“23:59:59”}	
DATETIME	12	{“t”:12,“v”:“2015-12-20 23:58:58”}	
YEAR	13	{“t”:13,“v”:1970}	

Type	Code	Output Example	Description
VARCHAR/VARBINARY	15/253	{“t”:15,“v”:“test”} / {“t”:15,“v”:“\\x89PNG\\r\\n\\x1a\\n”}	The value is encoded in UTF-8. When the upstream type is VARBINARY, invisible characters are escaped.
BIT	16	{“t”:16,“v”:81}	
JSON	245	{“t”:245,“v”:“{\”key1\“:\”value1\“}”}	
DECIMAL	246	{“t”:246,“v”:“129012.1230000”}	
ENUM	247	{“t”:247,“v”:1}	
SET	248	{“t”:248,“v”:3}	
TINYTEXT/TINYBLOB	249	{“t”:249,“v”:“Trie5rWL6K+VdGV4dA==”}	The value is encoded in Base64.

Type	Code	Output Example	Description
MEDIUMTEXT/MEDIUMBLOB	250	{“t”:250,“v”:“T2hlcrWL6K+VdGV4dA==”}	The value is encoded in Base64.
LONGTEXT/LONGBLOB	251	{“t”:251,“v”:“T2hlcrWL6K+VdGV4dA==”}	The value is encoded in Base64.
TEXT/BLOB	252	{“t”:252,“v”:“T2hlcrWL6K+VdGV4dA==”}	The value is encoded in Base64.

Type	Code	Output Example	Description
CHAR/BINARY	254	{“t”:254,“v”:“Test”} / {“t”:254,“v”:“\\x89PNG\\r\\n\\x1a\\n”}	The value encoded in UTF-8. When the upstream type is BINARY, invisible characters are escaped.
GEOMETRY	255		Unsupported

11.10.7.7 DDL Type Code

`DDL Type Code` represents the DDL statement type of the DDL Event.

Type	Code
Create Schema	1
Drop Schema	2
Create Table	3
Drop Table	4
Add Column	5
Drop Column	6
Add Index	7
Drop Index	8
Add Foreign Key	9

Type	Code
Drop Foreign Key	10
Truncate Table	11
Modify Column	12
Rebase Auto ID	13
Rename Table	14
Set Default Value	15
Shard RowID	16
Modify Table Comment	17
Rename Index	18
Add Table Partition	19
Drop Table Partition	20
Create View	21
Modify Table Charset And Collate	22
Truncate Table Partition	23
Drop View	24
Recover Table	25
Modify Schema Charset And Collate	26
Lock Table	27
Unlock Table	28
Repair Table	29
Set TiFlash Replica	30
Update TiFlash Replica Status	31
Add Primary Key	32
Drop Primary Key	33
Create Sequence	34
Alter Sequence	35
Drop Sequence	36

11.10.7.8 Bit flags of columns

The bit flags represent specific attributes of columns.

Bit	Value	Name	Description
1	0x01	BinaryFlag	Whether the column is a binary-encoded column.
2	0x02	HandleKeyFlag	Whether the column is a Handle index column.
3	0x04	GeneratedColumnFlag	Whether the column is a generated column.
4	0x08	PrimaryKeyFlag	Whether the column is a primary key column.
5	0x10	UniqueKeyFlag	Whether the column is a unique index column.
6	0x20	MultipleKeyFlag	Whether the column is a composite index column.
7	0x40	NullableFlag	Whether the column is a nullable column.
8	0x80	UnsignedFlag	Whether the column is an unsigned column.

Example:

If the value of a column flag is `85`, the column is a nullable column, a unique index column, a generated column, and a binary-encoded column.

```
85 == 0b_101_0101
   == NullableFlag | UniqueKeyFlag | GeneratedColumnFlag | BinaryFlag
```

If the value of a column is `46`, the column is a composite index column, a primary key column, a generated column, and a Handle key column.

```
46 == 0b_010_1110
   == MultipleKeyFlag | PrimaryKeyFlag | GeneratedColumnFlag | HandleKeyFlag
```

Note:

- `BinaryFlag` is meaningful only when the column type is BLOB/TEXT (including TINYBLOB/TINYTEXT and BINARY/CHAR). When the upstream column is the BLOB type, the `BinaryFlag` value is set to `1`. When the upstream column is the TEXT type, the `BinaryFlag` value is set to `0`.
- To replicate a table from the upstream, TiCDC selects a valid index as the Handle index. The `HandleKeyFlag` value of the Handle index column is set to `1`.

11.10.8 Quick Start Guide on Integrating TiDB with Confluent Platform

This document introduces how to integrate TiDB to Confluent Platform using TiCDC.

Warning:

This is still an experimental feature. Do **NOT** use it in a production environment.

Confluent Platform is a data streaming platform with Apache Kafka at its core. With many official and third-party sink connectors, Confluent Platform enables you to easily connect stream sources to relational or non-relational databases.

To integrate TiDB with Confluent Platform, you can use the TiCDC component with the Avro protocol. TiCDC can stream data changes to Kafka in the format that Confluent Platform recognizes. For the detailed integration guide, see the following sections:

11.10.8.1 Prerequisites

> **Note:**
>
> In this tutorial, the JDBC sink connector is used to replicate TiDB data to a downstream relational database. To make it simple, **SQLite** is used here as an example.

- Make sure that Zookeeper, Kafka, and Schema Registry are properly installed. It is recommended that you follow the Confluent Platform Quick Start Guide to deploy a local test environment.
- Make sure that JDBC sink connector is installed by running the following command. The result should contain `jdbc-sink`.

```
confluent local services connect connector list
```

11.10.8.2 Integration procedures

1. Save the following configuration into `jdbc-sink-connector.json`:

```
{
  "name": "jdbc-sink-connector",
  "config": {
    "connector.class": "io.confluent.connect.jdbc.JdbcSinkConnector",
    "tasks.max": "1",
    "topics": "testdb_test",
    "connection.url": "jdbc:sqlite:/tmp/test.db",
    "connection.ds.pool.size": 5,
    "table.name.format": "test",
    "auto.create": true,
    "auto.evolve": true
  }
}
```

2. Create an instance of the JDBC sink connector by running the following command (assuming Kafka is listening on `127.0.0.1:8083`):

```
curl -X POST -H "Content-Type: application/json" -d @jdbc-sink-
   ↪ connector.json http://127.0.0.1:8083/connectors
```

3. Deploy TiCDC in one of the following ways. If TiCDC is already deployed, you can skip this step.

    - Deploy a new TiDB cluster that includes TiCDC using TiUP
    - Add TiCDC to an existing TiDB cluster using TiUP
    - Add TiCDC to an existing TiDB cluster using binary (not recommended)

    Make sure that your TiDB and TiCDC clusters are healthy before proceeding.

4. Create a `changefeed` by running the `cdc cli` command:

```
./cdc cli changefeed create --pd="http://127.0.0.1:2379" --sink-uri="
    ↪ kafka://127.0.0.1:9092/testdb_test?protocol=avro" --opts "
    ↪ registry=http://127.0.0.1:8081"
```

> **Note:**
> Make sure that PD, Kafka, and Schema Registry are running on their respective default ports.

11.10.8.3 Test data replication

After TiDB is integrated with Confluent Platform, you can follow the example procedures below to test the data replication.

1. Create the `testdb` database in your TiDB cluster:

```
CREATE DATABASE IF NOT EXISTS testdb;
```

    Create the `test` table in `testdb`:

```
USE testdb;
CREATE TABLE test (
    id INT PRIMARY KEY,
    v TEXT
);
```

> **Note:**
> If you need to change the database name or the table name, change `topics` in `jdbc-sink-connector.json` accordingly.

2. Insert data into TiDB:

```
INSERT INTO test (id, v) values (1, 'a');
INSERT INTO test (id, v) values (2, 'b');
INSERT INTO test (id, v) values (3, 'c');
INSERT INTO test (id, v) values (4, 'd');
```

3. Wait a moment for data to be replicated to the downstream. Then check the downstream for data:

```
sqlite3 test.db
sqlite> SELECT * from test;
```

11.10.9 TiCDC Glossary

This glossary provides TiCDC-related terms and definitions. These terms appears in TiCDC logs, monitoring metrics, configurations, and documents.

For TiDB-related terms and definitions, refer to TiDB glossary.

11.10.9.1 C

11.10.9.1.1 Capture

A single TiCDC instance on which the replication task of the cluster runs. Multiple captures form a TiCDC cluster.

11.10.9.1.2 Changed data

The data to be written to TiCDC from the upstream TiDB cluster, including the DML-caused data changes and the DDL-caused table schema changes.

11.10.9.1.3 Changefeed

An incremental replication task in TiCDC, which outputs the data change logs of several tables in a TiDB cluster to the designated downstream.

11.10.9.2 O

11.10.9.2.1 Owner

A capture of a special role that manages the TiCDC cluster and schedules replication tasks of the cluster. An owner is elected by captures and there is at most one owner at any time.

11.10.9.3 P

11.10.9.3.1 Processor

TiCDC replication tasks allocate data tables on TiCDC instances, and the processor refers to the replication processing unit of these tables. Processor tasks include pulling, sorting, restoring, and distributing changed data.

11.11 Use Dumpling to Export Data

This document introduces the data export tool - Dumpling. Dumpling exports data stored in TiDB/MySQL as SQL or CSV data files and can be used to make a logical full backup or export. Dumpling also supports exporting data to Amazon S3.

You can get Dumpling using TiUP by running `tiup install dumpling`. Afterwards, you can use `tiup dumpling ...` to run Dumpling.

Dumpling is also included in the tidb-toolkit installation package and can be download here.

For detailed usage of Dumpling, use the `--help` option or refer to Option list of Dumpling.

When using Dumpling, you need to execute the export command on a running cluster.

TiDB also provides other tools that you can choose to use as needed.

- For backups of SST files (key-value pairs) or backups of incremental data that are not sensitive to latency, refer to BR.
- For real-time backups of incremental data, refer to TiCDC.
- All exported data can be imported back to TiDB using TiDB Lightning.

> **Note:**
>
> PingCAP previously maintained a fork of the mydumper project with enhancements specific to TiDB. For more information on Mydumper, refer to v4.0 Mydumper documentation. Starting from v7.5.0, Mydumper is deprecated and most of its features have been replaced by Dumpling. It is strongly recommended that you use Dumpling instead of Mydumper.

Compared to Mydumper, Dumpling has the following improvements:

- Support exporting data in multiple formats, including SQL and CSV.
- Support the table-filter feature, which makes it easier to filter data.
- Support exporting data to Amazon S3 cloud storage.
- More optimizations are made for TiDB:

- Support configuring the memory limit of a single TiDB SQL statement.
- Support automatic adjustment of TiDB GC time for TiDB v4.0.0 and later versions.
- Use TiDB's hidden column `_tidb_rowid` to optimize the performance of concurrent data export from a single table.
- For TiDB, you can set the value of `tidb_snapshot` to specify the time point of the data backup. This ensures the consistency of the backup, instead of using `FLUSH TABLES WITH READ LOCK` to ensure the consistency.

11.11.1 Export data from TiDB or MySQL

11.11.1.1 Required privileges

- SELECT
- RELOAD
- LOCK TABLES
- REPLICATION CLIENT
- PROCESS

11.11.1.2 Export to SQL files

This document assumes that there is a TiDB instance on the 127.0.0.1:4000 host and that this TiDB instance has a root user without a password.

Dumpling exports data to SQL files by default. You can also export data to SQL files by adding the `--filetype sql` flag:

```
dumpling \
  -u root \
  -P 4000 \
  -h 127.0.0.1 \
  --filetype sql \
  --t 8 \
  -o /tmp/test \
  -r 200000 \
  -F 256MiB
```

In the command above:

- The `-h`, `-p`, and `-u` option respectively mean the address, the port, and the user. If a password is required for authentication, you can use `-p $YOUR_SECRET_PASSWORD` to pass the password to Dumpling.
- The `-o` option specifies the export directory of the storage, which supports a local file path or a URL of an external storage.

- The `t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large.
- The `-r` option specifies the maximum number of rows in a single file. With this option specified, Dumpling enables the in-table concurrency to speed up the export and reduce the memory usage.
- The `-F` option is used to specify the maximum size of a single file (the unit here is `MiB`; inputs like `5GiB` or `8KB` are also acceptable). It is recommended to keep its value to 256 MiB or less if you plan to use TiDB Lightning to load this file into a TiDB instance.

> **Note:**
>
> If the size of a single exported table exceeds 10 GB, it is **strongly recommended to use** the `-r` and `-F` options.

11.11.1.3 Export to CSV files

If Dumpling exports data to CSV files (use `--filetype csv` to export to CSV files), you can also use `--sql <SQL>` to export the records selected by the specified SQL statement.

For example, you can export all records that match `id < 100` in `test.sbtest1` using the following command:

```
./dumpling \
  -u root \
  -P 4000 \
  -h 127.0.0.1 \
  -o /tmp/test \
  --filetype csv \
  --sql 'select * from `test`.`sbtest1` where id < 100'
```

> **Note:**
>
> - Currently, the `--sql` option can be used only for exporting to CSV files.
> - Here you need to execute the `select * from <table-name> where id <100` statement on all tables to be exported. If some tables do not have specified fields, the export fails.
> - Strings and keywords are not distinguished in CSV files. If the imported data is the Boolean type, you need to convert `true` and `false` to `1` and `0`.

11.11.1.4 Format of exported files

- `metadata`: The start time of the exported files and the position of the master binary log.

```
cat metadata
```

```
Started dump at: 2020-11-10 10:40:19
SHOW MASTER STATUS:
       Log: tidb-binlog
       Pos: 420747102018863124
Finished dump at: 2020-11-10 10:40:20
```

- `{schema}-schema-create.sql`: The SQL file used to create the schema

```
cat test-schema-create.sql
```

```
CREATE DATABASE `test` /*!40100 DEFAULT CHARACTER SET utf8mb4 */;
```

- `{schema}.{table}-schema.sql`: The SQL file used to create the table

```
cat test.t1-schema.sql
```

```
CREATE TABLE `t1` (
  `id` int(11) DEFAULT NULL
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin;
```

- `{schema}.{table}.{0001}.{sql|csv}`: The date source file

```
cat test.t1.0.sql
```

```
/*!40101 SET NAMES binary*/;
INSERT INTO `t1` VALUES
(1);
```

- `*-schema-view.sql`、`*-schema-trigger.sql`、`*-schema-post.sql`: Other exported files

11.11.1.5 Export data to Amazon S3 cloud storage

Starting from v4.0.8, Dumpling supports exporting data to cloud storages. If you need to back up data to Amazon S3, you need to specify the Amazon S3 storage path in the `-o` parameter.

You need to create an Amazon S3 bucket in the specified region (see the Amazon documentation - How do I create an S3 Bucket). If you also need to create a folder in the bucket, see the Amazon documentation - Creating a folder.

Pass `SecretKey` and `AccessKey` of the account with the permission to access the Amazon S3 backend storage to the Dumpling node as environment variables.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

Dumpling also supports reading credential files from `~/.aws/credentials`. For more Dumpling configuration, see the configuration of External storages.

When you back up data using Dumpling, explicitly specify the `--s3.region` parameter, which means the region of the S3 storage (for example, `ap-northeast-1`):

```
./dumpling \
  -u root \
  -P 4000 \
  -h 127.0.0.1 \
  -r 200000 \
  -o "s3://${Bucket}/${Folder}" \
  --s3.region "${region}"
```

11.11.1.6 Filter the exported data

11.11.1.6.1 Use the `--where` option to filter data

By default, Dumpling exports all databases except system databases (including `mysql`, `sys`, `INFORMATION_SCHEMA`, `PERFORMANCE_SCHEMA`, `METRICS_SCHEMA`, and `INSPECTION_SCHEMA`). You can use `--where <SQL where expression>` to select the records to be exported.

```
./dumpling \
  -u root \
  -P 4000 \
  -h 127.0.0.1 \
  -o /tmp/test \
  --where "id < 100"
```

The above command exports the data that matches `id < 100` from each table. Note that you cannot use the `--where` parameter together with `--sql`.

11.11.1.6.2 Use the `--filter` option to filter data

Dumpling can filter specific databases or tables by specifying the table filter with the `--filter` option. The syntax of table filters is similar to that of `.gitignore`. For details, see Table Filter.

```
./dumpling \
  -u root \
```

```
-P 4000 \
-h 127.0.0.1 \
-o /tmp/test \
-r 200000 \
--filter "employees.*" \
--filter "*.WorkOrder"
```

The above command exports all the tables in the `employees` database and the `WorkOrder` tables in all databases.

11.11.1.6.3 Use the `-B` or `-T` option to filter data

Dumpling can also export specific databases with the `-B` option or specific tables with the `-T` option.

> **Note:**
>
> - The `--filter` option and the `-T` option cannot be used at the same time.
> - The `-T` option can only accept a complete form of inputs like `database -name.table-name`, and inputs with only the table name are not accepted. Example: Dumpling cannot recognize `-T WorkOrder`.

Examples:

- `-B employees` exports the `employees` database.
- `-T employees.WorkOrder` exports the `employees.WorkOrder` table.

11.11.1.7 Improve export efficiency through concurrency

The exported file is stored in the `./export-<current local time>` directory by default. Commonly used options are as follows:

- The `t` option specifies the number of threads for the export. Increasing the number of threads improves the concurrency of Dumpling and the export speed, and also increases the database's memory consumption. Therefore, it is not recommended to set the number too large.
- The `-r` option specifies the maximum number of records (or the number of rows in the database) for a single file. When it is enabled, Dumpling enables concurrency in the table to improve the speed of exporting large tables.

- The `--compress gzip` option can be used to compress the dump. This can help to speed up dumping of data if storage is the bottleneck or if storage capacity is a concern. The drawback of this is an increase in CPU usage. Each file is compressed individually.

With the above options specified, Dumpling can have a quicker speed of data export.

11.11.1.8 Adjust Dumpling's data consistency options

> **Note:**
>
> The default value is `auto` for the data consistency option. In most scenarios, you do not need to adjust the default data consistency options of Dumpling.

Dumpling uses the `--consistency <consistency level>` option to control the way in which data is exported for "consistency assurance". For TiDB, data consistency is guaranteed by getting a snapshot of a certain timestamp by default (namely, `--consistency snapshot` ↪). When using snapshot for consistency, you can use the `--snapshot` option to specify the timestamp to be backed up. You can also use the following levels of consistency:

- `flush`: Use `FLUSH TABLES WITH READ LOCK` to temporarily interrupt the DML and DDL operations of the replica database, to ensure the global consistency of the backup connection, and to record the binlog position (POS) information. The lock is released after all backup connections start transactions. It is recommended to perform full backups during off-peak hours or on the MySQL replica database.
- `snapshot`: Get a consistent snapshot of the specified timestamp and export it.
- `lock`: Add read locks on all tables to be exported.
- `none`: No guarantee for consistency.
- `auto`: Use `flush` for MySQL and `snapshot` for TiDB.

After everything is done, you can see the exported file in `/tmp/test`:

```
ls -lh /tmp/test | awk '{print $5 "\t" $9}'
```

```
140B metadata
66B  test-schema-create.sql
300B test.sbtest1-schema.sql
190K test.sbtest1.0.sql
300B test.sbtest2-schema.sql
190K test.sbtest2.0.sql
300B test.sbtest3-schema.sql
190K test.sbtest3.0.sql
```

11.11.1.9 Export historical data snapshots of TiDB

Dumpling can export the data of a certain tidb_snapshot with the `--snapshot` option specified.

The `--snapshot` option can be set to a TSO (the `Position` field output by the `SHOW MASTER STATUS` command) or a valid time of the `datetime` data type (in the form of `YYYY-MM-DD hh:mm:ss`), for example:

```
./dumpling --snapshot 417773951312461825
./dumpling --snapshot "2020-07-02 17:12:45"
```

The TiDB historical data snapshots when the TSO is `417773951312461825` and the time is `2020-07-02 17:12:45` are exported.

11.11.1.10 Control the memory usage of exporting large tables

When Dumpling is exporting a large single table from TiDB, Out of Memory (OOM) might occur because the exported data size is too large, which causes connection abort and export failure. You can use the following parameters to reduce the memory usage of TiDB:

- Setting `-r` to split the data to be exported into chunks. This reduces the memory overhead of TiDB's data scan and enables concurrent table data dump to improve export efficiency.
- Reduce the value of `--tidb-mem-quota-query` to `8589934592` (8 GB) or lower. `--tidb-mem-quota-query` controls the memory usage of a single query statement in TiDB.
- Adjust the `--params "tidb_distsql_scan_concurrency=5"` parameter. tidb_distsql_scan_conc is a session variable which controls the concurrency of the scan operations in TiDB.

11.11.1.11 Set TiDB GC when exporting a large volume of data (more than 1 TB)

When exporting data from TiDB, if the TiDB version is greater than or equal to v4.0.0 and Dumpling can access the PD address of the TiDB cluster, Dumpling automatically extends the GC time without affecting the original cluster.

In other scenarios, if the data size is very large, to avoid export failure due to GC during the export process, you can extend the GC time in advance:

```
SET GLOBAL tidb_gc_life_time = '720h';
```

After your operation is completed, set the GC time back (the default value is `10m`):

```
SET GLOBAL tidb_gc_life_time = '10m';
```

11.11.2 Option list of Dumpling

Options	Usage	Default value
-V or -- ↪ version ↪	Output the Dumpling version and exit directly	
-B or -- ↪ database ↪	Export specified databases	
-T or -- ↪ tables ↪ - ↪ list ↪	Export specified tables	
-f or -- ↪ filter ↪	Export tables that match the filter pattern. For the filter syntax, see table-filter.	[*.*,!/^(↪ mysql ↪ | ↪ sys ↪ | ↪ INFORMATION_SCHEMA ↪ | ↪ PERFORMANCE_SCHEMA ↪ | ↪ METRICS_SCHEMA ↪ | ↪ INSPECTION_SCHEMA ↪)$ ↪ /.*] ↪ (export all databases or tables excluding system schemas)
-- ↪ case ↪ - ↪ sensitive ↪	whether table-filter is case-sensitive	false (case-insensitive)

Options	Usage	Default value
`-h` or `--host`	The IP address of the connected database host	"127.0.0.1"
`-t` or `--threads`	The number of concurrent backup threads	4
`-r` or `--rows`	Divide the table into specified rows of data (generally applicable for concurrent operations of splitting a large table into multiple files.	
`-L` or `--logfile`	Log output address. If it is empty, the log will be output to the console	""
`--loglevel`	Log level {debug,info,warn,error,dpanic,panic,fatal}	"info"
`--logfmt`	Log output format {text,json}	"text"
`-d` or `--no-data`	Do not export data (suitable for scenarios where only the schema is exported)	
`--no-header`	Export CSV files of the tables without generating header	
`-W` or `--no-views`	Do not export the views	true
`-m` or `--no-schemas`	Do not export the schema with only the data exported	

Options	Usage	Default value
`-s` or `--statement-size`	Control the size of the `INSERT` statements; the unit is bytes	
`-F` or `--filesize`	The file size of the divided tables. The unit must be specified such as `128B`, `64KiB`, `32MiB`, and `1.5GiB`.	
`--filetype`	Exported file type (csv/sql)	"sql"
`-o` or `--output`	The path of exported local files or the URL of the external storage	"./export-${time}"
`-S` or `--sql`	Export data according to the specified SQL statement. This command does not support concurrent export.	
`--consistency`	flush: use FTWRL before the dump snapshot: dump the TiDB data if necessary snapshot of a TSO lock: execute `lock tables read` on all tables to be dumped none: dump without adding locks, which cannot guarantee consistency auto: use –consistency flush for MySQL; use –consistency snapshot for TiDB	"auto"
`--snapshot`	Snapshot TSO; valid only when `consistency=snapshot`	
`--where`	Specify the scope of the table backup through the `where` condition	
`-p` or `--password`	The password of the connected database host	
`-P` or `--port`	The port of the connected database host	4000
`-u` or `--user`	The username of the connected database host	"root"

Options	Usage	Default value
--dump-empty-database	Export the CREATE DATABASE statements of the empty databases	true
--ca	The address of the certificate authority file for TLS connection	
--cert	The address of the client certificate file for TLS connection	
--key	The address of the client private key file for TLS connection	
--csv-delimiter	Delimiter of character type variables in CSV files	'"'
--csv-separator	Separator of each value in CSV files. It is not recommended to use the default ','. It is recommended to use '|+|' or other uncommon character combinations	','
--csv-null-value	Representation of null values in CSV files	"\N"
--escape-backslash	Use backslash (\) to escape special characters in the export file	true
--output-filename-template	The filename templates represented in the format of golang template Support the {{.DB}}, {{.Table}}, and {{.Index}} arguments The three arguments represent the database name, table name, and chunk ID of the data file	'{{.DB}}.{{.Table}}.{{.

Options	Usage	Default value
--status-addr	Dumpling's service address, including the address for Prometheus to pull metrics and pprof debugging	":8281"
--tidb-mem-quota-query	The memory limit of exporting SQL statements by a single line of Dumpling command, and the unit is byte. For v4.0.10 or later versions, if you do not set this parameter, TiDB uses the value of the `mem-quota-query` configuration item as the memory limit value by default. For versions earlier than v4.0.10, the parameter value defaults to 32 GB.	34359738368
--params	Specifies the session variable for the connection of the database to be exported. The required format is `"character_set_client=latin1,character_set_connection=latin1"`	

11.12 sync-diff-inspector

11.12.1 sync-diff-inspector User Guide

sync-diff-inspector is a tool used to compare data stored in the databases with the MySQL protocol. For example, it can compare the data in MySQL with that in TiDB, the data in MySQL with that in MySQL, or the data in TiDB with that in TiDB. In addition, you can also use this tool to repair data in the scenario where a small amount of data is inconsistent.

This guide introduces the key features of sync-diff-inspector and describes how to configure and use this tool. To download sync-diff-inspector, use one of the following methods:

- Binary package. Click tidb-community-toolkit-v5.1.4-linux-amd64 to download.
- Docker image. Execute the following command to download:

```
docker pull pingcap/tidb-enterprise-tools
```

11.12.1.1 Key features

- Compare the table schema and data
- Generate the SQL statements used to repair data if the data inconsistency exists
- Support data check for tables with different schema or table names
- Support data check in the sharding scenario
- Support data check for TiDB upstream-downstream clusters

11.12.1.2 Usage of sync-diff-inspector

11.12.1.2.1 Restrictions

- Online check is not supported for data migration between MySQL and TiDB. Ensure that no data is written into the upstream-downstream checklist, and that data in a certain range is not changed. You can check data in this range by setting `range`.
- Data of the `JSON` type is not supported. When you perform a data check, you need to set `ignore-columns` to skip checking this type of data.
- In TiDB and MySQL, `FLOAT`, `DOUBLE` and other floating-point types are implemented differently, so checksum might be calculated differently. If the data checks are inconsistent due to these data types, set `ignore-columns` to skip checking these columns.
- Support checking tables that do not contain the primary key or the unique index. However, if data is inconsistent, the generated SQL statements might not be able to repair the data correctly.

11.12.1.2.2 Database privilege

sync-diff-inspector needs to obtain the information of table schema, to query data, and to build the `checkpoint` database to save breakpoint information. The required database privileges are as follows:

- Upstream database
  - `SELECT` (checks data for comparison)
  - `SHOW_DATABASES` (views database name)
  - `RELOAD` (views table schema)
- Downstream database
  - `SELECT` (checks data for comparison)
  - `CREATE` (creates the `checkpoint` database and tables)
  - `DELETE` (deletes information in the `checkpoint` table)
  - `INSERT` (writes data into the `checkpoint` table)
  - `UPDATE` (modifies the `checkpoint` table)
  - `SHOW_DATABASES` (views database name)
  - `RELOAD` (views table schema)

11.12.1.2.3 Configuration file description

The configuration of sync-diff-inspector consists of three parts:

- `Global config`: General configurations, including log level, chunk size, number of threads to check.

- `Tables config`: Configures the tables for checking. If some tables have a certain mapping relationship between the upstream and downstream databases or have some special requirements, you must configure these tables.
- `Databases config`: Configures the instances of the upstream and downstream databases.

Below is the description of a complete configuration file:

```
### Diff Configuration.

########################### Global config ###########################

### The log level. You can set it to "info" or "debug".
log-level = "info"

### sync-diff-inspector divides the data into multiple chunks based on the
    ↪ primary key,
### unique key, or the index, and then compares the data of each chunk.
### Uses "chunk-size" to set the size of a chunk.
chunk-size = 1000

### The number of goroutines created to check data
check-thread-count = 4

### The proportion of sampling check. If you set it to 100, all the data is
    ↪ checked.
sample-percent = 100

### If enabled, the chunk's checksum is calculated and data is compared by
    ↪ checksum.
### If disabled, data is compared line by line.
use-checksum = true

### If it is set to true, data is checked only by calculating checksum. Data
    ↪  is not checked after inspection, even if the upstream and downstream
    ↪  checksums are inconsistent.
only-use-checksum = false

### Whether to use the checkpoint of the last check. If it is enabled, the
    ↪ inspector only checks the last unverified chunks and chunks that
    ↪ failed the verification.
use-checkpoint = true

### If it is set to true, data check is ignored.
### If it is set to false, data is checked.
```

```
ignore-data-check = false

### If it is set to true, the table struct comparison is ignored.
### If set to false, the table struct is compared.
ignore-struct-check = false

### The name of the file which saves the SQL statements used to repair data
fix-sql-file = "fix.sql"

############################ Tables config #########################

### To compare the data of a large number of tables with different schema
    ↪ names or table names, or check the data of multiple upstream sharded
    ↪ tables and downstream table family, use the table-rule to configure
    ↪ the mapping relationship. You can configure the mapping rule only for
    ↪  the schema or table. Also, you can configure the mapping rules for
    ↪ both the schema and the table.
#[[table-rules]]
    # schema-pattern and table-pattern support the wildcard *?
    # schema-pattern = "test_*"
    # table-pattern = "t_*"
    # target-schema = "test"
    # target-table = "t"

### Configures the tables of the target database that need to be compared.
[[check-tables]]
    # The name of the schema in the target database
    schema = "test"

    # The list of tables that need to be checked in the target database
    tables = ["test1", "test2", "test3"]

    # Supports using regular expressions to configure tables to be checked.
    # You need to start with '~'. For example, the following configuration
       ↪ checks
    # all the tables with the prefix 'test' in the table name.
    # tables = ["~^test.*"]
    # The following configuration checks all the tables in the database.
    # tables = ["~^"]

### Special configuration for some tables
### The configured table must be included in "check-tables'.
[[table-config]]
    # The name of the schema in the target database
    schema = "test"
```

```
    # The table name
    table = "test3"

    # Specifies the column used to divide data into chunks. If you do not
       ↪ configure it,
    # sync-diff-inspector chooses an appropriate column (primary key, unique
       ↪  key, or a field with index).
    index-fields = "id"

    # Specifies the range of the data to be checked
    # It needs to comply with the syntax of the WHERE clause in SQL.
    range = "age > 10 AND age < 20"

    # Sets it to "true" when comparing the data of multiple sharded tables
    # with the data of the combined table.
    is-sharding = false

    # The collation of the string type of data might be inconsistent in some
       ↪  conditions.
    # You can specify "collation" to guarantee the order consistency.
    # You need to keep it corresponding to the "charset" setting in the
       ↪ database.
    # collation = "latin1_bin"

    # Ignores checking some columns such as some types (json, bit, blob, etc
       ↪ .)
    # that sync-diff-inspector does not currently support.
    # The floating-point data type behaves differently in TiDB and MySQL.
       ↪ You can use
    # `ignore-columns` to skip checking these columns.
    # ignore-columns = ["name"]

### Configuration example of comparing two tables with different schema
   ↪ names and table names.
[[table-config]]
    # The name of the target schema
    schema = "test"

    # The name of the target table
    table = "test2"

    # Sets it to "false" in non-sharding scenarios.
    is-sharding = false
```

```
    # Configuration of the source data
    [[table-config.source-tables]]
        # The instance ID of the source schema
        instance-id = "source-1"
        # The name of the source schema
        schema = "test"
        # The name of the source table
        table = "test1"

############################ Databases config ##########################

### Configuration of the source database instance
[[source-db]]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = "123456"
    # The instance ID of the source database, the unique identifier of a
        ↪ database instance
    instance-id = "source-1"
    # Uses the snapshot function of TiDB.
    # If enabled, the history data is used for comparison.
    # snapshot = "2016-10-08 16:45:26"
    # Sets the `sql-mode` of the database to parse table structures.
    # sql-mode = ""

### Configuration of the target database instance
[target-db]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = "123456"
    # Uses the snapshot function of TiDB.
    # If enabled, the history data is used for comparison.
    # snapshot = "2016-10-08 16:45:26"
    # Sets the `sql-mode` of the database to parse table structures.
    # sql-mode = ""
```

11.12.1.2.4 Run sync-diff-inspector

Run the following command:

```
./bin/sync_diff_inspector --config=./config.toml
```

This command outputs a check report to the log and describes the check result of each

table. sync-diff-inspector generates the SQL statements to fix inconsistent data and stores these statements in a `fix.sql` file.

Log

The running sync-diff-inspector periodically (every 10 seconds) prints the progress in log in the following format:

```
[2020/11/12 17:47:00.170 +08:00] [INFO] [checkpoint.go:276] ["summary info"]
   ↪  [instance_id=target] [schema=test] [table=test_table] ["chunk num
   ↪ "=1000] ["success num"=80] ["failed num"=1] ["ignore num"=0]
```

- `chunk num`: The total number of chunks to be checked.
- `success num`: The number of chunks that have been checked as consistent.
- `failed num`: The number of chunks that fail the check. Check failure might be caused by errors or data inconsistency.
- `ignore num`: The number of chunks that are ignored for the check. If the value of `sample-percent` is smaller than `100`, sync-diff-inspector checks data by sampling, where some chunks are ignored.

Result

After the check is finished, sync-diff-inspector outputs a report.

- If the data is consistent, a log example is as follows:

```
[2020/11/12 17:47:00.174 +08:00] [INFO] [report.go:80] ["check result
   ↪ summary"] ["check passed num"=1] ["check failed num"=0]
[2020/11/12 17:47:00.174 +08:00] [INFO] [report.go:87] ["table check
   ↪ result"] [schema=test] [table=test_table] ["struct equal"=true]
   ↪ ["data equal"=true]
[2020/11/12 17:47:00.174 +08:00] [INFO] [main.go:75] ["check data
   ↪ finished"] [cost=353.462744ms]
[2020/11/12 17:47:00.174 +08:00] [INFO] [main.go:69] ["check pass!!!"]
```

- If the data is inconsistent or some errors occur, a log example is as follows:

```
[2020/11/12 18:16:17.068 +08:00] [INFO] [checkpoint.go:276] ["summary
   ↪ info"] [instance_id=target] [schema=test] [table=test1] ["chunk
   ↪ num"=1] ["success num"=0] ["failed num"=1] ["ignore num"=0]
[2020/11/12 18:16:17.071 +08:00] [INFO] [report.go:80] ["check result
   ↪ summary"] ["check passed num"=0] ["check failed num"=1]
[2020/11/12 18:16:17.071 +08:00] [INFO] [report.go:87] ["table check
   ↪ result"] [schema=test] [table=test_table] ["struct equal"=true]
   ↪ ["data equal"=false]
[2020/11/12 18:16:17.071 +08:00] [INFO] [main.go:75] ["check data
   ↪ finished"] [cost=319.849706ms]
```

```
[2020/11/12 18:16:17.071 +08:00] [WARN] [main.go:66] ["check failed
    ↪ !!!"]
```

The number of tables that have passed and failed the check is printed in `check result summary`. The results of all tables are printed in `table check result`.

11.12.1.2.5 Note

- sync-diff-inspector consumes a certain amount of server resources when checking data. Avoid using sync-diff-inspector to check data during peak business hours.
- TiDB uses the `utf8_bin` collation. If you need to compare the data in MySQL with that in TiDB, pay attention to the collation configuration of MySQL tables. If the primary key or unique key is the `varchar` type and the collation configuration in MySQL differs from that in TiDB, then the final check result might be incorrect because of the collation issue. You need to add collation to the sync-diff-inspector configuration file.
- sync-diff-inspector divides data into chunks first according to TiDB statistics and you need to guarantee the accuracy of the statistics. You can manually run the `analyze table {table_name}` command when the TiDB server's *workload is light*.
- Pay special attention to `table-rules`. If you configure `schema-pattern="test1"` and `target-schema="test2"`, the `test1` schema in the source database and the `test2` schema in the target database are compared. If the source database has a `test2` schema, this `test2` schema is also compared with the `test2` schema in the target database.
- The generated `fix.sql` is only used as a reference for repairing data, and you need to confirm it before executing these SQL statements to repair data.

11.12.2 Data Check for Tables with Different Schema or Table Names

When using replication tools such as TiDB Data Migration, you can set `route-rules` to replicate data to a specified table in the downstream. sync-diff-inspector enables you to verify tables with different schema names or table names.

Below is a simple example.

```
########################### Tables config ##########################

### Configure the tables of the target database that need to be checked
[[check-tables]]
    # The name of the schema in the target database
    schema = "test_2"

    # The table that needs to be checked
    tables = ["t_2"]
```

```
### Configuration example of comparing two tables with different schema
    ↪ names and table names
[[table-config]]
    # The name of the schema in the target database
    schema = "test_2"

    # The name of the target table
    table = "t_2"

    # Configuration of the source data
    [[table-config.source-tables]]
        # The instance ID of the source schema
        instance-id = "source-1"
        # The name of the source schema
        schema = "test_1"
        # The name of the source table
        table = "t_1"
```

This configuration can be used to check `test_2.t_2` in the downstream and `test_1.t_1` in the `source-1` instance.

To check a large number of tables with different schema names or table names, you can simplify the configuration by setting the mapping relationship by using `table-rule`. You can configure the mapping relationship of either schema or table, or of both. For example, all the tables in the upstream `test_1` database are replicated to the downstream `test_2` database, which can be checked through the following configuration:

```
############################ Tables config ##########################

### Configures the tables of the target database that need to be checked
[[check-tables]]
    # The name of the schema in the target database
    schema = "test_2"

    # Check all the tables
    tables = ["~^"]

[[table-rules]]
    # schema-pattern and table-pattern support the wildcards "*" and "?"
    schema-pattern = "test_1"
    #table-pattern = ""
    target-schema = "test_2"
    #target-table = ""
```

11.12.3 Data Check in the Sharding Scenario

sync-diff-inspector supports data check in the sharding scenario. Assume that you use the DM replication tool to replicate data from multiple MySQL instances into TiDB, and now you can use sync-diff-inspector to check upstream and downstream data.

11.12.3.1 Use `table-config` for configuration

You can use `table-config` to configure `table-0`, set `is-sharding=true` and configure the upstream table information in `table-config.source-tables`. This configuration method requires setting all sharded tables, which is suitable for scenarios where the number of upstream sharded tables is small and the naming rules of sharded tables do not have a pattern as shown below.

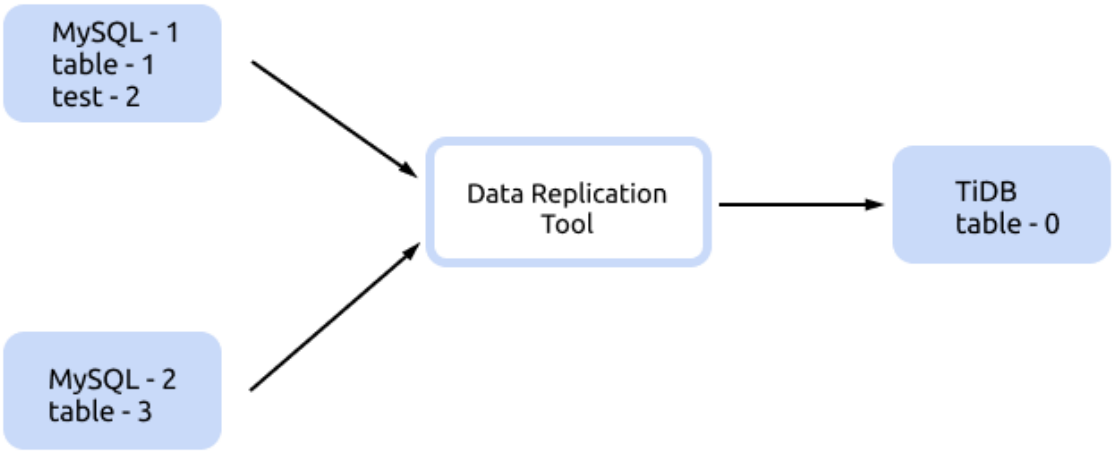

Figure 164: shard-table-replica-1

Below is a complete example of the sync-diff-inspector configuration.

```
### Diff Configuration.

############################ Global config ############################

### The log level. You can set it to "info" or "debug".
log-level = "info"

### sync-diff-inspector divides the data into multiple chunks based on the
    ↪ primary key,
### unique key, or the index, and then compares the data of each chunk.
### Compares data in each chunk. Uses "chunk-size" to set the size of a
    ↪ chunk.
```

```
chunk-size = 1000

### The number of goroutines created to check data
check-thread-count = 4

### The proportion of sampling check. If you set it to 100, all the data is
    ↪ checked.
sample-percent = 100

### If enabled, the chunk's checksum is calculated and data is compared by
    ↪ checksum.
### If disabled, data is compared line by line.
use-checksum = true

### If it is set to true, data is checked only by calculating checksum. Data
    ↪  is not checked after inspection, even if the upstream and downstream
    ↪  checksums are inconsistent.
only-use-checksum = false

### Whether to use the checkpoint of the last check. If it is enabled, the
    ↪ inspector only checks the last unchecked chunks and chunks that
    ↪ failed the verification.
use-checkpoint = true

### If it is set to true, data check is ignored.
### If it is set to false, data is checked.
ignore-data-check = false

### If it is set to true, the table struct comparison is ignored.
### If set to false, the table struct is compared.
ignore-struct-check = false

### The name of the file which saves the SQL statements used to repair data
fix-sql-file = "fix.sql"

############################ Tables config ##########################

### Configures the tables of the target database that need to be checked
[[check-tables]]
    # The name of the schema in the target database
    schema = "test"

    # The name of tables that need to be checked in the target database
    tables = ["table-0"]
```

```
### Configures the sharded tables corresponding to this table
[[table-config]]
    # The name of the target schema
    schema = "test"

    # The name of the table in the target schema
    table = "table-0"

    # Sets it to "true" in the sharding scenario
    is-sharding = true

    # Configuration of the source tables
    [[table-config.source-tables]]
    # The instance ID of the source database
    instance-id = "MySQL-1"
    schema = "test"
    table = "table-1"

    [[table-config.source-tables]]
    # The instance ID of the source database
    instance-id = "MySQL-1"
    schema = "test"
    table = "test-2"

    [[table-config.source-tables]]
    # The instance ID of the source database
    instance-id = "MySQL-2"
    schema = "test"
    table = "table-3"

############################ Databases config ############################

### Configuration of the source database instance
[[source-db]]
    host = "127.0.0.1"
    port = 3306
    user = "root"
    password = "123456"
    instance-id = "MySQL-1"

### Configuration of the source database instance
[[source-db]]
    host = "127.0.0.2"
    port = 3306
    user = "root"
```

```
    password = "123456"
    instance-id = "MySQL-2"

### Configuration of the target database instance
[target-db]
    host = "127.0.0.3"
    port = 4000
    user = "root"
    password = "123456"
    instance-id = "target-1"
```

11.12.3.2 Use `table-rules` for configuration

You can use `table-rules` for configuration when there are a large number of upstream sharded tables and the naming rules of all sharded tables have a pattern, as shown below:

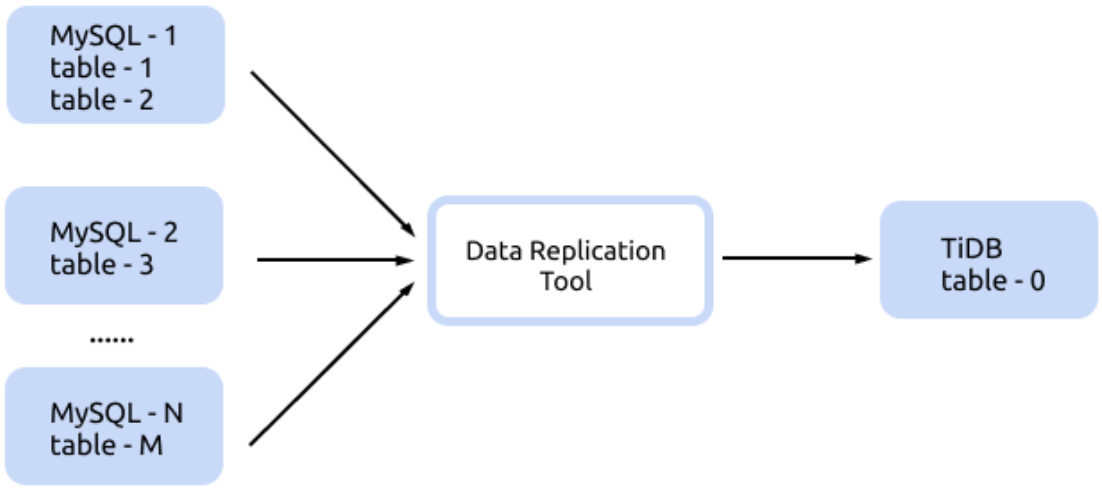

Figure 165: shard-table-replica-2

Below is a complete example of the sync-diff-inspector configuration.

```
### Diff Configuration.
############################ Global config ############################
### The log level. You can set it to "info" or "debug".
log-level = "info"

### sync-diff-inspector divides the data into multiple chunks based on the
    ↪ primary key,
### unique key, or the index, and then compares the data of each chunk.
```

```
### Uses "chunk-size" to set the size of a chunk.
chunk-size = 1000

### The number of goroutines created to check data
check-thread-count = 4

### The proportion of sampling check. If you set it to 100, all the data is
    ↪ checked.
sample-percent = 100

### If enabled, the chunk's checksum is calculated and data is compared by
    ↪ checksum.
### If disabled, data is compared line by line.
use-checksum = true

### If it is set to true, data is checked only by calculating checksum. Data
    ↪  is not checked after inspection, even if the upstream and downstream
    ↪  checksums are inconsistent.
only-use-checksum = false

### Whether to use the checkpoint of the last check. If it is enabled, the
    ↪ inspector only checks the last unchecked chunks and chunks that
    ↪ failed the verification.
use-checkpoint = true

### If it is set to true, data check is ignored.
### If it is set to false, data is checked.
ignore-data-check = false

### If it is set to true, the table struct comparison is ignored.
### If set to false, the table struct is compared.
ignore-struct-check = false

### The name of the file which saves the SQL statements used to repair data
fix-sql-file = "fix.sql"

############################ Tables config ############################

### Configures the tables of the target database that need to be checked
[[check-tables]]
    # The name of the schema in the target database
    schema = "test"

    # The name of tables that need to be checked in the target database
    tables = ["table-0"]
```

```
### Use `table-rule` to set the mapping relationship between the upstream
   ↪ sharded tables and the downstream table family. You can configure the
   ↪  mapping rule only for the schema or table, or the mapping rules for
   ↪ both the schema and table.
[[table-rules]]
    # schema-pattern and table-pattern support wildcard *?
    # All tables that meet the schema-pattern and table-pattern rules in
       ↪ the upstream database configured in source-db are the sharded
       ↪ tables of target-schema.target-table.
    schema-pattern = "test"
    table-pattern = "table-*"
    target-schema = "test"
    target-table = "table-0"

############################# Databases config #########################

### Configuration of the source database instance
[[source-db]]
   host = "127.0.0.1"
   port = 3306
   user = "root"
   password = "123456"
   instance-id = "MySQL-1"

### Configuration of the source database instance
[[source-db]]
   host = "127.0.0.2"
   port = 3306
   user = "root"
   password = "123456"
   instance-id = "MySQL-2"

### Configuration of the target database instance
[target-db]
   host = "127.0.0.3"
   port = 4000
   user = "root"
   password = "123456"
   instance-id = "target-1"
```

11.12.4 Data Check for TiDB Upstream and Downstream Clusters

You can use TiDB Binlog to build upstream and downstream clusters of TiDB. When Drainer replicates data to TiDB, the checkpoint is saved and the TSO mapping relationship between the upstream and downstream is also saved as `ts-map`. To check data between the upstream and downstream, configure `snapshot` in sync-diff-inspector.

11.12.4.1 Step 1: obtain `ts-map`

To obtain `ts-map`, execute the following SQL statement in the downstream TiDB cluster:

```
mysql> select * from tidb_binlog.checkpoint;
+--
    ↪ ------------------+------------------------------------------------------------
    ↪
| clusterID         | checkPoint
    ↪
    ↪ |
+--
    ↪ ------------------+------------------------------------------------------------
    ↪
| 6711243465327639221 | {"commitTS":409622383615541249,"ts-map":{"primary-ts
    ↪ ":409621863377928194,"secondary-ts":409621863377928345}} |
+--
    ↪ ------------------+------------------------------------------------------------
    ↪
```

11.12.4.2 Step 2: configure snapshot

Then configure the snapshot information of the upstream and downstream databases by using the `ts-map` information obtained in Step 1.

Here is a configuration example of the `Databases config` section:

```
############################ Databases config ##########################

### Configuration of the source database instance
[[source-db]]
    host = "127.0.0.1"
    port = 4000
    user = "root"
    password = "123456"
    # The instance ID of the source database, the unique identifier of a
        ↪ database instance
    instance-id = "source-1"
    # Uses the snapshot function of TiDB, corresponding to the primary-ts in
        ↪  ts-map
```

```
    snapshot = "409621863377928194"

### Configuration of the target database instance
[target-db]
    host = "127.0.0.1"
    port = 4001
    user = "root"
    password = "123456"
    # Uses the snapshot function of TiDB, corresponding to the secondary-ts
        ↪ in ts-map
    snapshot = "409621863377928345"
```

Note:

- Set `db-type` of Drainer to `tidb` to ensure that `ts-map` is saved in the checkpoint.
- Modify the Garbage Collection (GC) time of TiKV to ensure that the historical data corresponding to snapshot is not collected by GC during the data check. It is recommended that you modify the GC time to 1 hour and recover the setting after the check.
- In some versions of TiDB Binlog, `master-ts` and `slave-ts` are stored in `ts-map`. `master-ts` is equivalent to `primary-ts` and `slave-ts` is equivalent to `secondary-ts`.

11.13 TiSpark

11.13.1 TiSpark Quick Start Guide

To make it easy to try TiSpark, the TiDB cluster installed using TiUP integrates Spark and TiSpark jar package by default.

11.13.1.1 Deployment information

- Spark is deployed by default in the `spark` folder in the TiDB instance deployment directory.
- The TiSpark jar package is deployed by default in the `jars` folder in the Spark deployment directory.

```
spark/jars/tispark-${name_with_version}.jar
```

- TiSpark sample data and import scripts can be downloaded from TiSpark sample data.

```
tispark-sample-data/
```

11.13.1.2 Prepare the environment

11.13.1.2.1 Install JDK on the TiDB instance

Download the latest version of JDK 1.8 from Oracle JDK official download page. The version used in the following example is `jdk-8u141-linux-x64.tar.gz`.

Extract the package and set the environment variables based on your JDK deployment directory.

Edit the `~/.bashrc` file. For example:

```
export JAVA_HOME=/home/pingcap/jdk1.8.0_144
export PATH=$JAVA_HOME/bin:$PATH
```

Verify the validity of JDK:

```
$ java -version
java version "1.8.0_144"
Java(TM) SE Runtime Environment (build 1.8.0_144-b01)
Java HotSpot(TM) 64-Bit Server VM (build 25.144-b01, mixed mode)
```

11.13.1.2.2 Import the sample data

Assume that the TiDB cluster is started. The service IP of one TiDB instance is `192.168.0.2`, the port is `4000`, the user name is `root`, and the password is null.

```
wget http://download.pingcap.org/tispark-sample-data.tar.gz
tar -zxvf tispark-sample-data.tar.gz
cd tispark-sample-data
```

Edit the TiDB login information in `sample_data.sh`. For example:

```
mysql --local-infile=1 -h 192.168.0.2 -P 4000 -u root < dss.ddl
```

Run the script:

```
./sample_data.sh
```

Note:

You need to install the MySQL client on the machine that runs the script. If you are a CentOS user, you can install it through the command `yum -y install mysql`.

Log into TiDB and verify that the `TPCH_001` database and the following tables are included.

```
$ mysql -uroot -P4000 -h192.168.0.2
MySQL [(none)]> show databases;
+--------------------+
| Database           |
+--------------------+
| INFORMATION_SCHEMA |
| PERFORMANCE_SCHEMA |
| TPCH_001           |
| mysql              |
| test               |
+--------------------+
5 rows in set (0.00 sec)

MySQL [(none)]> use TPCH_001
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
MySQL [TPCH_001]> show tables;
+--------------------+
| Tables_in_TPCH_001 |
+--------------------+
| CUSTOMER           |
| LINEITEM           |
| NATION             |
| ORDERS             |
| PART               |
| PARTSUPP           |
| REGION             |
| SUPPLIER           |
+--------------------+
8 rows in set (0.00 sec)
```

11.13.1.3 Use example

First start the spark-shell:

```
$ cd spark
$ bin/spark-shell
```

Then query the TiDB table as you are using the native Spark SQL:

```
scala> spark.sql("use TPCH_001")
scala> spark.sql("select count(*) from lineitem").show
```

The result is:

```
+--------+
|count(1)|
+--------+
|   60175|
+--------+
```

Now run a more complex Spark SQL:

```
scala> spark.sql(
     """select
       |   l_returnflag,
       |   l_linestatus,
       |   sum(l_quantity) as sum_qty,
       |   sum(l_extendedprice) as sum_base_price,
       |   sum(l_extendedprice * (1 - l_discount)) as sum_disc_price,
       |   sum(l_extendedprice * (1 - l_discount) * (1 + l_tax)) as
          ↪ sum_charge,
       |   avg(l_quantity) as avg_qty,
       |   avg(l_extendedprice) as avg_price,
       |   avg(l_discount) as avg_disc,
       |   count(*) as count_order
       |from
       |   lineitem
       |where
       |   l_shipdate <= date '1998-12-01' - interval '90' day
       |group by
       |   l_returnflag,
       |   l_linestatus
       |order by
       |   l_returnflag,
       |   l_linestatus
     """.stripMargin).show
```

The result is:

```
+------------+------------+---------+--------------+--------------+
|l_returnflag|l_linestatus| sum_qty|sum_base_price|sum_disc_price|
+------------+------------+---------+--------------+--------------+
|           A|           F|380456.00| 532348211.65|505822441.4861|
|           N|           F| 8971.00|  12384801.37| 11798257.2080|
|           N|           O|742802.00| 1041502841.45|989737518.6346|
|           R|           F|381449.00| 534594445.35|507996454.4067|
+------------+------------+---------+--------------+--------------+
(Continued)
-----------------+---------+-----------+--------+-----------+
      sum_charge| avg_qty| avg_price|avg_disc|count_order|
-----------------+---------+-----------+--------+-----------+
 526165934.000839|25.575155|35785.709307|0.050081| 14876|
  12282485.056933|25.778736|35588.509684|0.047759| 348|

-----------------+---------+-----------+--------+-----------+
```

See more examples.

11.13.2 TiSpark User Guide

TiSpark is a thin layer built for running Apache Spark on top of TiDB/TiKV to answer the complex OLAP queries. It takes advantages of both the Spark platform and the distributed TiKV cluster and seamlessly glues to TiDB, the distributed OLTP database, to provide a Hybrid Transactional/Analytical Processing (HTAP) solution to serve as a one-stop solution for both online transactions and analysis.

TiSpark depends on the TiKV cluster and the PD cluster. You also need to set up a Spark cluster. This document provides a brief introduction to how to setup and use TiSpark. It requires some basic knowledge of Apache Spark. For more information, see Spark website.

11.13.2.1 Overview

TiSpark is an OLAP solution that runs Spark SQL directly on TiKV, the distributed storage engine.

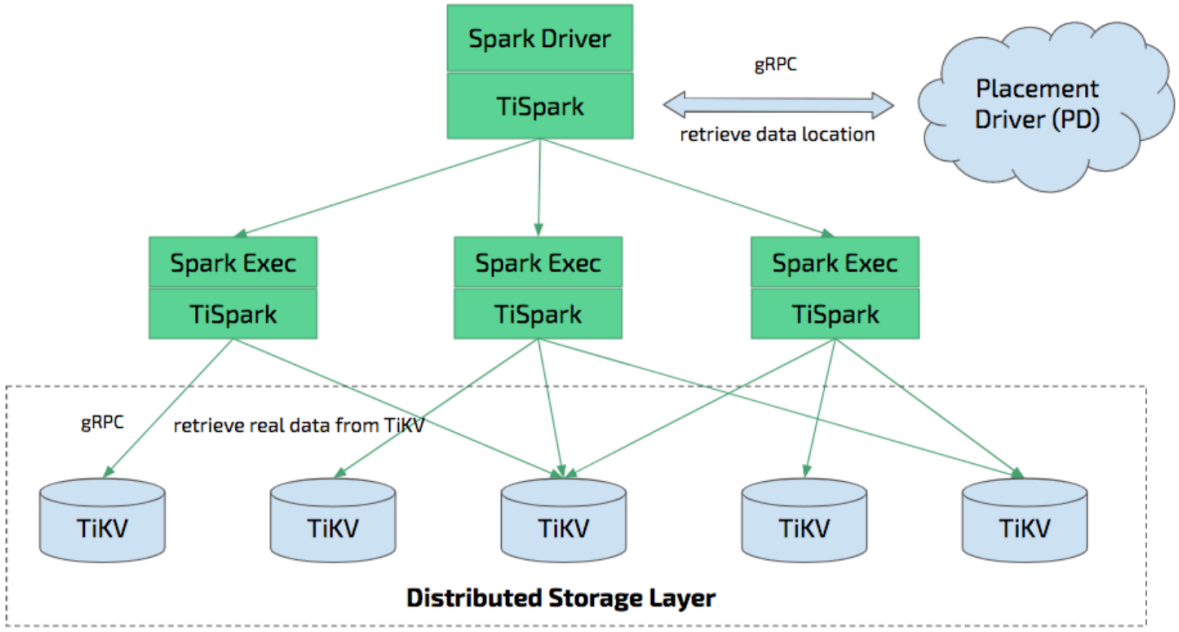

Figure 166: TiSpark architecture

- TiSpark integrates with Spark Catalyst Engine deeply. It provides precise control of the computing, which allows Spark read data from TiKV efficiently. It also supports index seek, which improves the performance of the point query execution significantly.
- It utilizes several strategies to push down the computing to reduce the size of dataset handling by Spark SQL, which accelerates the query execution. It also uses the TiDB built-in statistical information for the query plan optimization.
- From the data integration point of view, TiSpark and TiDB serve as a solution for running both transaction and analysis directly on the same platform without building and maintaining any ETLs. It simplifies the system architecture and reduces the cost of maintenance.
- You can deploy and utilize tools from the Spark ecosystem for further data processing and manipulation on TiDB. For example, using TiSpark for data analysis and ETL; retrieving data from TiKV as a machine learning data source; generating reports from the scheduling system and so on.
- Also, TiSpark supports distributed writes to TiKV. Compared to using Spark combined with JDBC to write to TiDB, distributed writes to TiKV can implement transactions (either all data are written successfully or all writes fail), and the writes are faster.

11.13.2.2 Environment setup

- The TiSpark 2.x supports Spark 2.3.x and Spark 2.4.x. If you want to use Spark 2.1.x, use TiSpark 1.x instead.

- TiSpark requires JDK 1.8+ and Scala 2.11 (Spark2.0 + default Scala version).
- TiSpark runs in any Spark mode such as YARN, Mesos, and Standalone.

11.13.2.3 Recommended configuration

This section describes the configuration of independent deployment of TiKV and TiSpark, independent deployment of Spark and TiSpark, and hybrid deployment of TiKV and TiSpark.

11.13.2.3.1 Configuration of independent deployment of TiKV and TiSpark

For independent deployment of TiKV and TiSpark, it is recommended to refer to the following recommendations:

- Hardware configuration
  - For general purposes, refer to the TiDB and TiKV hardware configuration recommendations.
  - If the usage is more focused on the analysis scenarios, you can increase the memory of the TiKV nodes to at least 64G.

11.13.2.3.2 Configuration of independent deployment of Spark and TiSpark

See the Spark official website for the detail hardware recommendations.

The following is a short overview of TiSpark configuration.

It is recommended to allocate 32G memory for Spark, and reserve at least 25% of the memory for the operating system and buffer cache.

It is recommended to provision at least 8 to 16 cores on per machine for Spark. Initially, you can assign all the CPU cores to Spark.

See the official configuration on the Spark website. The following is an example based on the `spark-env.sh` configuration:

```
SPARK_EXECUTOR_CORES: 5
SPARK_EXECUTOR_MEMORY: 10g
SPARK_WORKER_CORES: 5
SPARK_WORKER_MEMORY: 10g
```

In the `spark-defaults.conf` file, add the following lines:

```
spark.tispark.pd.addresses $your_pd_servers
spark.sql.extensions org.apache.spark.sql.TiExtensions
```

Add the following configuration in the `CDH` spark version:

```
spark.tispark.pd.addresses=$your_pd_servers
spark.sql.extensions=org.apache.spark.sql.TiExtensions
```

`your_pd_servers` are comma-separated PD addresses, with each in the format of `$your_pd_address:$port`.

For example, when you have multiple PD servers on `10.16.20.1,10.16.20.2,10.16.20.3` with the port 2379, put it as `10.16.20.1:2379,10.16.20.2:2379,10.16.20.3:2379`.

11.13.2.3.3 Configuration of hybrid deployment of TiKV and TiSpark

For the hybrid deployment of TiKV and TiSpark, add TiSpark required resources to the TiKV reserved resources, and allocate 25% of the memory for the system.

11.13.2.4 Deploy the TiSpark cluster

Download TiSpark's jar package here. Download your desired version of jar package and copy the content to the appropriate folder.

11.13.2.4.1 Deploy TiSpark on the existing Spark cluster

Running TiSpark on an existing Spark cluster does not require a reboot of the cluster. You can use Spark's `--jars` parameter to introduce TiSpark as a dependency:

```
spark-shell --jars $TISPARK_FOLDER/tispark-${name_with_version}.jar
```

11.13.2.4.2 Deploy TiSpark without the Spark cluster

If you do not have a Spark cluster, we recommend using the standalone mode. To use the Spark Standalone model, you can simply place a compiled version of Spark on each node of the cluster. If you encounter problems, see its official website. And you are welcome to file an issue on our GitHub.

Download and install

You can download Apache Spark

For the Standalone mode without Hadoop support, use Spark **2.3.x** and any version of Pre-build with Apache Hadoop 2.x with Hadoop dependencies. If you need to use the Hadoop cluster, choose the corresponding Hadoop version. You can also choose to build from the source code to match the previous version of the official Hadoop 2.x.

Suppose you already have a Spark binaries, and the current PATH is `SPARKPATH`, you can copy the TiSpark jar package to the `${SPARKPATH}/jars` directory.

Note:

If TiSpark could not communicate properly, please check your firewall configuration. You can adjust the firewall rules or disable it on your need.

Start a Master node

Execute the following command on the selected Spark Master node:

```
cd $SPARKPATH

./sbin/start-master.sh
```

After the above step is completed, a log file will be printed on the screen. Check the log file to confirm whether the Spark-Master is started successfully. You can open the http://$%7Bspark-master-hostname%7D:8080 to view the cluster information (if you does not change the Spark-Master default port number). When you start Spark-Worker, you can also use this panel to confirm whether the Worker is joined to the cluster.

Start a Worker node

Similarly, you can start a Spark-Worker node with the following command:

```
./sbin/start-slave.sh spark://${spark-master-hostname}:7077
```

After the command returns, you can see if the Worker node is joined to the Spark cluster correctly from the panel as well. Repeat the above command at all Worker nodes. After all Workers are connected to the master, you have a Standalone mode Spark cluster.

Spark SQL shell and JDBC server

TiSpark supports Spark 2.3, so you can use Spark's ThriftServer and SparkSQL directly.

11.13.2.5 Demo

Assuming that you have successfully started the TiSpark cluster as described above, here's a quick introduction to how to use Spark SQL for OLAP analysis. Here we use a table named `lineitem` in the `tpch` database as an example.

Assuming that your PD node is located at `192.168.1.100`, port `2379`, add the following command to `$SPARK_HOME/conf/spark-defaults.conf`:

```
spark.tispark.pd.addresses 192.168.1.100:2379
spark.sql.extensions org.apache.spark.sql.TiExtensions
```

And then enter the following command in the Spark-Shell as in native Apache Spark:

```
spark.sql("use tpch")

spark.sql("select count(*)from lineitem").show
```

The result is:

```
+-------------+
| Count (1) |
+-------------+
| 600000000 |
+-------------+
```

Spark SQL Interactive shell remains the same:

```
use tpch;
```

```
Time taken: 0.015 seconds
```

```
select count(*) from lineitem;
```

```
2000
Time taken: 0.673 seconds, Fetched 1 row(s)
```

For JDBC connection with Thrift Server, you can try it with various JDBC supported tools including SQuirreLSQL and hive-beeline. For example, to use it with beeline:

```
./beeline
Beeline version 1.2.2 by Apache Hive
beeline> !connect jdbc:hive2://localhost:10000

1: jdbc:hive2://localhost:10000> use testdb;
+---------+--+
| Result |
+---------+--+
+---------+--+
No rows selected (0.013 seconds)

select count(*) from account;
+-----------+--+
| count(1) |
+-----------+--+
| 1000000 |
+-----------+--+
1 row selected (1.97 seconds)
```

11.13.2.6 Use TiSpark together with Hive

You can use TiSpark together with Hive.

Before starting Spark, you need to set the `HADOOP_CONF_DIR` environment variable to your Hadoop configuration folder and copy `hive-site.xml` to the `spark/conf` folder.

```
val tisparkDF = spark.sql("select * from tispark_table").toDF
tisparkDF.write.saveAsTable("hive_table") // save table to hive
spark.sql("select * from hive_table a, tispark_table b where a.col1 = b.col1
    ↪ ").show // join table across Hive and Tispark
```

11.13.2.7 Batch write DataFrames into TiDB using TiSpark

Starting from v2.3, TiSpark natively supports batch writing DataFrames into TiDB clusters. This writing mode is implemented through the two-phase commit protocol of TiKV.

Compared with the writing through Spark + JDBC, the TiSpark batch writing has the following advantages:

Aspects to compare	TiSpark batch writes	Spark + JDBC writes
Atomicity	The DataFrames either are all written successfully or all fail to write.	If the Spark task fails and exits during the writing process, a part of the data might be written successfully.
Isolation	During the writing process, the data being written is invisible to other transactions.	During the writing process, some successfully written data is visible to other transactions.

Aspects to compare	TiSpark batch writes	Spark + JDBC writes
Error recovery	If the batch write fails, you only need to re-run Spark.	An application is required to achieve idempotence. For example, if the batch write fails, you need to clean up the part of the successfully written data and re-run Spark. You need to set `spark.task.maxFailures=1` to prevent data duplication caused by task retry.
Speed	Data is directly written into TiKV, which is faster.	Data is written to TiKV through TiDB, which affects the speed.

The following example shows how to batch write data using TiSpark via the scala API:

```
// select data to write
val df = spark.sql("select * from tpch.ORDERS")

// write data to tidb
df.write.
  format("tidb").
  option("tidb.addr", "127.0.0.1").
  option("tidb.port", "4000").
  option("tidb.user", "root").
  option("tidb.password", "").
  option("database", "tpch").
  option("table", "target_orders").
```

```
  mode("append").
  save()
```

If the amount of data to write is large and the writing time exceeds ten minutes, you need to ensure that the GC time is longer than the writing time.

```
update mysql.tidb set VARIABLE_VALUE="6h" where VARIABLE_NAME="
    ↪ tikv_gc_life_time";
```

Refer to this document for details.

11.13.2.8 Load Spark Dataframe into TiDB using JDBC

In addition to using TiSpark to batch write DataFrames into the TiDB cluster, you can also use Spark's native JDBC support for the data writing:

```
import org.apache.spark.sql.execution.datasources.jdbc.JDBCOptions

val customer = spark.sql("select * from customer limit 100000")
// You might repartition the source to make it balance across nodes
// and increase the concurrency.
val df = customer.repartition(32)
df.write
.mode(saveMode = "append")
.format("jdbc")
.option("driver", "com.mysql.jdbc.Driver")
 // Replace the host and port with that of your own and be sure to use the
     ↪  rewrite batch
.option("url", "jdbc:mysql://127.0.0.1:4000/test?rewriteBatchedStatements=
    ↪ true")
.option("useSSL", "false")
// As tested, 150 is good practice
.option(JDBCOptions.JDBC_BATCH_INSERT_SIZE, 150)
.option("dbtable", s"cust_test_select") // database name and table name
    ↪ here
.option("isolationLevel", "NONE") // recommended to set isolationLevel to
    ↪ NONE if you have a large DF to load.
.option("user", "root") // TiDB user here
.save()
```

It is recommended to set `isolationLevel` to `NONE` to avoid large single transactions which might potentially lead to TiDB OOM.

Note:

When you use JDBC, the default value of `isolationLevel` is `READ_UNCOMMITTED`, which causes the error of unsupported isolation level transactions. It is recommended to set the value of `isolationLevel` to `NONE`.

11.13.2.9 Statistics information

TiSpark uses TiDB statistic information for the following items:

1. Determining which index to ues in your query plan with the estimated lowest cost.
2. Small table broadcasting, which enables efficient broadcast join.

If you would like TiSpark to use statistic information, first you need to make sure that concerning tables have already been analyzed. Read more about how to analyze tables.

Starting from TiSpark 2.0, statistics information is default to auto load.

11.13.2.10 FAQ

Q: What are the pros/cons of independent deployment as opposed to a shared resource with an existing Spark / Hadoop cluster?

A: You can use the existing Spark cluster without a separate deployment, but if the existing cluster is busy, TiSpark will not be able to achieve the desired speed.

Q: Can I mix Spark with TiKV?

A: If TiDB and TiKV are overloaded and run critical online tasks, consider deploying TiSpark separately. You also need to consider using different NICs to ensure that OLTP's network resources are not compromised and affect online business. If the online business requirements are not high or the loading is not large enough, you can consider mixing TiSpark with TiKV deployment.

Q: What can I do if `warning: WARN ObjectStore:568 - Failed to get database` is returned when executing SQL statements using TiSpark?

A: You can ignore this warning. It occurs because Spark tries to load two nonexistent databases (`default` and `global_temp`) in its catalog. If you want to mute this warning, modify log4j by adding `log4j.logger.org.apache.hadoop.hive.metastore.` ↪ `ObjectStore=ERROR` to the `log4j` file in `tispark/conf`. You can add the parameter to the `log4j` file of the `config` under Spark. If the suffix is `template`, you can use the `mv` command to change it to `properties`.

Q: What can I do if `java.sql.BatchUpdateException: Data Truncated` is returned when executing SQL statements using TiSpark?

A: This error occurs because the length of the data written exceeds the length of the data type defined by the database. You can check the field length and adjust it accordingly.

Q: Does TiSpark read Hive metadata by default?

A: By default, TiSpark searches for the Hive database by reading the Hive metadata in hive-site. If the search task fails, it searches for the TiDB database instead, by reading the TiDB metadata.

If you do not need this default behavior, do not configure the Hive metadata in hive-site.

Q: What can I do if `Error: java.io.InvalidClassException: com.pingcap.tikv.region.TiRegion; local class incompatible: stream classdesc serialVersionUID ...` is returned when TiSpark is executing a Spark task?

A: The error message shows a `serialVersionUID` conflict, which occurs because you have used `class` and `TiRegion` of different versions. Because `TiRegion` only exists in TiSpark, multiple versions of TiSpark packages might be used. To fix this error, you need to make sure the version of TiSpark dependency is consistent among all nodes in the cluster.

12 Reference

12.1 Cluster Architecture

12.1.1 TiDB Architecture

Compared with the traditional standalone databases, TiDB has the following advantages:

- Has a distributed architecture with flexible and elastic scalability.
- Fully compatible with the MySQL 5.7 protocol, common features and syntax of MySQL. To migrate your applications to TiDB, you do not need to change a single line of code in many cases.
- Supports high availability with automatic failover when a minority of replicas fail; transparent to applications.
- Supports ACID transactions, suitable for scenarios requiring strong consistency such as bank transfer.
- Provides a rich series of data migration tools for migrating, replicating, or backing up data.

As a distributed database, TiDB is designed to consist of multiple components. These components communicate with each other and form a complete TiDB system. The architecture is as follows:

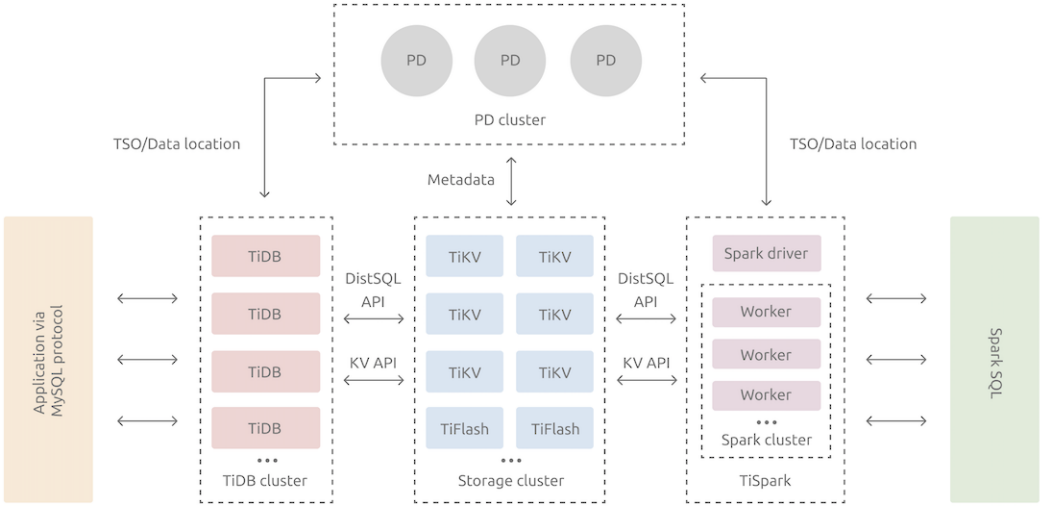

Figure 167: TiDB Architecture

12.1.1.1 TiDB server

The TiDB server is a stateless SQL layer that exposes the connection endpoint of the MySQL protocol to the outside. The TiDB server receives SQL requests, performs SQL parsing and optimization, and ultimately generates a distributed execution plan. It is horizontally scalable and provides the unified interface to the outside through the load balancing components such as Linux Virtual Server (LVS), HAProxy, or F5. It does not store data and is only for computing and SQL analyzing, transmitting actual data read request to TiKV nodes (or TiFlash nodes).

12.1.1.2 Placement Driver (PD) server

The PD server is the metadata managing component of the entire cluster. It stores metadata of real-time data distribution of every single TiKV node and the topology structure of the entire TiDB cluster, provides the TiDB Dashboard management UI, and allocates transaction IDs to distributed transactions. The PD server is "the brain" of the entire TiDB cluster because it not only stores metadata of the cluster, but also sends data scheduling command to specific TiKV nodes according to the data distribution state reported by TiKV nodes in real time. In addition, the PD server consists of three nodes at least and has high availability. It is recommended to deploy an odd number of PD nodes.

12.1.1.3 Storage servers

12.1.1.3.1 TiKV server

The TiKV server is responsible for storing data. TiKV is a distributed transactional key-value storage engine. Region is the basic unit to store data. Each Region stores the data for a particular Key Range which is a left-closed and right-open interval from StartKey to EndKey. Multiple Regions exist in each TiKV node. TiKV APIs provide native support to distributed transactions at the key-value pair level and supports the Snapshot Isolation level isolation by default. This is the core of how TiDB supports distributed transactions at the SQL level. After processing SQL statements, the TiDB server converts the SQL execution plan to an actual call to the TiKV API. Therefore, data is stored in TiKV. All the data in TiKV is automatically maintained in multiple replicas (three replicas by default), so TiKV has native high availability and supports automatic failover.

12.1.1.3.2 TiFlash server

The TiFlash Server is a special type of storage server. Unlike ordinary TiKV nodes, TiFlash stores data by column, mainly designed to accelerate analytical processing.

12.1.2 TiDB Storage

This document introduces some design ideas and key concepts of TiKV.

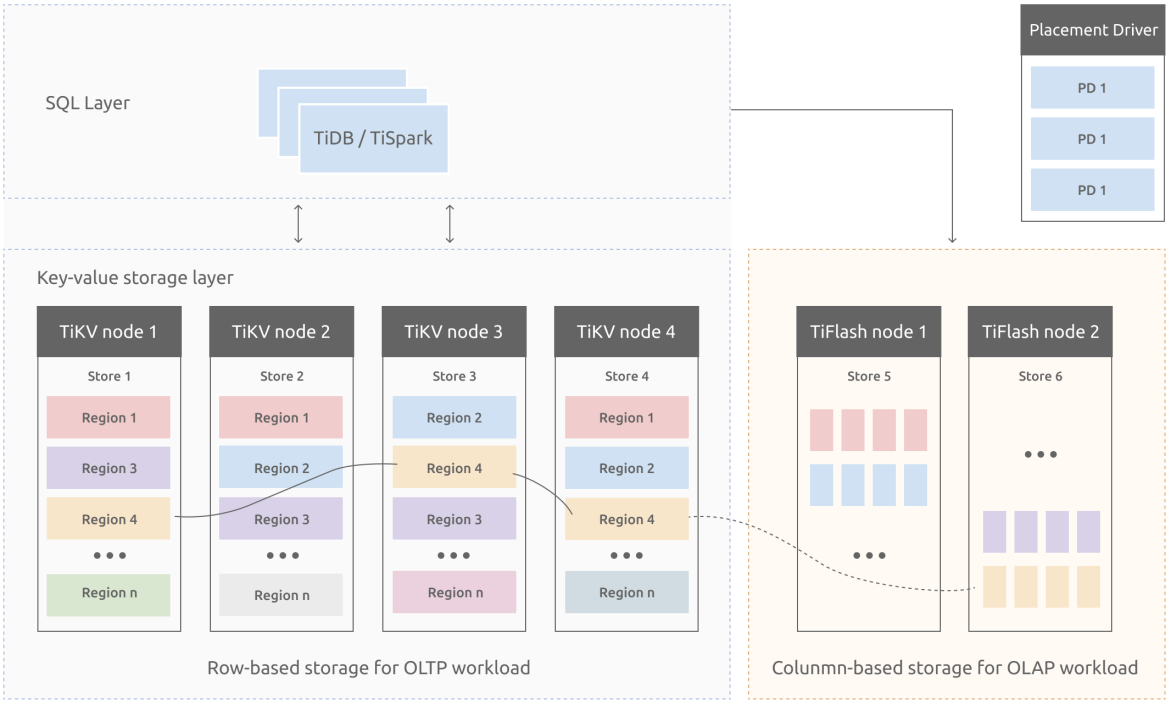

Figure 168: storage-architecture

12.1.2.1 Key-Value pairs

The first thing to decide for a data storage system is the data storage model, that is, in what form the data is saved. TiKV's choice is the Key-Value model and provides an ordered traversal method. There are two key points for TiKV data storage model:

- This is a huge Map (similar to `std::Map` in C++) , which stores Key-Value pairs.
- The Key-Value pair in the Map is ordered according to Keys' binary order, which means you can Seek the position of a particular Key and then call the Next method to get the Key-Value pairs larger than this Key in incremental order.

Note that the KV storage model for TiKV described in this document has nothing to do with tables of SQL. This document does not discuss any concepts related to SQL and only focuses on how to implement a high-performance, high-reliability, distributed Key-Value storage such as TiKV.

12.1.2.2 Local storage (RocksDB)

For any persistent storage engine, data is eventually saved on disk, and TiKV is no exception. TiKV does not write data directly on the disk, but stores data in RocksDB,

which is responsible for the data storage. The reason is that it costs a lot to develop a standalone storage engine, especially a high-performance standalone engine that requires careful optimization.

RocksDB is an excellent standalone storage engine open-sourced by Facebook. This engine can meet various requirements of TiKV for a single engine. Here, you can simply consider RocksDB as a single persistent Key-Value Map.

12.1.2.3 Raft protocol

What's more, the implementation of TiKV faces a more difficult thing: to secure data safety in case a single machine fails.

A simple way is to replicate data to multiple machines, so that even if one machine fails, the replicas on other machines are still available. In other words, you need a data replication scheme that is reliable, efficient, and able to handle the situation of a failed replica. All of these are made possible by the Raft algorithm.

Raft is a consensus algorithm. This document only briefly introduces Raft. For more details, you can see In Search of an Understandable Consensus Algorithm. The Raft has several important features:

- Leader election
- Membership changes (such as adding replicas, deleting replicas, transferring leaders, and so on)
- Log replication

TiKV use Raft to perform data replication. Each data change will be recorded as a Raft log. Through Raft log replication, data is safely and reliably replicated to multiple nodes of the Raft group. However, according to Raft protocol, successful writes only need that data is replicated to the majority of nodes.

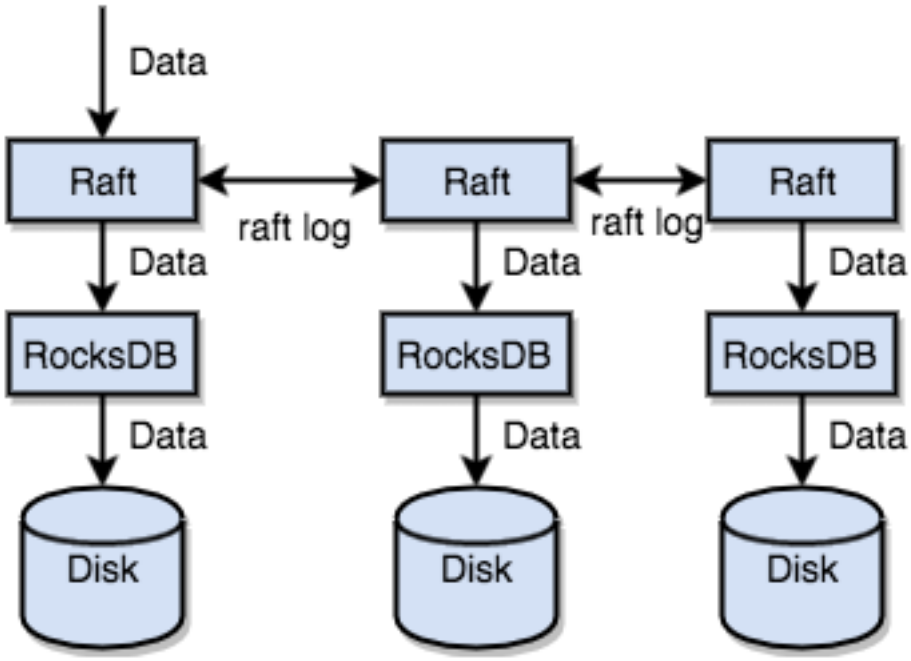

Figure 169: Raft in TiDB

In summary, TiKV can quickly store data on disk via the standalone machine RocksDB, and replicate data to multiple machines via Raft in case of machine failure. Data is written through the interface of Raft instead of to RocksDB. With the implementation of Raft, TiKV becomes a distributed Key-Value storage. Even with a few machine failures, TiKV can automatically complete replicas by virtue of the native Raft protocol, which does not impact the application.

12.1.2.4 Region

To make it easy to understand, let's assume that all data only has one replica. As mentioned earlier, TiKV can be regarded as a large, orderly KV Map, so data is distributed across multiple machines in order to achieve horizontal scalability. For a KV system, there are two typical solutions to distributing data across multiple machines:

- Hash: Create Hash by Key and select the corresponding storage node according to the Hash value.
- Range: Divide ranges by Key, where a segment of serial Key is stored on a node.

TiKV chooses the second solution that divides the whole Key-Value space into a series of consecutive Key segments. Each segment is called a Region. There is a size limit for each Region to store data (the default value is 96 MB and the size can be configured). Each Region can be described by `[StartKey, EndKey)`, a left-closed and right-open interval.

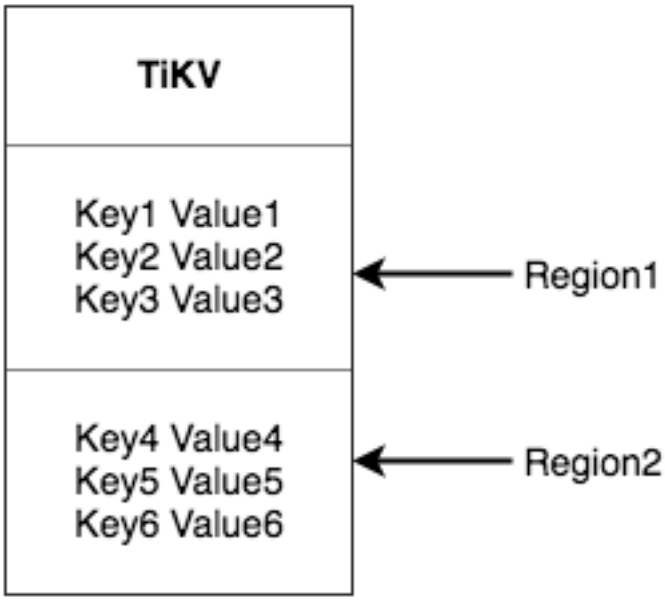

Figure 170: Region in TiDB

Note that the Region here has nothing to do with the table in SQL. In this document, forget about SQL and focus on KV for now. After dividing data into Regions, TiKV will perform two important tasks:

- Distributing data to all nodes in the cluster and use Region as the basic unit. Try its best to ensure that the number of Regions on each node is roughly similar.
- Performing Raft replication and membership management in Region.

These two tasks are very important and will be introduced one by one.

- First, data is divided into many Regions according to Key, and the data for each Region is stored on only one node (ignoring multiple replicas). The TiDB system has a PD component that is responsible for spreading Regions as evenly as possible across all nodes in the cluster. In this way, on one hand, the storage capacity is scaled horizontally (Regions on the other nodes are automatically scheduled to the newly added node); on the other hand, load balancing is achieved (the situation where one node has a lot of data while the others have little will not occur).

  At the same time, in order to ensure that the upper client can access the needed data, there is a component (PD) in the system to record the distribution of Regions on the node, that is, the exact Region of a Key and the node of that Region placed through any Key.

- For the second task, TiKV replicates data in Regions, which means that data in one Region will have multiple replicas with the name "Replica". Multiple Replicas of a

Region are stored on different nodes to form a Raft Group, which is kept consistent through the Raft algorithm.

One of the Replicas serves as the Leader of the Group and other as the Follower. By default, all reads and writes are processed through the Leader, where reads are done and write are replicated to followers. The following diagram shows the whole picture about Region and Raft group.

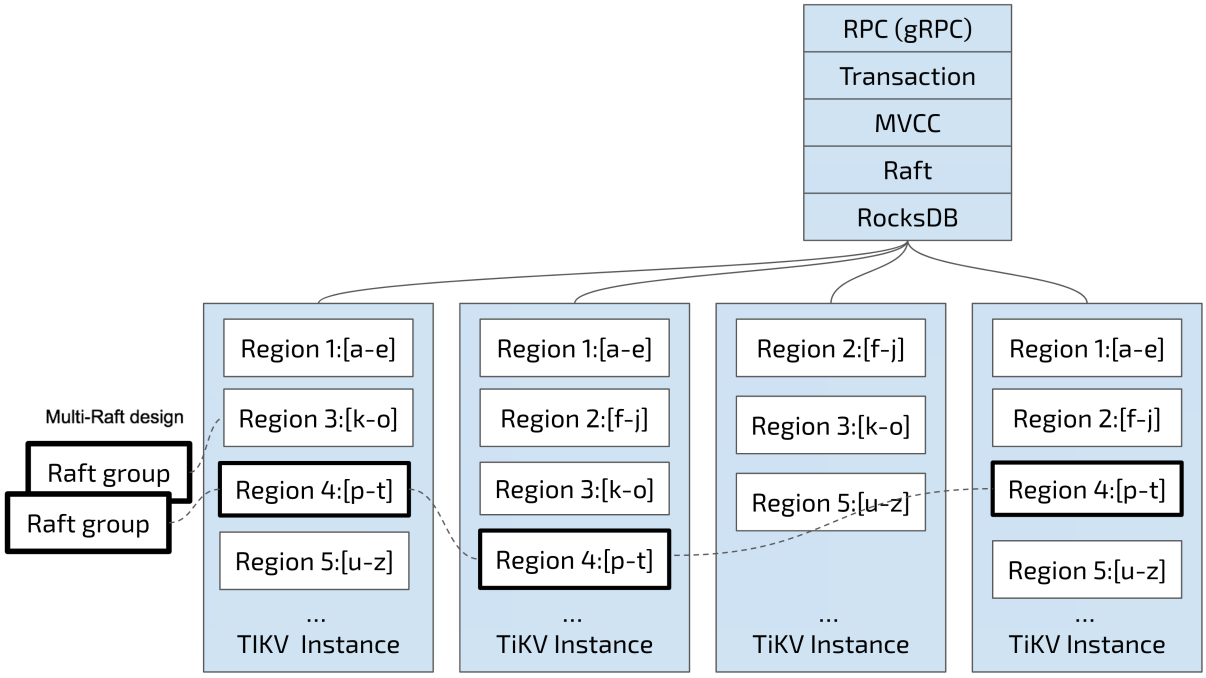

Figure 171: TiDB Storage

As we distribute and replicate data in Regions, we have a distributed Key-Value system that, to some extent, has the capability of disaster recovery. You no longer need to worry about the capacity, or disk failure and data loss.

12.1.2.5 MVCC

Many databases implement multi-version concurrency control (MVCC), and TiKV is no exception. Imagine the situation where two clients modify the value of a Key at the same time. Without MVCC, the data needs to be locked. In a distributed scenario, it might cause performance and deadlock problems. TiKV's MVCC implementation is achieved by appending a version number to Key. In short, without MVCC, TiKV's data layout can be seen as:

```
Key1 -> Value
Key2 -> Value
```

```
......
KeyN -> Value
```

With MVCC, the key array of TiKV is like this:

```
Key1_Version3 -> Value
Key1_Version2 -> Value
Key1_Version1 -> Value
......
Key2_Version4 -> Value
Key2_Version3 -> Value
Key2_Version2 -> Value
Key2_Version1 -> Value
......
KeyN_Version2 -> Value
KeyN_Version1 -> Value
......
```

Note that for multiple versions of the same Key, versions with larger numbers are placed first (see the Key-Value section where Keys are arranged in order), so that when you obtain Value through Key + Version, the Key of MVCC can be constructed with Key and Version, which is `Key_Version`. Then you can directly locate the first position greater than or equal to this `Key_Version` through RocksDB's `SeekPrefix(Key_Version)` API.

12.1.2.6 Distributed ACID transaction

Transaction of TiKV adopts the model used by Google in BigTable: Percolator. TiKV's implementation is inspired by this paper, with a lot of optimizations. See transaction overview for details.

12.1.3 TiDB Computing

Based on the distributed storage provided by TiKV, TiDB builds the computing engine that combines great capability of transactional processing with that of data analysis. This document starts by introducing a data mapping algorithm that maps data from TiDB database tables to (Key, Value) key-value pairs in TiKV, then introduces how TiDB manages metadata, and finally illustrates the architecture of the TiDB SQL layer.

For the storage solution on which the computing layer is dependent, this document only introduces the row-based storage structure of TiKV. For OLAP services, TiDB introduces a column-based storage solution TiFlash as a TiKV extension.

12.1.3.1 Mapping table data to Key-Value

This section describes the scheme for mapping data to (Key, Value) key-value pairs in TiDB. Data to be mapped here includes the following two types:

- Data of each row in the table, hereinafter referred to as table data.
- Data of all indexes in the table, hereinafter referred to as index data.

12.1.3.1.1 Mapping of table data to Key-Value

In a relational database, a table might have many columns. To map the data of each column in a row to a (Key, Value) key-value pair, you need to consider how to construct the Key. First of all, in OLTP scenarios, there are many operations such as adding, deleting, changing, and searching for data on a single or multiple rows, which needs the database to read a row of data quickly. Therefore, each key should have a unique ID (either explicit or implicit) to make it quick to locate. Then, many OLAP queries require a full table scan. If you can encode the keys of all rows in a table into a range, the whole table can be efficiently scanned by range queries.

Based on the considerations above, the mapping of table data to Key-Value in TiDB is designed as follows:

- To ensure that data from the same table is kept together for easy searching, TiDB assigns a table ID to each table represented by `TableID`. Table ID is an integer that is unique throughout the cluster.
- TiDB assigns a row ID, represented by `RowID`, to each row of data in the table. The row ID is also an integer, unique within the table. For row ID, TiDB has made a small optimization: if a table has an integer type primary key, TiDB uses the value of this primary key as the row ID.

Each row of data is encoded as a (Key, Value) key-value pair according to the following rule:

```
Key:   tablePrefix{TableID}_recordPrefixSep{RowID}
Value: [col1, col2, col3, col4]
```

`tablePrefix` and `recordPrefixSep` are both special string constants used to distinguish other data in Key space. The exact values of the string constants are introduced in Summary of mapping relationships.

12.1.3.1.2 Mapping of indexed data to Key-Value

TiDB supports both primary keys and secondary indexes (both unique and non-unique indexes). Similar to the table data mapping scheme, TiDB assigns an index ID to each index of the table represented by `IndexID`.

For primary keys and unique indexes, it is needed to quickly locate the corresponding `RowID` based on the key-value pair, so such a key-value pair is encoded as follows.

```
Key:   tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: RowID
```

For ordinary secondary indexes that do not need to satisfy the uniqueness constraint, a single key might correspond to multiple rows. It needs to query corresponding `RowID` according to the range of keys. Therefore, the key-value pair must be encoded according to the following rule:

```
Key:  tablePrefix{TableID}_indexPrefixSep{IndexID}_indexedColumnsValue_{
   ↪ RowID}
Value: null
```

12.1.3.1.3 Summary of mapping relationships

`tablePrefix`, `recordPrefixSep`, and `indexPrefixSep` in all of the above encoding rules are string constants that are used to distinguish a KV from other data in the Key space, which are defined as follows:

```
tablePrefix   = []byte{'t'}
recordPrefixSep = []byte{'r'}
indexPrefixSep = []byte{'i'}
```

Also note that in the above encoding schemes, no matter table data or index data key encoding scheme, all rows in a table have the same key prefix, and all data of an index also has the same prefix. Data with the same prefixes are thus arranged together in TiKV's key space. Therefore, by carefully designing the encoding scheme of the suffix part to ensure that the pre-encoding and post-encoding comparisons remain the same, the table data or index data can be stored in TiKV in an ordered manner. Using this encoding scheme, all row data in a table is arranged orderly by `RowID` in the TiKV's key space, and the data of a particular index is also arranged sequentially in the key space according to the specific value of the index data (`indexedColumnsValue`).

12.1.3.1.4 Example of Key-Value mapping relationship

This section shows a simple example for you to understand the Key-Value mapping relationship of TiDB. Suppose the following table exists in TiDB.

```
CREATE TABLE User (
    ID int,
    Name varchar(20),
    Role varchar(20),
    Age int,
    PRIMARY KEY (ID),
    KEY idxAge (Age)
);
```

Suppose there are 3 rows of data in the table.

```
1, "TiDB", "SQL Layer", 10
2, "TiKV", "KV Engine", 20
```

```
3, "PD", "Manager", 30
```

Each row of data is mapped to a (Key, Value) key-value pair, and the table has an `int` type primary key, so the value of `RowID` is the value of this primary key. Suppose the table's `TableID` is `10`, and then its table data stored on TiKV is:

```
t10_r1 --> ["TiDB", "SQL Layer", 10]
t10_r2 --> ["TiKV", "KV Engine", 20]
t10_r3 --> ["PD", " Manager", 30]
```

In addition to the primary key, the table has a non-unique ordinary secondary index, `idxAge`. Suppose the `IndexID` is `1`, and then its index data stored on TiKV is:

```
t10_i1_10_1 --> null
t10_i1_20_2 --> null
t10_i1_30_3 --> null
```

The above example shows the mapping rule from a relational model to a Key-Value model in TiDB, and the consideration behind this mapping scheme.

12.1.3.2 Metadata management

Each database and table in TiDB has metadata that indicates its definition and various attributes. This information also needs to be persisted, and TiDB stores this information in TiKV as well.

Each database or table is assigned a unique ID. As the unique identifier, when table data is encoded to Key-Value, this ID is encoded in the Key with the `m_` prefix. This constructs a key-value pair with the serialized metadata stored in it.

In addition, TiDB also uses a dedicated (Key, Value) key-value pair to store the latest version number of structure information of all tables. This key-value pair is global, and its version number is increased by `1` each time the state of the DDL operation changes. TiDB stores this key-value pair persistently in the PD server with the key of `/tidb/ddl` ↪ `/global_schema_version`, and Value is the version number value of the `int64` type. Meanwhile, because TiDB applies schema changes online, it keeps a background thread that constantly checks whether the version number of the table structure information stored in the PD server changes. This thread also ensures that the changes of version can be obtained within a certain period of time.

12.1.3.3 SQL layer overview

TiDB's SQL layer, TiDB Server, translates SQL statements into Key-Value operations, forwards the operations to TiKV, the distributed Key-Value storage layer, assembles the results returned by TiKV, and finally returns the query results to the client.

The nodes at this layer are stateless. These nodes themselves do not store data and are completely equivalent.

12.1.3.3.1 SQL computing

The simplest solution to SQL computing is the mapping of table data to Key-Value as described in the previous section, which maps SQL queries to KV queries, acquires the corresponding data through the KV interface, and performs various computations.

For example, to execute the `select count(*)from user where name = "TiDB"` SQL statement, TiDB needs to read all data in the table, then checks whether the `name` field is `TiDB`, and if so, returns this row. The process is as follows:

1. Construct the Key Range: all `RowID` in a table are in `[0, MaxInt64)` range. According to the row data `Key` encoding rule, using `0` and `MaxInt64` can construct a `[StartKey , EndKey)` range that is left-closed and right-open.
2. Scan Key Range: read the data in TiKV according to the key range constructed above.
3. Filter data: for each row of data read, calculate the `name = "TiDB"` expression. If the result is `true`, return to this row. If not, skip this row.
4. Calculate `Count(*)`: for each row that meets the requirements, add up to the result of `Count(*)`.

The entire process is illustrated as follows:

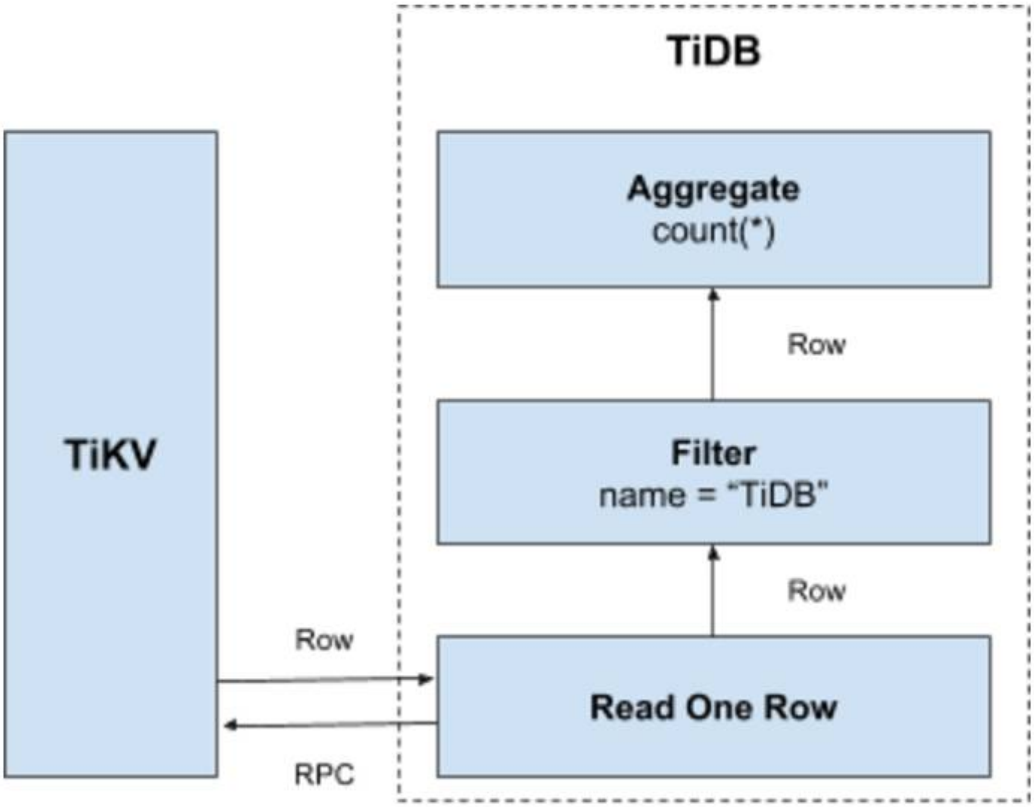

Figure 172: naive sql flow

This solution is intuitive and feasible, but has some obvious problems in a distributed database scenario:

- As the data is being scanned, each row is read from TiKV via a KV operation with at least one RPC overhead, which can be very high if there is a large amount of data to be scanned.
- It is not applicable to all rows. Data that does not meet the conditions does not need to be read.
- From the returned result of this query, only the number of rows that match the requirements is needed, not the value of those rows.

12.1.3.3.2 Distributed SQL operations

To solve the problems above, the computation should be as close to the storage node as possible to avoid a large number of RPC callings. First of all, the SQL predicate condition `name = "TiDB"` should be pushed down to the storage node for computation, so that only valid rows are returned, which avoids meaningless network transfers. Then, the aggregation function `Count(*)` can also be pushed down to the storage nodes for pre-aggregation, and each node only has to return a result of `Count(*)`. The SQL layer will sum up the `Count(*)` results returned by each node.

The following image shows how data returns layer by layer:

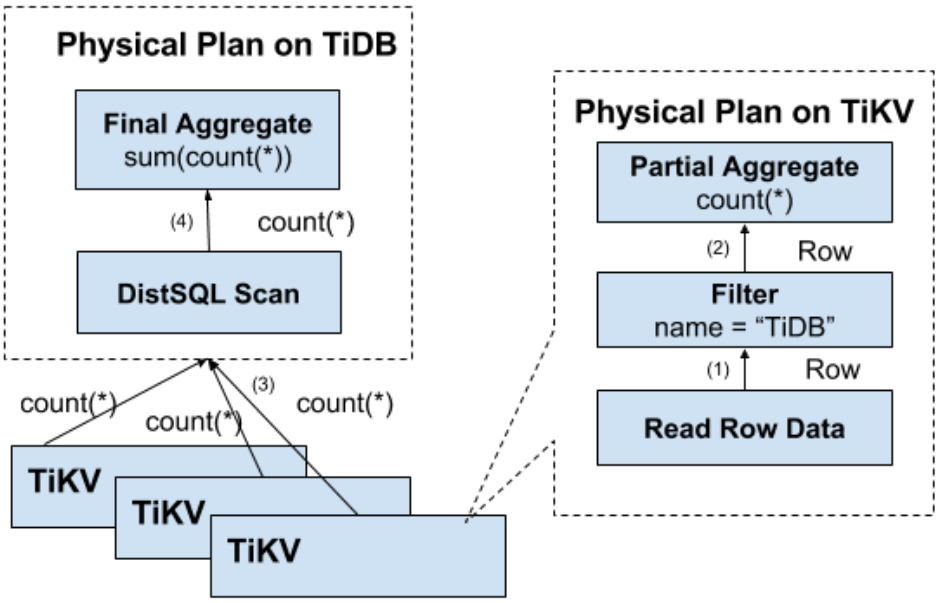

Figure 173: dist sql flow

12.1.3.3.3 Architecture of SQL layer

The previous sections introduce some functions of the SQL layer and I hope you have a basic understanding of how SQL statements are handled. In fact, TiDB's SQL layer is much more complicated, with many modules and layers. The following diagram lists the important modules and calling relationships:

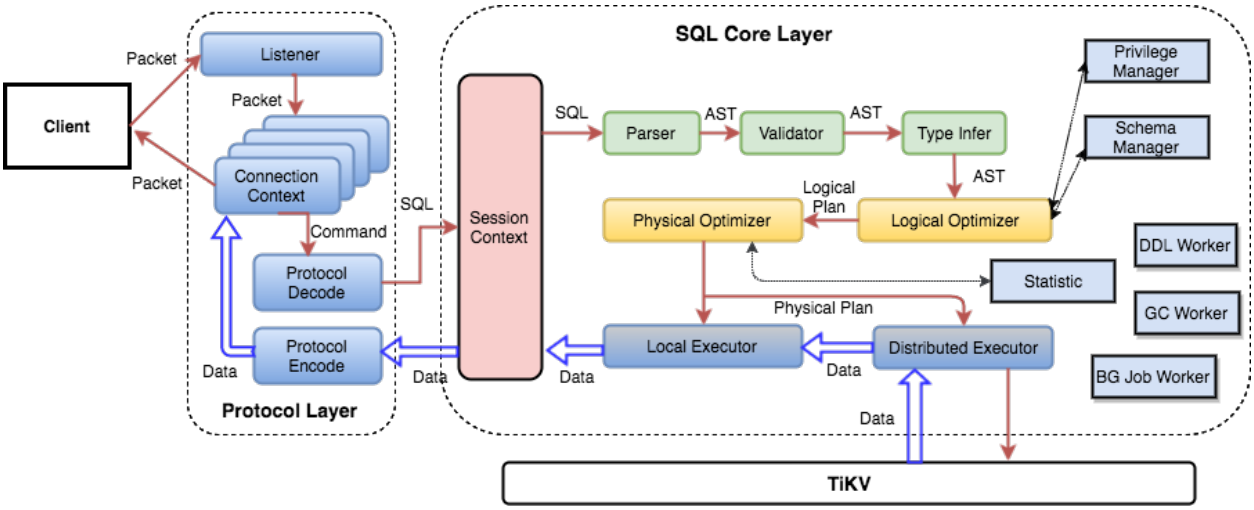

Figure 174: tidb sql layer

The user's SQL request is sent to TiDB Server either directly or via `Load Balancer`. TiDB Server will parse `MySQL Protocol Packet`, get the content of requests, parse the SQL request syntactically and semantically, develop and optimize query plans, execute a query plan, get and process the data. All data is stored in the TiKV cluster, so in this process, TiDB Server needs to interact with TiKV and get the data. Finally, TiDB Server needs to return the query results to the user.

12.1.4 TiDB Scheduling

The Placement Driver (PD) works as the manager in a TiDB cluster, and it also schedules Regions in the cluster. This article introduces the design and core concepts of the PD scheduling component.

12.1.4.1 Scheduling situations

TiKV is the distributed key-value storage engine used by TiDB. In TiKV, data is organized as Regions, which are replicated on several stores. In all replicas, a leader is responsible for reading and writing, and followers are responsible for replicating Raft logs from the leader.

Now consider about the following situations:

- To utilize storage space in a high-efficient way, multiple Replicas of the same Region need to be properly distributed on different nodes according to the Region size;
- For multiple data center topologies, one data center failure only causes one replica to fail for all Regions;
- When a new TiKV store is added, data can be rebalanced to it;
- When a TiKV store fails, PD needs to consider:

  - Recovery time of the failed store.
    * If it's short (for example, the service is restarted), whether scheduling is necessary or not.
    * If it's long (for example, disk fault, data is lost, etc.), how to do scheduling.
  - Replicas of all Regions.
    * If the number of replicas is not enough for some Regions, PD needs to complete them.
    * If the number of replicas is more than expected (for example, the failed store re-joins into the cluster after recovery), PD needs to delete them.

- Read/Write operations are performed on leaders, which can not be distributed only on a few individual stores;
- Not all Regions are hot, so loads of all TiKV stores need to be balanced;
- When Regions are in balancing, data transferring utilizes much network/disk traffic and CPU time, which can influence online services.

These situations can occur at the same time, which makes it harder to resolve. Also, the whole system is changing dynamically, so a scheduler is needed to collect all information about the cluster, and then adjust the cluster. So, PD is introduced into the TiDB cluster.

12.1.4.2 Scheduling requirements

The above situations can be classified into two types:

1. A distributed and highly available storage system must meet the following requirements:

    - The right number of replicas.
    - Replicas need to be distributed on different machines according to different topologies.
    - The cluster can perform automatic disaster recovery from TiKV peers' failure.

2. A good distributed system needs to have the following optimizations:

    - All Region leaders are distributed evenly on stores;
    - Storage capacity of all TiKV peers are balanced;
    - Hot spots are balanced;
    - Speed of load balancing for the Regions needs to be limited to ensure that online services are stable;
    - Maintainers are able to take peers online/offline manually.

After the first type of requirements is satisfied, the system will be failure tolerable. After the second type of requirements is satisfied, resources will be utilized more efficiently and the system will have better scalability.

To achieve the goals, PD needs to collect information firstly, such as state of peers, information about Raft groups and the statistics of accessing the peers. Then we need to specify some strategies for PD, so that PD can make scheduling plans from these information and strategies. Finally, PD distributes some operators to TiKV peers to complete scheduling plans.

12.1.4.3 Basic scheduling operators

All scheduling plans contain three basic operators:

- Add a new replica
- Remove a replica
- Transfer a Region leader between replicas in a Raft group

They are implemented by the Raft commands `AddReplica`, `RemoveReplica`, and `TransferLeader`.

12.1.4.4 Information collection

Scheduling is based on information collection. In short, the PD scheduling component needs to know the states of all TiKV peers and all Regions. TiKV peers report the following information to PD:

- State information reported by each TiKV peer:

  Each TiKV peer sends heartbeats to PD periodically. PD not only checks whether the store is alive, but also collects `StoreState` in the heartbeat message. `StoreState` includes:

  - Total disk space
  - Available disk space
  - The number of Regions
  - Data read/write speed
  - The number of snapshots that are sent/received (The data might be replicated between replicas through snapshots)
  - Whether the store is overloaded
  - Labels (See Perception of Topology)

  You can use PD control to check the status of a TiKV store, which can be Up, Disconnect, Offline, Down, or Tombstone. The following is a description of all statuses and their relationship.

  - **Up**: The TiKV store is in service.
  - **Disconnect**: Heartbeat messages between the PD and the TiKV store are lost for more than 20 seconds. If the lost period exceeds the time specified by `max-store-down-time`, the status "Disconnect" changes to "Down".

- **Down**: Heartbeat messages between the PD and the TiKV store are lost for a time longer than `max-store-down-time` (30 minutes by default). In this status, the TiKV store starts replenishing replicas of each Region on the surviving store.
- **Offline**: A TiKV store is manually taken offline through PD Control. This is only an intermediate status for the store to go offline. The store in this status moves all its Regions to other "Up" stores that meet the relocation conditions. When `leader_count` and `region_count` (obtained through PD Control) both show `0`, the store status changes to "Tombstone" from "Offline". In the "Offline" status, **do not** disable the store service or the physical server where the store is located. During the process that the store goes offline, if the cluster does not have target stores to relocate the Regions (for example, inadequate stores to hold replicas in the cluster), the store is always in the "Offline" status.
- **Tombstone**: The TiKV store is completely offline. You can use the `remove-tombstone` interface to safely clean up TiKV in this status.

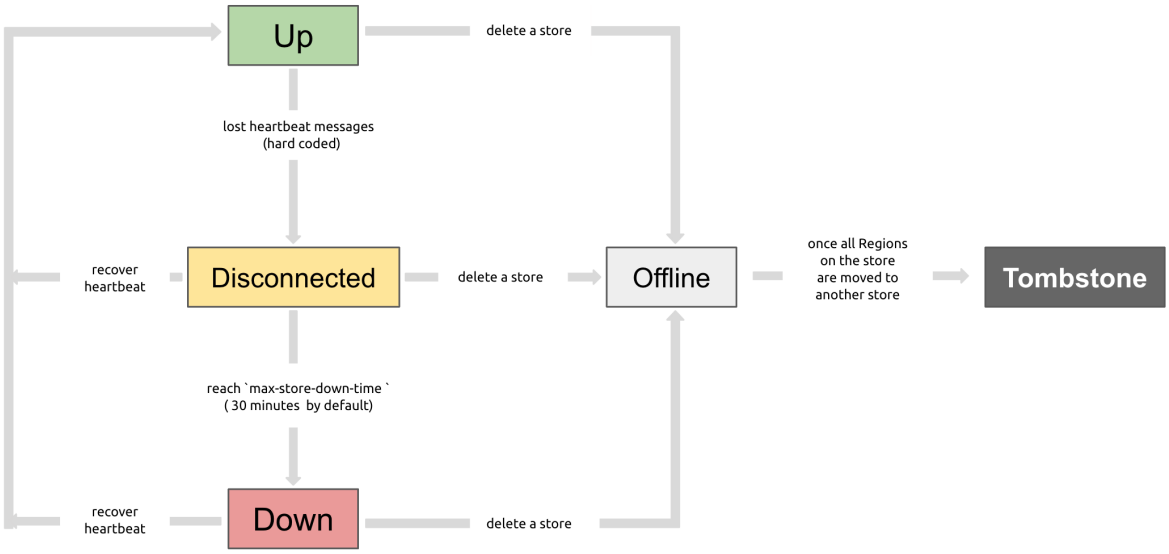

Figure 175: TiKV store status relationship

- Information reported by Region leaders:

  Each Region leader sends heartbeats to PD periodically to report `RegionState`, including:

  - Position of the leader itself
  - Positions of other replicas
  - The number of offline replicas

– data read/write speed

PD collects cluster information by the two types of heartbeats and then makes decision based on it.

Besides, PD can get more information from an expanded interface to make a more precise decision. For example, if a store's heartbeats are broken, PD can't know whether the peer steps down temporarily or forever. It just waits a while (by default 30min) and then treats the store as offline if there are still no heartbeats received. Then PD balances all regions on the store to other stores.

But sometimes stores are manually set offline by a maintainer, so the maintainer can tell PD this by the PD control interface. Then PD can balance all regions immediately.

12.1.4.5 Scheduling strategies

After collecting the information, PD needs some strategies to make scheduling plans.

Strategy 1: The number of replicas of a Region needs to be correct

PD can know that the replica count of a Region is incorrect from the Region leader's heartbeat. If it happens, PD can adjust the replica count by adding/removing replica(s). The reason for incorrect replica count can be:

- Store failure, so some Region's replica count is less than expected;
- Store recovery after failure, so some Region's replica count could be more than expected;
- `max-replicas` is changed.

Strategy 2: Replicas of a Region need to be at different positions

Note that here "position" is different from "machine". Generally PD can only ensure that replicas of a Region are not at a same peer to avoid that the peer's failure causes more than one replicas to become lost. However in production, you might have the following requirements:

- Multiple TiKV peers are on one machine;
- TiKV peers are on multiple racks, and the system is expected to be available even if a rack fails;
- TiKV peers are in multiple data centers, and the system is expected to be available even if a data center fails;

The key to these requirements is that peers can have the same "position", which is the smallest unit for failure toleration. Replicas of a Region must not be in one unit. So, we can configure labels for the TiKV peers, and set location-labels on PD to specify which labels are used for marking positions.

Strategy 3: Replicas need to be balanced between stores

The size limit of a Region replica is fixed, so keeping the replicas balanced between stores is helpful for data size balance.

Strategy 4: Leaders need to be balanced between stores

Read and write operations are performed on leaders according to the Raft protocol, so that PD needs to distribute leaders into the whole cluster instead of several peers.

Strategy 5: Hot spots need to be balanced between stores

PD can detect hot spots from store heartbeats and Region heartbeats, so that PD can distribute hot spots.

Strategy 6: Storage size needs to be balanced between stores

When started up, a TiKV store reports `capacity` of storage, which indicates the store's space limit. PD will consider this when scheduling.

Strategy 7: Adjust scheduling speed to stabilize online services

Scheduling utilizes CPU, memory, network and I/O traffic. Too much resource utilization will influence online services. Therefore, PD needs to limit the number of the concurrent scheduling tasks. By default this strategy is conservative, while it can be changed if quicker scheduling is required.

12.1.4.6 Scheduling implementation

PD collects cluster information from store heartbeats and Region heartbeats, and then makes scheduling plans from the information and strategies. Scheduling plans are a sequence of basic operators. Every time PD receives a Region heartbeat from a Region leader, it checks whether there is a pending operator on the Region or not. If PD needs to dispatch a new operator to a Region, it puts the operator into heartbeat responses, and monitors the operator by checking follow-up Region heartbeats.

Note that here "operators" are only suggestions to the Region leader, which can be skipped by Regions. Leader of Regions can decide whether to skip a scheduling operator or not based on its current status.

12.2 Storage Engine - TiKV

12.2.1 TiKV Overview

TiKV is a distributed and transactional key-value database, which provides transactional APIs with ACID compliance. With the implementation of the Raft consensus algorithm and consensus state stored in RocksDB, TiKV guarantees data consistency between multiple replicas and high availability. As the storage layer of the TiDB distributed database, TiKV provides the read and write service, and persist the written data from applications. It also stores the statistics data of the TiDB cluster.

12.2.1.1 Architecture Overview

TiKV implements the multi-raft-group replica mechanism based on the design of Google Spanner. A Region is a basic unit of the key-value data movement and refers to a data range in a Store. Each Region is replicated to multiple nodes. These multiple replicas form a Raft group. A replica of a Region is called a Peer. Typically there are 3 peers in a Region. One of them is the leader, which provides the read and write services. The PD component balances all the Regions automatically to guarantee that the read and write throughput is balanced among all the nodes in the TiKV cluster. With PD and carefully designed Raft groups, TiKV excels in horizontal scalability and can easily scale to store more than 100 TBs of data.

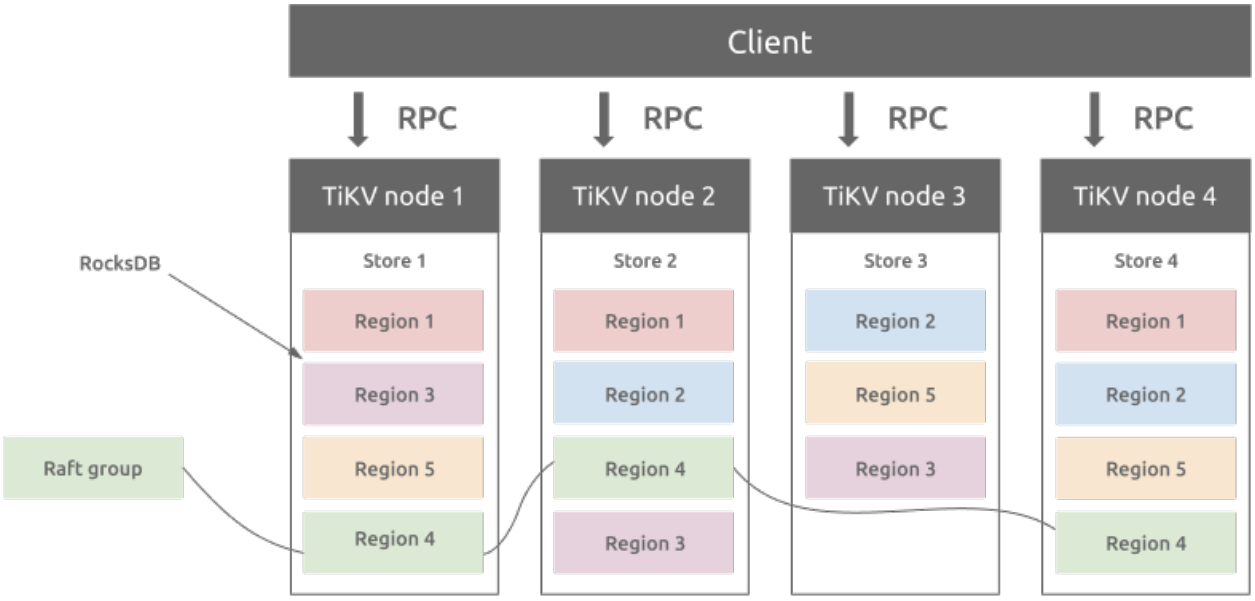

Figure 176: TiKV Architecture

12.2.1.1.1 Region and RocksDB

There is a RocksDB database within each Store and it stores data into the local disk. All the Region data are stored in the same RocksDB instance in each Store. All the logs used for the Raft consensus algorithm is stored in another RocksDB instance in each Store. This is because the performance of sequential I/O is better than random I/O. With different RocksDB instances storing raft logs and Region data, TiKV combines all the data write operations of raft logs and TiKV Regions into one I/O operation to improve the performance.

12.2.1.1.2 Region and Raft Consensus Algorithm

Data consistency between replicas of a Region is guaranteed by the Raft Consensus Algorithm. Only the leader of the Region can provide the writing service, and only when the data is written to the majority of replicas of a Region, the write operation succeeds.

When the size of a Region exceeds a threshold, which is 144 MB by default, TiKV splits it to two or more Regions. This operation guarantees the size of all the Regions in the cluster is nearly the same, which helps the PD component to balance Regions among nodes in a TiKV cluster. When the size of a Region is smaller than the threshold, TiKV merges the two smaller adjacent Regions into one Region.

When PD moves a replica from one TiKV node to another, it firstly adds a Learner replica on the target node, after the data in the Learner replica is nearly the same as that in the Leader replica, PD changes it to a Follower replica and removes the Follower replica on the source node.

Moving Leader replica from one node to another has a similar mechanism. The difference is that after the Learner replica becomes the Follower replica, there is a "Leader Transfer" operation in which the Follower replica actively proposes an election to elect itself as the Leader. Finally, the new Leader removes the old Leader replica in the source node.

12.2.1.2 Distributed Transaction

TiKV supports distributed transactions. Users (or TiDB) can write multiple key-value pairs without worrying about whether they belong to the same Region. TiKV uses two-phase commit to achieve ACID constraints. See TiDB Optimistic Transaction Model for details.

12.2.1.3 TiKV Coprocessor

TiDB pushes some data computation logic to TiKV Coprocessor. TiKV Coprocessor processes the computation for each Region. Each request sent to TiKV Coprocessor only involves the data of one Region.

12.2.2 RocksDB Overview

RocksDB is an LSM-tree storage engine that provides key-value store and read-write functions. It is developed by Facebook and based on LevelDB. Key-value pairs written by the user are firstly inserted into Write Ahead Log (WAL) and then written to the SkipList in memory (a data structure called MemTable). LSM-tree engines convert the random modification (insertion) to sequential writes to the WAL file, so they provide better write throughput than B-tree engines.

Once the data in memory reaches a certain size, RocksDB flushes the content into a Sorted String Table (SST) file in the disk. SST files are organized in multiple levels (the default is up to 6 levels). When the total size of a level reaches the threshold, RocksDB chooses part of the SST files and merges them into the next level. Each subsequent level is 10 times larger than the previous one, so 90% of the data is stored in the last layer.

RocksDB allows users to create multiple Column Families (CFs). CFs have their own SkipList and SST files, and they share the same WAL file. In this way, different CFs can have different settings according to the application characteristics. It does not increase the number of writes to WAL at the same time.

12.2.2.1 TiKV architecture

The architecture of TiKV is illustrated as follows:

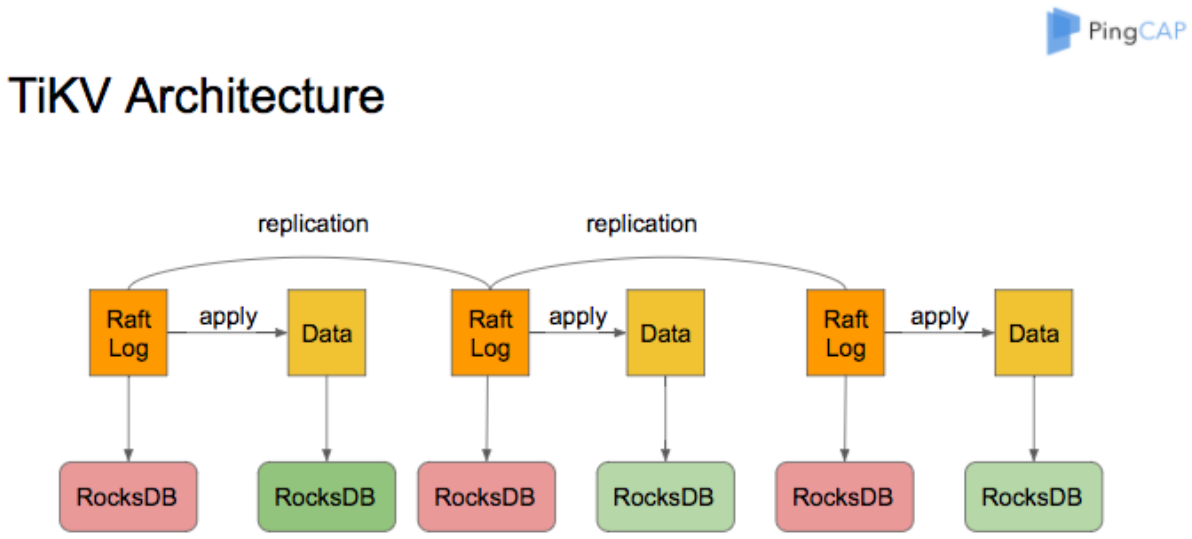

Figure 177: TiKV RocksDB

As the storage engine of TiKV, RocksDB is used to store Raft logs and user data. All data in a TiKV node shares two RocksDB instances. One is for Raft log (often called raftdb), and the other is for user data and MVCC metadata (often called kvdb). There are four CFs in kvdb: raft, lock, default, and write:

- raft CF: Store metadata of each Region. It occupies only a very small amount of space, and users do not need to care.
- lock CF: Store the pessimistic lock of pessimistic transactions and the Prewrite lock for distributed transactions. After the transaction is committed, the corresponding data in lock CF is deleted quickly. Therefore, the size of data in lock CF is usually very small (less than 1 GB). If the data in lock CF increases a lot, it means that a large number of transactions are waiting to be committed, and that the system meets a bug or failure.
- write CF: Store the user's real written data and MVCC metadata (the start timestamp and commit timestamp of the transaction to which the data belongs). When the user writes a row of data, it is stored in the write CF if the data length is less than 255 bytes. Otherwise, it is stored in the default CF. In TiDB, the secondary index only occupies the space of write CF, since the value stored in the non-unique index is empty and the value stored in the unique index is the primary key index.
- default CF: Store data longer than 255 bytes.

12.2.2.2 RocksDB memory usage

To improve the reading performance and reduce the reading operations to the disk, RocksDB divides the files stored on the disk into blocks based on a certain size (the default is 64 KB). When reading a block, it first checks if the data already exists in BlockCache in memory. If true, it can read the data directly from memory without accessing the disk.

BlockCache discards the least recently used data according to the LRU algorithm. By default, TiKV devotes 45% of the system memory to BlockCache. Users can also modify the `storage.block-cache.capacity` configuration to an appropriate value by themselves. However, it is not recommended to exceed 60% of the total system memory.

The data written to RocksDB is written to MemTable firstly. When the size of a MemTable exceeds 128 MB, it switches to a new MemTable. There are 2 RocksDB instances in TiKV, a total of 4 CFs. The size limit of a single MemTable for each CF is 128 MB. A maximum of 5 MemTables can exist at the same time; otherwise, the foreground writes is blocked. The memory occupied by this part is at most 2.5 GB (4 x 5 x 128 MB). It is not recommended to change this limit since it costs less memory.

12.2.2.3 RocksDB space usage

- Multi-version: As RocksDB is a key-value storage engine with LSM-tree structure, the data in MemTable is flushed to L0 first. Because the file is arranged in the order of which they are generated, there might be overlap between the ranges of SSTs at the L0. As a result, the same key might have multiple versions in L0. When a file is merged from L0 to L1, it is cut into multiple files in a certain size (the default is 8 MB). The key range of each file on the same level does not overlap with each other, so there is only one version for each key on L1 and subsequent levels.
- Space amplification: The total size of files on each level is x (the default is 10) times that of the previous level, so 90% of the data is stored in the last level. It also means that the space amplification of RocksDB does not exceed 1.11 (L0 has fewer data and can be ignored).
- Space amplification of TiKV: TiKV has it's own MVCC strategy. When a user writes a key, the real data written to RocksDB is key + commit_ts, that is to say, the update and deletion also write a new key to RocksDB. TiKV deletes the old version of the data (through the Delete interface of RocksDB) at intervals, so it can be considered that the actual space of the data stored by the user on TiKV is enlarged to 1.11 plus the data written in the last 10 minutes (assuming that TiKV cleans up the old data promptly).

12.2.2.4 RocksDB background threads and compaction

In RocksDB, operations such as converting the MemTable into SST files and merging SST files at various levels are performed in the background thread pool. The default size of the background thread pool is 8. When the number of CPUs in the machine is less than or equal to 8, the default size of the background thread pool is the number of CPUs minus one.

Generally speaking, users do not need to change this configuration. If the user deploys multiple TiKV instances on a machine, or the machine has a relatively high read load and a

low write load, you can adjust the `rocksdb/max-background-jobs` to 3 or 4 as appropriate.

12.2.2.5 WriteStall

The L0 of RocksDB is different from other levels. The SSTs of L0 are arranged in the order of generation. The key ranges between the SSTs can overlap. Therefore, each SST in L0 must be queried in turn when a query is performed. In order not to affect query performance, WriteStall is triggered to block writing when there are too many files in L0.

When encountering a sudden sharp increase in write delay, you can first check the **WriteStall Reason** metric on the Grafana RocksDB KV panel. If it is a WriteStall caused by too many L0 files, you can adjust the following configurations to 64.

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

12.2.3 Titan Overview

Titan is a high-performance RocksDB plugin for key-value separation. Titan can reduce write amplification in RocksDB when large values are used.

When the value size in Key-Value pairs is large, Titan performs better than RocksDB in write, update, and point read scenarios. However, Titan gets a higher write performance by sacrificing storage space and range query performance. As the price of SSDs continues to decrease, this trade-off will be more and more meaningful.

12.2.3.1 Key features

- Reduce write amplification by separating values from the log-structured merge-tree (LSM-tree) and storing them independently.
- Seamlessly upgrade RocksDB instances to Titan. The upgrade does not require human intervention and does not impact online services.
- Achieve 100% compatibility with all RocksDB features used by the current TiKV.

12.2.3.2 Usage scenarios

Titan is suitable for the scenarios where a huge volume of data is written to the TiKV foreground:

- RocksDB triggers a large amount of compactions, which consumes a lot of I/O bandwidth or CPU resources. This causes poor read and write performance of the foreground.

- The RocksDB compaction lags much behind (due to the I/O bandwidth limit or CPU bottleneck) and frequently causes write stalls.
- RocksDB triggers a large amount of compactions, which causes a lot of I/O writes and affects the life of the SSD disk.

12.2.3.3 Prerequisites

The prerequisites for enabling Titan are as follows:

- The average size of values is large, or the size of all large values accounts for much of the total value size. Currently, the size of a value greater than 1 KB is considered as a large value. In some situations, this number (1 KB) can be 512 B. Note that a single value written to TiKV cannot exceed 8 MB due to the limitation of the TiKV Raft layer. You can adjust the `raft-entry-max-size` configuration value to relax the limit.
- No range query will be performed or you do not need a high performance of range query. Because the data stored in Titan is not well-ordered, its performance of range query is poorer than that of RocksDB, especially for the query of a large range. According PingCAP's internal test, Titan's range query performance is 40% to a few times lower than that of RocksDB.
- Sufficient disk space, because Titan reduces write amplification at the cost of disk space. In addition, Titan compresses values one by one, and its compression rate is lower than that of RocksDB. RocksDB compresses blocks one by one. Therefore, Titan consumes more storage space than RocksDB, which is expected and normal. In some situations, Titan's storage consumption can be twice that of RocksDB.

If you want to improve the performance of Titan, see the blog post Titan: A RocksDB Plugin to Reduce Write Amplification.

12.2.3.4 Architecture and implementation

The following figure shows the architecture of Titan:

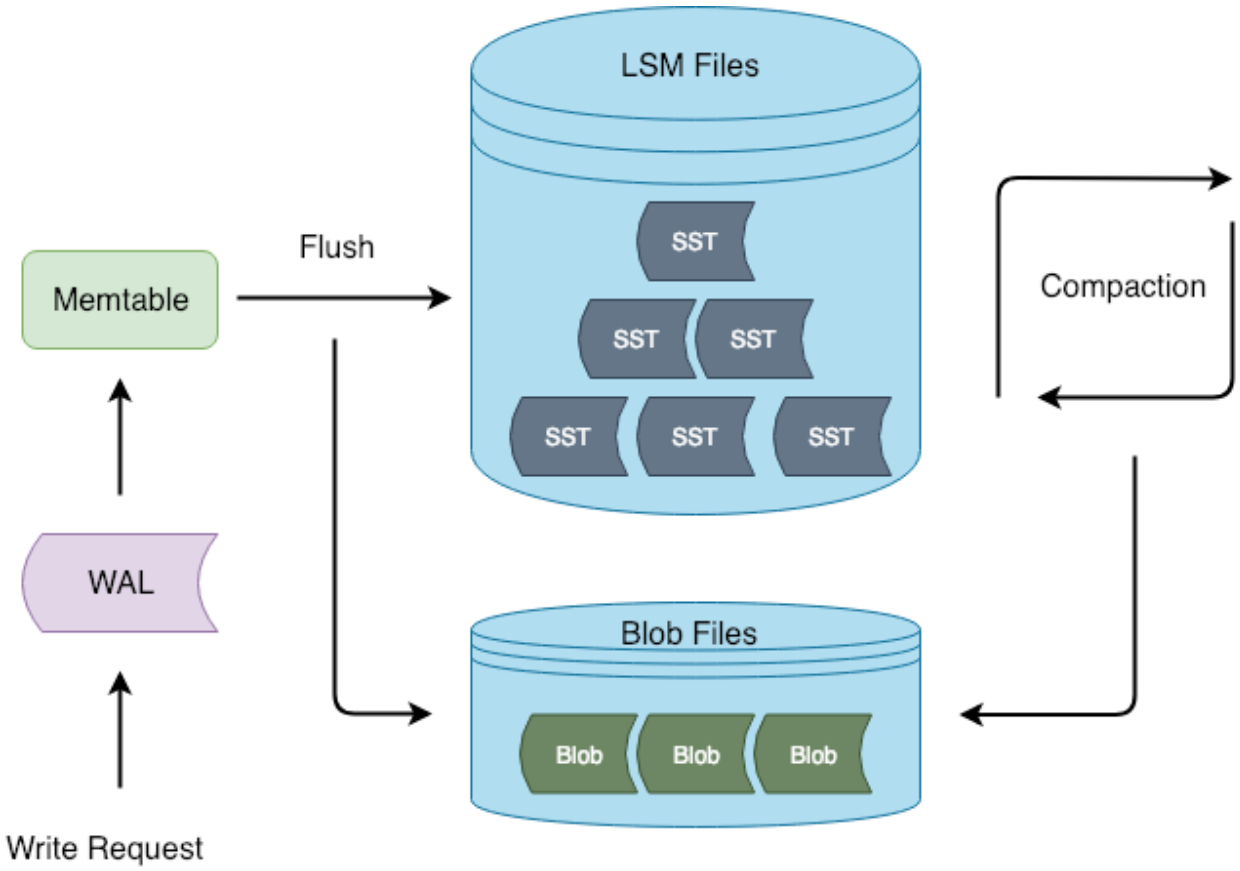

Figure 178: Titan Architecture

During flush and compaction operations, Titan separates values from the LSM-tree. The advantage of this approach is that the write process is consistent with RocksDB, which reduces the chance of invasive changes to RocksDB.

12.2.3.4.1 BlobFile

When Titan separates the value file from the LSM-tree, it stores the value file in the BlobFile. The following figure shows the BlobFile format:

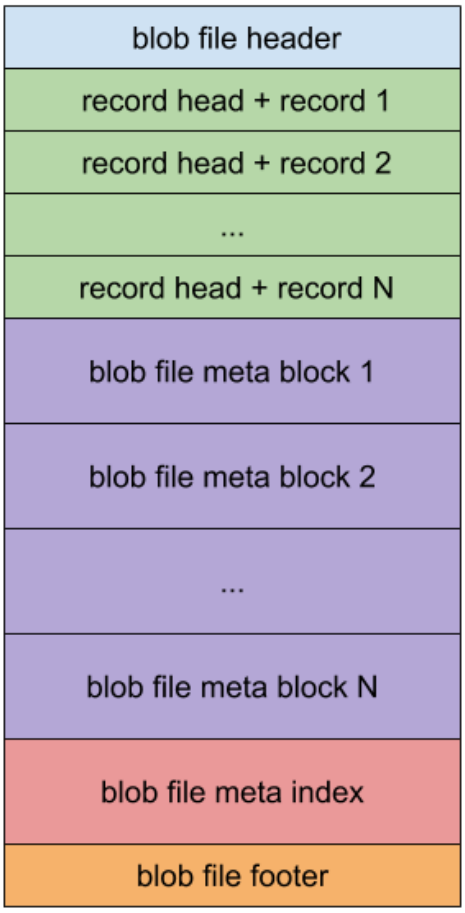

Figure 179: BlobFile Format

A blob file mainly consists of blob records, meta blocks, a meta index block, and a footer. Each block record stores a Key-Value pair. The meta blocks are used for scalability, and store properties related to the blob file. The meta index block is used for meta block searching.

Note:

- The Key-Value pairs in the blob file are stored in order, so that when the Iterator is implemented, the sequential reading performance can be improved via prefetching.
- Each blob record keeps a copy of the user key corresponding to the value. This way, when Titan performs Garbage Collection (GC), it can query the user key and identify whether the corresponding value is outdated. However, this process introduces some write amplification.

- BlobFile supports compression at the blob record level. Titan supports multiple compression algorithms, such as Snappy, LZ4, and Zstd. Currently, the default compression algorithm Titan uses is LZ4.

12.2.3.4.2 TitanTableBuilder

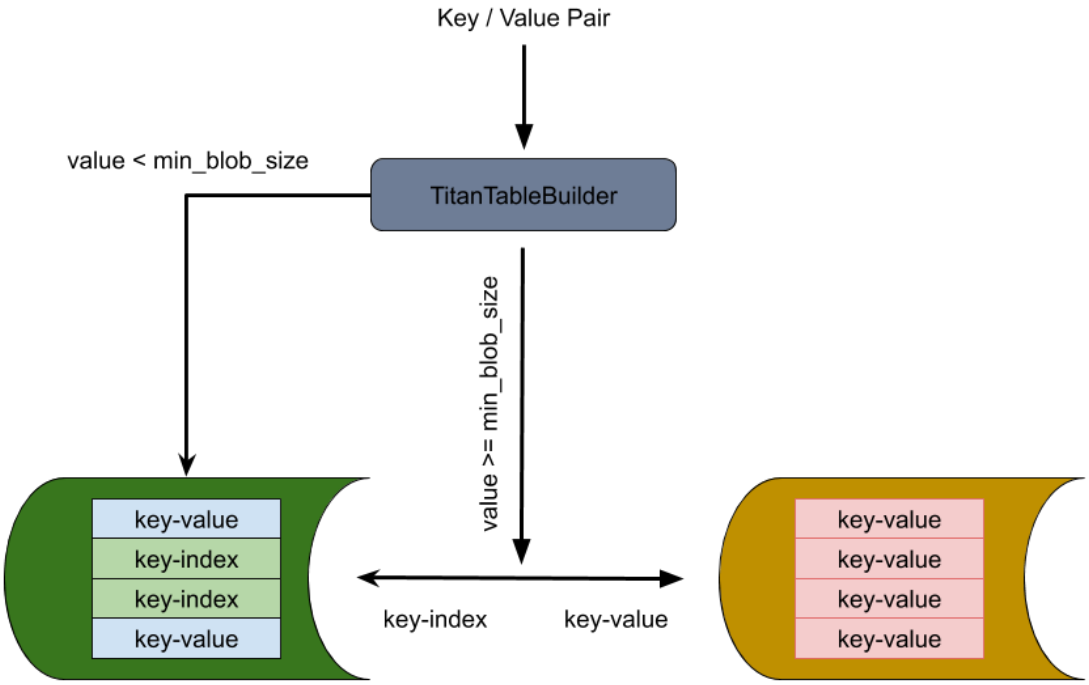

Figure 180: TitanTableBuilder

TitanTableBuilder is the key to achieving Key-Value separation. TitanTableBuilder determines the Key-Pair value size, and based on that, decides whether to separate the value from the Key-Value pair and store it in the blob file.

- If the value size is greater than or equal to `min_blob_size`, TitanTableBuilder separates the value and stores it in the blob file. TitanTableBuilder also generates an index and writes it into the SST.
- If the value size is smaller than `min_blob_size`, TitanTableBuilder writes the value directly into the SST.

Titan can also be downgraded to RocksDB in the process above. When RocksDB is performing compactions, the separated value can be written back to the newly generated SST files.

12.2.3.5 Garbage Collection

Titan uses Garbage Collection (GC) to reclaim space. As the keys are being reclaimed in the LSM-tree compaction, some values stored in blob files are not deleted at the same time. Therefore, Titan needs to perform GC periodically to delete outdated values. Titan provides the following two types of GC:

- Blob files are periodically integrated and rewritten to delete outdated values. This is the regular way of performing GC.
- Blob files are rewritten while the LSM-tree compaction is performed at the same time. This is the feature of Level Merge.

12.2.3.5.1 Regular GC

Titan uses the TablePropertiesCollector and EventListener components of RocksDB to collect the information for GC.

TablePropertiesCollector

RocksDB supports using BlobFileSizeCollector, a custom table property collector, to collect properties from the SST which are written into corresponding SST files. The collected properties are named BlobFileSizeProperties. The following figure shows the BlobFileSizeCollector workflow and data formats:

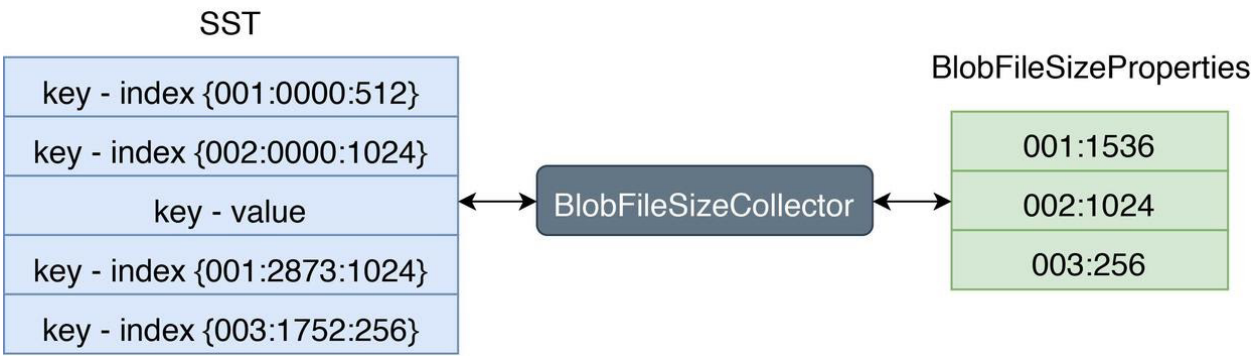

Figure 181: BlobFileSizeProperties

On the left is the SST index format. The first column is the blob file ID; the second column is the offset for the blob record in the blob file; the third column is the blob record size.

On the right is the BlobFileSizeProperties format. Each line represents a blob file and how much data is saved in this blob file. The first column is the blob file ID; the second column is the size of the data.

EventListener

RocksDB uses compaction to discard old data and reclaim space. After each compaction, some blob files in Titan might contain partly or entirely outdated data. Therefore, you can

trigger GC by listening to compaction events. During compaction, you can collect and compare the input/output blob file size properties of SST to determine which blob files require GC. The following figure shows the general process:

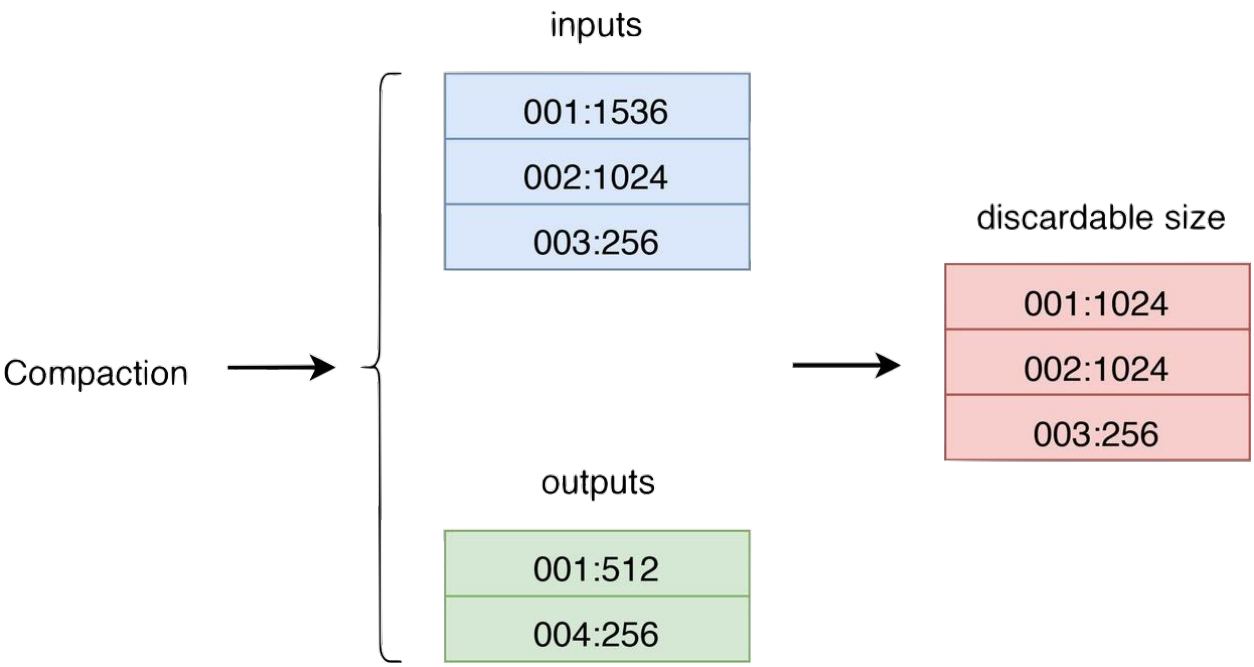

Figure 182: EventListener

- *inputs* stands for the blob file size properties for all SSTs that participate in the compaction.
- *outputs* stands for the blob file size properties for all SSTs generated in the compaction.
- *discardable size* is the size of the file to be discarded for each blob file, calculated based on inputs and outputs. The first column is the blob file ID. The second column is the size of the file to be discarded.

For each valid blob file, Titan maintains a discardable size variable in memory. After each compaction, this variable is accumulated for the corresponding blob file. Each time when GC starts, it picks the blob file with the greatest discardable size as the candidate file for GC. To reduce write amplification, a certain level of space amplification is allowed, which means GC can be started on a blob file only when the discardable file has reached a specific proportion in size.

For the selected blob file, Titan checks whether the blob index of the key corresponding to each value exists or has been updated to determine whether this value is outdated. If the value is not outdated, Titan merges and sorts the value into a new blob file, and writes the updated blob index into SST using WriteCallback or MergeOperator. Then, Titan records the latest sequence number of RocksDB and does not delete the old blob file until the sequence of the oldest snapshot exceeds the recorded sequence number. The reason is

that after the blob index is written back to SST, the old blob index is still accessible via the previous snapshot. Therefore, we need to ensure that no snapshot will access the old blob index before GC can safely deletes the corresponding blob file.

12.2.3.5.2 Level Merge

Level Merge is a newly introduced algorithm in Titan. According to the implementation principle of Level Merge, Titan merges and rewrites blob file that corresponds to the SST file, and generates new blob file while compactions are performed in LSM-tree. The following figure shows the general process:

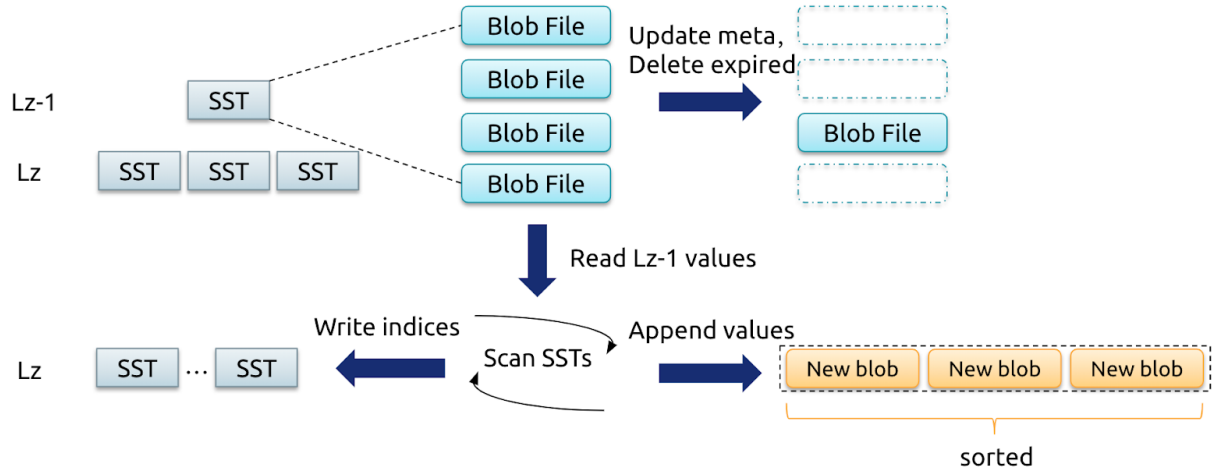

Figure 183: LevelMerge General Process

When compactions are performed on the SSTs of level z-1 and level z, Titan reads and writes Key-Value pairs in order. Then it writes the values of the selected blob files into new blob files in order, and updates the blob indexes of keys when new SSTs are generated. For the keys deleted in compactions, the corresponding values will not be written to the new blob file, which works similar to GC.

Compared with the regular way of GC, the Level Merge approach completes the blob GC while compactions are performed in LSM-tree. In this way, Titan no longer needs to check the status of blob index in LSM-tree or to write the new blob index into LSM-tree. This reduces the impact of GC on the foreground operations. As the blob file is repeatedly rewritten, fewer files overlap with each other, which makes the whole system in better order and improves the performance of scan.

However, layering blob files similar to tiering compaction brings write amplification. Because 99% of the data in LSM-tree is stored at the lowest two levels, Titan performs the Level Merge operation on the blob files corresponding to the data that is compacted only to the lowest two levels of LSM-tree.

Range Merge

Range Merge is an optimized approach of GC based on Level Merge. However, the bottom level of LSM-tree might be in poorer order in the following situations:

- When `level_compaction_dynamic_level_bytes` is enabled, data volume at each level of LSM-tree dynamically increases, and the sorted runs at the bottom level keep increasing.
- A specific range of data is frequently compacted, and this causes a lot of sorted runs in that range.

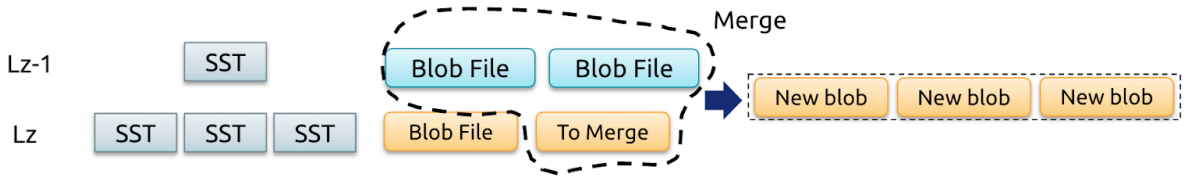

Figure 184: RangeMerge

Therefore, the Range Merge operation is needed to keep the number of sorted runs within a certain level. At the time of OnCompactionComplete, Titan counts the number of sorted runs in a range. If the number is large, Titan marks the corresponding blob file as ToMerge and rewrites it in the next compaction.

12.2.4 Titan Configuration

This document introduces how to enable and disable Titan using the corresponding configuration items, as well as the relevant parameters and the Level Merge feature.

12.2.4.1 Enable Titan

Titan is compatible with RocksDB, so you can directly enable Titan on the existing TiKV instances that use RocksDB. You can use one of the following two methods to enable Titan:

- Method 1: If you have deployed the cluster using TiUP, you can execute the `tiup cluster edit-config ${cluster-name}` command and edit the TiKV configuration file as the following example shows:

```
tikv:
  rocksdb.titan.enabled: true
```

Reload the configuration and TiKV will be rolling restarted online:

```
tiup cluster reload ${cluster-name} -R tikv
```

For the detailed command, see Modify the configuration using TiUP.

- Method 2: Directly edit the TiKV configuration file to enable Titan (**NOT** recommended for the production environment).

```
[rocksdb.titan]
enabled = true
```

After Titan is enabled, the existing data stored in RocksDB is not immediately moved to the Titan engine. As new data is written to the TiKV foreground and RocksDB performs compaction, the values are progressively separated from keys and written to Titan. You can view the **TiKV Details** -> **Titan kv** -> **blob file size** panel to confirm the size of the data stored in Titan.

If you want to speed up the writing process, compact data of the whole TiKV cluster manually using tikv-ctl. For details, see manual compaction.

> **Note:**
>
> When Titan is disabled, RocksDB cannot read data that has been migrated to Titan. If Titan is incorrectly disabled on a TiKV instance with Titan already enabled (mistakenly set `rocksdb.titan.enabled` to `false`), TiKV will fail to start, and the `You have disabled titan when its data directory is not empty` error appears in the TiKV log. To correctly disabled Titan, see Disable Titan.

12.2.4.2 Parameters

To adjust Titan-related parameters using TiUP, refer to Modify the configuration.

- Titan GC thread count.

  From the **TiKV Details** -> **Thread CPU** -> **RocksDB CPU** panel, if you observe that the Titan GC threads are at full capacity for a long time, consider increasing the size of the Titan GC thread pool.

```
[rocksdb.titan]
max-background-gc = 1
```

- Value size threshold.

  When the size of the value written to the foreground is smaller than the threshold, this value is stored in RocksDB; otherwise, this value is stored in the blob file of Titan. Based on the distribution of value sizes, if you increase the threshold, more values are stored in RocksDB and TiKV performs better in reading small values. If you decrease the threshold, more values go to Titan, which further reduces RocksDB compactions.

```
[rocksdb.defaultcf.titan]
min-blob-size = "1KB"
```

- The algorithm used for compressing values in Titan, which takes value as the unit.

```
[rocksdb.defaultcf.titan]
blob-file-compression = "lz4"
```

- The size of value caches in Titan.

  Larger cache size means higher read performance of Titan. However, too large a cache size causes Out of Memory (OOM). It is recommended to set the value of `storage.block-cache.capacity` to the store size minus the blob file size and set `blob-cache-size` to `memory size * 50% - block cache size` according to the monitoring metrics when the database is running stably. This maximizes the blob cache size when the block cache is large enough for the whole RocksDB engine.

```
[rocksdb.defaultcf.titan]
blob-cache-size = 0
```

- When the ratio of discardable data (the corresponding key has been updated or deleted) in a blob file exceeds the following threshold, Titan GC is triggered.

```
discardable-ratio = 0.5
```

  When Titan writes the useful data of this blob file to another file, you can use the `discardable-ratio` value to estimate the upper limits of write amplification and space amplification (assuming the compression is disabled).

  Upper limit of write amplification = 1 / discardable_ratio

  Upper limit of space amplification = 1 / (1 - discardable_ratio)

  From the two equations above, you can see that decreasing the value of `discardable_ratio` can reduce space amplification but causes GC to be more frequent in Titan. Increasing the value reduces Titan GC, the corresponding I/O bandwidth, and CPU consumption but increases disk usage.

- The following option limits the I/O rate of RocksDB compaction. During peak traffic, limiting RocksDB compaction, its I/O bandwidth, and its CPU consumption reduces its impact on the write and read performance of the foreground.

When Titan is enabled, this option limits the summed I/O rates of RocksDB compaction and Titan GC. If you find that the I/O and/or CPU consumption of RocksDB compaction and Titan GC is too large, set this option to a suitable value according the disk I/O bandwidth and the actual write traffic.

```
[rocksdb]
rate-bytes-per-sec = 0
```

12.2.4.3 Disable Titan (experimental)

To disable Titan, you can configure the `rocksdb.defaultcf.titan.blob-run-mode` option. The optional values for `blob-run-mode` are as follows:

- When the option is set to `normal`, Titan performs read and write operations normally.
- When the option is set to `read-only`, all newly written values are written into RocksDB, regardless of the value size.
- When the option is set to `fallback`, all newly written values are written into RocksDB, regardless of the value size. Also, all compacted values stored in the Titan blob file are automatically moved back to RocksDB.

To disable Titan, perform the following steps:

1. Update the configuration file of the TiKV nodes you wish to disable Titan for and restart TiKV:

```
[rocksdb.defaultcf.titan]
blob-run-mode = "fallback"
discardable-ratio = 1.0
merge-small-file-threshold = "0KB"
```

2. Perform a full compaction using tikv-ctl. This process will consume large amount of I/O and CPU resources.

```
tikv-ctl --pd <PD_ADDR> compact-cluster --bottommost force
```

3. After the compaction is finished, wait until the **Blob file count** metrics under **TiKV-Details/Titan - kv** decrease to `0`.

4. Update the configuration of these TiKV nodes to disable Titan.

```
[rocksdb.titan]
enabled = false
```

> **Warning:**
>
> Disabling Titan is an experimental feature. It is **NOT** recommended to use it if not necessary.

12.2.4.4 Level Merge (experimental)

In TiKV 4.0, Level Merge, a new algorithm, is introduced to improve the performance of range query and to reduce the impact of Titan GC on the foreground write operations. You can enable Level Merge using the following option:

```
[rocksdb.defaultcf.titan]
level-merge = true
```

Enabling Level Merge has the following benefits:

- Greatly improve the performance of Titan range query.
- Reduce the impact of Titan GC on the foreground write operations and improve write performance.
- Reduce space amplification of Titan and the disk usage (compared to the disk usage with the default configuration).

Accordingly, the write amplification with Level Merge enabled is slightly higher than that of Titan but is still lower than that of the native RocksDB.

12.3 Storage Engine - TiFlash

12.3.1 TiFlash Overview

TiFlash is the key component that makes TiDB essentially an Hybrid Transactional/-Analytical Processing (HTAP) database. As a columnar storage extension of TiKV, TiFlash provides both good isolation level and strong consistency guarantee.

In TiFlash, the columnar replicas are asynchronously replicated according to the Raft Learner consensus algorithm. When these replicas are read, the Snapshot Isolation level of consistency is achieved by validating Raft index and multi-version concurrency control (MVCC).

12.3.1.1 Architecture

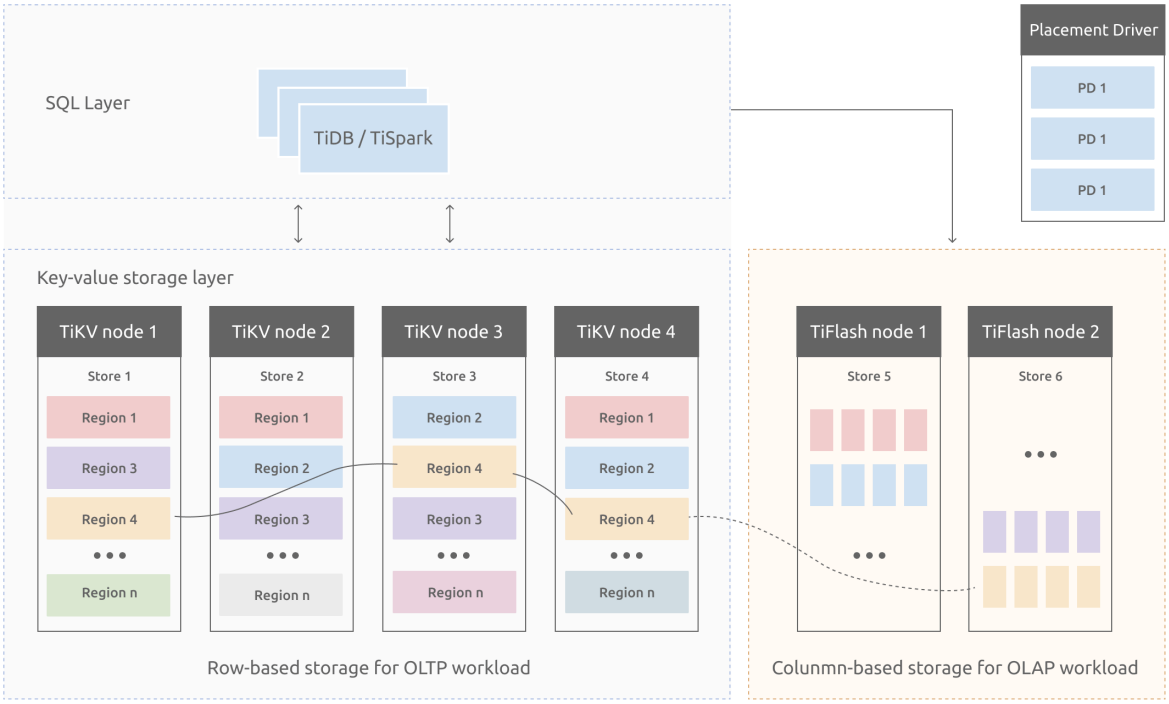

Figure 185: TiFlash Architecture

The above figure is the architecture of TiDB in its HTAP form, including TiFlash nodes.

TiFlash provides the columnar storage, with a layer of coprocessors efficiently implemented by ClickHouse. Similar to TiKV, TiFlash also has a Multi-Raft system, which supports replicating and distributing data in the unit of Region (see Data Storage for details).

TiFlash conducts real-time replication of data in the TiKV nodes at a low cost that does not block writes in TiKV. Meanwhile, it provides the same read consistency as in TiKV and ensures that the latest data is read. The Region replica in TiFlash is logically identical to those in TiKV, and is split and merged along with the Leader replica in TiKV at the same time.

TiFlash is compatible with both TiDB and TiSpark, which enables you to freely choose between these two computing engines.

It is recommended that you deploy TiFlash in different nodes from TiKV to ensure workload isolation. It is also acceptable to deploy TiFlash and TiKV in the same node if no business isolation is required.

Currently, data cannot be written directly into TiFlash. You need to write data in TiKV and then replicate it to TiFlash, because it connects to the TiDB cluster as a Learner role.

TiFlash supports data replication in the unit of table, but no data is replicated by default after deployment. To replicate data of a specified table, see Create TiFlash replicas for tables.

TiFlash has three components: the columnar storage module, `tiflash proxy`, and `pd buddy`. `tiflash proxy` is responsible for the communication using the Multi-Raft consensus algorithm. `pd buddy` works with PD to replicate data from TiKV to TiFlash in the unit of table.

When TiDB receives the DDL command to create replicas in TiFlash, the `pd buddy` component acquires the information of the table to be replicated via the status port of TiDB, and sends the information to PD. Then PD performs the corresponding data scheduling according to the information provided by `pd buddy`.

12.3.1.2 Key features

TiFlash has the following key features:

- Asynchronous replication
- Consistency
- Intelligent choice
- Computing acceleration

12.3.1.2.1 Asynchronous replication

The replica in TiFlash is asynchronously replicated as a special role, Raft Learner. This means when the TiFlash node is down or high network latency occurs, applications in TiKV can still proceed normally.

This replication mechanism inherits two advantages of TiKV: automatic load balancing and high availability.

- TiFlash does not rely on additional replication channels, but directly receives data from TiKV in a many-to-many manner.
- As long as the data is not lost in TiKV, you can restore the replica in TiFlash at any time.

12.3.1.2.2 Consistency

TiFlash provides the same Snapshot Isolation level of consistency as TiKV, and ensures that the latest data is read, which means that you can read the data previously written in TiKV. Such consistency is achieved by validating the data replication progress.

Every time TiFlash receives a read request, the Region replica sends a progress validation request (a lightweight RPC request) to the Leader replica. TiFlash performs the read operation only after the current replication progress includes the data covered by the timestamp of the read request.

12.3.1.2.3 Intelligent choice

TiDB can automatically choose to use TiFlash (column-wise) or TiKV (row-wise), or use both of them in one query to ensure the best performance.

This selection mechanism is similar to that of TiDB which chooses different indexes to execute query. TiDB optimizer makes the appropriate choice based on statistics of the read cost.

12.3.1.2.4 Computing acceleration

TiFlash accelerates the computing of TiDB in two ways:

- The columnar storage engine is more efficient in performing read operation.
- TiFlash shares part of the computing workload of TiDB.

TiFlash shares the computing workload in the same way as the TiKV Coprocessor does: TiDB pushes down the computing that can be completed in the storage layer. Whether the computing can be pushed down depends on the support of TiFlash. For details, see Supported pushdown calculations.

12.3.1.3 See also

- To deploy a new cluster with TiFlash nodes, see Deploy a TiDB cluster using TiUP.

- Use TiFlash.
- Maintain a TiFlash cluster.
- Tune TiFlash performance.
- Configure TiFlash.
- Monitor the TiFlash cluster.
- Learn TiFlash alert rules.
- Troubleshoot a TiFlash cluster.

12.3.2 Use TiFlash

After TiFlash is deployed, data replication does not automatically begin. You need to manually specify the tables to be replicated.

You can either use TiDB to read TiFlash replicas for medium-scale analytical processing, or use TiSpark to read TiFlash replicas for large-scale analytical processing, which is based on your own needs. See the following sections for details:

- Use TiDB to read TiFlash replicas
- Use TiSpark to read TiFlash replicas

12.3.2.1 Create TiFlash replicas for tables

After TiFlash is connected to the TiKV cluster, data replication by default does not begin. You can send a DDL statement to TiDB through a MySQL client to create a TiFlash replica for a specific table:

```
ALTER TABLE table_name SET TIFLASH REPLICA count;
```

The parameter of the above command is described as follows:

- `count` indicates the number of replicas. When the value is `0`, the replica is deleted.

If you execute multiple DDL statements on the same table, only the last statement is ensured to take effect. In the following example, two DDL statements are executed on the table `tpch50`, but only the second statement (to delete the replica) takes effect.

Create two replicas for the table:

```
ALTER TABLE `tpch50`.`lineitem` SET TIFLASH REPLICA 2;
```

Delete the replica:

```
ALTER TABLE `tpch50`.`lineitem` SET TIFLASH REPLICA 0;
```

Notes:

- If the table `t` is replicated to TiFlash through the above DDL statements, the table created using the following statement will also be automatically replicated to TiFlash:

  ```
  CREATE TABLE table_name like t;
  ```

- For versions earlier than v4.0.6, if you create the TiFlash replica before using TiDB Lightning to import the data, the data import will fail. You must import data to the table before creating the TiFlash replica for the table.
- If TiDB and TiDB Lightning are both v4.0.6 or later, no matter a table has TiFlash replica(s) or not, you can import data to that table using TiDB Lightning. Note that this might slow the TiDB Lightning procedure, which depends on the NIC bandwidth on the lightning host, the CPU and disk load of the TiFlash node, and the number of TiFlash replicas.
- It is recommended that you do not replicate more than 1,000 tables because this lowers the PD scheduling performance. This limit will be removed in later versions.
- In v5.1 and later versions, setting the replicas for the system tables is no longer supported. Before upgrading the cluster, you need to clear the replicas of the relevant system tables. Otherwise, you cannot modify the replica settings of the system tables after you upgrade the cluster to a later version.

12.3.2.1.1 Check replication progress

You can check the status of the TiFlash replicas of a specific table using the following statement. The table is specified using the `WHERE` clause. If you remove the `WHERE` clause, you will check the replica status of all tables.

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = '<
    ↪ db_name>' and TABLE_NAME = '<table_name>';
```

In the result of above statement:

- `AVAILABLE` indicates whether the TiFlash replicas of this table are available or not. `1` means available and `0` means unavailable. Once the replicas become available, this status does not change. If you use DDL statements to modify the number of replicas, the replication status will be recalculated.
- `PROGRESS` means the progress of the replication. The value is between `0.0` and `1.0`. `1` means at least one replica is replicated.

12.3.2.1.2 Speed up TiFlash replication

Before TiFlash replicas are added, each TiKV instance performs a full table scan and sends the scanned data to TiFlash as a "snapshot" to create replicas. By default, TiFlash replicas are added slowly with fewer resources usage in order to minimize the impact on the online service. If there are spare CPU and disk IO resources in your TiKV and TiFlash nodes, you can accelerate TiFlash replication by performing the following steps.

1. Temporarily increase the snapshot write speed limit for each TiKV and TiFlash instance by adjusting the TiFlash Proxy and TiKV configuration. For example, when using TiUP to manage configurations, the configuration is as below:

```
    yaml   tikv:     server.snap-max-write-bytes-per-sec: 300MiB # Default to
↪  100MiB. tiflash-learner: raftstore.snap-handle-pool-size: 10  # Default
↪  to 2. Can be adjusted to >= node's CPU num * 0.6. raftstore.apply-low-
↪ priority-pool-size: 10 # Default to 1. Can be adjusted to >= node's CPU
↪ num * 0.6. server.snap-max-write-bytes-per-sec: 300MiB # Default to 100
↪ MiB.
```

The configuration change takes effect after restarting the TiFlash and TiKV instances. The TiKV configuration can be also changed online by using the Dynamic Config SQL statement, which takes effect immediately without restarting TiKV instances:

```
    sql   SET CONFIG tikv `server.snap-max-write-bytes-per-sec` = '300MiB';
```

After adjusting the preceding configurations, you cannot observe the acceleration for now, as the replication speed is still restricted by the PD limit globally.

2. Use PD Control to progressively ease the new replica speed limit.

The default new replica speed limit is 30, which means, approximately 30 Regions add TiFlash replicas every minute. Executing the following command will adjust the limit to 60 for all TiFlash instances, which doubles the original speed:

```
shell  tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store
↪  limit all engine tiflash 60 add-peer
```

In the preceding command, you need to replace `<CLUSTER_VERSION>` with the actual cluster version and `<PD_ADDRESS>:2379` with the address of any PD node. For example:

```
tiup ctl:v6.1.1 pd -u http://192.168.1.4:2379 store limit all
   ↪ engine tiflash 60 add-peer
```

Within a few minutes, you will observe a significant increase in CPU and disk IO resource usage of the TiFlash nodes, and TiFlash should create replicas faster. At the same time, the TiKV nodes' CPU and disk IO resource usage increases as well.

If the TiKV and TiFlash nodes still have spare resources at this point and the latency of your online service does not increase significantly, you can further ease the limit, for example, triple the original speed:

```
shell  tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store
↪  limit all engine tiflash 90 add-peer
```

3. After the TiFlash replication is complete, revert to the default configuration to reduce the impact on online services.

Execute the following PD Control command to restore the default new replica speed limit:

```
shell  tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store
↪  limit all engine tiflash 30 add-peer
```

Comment out the changed configuration in TiUP to restore the default snapshot write speed limit:

```
yaml  # tikv:  #  server.snap-max-write-bytes-per-sec: 300MiB # tiflash
↪ -learner: # raftstore.snap-handle-pool-size: 10 # raftstore.apply-low-
↪ priority-pool-size: 10 # server.snap-max-write-bytes-per-sec: 300MiB
```

12.3.2.1.3 Set available zones

When configuring replicas, if you need to distribute TiFlash replicas to multiple data centers for disaster recovery, you can configure available zones by following the steps below:

1. Specify labels for TiFlash nodes in the cluster configuration file.

```
tiflash_servers:
  - host: 172.16.5.81
    config:
      flash.proxy.labels: zone=z1
  - host: 172.16.5.82
    config:
      flash.proxy.labels: zone=z1
  - host: 172.16.5.85
    config:
      flash.proxy.labels: zone=z2
```

2. After starting a cluster, specify the labels when creating replicas.

```
ALTER TABLE table_name SET TIFLASH REPLICA count LOCATION LABELS
    ↪ location_labels;
```

For example:

```
ALTER TABLE t SET TIFLASH REPLICA 2 LOCATION LABELS "zone";
```

3. PD schedules the replicas based on the labels. In this example, PD respectively schedules two replicas of the table `t` to two available zones. You can use pd-ctl to view the scheduling.

```
> tiup ctl:v<CLUSTER_VERSION> pd -u http://<PD_ADDRESS>:2379 store

    ...
    "address": "172.16.5.82:23913",
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z1" }
    ],
    "region_count": 4,

    ...
    "address": "172.16.5.81:23913",
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z1" }
    ],
    "region_count": 5,
    ...

    "address": "172.16.5.85:23913",
```

```
    "labels": [
      { "key": "engine", "value": "tiflash"},
      { "key": "zone", "value": "z2" }
    ],
    "region_count": 9,
    ...
```

For more information about scheduling replicas by using labels, see Schedule Replicas by Topology Labels, Multiple Data Centers in One City Deployment, and Three Data Centers in Two Cities Deployment.

12.3.2.2 Use TiDB to read TiFlash replicas

TiDB provides three ways to read TiFlash replicas. If you have added a TiFlash replica without any engine configuration, the CBO (cost-based optimization) mode is used by default.

12.3.2.2.1 Smart selection

For tables with TiFlash replicas, the TiDB optimizer automatically determines whether to use TiFlash replicas based on the cost estimation. You can use the `desc` or `explain analyze` statement to check whether or not a TiFlash replica is selected. For example:

```
desc select count(*) from test.t;
```

```
+-------------------------+---------+--------------+--------------+-------------------
    ↪
| id                      | estRows | task         | access object | operator
    ↪ info            |
+-------------------------+---------+--------------+--------------+-------------------
    ↪
| StreamAgg_9             | 1.00    | root         |               | funcs:count(1)
    ↪ ->Column#4    |
| └─TableReader_17        | 1.00    | root         |               | data:
    ↪ TableFullScan_16      |
|   └─TableFullScan_16    | 1.00    | cop[tiflash] | table:t       | keep order:
    ↪ false, stats:pseudo |
+-------------------------+---------+--------------+--------------+-------------------
    ↪
3 rows in set (0.00 sec)
```

```
explain analyze select count(*) from test.t;
```

```
+-------------------------+---------+---------+-------------+--------------+---------
   ↪
| id                      | estRows | actRows | task        | access object |
   ↪ execution info                                                  | operator
   ↪ info                | memory   | disk |
+-------------------------+---------+---------+-------------+--------------+---------
   ↪
| StreamAgg_9             | 1.00    | 1       | root        |               | time
   ↪ :83.8372ms, loops:2                                             | funcs:count
   ↪ (1)->Column#4    | 372 Bytes | N/A |
| └─TableReader_17        | 1.00    | 1       | root        |               | time
   ↪ :83.7776ms, loops:2, rpc num: 1, rpc time:83.5701ms, proc keys:0 |
   ↪ data:TableFullScan_16 | 152 Bytes | N/A |
|   └─TableFullScan_16    | 1.00    | 1       | cop[tiflash] | table:t    | time
   ↪ :43ms, loops:1                                                  | keep order:
   ↪ false, stats:pseudo | N/A  | N/A |
+-------------------------+---------+---------+-------------+--------------+---------
   ↪
```

`cop[tiflash]` means that the task will be sent to TiFlash for processing. If you have not selected a TiFlash replica, you can try to update the statistics using the `analyze table` statement, and then check the result using the `explain analyze` statement.

Note that if a table has only a single TiFlash replica and the related node cannot provide service, queries in the CBO mode will repeatedly retry. In this situation, you need to specify the engine or use the manual hint to read data from the TiKV replica.

12.3.2.2.2 Engine isolation

Engine isolation is to specify that all queries use a replica of the specified engine by configuring the corresponding variable. The optional engines are "tikv", "tidb" (indicates the internal memory table area of TiDB, which stores some TiDB system tables and cannot be actively used by users), and "tiflash", with the following two configuration levels:

- TiDB instance-level, namely, INSTANCE level. Add the following configuration item in the TiDB configuration file:

  ```
  [isolation-read]
  engines = ["tikv", "tidb", "tiflash"]
  ```

  The INSTANCE-level default configuration is `["tikv", "tidb", "tiflash"]` ↪ .

- SESSION level. Use the following statement to configure:

```
set @@session.tidb_isolation_read_engines = "engine list separated by
    ↪ commas";
```

or

```
set SESSION tidb_isolation_read_engines = "engine list separated by
    ↪ commas";
```

The default configuration of the SESSION level inherits from the configuration of the TiDB INSTANCE level.

The final engine configuration is the session-level configuration, that is, the session-level configuration overrides the instance-level configuration. For example, if you have configured "tikv" in the INSTANCE level and "tiflash" in the SESSION level, then the TiFlash replicas are read. If the final engine configuration is "tikv" and "tiflash", then the TiKV and TiFlash replicas are both read, and the optimizer automatically selects a better engine to execute.

Note:

Because TiDB Dashboard and other components need to read some system tables stored in the TiDB memory table area, it is recommended to always add the "tidb" engine to the instance-level engine configuration.

If the queried table does not have a replica of the specified engine (for example, the engine is configured as "tiflash" but the table does not have a TiFlash replica), the query returns an error.

12.3.2.2.3 Manual hint

Manual hint can force TiDB to use specified replicas for specific table(s) on the premise of satisfying engine isolation. Here is an example of using the manual hint:

```
select /*+ read_from_storage(tiflash[table_name]) */ ... from table_name;
```

If you set an alias to a table in a query statement, you must use the alias in the statement that includes a hint for the hint to take effect. For example:

```
select /*+ read_from_storage(tiflash[alias_a,alias_b]) */ ... from
    ↪ table_name_1 as alias_a, table_name_2 as alias_b where alias_a.
    ↪ column_1 = alias_b.column_2;
```

In the above statements, `tiflash[]` prompts the optimizer to read the TiFlash replicas. You can also use `tikv[]` to prompt the optimizer to read the TiKV replicas as needed. For hint syntax details, refer to READ_FROM_STORAGE.

If the table specified by a hint does not have a replica of the specified engine, the hint is ignored and a warning is reported. In addition, a hint only takes effect on the premise of engine isolation. If the engine specified in a hint is not in the engine isolation list, the hint is also ignored and a warning is reported.

> **Note:**
>
> The MySQL client of 5.7.7 or earlier versions clears optimizer hints by default. To use the hint syntax in these early versions, start the client with the `--comments` option, for example, `mysql -h 127.0.0.1 -P 4000 -uroot --comments`.

12.3.2.2.4 The relationship of smart selection, engine isolation, and manual hint

In the above three ways of reading TiFlash replicas, engine isolation specifies the overall range of available replicas of engines; within this range, manual hint provides statement-level and table-level engine selection that is more fine-grained; finally, CBO makes the decision and selects a replica of an engine based on cost estimation within the specified engine list.

> **Note:**
>
> Before v4.0.3, the behavior of reading from TiFlash replica in a non-read-only SQL statement (for example, `INSERT INTO ... SELECT`, `SELECT ... FOR UPDATE`, `UPDATE ...`, `DELETE ...`) is undefined. In v4.0.3 and later versions, internally TiDB ignores the TiFlash replica for a non-read-only SQL statement to guarantee the data correctness. That is, for smart selection, TiDB automatically selects the non-TiFlash replica; for engine isolation that specifies TiFlash replica **only**, TiDB reports an error; and for manual hint, TiDB ignores the hint.

12.3.2.3 Use TiSpark to read TiFlash replicas

Currently, you can use TiSpark to read TiFlash replicas in a method similar to the engine isolation in TiDB. This method is to configure the `spark.tispark.isolation_read_engines` parameter. The parameter value defaults to `tikv,tiflash`,

which means that TiDB reads data from TiFlash or from TiKV according to CBO's selection. If you set the parameter value to `tiflash`, it means that TiDB forcibly reads data from TiFlash.

> **Notes**
>
> When this parameter is set to `tiflash`, only the TiFlash replicas of all tables involved in the query are read and these tables must have TiFlash replicas; for tables that do not have TiFlash replicas, an error is reported. When this parameter is set to `tikv`, only the TiKV replica is read.

You can configure this parameter in one of the following ways:

- Add the following item in the `spark-defaults.conf` file:

```
spark.tispark.isolation_read_engines tiflash
```

- Add `--conf spark.tispark.isolation_read_engines=tiflash` in the initialization command when initializing Spark shell or Thrift server.
- Set `spark.conf.set("spark.tispark.isolation_read_engines", "tiflash")` in Spark shell in a real-time manner.
- Set `set spark.tispark.isolation_read_engines=tiflash` in Thrift server after the server is connected via beeline.

12.3.2.4 Supported push-down calculations

TiFlash supports the push-down of the following operators:

- TableScan: Reads data from tables.
- Selection: Filters data.
- HashAgg: Performs data aggregation based on the Hash Aggregation algorithm.
- StreamAgg: Performs data aggregation based on the Stream Aggregation algorithm. SteamAgg only supports the aggregation without the `GROUP BY` condition.
- TopN: Performs the TopN calculation.
- Limit: Performs the limit calculation.
- Project: Performs the projection calculation.
- HashJoin (Equi Join): Performs the join calculation based on the Hash Join algorithm, but with the following conditions:
  - The operator can be pushed down only in the MPP mode.
  - The push-down of `Full Outer Join` is not supported.

- HashJoin (Non-Equi Join): Performs the Cartesian Join algorithm, but with the following conditions:
  - The operator can be pushed down only in the MPP mode.
  - Cartesian Join is supported only in Broadcast Join.

In TiDB, operators are organized in a tree structure. For an operator to be pushed down to TiFlash, all of the following prerequisites must be met:

- All of its child operators can be pushed down to TiFlash.
- If an operator contains expressions (most of the operators contain expressions), all expressions of the operator can be pushed down to TiFlash.

Currently, TiFlash supports the following push-down expressions:

- Mathematical functions: `+, -, /, *, >=, <=, =, !=, <, >, round(int), round (double), abs, floor(int), ceil(int), ceiling(int)`
- Logical functions: `and, or, not, case when, if, ifnull, isnull, in`
- Bitwise operations: `bitand, bitor, bigneg, bitxor`
- String functions: `substr, char_length, replace, concat, concat_ws, left, right`
- Date functions: `date_format, timestampdiff, from_unixtime, unix_timestamp (int), unix_timestamp(decimal), str_to_date(date), str_to_date( datetime), datediff, year, month, day, extract(datetime)`
- JSON function: `json_length`
- Conversion functions: `cast(int as double), cast(int as decimal), cast(int as string), cast(int as time), cast(double as int), cast(double as decimal), cast(double as string), cast(double as time), cast(string as int), cast(string as double), cast(string as decimal), cast(string as time), cast(decimal as int), cast(decimal as string), cast (decimal as time), cast(time as int), cast(time as decimal), cast(time as string)`
- Aggregate functions: `min, max, sum, count, avg, approx_count_distinct`

In addition, expressions that contain the Time/Bit/Set/Enum/Geometry type cannot be pushed down to TiFlash.

If a query encounters unsupported push-down calculations, TiDB needs to complete the remaining calculations, which might greatly affect the TiFlash acceleration effect. The currently unsupported operators and expressions might be supported in future versions.

12.3.2.5 Use the MPP mode

TiFlash supports using the MPP mode to execute queries, which introduces cross-node data exchange (data shuffle process) into the computation. TiDB automatically determines whether to select the MPP mode using the optimizer's cost estimation. You can change the selection strategy by modifying the values of `tidb_allow_mpp` and `tidb_enforce_mpp`.

12.3.2.5.1 Control whether to select the MPP mode

The `tidb_allow_mpp` variable controls whether TiDB can select the MPP mode to execute queries. The `tidb_enforce_mpp` variable controls whether the optimizer's cost estimation is ignored and the MPP mode of TiFlash is forcibly used to execute queries.

The results corresponding to all values of these two variables are as follows:

	tidb_allow_mpp=off	tidb_allow_mpp=on (by default)
tidb_enforce_mpp=off (by default)	The MPP mode is not used.	The optimizer selects the MPP mode based on cost estimation. (by default)
tidb_enforce_mpp=on	The MPP mode is not used.	TiDB ignores the cost estimation and selects the MPP mode.

For example, if you do not want to use the MPP mode, you can execute the following statements:

```
set @@session.tidb_allow_mpp=1;
set @@session.tidb_enforce_mpp=0;
```

If you want TiDB's cost-based optimizer to automatically decide whether to use the MPP mode (by default), you can execute the following statements:

```
set @@session.tidb_allow_mpp=1;
set @@session.tidb_enforce_mpp=0;
```

If you want TiDB to ignore the optimizer's cost estimation and to forcibly select the MPP mode, you can execute the following statements:

```
set @@session.tidb_allow_mpp=1;
set @@session.tidb_enforce_mpp=1;
```

The initial value of the `tidb_enforce_mpp` session variable is equal to the `enforce-mpp` configuration value of this tidb-server instance (which is `false` by default). If multiple tidb-server instances in a TiDB cluster only perform analytical queries and you want to make sure that the MPP mode is used on these instances, you can change their `enforce-mpp` configuration values to `true`.

> **Note:**
>
> When `tidb_enforce_mpp=1` takes effect, the TiDB optimizer will ignore the cost estimation to choose the MPP mode. However, if other factors block the MPP mode, TiDB will not select the MPP mode. These factors include the absence of TiFlash replica, unfinished replication of TiFlash replicas, and

statements containing operators or functions that are not supported by the MPP mode.

If TiDB optimizer cannot select the MPP mode due to reasons other than cost estimation, when you use the `EXPLAIN` statement to check out the execution plan, a warning is returned to explain the reason. For example:

```
set @@session.tidb_enforce_mpp=1;
create table t(a int);
explain select count(*) from t;
show warnings;
```

```
+---------+------+-----------------------------------------------------------------
   ↪
| Level   | Code | Message
   ↪
   ↪ |
+---------+------+-----------------------------------------------------------------
   ↪
| Warning | 1105 | MPP mode may be blocked because there aren't
   ↪  tiflash replicas of table `t`. |
+---------+------+-----------------------------------------------------------------
   ↪
```

12.3.2.5.2 Algorithm support for the MPP mode

The MPP mode supports these physical algorithms: Broadcast Hash Join, Shuffled Hash Join, Shuffled Hash Aggregation, Union All, TopN, and Limit. The optimizer automatically determines which algorithm to be used in a query. To check the specific query execution plan, you can execute the `EXPLAIN` statement. If the result of the `EXPLAIN` statement shows ExchangeSender and ExchangeReceiver operators, it indicates that the MPP mode has taken effect.

The following statement takes the table structure in the TPC-H test set as an example:

```
explain select count(*) from customer c join nation n on c.c_nationkey=n.
   ↪ n_nationkey;
+--
   ↪ ----------------------------------+-----------+-----------------+------
   ↪
| id                                  | estRows   | task            | access
   ↪ object | operator info
   ↪                                                 |
+--
```

```
    ↪ ----------------------------------------+-----------+-----------------+------
    ↪

9 rows in set (0.00 sec)
```

In the example execution plan, the `ExchangeReceiver` and `ExchangeSender` operators are included. The execution plan indicates that after the `nation` table is read, the `ExchangeSender` operator broadcasts the table to each node, the `HashJoin` and `HashAgg` operations are performed on the `nation` table and the `customer` table, and then the results are returned to TiDB.

TiFlash provides the following two global/session variables to control whether to use Broadcast Hash Join:

- `tidb_broadcast_join_threshold_size`: The unit of the value is bytes. If the table size (in the unit of bytes) is less than the value of the variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

- `tidb_broadcast_join_threshold_count`: The unit of the value is rows. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set, so the size is determined by the number of rows in the result set. If the estimated number of rows in the subquery is less than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

12.3.2.5.3 Known issues of MPP

In the current version, TiFlash uses the `start_ts` of a query as the unique key of the query. In most cases, the `start_ts` of each query can uniquely identify a query, but in the following cases, different queries have the same `start_ts`:

- All queries in the same transaction have the same `start_ts`.
- When you use `tidb_snapshot` to read data at a specific historical time point, the same time point is manually specified.
- When Stale Read is enabled, the same time point is manually specified.

When `start_ts` cannot uniquely represent the MPP query, if TiFlash detects that different queries have the same `start_ts` at a given time, TiFlash might report an error. Typical error cases are as follows:

- When multiple queries with the same `start_ts` are sent to TiFlash at the same time, you might encounter the `task has been registered` error.
- When multiple simple queries with `LIMIT` are executed continuously in the same transaction, once the `LIMIT` condition is met, TiDB sends a cancel request to TiFlash to cancel the query. This request also uses `start_ts` to identify the query to be canceled. If there are other queries with the same `start_ts` in TiFlash, these queries might be canceled by mistake. An example of this issue can be found in #43426.

This issue is fixed in TiDB v6.6.0. It is recommended to use the latest LTS version.

12.3.2.6 Notes

Currently, TiFlash does not support some features. These features might be incompatible with the native TiDB:

- In the TiFlash computation layer:
  - Checking overflowed numerical values is not supported. For example, adding two maximum values of the `BIGINT` type `9223372036854775807 + 9223372036854775807`. The expected behavior of this calculation in TiDB is to return the `ERROR 1690 (22003): BIGINT value is out of range` error. However, if this calculation is performed in TiFlash, an overflow value of `-2` is returned without any error.

  - The window function is not supported.
  - Reading data from TiKV is not supported.
  - Currently, the `sum` function in TiFlash does not support the string-type argument. But TiDB cannot identify whether any string-type argument has been passed into the `sum` function during the compiling. Therefore, when you execute statements similar to `select sum(string_col)from t`, TiFlash returns the `[FLASH:Coprocessor:Unimplemented] CastStringAsReal is not supported` ↪ `. error`. To avoid such an error in this case, you need to modify this SQL statement to `select sum(cast(string_col as double))from t`.
  - Currently, TiFlash's decimal division calculation is incompatible with that of TiDB. For example, when dividing decimal, TiFlash performs the calculation always using the type inferred from the compiling. However, TiDB performs this calculation using a type that is more precise than that inferred from the compiling. Therefore, some SQL statements involving the decimal division return different execution results when executed in TiDB + TiKV and in TiDB + TiFlash. For example:

```
mysql> create table t (a decimal(3,0), b decimal(10, 0));
Query OK, 0 rows affected (0.07 sec)
mysql> insert into t values (43, 1044774912);
Query OK, 1 row affected (0.03 sec)
mysql> alter table t set tiflash replica 1;
Query OK, 0 rows affected (0.07 sec)
mysql> set session tidb_isolation_read_engines='tikv';
Query OK, 0 rows affected (0.00 sec)
mysql> select a/b, a/b + 0.0000000000001 from t where a/b;
+--------+-----------------------+
| a/b    | a/b + 0.0000000000001 |
+--------+-----------------------+
| 0.0000 |     0.0000000410001 |
+--------+-----------------------+
1 row in set (0.00 sec)
mysql> set session tidb_isolation_read_engines='tiflash';
Query OK, 0 rows affected (0.00 sec)
mysql> select a/b, a/b + 0.0000000000001 from t where a/b;
Empty set (0.01 sec)
```

    In the example above, `a/b`'s inferred type from the compiling is `Decimal(7,4)` both in TiDB and in TiFlash. Constrained by `Decimal(7,4)`, `a/b`'s returned type should be `0.0000`. In TiDB, `a/b`'s runtime precision is higher than `Decimal` ↪ `(7,4)`, so the original table data is not filtered by the `where a/b` condition. However, in TiFlash, the calculation of `a/b` uses `Decimal(7,4)` as the result type, so the original table data is filtered by the `where a/b` condition.

- The MPP mode in TiFlash does not support the following features:

  - If the new_collations_enabled_on_first_bootstrap configuration item's value is true, the MPP mode does not support the string-type join key or the string column type in the group by aggregation. For these two query types, the MPP mode is not selected by default.

12.4 System Variables

TiDB system variables behave similar to MySQL with some differences, in that settings might apply on a SESSION, INSTANCE, or GLOBAL scope, or on a scope that combines SESSION, INSTANCE, or GLOBAL.

- Changes to GLOBAL scoped variables **only apply to new connection sessions with TiDB**. Currently active connection sessions are not affected. These changes are persisted and valid after restarts.
- Changes to INSTANCE scoped variables apply to all active or new connection sessions with the current TiDB instance immediately after the changes are made. Other TiDB instances are not affected. These changes are not persisted and become invalid after TiDB restarts.
- Variables can also have NONE scope. These variables are read-only, and are typically used to convey static information that will not change after a TiDB server has started.

Variables can be set with the SET statement on a per-session, instance or global basis:

```
## These two identical statements change a session variable
SET tidb_distsql_scan_concurrency = 10;
SET SESSION tidb_distsql_scan_concurrency = 10;

## These two identical statements change a global variable
SET @@global.tidb_distsql_scan_concurrency = 10;
SET  GLOBAL tidb_distsql_scan_concurrency = 10;
```

Note:

Executing SET GLOBAL applies immediately on the TiDB server where the statement was issued. A notification is then sent to all TiDB servers to refresh their system variable cache, which will start immediately as a background operation. Because there is a risk that some TiDB servers might miss the notification, the system variable cache is also refreshed automatically every 30 seconds. This helps ensure that all servers are operating with the same configuration.

TiDB differs from MySQL in that GLOBAL scoped variables **persist** through TiDB server restarts. Additionally, TiDB presents several MySQL variables

as both readable and settable. This is required for compatibility, because it is common for both applications and connectors to read MySQL variables. For example, JDBC connectors both read and set query cache settings, despite not relying on the behavior.

Note:

Larger values do not always yield better performance. It is also important to consider the number of concurrent connections that are executing statements, because most settings apply to each connection.

Consider the unit of a variable when you determine safe values:

- For threads, safe values are typically up to the number of CPU cores.
- For bytes, safe values are typically less than the amount of system memory.
- For time, pay attention that the unit might be seconds or milliseconds.

Variables using the same unit might compete for the same set of resources.

12.4.1 Variable Reference

12.4.1.1 allow_auto_random_explicit_insert New in v4.0.3

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- Determines whether to allow explicitly specifying the values of the column with the `AUTO_RANDOM` attribute in the `INSERT` statement.

12.4.1.2 auto_increment_increment

- Scope: SESSION | GLOBAL
- Default value: `1`
- Range: `[1, 65535]`
- Controls the step size of `AUTO_INCREMENT` values to be allocated to a column. It is often used in combination with `auto_increment_offset`.

12.4.1.3 auto_increment_offset

- Scope: SESSION | GLOBAL
- Default value: `1`
- Range: `[1, 65535]`
- Controls the initial offset of `AUTO_INCREMENT` values to be allocated to a column. This setting is often used in combination with `auto_increment_increment`. For example:

```
mysql> CREATE TABLE t1 (a int not null primary key auto_increment);
Query OK, 0 rows affected (0.10 sec)

mysql> set auto_increment_offset=1;
Query OK, 0 rows affected (0.00 sec)

mysql> set auto_increment_increment=3;
Query OK, 0 rows affected (0.00 sec)

mysql> INSERT INTO t1 VALUES (),(),(),();
Query OK, 4 rows affected (0.04 sec)
Records: 4 Duplicates: 0 Warnings: 0

mysql> SELECT * FROM t1;
+----+
| a  |
+----+
|  1 |
|  4 |
|  7 |
| 10 |
+----+
4 rows in set (0.00 sec)
```

12.4.1.4 autocommit

- Scope: SESSION | GLOBAL
- Default value: `ON`
- Controls whether statements should automatically commit when not in an explicit transaction. See Transaction Overview for more information.

12.4.1.5 character_set_client

- Scope: SESSION | GLOBAL
- Default value: `utf8mb4`
- The character set for data sent from the client. See Character Set and Collation for details on the use of character sets and collations in TiDB. It is recommended to use `SET NAMES` to change the character set when needed.

12.4.1.6 character_set_connection

- Scope: SESSION | GLOBAL
- Default value: `utf8mb4`
- The character set for string literals that do not have a specified character set.

12.4.1.7 character_set_database

- Scope: SESSION | GLOBAL
- Default value: `utf8mb4`
- This variable indicates the character set of the default database in use. **It is NOT recommended to set this variable**. When a new default database is selected, the server changes the variable value.

12.4.1.8 character_set_results

- Scope: SESSION | GLOBAL
- Default value: `utf8mb4`
- The character set that is used when data is sent to the client.

12.4.1.9 character_set_server

- Scope: SESSION | GLOBAL
- Default value: `utf8mb4`
- The character set used for new schemas when no character set is specified in the `CREATE SCHEMA` statement.

12.4.1.10 cte_max_recursion_depth

- Scope: SESSION | GLOBAL
- Default value: `1000`
- Range: `[0, 4294967295]`
- Controls the maximum recursion depth in Common Table Expressions.

12.4.1.11 datadir

- Scope: NONE
- Default value: /tmp/tidb
- This variable indicates the location where data is stored. This location can be a local path or point to a PD server if the data is stored on TiKV.
- A value in the format of `ip_address:port` indicates the PD server that TiDB connects to on startup.

12.4.1.12 ddl_slow_threshold

- Scope: INSTANCE
- Default value: `300`
- DDL operations whose execution time exceeds the threshold value are output to the log. The unit is millisecond.

12.4.1.13 foreign_key_checks

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- For compatibility, TiDB returns foreign key checks as `OFF`.

12.4.1.14 hostname

- Scope: NONE
- Default value: (system hostname)
- The hostname of the TiDB server as a read-only variable.

12.4.1.15 init_connect

- Scope: GLOBAL
- Default value: “”
- The `init_connect` feature permits a SQL statement to be automatically executed when you first connect to a TiDB server. If you have the `CONNECTION_ADMIN` or `SUPER` privileges, this `init_connect` statement will not be executed. If the `init_connect` statement results in an error, your user connection will be terminated.

12.4.1.16 innodb_lock_wait_timeout

- Scope: SESSION | GLOBAL
- Default value: `50`
- Range: `[1, 1073741824]`
- The lock wait timeout for pessimistic transactions (default) in seconds.

12.4.1.17 interactive_timeout

- Scope: SESSION | GLOBAL
- Default value: `28800`
- Range: `[1, 31536000]`
- Unit: Seconds
- This variable represents the idle timeout of the interactive user session, which is measured in seconds. Interactive user session refers to the session established by calling `mysql_real_connect()` API using the `CLIENT_INTERACTIVE` option (for example, MySQL shell client). This variable is fully compatible with MySQL.

12.4.1.18 last_plan_from_binding New in v4.0

- Scope: SESSION
- Default value: `OFF`
- This variable is used to show whether the execution plan used in the previous statement was influenced by a plan binding

12.4.1.19 last_plan_from_cache New in v4.0

- Scope: SESSION
- Default value: `OFF`
- This variable is used to show whether the execution plan used in the previous `execute` statement is taken directly from the plan cache.

12.4.1.20 license

- Scope: NONE
- Default value: Apache License 2.0
- This variable indicates the license of your TiDB server installation.

12.4.1.21 max_execution_time

- Scope: SESSION | GLOBAL
- Default value: `0`
- Range: `[0, 2147483647]`
- Unit: Milliseconds
- The maximum execution time of a statement in milliseconds. The default value is unlimited (zero).

> **Note:**
>
> Unlike in MySQL, the `max_execution_time` system variable currently works on all kinds of statements in TiDB, not only restricted to the `SELECT` statement. The precision of the timeout value is roughly 100ms. This means the statement might not be terminated in accurate milliseconds as you specify.

12.4.1.22 port

- Scope: NONE
- Default value: `4000`
- Range: `[0, 65535]`
- The port that the `tidb-server` is listening on when speaking the MySQL protocol.

12.4.1.23 socket

- Scope: NONE
- Default value: “”
- The local unix socket file that the `tidb-server` is listening on when speaking the MySQL protocol.

12.4.1.24 sql_mode

- Scope: SESSION | GLOBAL
- Default value: `ONLY_FULL_GROUP_BY,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,`
  `↪ NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTI`
  `↪`
- This variable controls a number of MySQL compatibility behaviors. See SQL Mode for more information.

12.4.1.25 sql_select_limit New in v4.0.2

- Scope: SESSION | GLOBAL
- Default value: `18446744073709551615`
- Range: `[0, 18446744073709551615]`
- The maximum number of rows returned by the `SELECT` statements.

12.4.1.26 system_time_zone

- Scope: NONE
- Default value: (system dependent)
- This variable shows the system time zone from when TiDB was first bootstrapped. See also `time_zone`.

12.4.1.27 tidb_allow_batch_cop New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `1`
- Range: `[0, 2]`
- This variable is used to control how TiDB sends a coprocessor request to TiFlash. It has the following values:
  - `0`: Never send requests in batches
  - `1`: Aggregation and join requests are sent in batches
  - `2`: All coprocessor requests are sent in batches

12.4.1.28 tidb_allow_fallback_to_tikv New in v5.0

- Scope: SESSION | GLOBAL
- Default value: “”
- This variable is used to specify a list of storage engines that might fall back to TiKV. If the execution of a SQL statement fails due to a failure of the specified storage engine in the list, TiDB retries executing this SQL statement with TiKV. This variable can be set to “” or “tiflash”. When this variable is set to “tiflash”, if TiFlash returns a timeout error (error code: ErrTiFlashServerTimeout), TiDB retries executing this SQL statement with TiKV.

12.4.1.29 tidb_allow_mpp New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- Controls whether to use the MPP mode of TiFlash to execute queries. The value options are as follows:
  - `0` or `OFF`, which means that the MPP mode will not be used.
  - `1` or `ON`, which means that the optimizer determines whether to use the MPP mode based on the cost estimation (by default).

MPP is a distributed computing framework provided by the TiFlash engine, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. For details about the selection of the MPP mode, refer to Control whether to select the MPP mode.

12.4.1.30 tidb_allow_remove_auto_inc New in v2.1.18 and v3.0.4

- Scope: SESSION
- Default value: `OFF`
- This variable is used to set whether the `AUTO_INCREMENT` property of a column is allowed to be removed by executing `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE` statements. It is not allowed by default.

12.4.1.31 tidb_analyze_version New in v5.1.0

- Scope: SESSION | GLOBAL
- Value options: `1` and `2`
- Controls how TiDB collects statistics.
- The default value of `tidb_analyze_version` in each version of v5.1.x is as follows. For detailed information, see Introduction to Statistics.

Version	Default value
v5.1.0 - v5.1.3	2, which serves as an experimental feature
v5.1.4 and later v5.1.x versions	1

12.4.1.32 tidb_auto_analyze_end_time

- Scope: GLOBAL
- Default value: `23:59 +0000`
- This variable is used to restrict the time window that the automatic update of statistics is permitted. For example, to only allow automatic statistics updates between 1AM and 3AM, set `tidb_auto_analyze_start_time='01:00 +0000'` and `tidb_auto_analyze_end_time='03:00 +0000'`.

12.4.1.33 tidb_auto_analyze_ratio

- Scope: GLOBAL
- Default value: `0.5`
- This variable is used to set the threshold when TiDB automatically executes `ANALYZE TABLE` in a background thread to update table statistics. For example, a value of 0.5 means that auto-analyze is triggered when greater than 50% of the rows in a table have been modified. Auto-analyze can be restricted to only execute during certain hours of the day by specifying `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.

> **Note:**
>
> Only when the `run-auto-analyze` option is enabled in the starting configuration file of TiDB, the `auto_analyze` feature can be triggered.

12.4.1.34 tidb_auto_analyze_start_time

- Scope: GLOBAL
- Default value: `00:00 +0000`
- This variable is used to restrict the time window that the automatic update of statistics is permitted. For example, to only allow automatic statistics updates between 1AM and 3AM, set `tidb_auto_analyze_start_time='01:00 +0000'` and `tidb_auto_analyze_end_time='03:00 +0000'`.

12.4.1.35 tidb_backoff_lock_fast

- Scope: SESSION | GLOBAL
- Default value: `100`
- Range: `[1, 2147483647]`
- This variable is used to set the `backoff` time when the read request meets a lock.

12.4.1.36 tidb_backoff_weight

- Scope: SESSION | GLOBAL
- Default value: `2`
- Range: `[1, 2147483647]`
- This variable is used to increase the weight of the maximum time of TiDB `backoff`, that is, the maximum retry time for sending a retry request when an internal network or other component (TiKV, PD) failure is encountered. This variable can be used to adjust the maximum retry time and the minimum value is 1.

  For example, the base timeout for TiDB to take TSO from PD is 15 seconds. When `tidb_backoff_weight = 2`, the maximum timeout for taking TSO is: *base time * 2 = 30 seconds*.

  In the case of a poor network environment, appropriately increasing the value of this variable can effectively alleviate error reporting to the application end caused by timeout. If the application end wants to receive the error information more quickly, minimize the value of this variable.

12.4.1.37 tidb_broadcast_join_threshold_count New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `10240`
- Range: `[0, 9223372036854775807]`
- The unit of the variable is rows. If the objects of the join operation belong to a subquery, the optimizer cannot estimate the size of the subquery result set. In this situation, the size is determined by the number of rows in the result set. If the estimated number of rows in the subquery is less than the value of this variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

12.4.1.38 tidb_broadcast_join_threshold_size New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `104857600` (100 MiB)
- Range: `[0, 9223372036854775807]`
- Unit: Bytes
- If the table size is less than the value of the variable, the Broadcast Hash Join algorithm is used. Otherwise, the Shuffled Hash Join algorithm is used.

12.4.1.39 tidb_build_stats_concurrency

- Scope: SESSION | GLOBAL
- Default value: `4`
- This variable is used to set the concurrency of executing the `ANALYZE` statement.
- When the variable is set to a larger value, the execution performance of other queries is affected.

12.4.1.40 tidb_capture_plan_baselines New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to enable the baseline capturing feature. This feature depends on the statement summary, so you need to enable the statement summary before you use baseline capturing.
- After this feature is enabled, the historical SQL statements in the statement summary are traversed periodically, and bindings are automatically created for SQL statements that appear at least twice.

12.4.1.41 tidb_check_mb4_value_in_utf8

- Scope: INSTANCE
- Default value: `ON`
- This variable is used to enforce that the `utf8` character set only stores values from the Basic Multilingual Plane (BMP). To store characters outside the BMP, it is recommended to use the `utf8mb4` character set.
- You might need to disable this option when upgrading your cluster from an earlier version of TiDB where the `utf8` checking was more relaxed. For details, see FAQs After Upgrade.

12.4.1.42 tidb_checksum_table_concurrency

- Scope: SESSION
- Default value: `4`
- This variable is used to set the scan index concurrency of executing the `ADMIN CHECKSUM TABLE` statement.
- When the variable is set to a larger value, the execution performance of other queries is affected.

12.4.1.43 tidb_config

- Scope: SESSION
- Default value: “”
- This variable is read-only. It is used to obtain the configuration information of the current TiDB server.

12.4.1.44 tidb_constraint_check_in_place

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This setting only applies to optimistic transactions. When this variable is set to `OFF` ↪ , checking for duplicate values in UNIQUE indexes is deferred until the transaction commits. This helps improve performance, but might be an unexpected behavior for some applications. See Constraints for details.
  - When set to zero and using optimistic transactions:

```
tidb> create table t (i int key);
tidb> insert into t values (1);
tidb> begin optimistic;
tidb> insert into t values (1);
Query OK, 1 row affected
tidb> commit; -- Check only when a transaction is committed.
ERROR 1062 : Duplicate entry '1' for key 'PRIMARY'
```

  - When set to 1 and using optimistic transactions:

```
tidb> set @@tidb_constraint_check_in_place=1;
tidb> begin optimistic;
tidb> insert into t values (1);
ERROR 1062 : Duplicate entry '1' for key 'PRIMARY'
```

Constraint checking is always performed in place for pessimistic transactions (default).

12.4.1.45 tidb_current_ts

- Scope: SESSION
- Default value: `0`
- This variable is read-only. It is used to obtain the timestamp of the current transaction.

12.4.1.46 tidb_ddl_error_count_limit

- Scope: GLOBAL
- Default value: `512`
- Range: `[0, 9223372036854775807]`
- This variable is used to set the number of retries when the DDL operation fails. When the number of retries exceeds the parameter value, the wrong DDL operation is canceled.

12.4.1.47 tidb_ddl_reorg_batch_size

- Scope: GLOBAL
- Default value: `256`
- Range: `[32, 10240]`
- This variable is used to set the batch size during the `re-organize` phase of the DDL operation. For example, when TiDB executes the `ADD INDEX` operation, the index data needs to backfilled by `tidb_ddl_reorg_worker_cnt` (the number) concurrent workers. Each worker backfills the index data in batches.
  - If many updating operations such as `UPDATE` and `REPLACE` exist during the `ADD INDEX` operation, a larger batch size indicates a larger probability of transaction conflicts. In this case, you need to adjust the batch size to a smaller value. The minimum value is 32.
  - If the transaction conflict does not exist, you can set the batch size to a large value. The maximum value is 10240. This can increase the speed of the backfilling data, but the write pressure on TiKV also becomes higher.

12.4.1.48 tidb_ddl_reorg_priority

- Scope: SESSION
- Default value: `PRIORITY_LOW`
- This variable is used to set the priority of executing the `ADD INDEX` operation in the `re-organize` phase.
- You can set the value of this variable to `PRIORITY_LOW`, `PRIORITY_NORMAL` or `PRIORITY_HIGH`.

12.4.1.49 tidb_ddl_reorg_worker_cnt

- Scope: GLOBAL
- Default value: `4`
- Range: `[1, 128]`
- This variable is used to set the concurrency of the DDL operation in the `re-organize` phase.

12.4.1.50 tidb_disable_txn_auto_retry

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to set whether to disable the automatic retry of explicit optimistic transactions. The default value of `ON` means that transactions will not automatically

retry in TiDB and `COMMIT` statements might return errors that need to be handled in the application layer.

Setting the value to `OFF` means that TiDB will automatically retry transactions, resulting in fewer errors from `COMMIT` statements. Be careful when making this change, because it might result in lost updates.

This variable does not affect automatically committed implicit transactions and internally executed transactions in TiDB. The maximum retry count of these transactions is determined by the value of `tidb_retry_limit`.

For more details, see limits of retry.

This variable only applies to optimistic transactions, not to pessimistic transactions. The number of retries for pessimistic transactions is controlled by `max_retry_count`.

12.4.1.51 tidb_distsql_scan_concurrency

- Scope: SESSION | GLOBAL
- Default value: `15`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of the `scan` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.
- For OLAP scenarios, the maximum value cannot exceed the number of CPU cores of all the TiKV nodes.
- If a table has a lot of partitions, you can reduce the variable value appropriately to avoid TiKV becoming out of memory (OOM).

12.4.1.52 tidb_dml_batch_size

- Scope: SESSION | GLOBAL
- Default value: `0`
- Range: `[0, 2147483647]`
- When this value is greater than `0`, TiDB will batch commit statements such as `INSERT` or `LOAD DATA` into smaller transactions. This reduces memory usage and helps ensure that the `txn-total-size-limit` is not reached by bulk modifications.
- Only the value `0` provides ACID compliance. Setting this to any other value will break the atomicity and isolation guarantees of TiDB.

12.4.1.53 tidb_enable_1pc New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to specify whether to enable the one-phase commit feature for transactions that only affect one Region. Compared with the often-used two-phase commit, one-phase commit can greatly reduce the latency of transaction commit and increase the throughput.

Note:

- The default value of `ON` only applies to new clusters. if your cluster was upgraded from an earlier version of TiDB, the value `OFF` will be used instead.
- If you have enabled TiDB Binlog, enabling this variable cannot improve the performance. To improve the performance, it is recommended to use TiCDC instead.
- Enabling this parameter only means that one-phase commit becomes an optional mode of transaction commit. In fact, the most suitable mode of transaction commit is determined by TiDB.

12.4.1.54 tidb_enable_amend_pessimistic_txn New in v4.0.7

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to enable the `AMEND TRANSACTION` feature. If you enable the `AMEND TRANSACTION` feature in a pessimistic transaction, when concurrent DDL operations and SCHEMA VERSION changes exist on tables associated with this transaction, TiDB attempts to amend the transaction. TiDB corrects the transaction commit to make the commit consistent with the latest valid SCHEMA VERSION so that the transaction can be successfully committed without getting the `Information schema is changed` error. This feature is effective on the following concurrent DDL operations:
  - `ADD COLUMN` or `DROP COLUMN` operations.
  - `MODIFY COLUMN` or `CHANGE COLUMN` operations which increase the length of a field.
  - `ADD INDEX` or `DROP INDEX` operations in which the index column is created before the transaction is opened.

Note:

Currently, this feature is incompatible with TiDB Binlog in some scenarios and might cause semantic changes on a transaction. For more usage precautions of this feature, refer to Incompatibility issues about transaction semantic and Incompatibility issues about TiDB Binlog.

12.4.1.55 tidb_enable_async_commit New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable controls whether to enable the async commit feature for the second phase of the two-phase transaction commit to perform asynchronously in the background. Enabling this feature can reduce the latency of transaction commit.

> **Note:**
>
> - The default value of `ON` only applies to new clusters. if your cluster was upgraded from an earlier version of TiDB, the value `OFF` will be used instead.
> - If you have enabled TiDB Binlog, enabling this variable cannot improve the performance. To improve the performance, it is recommended to use TiCDC instead.
> - Enabling this parameter only means that Async Commit becomes an optional mode of transaction commit. In fact, the most suitable mode of transaction commit is determined by TiDB.

12.4.1.56 tidb_enable_change_multi_schema

> **Warning:**
>
> Currently, multi-schema change is an experimental feature. It is not recommended that you use it in the production environment. TiDB will support more types of multi-schema changes in the future. This system variable will be deleted in a future release of TiDB.

- Scope: GLOBAL
- Persists to cluster: Yes
- Type: Boolean
- Default value: `OFF`
- This variable is used to control whether multiple columns or indexes can be altered in one `ALTER TABLE` statement. When the value of this variable is `ON`, only the following multi-schema changes are supported:
  - Add multiple columns. For example, `ALTER TABLE t ADD COLUMN c1 INT, ADD COLUMN c2 INT;`.

- Drop multiple columns. For example, `ALTER TABLE t DROP COLUMN c1, DROP COLUMN c2;`.
- Drop multiple indexes. For example, `ALTER TABLE t DROP INDEX i1, DROP INDEX i2;`.
- Drop a column covered by a single-column index. For example, `ALTER TABLE t DROP COLUMN c1`, in which the schema contains `INDEX idx(c1)`.

12.4.1.57 tidb_enable_cascades_planner

> **Warning:**
>
> Currently, cascades planner is an experimental feature. It is not recommended that you use it in the production environment.

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to enable the cascades planner.

12.4.1.58 tidb_enable_chunk_rpc New in v4.0

- Scope: SESSION
- Default value: `ON`
- This variable is used to control whether to enable the `Chunk` data encoding format in Coprocessor.

12.4.1.59 tidb_enable_clustered_index New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `INT_ONLY`
- Possible values: `OFF`, `ON`, `INT_ONLY`
- This variable is used to control whether to create the primary key as a clustered index by default. "By default" here means that the statement does not explicitly specify the keyword `CLUSTERED`/`NONCLUSTERED`. Supported values are `OFF`, `ON`, and `INT_ONLY`:
  - `OFF` indicates that primary keys are created as non-clustered indexes by default.
  - `ON` indicates that primary keys are created as clustered indexes by default.
  - `INT_ONLY` indicates that the behavior is controlled by the configuration item `alter-primary-key`. If `alter-primary-key` is set to `true`, all primary keys are created as non-clustered indexes by default. If it is set to `false`, only the primary keys which consist of an integer column are created as clustered indexes.

12.4.1.60 tidb_enable_collect_execution_info

- Scope: INSTANCE
- Default value: `ON`
- This variable controls whether to record the execution information of each operator in the slow query log.

12.4.1.61 tidb_enable_enhanced_security

- Scope: NONE
- Default value: `OFF`
- This variable indicates whether the TiDB server you are connected to has the Security Enhanced Mode (SEM) enabled. To change its value, you need to modify the value of `enable-sem` in your TiDB server configuration file and restart the TiDB server.
- SEM is inspired by the design of systems such as Security-Enhanced Linux. It reduces the abilities of users with the MySQL `SUPER` privilege and instead requires `RESTRICTED` fine-grained privileges to be granted as a replacement. These fine-grained privileges include:
  - `RESTRICTED_TABLES_ADMIN`: The ability to write data to system tables in the `mysql` schema and to see sensitive columns on `information_schema` tables.
  - `RESTRICTED_STATUS_ADMIN`: The ability to see sensitive variables in the command `SHOW STATUS`.
  - `RESTRICTED_VARIABLES_ADMIN`: The ability to see and set sensitive variables in `SHOW [GLOBAL] VARIABLES` and `SET`.
  - `RESTRICTED_USER_ADMIN`: The ability to prevent other users from making changes or dropping a user account.

12.4.1.62 tidb_enable_fast_analyze

> **Warning:**
>
> Currently, `Fast Analyze` is an experimental feature. It is not recommended that you use it in the production environment.

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to set whether to enable the statistics `Fast Analyze` feature.
- If the statistics `Fast Analyze` feature is enabled, TiDB randomly samples about 10,000 rows of data as statistics. When the data is distributed unevenly or the data size is small, the statistics accuracy is low. This might lead to a non-optimal execution plan, for example, selecting a wrong index. If the execution time of the regular `Analyze` statement is acceptable, it is recommended to disable the `Fast Analyze` feature.

12.4.1.63 tidb_enable_index_merge New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to enable the index merge feature.

12.4.1.64 tidb_enable_list_partition New in v5.0

> **Warning:**
>
> Currently, List partition and List COLUMNS partition are experimental features. It is not recommended that you use it in the production environment.

- Scope: SESSION
- Default value: `OFF`
- This variable is used to set whether to enable the `LIST (COLUMNS)TABLE PARTITION` feature.

12.4.1.65 tidb_enable_noop_functions New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- By default, TiDB returns an error when you attempt to use the syntax for functionality that is not yet implemented. When the variable value is set to `ON`, TiDB silently ignores such cases of unavailable functionality, which is helpful if you cannot make changes to the SQL code.
- Enabling `noop` functions controls the following behaviors:
  - `get_lock` and `release_lock` functions
  - `LOCK IN SHARE MODE` syntax
  - `SQL_CALC_FOUND_ROWS` syntax
  - `CREATE TEMPORARY TABLE` syntax
  - `DROP TEMPORARY TABLE` syntax
  - `START TRANSACTION READ ONLY` and `SET TRANSACTION READ ONLY` syntax
  - The `tx_read_only`, `transaction_read_only`, `offline_mode`, `super_read_only` and `read_only` system variables

Warning:

Only the default value of `OFF` can be considered safe. Setting `tidb_enable_noop_functions=1` might lead to unexpected behaviors in your application, because it permits TiDB to ignore certain syntax without providing an error. For example, the syntax `START TRANSACTION READ ONLY` is permitted, but the transaction remains in read-write mode.

12.4.1.66 tidb_enable_parallel_apply New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable controls whether to enable concurrency for the `Apply` operator. The number of concurrencies is controlled by the `tidb_executor_concurrency` variable. The `Apply` operator processes correlated subqueries and has no concurrency by default, so the execution speed is slow. Setting this variable value to `1` can increase concurrency and speed up execution. Currently, concurrency for `Apply` is disabled by default.

12.4.1.67 tidb_enable_rate_limit_action

Note:

This variable is enabled by default, which makes the memory usage not under the control of `tidb_mem_quota_query` in some cases. Therefore, it is recommended to set the value of `tidb_enable_rate_limit_action` to `OFF`.

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable controls whether to enable the dynamic memory control feature for the operator that reads data. By default, this operator enables the maximum number of threads that `tidb_disql_scan_concurrency` allows to read data. When the memory usage of a single SQL statement exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.
- When the operator that reads data has only one thread left and the memory usage of a single SQL statement continues to exceed `tidb_mem_quota_query`, this SQL statement triggers other memory control behaviors, such as spilling data to disk.

12.4.1.68 tidb_enable_slow_log

- Scope: INSTANCE
- Default value: `ON`
- This variable is used to control whether to enable the slow log feature.

12.4.1.69 tidb_enable_stmt_summary New in v3.0.4

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to control whether to enable the statement summary feature. If enabled, SQL execution information like time consumption is recorded to the `information_schema.STATEMENTS_SUMMARY` system table to identify and troubleshoot SQL performance issues.

12.4.1.70 tidb_enable_strict_double_type_check New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to control if tables can be created with invalid definitions of type `DOUBLE`. This setting is intended to provide an upgrade path from earlier versions of TiDB, which were less strict in validating types.
- The default value of `ON` is compatible with MySQL.

For example, the type `DOUBLE(10)` is now considered invalid because the precision of floating point types is not guaranteed. After changing `tidb_enable_strict_double_type_check` ↪ to `OFF`, the table is created:

```
mysql> CREATE TABLE t1 (id int, c double(10));
ERROR 1149 (42000): You have an error in your SQL syntax; check the manual
    ↪ that corresponds to your MySQL server version for the right syntax to
    ↪  use

mysql> SET tidb_enable_strict_double_type_check = 'OFF';
Query OK, 0 rows affected (0.00 sec)

mysql> CREATE TABLE t1 (id int, c double(10));
Query OK, 0 rows affected (0.09 sec)
```

Note:

This setting only applies to the type `DOUBLE` since MySQL permits precision for `FLOAT` types. This behavior is deprecated starting with MySQL 8.0.17, and it is not recommended to specify precision for either `FLOAT` or `DOUBLE` types.

12.4.1.71 tidb_enable_table_partition

- Scope: SESSION | GLOBAL
- Default value: `ON`
- Possible values: `OFF`, `ON`, `AUTO`
- This variable is used to set whether to enable the `TABLE PARTITION` feature:
  - `ON` indicates enabling Range partitioning, Hash partitioning, and Range column partitioning with one single column.
  - `AUTO` functions the same way as `ON` does.
  - `OFF` indicates disabling the `TABLE PARTITION` feature. In this case, the syntax that creates a partition table can be executed, but the table created is not a partitioned one.

12.4.1.72 tidb_enable_telemetry New in v4.0.2

- Scope: GLOBAL
- Default value: `ON`
- This variable is used to dynamically control whether the telemetry collection in TiDB is enabled. By setting the value to `OFF`, the telemetry collection is disabled. If the `enable-telemetry` TiDB configuration item is set to `false` on all TiDB instances, the telemetry collection is always disabled and this system variable will not take effect. See Telemetry for details.

12.4.1.73 tidb_enable_vectorized_expression New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to control whether to enable vectorized execution.

12.4.1.74 tidb_enable_window_function

- Scope: SESSION | GLOBAL
- Default value: `ON`

- This variable is used to control whether to enable the support for window functions. Note that window functions may use reserved keywords. This might cause SQL statements that could be executed normally cannot be parsed after upgrading TiDB. In this case, you can set `tidb_enable_window_function` to `OFF`.

12.4.1.75 tidb_enforce_mpp New in v5.1

- Scope: SESSION
- Default value: `OFF`. To change this default value, modify the `performance.enforce-mpp` configuration value.
- Controls whether to ignore the optimizer's cost estimation and to forcibly use TiFlash's MPP mode for query execution. The value options are as follows:
  - `0` or `OFF`, which means that the MPP mode is not forcibly used (by default).
  - `1` or `ON`, which means that the cost estimation is ignored and the MPP mode is forcibly used. Note that this setting only takes effect when `tidb_allow_mpp=true`.

MPP is a distributed computing framework provided by the TiFlash engine, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. For details about the selection of the MPP mode, refer to Control whether to select the MPP mode.

12.4.1.76 tidb_evolve_plan_baselines New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to enable the baseline evolution feature. For detailed introduction or usage , see Baseline Evolution.
- To reduce the impact of baseline evolution on the cluster, use the following configurations:
  - Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is 600s.
  - Set `tidb_evolve_plan_task_start_time` and `tidb_evolve_plan_task_end_time` to limit the time window. The default values are respectively `00:00 +0000` and `23:59 +0000`.

12.4.1.77 tidb_evolve_plan_task_end_time New in v4.0

- Scope: GLOBAL
- Default value: `23:59 +0000`
- This variable is used to set the end time of baseline evolution in a day.

12.4.1.78 tidb_evolve_plan_task_max_time New in v4.0

- Scope: GLOBAL
- Default value: `600`
- Range: `[-1, 9223372036854775807]`
- This variable is used to limit the maximum execution time of each execution plan in the baseline evolution feature. The unit is second.

12.4.1.79 tidb_evolve_plan_task_start_time New in v4.0

- Scope: GLOBAL
- Default value: `00:00 +0000`
- This variable is used to set the start time of baseline evolution in a day.

12.4.1.80 tidb_executor_concurrency New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `5`
- Range: `[1, 2147483647]`

This variable is used to set the concurrency of the following SQL operators (to one value):

- `index lookup`
- `index lookup join`
- `hash join`
- `hash aggregation` (the `partial` and `final` phases)
- `window`
- `projection`

`tidb_executor_concurrency` incorporates the following existing system variables as a whole for easier management:

- `tidb_index_lookup_concurrency`
- `tidb_index_lookup_join_concurrency`
- `tidb_hash_join_concurrency`
- `tidb_hashagg_partial_concurrency`
- `tidb_hashagg_final_concurrency`
- `tidb_projection_concurrency`
- `tidb_window_concurrency`

Since v5.0, you can still separately modify the system variables listed above (with a deprecation warning returned) and your modification only affects the corresponding single operators. After that, if you use `tidb_executor_concurrency` to modify the operator concurrency, the separately modified operators will not be affected. If you want to use `tidb_executor_concurrency` to modify the concurrency of all operators, you can set the values of all variables listed above to `-1`.

For a system upgraded to v5.0 from an earlier version, if you have not modified any value of the variables listed above (which means that the `tidb_hash_join_concurrency` value is `5` and the values of the rest are `4`), the operator concurrency previously managed by these variables will automatically be managed by `tidb_executor_concurrency`. If you have modified any of these variables, the concurrency of the corresponding operators will still be controlled by the modified variables.

12.4.1.81 tidb_expensive_query_time_threshold

- Scope: INSTANCE
- Default value: `60`
- Range: `[10, 2147483647]`
- This variable is used to set the threshold value that determines whether to print expensive query logs. The unit is second. The difference between expensive query logs and slow query logs is:
  - Slow logs are printed after the statement is executed.
  - Expensive query logs print the statements that are being executed, with execution time exceeding the threshold value, and their related information.

12.4.1.82 tidb_force_priority

- Scope: INSTANCE
- Default value: `NO_PRIORITY`
- This variable is used to change the default priority for statements executed on a TiDB server. A use case is to ensure that a particular user that is performing OLAP queries receives lower priority than users performing OLTP queries.
- You can set the value of this variable to `NO_PRIORITY`, `LOW_PRIORITY`, `DELAYED` or `HIGH_PRIORITY`.

12.4.1.83 tidb_gc_concurrency New in v5.0

- Scope: GLOBAL
- Default value: `-1`
- Range: `[1, 128]`
- Specifies the number of threads in the Resolve Locks step of GC. A value of `-1` means that TiDB will automatically decide the number of garbage collection threads to use.

12.4.1.84 tidb_gc_enable New in v5.0

- Scope: GLOBAL
- Default value: `ON`
- Enables garbage collection for TiKV. Disabling garbage collection will reduce system performance, as old versions of rows will no longer be purged.

12.4.1.85 tidb_gc_life_time New in v5.0

- Scope: GLOBAL
- Default value: `10m0s`
- Range: `[10m0s, 8760h0m0s]`
- The time limit during which data is retained for each GC, in the format of Go Duration. When a GC happens, the current time minus this value is the safe point.

Note:

- In scenarios of frequent updates, a large value (days or even months) for `tidb_gc_life_time` may cause potential issues, such as:
  - Larger storage use
  - A large amount of history data may affect performance to a certain degree, especially for range queries such as `select count(*)from t`
- If there is any transaction that has been running longer than `tidb_gc_life_time`, during GC, the data since `start_ts` is retained for this transaction to continue execution. For example, if `tidb_gc_life_time` is configured to 10 minutes, among all transactions being executed, the transaction that starts earliest has been running for 15 minutes, GC will retain data of the recent 15 minutes.

12.4.1.86 tidb_gc_run_interval New in v5.0

- Scope: GLOBAL
- Default value: `10m0s`
- Range: `[10m0s, 8760h0m0s]`
- Specifies the GC interval, in the format of Go Duration, for example, `"1h30m"`, and `"15m"`

12.4.1.87 tidb_gc_scan_lock_mode New in v5.0

> **Warning:**
>
> Currently, Green GC is an experimental feature. It is not recommended that you use it in the production environment.

- Scope: GLOBAL
- Default value: `LEGACY`
- Possible values: `PHYSICAL`, `LEGACY`
  - `LEGACY`: Uses the old way of scanning, that is, disable Green GC.
  - `PHYSICAL`: Uses the physical scanning method, that is, enable Green GC.
- This variable specifies the way of scanning locks in the Resolve Locks step of GC. When the variable value is set to `LEGACY`, TiDB scans locks by Regions. When the value `PHYSICAL` is used, it enables each TiKV node to bypass the Raft layer and directly scan data, which can effectively mitigate the impact of GC wakening up all Regions when the Hibernate Region feature is enabled, thus improving the execution speed in the Resolve Locks step.

12.4.1.88 tidb_general_log

- Scope: INSTANCE
- Default value: `OFF`
- This variable is used to set whether to record all SQL statements in the log. This feature is disabled by default. If maintenance personnel needs to trace all SQL statements when locating issues, they can enable this feature.
- To see all records of this feature in the log, query the `"GENERAL_LOG"` string. The following information is recorded:
  - `conn`: The ID of the current session.
  - `user`: The current session user.
  - `schemaVersion`: The current schema version.
  - `txnStartTS`: The timestamp at which the current transaction starts.
  - `forUpdateTS`: In the pessimistic transactional model, `forUpdateTS` is the current timestamp of the SQL statement. When a write conflict occurs in the pessimistic transaction, TiDB retries the SQL statement currently being executed and updates this timestamp. You can configure the number of retries via `max-retry-count`. In the optimistic transactional model, `forUpdateTS` is equivalent to `txnStartTS`.
  - `isReadConsistency`: Indicates whether the current transactional isolation level is Read Committed (RC).

- `current_db`: The name of the current database.
- `txn_mode`: The transactional mode. Value options are `OPTIMISTIC` and `PESSIMISTIC`.
- `sql`: The SQL statement corresponding to the current query.

12.4.1.89 tidb_hash_join_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of the `hash join` algorithm.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.90 tidb_hashagg_final_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of executing the concurrent `hash aggregation` algorithm in the `final` phase.
- When the parameter of the aggregate function is not distinct, `HashAgg` is run concurrently and respectively in two phases - the `partial` phase and the `final` phase.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.91 tidb_hashagg_partial_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of executing the concurrent `hash aggregation` algorithm in the `partial` phase.
- When the parameter of the aggregate function is not distinct, `HashAgg` is run concurrently and respectively in two phases - the `partial` phase and the `final` phase.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.92 tidb_index_join_batch_size

- Scope: SESSION | GLOBAL
- Default value: `25000`
- Range: `[1, 2147483647]`
- This variable is used to set the batch size of the `index lookup join` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

12.4.1.93 tidb_index_lookup_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of the `index lookup` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.94 tidb_index_lookup_join_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of the `index lookup join` algorithm.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.95 tidb_index_lookup_size

- Scope: SESSION | GLOBAL
- Default value: `20000`
- Range: `[1, 2147483647]`
- This variable is used to set the batch size of the `index lookup` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

12.4.1.96 tidb_index_serial_scan_concurrency

- Scope: SESSION | GLOBAL
- Default value: `1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency of the `serial scan` operation.
- Use a bigger value in OLAP scenarios, and a smaller value in OLTP scenarios.

12.4.1.97 tidb_init_chunk_size

- Scope: SESSION | GLOBAL
- Default value: `32`
- Range: `[1, 32]`
- This variable is used to set the number of rows for the initial chunk during the execution process.

12.4.1.98 tidb_isolation_read_engines New in v4.0

- Scope: SESSION
- Default value: `tikv,tiflash,tidb`
- This variable is used to set the storage engine list that TiDB can use when reading data.

12.4.1.99 tidb_low_resolution_tso

- Scope: SESSION
- Default value: `OFF`
- This variable is used to set whether to enable the low precision TSO feature. After this feature is enabled, new transactions use a timestamp updated every 2 seconds to read data.
- The main applicable scenario is to reduce the overhead of acquiring TSO for small read-only transactions when reading old data is acceptable.

12.4.1.100 tidb_max_chunk_size

- Scope: SESSION | GLOBAL
- Default value: `1024`
- Range: `[32, 2147483647]`
- This variable is used to set the maximum number of rows in a chunk during the execution process. Setting to too large of a value may cause cache locality issues.

12.4.1.101 tidb_max_delta_schema_count New in v2.1.18 and v3.0.5

- Scope: GLOBAL
- Default value: `1024`
- Range: `[100, 16384]`
- This variable is used to set the maximum number of schema versions (the table IDs modified for corresponding versions) allowed to be cached. The value range is 100 ~ 16384.

12.4.1.102 tidb_mem_quota_apply_cache New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `33554432` (32 MiB)
- Range: `[0, 9223372036854775807]`
- Unit: Bytes
- This variable is used to set the memory usage threshold of the local cache in the `Apply` operator.
- The local cache in the `Apply` operator is used to speed up the computation of the `Apply` operator. You can set the variable to `0` to disable the `Apply` cache feature.

12.4.1.103 tidb_mem_quota_query

- Scope: SESSION
- Default value: `1073741824` (1 GiB)
- Range: `[-1, 9223372036854775807]`
- Unit: Bytes
- This variable is used to set the threshold value of memory quota for a query.
- If the memory quota of a query during execution exceeds the threshold value, TiDB performs the operation designated by the OOMAction option in the configuration file. The initial value of this variable is configured by `mem-quota-query`.

12.4.1.104 tidb_memory_usage_alarm_ratio

- Scope: INSTANCE
- Default value: `0.8`
- TiDB triggers an alarm when the percentage of the memory it takes exceeds a certain threshold. For the detailed usage description of this feature, see `memory-usage-alarm-ratio`.
- You can set the initial value of this variable by configuring `memory-usage-alarm-ratio`.

12.4.1.105 tidb_metric_query_range_duration New in v4.0

- Scope: SESSION
- Default value: `60`
- Range: `[10, 216000]`
- This variable is used to set the range duration of the Prometheus statement generated when querying METRIC_SCHEMA. The unit is second.

12.4.1.106 tidb_metric_query_step New in v4.0

- Scope: SESSION
- Default value: `60`
- Range: `[10, 216000]`
- This variable is used to set the step of the Prometheus statement generated when querying `METRIC_SCHEMA`. The unit is second.

12.4.1.107 tidb_multi_statement_mode New in v4.0.11

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- Possible values: `OFF`, `ON`, `WARN`

- This variable controls whether to allow multiple queries to be executed in the same `COM_QUERY` call.
- To reduce the impact of SQL injection attacks, TiDB now prevents multiple queries from being executed in the same `COM_QUERY` call by default. This variable is intended to be used as part of an upgrade path from earlier versions of TiDB. The following behaviors apply:

Client setting	`tidb_multi_statement_mode` value	Multiple statements permitted?
Multiple Statements = ON	OFF	Yes
Multiple Statements = ON	ON	Yes
Multiple Statements = ON	WARN	Yes
Multiple Statements = OFF	OFF	No
Multiple Statements = OFF	ON	Yes
Multiple Statements = OFF	WARN	Yes (+warning returned)

Note:

Only the default value of `OFF` can be considered safe. Setting `tidb_multi_statement_mode=ON` might be required if your application was specifically designed for an earlier version of TiDB. If your application requires multiple statement support, it is recommended to use the setting provided by your client library instead of the `tidb_multi_statement_mode` option. For example:

- go-sql-driver (`multiStatements`)
- Connector/J (`allowMultiQueries`)
- PHP mysqli (`mysqli_multi_query`)

12.4.1.108 tidb_opt_agg_push_down

- Scope: SESSION
- Default value: `OFF`
- This variable is used to set whether the optimizer executes the optimization operation of pushing down the aggregate function to the position before Join, Projection, and UnionAll.
- When the aggregate operation is slow in query, you can set the variable value to ON.

12.4.1.109 tidb_opt_correlation_exp_factor

- Scope: SESSION | GLOBAL

- Default value: `1`
- Range: `[0, 2147483647]`
- When the method that estimates the number of rows based on column order correlation is not available, the heuristic estimation method is used. This variable is used to control the behavior of the heuristic method.
  - When the value is 0, the heuristic method is not used.
  - When the value is greater than 0:
    * A larger value indicates that an index scan will probably be used in the heuristic method.
    * A smaller value indicates that a table scan will probably be used in the heuristic method.

12.4.1.110 tidb_opt_correlation_threshold

- Scope: SESSION | GLOBAL
- Default value: `0.9`
- This variable is used to set the threshold value that determines whether to enable estimating the row count by using column order correlation. If the order correlation between the current column and the `handle` column exceeds the threshold value, this method is enabled.

12.4.1.111 tidb_opt_distinct_agg_push_down

- Scope: SESSION
- Default value: `OFF`
- This variable is used to set whether the optimizer executes the optimization operation of pushing down the aggregate function with `distinct` (such as `select count(distinct a)from t`) to Coprocessor.
- When the aggregate function with the `distinct` operation is slow in the query, you can set the variable value to `1`.

In the following example, before `tidb_opt_distinct_agg_push_down` is enabled, TiDB needs to read all data from TiKV and execute `distinct` on the TiDB side. After `tidb_opt_distinct_agg_push_down` is enabled, `distinct a` is pushed down to Coprocessor, and a `group by` column `test.t.a` is added to `HashAgg_5`.

```
mysql> desc select count(distinct a) from test.t;
+--
   ↪ ----------------------+----------+-----------+---------------+-----------------
   ↪
| id                    | estRows | task      | access object | operator info
   ↪                       |
```

```
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
| StreamAgg_6           | 1.00    | root     |              | funcs:count(
   ↪ distinct test.t.a)->Column#4 |
|  ─TableReader_10      | 10000.00 | root    |              | data:
   ↪ TableFullScan_9                |
|    ─TableFullScan_9   | 10000.00 | cop[tikv] | table:t   | keep order:false
   ↪ , stats:pseudo      |
+--
   ↪ ---------------------+---------+----------+--------------+----------------
   ↪
3 rows in set (0.01 sec)

mysql> set session tidb_opt_distinct_agg_push_down = 1;
Query OK, 0 rows affected (0.00 sec)

mysql> desc select count(distinct a) from test.t;
+--
   ↪ ------------------------+---------+----------+--------------+--------------
   ↪
| id                       | estRows | task     | access object | operator info
   ↪                        |
+--

   ↪ distinct test.t.a)->Column#3 |
|  ─TableReader_9          | 1.00    | root     |              | data:HashAgg_5
   ↪                          |
|    ─HashAgg_5            | 1.00    | cop[tikv] |             | group by:test.
   ↪ t.a,                     |
|      ─TableFullScan_7    | 10000.00 | cop[tikv] | table:t   | keep order:
   ↪ false, stats:pseudo      |
+--
   ↪ ------------------------+---------+----------+--------------+--------------
   ↪
4 rows in set (0.00 sec)
```

12.4.1.112 tidb_opt_insubq_to_join_and_agg

- Scope: SESSION | GLOBAL
- Default value: `ON`

- This variable is used to set whether to enable the optimization rule that converts a subquery to join and aggregation.
- For example, after you enable this optimization rule, the subquery is converted as follows:

```
select * from t where t.a in (select aa from t1);
```

The subquery is converted to join as follows:

```
select t.* from t, (select aa from t1 group by aa) tmp_t where t.a =
    ↪ tmp_t.aa;
```

If `t1` is limited to be `unique` and `not null` in the `aa` column. You can use the following statement, without aggregation.

```
select t.* from t, t1 where t.a=t1.aa;
```

12.4.1.113 tidb_opt_prefer_range_scan New in v5.0

- Scope: SESSION
- Default value: `OFF`
- After you set the value of this variable to `1`, the optimizer always prefers index scans over full table scans.
- In the following example, before you enable `tidb_opt_prefer_range_scan`, the TiDB optimizer performs a full table scan. After you enable `tidb_opt_prefer_range_scan`, the optimizer selects an index scan.

```
explain select * from t where age=5;
+--
    ↪ ----------------------+-----------+----------+--------------+--------------
    ↪
| id                    | estRows   | task     | access object | operator info
    ↪  |
+--
    ↪ ----------------------+-----------+----------+--------------+--------------
    ↪
| TableReader_7         | 1048576.00 | root   |               | data:
    ↪ Selection_6 |
|  ─Selection_6         | 1048576.00 | cop[tikv] |            | eq(test.t.age,
    ↪  5) |
|    ─TableFullScan_5   | 1048576.00 | cop[tikv] | table:t  | keep order:
    ↪ false |
+--
    ↪ ----------------------+-----------+----------+--------------+--------------
    ↪
```

```
3 rows in set (0.00 sec)

set session tidb_opt_prefer_range_scan = 1;

explain select * from t where age=5;
+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
| id                          | estRows   | task     | access object
    ↪           | operator info              |
+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
| IndexLookUp_7               | 1048576.00 | root   |
    ↪                           |                              |
|  ─IndexRangeScan_5(Build)  | 1048576.00 | cop[tikv] | table:t, index:
    ↪ idx_age(age) | range:[5,5], keep order:false |
|  ─TableRowIDScan_6(Probe)  | 1048576.00 | cop[tikv] | table:t
    ↪               | keep order:false          |
+--
    ↪ ----------------------------+-----------+----------+-----------------------
    ↪
3 rows in set (0.00 sec)
```

12.4.1.114 tidb_opt_write_row_id

- Scope: SESSION
- Default value: `OFF`
- This variable is used to control whether to allow `INSERT`, `REPLACE`, and `UPDATE` statements to operate on the `_tidb_rowid` column. This variable can be used only when you import data using TiDB tools.

12.4.1.115 tidb_partition_prune_mode New in v5.1

> **Warning:**
>
> Currently, the dynamic pruning mode for partitioned tables is an experimental feature. It is not recommended that you use it in the production environment.

- Scope: SESSION | GLOBAL
- Default value: `static`
- Specifies whether to enable `dynamic` mode for partitioned tables. For details about the dynamic pruning mode, see Dynamic Pruning Mode for Partitioned Tables.

12.4.1.116 tidb_pprof_sql_cpu New in v4.0

- Scope: INSTANCE
- Default value: `0`
- Range: `[0, 1]`
- This variable is used to control whether to mark the corresponding SQL statement in the profile output to identify and troubleshoot performance issues.

12.4.1.117 tidb_projection_concurrency

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[-1, 2147483647]`
- This variable is used to set the concurrency of the `Projection` operator.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.118 tidb_query_log_max_len

- Scope: INSTANCE
- Default value: `4096` (4 KiB)
- Range: `[-1, 9223372036854775807]`
- Unit: Bytes
- The maximum length of the SQL statement output. When the output length of a statement is larger than the `tidb_query-log-max-len` value, the statement is truncated to output.

Usage example:

```
SET tidb_query_log_max_len = 20
```

12.4.1.119 tidb_record_plan_in_slow_log

- Scope: INSTANCE
- Default value: `ON`
- This variable is used to control whether to include the execution plan of slow queries in the slow log.

12.4.1.120 tidb_redact_log

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable controls whether to hide user information in the SQL statement being recorded into the TiDB log and slow log.
- When you set the variable to `1`, user information is hidden. For example, if the executed SQL statement is `insert into t values (1,2)`, the statement is recorded as `insert into t values (?,?)` in the log.

12.4.1.121 tidb_replica_read New in v4.0

- Scope: SESSION
- Default value: `leader`
- Possible values: `leader`, `follower`, `leader-and-follower`
- This variable is used to control where TiDB reads data. Here are three options:
  - leader: Read only from leader node
  - follower: Read only from follower node
  - leader-and-follower: Read from leader or follower node
- See follower reads for additional details.

12.4.1.122 tidb_retry_limit

- Scope: SESSION | GLOBAL
- Default value: `10`
- Range: `[-1, 9223372036854775807]`
- This variable is used to set the maximum number of the retries for optimistic transactions. When a transaction encounters retryable errors (such as transaction conflicts, very slow transaction commit, or table schema changes), this transaction is re-executed according to this variable. Note that setting `tidb_retry_limit` to `0` disables the automatic retry. This variable only applies to optimistic transactions, not to pessimistic transactions.

12.4.1.123 tidb_row_format_version

- Scope: GLOBAL
- Default value: `2`
- Range: `[1, 2]`
- Controls the format version of the newly saved data in the table. In TiDB v4.0, the new storage row format version `2` is used by default to save new data.
- If you upgrade from a TiDB version earlier than 4.0.0 to 4.0.0, the format version is not changed, and TiDB continues to use the old format of version `1` to write data to the table, which means that **only newly created clusters use the new data format by default**.
- Note that modifying this variable does not affect the old data that has been saved, but applies the corresponding version format only to the newly written data after modifying this variable.

12.4.1.124 tidb_scatter_region

- Scope: GLOBAL
- Default value: `OFF`
- By default, Regions are split for a new table when it is being created in TiDB. After this variable is enabled, the newly split Regions are scattered immediately during the execution of the `CREATE TABLE` statement. This applies to the scenario where data need to be written in batches right after the tables are created in batches, because the newly split Regions can be scattered in TiKV beforehand and do not have to wait to be scheduled by PD. To ensure the continuous stability of writing data in batches, the `CREATE TABLE` statement returns success only after the Regions are successfully scattered. This makes the statement's execution time multiple times longer than that when you disable this variable.
- Note that if `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` have been set when a table is created, the specified number of Regions are evenly split after the table creation.

12.4.1.125 tidb_skip_ascii_check New in v5.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to set whether to skip ASCII validation.
- Validating ASCII characters affects the performance. When you are sure that the input characters are valid ASCII characters, you can set the variable value to `ON`.

12.4.1.126 tidb_skip_isolation_level_check

- Scope: SESSION | GLOBAL
- Default value: `OFF`

- After this switch is enabled, if an isolation level unsupported by TiDB is assigned to `tx_isolation`, no error is reported. This helps improve compatibility with applications that set (but do not depend on) a different isolation level.

```
tidb> set tx_isolation='serializable';
ERROR 8048 (HY000): The isolation level 'serializable' is not supported.
    ↪ Set tidb_skip_isolation_level_check=1 to skip this error
tidb> set tidb_skip_isolation_level_check=1;
Query OK, 0 rows affected (0.00 sec)

tidb> set tx_isolation='serializable';
Query OK, 0 rows affected, 1 warning (0.00 sec)
```

12.4.1.127 tidb_skip_utf8_check

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to set whether to skip UTF-8 validation.
- Validating UTF-8 characters affects the performance. When you are sure that the input characters are valid UTF-8 characters, you can set the variable value to `ON`.

12.4.1.128 tidb_slow_log_threshold

- Scope: INSTANCE
- Default value: `300`
- Range: `[-1, 9223372036854775807]`
- Unit: Milliseconds
- This variable is used to output the threshold value of the time consumed by the slow log. When the time consumed by a query is larger than this value, this query is considered as a slow log and its log is output to the slow query log.

Usage example:

```
SET tidb_slow_log_threshold = 200;
```

12.4.1.129 tidb_slow_query_file

- Scope: SESSION
- Default value: “”
- When `INFORMATION_SCHEMA.SLOW_QUERY` is queried, only the slow query log name set by `slow-query-file` in the configuration file is parsed. The default slow query log name is “tidb-slow.log”. To parse other logs, set the `tidb_slow_query_file` session variable to a specific file path, and then query `INFORMATION_SCHEMA.SLOW_QUERY` to parse the slow query log based on the set file path. For details, see Identify Slow Queries.

12.4.1.130 tidb_snapshot

- Scope: SESSION
- Default value: “”
- This variable is used to set the time point at which the data is read by the session. For example, when you set the variable to “2017-11-11 20:20:20” or a TSO number like “400036290571534337”, the current session reads the data of this moment.

12.4.1.131 tidb_stmt_summary_history_size New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `24`
- Range: `[0, 255]`
- This variable is used to set the history capacity of statement summary tables.

12.4.1.132 tidb_stmt_summary_internal_query New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `OFF`
- This variable is used to control whether to include the SQL information of TiDB in statement summary tables.

12.4.1.133 tidb_stmt_summary_max_sql_length New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `4096`
- Range: `[0, 2147483647]`
- This variable is used to control the length of the SQL string in statement summary tables.

12.4.1.134 tidb_stmt_summary_max_stmt_count New in v4.0

- Scope: SESSION | GLOBAL
- Default value: Before v5.1.1, the default value is `200`. Since v5.1.1, the default value is `3000`.
- Range: `[1, 32767]`
- This variable is used to set the maximum number of statements that statement summary tables store in memory.

12.4.1.135 tidb_stmt_summary_refresh_interval New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `1800`
- Range: `[1, 2147483647]`
- This variable is used to set the refresh time of statement summary tables. The unit is second.

12.4.1.136 tidb_store_limit New in v3.0.4 and v4.0

- Scope: INSTANCE | GLOBAL
- Default value: `0`
- Range: `[0, 9223372036854775807]`
- This variable is used to limit the maximum number of requests TiDB can send to TiKV at the same time. 0 means no limit.

12.4.1.137 tidb_txn_mode

- Scope: SESSION | GLOBAL
- Default value: `pessimistic`
- Possible values: `pessimistic`, `optimistic`
- This variable is used to set the transaction mode. TiDB 3.0 supports the pessimistic transactions. Since TiDB 3.0.8, the pessimistic transaction mode is enabled by default.
- If you upgrade TiDB from v3.0.7 or earlier versions to v3.0.8 or later versions, the default transaction mode does not change. **Only the newly created clusters use the pessimistic transaction mode by default**.
- If this variable is set to "optimistic" or "", TiDB uses the optimistic transaction mode.

12.4.1.138 tidb_use_plan_baselines New in v4.0

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable is used to control whether to enable the execution plan binding feature. It is enabled by default, and can be disabled by assigning the `OFF` value. For the use of the execution plan binding, see Execution Plan Binding.

12.4.1.139 tidb_wait_split_region_finish

- Scope: SESSION
- Default value: `ON`

- It usually takes a long time to scatter Regions, which is determined by PD scheduling and TiKV loads. This variable is used to set whether to return the result to the client after all Regions are scattered completely when the `SPLIT REGION` statement is being executed:
  - `ON` requires that the `SPLIT REGIONS` statement waits until all Regions are scattered.
  - `OFF` permits the `SPLIT REGIONS` statement to return before finishing scattering all Regions.
- Note that when scattering Regions, the write and read performances for the Region that is being scattered might be affected. In batch-write or data importing scenarios, it is recommended to import data after Regions scattering is finished.

12.4.1.140 tidb_wait_split_region_timeout

- Scope: SESSION
- Default value: `300`
- Range: `[1, 2147483647]`
- This variable is used to set the timeout for executing the `SPLIT REGION` statement. The unit is second. If a statement is not executed completely within the specified time value, a timeout error is returned.

12.4.1.141 tidb_window_concurrency New in v4.0

> **Warning:**
>
> Since v5.0, this variable is deprecated. Instead, use `tidb_executor_concurrency` for setting.

- Scope: SESSION | GLOBAL
- Default value: `-1`
- Range: `[1, 2147483647]`
- This variable is used to set the concurrency degree of the window operator.
- A value of `-1` means that the value of `tidb_executor_concurrency` will be used instead.

12.4.1.142 time_zone

- Scope: SESSION | GLOBAL
- Default value: `SYSTEM`

- This variable returns the current time zone. Values can be specified as either an offset such as '-8:00' or a named zone 'America/Los_Angeles'.
- The value `SYSTEM` means that the time zone should be the same as the system host, which is available via the `system_time_zone` variable.

12.4.1.143 transaction_isolation

- Scope: SESSION | GLOBAL
- Default value: `REPEATABLE-READ`
- Possible values: `READ-UNCOMMITTED`, `READ-COMMITTED`, `REPEATABLE-READ`, `SERIALIZABLE`
- This variable sets the transaction isolation. TiDB advertises `REPEATABLE-READ` for compatibility with MySQL, but the actual isolation level is Snapshot Isolation. See transaction isolation levels for further details.

12.4.1.144 tx_isolation

This variable is an alias for *transaction_isolation*.

12.4.1.145 version

- Scope: NONE
- Default value: `5.7.25-TiDB-`(tidb version)
- This variable returns the MySQL version, followed by the TiDB version. For example '5.7.25-TiDB-v4.0.0-beta.2-716-g25e003253'.

12.4.1.146 version_comment

- Scope: NONE
- Default value: (string)
- This variable returns additional details about the TiDB version. For example, 'TiDB Server (Apache License 2.0) Community Edition, MySQL 5.7 compatible'.

12.4.1.147 wait_timeout

- Scope: SESSION | GLOBAL
- Default value: `0`
- Range: `[0, 31536000]`
- Unit: Seconds
- This variable controls the idle timeout of user sessions. A zero-value means unlimited.

12.4.1.148 warning_count

- Scope: SESSION
- Default value: `0`
- This read-only variable indicates the number of warnings that occurred in the statement that was previously executed.

12.4.1.149 windowing_use_high_precision

- Scope: SESSION | GLOBAL
- Default value: `ON`
- This variable controls whether to use the high precision mode when computing the window functions.

12.5 Configuration File Parameters

12.5.1 TiDB Configuration File

The TiDB configuration file supports more options than command-line parameters. You can download the default configuration file `config.toml.example` and rename it to `config.toml`. This document describes only the options that are not involved in command line options.

12.5.1.0.1 `split-table`

- Determines whether to create a separate Region for each table.
- Default value: `true`
- It is recommended to set it to `false` if you need to create a large number of tables.

12.5.1.0.2 `token-limit`

- The number of sessions that can execute requests concurrently.
- Type: Integer
- Default value: `1000`
- Minimum value: `1`
- Maximum Value (64-bit platforms): `18446744073709551615`
- Maximum Value (32-bit platforms): `4294967295`

12.5.1.0.3 mem-quota-query

- The maximum memory available for a single SQL statement.
- Default value: 1073741824 (in bytes)
- Note: When you upgrade the cluster from v2.0.x or v3.0.x to v4.0.9 or later versions, the default value of this configuration is 34359738368.
- Requests that require more memory than this value are handled based on the behavior defined by oom-action.
- This value is the initial value of the system variable tidb_mem_quota_query.

12.5.1.0.4 oom-use-tmp-storage

- Controls whether to enable the temporary storage for some operators when a single SQL statement exceeds the memory quota specified by mem-quota-query.
- Default value: true

12.5.1.0.5 tmp-storage-path

- Specifies the temporary storage path for some operators when a single SQL statement exceeds the memory quota specified by mem-quota-query.
- Default value: <temporary directory of OS>/<OS user ID>_tidb/MC4wLjAuMDo0MDAwLzAuMC4wL
  ↪ =/tmp-storage. MC4wLjAuMDo0MDAwLzAuMC4wLjA6MTAwODA= is the Base64 encoding result of <host>:<port>/<statusHost>:<statusPort>.
- This configuration takes effect only when oom-use-tmp-storage is true.

12.5.1.0.6 tmp-storage-quota

- Specifies the quota for the storage in tmp-storage-path. The unit is byte.
- When a single SQL statement uses a temporary disk and the total volume of the temporary disk of the TiDB server exceeds this configuration value, the current SQL operation is cancelled and the Out of Global Storage Quota! error is returned.
- When the value of this configuration is smaller than 0, the above check and limit do not apply.
- Default value: -1
- When the remaining available storage in tmp-storage-path is lower than the value defined by tmp-storage-quota, the TiDB server reports an error when it is started, and exits.

12.5.1.0.7 oom-action

- Specifies what operation TiDB performs when a single SQL statement exceeds the memory quota specified by mem-quota-query and cannot be spilled over to disk.

- Default value: `"cancel"` (In TiDB v4.0.2 and earlier versions, the default value is `"log"`)
- The valid options are `"log"` and `"cancel"`. When `oom-action="log"`, it prints the log only. When `oom-action="cancel"`, it cancels the operation and outputs the log.

12.5.1.0.8 `lower-case-table-names`

- Configures the value of the `lower-case-table-names` system variable.
- Default value: `2`
- For details, see the MySQL description of this variable.

> **Note:**
> Currently, TiDB only supports setting the value of this option to `2`. This means it is case-sensitive when you save a table name, but case-insensitive when you compare table names. The comparison is based on the lower case.

12.5.1.0.9 `lease`

- The timeout of the DDL lease.
- Default value: `45s`
- Unit: second

12.5.1.0.10 `compatible-kill-query`

- Determines whether to set the `KILL` statement to be MySQL compatible.
- Default value: `false`
- The behavior of `KILL xxx` in TiDB differs from the behavior in MySQL. TiDB requires the `TIDB` keyword, namely, `KILL TIDB xxx`. If `compatible-kill-query` is set to `true`, the `TIDB` keyword is not needed.
- This distinction is important because the default behavior of the MySQL command-line client, when the user hits Ctrl+C, is to create a new connection to the backend and execute the `KILL` statement in that new connection. If a load balancer or proxy has sent the new connection to a different TiDB server instance than the original session, the wrong session could be terminated, which could cause interruption to applications using the cluster. Enable `compatible-kill-query` only if you are certain that the connection you refer to in your `KILL` statement is on the same server to which you send the `KILL` statement.

12.5.1.0.11 `check-mb4-value-in-utf8`

- Determines whether to enable the `utf8mb4` character check. When this feature is enabled, if the character set is `utf8` and the `mb4` characters are inserted in `utf8`, an error is returned.
- Default value: `false`

12.5.1.0.12 `treat-old-version-utf8-as-utf8mb4`

- Determines whether to treat the `utf8` character set in old tables as `utf8mb4`.
- Default value: `true`

12.5.1.0.13 `alter-primary-key` (Deprecated)

- Determines whether to add or remove the primary key constraint to or from a column.
- Default value: `false`
- With this default setting, adding or removing the primary key constraint is not supported. You can enable this feature by setting `alter-primary-key` to `true`. However, if a table already exists before the switch is on, and the data type of its primary key column is an integer, dropping the primary key from the column is not possible even if you set this configuration item to `true`.

> **Note:**
>
> This configuration item has been deprecated, and currently takes effect only when the value of `@tidb_enable_clustered_index` is `INT_ONLY`. If you need to add or remove the primary key, use the `NONCLUSTERED` keyword instead when creating the table. For more details about the primary key of the `CLUSTERED` type, refer to clustered index.

12.5.1.0.14 `server-version`

- Modifies the version string returned by TiDB in the following situations:
  - When the built-in `VERSION()` function is used.
  - When TiDB establishes the initial connection to the client and returns the initial handshake packet with version string of the server. For details, see MySQL Initial Handshake Packet.
- Default value: ""
- By default, the format of the TiDB version string is `5.7.${mysql_latest_minor_version}-TiDB-${tidb_version}`.

12.5.1.0.15 `repair-mode`

- Determines whether to enable the untrusted repair mode. When the `repair-mode` is set to `true`, bad tables in the `repair-table-list` cannot be loaded.
- Default value: `false`
- The `repair` syntax is not supported by default. This means that all tables are loaded when TiDB is started.

12.5.1.0.16 `repair-table-list`

- `repair-table-list` is only valid when repair-mode is set to `true`. `repair-table-list` is a list of bad tables that need to be repaired in an instance. An example of the list is: [“db.table1”,“db.table2”…].
- Default value: []
- The list is empty by default. This means that there are no bad tables that need to be repaired.

12.5.1.0.17 `new_collations_enabled_on_first_bootstrap`

- Enables or disables the new collation support.
- Default value: `false`
- Note: This configuration takes effect only for the TiDB cluster that is first initialized. After the initialization, you cannot use this configuration item to enable or disable the new collation support. When a TiDB cluster is upgraded to v4.0, because the cluster has been initialized before, both `true` and `false` values of this configuration item are taken as `false`.

12.5.1.0.18 `max-server-connections`

- The maximum number of concurrent client connections allowed in TiDB. It is used to control resources.
- Default value: `0`
- By default, TiDB does not set limit on the number of concurrent client connections. When the value of this configuration item is greater than `0` and the number of actual client connections reaches this value, the TiDB server rejects new client connections.

12.5.1.0.19 `max-index-length`

- Sets the maximum allowable length of the newly created index.
- Default value: `3072`
- Unit: byte

- Currently, the valid value range is `[3072, 3072*4]`. MySQL and TiDB (version < v3.0.11) do not have this configuration item, but both limit the length of the newly created index. This limit in MySQL is `3072`. In TiDB (version =< 3.0.7), this limit is `3072*4`. In TiDB (3.0.7 < version < 3.0.11), this limit is `3072`. This configuration is added to be compatible with MySQL and earlier versions of TiDB.

12.5.1.0.20 `table-column-count-limit` New in v5.0

- Sets the limit on the number of columns in a single table.
- Default value: `1017`
- Currently, the valid value range is `[1017, 4096]`.

12.5.1.0.21 `index-limit` New in v5.0

- Sets the limit on the number of indexes in a single table.
- Default value: `64`
- Currently, the valid value range is `[64, 512]`.

12.5.1.0.22 `enable-telemetry` New in v4.0.2

- Enables or disables the telemetry collection in TiDB.
- Default value: `true`
- When this configuration is set to `false` on all TiDB instances, the telemetry collection in TiDB is disabled and the `tidb_enable_telemetry` system variable does not take effect. See Telemetry for details.

12.5.1.0.23 `enable-tcp4-only` New in v5.0

- Enables or disables listening on TCP4 only.
- Default value: `false`
- Enabling this option is useful when TiDB is used with LVS for load balancing because the real client IP from the TCP header can be correctly parsed by the "tcp4" protocol.

12.5.1.0.24 `enable-enum-length-limit` New in v5.0

- Determines whether to limit the maximum length of a single `ENUM` element and a single `SET` element.
- Default value: `true`
- When this configuration value is `true`, the maximum length of a single `ENUM` element and a single `SET` element is 255 characters, which is compatible with MySQL 8.0. When this configuration value is `false`, there is no limit on the length of a single element, which is compatible with TiDB (earlier than v5.0).

`graceful-wait-before-shutdown` New in v5.0

- Specifies the number of seconds that TiDB waits when you shut down the server, which allows the clients to disconnect.
- Default value: `0`
- When TiDB is waiting for shutdown (in the grace period), the HTTP status will indicate a failure, which allows the load balancers to reroute traffic.

12.5.1.0.25 `enable-forwarding` New in v5.0.0

- Controls whether the PD client and TiKV client in TiDB forward requests to the leader via the followers in the case of possible network isolation.
- Default value: `false`
- If the environment might have isolated network, enabling this parameter can reduce the window of service unavailability.
- If you cannot accurately determine whether isolation, network interruption, or downtime has occurred, using this mechanism has the risk of misjudgment and causes reduced availability and performance. If network failure has never occurred, it is not recommended to enable this parameter.

12.5.1.0.26 `enable-table-lock` New in v4.0.0

> **Warning:**
>
> The table lock is an experimental feature. It is not recommended that you use it in the production environment.

- Controls whether to enable the table lock feature.
- Default value: `false`
- The table lock is used to coordinate concurrent access to the same table among multiple sessions. Currently, the `READ`, `WRITE`, and `WRITE LOCAL` lock types are supported. When the configuration item is set to `false`, executing the `LOCK TABLES` or `UNLOCK TABLES` statement does not take effect and returns the "LOCK/UNLOCK TABLES is not supported" warning. For more information, see `LOCK TABLES` and `UNLOCK TABLES`.

12.5.1.1 Log

Configuration items related to log.

12.5.1.1.1 `level`

- Specifies the log output level.
- Value options: `debug`, `info`, `warn`, `error`, and `fatal`.
- Default value: `info`

12.5.1.1.2 `format`

- Specifies the log output format.
- Value options: `json` and `text`.
- Default value: `text`

12.5.1.1.3 `enable-timestamp`

- Determines whether to enable timestamp output in the log.
- Default value: `true`
- If you set the value to `false`, the log does not output timestamp.

> **Note:**
>
> To be backward compatible, the initial `disable-timestamp` configuration item remains valid. But if the value of `disable-timestamp` semantically conflicts with the value of `enable-timestamp` (for example, if both `enable-timestamp` and `disable-timestamp` are set to `true`), TiDB ignores the value for `disable-timestamp`. In later versions, the `disable-timestamp` configuration will be removed.
>
> Discard `disable-timestamp` and use `enable-timestamp` which is semantically easier to understand.

12.5.1.1.4 `enable-slow-log`

- Determines whether to enable the slow query log.
- Default value: `true`
- To enable the slow query log, set `enable-slow-log` to `true`. Otherwise, set it to `false`.

12.5.1.1.5 slow-query-file

- The file name of the slow query log.
- Default value: `tidb-slow.log`
- The format of the slow log is updated in TiDB v2.1.8, so the slow log is output to the slow log file separately. In versions before v2.1.8, this variable is set to "" by default.
- After you set it, the slow query log is output to this file separately.

12.5.1.1.6 slow-threshold

- Outputs the threshold value of consumed time in the slow log.
- Default value: `300ms`
- If the value in a query is larger than the default value, it is a slow query and is output to the slow log.

12.5.1.1.7 record-plan-in-slow-log

- Determines whether to record execution plans in the slow log.
- Default value: `1`
- `0` means to disable, and `1` (by default) means to enable. The value of this parameter is the initial value of the `tidb_record_plan_in_slow_log` system variable.

12.5.1.1.8 expensive-threshold

- Outputs the threshold value of the number of rows for the `expensive` operation.
- Default value: `10000`
- When the number of query rows (including the intermediate results based on statistics) is larger than this value, it is an `expensive` operation and outputs log with the `[ ↪ EXPENSIVE_QUERY]` prefix.

12.5.1.1.9 query-log-max-len

- The maximum length of SQL output.
- Default value: `4096`
- When the length of the statement is longer than `query-log-max-len`, the statement is truncated to output.

12.5.1.2 log.file

Configuration items related to log files.

`filename`

- The file name of the general log file.
- Default value: “”
- If you set it, the log is output to this file.

`max-size`

- The size limit of the log file.
- Default value: 300
- Unit: MB
- The maximum value is 4096.

`max-days`

- The maximum number of days that the log is retained.
- Default value: `0`
- The log is retained by default. If you set the value, the expired log is cleaned up after `max-days`.

`max-backups`

- The maximum number of retained logs.
- Default value: `0`
- All the log files are retained by default. If you set it to `7`, seven log files are retained at maximum.

12.5.1.3 Security

Configuration items related to security.

12.5.1.3.1 `enable-sem`

- Enables the Security Enhanced Mode (SEM).
- Default value: `false`
- The status of SEM is available via the system variable `tidb_enable_enhanced_security` ↪ .

12.5.1.3.2 `ssl-ca`

- The file path of the trusted CA certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-cert`, `--ssl-key` at the same time, TiDB authenticates the client certificate based on the list of trusted CAs specified by this option when the client presents the certificate. If the authentication fails, the connection is terminated.
- If you set this option but the client does not present the certificate, the secure connection continues without client certificate authentication.

12.5.1.3.3 `ssl-cert`

- The file path of the SSL certificate in the PEM format.
- Default value: “”
- If you set this option and `--ssl-key` at the same time, TiDB allows (but not forces) the client to securely connect to TiDB using TLS.
- If the specified certificate or private key is invalid, TiDB starts as usual but cannot receive secure connection.

12.5.1.3.4 `ssl-key`

- The file path of the SSL certificate key in the PEM format, that is, the private key of the certificate specified by `--ssl-cert`.
- Default value: “”
- Currently, TiDB does not support loading the private keys protected by passwords.

12.5.1.3.5 `cluster-ssl-ca`

- The CA root certificate used to connect TiKV or PD with TLS.
- Default value: “”

12.5.1.3.6 `cluster-ssl-cert`

- The path of the SSL certificate file used to connect TiKV or PD with TLS.
- Default value: “”

12.5.1.3.7 `cluster-ssl-key`

- The path of the SSL private key file used to connect TiKV or PD with TLS.
- Default value: “”

12.5.1.3.8 `spilled-file-encryption-method`

- Determines the encryption method used for saving the spilled files to disk.
- Default value: `"plaintext"`, which disables encryption.
- Optional values: `"plaintext"` and `"aes128-ctr"`

12.5.1.4 Performance

Configuration items related to performance.

12.5.1.4.1 `max-procs`

- The number of CPUs used by TiDB.
- Default value: `0`
- The default `0` indicates using all the CPUs on the machine. You can also set it to n, and then TiDB uses n CPUs.

12.5.1.4.2 `server-memory-quota` New in v4.0.9

> **Warning:**
>
> `server-memory-quota` is still an experimental feature. It is **NOT** recommended that you use it in a production environment.

- The memory usage limit of tidb-server instances.
- Default value: `0` (in bytes), which means no memory limit.

12.5.1.4.3 `memory-usage-alarm-ratio` New in v4.0.9

- TiDB triggers an alarm when the memory usage of tidb-server instance exceeds a certain threshold. The valid value for this configuration item ranges from `0` to `1`. If it is configured as `0` or `1`, this alarm feature is disabled.
- Default value: `0.8`
- When the memory usage alarm is enabled, if `server-memory-quota` is not set, then the threshold of memory usage is `the `memory-usage-alarm-ratio` value * the system memory size`; if `server-memory-quota` is set to a value greater than 0, then the threshold of memory usage is `the `memory-usage-alarm-ratio` value * the `server-memory-quota` value`.

- When TiDB detects that the memory usage of the tidb-server instance exceeds the threshold, it considers that there might be a risk of OOM. Therefore, it records ten SQL statements with the highest memory usage, ten SQL statements with the longest running time, and the heap profile among all SQL statements currently being executed to the directory `tmp-storage-path/record` and outputs a log containing the keyword `tidb-server has the risk of OOM`.
- The value of this configuration item is the initial value of the system variable `tidb_memory_usage_alarm_ratio`.

12.5.1.4.4 `max-txn-ttl`

- The longest time that a single transaction can hold locks. If this time is exceeded, the locks of a transaction might be cleared by other transactions so that this transaction cannot be successfully committed.
- Default value: `3600000`
- Unit: Millisecond
- The transaction that holds locks longer than this time can only be committed or rolled back. The commit might not be successful.

12.5.1.4.5 `committer-concurrency`

- The number of goroutines for requests related to executing commit in the commit phase of the single transaction.
- Default value: `128`
- If the transaction to commit is too large, the waiting time for the flow control queue when the transaction is committed might be too long. In this situation, you can increase the configuration value to speed up the commit.

12.5.1.4.6 `stmt-count-limit`

- The maximum number of statements allowed in a single TiDB transaction.
- Default value: `5000`
- If a transaction does not roll back or commit after the number of statements exceeds `stmt-count-limit`, TiDB returns the `statement count 5001 exceeds the transaction limitation, autocommit = false` error. This configuration takes effect **only** in the retriable optimistic transaction. If you use the pessimistic transaction or have disabled the transaction retry, the number of statements in a transaction is not limited by this configuration.

12.5.1.4.7 `txn-entry-size-limit` New in v5.0

- The size limit of a single row of data in TiDB.

- Default value: `6291456` (in bytes)
- The size limit of a single key-value record in a transaction. If the size limit is exceeded, TiDB returns the `entry too large` error. The maximum value of this configuration item does not exceed `125829120` (120 MB).
- Note that TiKV has a similar limit. If the data size of a single write request exceeds `raft-entry-max-size`, which is 8 MB by default, TiKV refuses to process this request. When a table has a row of large size, you need to modify both configurations at the same time.

12.5.1.4.8 `txn-total-size-limit`

- The size limit of a single transaction in TiDB.
- Default value: `104857600` (in bytes)
- In a single transaction, the total size of key-value records cannot exceed this value. The maximum value of this parameter is `10737418240` (10 GB). Note that if you have used the binlog to serve the downstream consumer Kafka (such as the `arbiter` cluster), the value of this parameter must be no more than `1073741824` (1 GB). This is because 1 GB is the upper limit of a single message size that Kafka can process. Otherwise, an error is returned if this limit is exceeded.

12.5.1.4.9 `tcp-keep-alive`

- Determines whether to enable `keepalive` in the TCP layer.
- Default value: `true`

12.5.1.4.10 `tcp-no-delay`

- Determines whether to enable TCP_NODELAY at the TCP layer. After it is enabled, TiDB disables the Nagle algorithm in the TCP/IP protocol and allows sending small data packets to reduce network latency. This is suitable for latency-sensitive applications with a small transmission volume of data.
- Default value: `true`

12.5.1.4.11 `cross-join`

- Default value: `true`
- TiDB supports executing the `JOIN` statement without any condition (the `WHERE` field) of both sides tables by default; if you set the value to `false`, the server refuses to execute when such a `JOIN` statement appears.

12.5.1.4.12 `stats-lease`

- The time interval of reloading statistics, updating the number of table rows, checking whether it is needed to perform the automatic analysis, using feedback to update statistics and loading statistics of columns.
- Default value: `3s`
  - At intervals of `stats-lease` time, TiDB checks the statistics for updates and updates them to the memory if updates exist.
  - At intervals of `20 * stats-lease` time, TiDB updates the total number of rows generated by DML and the number of modified rows to the system table.
  - At intervals of `stats-lease`, TiDB checks for tables and indexes that need to be automatically analyzed.
  - At intervals of `stats-lease`, TiDB checks for column statistics that need to be loaded to the memory.
  - At intervals of `200 * stats-lease`, TiDB writes the feedback cached in the memory to the system table.
  - At intervals of `5 * stats-lease`, TiDB reads the feedback in the system table, and updates the statistics cached in the memory.
