Table of Contents

1	Docs Home	27
2	About TiDB	27
2.1	TiDB Introduction	27
2.1.1	Key features	27
2.1.2	Use cases	28
2.1.3	See also	29
2.2	TiDB 5.4 Release Notes	29
2.2.1	Compatibility changes	30
2.2.2	New features	46
2.2.3	Improvements	53
2.2.4	Bug fixes	54
2.3	TiDB Features	57
2.3.1	Data types, functions, and operators	57
2.3.2	Indexing and constraints	58
2.3.3	SQL statements	58
2.3.4	Advanced SQL features	59
2.3.5	Data definition language (DDL)	59
2.3.6	Transactions	59
2.3.7	Partitioning	60
2.3.8	Statistics	60

2.3.9	Security	60
2.3.10	Data import and export	60
2.3.11	Management, observability, and tools	61
2.4	TiDB Experimental Features	61
2.4.1	Performance	61
2.4.2	Stability	62
2.4.3	Scheduling	62
2.4.4	SQL	62
2.4.5	Configuration management	62
2.4.6	Data sharing and subscription	62
2.4.7	Storage	63
2.4.8	Backup and restoration	63
2.4.9	Garbage collection	63
2.4.10	Diagnostics	63
2.5	Benchmarks	63
2.5.1	TiDB Sysbench Performance Test Report – v5.4.0 vs. v5.3.0	63
2.5.2	TiDB TPC-C Performance Test Report – v5.4.0 vs. v5.3.0	70
2.5.3	TiDB TPC-H Performance Test Report – TiDB v5.4 MPP mode vs. Greenplum 6.15.0 and Apache Spark 3.1.1	74
2.6	MySQL Compatibility	77
2.6.1	Unsupported features	78
2.6.2	Features that are different from MySQL	79
2.7	TiDB Limitations	84
2.7.1	Limitations on identifier length	84
2.7.2	Limitations on the total number of databases, tables, views, and connections	84
2.7.3	Limitations on a single database	85
2.7.4	Limitations on a single table	85
2.7.5	Limitation on a single row	85
2.7.6	Limitations on string types	85
2.7.7	Limitations on SQL statements	86

2.8	Credits	86
2.8.1	TiDB developers	86
2.8.2	Writers and translators for TiDB documentation	87
3	Quick Start	87
3.1	Quick Start Guide for the TiDB Database Platform	87
3.1.1	Deploy a local test cluster	88
3.1.2	Simulate production deployment on a single machine	92
3.1.3	What's next	98
3.2	Quick Start Guide for TiDB HTAP	99
3.2.1	Basic concepts	99
3.2.2	Steps	99
3.2.3	What's next	104
3.3	Explore SQL with TiDB	104
3.3.1	Category	104
3.3.2	Show, create and drop a database	104
3.3.3	Create, show, and drop a table	105
3.3.4	Create, show, and drop an index	105
3.3.5	Insert, update, and delete data	106
3.3.6	Query data	107
3.3.7	Create, authorize, and delete a user	107
3.4	Explore HTAP	108
3.4.1	Use cases	108
3.4.2	Architecture	109
3.4.3	Environment preparation	109
3.4.4	Data preparation	110
3.4.5	Data processing	110
3.4.6	Performance monitoring	110
3.4.7	Troubleshooting	111
3.4.8	What's next	111
3.5	Import Example Database	111
3.5.1	Download all data files	111
3.5.2	Load data into TiDB	112

4	Deploy	113
4.1	Software and Hardware Recommendations	113
4.1.1	Linux OS version requirements	113
4.1.2	Software recommendations	114
4.1.3	Server recommendations	114
4.1.4	Network requirements	117
4.1.5	Web browser requirements	123
4.2	TiDB Environment and System Configuration Check	123
4.2.1	Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV	123
4.2.2	Check and disable system swap	125
4.2.3	Check and stop the firewall service of target machines	126
4.2.4	Check and install the NTP service	126
4.2.5	Check and configure the optimal parameters of the operating system	129
4.2.6	Manually configure the SSH mutual trust and sudo without password	135
4.2.7	Install the numactl tool	136
4.3	Plan Cluster Topology	137
4.3.1	Minimal Deployment Topology	137
4.3.2	TiFlash Deployment Topology	139
4.3.3	TiCDC Deployment Topology	142
4.3.4	TiDB Binlog Deployment Topology	144
4.3.5	TiSpark Deployment Topology	149
4.3.6	Geo-Distributed Deployment Topology	152
4.3.7	Hybrid Deployment Topology	156
4.4	Install and Start	161
4.4.1	Deploy a TiDB Cluster Using TiUP	161
4.4.2	Deploy a TiDB Cluster in Kubernetes	176
4.5	Check Cluster Status	177
4.5.1	Check the TiDB cluster status	177
4.5.2	Log in to the database and perform simple operations	180
4.6	Test Cluster Performance	182
4.6.1	How to Test TiDB Using Sysbench	182
4.6.2	How to Run TPC-C Test on TiDB	187

5	Migrate	189
5.1	Data Migration Overview	189
5.1.1	Migrate data from Aurora MySQL to TiDB	190
5.1.2	Migrate data from MySQL to TiDB	190
5.1.3	Migrate and merge MySQL shards into TiDB	191
5.1.4	Migrate data from files to TiDB	191
5.1.5	More advanced migration solutions	191
5.2	TiDB Migration Tools Overview	191
5.2.1	Install tools using TiUP	193
5.2.2	See also	195
5.3	Migration Scenarios	195
5.3.1	Migrate Data from Amazon Aurora to TiDB	195
5.3.2	Migrate MySQL of Small Datasets to TiDB	208
5.3.3	Migrate MySQL of Large Datasets to TiDB	213
5.3.4	Migrate and Merge MySQL Shards of Small Datasets to TiDB	226
5.3.5	Migrate and Merge MySQL Shards of Large Datasets to TiDB	234
5.3.6	Migrate Data from CSV Files to TiDB	253
5.3.7	Migrate Data from SQL Files to TiDB	258
5.3.8	Replicate Incremental Data between TiDB Clusters in Real Time	261
5.4	Advanced Migration	263
5.4.1	Continuous Replication from Databases that Use gh-ost or pt-osc	263
5.4.2	Migrate Data to a Downstream TiDB Table with More Columns	265
5.4.3	Filter Binlog Events	273
5.4.4	Filter DML Events Using SQL Expressions	276
6	Maintain	279
6.1	Security	279
6.1.1	Best Practices for TiDB Security Configuration	279
6.1.2	Enable TLS between TiDB Clients and Servers	284
6.1.3	Enable TLS Between TiDB Components	289
6.1.4	Generate Self-Signed Certificates	293
6.1.5	Encryption at Rest	296
6.1.6	Enable Encryption for Disk Spill	303
6.1.7	Log Redaction	303

6.2	Upgrade	304
6.2.1	Upgrade TiDB Using TiUP	304
6.2.2	Use TiDB Operator	311
6.3	Scale	311
6.3.1	Scale a TiDB Cluster Using TiUP	311
6.3.2	Use TiDB Operator	322
6.4	Backup and Restore	322
6.4.1	Use BR Tool (Recommended)	322
6.5	Time Zone Support	396
6.6	Daily Check	398
6.6.1	Key indicators of TiDB Dashboard	398
6.7	Maintain a TiFlash Cluster	405
6.7.1	Check the TiFlash version	405
6.7.2	TiFlash critical logs	405
6.7.3	TiFlash system table	406
6.8	TiUP Common Operations	406
6.8.1	View the cluster list	407
6.8.2	Start the cluster	407
6.8.3	View the cluster status	408
6.8.4	Modify the configuration	408
6.8.5	Replace with a hotfix package	409
6.8.6	Rename the cluster	410
6.8.7	Stop the cluster	410
6.8.8	Clean up cluster data	411
6.8.9	Destroy the cluster	411
6.9	Modify Configuration Online	412
6.9.1	Common Operations	412
6.10	Online Unsafe Recovery	468
6.10.1	Feature description	468
6.10.2	User scenarios	469
6.10.3	Usage	469
7	Monitor and Alert	471

7.1	TiDB Monitoring Framework Overview	471
7.1.1	About Prometheus in TiDB	471
7.1.2	About Grafana in TiDB	472
7.2	TiDB Monitoring API	474
7.2.1	Use the status interface	474
7.2.2	Use the metrics interface	476
7.3	Deploy Monitoring Services for the TiDB Cluster	476
7.3.1	Deploy Prometheus and Grafana	476
7.3.2	Configure Grafana	480
7.3.3	View component metrics	481
7.4	Export Grafana Snapshots	482
7.4.1	Usage	483
7.4.2	FAQs	484
7.5	TiDB Cluster Alert Rules	484
7.5.1	TiDB alert rules	486
7.5.2	PD alert rules	490
7.5.3	TiKV alert rules	496
7.5.4	TiFlash alert rules	504
7.5.5	TiDB Binlog alert rules	504
7.5.6	TiCDC Alert rules	504
7.5.7	Node_exporter host alert rules	505
7.5.8	Blackbox_exporter TCP, ICMP, and HTTP alert rules	508
7.6	TiFlash Alert Rules	513
7.6.1	TiFlash_schema_error	513
7.6.2	TiFlash_schema_apply_duration	513
7.6.3	TiFlash_raft_read_index_duration	514
7.6.4	TiFlash_raft_wait_index_duration	514
7.7	Customize Configurations of Monitoring Servers	515
7.7.1	Customize Prometheus configurations	515
7.7.2	Customize Grafana configurations	516
7.7.3	Customize Alertmanager configurations	518

8.1	TiDB Troubleshooting Map	518
8.1.1	1. Service Unavailable	518
8.1.2	2. Latency increases significantly	519
8.1.3	3. TiDB issues	520
8.1.4	4. TiKV issues	524
8.1.5	5. PD issues	528
8.1.6	6. Ecosystem tools	531
8.1.7	7. Common log analysis	536
8.2	Identify Slow Queries	539
8.2.1	Usage example	539
8.2.2	Fields description	540
8.2.3	Related system variables	542
8.2.4	Memory mapping in slow log	544
8.2.5	<code>SLOW_QUERY</code> / <code>CLUSTER_SLOW_QUERY</code> usage examples	545
8.2.6	Query slow queries with pseudo <code>stats</code>	547
8.2.7	Identify problematic SQL statements	552
8.3	Analyze Slow Queries	557
8.3.1	Identify the performance bottleneck of the query	557
8.3.2	Analyze system issues	558
8.3.3	Analyze optimizer issues	565
8.4	SQL Diagnostics	565
8.4.1	Overview	566
8.4.2	Cluster information tables	566
8.4.3	Cluster monitoring tables	567
8.4.4	Automatic diagnostics	568
8.5	Top SQL	568
8.5.1	Enable Top SQL	568
8.5.2	Use Top SQL	569
8.6	Identify Expensive Queries	570
8.6.1	Expensive query log example	571
8.6.2	Fields description	571

8.7	Statement Summary Tables	572
8.7.1	<code>statements_summary</code>	573
8.7.2	<code>statements_summary_history</code>	574
8.7.3	<code>statements_summary_evicted</code>	575
8.7.4	The <code>cluster</code> tables for statement summary	575
8.7.5	Parameter configuration	575
8.7.6	Limitation	578
8.7.7	Troubleshooting examples	578
8.7.8	Fields description	579
8.8	Troubleshoot Hotspot Issues	582
8.8.1	Common hotspots	582
8.8.2	Identify hotspot issues	584
8.8.3	Use <code>SHARD_ROW_ID_BITS</code> to process hotspots	588
8.8.4	Handle auto-increment primary key hotspot tables using <code>AUTO_RANDOM</code>	591
8.8.5	Optimization of small table hotspots	594
8.9	Troubleshoot Increased Read and Write Latency	594
8.9.1	Common causes	594
8.9.2	Other causes	598
8.10	Use <code>PLAN REPLAYER</code> to Save and Restore the On-Site Information of a Cluster	599
8.10.1	Use <code>PLAN REPLAYER</code> to export cluster information	599
8.10.2	Use <code>PLAN REPLAYER</code> to import cluster information	601
8.11	TiDB Cluster Troubleshooting Guide	602
8.11.1	Cannot connect to the database	603
8.11.2	Cannot start <code>tidb-server</code>	603
8.11.3	Cannot start <code>tikv-server</code>	604
8.11.4	Cannot start <code>pd-server</code>	604
8.11.5	The TiDB/TiKV/PD process aborts unexpectedly	605
8.11.6	TiDB panic	605
8.11.7	The connection is rejected	605
8.11.8	Open too many files	605
8.11.9	Database access times out and the system load is too high	605

8.12	Troubleshoot High Disk I/O Usage in TiDB	606
8.12.1	Check the current I/O metrics	606
8.12.2	Handle I/O issues	609
8.13	Troubleshoot Lock Conflicts	609
8.13.1	Use Lock View to troubleshoot lock issues	609
8.13.2	Troubleshoot optimistic lock conflicts	614
8.13.3	Troubleshoot pessimistic lock conflicts	620
8.14	Troubleshoot a TiFlash Cluster	622
8.14.1	TiFlash fails to start	622
8.14.2	TiFlash replica is always unavailable	623
8.14.3	TiFlash query time is unstable, and the error log prints many <code>Lock Exception</code> messages	624
8.14.4	Some queries return the <code>Region Unavailable</code> error	624
8.14.5	Data file corruption	624
8.14.6	TiFlash analysis is slow	624
8.14.7	Data is not replicated to TiFlash	625
8.14.8	Data replication gets stuck	627
8.14.9	Data replication is slow	628
8.15	Troubleshoot Write Conflicts in Optimistic Transactions	629
8.15.1	The reason of write conflicts	629
8.15.2	Detect write conflicts	629
8.15.3	Resolve write conflicts	631
9	Performance Tuning	632
9.1	System Tuning	632
9.1.1	Operating System Tuning	632
9.2	Software Tuning	637
9.2.1	Configuration	637
9.2.2	Coprocessor Cache	658
9.3	SQL Tuning	660
9.3.1	SQL Tuning Overview	660
9.3.2	Understanding the Query Execution Plan	660
9.3.3	SQL Optimization Process	726
9.3.4	Control Execution Plans	800

10 Tutorials	835
10.1 Multiple Data Centers in One City Deployment	835
10.1.1 Raft protocol	835
10.1.2 Three DCs in one city deployment	836
10.2 Three Data Centers in Two Cities Deployment	842
10.2.1 Overview	842
10.2.2 Deployment architecture	842
10.2.3 Configuration	845
10.3 Two Data Centers in One City Deployment	849
10.3.1 Deployment architecture	849
10.3.2 Configuration	850
10.4 Read Historical Data	857
10.4.1 Use Stale Read (Recommended)	857
10.4.2 Read Historical Data Using the System Variable <code>tidb_snapshot</code>	867
10.5 Best Practices	872
10.5.1 TiDB Best Practices	872
10.5.2 Best Practices for Developing Java Applications with TiDB	879
10.5.3 Best Practices for Using HAProxy in TiDB	893
10.5.4 Highly Concurrent Write Best Practices	906
10.5.5 Best Practices for Monitoring TiDB Using Grafana	918
10.5.6 PD Scheduling Best Practices	929
10.5.7 Best Practices for TiKV Performance Tuning with Massive Regions	938
10.5.8 Best Practices for Three-Node Hybrid Deployment	945
10.5.9 Local Read under Three Data Centers Deployment	950
10.6 Placement Rules	951
10.6.1 Rule system	951
10.6.2 Configure rules	953
10.6.3 Typical usage scenarios	958
10.7 Load Base Split	961
10.7.1 Scenarios	962
10.7.2 Implementation principles	962
10.7.3 Usage	962

10.8	Store Limit	963
10.8.1	Implementation principles	963
10.8.2	Usage	964
11	TiDB Tools	965
11.1	TiDB Tools Overview	965
11.1.1	Deployment and operation Tools	965
11.1.2	Data management tools	966
11.1.3	OLAP Query tool	969
11.2	TiDB Tools Use Cases	969
11.2.1	Deploy and operate TiDB on physical or virtual machines	969
11.2.2	Deploy and operate TiDB in Kubernetes	969
11.2.3	Import data from CSV to TiDB	969
11.2.4	Import full data from MySQL/Aurora	969
11.2.5	Migrate data from MySQL/Aurora	969
11.2.6	Back up and restore TiDB cluster	970
11.2.7	Migrate data to TiDB	970
11.2.8	TiDB incremental data subscription	970
11.3	Download TiDB Tools	970
11.3.1	TiUP	970
11.3.2	TiDB Operator	970
11.3.3	TiDB Binlog	970
11.3.4	TiDB Lightning	971
11.3.5	BR (backup and restore)	972
11.3.6	TiDB DM (Data Migration)	973
11.3.7	Dumpling	974
11.3.8	sync-diff-inspector	975
11.3.9	TiCDC	976
11.4	TiUP	977
11.4.1	TiUP Documentation Map	977
11.4.2	TiUP Overview	977
11.4.3	TiUP Terminology and Concepts	980

11.4.4	Manage TiUP Components with TiUP Commands	981
11.4.5	TiUP FAQ	986
11.4.6	TiUP Troubleshooting Guide	987
11.4.7	Command Reference	989
11.4.8	Topology Configuration File for TiDB Deployment Using TiUP	1088
11.4.9	Topology Configuration File for DM Cluster Deployment Using TiUP	1112
11.4.10	TiUP Mirror Reference Guide	1123
11.4.11	TiUP Components	1133
11.5	TiDB Operator	1161
11.6	Backup & Restore (BR)	1161
11.6.1	BR Tool Overview	1161
11.6.2	Use BR Command-line for Backup and Restoration	1178
11.6.3	BR Use Cases	1191
11.6.4	External Storages	1211
11.6.5	BR Features	1222
11.6.6	Backup & Restore FAQ	1225
11.7	TiDB Binlog	1231
11.7.1	TiDB Binlog Cluster Overview	1231
11.7.2	TiDB Binlog Tutorial	1234
11.7.3	TiDB Binlog Cluster Deployment	1244
11.7.4	TiDB Binlog Cluster Operations	1256
11.7.5	TiDB Binlog Configuration File	1259
11.7.6	Upgrade TiDB Binlog	1278
11.7.7	TiDB Binlog Monitoring	1279
11.7.8	Reparo User Guide	1296
11.7.9	binlogctl	1300
11.7.10	Binlog Consumer Client User Guide	1303
11.7.11	TiDB Binlog Relay Log	1306
11.7.12	Bidirectional Replication between TiDB Clusters	1308
11.7.13	TiDB Binlog Glossary	1313
11.7.14	Troubleshoot	1313
11.7.15	TiDB Binlog FAQ	1315

11.8	TiDB Lightning	1323
11.8.1	TiDB Lightning Overview	1323
11.8.2	TiDB Lightning Tutorial	1326
11.8.3	TiDB Lightning Deployment	1330
11.8.4	TiDB Lightning Prechecks	1334
11.8.5	TiDB Lightning Configuration	1343
11.8.6	Key Features	1365
11.8.7	TiDB Lightning Monitoring	1410
11.8.8	TiDB Lightning FAQs	1428
11.8.9	TiDB Lightning Glossary	1438
11.8.10	TiDB Lightning Log Message Explanation	1443
11.9	TiDB Data Migration	1451
11.9.1	About TiDB Data Migration	1451
11.9.2	Quick Start	1497
11.9.3	Data Migration Scenario Overview	1515
11.9.4	Deploy	1517
11.9.5	Maintain	1548
11.9.6	Performance Tuning	1669
11.9.7	Reference	1671
11.9.8	Secure	1704
11.9.9	Data Migration Monitoring Metrics	1710
11.9.10	DM Alert Information	1734
11.9.11	Handle Errors	1735
11.9.12	TiDB Data Migration FAQ	1742
11.9.13	TiDB Data Migration Glossary	1755
11.9.14	Example	1759
11.9.15	TiDB Data Migration Release Notes	1769
11.10	TiCDC	1770
11.10.1	TiCDC Overview	1770
11.10.2	Deploy TiCDC	1780
11.10.3	Manage TiCDC Cluster and Replication Tasks	1783
11.10.4	Troubleshoot TiCDC	1803

11.10.5	Key Monitoring Metrics of TiCDC	1818
11.10.6	TiCDC Alert Rules	1824
11.10.7	TiCDC OpenAPI	1828
11.10.8	TiCDC Open Protocol	1841
11.10.9	TiCDC Canal-JSON Protocol	1853
11.10.10	Quick Start Guide on Integrating TiDB with Confluent Platform	1865
11.10.11	TiCDC Glossary	1867
11.11	Use Dumping to Export Data	1868
11.11.1	Export data from TiDB or MySQL	1869
11.11.2	Option list of Dumping	1876
11.12	sync-diff-inspector	1881
11.12.1	sync-diff-inspector User Guide	1881
11.12.2	Data Check for Tables with Different Schema or Table Names	1889
11.12.3	Data Check in the Sharding Scenario	1890
11.12.4	Data Check for TiDB Upstream and Downstream Clusters	1894
11.12.5	Data Check in the DM Replication Scenario	1896
11.13	TiSpark	1897
11.13.1	TiSpark User Guide	1897
12	Reference	1908
12.1	Cluster Architecture	1908
12.1.1	TiDB Architecture	1908
12.1.2	TiDB Storage	1909
12.1.3	TiDB Computing	1915
12.1.4	TiDB Scheduling	1922
12.2	Storage Engine - TiKV	1927
12.2.1	TiKV Overview	1927

2 About TiDB

2.1 TiDB Introduction

TiDB (/ˈta di bi:/, “Ti” stands for Titanium) is an open-source NewSQL database that supports Hybrid Transactional and Analytical Processing (HTAP) workloads. It is MySQL compatible and features horizontal scalability, strong consistency, and high availability. The goal of TiDB is to provide users with a one-stop database solution that covers OLTP (Online Transactional Processing), OLAP (Online Analytical Processing), and HTAP services. TiDB is suitable for various use cases that require high availability and strong consistency with large-scale data.

The following video introduces key features of TiDB.

2.1.1 Key features

- **Horizontally scaling out or scaling in easily**

The TiDB architecture design of separating computing from storage enables you to separately scale out or scale in the computing or storage capacity online as needed. The scaling process is transparent to application operations and maintenance staff.

- **Financial-grade high availability**

The data is stored in multiple replicas. Data replicas obtain the transaction log using the Multi-Raft protocol. A transaction can be committed only when data has been successfully written into the majority of replicas. This can guarantee strong consistency, and availability when a minority of replicas go down. To meet the requirements of different disaster tolerance levels, you can configure the geographic location and number of replicas as needed.

- **Real-time HTAP**

TiDB provides two storage engines: **TiKV**, a row-based storage engine, and **TiFlash**, a columnar storage engine. TiFlash uses the Multi-Raft Learner protocol to replicate data from TiKV in real time, ensuring that the data between the TiKV row-based storage engine and the TiFlash columnar storage engine are consistent. TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.

- **Cloud-native distributed database**

TiDB is a distributed database designed for the cloud, providing flexible scalability, reliability and security on the cloud platform. Users can elastically scale TiDB to meet the requirements of their changing workloads. In TiDB, each piece of data has 3 replicas at least, which can be scheduled in different cloud availability zones to tolerate

the outage of a whole data center. [TiDB Operator](#) helps manage TiDB on Kubernetes and automates tasks related to operating the TiDB cluster, which makes TiDB easier to deploy on any cloud that provides managed Kubernetes. [TiDB Cloud](#), the fully-managed TiDB service, is the easiest, most economical, and most resilient way to unlock the full power of [TiDB in the cloud](#), allowing you to deploy and run TiDB clusters with just a few clicks.

- **Compatible with the MySQL 5.7 protocol and MySQL ecosystem**

TiDB is compatible with the MySQL 5.7 protocol, common features of MySQL, and the MySQL ecosystem. To migrate your applications to TiDB, you do not need to change a single line of code in many cases or only need to modify a small amount of code. In addition, TiDB provides a series of [data migration tools](#) to help easily migrate application data into TiDB.

2.1.2 Use cases

- **Financial industry scenarios with high requirements for data consistency, reliability, availability, scalability, and disaster tolerance**

As we all know, the financial industry has high requirements for data consistency, reliability, availability, scalability, and disaster tolerance. The traditional solution is to provide services in two data centers in the same city, and provide data disaster recovery but no services in a third data center located in another city. This solution has the disadvantages of low resource utilization, high maintenance cost, and the fact that RTO (Recovery Time Objective) and RPO (Recovery Point Objective) cannot meet expectations. TiDB uses multiple replicas and the Multi-Raft protocol to schedule data to different data centers, racks, and machines. When some machines fail, the system can automatically switch to ensure that the system RTO = 30s and RPO = 0.

- **Massive data and high concurrency scenarios with high requirements for storage capacity, scalability, and concurrency**

As applications grow rapidly, the data surges. Traditional standalone databases cannot meet the data capacity requirements. The solution is to use sharding middleware or a NewSQL database (like TiDB), and the latter is more cost-effective. TiDB adopts a separate computing and storage architecture, which enables you to scale out or scale in the computing or storage capacity separately. The computing layer supports a maximum of 512 nodes, each node supports a maximum of 1,000 concurrencies, and the maximum cluster capacity is at the PB (petabytes) level.

- **Real-time HTAP scenarios**

With the fast growth of 5G, Internet of Things, and artificial intelligence, the data generated by a company keeps increasing tremendously, reaching a scale of hundreds of TB (terabytes) or even the PB level. The traditional solution is to process online transactional applications using an OLTP database and use an ETL (Extract, Transform, Load) tool to replicate the data into an OLAP database for data analysis. This solution

has multiple disadvantages such as high storage costs and poor real-time performance. TiDB introduces the TiFlash columnar storage engine in v4.0, which combines with the TiKV row-based storage engine to build TiDB as a true HTAP database. With a small amount of extra storage cost, you can handle both online transactional processing and real-time data analysis in the same system, which greatly saves the cost.

- **Data aggregation and secondary processing scenarios**

The application data of most companies are scattered in different systems. As the application grows, the decision-making leaders need to understand the business status of the entire company to make decisions in time. In this case, the company needs to aggregate the scattered data into the same system and execute secondary processing to generate a T+0 or T+1 report. The traditional solution is to use ETL and Hadoop, but the Hadoop system is complicated, with high operations and maintenance cost and storage cost. Compared with Hadoop, TiDB is much simpler. You can replicate data into TiDB using ETL tools or data migration tools provided by TiDB. Reports can be directly generated using SQL statements.

2.2 TiDB 5.4 Release Notes

Release date: February 15, 2022

TiDB version: 5.4.0

In v5.4, the key new features or improvements are as follows:

- Support the GBK character set
- Support using Index Merge to access data, which merges the filtering results of indexes on multiple columns
- Support reading stale data using a session variable
- Support persisting the configuration for collecting statistics
- Support using Raft Engine as the log storage engine of TiKV (experimental)
- Optimize the impact of backup on the cluster
- Support using Azure Blob storage as the backup storage
- Continuously improve the stability and performance of TiFlash and the MPP engine
- Add a switch in TiDB Lightning to determine whether to allow importing to an existing table with data
- Optimize the Continuous Profiling feature (experimental)
- TiSpark supports user identification and authentication

2.2.1 Compatibility changes

Note:

When upgrading from an earlier TiDB version to v5.4.0, if you want to know the compatibility change notes of all intermediate versions, you can check the [Release Notes](#) of the corresponding version.

2.2.1.1 System variables

Variable name	Change type	Description
<code>tidb_enable_new_predicate</code> ↔	Newly added	Controls whether to allow TiDB to collect PREDICATE ↔ COLUMNS. The default value is OFF.

Variable name	Change type	Description
<code>tidb_enable_paging</code> ↔	Newly added	Controls whether to use the method of paging to send coprocessor requests in <code>IndexLookUp</code> operator. The default value is <code>OFF</code> . For read queries that use <code>IndexLookup</code> and <code>Limit</code> and that <code>Limit</code> cannot be pushed down to <code>IndexScan</code> , there might be high latency for the read queries and high CPU usage for TiKV's unified ↔ <code>read</code> ↔ <code>pool</code> . In such cases, because the <code>Limit</code> operator only requires a small set of data, if you set <code>tidb_enable_paging</code> ↔ to <code>ON</code> , TiDB processes less data, which reduces query

Variable name	Change type	Description
<code>tidb_enable_top_sql</code> ↔	Newly added	Controls whether to enable the Top SQL feature. The default value is <code>OFF</code> .
<code>tidb_persist_analyze_options</code> ↔	Newly added	Controls whether to enable the <code>ANALYZE configuration persistence</code> feature. The default value is <code>ON</code> .
<code>tidb_read_stats</code> ↔	Newly added	Controls the range of historical data that can be read in the current session. The default value is <code>0</code> .
<code>tidb_regard_null_as_index</code> ↔	Newly added	Controls whether the optimizer can use a query condition including null equivalence as a prefix condition for index access.

Variable name	Change type	Description
<code>tidb_stats_load_synced</code> ↔	Newly added	Controls whether to enable the synchronously loading statistics feature. The default value 0 means that the feature is disabled and that the statistics is asynchronously loaded. When the feature is enabled, this variable controls the maximum time that SQL optimization can wait for synchronously loading statistics before timeout.

Variable name	Change type	Description
<code>tidb_stats_load_newly_added_indexes</code>	Newly added	Controls when synchronously loading statistics reaches timeout, whether SQL fails (OFF) or falls back to using pseudo statistics (ON). The default value is OFF.
<code>tidb_backoff_retry_times</code>	Modified	The default value is changed from 100 to 10.

| `tidb_enable_index_merge` | Modified | The default value is changed from OFF to ON.

If you upgrade a TiDB cluster from versions earlier than v4.0.0 to v5.4.0 or later, this variable is OFF by default.

If you upgrade a TiDB cluster from v4.0.0 or later to v5.4.0 or later, this variable remains the same as before the upgrade.

For the newly created TiDB clusters of v5.4.0 and later, this variable is ON by default.

|| `tidb_store_limit` | Modified | Before v5.4.0, this variable can be configured at instance level and globally. Starting from v5.4.0, this variable only supports global configuration. |

2.2.1.2 Configuration file parameters

Configuration file	Configuration	Change type	Description
TiDB	stats-load ↪ - ↪ concurrency ↪	Newly added	Controls the maximum number of columns that the TiDB synchronously loading statistics feature can process concurrently. The default value is 5.
TiDB	stats-load ↪ -queue- ↪ size	Newly added	Controls the maximum number of column requests that the TiDB synchronously loading statistics feature can cache. The default value is 1000.
TiKV	snap- ↪ generator ↪ -pool- ↪ size	Newly added	The size of the snap- ↪ generator ↪ thread pool. The default value is 2.

Configuration file	Configuration	Change type	Description
TiKV	log.file. ↪ max- ↪ size, log.file. ↪ max- ↪ days, log.file. ↪ max- ↪ backups	Newly added	For details, see TiKV Configuration File - log.file.

Configuration file	Configuration	Change type	Description
TiKV	<code>raft- ↪ engine</code>	Newly added	Includes <code>enable</code> , <code>dir</code> , <code>batch- ↪ compression</code> , <code>↪ -</code> , <code>↪ threshold</code> , <code>↪ ,</code> , <code>bytes-per- ↪ sync</code> , <code>target- ↪ file- ↪ size</code> , <code>purge- ↪ threshold</code> , <code>↪ ,</code> , <code>recovery- ↪ mode</code> , <code>recovery- ↪ read- ↪ block- ↪ size</code> , <code>recovery- ↪ read- ↪ block- ↪ size</code> , and <code>recovery- ↪ threads</code> . For details, see TiKV Configuration File - raft- ↪ engine .

Configuration file	Configuration	Change type	Description
TiKV	backup. ↔ enable- ↔ auto- ↔ tune	Newly added	In v5.3.0, the default value is false . Since v5.4.0, the default value is changed to true . This parameter controls whether to limit the resources used by backup tasks to reduce the impact on the cluster when the cluster resource utilization is high. In the default configuration, the speed of backup tasks might slow down.

Configuration file	Configuration	Change type	Description
TiKV	<code>log-level</code> , <code>log-format</code> , <code>log-file</code> , <code>log-</code> ↪ <code>rotation</code> ↪ <code>-size</code>	Modified	<p>The names of TiKV log parameters are replaced with the names that are consistent with TiDB log parameters, which are <code>log.level</code>, <code>log.format</code>, <code>log.file</code>.</p> <p>↪ <code>filename</code> ↪ <code>,</code> and <code>log.enable</code> ↪ <code>-</code> ↪ <code>timestamp</code> ↪ <code>.</code> If you only set the old parameters, and their values are set to non-default values, the old parameters remain compatible with the new parameters.</p> <p>If both old and new parameters are set, the new parameters take effect. For details, see TiKV Configuration File - 1</p>

Configuration file	Configuration	Change type	Description
TiKV	<code>log-</code> <code>↔ rotation</code> <code>↔ -</code> <code>↔ timespan</code> <code>↔</code>	Deleted	<p>The timespan between log rotations. After this timespan passes, a log file is rotated, which means a timestamp is appended to the file name of the current log file, and a new log file is created.</p>
TiKV	<code>allow-</code> <code>↔ remove-</code> <code>↔ leader</code>	Deleted	<p>Determines whether to allow deleting the main switch.</p>
TiKV	<code>raft-msg-</code> <code>↔ flush-</code> <code>↔ interval</code> <code>↔</code>	Deleted	<p>Determines the interval at which Raft messages are sent in batches. The Raft messages are sent in batches at every interval specified by this configuration item.</p>

Configuration file	Configuration	Change type	Description
PD	<code>log.level</code>	Modified	The default value is changed from “INFO” to “info”, guaranteed to be case-insensitive.
TiFlash	<code>profile.</code> <code>↪ default</code> <code>↪ .</code> <code>↪ enable_elastic_threadpool</code> <code>↪</code>	Newly added	Determines whether to enable or disable the elastic thread pool function. Enabling this configuration item can significantly improve TiFlash CPU utilization in high concurrency scenarios. The default value is <code>false</code> .

Configuration file	Configuration	Change type	Description
TiFlash	<code>storage.</code> ↪ <code>format_version</code> ↪	Newly added	Specifies the version of DTFile. The default value is 2, under which hashes are embedded in the data file. You can also set the value to 3. When it is 3, the data file contains metadata and token data checksum, and supports multiple hash algorithms.
TiFlash	<code>logger.</code> ↪ <code>count</code>	Modified	The default value is changed to 10.
TiFlash	<code>status.</code> ↪ <code>metrics_port</code> ↪	Modified	The default value is changed to 8234.
TiFlash	<code>raftstore.</code> ↪ <code>apply-</code> ↪ <code>pool-</code> ↪ <code>size</code>	Newly added	The allowable number of threads in the pool that flushes Raft data to storage. The default value is 4.

Configuration file	Configuration	Change type	Description
TiFlash	<code>raftstore.</code> ↔ <code>store-</code> ↔ <code>pool-</code> ↔ <code>size</code>	Newly added	The allowable number of threads that process Raft, which is the size of the Raftstore thread pool. The default value is 4.
TiDB Data Migration (DM)	<code>collation_compatible</code> ↔	Newly added	The mode to sync the default collation in CREATE SQL statements. The value options are “loose” (by default) and “strict”.
TiCDC	<code>max-</code> ↔ <code>message</code> ↔ <code>-bytes</code>	Modified	Change the default value of <code>max-</code> ↔ <code>message</code> ↔ <code>-bytes</code> in Kafka sink to 104857601 (10MB)

Configuration file	Configuration	Change type	Description
TiCDC	<code>partition- ↪ num</code>	Modified	Change the default value of <code>partition- ↪ num</code> in Kafka Sink from 4 to 3. It makes TiCDC send messages to Kafka partitions more evenly.
TiDB Lightning	<code>meta- ↪ schema- ↪ name</code>	Modified	Specifies the schema name for the metadata in the target TiDB. From v5.4.0, this schema is created only if you have enabled parallel import (the corresponding parameter is <code>tikv- ↪ importer ↪ . ↪ incremental ↪ -import ↪ = true ↪)</code>).

Configuration file	Configuration	Change type	Description
TiDB Lightning	<code>task-info- ↔ schema- ↔ name</code>	Newly added	Specifies the name of the database where duplicated data is stored when TiDB Lightning detects conflicts. By default, the value is “lightning_task_info”. Specify this parameter only if you have enabled the “duplicate-resolution” feature.
TiDB Lightning	<code>incremental ↔ -import</code>	Newly added	Determines whether to allow importing data to tables where data already exists. The default value is <code>false</code> .

2.2.1.3 Others

- An interface is added between TiDB and PD. When you use the `information_schema` ↔ `.TIDB_HOT_REGIONS_HISTORY` system table, TiDB needs to use PD in the corresponding version.
- TiDB Server, PD Server, and TiKV Server start using a unified naming method for the log-related parameters to manage log names, output formats, and the rules for rotation and expiration. For details, see [TiKV configuration file - log](#).

- Since v5.4.0, if you create a SQL binding for an execution plan that has been cached via Plan Cache, the binding invalidates the plan already cached for the corresponding query. The new binding does not affect execution plans cached before v5.4.0.
- In v5.3 and earlier versions, [TiDB Data Migration \(DM\)](#) documentation is independent of TiDB documentation. Since v5.4, DM documentation is integrated into TiDB documentation with the same version. You can directly read [DM documentation](#) without accessing the DM documentation site.
- Remove the experimental feature of Point-in-time recovery (PITR) along with cdclog. Since v5.4.0, cdclog-based PITR and cdclog are no longer supported.
- Make the behavior of setting system variables to the “DEFAULT” more MySQL-compatible [#29680](#)
- Set the system variable `lc_time_names` to read-only [#30084](#)
- Set the scope of `tidb_store_limit` from INSTANCE or GLOBAL to GLOBAL [#30756](#)
- Forbid converting the integer type column to the time type column when the column contains zero [#25728](#)
- Fix the issue that no error is reported for the Inf or NAN value when inserting floating-point values [#30148](#)
- Fix the issue that the REPLACE statement incorrectly changes other rows when the auto ID is out of range [#30301](#)

2.2.2 New features

2.2.2.1 SQL

- **TiDB supports the GBK character set since v5.4.0**

Before v5.4.0, TiDB supports `ascii`, `binary`, `latin1`, `utf8`, and `utf8mb4` character sets.

To better support Chinese users, TiDB supports the GBK character set since v5.4.0. After enabling the `new_collations_enabled_on_first_bootstrap` option in the TiDB configuration file when initializing a TiDB cluster for the first time, the TiDB GBK character set supports both `gbk_bin` and `gbk_chinese_ci` collations.

When using the GBK character set, you need to pay attention to the compatibility restrictions. For details, see [Character Set and Collation - GBK](#).

2.2.2.2 Security

- **TiSpark supports user authentication and authorization**

Since TiSpark 2.5.0, TiSpark supports both database user authentication and read/write authorization at a database or table level. After enabling this feature, you can prevent the business from running unauthorized batch tasks such as draws to obtain data, which improves the stability and data security of online clusters.

This feature is disabled by default. When it is enabled, if a user operating through TiSpark does not have the needed permissions, the user gets an exception from TiSpark.

[User document](#)

- **TiUP supports generating an initial password for the root user**

An `--init` parameter is introduced to the command for starting a cluster. With this parameter, in a TiDB cluster deployed using TiUP, TiUP generates an initial strong password for the database root user. This avoids security risks in using a root user with an empty password and ensures the security of databases.

[User document](#)

2.2.2.3 Performance

- **Continue improving the stability and performance of the columnar storage engine TiFlash and the computing engine MPP**

- Support pushing down more functions to the MPP engine:

- * String functions: `LPAD()`, `RPAD()`, `STRCMP()`

- * Date functions: `ADDDATE(string, real)`, `DATE_ADD(string, real)`, `DATE_SUB(string, real)`, `SUBDATE(string, real)`, `QUARTER()`

- Introduce the elastic thread pool feature to improve resource utilization (experimental)

- Improve the efficiency of converting data from row-based storage format to column-based storage format when replicating data from TiKV, which brings 50% improvement in the overall performance of data replication

- Improve TiFlash performance and stability by tuning the default values of some configuration items. In an HTAP hybrid load, the performance of simple queries on a single table improves up to 20%.

User documents: [Supported push-down calculations](#), [Configure the tiflash.toml file](#)

- **Read historical data within a specified time range through a session variable**

TiDB is a multi-replica distributed database based on the Raft consensus algorithm. In face of high-concurrency and high-throughput application scenarios, TiDB can scale out its read performance through follower replicas, separating read and write requests.

For different application scenarios, TiDB provides two modes of follower read: strongly consistent read and weakly consistent history read. The strongly consistent read mode is suitable for application scenarios that require real-time data. However, in this mode, because of the data replication latency between leaders and followers and the reduced throughput, the read request might have high latency, especially for geo-distributed deployments.

For the application scenarios that have less strict requirements on real-time data, the history read mode is recommended. This mode can reduce latency and improve throughput. TiDB currently supports reading historical data by the following methods: Use SQL statements to read data from a time point in the past, or start a read-only transaction based on a time point in the past. Both methods support reading the historical data of a specific point in time or within a specified time range. For details, refer to [Read Historical Data Using the AS OF TIMESTAMP Clause](#).

Since v5.4.0, TiDB improves the usability of the history read mode by supporting reading historical data within a specified time range through a session variable. This mode serves low-latency, high-throughput read requests in quasi-real-time scenarios. You can set the variable as follows:

```
set @@tidb_replica_read=leader_and_follower
set @@tidb_read_staleness="-5"
```

By this setting, TiDB can select the nearest leader or follower node and read the latest historical data within 5 seconds.

[User document](#)

- **GA for Index Merge**

Index Merge is introduced in TiDB v4.0 as an experimental feature for SQL optimization. This method greatly accelerates condition filtering when a query requires scanning of multiple columns of data. Take the following query as an example. In the `WHERE` statement, if the filtering conditions connected by `OR` have their respective indexes on columns `key1` and `key2`, the Index Merge feature filters the respective indexes at the same time, merges the query results, and returns the merged result.

```
SELECT * FROM table WHERE key1 <= 100 OR key2 = 200;
```

Before TiDB v4.0, a query on a table supports using only one index for filtering at one time. If you want to query multiple columns of data, you can enable Index Merge to get the exact query result in a short time by using the indexes in individual columns. Index Merge avoids unnecessary full table scans and does not require establishing a large number of composite indexes.

In v5.4.0, Index Merge becomes GA. However, you still need to pay attention to the following restrictions:

- Index Merge supports only disjunctive normal form ($X_1 \ X_2 \ \dots X_n$). That is, this feature only works when filtering conditions in a `WHERE` clause are connected by `OR`.
- For newly deployed TiDB clusters of v5.4.0 or later, this feature is enabled by default. For v5.4.0 or later TiDB clusters upgraded from earlier versions, this feature inherits the setting before the upgrade and you can change the setting as required (for TiDB clusters earlier than v4.0, this feature does not exist and is disabled by default).

User document

- **Support Raft Engine (experimental)**

Support using [Raft Engine](#) as the log storage engine in TiKV. Compared with RocksDB, Raft Engine can reduce TiKV I/O write traffic by up to 40% and CPU usage by 10%, while improving foreground throughput by about 5% and reducing tail latency by 20% under certain loads. In addition, Raft Engine improves the efficiency of log recycling and fixes the issue of log accumulation in extreme conditions.

Raft Engine is still an experimental feature and is disabled by default. Note that the data format of Raft Engine in v5.4.0 is not compatible with previous versions. Before upgrading the cluster, you need to make sure that Raft Engine on all TiKV nodes is disabled. It is recommended to use Raft Engine only in v5.4.0 or a later version.

User document

- **Support collecting statistics on PREDICATE COLUMNS (experimental)**

In most cases, when executing SQL statements, the optimizer only uses statistics of some columns (such as columns in the WHERE, JOIN, ORDER BY, and GROUP BY statements). These used columns are called PREDICATE COLUMNS.

Since v5.4.0, you can set the value of the `tidb_enable_column_tracking` system variable to ON to enable TiDB to collect PREDICATE COLUMNS.

After the setting, TiDB writes the PREDICATE COLUMNS information to the `mysql.column_stats_usage` system table every $100 * \text{stats-lease}$. When the query pattern of your business is stable, you can use the `ANALYZE TABLE TableName PREDICATE COLUMNS` syntax to collect statistics on the PREDICATE COLUMNS columns only, which can greatly reduce the overhead of collecting statistics.

User document

- **Support synchronously loading statistics (experimental)**

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature is disabled by default. After enabling the feature, TiDB can synchronously load large-sized statistics (such as histograms, TopN, and Count-Min Sketch statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

User document

2.2.2.4 Stability

- **Support persisting ANALYZE configurations**

Statistics are one type of the basic information that the optimizer refers to when generating execution plans. The accuracy of the statistics directly affects whether the generated execution plans are reasonable. To ensure the accuracy of the statistics,

sometimes it is necessary to set different collection configurations for different tables, partitions, and indexes.

Since v5.4.0, TiDB supports persisting some `ANALYZE` configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The `ANALYZE` configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is 2 and `tidb_persist_analyze_options` is `ON` by default). You can use this feature to record the persistence configurations specified in the `ANALYZE` statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configurations, TiDB will collect statistics according to the recorded configurations.

[User document](#)

2.2.2.5 High availability and disaster recovery

- **Reduce the impact of backup tasks on the cluster**

Backup & Restore (BR) introduces the auto-tune feature (enabled by default). This feature can reduce the impact of backup tasks on the cluster by monitoring the cluster resource usage and adjusting the number of threads used by the backup tasks. In some cases, if you increase the cluster hardware resource for backup and enable the auto-tune feature, it can limit the impact of backup tasks on the cluster to 10% or less.

[User document](#)

- **Support Azure Blob Storage as a target storage for backup**

Backup & Restore (BR) supports Azure Blob Storage as a remote backup storage. If you deploy TiDB in Azure Cloud, now you can back up the cluster data to the Azure Blob Storage service.

[User document](#back-up-and-restore-data-on-azure-blob-storage)

2.2.2.6 Data migration

- **TiDB Lightning introduces a new feature to determine whether to allow importing data to tables with data**

TiDB Lightning introduces a configuration item `incremental-import`. It determines whether to allow importing data to tables with data. The default value is `false`. When using the parallel import mode, you must set the configuration to `true`.

[User document](#)

- **TiDB Lightning introduces the schema name that stores the meta information for parallel import**

TiDB Lightning introduces the `meta-schema-name` configuration item. In parallel import mode, this parameter specifies the schema name that stores the meta information for each TiDB Lightning instance in the target cluster. By default, the value is “`lightning_metadata`”. The value set for this parameter must be the same for each TiDB Lightning instance that participates in the same parallel import; otherwise, the correctness of the imported data can not be ensured.

[User document](#)

- **TiDB Lightning introduces duplicate resolution**

In Local-backend mode, TiDB Lightning outputs duplicated data before the data import is completed, and then removes that duplicated data from the database. You can resolve the duplicated data after the import is completed and select suitable data to insert according to application rules. It is recommended to clean upstream data sources based on duplicated data to avoid data inconsistency caused by duplicated data encountered in the subsequent incremental data migration phase.

[User document](#)

- **Optimize the usage of relay log in TiDB Data Migration (DM)**

- Recover the `enable-relay` switch in the `source` configuration.
- Support dynamically enabling and disabling relay log using the `start-relay` and `stop-relay` commands.
- Bind the status of relay log to `source`. `source` keeps its original status of being enabled or disabled after it is migrated to any DM-worker.
- Move the storage path of relay log to the DM-worker configuration file.

[User document](#)

- **Optimize the processing of `collation` in DM**

Add the `collation_compatible` configuration item. The value options are `loose` (default) and `strict`:

- If your application does not have strict requirements on collation, and the collation of query results can be different between the upstream and downstream, you can use the default `loose` mode to avoid reporting errors.
- If your application has strict requirements on collation, and the collation must be consistent between the upstream and downstream, you can use the `strict` mode. However, if the downstream does not support the upstream’s default collation, the data replication might report errors.

User document

- **Optimize transfer source in DM to support running replication tasks smoothly**

When the DM-worker nodes have an unbalanced load, the `transfer source` command can be used to manually transfer the configuration of a `source` to another load. After the optimization, the `transfer source` command simplifies the manual operation. You can smoothly transfer the source instead of pausing all related tasks, because DM completes other operations internally.

- **DM OpenAPI becomes generally available (GA)**

DM supports daily management via API, including adding data sources and managing tasks. In v5.4.0, DM OpenAPI becomes GA.

User document

2.2.2.7 Diagnostic efficiency

- **Top SQL (experimental feature)**

A new experimental feature, Top SQL (disabled by default), is introduced to help you easily find source-consuming queries.

User document

2.2.2.8 TiDB data share subscription

- **Optimize the impact of TiCDC on clusters**

Significantly reduces the impact on the performance of TiDB clusters when you use TiCDC. In the test environment, the performance impact of TiCDC on TiDB can be reduced to less than 5%.

2.2.2.9 Deployment and maintenance

- **Enhance Continuous Profiling (experimental)**

- More components supported: Besides TiDB, PD, and TiKV, TiDB v5.4.0 also supports CPU profiling of TiFlash.
- More forms of profiling display: Supports showing CPU profiling and Goroutine results on flame charts.
- More deployment environments supported: Continuous Profiling can also be used for clusters deployed using TiDB Operator.

Continuous Profiling is disabled by default and can be enabled on TiDB Dashboard.

Continuous Profiling is applicable to clusters deployed or upgraded using
↳ TiUP of v1.9.0 or later or TiDB Operator of v1.3.0 or later.

[User document](#tidb-dashboard-instance-profiling---continuous-profiling)

2.2.3 Improvements

- TiDB
 - Support the `ADMIN {SESSION | INSTANCE | GLOBAL} PLAN_CACHE` syntax to clear the cached query plan [#30370](#)
- TiKV
 - Coprocessor supports paging API to process requests in a stream-like way [#11448](#)
 - Support `read-through-lock` so that read operations do not need to wait for secondary locks to be resolved [#11402](#)
 - Add a disk protection mechanism to avoid panic caused by disk space drainage [#10537](#)
 - Support archiving and rotating logs [#11651](#)
 - Reduce the system call by the Raft client and increase CPU efficiency [#11309](#)
 - Coprocessor supports pushing down substring to TiKV [#11495](#)
 - Improve the scan performance by skip reading locks in the Read Committed isolation level [#11485](#)
 - Reduce the default thread pool size used by backup operations and limit the use of thread pool when the stress is high [#11000](#)
 - Support dynamically adjusting the sizes of the Apply thread pool and the Store thread pool [#11159](#)
 - Support configuring the size of the `snap-generator` thread pool [#11247](#)
 - Optimize the issue of global lock race that occurs when there are many files with frequent reads and writes [#250](#)
- PD
 - Record the historic hotspot information by default [#25281](#)
 - Add signature for the HTTP component to identify the request source [#4490](#)
 - Update TiDB Dashboard to v2021.12.31 [#4257](#)
- TiFlash
 - Optimize the communication of local operators
 - Increase the non-temporary thread count of gRPC to avoid the frequent creation or destruction of threads

- Tools
 - Backup & Restore (BR)
 - * Add a validity check for the key when BR performs encrypted backup [#29794](#)
 - TiCDC
 - * Reduce the count of “EventFeed retry rate limited” logs [#4006](#)
 - * Reduce the replication latency when replicating many tables [#3900](#)
 - * Reduce the time for the KV client to recover when a TiKV store is down [#3191](#)
 - TiDB Data Migration (DM)
 - * Lower the usage rate of CPU when the relay is enabled [#2214](#)
 - TiDB Lightning
 - * Use optimistic transactions by default to write data to improve performance in TiDB-backend mode [#30953](#)
 - Dumpling
 - * Improve compatibility when Dumpling checks the database version [#29500](#)
 - * Add the default collation when dumping CREATE DATABASE and CREATE TABLE [#3420](#)

2.2.4 Bug fixes

- TiDB
 - Fix the issue of the `tidb_analyze_version` value change that occurs when upgrading the cluster from v4.x to v5.x [#25422](#)
 - Fix the issue of the wrong result that occurs when using different collations in a subquery [#30748](#)
 - Fix the issue that the result of `concat(ifnull(time(3))` in TiDB is different from that in MySQL [#29498](#)
 - Fix the issue of potential data index inconsistency in optimistic transaction mode [#30410](#)
 - Fix the issue that the query execution plan of IndexMerge is wrong when an expression cannot be pushed down to TiKV [#30200](#)
 - Fix the issue that concurrent column type change causes inconsistency between the schema and the data [#31048](#)
 - Fix the issue that the IndexMerge query result is wrong when there is a subquery [#30913](#)
 - Fix the panic issue that occurs when the FetchSize is set too large in the client [#30896](#)
 - Fix the issue that LEFT JOIN might be mistakenly converted to INNER JOIN [#20510](#)

- Fix the issue that panic might occur when the `CASE-WHEN` expression and collation are used together [#30245](#)
 - Fix the issue of wrong query result that occurs when the `IN` value contains a binary constant [#31261](#)
 - Fix the issue of wrong query result that occurs when CTE has a subquery [#31255](#)
 - Fix the issue that executing the `INSERT ... SELECT ... ON DUPLICATE KEY ↪ UPDATE` statement gets panic [#28078](#)
 - Fix the issue that `INDEX HASH JOIN` returns the `send on closed channel` error [#31129](#)
- TiKV
 - Fix the issue that the MVCC deletion records are not cleared by GC [#11217](#)
 - Fix the issue that retrying prewrite requests in the pessimistic transaction mode might cause the risk of data inconsistency in rare cases [#11187](#)
 - Fix the issue that GC scan causes memory overflow [#11410](#)
 - Fix the issue that RocksDB flush or compaction causes panic when the disk capacity is full [#11224](#)
- PD
 - Fix the issue that Region statistics are not affected by `flow-round-by-digit` [#4295](#)
 - Fix the issue that the scheduling operator cannot fail fast because the target store is down [#3353](#)
 - Fix the issue that Regions on offline stores cannot be merged [#4119](#)
 - Fix the issue that the cold hotspot data cannot be deleted from the hotspot statistics [#4390](#)
- TiFlash
 - Fix the issue that TiFlash might panic when an MPP query is stopped
 - Fix the issue that queries with the `where <string>` clause return wrong results
 - Fix the potential issue of data inconsistency that might occur when setting the column type of an integer primary key to a larger range
 - Fix the issue that when an input time is earlier than 1970-01-01 00:00:01 UTC, the behavior of `unix_timestamp` is inconsistent with that of TiDB or MySQL
 - Fix the issue that TiFlash might return the `EstablishMPPConnection` error after it is restarted
 - Fix the issue that the `CastStringAsDecimal` behavior is inconsistent in TiFlash and in TiDB/TiKV
 - Fix the issue that the `DB::Exception: Encode type of coprocessor ↪ response is not CHBlock` error is returned in the query result
 - Fix the issue that the `castStringAsReal` behavior is inconsistent in TiFlash and in TiDB/TiKV

- Fix the issue that the returned result of the `date_add_string_xxx` function in TiFlash is inconsistent with that in MySQL
- Tools
 - Backup & Restore (BR)
 - * Fix the potential issue that Region distribution might be uneven after a restore operation is finished [#30425](#)
 - * Fix the issue that `'/'` cannot be specified in endpoint when `minio` is used as the backup storage [#30104](#)
 - * Fix the issue that system tables cannot be restored because concurrently backing up system tables makes the table name fail to update [#29710](#)
 - TiCDC
 - * Fix the issue that replication cannot be performed when `min.insync.replicas` is smaller than `replication-factor` [#3994](#)
 - * Fix the issue that the `cached region` monitoring metric is negative [#4300](#)
 - * Fix the issue that `mq sink write row` does not have monitoring data [#3431](#)
 - * Fix the compatibility issue of `sql mode` [#3810](#)
 - * Fix the potential panic issue that occurs when a replication task is removed [#3128](#)
 - * Fix the issue of panic and data inconsistency that occurs when outputting the default column value [#3929](#)
 - * Fix the issue that default values cannot be replicated [#3793](#)
 - * Fix the potential issue that the deadlock causes a replication task to get stuck [#4055](#)
 - * Fix the issue that no log is output when the disk is fully written [#3362](#)
 - * Fix the issue that special comments in DDL statements cause the replication task to stop [#3755](#)
 - * Fix the issue that the service cannot be started because of a timezone issue in the RHEL release [#3584](#)
 - * Fix the issue of potential data loss caused by inaccurate checkpoint [#3545](#)
 - * Fix the OOM issue in the container environment [#1798](#)
 - * Fix the issue of replication stop caused by the incorrect configuration of `config.Metadata.Timeout` [#3352](#)
 - TiDB Data Migration (DM)
 - * Fix the issue that the `CREATE VIEW` statement interrupts data replication [#4173](#)
 - * Fix the issue the schema needs to be reset after a DDL statement is skipped [#4177](#)
 - * Fix the issue that the table checkpoint is not updated in time after a DDL statement is skipped [#4184](#)
 - * Fix a compatibility issue of the TiDB version with the Parser version [#4298](#)
 - * Fix the issue that syncer metrics are updated only when querying the status [#4281](#)

- TiDB Lightning
 - * Fix the issue of wrong import result that occurs when TiDB Lightning does not have the privilege to access the `mysql.tidb` table [#31088](#)
 - * Fix the issue that some checks are skipped when TiDB Lightning is restarted [#30772](#)
 - * Fix the issue that TiDB Lightning fails to report the error when the S3 path does not exist [#30674](#)
- TiDB Binlog
 - * Fix the issue that Drainer fails because it is incompatible with the `CREATE` \hookrightarrow `PLACEMENT POLICY` statement [#1118](#)

2.3 TiDB Features

This document lists the features supported in each TiDB version. Note that supports for experimental features might change before the final release.

2.3.1 Data types, functions, and operators

Data types, functions, and operators	5.4	5.3	5.2	5.1	5.0	4.0
Numeric types	Y	Y	Y	Y	Y	Y
Date and time types	Y	Y	Y	Y	Y	Y
String types	Y	Y	Y	Y	Y	Y
JSON type	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Control flow functions	Y	Y	Y	Y	Y	Y
String functions	Y	Y	Y	Y	Y	Y
Numeric functions and operators	Y	Y	Y	Y	Y	Y
Date and time functions	Y	Y	Y	Y	Y	Y
Bit functions and operators	Y	Y	Y	Y	Y	Y
Cast functions and operators	Y	Y	Y	Y	Y	Y
Encryption and compression functions	Y	Y	Y	Y	Y	Y
Information functions	Y	Y	Y	Y	Y	Y
JSON functions	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Aggregation functions	Y	Y	Y	Y	Y	Y
Window functions	Y	Y	Y	Y	Y	Y
Miscellaneous functions	Y	Y	Y	Y	Y	Y
Operators	Y	Y	Y	Y	Y	Y
Character sets and collations ¹	Y	Y	Y	Y	Y	Y

¹TiDB incorrectly treats latin1 as a subset of utf8. See [TiDB #18955](#) for more details.

2.3.2 Indexing and constraints

Indexing and constraints	5.4	5.3	5.2	5.1	5.0	4.0
Expression indexes	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Columnar storage (TiFlash)	Y	Y	Y	Y	Y	Y
RocksDB engine	Y	Y	Y	Y	Y	Y
Titan plugin	Y	Y	Y	Y	Y	Y
Invisible indexes	Y	Y	Y	Y	Y	N
Composite PRIMARY KEY	Y	Y	Y	Y	Y	Y
Unique indexes	Y	Y	Y	Y	Y	Y
Clustered index on integer PRIMARY KEY	Y	Y	Y	Y	Y	Y
Clustered index on composite or non-integer key	Y	Y	Y	Y	Y	N

2.3.3 SQL statements

SQL statements ²	5.4	5.3	5.2	5.1	5.0	4.0
Basic SELECT, INSERT, UPDATE, DELETE, REPLACE	Y	Y	Y	Y	Y	Y
INSERT ON DUPLICATE KEY ↔ UPDATE	Y	Y	Y	Y	Y	Y
LOAD DATA INFILE	Y	Y	Y	Y	Y	Y
SELECT INTO OUTFILE	Y	Y	Y	Y	Y	Y
INNER JOIN, LEFT RIGHT [OUTER] JOIN	Y	Y	Y	Y	Y	Y
UNION, UNION ALL	Y	Y	Y	Y	Y	Y
EXCEPT and INTERSECT operators	Y	Y	Y	Y	Y	N
GROUP BY, ORDER BY	Y	Y	Y	Y	Y	Y
Window Functions	Y	Y	Y	Y	Y	Y
Common Table Expressions (CTE)	Y	Y	Y	Y	N	N
START TRANSACTION, COMMIT, ROLLBACK	Y	Y	Y	Y	Y	Y
EXPLAIN	Y	Y	Y	Y	Y	Y
EXPLAIN ANALYZE	Y	Y	Y	Y	Y	Y
User-defined variables	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Table Lock	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental

2.3.4 Advanced SQL features

Advanced SQL features	5.4	5.3	5.2	5.1	5.0	4.0
Prepared statement cache	Y	Y	Experimental	Experimental	Experimental	Experimental
SQL plan management (SPM)	Y	Y	Y	Y	Y	Y
Coprocessor cache	Y	Y	Y	Y	Y	Y
Stale Read	Y	Y	Y	Y	Y	Y
Follower reads	Y	Y	Y	Y	Y	Y
Read historical data (tidb_snapshot)	Y	Y	Y	Y	Y	Y
Optimizer hints	Y	Y	Y	Y	Y	Y
MPP Execution Engine	Y	Y	Y	Y	Y	Y
Index Merge	Y	Experimental	Experimental	Experimental	Experimental	Experimental
Placement Rules in SQL	Experimental	Experimental	N	N	N	N

2.3.5 Data definition language (DDL)

Data definition language (DDL)	5.4	5.3	5.2	5.1	5.0	4.0
Basic CREATE, DROP, ALTER, RENAME, TRUNCATE	Y	Y	Y	Y	Y	Y
Generated columns	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Views	Y	Y	Y	Y	Y	Y
Sequences	Y	Y	Y	Y	Y	Y
Auto increment	Y	Y	Y	Y	Y	Y
Auto random	Y	Y	Y	Y	Y	Y
DDL algorithm assertions	Y	Y	Y	Y	Y	Y
Multi-schema change: add columns	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Change column type	Y	Y	Y	Y	N	N
Temporary tables	Y	Y	N	N	N	N

2.3.6 Transactions

Transactions	5.4	5.3	5.2	5.1	5.0	4.0
Async commit	Y	Y	Y	Y	Y	N
1PC	Y	Y	Y	Y	Y	N
Large transactions (10GB)	Y	Y	Y	Y	Y	Y
Pessimistic transactions	Y	Y	Y	Y	Y	Y
Optimistic transactions	Y	Y	Y	Y	Y	Y
Repeatable-read isolation (snapshot isolation)	Y	Y	Y	Y	Y	Y

Transactions	5.4	5.3	5.2	5.1	5.0	4.0
Read-committed isolation	Y	Y	Y	Y	Y	Y

2.3.7 Partitioning

Partitioning	5.4	5.3	5.2	5.1	5.0	4.0
Range partitioning	Y	Y	Y	Y	Y	Y
Hash partitioning	Y	Y	Y	Y	Y	Y
List partitioning	Experimental	Experimental	Experimental	Experimental	Experimental	N
List COLUMNS partitioning	Experimental	Experimental	Experimental	Experimental	Experimental	N
EXCHANGE PARTITION	Experimental	Experimental	Experimental	Experimental	Experimental	N
Dynamic Pruning	Experimental	Experimental	Experimental	Experimental	N	N

2.3.8 Statistics

Statistics	5.4	5.3	5.2	5.1	5.0	4.0
CMSketch	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Y
Histograms	Y	Y	Y	Y	Y	Y
Extended statistics (multiple columns)	Experimental	Experimental	Experimental	Experimental	Experimental	N
Statistics Feedback	Deprecated	Experimental	Experimental	Experimental	Experimental	Experimental

2.3.9 Security

Security	5.4	5.3	5.2	5.1	5.0	4.0
Transparent layer security (TLS)	Y	Y	Y	Y	Y	Y
Encryption at rest (TDE)	Y	Y	Y	Y	Y	Y
Role-based authentication (RBAC)	Y	Y	Y	Y	Y	Y
Certificate-based authentication	Y	Y	Y	Y	Y	Y
caching_sha2_password authentication	Y	Y	Y	N	N	N
MySQL compatible GRANT system	Y	Y	Y	Y	Y	Y
Dynamic Privileges	Y	Y	Y	Y	N	N
Security Enhanced Mode	Y	Y	Y	Y	N	N
Redacted Log Files	Y	Y	Y	Y	Y	N

2.3.10 Data import and export

Data import and export	5.4	5.3	5.2	5.1	5.0	4.0
Fast Importer (TiDB Lightning)	Y	Y	Y	Y	Y	Y
mydumper logical dumper	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated	Deprecated
Dumpling logical dumper	Y	Y	Y	Y	Y	Y
Transactional LOAD DATA	Y	Y	Y	Y	Y	N ³
Database migration toolkit (DM)	Y	Y	Y	Y	Y	Y
TiDB Binlog	Y	Y	Y	Y	Y	Y
Change data capture (CDC)	Y	Y	Y	Y	Y	Y

2.3.11 Management, observability, and tools

Management, observability, and tools	5.4	5.3	5.2	5.1	5.0	4.0
TiDB Dashboard	Y	Y	Y	Y	Y	Y
SQL diagnostics	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Information schema	Y	Y	Y	Y	Y	Y
Metrics schema	Y	Y	Y	Y	Y	Y
Statements summary tables	Y	Y	Y	Y	Y	Y
Slow query log	Y	Y	Y	Y	Y	Y
TiUP deployment	Y	Y	Y	Y	Y	Y
Ansible deployment	N	N	N	N	N	Deprecated
Kubernetes operator	Y	Y	Y	Y	Y	Y
Built-in physical backup	Y	Y	Y	Y	Y	Y
Global Kill	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Lock View	Y	Y	Y	Experimental	Experimental	Experimental
SHOW CONFIG	Y	Y	Y	Y	Y	Y
SET CONFIG	Experimental	Experimental	Experimental	Experimental	Experimental	Experimental
Continuous Profiling	Experimental	Experimental	N	N	N	N
Top SQL	Experimental	N	N	N	N	N

2.4 TiDB Experimental Features

This document introduces the experimental features of TiDB in different versions. It is **NOT** recommended to use these features in the production environment.

2.4.1 Performance

- **Automatically scale TiFlash thread pool.** (Introduced in v5.4)
- **Raft Engine.** (Introduced in v5.4)
- **Support collecting statistics for PREDICATE COLUMNS** (Introduced in v5.4)

³For TiDB v4.0, the LOAD DATA transaction does not guarantee atomicity.

- [Support synchronously loading statistics](#). (Introduced in v5.4)
- [Randomly sample about 10000 rows of data to quickly build statistics](#) (Introduced in v3.0)

2.4.2 Stability

- Improve the stability of the optimizer's choice of indexes: extend the statistics feature by collecting the multi-column order dependency information (Introduced in v5.0).

2.4.3 Scheduling

Elastic scheduling feature. It enables the TiDB cluster to dynamically scale out and in on Kubernetes based on real-time workloads, which effectively reduces the stress during your application's peak hours and saves overheads. See [Enable TidbCluster Auto-scaling](#) for details. (Introduced in v4.0)

2.4.4 SQL

- [Use SQL interface to set placement rules for data](#) (Introduced in v5.3)
- List Partition (Introduced in v5.0)
- List COLUMNS Partition (Introduced in v5.0)
- [Dynamic Pruning Mode for Partitioned Tables](#). (Introduced in v5.1)
- The expression index feature. The expression index is also called the function-based index. When you create an index, the index fields do not have to be a specific column but can be an expression calculated from one or more columns. This feature is useful for quickly accessing the calculation-based tables. See [Expression index](#) for details. (Introduced in v4.0)
- [Generated Columns](#) (Introduced in v2.1)
- [User-Defined Variables](#) (Introduced in v2.1)
- [JSON data type](#) and [JSON functions](#) (Introduced in v2.1)
- [Using ALTER TABLE to modify multiple columns or indexes](#) (Introduced in v5.0.0)
- [Cascades Planner](#): a cascades framework-based top-down query optimizer (Introduced in v3.0)
- [Table Lock](#) (Introduced in v4.0.0)

2.4.5 Configuration management

- Persistently store configuration parameters in PD, and support dynamically modifying configuration items. (Introduced in v4.0)

2.4.6 Data sharing and subscription

- [Integrate TiCDC with Kafka Connect \(Confluent Platform\)](#) (Introduced in v5.0)

2.4.7 Storage

- [Disable Titan](#) (Introduced in v4.0)
- [Titan Level Merge](#) (Introduced in v4.0)

2.4.8 Backup and restoration

- [Back up Raw KV](#) (Introduced in v3.1)

2.4.9 Garbage collection

- [Green GC](#) (Introduced in v5.0)

2.4.10 Diagnostics

- [SQL diagnostics](#) (Introduced in v4.0)
- [Cluster diagnostics](#) (Introduced in v4.0)
- [Continuous profiling](#) (Introduced in v5.3)
- [Online Unsafe Recovery](#) (Introduced in v5.3)
- [Top SQL](#) (Introduced in v5.4)

2.5 Benchmarks

2.5.1 TiDB Sysbench Performance Test Report – v5.4.0 vs. v5.3.0

2.5.1.1 Test overview

This test aims at comparing the Sysbench performance of TiDB v5.4.0 and TiDB v5.3.0 in the Online Transactional Processing (OLTP) scenario. The results show that performance of v5.4.0 is improved by 2.59% ~ 4.85% in the write-heavy workload.

2.5.1.2 Test environment (AWS EC2)

2.5.1.2.1 Hardware configuration

Service type	EC2 type	Instance count
PD	m5.xlarge	3
TiKV	i3.4xlarge	3
TiDB	c5.4xlarge	3
Sysbench	c5.9xlarge	1

2.5.1.2.2 Software version

Service type	Software version
PD	v5.3.0 and v5.4.0
TiDB	v5.3.0 and v5.4.0
TiKV	v5.3.0 and v5.4.0
Sysbench	1.1.0-ead2689

2.5.1.2.3 Parameter configuration

TiDB v5.4.0 and TiDB v5.3.0 use the same configuration.

TiDB parameter configuration

```
log.level: "error"
performance.max-procs: 20
prepared-plan-cache.enabled: true
tikv-client.max-batch-wait-time: 2000000
```

TiKV parameter configuration

```
storage.scheduler-worker-pool-size: 5
raftstore.store-pool-size: 3
raftstore.apply-pool-size: 3
rocksdb.max-background-jobs: 8
raftdb.max-background-jobs: 4
raftdb.allow-concurrent-memtable-write: true
server.grpc-concurrency: 6
readpool.unified.min-thread-count: 5
readpool.unified.max-thread-count: 20
readpool.storage.normal-concurrency: 10
pessimistic-txn.pipelined: true
```

TiDB global variable configuration

```
set global tidb_hashagg_final_concurrency=1;
set global tidb_hashagg_partial_concurrency=1;
set global tidb_enable_async_commit = 1;
set global tidb_enable_1pc = 1;
set global tidb_guarantee_linearizability = 0;
set global tidb_enable_clustered_index = 1;
```

HAProxy configuration - haproxy.cfg

For more details about how to use HAProxy on TiDB, see [Best Practices for Using HAProxy in TiDB](#).

```
global # Global configuration.
```

```
chroot    /var/lib/haproxy      # Changes the current directory and
    ↪ sets superuser privileges for the startup process to improve
    ↪ security.
pidfile   /var/run/haproxy.pid   # Writes the PIDs of HAProxy processes
    ↪ into this file.
maxconn   4000                # The maximum number of concurrent
    ↪ connections for a single HAProxy process.
user      haproxy            # The same with the UID parameter.
group     haproxy            # The same with the GID parameter. A
    ↪ dedicated user group is recommended.
nbproc    64                 # The number of processes created when
    ↪ going daemon. When starting multiple processes to forward requests
    ↪ , ensure that the value is large enough so that HAProxy does not
    ↪ block processes.
daemon    # Makes the process fork into
    ↪ background. It is equivalent to the command line "-D" argument. It
    ↪ can be disabled by the command line "-db" argument.
defaults  # Default configuration.
log global # Inherits the settings of the global
    ↪ configuration.
retries 2 # The maximum number of retries to
    ↪ connect to an upstream server. If the number of connection attempts
    ↪ exceeds the value, the backend server is considered unavailable.
timeout connect 2s # The maximum time to wait for a
    ↪ connection attempt to a backend server to succeed. It should be set
    ↪ to a shorter time if the server is located on the same LAN as
    ↪ HAProxy.
timeout client 30000s # The maximum inactivity time on the
    ↪ client side.
timeout server 30000s # The maximum inactivity time on the
    ↪ server side.
listen tidb-cluster # Database load balancing.
bind 0.0.0.0:3390 # The Floating IP address and
    ↪ listening port.
mode tcp # HAProxy uses layer 4, the transport
    ↪ layer.
balance roundrobin # The server with the fewest
    ↪ connections receives the connection. "leastconn" is recommended
    ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
    ↪ than protocols using short sessions, such as HTTP. The algorithm
    ↪ is dynamic, which means that server weights might be adjusted on
    ↪ the fly for slow starts for instance.
server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
    ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
    ↪ detected as successful twice, the server is considered available;
```

```
↪ if it is detected as failed three times, the server is considered
↪ unavailable.
server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

2.5.1.3 Test plan

1. Deploy TiDB v5.4.0 and v5.3.0 using TiUP.
2. Use Sysbench to import 16 tables, each table with 10 million rows of data.
3. Execute the `analyze table` statement on each table.
4. Back up the data used for restore before different concurrency tests, which ensures data consistency for each test.
5. Start the Sysbench client to perform the `point_select`, `read_write`, `update_index`, and `update_non_index` tests. Perform stress tests on TiDB via HAProxy. For each concurrency under each workload, the test takes 20 minutes.
6. After each type of test is completed, stop the cluster, overwrite the cluster with the backup data in step 4, and restart the cluster.

2.5.1.3.1 Prepare test data

Run the following command to prepare the test data:

```
sysbench oltp_common \  
  --threads=16 \  
  --rand-type=uniform \  
  --db-driver=mysql \  
  --mysql-db=sbtest \  
  --mysql-host=$aws_nlb_host \  
  --mysql-port=$aws_nlb_port \  
  --mysql-user=root \  
  --mysql-password=password \  
  prepare --tables=16 --table-size=10000000
```

2.5.1.3.2 Perform the test

Run the following command to perform the test:

```
sysbench $testname \  
  --threads=$threads \  
  --time=1200 \  
  --report-interval=1 \  
  --rand-type=uniform \  
  --db-driver=mysql \  
  --mysql-db=sbtest \  
  run
```

```

--mysql-host=$aws_nlb_host \
--mysql-port=$aws_nlb_port \
run --tables=16 --table-size=10000000

```

2.5.1.4 Test results

2.5.1.4.1 Point Select performance

Threads	v5.3.0 TPS	v5.4.0 TPS	v5.3.0 95% latency (ms)	v5.4.0 95% latency (ms)	TPS im- provement (%)
300	266041.84	264345.73	1.96	2.07	-0.64
600	351782.71	348715.98	3.43	3.49	-0.87
900	386553.31	399777.11	5.09	4.74	3.42

Compared with v5.3.0, the Point Select performance of v5.4.0 is slightly improved by 0.64%.

Figure 1: Point Select

2.5.1.4.2 Update Non-index performance

Threads	v5.3.0 TPS	v5.4.0 TPS	v5.3.0 95% latency (ms)	v5.4.0 95% latency (ms)	TPS im- provement (%)
300	40804.31	41187.1	11.87	11.87	0.94
600	51239.4	53172.03	20.74	19.65	3.77
900	57897.56	59666.8	27.66	27.66	3.06

Compared with v5.3.0, the Update Non-index performance of v5.4.0 is improved by 2.59%.

Figure 2: Update Non-index

2.5.1.4.3 Update Index performance

Threads	v5.3.0 TPS	v5.4.0 TPS	v5.3.0 95% latency (ms)	v5.4.0 95% latency (ms)	TPS im- provement (%)
300	17737.82	18716.5	26.2	24.83	5.52
600	21614.39	22670.74	44.98	42.61	4.89
900	23933.7	24922.05	62.19	61.08	4.13

Compared with v5.3.0, the Update Index performance of v5.4.0 is improved by 4.85%.

Figure 3: Update Index

2.5.1.4.4 Read Write performance

Threads	v5.3.0 TPS	v5.4.0 TPS	v5.3.0 95% latency (ms)	v5.4.0 95% latency (ms)	TPS im- provement (%)
300	3810.78	3929.29	108.68	106.75	3.11
600	4514.28	4684.64	193.38	186.54	3.77
900	4842.49	4988.49	282.25	277.21	3.01

Compared with v5.3.0, the Read Write performance of v5.4.0 is improved by 3.30%.

Figure 4: Read Write

2.5.2 TiDB TPC-C Performance Test Report – v5.4.0 vs. v5.3.0

2.5.2.1 Test overview

This test aims at comparing the TPC-C performance of TiDB v5.4.0 and v5.3.0 in the Online Transactional Processing (OLTP) scenario. The results show that compared with v5.3.0, the TPC-C performance of v5.4.0 is improved by 3.16%.

2.5.2.2 Test environment (AWS EC2)

2.5.2.2.1 Hardware configuration

Service type	EC2 type	Instance count
PD	m5.xlarge	3
TiKV	i3.4xlarge	3
TiDB	c5.4xlarge	3
TPC-C	c5.9xlarge	1

2.5.2.2.2 Software version

Service type	Software version
PD	v5.3.0 and v5.4.0

Service type	Software version
TiDB	v5.3.0 and v5.4.0
TiKV	v5.3.0 and v5.4.0
TiUP	1.5.1

2.5.2.2.3 Parameter configuration

TiDB v5.4.0 and TiDB v5.3.0 use the same configuration.

TiDB parameter configuration

```
log.level: "error"
performance.max-procs: 20
prepared-plan-cache.enabled: true
tikv-client.max-batch-wait-time: 2000000
```

TiKV parameter configuration

```
pessimistic-txn.pipelined: true
raftdb.allow-concurrent-memtable-write: true
raftdb.max-background-jobs: 4
raftstore.apply-max-batch-size: 2048
raftstore.apply-pool-size: 3
raftstore.store-max-batch-size: 2048
raftstore.store-pool-size: 3
readpool.storage.normal-concurrency: 10
readpool.unified.max-thread-count: 20
readpool.unified.min-thread-count: 5
rocksdb.max-background-jobs: 8
server.grpc-concurrency: 6
storage.scheduler-worker-pool-size: 20
```

TiDB global variable configuration

```
set global tidb_hashagg_final_concurrency=1;
set global tidb_hashagg_partial_concurrency=1;
set global tidb_enable_async_commit = 1;
set global tidb_enable_1pc = 1;
set global tidb_guarantee_linearizability = 0;
set global tidb_enable_clustered_index = 1;
```

HAProxy configuration - haproxy.cfg

For more details about how to use HAProxy on TiDB, see [Best Practices for Using HAProxy in TiDB](#).

```
global # Global configuration.
```

```
chroot    /var/lib/haproxy      # Changes the current directory and
    ↪ sets superuser privileges for the startup process to improve
    ↪ security.
pidfile   /var/run/haproxy.pid  # Writes the PIDs of HAProxy processes
    ↪ into this file.
maxconn   4000                # The maximum number of concurrent
    ↪ connections for a single HAProxy process.
user      haproxy            # The same with the UID parameter.
group     haproxy            # The same with the GID parameter. A
    ↪ dedicated user group is recommended.
nbproc    64                 # The number of processes created when
    ↪ going daemon. When starting multiple processes to forward requests
    ↪ , ensure that the value is large enough so that HAProxy does not
    ↪ block processes.
daemon    # Makes the process fork into
    ↪ background. It is equivalent to the command line "-D" argument. It
    ↪ can be disabled by the command line "-db" argument.
defaults  # Default configuration.
log global # Inherits the settings of the global
    ↪ configuration.
retries   2                  # The maximum number of retries to
    ↪ connect to an upstream server. If the number of connection attempts
    ↪ exceeds the value, the backend server is considered unavailable.
timeout connect 2s          # The maximum time to wait for a
    ↪ connection attempt to a backend server to succeed. It should be set
    ↪ to a shorter time if the server is located on the same LAN as
    ↪ HAProxy.
timeout client 30000s       # The maximum inactivity time on the
    ↪ client side.
timeout server 30000s      # The maximum inactivity time on the
    ↪ server side.
listen tidb-cluster        # Database load balancing.
bind 0.0.0.0:3390          # The Floating IP address and
    ↪ listening port.
mode tcp                    # HAProxy uses layer 4, the transport
    ↪ layer.
balance roundrobin         # The server with the fewest
    ↪ connections receives the connection. "leastconn" is recommended
    ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
    ↪ than protocols using short sessions, such as HTTP. The algorithm
    ↪ is dynamic, which means that server weights might be adjusted on
    ↪ the fly for slow starts for instance.
server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
    ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
    ↪ detected as successful twice, the server is considered available;
```

```

↪ if it is detected as failed three times, the server is considered
↪ unavailable.
server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3

```

2.5.2.2.4 Prepare test data

1. Deploy TiDB v5.4.0 and v5.3.0 using TiUP.
2. Create a database named `tpcc`: `create database tpcc;`
3. Use BenchmarkSQL to import the TPC-C 5000 Warehouse data: `tiup bench tpcc`
↪ `prepare --warehouses 5000 --db tpcc -H 127.0.0.1 -P 4000.`
4. Run the `tiup bench tpcc run -U root --db tpcc --host 127.0.0.1 --port`
↪ `4000 --time 1800s --warehouses 5000 --threads {{thread}}` command to perform stress tests on TiDB via HAProxy. For each concurrency, the test takes 30 minutes.
5. Extract the tpmC data of New Order from the result.

2.5.2.3 Test result

Compared with v5.3.0, the TPC-C performance of v5.4.0 is **improved by 3.16%**.

Threads	v5.3.0 tpmC	v5.4.0 tpmC	tpmC improvement (%)
50	43002.4	44204.4	2.80
100	50162.7	52305	4.27
200	55768.2	57690.7	3.45
400	56836.8	58034.6	2.11

Figure 5: TPC-C

2.5.3 TiDB TPC-H Performance Test Report – TiDB v5.4 MPP mode vs. Greenplum 6.15.0 and Apache Spark 3.1.1

2.5.3.1 Test overview

This test aims at comparing the TPC-H 100 GB performance of TiDB v5.4 in the MPP mode with that of Greenplum and Apache Spark, two mainstream analytics engines, in their latest versions. The test result shows that the performance of TiDB v5.4 in the MPP mode is two to three times faster than that of the other two solutions under TPC-H workload.

In v5.0, TiDB introduces the MPP mode for [TiFlash](#), which significantly enhances TiDB's Hybrid Transactional and Analytical Processing (HTAP) capabilities. Test objects in this report are as follows:

- TiDB v5.4 columnar storage in the MPP mode
- Greenplum 6.15.0
- Apache Spark 3.1.1 + Parquet

2.5.3.2 Test environment

2.5.3.2.1 Hardware prerequisite

Instance type	Instance count
PD	1
TiDB	1
TiKV	3
TiFlash	3

- CPU: Intel(R) Xeon(R) CPU E5-2630 v4 @ 2.20GHz, 40 cores
- Memory: 189 GB
- Disks: NVMe 3TB * 2

2.5.3.2.2 Software version

Service type	Software version
TiDB	5.4
Greenplum	6.15.0
Apache Spark	3.1.1

2.5.3.2.3 Parameter configuration

TiDB v5.4

For the v5.4 cluster, TiDB uses the default parameter configuration except for the following configuration items.

In the configuration file `users.toml` of TiFlash, configure `max_memory_usage` as follows:

```
[profiles.default]
max_memory_usage = 10000000000000
```

Set session variables with the following SQL statements:

```
set @@tidb_isolation_read_engines='tiflash';
set @@tidb_allow_mpp=1;
set @@tidb_mem_quota_query = 10 << 30;
```

All TPC-H test tables are replicated to TiFlash in columnar format, with no additional partitions or indexes.

Greenplum

Except for the initial 3 nodes, the Greenplum cluster is deployed using an additional master node. Each segment server contains 8 segments, which means 4 segments per NVMe SSD. So there are 24 segments in total. The storage format is append-only/column-oriented storage and partition keys are used as primary keys.

```
log_statement = all
```

```
gp_autostats_mode = none
statement_mem = 2048MB
gp_vmem_protect_limit = 16384
```

Apache Spark

The test of Apache Spark uses Apache Parquet as the storage format and stores the data on HDFS. The HDFS system consists of three nodes. Each node has two assigned NVMe SSD disks as the data disks. The Spark cluster is deployed in standalone mode, using NVMe SSD disks as the local directory of `spark.local.dir` to speed up the shuffle spill, with no additional partitions or indexes.

```
--driver-memory 20G
--total-executor-cores 120
--executor-cores 5
--executor-memory 15G
```

2.5.3.3 Test result

Note:

The following test results are the average data of three tests. All numbers are in seconds.

Query ID	TiDB v5.4	Greenplum 6.15.0	Apache Spark 3.1.1 + Parquet
1	8.08	64.1307	52.64
2	2.53	4.76612	11.83
3	4.84	15.62898	13.39
4	10.94	12.88318	8.54
5	12.27	23.35449	25.23
6	1.32	6.033	2.21
7	5.91	12.31266	25.45
8	6.71	11.82444	23.12
9	44.19	22.40144	35.2
10	7.13	12.51071	12.18
11	2.18	2.6221	10.99
12	2.88	7.97906	6.99
13	6.84	10.15873	12.26
14	1.69	4.79394	3.89
15	3.29	10.48785	9.82
16	5.04	4.64262	6.76
17	11.7	74.65243	44.65

Query ID	TiDB v5.4	Greenplum 6.15.0	Apache Spark 3.1.1 + Parquet
18	12.87	64.87646	30.27
19	4.75	8.08625	4.7
20	8.89	15.47016	8.4
21	24.44	39.08594	34.83
22	1.23	7.67476	4.59

TPC-H 100GB on 3 Nodes

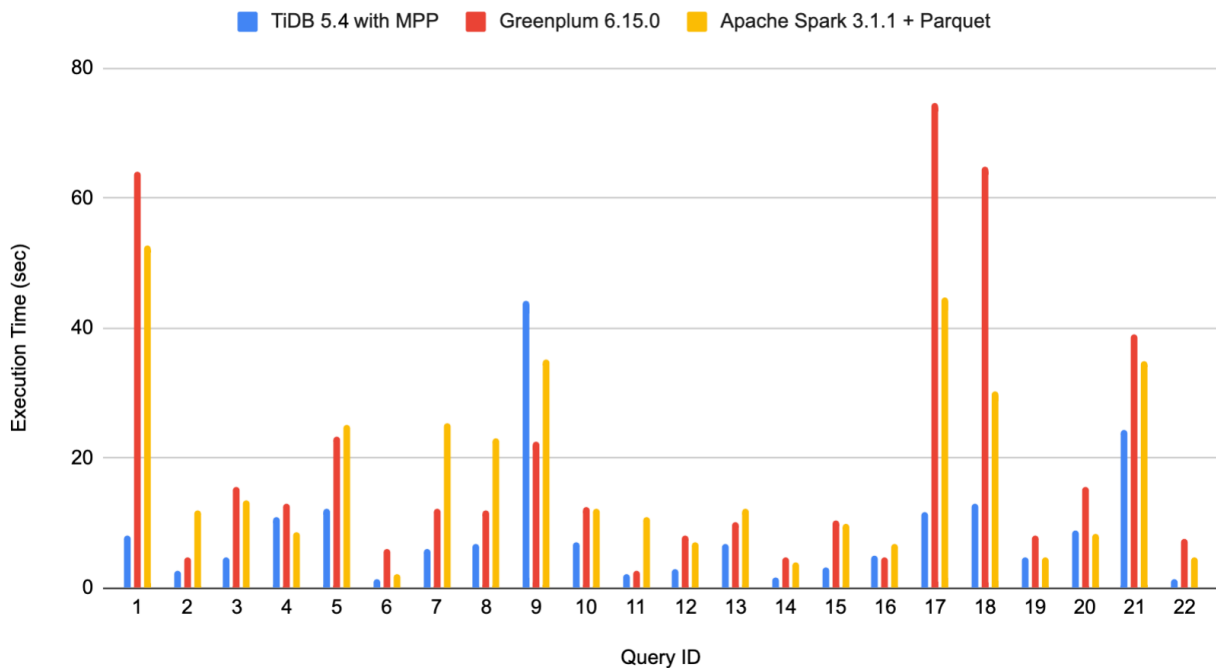

Figure 6: TPC-H

In the performance diagram above:

- Blue lines represent TiDB v5.4;
- Red lines represent Greenplum 6.15.0;
- Yellow lines represent Apache Spark 3.1.1.
- The y-axis represents the execution time of the query. The less the time is, the better the performance is.

2.6 MySQL Compatibility

TiDB is highly compatible with the MySQL 5.7 protocol and the common features and syntax of MySQL 5.7. The ecosystem tools for MySQL 5.7 (PHPMyAdmin, Navicat, MySQL

Workbench, mysqldump, and Mydumper/myloader) and the MySQL client can be used for TiDB.

However, some features of MySQL are not supported. This could be because there is now a better way to solve the problem (such as XML functions superseded by JSON), or a lack of current demand versus effort required (such as stored procedures and functions). Some features might also be difficult to implement as a distributed system.

In addition, TiDB does not support the MySQL replication protocol, but provides specific tools to replicate data with MySQL:

- Replicate data from MySQL: [TiDB Data Migration \(DM\)](#) is a tool that supports the full data migration and the incremental data replication from MySQL/MariaDB into TiDB.
- Replicate data to MySQL: [TiCDC](#) is a tool for replicating the incremental data of TiDB by pulling TiKV change logs. TiCDC uses the [MySQL sink](#) to replicate the incremental data of TiDB to MySQL.

Note:

This page describes general differences between MySQL and TiDB. See the dedicated pages for [Security](#) and [Pessimistic Transaction Mode](#) compatibility.

2.6.1 Unsupported features

- Stored procedures and functions
- Triggers
- Events
- User-defined functions
- FOREIGN KEY constraints [#18209](#)
- FULLTEXT syntax and indexes [#1793](#)
- SPATIAL (also known as GIS/GEOMETRY) functions, data types and indexes [#6347](#)
- Character sets other than `ascii`, `latin1`, `binary`, `utf8`, `utf8mb4`, and `gbk`.
- SYS schema
- Optimizer trace
- XML Functions
- X-Protocol [#1109](#)
- Savepoints [#6840](#)
- Column-level privileges [#9766](#)
- XA syntax (TiDB uses a two-phase commit internally, but this is not exposed via an SQL interface)
- CREATE TABLE `tblName AS SELECT stmt` syntax [#4754](#)
- CHECK TABLE syntax [#4673](#)

- CHECKSUM TABLE syntax [#1895](#)
- REPAIR TABLE syntax
- OPTIMIZE TABLE syntax
- GET_LOCK and RELEASE_LOCK functions [#14994](#)
- LOAD DATA with the REPLACE keyword [#24515](#)
- HANDLER statement
- CREATE TABLESPACE statement

2.6.2 Features that are different from MySQL

2.6.2.1 Auto-increment ID

- In TiDB, auto-incremental columns are globally unique. They are incremental on a single TiDB server, but *not* necessarily incremental among multiple TiDB servers or allocated sequentially. It is recommended that you do not mix default values and custom values. Otherwise, you might encounter the `Duplicated Error` error message.
- You can use the `tidb_allow_remove_auto_inc` system variable to allow or forbid removing the `AUTO_INCREMENT` column attribute. The syntax of removing the column attribute is `ALTER TABLE MODIFY` or `ALTER TABLE CHANGE`.
- TiDB does not support adding the `AUTO_INCREMENT` column attribute, and this attribute cannot be recovered once it is removed.
- See [AUTO_INCREMENT](#) for more details.

Note:

- If you have not specified the primary key when creating a table, TiDB uses `_tidb_rowid` to identify the row. The allocation of this value shares an allocator with the auto-increment column (if such a column exists). If you specify an auto-increment column as the primary key, TiDB uses this column to identify the row. In this situation, the following situation might happen:

```
mysql> CREATE TABLE t(id INT UNIQUE KEY AUTO_INCREMENT);
Query OK, 0 rows affected (0.05 sec)

mysql> INSERT INTO t VALUES(),(),();
Query OK, 3 rows affected (0.00 sec)
Records: 3 Duplicates: 0 Warnings: 0
```

```
mysql> SELECT _tidb_rowid, id FROM t;
+-----+-----+
| _tidb_rowid | id |
+-----+-----+
|          4 |  1 |
|          5 |  2 |
|          6 |  3 |
+-----+-----+
3 rows in set (0.01 sec)
```

Note:

The `AUTO_INCREMENT` attribute might cause hotspot in production environments. See [Troubleshoot HotSpot Issues](#) for details. It is recommended to use `AUTO_RANDOM` instead.

2.6.2.2 Performance schema

TiDB uses a combination of [Prometheus and Grafana](#) to store and query the performance monitoring metrics. Performance schema tables return empty results in TiDB.

2.6.2.3 Query Execution Plan

The output format, output content, and the privilege setting of Query Execution Plan (`EXPLAIN/EXPLAIN FOR`) in TiDB is greatly different from those in MySQL.

The MySQL system variable `optimizer_switch` is read-only in TiDB and has no effect on query plans. You can also use [optimizer hints](#) in similar syntax to MySQL, but the available hints and implementation might differ.

See [Understand the Query Execution Plan](#) for more details.

2.6.2.4 Built-in functions

TiDB supports most of the MySQL built-in functions, but not all. The statement `SHOW ↵ BUILTINS` provides a list of functions that are available.

See also: [TiDB SQL Grammar](#).

2.6.2.5 DDL

In TiDB, all supported DDL changes are performed online. Compared with DDL operations in MySQL, the DDL operations in TiDB have the following major restrictions:

- Multiple operations cannot be completed in a single `ALTER TABLE` statement. For example, it is not possible to add multiple columns or indexes in a single statement. Otherwise, the `Unsupported multi schema change` error might be output.
- `ALTER TABLE` in TiDB does not support the changes of some data types. For example, TiDB does not support the change from the `DECIMAL` type to the `DATE` type. If a data type change is unsupported, TiDB reports the `Unsupported modify column: type ↪ %d not match origin %d` error. Refer to [ALTER TABLE](#) for more details.
- The `ALGORITHM={INSTANT,INPLACE,COPY}` syntax functions only as an assertion in TiDB, and does not modify the `ALTER` algorithm. See [ALTER TABLE](#) for further details.
- Adding/Dropping the primary key of the `CLUSTERED` type is unsupported. For more details about the primary key of the `CLUSTERED` type, refer to [clustered index](#).
- Different types of indexes (`HASH|BTREE|RTREE|FULLTEXT`) are not supported, and will be parsed and ignored when specified.
- TiDB supports `HASH`, `RANGE`, and `LIST` partitioning types. For an unsupported partition type, TiDB returns `Warning: Unsupported partition type, treat as ↪ normal table`, where `%s` is a specific partition type.
- Table partitioning supports `ADD`, `DROP`, and `TRUNCATE` operations. Other partition operations are ignored. The following table partition syntaxes are not supported:

- `PARTITION BY KEY`
- `SUBPARTITION`
- `{CHECK|OPTIMIZE|REPAIR|IMPORT|DISCARD|REBUILD|REORGANIZE|COALESCE} ↪ PARTITION`

For more details, see [Partitioning](#).

2.6.2.6 Analyze table

[Statistics Collection](#) works differently in TiDB than in MySQL, in that it is a relatively lightweight and short-lived operation in MySQL/InnoDB, while in TiDB it completely rebuilds the statistics for a table and can take much longer to complete.

These differences are documented further in [ANALYZE TABLE](#).

2.6.2.7 Limitations of SELECT syntax

- The syntax `SELECT ... INTO @variable` is not supported.
- The syntax `SELECT ... GROUP BY ... WITH ROLLUP` is not supported.
- The syntax `SELECT .. GROUP BY expr` does not imply `GROUP BY expr ORDER BY ↪ expr` as it does in MySQL 5.7.

For details, see the [SELECT](#) statement reference.

2.6.2.8 UPDATE statement

See the [UPDATE](#) statement reference.

2.6.2.9 Views

Views in TiDB are not updatable. They do not support write operations such as UPDATE, INSERT, and DELETE.

2.6.2.10 Temporary tables

For details, see [Compatibility between TiDB local temporary tables and MySQL temporary tables](#).

2.6.2.11 Character sets and collations

- To learn the details of the character sets and collations supported by TiDB, see [Character Set and Collation Overview](#).
- To learn the MySQL compatibility of the GBK character set, see [GBK compatibility](#).

2.6.2.12 Storage engines

For compatibility reasons, TiDB supports the syntax to create tables with alternative storage engines. In implementation, TiDB describes the metadata as the InnoDB storage engine.

TiDB supports storage engine abstraction similar to MySQL, but you need to specify the storage engine using the `--store` option when you start the TiDB server.

2.6.2.13 SQL modes

TiDB supports most [SQL modes](#):

- The compatibility modes, such as Oracle and PostgreSQL are parsed but ignored. Compatibility modes are deprecated in MySQL 5.7 and removed in MySQL 8.0.
- The ONLY_FULL_GROUP_BY mode has minor [semantic differences](#) from MySQL 5.7.
- The NO_DIR_IN_CREATE and NO_ENGINE_SUBSTITUTION SQL modes in MySQL are accepted for compatibility, but are not applicable to TiDB.

2.6.2.14 Default differences

- Default character set:
 - The default value in TiDB is `utf8mb4`.
 - The default value in MySQL 5.7 is `latin1`.
 - The default value in MySQL 8.0 is `utf8mb4`.
- Default collation:
 - The default collation of `utf8mb4` in TiDB is `utf8mb4_bin`.

- The default collation of `utf8mb4` in MySQL 5.7 is `utf8mb4_general_ci`.
- The default collation of `utf8mb4` in MySQL 8.0 is `utf8mb4_0900_ai_ci`.
- Default value of `foreign_key_checks`:
 - The default value in TiDB is `OFF` and currently TiDB only supports `OFF`.
 - The default value in MySQL 5.7 is `ON`.
- Default SQL mode:
 - The default SQL mode in TiDB includes these modes: `ONLY_FULL_GROUP_BY`,
↔ `STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO`
↔ `,NO_AUTO_CREATE_USER,NO_ENGINE_SUBSTITUTION`.
 - The default SQL mode in MySQL:
 - * The default SQL mode in MySQL 5.7 is the same as TiDB.
 - * The default SQL mode in MySQL 8.0 includes these modes: `ONLY_FULL_GROUP_BY`
↔ `,STRICT_TRANS_TABLES,NO_ZERO_IN_DATE,NO_ZERO_DATE,ERROR_FOR_DIVISION_BY_ZERO`
↔ `,NO_ENGINE_SUBSTITUTION`.
- Default value of `lower_case_table_names`:
 - The default value in TiDB is 2 and currently TiDB only supports 2.
 - The default value in MySQL:
 - * On Linux: 0
 - * On Windows: 1
 - * On macOS: 2
- Default value of `explicit_defaults_for_timestamp`:
 - The default value in TiDB is `ON` and currently TiDB only supports `ON`.
 - The default value in MySQL:
 - * For MySQL 5.7: `OFF`.
 - * For MySQL 8.0: `ON`.

2.6.2.15 Date and Time

2.6.2.15.1 Named timezone

- TiDB uses all time zone rules currently installed in the system for calculation (usually the `tzdata` package). You can use all time zone names without importing the time zone table data. You cannot modify the calculation rules by importing the time zone table data.
- MySQL uses the local time zone by default and relies on the current time zone rules built into the system (such as when to start daylight saving time) for calculation; and the time zone cannot be specified by the time zone name without [importing the time zone table data](#).

2.6.2.16 Type system differences

The following column types are supported by MySQL, but **NOT** by TiDB:

- FLOAT4/FLOAT8
- SQL_TSI_* (including SQL_TSI_MONTH, SQL_TSI_WEEK, SQL_TSI_DAY, SQL_TSI_HOUR, SQL_TSI_MINUTE and SQL_TSI_SECOND, excluding SQL_TSI_YEAR)

2.6.2.17 Incompatibility caused by deprecated features

TiDB does not implement certain features that have been marked as deprecated in MySQL, including:

- Specifying precision for floating point types. MySQL 8.0 [deprecates](#) this feature, and it is recommended to use the DECIMAL type instead.
- The ZEROFILL attribute. MySQL 8.0 [deprecates](#) this feature, and it is recommended to instead pad numeric values in your application.

2.7 TiDB Limitations

This document describes the common usage limitations of TiDB, including the maximum identifier length and the maximum number of supported databases, tables, indexes, partitioned tables, and sequences.

2.7.1 Limitations on identifier length

Identifier type	Maximum length (number of characters allowed)
Database	64
Table	64
Column	64
Index	64
View	64
Sequence	64

2.7.2 Limitations on the total number of databases, tables, views, and connections

Identifier type	Maximum number
Databases	unlimited
Tables	unlimited
Views	unlimited

Identifier type	Maximum number
Connections	unlimited

2.7.3 Limitations on a single database

Type	Upper limit
Tables	unlimited

2.7.4 Limitations on a single table

Type	Upper limit (default value)
Columns	Defaults to 1017 and can be adjusted up to 4096
Indexes	Defaults to 64 and can be adjusted up to 512
Rows	unlimited
Size	unlimited
Partitions	8192

- The upper limit of `Columns` can be modified via `table-column-count-limit`.
- The upper limit of `Indexes` can be modified via `index-limit`.

2.7.5 Limitation on a single row

Type	Upper limit
Size	6 MB

You can adjust the size limit via the `txn-entry-size-limit` configuration item.

2.7.6 Limitations on string types

Type	Upper limit
CHAR	255 characters
BINARY	255 characters
VARBINARY	65535 characters
VARCHAR	16383 characters
TEXT	6 MB
BLOB	6 MB

2.7.7 Limitations on SQL statements

Type	Upper limit
The maximum number of SQL statements in a single transaction	When the optimistic transaction is used and the transaction retry is enabled, the upper limit is 5000.

You can modify the limit via the `stmt-count-limit` configuration item.

2.8 Credits

Each contributor has played an important role in promoting the robust development of TiDB. We sincerely appreciate all contributors who have submitted code, written and translated documents for TiDB.

2.8.1 TiDB developers

TiDB developers contribute to new feature development, performance improvement, stability guarantee, and bug fixes. The following is the list of contributors in TiDB related repos:

- [pingcap/tidb](#)
- [tikv/tikv](#)
- [pingcap/parser](#)
- [tikv/pd](#)
- [pingcap/tidb-operator](#)
- [pingcap/tiup](#)
- [pingcap/br](#)
- [pingcap/dm](#)
- [pingcap/tidb-binlog](#)
- [pingcap/tidb-dashboard](#)
- [pingcap/tiflow](#)
- [pingcap/tidb-tools](#)
- [pingcap/tidb-lightning](#)
- [pingcap/tispark](#)

- [pingcap/dumpling](#)
- [tikv/client-java](#)
- [tidb-incubator/TiBigData](#)
- [ti-community-infra](#)

2.8.2 Writers and translators for TiDB documentation

Writers and translators write and translate documents for TiDB and the related projects. The following is the list of contributors in TiDB documentation related repos:

- [pingcap/docs-cn](#)
- [pingcap/docs](#)
- [pingcap/docs-tidb-operator](#)
- [tikv/website](#)

3 Quick Start

3.1 Quick Start Guide for the TiDB Database Platform

This guide walks you through the quickest way to get started with TiDB. For non-production environments, you can deploy your TiDB database by either of the following methods:

- [Deploy a local test cluster](#) (for macOS and Linux)
- [Simulate production deployment on a single machine](#) (for Linux only)

Note:

- TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see [Telemetry](#).
- The deployment method provided in this guide is **ONLY FOR** quick start, **NOT FOR** production.
 - To deploy a self-hosted production cluster, see [production installation guide](#).
 - To deploy TiDB in Kubernetes, see [Get Started with TiDB in Kubernetes](#).
 - To manage TiDB in the cloud, see [TiDB Cloud Quick Start](#).

3.1.1 Deploy a local test cluster

- Scenario: Quickly deploy a local TiDB cluster for testing using a single macOS or Linux server. By deploying such a cluster, you can learn the basic architecture of TiDB and the operation of its components, such as TiDB, TiKV, PD, and the monitoring components.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
↪ install.sh | sh
```

If the following message is displayed, you have installed TiUP successfully:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com  
Detected shell: zsh  
Shell profile: /Users/user/.zshrc  
/Users/user/.zshrc has been modified to add tiup to PATH  
open a new terminal or source /Users/user/.zshrc to use it  
Installed path: /Users/user/.tiup/bin/tiup  
=====  
Have a try:   tiup playground  
=====
```

Note the Shell profile path in the output above. You need to use the path in the next step.

2. Declare the global environment variable:

Note:

After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path. In this case, `$` ↪ `{your_shell_profile}` is `/Users/user/.zshrc` from the output of Step 1.

```
source ${your_shell_profile}
```

3. Start the cluster in the current session:

- If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

```
tiup playground
```

- If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

```
tiup playground v5.4.3 --db 2 --pd 3 --kv 3
```

The command downloads a version cluster to the local machine and starts it, such as v5.4.3. To view the latest version, run `tiup list tidb`.

This command returns the access methods of the cluster:

```
CLUSTER START SUCCESSFULLY, Enjoy it ^-^
To connect TiDB: mysql --comments --host 127.0.0.1 --port 4001 -u
  ↪ root -p (no password)
To connect TiDB: mysql --comments --host 127.0.0.1 --port 4000 -u
  ↪ root -p (no password)
To view the dashboard: http://127.0.0.1:2379/dashboard
PD client endpoints: [127.0.0.1:2379 127.0.0.1:2382 127.0.0.1:2384]
To view Prometheus: http://127.0.0.1:9090
To view Grafana: http://127.0.0.1:3000
```

Note:

- Since v5.2.0, TiDB supports running `tiup playground` on the machine that uses the Apple M1 chip.
- For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command.
- If you want the data to be persisted on storage, run `tiup --tag <your-tag> playground` For details, refer to [TiUP Reference Guide](#).

4. Start a new session to access TiDB:

- Use the TiUP client to connect to TiDB.

```
tiup client
```

- You can also use the MySQL client to connect to TiDB.

```
mysql --host 127.0.0.1 --port 4000 -u root
```

5. Access the Prometheus dashboard of TiDB at <http://127.0.0.1:9090>.

6. Access the **TiDB Dashboard** at <http://127.0.0.1:2379/dashboard>. The default username is `root`, with an empty password.
7. Access the Grafana dashboard of TiDB through <http://127.0.0.1:3000>. Both the default username and password are `admin`.
8. (Optional) **Load data to TiFlash** for analysis.
9. Clean up the cluster after the test deployment:
 1. Stop the above TiDB service by pressing Control+C.
 2. Run the following command after the service is stopped:

```
tiup clean --all
```

Note:

TiUP Playground listens on 127.0.0.1 by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

As a distributed system, a basic TiDB test cluster usually consists of 2 TiDB instances, 3 TiKV instances, 3 PD instances, and optional TiFlash instances. With TiUP Playground, you can quickly build the test cluster by taking the following steps:

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
↪ install.sh | sh
```

If the following message is displayed, you have installed TiUP successfully:

```
Successfully set mirror to https://tiup-mirrors.pingcap.com  
Detected shell: zsh  
Shell profile: /Users/user/.zshrc  
/Users/user/.zshrc has been modified to add tiup to PATH  
open a new terminal or source /Users/user/.zshrc to use it  
Installed path: /Users/user/.tiup/bin/tiup  
=====  
Have a try:   tiup playground  
=====
```

Note the Shell profile path in the output above. You need to use the path in the next step.

2. Declare the global environment variable:

Note:

After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `#{your_shell_profile}` in the following `source` command according to the path.

```
source #{your_shell_profile}
```

3. Start the cluster in the current session:

- If you want to start a TiDB cluster of the latest version with 1 TiDB instance, 1 TiKV instance, 1 PD instance, and 1 TiFlash instance, run the following command:

```
tiup playground
```

- If you want to specify the TiDB version and the number of the instances of each component, run a command like this:

```
tiup playground v5.4.3 --db 2 --pd 3 --kv 3
```

The command downloads a version cluster to the local machine and starts it, such as v5.4.3. To view the latest version, run `tiup list tidb`.

This command returns the access methods of the cluster:

```
CLUSTER START SUCCESSFULLY, Enjoy it ^-^
To connect TiDB: mysql --host 127.0.0.1 --port 4000 -u root -p (no
  ↪ password) --comments
To view the dashboard: http://127.0.0.1:2379/dashboard
PD client endpoints: [127.0.0.1:2379]
To view the Prometheus: http://127.0.0.1:9090
To view the Grafana: http://127.0.0.1:3000
```

Note:

For the playground operated in this way, after the test deployment is finished, TiUP will clean up the original cluster data. You will get a new cluster after re-running the command. If you want the data to be persisted on storage, run `tiup --tag <your-tag> playground ↪` For details, refer to [TiUP Reference Guide](#).

4. Start a new session to access TiDB:

- Use the TiUP client to connect to TiDB.

```
tiup client
```

- You can also use the MySQL client to connect to TiDB.

```
mysql --host 127.0.0.1 --port 4000 -u root
```

5. Access the Prometheus dashboard of TiDB at <http://127.0.0.1:9090>.

6. Access the **TiDB Dashboard** at <http://127.0.0.1:2379/dashboard>. The default username is `root`, with an empty password.

7. Access the Grafana dashboard of TiDB through <http://127.0.0.1:3000>. Both the default username and password are `admin`.

8. (Optional) **Load data to TiFlash** for analysis.

9. Clean up the cluster after the test deployment:

1. Stop the process by pressing Control+C.
2. Run the following command after the service is stopped:

```
tiup clean --all
```

Note:

TiUP Playground listens on `127.0.0.1` by default, and the service is only locally accessible. If you want the service to be externally accessible, specify the listening address using the `--host` parameter to bind the network interface card (NIC) to an externally accessible IP address.

3.1.2 Simulate production deployment on a single machine

- Scenario: Experience the smallest TiDB cluster with the complete topology and simulate the production deployment steps on a single Linux server.

This section describes how to deploy a TiDB cluster using a YAML file of the smallest topology in TiUP.

3.1.2.1 Prepare

Prepare a target machine that meets the following requirements:

- CentOS 7.3 or a later version is installed
- The Linux OS has access to the Internet, which is required to download TiDB and related software installation packages

The smallest TiDB cluster topology is as follows:

Note:

The IP address of the following instances only serves as an example IP. In your actual deployment, you need to replace the IP with your actual IP.

Instance	Count	IP	Configuration
TiKV	3	10.0.1.1	Avoid 10.0.1.1 10.0.1.1 between the port and the di- rec- tory
TiDB	1	10.0.1.1	The de- fault port Global di- rec- tory con- fig- u- ra- tion

Instance	Count	IP	Configuration
PD	1	10.0.1.1	The default port Global directory configuration
TiFlash	1	10.0.1.1	The default port Global directory configuration
Monitor	1	10.0.1.1	The default port Global directory configuration

Other requirements for the target machine:

- The `root` user and its password is required

- **Stop the firewall service of the target machine**, or open the port needed by the TiDB cluster nodes
- Currently, the TiUP cluster supports deploying TiDB on the x86_64 (AMD64) and ARM architectures:
 - It is recommended to use CentOS 7.3 or later versions on AMD64
 - It is recommended to use CentOS 7.6 1810 on ARM

3.1.2.2 Deploy

Note:

You can log in to the target machine as a regular user or the `root` user. The following steps use the `root` user as an example.

1. Download and install TiUP:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
↪ install.sh | sh
```

2. Declare the global environment variable.

Note:

After the installation, TiUP displays the absolute path of the corresponding Shell profile file. You need to modify `${your_shell_profile}` in the following `source` command according to the path.

```
source ${your_shell_profile}
```

3. Install the cluster component of TiUP:

```
tiup cluster
```

4. If the TiUP cluster is already installed on the machine, update the software version:

```
tiup update --self && tiup update cluster
```

5. Use the root user privilege to increase the connection limit of the `sshd` service. This is because TiUP needs to simulate deployment on multiple machines.

1. Modify `/etc/ssh/sshd_config`, and set `MaxSessions` to 20.
2. Restart the `sshd` service:

```
service sshd restart
```

6. Create and start the cluster:

Edit the configuration file according to the following template, and name it as `topo`.

↪ `yaml`:

```
# # Global variables are applied to all deployments and used as the
  ↪ default value of
# # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"

# # Monitored variables are applied to all the machines.
monitored:
  node_exporter_port: 9100
  blackbox_exporter_port: 9115

server_configs:
  tidb:
    log.slow-threshold: 300
  tikv:
    readpool.storage.use-unified-pool: false
    readpool.coprocessor.use-unified-pool: true
  pd:
    replication.enable-placement-rules: true
    replication.location-labels: ["host"]
  tiflash:
    logger.level: "info"

pd_servers:
- host: 10.0.1.1

tidb_servers:
- host: 10.0.1.1

tikv_servers:
- host: 10.0.1.1
  port: 20160
  status_port: 20180
```

```
config:
  server.labels: { host: "logic-host-1" }

- host: 10.0.1.1
  port: 20161
  status_port: 20181
  config:
    server.labels: { host: "logic-host-2" }

- host: 10.0.1.1
  port: 20162
  status_port: 20182
  config:
    server.labels: { host: "logic-host-3" }

tiflash_servers:
- host: 10.0.1.1

monitoring_servers:
- host: 10.0.1.1

grafana_servers:
- host: 10.0.1.1
```

- **user: "tidb"**: Use the `tidb` system user (automatically created during deployment) to perform the internal management of the cluster. By default, use port 22 to log in to the target machine via SSH.
- **replication.enable-placement-rules**: This PD parameter is set to ensure that TiFlash runs normally.
- **host**: The IP of the target machine.

7. Execute the cluster deployment command:

```
tiup cluster deploy <cluster-name> <tidb-version> ./topo.yaml --user
↳ root -p
```

- **<cluster-name>**: Set the cluster name
- **<tidb-version>**: Set the TiDB cluster version. You can see all the supported TiDB versions by running the `tiup list tidb` command
- **-p**: Specify the password used to connect to the target machine.

Note:

If you use secret keys, you can specify the path of the keys through `-i`. Do not use `-i` and `-p` at the same time.

Enter “y” and the root user’s password to complete the deployment:

```
Do you want to continue? [y/N]: y
Input SSH password:
```

8. Start the cluster:

```
tiup cluster start <cluster-name>
```

9. Access the cluster:

- Install the MySQL client. If it is already installed, skip this step.

```
yum -y install mysql
```

- Access TiDB. The password is empty:

```
mysql -h 10.0.1.1 -P 4000 -u root
```

- Access the Grafana monitoring dashboard at <http://%7Bgrafana-ip%7D:3000>. The default username and password are both `admin`.
- Access the [TiDB Dashboard](http://%7Bpd-ip%7D:2379/dashboard) at <http://%7Bpd-ip%7D:2379/dashboard>. The default username is `root`, and the password is empty.
- To view the currently deployed cluster list:

```
tiup cluster list
```

- To view the cluster topology and status:

```
tiup cluster display <cluster-name>
```

3.1.3 What’s next

- If you have just deployed a TiDB cluster for the local test environment:
 - Learn [Basic SQL operations in TiDB](#)
 - [Migrate data to TiDB](#)
- If you are ready to deploy a TiDB cluster for the production environment:
 - [Deploy TiDB using TiUP](#)
 - [Deploy TiDB on Cloud using TiDB Operator](#)
- If you’re looking for analytics solution with TiFlash:
 - [Use TiFlash](#)
 - [TiFlash Overview](#)

3.2 Quick Start Guide for TiDB HTAP

This guide walks you through the quickest way to get started with TiDB's one-stop solution of Hybrid Transactional and Analytical Processing (HTAP).

Note:

The steps provided in this guide is ONLY for quick start in the test environment. For production environments, [explore HTAP](#) is recommended.

3.2.1 Basic concepts

Before using TiDB HTAP, you need to have some basic knowledge about [TiKV](#), a row-based storage engine for TiDB Online Transactional Processing (OLTP), and [TiFlash](#), a columnar storage engine for TiDB Online Analytical Processing (OLAP).

- Storage engines of HTAP: The row-based storage engine and the columnar storage engine co-exist for HTAP. Both storage engines can replicate data automatically and keep strong consistency. The row-based storage engine optimizes OLTP performance, and the columnar storage engine optimizes OLAP performance.
- Data consistency of HTAP: As a distributed and transactional key-value database, TiKV provides transactional interfaces with ACID compliance, and guarantees data consistency between multiple replicas and high availability with the implementation of the [Raft consensus algorithm](#). As a columnar storage extension of TiKV, TiFlash replicates data from TiKV in real time according to the Raft Learner consensus algorithm, which ensures that data is strongly consistent between TiKV and TiFlash.
- Data isolation of HTAP: TiKV and TiFlash can be deployed on different machines as needed to solve the problem of HTAP resource isolation.
- MPP computing engine: [MPP](#) is a distributed computing framework provided by the TiFlash engine since TiDB 5.0, which allows data exchange between nodes and provides high-performance, high-throughput SQL algorithms. In the MPP mode, the run time of the analytic queries can be significantly reduced.

3.2.2 Steps

In this document, you can experience the convenience and high performance of TiDB HTAP by querying an example table in a [TPC-H](#) dataset. TPC-H is a popular decision support benchmark that consists of a suite of business oriented ad-hoc queries with large volumes of data and a high degree of complexity. To experience 22 complete SQL queries using TPC-H, visit [tidb-bench repo](#) or [TPC-H](#) for instructions on how to generate query statements and data.

3.2.2.1 Step 1. Deploy a local test environment

Before using TiDB HTAP, follow the steps in the [Quick Start Guide for the TiDB Database Platform](#) to prepare a local test environment, and run the following command to deploy a TiDB cluster:

```
tiup playground
```

Note:

tiup playground command is ONLY for quick start, NOT for production.

3.2.2.2 Step 2. Prepare test data

In the following steps, you can create a [TPC-H](#) dataset as the test data to use TiDB HTAP. If you are interested in TPC-H, see [General Implementation Guidelines](#).

Note:

If you want to use your existing data for analytic queries, you can [migrate your data to TiDB](#). If you want to design and create your own test data, you can create it by executing SQL statements or using related tools.

1. Install the test data generation tool by running the following command:

```
tiup install bench
```

2. Generate the test data by running the following command:

```
tiup bench tpch --sf=1 prepare
```

If the output of this command shows **Finished**, it indicates that the data is created.

3. Execute the following SQL statement to view the generated data:

```
SELECT
  CONCAT(table_schema, '.', table_name) AS 'Table Name',
  table_rows AS 'Number of Rows',
  FORMAT_BYTES(data_length) AS 'Data Size',
  FORMAT_BYTES(index_length) AS 'Index Size',
  FORMAT_BYTES(data_length+index_length) AS 'Total'
```

```
FROM
  information_schema.TABLES
WHERE
  table_schema='test';
```

As you can see from the output, eight tables are created in total, and the largest table has 6.5 million rows (the number of rows created by the tool depends on the actual SQL query result because the data is randomly generated).

```
sql +-----+-----+-----+-----+-----+
↪ | Table Name | Number of Rows | Data Size | Index Size | Total |
↪ +-----+-----+-----+-----+-----+
↪ | test.nation | 25 | 2.44 KiB | 0 bytes | 2.44 KiB | | test.region
↪ | 5 | 416 bytes | 0 bytes | 416 bytes | | test.part | 200000
↪ | 25.07 MiB | 0 bytes | 25.07 MiB | | test.supplier | 10000 |
↪ | 1.45 MiB | 0 bytes | 1.45 MiB | | test.partsupp | 800000 |
↪ | 120.17 MiB | 12.21 MiB | 132.38 MiB | | test.customer | 150000 | 24.77
↪ | MiB | 0 bytes | 24.77 MiB | | test.orders | 1527648 | 174.40
↪ | MiB | 0 bytes | 174.40 MiB | | test.lineitem | 6491711 | 849.07 MiB |
↪ | 99.06 MiB | 948.13 MiB | +-----+-----+-----+
↪ | 8 rows in set (0.06 sec)
```

This is a database of a commercial ordering system. In which, the `test.nation` table indicates the information about countries, the `test.region` table indicates the information about regions, the `test.part` table indicates the information about parts, the `test.supplier` table indicates the information about suppliers, the `test.partsupp` table indicates the information about parts of suppliers, the `test.customer` table indicates the information about customers, the `test.orders` table indicates the information about orders, and the `test.lineitem` table indicates the information about online items.

3.2.2.3 Step 3. Query data with the row-based storage engine

To know the performance of TiDB with only the row-based storage engine, execute the following SQL statements:

```
SELECT
  l_orderkey,
  SUM(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_orderdate,
  o_shippriority
FROM
  customer,
  orders,
  lineitem
```

```
WHERE
  c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
  l_orderkey,
  o_orderdate,
  o_shippriority
ORDER BY
  revenue DESC,
  o_orderdate
limit 10;
```

This is a shipping priority query, which provides the priority and potential revenue of the highest-revenue order that has not been shipped before a specified date. The potential revenue is defined as the sum of `l_extendedprice * (1-l_discount)`. The orders are listed in the descending order of revenue. In this example, this query lists the unshipped orders with potential query revenue in the top 10.

3.2.2.4 Step 4. Replicate the test data to the columnar storage engine

After TiFlash is deployed, TiKV does not replicate data to TiFlash immediately. You need to execute the following DDL statements in a MySQL client of TiDB to specify which tables need to be replicated. After that, TiDB will create the specified replicas in TiFlash accordingly.

```
ALTER TABLE test.customer SET TIFLASH REPLICA 1;
ALTER TABLE test.orders SET TIFLASH REPLICA 1;
ALTER TABLE test.lineitem SET TIFLASH REPLICA 1;
```

To check the replication status of the specific tables, execute the following statements:

```
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
  ↪ ' and TABLE_NAME = 'customer';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
  ↪ ' and TABLE_NAME = 'orders';
SELECT * FROM information_schema.tiflash_replica WHERE TABLE_SCHEMA = 'test
  ↪ ' and TABLE_NAME = 'lineitem';
```

In the result of the above statements:

- `AVAILABLE` indicates whether the TiFlash replica of a specific table is available or not. 1 means available and 0 means unavailable. Once a replica becomes available, this status does not change any more. If you use DDL statements to modify the number of replicas, the replication status will be recalculated.

- **PROGRESS** means the progress of the replication. The value is between 0.0 and 1.0. 1 means at least one replica is replicated.

3.2.2.5 Step 5. Analyze data faster using HTAP

Execute the SQL statements in [Step 3](#) again, and you can see the performance of TiDB HTAP.

For tables with TiFlash replicas, the TiDB optimizer automatically determines whether to use TiFlash replicas based on the cost estimation. To check whether or not a TiFlash replica is selected, you can use the `desc` or `explain analyze` statement. For example:

```
explain analyze SELECT
  l_orderkey,
  SUM(
    l_extendedprice * (1 - l_discount)
  ) AS revenue,
  o_orderdate,
  o_shippriority
FROM
  customer,
  orders,
  lineitem
WHERE
  c_mktsegment = 'BUILDING'
AND c_custkey = o_custkey
AND l_orderkey = o_orderkey
AND o_orderdate < DATE '1996-01-01'
AND l_shipdate > DATE '1996-02-01'
GROUP BY
  l_orderkey,
  o_orderdate,
  o_shippriority
ORDER BY
  revenue DESC,
  o_orderdate
limit 10;
```

If the result of the `EXPLAIN` statement shows `ExchangeSender` and `ExchangeReceiver` operators, it indicates that the MPP mode has taken effect.

In addition, you can specify that each part of the entire query is computed using only the TiFlash engine. For detailed information, see [Use TiDB to read TiFlash replicas](#).

You can compare query results and query performance of these two methods.

3.2.3 What's next

- [Architecture of TiDB HTAP](#)
- [Explore HTAP](#)
- [Use TiFlash](#)

3.3 Explore SQL with TiDB

TiDB is compatible with MySQL, you can use MySQL statements directly in most of the cases. For unsupported features, see [Compatibility with MySQL](#).

To experiment with SQL and test out TiDB compatibility with MySQL queries, you can [run TiDB directly in your web browser without installing it](#). You can also first deploy a TiDB cluster and then run SQL statements in it.

This page walks you through the basic TiDB SQL statements such as DDL, DML and CRUD operations. For a complete list of TiDB statements, see [TiDB SQL Syntax Diagram](#).

3.3.1 Category

SQL is divided into the following 4 types according to their functions:

- DDL (Data Definition Language): It is used to define database objects, including databases, tables, views, and indexes.
- DML (Data Manipulation Language): It is used to manipulate application related records.
- DQL (Data Query Language): It is used to query the records after conditional filtering.
- DCL (Data Control Language): It is used to define access privileges and security levels.

Common DDL features are creating, modifying, and deleting objects (such as tables and indexes). The corresponding commands are `CREATE`, `ALTER`, and `DROP`.

3.3.2 Show, create and drop a database

A database in TiDB can be considered as a collection of objects such as tables and indexes.

To show the list of databases, use the `SHOW DATABASES` statement:

```
SHOW DATABASES;
```

To use the database named `mysql`, use the following statement:

```
USE mysql;
```

To show all the tables in a database, use the `SHOW TABLES` statement:

```
SHOW TABLES FROM mysql;
```

To create a database, use the `CREATE DATABASE` statement:

```
CREATE DATABASE db_name [options];
```

To create a database named `samp_db`, use the following statement:

```
CREATE DATABASE IF NOT EXISTS samp_db;
```

Add `IF NOT EXISTS` to prevent an error if the database exists.

To delete a database, use the `DROP DATABASE` statement:

```
DROP DATABASE samp_db;
```

3.3.3 Create, show, and drop a table

To create a table, use the `CREATE TABLE` statement:

```
CREATE TABLE table_name column_name data_type constraint;
```

For example, to create a table named `person` which includes fields such as number, name, and birthday, use the following statement:

```
CREATE TABLE person (  
  id INT(11),  
  name VARCHAR(255),  
  birthday DATE  
);
```

To view the statement that creates the table (DDL), use the `SHOW CREATE` statement:

```
SHOW CREATE table person;
```

To delete a table, use the `DROP TABLE` statement:

```
DROP TABLE person;
```

3.3.4 Create, show, and drop an index

Indexes are used to speed up queries on indexed columns. To create an index for the column whose value is not unique, use the `CREATE INDEX` statement:

```
CREATE INDEX person_id ON person (id);
```

Or use the ALTER TABLE statement:

```
ALTER TABLE person ADD INDEX person_id (id);
```

To create a unique index for the column whose value is unique, use the CREATE UNIQUE INDEX statement:

```
CREATE UNIQUE INDEX person_unique_id ON person (id);
```

Or use the ALTER TABLE statement:

```
ALTER TABLE person ADD UNIQUE person_unique_id (id);
```

To show all the indexes in a table, use the SHOW INDEX statement:

```
SHOW INDEX FROM person;
```

To delete an index, use the DROP INDEX or ALTER TABLE statement. DROP INDEX can be nested in ALTER TABLE:

```
DROP INDEX person_id ON person;
```

```
ALTER TABLE person DROP INDEX person_unique_id;
```

Note:

DDL operations are not transactions. You don't need to run a COMMIT statement when executing DDL operations.

3.3.5 Insert, update, and delete data

Common DML features are adding, modifying, and deleting table records. The corresponding commands are INSERT, UPDATE, and DELETE.

To insert data into a table, use the INSERT statement:

```
INSERT INTO person VALUES(1, 'tom', '20170912');
```

To insert a record containing data of some fields into a table, use the INSERT statement:

```
INSERT INTO person(id,name) VALUES('2', 'bob');
```

To update some fields of a record in a table, use the UPDATE statement:

```
UPDATE person SET birthday='20180808' WHERE id=2;
```

To delete the data in a table, use the `DELETE` statement:

```
DELETE FROM person WHERE id=2;
```

Note:

The `UPDATE` and `DELETE` statements without the `WHERE` clause as a filter operate on the entire table.

3.3.6 Query data

DQL is used to retrieve the desired data rows from a table or multiple tables.

To view the data in a table, use the `SELECT` statement:

```
SELECT * FROM person;
```

To query a specific column, add the column name after the `SELECT` keyword:

```
SELECT name FROM person;
```

```
+-----+  
| name |  
+-----+  
| tom  |  
+-----+  
1 rows in set (0.00 sec)
```

Use the `WHERE` clause to filter all records that match the conditions and then return the result:

```
SELECT * FROM person where id<5;
```

3.3.7 Create, authorize, and delete a user

DCL are usually used to create or delete users, and manage user privileges.

To create a user, use the `CREATE USER` statement. The following example creates a user named `tiuser` with the password `123456`:

```
CREATE USER 'tiuser'@'localhost' IDENTIFIED BY '123456';
```

To grant `tiuser` the privilege to retrieve the tables in the `samp_db` database:

```
GRANT SELECT ON samp_db.* TO 'tiuser'@'localhost';
```

To check the privileges of `tiuser`:

```
SHOW GRANTS for tiuser@localhost;
```

To delete `tiuser`:

```
DROP USER 'tiuser'@'localhost';
```

3.4 Explore HTAP

This guide describes how to explore and use the features of TiDB Hybrid Transactional and Analytical Processing (HTAP).

Note:

If you are new to TiDB HTAP and want to start using it quickly, see [Quick start with HTAP](#).

3.4.1 Use cases

TiDB HTAP can handle the massive data that increases rapidly, reduce the cost of DevOps, and be deployed in either self-hosted or cloud environments easily, which brings the value of data assets in real time.

The following are the typical use cases of HTAP:

- Hybrid workload

When using TiDB for real-time Online Analytical Processing (OLAP) in hybrid load scenarios, you only need to provide an entry point of TiDB to your data. TiDB automatically selects different processing engines based on the specific business.

- Real-time stream processing

When using TiDB in real-time stream processing scenarios, TiDB ensures that all the data flowed in constantly can be queried in real time. At the same time, TiDB also can handle highly concurrent data workloads and Business Intelligence (BI) queries.

- Data hub

When using TiDB as a data hub, TiDB can meet specific business needs by seamlessly connecting the data for the application and the data warehouse.

For more information about use cases of TiDB HTAP, see [blogs about HTAP on the PingCAP website](#).

3.4.2 Architecture

In TiDB, a row-based storage engine [TiKV](#) for Online Transactional Processing (OLTP) and a columnar storage engine [TiFlash](#) for Online Analytical Processing (OLAP) co-exist, replicate data automatically, and keep strong consistency.

For more information about the architecture, see [architecture of TiDB HTAP](#).

3.4.3 Environment preparation

Before exploring the features of TiDB HTAP, you need to deploy TiDB and the corresponding storage engines according to the data volume. If the data volume is large (for example, 100 T), it is recommended to use TiFlash Massively Parallel Processing (MPP) as the primary solution and TiSpark as the supplementary solution.

- [TiFlash](#)
 - If you have deployed a TiDB cluster with no TiFlash node, add the TiFlash nodes in the current TiDB cluster. For detailed information, see [Scale out a TiFlash cluster](#).
 - If you have not deployed a TiDB cluster, see [Deploy a TiDB Cluster using TiUP](#). Based on the minimal TiDB topology, you also need to deploy the [topology of TiFlash](#).
 - When deciding how to choose the number of TiFlash nodes, consider the following scenarios:
 - * If your use case requires OLTP with small-scale analytical processing and Ad-Hoc queries, deploy one or several TiFlash nodes. They can dramatically increase the speed of analytic queries.
 - * If the OLTP throughput does not cause significant pressure to I/O usage rate of the TiFlash nodes, each TiFlash node uses more resources for computation, and thus the TiFlash cluster can have near-linear scalability. The number of TiFlash nodes should be tuned based on expected performance and response time.
 - * If the OLTP throughput is relatively high (for example, the write or update throughput is higher than 10 million lines/hours), due to the limited write capacity of network and physical disks, the I/O between TiKV and TiFlash becomes a bottleneck and is also prone to read and write hotspots. In this case, the number of TiFlash nodes has a complex non-linear relationship with the computation volume of analytical processing, so you need to tune the number of TiFlash nodes based on the actual status of the system.
- [TiSpark](#)
 - If your data needs to be analyzed with Spark, deploy TiSpark. For specific process, see [TiSpark User Guide](#).

3.4.4 Data preparation

After TiFlash is deployed, TiKV does not replicate data to TiFlash automatically. You need to manually specify which tables need to be replicated to TiFlash. After that, TiDB creates the corresponding TiFlash replicas.

- If there is no data in the TiDB Cluster, migrate the data to TiDB first. For detailed information, see [data migration](#).
- If the TiDB cluster already has the replicated data from upstream, after TiFlash is deployed, data replication does not automatically begin. You need to manually specify the tables to be replicated to TiFlash. For detailed information, see [Use TiFlash](#).

3.4.5 Data processing

With TiDB, you can simply enter SQL statements for query or write requests. For the tables with TiFlash replicas, TiDB uses the front-end optimizer to automatically choose the optimal execution plan.

Note:

The MPP mode of TiFlash is enabled by default. When an SQL statement is executed, TiDB automatically determines whether to run in the MPP mode through the optimizer.

- To disable the MPP mode of TiFlash, set the value of the `tidb_allow_mpp` system variable to `OFF`.
- To forcibly enable MPP mode of TiFlash for query execution, set the values of `tidb_allow_mpp` and `tidb_enforce_mpp` to `ON`.
- To check whether TiDB chooses the MPP mode to execute a specific query, see [Explain Statements in the MPP Mode](#). If the output of `EXPLAIN` statement includes the `ExchangeSender` and `ExchangeReceiver` operators, the MPP mode is in use.

3.4.6 Performance monitoring

When using TiDB, you can monitor the TiDB cluster status and performance metrics in either of the following ways:

- [TiDB Dashboard](#): you can see the overall running status of the TiDB cluster, analyse distribution and trends of read and write traffic, and learn the detailed execution information of slow queries.

- [Monitoring system \(Prometheus & Grafana\)](#): you can see the monitoring parameters of TiDB cluster-related components including PD, TiDB, TiKV, TiFlash, TiCDC, and Node_exporter.

To see the alert rules of TiDB cluster and TiFlash cluster, see [TiDB cluster alert rules](#) and [TiFlash alert rules](#).

3.4.7 Troubleshooting

If any issue occurs during using TiDB, refer to the following documents:

- [Analyze slow queries](#)
- [Identify expensive queries](#)
- [Troubleshoot hotspot issues](#)
- [TiDB cluster troubleshooting guide](#)
- [Troubleshoot a TiFlash Cluster](#)

You are also welcome to create [Github Issues](#) or submit your questions on [AskTUG](#).

3.4.8 What's next

- To check the TiFlash version, critical logs, system tables, see [Maintain a TiFlash cluster](#).
- To remove a specific TiFlash node, see [Scale out a TiFlash cluster](#).

3.5 Import Example Database

Examples used in the TiDB manual use [System Data](#) from Capital Bikeshare, released under the [Capital Bikeshare Data License Agreement](#).

3.5.1 Download all data files

The system data is available [for download in .zip files](#) organized per year. Downloading and extracting all files requires approximately 3GB of disk space. To download all files for years 2010-2017 using a bash script:

```
mkdir -p bikeshare-data && cd bikeshare-data

curl -L --remote-name-all https://s3.amazonaws.com/capitalbikeshare-data
  ↪ /{2010..2017}-capitalbikeshare-tripdata.zip
unzip \*-tripdata.zip
```

3.5.2 Load data into TiDB

The system data can be imported into TiDB using the following schema:

```
CREATE DATABASE bikeshare;
USE bikeshare;

CREATE TABLE trips (
  trip_id bigint NOT NULL PRIMARY KEY AUTO_INCREMENT,
  duration integer not null,
  start_date datetime,
  end_date datetime,
  start_station_number integer,
  start_station varchar(255),
  end_station_number integer,
  end_station varchar(255),
  bike_number varchar(255),
  member_type varchar(255)
);
```

You can import files individually using the example LOAD DATA command here, or import all files using the bash loop below:

```
SET tidb_dml_batch_size = 20000;
LOAD DATA LOCAL INFILE '2017Q1-capitalbikeshare-tripdata.csv' INTO TABLE
  ↪ trips
  FIELDS TERMINATED BY ',' ENCLOSED BY '"'
  LINES TERMINATED BY '\r\n'
  IGNORE 1 LINES
(duration, start_date, end_date, start_station_number, start_station,
end_station_number, end_station, bike_number, member_type);
```

3.5.2.1 Import all files

Note:

When you start the MySQL client, use the `--local-infile=1` option.

To import all *.csv files into TiDB in a bash loop:

```
for FILE in *.csv; do
  echo "== $FILE =="
```

```
mysql bikeshare --local-infile=1 -e "SET tidb_dml_batch_size = 20000; LOAD
↳ DATA LOCAL INFILE '${FILE}' INTO TABLE trips FIELDS TERMINATED BY
↳ ',' ENCLOSED BY '\"' LINES TERMINATED BY '\r\n' IGNORE 1 LINES (
↳ duration, start_date, end_date, start_station_number, start_station,
↳ end_station_number, end_station, bike_number, member_type);"
done;
```

4 Deploy

4.1 Software and Hardware Recommendations

As an open source distributed NewSQL database with high performance, TiDB can be deployed in the Intel architecture server, ARM architecture server, and major virtualization environments and runs well. TiDB supports most of the major hardware networks and Linux operating systems.

4.1.1 Linux OS version requirements

Linux OS	Version
Red Hat Enterprise Linux	7.3 or later 7.x releases
CentOS	7.3 or later 7.x releases
Oracle Enterprise Linux	7.3 or later 7.x releases
Ubuntu LTS	16.04 or later

Note:

- For Oracle Enterprise Linux, TiDB supports the Red Hat Compatible Kernel (RHCK) and does not support the Unbreakable Enterprise Kernel provided by Oracle Enterprise Linux.
- A large number of TiDB tests have been run on the CentOS 7.3 system, and in our community there are a lot of best practices in which TiDB is deployed on the Linux operating system. Therefore, it is recommended to deploy TiDB on CentOS 7.3 or later.
- The support for the Linux operating systems above includes the deployment and operation in physical servers as well as in major virtualized environments like VMware, KVM and XEN.
- Red Hat Enterprise Linux 8.0, CentOS 8 Stream, and Oracle Enterprise Linux 8.0 are not supported yet as the testing of these platforms is in progress.

- Support for CentOS 8 Linux is not planned because its upstream support ends on December 31, 2021.
- Support for Ubuntu 16.04 will be removed in future versions of TiDB. Upgrading to Ubuntu 18.04 or later is strongly recommended.

Other Linux OS versions such as Debian Linux and Fedora Linux might work but are not officially supported.

4.1.2 Software recommendations

4.1.2.1 Control machine

Software	Version
sshpas	1.06 or later
TiUP	1.5.0 or later

Note:

It is required that you [deploy TiUP on the control machine](#) to operate and manage TiDB clusters.

4.1.2.2 Target machines

Software	Version
sshpas	1.06 or later
numa	2.0.12 or later
tar	any

4.1.3 Server recommendations

You can deploy and run TiDB on the 64-bit generic hardware server platform in the Intel x86-64 architecture or on the hardware server platform in the ARM architecture. The requirements and recommendations about server hardware configuration (ignoring the resources occupied by the operating system itself) for development, test, and production environments are as follows:

4.1.3.1 Development and test environments

Component	CPU	Memory	Local Storage	Network	Instance Number (Minimum Requirement)
TiDB	8 core+	16 GB+	No special requirements	Gigabit network card	1 (can be deployed on the same machine with PD)
PD	4 core+	8 GB+	SAS, 200 GB+	Gigabit network card	1 (can be deployed on the same machine with TiDB)
TiKV	8 core+	32 GB+	SAS, 200 GB+	Gigabit network card	3
TiFlash	32 core+	64 GB+	SSD, 200 GB+	Gigabit network card	1
TiCDC	8 core+	16 GB+	SAS, 200 GB+	Gigabit network card	1

Note:

- In the test environment, the TiDB and PD instances can be deployed on the same server.
- For performance-related test, do not use low-performance storage and network hardware configuration, in order to guarantee the correctness of the test result.
- For the TiKV server, it is recommended to use NVMe SSDs to ensure faster reads and writes.
- If you only want to test and verify the features, follow [Quick Start Guide for TiDB](#) to deploy TiDB on a single machine.
- The TiDB server uses the disk to store server logs, so there are no special requirements for the disk type and capacity in the test environment.

4.1.3.2 Production environment

Component	CPU	Memory	Hard Disk Type	Network	Instance Name
TiDB	16 core+	48 GB+	SAS	10 Gigabit network card (2 preferred)	
PD	8 core+	16 GB+	SSD	10 Gigabit network card (2 preferred)	
TiKV	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
TiFlash	48 core+	128 GB+	1 or more SSDs	10 Gigabit network card (2 preferred)	
TiCDC	16 core+	64 GB+	SSD	10 Gigabit network card (2 preferred)	
Monitor	8 core+	16 GB+	SAS	Gigabit network card	

Note:

- In the production environment, the TiDB and PD instances can be deployed on the same server. If you have a higher requirement for performance and reliability, try to deploy them separately.
- It is strongly recommended to use higher configuration in the production environment.
- It is recommended to keep the size of TiKV hard disk within 2 TB if you are using PCIe SSDs or within 1.5 TB if you are using regular SSDs.

Before you deploy TiFlash, note the following items:

- TiFlash can be **deployed on multiple disks**.
- It is recommended to use a high-performance SSD as the first disk of the TiFlash data directory to buffer the real-time replication of TiKV data. The performance of this disk should not be lower than that of TiKV, such as PCI-E SSD. The disk capacity should be no less than 10% of the total capacity; otherwise, it might become the bottleneck of this node. You can deploy ordinary SSDs for other disks, but note that a better PCI-E SSD brings better performance.
- It is recommended to deploy TiFlash on different nodes from TiKV. If you must deploy TiFlash and TiKV on the same node, increase the number of CPU cores and memory, and try to deploy TiFlash and TiKV on different disks to avoid interfering each other.
- The total capacity of the TiFlash disks is calculated in this way: **the data volume** \leftrightarrow **of the entire TiKV cluster to be replicated / the number of TiKV** \leftrightarrow **replicas * the number of TiFlash replicas**. For example, if the overall planned capacity of TiKV is 1 TB, the number of TiKV replicas is 3, and the number of TiFlash replicas is 2, then the recommended total capacity of TiFlash is $1024 \text{ GB} / 3 * 2$. You can replicate only the data of some tables. In such case, determine the TiFlash capacity according to the data volume of the tables to be replicated.

Before you deploy TiCDC, note that it is recommended to deploy TiCDC on PCIe-SSD disks larger than 1 TB.

4.1.4 Network requirements

As an open source distributed NewSQL database, TiDB requires the following network port configuration to run. Based on the TiDB deployment in actual environments, the administrator can open relevant ports in the network side and host side.

	Default	
Component	Port	Description
TiDB	4000	the communication port for the application and DBA tools
TiDB	10080	the communication port to report TiDB status
TiKV	20160	the TiKV communication port

	Default	
Component	Port	Description
TiKV	20180	the communication port to report TiKV status
PD	2379	the communication port between TiDB and PD
PD	2380	the inter-node communication port within the PD cluster

Component	Port	Description
TiFlash	9000	the TiFlash TCP service port
TiFlash	8123	the TiFlash HTTP service port
TiFlash	3930	the TiFlash RAFT and Co-processor service port
TiFlash	20170	the TiFlash Proxy service port

Component	Port	Description
TiFlash	20292	the port for Prometheus to pull TiFlash Proxy metrics
TiFlash	8234	the port for Prometheus to pull TiFlash metrics
Pump	8250	the Pump communication port
Drainer	8249	the Drainer communication port
TiCDC	8300	the TiCDC communication port

	Default	
Component	Port	Description
Prometheus	9090	the communication port for the Prometheus service
Node_exporter	9100	the communication port to report the system information of every TiDB cluster node

Component	Port	Description
Blackbox	9115	Black-box_exporter communication port, used to monitor the ports in the TiDB cluster
Grafana	3000	the port for the external Web monitoring service and client (Browser) access

	Default	
Component	Port	Description
Alertmanager	9093	the port for the alert web service
Alertmanager	9094	the alert communication port

4.1.5 Web browser requirements

TiDB relies on [Grafana](#) to provide visualization of database metrics. A recent version of Internet Explorer, Chrome or Firefox with Javascript enabled is sufficient.

4.2 TiDB Environment and System Configuration Check

This document describes the environment check operations before deploying TiDB. The following steps are ordered by priorities.

4.2.1 Mount the data disk ext4 filesystem with options on the target machines that deploy TiKV

For production deployments, it is recommended to use NVMe SSD of EXT4 filesystem to store TiKV data. This configuration is the best practice, whose reliability, security, and stability have been proven in a large number of online scenarios.

Log in to the target machines using the `root` user account.

Format your data disks to the ext4 filesystem and add the `nodelalloc` and `noatime` mount options to the filesystem. It is required to add the `nodelalloc` option, or else the TiUP deployment cannot pass the precheck. The `noatime` option is optional.

Note:

If your data disks have been formatted to ext4 and have added the mount options, you can uninstall it by running the `umount /dev/nvme0n1p1` command, skip directly to the fifth step below to edit the `/etc/fstab` file, and add the options again to the filesystem.

Take the `/dev/nvme0n1` data disk as an example:

1. View the data disk.

```
fdisk -l
```

```
Disk /dev/nvme0n1: 1000 GB
```

2. Create the partition.

```
parted -s -a optimal /dev/nvme0n1 mklabel gpt -- mkpart primary ext4 1  
↪ -1
```

Note:

Use the `lsblk` command to view the device number of the partition: for a NVMe disk, the generated device number is usually `nvme0n1p1`; for a regular disk (for example, `/dev/sdb`), the generated device number is usually `sdb1`.

3. Format the data disk to the ext4 filesystem.

```
mkfs.ext4 /dev/nvme0n1p1
```

4. View the partition UUID of the data disk.

In this example, the UUID of `nvme0n1p1` is `c51eb23b-195c-4061-92a9-3`
↪ `fad812cc12f`.

```
lsblk -f
```

NAME	FSTYPE	LABEL	UUID	MOUNTPOINT
sda				
- sda1	ext4		237b634b-a565-477b-8371-6dff0c41f5ab	/boot
- sda2	swap		f414c5c0-f823-4bb1-8fdf-e531173a72ed	
- sda3	ext4		547909c1-398d-4696-94c6-03e43e317b60	/

```
sr0
nvme0n1
-nvme0n1p1 ext4          c51eb23b-195c-4061-92a9-3fad812cc12f
```

5. Edit the `/etc/fstab` file and add the `nodelalloc` mount options.

```
vi /etc/fstab
```

```
UUID=c51eb23b-195c-4061-92a9-3fad812cc12f /data1 ext4 defaults,
↪ nodelalloc,noatime 0 2
```

6. Mount the data disk.

```
mkdir /data1 && \
mount -a
```

7. Check using the following command.

```
mount -t ext4
```

```
/dev/nvme0n1p1 on /data1 type ext4 (rw,noatime,nodelalloc,data=ordered)
```

If the filesystem is `ext4` and `nodelalloc` is included in the mount options, you have successfully mount the data disk `ext4` filesystem with options on the target machines.

4.2.2 Check and disable system swap

TiDB needs sufficient memory space for operation. When memory is insufficient, using swap as a buffer might degrade performance. Therefore, it is recommended to disable the system swap permanently by executing the following commands:

```
echo "vm.swappiness = 0">> /etc/sysctl.conf
swapoff -a && swapon -a
sysctl -p
```

Note:

- Executing `swapoff -a` and then `swapon -a` is to refresh swap by dumping data to memory and cleaning up swap. If you drop the `swappiness` change and execute only `swapoff -a`, swap will be enabled again after you restart the system.
- `sysctl -p` is to make the configuration effective without restarting the system.

4.2.3 Check and stop the firewall service of target machines

In TiDB clusters, the access ports between nodes must be open to ensure the transmission of information such as read and write requests and data heartbeats. In common online scenarios, the data interaction between the database and the application service and between the database nodes are all made within a secure network. Therefore, if there are no special security requirements, it is recommended to stop the firewall of the target machine. Otherwise, refer to [the port usage](#) and add the needed port information to the allowlist of the firewall service.

The rest of this section describes how to stop the firewall service of a target machine.

1. Check the firewall status. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo firewall-cmd --state
sudo systemctl status firewalld.service
```

2. Stop the firewall service.

```
sudo systemctl stop firewalld.service
```

3. Disable automatic start of the firewall service.

```
sudo systemctl disable firewalld.service
```

4. Check the firewall status.

```
sudo systemctl status firewalld.service
```

4.2.4 Check and install the NTP service

TiDB is a distributed database system that requires clock synchronization between nodes to guarantee linear consistency of transactions in the ACID model.

At present, the common solution to clock synchronization is to use the Network Time Protocol (NTP) services. You can use the pool.ntp.org timing service on the Internet, or build your own NTP service in an offline environment.

To check whether the NTP service is installed and whether it synchronizes with the NTP server normally, take the following steps:

1. Run the following command. If it returns **running**, then the NTP service is running.

```
sudo systemctl status ntpd.service
```

```
ntp.service - Network Time Service
Loaded: loaded (/usr/lib/systemd/system/ntp.service; disabled; vendor
       ↪ preset: disabled)
Active: active (running) since — 2017-12-18 13:13:19 CST; 3s ago
```

- If it returns `Unit ntp.service could not be found.`, then try the following command to see whether your system is configured to use `chronyd` instead of `ntpd` to perform clock synchronization with NTP:

```
sudo systemctl status chronyd.service
```

```
chronyd.service - NTP client/server
Loaded: loaded (/usr/lib/systemd/system/chronyd.service; enabled;
       ↪ vendor preset: enabled)
Active: active (running) since Mon 2021-04-05 09:55:29 EDT; 3 days
       ↪ ago
```

If the result shows that neither `chronyd` nor `ntpd` is configured, it means that neither of them is installed in your system. You should first install `chronyd` or `ntpd` and ensure that it can be automatically started. By default, `ntpd` is used.

If your system is configured to use `chronyd`, proceed to step 3.

2. Run the `ntpstat` command to check whether the NTP service synchronizes with the NTP server.

Note:

For the Ubuntu system, you need to install the `ntpstat` package.

```
ntpstat
```

- If it returns `synchronised to NTP server` (synchronizing with the NTP server), then the synchronization process is normal.

```
synchronised to NTP server (85.199.214.101) at stratum 2
time correct to within 91 ms
polling server every 1024 s
```

- The following situation indicates the NTP service is not synchronizing normally:

```
unsynchronised
```

- The following situation indicates the NTP service is not running normally:

```
Unable to talk to NTP daemon. Is it running?
```

3. Run the `chronyc tracking` command to check whether the Chrony service synchronizes with the NTP server.

Note:

This only applies to systems that use Chrony instead of NTPd.

```
chronyc tracking
```

- If the command returns `Leap status : Normal`, the synchronization process is normal.

```
Reference ID : 5EC69F0A (ntp1.time.nl)
Stratum      : 2
Ref time (UTC) : Thu May 20 15:19:08 2021
System time   : 0.000022151 seconds slow of NTP time
Last offset   : -0.000041040 seconds
RMS offset    : 0.000053422 seconds
Frequency     : 2.286 ppm slow
Residual freq : -0.000 ppm
Skew          : 0.012 ppm
Root delay    : 0.012706812 seconds
Root dispersion : 0.000430042 seconds
Update interval : 1029.8 seconds
Leap status   : Normal
```

- If the command returns the following result, an error occurs in the synchronization:

```
Leap status : Not synchronised
```

- If the command returns the following result, the `chronyd` service is not running normally:

```
506 Cannot talk to daemon
```

To make the NTP service start synchronizing as soon as possible, run the following command. Replace `pool.ntp.org` with your NTP server.

```
sudo systemctl stop ntpd.service && \
sudo ntpdate pool.ntp.org && \
sudo systemctl start ntpd.service
```

To install the NTP service manually on the CentOS 7 system, run the following command:

```
sudo yum install ntp ntpdate && \  
sudo systemctl start ntpd.service && \  
sudo systemctl enable ntpd.service
```

4.2.5 Check and configure the optimal parameters of the operating system

For TiDB in the production environment, it is recommended to optimize the operating system configuration in the following ways:

1. Disable THP (Transparent Huge Pages). The memory access pattern of databases tends to be sparse rather than consecutive. If the high-level memory fragmentation is serious, higher latency will occur when THP pages are allocated.
2. Set the I/O Scheduler of the storage media to **noop**. For the high-speed SSD storage media, the kernel's I/O scheduling operations can cause performance loss. After the Scheduler is set to **noop**, the performance is better because the kernel directly sends I/O requests to the hardware without other operations. Also, the **noop** Scheduler is better applicable.
3. Choose the **performance** mode for the **cpufreq** module which controls the CPU frequency. The performance is maximized when the CPU frequency is fixed at its highest supported operating frequency without dynamic adjustment.

Take the following steps to check the current operating system configuration and configure optimal parameters:

1. Execute the following command to see whether THP is enabled or disabled:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
[always] madvise never
```

Note:

If `[always] madvise never` is output, THP is enabled. You need to disable it.

2. Execute the following command to see the I/O Scheduler of the disk where the data directory is located. Assume that you create data directories on both `sdb` and `sd` disks:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
noop [deadline] cfq
noop [deadline] cfq
```

Note:

If `noop [deadline] cfq` is output, the I/O Scheduler for the disk is in the `deadline` mode. You need to change it to `noop`.

- Execute the following command to see the `ID_SERIAL` of the disk:

```
udevadm info --name=/dev/sdb | grep ID_SERIAL
```

```
E: ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81
E: ID_SERIAL_SHORT=6d0946606d79f90025f3e09a0c1f9e81
```

Note:

If multiple disks are allocated with data directories, you need to execute the above command several times to record the `ID_SERIAL` of each disk.

- Execute the following command to see the power policy of the `cpufreq` module:

```
cpupower frequency-info --policy
```

```
analyzing CPU 0:
current policy: frequency should be within 1.20 GHz and 3.10 GHz.
                The governor "powersave" may decide which speed to use
                ↪ within this range.
```

Note:

If The governor `"powersave"` is output, the power policy of the `cpufreq` module is `powersave`. You need to modify it to `performance`. If you use a virtual machine or a cloud host, the output is usually `Unable to ↪ determine current policy`, and you do not need to change anything.

- Configure optimal parameters of the operating system:

- Method one: Use `tuned` (Recommended)

1. Execute the `tuned-adm list` command to see the tuned profile of the current operating system:

```
tuned-adm list
```

```
Available profiles:
```

```
- balanced                - General non-specialized tuned
  ↳ profile
- desktop                 - Optimize for the desktop use-case
- hpc-compute             - Optimize for HPC compute workloads
- latency-performance    - Optimize for deterministic
  ↳ performance at the cost of increased power consumption
- network-latency        - Optimize for deterministic
  ↳ performance at the cost of increased power consumption,
  ↳ focused on low latency network performance
- network-throughput     - Optimize for streaming network
  ↳ throughput, generally only necessary on older CPUs or 40G
  ↳ + networks
- powersave              - Optimize for low power consumption
- throughput-performance - Broadly applicable tuning that
  ↳ provides excellent performance across a variety of common
  ↳ server workloads
- virtual-guest           - Optimize for running inside a
  ↳ virtual guest
- virtual-host            - Optimize for running KVM guests
Current active profile: balanced
```

The output `Current active profile: balanced` means that the tuned profile of the current operating system is `balanced`. It is recommended to optimize the configuration of the operating system based on the current profile.

2. Create a new tuned profile:

```
mkdir /etc/tuned/balanced-tidb-optimal/
vi /etc/tuned/balanced-tidb-optimal/tuned.conf
```

```
[main]
include=balanced

[cpu]
governor=performance

[vm]
transparent_hugepages=never

[disk]
devices_udev_regex=(ID_SERIAL=36d0946606d79f90025f3e09a0c1fc035
  ↳ )|(ID_SERIAL=36d0946606d79f90025f3e09a0c1f9e81)
```

```
elevator=noop
```

The output `include=balanced` means to add the optimization configuration of the operating system to the current `balanced` profile.

3. Apply the new tuned profile:

```
tuned-adm profile balanced-tidb-optimal
```

- Method two: Configure using scripts. Skip this method if you already use method one.

1. Execute the `grubby` command to see the default kernel version:

Note:

Install the `grubby` package first before you execute `grubby`.

```
grubby --default-kernel
```

```
/boot/vmlinuz-3.10.0-957.el7.x86_64
```

2. Execute `grubby --update-kernel` to modify the kernel configuration:

```
grubby --args="transparent_hugepage=never" --update-kernel /  
↳ boot/vmlinuz-3.10.0-957.el7.x86_64
```

Note:

`--update-kernel` is followed by the actual default kernel version.

3. Execute `grubby --info` to see the modified default kernel configuration:

```
grubby --info /boot/vmlinuz-3.10.0-957.el7.x86_64
```

Note:

`--info` is followed by the actual default kernel version.

```
index=0  
kernel=/boot/vmlinuz-3.10.0-957.el7.x86_64  
args="ro crashkernel=auto rd.lvm.lv=centos/root rd.lvm.lv=  
↳ centos/swap rhgb quiet LANG=en_US.UTF-8  
↳ transparent_hugepage=never"  
root=/dev/mapper/centos-root  
initrd=/boot/initramfs-3.10.0-957.el7.x86_64.img  
title=CentOS Linux (3.10.0-957.el7.x86_64) 7 (Core)
```

4. Modify the current kernel configuration to immediately disable THP:

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

5. Configure the I/O Scheduler in the udev script:

```
vi /etc/udev/rules.d/60-tidb-schedulers.rules
```

```
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
↳ d0946606d79f90025f3e09a0c1fc035", ATTR{queue/scheduler}="
↳ noop"
ACTION=="add|change", SUBSYSTEM=="block", ENV{ID_SERIAL}=="36
↳ d0946606d79f90025f3e09a0c1f9e81", ATTR{queue/scheduler}="
↳ noop"
```

6. Apply the udev script:

```
udevadm control --reload-rules
udevadm trigger --type=devices --action=change
```

7. Create a service to configure the CPU power policy:

```
cat >> /etc/systemd/system/cpupower.service << EOF
[Unit]
Description=CPU performance
[Service]
Type=oneshot
ExecStart=/usr/bin/cpupower frequency-set --governor
↳ performance
[Install]
WantedBy=multi-user.target
EOF
```

8. Apply the CPU power policy configuration service:

```
systemctl daemon-reload
systemctl enable cpupower.service
systemctl start cpupower.service
```

6. Execute the following command to verify the THP status:

```
cat /sys/kernel/mm/transparent_hugepage/enabled
```

```
always madvise [never]
```

7. Execute the following command to verify the I/O Scheduler of the disk where the data directory is located:

```
cat /sys/block/sd[bc]/queue/scheduler
```

```
[noop] deadline cfq
[noop] deadline cfq
```

8. Execute the following command to see the power policy of the cpufreq module:

```
cpupower frequency-info --policy
^^^
```

analyzing CPU 0: current policy: frequency should be within 1.20 GHz and 3.10 GHz. The governor “performance” may decide which speed to use within this range. “

9. Execute the following commands to modify the sysctl parameters:

```
echo "fs.file-max = 1000000">> /etc/sysctl.conf
echo "net.core.somaxconn = 32768">> /etc/sysctl.conf
echo "net.ipv4.tcp_tw_recycle = 0">> /etc/sysctl.conf
echo "net.ipv4.tcp_syncookies = 0">> /etc/sysctl.conf
echo "vm.overcommit_memory = 1">> /etc/sysctl.conf
echo "vm.min_free_kbytes = 1048576">> /etc/sysctl.conf
sysctl -p
```

Note:

- `vm.min_free_kbytes` is a Linux kernel parameter that controls the minimum amount of free memory reserved by the system, measured in KiB.
- The setting of `vm.min_free_kbytes` affects the memory reclaim mechanism. Setting it too large reduces the available memory, while setting it too small might cause memory request speeds to exceed background reclaim speeds, leading to memory reclamation and consequent delays in memory allocation.
- It is recommended to set `vm.min_free_kbytes` to 1048576 KiB (1 GiB) at least. If **NUMA is installed**, it is recommended to set it to `number of NUMA nodes * 1048576 KiB`.
- For servers with memory sizes less than 16 GiB, it is recommended to keep the default value of `vm.min_free_kbytes` unchanged.

10. Execute the following command to configure the user’s `limits.conf` file:

```
cat << EOF >>/etc/security/limits.conf
tidb      soft   nofile   1000000
tidb      hard   nofile   1000000
```

```
tidb      soft  stack  32768
tidb      hard  stack  32768
EOF
```

4.2.6 Manually configure the SSH mutual trust and sudo without password

This section describes how to manually configure the SSH mutual trust and sudo without password. It is recommended to use TiUP for deployment, which automatically configure SSH mutual trust and login without password. If you deploy TiDB clusters using TiUP, ignore this section.

1. Log in to the target machine respectively using the `root` user account, create the `tidb` user and set the login password.

```
useradd tidb && \  
passwd tidb
```

2. To configure sudo without password, run the following command, and add `tidb ALL ↪ =(ALL)NOPASSWD: ALL` to the end of the file:

```
visudo
```

```
tidb ALL=(ALL) NOPASSWD: ALL
```

3. Use the `tidb` user to log in to the control machine, and run the following command. Replace `10.0.1.1` with the IP of your target machine, and enter the `tidb` user password of the target machine as prompted. After the command is executed, SSH mutual trust is already created. This applies to other machines as well. Newly created `tidb` users do not have the `.ssh` directory. To create such a directory, execute the command that generates the RSA key. To deploy TiDB components on the control machine, configure mutual trust for the control machine and the control machine itself.

```
ssh-keygen -t rsa  
ssh-copy-id -i ~/.ssh/id_rsa.pub 10.0.1.1
```

4. Log in to the control machine using the `tidb` user account, and log in to the IP of the target machine using `ssh`. If you do not need to enter the password and can successfully log in, then the SSH mutual trust is successfully configured.

```
ssh 10.0.1.1
```

```
[tidb@10.0.1.1 ~]$
```

5. After you log in to the target machine using the `tidb` user, run the following command. If you do not need to enter the password and can switch to the `root` user, then `sudo` without password of the `tidb` user is successfully configured.

```
sudo -su root
```

```
[root@10.0.1.1 tidb]#
```

4.2.7 Install the `numactl` tool

This section describes how to install the NUMA tool. In online environments, because the hardware configuration is usually higher than required, to better plan the hardware resources, multiple instances of TiDB or TiKV can be deployed on a single machine. In such scenarios, you can use NUMA tools to prevent the competition for CPU resources which might cause reduced performance.

Note:

- Binding cores using NUMA is a method to isolate CPU resources and is suitable for deploying multiple instances on highly configured physical machines.
- After completing deployment using `tiup cluster deploy`, you can use the `exec` command to perform cluster level management operations.

To install the NUMA tool, take either of the following two methods:

Method 1: Log in to the target node to install NUMA. Take CentOS Linux release 7.7.1908 (Core) as an example.

```
sudo yum -y install numactl
```

Method 2: Install NUMA on an existing cluster in batches by running the `tiup ↪ cluster exec` command.

1. Follow [Deploy a TiDB Cluster Using TiUP](#) to deploy a cluster `tidb-test`. If you have installed a TiDB cluster, you can skip this step.

```
tiup cluster deploy tidb-test v5.4.3 ./topology.yaml --user root [-p]
  ↪ [-i /home/root/.ssh/gcp_rsa]
```

2. Run the `tiup cluster exec` command using the `sudo` privilege to install NUMA on all the target machines in the `tidb-test` cluster:

```
tiup cluster exec tidb-test --sudo --command "yum -y install numactl"
```

To get help information of the `tiup cluster exec` command, run the `tiup cluster ↪ exec --help` command.

4.3 Plan Cluster Topology

4.3.1 Minimal Deployment Topology

This document describes the minimal deployment topology of TiDB clusters.

4.3.1.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16VCores 32GB	10.0.1.1 10.0.1.2 10.0.1.3	Default port Global di- rec- tory con- fig- u- ra- tion
PD	3	4VCores 8GB	10.0.1.4 10.0.1.5 10.0.1.6	Default port Global di- rec- tory con- fig- u- ra- tion

Instance	Count	IP	Configuration
TiKV3	16	10.0.1.1	Default VCores 32GB 2TB (nvme ssd) * 1
Monitoring & Grafana	4	10.0.1.1	Default port Global di- rec- tory con- fig- u- ra- tion

4.3.1.1.1 Topology templates

- [The simple template for the minimal topology](#)
- [The complex template for the minimal topology](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.2 TiFlash Deployment Topology

This document describes the deployment topology of **TiFlash** based on the minimal TiDB topology.

TiFlash is a columnar storage engine, and gradually becomes the standard cluster topology. It is suitable for real-time HTAP applications.

4.3.2.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	3	16VCores	10.0.1.10	Default
		32GB	10.0.1.11	Global
	* 1			directory configuration

Instance	Count	Machine Configuration	IP	Configuration
PD	3	4 VCore 8GB * 1	10.0.1.10	Default port Global di- rec- tory con- fig- u- ra- tion
TiKV	3	16 VCore 32GB 2TB (nvme ssd) * 1	10.0.1.12	Default port Global di- rec- tory con- fig- u- ra- tion
TiFlash	1	32 VCore 64 GB 2TB (nvme ssd) * 1	10.0.1.14	Default port Global di- rec- tory con- fig- u- ra- tion

Instance	Count	IP	Configuration
Monitoring & Grafana	4	10.0.1.10	Default port Global distribution
			VCORE * 1 8GB 500GB (ssd)

4.3.2.1.1 Topology templates

- [The simple template for the TiFlash topology](#)
- [The complex template for the TiFlash topology](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

4.3.2.1.2 Key parameters

- To enable the [Placement Rules](#) feature of PD, set the value of `replication.enable-placement-rules` in the configuration template to `true`.
- The instance level `-host` configuration in `tiflash_servers` only supports IP, not domain name.
- For detailed TiFlash parameter description, see [TiFlash Configuration](#).

Note:

- You do not need to manually create the `tiddb` user in the configuration file. The TiUP cluster component automatically creates the `tiddb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.

- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.3 TiCDC Deployment Topology

Note:

TiCDC is a feature for general availability (GA) since v4.0.6. You can use it in the production environment.

This document describes the deployment topology of **TiCDC** based on the minimal cluster topology.

TiCDC is a tool for replicating the incremental data of TiDB, introduced in TiDB 4.0. It supports multiple downstream platforms, such as TiDB, MySQL, and MQ. Compared with TiDB Binlog, TiCDC has lower latency and native high availability.

4.3.3.1 Topology information

Instance	Count	IP	Configuration
TiDB	3	10.0.1.1	Default
VC	16	10.0.1.2	Core
	32GB	10.0.1.3	Global
	* 1		di-rec-tory con-fig-u-ra-tion

Instance	Count	Machine Configuration	IP	Configuration
PD	3	4 VCores 8GB * 1	10.0.1.10 10.0.1.15 10.0.1.16	Default port Global di- rec- tory con- fig- u- ra- tion
TiKV	3	16 VCores 32GB 2TB (nvme ssd) * 1	10.0.1.17 10.0.1.18 10.0.1.19	Default port Global di- rec- tory con- fig- u- ra- tion
CDC	3	8 VCores 16GB * 1	10.0.1.10 10.0.1.11 10.0.1.12	Default port Global di- rec- tory con- fig- u- ra- tion

Instance	Count	IP	Configuration
Physical ma- chine con- fig- u- ra-			
Monitoring & Grafana	4 VC 8GB * 1 500GB (ssd)	10.0.1.1	Default port Global di- rec- tory con- fig- u- ra- tion

4.3.3.1.1 Topology templates

- [The simple template for the TiCDC topology](#)
- [The complex template for the TiCDC topology](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.4 TiDB Binlog Deployment Topology

This document describes the deployment topology of [TiDB Binlog](#) based on the minimal TiDB topology.

TiDB Binlog is the widely used component for replicating incremental data. It provides near real-time backup and replication.

4.3.4.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB 3	16	16 VCore	10.0.1.2	Default port
	32	32 GB	10.0.1.3	Configuration; enable enable_binlog ↔ ; enable ignore ↔ - ↔ error ↔
PD 3	4	4 VCore	10.0.1.5	Default port
	8	8 GB	10.0.1.6	Configuration
TiKV 3	16	16 VCore	10.0.1.8	Default port
	32	32 GB	10.0.1.9	Configuration

Instance	Count	Machine	IP	Configuration
Pump3	8	Physical ma- chine con- fig- u- ra-	10.0.1.17	Default
		VCore	10.0.1.18	port
		16GB	10.0.1.18	on- fig- u- ra- tion; Set GC time to 7 days

Instance	Count	Physical machine con- fig- u- ra-	IP	Configuration
DrainDr	8	VCore 16GB	10.0.1.12	Default port con- fig- u- ra- tion; Set the de- fault ini- tial- iza- tion com- mitTS -1 as the lat- est times- tamp; Con- fig- ure the down- stream tar- get TiDB as 10.0.1.12:4000 ↔

4.3.4.1.1 Topology templates

- The simple template for the TiDB Binlog topology (with `mysql` as the downstream type)
- The simple template for the TiDB Binlog topology (with `file` as the downstream type)
- The complex template for the TiDB Binlog topology

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

4.3.4.1.2 Key parameters

The key parameters in the topology configuration templates are as follows:

- `server_configs.tidb.binlog.enable: true`
 - Enables the binlog service.
 - Default value: `false`.
- `server_configs.tidb.binlog.ignore-error: true`
 - It is recommended to enable this configuration in high availability scenarios.
 - If set to `true`, when an error occurs, TiDB stops writing data into binlog, and adds 1 to the value of the `tidb_server_critical_error_total` monitoring metric.
 - If set to `false`, when TiDB fails to write data into binlog, the whole TiDB service is stopped.
- `drainer_servers.config.syncer.db-type`

The downstream type of TiDB Binlog. Currently, `mysql`, `tidb`, `kafka`, and `file` are supported.
- `drainer_servers.config.syncer.to`

The downstream configuration of TiDB Binlog. Depending on different `db-types`, you can use this configuration item to configure the connection parameters of the downstream database, the connection parameters of Kafka, and the file save path. For details, refer to [TiDB Binlog Configuration File](#).

Note:

- When editing the configuration file template, if you do not need custom ports or directories, modify the IP only.

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.5 TiSpark Deployment Topology

Warning:

TiSpark support in the TiUP cluster is still an experimental feature. It is **NOT** recommended to use it in the production environment.

This document introduces the TiSpark deployment topology and how to deploy TiSpark based on the minimum cluster topology.

TiSpark is a component built for running Apache Spark on top of TiDB/TiKV to answer complex OLAP queries. It brings benefits of both the Spark platform and the distributed TiKV cluster to TiDB and makes TiDB a one-stop solution for both online transactions and analytics.

For more information about the TiSpark architecture and how to use it, see [TiSpark User Guide](#).

4.3.5.1 Topology information

Instance	Count	Machine Configuration	IP	Configuration
TiDB	3	16 VCores 32GB * 1	10.0.1.1 10.0.1.2 10.0.1.3	Default Port Global di- rec- tory con- fig- u- ra- tion
PD	3	4 VCores 8GB * 1	10.0.1.4 10.0.1.5 10.0.1.6	Default Port Global di- rec- tory con- fig- u- ra- tion
TiKV	3	16 VCores 32GB 2TB (nvme ssd) * 1	10.0.1.7 10.0.1.8 10.0.1.9	Default Port Global di- rec- tory con- fig- u- ra- tion

Instance	Count	IP	Configuration
Physical ma- chine con- fig- u- ra-			
TiSpark	8	10.0.1.21	Default VCores 16GB * 1
		10.0.1.22	(master) Global
		10.0.1.23	(worker) Global
		10.0.1.24	(worker) Global
		10.0.1.25	(worker) Global
		10.0.1.26	(worker) Global
Monitoring & Grafana	4	10.0.1.27	Default VCores 8GB * 1
		10.0.1.28	500GB (ssd)
		10.0.1.29	rec- tory
		10.0.1.30	con- fig- u- ra- tion

4.3.5.2 Topology templates

- [Simple TiSpark topology template](#)
- [Complex TiSpark topology template](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.5.3 Prerequisites

TiSpark is based on the Apache Spark cluster, so before you start the TiDB cluster that contains TiSpark, you must ensure that Java Runtime Environment (JRE) 8 is installed on the server that deploys TiSpark. Otherwise, TiSpark cannot be started.

TiUP does not support installing JRE automatically. You need to install it on your own. For detailed installation instruction, see [How to download and install prebuilt OpenJDK packages](#).

If JRE 8 has already been installed on the deployment server but is not in the path of the system's default package management tool, you can specify the path of the JRE environment to be used by setting the `java_home` parameter in the topology configuration. This parameter corresponds to the `JAVA_HOME` system environment variable.

4.3.6 Geo-Distributed Deployment Topology

This document takes the typical architecture of three data centers (DC) in two cities as an example, and introduces the geo-distributed deployment architecture and the key configuration. The cities used in this example are Shanghai (referred to as `sha`) and Beijing (referred to as `bj` and `bjb`).

4.3.6.1 Topology information

		Physical ma- chine con- fig- u- ra- BJ SH			Configuration
Instan	Count	IP	IP		
TiDB	5	16	10.0.1.10	10.0.1.11	Default
		VCore	10.0.1.2		port
		32GB	10.0.1.3		Global
		* 1	10.0.1.4		di- rec- tory con- fig- u- ra- tion
PD	5	4	10.0.1.10	10.0.1.11	Default
		VCore	10.0.1.7		port
		8GB	10.0.1.8		Global
		* 1	10.0.1.9		di- rec- tory con- fig- u- ra- tion
TiKV	5	16	10.0.1.10	10.0.1.11	Default
		VCore	10.0.1.12		port
		32GB	10.0.1.13		Global
		2TB	10.0.1.14		di- rec- tory (nvme ssd) * 1
					con- fig- u- ra- tion

Instance	Count	BJ IP	SH IP	Configuration
Monitoring & Grafana	4	10.0.1.16		Default port Global directory configuration

4.3.6.1.1 Topology templates

- [The geo-distributed topology template](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

4.3.6.1.2 Key parameters

This section describes the key parameter configuration of the TiDB geo-distributed deployment.

TiKV parameters

- The gRPC compression format (`none` by default):

To increase the transmission speed of gRPC packages between geo-distributed target nodes, set this parameter to `gzip`.

```
server.grpc-compression-type: gzip
```

- The label configuration:

Since TiKV is deployed across different data centers, if the physical machines go down, the Raft Group might lose three of the default five replicas, which causes the cluster

unavailability. To address this issue, you can configure the labels to enable the smart scheduling of PD, which ensures that the Raft Group does not allow three replicas to be located in TiKV instances on the same machine in the same cabinet of the same data center.

- The TiKV configuration:

The same host-level label information is configured for the same physical machine.

```
config:
  server.labels:
    zone: bj
    dc: bja
    rack: rack1
    host: host2
```

- To prevent remote TiKV nodes from launching unnecessary Raft elections, it is required to increase the minimum and maximum number of ticks that the remote TiKV nodes need to launch an election. The two parameters are set to 0 by default.

```
raftstore.raft-min-election-timeout-ticks: 1000
raftstore.raft-max-election-timeout-ticks: 1020
```

PD parameters

- The PD metadata information records the topology of the TiKV cluster. PD schedules the Raft Group replicas on the following four dimensions:

```
replication.location-labels: ["zone","dc","rack","host"]
```

- To ensure high availability of the cluster, adjust the number of Raft Group replicas to be 5:

```
replication.max-replicas: 5
```

- Forbid the remote TiKV Raft replica being elected as Leader:

```
label-property:
  reject-leader:
    - key: "dc"
      value: "sha"
```

Note:

Since TiDB 5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the [placement rules](#).

For the further information about labels and the number of Raft Group replicas, see [Schedule Replicas by Topology Labels](#).

Note:

- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.3.7 Hybrid Deployment Topology

This document describes the topology and key parameters of the TiKV and TiDB hybrid deployment.

The hybrid deployment is usually used in the following scenario:

The deployment machine has multiple CPU processors with sufficient memory. To improve the utilization rate of the physical machine resources, multiple instances can be deployed on a single machine, that is, TiDB and TiKV's CPU resources are isolated through NUMA node bindings. PD and Prometheus are deployed together, but their data directories need to use separate file systems.

4.3.7.1 Topology information

Instance	Count	Physical machine configuration	IP	Configuration
TiDB	6	32VCores 64GB	10.0.1.13	Configure NUMA bind CPU cores

Instance	Count	Unit	IP	Configuration

Instance	Count	Physical ma- chine con- fig- u- ra-	IP	Configuration
Monitoring & Grafana	4	VCORE 8GB * 1 500GB (ssd)	10.0.1.10	Default con- fig- u- ra- tion

4.3.7.1.1 Topology templates

- [The simple template for the hybrid deployment](#)
- [The complex template for the hybrid deployment](#)

For detailed descriptions of the configuration items in the above TiDB cluster topology file, see [Topology Configuration File for Deploying TiDB Using TiUP](#).

4.3.7.1.2 Key parameters

This section introduces the key parameters when you deploy multiple instances on a single machine, which is mainly used in scenarios when multiple instances of TiDB and TiKV are deployed on a single machine. You need to fill in the results into the configuration template according to the calculation methods provided below.

- Optimize the configuration of TiKV
 - To configure `readpool` to be self-adaptive to the thread pool. By configuring the `readpool.unified.max-thread-count` parameter, you can make `readpool.storage` and `readpool.coprocessor` share a unified thread pool, and set the self-adaptive switch respectively.

- * Enable `readpool.storage` and `readpool.coprocessor`:

```
readpool.storage.use-unified-pool: true
readpool.coprocessor.use-unified-pool: true
```

- * The calculation method:

```
readpool.unified.max-thread-count = cores * 0.8 / the number of
↳ TiKV instances
```

- To configure the storage CF (all RocksDB column families) to be self-adaptive to memory. By configuring the `storage.block-cache.capacity` parameter, you can make CF automatically balance the memory usage.

- * `storage.block-cache` enables the CF self-adaptation by default. You do not need to modify it.

```
storage.block-cache.shared: true
```

- * The calculation method:

```
storage.block-cache.capacity = (MEM_TOTAL * 0.5 / the number of
↳ TiKV instances)
```

- If multiple TiKV instances are deployed on the same physical disk, add the `capacity` parameter in the TiKV configuration:

```
raftstore.capacity = disk total capacity / the number of TiKV
↳ instances
```

- The label scheduling configuration

Since multiple instances of TiKV are deployed on a single machine, if the physical machines go down, the Raft Group might lose two of the default three replicas, which causes the cluster unavailability. To address this issue, you can use the label to enable the smart scheduling of PD, which ensures that the Raft Group has more than two replicas in multiple TiKV instances on the same machine.

- The TiKV configuration

The same host-level label information is configured for the same physical machine:

```
config:
  server.labels:
    host: tikv1
```

- The PD configuration

To enable PD to identify and scheduling Regions, configure the labels type for PD:

```
pd:
  replication.location-labels: ["host"]
```

- `numa_node` core binding

- In the instance parameter module, configure the corresponding `numa_node` parameter and add the number of CPU cores.
- Before using NUMA to bind cores, make sure that the `numactl` tool is installed, and confirm the information of CPUs in the physical machines. After that, configure the parameters.
- The `numa_node` parameter corresponds to the `numactl --mbind` configuration.

Note:

- When editing the configuration file template, modify the required parameter, IP, port, and directory.
- Each component uses the global `<deploy_dir>/<components_name>-<port>` as their `deploy_dir` by default. For example, if TiDB specifies the 4001 port, its `deploy_dir` is `/tidb-deploy/tidb-4001` by default. Therefore, in multi-instance scenarios, when specifying a non-default port, you do not need to specify the directory again.
- You do not need to manually create the `tidb` user in the configuration file. The TiUP cluster component automatically creates the `tidb` user on the target machines. You can customize the user, or keep the user consistent with the control machine.
- If you configure the deployment directory as a relative path, the cluster will be deployed in the home directory of the user.

4.4 Install and Start

4.4.1 Deploy a TiDB Cluster Using TiUP

[TiUP](#) is a cluster operation and maintenance tool introduced in TiDB 4.0. TiUP provides [TiUP cluster](#), a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

TiUP supports deploying TiDB, TiFlash, TiDB Binlog, TiCDC, and the monitoring system. This document introduces how to deploy TiDB clusters of different topologies.

Note:

TiDB, TiUP and TiDB Dashboard share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see [Telemetry](#).

4.4.1.1 Step 1. Prerequisites and precheck

Make sure that you have read the following documents:

- [Hardware and software requirements](#)
- [Environment and system configuration check](#)

4.4.1.2 Step 2. Deploy TiUP on the control machine

You can deploy TiUP on the control machine in either of the two ways: online deployment and offline deployment.

4.4.1.2.1 Deploy TiUP online

Log in to the control machine using a regular user account (take the `tidb` user as an example). Subsequent TiUP installation and cluster management can be performed by the `tidb` user.

1. Install TiUP by running the following command:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
  ↪ install.sh | sh
```

2. Set TiUP environment variables:

1. Redeclare the global environment variables:

```
source .bash_profile
```

2. Confirm whether TiUP is installed:

```
which tiup
```

3. Install the TiUP cluster component:

```
tiup cluster
```

4. If TiUP is already installed, update the TiUP cluster component to the latest version:

```
tiup update --self && tiup update cluster
```

If “Update successfully!” is displayed, the TiUP cluster is updated successfully.

5. Verify the current version of your TiUP cluster:

```
tiup --binary cluster
```

4.4.1.2.2 Deploy TiUP offline

Perform the following steps in this section to deploy a TiDB cluster offline using TiUP:

Prepare the TiUP offline component package

To prepare the TiUP offline component package, you can manually pack an offline component package using `tiup mirror clone`.

1. Install the TiUP package manager online.

1. Install the TiUP tool:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/install.sh | sh
```

2. Redeclare the global environment variables:

```
source .bash_profile
```

3. Confirm whether TiUP is installed:

```
which tiup
```

2. Pull the mirror using TiUP.

1. Pull the needed components on a machine that has access to the Internet:

```
tiup mirror clone tidb-community-server- $\{\text{version}\}$ -linux-amd64  $\{\text{version}\}$  --os=linux --arch=amd64
```

The command above creates a directory named `tidb-community-server- $\{\text{version}\}$ -linux-amd64` in the current directory, which contains the component package necessary for starting a cluster.

2. Pack the component package by using the `tar` command and send the package to the control machine in the isolated environment:

```
tar czvf tidb-community-server- $\{\text{version}\}$ -linux-amd64.tar.gz tidb-community-server- $\{\text{version}\}$ -linux-amd64
```

`tidb-community-server- $\{\text{version}\}$ -linux-amd64.tar.gz` is an independent offline environment package.

3. Customize the offline mirror, or adjust the contents of an existing offline mirror.

If you want to adjust an existing offline mirror (such as adding a new version of a component), take the following steps:

1. When pulling an offline mirror, you can get an incomplete offline mirror by specifying specific information via parameters, such as the component and version information. For example, you can pull an offline mirror that includes only the offline mirror of TiUP v1.9.0 and TiUP Cluster v1.9.0 by running the following command:

```
tiup mirror clone tiup-custom-mirror-v1.9.0 --tiup v1.9.0 --cluster  
↪ v1.9.0
```

If you only need the components for a particular platform, you can specify them using the `--os` or `--arch` parameters.

2. Refer to the step 2 of “Pull the mirror using TiUP”, and send this incomplete offline mirror to the control machine in the isolated environment.
3. Check the path of the current offline mirror on the control machine in the isolated environment. If your TiUP tool is of a recent version, you can get the current mirror address by running the following command:

```
tiup mirror show
```

If the output of the above command indicates that the `show` command does not exist, you might be using an older version of TiUP. In this case, you can get the current mirror address from `$HOME/.tiup/tiup.toml`. Record this mirror address. In the following steps, `{base_mirror}` is used to refer to this address.

4. Merge an incomplete offline mirror into an existing offline mirror:
First, copy the `keys` directory in the current offline mirror to the `$HOME/.tiup` directory:

```
cp -r {base_mirror}/keys $HOME/.tiup/
```

Then use the TiUP command to merge the incomplete offline mirror into the mirror in use:

```
tiup mirror merge tiup-custom-mirror-v1.9.0
```

5. When the above steps are completed, check the result by running the `tiup list` command. In this document’s example, the outputs of both `tiup list tiup` and `tiup list cluster` show that the corresponding components of v1.9.0 are available.

Deploy the offline TiUP component

After sending the package to the control machine of the target cluster, install the TiUP component by running the following commands:

```
tar xzvf tidb-community-server-{version}-linux-amd64.tar.gz && \  
sh tidb-community-server-{version}-linux-amd64/local_install.sh && \  
source /home/tidb/.bash_profile
```

The `local_install.sh` script automatically runs the `tiup mirror set tidb-community-server- $\{version\}$ -linux-amd64` command to set the current mirror address to `tidb-community-server- $\{version\}$ -linux-amd64`.

To switch the mirror to another directory, run the `tiup mirror set <mirror-dir>` command. To switch the mirror to the online environment, run the `tiup mirror set \leftrightarrow https://tiup-mirrors.pingcap.com` command.

4.4.1.3 Step 3. Initialize cluster topology file

Run the following command to create a cluster topology file:

```
tiup cluster template > topology.yaml
```

In the following two common scenarios, you can generate recommended topology templates by running commands:

- For hybrid deployment: Multiple instances are deployed on a single machine. For details, see [Hybrid Deployment Topology](#).

```
tiup cluster template --full > topology.yaml
```

- For geo-distributed deployment: TiDB clusters are deployed in geographically distributed data centers. For details, see [Geo-Distributed Deployment Topology](#).

```
tiup cluster template --multi-dc > topology.yaml
```

Run `vi topology.yaml` to see the configuration file content:

```
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/tidb-deploy"
  data_dir: "/tidb-data"
server_configs: {}
pd_servers:
  - host: 10.0.1.4
  - host: 10.0.1.5
  - host: 10.0.1.6
tidb_servers:
  - host: 10.0.1.7
  - host: 10.0.1.8
  - host: 10.0.1.9
tikv_servers:
  - host: 10.0.1.1
  - host: 10.0.1.2
```

```

- host: 10.0.1.3
monitoring_servers:
- host: 10.0.1.4
grafana_servers:
- host: 10.0.1.4
alertmanager_servers:
- host: 10.0.1.4

```

The following examples cover seven common scenarios. You need to modify the configuration file (named `topology.yaml`) according to the topology description and templates in the corresponding links. For other scenarios, edit the configuration template accordingly.

Application	Configuration template	Topology description
OLTP	Deploy Simple	This is the basic cluster topology, including tidb-server, tikv-server, and pd-server.

Configuration file description Application platform
 Deployment topology
 This document describes the architecture and configuration of the distributed deployment of TiDB clusters across data centers. It introduces the geo-distributed deployment architecture and the key configuration parameters.

Configuration
file description
Application template

Note:

- For parameters that should be globally effective, configure these parameters of corresponding components in the `server_configs` section of the configuration file.
- For parameters that should be effective on a specific node, configure these parameters in the `config` of this node.
- Use `.` to indicate the subcategory of the configuration, such as `log.slow` \hookrightarrow `-threshold`. For more formats, see [TiUP configuration template](#).
- If you need to specify the user group name to be created on the target machine, see [this example](#).

For more configuration description, see the following configuration examples:

- [TiDB config.toml.example](#)
- [TiKV config.toml.example](#)
- [PD config.toml.example](#)
- [TiFlash config.toml.example](#)

4.4.1.4 Step 4. Run the deployment command

Note:

You can use secret keys or interactive passwords for security authentication when you deploy TiDB using TiUP:

- If you use secret keys, specify the path of the keys through `-i` or `--` \hookrightarrow `identity_file`.
- If you use passwords, add the `-p` flag to enter the password interaction window.
- If password-free login to the target machine has been configured, no authentication is required.

In general, TiUP creates the user and group specified in the `topology.yaml` file on the target machine, with the following exceptions:

- The user name configured in `topology.yaml` already exists on the target machine.
- You have used the `--skip-create-user` option in the command line to explicitly skip the step of creating the user.

Before you run the `deploy` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

1. Check for potential risks:

```
tiup cluster check ./topology.yaml --user root [-p] [-i /home/root/.ssh  
↪ /gcp_rsa]
```

2. Enable automatic repair:

```
tiup cluster check ./topology.yaml --apply --user root [-p] [-i /home/  
↪ root/.ssh/gcp_rsa]
```

3. Deploy a TiDB cluster:

```
tiup cluster deploy tidb-test v5.4.3 ./topology.yaml --user root [-p]  
↪ [-i /home/root/.ssh/gcp_rsa]
```

In the `tiup cluster deploy` command above:

- `tidb-test` is the name of the TiDB cluster to be deployed.
- `v5.4.3` is the version of the TiDB cluster to be deployed. You can see the latest supported versions by running `tiup list tidb`.
- `topology.yaml` is the initialization configuration file.
- `--user root` indicates logging into the target machine as the `root` user to complete the cluster deployment. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

At the end of the output log, you will see `Deployed cluster `tidb-test`
↪ successfully`. This indicates that the deployment is successful.

4.4.1.5 Step 5. Check the clusters managed by TiUP

```
tiup cluster list
```

TiUP supports managing multiple TiDB clusters. The preceding command outputs information of all the clusters currently managed by TiUP, including the cluster name, deployment user, version, and secret key information:

4.4.1.6 Step 6. Check the status of the deployed TiDB cluster

For example, run the following command to check the status of the `tidb-test` cluster:

```
tiup cluster display tidb-test
```

Expected output includes the instance ID, role, host, listening port, and status (because the cluster is not started yet, so the status is `Down/inactive`), and directory information.

4.4.1.7 Step 7. Start a TiDB cluster

Since TiUP cluster v1.9.0, safe start is introduced as a new start method. Starting a database using this method improves the security of the database. It is recommended that you use this method.

After safe start, TiUP automatically generates a password for the TiDB root user and returns the password in the command-line interface.

Note:

- After safe start of a TiDB cluster, you cannot log in to TiDB using a root user without a password. Therefore, you need to record the password returned in the command output for future logins.
- The password is generated only once. If you do not record it or you forgot it, refer to [Forget the root password](#) to change the password.

Method 1: Safe start

```
tiup cluster start tidb-test --init
```

If the output is as follows, the start is successful:

```
Started cluster `tidb-test` successfully.
The root password of TiDB database has been changed.
The new password is: 'y_+3Hwp=*AWz8971s6'.
Copy and record it to somewhere safe, it is only displayed once, and will
↪ not be stored.
```

The generated password can NOT be got again in future.

Method 2: Standard start

```
tiup cluster start tidb-test
```

If the output log includes `Started cluster `tidb-test` successfully`, the start is successful. After standard start, you can log in to a database using a root user without a password.

4.4.1.8 Step 8. Verify the running status of the TiDB cluster

```
tiup cluster display tidb-test
```

If the output log shows `Up` status, the cluster is running properly.

4.4.1.9 See also

If you have deployed [TiFlash](#) along with the TiDB cluster, see the following documents:

- [Use TiFlash](#)
- [Maintain a TiFlash Cluster](#)
- [TiFlash Alert Rules and Solutions](#)
- [Troubleshoot TiFlash](#)

If you have deployed [TiCDC](#) along with the TiDB cluster, see the following documents:

- [Manage TiCDC Cluster and Replication Tasks](#)
- [Troubleshoot TiCDC](#)

4.4.2 Deploy a TiDB Cluster in Kubernetes

You can use [TiDB Operator](#) to deploy TiDB clusters in Kubernetes. TiDB Operator is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB in Kubernetes documentation is independent of the TiDB documentation. For detailed steps on how to deploy TiDB clusters in Kubernetes using TiDB Operator, see [TiDB in Kubernetes documentation](#).

4.5 Check Cluster Status

After a TiDB cluster is deployed, you need to check whether the cluster runs normally. This document introduces how to check the cluster status using TiUP commands, [TiDB Dashboard](#) and Grafana, and how to log into the TiDB database to perform simple SQL operations.

4.5.1 Check the TiDB cluster status

This section describes how to check the TiDB cluster status using TiUP commands, [TiDB Dashboard](#), and Grafana.

4.5.1.1 Use TiUP

Use the `tiup cluster display <cluster-name>` command to check the cluster status. For example:

```
tiup cluster display tidb-test
```

Expected output: If the **Status** information of each node is **Up**, the cluster runs normally.

4.5.1.2 Use TiDB Dashboard

1. Log in to TiDB Dashboard at `${pd-ip}:${pd-port}/dashboard`. The username and password is the same as that of the TiDB `root` user. If you have modified the `root` password, enter the modified password. The password is empty by default.

Figure 7: TiDB-Dashboard

2. The home page displays the node information in the TiDB cluster.

Figure 8: TiDB-Dashboard-status

4.5.1.3 Use Grafana

1. Log in to the Grafana monitoring at `10.0.1.4:3000`. The default username and password are both `admin`.
2. To check the TiDB port status and load monitoring information, click **Overview**.

Figure 9: Grafana-overview

4.5.2 Log in to the database and perform simple operations

Note:

Install the MySQL client before you log in to the database.

Log in to the database by running the following command:

```
mysql -u root -h ${tidb_server_host_IP_address} -P 4000
```

`${tidb_server_host_IP_address}` is one of the IP addresses set for `tidb_servers` when you [initialize the cluster topology file](#), such as 10.0.1.7.

The following information indicates successful login:

```
Welcome to the MySQL monitor. Commands end with ; or \g.
Your MySQL connection id is 3
Server version: 5.7.25-TiDB-v5.0.0 TiDB Server (Apache License 2.0)
  ↪ Community Edition, MySQL 5.7 compatible

Type 'help;' or '\h' for help. Type '\c' to clear the current input
  ↪ statement.
```

4.5.2.1 Database operations

- Check the version of TiDB:

```
select tidb_version()\G
```

Expected output:

```
***** 1. row *****
tidb_version(): Release Version: v5.0.0
Edition: Community
Git Commit Hash: 689a6b6439ae7835947fcacccf329a3fc303986cb
Git Branch: HEAD
UTC Build Time: 2020-05-28 11:09:45
GoVersion: go1.13.4
```

```
Race Enabled: false
TiKV Min Version: v3.0.0-60965b006877ca7234adaced7890d7b029ed1306
Check Table Before Drop: false
1 row in set (0.00 sec)
```

- Create a database named pingcap:

```
create database pingcap;
```

Expected output:

```
Query OK, 0 rows affected (0.10 sec)
```

Switch to the pingcap database:

```
use pingcap;
```

Expected output:

```
Database changed
```

- Create a table named tab_tidb:

```
CREATE TABLE `tab_tidb` (
  `id` int(11) NOT NULL AUTO_INCREMENT,
  `name` varchar(20) NOT NULL DEFAULT '',
  `age` int(11) NOT NULL DEFAULT 0,
  `version` varchar(20) NOT NULL DEFAULT '',
  PRIMARY KEY (`id`),
  KEY `idx_age` (`age`));
```

Expected output:

```
Query OK, 0 rows affected (0.11 sec)
```

- Insert data:

```
insert into `tab_tidb` values (1,'TiDB',5,'TiDB-v5.0.0');
```

Expected output:

```
Query OK, 1 row affected (0.03 sec)
```

- View the entries in tab_tidb:

```
select * from tab_tidb;
```

Expected output:

```

+-----+-----+-----+-----+
| id | name | age | version |
+-----+-----+-----+-----+
|  1 | TiDB |  5 | TiDB-v5.0.0 |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

- View the store state, `store_id`, capacity, and uptime of TiKV:

```

select STORE_ID,ADDRESS,STORE_STATE,STORE_STATE_NAME,CAPACITY,AVAILABLE
       ↪ ,UPTIME from INFORMATION_SCHEMA.TIKV_STORE_STATUS;

```

Expected output:

```

+---
↪ -----+-----+-----+-----+-----+
↪
| STORE_ID | ADDRESS          | STORE_STATE | STORE_STATE_NAME | CAPACITY

```

4.6 Test Cluster Performance

4.6.1 How to Test TiDB Using Sysbench

It is recommended to use Sysbench 1.0 or later, which can be [downloaded here](#).

4.6.1.1 Test plan

4.6.1.1.1 TiDB configuration

Higher log level means fewer logs to be printed and thus positively influences TiDB performance. Enable `prepared plan cache` in the TiDB configuration to lower the cost of optimizing execution plan. Specifically, you can add the following command in the TiUP configuration file:

```
server_configs:
  tidb:
    log.level: "error"
    prepared-plan-cache.enabled: true
```

4.6.1.1.2 TiKV configuration

Higher log level also means better performance for TiKV.

There are multiple Column Families on TiKV cluster which are mainly used to store different types of data, including Default CF, Write CF, and Lock CF. For the Sysbench test, you only need to focus on Default CF and Write CF. The Column Family that is used to import data has a constant proportion among TiDB clusters:

Default CF : Write CF = 4 : 1

Configuring the block cache of RocksDB on TiKV should be based on the machine's memory size, in order to make full use of the memory. To deploy a TiKV cluster on a 40GB virtual machine, it is recommended to configure the block cache as follows:

```
server_configs:
  tikv:
    log-level: "error"
    rocksdb.defaultcf.block-cache-size: "24GB"
    rocksdb.writecf.block-cache-size: "6GB"
```

You can also configure TiKV to share block cache:

```
server_configs:
  tikv:
    storage.block-cache.capacity: "30GB"
```

For more detailed information on TiKV performance tuning, see [Tune TiKV Performance](#).

4.6.1.2 Test process

Note:

The test in this document was performed without load balancing tools such as HAProxy. We run the Sysbench test on individual TiDB node and added the results up. The load balancing tools and the parameters of different versions might also impact the performance.

4.6.1.2.1 Sysbench configuration

This is an example of the Sysbench configuration file:

```
mysql-host={TIDB_HOST}
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads={8, 16, 32, 64, 128, 256}
report-interval=10
db-driver=mysql
```

The above parameters can be adjusted according to actual needs. Among them, `TIDB_HOST` is the IP address of the TiDB server (because we cannot include multiple addresses in the configuration file), `threads` is the number of concurrent connections in the test, which can be adjusted in “8, 16, 32, 64, 128, 256”. When importing data, it is recommended to set `threads = 8` or `16`. After adjusting `threads`, save the file named **config**.

See the following as a sample **config** file:

```
mysql-host=172.16.30.33
mysql-port=4000
mysql-user=root
mysql-password=password
mysql-db=sbtest
time=600
threads=16
report-interval=10
db-driver=mysql
```

4.6.1.2.2 Data import

Note:

If you enable the optimistic transaction model (TiDB uses the pessimistic transaction mode by default), TiDB rolls back transactions when a concurrency conflict is found. Setting `tidb_disable_txn_auto_retry` to `off` turns on the automatic retry mechanism after meeting a transaction conflict, which can prevent Sysbench from quitting because of the transaction conflict error.

Before importing the data, it is necessary to make some settings to TiDB. Execute the following command in MySQL client:

```
set global tidb_disable_txn_auto_retry = off;
```

Then exit the client.

Restart MySQL client and execute the following SQL statement to create a database `sbtest`:

```
create database sbtest;
```

Adjust the order in which Sysbench scripts create indexes. Sysbench imports data in the order of “Build Table -> Insert Data -> Create Index”, which takes more time for TiDB to import data. Users can adjust the order to speed up the import of data. Suppose that you use the Sysbench version [1.0.14](#). You can adjust the order in either of the following two ways:

- Download the modified [oltp_common.lua](#) file for TiDB and overwrite the `/usr/share` \hookrightarrow `/sysbench/oltp_common.lua` file with it.
- In `/usr/share/sysbench/oltp_common.lua`, move the lines [235-240](#) to be right behind the line 198.

Note:

This operation is optional and is only to save the time consumed by data import.

At the command line, enter the following command to start importing data. The config file is the one configured in the previous step:

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size  
 $\hookrightarrow$  =10000000 prepare
```

4.6.1.2.3 Warming data and collecting statistics

To warm data, we load data from disk into the block cache of memory. The warmed data has significantly improved the overall performance of the system. It is recommended to warm data once after restarting the cluster.

Sysbench 1.0.14 does not provide data warming, so it must be done manually. If you are using a later version of Sysbench, you can use the data warming feature included in the tool itself.

Take a table `sbtest7` in Sysbench as an example. Execute the following SQL to warming up data:

```
SELECT COUNT(pad) FROM sbtest7 USE INDEX (k_7);
```

Collecting statistics helps the optimizer choose a more accurate execution plan. The `analyze` command can be used to collect statistics on the table `sbtest`. Each table needs statistics.

```
ANALYZE TABLE sbtest7;
```

4.6.1.2.4 Point select test command

```
sysbench --config-file=config oltp_point_select --tables=32 --table-size  
↳ =10000000 run
```

4.6.1.2.5 Update index test command

```
sysbench --config-file=config oltp_update_index --tables=32 --table-size  
↳ =10000000 run
```

4.6.1.2.6 Read-only test command

```
sysbench --config-file=config oltp_read_only --tables=32 --table-size  
↳ =10000000 run
```

4.6.1.3 Common issues

4.6.1.3.1 TiDB and TiKV are both properly configured under high concurrency, why is the overall performance still low?

This issue often has things to do with the use of a proxy. You can add pressure on single TiDB server, sum each result up and compare the summed result with the result with proxy.

Take HAproxy as an example. The parameter `nbproc` can increase the number of processes it can start at most. Later versions of HAproxy also support `nbthread` and `cpu-map`. All of these can mitigate the negative impact of proxy use on performance.

4.6.1.3.2 Under high concurrency, why is the CPU utilization rate of TiKV still low?

Although the overall CPU utilization rate is low for TiKV, the CPU utilization rate of some modules in the cluster might be high.

The maximum concurrency limits for other modules on TiKV, such as storage readpool, coprocessor, and gRPC, can be adjusted through the TiKV configuration file.

The actual CPU usage can be observed through Grafana's TiKV Thread CPU monitor panel. If there is a bottleneck on the modules, it can be adjusted by increasing the concurrency of the modules.

4.6.1.3.3 Given that TiKV has not yet reached the CPU usage bottleneck under high concurrency, why is TiDB's CPU utilization rate still low?

CPU of NUMA architecture is used on some high-end equipment where cross-CPU access to remote memory will greatly reduce performance. By default, TiDB will use all CPUs of the server, and goroutine scheduling will inevitably lead to cross-CPU memory access.

Therefore, it is recommended to deploy n TiDBs (n is the number of NUMA CPUs) on the server of NUMA architecture, and meanwhile set the TiDB parameter `max-procs` to a value that is the same as the number of NUMA CPU cores.

4.6.2 How to Run TPC-C Test on TiDB

This document describes how to test TiDB using [TPC-C](#).

TPC-C is an online transaction processing (OLTP) benchmark. It tests the OLTP system by using a commodity sales model that involves the following five transactions of different types:

- NewOrder
- Payment
- OrderStatus
- Delivery
- StockLevel

4.6.2.1 Prepare

Before testing, TPC-C Benchmark specifies the initial state of the database, which is the rule for data generation in the database. The `ITEM` table contains a fixed number of 100,000 items, while the number of warehouses can be adjusted. If there are W records in the `WAREHOUSE` table, then:

- The `STOCK` table has $W * 100,000$ records (Each warehouse corresponds to the stock data of 100,000 items)

- The `DISTRICT` table has $W * 10$ records (Each warehouse provides services to 10 districts)
- The `CUSTOMER` table has $W * 10 * 3,000$ records (Each district has 3,000 customers)
- The `HISTORY` table has $W * 10 * 3,000$ records (Each customer has one transaction history)
- The `ORDER` table has $W * 10 * 3,000$ records (Each district has 3,000 orders and the last 900 orders generated are added to the `NEW-ORDER` table. Each order randomly generates 5 ~ 15 `ORDER-LINE` records.

In this document, the testing uses 1,000 warehouses as an example to test TiDB.

TPC-C uses tpmC (transactions per minute) to measure the maximum qualified throughput (MQTh, Max Qualified Throughput). The transactions are the NewOrder transactions and the final unit of measure is the number of new orders processed per minute.

The test in this document is implemented based on [go-tpc](#). You can download the test program using [TiUP](#) commands.

```
tiup install bench
```

For detailed usage of the TiUP Bench component, see [TiUP Bench](#).

4.6.2.2 Load data

Loading data is usually the most time-consuming and problematic stage of the entire TPC-C test. This section provides the following command to load data.

Execute the following TiUP command in Shell:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 prepare
```

Based on different machine configurations, this loading process might take a few hours. If the cluster size is small, you can use a smaller `WAREHOUSE` value for the test.

After the data is loaded, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

4.6.2.3 Run the test

Execute the following command to run the test:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 1000 run
```

During the test, test results are continuously printed on the console:

```
[Current] NEW_ORDER - Takes(s): 4.6, Count: 5, TPM: 65.5, Sum(ms): 4604, Avg  
  ↪ (ms): 920, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms): 1500  
[Current] ORDER_STATUS - Takes(s): 1.4, Count: 1, TPM: 42.2, Sum(ms): 256,  
  ↪ Avg(ms): 256, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
```

```
[Current] PAYMENT - Takes(s): 6.9, Count: 5, TPM: 43.7, Sum(ms): 2208, Avg(
  ↪ ms): 441, 90th(ms): 512, 99th(ms): 512, 99.9th(ms): 512
[Current] STOCK_LEVEL - Takes(s): 4.4, Count: 1, TPM: 13.8, Sum(ms): 224,
  ↪ Avg(ms): 224, 90th(ms): 256, 99th(ms): 256, 99.9th(ms): 256
...
```

After the test is finished, the test summary results are printed:

```
[Summary] DELIVERY - Takes(s): 455.2, Count: 32, TPM: 4.2, Sum(ms): 44376,
  ↪ Avg(ms): 1386, 90th(ms): 2000, 99th(ms): 4000, 99.9th(ms): 4000
[Summary] DELIVERY_ERR - Takes(s): 455.2, Count: 1, TPM: 0.1, Sum(ms): 953,
  ↪ Avg(ms): 953, 90th(ms): 1000, 99th(ms): 1000, 99.9th(ms): 1000
[Summary] NEW_ORDER - Takes(s): 487.8, Count: 314, TPM: 38.6, Sum(ms):
  ↪ 282377, Avg(ms): 899, 90th(ms): 1500, 99th(ms): 1500, 99.9th(ms):
  ↪ 1500
[Summary] ORDER_STATUS - Takes(s): 484.6, Count: 29, TPM: 3.6, Sum(ms):
  ↪ 8423, Avg(ms): 290, 90th(ms): 512, 99th(ms): 1500, 99.9th(ms): 1500
[Summary] PAYMENT - Takes(s): 490.1, Count: 321, TPM: 39.3, Sum(ms): 144708,
  ↪ Avg(ms): 450, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1500
[Summary] STOCK_LEVEL - Takes(s): 487.6, Count: 41, TPM: 5.0, Sum(ms): 9318,
  ↪ Avg(ms): 227, 90th(ms): 512, 99th(ms): 1000, 99.9th(ms): 1000
```

After the test is finished, you can execute the `tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 check` command to validate the data correctness.

4.6.2.4 Clean up test data

Execute the following command to clean up the test data:

```
tiup bench tpcc -H 172.16.5.140 -P 4000 -D tpcc --warehouses 4 cleanup
```

5 Migrate

5.1 Data Migration Overview

This document gives an overview of the data migration solutions that you can use with TiDB. The data migration solutions are as follows:

- Full data migration.
 - To import Amazon Aurora snapshots, CSV files, or Mydumper SQL files into TiDB, you can use TiDB Lightning to perform the full migration.
 - To export all TiDB data as CSV files or Mydumper SQL files, you can use Dumpling to perform the full migration, which makes data migration from MySQL or MariaDB easier.

- To migrate all data from a database with a small data size volume (for example, less than 1 TiB), you can also use TiDB Data Migration (DM).
- Quick initialization of TiDB. TiDB Lightning supports quickly importing data and can quickly initialize a specific table in TiDB. Before you use this feature, pay attention that the quick initialization has a great impact on TiDB and the cluster does not provide services during the initialization period.
- Incremental replication. You can use TiDB DM to replicate binlogs from MySQL, MariaDB, or Aurora to TiDB, which greatly reduces the window downtime during the replication period.
- Data replication between TiDB clusters. TiDB supports backup and restore. This feature can initialize a snapshot in an existing TiDB cluster to a new TiDB cluster.

You might choose different migration solutions according to the database type, deployment location, application data size, and application needs. The following sections introduce some common migration scenarios, and you can refer to these sections to determine the most suitable solution according to your needs.

5.1.1 Migrate data from Aurora MySQL to TiDB

When you migrate data from Aurora to a TiDB cluster deployed on AWS, your data migration takes two operations: full data migration and incremental replication. You can choose the corresponding operation according to your application needs.

- [Migrate Data from Amazon Aurora to TiDB](#).

5.1.2 Migrate data from MySQL to TiDB

If cloud storage (S3) service is not used, the network connectivity is good, and the network latency is low, you can use the following method to migrate data from MySQL to TiDB.

- [Migrate MySQL of Small Datasets to TiDB](#)

If you have a high demand on migration speed, or if the data size is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly import data. Then, you can use DM to replicate incremental data (binlog) based on your application needs.

- [Migrate MySQL of Large Datasets to TiDB](#)

5.1.3 Migrate and merge MySQL shards into TiDB

Suppose that your application uses MySQL shards for data storage, and you need to migrate these shards into TiDB as one table. In this case, you can use DM to perform the shard merge and migration.

- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)

If the data size of the sharded tables is large (for example, larger than 1 TiB), and you do not allow other applications to write to TiDB during the migration period, you can use TiDB Lightning to quickly merge and import the sharded tables. Then, you can use DM to replicate incremental sharding data (binlog) based on your application needs.

- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

5.1.4 Migrate data from files to TiDB

- [Migrate data from CSV files to TiDB](#)
- [Migrate data from SQL files to TiDB](#)

5.1.5 More advanced migration solutions

The following features can improve the migration process and might meet more needs in your application.

- [Continuous Replication from Databases that Use gh-ost or pt-osc](#)
- [Migrate Data to a Downstream TiDB Table with More Columns](#)
- [Filter Binlog Events](#)
- [Filter DML Events Using SQL Expressions](#)

5.2 TiDB Migration Tools Overview

TiDB provides multiple data migration tools for different scenarios such as full data migration, incremental data migration, backup and restore, and data replication.

This document introduces the user scenarios, advantages, and limitations of these tools. You can choose the right tool according to your needs.

The following table introduces the user scenarios, the supported upstreams and downstreams of migration tools.

Tool name	User scenario	Upstream (or the im-ported source file)	Downstream (or the put file)	Advantages	Disadvantages
-----------	---------------	---	------------------------------	------------	---------------

| [TiDB Data Migration \(DM\)](#) | Data migration from MySQL-compatible databases to TiDB | MySQL, MariaDB, Aurora, MySQL | TiDB |

A convenient and unified data migration task management tool that supports full data migration and incremental replication

Support filtering tables and operations

Support shard merge and migration

| Data import speed is roughly the same as that of TiDB Lightning's TiDB-backend, and much lower than that of TiDB Lightning's Local-backend. So it is recommended to use DM to migrate full data with a size of less than 1 TiB. | | [Dumpling](#) | Full data export from MySQL or TiDB | MySQL, TiDB | SQL, CSV |

Support the table-filter feature that enables you to filter data easier

Support exporting data to Amazon S3

|

If you want to restore the exported data to a database other than TiDB, it is recommended to use Dumpling.

If you want to restore the exported data to another TiDB cluster, it is recommended to use Backup & Restore (BR).

| | [TiDB Lightning](#) | Full data import into TiDB |

Files exported from Dumpling

CSV files

Data read from local disks or Amazon S3

| TiDB |

Support quickly importing a large amount of data and quickly initializing a specific table in a TiDB cluster

Support checkpoints to store the import progress, so that `tidb-lightning` continues importing from where it lefts off after restarting

Support data filtering

|

If Local-backend is used for data import, during the import process, the TiDB cluster cannot provide services.

If you do not want the TiDB services to be impacted, perform the data import according to TiDB Lightning TiDB-backend.

| **Backup & Restore (BR)** | Migrate a large amount of TiDB cluster data by backing up and restoring data. | TiDB | SST, backup.meta files, backup.lock files |

Suitable for migrating data to another TiDB cluster

Support backing up data to an external storage for disaster recovery

|

When BR restores data to the upstream cluster of TiCDC or Drainer, the restored data cannot be replicated to the downstream by TiCDC or Drainer.

BR supports operations only between clusters that have the same `new_collations_enabled_on_first` value.

| **TiCDC** | This tool is implemented by pulling TiKV change logs. It can restore data to a consistent state with any upstream TSO, and support other systems to subscribe to data changes. | TiDB | TiDB, MySQL, Apache Pulsar, Kafka, Confluent | Provide TiCDC Open Protocol | TiCDC only replicates tables that have at least one valid index. The following scenarios are not supported:

the TiKV cluster that uses RawKV alone.

the DDL operation `CREATE SEQUENCE` and the `SEQUENCE` function in TiDB.

| **TiDB Binlog** | Incremental replication between TiDB clusters, such as using one TiDB cluster as the secondary cluster of another TiDB cluster | TiDB | TiDB, MySQL, Kafka, incremental backup files | Support real-time backup and restore. Back up TiDB cluster data to be restored for disaster recovery | Incompatible with some TiDB versions | **sync-diff-inspector** | Comparing data stored in the databases with the MySQL protocol | TiDB, MySQL | TiDB, MySQL | Can be used to repair data in the scenario where a small amount of data is inconsistent |

Online check is not supported for data migration between MySQL and TiDB.

JSON, BIT, BINARY, BLOB and other types of data are not supported.

|

5.2.1 Install tools using TiUP

Since TiDB v4.0, TiUP acts as a package manager that helps you manage different cluster components in the TiDB ecosystem. Now you can manage any cluster component using a single command.

5.2.1.1 Step 1. Install TiUP

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
  ↪ install.sh | sh
```

Redeclare the global environment variable:

```
source ~/.bash_profile
```

5.2.1.2 Step 2. Install components

You can use the following command to see all the available components:

```
tiup list
```

The command output lists all the available components:

```
Available components:  
Name           Owner    Description  
-----  
bench          pingcap Benchmark database with different workloads  
br             pingcap TiDB/TiKV cluster backup restore tool  
cdc            pingcap CDC is a change data capture tool for TiDB  
client         pingcap Client to connect playground  
cluster        pingcap Deploy a TiDB cluster for production  
ctl            pingcap TiDB controller suite  
dm             pingcap Data Migration Platform manager  
dmctl          pingcap dmctl component of Data Migration Platform  
errdoc         pingcap Document about TiDB errors  
pd-recover     pingcap PD Recover is a disaster recovery tool of PD, used to  
  ↪ recover the PD cluster which cannot start or provide services  
  ↪ normally  
playground     pingcap Bootstrap a local TiDB cluster for fun  
tidb           pingcap TiDB is an open source distributed HTAP database  
  ↪ compatible with the MySQL protocol  
tidb-lightning pingcap TiDB Lightning is a tool used for fast full import  
  ↪ of large amounts of data into a TiDB cluster  
tiup           pingcap TiUP is a command-line component management tool that  
  ↪ can help to download and install TiDB platform components to the  
  ↪ local system
```

Choose the components to install:

```
tiup install dumpling tidb-lightning
```

Note:

To install a component of a specific version, use the `tiup install <component>[:version]` command.

5.2.1.3 Step 3. Update TiUP and its components (optional)

It is recommended to see the release log and compatibility notes of the new version.

```
tiup update --self && tiup update dm
```

5.2.2 See also

- [Download and install tools in binary](#)

5.3 Migration Scenarios

5.3.1 Migrate Data from Amazon Aurora to TiDB

This document describes how to migrate data from Amazon Aurora to TiDB. The migration process uses [DB snapshot](#), which saves a lot of space and time.

The whole migration has two processes:

- Import full data to TiDB using TiDB Lightning
- Replicate incremental data to TiDB using DM (optional)

5.3.1.1 Prerequisites

- [Install Dumpling and TiDB Lightning](#)
- [Get the target database privileges required for TiDB Lightning.](#)

5.3.1.2 Import full data to TiDB

5.3.1.2.1 Step 1. Export an Aurora snapshot to Amazon S3

1. In Aurora, query the current binlog position by running the following command:

```
mysql> SHOW MASTER STATUS;
```

The output is similar to the following. Record the binlog name and position for later use.

```

+-----+-----+-----+-----+
  ↪
| File          | Position | Binlog_Do_DB | Binlog_Ignore_DB |
  ↪ Executed_Gtid_Set |
+-----+-----+-----+-----+
  ↪
| mysql-bin.000002 | 52806 |          |          |
  ↪
+-----+-----+-----+-----+
  ↪
1 row in set (0.012 sec)

```

2. Export the Aurora snapshot. For detailed steps, refer to [Exporting DB snapshot data to Amazon S3](#).

After you obtain the binlog position, export the snapshot within 5 minutes. Otherwise, the recorded binlog position might be outdated and thus cause data conflict during the incremental replication.

After the two steps above, make sure you have the following information ready:

- The Aurora binlog name and position at the time of the snapshot creation.
- The S3 path where the snapshot is stored, and the SecretKey and AccessKey with access to the S3 path.

5.3.1.2.2 Step 2. Export schema

Because the snapshot file from Aurora does not contain the DDL statements, you need to export the schema using Dumpling and create the schema in the target database using TiDB Lightning. If you want to manually create the schema, you can skip this step.

Export the schema using Dumpling by running the following command. The command includes the `--filter` parameter to only export the desired table schema:

```

tiup dumpling --host ${host} --port 3306 --user root --password ${password}
  ↪ --filter 'my_db1.table[12]' --no-data --output 's3://my-bucket/schema
  ↪ -backup?region=us-west-2' --filter "mydb.*"

```

The parameters used in the command above are as follows. For more parameters, refer to [Dumpling overview](#).

<u>Parameter</u>	<u>Description</u>

5.3.1.2.3 Step 3. Create the TiDB Lightning configuration file

Create the `tidb-lightning.toml` configuration file as follows:

```
vim tidb-lightning.toml
```

```
[tidb]

### The target TiDB cluster information.
host = ${host}           # e.g.: 172.16.32.1
port = ${port}          # e.g.: 4000
user = "${user_name}"   # e.g.: "root"
```

```

password = "${password}" # e.g.: "rootroot"
status-port = ${status-port} # Obtains the table schema information from
    ↪ TiDB status port, e.g.: 10080
pd-addr = "${ip}:${port}" # The cluster PD address, e.g.: 172.16.31.3:2379.
    ↪ TiDB Lightning obtains some information from PD. When backend = "
    ↪ local", you must specify status-port and pd-addr correctly. Otherwise
    ↪ , the import will be abnormal.

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
    ↪ large volumes of data (1 TiB or more). During the import, the target
    ↪ TiDB cluster cannot provide any service.
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
    ↪ . During the import, the target TiDB cluster can provide service
    ↪ normally.
backend = "local"

### Set the temporary storage directory for the sorted Key-Value files. The
    ↪ directory must be empty, and the storage space must be greater than
    ↪ the size of the dataset to be imported. For better import performance
    ↪ , it is recommended to use a directory different from `data-source-
    ↪ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
### The path that stores the snapshot file.
data-source-dir = "${s3_path}" # e.g.: s3://my-bucket/sql-backup?region=us-
    ↪ west-2

[[mydumper.files]]
### The expression that parses the parquet file.
pattern = '(?i)^(?:[~/]*/*)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[~/]*/*)*(?:[a-z0
    ↪ -9\-\_\.]+\.(parquet))$'
schema = '$1'
table = '$2'
type = '$3'

```

If you need to enable TLS in the TiDB cluster, refer to [TiDB Lightning Configuration](#).

5.3.1.2.4 Step 4. Import full data to TiDB

1. Create the tables in the target database using TiDB Lightning:

```

tiup tidb-lightning -config tidb-lightning.toml -d ./schema -no-schema=
    ↪ false

```

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

Pass the `SecretKey` and `AccessKey` that have access to the S3 storage path as environment variables to the Dumping node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml -no-schema=true >
  ↪ nohup.out 2>&1 &
```

3. After the import starts, you can check the progress of the import by either of the following methods:
 - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
 - Check progress in [the monitoring dashboard](#).
 - Check progress in [the TiDB Lightning web interface](#).
4. After TiDB Lightning completes the import, it exits automatically. If you find the last 5 lines of its log print `the whole procedure completed`, the import is successful.

Note:

Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If you encounter any problem during the import, refer to [TiDB Lightning FAQ](#) for troubleshooting.

5.3.1.3 Replicate incremental data to TiDB (optional)

5.3.1.3.1 Prerequisites

- [Install DM](#).
- [Get the source database and target database privileges required for DM](#).

5.3.1.3.2 Step 1: Create the data source

1. Create the `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"
# Configures whether DM-worker uses the global transaction identifier (
  ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
  ↪ must also enable GTID. If the upstream MySQL service is
  ↪ configured to switch master between different nodes automatically
  ↪ , GTID mode is required.
enable-gtid: false

from:
  host: "${host}"      # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use
    ↪ plaintext password. It is recommended to use `dmctl encrypt` to
    ↪ encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
  ↪ source1.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master</code>	The master node address.
<code>--advertise-addr</code>	The address of the master node in the cluster where dmctl is connected, e.g.: <code>172.16.10.71:8261</code> .
<code>--source-addr</code>	The source address of the DM cluster.

5.3.1.3.3 Step 2: Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Multiple tasks that are running at the same time must each
  ↪ have a unique name.
name: "test"
### Task mode. Options are:
### - full: only performs full data migration.
```

```
### - incremental: only performs binlog real-time replication.
### - all: full data migration + binlog real-time replication.
task-mode: "incremental"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"          # e.g.: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}" # Supported but not recommended to use a
    ↪ plaintext password. It is recommended to use `dmctl encrypt` to
    ↪ encrypt the plaintext password before using it.

### Global configuration for block and allow lists. Each instance can
    ↪ reference the configuration by name.
block-allow-list:          # If the DM version is earlier than v2
    ↪ .0.0-beta.2, use black-white-list.
  listA:                  # Name.
  do-tables:              # Allow list for the upstream tables to be
    ↪ migrated.
  - db-name: "test_db"    # Name of databases to be migrated.
    tbl-name: "test_table" # Name of tables to be migrated.

### Configures the data source.
mysql-instances:
  - source-id: "mysql-01" # Data source ID, i.e., source-id in
    ↪ source1.yaml
  block-allow-list: "listA" # References the block-allow-list
    ↪ configuration above.
###   syncer-config-name: "global" # Name of the syncer configuration.
  meta:                  # When task-mode is "incremental" and the
    ↪ downstream database does not have a checkpoint, DM uses the
    ↪ binlog position as the starting point. If the downstream database
    ↪ has a checkpoint, DM uses the checkpoint as the starting point.
  binlog-name: "mysql-bin.000004" # The binlog position recorded in "
    ↪ Step 1. Export an Aurora snapshot to Amazon S3". When the
    ↪ upstream database has source-replica switching, GTID mode is
    ↪ required.
  binlog-pos: 109227
  # binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

### (Optional) If you need to incrementally replicate data that has already
    ↪ been migrated in the full data migration, you need to enable the safe
    ↪ mode to avoid the incremental data replication error.
  # This scenario is common in the following case: the full migration data
    ↪ does not belong to the data source's consistency snapshot, and
```

```
    ↪ after that, DM starts to replicate incremental data from a position
    ↪ earlier than the full migration.
# syncers:          # The running configurations of the sync processing
    ↪ unit.
# global:          # Configuration name.
#   safe-mode: true # If this field is set to true, DM changes INSERT of
    ↪ the data source to REPLACE for the target database, and changes
    ↪ UPDATE of the data source to DELETE and REPLACE for the target
    ↪ database. This is to ensure that when the table schema contains a
    ↪ primary key or unique index, DML statements can be imported
    ↪ repeatedly. In the first minute of starting or resuming an
    ↪ incremental replication task, DM automatically enables the safe
    ↪ mode.
```

The YAML file above is the minimum configuration required for the migration task. For more configuration items, refer to [DM Advanced Task Configuration File](#).

5.3.1.3.4 Step 3. Run the migration task

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

After that, start the migration task by running `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master-addr</code>	The master-addr of any DM-master in the cluster where dmctl is connected, e.g.: 172.16.10.71:8261
<code>--start-task</code>	Starts the task migration task.

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to [DM error handling](#) and [DM FAQ](#).

5.3.1.3.5 Step 4. Check the migration task status

To learn whether the DM cluster has an ongoing migration task and the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to [Query Status](#).

5.3.1.3.6 Step 5. Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

5.3.1.4 What's next

- [Pause the migration task.](#)
- [Resume the migration task.](#)
- [Stop the migration task.](#)
- [Export and import the cluster data source and task configuration.](#)
- [Handle failed DDL statements.](#)

5.3.2 Migrate MySQL of Small Datasets to TiDB

This document describes how to use TiDB Data Migration (DM) to migrate MySQL of small datasets to TiDB in the full migration mode and incremental replication mode. “Small datasets” in this document mean data size less than 1 TiB.

The migration speed varies from 30 GB/h to 50 GB/h, depending on multiple factors such as the number of indexes in the table schema, hardware, and network environment.

5.3.2.1 Prerequisites

- [Deploy a DM Cluster Using TiUP](#)
- [Grant the required privileges for the source database and the target database of DM](#)

5.3.2.2 Step 1. Create the data source

First, create the `source1.yaml` file as follows:

```
### The ID must be unique.  
source-id: "mysql-01"
```

```
### Configures whether DM-worker uses the global transaction identifier (
↳ GTID) to pull binlogs. To enable GTID, the upstream MySQL must have
↳ enabled GTID. If the upstream MySQL has automatic source-replica
↳ switching, the GTID mode is required.
enable-gtid: true

from:
  host: "${host}"      # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext password is supported but not
↳ recommended. It is recommended to use dmctl encrypt to encrypt the
↳ plaintext password before using the password.
  port: 3306
```

Then, load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
↳ yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master-addr</code>	The address of the DM-master node in the cluster where dmctl is to connect. For example, 172.16.10.71:8261.
<code>--source</code>	the source database
<code>--target</code>	the target database
<code>--create</code>	the DM cluster.

5.3.2.3 Step 2. Create the migration task

Create the `task1.yaml` file as follows:

```
### Task name. Each of the multiple tasks running at the same time must have
↳ a unique name.
name: "test"
### Task mode. Options are:
### full: only performs full data migration.
### incremental: only performs binlog real-time replication.
```

```

### all: full data migration + binlog real-time replication.
task-mode: "all"
### The configuration of the target TiDB database.
target-database:
  host: "${host}"                # For example: 172.16.10.83
  port: 4000
  user: "root"
  password: "${password}"        # Plaintext password is supported but not
    ↪ recommended. It is recommended to use dmctl encrypt to encrypt the
    ↪ plaintext password before using the password.

### The configuration of all MySQL instances of source database required for
    ↪ the current migration task.
mysql-instances:
-
  # The ID of an upstream instance or a replication group
  source-id: "mysql-01"
  # The names of the block list and allow list configuration of the schema
    ↪ name or table name that is to be migrated. These names are used to
    ↪ reference the global configuration of the block and allowlist. For
    ↪ the global configuration, refer to the `block-allow-list`
    ↪ configuration below.
  block-allow-list: "listA"

### The global configuration of blocklist and allowlist. Each instance is
    ↪ referenced by a configuration item name.
block-allow-list:
  listA:                          # name
    do-tables:                    # The allowlist of upstream tables that
      ↪ need to be migrated.
    - db-name: "test_db"          # The schema name of the table to be
      ↪ migrated.
      tbl-name: "test_table"      # The name of the table to be migrated.

```

The above is the minimum task configuration to perform the migration. For more configuration items regarding the task, refer to [DM task complete configuration file introduction](#).

5.3.2.4 Step 3. Start the migration task

To avoid errors, before starting the migration task, it is recommended to use the `check` ↪ `-task` command to check whether the configuration meets the requirements of DM configuration.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Start the migration task by running the following command with `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master-addr</code>	The DM-master node in the cluster where dmctl is to connect. For example: 172.16.10.71:8261.
<code>start-task</code>	Start the migration task

If the task fails to start, after changing the configuration according to the returned result, you can run the `start-task task.yaml` command to restart the task. If you encounter problems, refer to [Handle Errors](#) and [FAQ](#).

5.3.2.5 Step 4: Check the migration task status

To learn whether the DM cluster has an ongoing migration task, the task status and

some other information, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to [Query Status](#).

5.3.2.6 Step 5. Monitor the task and view logs (optional)

To view the historical status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when deploying DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select the DM dashboard to view DM-related monitoring metrics.

- The log directory of DM-master: specified by the DM-master process parameter `--log-file`. If you have deployed DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- The log directory of DM-worker: specified by the DM-worker process parameter `--log-file`. If you have deployed DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

5.3.2.7 What's next

- [Pause the migration task](#)
- [Resume the migration task](#)
- [Stop the migration task](#)
- [Export and import the cluster data source and task configuration](#)
- [Handle failed DDL statements](#)

5.3.3 Migrate MySQL of Large Datasets to TiDB

When the data volume to be migrated is small, you can easily [use DM to migrate data](#), both for full migration and incremental replication. However, because DM imports data at a slow speed (30~50 GiB/h), when the data volume is large, the migration might take a long time. “Large datasets” in this document usually mean data around one TiB or more.

This document describes how to migrate large datasets from MySQL to TiDB. The whole migration has two processes:

1. *Full migration.* Use Dumping and TiDB Lightning to perform the full migration. TiDB Lightning's **local backend** mode can import data at a speed of up to 500 GiB/h.
2. *Incremental replication.* After the full migration is completed, you can replicate the incremental data using DM.

5.3.3.1 Prerequisites

- [Install DM](#).
- [Install Dumpling and TiDB Lightning](#).
- [Grant the source database and target database privileges required for DM](#).
- [Grant the target database privileges required for TiDB Lightning](#).
- [Grant the source database privileges required for Dumpling](#).

5.3.3.2 Resource requirements

Operating system: The example in this document uses fresh CentOS 7 instances. You can deploy a virtual machine either on your local host or in the cloud. Because TiDB Lightning consumes as much CPU resources as needed by default, it is recommended that you deploy it on a dedicated server. If this is not possible, you can deploy it on a single server together with other TiDB components (for example, `tikv-server`) and then configure `region-concurrency` to limit the CPU usage from TiDB Lightning. Usually, you can configure the size to 75% of the logical CPU.

Memory and CPU: Because TiDB Lightning consumes high resources, it is recommended to allocate more than 64 GiB of memory and more than 32 CPU cores. To get the best performance, make sure that the CPU core to memory (GiB) ratio is greater than 1:2.

Disk space:

- Dumpling requires a disk space that can store the whole data source (or to store all upstream tables to be exported). SSD is recommended.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.
- If the full data volume is large, you can increase the binlog storage time in the upstream. This is to ensure that the binlogs are not lost during the incremental replication.

Note: It is difficult to calculate the exact data volume exported by Dumpling from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `data-length` field in the `information_schema.tables` table:

```
/* Calculate the size of all schemas, in MiB. Replace ${schema_name} with  
↳ your schema name. */  
SELECT table_schema,SUM(data_length)/1024/1024 AS data_length,SUM(  
↳ index_length)/1024/1024 AS index_length,SUM(data_length+index_length)  
↳ /1024/1024 AS SUM FROM information_schema.tables WHERE table_schema =  
↳ "${schema_name}" GROUP BY table_schema;  
  
/* Calculate the size of the largest table, in MiB. Replace ${schema_name}  
↳ with your schema name. */
```

```
SELECT table_name,table_schema,SUM(data_length)/1024/1024 AS data_length,
↳ SUM(index_length)/1024/1024 AS index_length,SUM(data_length+
↳ index_length)/1024/1024 AS SUM from information_schema.tables WHERE
↳ table_schema = "${schema_name}" GROUP BY table_name,table_schema
↳ ORDER BY SUM DESC LIMIT 5;
```

5.3.3.2.1 Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to [the standard hardware requirements](#), the storage space of the target TiKV cluster must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has x 2 because:

- Index might take extra space.
- RocksDB has a space amplification effect.

5.3.3.3 Step 1. Export all data from MySQL

1. Export all data from MySQL by running the following command:

```
tiup dumpling -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MiB -B
↳ my_db1 -f 'my_db1.table[12]' -o 's3://my-bucket/sql-backup?region
↳ =us-west-2'
```

Dumpling exports data in SQL files by default. You can specify a different file format by adding the `--filetype` option.

The parameters used above are as follows. For more Dumpling parameters, refer to [Dumpling Overview](#).

parameter	Description
- MySQL	
↳ user	
↳	
or	
--	
↳ user	
↳	
- MySQL	
↳ puser	
↳ pass-	
or word	
--	
↳ password	
↳	
215	

```
-----
parameter            Description
- MySQL
↳ port
↳
or
--
↳ port
↳
- MySQL
↳ IP
↳ ad-
or dress
--
↳ host
↳
- The
↳ num-
↳ ber
or of
-- threads
↳ thread
↳ for
  ex-
  port
```

parameter description

- The
↳ **cli-**
↳ rec-
or tory
-- that
↳ **storage**
↳ the
ex-
ported
file.
Sup-
ports
a
lo-
cal
path
or
an
ex-
ter-
nal
stor-
age
URL

- The
↳ **max-**
↳ i-
or mum
-- num-
↳ **row**
↳ of
rows
in
a
sin-
gle
file

parameter	Description
- <code>max-size</code>	The maximum size of a single file, in MiB. Recommended value: 256 MiB.
- <code>database</code>	Specifies a database or database -- to <code>database</code>
- <code>export</code>	Exports files or that -- match <code>filter</code>
- <code>filter</code>	pattern. Refer to <code>table-filter</code> for the syntax.

Make sure `${data-path}` has the space to store all exported upstream tables. To prevent the export from being interrupted by a large table consuming all the spaces, it is strongly recommended to use the `-F` option to limit the size of a single file.

2. View the `metadata` file in the `${data-path}` directory. This is a Dumpling-generated metadata file. Record the binlog position information, which is required for the incremental replication in Step 3.

```
SHOW MASTER STATUS:
Log: mysql-bin.000004
Pos: 109227
GTID:
```

5.3.3.4 Step 2. Import full data to TiDB

1. Create the `tidb-lightning.toml` configuration file:

```
[lightning]
# log.
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# "local": Default backend. The local backend is recommended to import
  ↳ large volumes of data (1 TiB or more). During the import, the
  ↳ target TiDB cluster cannot provide any service.
# "tidb": The "tidb" backend is recommended to import data less than 1
  ↳ TiB. During the import, the target TiDB cluster can provide
  ↳ service normally. For more information on the backends, refer to
  ↳ https://docs.pingcap.com/tidb/stable/tidb-lightning-backends.
backend = "local"
# Sets the temporary storage directory for the sorted Key-Value files.
  ↳ The directory must be empty, and the storage space must be
  ↳ greater than the size of the dataset to be imported. For better
  ↳ import performance, it is recommended to use a directory
  ↳ different from `data-source-dir` and use flash storage, which can
  ↳ use I/O exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
# The data source directory. The same directory where Dumpling exports
  ↳ data in "Step 1. Export all data from MySQL".
data-source-dir = "${data-path}" # A local path or S3 path. For example
  ↳ , 's3://my-bucket/sql-backup?region=us-west-2'.
```

```
[tidb]
# The target TiDB cluster information.
host = ${host}           # e.g.: 172.16.32.1
port = ${port}           # e.g.: 4000
user = "${user_name}"    # e.g.: "root"
password = "${password}" # e.g.: "rootroot"
status-port = ${status-port} # During the import, TiDB Lightning needs
    ↪ to obtain the table schema information from the TiDB status port.
    ↪ e.g.: 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
    ↪ 172.16.31.3:2379. TiDB Lightning obtains some information from PD
    ↪ . When backend = "local", you must specify status-port and pd-
    ↪ addr correctly. Otherwise, the import will be abnormal.
```

For more information on TiDB Lightning configuration, refer to [TiDB Lightning Configuration](#).

2. Start the import by running `tidb-lightning`. If you launch the program directly in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

If you import data from S3, pass the `SecretKey` and `AccessKey` that have access to the S3 storage path as environment variables to the TiDB Lightning node. You can also read the credentials from `~/.aws/credentials`.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After the import starts, you can check the progress of the import by one of the following methods:
 - `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
 - Check progress in [the monitoring dashboard](#).
 - Check progress in [the TiDB Lightning web interface](#).
4. After TiDB Lightning completes the import, it exits automatically. If you find the last 5 lines of its log print `the whole procedure completed`, the import is successful.

Note:

Whether the import is successful or not, the last line of the log shows `tidb` ↪ `lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to [TiDB Lightning FAQ](#) for troubleshooting.

5.3.3.5 Step 3. Replicate incremental data to TiDB

5.3.3.5.1 Add the data source

1. Create a `source1.yaml` file as follows:

```
# Must be unique.
source-id: "mysql-01"

# Configures whether DM-worker uses the global transaction identifier (
  ↪ GTID) to pull binlogs. To enable this mode, the upstream MySQL
  ↪ must also enable GTID. If the upstream MySQL service is
  ↪ configured to switch master between different nodes automatically
  ↪ , GTID mode is required.
enable-gtid: true

from:
  host: "${host}"          # e.g.: 172.16.10.81
  user: "root"
  password: "${password}" # Supported but not recommended to use a
    ↪ plaintext password. It is recommended to use `dmctl encrypt` to
    ↪ encrypt the plaintext password before using it.
  port: 3306
```

2. Load the data source configuration to the DM cluster using `tiup dmctl` by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create
  ↪ source1.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master</code>	The master
<code>--advertise</code>	advertise
<code>--addr</code>	addr
<code>--addr</code>	addr
<code>}</code>	}
	of
	any
	DM-
	master
	in
	the
	clus-
	ter
	where
	<code>dmctl</code>
	is
	to
	be
	con-
	nected,
	e.g.:
	<code>172.16.10.71:8261</code>
<code>operationals</code>	operationals
<code>source</code>	the
<code>source</code>	source
<code>source</code>	source
<code>create</code>	create
<code>create</code>	the
<code>create</code>	DM
<code>create</code>	clus-
<code>create</code>	ter.

5.3.3.5.2 Add a replication task

1. Edit the `task.yaml` file. Configure the incremental replication mode and the starting point of each data source:

```
name: task-test           # Task name. Must be globally unique.
task-mode: incremental   # Task mode. The "incremental" mode
  ↪ only performs incremental data replication.
```

```
# Configures the target TiDB database.
target-database:          # The target database instance.
  host: "${host}"        # e.g.: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}" # It is recommended to use `dmctl
    ↪ encrypt` to encrypt the plaintext password before using it.

# Use block and allow lists to specify the tables to be replicated.
block-allow-list:        # The collection of filtering rules
    ↪ that matches the tables in the source database instance. If the
    ↪ DM version is earlier than v2.0.0-beta.2, use black-white-list.
bw-rule-1:               # The block-allow-list configuration
    ↪ item ID.
do-dbs: ["${db-name}"]  # Name of databases to be replicated.

# Configures the data source.
mysql-instances:
- source-id: "mysql-01"  # Data source ID, i.e., source-id in
    ↪ source1.yaml
  block-allow-list: "bw-rule-1" # You can use the block-allow-list
    ↪ configuration above.
  # syncer-config-name: "global" # You can use the syncers
    ↪ incremental data configuration below.
  meta:                  # When task-mode is "incremental" and
    ↪ the target database does not have a checkpoint, DM uses the
    ↪ binlog position as the starting point. If the target database
    ↪ has a checkpoint, DM uses the checkpoint as the starting
    ↪ point.
  # binlog-name: "mysql-bin.000004" # The binlog position recorded
    ↪ in "Step 1. Export all data from MySQL". If the upstream
    ↪ database service is configured to switch master between
    ↪ different nodes automatically, GTID mode is required.
  # binlog-pos: 109227
  binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"

# (Optional) If you need to incrementally replicate data that has
    ↪ already been migrated in the full data migration, you need to
    ↪ enable the safe mode to avoid the incremental data replication
    ↪ error.

# This scenario is common in the following case: the full migration
    ↪ data does not belong to the data source's consistency snapshot,
    ↪ and after that, DM starts to replicate incremental data from a
    ↪ position earlier than the full migration.
```

```
# syncers:          # The running configurations of the sync processing
  ↪ unit.
# global:          # Configuration name.
#   safe-mode: true # If this field is set to true, DM changes INSERT
  ↪ of the data source to REPLACE for the target database, and
  ↪ changes UPDATE of the data source to DELETE and REPLACE for the
  ↪ target database. This is to ensure that when the table schema
  ↪ contains a primary key or unique index, DML statements can be
  ↪ imported repeatedly. In the first minute of starting or resuming
  ↪ an incremental replication task, DM automatically enables the
  ↪ safe mode.
```

The YAML above is the minimum configuration required for the migration task. For more configuration items, refer to [DM Advanced Task Configuration File](#).

Before you start the migration task, to reduce the probability of errors, it is recommended to confirm that the configuration meets the requirements of DM by running the `check-task` command:

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

2. Start the migration task by running the following command:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters used in the command above are described as follows:

Parameter	Description
<code>--master-addr</code>	The DM-master in the cluster where <code>dmctl</code> is to be connected, e.g.: <code>172.16.10.71:8261</code>
<code>--start-task</code>	Starts the migration task.

If the task fails to start, check the prompt message and fix the configuration. After that, you can re-run the command above to start the task.

If you encounter any problem, refer to [DM error handling](#) and [DM FAQ](#).

5.3.3.5.3 Check the migration task status

To learn whether the DM cluster has an ongoing migration task and view the task status, run the `query-status` command using `tiup dmctl`:

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For a detailed interpretation of the results, refer to [Query Status](#).

5.3.3.5.4 Monitor the task and view logs

To view the history status of the migration task and other internal metrics, take the following steps.

If you have deployed Prometheus, Alertmanager, and Grafana when you deployed DM using TiUP, you can access Grafana using the IP address and port specified during the deployment. You can then select DM dashboard to view DM-related monitoring metrics.

When DM is running, DM-worker, DM-master, and dmctl print the related information in logs. The log directories of these components are as follows:

- DM-master: specified by the DM-master process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/` by default.
- DM-worker: specified by the DM-worker process parameter `--log-file`. If you deploy DM using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/` by default.

5.3.3.6 What's next

- [Pause a Data Migration Task](#)
- [Resume a Data Migration Task](#)
- [Stop a Data Migration Task](#)
- [Export and Import Data Sources and Task Configuration of Clusters](#)
- [Handle Failed DDL Statements](#)

5.3.4 Migrate and Merge MySQL Shards of Small Datasets to TiDB

If you want to migrate and merge multiple MySQL database instances upstream to one TiDB database downstream, and the amount of data is not too large, you can use DM to migrate MySQL shards. “Small datasets” in this document usually mean data around or less than one TiB. Through examples in this document, you can learn the operation steps, precautions, and troubleshooting of the migration.

This document applies to migrating MySQL shards less than 1 TiB in total. If you want to migrate MySQL shards with a total of more than 1 TiB of data, it will take a long time to migrate only using DM. In this case, it is recommended that you follow the operation introduced in [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#) to perform migration.

This document takes a simple example to illustrate the migration procedure. The MySQL shards of the two data source MySQL instances in the example are migrated to the downstream TiDB cluster. The diagram is shown as follows.

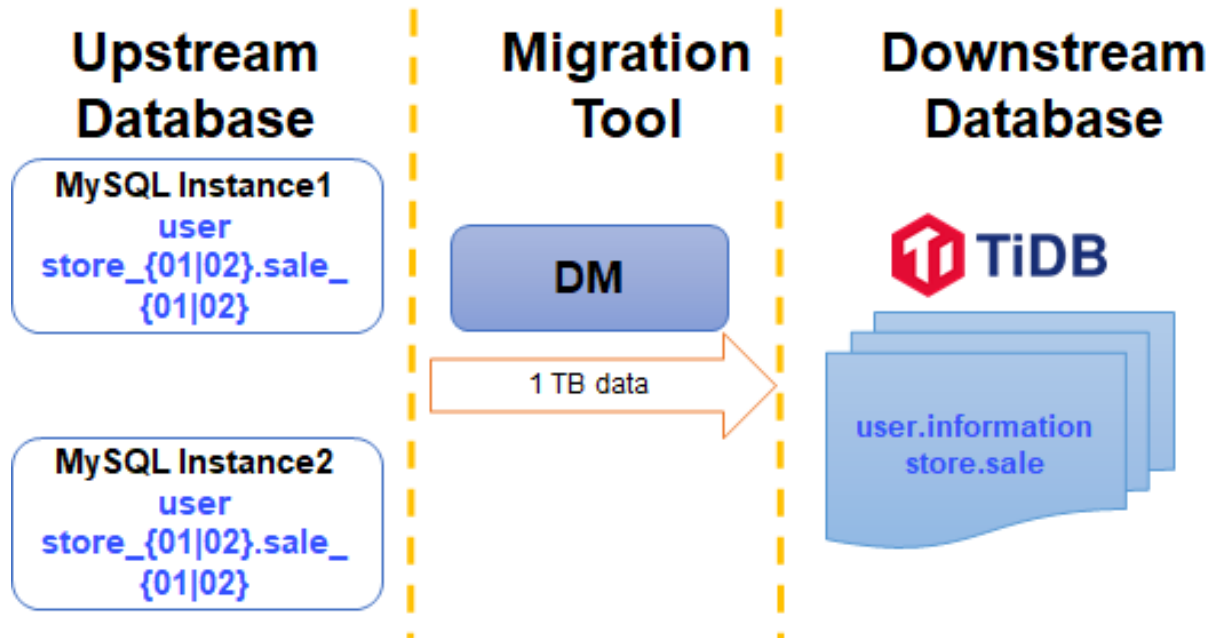

Figure 10: Use DM to Migrate Sharded Tables

Both MySQL Instance 1 and MySQL Instance 2 contain the following schemas and tables. In this example, you migrate and merge tables from `store_01` and `store_02` schemas with a `sale` prefix in both instances, into the downstream `sale` table in the `store` schema.

Schema	Table
store_01	sale_01, sale_02
store_02	sale_01, sale_02

Target schemas and tables:

Schema	Table
store	sale

5.3.4.1 Prerequisites

Before starting the migration, make sure you have completed the following tasks:

- [Deploy a DM Cluster Using TiUP](#)
- [Privileges required by DM-worker](#)

5.3.4.1.1 Check conflicts for the sharded tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid the conflicts. For more details, see [Handle conflicts between primary keys or unique indexes across multiple sharded tables](#). The following is a brief description.

In this example, `sale_01` and `sale_02` have the same table structure as follows

```
CREATE TABLE `sale_01` (  
  `id` bigint(20) NOT NULL AUTO_INCREMENT,  
  `sid` bigint(20) NOT NULL,  
  `pid` bigint(20) NOT NULL,  
  `comment` varchar(255) DEFAULT NULL,  
  PRIMARY KEY (`id`),  
  UNIQUE KEY `sid` (`sid`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

The `id` column is the primary key, and the `sid` column is the sharding key. The `id` column is auto-incremental, and duplicated multiple sharded table ranges will cause data conflicts. The `sid` can ensure that the index is globally unique, so you can follow the steps in [Remove the primary key attribute of the auto-increment primary key](#) to bypasses the `id` column.

```
CREATE TABLE `sale` (  
  `id` bigint(20) NOT NULL,  
  `sid` bigint(20) NOT NULL,  
  `pid` bigint(20) NOT NULL,  
  `comment` varchar(255) DEFAULT NULL,  
  INDEX (`id`),  
  UNIQUE KEY `sid` (`sid`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

5.3.4.2 Step 1. Load data sources

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.  
source-id: "mysql-01" # Must be unique.  
### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction  
  ↪ Identifier).  
### The prerequisite is that you have already enabled GTID in the upstream  
  ↪ MySQL.  
### If you have configured the upstream database service to switch master  
  ↪ between different nodes automatically, you must enable GTID.  
enable-gtid: true  
from:
```

```

host: "${host}"          # For example: 172.16.10.81
user: "root"
password: "${password}" # Plaintext passwords are supported but not
    ↪ recommended. It is recommended that you use dmctl encrypt to encrypt
    ↪ plaintext passwords.
port: ${port}           # For example: 3306

```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```

tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
    ↪ yaml

```

The parameters are described as follows.

Parameter	Description
<code>--master-addr</code>	DM-master node in the cluster that dmctl connects to. For example: 172.16.10.71:8261
<code>operate-source create</code>	Load data sources to the DM clusters.

Parameter	Description
-----------	-------------

Repeat the above steps until all data sources are added to the DM cluster.

5.3.4.3 Step 2. Configure the migration task

Create a task configuration file named `task1.yaml` and writes the following content to it:

```

name: "shard_merge"           # The name of the task. Should be globally
    ↪ unique.
### Task mode. You can set it to the following:
### - full: Performs only full data migration (incremental replication is
    ↪ skipped)
### - incremental: Only performs real-time incremental replication using
    ↪ binlog. (full data migration is skipped)
### - all: Performs both full data migration and incremental replication.
    ↪ For migrating small to medium amount of data here, use this option.
task-mode: all
### Required for the MySQL shards. By default, the "pessimistic" mode is
    ↪ used.
### If you have a deep understanding of the principles and usage limitations
    ↪ of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
    ↪ https://docs.pingcap.com/tidb/dev/feature-shard-merge/)
shard-mode: "pessimistic"
meta-schema: "dm_meta"       # A schema will be created in the
    ↪ downstream database to store the metadata
ignore-checking-items: ["auto_increment_ID"] # In this example, there are
    ↪ auto-incremental primary keys upstream, so you do not need to check
    ↪ this item.

target-database:
  host: "${host}"           # For example: 192.168.0.1
  port: 4000
  user: "root"
  password: "${password}"   # Plaintext passwords are supported
    ↪ but not recommended. It is recommended that you use dmctl encrypt
    ↪ to encrypt plaintext passwords.

mysql-instances:
-
  source-id: "mysql-01"     # ID of the data
    ↪ source, which is source-id in source1.yaml

```

```
route-rules: ["sale-route-rule"] # Table route rules
  ↳ applied to the data source
filter-rules: ["store-filter-rule", "sale-filter-rule"] # Binlog event
  ↳ filter rules applied to the data source
block-allow-list: "log-bak-ignored" # Block & Allow Lists
  ↳ rules applied to the data source
-
source-id: "mysql-02"
route-rules: ["sale-route-rule"]
filter-rules: ["store-filter-rule", "sale-filter-rule"]
block-allow-list: "log-bak-ignored"

### Configurations for merging MySQL shards
routes: # Table renaming rules ('routes') from upstream
  ↳ to downstream tables, in order to support merging different sharded
  ↳ tables into a single target table.
sale-route-rule: # Rule name. Migrate and merge tables from
  ↳ upstream to the downstream.
schema-pattern: "store_*" # Rule for matching upstream schema names. It
  ↳ supports the wildcards "*" and "?".
table-pattern: "sale_*" # Rule for matching upstream table names. It
  ↳ supports the wildcards "*" and "?".
target-schema: "store" # Name of the target schema.
target-table: "sale" # Name of the target table.

### Filters out some DDL events.
filters:
sale-filter-rule: # Filter name.
  schema-pattern: "store_*" # The binlog events or DDL SQL statements of
    ↳ upstream MySQL instance schemas that match schema-pattern are
    ↳ filtered by the rules below.
  table-pattern: "sale_*" # The binlog events or DDL SQL statements of
    ↳ upstream MySQL instance tables that match table-pattern are
    ↳ filtered by the rules below.
  events: ["truncate table", "drop table", "delete"] # The binlog event
    ↳ array.
  action: Ignore # The string (`Do`/`Ignore
    ↳ `). `Do` is the allow list. `Ignore` is the block list.
store-filter-rule:
  schema-pattern: "store_*"
  events: ["drop database"]
  action: Ignore

### Block and allow list
block-allow-list: # filter or only migrate all operations of some
```

```
↪ databases or some tables.  
log-bak-ignored:      # Rule name.  
do-dbs: ["store_*"]  # The allow list of the schemas to be migrated,  
↪ similar to replicate-do-db in MySQL.
```

The above example is the minimum configuration to perform the migration task. For more information, see [DM Advanced Task Configuration File](#).

For more information on `routes`, `filters` and other configurations in the task file, see the following documents:

- [Table routing](#)
- [Block & Allow Table Lists](#)
- [Binlog event filter](#)
- [Filter Certain Row Changes Using SQL Expressions](#)

5.3.4.4 Step 3. Start the task

Before starting a migration task, run the `check-task` subcommand in `tiup dmctl` to check whether the configuration meets the requirements of DM so as to avoid possible errors.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Run the following command in `tiup dmctl` to start a migration task:

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

Parameter	Description
<code>--master-addr</code>	<p> <code>{advertise-addr}</code> address of any DM-master node in the cluster that dmctl connects to. For example: <code>172.16.10.71:8261</code> </p>
<code>start-task</code>	<p>Starts the data migration task.</p>

If the migration task fails to start, modify the configuration information according to the error information, and then run `start-task task.yaml` again to start the migration task. If you encounter problems, see [Handle Errors](#) and [FAQ](#).

5.3.4.5 Step 4. Check the task

After starting the migration task, you can use `dmctl tiup` to run `query-status` to view the status of the task.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

If you encounter errors, use `query-status <name of the error task>` to view more detailed information. For details about the query results, task status and sub task status of the `query-status` command, see [TiDB Data Migration Query Status](#).

5.3.4.6 Step 5. Monitor tasks and check logs (optional)

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

- DM-master log directory: It is specified by the DM-master process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-master-8261/log/`.
- DM-worker log directory: It is specified by the DM-worker process parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy/dm-worker-8262/log/`.

- [Merge and Migrate Data from Sharded Tables](#)
- [Best Practices of Data Migration in the Shard Merge Scenario](#)
- [Handle Errors](#)
- [Handle Performance Issues](#)
- [FAQ](#)

5.3.5 Migrate and Merge MySQL Shards of Large Datasets to TiDB

If you want to migrate a large MySQL dataset (for example, more than 1 TiB) from different partitions into TiDB, and you are able to suspend all the TiDB cluster write operations from your business during the migration, you can use TiDB Lightning to do the migration quickly. After migration, you can also use TiDB DM to perform incremental replication according to your business needs. “Large datasets” in this document usually mean data around one TiB or more.

This document uses an example to walk through the whole procedure of such kind of migration.

If the data size of the MySQL shards is less than 1 TiB, you can follow the procedure described in [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#), which supports both full and incremental migration and the steps are easier.

The following diagram shows how to migrate and merge MySQL sharded tables to TiDB using Dumpling and TiDB Lightning.

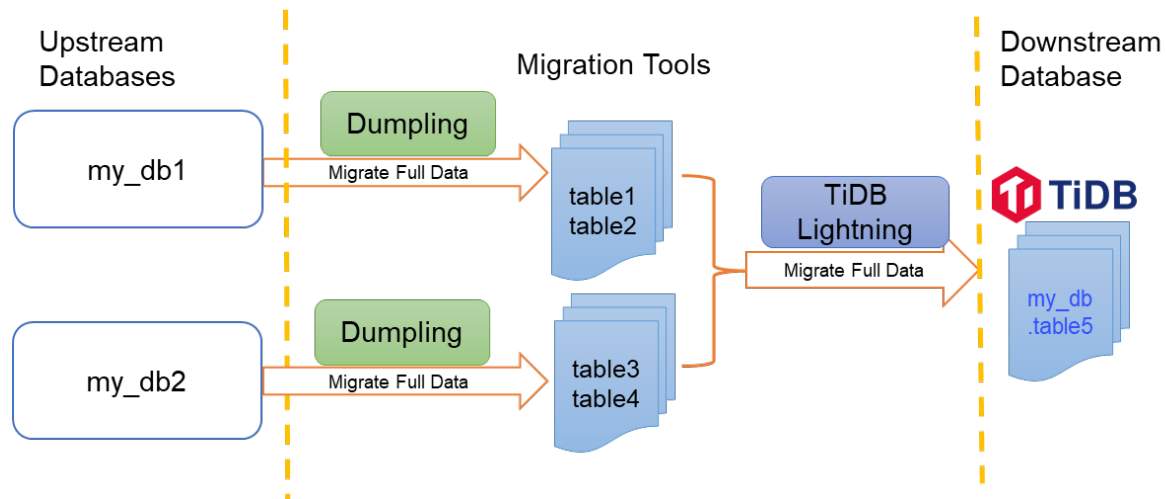

Figure 11: Use Dumpling and TiDB Lightning to migrate and merge MySQL shards to TiDB

This example assumes that you have two databases, `my_db1` and `my_db2`. You use Dumpling to export two tables `table1` and `table2` from `my_db1`, and two tables `table3` and `table4` from `my_db2`, respectively. After that, you use TiDB Lightning to import and merge the four exported tables into the same `table5` from `mydb` in the target TiDB.

In this document, you can migrate data following this procedure:

1. Use Dumpling to export full data. In this example, you export 2 tables respectively from 2 upstream databases:
 - Export `table1` and `table2` from `my_db1`
 - Export `table3` and `table4` from `my_db2`
2. Start TiDB Lightning to migrate data to `mydb.table5` in TiDB.
3. (Optional) Use TiDB DM to perform incremental replication.

5.3.5.1 Prerequisites

Before getting started, see the following documents to prepare for the migration task.

- [Deploy a DM Cluster Using TiUP](#)
- [Privileges required by DM-worker](#)

5.3.5.1.1 Resource requirements

Operating system: Examples in this document use new, clean CentOS 7 instances. You can deploy a virtual machine on your own host locally, or on a vendor-provided cloud platform. TiDB Lightning consumes as much CPU resources as needed by default, so it is recommended to deploy TiDB Lightning on a dedicated machine. If you do not have a dedicated machine for TiDB Lightning, you can deploy TiDB Lightning on a shared machine with other components (such as `tikv-server`) and limit TiDB Lightning's CPU usage by configuring `region-concurrency` to 75% of the number of logical CPUs.

Memory and CPU: TiDB Lightning consumes high resources, so it is recommended to allocate more than 64 GB of memory and 32-core CPU for TiDB Lightning. To get the best performance, make sure the CPU core to memory (GB) ratio is more than 1:2.

Disk space:

- Dumping requires enough disk space to store the whole data source. SSD is recommended.
- During the import, TiDB Lightning needs temporary space to store the sorted key-value pairs. The disk space should be enough to hold the largest single table from the data source.
- If the full data volume is large, you can increase the binlog storage time in the upstream. This is to ensure that the binlogs are not lost during the incremental replication.

Note: You cannot calculate the exact data volume exported by Dumping from MySQL, but you can estimate the data volume by using the following SQL statement to summarize the `data-length` field in the `information_schema.tables` table:

```
/* Calculate the size of all schemas, in MiB. Replace ${schema_name} with  
↳ your schema name. */  
SELECT table_schema,SUM(data_length)/1024/1024 AS data_length,SUM(  
↳ index_length)/1024/1024 AS index_length,SUM(data_length+index_length)  
↳ /1024/1024 AS SUM FROM information_schema.tables WHERE table_schema =  
↳ "${schema_name}" GROUP BY table_schema;  
  
/* Calculate the size of the largest table, in MiB. Replace ${schema_name}  
↳ with your schema name. */  
SELECT table_name,table_schema,SUM(data_length)/1024/1024 AS data_length,  
↳ SUM(index_length)/1024/1024 AS index_length,SUM(data_length+  
↳ index_length)/1024/1024 AS SUM from information_schema.tables WHERE  
↳ table_schema = "${schema_name}" GROUP BY table_name,table_schema  
↳ ORDER BY SUM DESC LIMIT 5;
```

5.3.5.1.2 Disk space for the target TiKV cluster

The target TiKV cluster must have enough disk space to store the imported data. In addition to [the standard hardware requirements](#), the storage space of the target TiKV cluster

must be larger than **the size of the data source x the number of replicas x 2**. For example, if the cluster uses 3 replicas by default, the target TiKV cluster must have a storage space larger than 6 times the size of the data source. The formula has $\times 2$ because:

- Index might take extra space.
- RocksDB has a space amplification effect.

5.3.5.1.3 Check conflicts for Sharded Tables

If the migration involves merging data from different sharded tables, primary key or unique index conflicts may occur during the merge. Therefore, before migration, you need to take a deep look at the current sharding scheme from the business point of view, and find a way to avoid the conflicts. For more details, see [Handle conflicts between primary keys or unique indexes across multiple sharded tables](#). The following is a brief description.

Assume that tables 1~4 have the same table structure as follows.

```
CREATE TABLE `table1` (  
  `id` bigint(20) NOT NULL AUTO_INCREMENT,  
  `sid` bigint(20) NOT NULL,  
  `pid` bigint(20) NOT NULL,  
  `comment` varchar(255) DEFAULT NULL,  
  PRIMARY KEY (`id`),  
  UNIQUE KEY `sid` (`sid`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

For those four tables, the `id` column is the primary key. It is auto-incremental, which will cause different sharded tables to generate duplicated `id` ranges and cause the primary key conflict on the target table during the migration. On the other hand, the `sid` column is the sharding key, which ensures that the index is unique globally. So you can remove the unique constraint of the `id` column in the target `table5` to avoid the data merge conflicts.

```
CREATE TABLE `table5` (  
  `id` bigint(20) NOT NULL,  
  `sid` bigint(20) NOT NULL,  
  `pid` bigint(20) NOT NULL,  
  `comment` varchar(255) DEFAULT NULL,  
  INDEX (`id`),  
  UNIQUE KEY `sid` (`sid`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

5.3.5.2 Step1. Use Dumping to export full data

If those multiple sharded tables to be exported are in the same upstream MySQL instance, you can directly use the `-f` parameter of Dumping to export them in a single operation.

If the sharded tables are stored in different MySQL instances, you can use Dumping to export them respectively and place the exported results in the same parent directory.

In the following example, both methods are used, and then the exported data is stored in the same parent directory.

First, run the following command to use Dumping to export `table1` and `table2` from `my_db1`:

```
tiup dumping -h ${ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db1 -f
↳ 'my_db1.table[12]' -o ${data-path}/my_db1
```

The following table describes parameters in the command above. For more information about Dumping parameters, see [Dumping Overview](#).

Parameter	Description
-u	Specifies the user or name
--to-user	to user used.
-P	Specifies the password or word
--to-password	to password used.
-P	Specifies the port or to
--to-port	to port used.
-h	Specifies the IP or address
--to-host	to host the data source.

Parameter	Description
-----------	-------------

-	Specifies
↪	the
↪	num-
or	ber
--	of
↪	threads
↪	for
	the
	ex-
	port.
	In-
	creas-
	ing
	the

	filter

Ensure that there is enough free space in `#{data-path}`. It is strongly recommended to use the `-F` option to avoid interruptions in the backup process due to oversized single tables.

Then, run the following command to use Dumping to export `table3` and `table4` from `my_db2`. Note that the path is `#{data-path}/my_db2` instead of `#{data-path}/my_db1`.

```
tiup dumpling -h #{ip} -P 3306 -u root -t 16 -r 200000 -F 256MB -B my_db2 -f
↪ 'my_db2.table[34]' -o #{data-path}/my_db2
```

After the preceding procedures, all source data tables are now exported to the `#{data-
↪ path}` directory. Putting all the exported data on the same directory makes subsequent import by TiDB Lightning convenient.

The starting position information needed for incremental replication is in the `metadata` files in `my_db1` and `my_db2` sub-directories of `#{data-path}` directory respectively. They are meta-information files automatically generated by Dumping. To perform incremental replication, you need to record the binlog locations information in these files.

5.3.5.3 Step 2. Start TiDB Lightning to import full exported data

Before starting TiDB Lightning for migration, it is recommended that you understand how to handle checkpoints, and then choose the appropriate way to proceed according to your needs.

5.3.5.3.1 Checkpoints

Migrating a large volume of data usually takes hours or even days. There is a certain chance that the long-running process is interrupted unexpectedly. It can be very frustrating to redo everything from scratch, even if some part of data has already been imported.

Fortunately, TiDB Lightning provides a feature called **checkpoints**, which makes TiDB Lightning save the import progress as **checkpoints** from time to time, so that an interrupted import task can be resumed from the latest checkpoint upon restart.

If the TiDB Lightning task crashes due to unrecoverable errors (for example, data corruption), it will not pick up from the checkpoint, but will report an error and quit the task. To ensure the safety of the imported data, you must resolve these errors by using the `tidb-lightning-ctl` command before proceeding with other steps. The options include:

- `-checkpoint-error-destroy`: This option allows you to restart importing data into failed target tables from scratch by destroying all the existing data in those tables first.
- `-checkpoint-error-ignore`: If migration has failed, this option clears the error status as if no errors ever happened.
- `-checkpoint-remove`: This option simply clears all checkpoints, regardless of errors.

For more information, see [TiDB Lightning Checkpoints](#).

5.3.5.3.2 Create a target schema

Create `mydb.table5` at downstream.

```
CREATE TABLE `table5` (  
  `id` bigint(20) NOT NULL,  
  `sid` bigint(20) NOT NULL,  
  `pid` bigint(20) NOT NULL,  
  `comment` varchar(255) DEFAULT NULL,  
  INDEX (`id`),  
  UNIQUE KEY `sid` (`sid`)  
) ENGINE=InnoDB DEFAULT CHARSET=latin1
```

5.3.5.3.3 Start the migration task

Follow these steps to start `tidb-lightning`:

1. Edit the toml file. `tidb-lightning.toml` is used in the following example:

```
[lightning]  
# Logs  
level = "info"  
file = "tidb-lightning.log"
```

```
[mydumper]
data-source-dir = ${data-path}

[tikv-importer]
# Choose a local backend.
# "local": The default mode. It is used for large data volumes greater
  ↪ than 1 TiB. During migration, downstream TiDB cannot provide
  ↪ services.
# "tidb": Used for data volumes less than 1 TiB. During migration,
  ↪ downstream TiDB can provide services normally.
# For more information, see [TiDB Lightning Backends](https://docs.
  ↪ pingcap.com/tidb/stable/tidb-lightning-backends)
backend = "local"
# Set the temporary directory for the sorted key value pairs. It must
  ↪ be empty.
# The free space must be greater than the size of the dataset to be
  ↪ imported.
# It is recommended that you use a directory different from `data-
  ↪ source-dir` to get better migration performance by consuming I/O
  ↪ resources exclusively.
sorted-kv-dir = "${sorted-kv-dir}"

# Set the renaming rules ('routes') from source to target tables, in
  ↪ order to support merging different table shards into a single
  ↪ target table. Here you migrate `table1` and `table2` in `my_db1`,
  ↪ and `table3` and `table4` in `my_db2`, to the target `table5` in
  ↪ downstream `my_db`.

[[mydumper.files]]
pattern = '(^|/)my_db1\\.table[1-2]\\..*\\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

[[mydumper.files]]
pattern = '(^|/)my_db2\\.table[3-4]\\..*\\.sql$'
schema = "my_db"
table = "table5"
type = "sql"

# Information of the target TiDB cluster. For example purposes only.
  ↪ Replace the IP address with your IP address.
[tidb]
# Information of the target TiDB cluster.
# Values here are only for illustration purpose. Replace them with your
  ↪ own values.
```

```
host = ${host}          # For example: "172.16.31.1"
port = ${port}          # For example: 4000
user = "${user_name}"  # For example: "root"
password = "${password}" # For example: "rootroot"
status-port = ${status-port} # The table information is read from the
    ↪ status port. For example: 10080
# the IP address of the PD cluster. TiDB Lightning gets some
    ↪ information through the PD cluster.
# For example: "172.16.31.3:2379".
# When backend = "local", make sure that the values of status-port and
    ↪ pd-addr are correct. Otherwise an error will occur.
pd-addr = "${ip}:${port}"
```

2. Run `tidb-lightning`. If you run the program by directly invoking the program name in a shell, the process may quit unexpectedly after receiving a `SIGHUP` signal. It is recommended that you run the program using tools such as `nohup` or `screen` or `tiup`, and put the process to the shell background. If you migrate from S3, the `SecretKey` and `AccessKey` of the account that has access to the Amazon S3 backend store needs to be passed into the Lightning node as environment variables. Reading credential files from `~/.aws/credentials` is also supported. For example:

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1
    ↪ &
```

3. After starting the migration task, you can check the progress by using either of the following methods:
 - Use `grep` tool to search the keyword `progress` in the log. By default, a message reporting the progress is flushed into the log file every 5 minutes.
 - View progress via the monitoring dashboard. For more information, see [TiDB Lightning Monitoring](#).
 - View the progress via the Web page. See [Web Interface](#).

After the importing finishes, TiDB Lightning will exit automatically. To make sure that the data is imported successfully, check for the `whole procedure completed` among the last 5 lines in the log.

Note:

Whether the migration is successful or not, the last line in the log will always be `tidb lightning exit`. It just means that TiDB Lightning quits normally, and does not guarantee that the importing task is completed successfully.

If you encounter any problems during migration, see [TiDB Lightning FAQs](#).

5.3.5.4 Step 3. (Optional) Use DM to perform incremental replication

To replicate the data changes based on binlog from a specified position in the source database to TiDB, you can use TiDB DM to perform incremental replication.

5.3.5.4.1 Add the data source

Create a new data source file called `source1.yaml`, which configures an upstream data source into DM, and add the following content:

```
### Configuration.
source-id: "mysql-01" # Must be unique.

### Specifies whether DM-worker pulls binlogs with GTID (Global Transaction
↳ Identifier).
### The prerequisite is that you have already enabled GTID in the upstream
↳ MySQL.
### If you have configured the upstream database service to switch master
↳ between different nodes automatically, you must enable GTID.
enable-gtid: true

from:
  host: "${host}"          # For example: 172.16.10.81
  user: "root"
  password: "${password}" # Plaintext passwords are supported but not
↳ recommended. It is recommended that you use dmctl encrypt to encrypt
↳ plaintext passwords.
  port: ${port}           # For example: 3306
```

Run the following command in a terminal. Use `tiup dmctl` to load the data source configuration into the DM cluster:

```
tiup dmctl --master-addr ${advertise-addr} operate-source create source1.
↳ yaml
```

The parameters are described as follows.

Parameter	Description
<code>advertise-master-addr</code>	Address of any DM-master node in the cluster that dm-ctl connects to. For example: <code>172.16.10.71:8261</code>
<code>operate-data-sources</code>	Used to create DM clusters.

Repeat the above steps until all MySQL upstream instances are added to the DM as data sources.

5.3.5.4.2 Create a replication task

Edit a task configuration file called `task.yaml`, to configure the incremental replication mode and replication starting point for each data source.

```
name: task-test          # The name of the task. Should be globally unique
  ↳ .
task-mode: incremental  # The mode of the task. "incremental" means full
  ↳ data migration is skipped and only incremental replication is
  ↳ performed.
```

```
### Required for incremental replication from sharded tables. By default,
↳ the "pessimistic" mode is used.
### If you have a deep understanding of the principles and usage limitations
↳ of the optimistic mode, you can also use the "optimistic" mode.
### For more information, see [Merge and Migrate Data from Sharded Tables](
↳ https://docs.pingcap.com/zh/tidb/dev/feature-shard-merge/).

shard-mode: "pessimistic"

### Configure the access information of the target TiDB database instance:
target-database:          # The target database instance
  host: "${host}"        # For example: 127.0.0.1
  port: 4000
  user: "root"
  password: "${password}" # It is recommended to use a dmctl encrypted
  ↳ password.

### Use block-allow-list to configure tables that require sync:
block-allow-list:        # The set of filter rules on matching tables in
  ↳ the data sources, to decide which tables need to migrate and which
  ↳ not. Use the black-white-list if the DM version is earlier than or
  ↳ equal to v2.0.0-beta.2.
bw-rule-1:               # The ID of the block and allow list rule.
  do-dbs: ["my_db1"]     # The databases to be migrated. Here, my_db1 of
  ↳ instance 1 and my_db2 of instance 2 are configured as two separate
  ↳ rules to demonstrate how to prevent my_db2 of instance 1 from
  ↳ being replicated.
bw-rule-2:
  do-dbs: ["my_db2"]

routes:                  # Table renaming rules ('routes') from
  ↳ upstream to downstream tables, in order to support merging different
  ↳ sharded table into a single target table.
route-rule-1:           # Rule name. Migrate and merge table1 and
  ↳ table2 from my_db1 to the downstream my_db.table5.
  schema-pattern: "my_db1" # Rule for matching upstream schema names.
  ↳ It supports the wildcards "*" and "?".
  table-pattern: "table[1-2]" # Rule for matching upstream table names.
  ↳ It supports the wildcards "*" and "?".
  target-schema: "my_db"   # Name of the target schema.
  target-table: "table5"  # Name of the target table.
route-rule-2:           # Rule name. Migrate and merge table3 and
  ↳ table4 from my_db2 to the downstream my_db.table5.
  schema-pattern: "my_db2"
  table-pattern: "table[3-4]"
  target-schema: "my_db"
```

```
target-table: "table5"

### Configure data sources. The following uses two data sources as an
↳ example.
mysql-instances:
  - source-id: "mysql-01"          # Data source ID. It is the source-id in
    ↳ source1.yaml.
    block-allow-list: "bw-rule-1" # Use the block and allow list
    ↳ configuration above. Replicate `my_db1` in instance 1.
    route-rules: ["route-rule-1"] # Use the configured routing rule above to
    ↳ merge upstream tables.
###   syncer-config-name: "global" # Use the syncers configuration below.
meta:                                # The migration starting point of binlog
  ↳ when task-mode is incremental and there is no checkpoint in the
  ↳ downstream database. If there is a checkpoint, the checkpoint will
  ↳ be used.
  binlog-name: "${binlog-name}" # The log location recorded in ${data-
    ↳ path}/my_db1/metadata in Step 1. You can either specify binlog-
    ↳ name + binlog-pos or binlog-gtid. When the upstream database
    ↳ service is configured to switch master between different nodes
    ↳ automatically, use binlog GTID here.
  binlog-pos: ${binlog-position}
  # binlog-gtid: "09bec856-ba95-11ea-850a-58
    ↳ f2b4af5188:1-9"
  - source-id: "mysql-02"          # Data source ID. It is the source-id in
    ↳ source1.yaml.
    block-allow-list: "bw-rule-2" # Use the block and allow list
    ↳ configuration above. Replicate `my_db2` in instance2.
    route-rules: ["route-rule-2"] # Use the routing rule configured above.

###   syncer-config-name: "global" # Use the syncers configuration below.
meta:                                # The migration starting point of binlog
  ↳ when task-mode is incremental and there is no checkpoint in the
  ↳ downstream database. If there is a checkpoint, the checkpoint will
  ↳ be used.
  # binlog-name: "${binlog-name}" # The log location recorded in ${data-
    ↳ path}/my_db2/metadata in Step 1. You can either specify binlog-
    ↳ name + binlog-pos or binlog-gtid. When the upstream database
    ↳ service is configured to switch master between different nodes
    ↳ automatically, use binlog GTID here.
  # binlog-pos: ${binlog-position}
  binlog-gtid: "09bec856-ba95-11ea-850a-58f2b4af5188:1-9"
### (Optional) If you need to incrementally replicate some data changes that
↳ have been covered in the full migration, you need to enable the safe
↳ mode to avoid data migration errors during incremental replication.
```

```
### This scenario is common when the fully migrated data is not part of a
↳ consistent snapshot of the data source, and the incremental data is
↳ replicated from a location earlier than the fully migrated data.
### syncers:          # The running parameters of the sync processing unit.
### global:          # Configuration name.
### If set to true, DM changes INSERT to REPLACE, and changes UPDATE to a
↳ pair of DELETE and REPLACE for data source replication operations.
### Thus, it can apply DML repeatedly during replication when primary keys
↳ or unique indexes exist in the table structure.
### TiDB DM automatically starts safe mode within 1 minute before starting
↳ or resuming an incremental replication task.
###   safe-mode: true
```

For more configurations, see [DM Advanced Task Configuration File](#).

Before you start the data migration task, it is recommended to use the `check-task` `↳` subcommand in `tiup dmctl` to check if the configuration meets the DM configuration requirements.

```
tiup dmctl --master-addr ${advertise-addr} check-task task.yaml
```

Use `tiup dmctl` to run the following command to start the data migration task.

```
tiup dmctl --master-addr ${advertise-addr} start-task task.yaml
```

The parameters in this command are described as follows.

Parameter	Description
<code>--master-addr</code>	<p> <code>{advertise-addr}</code> address of any DM-master node in the cluster that <code>dmctl</code> connects to. For example: <code>172.16.10.71:8261</code> </p>
<code>start-task</code>	<p> Starts the data migration task. </p>

If the task fails to start, first make configuration changes according to the prompt messages from the returned result, and then run the `start-task task.yaml` subcommand in `tiup dmctl` to restart the task. If you encounter problems, see [Handle Errors](#) and [TiDB Data Migration FAQ](#).

5.3.5.4.3 Check the migration status

You can check if there are running migration tasks in the DM cluster and their status by running the `query-status` command in `tiup dmctl`.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

For more information, see [Query Status](#).

5.3.5.4.4 Monitor tasks and view logs

You can view the history of a migration task and internal operational metrics through Grafana or logs.

- Via Grafana

If Prometheus, Alertmanager, and Grafana are correctly deployed when you deploy the DM cluster using TiUP, you can view DM monitoring metrics in Grafana. Specifically, enter the IP address and port specified during deployment in Grafana and select the DM dashboard.

- Via logs

When DM is running, DM-master, DM-worker, and dmctl output logs, which includes information about migration tasks. The log directory of each component is as follows.

- DM-master log directory: It is specified by the DM-master command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy ↪ /dm-master-8261/log/`.
- DM-worker log directory: It is specified by the DM-worker command line parameter `--log-file`. If DM is deployed using TiUP, the log directory is `/dm-deploy ↪ /dm-worker-8262/log/`.

5.3.6 Migrate Data from CSV Files to TiDB

This document describes how to migrate data from CSV files to TiDB.

TiDB Lightning can read data from CSV files and other delimiter formats, such as tab-separated values (TSV). For other flat file data sources, you can also refer to this document and migrate data to TiDB.

5.3.6.1 Prerequisites

- [Install TiDB Lightning](#).
- [Get the target database privileges required for TiDB Lightning](#).

5.3.6.2 Step 1. Prepare the CSV files

Put all the CSV files in the same directory. If you need TiDB Lightning to recognize all CSV files, the file names should meet the following requirements:

- If a CSV file contains the data for an entire table, name the file `${db_name}.${table_name}.csv`.
- If the data of one table is separated into multiple CSV files, append a numeric suffix to these CSV files. For example, `${db_name}.${table_name}.003.csv`. The numeric suffixes can be inconsecutive but must be in ascending order. You also need to add extra zeros before the number to ensure all the suffixes are in the same length.

TiDB Lightning recursively searches for all `.csv` files in this directory and its subdirectories.

5.3.6.3 Step 2. Create the target table schema

Because CSV files do not contain schema information, before importing data from CSV files into TiDB, you need to create the target table schema. You can create the target table schema by either of the following two methods:

- **Method 1:** create the target table schema using TiDB Lightning.

Create SQL files that contain the required DDL statements:

- Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
- Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2:** create the target table schema manually.

5.3.6.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default backend. The local backend is recommended to import
↳ large volumes of data (1 TiB or more). During the import, the target
↳ TiDB cluster cannot provide any service.
### "tidb": The "tidb" backend is recommended to import data less than 1 TiB
↳ . During the import, the target TiDB cluster can provide service
↳ normally.
```

```
backend = "local"
### Set the temporary storage directory for the sorted Key-Value files. The
  ↳ directory must be empty, and the storage space must be greater than
  ↳ the size of the dataset to be imported. For better import performance
  ↳ , it is recommended to use a directory different from `data-source-
  ↳ dir` and use flash storage, which can use I/O exclusively.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
### Directory of the data source.
data-source-dir = "${data-path}" # A local path or S3 path. For example, 's3
  ↳ ://my-bucket/sql-backup?region=us-west-2'.

### Defines CSV format.
[mydumper.csv]
### Field separator of the CSV file. Must not be empty. If the source file
  ↳ contains fields that are not string or numeric, such as binary, blob,
  ↳ or bit, it is recommended not to use simple delimiters such as ",",
  ↳ and use an uncommon character combination like "|+|" instead.
separator = ','
### Delimiter. Can be zero or multiple characters.
delimiter = ''
### Configures whether the CSV file has a table header.
### If this item is set to true, TiDB Lightning uses the first line of the
  ↳ CSV file to parse the corresponding relationship of fields.
header = true
### Configures whether the CSV file contains NULL.
### If this item is set to true, any column of the CSV file cannot be parsed
  ↳ as NULL.
not-null = false
### If `not-null` is set to false (CSV contains NULL),
### The following value is parsed as NULL.
null = '\N'
### Whether to treat the backslash ('\') in the string as an escape
  ↳ character.
backslash-escape = true
### Whether to trim the last separator at the end of each line.
trim-last-separator = false

[tidb]
### The target cluster.
host = ${host} # e.g.: 172.16.32.1
port = ${port} # e.g.: 4000
user = "${user_name}" # e.g.: "root"
password = "${password}" # e.g.: "rootroot"
```

```
status-port = ${status-port} # During the import, TiDB Lightning needs to
  ↳ obtain the table schema information from the TiDB status port. e.g.:
  ↳ 10080
pd-addr = "${ip}:${port}" # The address of the PD cluster, e.g.:
  ↳ 172.16.31.3:2379. TiDB Lightning obtains some information from PD.
  ↳ When backend = "local", you must specify status-port and pd-addr
  ↳ correctly. Otherwise, the import will be abnormal.
```

For more information on the configuration file, refer to [TiDB Lightning Configuration](#).

5.3.6.5 Step 4. Tune the import performance (optional)

When you import data from CSV files with a uniform size of about 256 MiB, TiDB Lightning works in the best performance. However, if you import data from a single large CSV file, TiDB Lightning can only use one thread to process the import by default, which might slow down the import speed.

To speed up the import, you can split a large CSV file into smaller ones. For a CSV file in a common format, before TiDB Lightning reads the entire file, it is hard to quickly locate the beginning and ending positions of each line. Therefore, TiDB Lightning does not automatically split CSV files by default. But if your CSV files to be imported meet certain format requirements, you can enable the `strict-format` mode. In this mode, TiDB Lightning automatically splits a single large CSV file into multiple files, each in about 256 MiB, and processes them in parallel.

Note:

If a CSV file is not in a strict format but the `strict-format` mode is set to `true` by mistake, a field that spans multiple lines will be split into two fields. This causes the parsing to fail, and TiDB Lightning might import the corrupted data without reporting any error.

In a strict-format CSV file, each field only takes up one line. It must meet the following requirements:

- The delimiter is empty.
- Each field does not contain CR (`\r`) or LF (`\n`).

If your CSV file meets the above requirements, you can speed up the import by enabling the `strict-format` mode as follows:

```
[mydumper]
strict-format = true
```

5.3.6.6 Step 5. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the process might exit unexpectedly after receiving a `SIGHUP` signal. In this case, it is recommended to run the program using a `nohup` or `screen` tool. For example:

```
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

After the import starts, you can check the progress of the import by either of the following methods:

- `grep` the keyword `progress` in the log. The progress is updated every 5 minutes by default.
- Check progress in [the monitoring dashboard](#).
- Check progress in [the TiDB Lightning web interface](#).

After TiDB Lightning completes the import, it exits automatically. If you find the last 5 lines of its log print `the whole procedure completed`, the import is successful.

Note:

Whether the import is successful or not, the last line of the log shows `tidb ↪ lightning exit`. It means that TiDB Lightning exits normally, but does not necessarily mean that the import is successful.

If the import fails, refer to [TiDB Lightning FAQ](#) for troubleshooting.

5.3.6.7 Other file formats

If your data source is in other formats, to migrate data from your data source, you must end the file name with `.csv` and make corresponding changes in the `[mydumper.csv ↪]` section of the `tidb-lightning.toml` configuration file. Here are example changes for common formats:

TSV:

```
### Format example
### ID   Region  Count
### 1    East    32
### 2    South   NULL
### 3    West    10
### 4    North   39

### Format configuration
```

```
[mydumper.csv]
separator = "\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
trim-last-separator = false
```

TPC-H DBGEN:

```
### Format example
### 1|East|32|
### 2|South|0|
### 3|West|10|
### 4|North|39|

### Format configuration
[mydumper.csv]
separator = '|'
delimiter = ''
header = false
not-null = true
backslash-escape = false
trim-last-separator = true
```

5.3.6.8 What's next

- [CSV Support and Restrictions.](#)

5.3.7 Migrate Data from SQL Files to TiDB

This document describes how to migrate data from MySQL SQL files to TiDB using TiDB Lightning. For how to generate MySQL SQL files, refer to [Export to SQL files using Dumping](#).

5.3.7.1 Prerequisites

- [Install TiDB Lightning using TiUP](#)
- [Grant the required privileges to the target database for TiDB Lightning](#)

5.3.7.2 Step 1. Prepare SQL files

Put all the SQL files in the same directory, like `/data/my_datasource/` or `s3://my ↵ -bucket/sql-backup?region=us-west-2`. TiDB Lightning recursively searches for all `.sql` files in this directory and its subdirectories.

5.3.7.3 Step 2. Define the target table schema

To import data to TiDB, you need to create the table schema for the target database.

If you use Dumping to export data, the table schema file is automatically exported. For the data exported in other ways, you can create the table schema in one of the following methods:

- **Method 1:** Create the target table schema using TiDB Lightning.

Create SQL files that contain the required DDL statements:

- Add `CREATE DATABASE` statements in the `${db_name}-schema-create.sql` files.
- Add `CREATE TABLE` statements in the `${db_name}.${table_name}-schema.sql` files.

- **Method 2:** Create the target table schema manually.

5.3.7.4 Step 3. Create the configuration file

Create a `tidb-lightning.toml` file with the following content:

```
[lightning]
### Log
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
### "local": Default. The local backend is used to import large volumes of
↵ data (around or more than 1 TiB). During the import, the target TiDB
↵ cluster cannot provide any service.
### "tidb": The "tidb" backend can also be used to import small volumes of
↵ data (less than 1 TiB). During the import, the target TiDB cluster
↵ can provide service normally. For the information about backend mode,
↵ refer to https://docs.pingcap.com/tidb/stable/tidb-lightning-
↵ backends.

backend = "local"
### Sets the temporary storage directory for the sorted key-value files. The
↵ directory must be empty, and the storage space must be greater than
↵ the size of the dataset to be imported. For better import performance
↵ , it is recommended to use a directory different from `data-source-
↵ dir` and use flash storage and exclusive I/O for the directory.
```

```
sorted-kv-dir = "${sorted-kv-dir}"

[mydumper]
### Directory of the data source
data-source-dir = "${data-path}" # Local or S3 path, such as 's3://my-bucket
    ↪ /sql-backup?region=us-west-2'

[tidb]
### The information of target cluster
host = ${host}           # For example, 172.16.32.1
port = ${port}          # For example, 4000
user = "${user_name}"   # For example, "root"
password = "${password}" # For example, "rootroot"
status-port = ${status-port} # During the import process, TiDB Lightning
    ↪ needs to obtain table schema information from the "Status Port" of
    ↪ TiDB, such as 10080.
pd-addr = "${ip}:${port}" # The address of the cluster's PD. TiDB Lightning
    ↪ obtains some information through PD, such as 172.16.31.3:2379. When
    ↪ backend = "local", you must correctly specify status-port and pd-addr
    ↪ . Otherwise, the import will encounter errors.
```

For more information about the configuration file, refer to [TiDB Lightning Configuration](#).

5.3.7.5 Step 4. Import the data

To start the import, run `tidb-lightning`. If you launch the program in the command line, the program might exit because of the `SIGHUP` signal. In this case, it is recommended to run the program with a `nohup` or `screen` tool.

If you import the data from S3, you need to pass in `SecretKey` and `AccessKey` of the account as environment variables. The account has the permission to access the S3 backend storage.

```
export AWS_ACCESS_KEY_ID=${access_key}
export AWS_SECRET_ACCESS_KEY=${secret_key}
nohup tiup tidb-lightning -config tidb-lightning.toml > nohup.out 2>&1 &
```

TiDB Lightning also supports reading credential files from `~/.aws/credentials`.

After the import is started, you can check the progress in one of the following ways:

- Search the `progress` keyword in the `grep` log, which is updated every 5 minutes by default.
- Use the Grafana dashboard. For details, see [TiDB Lightning Monitoring](#).
- Use web interface. For details, see [TiDB Lightning Web Interface](#).

After the import is completed, TiDB Lightning automatically exits. If the whole `↔ procedure completed` is in the last 5 lines of the log, it means that the import is successfully completed.

Note:

No matter whether the import is successful or not, the last line displays `tidb ↔ lightning exit`. It only means that TiDB Lightning has exited normally, not the completion of the task. If you encounter problems during the import process, refer to [TiDB Lightning FAQ](#) for troubleshooting.

5.3.8 Replicate Incremental Data between TiDB Clusters in Real Time

This document describes how to configure a TiDB cluster and its secondary MySQL or TiDB cluster, and how to replicate the incremental data from the primary cluster to the secondary cluster in real time.

If you need to configure a running TiDB cluster and its secondary cluster for replicating incremental data in real time, use the [Backup & Restore \(BR\)](#), [Dumpling](#) and [TiDB Binlog](#).

5.3.8.1 Implementation principles

Each transaction written to TiDB is allocated a unique commit timestamp (commit TS). Through this TS, you can get the global consistency status of a TiDB cluster.

The cluster data is exported using BR or Dumpling at a globally consistent point in time. Then starting from this point in time, TiDB Binlog is used to replicate incremental data. That is, the replication process is divided into two stages: full replication and incremental replication.

1. Perform a full backup and get the commit TS of the backup data.
2. Perform incremental replication. Make sure that the start time of incremental replication is the commit TS of the backup data.

Note:

The commit TS obtained after exporting the backup data is a closed interval. The initial-commit-ts obtained after starting the replication process using TiDB Binlog is an open interval.

5.3.8.2 Replication process

Suppose that the existing cluster A works properly. First, you need to create a new cluster B as the secondary cluster of cluster A and then replicate the incremental data in cluster A to cluster B in real time. See the following steps for instruction.

5.3.8.2.1 Step 1. Enable TiDB Binlog

Make sure that TiDB Binlog has been deployed and enabled in cluster A.

5.3.8.2.2 Step 2. Export all cluster data

1. Export the data in cluster A (with global consistency ensured) to the specified path by using any of the following tools:

- Use [BR for full backup](#)
- Use [Dumpling to import full data](#)

2. Obtain a globally consistent timestamp `COMMIT_TS`:

- Use the `BR validate` command to obtain the backup timestamp. For example:

```
COMMIT_TS=`br validate decode --field="end-version" -s local:///
↳ home/tidb/backupdata | tail -n1`
```

- Or check the Dumpling metadata and obtain Pos (`COMMIT_TS`).

```
cat metadata
```

```
Started dump at: 2020-11-10 10:40:19
SHOW MASTER STATUS:
  Log: tidb-binlog
  Pos: 420747102018863124

Finished dump at: 2020-11-10 10:40:20
```

3. Export the data in cluster A to cluster B.

5.3.8.2.3 Step 3. Replicate incremental data

Modify the `drainer.toml` configuration file of TiDB Binlog by adding the following configuration to specify the `COMMIT_TS` from which TiDB Binlog starts replicating data to cluster B.

```
initial-commit-ts = COMMIT_TS
[syncer.to]
host = {the IP address of cluster B}
port = 3306
```

5.4 Advanced Migration

5.4.1 Continuous Replication from Databases that Use gh-ost or pt-osc

In production scenarios, table locking during DDL execution can block the reads from or writes to the database to a certain extent. Therefore, online DDL tools are often used to execute DDLs to minimize the impact on reads and writes. Common DDL tools are [gh-ost](#) and [pt-osc](#).

When using DM to migrate data from MySQL to TiDB, you can enable `online-ddl` to allow collaboration of DM and gh-ost or pt-osc.

For the detailed replication instructions, refer to the following documents by scenarios:

- [Migrate MySQL of Small Datasets to TiDB](#)
- [Migrate MySQL of Large Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

5.4.1.1 Enable online-ddl on DM

In the task configuration file of DM, set the global parameter `online-ddl` to `true`, as shown below:

```
### ----- Global configuration -----
#### ***** Basic configuration *****
name: test                # The name of the task. Should be globally
    ↪ unique.
task-mode: all            # The task mode. Can be set to `full`, `
    ↪ incremental`, or `all`.
shard-mode: "pessimistic" # The shard merge mode. Optional modes are `
    ↪ pessimistic` and `optimistic`. The `pessimistic` mode is used by
    ↪ default. After understanding the principles and restrictions of the "
    ↪ optimistic" mode, you can set it to the "optimistic" mode.
meta-schema: "dm_meta"   # The downstream database that stores the `meta`
    ↪ information.
online-ddl: true          # Enable online-ddl support on DM to support
    ↪ automatic processing of "gh-ost" and "pt-osc" for the upstream
    ↪ database.
```

5.4.1.2 Workflow after enabling online-ddl

After `online-ddl` is enabled on DM, the DDL statements generated by DM replicating gh-ost or pt-osc will change.

The workflow of gh-ost or pt-osc:

- Create a ghost table according to the table schema of the DDL real table.
- Apply DDLs on the ghost table.
- Replicate the data of the DDL real table to the ghost table.
- After the data are consistent between the two tables, use the rename statement to replace the real table with the ghost table.

The workflow of DM:

- Skip creating the ghost table downstream.
- Record DDLs applied to the ghost table.
- Replicate data only from the ghost table.
- Apply DDLs recorded downstream.

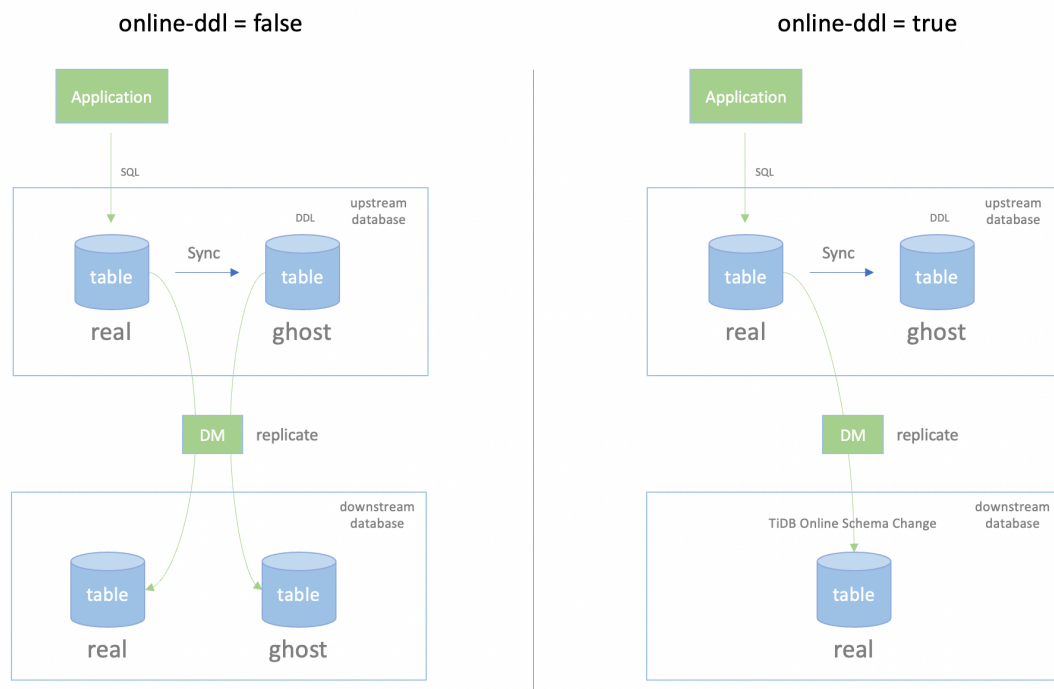

Figure 12: dm-online-ddl

The change in the workflow brings the following advantages:

- The downstream TiDB does not need to create and replicate the ghost table, saving the storage space and network transmission overhead.
- When you migrate and merge data from sharded tables, the RENAME operation is ignored for each sharded ghost table to ensure the correctness of the replication.

5.4.1.3 See also

[Working details for DM with online DDL tools](#)

5.4.2 Migrate Data to a Downstream TiDB Table with More Columns

This document provides the additional steps to be taken when you migrate data to a downstream TiDB table with more columns than the corresponding upstream table. For regular migration steps, see the following migration scenarios:

- [Migrate MySQL of Small Datasets to TiDB](#)
- [Migrate MySQL of Large Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

5.4.2.1 Use DM to migrate data to a downstream TiDB table with more columns

When replicating the upstream binlog, DM tries to use the current table schema of the downstream to parse the binlog and generate the corresponding DML statements. If the column number of the table in the upstream binlog does not match the column number in the downstream table schema, the following error occurs:

```
"errors": [
  {
    "ErrCode": 36027,
    "ErrClass": "sync-unit",
    "ErrScope": "internal",
    "ErrLevel": "high",
    "Message": "startLocation: [position: (mysql-bin.000001, 2022), gtid-
      ↪ set:09bec856-ba95-11ea-850a-58f2b4af5188:1-9 ], endLocation: [
      ↪ position: (mysql-bin.000001, 2022), gtid-set: 09bec856-ba95
      ↪ -11ea-850a-58f2b4af5188:1-9]: gen insert sqls failed, schema:
      ↪ log, table: messages: Column count doesn't match value count:
      ↪ 3 (columns) vs 2 (values)",
    "RawCause": "",
    "Workaround": ""
  }
]
```

The following is an example upstream table schema:

```
### Upstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
)
```

The following is an example downstream table schema:

```
### Downstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  `message` varchar(255) DEFAULT NULL, # This is the additional column that
  ↪ only exists in the downstream table.
  PRIMARY KEY (`id`)
)
```

When DM tries to use the downstream table schema to parse the binlog event generated by the upstream, DM reports the above `Column count doesn't match` error.

In such cases, you can use the `operate-schema` command to set a table schema for the table to be migrated from the data source. The specified table schema needs to correspond to the binlog event data to be replicated by DM. If you are migrating sharded tables, for each sharded table, you need to set a table schema in DM to parse binlog event data. The steps are as follows:

1. Create a SQL file in DM and add the `CREATE TABLE` statement that corresponds to the upstream table schema to the file. For example, save the following table schema to `log.messages.sql`.

```
# Upstream table schema
CREATE TABLE `messages` (
  `id` int(11) NOT NULL,
  PRIMARY KEY (`id`)
)
```

2. Use the `operate-schema` command to set the table schema for the table to be migrated from the data source (At this time, the data migration task should be in the Paused state due to the above `Column count doesn't match` error).

```
tiup dmctl --master-addr ${advertise-addr} operate-schema set -s ${
  ↪ source-id} ${task-name} -d ${database-name} -t ${table-name} ${
  ↪ schema-file}
```

The descriptions of parameters in this command are as follows:

Parameter Description

<u>Parameter</u>	<u>Description</u>
oper-schema	Manually set the schema information.

Parameter	Description
-----------	-------------

-s	Specifies the source. \$ ↪ { ↪ source ↪ - ↪ id ↪ } ↪ in- di- cates the source ID of MySQL data. \$ ↪ { ↪ task ↪ - ↪ name ↪ } ↪ in- di- cates the name of the synchronization task defined in the task ↪ . ↪ yaml
----	--

<u>Parameter</u>	<u>Description</u>
- d	Specifies the database.
\$	
↪ {	
↪ database	
↪ -	
↪ name	
↪ }	
↪	
	indicates the name of the upstream database.

Parameter	Description
-t	Specifies table. \$ ↪ { ↪ table ↪ - ↪ name ↪ } ↪ indicates the name of the upstream data table. \$ ↪ { ↪ schema ↪ - ↪ file ↪ } ↪ indicates the table schema file to be set.

For example:

```
tiup dmctl --master-addr 172.16.10.71:8261 operate-schema set -s mysql
  ↪ -01 task-test -d log -t message log.message.sql
```

3. Use the `resume-task` command to resume the migration task in the Paused state.

```
tiup dmctl --master-addr ${advertise-addr} resume-task ${task-name}
```

4. Use the `query-status` command to confirm that the data migration task is running correctly.

```
tiup dmctl --master-addr ${advertise-addr} query-status ${task-name}
```

5.4.3 Filter Binlog Events

This document describes how to filter binlog events when you use DM to perform continuous incremental data replication. For the detailed replication instructions, refer to the following documents by scenarios:

- [Migrate MySQL of Small Datasets to TiDB](#)
- [Migrate MySQL of Large Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

5.4.3.1 Configuration

To use binlog event filter, add a `filter` to the task configuration file of DM, as shown below:

```
filters:
  rule-1:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table"]
    sql-pattern: ["^DROP\\s+PROCEDURE", "^CREATE\\s+PROCEDURE"]
    action: Ignore
```

- `schema-pattern/table-pattern`: Filters matching schemas or tables
- `events`: Filters binlog events. Supported events are listed in the table below:

Event	Category	Description
all		Includes all events
all dml		Includes all DML events
all ddl		Includes all DDL events

Event	Category	Description
none		Includes no event
none ddl		Excludes all DDL events
none dml		Excludes all DML events
insert	DML	Insert DML event
update	DML	Update DML event
delete	DML	Delete DML event
create database	DDL	Create database event
drop database	DDL	Drop database event
create table	DDL	Create table event
create index	DDL	Create index event
drop table	DDL	Drop table event
truncate table	DDL	Truncate table event
rename table	DDL	Rename table event
drop index	DDL	Drop index event
alter table	DDL	Alter table event

- **sql-pattern:** Filters specified DDL SQL statements. The matching rule supports using a regular expression.
- **action:** Do or Ignore
 - **Do:** the allow list. A binlog event is replicated if meeting either of the following two conditions:
 - * The event matches the rule setting.
 - * sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.
 - **Ignore:** the block list. A binlog event is filtered out if meeting either of the following two conditions:
 - * The event matches the rule setting.
 - * sql-pattern has been specified and the SQL statement of the event matches any of the sql-pattern options.

If both **Do** and **Ignore** are configured, **Ignore** has higher priority over **Do**. That is, an event satisfying both **Ignore** and **Do** conditions will be filtered out.

5.4.3.2 Application scenarios

This section describes the application scenarios of binlog event filter.

5.4.3.2.1 Filter out all sharding deletion operations

To filter out all deletion operations, configure a **filter-table-rule** and a **filter-schema-rule**, as shown below:

```
filters:
  filter-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["truncate table", "drop table", "delete"]
    action: Ignore
  filter-schema-rule:
    schema-pattern: "test_*"
    events: ["drop database"]
    action: Ignore
```

5.4.3.2.2 Migrate only DML operations of sharded schemas and tables

To replicate only DML statements, configure two Binlog event filter rule, as shown below:

```
filters:
  do-table-rule:
    schema-pattern: "test_*"
    table-pattern: "t_*"
    events: ["create table", "all dml"]
    action: Do
  do-schema-rule:
    schema-pattern: "test_*"
    events: ["create database"]
    action: Do
```

5.4.3.2.3 Filter out SQL statements not supported by TiDB

To filter out SQL statements not supported by TiDB, configure a `filter-procedure-`
↪ `rule`, as shown below:

```
filters:
  filter-procedure-rule:
    schema-pattern: "*"
    sql-pattern: [".*\s+DROP\s+PROCEDURE", ".*\s+CREATE\s+PROCEDURE", "
    ↪ ALTER\s+TABLE[\s\S]*ADD\s+PARTITION", "ALTER\s+TABLE[\s\S]*
    ↪ DROP\s+PARTITION"]
    action: Ignore
```

Warning:

To avoid filtering out data that needs to be migrated, configure the global filtering rule as strictly as possible.

5.4.3.3 See also

[Filter Binlog Events Using SQL Expressions](#)

5.4.4 Filter DML Events Using SQL Expressions

This document introduces how to filter binlog events using SQL expressions when you use DM to perform continuous incremental data replication. For the detailed replication instruction, refer to the following documents:

- [Migrate MySQL of Small Datasets to TiDB](#)
- [Migrate MySQL of Large Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Small Datasets to TiDB](#)
- [Migrate and Merge MySQL Shards of Large Datasets to TiDB](#)

When performing incremental data replication, you can use the [Binlog Event Filter](#) to filter certain types of binlog events. For example, you can choose not to replicate `DELETE` events to the downstream for the purposes like archiving and auditing. However, the Binlog Event Filter cannot determine whether to filter the `DELETE` event of a row that requires finer granularity.

To address the issue, since v2.0.5, DM supports using `binlog value filter` in incremental data replication to filter data. Among the DM-supported and `ROW`-formatted binlog, the binlog events carry values of all columns, and you can configure SQL expressions based on these values. If the expression calculates a row change as `TRUE`, DM does not replicate this row change to the downstream.

Similar to [Binlog Event Filter](#), you need to configure `binlog value filter` in the task configuration file. For details, see the following configuration example. For the advanced task configuration and the description, refer to [DM advanced task configuration file](#).

```
name: test
task-mode: all

mysql-instances:
- source-id: "mysql-replica-01"
  expression-filters: ["even_c"]

expression-filter:
  even_c:
    schema: "expr_filter"
```

```
table: "tbl"
insert-value-expr: "c % 2 = 0"
```

In the above configuration example, the `even_c` rule is configured and referenced by the data source `mysql-replica-01`. According to this rule, for the `tbl` table in the `expr_filter` \leftrightarrow schema, when an even number is inserted into the `c` column (`c % 2 = 0`), this `insert` statement is not replicated to the downstream. The following example shows the effect of this rule.

Incrementally insert the following data in the upstream data source:

```
INSERT INTO tbl(id, c) VALUES (1, 1), (2, 2), (3, 3), (4, 4);
```

Then query the `tbl` table on downstream. You can see that only the rows with odd numbers on `c` are replicated.

```
MySQL [test]> select * from tbl;
+-----+-----+
| id  | c  |
+-----+-----+
|  1  |  1 |
|  3  |  3 |
+-----+-----+
2 rows in set (0.001 sec)
```

5.4.4.1 Configuration parameters and description

- **schema**: The name of the upstream schema to match. Wildcard matching or regular matching is not supported.
- **table**: The name of the upstream table to match. Wildcard matching or regular matching is not supported.
- **insert-value-expr**: Configures an expression that takes effect on values carried by the `INSERT` type binlog events (`WRITE_ROWS_EVENT`). You cannot use this expression together with `update-old-value-expr`, `update-new-value-expr` or `delete-value-expr` in the same configuration item.
- **update-old-value-expr**: Configures an expression that takes effect on the old values carried by the `UPDATE` type binlog events (`UPDATE_ROWS_EVENT`). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.
- **update-new-value-expr**: Configures an expression that takes effect on the new values carried by the `UPDATE` type binlog events (`UPDATE_ROWS_EVENT`). You cannot use this expression together with `insert-value-expr` or `delete-value-expr` in the same configuration item.

- `delete-value-expr`: Configures an expression that takes effect on values carried by the `DELETE` type binlog events (`DELETE_ROWS_EVENT`). You cannot use this expression together with `insert-value-expr`, `update-old-value-expr` or `update-new-value-expr`.

Note:

- You can configure `update-old-value-expr` and `update-new-value-expr` together.
- When `update-old-value-expr` and `update-new-value-expr` are configured together, the rows whose “update + old values” meet `update-old-value-expr` and whose “update + new values” meet `update-new-value-expr` are filtered.
- When one of `update-old-value-expr` and `update-new-value-expr` is configured, the configured expression determines whether to filter the **entire row change**, which means that the deletion of old values and the insertion of new values are filtered as a whole.

You can use the SQL expression on one column or on multiple columns. You can also use the SQL functions supported by TiDB, such as `c % 2 = 0`, `a*a + b*b = c*c`, and `ts > NOW()`.

The `TIMESTAMP` default time zone is the time zone specified in the task configuration file. The default value is the time zone of the downstream. You can explicitly specify the time zone in a way like `c_timestamp = '2021-01-01 12:34:56.5678+08:00'`.

You can configure multiple filtering rules under the `expression-filter` configuration item. The upstream data source references the required rule in `expression-filters` to make it effective. When multiple rules are used, if **any** one of the rules are matched, the entire row change is filtered.

Note:

Configuring too many expression filtering rules increases the calculation overhead of DM and slows down the data replication.

6 Maintain

6.1 Security

6.1.1 Best Practices for TiDB Security Configuration

The security of TiDB is crucial for protecting data integrity and confidentiality. This document provides guidelines for configuring TiDB clusters securely during deployment. By following these best practices, you can effectively reduce potential security risks, prevent data breaches, and ensure the continuous, stable, and reliable operation of your TiDB database system.

Note:

This document offers general recommendations on TiDB security configurations. PingCAP does not guarantee the completeness or accuracy of the information, and it assumes no responsibility for any issues arising from the use of this guide. Users should assess these recommendations based on their specific needs and consult professionals for tailored advice.

6.1.1.1 Set the initial password for the root user

By default, the root user in a newly created TiDB cluster has no password, which poses a potential security risk. If a password is not set, anyone can attempt to log in to the TiDB database as the root user, potentially gaining access to and modifying data.

To avoid this risk, it is recommended to set a root password during deployment:

- For deployments using TiUP, refer to [Deploy TiDB Cluster Using TiUP](#) to generate a random password for the root user.
- For deployments using TiDB Operator, refer to [Set initial account and password](#) to set the root password.

6.1.1.2 Change the default Grafana password

TiDB installation includes the Grafana component by default, and the default username and password are typically `admin/admin`. If the password is not changed promptly, attackers could exploit this to gain control of the system.

It is recommended to immediately change the Grafana password to a strong one during the TiDB deployment, and regularly update the password to ensure system security. Here are the steps to change the Grafana password:

- Upon first login to Grafana, follow the prompts to change the password.

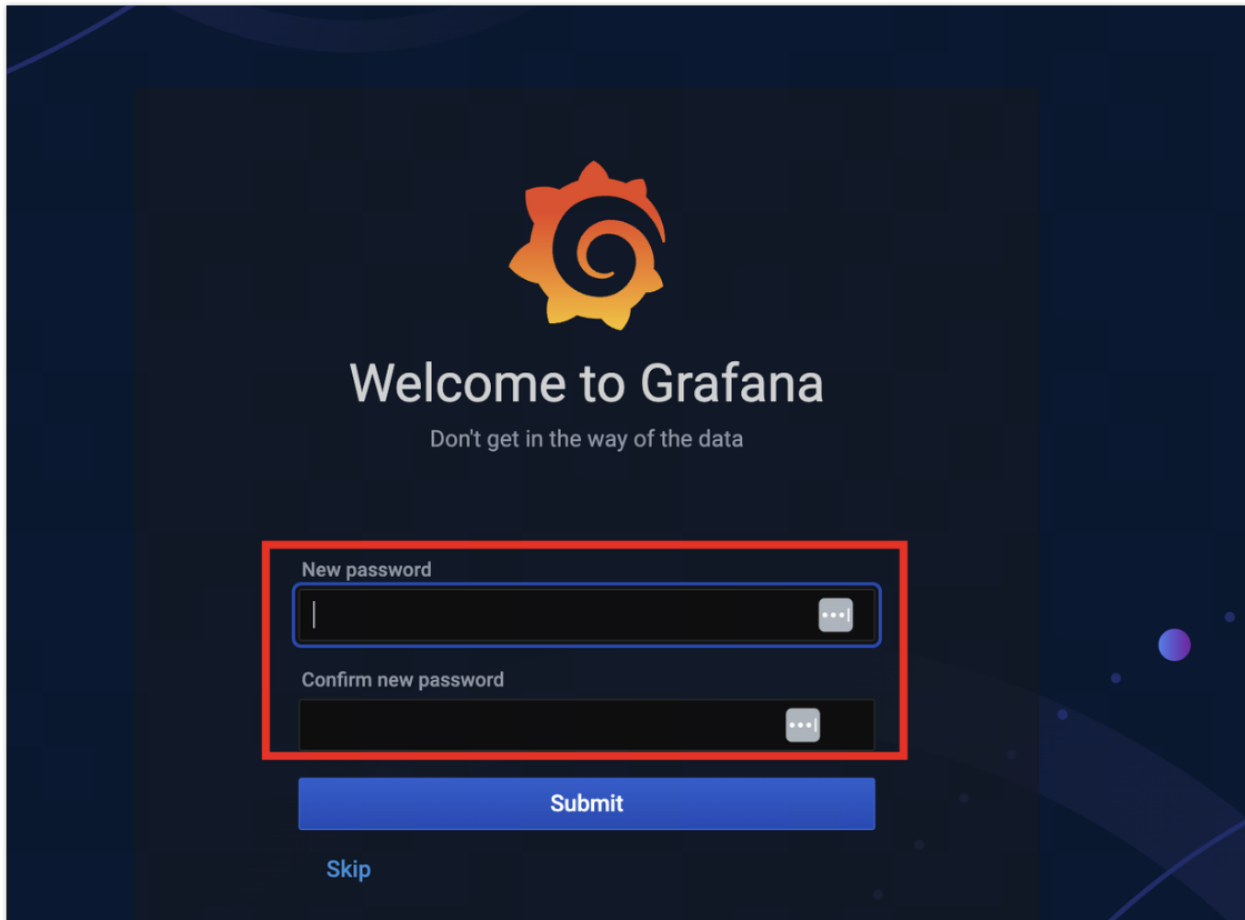

Figure 13: Grafana Password Reset Guide

- Access the Grafana personal configuration center to change the password.

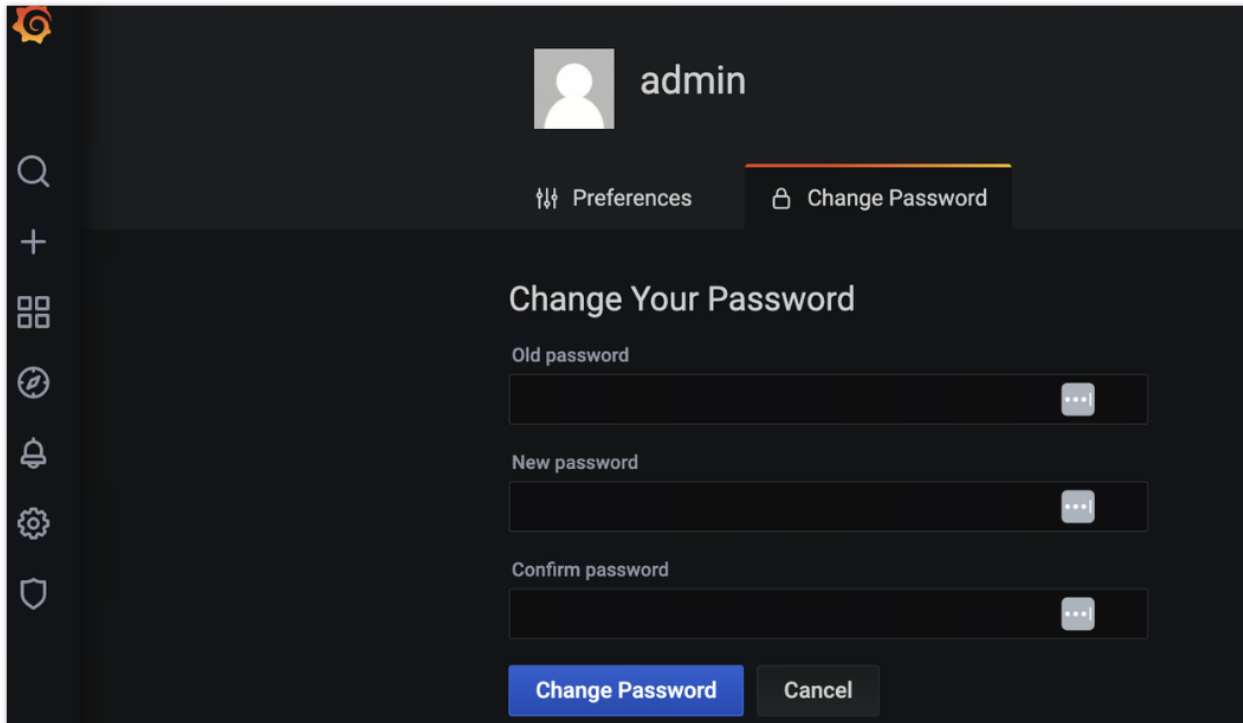

Figure 14: Grafana Password Reset Guide

6.1.1.3 Enhance TiDB Dashboard security

6.1.1.3.1 Use a least privilege user

TiDB Dashboard shares the account system with TiDB SQL users, and TiDB Dashboard authorization is based on TiDB SQL user permissions. TiDB Dashboard requires minimal permissions and can even operate with read-only access.

To enhance security, it is recommended to create a **least-privilege SQL user** for accessing the TiDB Dashboard and to avoid using high-privilege users.

6.1.1.3.2 Restrict access control

By default, TiDB Dashboard is designed for trusted users. The default port includes additional API interfaces besides TiDB Dashboard. If you want to allow access to TiDB Dashboard from external networks or untrusted users, take the following measures to avoid security vulnerabilities:

- Use a firewall or other mechanisms to restrict the default 2379 port to trusted domains, preventing access by external users.

Note:

TiDB, TiKV, and other components need to communicate with the PD component via the PD client port. Do not block internal network access between components, which will make the cluster unavailable.

- **Configure a reverse proxy** to securely provide TiDB Dashboard services to external users on a different port.

6.1.1.4 Protect internal ports

By default, TiDB installation includes several privileged interfaces for inter-component communication. These ports typically do not need to be accessible to users, because they are primarily for internal communication. Exposing these ports on public networks increases the attack surface, violates the principle of least privilege, and raises the risk of security vulnerabilities. The following table lists the default listening ports in a TiDB cluster:

Component	Default port	Protocol
TiDB	4000	MySQL
TiDB	10080	HTTP
TiKV	20160	Protocol
TiKV	20180	HTTP
PD	2379	HTTP/Protocol
PD	2380	Protocol
TiFlash	3930	Protocol
TiFlash	20170	Protocol
TiFlash	20292	HTTP
TiFlash	8234	HTTP
TiFlow	8261	HTTP
TiFlow	8291	HTTP
TiFlow	8262	HTTP
TiFlow	8300	HTTP
TiDB Lightning	8289	HTTP
TiDB Operator	6060	HTTP
TiDB Dashboard	2379	HTTP
TiDB Binlog	8250	HTTP
TiDB Binlog	8249	HTTP
TMS	8082	HTTP
TEM	8080	HTTP
TEM	8000	HTTP
TEM	4110	HTTP
TEM	4111	HTTP
TEM	4112	HTTP
TEM	4113	HTTP

Component	Default port	Protocol
TEM	4124	HTTP
Prometheus	9090	HTTP
Grafana	3000	HTTP
AlertManager	9093	HTTP
AlertManager	9094	Protocol
Node Exporter	9100	HTTP
Blackbox Exporter	9115	HTTP
NG Monitoring	12020	HTTP

It is recommended to only expose the 4000 port for the database and the 9000 port for the Grafana dashboard to ordinary users, while restricting access to other ports using network security policies or firewalls. The following is an example of using `iptables` to restrict port access:

```
### Allow internal port communication from the whitelist of component IP
↳ addresses
sudo iptables -A INPUT -s internal IP address range -j ACCEPT

### Only open ports 4000 and 9000 to external users
sudo iptables -A INPUT -p tcp --dport 4000 -j ACCEPT
sudo iptables -A INPUT -p tcp --dport 9000 -j ACCEPT

### Deny all other traffic by default
sudo iptables -P INPUT DROP
```

If you need to access TiDB Dashboard, it is recommended to [configure a reverse proxy](#) to securely provide services to external networks on a separate port.

6.1.1.5 Resolving false positives from third-party MySQL vulnerability scanners

Most vulnerability scanners detect MySQL vulnerabilities based on version information. Because TiDB is MySQL protocol-compatible but not MySQL itself, version-based vulnerability scans might lead to false positives. It is recommended to focus vulnerability scans on principle-based assessments. If compliance scanning tools require a specific MySQL version, you can [modify the server version number](#) to meet the requirement.

By changing the server version number, you can avoid false positives from vulnerability scanners. The `server-version` value is used by TiDB nodes to verify the current TiDB version. Before upgrading the TiDB cluster, ensure that the `server-version` value is either empty or the actual version of TiDB to avoid unexpected behavior.

6.1.2 Enable TLS between TiDB Clients and Servers

Non-encrypted connection between TiDB's server and clients is allowed by default, which enables third parties that monitor channel traffic to know the data sent and received between the server and the client, including but not limited to query content, query results, and so on. If a channel is untrustworthy (such as if the client is connected to the TiDB server via a public network), then a non-encrypted connection is prone to information leakage. In this case, for security reasons, it is recommended to require an encrypted connection.

The TiDB server supports the encrypted connection based on the TLS (Transport Layer Security). The protocol is consistent with MySQL encrypted connections and is directly supported by existing MySQL clients such as MySQL Client, MySQL Shell and MySQL drivers. TLS is sometimes referred to as SSL (Secure Sockets Layer). Because the SSL protocol has [known security vulnerabilities](#), TiDB does not support SSL. TiDB supports the following protocols: TLSv1.0, TLSv1.1, TLSv1.2 and TLSv1.3.

When an encrypted connection is used, the connection has the following security properties:

- Confidentiality: the traffic plaintext is encrypted to avoid eavesdropping
- Integrity: the traffic plaintext cannot be tampered
- Authentication: (optional) the client can verify the identity of the server and the server can verify the identity of the client to avoid man-in-the-middle attacks

To use connections secured with TLS, you first need to configure the TiDB server to enable TLS. Then you need to configure the client application to use TLS. Most client libraries enable TLS automatically when the server has TLS support configured correctly.

Similar to MySQL, TiDB allows TLS and non-TLS connections on the same TCP port. For a TiDB server with TLS enabled, you can choose to securely connect to the TiDB server through an encrypted connection, or to use an unencrypted connection. You can use the following ways to require the use of secure connections:

- Configure the launch parameter `--require-secure-transport` to require secure connections to the TiDB server for all users.
- Specify `REQUIRE SSL` when you create a user (`create user`), or modify an existing user (`alter user`), which is to specify that specified users must use the encrypted connection to access TiDB. The following is an example of creating a user:

```
CREATE USER 'u1'@'%' IDENTIFIED BY 'my_random_password' REQUIRE SSL;
```

Note:

If the login user has configured using the [TiDB Certificate-Based Authentication for Login](#), the user is implicitly required to enable the encrypted connection to TiDB.

6.1.2.1 Configure TiDB server to use secure connections

See the following descriptions about the related parameters to enable secure connections:

- **auto-tls**: enables automatic certificate generation (since v5.2.0)
- **ssl-cert**: specifies the file path of the SSL certificate
- **ssl-key**: specifies the private key that matches the certificate
- **ssl-ca**: (optional) specifies the file path of the trusted CA certificate
- **tls-version**: (optional) specifies the minimum TLS version, e.g. “TLSv1.2”

auto-tls allows secure connections but does not provide client certificate validation. For certificate validation, and to control how certificates are generated, see the advice on configuring the **ssl-cert**, **ssl-key** and **ssl-ca** variables below.

To enable secure connections with your own certificates in the TiDB server, you must specify both of the **ssl-cert** and **ssl-key** parameters in the configuration file when you start the TiDB server. You can also specify the **ssl-ca** parameter for client authentication (see [Enable authentication](#)).

All the files specified by the parameters are in PEM (Privacy Enhanced Mail) format. Currently, TiDB does not support the import of a password-protected private key, so it is required to provide a private key file without a password. If the certificate or private key is invalid, the TiDB server starts as usual, but the client cannot connect to the TiDB server through an encrypted connection.

If the certificate parameters are correct, TiDB outputs `secure connection is enabled` when started; otherwise, it outputs `secure connection is NOT ENABLED`.

For TiDB versions earlier than v5.2.0, you can use `mysql_ssl_rsa_setup --datadir ↪ =./certs` to generate certificates. The `mysql_ssl_rsa_setup` tool is a part of MySQL Server.

6.1.2.2 Configure the MySQL client to use encrypted connections

The client of MySQL 5.7 or later versions attempts to establish an encrypted connection by default. If the server does not support encrypted connections, it automatically returns to unencrypted connections. The client of MySQL earlier than version 5.7 uses the unencrypted connection by default.

You can change the connection behavior of the client using the following **--ssl-mode** parameters:

- **--ssl-mode=REQUIRED**: The client requires an encrypted connection. The connection cannot be established if the server side does not support encrypted connections.
- In the absence of the **--ssl-mode** parameter: The client attempts to use an encrypted connection, but the encrypted connection cannot be established if the server side does not support encrypted connections. Then the client uses an unencrypted connection.
- **--ssl-mode=DISABLED**: The client uses an unencrypted connection.

MySQL 8.0 clients have two SSL modes in addition to this parameter:

- `--ssl-mode=VERIFY_CA`: Validates the certificate from the server against the CA that requires `--ssl-ca`.
- `--ssl-mode=VERIFY_IDENTITY`: The same as `VERIFY_CA`, but also validating whether the hostname you are connecting to matches the certificate.

For more information, see [Client-Side Configuration for Encrypted Connections](#) in MySQL.

6.1.2.3 Enable authentication

If the `ssl-ca` parameter is not specified in the TiDB server or MySQL client, the client or the server does not perform authentication by default and cannot prevent man-in-the-middle attack. For example, the client might “securely” connect to a disguised client. You can configure the `ssl-ca` parameter for authentication in the server and client. Generally, you only need to authenticate the server, but you can also authenticate the client to further enhance the security.

- To authenticate the TiDB server from the MySQL client:
 1. Specify the `ssl-cert` and `ssl-key` parameters in the TiDB server.
 2. Specify the `--ssl-ca` parameter in the MySQL client.
 3. Specify the `--ssl-mode` to `VERIFY_CA` at least in the MySQL client.
 4. Make sure that the certificate (`ssl-cert`) configured in the TiDB server is signed by the CA specified by the client `--ssl-ca` parameter; otherwise, the authentication fails.
- To authenticate the MySQL client from the TiDB server:
 1. Specify the `ssl-cert`, `ssl-key`, and `ssl-ca` parameters in the TiDB server.
 2. Specify the `--ssl-cert` and `--ssl-key` parameters in the client.
 3. Make sure the server-configured certificate and the client-configured certificate are both signed by the `ssl-ca` specified by the server.
- To perform mutual authentication, meet both of the above requirements.

By default, the server-to-client authentication is optional. Even if the client does not present its certificate of identification during the TLS handshake, the TLS connection can be still established. You can also require the client to be authenticated by specifying `require` \leftrightarrow `x509` when creating a user (`create user`), granting permissions (`grant`), or modifying an existing user (`alter user`). The following is an example of creating a user:

```
create user 'u1'@'%' require x509;
```

Note:

If the login user has configured using the [TiDB Certificate-Based Authentication for Login](#), the user is implicitly required to enable the encrypted connection to TiDB.

6.1.2.4 Check whether the current connection uses encryption

Use the `SHOW STATUS LIKE "%Ssl%";` statement to get the details of the current connection, including whether encryption is used, the encryption protocol used by encrypted connections, the TLS version number and so on.

See the following example of the result in an encrypted connection. The results change according to different TLS versions or encryption protocols supported by the client.

```
mysql> SHOW STATUS LIKE "%Ssl%";
.....
| Ssl_verify_mode | 5 |
| Ssl_version     | TLSv1.2 |
| Ssl_cipher      | ECDHE-RSA-AES128-GCM-SHA256 |
.....
```

For the official MySQL client, you can also use the `STATUS` or `\s` statement to view the connection status:

```
mysql> \s
...
SSL: Cipher in use is ECDHE-RSA-AES128-GCM-SHA256
...
```

6.1.2.5 Supported TLS versions, key exchange protocols, and encryption algorithms

The TLS versions, key exchange protocols and encryption algorithms supported by TiDB are determined by the official Golang libraries.

The crypto policy for your operating system and the client library you are using might also impact the list of supported protocols and cipher suites.

6.1.2.5.1 Supported TLS versions

- TLSv1.0 (disabled by default)
- TLSv1.1

- TLSv1.2
- TLSv1.3

The `tls-version` configuration option can be used to limit the TLS versions that can be used.

The actual TLS versions that can be used depend on the OS crypto policy, MySQL client version and the SSL/TLS library that is used by the client.

6.1.2.5.2 Supported key exchange protocols and encryption algorithms

- TLS_RSA_WITH_AES_128_CBC_SHA
- TLS_RSA_WITH_AES_256_CBC_SHA
- TLS_RSA_WITH_AES_128_CBC_SHA256
- TLS_RSA_WITH_AES_128_GCM_SHA256
- TLS_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA
- TLS_ECDHE_RSA_WITH_AES_256_CBC_SHA
- TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_CBC_SHA256
- TLS_ECDHE_RSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256
- TLS_ECDHE_RSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_ECDSA_WITH_AES_256_GCM_SHA384
- TLS_ECDHE_RSA_WITH_CHACHA20_POLY1305_SHA256
- TLS_ECDHE_ECDSA_WITH_CHACHA20_POLY1305_SHA256
- TLS_AES_128_GCM_SHA256
- TLS_AES_256_GCM_SHA384
- TLS_CHACHA20_POLY1305_SHA256

6.1.2.6 Reload certificate, key, and CA

To replace the certificate, the key or CA, first replace the corresponding files, then execute the `ALTER INSTANCE RELOAD TLS` statement on the running TiDB instance to reload the certificate (`ssl-cert`), the key (`ssl-key`), and the CA (`ssl-ca`) from the original configuration path. In this way, you do not need to restart the TiDB instance.

The newly loaded certificate, key, and CA take effect on the connection that is established after the statement is successfully executed. The connection established before the statement execution is not affected.

6.1.2.7 Monitoring

Since TiDB v5.2.0, you can use the `Ssl_server_not_after` and `Ssl_server_not_before` status variables to monitor the start and end dates of the validity of the certificate.

```
SHOW GLOBAL STATUS LIKE 'Ssl\_server\_not\_%';
```

```
+-----+-----+
| Variable_name      | Value                |
+-----+-----+
| Ssl_server_not_after | Nov 28 06:42:32 2021 UTC |
| Ssl_server_not_before | Aug 30 06:42:32 2021 UTC |
+-----+-----+
2 rows in set (0.0076 sec)
```

6.1.2.8 See also

- [Enable TLS Between TiDB Components.](#)

6.1.3 Enable TLS Between TiDB Components

This document describes how to enable encrypted data transmission between components within a TiDB cluster. Once enabled, encrypted transmission is used between the following components:

- TiDB and TiKV; TiDB and PD
- TiKV and PD
- TiDB Control and TiDB; TiKV Control and TiKV; PD Control and PD
- Internal communication within each TiKV, PD, TiDB cluster

Currently, it is not supported to only enable encrypted transmission of some specific components.

6.1.3.1 Configure and enable encrypted data transmission

1. Prepare certificates.

It is recommended to prepare a server certificate for TiDB, TiKV, and PD separately. Make sure that these components can authenticate each other. The Control tools of TiDB, TiKV, and PD can choose to share one client certificate.

You can use tools like `openssl`, `easy-rsa` and `cfssl` to generate self-signed certificates.

If you choose `openssl`, you can refer to [generating self-signed certificates](#).

2. Configure certificates.

To enable mutual authentication among TiDB components, configure the certificates of TiDB, TiKV, and PD as follows.

- TiDB

Configure in the configuration file or command-line arguments:

```
[security]
# Path of the file that contains list of trusted SSL CAs for
  ↳ connection with cluster components.
cluster-ssl-ca = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format for
  ↳ connection with cluster components.
cluster-ssl-cert = "/path/to/tidb-server.pem"
# Path of the file that contains X509 key in PEM format for
  ↳ connection with cluster components.
cluster-ssl-key = "/path/to/tidb-server-key.pem"
```

- TiKV

Configure in the configuration file or command-line arguments, and set the corresponding URL to https:

```
[security]
## The path for certificates. An empty string means that secure
  ↳ connections are disabled.
# Path of the file that contains a list of trusted SSL CAs. If it
  ↳ is set, the following settings `cert_path` and `key_path`
  ↳ are also needed.
ca-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/tikv-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/tikv-server-key.pem"
```

- PD

Configure in the configuration file or command-line arguments, and set the corresponding URL to https:

```
[security]
## The path for certificates. An empty string means that secure
  ↳ connections are disabled.
# Path of the file that contains a list of trusted SSL CAs. If it
  ↳ is set, the following settings `cert_path` and `key_path`
  ↳ are also needed.
cacert-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/pd-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/pd-server-key.pem"
```

- TiFlash (New in v4.0.5)

Configure in the `tiflash.toml` file, and change the `http_port` item to `https_port`:

```
toml [security] ## The path for certificates. An empty string means
↳ that secure connections are disabled. # Path of the file that
↳ contains a list of trusted SSL CAs. If it is set, the following
↳ settings `cert_path` and `key_path` are also needed. ca_path
↳ = "/path/to/ca.pem" # Path of the file that contains X509
↳ certificate in PEM format. cert_path = "/path/to/tiflash-server
↳ .pem" # Path of the file that contains X509 key in PEM format.
↳ key_path = "/path/to/tiflash-server-key.pem"
```

Configure in the `tiflash-learner.toml` file:

```
[security]
# Path of the file that contains a list of trusted SSL CAs. If it
↳ is set, the following settings `cert_path` and `key_path`
↳ are also needed.
ca-path = "/path/to/ca.pem"
# Path of the file that contains X509 certificate in PEM format.
cert-path = "/path/to/tiflash-server.pem"
# Path of the file that contains X509 key in PEM format.
key-path = "/path/to/tiflash-server-key.pem"
```

- TiCDC

Configure in the command-line arguments and set the corresponding URL to `https`:

```
cdc server --pd=https://127.0.0.1:2379 --log-file=ticdc.log --addr
↳ =0.0.0.0:8301 --advertise-addr=127.0.0.1:8301 --ca=/path/to/
↳ ca.pem --cert=/path/to/ticdc-cert.pem --key=/path/to/ticdc-
↳ key.pem
```

Now, encrypted transmission among TiDB components is enabled.

Note:

After enabling encrypted transmission in a TiDB cluster, if you need to connect to the cluster using `tidb-ctl`, `tikv-ctl`, or `pd-ctl`, specify the client certificate. For example:

```
./tidb-ctl -u https://127.0.0.1:10080 --ca /path/to/ca.pem --ssl-cert /
↳ path/to/client.pem --ssl-key /path/to/client-key.pem
```

```
tiup ctl:<cluster-version> pd -u https://127.0.0.1:2379 --cacert /path/  
  ↪ to/ca.pem --cert /path/to/client.pem --key /path/to/client-key.  
  ↪ pem
```

```
./tikv-ctl --host="127.0.0.1:20160" --ca-path="/path/to/ca.pem" --cert-  
  ↪ path="/path/to/client.pem" --key-path="/path/to/client-key.pem"
```

6.1.3.1.1 Verify component caller's identity

The Common Name is used for caller verification. In general, the callee needs to verify the caller's identity, in addition to verifying the key, the certificates, and the CA provided by the caller. For example, TiKV can only be accessed by TiDB, and other visitors are blocked even though they have legitimate certificates.

To verify component caller's identity, you need to mark the certificate user identity using `Common Name` when generating the certificate, and to check the caller's identity by configuring the `Common Name` list for the callee.

- TiDB

Configure in the configuration file or command-line arguments:

```
[security]  
cluster-verify-cn = [  
  "TiDB-Server",  
  "TiKV-Control",  
]
```

- TiKV

Configure in the configuration file or command-line arguments:

```
[security]  
cert-allowed-cn = [  
  "TiDB-Server", "PD-Server", "TiKV-Control", "RawKvClient1",  
]
```

- PD

Configure in the configuration file or command-line arguments:

```
[security]  
cert-allowed-cn = ["TiKV-Server", "TiDB-Server", "PD-Control"]
```

- TiCDC

Configure in the command-line arguments:

```
cdc server --pd=https://127.0.0.1:2379 --log-file=ticdc.log --addr
  ↪ =0.0.0.0:8301 --advertise-addr=127.0.0.1:8301 --ca=/path/to/ca.
  ↪ pem --cert=/path/to/ticdc-cert.pem --key=/path/to/ticdc-key.pem
  ↪ --cert-allowed-cn="client1,client2"
```

- TiFlash (New in v4.0.5)

Configure in the `tiflash.toml` file or command-line arguments:

```
[security]
cert_allowed_cn = ["TiKV-Server", "TiDB-Server"]
```

Configure in the `tiflash-learner.toml` file:

```
[security]
cert-allowed-cn = ["PD-Server", "TiKV-Server", "TiFlash-Server"]
```

6.1.3.1.2 Reload certificates

To reload the certificates and the keys, TiDB, PD, TiKV, and all kinds of clients reread the current certificates and the key files each time a new connection is created. Currently, you cannot reload the CA certificate.

6.1.3.2 See also

- [Enable TLS Between TiDB Clients and Servers](#)

6.1.4 Generate Self-Signed Certificates

Note:

To enable TLS between clients and servers, you only need to set `auto-tls`.

This document provides an example of using `openssl` to generate a self-signed certificate. You can also generate certificates and keys that meet requirements according to your demands.

Assume that the topology of the instance cluster is as follows:

Name	Host IP	Services
node1	172.16.10.11	PD1, TiDB1

Name	Host IP	Services
node2	172.16.10.12	PD2
node3	172.16.10.13	PD3
node4	172.16.10.14	TiKV1
node5	172.16.10.15	TiKV2
node6	172.16.10.16	TiKV3

6.1.4.1 Install OpenSSL

- For Debian or Ubuntu OS:

```
apt install openssl
```

- For RedHat or CentOS OS:

```
yum install openssl
```

You can also refer to OpenSSL's official [download document](#) for installation.

6.1.4.2 Generate the CA certificate

A certificate authority (CA) is a trusted entity that issues digital certificates. In practice, contact your administrator to issue the certificate or use a trusted CA. CA manages multiple certificate pairs. Here you only need to generate an original pair of certificates as follows.

1. Generate the root key:

```
openssl genrsa -out root.key 4096
```

2. Generate root certificates:

```
openssl req -new -x509 -days 1000 -key root.key -out root.crt
```

3. Validate root certificates:

```
openssl x509 -text -in root.crt -noout
```

6.1.4.3 Issue certificates for individual components

This section describes how to issue certificates for individual components.

6.1.4.3.1 Certificates that might be used in the cluster

- tidb-server certificate: used by TiDB to authenticate TiDB for other components and clients
- tikv-server certificate: used by TiKV to authenticate TiKV for other components and clients
- pd-server certificate: used by PD to authenticate PD for other components and clients
- client certificate: used to authenticate the clients from PD, TiKV and TiDB, such as `pd-ctl`, `tikv-ctl`

6.1.4.3.2 Issue certificates to TiKV instances

To issue a certificate to a TiKV instance, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out tikv.key 2048
```

2. Make a copy of the OpenSSL configuration template file (Refer to the actual location of your template file because it might have more than one location):

```
cp /usr/lib/ssl/openssl.cnf .
```

If you do not know the actual location, look for it in the root directory:

```
find / -name openssl.cnf
```

3. Edit `openssl.cnf`, add `req_extensions = v3_req` under the `[req]` field, and add `subjectAltName = @alt_names` under the `[v3_req]` field. Finally, create a new field and edit the information of SAN.

```
[ alt_names ]
IP.1 = 127.0.0.1
IP.2 = 172.16.10.14
IP.3 = 172.16.10.15
IP.4 = 172.16.10.16
```

4. Save the `openssl.cnf` file, and generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key tikv.key -out tikv.csr -config openssl.cnf
```

5. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA root.crt -CAkey root.key -  
  ↪ CACreateserial -in tikv.csr -out tikv.crt -extensions v3_req -  
  ↪ extfile openssl.cnf
```

6. Verify that the certificate includes the SAN field (optional):

```
openssl x509 -text -in tikv.crt -noout
```

7. Confirm that the following files exist in your current directory:

```
root.crt  
tikv.crt  
tikv.key
```

The process of issuing certificates for other TiDB components is similar and will not be repeated in this document.

6.1.4.3.3 Issue certificates for clients

To issue a certificate to a client, perform the following steps:

1. Generate the private key corresponding to the certificate:

```
openssl genrsa -out client.key 2048
```

2. Generate the certificate request file (in this step, you can also assign a Common Name to the certificate, which is used to allow the server to validate the identity of the client. Each component does not enable the validation by default, and you can enable it in the configuration file):

```
openssl req -new -key client.key -out client.csr
```

3. Issue and generate the certificate:

```
openssl x509 -req -days 365 -CA root.crt -CAkey root.key -  
  ↪ CACreateserial -in client.csr -out client.crt
```

6.1.5 Encryption at Rest

Note:

If your cluster is deployed on AWS and uses the EBS storage, it is recommended to use the EBS encryption. See [AWS documentation - EBS Encryption](#). You are using the non-EBS storage on AWS such as the local NVMe storage, it is recommended to use encryption at rest introduced in this document.

Encryption at rest means that data is encrypted when it is stored. For databases, this feature is also referred to as TDE (transparent data encryption). This is opposed to encryption in flight (TLS) or encryption in use (rarely used). Different things could be doing encryption at rest (SSD drive, file system, cloud vendor, etc), but by having TiKV do the encryption before storage this helps ensure that attackers must authenticate with the database to gain access to data. For example, when an attacker gains access to the physical machine, data cannot be accessed by copying files on disk.

6.1.5.1 Encryption support in different TiDB components

In a TiDB cluster, different components use different encryption methods. This section introduces the encryption supports in different TiDB components such as TiKV, TiFlash, PD, and Backup & Restore (BR).

When a TiDB cluster is deployed, the majority of user data is stored on TiKV and TiFlash nodes. Some metadata is stored on PD nodes (for example, secondary index keys used as TiKV Region boundaries). To get the full benefits of encryption at rest, you need to enable encryption for all components. Backups, log files, and data transmitted over the network should also be considered when you implement encryption.

6.1.5.1.1 TiKV

TiKV supports encryption at rest. This feature allows TiKV to transparently encrypt data files using [AES](#) in [CTR](#) mode. To enable encryption at rest, an encryption key must be provided by the user and this key is called master key. TiKV automatically rotates data keys that it used to encrypt actual data files. Manually rotating the master key can be done occasionally. Note that encryption at rest only encrypts data at rest (namely, on disk) and not while data is transferred over network. It is advised to use TLS together with encryption at rest.

Optionally, you can use AWS KMS for both cloud and self-hosted deployments. You can also supply the plaintext master key in a file.

TiKV currently does not exclude encryption keys and user data from core dumps. It is advised to disable core dumps for the TiKV process when using encryption at rest. This is not currently handled by TiKV itself.

TiKV tracks encrypted data files using the absolute path of the files. As a result, once encryption is turned on for a TiKV node, the user should not change data file paths configuration such as `storage.data-dir`, `raftstore.raftdb-path`, `rocksdb.wal-dir` and `raftdb.wal-dir`.

6.1.5.1.2 TiFlash

TiFlash supports encryption at rest. Data keys are generated by TiFlash. All files (including data files, schema files, and temporary files) written into TiFlash (including TiFlash Proxy) are encrypted using the current data key. The encryption algorithms, the encryption configuration (in the `tiflash-learner.toml` file) supported by TiFlash, and the meanings of monitoring metrics are consistent with those of TiKV.

If you have deployed TiFlash with Grafana, you can check the **TiFlash-Proxy-Details** -> **Encryption** panel.

6.1.5.1.3 PD

Encryption-at-rest for PD is an experimental feature, which is configured in the same way as in TiKV.

6.1.5.1.4 Backups with BR

BR supports S3 server-side encryption (SSE) when backing up data to S3. A customer-owned AWS KMS key can also be used together with S3 server-side encryption. See [BR S3 server-side encryption](#) for details.

6.1.5.1.5 Logging

TiKV, TiDB, and PD info logs might contain user data for debugging purposes. The info log and this data in it are not encrypted. It is recommended to enable [log redaction](#).

6.1.5.2 TiKV encryption at rest

6.1.5.2.1 Overview

TiKV currently supports encrypting data using AES128, AES192 or AES256, in CTR mode. TiKV uses envelope encryption. As a result, two types of keys are used in TiKV when encryption is enabled.

- Master key. The master key is provided by user and is used to encrypt the data keys TiKV generates. Management of master key is external to TiKV.
- Data key. The data key is generated by TiKV and is the key actually used to encrypt data.

The same master key can be shared by multiple instances of TiKV. The recommended way to provide a master key in production is via AWS KMS. Create a customer master key (CMK) through AWS KMS, and then provide the CMK key ID to TiKV in the configuration file. The TiKV process needs access to the KMS CMK while it is running, which can be done by using an [IAM role](#). If TiKV fails to get access to the KMS CMK, it will fail to start or restart. Refer to AWS documentation for [KMS](#) and [IAM](#) usage.

Alternatively, if using custom key is desired, supplying the master key via file is also supported. The file must contain a 256 bits (or 32 bytes) key encoded as hex string, end with a newline (namely, `\n`), and contain nothing else. Persisting the key on disk, however, leaks the key, so the key file is only suitable to be stored on the `tempfs` in RAM.

Data keys are passed to the underlying storage engine (namely, RocksDB). All files written by RocksDB, including SST files, WAL files, and the MANIFEST file, are encrypted by the current data key. Other temporary files used by TiKV that may include user data are also encrypted using the same data key. Data keys are automatically rotated by TiKV every week by default, but the period is configurable. On key rotation, TiKV does not rewrite all existing files to replace the key, but RocksDB compaction are expected to rewrite old data into new data files, with the most recent data key, if the cluster gets constant write workload. TiKV keeps track of the key and encryption method used to encrypt each of the files and use the information to decrypt the content on reads.

Regardless of data encryption method, data keys are encrypted using AES256 in GCM mode for additional authentication. This required the master key to be 256 bits (32 bytes), when passing from file instead of KMS.

6.1.5.2.2 Key creation

To create a key on AWS, follow these steps:

1. Go to the [AWS KMS](#) on the AWS console.
2. Make sure that you have selected the correct region on the top right corner of your console.
3. Click **Create key** and select **Symmetric** as the key type.
4. Set an alias for the key.

You can also perform the operations using the AWS CLI:

```
aws --region us-west-2 kms create-key
aws --region us-west-2 kms create-alias --alias-name "alias/tidb-tde" --
↳ target-key-id 0987dcba-09fe-87dc-65ba-ab0987654321
```

The `--target-key-id` to enter in the second command is in the output of the first command.

6.1.5.2.3 Configure encryption

To enable encryption, you can add the encryption section in the configuration files of TiKV and PD:

```
[security.encryption]
data-encryption-method = "aes128-ctr"
data-key-rotation-period = "168h" # 7 days
```

Possible values for `data-encryption-method` are “aes128-ctr”, “aes192-ctr”, “aes256-ctr” and “plaintext”. The default value is “plaintext”, which means encryption is not turned on. `data-key-rotation-period` defines how often TiKV rotates the data key. Encryption can be turned on for a fresh TiKV cluster, or an existing TiKV cluster, though only data written after encryption is enabled is guaranteed to be encrypted. To disable encryption, remove `data-encryption-method` in the configuration file, or reset it to “plaintext”, and restart TiKV. To change encryption method, update `data-encryption-method` in the configuration file and restart TiKV.

The master key has to be specified if encryption is enabled (that is, `data-encryption-method` is not “plaintext”). To specify a AWS KMS CMK as master key, add the `encryption.master-key` section after the encryption section:

```
[security.encryption.master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
endpoint = "https://kms.us-west-2.amazonaws.com"
```

The `key-id` specifies the key ID for the KMS CMK. The `region` is the AWS region name for the KMS CMK. The `endpoint` is optional and you do not need to specify it normally unless you are using an AWS KMS-compatible service from a non-AWS vendor or need to use a [VPC endpoint for KMS](#).

You can also use [multi-Region keys](#) in AWS. For this, you need to set up a primary key in a specific region and add replica keys in the regions you require.

To specify a master key that’s stored in a file, the master key configuration would look like the following:

```
[security.encryption.master-key]
type = "file"
path = "/path/to/key/file"
```

Here `path` is the path to the key file. The file must contain a 256 bits (or 32 bytes) key encoded as hex string, end with a newline (`\n`) and contain nothing else. Example of the file content:

```
3b5896b5be691006e0f71c3040a29495ddcad20b14aff61806940ebd780d3c62
```

6.1.5.2.4 Rotate the master key

To rotate master key, you have to specify both of the new master key and old master key in the configuration, and restart TiKV. Use `security.encryption.master-key` to specify the new master key, and use `security.encryption.previous-master-key` to specify the old master key. The configuration format for `security.encryption.previous-master-key` \leftrightarrow is the same as `encryption.master-key`. On restart TiKV must access both of the old and new master key, but once TiKV is up and running, TiKV will only need access to the new key. It is okay to leave the `encryption.previous-master-key` configuration in the configuration file from that on. Even on restart, TiKV only tries to use the old key if it fails to decrypt existing data using the new master key.

Currently online master key rotation is not supported, so you need to restart TiKV. It is advised to do a rolling restart to a running TiKV cluster serving online query.

Here is an example configuration for rotating the KMS CMK:

```
[security.encryption.master-key]
type = "kms"
key-id = "50a0c603-1c6f-11e6-bb9e-3fadde80ce75"
region = "us-west-2"

[security.encryption.previous-master-key]
type = "kms"
key-id = "0987dcba-09fe-87dc-65ba-ab0987654321"
region = "us-west-2"
```

6.1.5.2.5 Monitoring and debugging

To monitor encryption at rest, if you deploy TiKV with Grafana, you can look at the **Encryption** panel in the **TiKV-Details** dashboard. There are a few metrics to look for:

- Encryption initialized: 1 if encryption is initialized during TiKV startup, 0 otherwise. In case of master key rotation, after encryption is initialized, TiKV do not need access to the previous master key.
- Encryption data keys: number of existing data keys. The number is bumped by 1 after each time data key rotation happened. Use this metrics to monitor if data key rotation works as expected.
- Encrypted files: number of encrypted data files currently exists. Compare this number to existing data files in the data directory to estimate portion of data being encrypted, when turning on encryption for a previously unencrypted cluster.
- Encryption meta file size: size of the encryption meta data files.
- Read/Write encryption meta duration: the extra overhead to operate on metadata for encryption.

For debugging, the `tikv-ctl` command can be used to dump encryption metadata such as encryption method and data key id used to encryption the file, as well as list of data keys.

Since the operation can expose sensitive data, it is not recommended to use in production. Please refer to [TiKV Control](#) document.

6.1.5.2.6 Compatibility between TiKV versions

To reduce the overhead caused by I/O and mutex contention when TiKV manages the encryption metadata, an optimization is introduced in TiKV v4.0.9 and controlled by `security.encryption.enable-file-dictionary-log` in the TiKV configuration file. This configuration parameter takes effect only on TiKV v4.0.9 or later versions.

When it is enabled (by default), the data format of encryption metadata is unrecognizable by TiKV v4.0.8 or earlier versions. For example, assume that you use TiKV v4.0.9 or later with encryption at rest and the default `enable-file-dictionary-log` configuration. If you downgrade your cluster to TiKV v4.0.8 or earlier, TiKV will fail to start, with an error in the info log similar to the following one:

```
[2020/12/07 07:26:31.106 +08:00] [ERROR] [mod.rs:110] ["encryption: failed
↳ to load file dictionary."]
[2020/12/07 07:26:33.598 +08:00] [FATAL] [lib.rs:483] ["called `Result::
↳ unwrap()` on an `Err` value: Other(\"[components/encryption/src/
↳ encrypted_file/header.rs:18]: unknown version 2\")"]
```

To avoid the error above, you can first set `security.encryption.enable-file-dictionary-log` to `false` and start TiKV with v4.0.9 or later. Once TiKV starts successfully, the data format of encryption metadata is downgraded to the version recognizable to earlier TiKV versions. At this point, you can then downgrade your TiKV cluster to an earlier version.

6.1.5.3 BR S3 server-side encryption

To enable S3 server-side encryption when backup to S3 using BR, pass `--s3.sse` argument and set value to `aws:kms`. S3 will use its own KMS key for encryption. Example:

```
./br backup full --pd <pd-address> --storage "s3://<bucket>/<prefix>" --s3.
↳ sse aws:kms
```

To use a custom AWS KMS CMK that you created and owned, pass `--s3.sse-kms-key-id` in addition. In this case, both the BR process and all the TiKV nodes in the cluster would need access to the KMS CMK (for example, via AWS IAM), and the KMS CMK needs to be in the same AWS region as the S3 bucket used to store the backup. It is advised to grant access to the KMS CMK to BR process and TiKV nodes via AWS IAM. Refer to AWS documentation for usage of [IAM](#). For example:

```
./br backup full --pd <pd-address> --storage "s3://<bucket>/<prefix>" --s3.
↳ region <region> --s3.sse aws:kms --s3.sse-kms-key-id 0987dcba-09fe-87
↳ dc-65ba-ab0987654321
```

When restoring the backup, both `--s3.sse` and `--s3.sse-kms-key-id` should NOT be used. S3 will figure out encryption settings by itself. The BR process and TiKV nodes in the cluster to restore the backup would also need access to the KMS CMK, or the restore will fail. Example:

```
./br restore full --pd <pd-address> --storage "s3://<bucket>/<prefix> --s3.  
  ↪ region <region>"
```

6.1.6 Enable Encryption for Disk Spill

When the `oom-use-tmp-storage` configuration item is set to `true`, if the memory usage of a single SQL statement exceeds the limit of `mem-quota-query` setting, some operators can save the intermediate results during execution as a temporary file to the disk and delete the file after the query is completed.

You can enable encryption for disk spill to prevent attackers from accessing data by reading these temporary files.

6.1.6.1 Configure

To enable encryption for the disk spill files, you can configure the item `spilled-file-encryption-method` in the `[security]` section of the TiDB configuration file.

```
[security]  
spilled-file-encryption-method = "aes128-ctr"
```

Value options for `spilled-file-encryption-method` are `aes128-ctr` and `plaintext`. The default value is `plaintext`, which means that encryption is disabled.

6.1.7 Log Redaction

When TiDB provides detailed log information, it might print sensitive data (for example, user data) in the log, which causes data security risks. To avoid such risks, each component (TiDB, TiKV, and PD) provides a configuration item that enables log redaction to shield user data values.

6.1.7.1 Log redaction in TiDB side

To enable log redaction in the TiDB side, set the value of `global.tidb_redact_log` to 1. This configuration value defaults to 0, which means that log redaction is disabled.

You can use the `set` syntax to set the global variable `tidb_redact_log`:

```
set @@global.tidb_redact_log=1;
```

After the setting, all logs generated in new sessions are redacted:

```
create table t (a int, unique key (a));
Query OK, 0 rows affected (0.00 sec)

insert into t values (1),(1);
ERROR 1062 (23000): Duplicate entry '1' for key 'a'
```

The error log for the INSERT statement above is printed as follows:

```
[2020/10/20 11:45:49.539 +08:00] [INFO] [conn.go:800] ["command dispatched
↳ failed"] [conn=5] [connInfo="id:5, addr:127.0.0.1:57222 status:10,
↳ collation:utf8_general_ci, user:root"] [command=Query] [status="inTxn
↳ :0, autocommit:1"] [sql="insert into t values ( ? ) , ( ? )"] [
↳ txn_mode=OPTIMISTIC] [err="[kv:1062]Duplicate entry '?' for key 'a'"]
```

From the error log above, you can see that all sensitive information is shielded using ? after `tidb_redact_log` is enabled. In this way, data security risks are avoided.

6.1.7.2 Log redaction in TiKV side

To enable log redaction in the TiKV side, set the value of `security.redact-info-log` ↪ to `true`. This configuration value defaults to `false`, which means that log redaction is disabled.

6.1.7.3 Log redaction in PD side

To enable log redaction in the PD side, set the value of `security.redact-info-log` to `true`. This configuration value defaults to `false`, which means that log redaction is disabled.

6.1.7.4 Log redaction in TiFlash side

To enable log redaction in the TiFlash side, set both the `security.redact_info_log` value in `tiflash-server` and the `security.redact-info-log` value in `tiflash-learner` to `true`. Both configuration values default to `false`, which means that log redaction is disabled.

6.2 Upgrade

6.2.1 Upgrade TiDB Using TiUP

This document is targeted for the following upgrade paths:

- Upgrade from TiDB 4.0 versions to TiDB 5.4 versions.
- Upgrade from TiDB 5.0 versions to TiDB 5.4 versions.
- Upgrade from TiDB 5.1 versions to TiDB 5.4 versions.
- Upgrade from TiDB 5.2 versions to TiDB 5.4 versions.

- Upgrade from TiDB 5.3 versions to TiDB 5.4 versions.

Warning:

- You cannot upgrade TiFlash online from versions earlier than 5.3 to 5.3 or later. Instead, you must first stop all the TiFlash instances of the early version, and then upgrade the cluster offline. If other components (such as TiDB and TiKV) do not support an online upgrade, follow the instructions in warnings in [Online upgrade](#).
- **DO NOT** upgrade a TiDB cluster when a DDL statement is being executed in the cluster (usually for the time-consuming DDL statements such as `ADD INDEX` and the column type changes).
- Before the upgrade, it is recommended to use the `ADMIN SHOW DDL` command to check whether the TiDB cluster has an ongoing DDL job. If the cluster has a DDL job, to upgrade the cluster, wait until the DDL execution is finished or use the `ADMIN CANCEL DDL` command to cancel the DDL job before you upgrade the cluster.
- In addition, during the cluster upgrade, **DO NOT** execute any DDL statement. Otherwise, the issue of undefined behavior might occur.

Note:

If your cluster to be upgraded is v3.1 or an earlier version (v3.0 or v2.1), the direct upgrade to v5.4 or its patch versions is not supported. You need to upgrade your cluster first to v4.0 and then to v5.4.

6.2.1.1 Upgrade caveat

- TiDB currently does not support version downgrade or rolling back to an earlier version after the upgrade.
- For the v4.0 cluster managed using TiDB Ansible, you need to import the cluster to TiUP (`tiup cluster`) for new management according to [Upgrade TiDB Using TiUP \(v4.0\)](#). Then you can upgrade the cluster to v5.4 or its patch versions according to this document.
- To update versions earlier than 3.0 to 5.4:
 1. Update this version to 3.0 using [TiDB Ansible](#).
 2. Use TiUP (`tiup cluster`) to import the TiDB Ansible configuration.

3. Update the 3.0 version to 4.0 according to [Upgrade TiDB Using TiUP \(v4.0\)](#).
 4. Upgrade the cluster to v5.4 according to this document.
- Support upgrading the versions of TiDB Binlog, TiCDC, TiFlash, and other components.
 - For detailed compatibility changes of different versions, see the [Release Notes](#) of each version. Modify your cluster configuration according to the “Compatibility Changes” section of the corresponding release notes.
 - For clusters that upgrade from versions earlier than v5.3 to v5.3 or later versions, the default deployed Prometheus will upgrade from v2.8.1 to v2.27.1. Prometheus v2.27.1 provides more features and fixes a security issue. Compared with v2.8.1, alert time representation in v2.27.1 is changed. For more details, see [Prometheus commit](#) for more details.

6.2.1.2 Preparations

This section introduces the preparation works needed before upgrading your TiDB cluster, including upgrading TiUP and the TiUP Cluster component.

6.2.1.2.1 Step 1: Upgrade TiUP or TiUP offline mirror

Before upgrading your TiDB cluster, you first need to upgrade TiUP or TiUP mirror.

Upgrade TiUP and TiUP Cluster

Note:

If the control machine of the cluster to upgrade cannot access <https://tiup-mirrors.pingcap.com>, skip this section and see [Upgrade TiUP offline mirror](#).

1. Upgrade the TiUP version. It is recommended that the TiUP version is 1.9.0 or later.

```
tiup update --self
tiup --version
```

2. Upgrade the TiUP Cluster version. It is recommended that the TiUP Cluster version is 1.9.0 or later.

```
tiup update cluster
tiup cluster --version
```

Upgrade TiUP offline mirror

Note:

If the cluster to upgrade was deployed not using the offline method, skip this step.

Refer to [Deploy a TiDB Cluster Using TiUP - Deploy TiUP offline](#) to download the TiUP mirror of the new version and upload it to the control machine. After executing `local_install.sh`, TiUP will complete the overwrite upgrade.

```
tar xzvf tidb-community-server- $\{\text{version}\}$ -linux-amd64.tar.gz
sh tidb-community-server- $\{\text{version}\}$ -linux-amd64/local_install.sh
source /home/tidb/.bash_profile
```

After the overwrite upgrade, execute the following command to upgrade the TiUP Cluster component.

```
tiup update cluster
```

Now, the offline mirror has been upgraded successfully. If an error occurs during TiUP operation after the overwriting, it might be that the `manifest` is not updated. You can try `rm -rf ~/.tiup/manifests/*` before running TiUP again.

6.2.1.2.2 Step 2: Edit TiUP topology configuration file

Note:

Skip this step if one of the following situations applies:

- You have not modified the configuration parameters of the original cluster. Or you have modified the configuration parameters using `tiup ↔ cluster` but no more modification is needed.
- After the upgrade, you want to use v5.4's default parameter values for the unmodified configuration items.

1. Enter the vi editing mode to edit the topology file:

```
tiup cluster edit-config <cluster-name>
```

2. Refer to the format of [topology](#) configuration template and fill the parameters you want to modify in the `server_configs` section of the topology file.

3. After the modification, enter `: + w + q` to save the change and exit the editing mode. Enter `Y` to confirm the change.

Note:

Before you upgrade the cluster to v5.4, make sure that the parameters you have modified in v4.0 are compatible in v5.4. For details, see [TiKV Configuration File](#).

6.2.1.2.3 Step 3: Check the health status of the current cluster

To avoid the undefined behaviors or other issues during the upgrade, it is recommended to check the health status of Regions of the current cluster before the upgrade. To do that, you can use the `check` sub-command.

```
tiup cluster check <cluster-name> --cluster
```

After the command is executed, the “Region status” check result will be output.

- If the result is “All Regions are healthy”, all Regions in the current cluster are healthy and you can continue the upgrade.
- If the result is “Regions are not fully healthy: m miss-peer, n pending-peer” with the “Please fix unhealthy regions before other operations.” prompt, some Regions in the current cluster are abnormal. You need to troubleshoot the anomalies until the check result becomes “All Regions are healthy”. Then you can continue the upgrade.

6.2.1.3 Upgrade the TiDB cluster

This section describes how to upgrade the TiDB cluster and verify the version after the upgrade.

6.2.1.3.1 Upgrade the TiDB cluster to a specified version

You can upgrade your cluster in one of the two ways: online upgrade and offline upgrade.

By default, TiUP Cluster upgrades the TiDB cluster using the online method, which means that the TiDB cluster can still provide services during the upgrade process. With the online method, the leaders are migrated one by one on each node before the upgrade and restart. Therefore, for a large-scale cluster, it takes a long time to complete the entire upgrade operation.

If your application has a maintenance window for the database to be stopped for maintenance, you can use the offline upgrade method to quickly perform the upgrade operation.

Online upgrade

```
tiup cluster upgrade <cluster-name> <version>
```

For example, if you want to upgrade the cluster to v5.4.3:

```
tiup cluster upgrade <cluster-name> v5.4.3
```

Note:

- An online upgrade upgrades all components one by one. During the upgrade of TiKV, all leaders in a TiKV instance are evicted before stopping the instance. The default timeout time is 5 minutes (300 seconds). The instance is directly stopped after this timeout time.
- You can use the `--force` parameter to upgrade the cluster immediately without evicting the leader. However, the errors that occur during the upgrade will be ignored, which means that you are not notified of any upgrade failure. Therefore, use the `--force` parameter with caution.
- To keep a stable performance, make sure that all leaders in a TiKV instance are evicted before stopping the instance. You can set `--transfer ↪ -timeout` to a larger value, for example, `--transfer-timeout 3600` (unit: second).
- To upgrade TiFlash from versions earlier than 5.3 to 5.3 or later, you should stop TiFlash and then upgrade it. The following steps help you upgrade TiFlash without interrupting other components:
 1. Stop the TiFlash instance: `tiup cluster stop <cluster-name> -R ↪ tiflash`
 2. Upgrade the TiDB cluster without restarting it (only updating the files): `tiup cluster upgrade <cluster-name> <version> --offline`
 3. Reload the TiDB cluster: `tiup cluster reload <cluster-name>`. After the reload, the TiFlash instance is started and you do not need to manually start it.

Offline upgrade

1. Before the offline upgrade, you first need to stop the entire cluster.

```
tiup cluster stop <cluster-name>
```

2. Use the `upgrade` command with the `--offline` option to perform the offline upgrade.

```
tiup cluster upgrade <cluster-name> <version> --offline
```

3. After the upgrade, the cluster will not be automatically restarted. You need to use the `start` command to restart it.

```
tiup cluster start <cluster-name>
```

6.2.1.3.2 Verify the cluster version

Execute the `display` command to view the latest cluster version TiDB Version:

```
tiup cluster display <cluster-name>
```

```
Cluster type:      tidb
Cluster name:      <cluster-name>
Cluster version:  v5.4.3
```

Note:

By default, TiUP and TiDB share usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see [Telemetry](#).

6.2.1.4 FAQ

This section describes common problems encountered when updating the TiDB cluster using TiUP.

6.2.1.4.1 If an error occurs and the upgrade is interrupted, how to resume the upgrade after fixing this error?

Re-execute the `tiup cluster upgrade` command to resume the upgrade. The upgrade operation restarts the nodes that have been previously upgraded. If you do not want the upgraded nodes to be restarted, use the `replay` sub-command to retry the operation:

1. Execute `tiup cluster audit` to see the operation records:

```
tiup cluster audit
```

Find the failed upgrade operation record and keep the ID of this operation record. The ID is the `<audit-id>` value in the next step.

2. Execute `tiup cluster replay <audit-id>` to retry the corresponding operation:

```
tiup cluster replay <audit-id>
```

6.2.1.4.2 The evict leader has waited too long during the upgrade. How to skip this step for a quick upgrade?

You can specify `--force`. Then the processes of transferring PD leader and evicting TiKV leader are skipped during the upgrade. The cluster is directly restarted to update the version, which has a great impact on the cluster that runs online. Here is the command:

```
tiup cluster upgrade <cluster-name> <version> --force
```

6.2.1.4.3 How to update the version of tools such as `pd-ctl` after upgrading the TiDB cluster?

You can upgrade the tool version by using TiUP to install the `ctl` component of the corresponding version:

```
tiup install ctl:v5.4.3
```

6.2.1.5 TiDB 5.4 compatibility changes

- See TiDB 5.4 Release Notes for the compatibility changes.
- Try to avoid creating a new clustered index table when you apply rolling updates to the clusters using TiDB Binlog.

6.2.2 Use TiDB Operator

6.3 Scale

6.3.1 Scale a TiDB Cluster Using TiUP

The capacity of a TiDB cluster can be increased or decreased without interrupting the online services.

This document describes how to scale the TiDB, TiKV, PD, TiCDC, or TiFlash cluster using TiUP. If you have not installed TiUP, refer to the steps in [Step 2. Deploy TiUP on the control machine](#).

To view the current cluster name list, run `tiup cluster list`.

For example, if the original topology of the cluster is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash

Host IP	Service
10.0.1.4	TiDB + PD
10.0.1.5	TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.1 Scale out a TiDB/PD/TiKV cluster

This section exemplifies how to add a TiDB node to the 10.0.1.5 host.

Note:

You can take similar steps to add a PD node. Before you add a TiKV node, it is recommended that you adjust the PD scheduling parameters in advance according to the cluster load.

1. Configure the scale-out topology:

Note:

- The port and directory information is not required by default.
- If multiple instances are deployed on a single machine, you need to allocate different ports and directories for them. If the ports or directories have conflicts, you will receive a notification during deployment or scaling.
- Since TiUP v1.0.0, the scale-out configuration inherits the global configuration of the original cluster.

Add the scale-out topology configuration in the `scale-out.yml` file:

```
vi scale-out.yml
```

```
tidb_servers:  
- host: 10.0.1.5  
  ssh_port: 22  
  port: 4000  
  status_port: 10080  
  deploy_dir: /tidb-deploy/tidb-4000  
  log_dir: /tidb-deploy/tidb-4000/log
```

Here is a TiKV configuration file template:

```
tikv_servers:  
- host: 10.0.1.5  
  ssh_port: 22  
  port: 20160  
  status_port: 20180  
  deploy_dir: /tidb-deploy/tikv-20160  
  data_dir: /tidb-data/tikv-20160  
  log_dir: /tidb-deploy/tikv-20160/log
```

Here is a PD configuration file template:

```
pd_servers:  
- host: 10.0.1.5  
  ssh_port: 22  
  name: pd-1  
  client_port: 2379  
  peer_port: 2380  
  deploy_dir: /tidb-deploy/pd-2379  
  data_dir: /tidb-data/pd-2379  
  log_dir: /tidb-deploy/pd-2379/log
```

To view the configuration of the current cluster, run `tiup cluster edit-config <cluster-name>`. Because the parameter configuration of `global` and `server_configs` is inherited by `scale-out.yml` and thus also takes effect in `scale-out.yml`.

2. Run the scale-out command:

Before you run the `scale-out` command, use the `check` and `check --apply` commands to detect and automatically repair potential risks in the cluster:

1. Check for potential risks:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --user  
↪ root [-p] [-i /home/root/.ssh/gcp_rsa]
```

2. Enable automatic repair:

```
tiup cluster check <cluster-name> scale-out.yml --cluster --apply  
↪ --user root [-p] [-i /home/root/.ssh/gcp_rsa]
```

3. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yml [-p] [-i /home/  
↪ root/.ssh/gcp_rsa]
```

In the preceding commands:

- `scale-out.yml` is the scale-out configuration file.
- `--user root` indicates logging in to the target machine as the `root` user to complete the cluster scale out. The `root` user is expected to have `ssh` and `sudo` privileges to the target machine. Alternatively, you can use other users with `ssh` and `sudo` privileges to complete the deployment.
- `[-i]` and `[-p]` are optional. If you have configured login to the target machine without password, these parameters are not required. If not, choose one of the two parameters. `[-i]` is the private key of the root user (or other users specified by `--user`) that has access to the target machine. `[-p]` is used to input the user password interactively.

If you see `Scaled cluster <cluster-name> out successfully`, the scale-out operation succeeds.

3. Check the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at <http://10.0.1.5:3000> using your browser to monitor the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD
10.0.1.5	TiDB + TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.2 Scale out a TiFlash cluster

This section exemplifies how to add a TiFlash node to the `10.0.1.4` host.

Note:

When adding a TiFlash node to an existing TiDB cluster, note the following:

- Confirm that the current TiDB version supports using TiFlash. Otherwise, upgrade your TiDB cluster to v5.0 or later versions.
- Run the `tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> config set enable-placement-rules true` command to enable the Placement Rules feature. Or run the corresponding command in `pd-ctl`.

1. Add the node information to the `scale-out.yml` file:

Create the `scale-out.yml` file to add the TiFlash node information.

```
tiflash_servers:  
- host: 10.0.1.4
```

Currently, you can only add IP addresses but not domain names.

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

Note:

The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at <http://10.0.1.5:3000> using your browser, and view the status of the cluster and the new node.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash
10.0.1.4	TiDB + PD + TiFlash
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.3 Scale out a TiCDC cluster

This section exemplifies how to add two TiCDC nodes to the 10.0.1.3 and 10.0.1.4 hosts.

1. Add the node information to the `scale-out.yml` file:

Create the `scale-out.yml` file to add the TiCDC node information.

```
cdc_servers:
  - host: 10.0.1.3
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
  - host: 10.0.1.4
    gc-ttl: 86400
    data_dir: /tidb-data/cdc-8300
```

2. Run the scale-out command:

```
tiup cluster scale-out <cluster-name> scale-out.yml
```

Note:

The preceding command is based on the assumption that the mutual trust has been configured for the user to run the command and the new machine. If the mutual trust cannot be configured, use the `-p` option to enter the password of the new machine, or use the `-i` option to specify the private key file.

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at <http://10.0.1.5:3000> using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiFlash + TiCDC
10.0.1.5	TiDB+ TiKV + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.4 Scale in a TiDB/PD/TiKV cluster

This section exemplifies how to remove a TiKV node from the 10.0.1.5 host.

Note:

- You can take similar steps to remove a TiDB or PD node.
- Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously and the stopping process takes a long time, TiUP takes them offline in different methods. For details, see [Particular handling of components' offline process](#).
- The PD Client in TiKV caches the list of PD nodes. The current version of TiKV has a mechanism to automatically and regularly update PD nodes, which can help mitigate the issue of an expired list of PD nodes cached by TiKV. However, after scaling out PD, you should try to avoid directly removing all PD nodes at once that exist before the scaling. If necessary, before making all the previously existing PD nodes offline, make sure to switch the PD leader to a newly added PD node.

1. View the node ID information:

```
tiup cluster display <cluster-name>
```

```
Starting /root/.tiup/components/cluster/v1.9.0/cluster display <cluster
↳ -name>
TiDB Cluster: <cluster-name>
TiDB Version: v5.4.3
ID          Role      Host      Ports      Status
↳ Data Dir  Deploy Dir
--          -
↳ -----
10.0.1.3:8300 cdc      10.0.1.3  8300      Up
↳ data/cdc-8300      deploy/cdc-8300
10.0.1.4:8300 cdc      10.0.1.4  8300      Up
↳ data/cdc-8300      deploy/cdc-8300
10.0.1.4:2379 pd       10.0.1.4  2379/2380
↳ Healthy data/pd-2379      deploy/pd-2379
10.0.1.1:20160 tikv     10.0.1.1  20160/20180
↳ data/tikv-20160      deploy/tikv-20160
10.0.1.2:20160 tikv     10.0.1.2  20160/20180
↳ data/tikv-20160      deploy/tikv-20160
10.0.1.5:20160 tikv     10.0.1.5  20160/20180
↳ data/tikv-20160      deploy/tikv-20160
10.0.1.3:4000 tidb     10.0.1.3  4000/10080
↳ -                    deploy/tidb-4000
```

10.0.1.4:4000	tidb	10.0.1.4	4000/10080	Up
↔	-		deploy/tidb-4000	
10.0.1.5:4000	tidb	10.0.1.5	4000/10080	Up
↔	-		deploy/tidb-4000	
10.0.1.3:9000	tiflash	10.0.1.3	9000/8123/3930/20170/20292/8234	Up
↔	data/tiflash-9000		deploy/tiflash-9000	
10.0.1.4:9000	tiflash	10.0.1.4	9000/8123/3930/20170/20292/8234	Up
↔	data/tiflash-9000		deploy/tiflash-9000	
10.0.1.5:9090	prometheus	10.0.1.5	9090	Up
↔	data/prometheus-9090		deploy/prometheus-9090	
10.0.1.5:3000	grafana	10.0.1.5	3000	Up
↔	-		deploy/grafana-3000	
10.0.1.5:9093	alertmanager	10.0.1.5	9093/9294	Up
↔	data/alertmanager-9093		deploy/alertmanager-9093	

2. Run the scale-in command:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.5:20160
```

The `--node` parameter is the ID of the node to be taken offline.

If you see `Scaled cluster <cluster-name>` in successfully, the scale-in operation succeeds.

3. Check the cluster status:

The scale-in process takes some time. You can run the following command to check the scale-in status:

```
tiup cluster display <cluster-name>
```

If the node to be scaled in becomes `Tombstone`, the scale-in operation succeeds.

Access the monitoring platform at <http://10.0.1.5:3000> using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiFlash + TiCDC
10.0.1.5	TiDB + Monitor (TiKV is deleted)
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.5 Scale in a TiFlash cluster

This section exemplifies how to remove a TiFlash node from the 10.0.1.4 host.

6.3.1.5.1 1. Adjust the number of replicas of the tables according to the number of remaining TiFlash nodes

Before the node goes down, make sure that the number of remaining nodes in the TiFlash cluster is no smaller than the maximum number of replicas of all tables. Otherwise, modify the number of TiFlash replicas of the related tables.

1. For all tables whose replicas are greater than the number of remaining TiFlash nodes in the cluster, run the following command in the TiDB client:

```
ALTER TABLE <db-name>.<table-name> SET tiflash replica 0;
```

2. Wait for the TiFlash replicas of the related tables to be deleted. **Check table replication progress** and the replicas are deleted if the replication information of the related tables is not found.

6.3.1.5.2 2. Perform the scale-in operation

Perform the scale-in operation with one of the following solutions.

Solution 1. Use TiUP to remove a TiFlash node

1. Confirm the name of the node to be taken down:

```
tiup cluster display <cluster-name>
```

2. Remove the TiFlash node (assume that the node name is 10.0.1.4:9000 from Step 1):

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:9000
```

Solution 2. Manually remove a TiFlash node

In special cases (such as when a node needs to be forcibly taken down), or if the TiUP scale-in operation fails, you can manually remove a TiFlash node with the following steps.

1. Use the store command of pd-ctl to view the store ID corresponding to this TiFlash node.
 - Enter the store command in **pd-ctl** (the binary file is under **resources/bin** in the **tidb-ansible** directory).
 - If you use TiUP deployment, replace **pd-ctl** with **tiup ctl:<cluster-version>**
↪ > pd:

```
tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store
```

Note:

If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

2. Remove the TiFlash node in pd-ctl:

- Enter `store delete <store_id>` in `pd-ctl` (`<store_id>` is the store ID of the TiFlash node found in the previous step).
- If you use TiUP deployment, replace `pd-ctl` with `tiup ctl:<cluster-version> ↵ > pd:`

```
tiup ctl:<cluster-version> pd -u http://<pd_ip>:<pd_port> store  
  ↵ delete <store_id>
```

Note:

If multiple PD instances exist in the cluster, you only need to specify the IP address:port of an active PD instance in the above command.

3. Wait for the store of the TiFlash node to disappear or for the `state_name` to become `Tombstone` before you stop the TiFlash process.
4. Manually delete TiFlash data files (the location can be found in the `data_dir` directory under the TiFlash configuration of the cluster topology file).
5. Delete information about the TiFlash node that goes down from the cluster topology using the following command:

```
tiup cluster scale-in <cluster-name> --node <pd_ip>:<pd_port> --force
```

Note:

Before all TiFlash nodes in the cluster stop running, if not all tables replicated to TiFlash are canceled, you need to manually clean up the replication rules in PD, or the TiFlash node cannot be taken down successfully.

The steps to manually clean up the replication rules in PD are below:

1. View all data replication rules related to TiFlash in the current PD instance:

```
curl http://<pd_ip>:<pd_port>/pd/api/v1/config/rules/group/tiflash
```

```
[
  {
    "group_id": "tiflash",
    "id": "table-45-r",
    "override": true,
    "start_key": "7480000000000000FF2D5F720000000000FA",
    "end_key": "7480000000000000FF2E00000000000000F8",
    "role": "learner",
    "count": 1,
    "label_constraints": [
      {
        "key": "engine",
        "op": "in",
        "values": [
          "tiflash"
        ]
      }
    ]
  }
]
```

2. Remove all data replication rules related to TiFlash. Take the rule whose id is table-45-r as an example. Delete it by the following command:

```
curl -v -X DELETE http://<pd_ip>:<pd_port>/pd/api/v1/config/rule/
  ↪ tiflash/table-45-r
```

3. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at <http://10.0.1.5:3000> using your browser, and view the status of the cluster and the new nodes.

After the scale-out, the cluster topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + TiCDC (TiFlash is deleted)
10.0.1.5	TiDB+ Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.1.6 Scale in a TiCDC cluster

This section exemplifies how to remove the TiCDC node from the 10.0.1.4 host.

1. Take the node offline:

```
tiup cluster scale-in <cluster-name> --node 10.0.1.4:8300
```

2. View the cluster status:

```
tiup cluster display <cluster-name>
```

Access the monitoring platform at <http://10.0.1.5:3000> using your browser, and view the status of the cluster.

The current topology is as follows:

Host IP	Service
10.0.1.3	TiDB + TiFlash + TiCDC
10.0.1.4	TiDB + PD + (TiCDC is deleted)
10.0.1.5	TiDB + Monitor
10.0.1.1	TiKV
10.0.1.2	TiKV

6.3.2 Use TiDB Operator

6.4 Backup and Restore

6.4.1 Use BR Tool (Recommended)

6.4.1.1 BR Tool Overview

BR (Backup & Restore) is a command-line tool for distributed backup and restoration of the TiDB cluster data.

Compared with **Dumpling**, BR is more suitable for scenarios involved huge data volumes.

In addition to regular backup and restoration, you can also use BR for large-scale data migration as long as compatibility is ensured.

This document describes BR's implementation principles, recommended deployment configuration, usage restrictions and several methods to use BR.

6.4.1.1.1 Implementation principles

BR sends the backup or restoration commands to each TiKV node. After receiving these commands, TiKV performs the corresponding backup or restoration operations.

Each TiKV node has a path in which the backup files generated in the backup operation are stored and from which the stored backup files are read during the restoration.

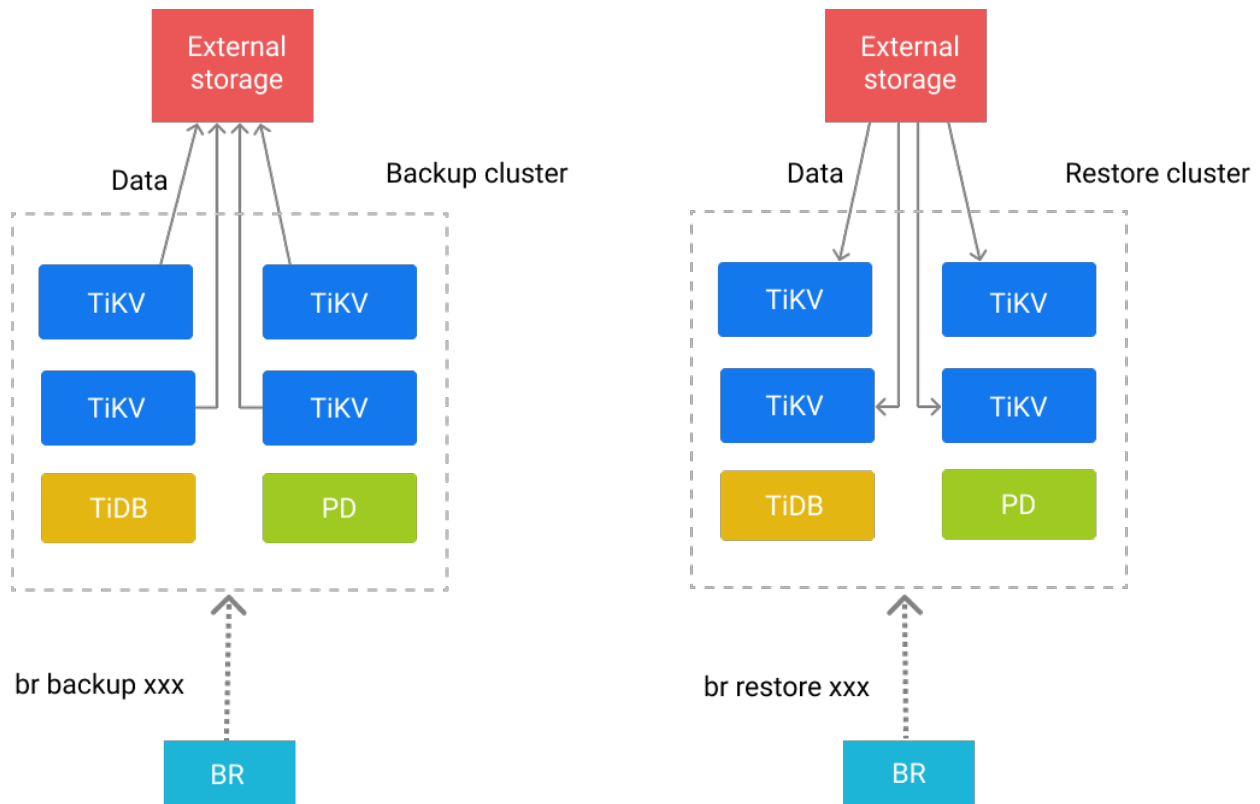

Figure 15: br-arch

Backup principle

When BR performs a backup operation, it first obtains the following information from PD:

- The current TS (timestamp) as the time of the backup snapshot
- The TiKV node information of the current cluster

According to these information, BR starts a TiDB instance internally to obtain the database or table information corresponding to the TS, and filters out the system databases (`information_schema`, `performance_schema`, `mysql`) at the same time.

According to the backup sub-command, BR adopts the following two types of backup logic:

- Full backup: BR traverses all the tables and constructs the KV range to be backed up according to each table.

- Single table backup: BR constructs the KV range to be backed up according a single table.

Finally, BR collects the KV range to be backed up and sends the complete backup request to the TiKV node of the cluster.

The structure of the request:

```
BackupRequest{
  ClusterId,    // The cluster ID.
  StartKey,     // The starting key of the backup (backed up).
  EndKey,       // The ending key of the backup (not backed up).
  StartVersion, // The version of the last backup snapshot, used for the
                // ↔ incremental backup.
  EndVersion,   // The backup snapshot time.
  StorageBackend, // The path where backup files are stored.
  RateLimit,    // Backup speed (MB/s).
}
```

After receiving the backup request, the TiKV node traverses all Region leaders on the node to find the Regions that overlap with the KV ranges in this request. The TiKV node backs up some or all of the data within the range, and generates the corresponding SST file.

After finishing backing up the data of the corresponding Region, the TiKV node returns the metadata to BR. BR collects the metadata and stores it in the `backupmeta` file which is used for restoration.

If `StartVersion` is not 0, the backup is seen as an incremental backup. In addition to KVs, BR also collects DDLs between [`StartVersion`, `EndVersion`). During data restoration, these DDLs are restored first.

If checksum is enabled when you execute the backup command, BR calculates the checksum of each backed up table for data check.

Types of backup files

Two types of backup files are generated in the path where backup files are stored:

- **The SST file:** stores the data that the TiKV node backed up.
- **The `backupmeta` file:** stores the metadata of this backup operation, including the number, the key range, the size, and the Hash (sha256) value of the backup files.
- **The `backup.lock` file:** prevents multiple backup operations from storing data to the same directory.

The format of the SST file name

The SST file is named in the format of `storeID_regionID_regionEpoch_keyHash_cf`, where

- `storeID` is the TiKV node ID;
- `regionID` is the Region ID;
- `regionEpoch` is the version number of the Region;
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a key;
- `cf` indicates the **Column Family** of RocksDB (`default` or `write` by default).

Restoration principle

During the data restoration process, BR performs the following tasks in order:

1. It parses the `backupmeta` file in the backup path, and then starts a TiDB instance internally to create the corresponding databases and tables based on the parsed information.
2. It aggregates the parsed SST files according to the tables.
3. It pre-splits Regions according to the key range of the SST file so that every Region corresponds to at least one SST file.
4. It traverses each table to be restored and the SST file corresponding to each tables.
5. It finds the Region corresponding to the SST file and sends a request to the corresponding TiKV node for downloading the file. Then it sends a request for loading the file after the file is successfully downloaded.

After TiKV receives the request to load the SST file, TiKV uses the Raft mechanism to ensure the strong consistency of the SST data. After the downloaded SST file is loaded successfully, the file is deleted asynchronously.

After the restoration operation is completed, BR performs a checksum calculation on the restored data to compare the stored data with the backed up data.

6.4.1.1.2 Deploy and use BR

Recommended deployment configuration

- It is recommended that you deploy BR on the PD node.
- It is recommended that you mount a high-performance SSD to BR nodes and all TiKV nodes. A 10-gigabit network card is recommended. Otherwise, bandwidth is likely to be the performance bottleneck during the backup and restore process.

Note:

- If you do not mount a network disk or use other shared storage, the data backed up by BR will be generated on each TiKV node. Because BR only backs up leader replicas, you should estimate the space reserved for each node based on the leader size.
- Because TiDB uses leader count for load balancing by default, leaders can greatly differ in size. This might result in an uneven distribution of backup data on each node.

Usage restrictions

The following are the limitations of using BR for backup and restoration:

- When BR restores data to the upstream cluster of TiCDC/Drainer, TiCDC/Drainer cannot replicate the restored data to the downstream.
- BR supports operations only between clusters with the same `new_collations_enabled_on_first_bootstrap` value because BR only backs up KV data. If the cluster to be backed up and the cluster to be restored use different collations, the data validation fails. Therefore, before restoring a cluster, make sure that the switch value from the query result of the `select VARIABLE_VALUE from mysql.tidb where VARIABLE_NAME='new_collation_enabled'`; statement is consistent with that during the backup process.

Compatibility

The compatibility issues of BR and the TiDB cluster are divided into the following categories:

- Some versions of BR are not compatible with the interface of the TiDB cluster.
 - BR versions earlier than v5.4.0 do not support recovering `charset=GBK` tables. No version of BR supports recovering `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- The KV format might change when some features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

These features are as follows:

Related
is-

Features	Issues	Solutions
----------	--------	-----------

Related
is-

Features	Issues	Solutions
----------	--------	-----------

Clustered index	#1565	Make sure that the value of the <code>tidb_enable_clustered_index</code>
-----------------	-------	--

↔ and inconsistent

	Related is-	
Features	Issues	Solutions
New collation	#352	Make sure that the value of the <code>new_collations_enabled_on_first_bootstrap</code> ↪ variable is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass.

Features	Related issues	Solutions
enabled on the restore cluster	TiCDC #364	Currently, TiKV cannot push down the BR-ingested SST files to TiCDC. Therefore, you need to disable TiCDC when using BR to restore data.

Related is-	
Features	Solutions
Global temporary tables	Make sure that you are using BR v5.3.0 or a later version to back up and restore data. Otherwise, an error occurs in the definition of the backed global temporary tables.

However, even after you have ensured that the above features are consistently enabled or disabled during backup and restore, compatibility issues might still occur due to the inconsistent internal versions or inconsistent interfaces between BR and TiKV/TiDB/PD. To avoid such cases, BR has the built-in version check.

Version check

Before performing backup and restore, BR compares and checks the TiDB cluster version and the BR version. If there is a major-version mismatch (for example, BR v4.x and TiDB v5.x), BR prompts a reminder to exit. To forcibly skip the version check, you can set `--check-requirements=false`.

Note that skipping the version check might introduce incompatibility. The version compatibility information between BR and TiDB versions are as follows:

Backup ver- sion (ver- tical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Use BR nightly to back up TiDB nightly	(If a table with the pri- mary key of the non- integer clus- tered index type is re- stored to a TiDB v4.0 clus- ter, BR will cause data error with- out warn- ing.)		

Backup ver- sion (ver- tical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Re- store ver- sion (hori- zon- tal)	Use BR v5.0 to back up TiDB v5.0	(If a table with the pri- mary key of the non- integer clus- tered index type is re- stored to a TiDB v4.0 clus- ter, BR will cause data error with- out warn- ing.)	

Backup version (vertical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Re-store version (horizontal)			
Use BR v4.0 to back up TiDB v4.0			(If TiKV >= v4.0.0- rc.1, and if BR con- tains the #233 bug fix and TiKV does not con- tain the #7241 bug fix, BR will cause the TiKV node to restart.)

Backup ver- sion (ver- tical)	Re- store ver- sion (hori- zon- tal)	Use BR nightly to re- store TiDB nightly	Use BR v5.0 to re- store TiDB v5.0	Use BR v4.0 to re- store TiDB v4.0
Use BR nightly or v5.0 to back up TiDB v4.0	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	

Back up and restore table data in the `mysql` system schema (experimental feature)

Warning:

This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default.

If you want the data of a system table (for example, `mysql.usertable1`) to be restored to the system schema `mysql`, you can set the `filter parameter` to filter the table name (`-↪ f "mysql.usertable1"`). After the setting, the system table is first restored to the temporary schema, and then to the system schema through renaming.

It should be noted that the following system tables cannot be restored correctly due to technical reasons. Even if `-f "mysql.*"` is specified, these tables will not be restored:

- Tables related to statistics: “stats_buckets”, “stats_extended”, “stats_feedback”, “stats_fm_sketch”, “stats_histograms”, “stats_meta”, “stats_top_n”
- Tables related to privileges or the system: “tidb”, “global_variables”, “columns_priv”, “db”, “default_roles”, “global_grants”, “global_priv”, “role_edges”, “tables_priv”, “user”, “gc_delete_range”, “Gc_delete_range_done”, “schema_index_usage”

Minimum machine configuration required for running BR

The minimum machine configuration required for running BR is as follows:

CPU	Memory	Hard Disk Type	Network
1 core	4 GB	HDD	Gigabit network card

In general scenarios (less than 1000 tables for backup and restore), the CPU consumption of BR at runtime does not exceed 200%, and the memory consumption does not exceed 4 GB. However, when backing up and restoring a large number of tables, BR might consume more than 4 GB of memory. In a test of backing up 24000 tables, BR consumes about 2.7 GB of memory, and the CPU consumption remains below 100%.

Best practices

The following are some recommended operations for using BR:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- When restoring data, BR consumes resources of the target cluster as much as possible. Therefore, it is recommended that you restore data to new clusters or offline clusters. Do not restore data to a production cluster in service. Otherwise, services might be affected.
- It is recommended that you execute multiple backup or restoration operations one by one. Running backup or restoration operations in parallel reduces performance and also affects online applications. Worse still, lack of collaboration between multiple tasks might result in task failures and affect cluster performance.
- Amazon S3, Google Cloud Storage, and Azure Blob Storage are recommended to store backup data.
- Make sure that the BR and TiKV nodes, and the backup storage backend have sufficient network bandwidth to ensure read and write performance. Insufficient storage capacity might be the bottleneck for a backup or restoration operation.

How to use BR

Currently, the following methods are supported to run the BR tool:

- Use SQL statements
- Use the command-line tool
- Use BR In the Kubernetes environment

Use SQL statements

TiDB supports both [BACKUP](#) and [RESTORE](#) SQL statements. The progress of these operations can be monitored with the statement [SHOW BACKUPS|RESTORES](#).

Use the command-line tool

The `br` command-line utility is available as a [separate download](#). For details, see [Use BR Command-line for Backup and Restoration](#).

In the Kubernetes environment

In the Kubernetes environment, you can use the BR tool to back up TiDB cluster data to S3-compatible storage, Google Cloud Storage (GCS) and persistent volumes (PV), and restore them:

Note:

For Amazon S3 and Google Cloud Storage parameter descriptions, see the [External Storages](#) document.

- [Back up Data to S3-Compatible Storage Using BR](#)
- [Restore Data from S3-Compatible Storage Using BR](#)
- [Back up Data to GCS Using BR](#)
- [Restore Data from GCS Using BR](#)
- [Back up Data to PV Using BR](#)
- [Restore Data from PV Using BR](#)

6.4.1.2 Use BR Command-line for Backup and Restoration

This document describes how to back up and restore TiDB cluster data using the BR command line.

Make sure you have read [BR Tool Overview](#), especially [Usage Restrictions](#) and [Best Practices](#).

6.4.1.2.1 BR command-line description

A `br` command consists of sub-commands, options, and parameters.

- Sub-command: the characters without `-` or `--`.
- Option: the characters that start with `-` or `--`.
- Parameter: the characters that immediately follow behind and are passed to the sub-command or the option.

This is a complete `br` command:

```
br backup full --pd "${PDIP}:2379" -s "local:///tmp/backup"
```

Explanations for the above command are as follows:

- `backup`: the sub-command of `br`.
- `full`: the sub-command of `backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored.
- `"local:///tmp/backup"`: the parameter of `-s`. `/tmp/backup` is the path in the local disk where the backed up files of each TiKV node are stored.
- `--pd`: the option that specifies the Placement Driver (PD) service address.
- `"${PDIP}:2379"`: the parameter of `--pd`.

Note:

- When the `local` storage is used, the backup data are scattered in the local file system of each node.
- It is **not recommended** to back up to a local disk in the production environment because you **have to** manually aggregate these data to complete the data restoration. For more information, see [Restore Cluster Data](#).
- Aggregating these backup data might cause redundancy and bring troubles to operation and maintenance. Even worse, if restoring data without aggregating these data, you can receive a rather confusing error message `SST file not found`.
- It is recommended to mount the NFS disk on each node, or back up to the S3 object storage.

Sub-commands

A `br` command consists of multiple layers of sub-commands. Currently, BR has the following three sub-commands:

- `br backup`: used to back up the data of the TiDB cluster.
- `br restore`: used to restore the data of the TiDB cluster.

Each of the above three sub-commands might still include the following three sub-commands to specify the scope of an operation:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore the specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

Common options

- `--pd`: used for connection, specifying the PD server address. For example, "`}${PDIP}↔}:2379`".
- `-h` (or `--help`): used to get help on all sub-commands. For example, `br backup --↔ help`.
- `-V` (or `--version`): used to check the version of BR.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.
- `--status-addr`: specifies the listening address through which BR provides statistics to Prometheus.

6.4.1.2.2 Use BR command-line to back up cluster data

To back up the cluster data, use the `br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster or a single table.

Back up all the cluster data

To back up all the cluster data, execute the `br backup full` command. To get help on this command, execute `br backup full -h` or `br backup full --help`.

Usage example:

Back up all the cluster data to the `/tmp/backup` path of each TiKV node and write the `backupmeta` file to this path.

Note:

- If the backup disk and the service disk are different, it has been tested that online backup reduces QPS of the read-only online service by about 15%-25% in case of full-speed backup. If you want to reduce the impact on QPS, use `--ratelimit` to limit the rate.
- If the backup disk and the service disk are the same, the backup competes with the service for I/O resources. This might decrease the QPS of the read-only online service by more than half. Therefore, it is **highly not recommended** to back up the online service data to the TiKV data disk.

```
br backup full \
  --pd "${PDIP}:2379" \
  --storage "local:///tmp/backup" \
  --ratelimit 128 \
  --log-file backupfull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a backup operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `backupfull.log` file.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety. The progress bar is displayed as follows:

```
br backup full \
  --pd "${PDIP}:2379" \
  --storage "local:///tmp/backup" \
  --ratelimit 128 \
  --log-file backupfull.log
Full Backup <-----/.....>
↔ 17.12%.
```

Back up a database

To back up a database in the cluster, execute the `br backup db` command. To get help on this command, execute `br backup db -h` or `br backup db --help`.

Usage example:

Back up the data of the `test` database to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup db \  
  --pd "${PDIP}:2379" \  
  --db test \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backupdb.log
```

In the above command, `--db` specifies the name of the database to be backed up. For descriptions of other options, see [Back up all the cluster data](#).

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

Back up a table

To back up the data of a single table in the cluster, execute the `br backup table` command. To get help on this command, execute `br backup table -h` or `br backup ↵ table --help`.

Usage example:

Back up the data of the `test.usertable` table to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup table \  
  --pd "${PDIP}:2379" \  
  --db test \  
  --table usertable \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backuptable.log
```

The `table` sub-command has two options:

- `--db`: specifies the database name
- `--table`: specifies the table name.

For descriptions of other options, see [Back up all cluster data](#).

A progress bar is displayed in the terminal during the backup operation. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

Back up with table filter

To back up multiple tables with more complex criteria, execute the `br backup full` command and specify the [table filters](#) with `--filter` or `-f`.

Usage example:

The following command backs up the data of all tables in the form `db*.tbl*` to the `/tmp/backup` path on each TiKV node and writes the `backupmeta` file to this path.

```
br backup full \  
  --pd "${PDIP}:2379" \  
  --filter 'db*.tbl*' \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backupfull.log
```

Back up data to Amazon S3 backend

If you back up the data to the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

You can refer to the [AWS Official Document](#) to create an S3 Bucket in the specified Region. You can also refer to another [AWS Official Document](#) to create a Folder in the Bucket.

Note:

To complete one backup, TiKV and BR usually require the minimum privileges of `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}  
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When backing up using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

```
br backup full \  
  --pd "${PDIP}:2379" \  
  --storage "s3://${Bucket}/${Folder}" \  
  --s3.region "${region}" \  
  --send-credentials-to-tikv=true \  
  --ratelimit 128 \  
  --log-file backupfull.log
```

Back up incremental data

This feature is currently experimental and is not recommended for use in the production environment.

If you want to back up incrementally, you only need to specify the **last backup timestamp** `--lastbackupts`.

The incremental backup has two limitations:

- The incremental backup needs to be under a different path from the previous full backup.
- GC (Garbage Collection) safepoint must be before the `lastbackupts`.

To back up the incremental data between (`LAST_BACKUP_TS`, current PD timestamp], execute the following command:

```
br backup full\  
  --pd ${PDIP}:2379 \  
  --ratelimit 128 \  
  -s local:///home/tidb/backupdata/incr \  
  --lastbackupts ${LAST_BACKUP_TS}
```

To get the timestamp of the last backup, execute the `validate` command. For example:

```
LAST_BACKUP_TS=`br validate decode --field="end-version" -s local:///home/  
↪ tidb/backupdata | tail -n1`
```

In the above example, for the incremental backup data, BR records the data changes and the DDL operations during (`LAST_BACKUP_TS`, current PD timestamp]. When restoring data, BR first restores DDL operations and then the data.

Encrypt data during backup (experimental feature)

Since TiDB v5.3.0, TiDB supports backup encryption. You can configure the following parameters to encrypt data during backup:

- `--crypter.method`: Encryption algorithm. Supports three algorithms `aes128-ctr/` `↪ aes192-ctr/aes256-ctr`. The default value is `plaintext` and indicates no encryption.
- `--crypter.key`: Encryption key in hexadecimal string format. `aes128-ctr` means 128 bit (16 bytes) key length, `aes192-ctr` means 24 bytes and `aes256-ctr` means 32 bytes.
- `--crypter.key-file`: The key file. You can directly pass in the file path where the key is stored as a parameter without passing in “`crypter.key`”

Warning:

- This is still an experimental feature. It is **NOT** recommended that you use it in the production environment.
- If the key is lost, the backup data cannot be restored to the cluster.
- The encryption feature needs to be used on BR tools and TiDB clusters v5.3.0 or later versions, and the encrypted backup data cannot be restored on clusters earlier than v5.3.0.

The configuration example for backup encryption is as follows:

```
br backup full\  
  --pd ${PDIP}:2379 \  
  -s local:///home/tidb/backupdata/incr \  
  --crypter.method aes128-ctr \  
  --crypter.key 0123456789abcdef0123456789abcdef
```

Back up Raw KV (experimental feature)

Warning:

This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

In some scenarios, TiKV might run independently of TiDB. Given that, BR also supports bypassing the TiDB layer and backing up data in TiKV.

For example, you can execute the following command to back up all keys between [0x31 ↪ , 0x3130303030303030) in the default CF to \$BACKUP_DIR:

```
br backup raw --pd $PD_ADDR \  
  -s "local://$BACKUP_DIR" \  
  --start 31 \  
  --ratelimit 128 \  
  --end 3130303030303030 \  
  --format hex \  
  --cf default
```

Here, the parameters of `--start` and `--end` are decoded using the method specified by `--format` before being sent to TiKV. Currently, the following methods are available:

- “raw”: The input string is directly encoded as a key in binary format.
- “hex”: The default encoding method. The input string is treated as a hexadecimal number.
- “escape”: First escape the input string, and then encode it into binary format.

6.4.1.2.3 Use BR command-line to restore cluster data

To restore the cluster data, use the `br restore` command. You can add the `full`, `db` or `table` sub-command to specify the scope of your restoration: the whole cluster, a database or a single table.

Note:

If you use the local storage, you **must** copy all back up SST files to every TiKV node in the path specified by `--storage`.

Even if each TiKV node eventually only need to read a part of the all SST files, they all need full access to the complete archive because:

- Data are replicated into multiple peers. When ingesting SSTs, these files have to be present on *all* peers. This is unlike back up where reading from a single node is enough.
- Where each peer is scattered to during restore is random. We don't know in advance which node will read which file.

These can be avoided using shared storage, for example mounting an NFS on the local path, or using S3. With network storage, every node can automatically read every SST file, so these caveats no longer apply.

Also, note that you can only run one restore operation for a single cluster at the same time. Otherwise, unexpected behaviors might occur. For details, see [FAQ](#).

Restore all the backup data

To restore all the backup data to the cluster, execute the `br restore full` command. To get help on this command, execute `br restore full -h` or `br restore full --help`.

Usage example:

Restore all the backup data in the `/tmp/backup` path to the cluster.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file restorefull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a restoration operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `restorefull.log` file.

A progress bar is displayed in the terminal during the restoration. When the progress bar advances to 100%, the restoration is complete. Then the BR also checks the backup data to ensure data safety.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file restorefull.log  
Full Restore <-----/.....>  
↔ 17.12%.
```

Restore a database

To restore a database to the cluster, execute the `br restore db` command. To get help on this command, execute `br restore db -h` or `br restore db --help`.

Usage example:

Restore a database backed up in the `/tmp/backup` path to the cluster.

```
br restore db \  
  --pd "${PDIP}:2379" \  
  --db "test" \  
  --ratelimit 128 \  
  --storage "local:///tmp/backup" \  
  --log-file restoredb.log
```

In the above command, `--db` specifies the name of the database to be restored. For descriptions of other options, see [Restore all backup data](#)).

Note:

When you restore the backup data, the name of the database specified by `--db` ↔ must be the same as the one specified by `--db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

Restore a table

To restore a single table to the cluster, execute the `br restore table` command. To get help on this command, execute `br restore table -h` or `br restore table --help`.

Usage example:

Restore a table backed up in the `/tmp/backup` path to the cluster.

```
br restore table \  
  --pd "${PDIP}:2379" \  
  --db "test" \  
  --table "usertable" \  
  --ratelimit 128 \  
  --storage "local:///tmp/backup" \  
  --log-file restoretable.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see [Restore all backup data](#) and [Restore a database](#).

Restore with table filter

To restore multiple tables with more complex criteria, execute the `br restore full` command and specify the [table filters](#) with `--filter` or `-f`.

Usage example:

The following command restores a subset of tables backed up in the `/tmp/backup` path to the cluster.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --filter 'db*.tbl*' \  
  --storage "local:///tmp/backup" \  
  --log-file restorefull.log
```

Restore data from Amazon S3 backend

If you restore data from the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

Note:

To complete one restore, TiKV and BR usually require the minimum privileges of `s3:ListBucket` and `s3:GetObject`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When restoring data using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

`Bucket` and `Folder` in the `--storage` parameter represent the S3 bucket and the folder where the data to be restored is located.

```
br restore full \
  --pd "${PDIP}:2379" \
  --storage "s3://${Bucket}/${Folder}" \
  --s3.region "${region}" \
  --ratelimit 128 \
  --send-credentials-to-tikv=true \
  --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see [Restore a database](#).

Restore incremental data

This feature is currently experimental and is not recommended for use in the production environment.

Restoring incremental data is similar to [restoring full data using BR](#). Note that when restoring incremental data, make sure that all the data backed up before `last backup ts` has been restored to the target cluster.

Restore tables created in the `mysql` schema (experimental feature)

BR backs up tables created in the `mysql` schema by default.

When you restore data using BR, the tables created in the `mysql` schema are not restored by default. If you need to restore these tables, you can explicitly include them using the [table filter](#). The following example restores `mysql.usertable` created in `mysql` schema. The command restores `mysql.usertable` along with other data.

```
br restore full -f '.*' -f '!mysql.*' -f 'mysql.usertable' -s
  ↪ $external_storage_url --ratelimit 128
```

In the above command, `-f '.*'` is used to override the default rules and `-f '!mysql. ↪ .*'` instructs BR not to restore tables in `mysql` unless otherwise stated. `-f 'mysql.usertable'` indicates that `mysql.usertable` is required for restore. For detailed implementation, refer to the [table filter document](#).

If you only need to restore `mysql.usertable`, use the following command:

```
br restore full -f 'mysql.usertable' -s $external_storage_url --ratelimit  
↪ 128
```

Warning:

Although you can back up system tables (such as `mysql.tidb`) using the BR tool, BR ignores the following system tables even if you use the `--filter` setting to perform the restoration:

- Statistical information tables (`mysql.stat_*`)
- System variable tables (`mysql.tidb`, `mysql.global_variables`)
- User information tables (such as `mysql.user` and `mysql.columns_priv`)
- [Other system tables](#)

Decrypt data during restore (experimental feature)

Warning:

This is still an experimental feature. It is **NOT** recommended that you use it in the production environment.

After encrypting the backup data, you need to pass in the corresponding decryption parameters to restore the data. You need to ensure that the decryption parameters and encryption parameters are consistent. If the decryption algorithm or key is incorrect, the data cannot be restored.

The following is an example of decrypting the backup data:

```
br restore full\  
  --pd ${PDIP}:2379 \  
  -s local:///home/tidb/backupdata/incr \  
  --crypter.method aes128-ctr \  
  --crypter.key 0123456789abcdef0123456789abcdef
```

Restore Raw KV (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Similar to [backing up Raw KV](#), you can execute the following command to restore Raw KV:

```
br restore raw --pd $PD_ADDR \  
  -s "local://$BACKUP_DIR" \  
  --start 31 \  
  --end 3130303030303030 \  
  --ratelimit 128 \  
  --format hex \  
  --cf default
```

In the above example, all the backed up keys in the range [0x31, 0x3130303030303030 ↪) are restored to the TiKV cluster. The coding methods of these keys are identical to that of [keys during the backup process](#)

Online restore (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It also relies on the unstable **Placement Rules** feature of PD. It is highly **not recommended** to use this feature in the production environment.

During data restoration, writing too much data affects the performance of the online cluster. To avoid this effect as much as possible, BR supports [Placement rules](#) to isolate resources. In this case, downloading and importing SST are only performed on a few specified nodes (or “restore nodes” for short). To complete the online restore, take the following steps.

1. Configure PD, and start Placement rules:

```
echo "config set enable-placement-rules true" | pd-ctl
```

2. Edit the configuration file of the “restore node” in TiKV, and specify “restore” to the **server** configuration item:

```
[server]  
labels = { exclusive = "restore" }
```

3. Start TiKV of the “restore node” and restore the backed up files using BR. Compared with the offline restore, you only need to add the `--online` flag:

```
br restore full \  
  -s "local://$BACKUP_DIR" \  
  --ratelimit 128 \  
  --pd $PD_ADDR \  
  --online
```

6.4.1.3 BR Use Cases

BR is a tool for distributed backup and restoration of the TiDB cluster data.

This document describes how to run BR in the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

This document aims to help you achieve the following goals:

- Back up and restore data using a network disk or local disk correctly.
- Get the status of a backup or restoration operation through monitoring metrics.
- Learn how to tune performance during the operation.
- Troubleshoot the possible anomalies during the backup operation.

6.4.1.3.1 Audience

You are expected to have a basic understanding of TiDB and [TiKV](#).

Before reading on, make sure you have read [BR Tool Overview](#), especially [Usage Restrictions](#) and [Best Practices](#).

6.4.1.3.2 Prerequisites

This section introduces the recommended method of deploying TiDB, cluster versions, the hardware information of the TiKV cluster, and the cluster configuration for the use case demonstrations.

You can estimate the performance of your backup or restoration operation based on your own hardware and configuration.

Deployment method

It is recommended that you deploy the TiDB cluster using [TiUP](#) and get BR by downloading [TiDB Toolkit](#).

Cluster versions

- TiDB: v5.0.0
- TiKV: v5.0.0
- PD: v5.0.0
- BR: v5.0.0

Note:

v5.0.0 was the latest version at the time this document was written. It is recommended that you use the latest version of **TiDB/TiKV/PD/BR** and make sure that the BR version is **consistent with** the TiDB version.

TiKV hardware information

- Operating system: CentOS Linux release 7.6.1810 (Core)
- CPU: 16-Core Common KVM processor
- RAM: 32GB
- Disk: 500G SSD * 2
- NIC: 10 Gigabit network card

Cluster configuration

BR directly sends commands to the TiKV cluster and are not dependent on the TiDB server, so you do not need to configure the TiDB server when using BR.

- TiKV: default configuration
- PD: default configuration

6.4.1.3.3 Use cases

This document describes the following use cases:

- **Back up a single table to a network disk (recommended in production environment)**
- **Restore data from a network disk (recommended in production environment)**
- **Back up a single table to a local disk (recommended in testing environment)**
- **Restore data from a local disk (recommended in testing environment)**

It is recommended that you use a network disk to back up and restore data. This spares you from collecting backup files and greatly improves the backup efficiency especially when the TiKV cluster is in a large scale.

Before the backup or restoration operations, you need to do some preparations:

- [Preparation for backup](#)
- [Preparation for restoration](#)

Preparation for backup

The BR tool already supports self-adapting to GC. It automatically registers `backupTS` (the latest PD timestamp by default) to PD's `safePoint` to ensure that TiDB's GC Safe Point does not move forward during the backup, thus avoiding manually setting GC configurations.

For the detailed usage of the `br backup` command, refer to [Use BR Command-line for Backup and Restoration](#).

1. Before executing the `br backup` command, ensure that no DDL is running on the TiDB cluster.
2. Ensure that the storage device where the backup will be created has sufficient space (no less than 1/3 of the disk space of the backup cluster).

Preparation for restoration

Before executing the `br restore` command, check the new cluster to make sure that the table in the cluster does not have a duplicate name.

Back up a single table to a network disk (recommended in production environment)

Use the `br backup` command to back up the single table data `--db batchmark --table order_line` to the specified path `local:///br_data` in the network disk.

Backup prerequisites

- [Preparation for backup](#)
- Configure a high-performance SSD hard disk host as the NFS server to store data, and all BR nodes, TiKV nodes, and TiFlash nodes as NFS clients. Mount the same path (for example, `/br_data`) to the NFS server for NFS clients to access the server.
- The total transfer rate between the NFS server and all NFS clients must reach at least the number of TiKV instances * 150MB/s. Otherwise the network I/O might become the performance bottleneck.

Note:

- During data backup, because only the data of leader replicas are backed up, even if there is a TiFlash replica in the cluster, BR can complete the backup without mounting TiFlash nodes.
- When restoring data, BR will restore the data of all replicas. Also, TiFlash nodes need access to the backup data for BR to complete the restore. Therefore, before the restore, you must mount TiFlash nodes to the NFS server.

Topology

The following diagram shows the topology of BR:

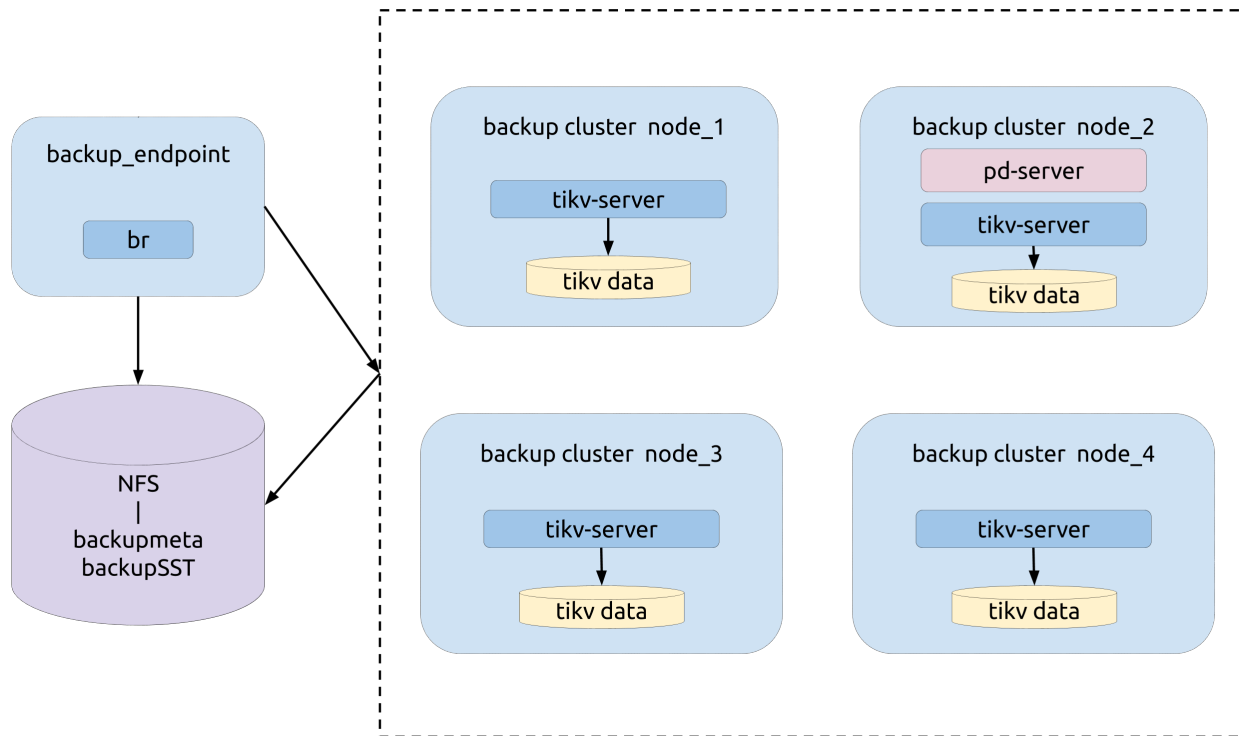

Figure 16: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark` \leftrightarrow `--table order_line`). The following image shows an example of this information:

```

+-----+-----+-----+-----+-----+
| Db_name   | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+-----+-----+-----+-----+-----+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----+-----+-----+-----+-----+
1 row in set (5 min 47.59 sec)

```

Figure 17: img

Execute the `br backup` command:

```
bin/br backup table \
  --db batchmark \
  --table order_line \
  -s local:///br_data \
  --pd ${PD_ADDR}:2379 \
  --log-file backup-nfs.log
```

Monitoring metrics for the backup

During the backup process, pay attention to the following metrics on the monitoring panels to get the status of the backup process.

Backup CPU Utilization: the CPU usage rate of each working TiKV node in the backup operation (for example, backup-worker and backup-endpoint).

Figure 18: img

IO Utilization: the I/O usage rate of each working TiKV node in the backup operation.

Figure 19: img

BackupSST Generation Throughput: the backupSST generation throughput of each working TiKV node in the backup operation, which is normally around 150MB/s.

Figure 20: img

One Backup Range Duration: the duration of backing up a range, which is the total time cost of scanning KVs and storing the range as the backupSST file.

Figure 21: img

One Backup Subtask Duration: the duration of each sub-task into which a backup task is divided.

Note:

- In this task, the single table to be backed up has three indexes and the task is normally divided into four sub-tasks.

- The panel in the following image has thirteen points on it, which means nine (namely, 13-4) retries. Region scheduling might occur during the backup process, so a few retries is normal.

Figure 22: img

Backup Errors: the errors occurred during the backup process. No error occurs in normal situations. Even if a few errors occur, the backup operation has the retry mechanism which might increase the backup time but does not affect the operation correctness.

Figure 23: img

Checksum Request Duration: the duration of the admin checksum request in the backup cluster.

Figure 24: img

Backup results explanation

When finishing the backup, BR outputs the backup summary to the console.

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search “summary” in this log, you can see the following information:

```
[Full backup Success summary:
total backup ranges: 2,
total success: 2,
total failed: 0,
total take(Full backup time): 31.802912166s,
total take(real time): 49.799662427s,
total size(MB): 5997.49,
avg speed(MB/s): 188.58,
total kv: 120000000]
["backup checksum"]=17.907153678s]
["backup fast checksum"]=349.333μs]
["backup total regions"]=43]
[BackupTS=422618409346269185]
[Size=826765915]
```

The above log includes the following information:

- Backup duration: total take(Full backup time): 31.802912166s
- Total runtime of the application: total take(real time): 49.799662427s
- Backup data size: total size(MB): 5997.49
- Backup throughput: avg speed(MB/s): 188.58
- Number of backed-up KV pairs: total kv: 120000000
- Backup checksum duration: ["backup checksum"]=17.907153678s]
- Total duration of calculating the checksum, KV pairs, and bytes of each table: ["↔ backup fast checksum"]=349.333μs]

- Total number of backup Regions: ["backup total regions"]=43]
- The actual size of the backup data in the disk after compression: [Size=826765915]
- Snapshot timestamp of the backup data: [BackupTS=422618409346269185]

From the above information, the throughput of a single TiKV instance can be calculated:
 $\text{avg speed(MB/s)/tikv_count} = 62.86$.

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the backup process (for example, in the [Monitoring metrics for the backup](#), the highest CPU usage rate of backup-worker is around 1500% and the overall I/O usage rate is below 30%), you can try to increase the value of `--concurrency` (4 by default) to tune the performance. But this performance tuning method is not suitable for the use cases of many small tables. See the following example:

```
bin/br backup table \  
  --db batchmark \  
  --table order_line \  
  -s local:///br_data/ \  
  --pd ${PD_ADDR}:2379 \  
  --log-file backup-nfs.log \  
  --concurrency 16
```

Figure 25: img

Figure 26: img

The tuned performance results are as follows (with the same data size):

- Backup duration: `total take(s)` reduced from 986.43 to 535.53
- Backup throughput: `avg speed(MB/s)` increased from 358.09 to 659.59
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from 89 to 164.89

Restore data from a network disk (recommended in production environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- [Preparation for restoration](#)

Topology

The following diagram shows the typology of BR:

Figure 27: img

Restoration operation

Before the restoration, refer to [Preparation for restoration](#) for the preparation.

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data
↔ --pd 172.16.5.198:2379 --log-file restore-nfs.log
```

Monitoring metrics for the restoration

During the restoration process, pay attention to the following metrics on the monitoring panels to get the status of the restoration process.

CPU Utilization: the CPU usage rate of each working TiKV node in the restoration operation.

Figure 28: img

IO Utilization: the I/O usage rate of each working TiKV node in the restoration operation.

Figure 29: img

Region: the Region distribution. The more even Regions are distributed, the better the restoration resources are used.

Figure 30: img

Process SST Duration: the delay of processing the SST files. When restoring a table, if tableID is changed, you need to rewrite tableID. Otherwise, tableID is renamed. Generally, the delay of rewriting is longer than that of renaming.

Figure 31: img

DownLoad SST Throughput: the throughput of downloading SST files from External Storage.

Figure 32: img

Restore Errors: the errors occurred during the restoration process.

Figure 33: img

Checksum Request duration: the duration of the admin checksum request. This duration for the restoration is longer than that for the backup.

Figure 34: img

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search “summary” in this log, you can see the following information:

```
[Table Restore summary:
  total restore tables: 1,
  total success: 1,
  total failed: 0,
  total take(Full restore time): 17m1.001611365s,
  total take(real time): 16m1.371611365s,
  total kv: 5659888624,
  total size(MB): 353227.18,
  avg speed(MB/s): 367.42]
["restore files"]=9263]
["restore ranges"]=6888]
["split region"]=49.049182743s]
["restore checksum"]=6m34.879439498s]
[Size=48693068713]
```

The above log includes the following information:

- Restore duration: total take(Full restore time): 17m1.001611365s
- Total runtime of the application: total take(real time): 16m1.371611365s
- Restore data size: total size(MB): 353227.18
- Restore KV pair number: total kv: 5659888624
- Restore throughput: avg speed(MB/s): 367.42
- Region Split duration: take=49.049182743s
- Restore checksum duration: restore checksum=6m34.879439498s

- The actual size of the restored data in the disk: [Size=48693068713]

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: $\text{avg speed(MB/s)}/\text{tikv_count} = 91.8$
- The average restore speed of a single TiKV instance: $\text{total size(MB)}/(\text{split time} + \text{restore time})/\text{tikv_count} = 87.4$

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the restore process, you can try to increase the value of `--concurrency` which is 128 by default. See the following example:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data/  
  ↪ --pd 172.16.5.198:2379 --log-file restore-concurrency.log --  
  ↪ concurrency 1024
```

The tuned performance results are as follows (with the same data size):

- Restore duration: `total take(s)` reduced from 961.37 to 443.49
- Restore throughput: `avg speed(MB/s)` increased from 367.42 to 796.47
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from 91.8 to 199.1
- Average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` increased from 87.4 to 162.3

Back up a single table to a local disk (recommended in testing environment)

Use the `br backup` command to back up the single table `--db batchmark --table order_line` to the specified path `local:///home/tidb/backup_local` in the local disk.

Backup prerequisites

- **Preparation for backup**
- Each TiKV node has a separate disk to store the backupSST file.
- The `backup_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `backup_endpoint` node must have the same directory for the backup (for example, `/home/tidb/backup_local`).

Topology

The following diagram shows the typology of BR:

Figure 35: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark` \leftrightarrow `--table order_line`). The following image shows an example of this information:

```

+-----+-----+-----+-----+
| Db_name   | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+-----+-----+-----+-----+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----+-----+-----+-----+
1 row in set (5 min 47.59 sec)

```

Figure 36: img

Execute the `br backup` command:

```

bin/br backup table \
  --db batchmark \
  --table order_line \
  -s local:///home/tidb/backup_local/ \

```

```
--pd ${PD_ADDR}:2379 \  
--log-file backup_local.log
```

During the backup process, pay attention to the metrics on the monitoring panels to get the status of the backup process. See [Monitoring metrics for the backup](#) for details.

Backup results explanation

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search “summary” in this log, you can see the following information:

```
["Table backup summary: total backup ranges: 4, total success: 4, total  
↪ failed: 0, total take(s): 551.31, total kv: 5659888624, total size(MB  
↪ ): 353227.18, avg speed(MB/s): 640.71"] ["backup total regions"=6795]  
↪ ["backup checksum"=6m33.962719217s] ["backup fast checksum  
↪ "=22.995552ms]
```

The information from the above log includes:

- Backup duration: `total take(s): 551.31`
- Data size: `total size(MB): 353227.18`
- Backup throughput: `avg speed(MB/s): 640.71`
- Backup checksum duration: `take=6m33.962719217s`

From the above information, the throughput of a single TiKV instance can be calculated:
`avg speed(MB/s)/tikv_count = 160`.

Restore data from a local disk (recommended in testing environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- [Preparation for restoration](#)
- The TiKV cluster and the backup data do not have a duplicate database or table. Currently, BR does not support table route.
- Each TiKV node has a separate disk to store the backupSST file.
- The `restore_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `restore_endpoint` node must have the same directory for the restoration (for example, `/home/tidb/backup_local/`).

Before the restoration, follow these steps:

1. Collect all backupSST files into the same directory.
2. Copy the collected backupSST files to all TiKV nodes of the cluster.

3. Copy the backupmeta file to the restore endpoint node.

Topology

The following diagram shows the typology of BR:

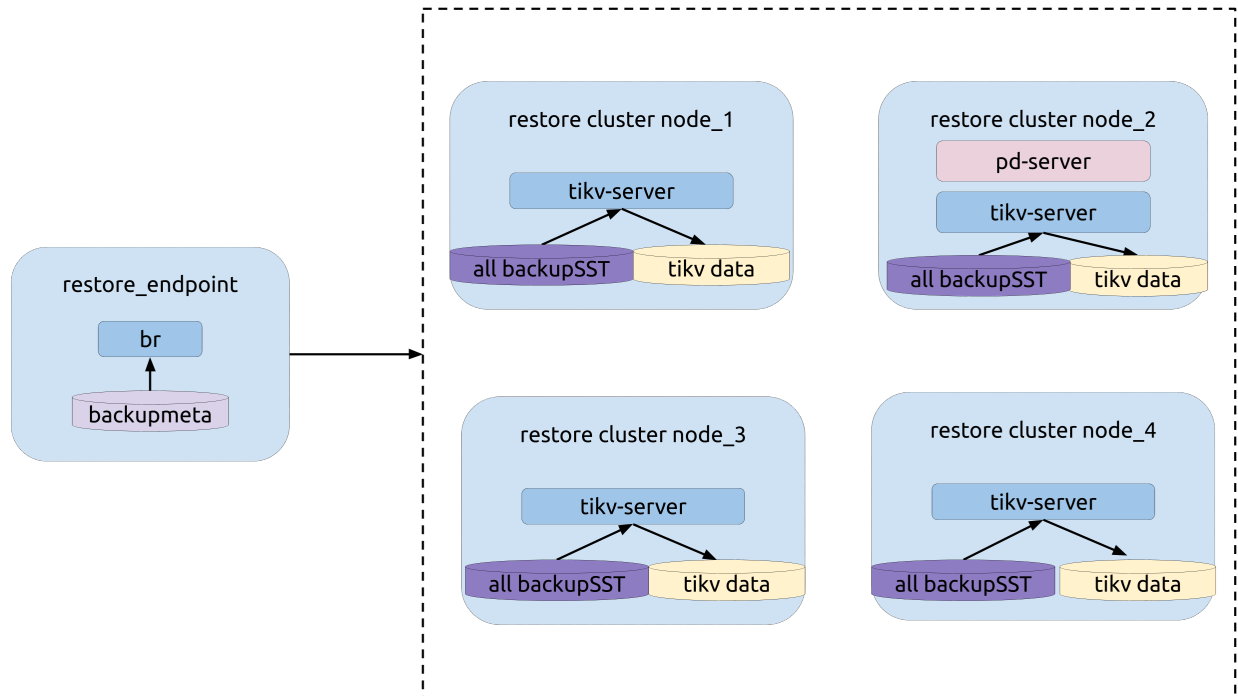

Figure 37: img

Restoration operation

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///home/tidb
↔ /backup_local/ --pd 172.16.5.198:2379 --log-file restore_local.log
```

During the restoration process, pay attention to the metrics on the monitoring panels to get the status of the restoration process. See [Monitoring metrics for the restoration](#) for details.

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search “summary” in this log, you can see the following information:

```
["Table Restore summary: total restore tables: 1, total success: 1, total
↳ failed: 0, total take(s): 908.42, total kv: 5659888624, total size(MB
↳ ): 353227.18, avg speed(MB/s): 388.84"] ["restore files"=9263] ["
↳ restore ranges"=6888] ["split region"=58.7885518s] ["restore checksum
↳ "=6m19.349067937s]
```

The above log includes the following information:

- Restoration duration: `total take(s): 908.42`
- Data size: `total size(MB): 353227.18`
- Restoration throughput: `avg speed(MB/s): 388.84`
- Region Split duration: `take=58.7885518s`
- Restoration checksum duration: `take=6m19.349067937s`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count = 97.2`
- The average restoration speed of a single TiKV instance: `total size(MB)/(split
↳ time + restore time)/tikv_count = 92.4`

6.4.1.3.4 Error handling during backup

This section introduces the common errors occurred during the backup process.

key locked Error in the backup log

Error message in the log: `log - ["backup occur kv error"] [error="{\"KvError
↳ \":{\"locked\"}:`

If a key is locked during the backup process, BR tries to resolve the lock. A small number of these errors do not affect the correctness of the backup.

Backup failure

Error message in the log: `log - Error: msg:"Io(Custom { kind: AlreadyExists,
↳ error: \"[5_5359_42_123_default.sst] is already exists in /dir/backup_local
↳ /\ " })"`

If the backup operation fails and the above message occurs, perform one of the following operations and then start the backup operation again:

- Change the directory for the backup. For example, change `/dir/backup-2020-01-01/` to `/dir/backup_local/`.
- Delete the backup directory of all TiKV nodes and BR nodes.

6.4.1.4 External Storages

6.4.1.4.1 External Storages

Backup & Restore (BR), TiDB Lightning, and Dumping support reading and writing data on the local filesystem and on Amazon S3. BR also supports reading and writing data on the Google Cloud Storage (GCS) and [Azure Blob Storage \(Azblob\)](#). These are distinguished by the URL scheme in the `--storage` parameter passed into BR, in the `-d` parameter passed into TiDB Lightning, and in the `--output (-o)` parameter passed into Dumping.

Schemes

The following services are supported:

Service	Schemes	Example URL
Local filesystem, distributed on every node	local	local:///path/to/dest/
Amazon S3 and compatible services	s3	s3://bucket-name/prefix/of/dest/
Google Cloud Storage (GCS)	gcs, gs	gcs://bucket-name/prefix/of/dest/
Azure Blob Storage	azure, azblob	azure://container-name/prefix/of/dest/
Write to nowhere (for benchmarking only)	noop	noop://

URL parameters

Cloud storages such as S3, GCS and Azblob sometimes require additional configuration for connection. You can specify parameters for such configuration. For example:

- Use Dumping to export data to S3:

```
./dumping -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
-o 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3 (using the path style in the request mode):

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
↪ ://10.154.10.132:8088'
```

- Use BR to back up data to GCS:

```
./br backup full -u 127.0.0.1:2379 \
-s 'gcs://bucket-name/prefix'
```

- Use BR to back up data to Azblob:

```
./br backup full -u 127.0.0.1:2379 \
  -s 'azure://container-name/prefix'
```

S3 URL parameters

URL parameter	Description
<code>access-key</code>	The access key
<code>secret-access-key</code>	The secret access key
<code>region</code>	Service Region for Amazon S3 (default to <code>us-east-1</code>)
<code>use-accelerate-endpoint</code>	Whether to use the accelerate endpoint on Amazon S3 (default to <code>false</code>)
<code>endpoint</code>	URL of custom endpoint for S3-compatible services (for example, <code>https://s3.example.com/</code>)
<code>force-path-style</code>	Use path style access rather than virtual hosted style access (default to <code>false</code>)

URL parameter	Description
<code>storage-class</code>	Storage class of the uploaded objects (for example, <code>STANDARD</code> , <code>STANDARD_IA</code>)
<code>sse</code>	Server-side encryption algorithm used to encrypt the upload (empty, <code>aws:kms</code>)
<code>sse-kms-key-id</code>	If <code>sse</code> is set to <code>aws:kms</code> , specifies the KMS ID
<code>acl</code>	Canned ACL of the uploaded objects (for example, <code>private</code> , <code>authenticated-read</code>)

Note:

It is not recommended to pass in the access key and secret access key directly in the storage URL, because these keys are logged in plain text. The migration tools try to infer these keys from the environment in the following order:

1. `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables
2. `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables

3. Shared credentials file on the tool node at the path specified by the `$AWS_SHARED_CREDENTIALS_FILE`
 ↪ environment variable
4. Shared credentials file on the tool node at `~/.aws/credentials`
5. Current IAM role of the Amazon EC2 container
6. Current IAM role of the Amazon ECS task

GCS URL parameters

URL parameter	Description
<code>credentials</code> ↪ <code>-file</code>	The path to the credentials JSON file on the tool node
<code>storage-class</code> ↪ <code>class</code>	Storage class of the uploaded objects (for example, STANDARD, COLDLINE)
<code>predefined-acl</code> ↪ <code>-acl</code>	Predefined ACL of the uploaded objects (for example, private, project-private) ↪ <code>private</code> ↪ <code>)</code>

When `credentials-file` is not specified, the migration tool will try to infer the credentials from the environment, in the following order:

1. Content of the file on the tool node at the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS`
 ↪ environment variable
2. Content of the file on the tool node at `~/.config/gcloud/application_default_credentials.json`
 ↪ `.json`
3. When running in GCE or GAE, the credentials fetched from the metadata server.

Azblob URL parameters

URL parameter	Description
<code>account- ↪ name</code>	The account name of the storage
<code>account- ↪ key</code>	The access key
<code>access- ↪ tier</code>	Access tier of the uploaded objects (for example, <code>Hot</code> , <code>Cool</code> , <code>Archive</code> ↪). If <code>access</code> ↪ - ↪ <code>tier</code> ↪ is not set (the value is empty), the value is <code>Hot</code> by default.

To ensure that TiKV and BR use the same storage account, BR determines the value of `account-name`. That is, `send-credentials-to-tikv = true` is set by default. BR infers these keys from the environment in the following order:

1. If both `account-name` **and** `account-key` are specified, the key specified by this parameter is used.
2. If `account-key` is not specified, then BR tries to read the related credentials from environment variables on the node of BR.

- BR reads `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` first. At the same time, BR allows TiKV to read the above three environment variables from the respective nodes and access using Azure AD (Azure Active Directory).
 - `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` respectively refer to the application ID `client_id`, the tenant ID `tenant_id`, and the client password `client_secret` of Azure application.
 - To learn how to check whether the operating system has configured `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET`, or if you need to configure these variables as parameters, refer to [Configure environment variables as parameters](#).
3. If the above three environment variables are not configured in the BR node, BR tries to read `$AZURE_STORAGE_KEY` using an access key.

Note:

When using Azure Blob Storage as the external storage, you must set `send-credentials-to-tikv = true` (which is set by default). Otherwise, the backup task will fail.

Command-line parameters

In addition to the URL parameters, BR and Dumpling also support specifying these configurations using command-line parameters. For example:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \  
-o 's3://my-bucket/sql-backup' \  
--s3.region 'us-west-2'
```

If you have specified URL parameters and command-line parameters at the same time, the URL parameters are overwritten by the command-line parameters.

S3 command-line parameters

Command-line parameter	Description
<code>--s3. ↪ region</code>	Amazon S3's service region, which defaults to <code>us-east-1</code> .
<code>--s3. ↪ endpoint ↪</code>	The URL of custom endpoint for S3-compatible services. For example, <code>https://s3.example.com/</code> .
<code>--s3. ↪ storage ↪ -class</code>	The storage class of the upload object. For example, <code>STANDARD</code> and <code>STANDARD_IA</code> .

Command-line parameter	Description
<code>--s3.sse</code>	The server-side encryption algorithm used to encrypt the upload. The value options are empty, <code>AES256</code> and <code>aws:</code> <code>↪ kms.</code>
<code>--s3.sse- ↪ kms-key ↪ -id</code>	If <code>--s3. ↪ sse</code> is configured as <code>aws: ↪ kms,</code> this parameter is used to specify the KMS ID.

Command-line parameter	Description
<code>--s3.acl</code>	The canned ACL of the upload object. For example, <code>private</code> ↪ and <code>authenticated</code> ↪ - ↪ <code>read</code> ↪ .
<code>--s3.</code> ↪ <code>provider</code> ↪	The type of the S3-compatible service. The supported types are <code>aws</code> , <code>alibaba</code> ↪ , <code>ceph</code> , <code>netease</code> ↪ and <code>other</code> .

To export data to non-AWS S3 cloud storage, specify the cloud provider and whether to use `virtual-hosted` style. In the following examples, data is exported to the Alibaba Cloud OSS storage:

- Export data to Alibaba Cloud OSS using Dumpling:

```
./dumpling -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
-o "s3://my-bucket/dumpling/" \
--s3.endpoint="http://oss-cn-hangzhou-internal.aliyuncs.com" \
--s3.provider="alibaba" \
```

```
-r 200000 -F 256MiB
```

- Back up data to Alibaba Cloud OSS using BR:

```
./br backup full --pd "127.0.0.1:2379" \
  --storage "s3://my-bucket/full/" \
  --s3.endpoint="http://oss-cn-hangzhou-internal.aliyuncs.com" \
  --s3.provider="alibaba" \
  --send-credentials-to-tikv=true \
  --ratelimit 128 \
  --log-file backuptable.log
```

- Export data to Alibaba Cloud OSS using TiDB Lightning. You need to specify the following content in the YAML-formatted configuration file:

```
[mydumper]
data-source-dir = "s3://my-bucket/dumpling/?endpoint=http://oss-cn-
  ↳ hangzhou-internal.aliyuncs.com&provider=alibaba"
```

GCS command-line parameters

Command-line parameter	Description
<code>--gcs.↳ credentials</code> <code>↳ -file</code>	The path of the JSON-formatted credential on the tool node.
<code>--gcs.↳ storage</code> <code>↳ -class</code>	The storage type of the upload object, such as STANDARD ↳ and COLDLINE ↳ .

Command-line parameter	Description
<code>--gcs.</code>	The pre-
<code>↪ predefined</code>	defined
<code>↪ -acl</code>	ACL of the upload object, such as private
	<code>↪ and project</code>
	<code>↪ -</code>
	<code>↪ private</code>
	<code>↪ .</code>

Azblob command-line parameters

Command-line parameter	Description
<code>--azblob.account-name</code>	The account name of the storage
<code>--azblob.account-key</code>	The access key
<code>--azblob.access-tier</code>	Access tier of the uploaded objects (for example, Hot, Cool, Archive). If <code>access-tier</code> is not set (the value is empty), the value is Hot by default.

BR sending credentials to TiKV

By default, when using S3, GCS, or Azblob destinations, BR will send the credentials to every TiKV node to reduce setup complexity.

However, this is unsuitable on cloud environment, where every node has their own role and permission. In such cases, you need to disable credentials sending with `--send` `↪ -credentials-to-tikv=false` (or the short form `-c=0`):

```
./br backup full -c=0 -u pd-service:2379 -s 's3://bucket-name/prefix'
```

When using SQL statements to **back up** and **restore** data, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
↪ FALSE;
```

This option is not supported in TiDB Lightning and Dumpling, because the two applications are currently standalone.

6.4.1.4.2 Back up and Restore Data on Azure Blob Storage

The Backup & Restore (BR) tool supports using Azure Blob Storage as the external storage for backing up and restoring data.

For detailed information on other external storages supported by BR, refer to [External Storages](#).

User scenario

Azure virtual machines can quickly store large-scale data on Azure Blob Storage. If you are using Azure virtual machines to deploy your cluster, you can back up your data on Azure Blob Storage.

Usage

With BR, you can back up and restore data on Azure Blob Storage by the following two methods:

- Back up and restore data using Azure AD (Azure Active Directory)
- Back up and restore data using an access key

In common cases, to avoid exposing the key information (such as `account-key`) in command lines, it is recommended to use Azure AD.

The following is an example of backup and restore operations on Azure Blob Storage using the above two methods. The purpose of the operations are as follows:

- Back up: Back up the `test` database to a space in the `container=test` container with `t1` as the path prefix in Azure Blob Storage.
- Restore: Restore data from a space in the `container=test` container with `t1` as the path prefix in Azure Blob Storage to the `test` database.

Method 1: Back up and restore using Azure AD (recommended)

In the operating environment of BR and TiKV, the environment variables `$AZURE_CLIENT_ID` ↪ , `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` must be configured. When these variables are configured, BR can use Azure AD to access Azure Blob Storage without configuring `account-key`. This method is safer and therefore recommended. `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` refer to the application ID `client_id`, the tenant ID `tenant_id`, and the client password `client_secret` of Azure application.

To learn how to check `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` ↪ are in your operating environment, or if you want to configure these environment variables as parameters, refer to [Configure environment variables as parameters](#).

Back up

When backing up data using Azure AD, you need to specify `account-name` and `access` ↪ `-tier`. If `access-tier` is not set (the value is empty), the value is `Hot` by default.

Note:

When using Azure Blob Storage as the external storage, you must set `send-credentials-to-tikv = true` (which is set by default). Otherwise, the backup task will fail.

This section shows backing up data to `cool` tier, that is, the access tier of the uploaded object is `Cool`. You can specify `account-name` and `access-tier` in two ways:

- Write the parameters information in URL parameters:

```
tiup br backup db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?
↳ account-name=devstoreaccount1&access-tier=Cool'
```

- Write the parameters information in command-line parameters:

```
tiup br backup db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?' --
↳ azblob.account-name=devstoreaccount1 --azblob.access-tier=Cool
```

Restore

When restoring data using Azure AD, you need to specify `account-name`. You can specify it in two ways:

- Write the parameter information in URL parameters:

```
tiup br restore db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?
↳ account-name=devstoreaccount1'
```

- Write the parameter information in command-line parameters:

```
tiup br restore db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?' --
↳ azblob.account-name=devstoreaccount1
```

Method 2: Back up and restore using an access key (easy)

Back up

When backing up data using an access key, you need to specify `account-name`, `account-key`, and `access-tier`. If `access-tier` is not set (the value is empty), the value is `Hot` by default.

Note:

When using Azure Blob Storage as the external storage, you must set `send-credentials-to-tikv = true` (which is set by default). Otherwise, the backup task will fail.

This section shows backing up data to `cool` tier, that is, the access tier of the uploaded object is `Cool`. You can specify `account-name`, `account-key`, and `access-tier` in two ways:

- Write the parameter information in URL parameters:

```
tiup br backup db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?
  ↪ account-name=devstoreaccount1&account-key=
  ↪ Eby8vdM02xN0cqFlqUwJPLlmEt1CDXJ10UzFT50uSRZ6IFsuFq2UVERCz4I6tq/
  ↪ K1SZFPT0tr/KBHBeksoGMGw==&access-tier=Cool'
```

- Write the parameter information in command-line parameters:

```
tiup br backup db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?' --
  ↪ azblob.account-name=devstoreaccount1 --azblob.account-key=
  ↪ Eby8vdM02xN0cqFlqUwJPLlmEt1CDXJ10UzFT50uSRZ6IFsuFq2UVERCz4I6tq/
  ↪ K1SZFPT0tr/KBHBeksoGMGw== --azblob.access-tier=Cool
```

Restore

When restoring data using an access key, you need to specify `account-name` and `account-key`. You can specify the parameters in two ways:

- Write the parameters information in URL parameters:

```
tiup br restore db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?
  ↪ account-name=devstoreaccount1&account-key=
  ↪ Eby8vdM02xN0cqFlqUwJPLlmEt1CDXJ10UzFT50uSRZ6IFsuFq2UVERCz4I6tq/
  ↪ K1SZFPT0tr/KBHBeksoGMGw=='
```

- Write the parameters information in command-line parameters:

```
tiup br restore db --db test -u 127.0.0.1:2379 -s 'azure://test/t1?' --
  ↪ azblob.account-name=devstoreaccount1 --azblob.account-key=
  ↪ Eby8vdM02xN0cqFlqUwJPLlmEt1CDXJ10UzFT50uSRZ6IFsuFq2UVERCz4I6tq/
  ↪ K1SZFPT0tr/KBHBeksoGMGw=='
```

Parameter description

During the backup and restore process, you need to use `account-name`, `account-key`, and `access-tier`. The following is the detailed description of the parameters:

- [URL parameters](#)
- [Command-line parameters](#)

Configure environment variables as parameters

When backing up and restoring data using Azure AD, the environment variables `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` must be configured in the operating environment of BR and TiKV.

- When you start a cluster using TiUP, TiKV uses the “systemd” service. The following example provides how to configure the above three environment variables as parameters for TiKV:

Note:

You need to restart TiKV in Step 3. If your TiKV cannot be restarted, you can back up and restore data using the [Method 2](#).

1. Suppose that the TiKV port on this node is 24000, that is, the name of the “systemd” service is “tikv-24000”:

```
systemctl edit tikv-24000
```

2. Fill in the environment variable information:

```
[Service]
Environment="AZURE_CLIENT_ID=aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
Environment="AZURE_TENANT_ID=aaaaaaaa-aaaa-aaaa-aaaa-aaaaaaaaaaaa"
Environment="AZURE_CLIENT_SECRET=
↳ aaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaaa"
```

3. Reload the configuration and restart TiKV:

```
systemctl daemon-reload
systemctl restart tikv-24000
```

- For TiKV and BR started with command lines, to configure the Azure AD information for them, you only need to check whether the environment variables `$AZURE_CLIENT_ID` \leftrightarrow , `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` are configured in the operating environment. You can check whether the variables are in the operating environment of BR and TiKV by running the following commands:

```
echo $AZURE_CLIENT_ID
echo $AZURE_TENANT_ID
echo $AZURE_CLIENT_SECRET
```

Compatibility

This feature is **only compatible** with v5.4.0 and later versions.

6.4.1.5 BR Features

6.4.1.5.1 BR Auto-Tune New in v5.4.0

Before TiDB v5.4.0, when you back up data using BR, the number of threads used for backup makes up 75% of the logical CPU cores. Without a speed limit, the backup process can consume a lot of cluster resources, which has a considerable impact on the performance of the online cluster. Although you can reduce the impact of backup by adjusting the size of the thread pool, it is a tedious task to observe the CPU load and manually adjust the thread pool size.

To reduce the impact of backup tasks on the cluster, starting from TiDB v5.4.0, BR introduces the auto-tune feature. When the cluster resource utilization is high, BR automatically limits the resources used by backup tasks and thereby reduces their impact on the cluster. The auto-tune feature is enabled by default.

User scenario

If you want to reduce the impact of backup tasks on the cluster, you can enable the auto-tune feature. With this feature enabled, BR performs backup tasks as fast as possible without excessively affecting the cluster.

Alternatively, you can limit the backup speed by using the TiKV configuration item `backup.num-threads` or using the parameter `--rate-limit`.

Use auto-tune

The auto-tune feature is enabled by default, without additional configuration.

Note:

For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To manually enable the auto-tune feature, you need to set the TiKV configuration item `backup.enable-auto-tune` to `true`.

TiKV supports dynamically configuring the auto-tune feature. You can enable or disable the feature without restarting your cluster. To dynamically enable or disable the auto-tune feature, run the following command:

```
tikv-ctl modify-tikv-config -n backup.enable-auto-tune -v <true|false>
```

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

Limitations

Auto-tune is a coarse-grained solution for limiting backup speed. It reduces the need for manual tuning. However, because of the lack of fine-grained control, auto-tune might not be able to completely remove the impact of backup on the cluster.

The auto-tune feature has the following issues and corresponding solutions:

- Issue 1: For **write-heavy clusters**, auto-tune might put the workload and backup tasks into a “positive feedback loop”: the backup tasks take up too many resources, which causes the cluster to use fewer resources; at this point, auto-tune might mistakenly assume that the cluster is not under heavy workload and thus allow BR to run faster. In such cases, auto-tune is ineffective.
 - Solution: Manually adjust `backup.num-threads` to a smaller number to limit the number of threads used by backup tasks. The working principle is as follows:
The backup process includes lots of SST decoding, encoding, compression, and decompression, which consume CPU resources. In addition, previous test cases have shown that during the backup process, the CPU utilization of the thread pool used for backup is close to 100%. This means that the backup tasks take up a lot of CPU resources. By adjusting the number of threads used by the backup tasks, TiKV can limit the CPU cores used by backup tasks, thus reducing the impact of backup tasks on the cluster performance.
- Issue 2: For **clusters with hotspots**, backup tasks on the TiKV node that has hotspots might be excessively limited, which slows down the overall backup process.
 - Solution: Eliminate the hotspot node, or disable auto-tune on the hotspot node (this might reduce the cluster performance).
- Issue 3: For scenarios with **high traffic jitter**, because auto-tune adjusts the speed limit on a fixed interval (1 minute by default), it might not be able to handle high traffic jitter. For details, see [auto-tune-refresh-interval](#).
 - Solution: Disable auto-tune.

Implementation

Auto-tune adjusts the size of the thread pool used by backup tasks using BR to ensure that the overall CPU utilization of the cluster does not exceed a specific threshold.

This feature has two related configuration items not listed in the TiKV configuration file. These two configuration items are only for internal tuning. You do **not** need to configure these two configuration items when you perform backup tasks.

- `backup.auto-tune-remain-threads`:
 - Auto-tune controls the resources used by the backup tasks and ensures that at least `backup.auto-tune-remain-threads` cores are available for other tasks on the same node.
 - Default value: `round(0.2 * vCPU)`
- `backup.auto-tune-refresh-interval`:
 - Every `backup.auto-tune-refresh-interval` minute(s), auto-tune refreshes the statistics and recalculates the maximum number of CPU cores that backup tasks can use.
 - Default value: `1m`

The following is an example of how auto-tune works. * denotes a CPU core used by backup tasks. ^ denotes a CPU core used by other tasks. - denotes an idle CPU core.

```
|-----| The server has 8 logical CPU cores.
|****---| By default, `backup.num-threads` is `4`. Note that auto-tune
  ↪ makes sure that the thread pool size is never larger than `backup.num
  ↪ -threads`.
|^~****--| By default, `auto-tune-remain-threads` =  $\text{round}(8 * 0.2) = 2$ . Auto
  ↪ -tune adjusts the size of the thread pool to `4`.
|^~~~**--| Because the cluster workload gets higher, auto-tune adjusts the
  ↪ size of the thread pool to `2`. After that, the cluster still has 2
  ↪ idle CPU cores.
```

In the **Backup CPU Utilization** panel, you can see the size of the thread pool adjusted by auto-tune:

Figure 38: Grafana dashboard example of backup auto-tune metrics

In the image above, the yellow semi-transparent area represents the threads available for backup tasks. You can see the CPU utilization of backup tasks does not go beyond the yellow area.

6.4.1.6 Backup & Restore FAQ

This document lists the frequently asked questions (FAQs) and the solutions about Backup & Restore (BR).

6.4.1.6.1 In TiDB v5.4.0 and later versions, when backup tasks are performed on the cluster under high workload, why does the speed of backup tasks become slow?

Starting from TiDB v5.4.0, BR introduces the auto-tune feature for backup tasks. For clusters in v5.4.0 or later versions, this feature is enabled by default. When the cluster workload is heavy, the feature limits the resources used by backup tasks to reduce the impact on the online cluster. For more information, refer to [BR Auto-Tune](#).

TiKV supports [dynamically configuring](#) the auto-tune feature. You can enable or disable the feature by the following methods without restarting your cluster:

- Disable auto-tune: Set the TiKV configuration item `backup.enable-auto-tune` to `false`.
- Enable auto-tune: Set `backup.enable-auto-tune` to `true`. For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To use `tikv-ctl` to enable or disable auto-tune, refer to [Use auto-tune](#).

In addition, this feature also reduces the default number of threads used by backup tasks. For details, see `backup.num-threads` ([/tikv-configuration-file.md#num-threads-1](#)). Therefore, on the Grafana Dashboard, the speed, CPU usage, and I/O resource utilization used by backup tasks are lower than those of versions earlier than v5.4. Before v5.4, the

default value of `backup.num-threads` was $\text{CPU} * 0.75$, that is, the number of threads used by backup tasks makes up 75% of the logical CPU cores. The maximum value of it was 32. Starting from v5.4, the default value of this configuration item is $\text{CPU} * 0.5$, and its maximum value is 8.

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

6.4.1.6.2 What should I do if the error message could not read local://...:download sst failed is returned during data restoration?

When you restore data, each node must have access to **all** backup files (SST files). By default, if `local` storage is used, you cannot restore data because the backup files are scattered among different nodes. Therefore, you have to copy the backup file of each TiKV node to the other TiKV nodes.

It is recommended to mount an NFS disk as a backup disk during backup. For details, see [Back up a single table to a network disk](#).

6.4.1.6.3 How much does it affect the cluster during backup using BR?

For TiDB v5.4.0 or later versions, BR not only reduces the default CPU utilization used by backup tasks but also limits the resources used by backup tasks in the cluster with heavy workloads. Therefore, when you use the default configuration for backup tasks in the v5.4.0 cluster with heavy workloads, the impact of the tasks on the cluster performance is significantly less than the impact for the clusters earlier than v5.4.0. For details, see [BR Auto-tune](#).

The following is an internal test on a single node. The test results show that when you use the default configuration of v5.4.0 and v5.3.0 in the **full-speed backup** scenario, the impact of backup using BR on cluster performance is quite different. The detailed test results are as follows:

- When BR uses the default configuration of v5.3.0, the QPS of write-only workload is reduced by 75%.
- When BR uses the default configuration of v5.4.0, the QPS for the same workload is reduced by 25%. However, when this configuration is used, the speed of backup tasks using BR becomes correspondingly slower. The time required is 1.7 times that of the v5.3.0 configuration.

If you need to manually control the impact of backup tasks on cluster performance, you can use the following solutions. These two methods can reduce the impact of backup tasks on the cluster, but they also reduce the speed of backup tasks.

- Use the `--ratelimit` parameter to limit the speed of backup tasks. Note that this parameter limits the speed of **saving backup files to external storage**. When calculating the total size of backup files, use the `backup data size(after compressed)` in the backup log as a benchmark.

- Adjust the TiKV configuration item `backup.num-threads` to limit the resources used by backup tasks. This configuration item determines the number of threads used by backup tasks. When BR uses no more than 8 threads for backup tasks, and the total CPU utilization of the cluster does not exceed 60%, the backup tasks have little impact on the cluster, regardless of the read and write workload.

6.4.1.6.4 Does BR back up system tables? During data restoration, do they raise conflicts?

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`.

During data restoration, system tables do not raise conflicts. The technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default, which means no conflicts will be raised. For more details, refer to the [Back up and restore table data in the mysql system schema \(experimental feature\)](#).

6.4.1.6.5 What should I do to handle the Permission denied or No such file or directory error, even if I have tried to run BR using root in vain?

You need to confirm whether TiKV has access to the backup directory. To back up data, confirm whether TiKV has the write permission. To restore data, confirm whether it has the read permission.

During the backup operation, if the storage medium is the local disk or a network file system (NFS), make sure that the user to start BR and the user to start TiKV are consistent (if BR and TiKV are on different machines, the users' UIDs must be consistent). Otherwise, the `Permission denied` issue might occur.

Running BR with the root access might fail due to the disk permission, because the backup files (SST files) are saved by TiKV.

Note:

You might encounter the same problem during data restoration. When the SST files are read for the first time, the read permission is verified. The execution duration of DDL suggests that there might be a long interval between checking the permission and running BR. You might receive the error message `Permission denied` after waiting for a long time.

Therefore, it is recommended to check the permission before data restore according to the following steps:

1. Run the Linux-native command for process query:

```
ps aux | grep tikv-server
```

The output of the above command:

```
tidb_ouo 9235 10.9 3.8 2019248 622776 ? Ssl 08:28 1:12 bin/tikv-
↳ server --addr 0.0.0.0:20162 --advertise-addr 172.16.6.118:20162
↳ --status-addr 0.0.0.0:20188 --advertise-status-addr
↳ 172.16.6.118:20188 --pd 172.16.6.118:2379 --data-dir /home/user1/
↳ tidb-data/tikv-20162 --config conf/tikv.toml --log-file /home/
↳ user1/tidb-deploy/tikv-20162/log/tikv.log
tidb_ouo 9236 9.8 3.8 2048940 631136 ? Ssl 08:28 1:05 bin/tikv-
↳ server --addr 0.0.0.0:20161 --advertise-addr 172.16.6.118:20161
↳ --status-addr 0.0.0.0:20189 --advertise-status-addr
↳ 172.16.6.118:20189 --pd 172.16.6.118:2379 --data-dir /home/user1/
↳ tidb-data/tikv-20161 --config conf/tikv.toml --log-file /home/
↳ user1/tidb-deploy/tikv-20161/log/tikv.log
```

Or you can run the following command:

```
ps aux | grep tikv-server | awk '{print $1}'
```

The output of the above command:

```
tidb_ouo
tidb_ouo
```

2. Query the startup information of the cluster using the TiUP command:

```
tiup cluster list
```

The output of the above command:

```
[root@Copy-of-VM-EE-CentOS76-v1 br]# tiup cluster list
Starting component `cluster`: /root/.tiup/components/cluster/v1.5.2/
↳ tiup-cluster list
Name          User      Version Path
↳
-----
PrivateKey
↳
tidb_cluster tidb_ouo v5.0.2 /root/.tiup/storage/cluster/clusters/
↳ tidb_cluster /root/.tiup/storage/cluster/clusters/tidb_cluster/
↳ ssh/id_rsa
```

3. Check the permission for the backup directory. For example, backup is for backup data storage:

```
ls -al backup
```

The output of the above command:

```
[root@Copy-of-VM-EE-CentOS76-v1 user1]# ls -al backup
total 0
drwxr-xr-x 2 root root 6 Jun 28 17:48 .
drwxr-xr-x 11 root root 310 Jul 4 10:35 ..
```

From the above output, you can find that the `tikv-server` instance is started by the user `tidb_ouo`. But the user `tidb_ouo` does not have the write permission for `backup`, the backup fails.

6.4.1.6.6 What should I do to handle the `Io(0s...)` error?

Almost all of these problems are system call errors that occur when TiKV writes data to the disk. For example, if you encounter error messages such as `Io(0s {code: 13, kind: PermissionDenied...})` or `Io(0s {code: 2, kind: NotFound...})`, you can first check the mounting method and the file system of the backup directory, and try to back up data to another folder or another hard disk.

For example, you might encounter the `Code: 22(invalid argument)` error when backing up data to the network disk built by `samba`.

6.4.1.6.7 What should I do to handle the `rpc error: code = Unavailable desc =... error occurred in BR?`

This error might occur when the capacity of the cluster to restore (using BR) is insufficient. You can further confirm the cause by checking the monitoring metrics of this cluster or the TiKV log.

To handle this issue, you can try to scale out the cluster resources, reduce the concurrency during restore, and enable the `RATE_LIMIT` option.

6.4.1.6.8 Where are the backed up files stored when I use local storage?

When you use local storage, `backupmeta` is generated on the node where BR is running, and backup files are generated on the Leader nodes of each Region.

6.4.1.6.9 How about the size of the backup data? Are there replicas of the backup?

During data backup, backup files are generated on the Leader nodes of each Region. The size of the backup is equal to the data size, with no redundant replicas. Therefore, the total data size is approximately the total number of TiKV data divided by the number of replicas.

However, if you want to restore data from local storage, the number of replicas is equal to that of the TiKV nodes, because each TiKV must have access to all backup files.

6.4.1.6.10 What should I do when BR restores data to the upstream cluster of TiCDC/Drainer?

- **The data restored using BR cannot be replicated to the downstream.** This is because BR directly imports SST files but the downstream cluster currently cannot obtain these files from the upstream.
- Before v4.0.3, DDL jobs generated during the BR restore might cause unexpected DDL executions in TiCDC/Drainer. Therefore, if you need to perform restore on the upstream cluster of TiCDC/Drainer, add all tables restored using BR to the TiCDC/Drainer block list.

You can use `filter.rules` to configure the block list for TiCDC and use `syncer.ignore` ↪ `-table` to configure the block list for Drainer.

6.4.1.6.11 Does BR back up the SHARD_ROW_ID_BITS and PRE_SPLIT_REGIONS information of a table? Does the restored table have multiple Regions?

Yes. BR backs up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table. The data of the restored table is also split into multiple Regions.

6.4.1.6.12 Why is the region is unavailable error reported for a SQL query after I use BR to restore the backup data?

If the cluster backed up using BR has TiFlash, `TableInfo` stores the TiFlash information when BR restores the backup data. If the cluster to be restored does not have TiFlash, the `region is unavailable` error is reported.

6.4.1.6.13 Does BR support in-place full recovery of some historical backup?

No. BR does not support in-place full recovery of some historical backup.

6.4.1.6.14 How can I use BR for incremental backup in the Kubernetes environment?

To get the `commitTs` field of the last BR backup, run the `kubectl -n ${namespace} ↪ } get bk ${name}` command using `kubectl`. You can use the content of this field as `--lastbackupts`.

6.4.1.6.15 How can I convert BR backupTS to Unix time?

BR `backupTS` defaults to the latest timestamp obtained from PD before the backup starts. You can use `pd-ctl tso timestamp` to parse the timestamp to obtain an accurate value, or use `backupTS >> 18` to quickly obtain an estimated value.

6.4.1.6.16 After BR restores the backup data, do I need to execute the ANALYZE statement on the table to update the statistics of TiDB on the tables and indexes?

BR does not back up statistics (except in v4.0.9). Therefore, after restoring the backup data, you need to manually execute `ANALYZE TABLE` or wait for TiDB to automatically execute `ANALYZE`.

In v4.0.9, BR backs up statistics by default, which consumes too much memory. To ensure that the backup process goes well, the backup for statistics is disabled by default starting from v4.0.10.

If you do not execute `ANALYZE` on the table, TiDB will fail to select the optimized execution plan due to inaccurate statistics. If query performance is not a key concern, you can ignore `ANALYZE`.

6.4.1.6.17 Can I use multiple BR processes at the same time to restore the data of a single cluster?

It is strongly not recommended to use multiple BR processes at the same time to restore the data of a single cluster for the following reasons:

- When BR restores data, it modifies some global configurations of PD. Therefore, if you use multiple BR processes for data restore at the same time, these configurations might be mistakenly overwritten and cause abnormal cluster status.
- BR consumes a lot of cluster resources to restore data, so in fact, running BR processes in parallel improves the restore speed only to a limited extent.
- There has been no test for running multiple BR processes in parallel for data restore, so it is not guaranteed to succeed.

6.5 Time Zone Support

The time zone in TiDB is decided by the global `time_zone` system variable and the session `time_zone` system variable. The default value of `time_zone` is `SYSTEM`. The actual time zone corresponding to `System` is configured when the TiDB cluster bootstrap is initialized. The detailed logic is as follows:

- Prioritize the use of the TZ environment variable.
- If the TZ environment variable fails, extract the time zone from the actual soft link address of `/etc/localtime`.
- If both of the above methods fail, use UTC as the system time zone.

You can use the following statement to set the global server `time_zone` value at runtime:

```
SET GLOBAL time_zone = timezone;
```

Each client has its own time zone setting, given by the session `time_zone` variable. Initially, the session variable takes its value from the global `time_zone` variable, but the client can change its own time zone with this statement:

```
SET time_zone = timezone;
```

You can use the following statement to view the current values of the global, client-specific and system time zones:

```
SELECT @@global.time_zone, @@session.time_zone, @@global.system_time_zone;
```

To set the format of the value of the `time_zone`:

- The value 'SYSTEM' indicates that the time zone should be the same as the system time zone.
- The value can be given as a string indicating an offset from UTC, such as '+10:00' or '-6:00'.
- The value can be given as a named time zone, such as 'Europe/Helsinki', 'US/Eastern', or 'MET'.

The current session time zone setting affects the display and storage of time values that are zone-sensitive. This includes the values displayed by functions such as `NOW()` or `CURTIME()`.

Note:

Only the values of the Timestamp data type is affected by time zone. This is because the Timestamp data type uses the literal value + time zone information. Other data types, such as Datetime/Date/Time, do not have time zone information, thus their values are not affected by the changes of time zone.

```
create table t (ts timestamp, dt datetime);
```

```
Query OK, 0 rows affected (0.02 sec)
```

```
set @@time_zone = 'UTC';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
insert into t values ('2017-09-30 11:11:11', '2017-09-30 11:11:11');
```

```
Query OK, 1 row affected (0.00 sec)
```

```
set @@time_zone = '+8:00';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+-----+
| ts          | dt          |
+-----+-----+
| 2017-09-30 19:11:11 | 2017-09-30 11:11:11 |
+-----+-----+
1 row in set (0.00 sec)
```

In this example, no matter how you adjust the value of the time zone, the value of the Datetime data type is not affected. But the displayed value of the Timestamp data type changes if the time zone information changes. In fact, the value that is stored in the storage does not change, it's just displayed differently according to different time zone setting.

Note:

- Time zone is involved during the conversion of the value of Timestamp and Datetime, which is handled based on the current `time_zone` of the session.
- For data migration, you need to pay special attention to the time zone setting of the primary database and the secondary database.

6.6 Daily Check

As a distributed database, TiDB is more complicated than the stand-alone database in terms of the mechanism, and monitoring items. To help operate and maintain TiDB in a more convenient way, this document introduces some key performance indicators.

6.6.1 Key indicators of TiDB Dashboard

Starting from v4.0, TiDB provides a new operation and maintenance management tool, **TiDB Dashboard**. This tool is integrated into the PD component. You can access TiDB Dashboard at the default address `http://{pd-ip}:{pd_port}/dashboard`.

TiDB Dashboard simplifies the operation and maintenance of the TiDB database. You can view the running status of the entire TiDB cluster through one interface. The following are descriptions of some performance indicators.

6.6.1.1 Instance panel

Instances		Hosts				
Address	Status	Up Time	Version	Deployment Directory	Git Hash	
▼ tidb (1)						
127.0.0.1:4000	● Up	Today at 2:19 PM	v4.0.0	/Users/wangjun/tiup/compo...	689a6b6439ae7835...	
▼ tikv (1)						
127.0.0.1:20160	● Up	Today at 2:19 PM	v4.0.0	/Users/wangjun/tiup/compo...	198a2cea01734ce8...	
▼ pd (1)						
127.0.0.1:2379	● Up	Today at 2:19 PM	v4.0.0	/Users/wangjun/tiup/compo...	56d4c3d2237f5bf6f...	

Figure 39: Instance panel

- **Status:** This indicator is used to check whether the status is normal. For an online node, this can be ignored.
- **Up Time:** The key indicator. If you find that the **Up Time** is changed, you need to locate the reason why the component is restarted.
- **Version, Deployment Directory, Git Hash:** These indicators need to be checked to avoid inconsistent or even incorrect version/deployment directory.

6.6.1.2 Host panel

Instances		Hosts					
Address	CPU	CPU Usage	Memory	Memory Usage	Disk	Disk Size	Disk Usage
127.0.0.1	4 vCPU		8.0 GiB		1 TiDB, 1 TiKV, 1 PD: APF:	233.5 GiB	

Figure 40: Host panel

You can view the usage of CPU, memory, and disk. When the usage of any resource exceeds 80%, it is recommended to scale out the capacity accordingly.

6.6.1.3 SQL analysis panel

Recent 30 min

SHOW DATABASES	3.9 ms	1.3 ms	3	0 B	

Figure 41: SQL analysis panel

You can locate the slow SQL statement executed in the cluster. Then you can optimize the specific SQL statement.

6.6.1.4 Region panel

Figure 42: Region panel

- **miss-peer-region-count**: The number of Regions without enough replicas. This value is not always greater than 0.
- **extra-peer-region-count**: The number of Regions with extra replicas. These Regions are generated during the scheduling process.
- **empty-region-count**: The number of empty Regions, generated by executing the TRUNCATE TABLE/DROP TABLE statement. If this number is large, you can consider enabling Region Merge to merge Regions across tables.
- **pending-peer-region-count**: The number of Regions with outdated Raft logs. It is normal that a few pending peers are generated in the scheduling process. However, it is not normal if this value is large for a period of time (longer than 30 minutes).
- **down-peer-region-count**: The number of Regions with an unresponsive peer reported by the Raft leader.
- **offline-peer-region-count**: The number of Regions during the offline process.

Generally, it is normal that these values are not 0. However, it is not normal that they are not 0 for quite a long time.

6.6.1.5 KV Request Duration

Figure 43: TiKV request duration

The KV request duration 99 in TiKV. If you find nodes with a long duration, check whether there are hot spots, or whether there are nodes with poor performance.

6.6.1.6 PD TSO Wait Duration

Figure 44: TiDB TSO Wait Duration

The time it takes for TiDB to obtain TSO from PD. The following are reasons for the long wait duration:

- High network latency from TiDB to PD. You can manually execute the ping command to test the network latency.
- High load for the TiDB server.
- High load for the PD server.

6.6.1.7 Overview panel

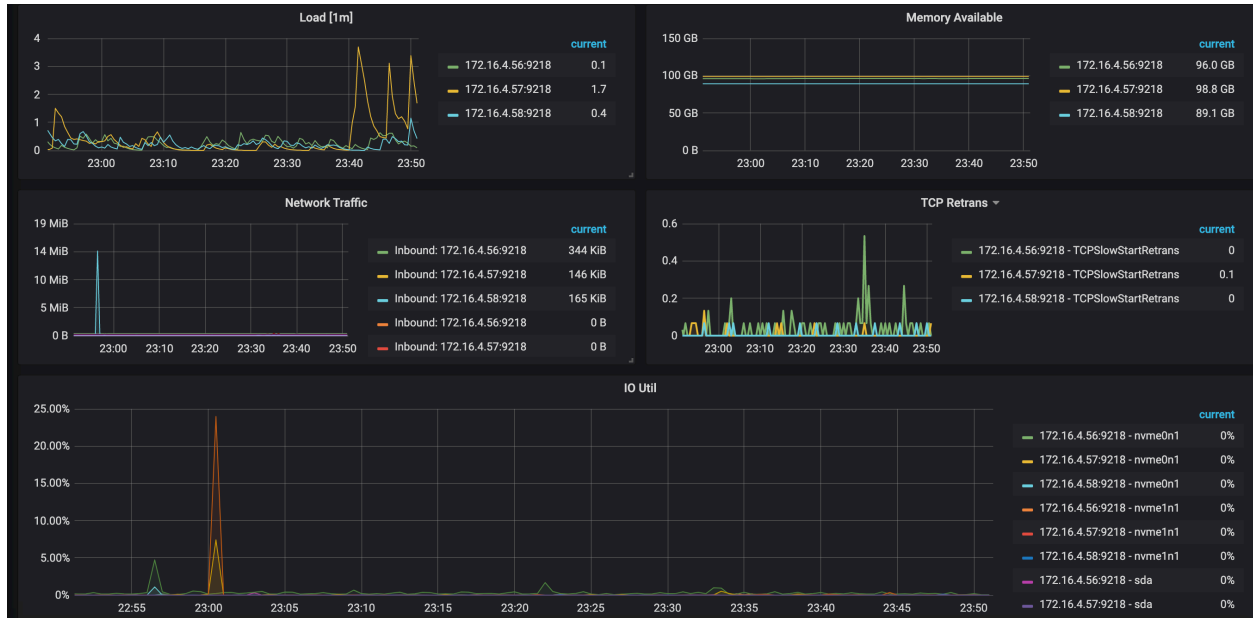

Figure 45: Overview panel

You can view the load, memory available, network traffic, and I/O utilities. When a bottleneck is found, it is recommended to scale out the capacity, or to optimize the cluster topology, SQL, cluster parameters, etc.

6.6.1.8 Exceptions

Figure 46: Exceptions

You can view the errors triggered by the execution of SQL statements on each TiDB instance. These include syntax error, primary key conflicts, etc.

6.6.1.9 GC status

```
(root@127.0.0.1) [(none)]>select * from mysql.tidb;
```

VARIABLE_NAME	VARIABLE_VALUE	COMMENT
bootstrapped	True	Bootstrap flag. Do not <i>delete</i> .
tidb_server_version	44	Bootstrap version. Do not <i>delete</i> .
system_tz	Asia/Shanghai	TiDB Global System Timezone.
new_collation_enabled	False	If the new collations are enabled. Do not
tikv_gc_leader_uuid	5c8c8865ca80006	Current GC worker leader UUID. (DO NOT
tikv_gc_leader_desc	host:wangjundeMacBook-Pro.local, pid:81322, start at 2020-05-20 20:49:21.735312 +0800 CST m--7,904021075	Host name and pid of current GC leader.
tikv_gc_leader_lease	20200522-00:06:30 +0800	Current GC worker leader lease. (DO NOT

tikv_gc_mode	distributed	Mode of GC, "central" or "distributed"

```
14 rows in set (0.01 sec)
```

Figure 47: GC status

You can check whether the GC (Garbage Collection) status is normal by viewing the time when the last GC happens. If the GC is abnormal, it might lead to excessive historical data, thereby decreasing the access efficiency.

6.7 Maintain a TiFlash Cluster

This document describes how to perform common operations when you maintain a **TiFlash** cluster, including checking the TiFlash version. This document also introduces critical logs and a system table of TiFlash.

6.7.1 Check the TiFlash version

There are two ways to check the TiFlash version:

- If the binary file name of TiFlash is `tiflash`, you can check the version by executing the `./tiflash version` command.

However, to execute the above command, you need to add the directory path which includes the `libtiflash_proxy.so` dynamic library to the `LD_LIBRARY_PATH` environment variable. This is because the running of TiFlash relies on the `libtiflash_proxy` \leftrightarrow `.so` dynamic library.

For example, when `tiflash` and `libtiflash_proxy.so` are in the same directory, you can first switch to this directory, and then use the following command to check the TiFlash version:

```
LD_LIBRARY_PATH=./ ./tiflash version
```

- Check the TiFlash version by referring to the TiFlash log. For the log path, see the `[logger]` part in [the `tiflash.toml` file](#). For example:

```
<information>: TiFlash version: TiFlash 0.2.0 master-375035282451103999  
   $\leftrightarrow$  f3863c691e2fc2
```

6.7.2 TiFlash critical logs

Log Information	Log Description
[INFO] [<unknown> [“KVStore: Start to persist [region 47, applied: term 6 index 10]”] [thread_id=23]	Data starts to be replicated (the number in the square brackets at the start of the log refers to the thread ID

Log Information	Log Description
[DEBUG] [<unknown> [“CoprocessorHandler: grpc::Status DB::CoprocessorHandler::execute(): Handling DAG request”] [thread_id=30]	Handling DAG request, that is, TiFlash starts to handle a Coprocessor request
[DEBUG] [<unknown> [“CoprocessorHandler: grpc::Status DB::CoprocessorHandler::execute(): Handle DAG request done”] [thread_id=30]	Handling DAG request done, that is, TiFlash finishes handling a Coprocessor request

You can find the beginning or the end of a Coprocessor request, and then locate the related logs of the Coprocessor request through the thread ID printed at the start of the log.

6.7.3 TiFlash system table

The column names and their descriptions of the `information_schema.tiflash_replica` system table are as follows:

Column Name	Description
TABLE_SCHEMA	database name
TABLE_NAME	table name
TABLE_ID	table ID
REPLICA_COUNT	number of TiFlash replicas
AVAILABLE	available or not (0/1)
PROGRESS	replication progress [0.0~1.0]

6.8 TiUP Common Operations

This document describes the following common operations when you operate and maintain a TiDB cluster using TiUP.

- View the cluster list

- Start the cluster
- View the cluster status
- Modify the configuration
- Stop the cluster
- Destroy the cluster

6.8.1 View the cluster list

You can manage multiple TiDB clusters using the TiUP cluster component. When a TiDB cluster is deployed, the cluster appears in the TiUP cluster list.

To view the list, run the following command:

```
tiup cluster list
```

6.8.2 Start the cluster

The components in the TiDB cluster are started in the following order:

PD > TiKV > Pump > TiDB > TiFlash > Drainer > TiCDC > Prometheus > Grafana > Alertmanager

To start the cluster, run the following command:

```
tiup cluster start ${cluster-name}
```

Note:

Replace `${cluster-name}` with the name of your cluster. If you forget the cluster name, check it by running `tiup cluster list`.

You can start only some of the components by adding the `-R` or `-N` parameters in the command. For example:

- This command starts only the PD component:

```
tiup cluster start ${cluster-name} -R pd
```

- This command starts only the PD components on the 1.2.3.4 and 1.2.3.5 hosts:

```
tiup cluster start ${cluster-name} -N 1.2.3.4:2379,1.2.3.5:2379
```

Note:

If you start the specified component by using the `-R` or `-N` parameters, make sure the starting order is correct. For example, start the PD component before the TiKV component. Otherwise, the start might fail.

6.8.3 View the cluster status

After starting the cluster, check the status of each component to ensure that they work normally. TiUP provides the `display` command, so you do not have to log in to every machine to view the component status.

```
tiup cluster display ${cluster-name}
```

6.8.4 Modify the configuration

When the cluster is in operation, if you need to modify the parameters of a component, run the `edit-config` command. The detailed steps are as follows:

1. Open the configuration file of the cluster in the editing mode:

```
tiup cluster edit-config ${cluster-name}
```

2. Configure the parameters:

- If the configuration is globally effective for a component, edit `server_configs`:

```
server_configs:
  tidb:
    log.slow-threshold: 300
```

- If the configuration takes effect on a specific node, edit the configuration in `config` of the node:

```
tidb_servers:
- host: 10.0.1.11
  port: 4000
  config:
    log.slow-threshold: 300
```

For the parameter format, see the [TiUP parameter template](#).

Use `.` to represent the hierarchy of the configuration items.

For more information on the configuration parameters of components, refer to [TiDB config.toml.example](#), [TiKV config.toml.example](#), and [PD config.toml.example](#)
↔ `.`

3. Rolling update the configuration and restart the corresponding components by running the `reload` command:

```
tiup cluster reload ${cluster-name} [-N <nodes>] [-R <roles>]
```

6.8.4.1 Example

If you want to set the transaction size limit parameter (`txn-total-size-limit` in the [performance](#) module) to 1G in `tidb-server`, edit the configuration as follows:

```
server_configs:
  tidb:
    performance.txn-total-size-limit: 1073741824
```

Then, run the `tiup cluster reload ${cluster-name} -R tidb` command to rolling restart the TiDB component.

6.8.5 Replace with a hotfix package

For normal upgrade, see [Upgrade TiDB Using TiUP](#). But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

Replace the remote package with a specified package and restart the service

Usage:

```
cluster patch <cluster-name> <package-path> [flags]
```

Flags:

<code>-h, --help</code>	help for patch
<code>-N, --node strings</code>	Specify the nodes
<code>--overwrite</code>	Use this package in the future scale-out ↔ operations
<code>-R, --role strings</code>	Specify the role
<code>--transfer-timeout int</code>	Timeout in seconds when transferring PD and ↔ TiKV store leaders (default 300)

Global Flags:

```
--native-ssh      Use the system's native SSH client
--wait-timeout int Timeout of waiting the operation
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
                  ↪ for operations that don't need an SSH connection. (default 5)
-y, --yes         Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

6.8.6 Rename the cluster

After deploying and starting the cluster, you can rename the cluster using the `tiup cluster rename` command:

```
tiup cluster rename ${cluster-name} ${new-name}
```

Note:

- The operation of renaming a cluster restarts the monitoring system (Prometheus and Grafana).
- After a cluster is renamed, some panels with the old cluster name might remain on Grafana. You need to delete them manually.

6.8.7 Stop the cluster

The components in the TiDB cluster are stopped in the following order (The monitoring component is also stopped):

Alertmanager > Grafana > Prometheus > TiCDC > Drainer > TiFlash > TiDB > Pump > TiKV > PD

To stop the cluster, run the following command:

```
tiup cluster stop ${cluster-name}
```

Similar to the `start` command, the `stop` command supports stopping some of the components by adding the `-R` or `-N` parameters. For example:

- This command stops only the TiDB component:

```
tiup cluster stop ${cluster-name} -R tidb
```

- This command stops only the TiDB components on the 1.2.3.4 and 1.2.3.5 hosts:

```
tiup cluster stop ${cluster-name} -N 1.2.3.4:4000,1.2.3.5:4000
```

6.8.8 Clean up cluster data

The operation of cleaning up cluster data stops all the services and cleans up the data directory or/and log directory. The operation cannot be reverted, so proceed **with caution**.

- Clean up the data of all services in the cluster, but keep the logs:

```
tiup cluster clean ${cluster-name} --data
```

- Clean up the logs of all services in the cluster, but keep the data:

```
tiup cluster clean ${cluster-name} --log
```

- Clean up the data and logs of all services in the cluster:

```
tiup cluster clean ${cluster-name} --all
```

- Clean up the logs and data of all services except Prometheus:

```
tiup cluster clean ${cluster-name} --all --ignore-role prometheus
```

- Clean up the logs and data of all services except the 172.16.13.11:9000 instance:

```
tiup cluster clean ${cluster-name} --all --ignore-node  
↳ 172.16.13.11:9000
```

- Clean up the logs and data of all services except the 172.16.13.12 node:

```
tiup cluster clean ${cluster-name} --all --ignore-node 172.16.13.12
```

6.8.9 Destroy the cluster

The destroy operation stops the services and clears the data directory and deployment directory. The operation cannot be reverted, so proceed **with caution**.

```
tiup cluster destroy ${cluster-name}
```

6.9 Modify Configuration Online

This document describes how to modify the cluster configuration online.

Note:

This feature is experimental. It is **NOT** recommended to use this feature in the production environment.

You can update the configuration of components (including TiDB, TiKV, and PD) online using SQL statements, without restarting the cluster components. Currently, the method of changing TiDB instance configuration is different from that of changing configuration of other components (such TiKV and PD).

6.9.1 Common Operations

This section describes the common operations of modifying configuration online.

6.9.1.1 View instance configuration

To view the configuration of all instances in the cluster, use the `show config` statement. The result is as follows:

```
show config;
```

```
+--  
  ↳ -----+-----+  
  ↳  
 | Type | Instance      | Name |  
  ↳ Value |  
  ↳ |  
  ↳ |  
+--  
  ↳ -----+-----+  
  ↳  
 | tidb | 127.0.0.1:4001 | advertise-address |  
  ↳ 127.0.0.1 |  
  ↳ |  
  ↳ |  
 | tidb | 127.0.0.1:4001 | binlog.binlog-socket |  
  ↳ |  
  ↳ |  
  ↳ |
```

```

| tidb | 127.0.0.1:4001 | binlog.enable |
  ↪ false
  ↪
  ↪ |
| tidb | 127.0.0.1:4001 | binlog.ignore-error |
  ↪ false
  ↪
  ↪ |
| tidb | 127.0.0.1:4001 | binlog.strategy |
  ↪ range
  ↪
  ↪ |
| tidb | 127.0.0.1:4001 | binlog.write-timeout |
  ↪ 15s
  ↪
  ↪ |
| tidb | 127.0.0.1:4001 | check-mb4-value-in-utf8 |
  ↪ true
  ↪
  ↪ |
...

```

You can filter the result by fields. For example:

```

show config where type='tidb'
show config where instance in (...)
show config where name like '%log%'
show config where type='tikv' and name='log.level'

```

6.9.1.2 Modify TiKV configuration online

Note:

- After changing TiKV configuration items online, the TiKV configuration file is automatically updated. However, you also need to modify the corresponding configuration items by executing `tiup edit-config`; otherwise, operations such as `upgrade` and `reload` will overwrite your changes. For details of modifying configuration items, refer to [Modify configuration using TiUP](#).
- After executing `tiup edit-config`, you do not need to execute `tiup ↪ reload`.

When using the `set config` statement, you can modify the configuration of a single instance or of all instances according to the instance address or the component type.

- Modify the configuration of all TiKV instances:

Note:

It is recommended to wrap variable names in backticks.

```
set config tikv `split.qps-threshold`=1000;
```

- Modify the configuration of a single TiKV instance:

```
set config "127.0.0.1:20180" `split.qps-threshold`=1000;
```

If the modification is successful, Query OK is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If an error occurs during the batch modification, a warning is returned:

```
set config tikv `log-level`='warn';
```

```
Query OK, 0 rows affected, 1 warning (0.04 sec)
```

```
show warnings;
```

```
+--
  ↳ -----+-----+-----
  ↳
  | Level | Code | Message
  ↳
  ↳ |
+--
  ↳ -----+-----+-----
  ↳
  | Warning | 1105 | bad request to http://127.0.0.1:20180/config: fail to
  ↳ update, error: "config log-level can not be changed" |
+--
  ↳ -----+-----+-----
  ↳
1 row in set (0.00 sec)
```

The batch modification does not guarantee atomicity. The modification might succeed on some instances, while failing on others. If you modify the configuration of the entire TiKV cluster using `set tikv key=val`, your modification might fail on some instances. You can use `show warnings` to check the result.

If some modifications fail, you need to re-execute the corresponding statement or modify each failed instance. If some TiKV instances cannot be accessed due to network issues or machine failure, modify these instances after they are recovered.

If a configuration item is successfully modified, the result is persisted in the configuration file, which will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words, such as `limit` and `key`. For these configuration items, use backtick ``` to enclose them. For example, ``raftstore.raft-log-gc-size-limit`` → ```.

The following TiKV configuration items can be modified online:

Configuration item	Description
<code>raftstore-max-entries-in-memory</code>	The maximum number of entries in memory.
<code>raftstore-max-logs-in-memory</code>	The maximum number of logs in memory.
<code>raftstore-raft-log-gc-size-limit</code>	The maximum size of Raft logs that can be garbage collected.
<code>raftstore-raft-log-gc-timer-interval</code>	The interval of Raft log garbage collection timer.
<code>raftstore-raft-log-gc-threshold</code>	The threshold of Raft log garbage collection.
<code>raftstore-raft-log-gc-timer-interval</code>	The interval of Raft log garbage collection timer.
<code>raftstore-raft-log-gc-threshold</code>	The threshold of Raft log garbage collection.

<code>cdc.incremental.scanning.tasks.for.historical.data</code>	The number of concurrent incremental scanning tasks for historical data

In the table above, parameters with the `{db-name}` or `{db-name}.{cf-name}` prefix are configurations related to RocksDB. The optional values of `db-name` are `rocksdb` and `raftdb`.

- When `db-name` is `rocksdb`, the optional values of `cf-name` are `defaultcf`, `writecf`, `lockcf`, and `raftcf`.
- When `db-name` is `raftdb`, the value of `cf-name` can be `defaultcf`.

For detailed parameter description, refer to [TiKV Configuration File](#).

6.9.1.3 Modify PD configuration online

Currently, PD does not support the separate configuration for each instance. All PD instances share the same configuration.

You can modify the PD configurations using the following statement:

```
set config pd `log.level`='info';
```

If the modification is successful, Query OK is returned:

```
Query OK, 0 rows affected (0.01 sec)
```

If a configuration item is successfully modified, the result is persisted in etcd instead of in the configuration file; the configuration in etcd will prevail in the subsequent operations. The names of some configuration items might conflict with TiDB reserved words. For these configuration items, use backtick ``` to enclose them. For example, ``schedule.leader-
↪ schedule-limit``.

The following PD configuration items can be modified online:

Configuration item	Description
<code>log.level</code>	The log level
<code>cluster-version</code>	The cluster version
<code>schedule.merge-region-size</code>	Controls the size of the region to be merged (in MiB)

Configuration item	Description
<code>schedule.merge</code>	Specifies the maximum number of regions to be merged at a time.
<code>schedule.mergeRegionKeys</code>	Specifies the keys to be merged.
<code>schedule.mergeRegionKeysMerge</code>	Specifies the merge operation.
<code>schedule.mergeRegionKeysKeys</code>	Specifies the keys to be merged.
<code>schedule.patrolFrequency</code>	Determines the frequency of patrol.
<code>schedule.patrolRegion</code>	Specifies the region to be patrolled.
<code>schedule.patrolRegionWhich</code>	Specifies which region to be patrolled.
<code>interReplicaChecker</code>	Checks the health state of a Region.

6.9.1.4 Modify TiDB configuration online

Currently, the method of changing TiDB configuration is different from that of changing TiKV and PD configurations. You can modify TiDB configuration by using [system variables](#).

The following example shows how to modify `slow-threshold` online by using the `tidb_slow_log_threshold` variable.

The default value of `slow-threshold` is 300 ms. You can set it to 200 ms by using `tidb_slow_log_threshold`.

```
set tidb_slow_log_threshold = 200;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select @@tidb_slow_log_threshold;
```

```
+-----+
| @@tidb_slow_log_threshold |
+-----+
| 200                        |
+-----+
1 row in set (0.00 sec)
```

The following TiDB configuration items can be modified online:

Configuration item	SQL variable
<code>mem-quota-query</code>	<code>tidb_mem_quota_query</code>
<code>log.enable-slow-log</code>	<code>tidb_enable_slow_log</code>
<code>log.slow-threshold</code>	<code>tidb_slow_log_threshold</code>
<code>log.expensive-threshold</code>	<code>tidb_expensive_query_time_threshold</code>

6.10 Online Unsafe Recovery

Warning:

- Online Unsafe Recovery is a type of lossy recovery. If you use this feature, the integrity of data and data indexes cannot be guaranteed.
- Online Unsafe Recovery is an experimental feature, and it is **NOT** recommended to use it in the production environment. The interface, strategy, and internal implementation of this feature might change when it becomes generally available (GA). Although this feature has been tested in some scenarios, it is not thoroughly validated and might cause system unavailability.
- It is recommended to perform the feature-related operations with the support from the TiDB team. If any misoperation is performed, it might be hard to recover the cluster.

When permanently damaged replicas cause part of data on TiKV to be unreadable and unwritable, you can use the Online Unsafe Recovery feature to perform a lossy recovery operation.

6.10.1 Feature description

In TiDB, the same data might be stored in multiple stores at the same time according to the replica rules defined by users. This guarantees that data is still readable and writable even if a single or a few stores are temporarily offline or damaged. However, when most or all replicas of a Region go offline during a short period of time, the Region becomes temporarily unavailable, by design, to ensure data integrity.

Suppose that multiple replicas of a data range encounter issues like permanent damage (such as disk damage), and these issues cause the stores to stay offline. In this case, this data range is temporarily unavailable. If you want the cluster back in use and also accept data rewind or data loss, in theory, you can re-form the majority of replicas by manually removing the failed replicas from the group. This allows application-layer services to read and write this data range (might be stale or empty) again.

In this case, if some stores with loss-tolerant data are permanently damaged, you can perform a lossy recovery operation by using Online Unsafe Recovery. Using this feature, PD, under its global perspective, collects the metadata of data shards from all stores and generates a real-time and complete recovery plan. Then, PD distributes the plan to all surviving stores to make them perform data recovery tasks. In addition, once the data recovery plan is distributed, PD periodically monitors the recovery progress and re-send the plan when necessary.

6.10.2 User scenarios

The Online Unsafe Recovery feature is suitable for the following scenarios:

- The data for application services is unreadable and unwritable, because permanently damaged stores cause the stores to fail to restart.
- You can accept data loss and want the affected data to be readable and writable.
- You want to perform a one-stop online data recovery operation.

6.10.3 Usage

6.10.3.1 Prerequisites

Before using Online Unsafe Recovery, make sure that the following requirements are met:

- The offline stores indeed cause some pieces of data to be unavailable.
- The offline stores cannot be automatically recovered or restarted.

6.10.3.2 Step 1. Disable all types of scheduling

You need to temporarily disable all types of internal scheduling, such as load balancing. After disabling them, it is recommended to wait for about 10 minutes so that the triggered scheduling can have sufficient time to complete the scheduled tasks.

Note:

After the scheduling is disabled, the system cannot resolve data hotspot issues. Therefore, you need to enable the scheduling as soon as possible after the recovery is completed.

1. Use PD Control to get the current configuration by running the `config show` command.
2. Use PD Control to disable all types of scheduling. For example:
 - `config set region-schedule-limit 0`
 - `config set replica-schedule-limit 0`
 - `config set merge-schedule-limit 0`

6.10.3.3 Step 2. Remove the stores that cannot be automatically recovered

Use PD Control to remove the stores that cannot be automatically recovered by running the `unsafe remove-failed-stores <store_id>[,<store_id>,...]` command.

Note:

The returned result of this command only indicates that the request is accepted, not that the recovery is completed successfully. The stores are actually recovered in the background.

6.10.3.4 Step 3. Check the progress

When the above store removal command runs successfully, you can use PD Control to check the removal progress by running the `unsafe remove-failed-stores show` command. When the command result shows “Last recovery has finished”, the system recovery is completed.

6.10.3.5 Step 4. Test read and write tasks

After the progress command shows that the recovery task is completed, you can try to execute some simple SQL queries like the following example or perform write tasks to ensure that the data is readable and writable.

```
select count(*) from table_that_suffered_from_group_majority_failure;
```

Note:

The situation that data can be read and written does not indicate there is no data loss.

6.10.3.6 Step 5. Restart the scheduling

To restart the scheduling, you need to adjust the 0 value of config set `region-schedule-limit` 0, config set `replica-schedule-limit` 0, and config set `merge-schedule-limit` 0 modified in step 1 to the initial values.

Then, the whole process is finished.

7 Monitor and Alert

7.1 TiDB Monitoring Framework Overview

The TiDB monitoring framework adopts two open source projects: Prometheus and Grafana. TiDB uses [Prometheus](#) to store the monitoring and performance metrics and [Grafana](#) to visualize these metrics.

7.1.1 About Prometheus in TiDB

As a time series database, Prometheus has a multi-dimensional data model and flexible query language. As one of the most popular open source projects, Prometheus has been adopted by many companies and organizations and has a very active community. PingCAP is one of the active developers and adopters of Prometheus for monitoring and alerting in TiDB, TiKV and PD.

Prometheus consists of multiple components. Currently, TiDB uses the following of them:

- The Prometheus Server to scrape and store time series data
- The client libraries to customize necessary metrics in the application
- An Alertmanager for the alerting mechanism

The diagram is as follows:

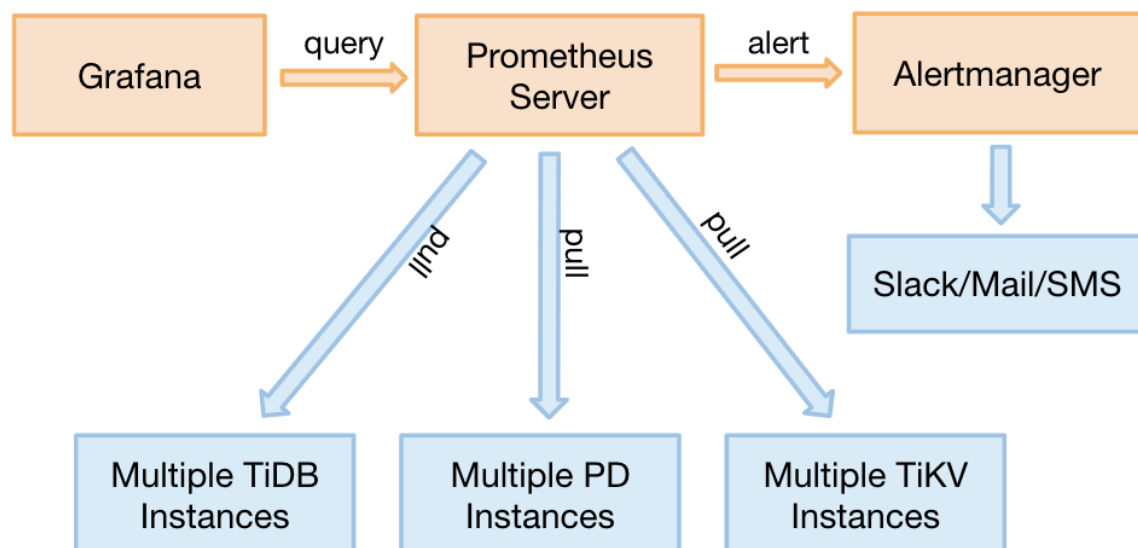

Figure 48: diagram

7.1.2 About Grafana in TiDB

Grafana is an open source project for analyzing and visualizing metrics. TiDB uses Grafana to display the performance metrics as follows:

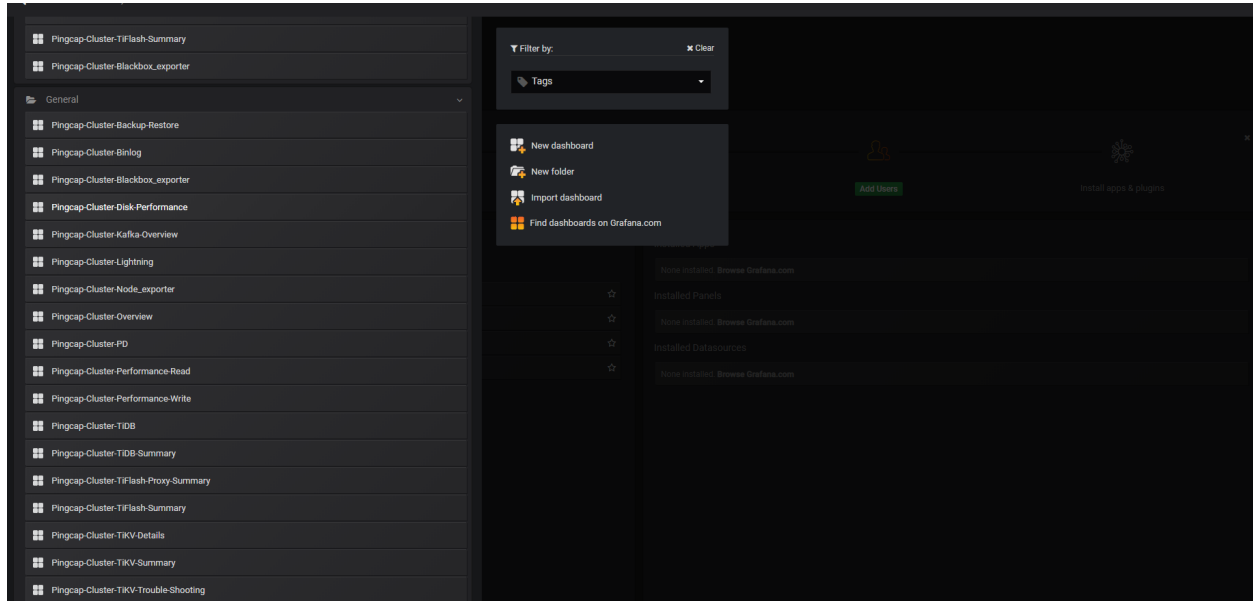

Figure 49: Grafana monitored_groups

- {TiDB_Cluster_name}-Backup-Restore: Monitoring metrics related to backup and restore.
- {TiDB_Cluster_name}-Binlog: Monitoring metrics related to TiDB Binlog.
- {TiDB_Cluster_name}-Blackbox_exporter: Monitoring metrics related to network probe.
- {TiDB_Cluster_name}-Disk-Performance: Monitoring metrics related to disk performance.
- {TiDB_Cluster_name}-Kafka-Overview: Monitoring metrics related to Kafka.
- {TiDB_Cluster_name}-Lightning: Monitoring metrics related to TiDB Lightning.
- {TiDB_Cluster_name}-Node_exporter: Monitoring metrics related to the operating system.
- {TiDB_Cluster_name}-Overview: Monitoring overview related to important components.
- {TiDB_Cluster_name}-PD: Monitoring metrics related to the PD server.
- {TiDB_Cluster_name}-Performance-Read: Monitoring metrics related to read performance.
- {TiDB_Cluster_name}-Performance-Write: Monitoring metrics related to write performance.
- {TiDB_Cluster_name}-TiDB: Detailed monitoring metrics related to the TiDB server.

- {TiDB_Cluster_name}-TiDB-Summary: Monitoring overview related to TiDB.
- {TiDB_Cluster_name}-TiFlash-Proxy-Summary: Monitoring overview of the proxy server that is used to replicate data to TiFlash.
- {TiDB_Cluster_name}-TiFlash-Summary: Monitoring overview related to TiFlash.
- {TiDB_Cluster_name}-TiKV-Details: Detailed monitoring metrics related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Summary: Monitoring overview related to the TiKV server.
- {TiDB_Cluster_name}-TiKV-Trouble-Shooting: Monitoring metrics related to the TiKV error diagnostics.
- {TiDB_Cluster_name}-TiCDC: Detailed monitoring metrics related to TiCDC.

Each group has multiple panel labels of monitoring metrics, and each panel contains detailed information of multiple monitoring metrics. For example, the **Overview** monitoring group has five panel labels, and each labels corresponds to a monitoring panel. See the following UI:

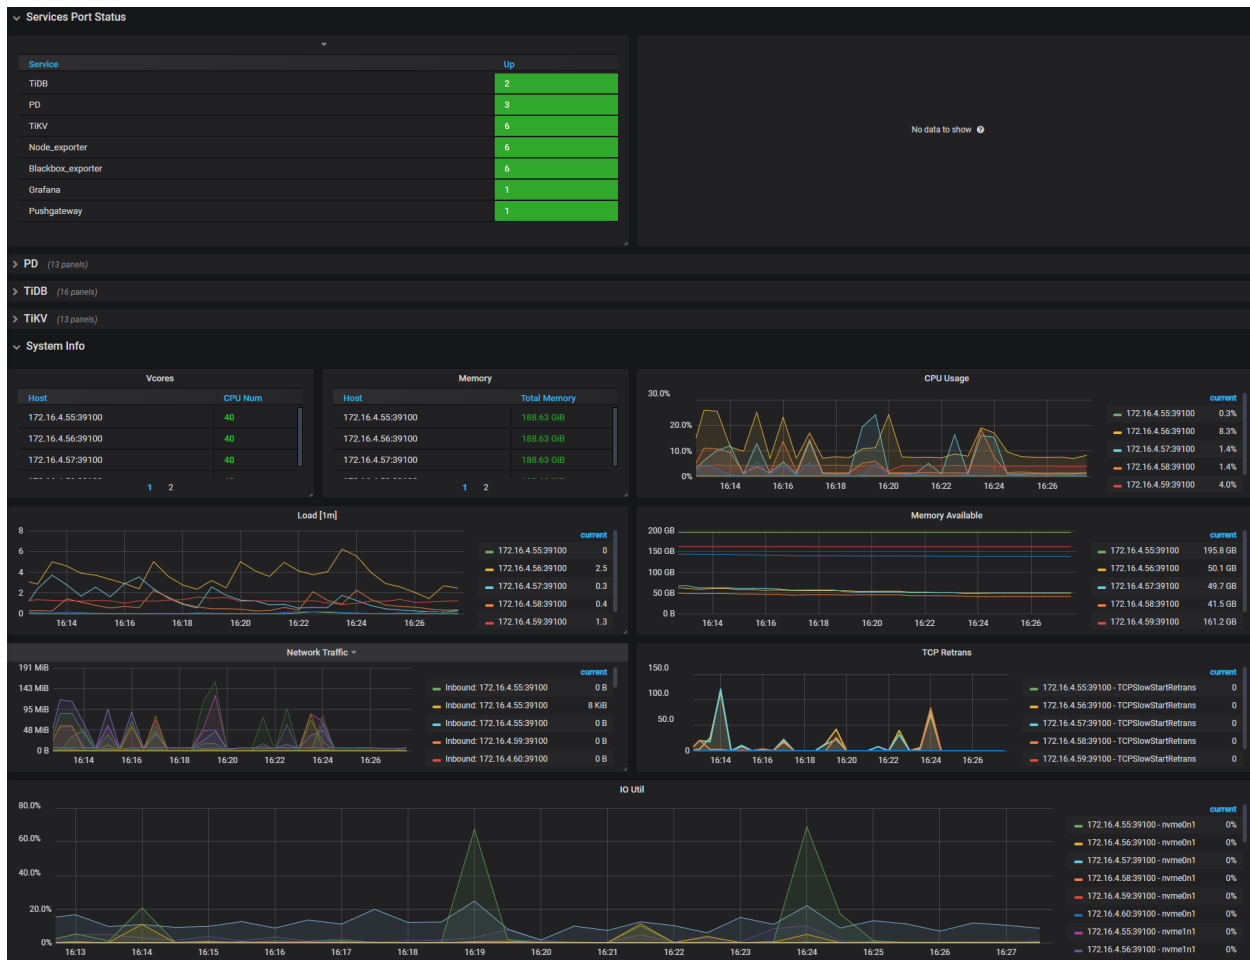

Figure 50: Grafana Overview

7.2 TiDB Monitoring API

You can use the following types of interfaces to monitor the TiDB cluster status:

- **The status interface:** this interface uses the HTTP interface to get the component information. Using this interface, you can get the **running status** of the current TiDB server and the **storage information** of a table.
- **The metrics interface:** this interface uses Prometheus to record the detailed information of the various operations in components and views these metrics using Grafana.

7.2.1 Use the status interface

The status interface monitors the basic information of a specific component in the TiDB cluster. It can also act as the monitor interface for Keepalive messages. In addition, the status interface for the Placement Driver (PD) can get the details of the entire TiKV cluster.

7.2.1.1 TiDB server

- TiDB API address: `http://{host}:{port}`
- Default port: 10080

7.2.1.2 Running status

The following example uses `http://{host}:{port}/status` to get the current status of the TiDB server and to determine whether the server is alive. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/status
{
  connections: 0, # The current number of clients connected to the TiDB
    ↪ server.
  version: "5.7.25-TiDB-v3.0.0-beta-250-g778c3f4a5", # The TiDB version
    ↪ number.
  git_hash: "778c3f4a5a716880bcd1d71b257c8165685f0d70" # The Git Hash of
    ↪ the current TiDB code.
}
```

7.2.1.2.1 Storage information

The following example uses `http://{host}:{port}/schema_storage/{db}/{table}` to get the storage information of the specific data table. The result is returned in **JSON** format.

```
curl http://127.0.0.1:10080/schema_storage/mysql/stats_histograms
```

```
{
  "table_schema": "mysql",
  "table_name": "stats_histograms",
  "table_rows": 0,
  "avg_row_length": 0,
  "data_length": 0,
  "max_data_length": 0,
  "index_length": 0,
  "data_free": 0
}
```

```
curl http://127.0.0.1:10080/schema_storage/test
```

```
[
  {
    "table_schema": "test",
    "table_name": "test",
    "table_rows": 0,
    "avg_row_length": 0,

]
```

7.2.1.3 PD server

- PD API address: `http://${host}:${port}/pd/api/v1/${api_name}`
- Default port: 2379
- Details about API names: see [PD API doc](#)

The PD interface provides the status of all the TiKV servers and the information about load balancing. See the following example for the information about a single-node TiKV cluster:

```
curl http://127.0.0.1:2379/pd/api/v1/stores
{
  "count": 1, # The number of TiKV nodes.
  "stores": [ # The list of TiKV nodes.
    # The details about the single TiKV node.
    {
      "store": {
```

```
"id": 1,
"address": "127.0.0.1:20160",
"version": "3.0.0-beta",
"state_name": "Up"
},
"status": {
  "capacity": "20 GiB", # The total capacity.
  "available": "16 GiB", # The available capacity.
  "leader_count": 17,
  "leader_weight": 1,
  "leader_score": 17,
  "leader_size": 17,
  "region_count": 17,
  "region_weight": 1,
  "region_score": 17,
  "region_size": 17,
  "start_ts": "2019-03-21T14:09:32+08:00", # The starting timestamp.
  "last_heartbeat_ts": "2019-03-21T14:14:22.961171958+08:00", # The
    ↪ timestamp of the last heartbeat.
  "uptime": "4m50.961171958s"
}
}
]
```

7.2.2 Use the metrics interface

The metrics interface monitors the status and performance of the entire TiDB cluster.

- If you use other deployment ways, [deploy Prometheus and Grafana](#) before using this interface.

After Prometheus and Grafana are successfully deployed, [configure Grafana](#).

7.3 Deploy Monitoring Services for the TiDB Cluster

This document is intended for users who want to manually deploy TiDB monitoring and alert services.

If you deploy the TiDB cluster using TiUP, the monitoring and alert services are automatically deployed, and no manual deployment is needed.

7.3.1 Deploy Prometheus and Grafana

Assume that the TiDB cluster topology is as follows:

Name	Host IP	Services
Node1	192.168.199.113	PD1, TiDB, node_export, Prometheus, Grafana
Node2	192.168.199.114	PD2, node_export
Node3	192.168.199.115	PD3, node_export
Node4	192.168.199.116	TiKV1, node_export
Node5	192.168.199.117	TiKV2, node_export
Node6	192.168.199.118	TiKV3, node_export

7.3.1.1 Step 1: Download the binary package

```
## Downloads the package.
```

```
wget https://download.pingcap.org/prometheus-2.27.1.linux-amd64.tar.gz
wget https://download.pingcap.org/node_exporter-0.17.0.linux-amd64.tar.gz
wget https://download.pingcap.org/grafana-7.5.11.linux-amd64.tar.gz
```

```
## Extracts the package.
```

```
tar -xzf prometheus-2.27.1.linux-amd64.tar.gz
tar -xzf node_exporter-0.17.0.linux-amd64.tar.gz
tar -xzf grafana-7.5.11.linux-amd64.tar.gz
```

7.3.1.2 Step 2: Start node_exporter on Node1, Node2, Node3, and Node4

```
cd node_exporter-0.17.0.linux-amd64
```

```
## Starts the node_exporter service.
```

```
$ ./node_exporter --web.listen-address=":9100" \
  --log.level="info" &
```

7.3.1.3 Step 3: Start Prometheus on Node1

Edit the Prometheus configuration file:

```
cd prometheus-2.27.1.linux-amd64 &&
vi prometheus.yml
```

```
...

global:
  scrape_interval: 15s # By default, scrape targets every 15 seconds.
  evaluation_interval: 15s # By default, scrape targets every 15 seconds.
  # scrape_timeout is set to the global default value (10s).
  external_labels:
    cluster: 'test-cluster'
    monitor: "prometheus"
```

```
scrape_configs:
- job_name: 'overwritten-nodes'
  honor_labels: true # Do not overwrite job & instance labels.
  static_configs:
  - targets:
    - '192.168.199.113:9100'
    - '192.168.199.114:9100'
    - '192.168.199.115:9100'
    - '192.168.199.116:9100'
    - '192.168.199.117:9100'
    - '192.168.199.118:9100'

- job_name: 'tidb'
  honor_labels: true # Do not overwrite job & instance labels.
  static_configs:
  - targets:
    - '192.168.199.113:10080'

- job_name: 'pd'
  honor_labels: true # Do not overwrite job & instance labels.
  static_configs:
  - targets:
    - '192.168.199.113:2379'
    - '192.168.199.114:2379'
    - '192.168.199.115:2379'

- job_name: 'tikv'
  honor_labels: true # Do not overwrite job & instance labels.
  static_configs:
  - targets:
    - '192.168.199.116:20180'
    - '192.168.199.117:20180'
    - '192.168.199.118:20180'

...
```

Start the Prometheus service:

```
$ ./prometheus \
  --config.file="./prometheus.yml" \
  --web.listen-address=":9090" \
  --web.external-url="http://192.168.199.113:9090/" \
  --web.enable-admin-api \
  --log.level="info" \
```

```
--storage.tsdb.path="./data.metrics" \  
--storage.tsdb.retention="15d" &
```

7.3.1.4 Step 4: Start Grafana on Node1

Edit the Grafana configuration file:

```
cd grafana-7.5.11 &&  
vi conf/grafana.ini  
  
...  
  
[paths]  
data = ./data  
logs = ./data/log  
plugins = ./data/plugins  
[server]  
http_port = 3000  
domain = 192.168.199.113  
[database]  
[session]  
[analytics]  
check_for_updates = true  
[security]  
admin_user = admin  
admin_password = admin  
[snapshots]  
[users]  
[auth.anonymous]  
[auth.basic]  
[auth.ldap]  
[smtp]  
[emails]  
[log]  
mode = file  
[log.console]  
[log.file]  
level = info  
format = text  
[log.syslog]  
[event_publisher]  
[dashboards.json]  
enabled = false  
path = ./data/dashboards  
[metrics]
```

```
[grafana_net]
url = https://grafana.net
...

```

Start the Grafana service:

```
$ ./bin/grafana-server \
  --config="./conf/grafana.ini" &

```

7.3.2 Configure Grafana

This section describes how to configure Grafana.

7.3.2.1 Step 1: Add a Prometheus data source

1. Log in to the Grafana Web interface.
 - Default address: <http://localhost:3000>
 - Default account: admin
 - Default password: admin

Note:

For the **Change Password** step, you can choose **Skip**.

2. In the Grafana sidebar menu, click **Data Source** within the **Configuration**.
3. Click **Add data source**.
4. Specify the data source information.
 - Specify a **Name** for the data source.
 - For **Type**, select **Prometheus**.
 - For **URL**, specify the Prometheus address.
 - Specify other fields as needed.
5. Click **Add** to save the new data source.

7.3.2.2 Step 2: Import a Grafana dashboard

To import a Grafana dashboard for the PD server, the TiKV server, and the TiDB server, take the following steps respectively:

1. Click the Grafana logo to open the sidebar menu.
2. In the sidebar menu, click **Dashboards** -> **Import** to open the **Import Dashboard** window.
3. Click **Upload .json File** to upload a JSON file (Download TiDB Grafana configuration files from [pingcap/tidb](#), [tikv/tikv](#), and [tikv/pd](#)).

Note:

For the TiKV, PD, and TiDB dashboards, the corresponding JSON files are `tikv_summary.json`, `tikv_details.json`, `tikv_trouble_shooting` ↪ `.json`, `pd.json`, `tidb.json`, and `tidb_summary.json`.

4. Click **Load**.
5. Select a Prometheus data source.
6. Click **Import**. A Prometheus dashboard is imported.

7.3.3 View component metrics

Click **New dashboard** in the top menu and choose the dashboard you want to view.

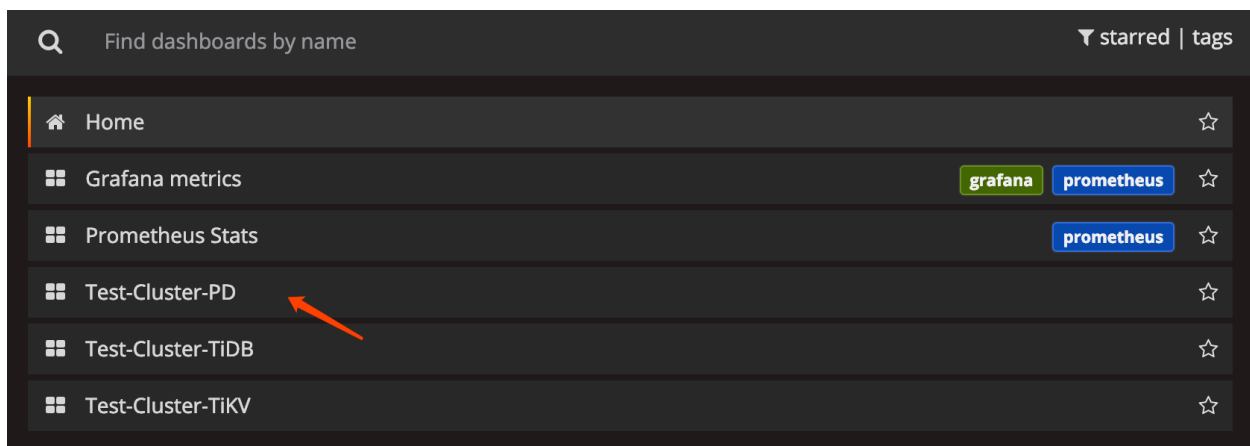

Figure 51: view dashboard

You can get the following metrics for cluster components:

- **TiDB server:**
 - Query processing time to monitor the latency and throughput
 - The DDL process monitoring
 - TiKV client related monitoring
 - PD client related monitoring
- **PD server:**
 - The total number of times that the command executes
 - The total number of times that a certain command fails
 - The duration that a command succeeds
 - The duration that a command fails
 - The duration that a command finishes and returns result
- **TiKV server:**
 - Garbage Collection (GC) monitoring
 - The total number of times that the TiKV command executes
 - The duration that Scheduler executes commands
 - The total number of times of the Raft propose command
 - The duration that Raft executes commands
 - The total number of times that Raft commands fail
 - The total number of times that Raft processes the ready state

7.4 Export Grafana Snapshots

Note:

Currently, MetricsTool can only be used with Grafana v6.x.x.

Metrics data is important in troubleshooting. When you request remote assistance, sometimes the support staff need to view the Grafana dashboards to diagnose problems. [MetricsTool](#) can help export snapshots of Grafana dashboards as local files and visualize these snapshots. You can share these snapshots with outsiders and allow them to accurately read out the graphs, without giving out access to other sensitive information on the Grafana server.

7.4.1 Usage

MetricsTool can be accessed from <https://metricstool.pingcap.net/>. It consists of three sets of tools:

- **Export:** A user script running on the browser's Developer Tool, allowing you to download a snapshot of all visible panels in the current dashboard on any Grafana v6.x.x server.

Figure 52: Screenshot of MetricsTool Exporter after running the user script

- **Visualize:** A web page visualizing the exported snapshot files. The visualized snapshots can be operated in the same way as live Grafana dashboards.

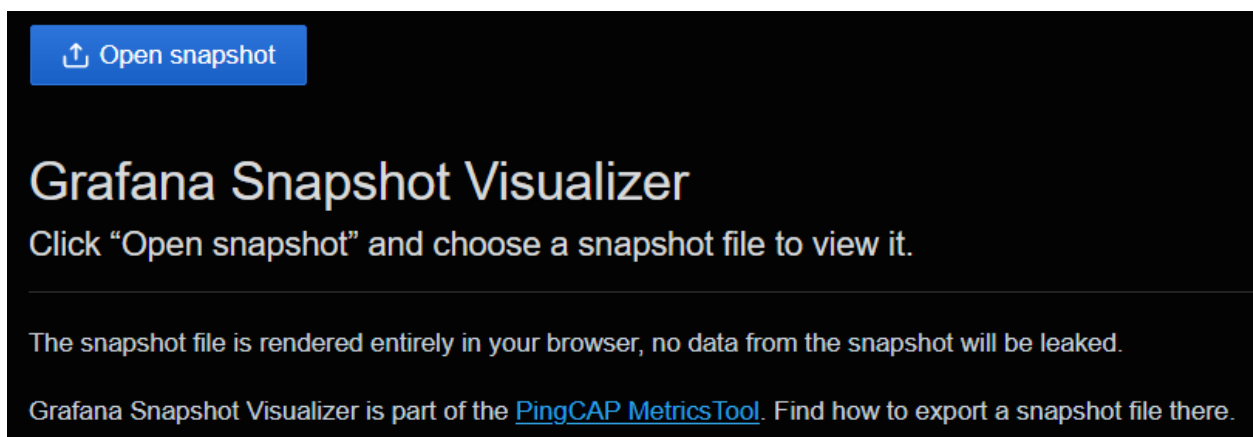

Figure 53: Screenshot of MetricsTool Visualizer

- **Import:** Instructions to import the exported snapshot back into an actual Grafana instance.

7.4.2 FAQs

7.4.2.1 What is the advantage of this tool compared with screenshot or PDF printing?

The snapshot files exported by MetricsTool contain the actual values when they are taken. And the Visualizer allows you to interact with the rendered graphs as if it is a live Grafana dashboard, supporting operations like toggling series, zooming into a smaller time range, and checking the precise value at a given time. This makes MetricsTool much more powerful than images or PDFs.

7.4.2.2 What are included in the snapshot file?

The snapshot file contains the values of all graphs and panels in the selected time range. It does not save the original metrics from the data sources (and thus you cannot edit the query expression in the Visualizer).

7.4.2.3 Will the Visualizer save the uploaded snapshot files in PingCAP's servers?

No, the Visualizer parses the snapshot files entirely inside your browser. Nothing will be sent to PingCAP. You are free to view snapshot files received from sensitive sources, and no need to worry about these leaking to third parties through the Visualizer.

7.4.2.4 Will there be problems to execute the script before all metrics are loaded?

No, the script UI will notify you to wait for all metrics to be loaded. However, you can manually skip waiting and export the snapshot in case of some metrics loading for too long.

7.4.2.5 Can we share a link to a visualized snapshot?

No, but you can share the snapshot file, with instruction on how to use the Visualizer to view it. If you truly need a world-readable URL, you may also try the public `snapshot`. ↔ `raintank.io` service built into Grafana, but make sure all privacy concerns are cleared before doing so.

7.5 TiDB Cluster Alert Rules

This document describes the alert rules for different components in a TiDB cluster, including the rule descriptions and solutions of the alert items in TiDB, TiKV, PD, TiFlash, TiDB Binlog, TiCDC, `Node_exporter` and `Blackbox_exporter`.

According to the severity level, alert rules are divided into three categories (from high to low): emergency-level, critical-level, and warning-level. This division of severity levels applies to all alert items of each component below.

Severity level	Description
Emergency-level	The highest severity level at which the service is unavailable. Emergency-level alerts are often caused by a service or node failure. Manual intervention is required immediately.

Severity level	Description
Critical-level	Decreased service availability. For the critical-level alerts, a close watch on the abnormal metrics is required.
Warning-level	Warning-level alerts are a reminder for an issue or error.

7.5.1 TiDB alert rules

This section gives the alert rules for the TiDB component.

7.5.1.1 Emergency-level alerts

7.5.1.1.1 TiDB_schema_error

- Alert rule:

```
increase(tidb_session_schema_lease_error_total{type="outdated"}[15m])>
↔ 0
```

- Description:

The latest schema information is not reloaded in TiDB within one lease. When TiDB fails to continue providing services, an alert is triggered.

- Solution:

It is often caused by an unavailable Region or a TiKV timeout. You need to locate the issue by checking the TiKV monitoring items.

7.5.1.1.2 TiDB_tikvclient_region_err_total

- Alert rule:

```
increase(tidb_tikvclient_region_err_total[10m])> 6000
```

- Description:

When TiDB accesses TiKV, a Region error occurs. When the error is reported over 6000 times in 10 minutes, an alert is triggered.

- Solution:

View the monitoring status of TiKV.

7.5.1.1.3 TiDB_domain_load_schema_total

- Alert rule:

```
increase(tidb_domain_load_schema_total{type="failed"}[10m])> 10
```

- Description:

The total number of failures to reload the latest schema information in TiDB. If the reloading failure occurs over 10 times in 10 minutes, an alert is triggered.

- Solution:

Same as [TiDB_schema_error](#).

7.5.1.1.4 TiDB_monitor_keep_alive

- Alert rule:

```
increase(tidb_monitor_keep_alive_total[10m])< 100
```

- Description:

Indicates whether the TiDB process still exists. If the number of times for `tidb_monitor_keep_alive_total` increases less than 100 in 10 minutes, the TiDB process might already exit and an alert is triggered.

- Solution:

- Check whether the TiDB process is out of memory.
- Check whether the machine has restarted.

7.5.1.2 Critical-level alerts

7.5.1.2.1 TiDB_server_panic_total

- Alert rule:
`increase(tidb_server_panic_total[10m]) > 0`
- Description:
The number of panicked TiDB threads. When a panic occurs, an alert is triggered. The thread is often recovered, otherwise, TiDB will frequently restart.
- Solution:
Collect the panic logs to locate the issue.

7.5.1.3 Warning-level alerts

7.5.1.3.1 TiDB_memory_abnormal

- Alert rule:
`go_memstats_heap_inuse_bytes{job="tidb"} > 1e+10`
- Description:
The monitoring on the TiDB memory usage. If the usage exceeds 10 G, an alert is triggered.
- Solution:
Use the HTTP API to troubleshoot the goroutine leak issue.

7.5.1.3.2 TiDB_query_duration

- Alert rule:
`histogram_quantile(0.99, sum(rate(tidb_server_handle_query_duration_seconds_bucket ↪ [1m]))BY (1e, instance)) > 1`
- Description:
The latency of handling a request in TiDB. If the ninety-ninth percentile latency exceeds 1 second, an alert is triggered.
- Solution:
View TiDB logs and search for the SLOW_QUERY and TIME_COP_PROCESS keywords to locate the slow SQL queries.

7.5.1.3.3 TiDB_server_event_error

- Alert rule:

```
increase(tidb_server_event_total{type=~"server_start|server_hang"}[15m  
↔ ])> 0
```

- Description:

The number of events that happen in the TiDB service. An alert is triggered when the following events happen:

1. start: The TiDB service starts.
2. hang: When a critical-level event (currently there is only one scenario: TiDB cannot write binlog) happens, TiDB enters the hang mode and waits to be killed manually.

- Solution:

- Restart TiDB to recover the service.
- Check whether the TiDB Binlog service is normal.

7.5.1.3.4 TiDB_tikvclient_backoff_seconds_count

- Alert rule:

```
increase(tidb_tikvclient_backoff_seconds_count[10m])> 10
```

- Description:

The number of retries when TiDB fails to access TiKV. When the retry times is over 10 in 10 minutes, an alert is triggered.

- Solution:

View the monitoring status of TiKV.

7.5.1.3.5 TiDB_monitor_time_jump_back_error

- Alert rule:

```
increase(tidb_monitor_time_jump_back_total[10m])> 0
```

- Description:

When the time of the machine that holds TiDB rewinds, an alert is triggered.

- Solution:

Troubleshoot the NTP configurations.

7.5.1.3.6 TiDB_ddl_waiting_jobs

- Alert rule:

```
sum(tidb_ddl_waiting_jobs)> 5
```

- Description:

When the number of DDL tasks pending for execution in TiDB exceeds 5, an alert is triggered.

- Solution:

Check whether there is any time-consuming `add index` operation that is being executed by running `admin show ddl`.

7.5.2 PD alert rules

This section gives the alert rules for the PD component.

7.5.2.1 Emergency-level alerts

7.5.2.1.1 PD_cluster_down_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_down_count"})by (instance)> 0)and (  
↔ sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

PD has not received a TiKV/TiFlash heartbeat for a long time (the default configuration is 30 minutes).

- Solution:

- Check whether the TiKV/TiFlash process is normal, the network is isolated or the load is too high, and recover the service as much as possible.
- If the TiKV/TiFlash instance cannot be recovered, you can make it offline.

7.5.2.2 Critical-level alerts

7.5.2.2.1 PD_etcd_write_disk_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_disk_wal_fsync_duration_seconds_bucket  
↔ [1m]))by (instance, job, le))> 1
```

- Description:

If the latency of the fsync operation exceeds 1 second, it indicates that etcd writes data to disk at a lower speed than normal. It might lead to PD leader timeout or failure to store TSO on disk in time, which will shut down the service of the entire cluster.

- Solution:

- Find the cause of slow writes. It might be other services that overload the system. You can check whether PD itself occupies a large amount of CPU or I/O resources.
- Try to restart PD or manually transfer leader to another PD to recover the service.
- If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.2.2 PD_miss_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="miss-peer-region-count"})by (instance)>  
↔ 100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

The number of Region replicas is smaller than the value of `max-replicas`.

- Solution:

- Find the cause of the issue by checking whether there is any TiKV machine that is down or being made offline.
- Watch the Region health panel and see whether `miss-peer-region-count` is continuously decreasing.

7.5.2.3 Warning-level alerts

7.5.2.3.1 PD_cluster_lost_connect_store_nums

- Alert rule:

```
(sum(pd_cluster_status{type="store_disconnected_count"})by (instance)>  
↔ 0)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

PD does not receive a TiKV/TiFlash heartbeat within 20 seconds. Normally a TiKV/TiFlash heartbeat comes in every 10 seconds.
- Solution:
 - Check whether the TiKV/TiFlash instance is being restarted.
 - Check whether the TiKV/TiFlash process is normal, the network is isolated, and the load is too high, and recover the service as much as possible.
 - If you confirm that the TiKV/TiFlash instance cannot be recovered, you can make it offline.
 - If you confirm that the TiKV/TiFlash instance can be recovered, but not in the short term, you can consider increasing the value of `max-down-time`. It will prevent the TiKV/TiFlash instance from being considered as irrecoverable and the data from being removed from the TiKV/TiFlash.

7.5.2.3.2 PD_cluster_low_space

- Alert rule:

```
(sum(pd_cluster_status{type="store_low_space_count"})by (instance)> 0)
↔ and (sum(etcd_server_is_leader)by (instance)> 0)
```
- Description:

Indicates that there is no sufficient space on the TiKV/TiFlash node.
- Solution:
 - Check whether the space in the cluster is generally insufficient. If so, increase its capacity.
 - Check whether there is any issue with Region balance scheduling. If so, it will lead to uneven data distribution.
 - Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, core dump, etc.
 - Lower the Region weight of the node to reduce the data volume.
 - When it is not possible to release the space, consider proactively making the node offline. This prevents insufficient disk space that leads to downtime.

7.5.2.3.3 PD_etcd_network_peer_latency

- Alert rule:

```
histogram_quantile(0.99, sum(rate(etcd_network_peer_round_trip_time_seconds_bucket
↔ [1m]))by (To, instance, job, le))> 1
```

- Description:

The network latency between PD nodes is high. It might lead to the leader timeout and TSO disk storage timeout, which impacts the service of the cluster.
- Solution:
 - Check the network and system load status.
 - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.4 PD_tidb_handle_requests_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(pd_client_request_handle_requests_duration_seconds ↵ {type="tso"}[1m]))by (instance, job, le))> 0.1
```
- Description:

It takes a longer time for PD to handle the TSO request. It is often caused by a high load.
- Solution:
 - Check the load status of the server.
 - Use pprof to analyze the CPU profile of PD.
 - Manually switch the PD leader.
 - If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.5 PD_down_peer_region_nums

- Alert rule:

```
(sum(pd_regions_status{type="down-peer-region-count"})by (instance)> 0) ↵ and (sum(etcd_server_is_leader)by (instance)> 0)
```
- Description:

The number of Regions with an unresponsive peer reported by the Raft leader.
- Solution:
 - Check whether there is any TiKV that is down, or that was just restarted, or that is busy.
 - Watch the Region health panel and see whether `down_peer_region_count` is continuously decreasing.
 - Check the network between TiKV servers.

7.5.2.3.6 PD_pending_peer_region_count

- Alert rule:

```
(sum(pd_regions_status{type="pending-peer-region-count"})by (instance)>
↪ 100)and (sum(etcd_server_is_leader)by (instance)> 0)
```

- Description:

There are too many Regions that have lagged Raft logs. It is normal that scheduling leads to a small number of pending peers, but if the number remains high, there might be an issue.

- Solution:

- Watch the Region health panel and see whether `pending_peer_region_count` is continuously decreasing.
- Check the network between TiKV servers, especially whether there is enough bandwidth.

7.5.2.3.7 PD_leader_change

- Alert rule:

```
count(changes(pd_tso_events{type="save"}[10m])> 0)>= 2
```

- Description:

The PD leader is recently switched.

- Solution:

- Exclude the human factors, such as restarting PD, manually transferring leader, adjusting leader priority, etc.
- Check the network and system load status.
- If the problematic PD instance cannot be recovered due to environmental factors, make it offline and replace it.

7.5.2.3.8 TiKV_space_used_more_than_80%

- Alert rule:

```
sum(pd_cluster_status{type="storage_size"})/ sum(pd_cluster_status{type
↪ ="storage_capacity"})* 100 > 80
```

- Description:

Over 80% of the cluster space is occupied.

- Solution:

- Check whether it is needed to increase capacity.
- Check whether there is any file that occupies a large amount of disk space, such as the log, snapshot, core dump, etc.

7.5.2.3.9 PD_system_time_slow

- Alert rule:
`changes(pd_tso_events{type="system_time_slow"}[10m])>= 1`
- Description:
The system time rewind might happen.
- Solution:
Check whether the system time is configured correctly.

7.5.2.3.10 PD_no_store_for_making_replica

- Alert rule:
`increase(pd_checker_event_count{type="replica_checker", name="no_target_store"}[1m])> 0`
- Description:
There is no appropriate store for additional replicas.
- Solution:
 - Check whether there is enough space in the store.
 - Check whether there is any store for additional replicas according to the label configuration if it is configured.

7.5.2.3.11 PD_cluster_slow_tikv_nums

- Alert rule:
`sum(pd_cluster_status{type="store_slow_count"})by (instance)> 0)and (sum(etcd_server_is_leader)by (instance)> 0)`
- Description:
There is a slow TiKV node. `raftstore.inspect-interval` controls the detection of TiKV slow nodes. For more information, see [raftstore.inspect-interval](#).
- Solution:
 - Check whether the performance of the store is proper.
 - Set the `raftstore.inspect-interval` configuration item to a larger value to increase the timeout limit of latency.

7.5.3 TiKV alert rules

This section gives the alert rules for the TiKV component.

7.5.3.1 Emergency-level alerts

7.5.3.1.1 TiKV_memory_used_too_fast

- Alert rule:

```
process_resident_memory_bytes{job=~"tikv",instance=~".*"} - (process_resident_memory_bytes{job=~"tikv",instance=~".*"} offset 5m) > 5*1024*1024*1024
```

- Description:

Currently, there are no TiKV monitoring items about memory. You can monitor the memory usage of the machines in the cluster by Node_exporter. The above rule indicates that when the memory usage exceeds 5 GB within 5 minutes (the memory is occupied too fast in TiKV), an alert is triggered.

- Solution:

Adjust the `block-cache-size` value of both `rocksdb.defaultcf` and `rocksdb.writecf`

```
↔ .
```

7.5.3.1.2 TiKV_GC_can_not_work

- Alert rule:

```
sum(increase(tikv_gcworker_gc_tasks_vec{task="gc"}[1d])) < 1 and (sum(increase(tikv_gc_compaction_filter_perform[1d])) < 1 and sum(increase(tikv_engine_event_total{db="kv", cf="write", type="compaction"}[1d]))) >= 1)
```

- Description:

GC is not performed successfully on a TiKV instance within 24 hours, which indicates that GC is not working properly. If GC does not run in a short term, it will not cause much trouble; but if GC keeps down, more and more versions are retained, which slows down the query.

- Solution:

- Perform `SELECT VARIABLE_VALUE FROM mysql.tidb WHERE VARIABLE_NAME = "tikv_gc_leader_desc"` to locate the `tidb-server` corresponding to the GC leader;
- View the log of the `tidb-server`, and `grep gc_worker tidb.log`;

3. If you find that the GC worker has been resolving locks (the last log is “start resolve locks”) or deleting ranges (the last log is “start delete {number} ranges”) during this time, it means the GC process is running normally. Otherwise, contact support@pingcap.com to resolve this issue.

7.5.3.2 Critical-level alerts

7.5.3.2.1 TiKV_server_report_failure_msg_total

- Alert rule:

```
sum(rate(tikv_server_report_failure_msg_total{type="unreachable"}[10m])
↪ )BY (store_id)> 10
```

- Description:

Indicates that the remote TiKV cannot be connected.

- Solution:

1. Check whether the network is clear.
2. Check whether the remote TiKV is down.
3. If the remote TiKV is not down, check whether the pressure is too high. Refer to the solution in [TiKV_channel_full_total](#).

7.5.3.2.2 TiKV_channel_full_total

- Alert rule:

```
sum(rate(tikv_channel_full_total[10m]))BY (type, instance)> 0
```

- Description:

This issue is often caused by the stuck Raftstore thread and high pressure on TiKV.

- Solution:

1. Watch the Raft Propose monitor, and see whether the alerted TiKV node has a much higher Raft propose than other TiKV nodes. If so, it means that there are one or more hot spots on this TiKV. You need to check whether the hot spot scheduling can work properly.
2. Watch the Raft I/O monitor, and see whether the latency increases. If the latency is high, it means a bottleneck might exist in the disk. One feasible but unsafe solution is setting `sync-log` to `false`.
3. Watch the Raft Process monitor, and see whether the tick duration is high. If so, you need to add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

7.5.3.2.3 TiKV_write_stall

- Alert rule:

```
delta(tikv_engine_write_stall[10m])> 0
```

- Description:

The write pressure on RocksDB is too high, and a stall occurs.

- Solution:

1. View the disk monitor, and troubleshoot the disk issues;
2. Check whether there is any write hot spot on the TiKV;
3. Set `max-sub-compactions` to a larger value under the `[rocksdb]` and `[raftdb]` configurations.

7.5.3.2.4 TiKV_raft_log_lag

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_log_lag_bucket[1m]))by  
↪ (le, instance))> 5000
```

- Description:

If this value is relatively large, it means Follower has lagged far behind Leader, and Raft cannot be replicated normally. It is possibly because the TiKV machine where Follower is located is stuck or down.

7.5.3.2.5 TiKV_async_request_snapshot_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_seconds  
↪ {type="snapshot"}[1m]))by (le, instance, type))> 1
```

- Description:

If this value is relatively large, it means the load pressure on Raftstore is too high, and it might be stuck already.

- Solution:

Refer to the solution in [TiKV_channel_full_total](#).

7.5.3.2.6 TiKV_async_request_write_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_storage_engine_async_request_duration_seconds  
↔ {type="write"}[1m]))by (1e, instance, type))> 1
```

- Description:

If this value is relatively large, it means the Raft write takes a long time.

- Solution:

1. Check the pressure on Raftstore. See the solution in [TiKV_channel_full_total](#).
2. Check the pressure on the apply worker thread.

7.5.3.2.7 TiKV_coprocessor_request_wait_seconds

- Alert rule:

```
histogram_quantile(0.9999, sum(rate(tikv_coprocessor_request_wait_seconds_bucket  
↔ [1m]))by (1e, instance, req))> 10
```

- Description:

If this value is relatively large, it means the pressure on the Coprocessor worker is high. There might be a slow task that makes the Coprocessor thread stuck.

- Solution:

1. View the slow query log from the TiDB log to see whether the index or full table scan is used in a query, or see whether it is needed to analyze;
2. Check whether there is a hot spot;
3. View the Coprocessor monitor and see whether `total` and `process` in `coprocessor table/index scan` match. If they differ a lot, it indicates too many invalid queries are performed. You can see whether there is `over seek` ↔ `bound`. If so, there are too many versions that GC does not handle in time. Then you need to increase the number of parallel GC threads.

7.5.3.2.8 TiKV_raftstore_thread_cpu_seconds_total

- Alert rule:

```
sum(rate(tikv_thread_cpu_seconds_total{name=~"raftstore_.*"}[1m]))by (↔ instance)> 1.6
```

- Description:

This rule monitors CPU usage by Raftstore. If the value is high, it indicates pressure on Raftstore threads is heavy.

The alert threshold is 80% of the `raftstore.store-pool-size` value. `raftstore.store-pool-size` is 2 by default, so the alert threshold is 1.6.

- Solution:

Refer to the solution in `TiKV_channel_full_total`.

7.5.3.2.9 TiKV_raft_append_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_append_log_duration_seconds_bucket  
↪ [1m]))by (1e, instance))> 1
```

- Description:

Indicates the time cost of appending Raft log. If it is high, it usually means I/O is too busy.

7.5.3.2.10 TiKV_raft_apply_log_duration_secs

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_apply_log_duration_seconds_bucket  
↪ [1m]))by (1e, instance))> 1
```

- Description:

Indicates the time cost of applying Raft log. If it is high, it usually means I/O is too busy.

7.5.3.2.11 TiKV_scheduler_latch_wait_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_latch_wait_duration_seconds_bucket  
↪ [1m]))by (1e, instance, type))> 1
```

- Description:

The waiting time for the write operations to obtain the memory lock in Scheduler. If it is high, there might be many write conflicts, or that some operations that lead to conflicts take a long time to finish and block other operations that wait for the same lock.

- Solution:

1. View the scheduler command duration in the Scheduler-All monitor and see which command is most time-consuming;
2. View the scheduler scan details in the Scheduler-All monitor and see whether `total` and `process` match. If they differ a lot, there are many invalid scans. You can also see whether there is `over seek bound`. If there is too much, it indicates GC does not work in time;
3. View the storage async snapshot/write duration in the Storage monitor and see whether the Raft operation is performed in time.

7.5.3.2.12 TiKV_thread_apply_worker_cpu_seconds

- Alert rule:

```
max(rate(tikv_thread_cpu_seconds_total{name=~"apply_.*"}[1m]))by (
↪ instance)> 0.9
```

- Description:

The apply Raft log thread is under great pressure and is approaching or has exceeded its limit. This is often caused by a burst of writes.

7.5.3.3 Warning-level alerts

7.5.3.3.1 TiKV_leader_drops

- Alert rule:

```
delta(tikv_pd_heartbeat_tick_total{type="leader"}[30s])< -10
```

- Description:

It is often caused by a stuck Raftstore thread.

- Solution:

1. Refer to [TiKV_channel_full_total](#).
2. If there is low pressure on TiKV, consider whether the PD scheduling is too frequent. You can view the Operator Create panel on the PD page, and check the types and number of the PD scheduling.

7.5.3.3.2 TiKV_raft_process_ready_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket
↪ {type='ready'}[1m]))by (le, instance, type))> 2
```

- Description:

Indicates the time cost of handling Raft ready. If this value is large, it is often caused by the stuck appending log task.

7.5.3.3.3 TiKV_raft_process_tick_duration_secs

- Alert rule:

```
histogram_quantile(0.999, sum(rate(tikv_raftstore_raft_process_duration_secs_bucket  
↔ {type=' tick' }[1m]))by (le, instance, type))> 2
```

- Description:

Indicates the time cost of handling Raft tick. If this value is large, it is often caused by too many Regions.

- Solution:

1. Consider using a higher-level log such as `warn` or `error`.
2. Add `raft-base-tick-interval = "2s"` under the `[raftstore]` configuration.

7.5.3.3.4 TiKV_scheduler_context_total

- Alert rule:

```
abs(delta( tikv_scheduler_context_total[5m]))> 1000
```

- Description:

The number of write commands that are being executed by Scheduler. If this value is large, it means the task is not finished timely.

- Solution:

Refer to [TiKV_scheduler_latch_wait_duration_seconds](#).

7.5.3.3.5 TiKV_scheduler_command_duration_seconds

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_scheduler_command_duration_seconds_bucket  
↔ [1m]))by (le, instance, type))> 1
```

- Description:

Indicates the time cost of executing the Scheduler command.

- Solution:

Refer to [TiKV_scheduler_latch_wait_duration_seconds](#).

7.5.3.3.6 TiKV_coprocessor_outdated_request_wait_seconds

- Alert rule:
`delta(tikv_coprocessor_outdated_request_wait_seconds_count[10m])> 0`
- Description:
The waiting time of the expired requests by Coprocessor. If this value is large, it means there is high pressure on Coprocessor.
- Solution:
Refer to [TiKV_coprocessor_request_wait_seconds](#).

7.5.3.3.7 TiKV_coprocessor_pending_request

- Alert rule:
`delta(tikv_coprocessor_pending_request[10m])> 5000`
- Description:
The queuing requests of Coprocessor.
- Solution:
Refer to [TiKV_coprocessor_request_wait_seconds](#).

7.5.3.3.8 TiKV_batch_request_snapshot_nums

- Alert rule:
`sum(rate(tikv_thread_cpu_seconds_total{name=~"cop_.*"}[1m]))by (instance ↵)/ (count(tikv_thread_cpu_seconds_total{name=~"cop_.*"})* 0.9)/ ↵ count(count(tikv_thread_cpu_seconds_total)by (instance))> 0`
- Description:
The Coprocessor CPU usage of a TiKV machine exceeds 90%.

7.5.3.3.9 TiKV_pending_task

- Alert rule:
`sum(tikv_worker_pending_task_total)BY (instance,name)> 1000`
- Description:
The number of pending tasks of TiKV.
- Solution:
Check which kind of tasks has a higher value. You can normally find a solution to the Coprocessor and apply worker tasks from other metrics.

7.5.3.3.10 TiKV_low_space

- Alert rule:

```
sum(tikv_store_size_bytes{type="available"})by (instance)/ sum(tikv_store_size_byte
↪ {type="capacity"})by (instance)< 0.2
```

- Description:

The data volume of TiKV exceeds 80% of the configured node capacity or the disk capacity of the machine.

- Solution:

- Check the balance condition of node space.
- Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.3.3.11 TiKV_approximate_region_size

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tikv_raftstore_region_size_bucket[1m
↪ ]))by (1e))> 1073741824
```

- Description:

The maximum Region approximate size that is scanned by the TiKV split checker is continually larger than 1 GB within one minute.

- Solution:

The speed of splitting Regions is slower than the write speed. To alleviate this issue, you'd better update TiDB to a version that supports batch-split ($\geq 2.1.0$ -rc1). If it is not possible to update temporarily, you can use `pd-ctl operator add split-`
`↪ region <region_id> --policy=approximate` to manually split Regions.

7.5.4 TiFlash alert rules

For the detailed descriptions of TiFlash alert rules, see [TiFlash Alert Rules](#).

7.5.5 TiDB Binlog alert rules

For the detailed descriptions of TiDB Binlog alert rules, see [TiDB Binlog monitoring document](#).

7.5.6 TiCDC Alert rules

For the detailed descriptions of TiCDC alert rules, see [TiCDC Alert Rules](#).

7.5.7 Node_exporter host alert rules

This section gives the alert rules for the Node_exporter host.

7.5.7.1 Emergency-level alerts

7.5.7.1.1 NODE_disk_used_more_than_80%

- Alert rule:

```
node_filesystem_avail_bytes{fstype=~"(ext.|xfs)", mountpoint!~/boot"}  
↔ / node_filesystem_size_bytes{fstype=~"(ext.|xfs)", mountpoint!~/  
↔ boot"} * 100 <= 20
```

- Description:

The disk space usage of the machine exceeds 80%.

- Solution:

- Log in to the machine, run the `df -h` command to check the disk space usage.
- Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.7.1.2 NODE_disk_inode_more_than_80%

- Alert rule:

```
node_filesystem_files_free{fstype=~"(ext.|xfs)"} / node_filesystem_files  
↔ {fstype=~"(ext.|xfs)"} * 100 < 20
```

- Description:

The inode usage of the filesystem on the machine exceeds 80%.

- Solution:

- Log in to the machine and run the `df -i` command to view the node usage of the filesystem.
- Make a plan to increase the disk capacity or delete some data or increase cluster node depending on different situations.

7.5.7.1.3 NODE_disk_readonly

- Alert rule:

```
node_filesystem_readonly{fstype=~"(ext.|xfs)"} == 1
```

- Description:

The filesystem is read-only and data cannot be written in it. It is often caused by disk failure or filesystem corruption.

- Solution:

- Log in to the machine and create a file to test whether it is normal.
- Check whether the disk LED is normal. If not, replace the disk and repair the filesystem of the machine.

7.5.7.2 Critical-level alerts

7.5.7.2.1 NODE_memory_used_more_than_80%

- Alert rule:

```
((node_memory_MemTotal_bytes-node_memory_MemFree_bytes-node_memory_Cached_bytes  
↪ )/(node_memory_MemTotal_bytes)*100))>= 80
```

- Description:

The memory usage of the machine exceeds 80%.

- Solution:

- View the Memory panel of the host in the Grafana Node Exporter dashboard, and see whether Used memory is too high and Available memory is too low.
- Log in to the machine and run the `free -m` command to view the memory usage. You can run `top` to check whether there is any abnormal process that has an overly high memory usage.

7.5.7.3 Warning-level alerts

7.5.7.3.1 NODE_node_overload

- Alert rule:

```
(node_load5 / count without (cpu, mode)(node_cpu_seconds_total{mode="  
↪ system"}))> 1
```

- Description:
The CPU load on the machine is relatively high.
- Solution:
 - View the CPU Usage and Load Average of the host in the Grafana Node Exporter dashboard to check whether they are too high.
 - Log in to the machine and run `top` to check the load average and the CPU usage, and see whether there is any abnormal process that has an overly high CPU usage.

7.5.7.3.2 NODE_cpu_used_more_than_80%

- Alert rule:

```
avg(irate(node_cpu_seconds_total{mode="idle"}[5m]))by(instance)* 100 <=  
↪ 20
```
- Description:
The CPU usage of the machine exceeds 80%.
- Solution:
 - View the CPU Usage and Load Average of the host on the Grafana Node Exporter dashboard to check whether they are too high.
 - Log in to the machine and run `top` to check the Load Average and the CPU Usage, and see whether there is any abnormal process that has an overly high CPU usage.

7.5.7.3.3 NODE_tcp_estab_num_more_than_50000

- Alert rule:

```
node_netstat_Tcp_CurrEstab > 50000
```
- Description:
There are more than 50,000 TCP links in the “establish” status on the machine.
- Solution:
 - Log in to the machine and run `ss -s` to check the number of TCP links in the “estab” status in the current system.
 - Run `netstat` to check whether there is any abnormal link.

7.5.7.3.4 NODE_disk_read_latency_more_than_32ms

- Alert rule:

```
((rate(node_disk_read_time_seconds_total{device=~".+"}[5m])/ rate(
↪ node_disk_reads_completed_total{device=~".+"}[5m]))or (irate(node_disk_read_time
↪ {device=~".+"}[5m])/ irate(node_disk_reads_completed_total{device
↪ =~".+"}[5m])))* 1000 > 32
```

- Description:

The read latency of the disk exceeds 32 ms.

- Solution:

- Check the disk status by viewing the Grafana Disk Performance dashboard.
- Check the read latency of the disk by viewing the Disk Latency panel.
- Check the I/O usage by viewing the Disk I/O Utilization panel.

7.5.7.3.5 NODE_disk_write_latency_more_than_16ms

- Alert rule:

```
((rate(node_disk_write_time_seconds_total{device=~".+"}[5m])/ rate
↪ (node_disk_writes_completed_total{device=~".+"}[5m]))or (irate(
↪ node_disk_write_time_seconds_total{device=~".+"}[5m])/ irate(node_disk_writes_co
↪ {device=~".+"}[5m]))> 16
```

- Description:

The write latency of the disk exceeds 16ms.

- Solution:

- Check the disk status by viewing the Grafana Disk Performance dashboard.
- Check the write latency of the disk by viewing the Disk Latency panel.
- Check the I/O usage by viewing the Disk I/O Utilization panel.

7.5.8 Blackbox_exporter TCP, ICMP, and HTTP alert rules

This section gives the alert rules for the Blackbox_exporter TCP, ICMP, and HTTP.

7.5.8.1 Emergency-level alerts

7.5.8.1.1 TiDB_server_is_down

- Alert rule:
`probe_success{group="tidb"} == 0`
- Description:
Failure to probe the TiDB service port.
- Solution:
 - Check whether the machine that provides the TiDB service is down.
 - Check whether the TiDB process exists.
 - Check whether the network between the monitoring machine and the TiDB machine is normal.

7.5.8.1.2 TiFlash_server_is_down

- Alert rule:
`probe_success{group="tiflash"} == 0`
- Description:
Failure to probe the TiFlash service port.
- Solution:
 - Check whether the machine that provides the TiFlash service is down.
 - Check whether the TiFlash process exists.
 - Check whether the network between the monitoring machine and the TiFlash machine is normal.

7.5.8.1.3 Pump_server_is_down

- Alert rule:
`probe_success{group="pump"} == 0`
- Description:
Failure to probe the pump service port.
- Solution:
 - Check whether the machine that provides the pump service is down.
 - Check whether the pump process exists.
 - Check whether the network between the monitoring machine and the pump machine is normal.

7.5.8.1.4 Drainer_server_is_down

- Alert rule:
`probe_success{group="drainer"} == 0`
- Description:
Failure to probe the Drainer service port.
- Solution:
 - Check whether the machine that provides the Drainer service is down.
 - Check whether the Drainer process exists.
 - Check whether the network between the monitoring machine and the Drainer machine is normal.

7.5.8.1.5 TiKV_server_is_down

- Alert rule:
`probe_success{group="tikv"} == 0`
- Description:
Failure to probe the TiKV service port.
- Solution:
 - Check whether the machine that provides the TiKV service is down.
 - Check whether the TiKV process exists.
 - Check whether the network between the monitoring machine and the TiKV machine is normal.

7.5.8.1.6 PD_server_is_down

- Alert rule:
`probe_success{group="pd"} == 0`
- Description:
Failure to probe the PD service port.
- Solution:
 - Check whether the machine that provides the PD service is down.
 - Check whether the PD process exists.
 - Check whether the network between the monitoring machine and the PD machine is normal.

7.5.8.1.7 Node_exporter_server_is_down

- Alert rule:
`probe_success{group="node_exporter"} == 0`
- Description:
Failure to probe the Node_exporter service port.
- Solution:
 - Check whether the machine that provides the Node_exporter service is down.
 - Check whether the Node_exporter process exists.
 - Check whether the network between the monitoring machine and the Node_exporter machine is normal.

7.5.8.1.8 Blackbox_exporter_server_is_down

- Alert rule:
`probe_success{group="blackbox_exporter"} == 0`
- Description:
Failure to probe the Blackbox_Exporter service port.
- Solution:
 - Check whether the machine that provides the Blackbox_Exporter service is down.
 - Check whether the Blackbox_Exporter process exists.
 - Check whether the network between the monitoring machine and the Blackbox_Exporter machine is normal.

7.5.8.1.9 Grafana_server_is_down

- Alert rule:
`probe_success{group="grafana"} == 0`
- Description:
Failure to probe the Grafana service port.
- Solution:
 - Check whether the machine that provides the Grafana service is down.
 - Check whether the Grafana process exists.
 - Check whether the network between the monitoring machine and the Grafana machine is normal.

7.5.8.1.10 Pushgateway_server_is_down

- Alert rule:
`probe_success{group="pushgateway"} == 0`
- Description:
Failure to probe the Pushgateway service port.
- Solution:
 - Check whether the machine that provides the Pushgateway service is down.
 - Check whether the Pushgateway process exists.
 - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

7.5.8.1.11 Kafka_exporter_is_down

- Alert rule:
`probe_success{group="kafka_exporter"} == 0`
- Description:
Failure to probe the Kafka_Exporter service port.
- Solution:
 - Check whether the machine that provides the Kafka_Exporter service is down.
 - Check whether the Kafka_Exporter process exists.
 - Check whether the network between the monitoring machine and the Kafka_Exporter machine is normal.

7.5.8.1.12 Pushgateway_metrics_interface

- Alert rule:
`probe_success{job="blackbox_exporter_http"} == 0`
- Description:
Failure to probe the Pushgateway service http interface.
- Solution:
 - Check whether the machine that provides the Pushgateway service is down.
 - Check whether the Pushgateway process exists.
 - Check whether the network between the monitoring machine and the Pushgateway machine is normal.

7.5.8.2 Warning-level alerts

7.5.8.2.1 BLACKER_ping_latency_more_than_1s

- Alert rule:

```
max_over_time(probe_duration_seconds{job=~"blackbox_exporter.*_icmp"}[1  
↪ m])> 1
```

- Description:

The ping latency exceeds 1 second.

- Solution:

- View the ping latency between the two nodes on the Grafana Blackbox Exporter page to check whether it is too high.
- Check the TCP panel on the Grafana Node Exporter page to check whether there is any packet loss.

7.6 TiFlash Alert Rules

This document introduces the alert rules of the TiFlash cluster.

7.6.1 TiFlash_schema_error

- Alert rule:

```
increase(tiflash_schema_apply_count{type="failed"}[15m])> 0
```

- Description:

When the schema apply error occurs, an alert is triggered.

- Solution:

The error might be caused by some wrong logic. Contact [TiFlash R&D](#) for support.

7.6.2 TiFlash_schema_apply_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_schema_apply_duration_seconds_bucket  
↪ [1m]))BY (1e, instance))> 20
```

- Description:

When the probability that the apply duration exceeds 20 seconds is over 99%, an alert is triggered.

- Solution:

It might be caused by the internal problems of the TiFlash storage engine. Contact [TiFlash R&D](#) for support.

7.6.3 TiFlash_raft_read_index_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_read_index_duration_seconds_bucket  
↔ [1m]))BY (1e, instance))> 3
```

- Description:

When the probability that the read index duration exceeds 3 seconds is over 99%, an alert is triggered.

Note:

`read_index` is the kvproto request sent to the TiKV leader. TiKV region retries, busy store, or network problems might lead to long request time of `read_index`.

- Solution:

The frequent retries might be caused by frequent splitting or migration of the TiKV cluster. You can check the TiKV cluster status to identify the retry reason.

7.6.4 TiFlash_raft_wait_index_duration

- Alert rule:

```
histogram_quantile(0.99, sum(rate(tiflash_raft_wait_index_duration_seconds_bucket  
↔ [1m]))BY (1e, instance))> 2
```

- Description:

When the probability that the waiting time for Region Raft Index in TiFlash exceeds 2 seconds is over 99%, an alert is triggered.

- Solution:

It might be caused by a communication error between TiKV and the proxy. Contact [TiFlash R&D](#) for support.

7.7 Customize Configurations of Monitoring Servers

When you deploy a TiDB cluster using TiUP, TiUP also deploys monitoring servers, such as Prometheus, Grafana, and Alertmanager. In the meantime, if you scale out this cluster, TiUP also adds the new nodes into monitoring scope.

To customize the configurations of the monitoring servers mentioned above, you can follow the instructions below to add related configuration items in the `topology.yaml` of the TiDB cluster.

Note:

- Do not modify the configurations files of the monitoring server directly. Because these modifications will be overwritten by later TiUP operations such as deployment, scaling out, scaling in, and reloading.
- If your monitoring servers are not deployed and managed by TiUP, you can directly modify the configuration files of the monitoring servers instead of referring to this document.
- This feature is supported in TiUP v1.9.0 and above. Therefore, check the TiUP version before using this feature.

7.7.1 Customize Prometheus configurations

Currently, TiUP supports customizing Prometheus rule and scrape configuration files.

7.7.1.1 Customize Prometheus rule configuration

1. Customize the rule configuration file and place it under a directory of the machine where TiUP locates.
2. In the `topology.yaml` file, set `rule_dir` to the directory of the customized rule configuration file.

The following is a configuration example of `monitoring_servers` in the `topology.yaml` file:

```
# # Server configs are used to specify the configuration of Prometheus
  ↪ Server.
monitoring_servers:
  # # The ip address of the Monitoring Server.
- host: 127.0.0.1
  rule_dir: /home/tidb/prometheus_rule # prometheus rule dir on TiUP
  ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized rule configurations from `rule_dir` (for example, `/home/tidb/prometheus_rule`) and sends them to the Prometheus Server to replace the default rule configuration.

7.7.1.2 Customize Prometheus scrape configuration

1. Open the `topology.yaml` file of the TiDB cluster.
2. In the `monitoring_servers` configuration, add the `additional_scrape_conf` field.

The following is a configuration example of `monitoring_servers` in the `topology.yaml` file:

```
monitoring_servers:
- host: xxxxxxxx
ssh_port: 22
port: 9090
deploy_dir: /tidb-deploy/prometheus-9090
data_dir: /tidb-data/prometheus-9090
log_dir: /tidb-deploy/prometheus-9090/log
external_alertmanagers: []
arch: amd64
os: linux
additional_scrape_conf:
  metric_relabel_configs:
    - source_labels: [__name__]
      separator: ;
      regex: tikv_thread_nonvoluntary_context_switches|
        ↪ tikv_thread_voluntary_context_switches|
        ↪ tikv_threads_io_bytes_total
      action: drop
    - source_labels: [__name__,name]
      separator: ;
      regex: tikv_thread_cpu_seconds_total;(tokio|rocksdb).+
      action: drop
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `additional_scrape_conf` field to the corresponding parameters of the Prometheus configuration file.

7.7.2 Customize Grafana configurations

Currently, TiUP supports customizing Grafana Dashboard and other configurations.

7.7.2.1 Customize Grafana Dashboard

1. Customize the configuration file of the Grafana Dashboard and place it under a directory of the machine where TiUP locates.
2. In the topology.yaml file, set `dashboard_dir` to the directory of the customized Dashboard configuration file.

The following is a configuration example of `grafana_servers` in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
  ↪ Servers.
grafana_servers:
  # # The ip address of the Grafana Server.
  - host: 127.0.0.1
    dashboard_dir: /home/tidb/dashboards # grafana dashboard dir on TiUP
      ↪ machine
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP loads the customized Dashboard configurations from `dashboard_dir` (for example, `/home/tidb/dashboards`) and sends the configurations to the Grafana Server to replace the default Dashboard configuration.

7.7.2.2 Customize other Grafana configurations

1. Open the topology.yaml file of the TiDB cluster.
2. Add other configuration items in the `grafana_servers` configuration.

The following is a configuration example of the `[log.file] level` and `smtp` fields in the topology.yaml file:

```
# # Server configs are used to specify the configuration of Grafana
  ↪ Servers.
grafana_servers:
  # # The ip address of the Grafana Server.
  - host: 127.0.0.1
    config:
      log.file.level: warning
      smtp.enabled: true
      smtp.host: {IP}:{port}
      smtp.user: example@pingcap.com
      smtp.password: {password}
      smtp.skip_verify: true
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `config` field to the Grafana configuration file `grafana.ini`.

7.7.3 Customize Alertmanager configurations

Currently, TiUP supports customizing the listening address of Alertmanager.

Alertmanager deployed by TiUP listens to `alertmanager_servers.host` by default. You cannot access Alertmanager if you use a proxy. To address this issue, you can specify the listening address by adding `listen_host` to the cluster configuration file `topology.yaml`. The recommended value is `0.0.0.0`.

The following example sets the `listen_host` field to `0.0.0.0`.

```
alertmanager_servers:
# # The ip address of the Alertmanager Server.
- host: 172.16.7.147
  listen_host: 0.0.0.0
# # SSH port of the server.
ssh_port: 22
```

After the preceding configuration is done, when you deploy, scale out, scale in, or reload a TiDB cluster, TiUP adds the `listen_host` field to `--web.listen-address` in Alertmanager startup parameters.

8 Troubleshoot

8.1 TiDB Troubleshooting Map

This document summarizes common issues in TiDB and other components. You can use this map to diagnose and solve issues when you encounter related problems.

8.1.1 1. Service Unavailable

8.1.1.1 1.1 The client reports `Region is Unavailable` error

- 1.1.1 The `Region is Unavailable` error is usually because a Region is not available for a period of time. You might encounter `TiKV server is busy`, or the request to TiKV fails due to `not leader` or `epoch not match`, or the request to TiKV time out. In such cases, TiDB performs a `backoff` retry mechanism. When the `backoff` exceeds a threshold (20s by default), the error will be sent to the client. Within the `backoff` threshold, this error is not visible to the client.
- 1.1.2 Multiple TiKV instances are OOM at the same time, which causes no Leader during the OOM period. See [case-991](#) in Chinese.
- 1.1.3 TiKV reports `TiKV server is busy`, and exceeds the `backoff` time. For more details, refer to [4.3](#). `TiKV server is busy` is a result of the internal flow control mechanism and should not be counted in the `backoff` time. This issue will be fixed.

- 1.1.4 Multiple TiKV instances failed to start, which causes no Leader in a Region. When multiple TiKV instances are deployed in a physical machine, the failure of the physical machine can cause no Leader in a Region if the label is not properly configured. See [case-228](#) in Chinese.
- 1.1.5 When a Follower apply is lagged in a previous epoch, after the Follower becomes a Leader, it rejects the request with `epoch not match`. See [case-958](#) in Chinese (TiKV needs to optimize its mechanism).

8.1.1.2 1.2 PD errors cause service unavailable

Refer to [5 PD issues](#).

8.1.2 2. Latency increases significantly

8.1.2.1 2.1 Transient increase

- 2.1.1 Wrong TiDB execution plan causes latency increase. Refer to [3.3](#).
- 2.1.2 PD Leader election issue or OOM. Refer to [5.2](#) and [5.3](#).
- 2.1.3 A significant number of Leader drops in some TiKV instances. Refer to [4.4](#).

8.1.2.2 2.2 Persistent and significant increase

- 2.2.1 TiKV single thread bottleneck
 - Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana -> TiKV-details -> Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate` \leftrightarrow `Region` to resolve the issue. See [case-612](#) in Chinese.
 - For versions earlier than v3.0, when the raftstore thread or the apply thread becomes the bottleneck (**Grafana -> TiKV-details -> Thread CPU/raft store CPU and Async apply CPU** metrics exceed 80%), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.
- 2.2.2 CPU load increases.
- 2.2.3 TiKV slow write. Refer to [4.5](#).
- 2.2.4 TiDB wrong execution plan. Refer to [3.3](#).

8.1.3 3. TiDB issues

8.1.3.1 3.1 DDL

- 3.1.1 An error `ERROR 1105 (HY000): unsupported modify decimal column ↪ precision` is reported when you modify the length of the decimal field. TiDB does not support changing the length of the decimal field.
- 3.1.2 TiDB DDL job hangs or executes slowly (use `admin show ddl jobs` to check DDL progress)
 - Cause 1: Network issue with other components (PD/TiKV).
 - Cause 2: Early versions of TiDB (earlier than v3.0.8) have heavy internal load because of a lot of goroutine at high concurrency.
 - Cause 3: In early versions (v2.1.15 & versions < v3.0.0-rc1), PD instances fail to delete TiDB keys, which causes every DDL change to wait for two leases.
 - For other unknown causes, [report a bug](#).
 - Solution:
 - * For cause 1, check the network connection between TiDB and TiKV/PD.
 - * For cause 2 and 3, the issues are already fixed in later versions. You can upgrade TiDB to a later version.
 - * For other causes, you can use the following solution of migrating the DDL owner.
 - DDL owner migration:
 - * If you can connect to the TiDB server, execute the owner election command again: `curl -X POST http://{TiDBIP}:10080/ddl/owner/resign`
 - * If you cannot connect to the TiDB server, use `tidb-ctl` to delete the DDL owner from the etcd of the PD cluster to trigger re-election: `tidb-ctl etcd ↪ delowner [LeaseID] [flags] + ownerKey`
- 3.1.3 TiDB reports `information schema is changed` error in log
 - Cause 1: The DML operation touches a table that is under DDL. You can use `admin show ddl job` to check the DDLs that are currently in progress.
 - Cause 2: The current DML operation is executed too long. During the time, many DDL operations are executed, which causes `schema version` changes to be more than 1024. The new version `lock table` might also cause schema version changes.
 - Cause 3: The TiDB instance that is currently executing DML statements cannot load the new `schema information` (maybe caused by network issues with PD or TiKV). During this time, many DDL statements are executed (including `lock ↪ table`), which causes `schema version` changes to be more than 1024.

- **Solution:** The first two causes do not impact the application, as the related DML operations retry after failure. For cause 3, you need to check the network between TiDB and TiKV/PD.
 - **Background:** The increased number of `schema version` is consistent with the number of `schema state` of each DDL change operation. For example, the `create table` operation has 1 version change, and the `add column` operation has 4 version changes. Therefore, too many column change operations might cause `schema version` to increase fast. For details, refer to [online schema change](#).
- 3.1.4 TiDB reports `information schema is out of date` in log
 - **Cause 1:** The TiDB server that is executing the DML statement is stopped by `graceful kill` and prepares to exit. The execution time of the transaction that contains the DML statement exceeds one DDL lease. An error is reported when the transaction is committed.
 - **Cause 2:** The TiDB server cannot connect to PD or TiKV when it is executing the DML statement. As a result, the TiDB server did not load the new schema within one DDL lease (45s by default), or the TiDB server disconnects from PD with the `keep alive` setting.
 - **Cause 3:** TiKV has high load or network timed out. Check the node loads in **Grafana** -> **TiDB** and **TiKV**.
 - **Solution:**
 - * For cause 1, retry the DML operation when TiDB is started.
 - * For cause 2, check the network between the TiDB server and PD/TiKV.
 - * For cause 3, investigate why TiKV is busy. Refer to [4 TiKV issues](#).

8.1.3.2 3.2 OOM issues

- 3.2.1 Symptom
 - **Client:** The client reports the error `ERROR 2013 (HY000): Lost connection to MySQL server during query`.
 - Check the log
 - * Execute `dmesg -T | grep tidb-server`. The result shows the OOM-killer log around the time point when the error occurs.
 - * Grep the “Welcome to TiDB” log in `tidb.log` around the time point after the error occurs (namely, the time when `tidb-server` restarts).
 - * Grep `fatal error: runtime: out of memory` or `cannot allocate memory` in `tidb_stderr.log`.
 - * In v2.1.8 or earlier versions, you can grep `fatal error: stack overflow` in the `tidb_stderr.log`.

- **Monitor:** The memory usage of tidb-server instances increases sharply in a short period of time.
- 3.2.2 Locate the SQL statement that causes OOM. (Currently all versions of TiDB cannot locate SQL accurately. You still need to analyze whether OOM is caused by the SQL statement after you locate one.)
 - For versions \geq v3.0.0, grep “expensive_query” in `tidb.log`. That log message records SQL queries that timed out or exceed memory quota.
 - For versions $<$ v3.0.0, grep “memory exceeds quota” in `tidb.log` to locate SQL queries that exceed memory quota.

Note:

The default threshold for a single SQL memory usage is 1GB (in bytes, `scope:SESSION`). You can set this parameter by configuring `tidb_mem_quota_query`. You can also modify the `mem-quota-query` item (in bytes) in the configuration file by hot loading the configuration items.

- 3.2.3 Mitigate OOM issues
 - By enabling **SWAP**, you can mitigate the OOM issue caused by overuse of memory by large queries. When the memory is insufficient, this method can have impact on the performance of large queries due to the I/O overhead. The degree to which the performance is affected depends on the remaining memory space and the disk I/O speed.
- 3.2.4 Typical reasons for OOM
 - The SQL query has `join`. If you view the SQL statement by using `explain`, you can find that the `join` operation selects the `HashJoin` algorithm and the inner table is large.
 - The data volume of a single `UPDATE/DELETE` query is too large. See [case-882](#) in Chinese.
 - The SQL contains multiple sub-queries connected by `Union`. See [case-1828](#) in Chinese.

8.1.3.3 3.3 Wrong execution plan

- 3.3.1 Symptom

- SQL query execution time is much longer compared with that of previous executions, or the execution plan suddenly changes. If the execution plan is logged in the slow log, you can directly compare the execution plans.
 - SQL query execution time is much longer compared with that of other databases such as MySQL. Compare the execution plan with other databases to see the differences, such as `Join Order`.
 - In slow log, the number of SQL execution time `Scan Keys` is large.
- 3.3.2 Investigate the execution plan
 - `explain analyze {SQL}`. When the execution time is acceptable, compare `count` in the result of `explain analyze` and the number of `row` in `execution info`. If a large difference is found in the `TableScan/IndexScan` row, it is likely that the statistics is incorrect. If a large difference is found in other rows, the problem might not be in the statistics.
 - `select count(*)`. When the execution plan contains a join operation, `explain ↪ analyze` might take a long time. You can check whether the problem is in the statistics by executing `select count(*)` for the conditions on `TableScan/ ↪ IndexScan` and comparing the `row count` information in the `explain` result.
 - 3.3.3 Mitigation
 - For v3.0 and later versions, use the `SQL Bind` feature to bind the execution plan.
 - Update the statistics. If you are roughly sure that the problem is caused by the statistics, `dump the statistics`. If the cause is outdated statistics, such as the `modify count/row count` in `show stats_meta` is greater than a certain value (for example, 0.3), or the table has an index of time column, you can try recovering by using `analyze table`. If `auto analyze` is configured, check whether the `tidb_auto_analyze_ratio` system variable is too large (for example, greater than 0.3), and whether the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`.
 - For other situations, [report a bug](#).

8.1.3.4 3.4 SQL execution error

- 3.4.1 The client reports the `ERROR 1265(01000)Data Truncated` error. This is because the way TiDB internally calculates the precision of `Decimal` type is incompatible with that of MySQL. This issue has been fixed in v3.0.10 ([#14438](#)).
 - Cause:
In MySQL, if two large-precision `Decimal` are divided and the result exceeds the maximum decimal precision (30), only 30 digits are reserved and no error is reported;

In TiDB, the calculation result is the same as in MySQL, but inside the data structure that represents `Decimal`, a field for decimal precision still retains the actual precision.

Take $(0.1^{30}) / 10$ as an example. The results in TiDB and MySQL are both 0, because the precision is 30 at most. However, in TiDB, the field for decimal precision is still 31.

After multiple `Decimal` divisions, even though the result is correct, this precision field could grow larger and larger, and eventually exceeds the threshold in TiDB (72), and the `Data Truncated` error is reported.

The multiplication of `Decimal` does not have this issue, because the out-of-bounds is bypassed, and the precision is set to the maximum precision limit.

- Solution: You can bypass this issue by manually adding `Cast(xx as decimal(a ↪ , b))`, in which `a` and `b` are the target precisions.

8.1.4 4. TiKV issues

8.1.4.1 4.1 TiKV panics and fails to start

- 4.1.1 `sync-log = false`. The unexpected raft log index: last_index X < ↪ applied_index Y error is returned after the machine is powered off.

This issue is expected. You can restore the Region using `tikv-ctl`.

- 4.1.2 If TiKV is deployed on a virtual machine, when the virtual machine is killed or the physical machine is powered off, the `entries[X, Y]` is unavailable from storage error is reported.

This issue is expected. The `fsync` of virtual machines is not reliable, so you need to restore the Region using `tikv-ctl`.

- 4.1.3 For other unexpected causes, [report a bug](#).

8.1.4.2 4.2 TiKV OOM

- 4.2.1 If the `block-cache` configuration is too large, it might cause OOM.

To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana** -> **TiKV-details**.

Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB" ↪ parameter` is set properly. By default, TiKV's `block-cache` is set to 45% of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.

- 4.2.2 Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM.

To verify the cause, you can check whether `response size` exceeds the `network`
↔ `outbound traffic` by viewing the monitor **Grafana** -> **TiKV-details** -> **coprocessor overview**.

- 4.2.3 Other components occupy too much memory.

This issue is unexpected. You can [report a bug](#).

8.1.4.3 4.3 The client reports the server is busy error

Check the specific cause for busy by viewing the monitor **Grafana** -> **TiKV** -> **errors**. `server is busy` is caused by the flow control mechanism of TiKV, which informs `tidb/ti`
↔ `-client` that TiKV is currently under too much pressure and will retry later.

- 4.3.1 TiKV RocksDB encounters `write stall`.

A TiKV instance has two RocksDB instances, one in `data/raft` to save the Raft log, another in `data/db` to save the real data. You can check the specific cause for stall by running `grep "Stalling" RocksDB` in the log. The RocksDB log is a file starting with `LOG`, and `LOG` is the current log.

- Too many `level0 sst` causes stall. You can add the `[rocksdb] max-sub-compactions = 2` (or 3) parameter to speed up `level0 sst` compaction. The compaction task from level0 to level1 is divided into several subtasks (the max number of subtasks is the value of `max-sub-compactions`) to be executed concurrently. See [case-815](#) in Chinese.
- Too many `pending compaction bytes` causes stall. The disk I/O fails to keep up with the write operations in business peaks. You can mitigate this problem by increasing the `soft-pending-compaction-bytes-limit` and `hard-pending-compaction-bytes-limit` of the corresponding CF.
 - * The default value of `[rocksdb.defaultcf] soft-pending-compaction-bytes-limit` is 64GB. If the pending compaction bytes reaches the threshold, RocksDB slows down the write speed. You can set `[rocksdb.defaultcf] soft-pending-compaction-bytes-limit` to 128GB.
 - * The default value of `hard-pending-compaction-bytes-limit` is 256GB. If the pending compaction bytes reaches the threshold (this is not likely to happen, because RocksDB slows down the write after the pending compaction bytes reaches `soft-pending-compaction-bytes-limit`), RocksDB stops the write operation. You can set `hard-pending-compaction-bytes-limit` to 512GB.
 - * If the disk I/O capacity fails to keep up with the write for a long time, it is recommended to scale up your disk. If the disk throughput reaches the

upper limit and causes write stall (for example, the SATA SSD is much lower than NVME SSD), while the CPU resources is sufficient, you may apply a compression algorithm of higher compression ratio. This way, the CPU resources is traded for disk resources, and the pressure on the disk is eased.

- * If the default CF compaction sees a high pressure, change the `[rocksdb.defaultcf] compression-per-level` parameter from `["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

- Too many memtables causes stall. This usually occurs when the amount of instant writes is large and the memtables flush to the disk slowly. If the disk write speed cannot be improved, and this issue only occurs during business peaks, you can mitigate it by increasing the `max-write-buffer-number` of the corresponding CF.
 - * For example, set `[rocksdb.defaultcf] max-write-buffer-number` to 8 (5 by default). Note that this might cause more memory usage in the peak, because more memtables might be in the memory.

- 4.3.2 scheduler too busy

- Serious write conflict. `latch wait duration` is high. You can view `latch wait duration` in the monitor **Grafana** -> **TiKV-details** -> **scheduler prewrite/scheduler commit**. When the write tasks pile up in the scheduler, the pending write tasks exceed the threshold set in `[storage] scheduler-pending write-threshold` (100MB). You can verify the cause by viewing the metric corresponding to `MVCC_CONFLICT_COUNTER`.
- Slow write causes write tasks to pile up. The data being written to TiKV exceeds the threshold set by `[storage] scheduler-pending-write-threshold` (100MB). Refer to [4.5](#).

- 4.3.3 raftstore is busy. The processing of messages is slower than the receiving of messages. The short-term `channel full` status does not affect the service, but if the error persists for a long time, it might cause Leader switch.

- `append log` encounters stall. Refer to [4.3.1](#).
- `append log duration` is high, which causes slow processing of messages. You can refer to [4.5](#) to analyze why `append log duration` is high.
- raftstore receives a large batch of messages in an instant (check in the TiKV Raft messages dashboard), and fails to process them. Usually the short-term `channel full` status does not affect the service.

- 4.3.4 TiKV coprocessor is in a queue. The number of piled up tasks exceeds `coprocessor threads * readpool.coprocessor.max-tasks-per-worker-[normal|low|high]`. Too many large queries leads to the tasks piling up in coprocessor. You need to check whether a execution plan change causes a large number of table scan operations. Refer to [3.3](#).

8.1.4.4 4.4 Some TiKV nodes drop Leader frequently

- 4.4.1 Re-election because TiKV is restarted
 - After TiKV panics, it is pulled up by systemd and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, [report a bug](#) if it happens.
 - TiKV is stopped or killed by a third party and then pulled up by systemd. Check the cause by viewing `dmesg` and the TiKV log.
 - TiKV is OOM, which causes restart. Refer to [4.2](#).
 - TiKV is hung because of dynamically adjusting THP (Transparent Hugepage). See case [case-500](#) in Chinese.
- 4.4.2 TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana** -> **TiKV-details** -> **errors** shows **server is busy**. Refer to [4.3.1](#).
- 4.4.3 Re-election because of network isolation.

8.1.4.5 4.5 TiKV write is slow

- 4.5.1 Check whether the TiKV write is low by viewing the `prewrite/commit/raw-put` duration of TiKV gRPC (only for raw KV clusters). Generally, you can locate the slow phase according to the [performance-map](#). Some common situations are listed as follows.
- 4.5.2 The scheduler CPU is busy (only for transaction kv).

The `scheduler command duration` of `prewrite/commit` is longer than the sum of `scheduler latch wait duration` and `storage async write duration`. The scheduler worker has a high CPU demand, such as over 80% of `scheduler-worker-pool-size * 100%`, or the CPU resources of the entire machine are relatively limited. If the write workload is large, check if `[storage] scheduler-worker-pool-size` is set too small.

For other situations, [report a bug](#).
- 4.5.3 Append log is slow.

The **Raft IO/append log duration** in TiKV Grafana is high, usually because the disk write operation is slow. You can verify the cause by checking the **WAL Sync** \leftrightarrow **Duration max** value of RocksDB - raft.

For other situations, [report a bug](#).
- 4.5.4 The raftstore thread is busy.

The **Raft Propose/propose wait duration** is significantly larger than the append log duration in TiKV Grafana. Take the following methods:

- Check whether the `[raftstore] store-pool-size` configuration value is too small. It is recommended to set the value between 1 and 5 and not too large.
 - Check whether the CPU resources on the machine are insufficient.
- 4.5.5 Apply is slow.

The **Raft IO/apply log duration** in TiKV Grafana is high, which usually comes with a high **Raft Propose/apply wait duration**. The possible causes are as follows:

- `[raftstore] apply-pool-size` is too small (it is recommended to set the value between 1 and 5 and not too large), and the **Thread CPU/apply CPU** is large.
 - The CPU resources on the machine are insufficient.
 - Region write hot spot. A single apply thread has high CPU usage. Currently, we cannot properly address the hot spot problem on a single Region, which is being improved. To view the CPU usage of each thread, modify the Grafana expression and add `by (instance, name)`.
 - RocksDB write is slow. **RocksDB kv/max write duration** is high. A single Raft log might contain multiple KVs. When writing into RocksDB, 128 KVs are written into RocksDB in a write batch. Therefore, an apply log might be associated with multiple writes in RocksDB.
 - For other situations, [report a bug](#).
- 4.5.6 Raft commit log is slow.
- The **Raft IO/commit log duration** in TiKV Grafana is high (this metric is only supported in Grafana after v4.x). Every Region corresponds to an independent Raft group. Raft has a flow control mechanism, similar to the sliding window mechanism of TCP. You can control the size of the sliding window by configuring the `[raftstore] ↪ raft-max-inflight-msgs = 256` parameter. If there is a write hot spot and the **commit log duration** is high, you can adjust the parameter, such as increasing it to 1024.
- 4.5.7 For other situations, refer to the write path on [performance-map](#) and analyze the cause.

8.1.5 5. PD issues

8.1.5.1 5.1 PD scheduling

- 5.1.1 Merge
 - Empty Regions across tables cannot be merged. You need to modify the `[coprocessor] split-region-on-table` parameter in TiKV, which is set to `false` in v4.x by default. See [case-896](#) in Chinese.

- Region merge is slow. You can check whether the merged operator is generated by accessing the monitor dashboard in **Grafana -> PD -> operator**. To accelerate the merge, increase the value of `merge-schedule-limit`.
- 5.1.2 Add replicas or take replicas online/offline
 - The TiKV disk uses 80% of the capacity, and PD does not add replicas. In this situation, the number of miss peers increases, so TiKV needs to be scaled out. See [case-801](#) in Chinese.
 - When a TiKV node is taken offline, some Region cannot be migrated to other nodes. This issue has been fixed in v3.0.4 ([#5526](#)). See [case-870](#) in Chinese.
- 5.1.3 Balance
 - The Leader/Region count is not evenly distributed. See [case-394](#) and [case-759](#) in Chinese. The major cause is that the balance performs scheduling based on the size of Region/Leader, so this might result in the uneven distribution of the count. In TiDB 4.0, the `[leader-schedule-policy]` parameter is introduced, which enables you to set the scheduling policy of Leader to be `count-based` or `size-based`.

8.1.5.2 5.2 PD election

- 5.2.1 PD switches Leader.
 - Cause 1: Disk. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana -> disk performance -> latency/load**. You can also use the FIO tool to run a check on the disk if necessary. See [case-292](#) in Chinese.
 - Cause 2: Network. The PD log shows `lost the TCP streaming connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana -> PD -> etcd**. See [case-177](#) in Chinese.
 - Cause 3: High system load. The log shows `server is likely overloaded`. See [case-214](#) in Chinese.
- 5.2.2 PD cannot elect a Leader or the election is slow.
 - PD cannot elect a Leader: The PD log shows `lease is not expired`. [This issue](#) has been fixed in v3.0.x and v2.1.19. See [case-875](#) in Chinese.

- The election is slow: The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region` \leftrightarrow `-storage` to `true`, which significantly reduce the Region loading duration. See [case-429](#) in Chinese.
- 5.2.3 PD timed out when TiDB executes SQL statements.
 - PD doesn't have a Leader or switches Leader. Refer to [5.2.1](#) and [5.2.2](#).
 - Network issue. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana** -> **blackbox_exporter** -> **ping latency**.
 - PD panics. [Report a bug](#).
 - PD is OOM. Refer to [5.3](#).
 - If the issue has other causes, get goroutine by running `curl http://127.0.0.1:2379/debug/pprof/goroutine?debug=2` and [report a bug](#).
- 5.2.4 Other issues
 - PD reports the FATAL error, and the log shows `range failed to find revision` \leftrightarrow `pair`. This issue has been fixed in v3.0.8 ([#2040](#)). For details, see [case-947](#) in Chinese.
 - For other situations, [report a bug](#).

8.1.5.3 5.3 PD OOM

- 5.3.1 When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 ([#1986](#)).
- 5.3.2 PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that TCP InSegs is relatively large. This issue has been fixed in v3.0.6 ([#1952](#)).

8.1.5.4 5.4 Grafana display

- 5.4.1 The monitor in **Grafana** -> **PD** -> **cluster** -> **role** displays follower. The Grafana expression issue has been fixed in v3.0.8.

8.1.6 6. Ecosystem tools

8.1.6.1 6.1 TiDB Binlog

- 6.1.1 TiDB Binlog is a tool that collects changes from TiDB and provides backup and replication to downstream TiDB or MySQL platforms. For details, see [TiDB Binlog on GitHub](#).
- 6.1.2 The `Update Time` in Pump/Drainer Status is updated normally, and no anomaly shows in the log, but no data is written to the downstream.
 - Binlog is not enabled in the TiDB configuration. Modify the `[binlog]` configuration in TiDB.
- 6.1.3 `sarama` in Drainer reports the EOF error.
 - The Kafka client version in Drainer is inconsistent with the version of Kafka. You need to modify the `[syncer.to] kafka-version` configuration.
- 6.1.4 Drainer fails to write to Kafka and panics, and Kafka reports the `Message was too large` error.

- The binlog data is too large, so the single message written to Kafka is too large. You need to modify the following configuration of Kafka:

```
message.max.bytes=1073741824
replica.fetch.max.bytes=1073741824
fetch.message.max.bytes=1073741824
```

For details, see [case-789](#) in Chinese.

- 6.1.5 Inconsistent data in upstream and downstream
 - Some TiDB nodes do not enable binlog. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the <http://127.0.0.1:10080/info/all> interface. For versions earlier than v3.0.6, you can check the binlog status by viewing the configuration file.
 - Some TiDB nodes go into the `ignore binlog` status. For v3.0.6 or later versions, you can check the binlog status of all the nodes by accessing the <http://127.0.0.1:10080/info/all> interface. For versions earlier than v3.0.6, check the TiDB log to see whether it contains the `ignore binlog` keyword.
 - The value of the timestamp column is inconsistent in upstream and downstream.
 - * This is caused by different time zones. You need to ensure that Drainer is in the same time zone as the upstream and downstream databases. Drainer obtains its time zone from `/etc/localtime` and does not support the TZ environment variable. See [case-826](#) in Chinese.

- * In TiDB, the default value of timestamp is `null`, but the same default value in MySQL 5.7 (not including MySQL 8) is the current time. Therefore, when the timestamp in upstream TiDB is `null` and the downstream is MySQL 5.7, the data in the timestamp column is inconsistent. You need to run `set @@global.explicit_defaults_for_timestamp=on;` in the upstream before enabling binlog.
 - For other situations, [report a bug](#).
- 6.1.6 Slow replication
 - The downstream is TiDB/MySQL, and the upstream performs frequent DDL operations. See [case-1023](#) in Chinese.
 - The downstream is TiDB/MySQL, and the table to be replicated has no primary key and no unique index, which causes reduced performance in binlog. It is recommended to add the primary key or unique index.
 - If the downstream outputs to files, check whether the output disk or network disk is slow.
 - For other situations, [report a bug](#).
- 6.1.7 Pump cannot write binlog and reports the `no space left on device` error.
 - The local disk space is insufficient for Pump to write binlog data normally. You need to clean up the disk space and then restart Pump.
- 6.1.8 Pump reports the `fail to notify all living drainer` error when it is started.
 - Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.
 - Solution: Use the `binlogctl` tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the `binlogctl` tool to change its state and then restart Pump. See the case [fail-to-notify-all-living-drainer](#).
- 6.1.9 Drainer reports the `gen update sqls failed: table xxx: row data is corruption []` error.
 - Trigger: The upstream performs DML operations on this table while performing `DROP COLUMN` DDL. This issue has been fixed in v3.0.6. See [case-820](#) in Chinese.
- 6.1.10 Drainer replication is hung. The process remains active but the checkpoint is not updated.
 - This issues has been fixed in v3.0.4. See [case-741](#) in Chinese.

- 6.1.11 Any component panics.
 - [Report a bug](#).

8.1.6.2 6.2 Data Migration

- 6.2.1 TiDB Data Migration (DM) is a migration tool that supports data migration from MySQL/MariaDB into TiDB. For details, see [DM on GitHub](#).
- 6.2.2 Access denied for user 'root'@'172.31.43.27' (using password: YES) shows when you run `query status` or check the log.
 - The database related passwords in all the DM configuration files should be encrypted by `dmctl`. If a database password is empty, it is unnecessary to encrypt the password. Cleartext passwords can be used since v1.0.6.
 - During DM operation, the user of the upstream and downstream databases must have the corresponding read and write privileges. Data Migration also **prechecks the corresponding privileges** automatically while starting the data replication task.
 - To deploy different versions of DM-worker/DM-master/dmctl in a DM cluster, see the [case study on AskTUG](#) in Chinese.
- 6.2.3 A replication task is interrupted with the `driver: bad connection` error returned.
 - The `driver: bad connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart and so on), and that the data of the current request has not yet been sent to TiDB.
 - * For versions earlier than DM 1.0.0 GA, stop the task by running `stop-task` and then restart the task by running `start-task`.
 - * For DM 1.0.0 GA or later versions, an automatic retry mechanism for this type of error is added. See [#265](#).
- 6.2.4 A replication task is interrupted with the `invalid connection` error.
 - The `invalid connection` error indicates that an anomaly has occurred in the connection between DM and the downstream TiDB database (such as network failure, TiDB restart, TiKV busy and so on), and that a part of the data for the current request has been sent to TiDB. Because DM has the feature of concurrently replicating data to the downstream in replication tasks, several errors might occur when a task is interrupted. You can check these errors by running `query-status` or `query-error`.
 - * If only the `invalid connection` error occurs during the incremental replication process, DM retries the task automatically.

- * If DM does not retry or fails to retry automatically because of version problems (automatic retry is introduced in v1.0.0-rc.1), use `stop-task` to stop the task and then use `start-task` to restart the task.
- 6.2.5 The relay unit reports the error `event from * in * diff from passed-in`
 - ↪ `event *`, or a replication task is interrupted with an error that fails to get or parse binlog, such as `get binlog error ERROR 1236 (HY000)and binlog checksum`
 - ↪ `mismatch, data may be corrupted returned`
 - During the process that DM pulls relay log or the incremental replication, this two errors might occur if the size of the upstream binlog file exceeds 4 GB.
 - Cause: When writing relay logs, DM needs to perform event verification based on binlog positions and the binlog file size, and store the replicated binlog positions as checkpoints. However, the official MySQL uses `uint32` to store binlog positions, which means the binlog position for a binlog file over 4 GB overflows, and then the errors above occur.
 - Solution:
 - * For relay processing units, [manually recover replication](#).
 - * For binlog replication processing units, [manually recover replication](#).
- 6.2.6 The DM replication is interrupted, and the log returns `ERROR 1236 (HY000)`
 - ↪ The slave is connecting using `CHANGE MASTER TO MASTER_AUTO_POSITION`
 - ↪ `= 1`, but the master has purged binary logs containing GTIDs that the
 - ↪ slave requires.
 - Check whether the master binlog is purged.
 - Check the position information recorded in `relay.meta`.
 - * `relay.meta` has recorded the empty GTID information. DM-worker saves the GTID information in memory to `relay.meta` when it exits or in every 30s. When DM-worker does not obtain the upstream GTID information, it saves the empty GTID information to `relay.meta`. See [case-772](#) in Chinese.
 - * The binlog event recorded in `relay.meta` triggers the incomplete recover process and records the wrong GTID information. This issue is fixed in v1.0.2, and might occur in earlier versions.
- 6.2.7 The DM replication process returns an error `Error 1366: incorrect utf8`
 - ↪ `value eda0bdedb29d(\ufffd\ufffd\ufffd\ufffd\ufffd\ufffd)`.
 - This value cannot be successfully written into MySQL 8.0 or TiDB, but can be written into MySQL 5.7. You can skip the data format check by enabling the `tidb_skip_utf8_check` parameter.

8.1.6.3 6.3 TiDB Lightning

- 6.3.1 TiDB Lightning is a tool for fast full import of large amounts of data into a TiDB cluster. See [TiDB Lightning on GitHub](#).
- 6.3.2 Import speed is too slow.
 - `region-concurrency` is set too high, which causes thread contention and reduces performance. Three ways to troubleshoot:
 - * The setting can be found from the start of the log by searching `region-↵ concurrency`.
 - * If TiDB Lightning shares a server with other services (for example, Importer), you must manually set `region-concurrency` to 75% of the total number of CPU cores on that server.
 - * If there is a quota on CPU (for example, limited by Kubernetes settings), TiDB Lightning might not be able to read this out. In this case, `region-↵ concurrency` must also be manually reduced.
 - Every additional index introduces a new KV pair for each row. If there are N indices, the actual size to be imported would be approximately (N+1) times the size of the [Mydumper](#) output. If the indices are negligible, you may first remove them from the schema, and add them back via `CREATE INDEX` after the import is complete.
 - The version of TiDB Lightning is old. Try the latest version, which might improve the import speed.
- 6.3.3 checksum failed: checksum mismatched remote vs local.
 - Cause 1: The table might already have data. These old data can affect the final checksum.
 - Cause 2: If the checksum of the target database is 0, which means nothing is imported, it is possible that the cluster is too hot and fails to take in any data.
 - Cause 3: If the data source is generated by the machine and not backed up by [Mydumper](#), ensure it respects the constraints of the table. For example:
 - * `AUTO_INCREMENT` columns need to be positive, and do not contain the value “0”.
 - * `UNIQUE` and `PRIMARY KEY`s must not have duplicate entries.
 - Solution: See [Troubleshooting Solution](#).
- 6.3.4 Checkpoint for ... has invalid status:(error code)
 - Cause: Checkpoint is enabled, and Lightning/Importer has previously abnormally exited. To prevent accidental data corruption, TiDB Lightning will not start until the error is addressed. The error code is an integer less than 25, with possible

values as 0, 3, 6, 9, 12, 14, 15, 17, 18, 20 and 21. The integer indicates the step where the unexpected exit occurs in the import process. The larger the integer is, the later the exit occurs.

– Solution: See [Troubleshooting Solution](#).

- 6.3.5 `ResourceTemporarilyUnavailable("Too many open engines ::: 8")`

– Cause: The number of concurrent engine files exceeds the limit specified by `tikv-importer`. This could be caused by misconfiguration. In addition, even when the configuration is correct, if `tidb-lightning` has exited abnormally before, an engine file might be left at a dangling open state, which could cause this error as well.

– Solution: See [Troubleshooting Solution](#).

- 6.3.6 `cannot guess encoding for input file, please convert to UTF-8`
↪ manually

– Cause: TiDB Lightning only supports the UTF-8 and GB-18030 encodings. This error means the file is not in any of these encodings. It is also possible that the file has mixed encoding, such as containing a string in UTF-8 and another string in GB-18030, due to historical `ALTER TABLE` executions.

– Solution: See [Troubleshooting Solution](#).

- 6.3.7 `[sql2kv] sql encode error = [types:1292]invalid time format:`
↪ `'{1970 1 1 0 45 0 0}'`

– Cause: A timestamp type entry has a time value that does not exist. This is either because of DST changes or because the time value has exceeded the supported range (from Jan 1, 1970 to Jan 19, 2038).

– Solution: See [Troubleshooting Solution](#).

8.1.7 7. Common log analysis

8.1.7.1 7.1 TiDB

- 7.1.1 GC life time is shorter than transaction duration.

The transaction duration exceeds the GC lifetime (10 minutes by default).

You can increase the GC lifetime by modifying the `tidb_gc_life_time` system variable. Generally, it is not recommended to modify this parameter, because changing it might cause many old versions to pile up if this transaction has a large number of `UPDATE` and `DELETE` statements.

- 7.1.2 `txn` takes too much time.

This error is returned when you commit a transaction that has not been committed for a long time (over 590 seconds).

If your application needs to execute a transaction of such a long time, you can increase the `[tikv-client] max-txn-time-use = 590` parameter and the GC lifetime to avoid this issue. It is recommended to check whether your application needs such a long transaction time.

- 7.1.3 `coprocessor.go` reports `request outdated`.

This error is returned when the coprocessor request sent to TiKV waits in a queue at TiKV for over 60 seconds.

You need to investigate why the TiKV coprocessor is in a long queue.

- 7.1.4 `region_cache.go` reports a large number of `switch region peer to next due` \leftrightarrow `to send request fail`, and the error message is `context deadline exceeded`.

The request for TiKV timed out and triggers the region cache to switch the request to other nodes. You can continue to run the `grep "<addr> cancelled` command on the `addr` field in the log and take the following steps according to the `grep` results:

- `send request is cancelled`: The request timed out during the sending phase. You can investigate the monitoring **Grafana** -> **TiDB** -> **Batch Client/Pending Request Count** by TiKV and see whether the Pending Request Count is greater than 128:
 - * If the value is greater than 128, the sending goes beyond the processing capacity of KV, so the sending piles up.
 - * If the value is not greater than 128, check the log to see if the report is caused by the operation and maintenance changes of the corresponding KV; otherwise, this error is unexpected, and you need to [report a bug](#).
- `wait response is cancelled`: The request timed out after it is sent to TiKV. You need to check the response time of the corresponding TiKV address and the Region logs in PD and KV at that time.

- 7.1.5 `distsql.go` reports `inconsistent index`.

The data index seems to be inconsistent. Run the `admin check table <TableName>` command on the table where the reported index is. If the check fails, disable garbage collection by running the following command, and [report a bug](#):

```
SET GLOBAL tidb_gc_enable = 0;
```

8.1.7.2 7.2 TiKV

- 7.2.1 `key is locked`.

The read and write have conflict. The read request encounters data that has not been committed and needs to wait until the data is committed.

A small number of this error has no impact on the business, but a large number of this error indicates that the read-write conflict is severe in your business.

- 7.2.2 `write conflict`.

This is the write-write conflict in optimistic transactions. If multiple transactions modify the same key, only one transaction succeed and other transactions automatically obtain the timestamp again and retry the operation, with no impact on the business.

If the conflict is severe, it might cause transaction failure after multiple retries. In this case, it is recommended to use the pessimistic lock.

- 7.2.3 `TxnLockNotFound`.

This transaction commit is too slow, causing it to be rolled back by other transactions after Time To Live (TTL). This transaction will automatically retry, so the business is usually not affected. For a transaction with a size of 0.25 MB or smaller, the default TTL is 3 seconds.

- 7.2.4 `PessimisticLockNotFound`.

Similar to `TxnLockNotFound`. The pessimistic transaction commit is too slow and thus rolled back by other transactions.

- 7.2.5 `stale_epoch`.

The request epoch is outdated, so TiDB re-sends the request after updating the routing. The business is not affected. Epoch changes when Region has a split/merge operation or a replica is migrated.

- 7.2.6 `peer is not leader`.

The request is sent to a replica that is not Leader. If the error response indicates which replica is the latest Leader, TiDB updates the local routing according the error and sends a new request to the latest Leader. Usually, the business is not affected.

In v3.0 and later versions, TiDB tries other peers if the request to the previous Leader fails, which might lead to frequent `peer is not leader` in TiKV log. You can check the `switch region peer to next due to send request fail` log of the corresponding Region in TiDB to determine the root cause of the sending failure. For details, refer to [7.1.4](#).

This error might also be returned if a Region has no Leader due to other reasons. For details, see [4.4](#).

8.2 Identify Slow Queries

To help users identify slow queries, analyze and improve the performance of SQL execution, TiDB outputs the statements whose execution time exceeds `slow-threshold` (The default value is 300 milliseconds) to `slow-query-file` (The default value is “tidb-slow.log”).

TiDB enables the slow query log by default. You can enable or disable the feature by modifying the configuration `enable-slow-log`.

8.2.1 Usage example

```
## Time: 2019-08-14T09:26:59.487776265+08:00

8.2.2 Fields description

Note:

The unit of all the following time fields in the slow query log is “second”.

Slow query basics:

- **Time:** The print time of log.
- **Query_time:** The execution time of a statement.
- **Parse_time:** The parsing time for the statement.
- **Compile_time:** The duration of the query optimization.
- **Query:** A SQL statement. Query is not printed in the slow log, but the corresponding field is called **Query** after the slow log is mapped to the memory table.
- **Digest:** The fingerprint of the SQL statement.
- **Txn_start_ts:** The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- **Is_internal:** Whether a SQL statement is TiDB internal. **true** indicates that a SQL statement is executed internally in TiDB and **false** indicates that a SQL statement is executed by the user.
- **Index_ids:** The IDs of the indexes involved in a statement.
- **Succ:** Whether a statement is executed successfully.
- **Backoff_time:** The waiting time before retry when a statement encounters errors that require a retry. The common errors as such include: **lock occurs**, **Region split**, and **tikv server is busy**.
- **Plan:** The execution plan of the statement. Use the `select tidb_decode_plan('xxx ↪ ...')` statement to parse the specific execution plan.
- **Prepared:** Whether this statement is a **Prepare** or **Execute** request or not.

- **Plan_from_cache**: Whether this statement hits the execution plan cache.
- **Rewrite_time**: The time consumed for rewriting the query of this statement.
- **Preproc_subqueries**: The number of subqueries (in the statement) that are executed in advance. For example, the `where id in (select if from t)` subquery might be executed in advance.
- **Preproc_subqueries_time**: The time consumed for executing the subquery of this statement in advance.
- **Exec_retry_count**: The retry times of this statement. This field is usually for pessimistic transactions in which the statement is retried when the lock is failed.
- **Exec_retry_time**: The execution retry duration of this statement. For example, if a statement has been executed three times in total (failed for the first two times), **Exec_retry_time** means the total duration of the first two executions. The duration of the last execution is **Query_time** minus **Exec_retry_time**.

The following fields are related to transaction execution:

- **Prewrite_time**: The duration of the first phase (prewrite) of the two-phase transaction commit.
- **Commit_time**: The duration of the second phase (commit) of the two-phase transaction commit.
- **Get_commit_ts_time**: The time spent on getting **commit_ts** during the second phase (commit) of the two-phase transaction commit.
- **Local_latch_wait_time**: The time that TiDB spends on waiting for the lock before the second phase (commit) of the two-phase transaction commit.
- **Write_keys**: The count of keys that the transaction writes to the Write CF in TiKV.
- **Write_size**: The total size of the keys or values to be written when the transaction commits.
- **Prewrite_region**: The number of TiKV Regions involved in the first phase (prewrite) of the two-phase transaction commit. Each Region triggers a remote procedure call.

Memory usage fields:

- **Mem_max**: The maximum memory space used during the execution period of a SQL statement (the unit is byte).

Hard disk fields:

- **Disk_max**: The maximum disk space used during the execution period of a SQL statement (the unit is byte).

User fields:

- **User**: The name of the user who executes this statement.

- **Conn_ID**: The Connection ID (session ID). For example, you can use the keyword `con:3` to search for the log whose session ID is 3.
- **DB**: The current database.

TiKV Coprocessor Task fields:

- **Request_count**: The number of Coprocessor requests that a statement sends.
- **Total_keys**: The number of keys that Coprocessor has scanned.
- **Process_time**: The total processing time of a SQL statement in TiKV. Because data is sent to TiKV concurrently, this value might exceed **Query_time**.
- **Wait_time**: The total waiting time of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- **Process_keys**: The number of keys that Coprocessor has processed. Compared with **total_keys**, **processed_keys** does not include the old versions of MVCC. A great difference between **processed_keys** and **total_keys** indicates that many old versions exist.
- **Cop_proc_avg**: The average execution time of cop-tasks.
- **Cop_proc_p90**: The P90 execution time of cop-tasks.
- **Cop_proc_max**: The maximum execution time of cop-tasks.
- **Cop_proc_addr**: The address of the cop-task with the longest execution time.
- **Cop_wait_avg**: The average waiting time of cop-tasks.
- **Cop_wait_p90**: The P90 waiting time of cop-tasks.
- **Cop_wait_max**: The maximum waiting time of cop-tasks.
- **Cop_wait_addr**: The address of the cop-task whose waiting time is the longest.
- **Cop_backoff_{backoff-type}_total_times**: The total times of backoff caused by an error.
- **Cop_backoff_{backoff-type}_total_time**: The total time of backoff caused by an error.
- **Cop_backoff_{backoff-type}_max_time**: The longest time of backoff caused by an error.
- **Cop_backoff_{backoff-type}_max_addr**: The address of the cop-task that has the longest backoff time caused by an error.
- **Cop_backoff_{backoff-type}_avg_time**: The average time of backoff caused by an error.
- **Cop_backoff_{backoff-type}_p90_time**: The P90 percentile backoff time caused by an error.

8.2.3 Related system variables

- **tidb_slow_log_threshold**: Sets the threshold for the slow log. The SQL statement whose execution time exceeds this threshold is recorded in the slow log. The default value is 300 (ms).

- `tidb_query_log_max_len`: Sets the maximum length of the SQL statement recorded in the slow log. The default value is 4096 (byte).
- `tidb_redact_log`: Determines whether to desensitize user data using ? in the SQL statement recorded in the slow log. The default value is 0, which means to disable the feature.
- `tidb_enable_collect_execution_info`: Determines whether to record the physical execution information of each operator in the execution plan. The default value is 1. This feature impacts the performance by approximately 3%. After enabling this feature, you can view the Plan information as follows:

```

> select tidb_decode_plan('
  ↪ jAOIMAk1XzE3CTAJMqlmdW5jczpjb3VudChDb2x1bW4jNyktPkMJC/
  ↪ BMNQkxCXRpbWU6MTAuOTMxNTA1bXMsIGxvb3BzOjIJMzcyIEJ5dGVzCU4vQQoxCTMyXzE4CTAJMQ1
  ↪ ');
+--

  ↪ :25                          N/A          N
  ↪ /A                          |
+-----+-----+

```

↪

If you are conducting a performance test, you can disable the feature of automatically collecting the execution information of operators:

```
set @@tidb_enable_collect_execution_info=0;
```

The returned result of the `Plan` field has roughly the same format with that of `EXPLAIN` or `EXPLAIN ANALYZE`. For more details of the execution plan, see [EXPLAIN](#) or [EXPLAIN ANALYZE](#).

For more information, see [TiDB specific variables and syntax](#).

8.2.4 Memory mapping in slow log

You can query the content of the slow query log by querying the `INFORMATION_SCHEMA.SLOW_QUERY` table. Each column name in the table corresponds to one field name in the slow log. For table structure, see the introduction to the `SLOW_QUERY` table in [Information Schema](#).

Note:

Every time you query the `SLOW_QUERY` table, TiDB reads and parses the current slow query log.

For TiDB 4.0, `SLOW_QUERY` supports querying the slow log of any period of time, including the rotated slow log file. You need to specify the `TIME` range to locate the slow log files that need to be parsed. If you don't specify the `TIME` range, TiDB only parses the current slow log file. For example:

- If you don't specify the time range, TiDB only parses the slow query data that TiDB is writing to the slow log file:

```
select count(*),
       min(time),
       max(time)
from slow_query;
```

```
+-----+-----+-----+
| count(*) | min(time)          | max(time)          |
+-----+-----+-----+
| 122492   | 2020-03-11 23:35:20.908574 | 2020-03-25 19:16:38.229035 |
+-----+-----+-----+
```

- If you specify the time range, for example, from 2020-03-10 00:00:00 to 2020-03-11 00:00:00, TiDB first locates the slow log files of the specified time range, and then parses the slow query information:

```
select count(*),
       min(time),
       max(time)
from slow_query
where time > '2020-03-10 00:00:00'
      and time < '2020-03-11 00:00:00';
```

count(*)	min(time)	max(time)
2618049	2020-03-10 00:00:00.427138	2020-03-10 23:00:22.716728

Note:

If the slow log files of the specified time range are removed, or there is no slow query, the query returns NULL.

TiDB 4.0 adds the **CLUSTER_SLOW_QUERY** system table to query the slow query information of all TiDB nodes. The table schema of the **CLUSTER_SLOW_QUERY** table differs from that of the **SLOW_QUERY** table in that an **INSTANCE** column is added to **CLUSTER_SLOW_QUERY**. The **INSTANCE** column represents the TiDB node address of the row information on the slow query. You can use **CLUSTER_SLOW_QUERY** the way you do with **SLOW_QUERY**.

When you query the **CLUSTER_SLOW_QUERY** table, TiDB pushes the computation and the judgment down to other nodes, instead of retrieving all slow query information from other nodes and executing the operations on one TiDB node.

8.2.5 SLOW_QUERY / CLUSTER_SLOW_QUERY usage examples

8.2.5.1 Top-N slow queries

Query the Top 2 slow queries of users. **Is_internal=false** means excluding slow queries inside TiDB and only querying slow queries of users.

```
select query_time, query
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 2;
```

Output example:

query_time	query
12.77583857	select * from t_slim, t_wide where t_slim.c0=t_wide.c0;
0.734982725	select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1.c0;

8.2.5.2 Query the Top-N slow queries of the test user

In the following example, the slow queries executed by the `test` user are queried, and the first two results are displayed in reverse order of execution time.

```
select query_time, query, user
from information_schema.slow_query
where is_internal = false
and user = "test"
order by query_time desc
limit 2;
```

Output example:

Query_time	query	user
0.676408014	select t0.c0, t1.c1 from t_slim t0, t_wide t1 where t0.c0=t1.c1;	test

8.2.5.3 Query similar slow queries with the same SQL fingerprints

After querying the Top-N SQL statements, continue to query similar slow queries using the same fingerprints.

1. Acquire Top-N slow queries and the corresponding SQL fingerprints.

```
select query_time, query, digest
from information_schema.slow_query
where is_internal = false
order by query_time desc
limit 1;
```

Output example:

```
+-----+-----+-----+
| query_time | query | digest |
+-----+-----+-----+
| 0.302558006 | select * from t1 where a=1; | 4751 |
|             |             |             |
|             |             |             |
+-----+-----+-----+
```

2. Query similar slow queries with the fingerprints.

```
select query, query_time
from information_schema.slow_query
where digest = "4751
↳ cb6008fda383e22dacb601fde85425dc8f8cf669338d55d944bafb46a6fa";
```

Output example:

```
+-----+-----+
| query | query_time |
+-----+-----+
| select * from t1 where a=1; | 0.302558006 |
| select * from t1 where a=2; | 0.401313532 |
+-----+-----+
```

8.2.6 Query slow queries with pseudo stats

```
select query, query_time, stats
from information_schema.slow_query
where is_internal = false
and stats like '%pseudo%';
```

Output example:

query	query_time	stats
select * from t1 where a=1;	0.302558006	t1:pseudo
select * from t1 where a=2;	0.401313532	t1:pseudo
select * from t1 where a>2;	0.602011247	t1:pseudo
select * from t1 where a>3;	0.50077719	t1:pseudo
select * from t1 join t2;	0.931260518	t1:407872303825682445,t2:pseudo

8.2.6.1 Query slow queries whose execution plan is changed

When the execution plan of SQL statements of the same category is changed, the execution slows down, because the statistics is outdated, or the statistics is not accurate enough to reflect the real data distribution. You can use the following SQL statement to query SQL statements with different execution plans.

```
select count(distinct plan_digest) as count,
       digest,
       min(query)
from cluster_slow_query
group by digest
having count > 1
limit 3\G
```

Output example:

```
*****[ 1. row ]*****
count      | 2
digest     | 17b4518fde82e32021877878bec2bb309619d384fca944106faf9c93b536e94
min(query) | SELECT DISTINCT c FROM sbtest25 WHERE id BETWEEN ? AND ? ORDER
           ↪ BY c [arguments: (291638, 291737)];
*****[ 2. row ]*****
count      | 2
digest     | 9337865f3e2ee71c1c2e740e773b6dd85f23ad00f8fa1f11a795e62e15fc9b23
min(query) | SELECT DISTINCT c FROM sbtest22 WHERE id BETWEEN ? AND ? ORDER
           ↪ BY c [arguments: (215420, 215519)];
*****[ 3. row ]*****
count      | 2
digest     | db705c89ca2dfc1d39d10e0f30f285cbbadec7e24da4f15af461b148d8fffb020
```

```
min(query) | SELECT DISTINCT c FROM sbtest11 WHERE id BETWEEN ? AND ? ORDER
↳ BY c [arguments: (303359, 303458)];
```

Then you can query the different plans using the SQL fingerprint in the query result above:

```
select min(plan),
       plan_digest
from cluster_slow_query
where digest='17
↳ b4518fde82e32021877878bec2bb309619d384fca944106caf9c93b536e94'
group by plan_digest\G
```

Output example:

```
***** 1. row *****
min(plan):  Sort_6                root  100.00131380758702  sbtest.
↳ sbtest25.c:asc
  -HashAgg_10          root  100.00131380758702  group by:sbtest.
↳ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
↳ .c
  -TableReader_15     root  100.00131380758702  data:
↳ TableRangeScan_14
  -TableScan_14       cop   100.00131380758702  table:sbtest25,
↳ range:[502791,502890], keep order:false
plan_digest: 6
↳ afbbd21f60ca6c6fdf3d3cd94f7c7a49dd93c00fcf8774646da492e50e204ee
***** 2. row *****
min(plan):  Sort_6                root  1
↳ sbtest25.c:asc
  -HashAgg_12          root  1
↳ sbtest25.c, funcs:firstrow(sbtest.sbtest25.c)->sbtest.sbtest25
↳ .c
  -TableReader_13     root  1
↳ data:HashAgg_8
  -HashAgg_8          cop   1
↳ group by:sbtest.
↳ sbtest25.c,
  -TableScan_11       cop   1.2440069558121831  table:sbtest25,
↳ range:[472745,472844], keep order:false
```

8.2.6.2 Query the number of slow queries for each TiDB node in a cluster

```
select instance, count(*) from information_schema.cluster_slow_query where
↳ time >= "2020-03-06 00:00:00" and time < now() group by instance;
```

Output example:

```

+-----+-----+
| instance | count(*) |
+-----+-----+
| 0.0.0.0:10081 | 124 |
| 0.0.0.0:10080 | 119771 |
+-----+-----+

```

8.2.6.3 Query slow logs occurring only in abnormal time period

If you find problems such as decreased QPS or increased latency for the time period from 2020-03-10 13:24:00 to 2020-03-10 13:27:00, the reason might be that a large query crops up. Run the following SQL statement to query slow logs that occur only in abnormal time period. The time range from 2020-03-10 13:20:00 to 2020-03-10 13:23:00 refers to the normal time period.

```

SELECT * FROM
  (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ count(*),
    min(time),
    sum(query_time) AS sum_query_time,
    sum(Process_time) AS sum_process_time,
    sum(Wait_time) AS sum_wait_time,
    sum(Commit_time),
    sum(Request_count),
    sum(process_keys),
    sum(Write_keys),
    max(Cop_proc_max),
    min(query),min(prev_stmt),
    digest
  FROM information_schema.CLUSTER_SLOW_QUERY
  WHERE time >= '2020-03-10 13:24:00'
        AND time < '2020-03-10 13:27:00'
        AND Is_internal = false
  GROUP BY digest) AS t1
WHERE t1.digest NOT IN
  (SELECT /*+ AGG_TO_COP(), HASH_AGG() */ digest
  FROM information_schema.CLUSTER_SLOW_QUERY
  WHERE time >= '2020-03-10 13:20:00'
        AND time < '2020-03-10 13:23:00'
  GROUP BY digest)
ORDER BY t1.sum_query_time DESC limit 10\G

```

Output example:

```

*****[ 1. row ]*****
count(*)          | 200

```

```

min(time)          | 2020-03-10 13:24:27.216186
sum_query_time    | 50.114126194
sum_process_time  | 268.351
sum_wait_time     | 8.476
sum(Commit_time) | 1.044304306
sum(Request_count)| 6077
sum(process_keys) | 202871950
sum(Write_keys)   | 319500
max(Cop_proc_max) | 0.263
min(query)        | delete from test.tcs2 limit 5000;
min(prev_stmt)    |
digest            | 24
                  ↪ bd6d8a9b238086c9b8c3d240ad4ef32f79ce94cf5a468c0b8fe1eb5f8d03df

```

8.2.6.4 Parse other TiDB slow log files

TiDB uses the session variable `tidb_slow_query_file` to control the files to be read and parsed when querying `INFORMATION_SCHEMA.SLOW_QUERY`. You can query the content of other slow query log files by modifying the value of the session variable.

```
set tidb_slow_query_file = "/path-to-log/tidb-slow.log"
```

8.2.6.5 Parse TiDB slow logs with `pt-query-digest`

Use `pt-query-digest` to parse TiDB slow logs.

Note:

It is recommended to use `pt-query-digest` 3.0.13 or later versions.

For example:

```
pt-query-digest --report tidb-slow.log
```

Output example:

```

## 320ms user time, 20ms system time, 27.00M rss, 221.32M vsz
## Current date: Mon Mar 18 13:18:51 2019
## Hostname: localhost.localdomain
## Files: tidb-slow.log
## Overall: 1.02k total, 21 unique, 0 QPS, 0x concurrency -----
## Time range: 2019-03-18-12:22:16 to 2019-03-18-13:08:52
## Attribute      total      min      max      avg      95% stddev median

```

8.2.7 Identify problematic SQL statements

Not all of the `SLOW_QUERY` statements are problematic. Only those whose `process_time` is very large increase the pressure on the entire cluster.

The statements whose `wait_time` is very large and `process_time` is very small are usually not problematic. This is because the statement is blocked by real problematic statements and it has to wait in the execution queue, which leads to a much longer response time.

8.2.7.1 admin show slow command

In addition to the TiDB log file, you can identify slow queries by running the `admin show slow` command:

```
admin show slow recent N
admin show slow top [internal | all] N
```

`recent N` shows the recent `N` slow query records, for example:

```
admin show slow recent 10
```

`top N` shows the slowest `N` query records recently (within a few days). If the `internal` option is provided, the returned results would be the inner SQL executed by the system; If the `all` option is provided, the returned results would be the user's SQL combined with inner SQL; Otherwise, this command would only return the slow query records from the user's SQL.

```
admin show slow top 3
admin show slow top internal 3
admin show slow top all 5
```

TiDB stores only a limited number of slow query records because of the limited memory. If the value of `N` in the query command is greater than the records count, the number of returned records is smaller than `N`.

The following table shows output details:

Column name	Description
start	The start- ing time of the SQL execu- tion
duration	The dura- tion of the SQL execu- tion
details	The de- tails of the SQL execu- tion

Column name	Description
succ	Whether the SQL statement is executed successfully. 1 means success and 0 means failure.
conn_id	The connection ID for the session
transcation_id	The commit \hookrightarrow \hookrightarrow ts for a transaction commit

Column name	Description
user	The user name for the execution of the statement
db	The database involved when the statement is executed
table_ids	The ID of the table involved when the SQL statement is executed

Column name	Description
index_ids	The ID of the index involved when the SQL statement is executed
internal	This is a TiDB internal SQL statement
digest	The fingerprint of the SQL statement
sql	The SQL statement that is being executed or has been executed

8.3 Analyze Slow Queries

To address the issue of slow queries, you need to take the following two steps:

1. Among many queries, identify which type of queries are slow.
2. Analyze why this type of queries are slow.

You can easily perform step 1 using the [slow query log](#) and the [statement summary table](#) features. It is recommended to use [TiDB Dashboard](#), which integrates the two features and directly displays the slow queries in your browser.

This document focuses on how to perform step 2 - analyze why this type of queries are slow.

Generally, slow queries have the following major causes:

- Optimizer issues, such as wrong index selected, wrong join type or sequence selected.
- System issues. All issues not caused by the optimizer are system issues. For example, a busy TiKV instance processes requests slowly; outdated Region information causes slow queries.

In actual situations, optimizer issues might cause system issues. For example, for a certain type of queries, the optimizer uses a full table scan instead of the index. As a result, the SQL queries consume many resources, which causes the CPU usage of some TiKV instances to soar. This seems like a system issue, but in essence, it is an optimizer issue.

To identify system issues is relatively simple. To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. Therefore, it is recommended to analyze slow queries by following these procedures:

1. Identify the performance bottleneck of the query, that is, the time-consuming part of the query process.
2. Analyze the system issues: analyze the possible causes according to the query bottleneck and the monitoring/log information of that time.
3. Analyze the optimizer issues: analyze whether there is a better execution plan.

The procedures above are explained in the following sections.

8.3.1 Identify the performance bottleneck of the query

First, you need to have a general understanding of the query process. The key stages of the query execution process in TiDB are illustrated in [TiDB performance map](#).

You can get the duration information using the following methods:

- **Slow log.** It is recommended to view the slow log in [TiDB Dashboard](#).
- **EXPLAIN ANALYZE statement.**

The methods above are different in the following aspects:

- The slow log records the duration of almost all stages of a SQL execution, from parsing to returning results, and is relatively comprehensive (you can query and analyze the slow log in TiDB Dashboard in an intuitive way).
- By executing **EXPLAIN ANALYZE**, you can learn the time consumption of each operator in an actual SQL execution. The results have more detailed statistics of the execution duration.

In summary, the slow log and **EXPLAIN ANALYZE** statements help you determine the SQL query is slow in which component (TiDB or TiKV) at which stage of the execution. Therefore, you can accurately identify the performance bottleneck of the query.

In addition, since v4.0.3, the **Plan** field in the slow log also includes the SQL execution information, which is the result of **EXPLAIN ANALYZE**. So you can find all information of SQL duration in the slow log.

8.3.2 Analyze system issues

System issues can be divided into the following types according to different execution stages of a SQL statement:

1. TiKV is slow in data processing. For example, the TiKV coprocessor processes data slowly.
2. TiDB is slow in execution. For example, a **Join** operator processes data slowly.
3. Other key stages are slow. For example, getting the timestamp takes a long time.

For each slow query, first determine to which type the query belongs, and then analyze it in detail.

8.3.2.1 TiKV is slow in data processing

If TiKV is slow in data processing, you can easily identify it in the result of **EXPLAIN** \hookrightarrow **ANALYZE**. In the following example, **StreamAgg_8** and **TableFullScan_15**, two **tikv-** \hookrightarrow **tasks** (as indicated by **cop[tikv]** in the **task** column), take **170ms** to execute. After subtracting **170ms**, the execution time of TiDB operators account for a very small proportion of the total execution time. This indicates that the bottleneck is in TiKV.

```

| id | estRows | actRows | task | access object |
  ↳ execution info
  ↳ operator info | memory | disk |
+---+
  ↳ -----+-----+-----+-----+-----+
  ↳
| StreamAgg_16 | 1.00 | 1 | root | | time
  ↳ :170.08572ms, loops:2
  ↳ funcs:count(Column#5)->Column#3 | 372 Bytes | N/A |
| -TableReader_17 | 1.00 | 1 | root | | time
  ↳ :170.080369ms, loops:2, rpc num: 1, rpc time:17.023347ms, proc keys
  ↳ :28672 | data:StreamAgg_8 | 202 Bytes | N/A |
| -StreamAgg_8 | 1.00 | 1 | cop[tikv] | | time
  ↳ :170ms, loops:29
  ↳ funcs:count(1)->Column#5 | N/A | N/A |
| -TableFullScan_15 | 7.00 | 28672 | cop[tikv] | table:t | time
  ↳ :170ms, loops:29
  ↳ keep order:false, stats:pseudo | N/A | N/A |
+---+
  ↳ -----+-----+-----+-----+-----+
  ↳

```

In addition, the `Cop_process` and `Cop_wait` fields in the slow log can also help your analysis. In the following example, the total duration of the query is around 180.85ms, and the largest coptask takes 171ms. This indicates that the bottleneck of this query is on the TiKV side.

For the description of each field in the slow log, see [fields description](#).

```

## Query_time: 0.18085
...
## Num_cop_tasks: 1
## Cop_process: Avg_time: 170ms P90_time: 170ms Max_time: 170ms Max_addr:
  ↳ 10.6.131.78
## Cop_wait: Avg_time: 1ms P90_time: 1ms Max_time: 1ms Max_Addr: 10.6.131.78

```

After identifying that TiKV is the bottleneck, you can find out the cause as described in the following sections.

8.3.2.1.1 TiKV instance is busy

During the execution of a SQL statement, TiDB might fetch data from multiple TiKV instances. If one TiKV instance responds slowly, the overall SQL execution speed is slowed down.

The `Cop_wait` field in the slow log can help you determine this cause.

```
## Cop_wait: Avg_time: 1ms P90_time: 2ms Max_time: 110ms Max_Addr:  
↳ 10.6.131.78
```

The log above shows that a `cop-task` sent to the `10.6.131.78` instance waits `110ms` `↳` before being executed. It indicates that this instance is busy. You can check the CPU monitoring of that time to confirm the cause.

8.3.2.1.2 Too many outdated keys

A TiKV instance has much outdated data, which needs to be cleaned up for data scan. This impacts the processing speed.

Check `Total_keys` and `Processed_keys`. If they are greatly different, the TiKV instance has too many keys of the older versions.

```
...  
## Total_keys: 2215187529 Processed_keys: 1108056368  
...
```

8.3.2.2 Other key stages are slow

8.3.2.2.1 Slow in getting timestamps

You can compare `Wait_TS` and `Query_time` in the slow log. The timestamps are prefetched, so generally `Wait_TS` should be low.

```
## Query_time: 0.0300000  
...  
## Wait_TS: 0.02500000
```

8.3.2.2.2 Outdated Region information

Region information on the TiDB side might be outdated. In this situation, TiKV might return the `regionMiss` error. Then TiDB gets the Region information from PD again, which is reflected in the `Cop_backoff` information. Both the failed times and the total duration are recorded.

```
## Cop_backoff_regionMiss_total_times: 200 Cop_backoff_regionMiss_total_time  
↳ : 0.2 Cop_backoff_regionMiss_max_time: 0.2  
↳ Cop_backoff_regionMiss_max_addr: 127.0.0.1  
↳ Cop_backoff_regionMiss_avg_time: 0.2 Cop_backoff_regionMiss_p90_time:  
↳ 0.2  
## Cop_backoff_rpcPD_total_times: 200 Cop_backoff_rpcPD_total_time: 0.2  
↳ Cop_backoff_rpcPD_max_time: 0.2 Cop_backoff_rpcPD_max_addr: 127.0.0.1  
↳ Cop_backoff_rpcPD_avg_time: 0.2 Cop_backoff_rpcPD_p90_time: 0.2
```

8.3.2.2.3 Subqueries are executed in advance

For statements with non-correlated subqueries, the subquery part might be executed in advance. For example, in `select * from t1 where a = (select max(a) from t2)`, the `select max(a) from t2` part might be executed in advance in the optimization stage. The result of `EXPLAIN ANALYZE` does not show the duration of this type of subqueries.

```
mysql> explain analyze select count(*) from t where a=(select max(t1.a)
  ↳ from t t1, t t2 where t1.a=t2.a);
+---
  ↳
  ↳
| id          | estRows | actRows | task      | access object |
  ↳ execution info | operator info | memory | disk |
+---
  ↳
  ↳
| StreamAgg_59 | 1.00    | 1       | root      |                | time
  ↳ :4.69267ms, loops:2 | funcs:count(Column#10)->Column#8 | 372 Bytes |
  ↳ N/A |
| -TableReader_60 | 1.00    | 1       | root      |                |
  ↳ time:4.690428ms, loops:2 | data:StreamAgg_48 | 141 Bytes | N/A
  ↳ |
| -StreamAgg_48   | 1.00    |         | cop[tikv] |                |
  ↳ time:0ns, loops:0 | funcs:count(1)->Column#10 | N/A      | N/A
  ↳ |
| -Selection_58   | 16384.00 |         | cop[tikv] |                |
  ↳ time:0ns, loops:0 | eq(test.t.a, 1) | N/A      | N/A
  ↳ |
| -TableFullScan_57 | 16384.00 | -1      | cop[tikv] | table:t        |
  ↳ time:0s, loops:0 | keep order:false | N/A      | N/A
  ↳ |
+---
  ↳
  ↳
5 rows in set (7.77 sec)
```

But you can identify this type of subquery execution in the slow log:

```
## Query_time: 7.770634843
...
## Rewrite_time: 7.765673663 Preproc_subqueries: 1 Preproc_subqueries_time:
  ↳ 7.765231874
```

From log record above, you can see that a subquery is executed in advance and takes 7.76s.

8.3.2.3 TiDB is slow in execution

Assume that the execution plan in TiDB is correct but the execution is slow. To solve this type of issue, you can adjust parameters or use the hint according to the result of `EXPLAIN ANALYZE` for the SQL statement.

If the execution plan is incorrect, see the [Analyze optimizer issues](#) section.

8.3.2.3.1 Low concurrency

If the bottleneck is in the operator with concurrency, speed up the execution by adjusting the concurrency. For example:

```
mysql> explain analyze select sum(t1.a) from t t1, t t2 where t1.a=t2.a;
+--
↪ -----+-----+-----+-----+
↪
| id          | estRows  | actRows | task      | access
↪ object | execution info
↪                                     | operator
↪ info          | memory   | disk    |
+--
↪ -----+-----+-----+-----+
↪
| HashAgg_11          | 1.00    | 1      | root      |
↪      | time:9.666832189s, loops:2, PartialConcurrency:4,
↪ FinalConcurrency:4 | funcs:sum(Column#6)->Column#5
↪ 322.125 KB | N/A |
| -Projection_24      | 268435456.00 | 268435456 | root |
↪      | time:9.098644711s, loops:262145, Concurrency:4
↪      | cast(test.t.a, decimal(65,0) BINARY)->
↪ Column#6 | 199 KB | N/A |
| -HashJoin_14        | 268435456.00 | 268435456 | root |
↪      | time:6.616773501s, loops:262145, Concurrency:5, probe
↪ collision:0, build:881.404µs | inner join, equal:[eq(test.t.a, test.t
↪ .a)] | 131.75 KB | 0 Bytes |
| -TableReader_21(Build) | 16384.00 | 16384 | root |
↪      | time:6.553717ms, loops:17
↪                                     | data:Selection_20
↪      | 33.6318359375 KB | N/A |
| -Selection_20       | 16384.00 | | cop[tikv] |
↪      | time:0ns, loops:0
↪                                     | not(isnull(
↪ test.t.a)) | N/A | N/A |
| -TableFullScan_19   | 16384.00 | -1 | cop[tikv] | table:
↪ t2 | time:0s, loops:0
↪                                     | keep order:
```

```

↪ false | N/A | N/A |
| -TableReader_18(Probe) | 16384.00 | 16384 | root |
↪ | time:6.880923ms, loops:17
↪ | data:Selection_17
↪ | 33.6318359375 KB | N/A |
| -Selection_17 | 16384.00 | | cop[tikv] |
↪ | time:0ns, loops:0
↪ | not(isnull(
↪ test.t.a)) | N/A | N/A |
| -TableFullScan_16 | 16384.00 | -1 | cop[tikv] | table:
↪ t1 | time:0s, loops:0
↪ | keep order:
↪ false | N/A | N/A |
+--
↪ -----+-----+-----+-----+
↪
9 rows in set (9.67 sec)

```

As shown above, HashJoin_14 and Projection_24 consume much of the execution time. Consider increasing their concurrency using SQL variables to speed up execution.

All system variables are documented in [system-variables](#). To increase the concurrency of HashJoin_14, you can modify the `tidb_hash_join_concurrency` system variable.

8.3.2.3.2 Data is spilled to disk

Another cause of slow execution is disk spill that occurs during execution if the memory limit is reached. You can find out this cause in the execution plan and the slow log:

```

+--
↪ -----+-----+-----+-----+
↪
| id | estRows | actRows | task | access object |
↪ execution info | operator info | memory |
↪ disk |
+--
↪ -----+-----+-----+-----+
↪
| Sort_4 | 462144.00 | 462144 | root | | time
↪ :2.02848898s, loops:453 | test.t.a | 149.68795776367188 MB |
↪ 219.3203125 MB |
| -TableReader_8 | 462144.00 | 462144 | root | | time
↪ :616.211272ms, loops:453 | data:TableFullScan_7 | 197.49601364135742
↪ MB | N/A |
| -TableFullScan_7 | 462144.00 | -1 | cop[tikv] | table:t | time:0
↪ s, loops:0 | keep order:false | N/A | N/A

```

```

↪      |
+--
↪ -----+-----+-----+-----+
↪

```

```

...
## Disk_max: 229974016
...

```

8.3.2.3.3 Join operations with Cartesian product

Join operations with Cartesian product generate data volume as large as left child
 ↪ row count * right child row count. This is inefficient and should be avoided.

This type of join operations is marked CARTESIAN in the execution plan. For example:

```

mysql> explain select * from t t1, t t2 where t1.a>t2.a;
+--
↪ -----+-----+-----+-----+
↪
| id          | estRows  | task      | access object | operator
↪ info
+--
↪ -----+-----+-----+-----+
↪
| HashJoin_8      | 99800100.00 | root      |                | CARTESIAN
↪ inner join, other cond:gt(test.t.a, test.t.a) |
| -TableReader_15(Build) | 9990.00 | root      |                | data:
↪ Selection_14
|   -Selection_14      | 9990.00 | cop[tikv] |                | not(
↪ isnull(test.t.a))
|     -TableFullScan_13 | 10000.00 | cop[tikv] | table:t2      | keep
↪ order:false, stats:pseudo
| -TableReader_12(Probe) | 9990.00 | root      |                | data:
↪ Selection_11
|   -Selection_11      | 9990.00 | cop[tikv] |                | not(
↪ isnull(test.t.a))
|     -TableFullScan_10 | 10000.00 | cop[tikv] | table:t1      | keep
↪ order:false, stats:pseudo
+--
↪ -----+-----+-----+-----+
↪

```

8.3.3 Analyze optimizer issues

To analyze optimizer issues, you need to determine whether the execution plan is reasonable or not. You need to have some understanding of the optimization process and each operator.

For the following examples, assume that the table schema is `create table t (id int ↪ , a int, b int, c int, primary key(id), key(a), key(b, c))`.

1. `select * from t`: There is no filter condition and a full table scan is performed. So the `TableFullScan` operator is used to read data.
2. `select a from t where a=2`: There is a filter condition and only the index columns are read, so the `IndexReader` operator is used to read data.
3. `select * from t where a=2`: There is a filter condition for `a` but the `a` index cannot fully cover the data to be read, so the `IndexLookup` operator is used.
4. `select b from t where c=3`: Without the prefix condition, the multi-column index cannot be used. So the `IndexFullScan` is used.
5. ...

The examples above are operators used for data reads. For more operators, see [Understand TiDB Execution Plan](#).

In addition, reading [SQL Tuning Overview](#) helps you better understand the TiDB optimizer and determine whether the execution plan is reasonable or not.

Most optimizer issues are explained in [SQL Tuning Overview](#). For the solutions, see the following documents:

1. [Wrong Index Solution](#)
2. [Wrong join order](#)
3. [Expressions are not pushed down](#)

8.4 SQL Diagnostics

Warning:

SQL diagnostics is still an experimental feature. It is **NOT** recommended that you use it in the production environment.

SQL diagnostics is a feature introduced in TiDB v4.0. You can use this feature to locate problems in TiDB with higher efficiency. Before TiDB v4.0, you need to use different tools to obtain different information.

The SQL diagnostic system has the following advantages:

- It integrates information from all components of the system as a whole.
- It provides a consistent interface to the upper layer through system tables.
- It provides monitoring summaries and automatic diagnostics.
- You will find it easier to query cluster information.

8.4.1 Overview

The SQL diagnostic system consists of three major parts:

- **Cluster information table:** The SQL diagnostics system introduces cluster information tables that provide a unified way to get the discrete information of each instance. This system fully integrates the cluster topology, hardware information, software information, kernel parameters, monitoring, system information, slow queries, statements, and logs of the entire cluster into the table. So you can query these information using SQL statements.
- **Cluster monitoring table:** The SQL diagnostic system introduces cluster monitoring tables. All of these tables are in `metrics_schema`, and you can query monitoring information using SQL statements. Compared to the visualized monitoring before v4.0, you can use this SQL-based method to perform correlated queries on all the monitoring information of the entire cluster, and compare the results of different time periods to quickly identify performance bottlenecks. Because the TiDB cluster has many monitoring metrics, the SQL diagnostic system also provides monitoring summary tables, so you can find abnormal monitoring items more easily.

Automatic diagnostics: Although you can manually execute SQL statements to query cluster information tables, cluster monitoring tables, and summary tables to locate issues, the automatic diagnostics allows you to quickly locate common issues. The SQL diagnostic system performs automatic diagnostics based on the existing cluster information tables and monitoring tables, and provides relevant diagnostic result tables and diagnostic summary tables.

8.4.2 Cluster information tables

The cluster information tables bring together the information of all instances and instances in a cluster. With these tables, you can query all cluster information using only one SQL statement. The following is a list of cluster information tables:

- From the cluster topology table `information_schema.cluster_info`, you can get the current topology information of the cluster, the version of each instance, the Git Hash corresponding to the version, the starting time of each instance, and the running time of each instance.

- From the cluster configuration table `information_schema.cluster_config`, you can get the configuration of all instances in the cluster. For versions earlier than 4.0, you need to access the HTTP API of each instance one by one to get these configuration information.
- On the cluster hardware table `information_schema.cluster_hardware`, you can quickly query the cluster hardware information.
- On the cluster load table `information_schema.cluster_load`, you can query the load information of different instances and hardware types of the cluster.
- On the kernel parameter table `information_schema.cluster_systeminfo`, you can query the kernel configuration information of different instances in the cluster. Currently, TiDB supports querying the `sysctl` information.
- On the cluster log table `information_schema.cluster_log`, you can query cluster logs. By pushing down query conditions to each instance, the impact of the query on cluster performance is less than that of the `grep` command.

On the system tables earlier than TiDB v4.0, you can only view the current instance. TiDB v4.0 introduces the corresponding cluster tables and you can have a global view of the entire cluster on a single TiDB instance. These tables are currently in `information_schema`, and the query method is the same as other `information_schema` system tables.

8.4.3 Cluster monitoring tables

To dynamically observe and compare cluster conditions in different time periods, the SQL diagnostic system introduces cluster monitoring system tables. All monitoring tables are in `metrics_schema`, and you can query the monitoring information using SQL statements. Using this method, you can perform correlated queries on all monitoring information of the entire cluster and compare the results of different time periods to quickly identify performance bottlenecks.

- `information_schema.metrics_tables`: Because many system tables exist now, you can query meta-information of these monitoring tables on the `information_schema.metrics_tables` table.

Because the TiDB cluster has many monitoring metrics, TiDB provides the following monitoring summary tables in v4.0:

- The monitoring summary table `information_schema.metrics_summary` summarizes all monitoring data to for you to check each monitoring metric with higher efficiency.
- `information_schema.metrics_summary_by_label` also summarizes all monitoring data. Particularly, this table aggregates statistics using different labels of each monitoring metric.

8.4.4 Automatic diagnostics

On the cluster information tables and cluster monitoring tables above, you need to manually execute SQL statements to troubleshoot the cluster. TiDB v4.0 supports the automatic diagnostics. You can use diagnostic-related system tables based on the existing basic information tables, so that the diagnostics is automatically executed. The following are the system tables related to the automatic diagnostics:

- The diagnostic result table `information_schema.inspection_result` displays the diagnostic result of the system. The diagnostics is passively triggered. Executing `select ↵ * from inspection_result` triggers all diagnostic rules to diagnose the system, and the faults or risks in the system are displayed in the results.
- The diagnostic summary table `information_schema.inspection_summary` summarizes the monitoring information of a specific link or module. You can troubleshoot and locate problems based on the context of the entire module or link.

8.5 Top SQL

Warning:

Currently, Top SQL is an experimental feature. It is not recommended that you use it for production environments.

This document describes how to use Top SQL to locate SQL queries that contribute to a high load of a TiDB or TiKV node in a specified time range. For example, you can use Top SQL to locate an analytic query that consumes 99% of the load for a low-load database.

For a specified TiDB or TiKV node, Top SQL provides the following features:

- Show the top 5 types of SQL queries that contribute the most to the load in a specified time range.
- Show information such as CPU usage, requests per second, average latency, and query plan of a particular query, which can be used for potential performance optimization to improve your business.

8.5.1 Enable Top SQL

The Top SQL feature is disabled by default. You can enable the feature for the entire cluster using either of the following methods:

- Method 1: Log in to TiDB Dashboard, click **Top SQL** in the left pane, click the gear button in the upper-right corner of the page, and then enable the Top SQL feature.

- Method 2: Set the value of the TiDB system variable `tidb_enable_top_sql` to `ON`.

Note:

Enabling Top SQL has a slight impact on the performance of your cluster.

8.5.2 Use Top SQL

Once Top SQL is enabled, you can log into TiDB Dashboard, and then click **Top SQL** in the left pane to use it.

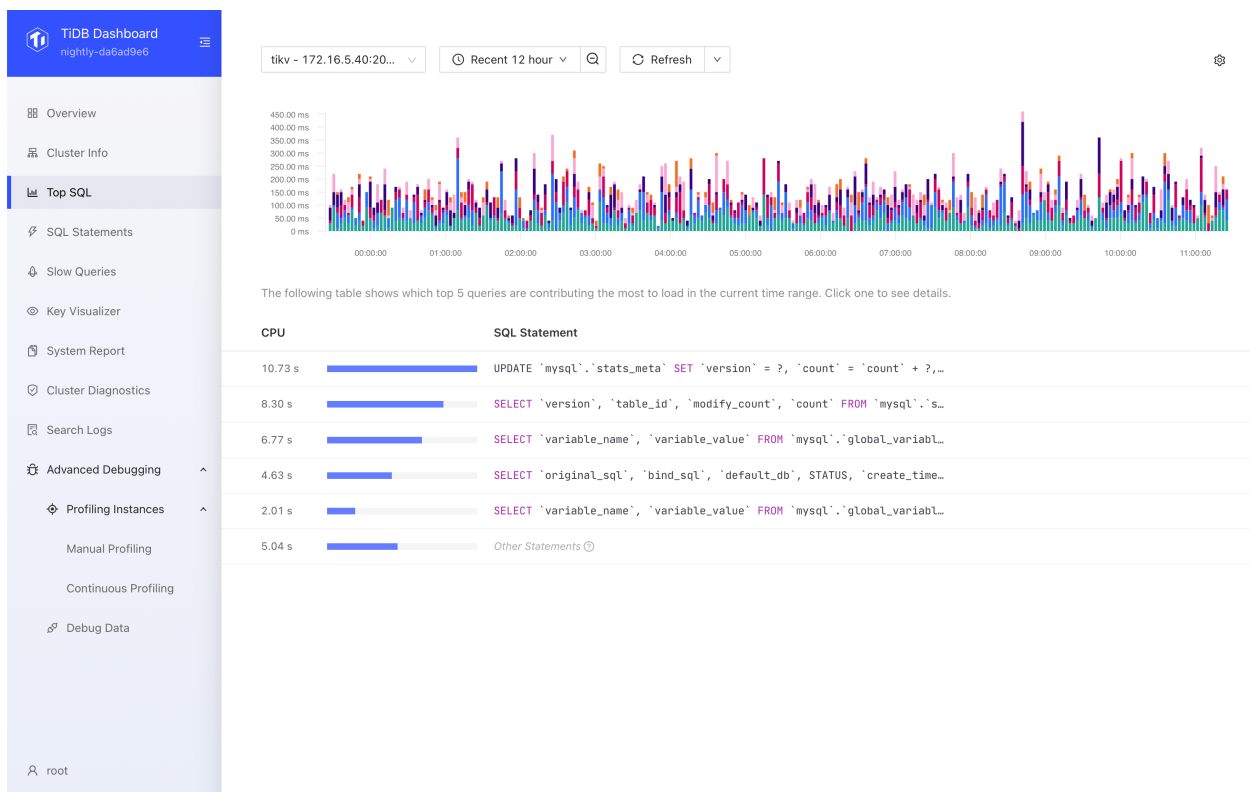

Figure 54: Top SQL

Usage tips:

- You can select the target node and time range in the drop-down lists at the top of the page, or you can select the time range in the chart.
- If the data in the chart is out of date, you can click **Refresh**, or select auto-refresh and specify the auto-refresh interval in the **Refresh** drop-down list.

- The chart shows the top 5 types of queries that contribute the most to the load of the selected node in the selected time range.
- You can select a query type in the list to view the execution plan of that query type on this node and the execution details such as the Call/sec, Scan Rows/sec, Scan Indexes/sec, and Latency/call.

The below are top 5 SQL statements that costs most CPU resources in the current time range. Click one to see details.

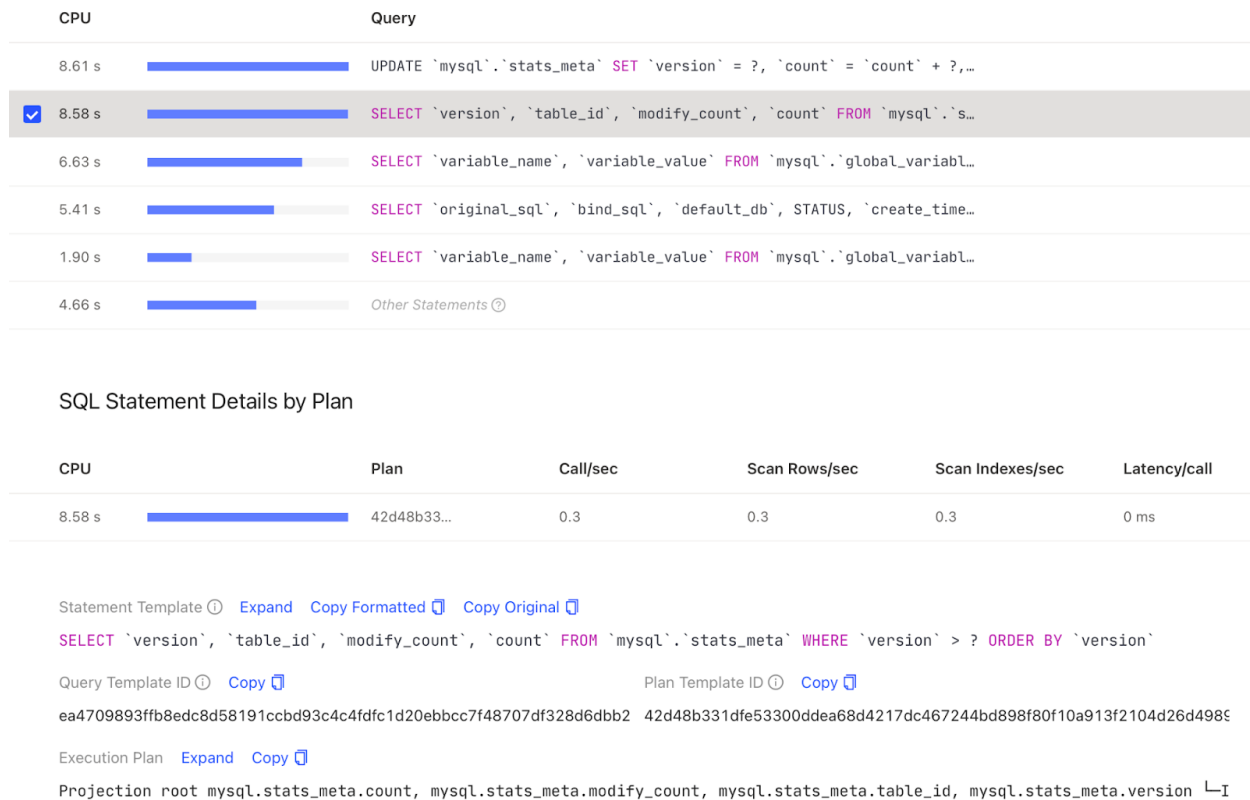

Figure 55: Top SQL Details

8.6 Identify Expensive Queries

TiDB allows you to identify expensive queries during SQL execution, so you can diagnose and improve the performance of SQL execution. Specifically, TiDB prints the information about statements whose execution time exceeds `tidb_expensive_query_time_threshold` (60 seconds by default) or memory usage exceeds `mem-quota-query` (1 GB by default) to the `tidb-server log file` (“tidb.log” by default).

Note:

The expensive query log differs from the **slow query log** in this way: TiDB prints statement information to the expensive query log **as soon as** the statement exceeds the threshold of resource usage (execution time or memory usage); while TiDB prints statement information to the slow query log **after** the statement execution.

8.6.1 Expensive query log example

```
[2020/02/05 15:32:25.096 +08:00] [WARN] [expensivequery.go:167] [
  ↪ expensive_query] [cost_time=60.008338935s] [wait_time=0s] [

  ↪ [process_avg_time=0s] [process_p90_time=0s] [process_max_time=0s] [
  ↪ process_max_addr=10.0.1.9:20160] [wait_avg_time=0.002s] [
  ↪ wait_p90_time=0.002s] [wait_max_time=0.002s] [wait_max_addr
  ↪ =10.0.1.9:20160] [stats=t:pseudo] [conn_id=60026] [user=root] [
  ↪ database=test] [table_ids="[122]"] [txn_start_ts=414420273735139329]
  ↪ [mem_max="1035 Bytes (1.0107421875 KB)"] [sql="insert into t select
  ↪ sleep(1) from t"]
```

8.6.2 Fields description

Basic fields:

- **cost_time**: The execution time of a statement when the log is printed.
- **stats**: The version of statistics used by the tables or indexes involved in a statement. If the value is **pseudo**, it means that there are no available statistics. In this case, you need to analyze the tables or indexes.
- **table_ids**: The IDs of the tables involved in a statement.
- **txn_start_ts**: The start timestamp and the unique ID of a transaction. You can use this value to search for the transaction-related logs.
- **sql**: The sql statement.

Memory usage related fields:

- **mem_max**: Memory usage of a statement when the log is printed. This field has two kinds of units to measure memory usage: byte and other readable and adaptable units (such as MB and GB).

User related fields:

- `user`: The name of the user who executes the statement.
- `conn_id`: The connection ID (session ID). For example, you can use the keyword `con:60026` to search for the log whose session ID is 60026.
- `database`: The database where the statement is executed.

TiKV Coprocessor task related fields:

- `wait_time`: The total waiting time of all Coprocessor requests of a statement in TiKV. Because the Coprocessor of TiKV runs a limited number of threads, requests might queue up when all threads of Coprocessor are working. When a request in the queue takes a long time to process, the waiting time of the subsequent requests increases.
- `request_count`: The number of Coprocessor requests that a statement sends.
- `total_keys`: The number of keys that Coprocessor has scanned.
- `processed_keys`: The number of keys that Coprocessor has processed. Compared with `total_keys`, `processed_keys` does not include the old versions of MVCC. A great difference between `processed_keys` and `total_keys` indicates that many old versions exist.
- `num_cop_tasks`: The number of Coprocessor requests that a statement sends.
- `process_avg_time`: The average execution time of Coprocessor tasks.
- `process_p90_time`: The P90 execution time of Coprocessor tasks.
- `process_max_time`: The maximum execution time of Coprocessor tasks.
- `process_max_addr`: The address of the Coprocessor task with the longest execution time.
- `wait_avg_time`: The average waiting time of Coprocessor tasks.
- `wait_p90_time`: The P90 waiting time of Coprocessor tasks.
- `wait_max_time`: The maximum waiting time of Coprocessor tasks.
- `wait_max_addr`: The address of the Coprocessor task with the longest waiting time.

8.7 Statement Summary Tables

To better handle SQL performance issues, MySQL has provided [statement summary tables](#) in `performance_schema` to monitor SQL with statistics. Among these tables, `events_statements_summary_by_digest` is very useful in locating SQL problems with its abundant fields such as latency, execution times, rows scanned, and full table scans.

Therefore, starting from v4.0.0-rc.1, TiDB provides system tables in `information_schema` ↪ (*not* `performance_schema`) that are similar to `events_statements_summary_by_digest` ↪ in terms of features.

- `statements_summary`
- `statements_summary_history`
- `cluster_statements_summary`
- `cluster_statements_summary_history`
- `statements_summary_evicted`

This document details these tables and introduces how to use them to troubleshoot SQL performance issues.

8.7.1 `statements_summary`

`statements_summary` is a system table in `information_schema`. `statements_summary` groups the SQL statements by the SQL digest and the plan digest, and provides statistics for each SQL category.

The “SQL digest” here means the same as used in slow logs, which is a unique identifier calculated through normalized SQL statements. The normalization process ignores constant, blank characters, and is case insensitive. Therefore, statements with consistent syntaxes have the same digest. For example:

```
SELECT * FROM employee WHERE id IN (1, 2, 3) AND salary BETWEEN 1000 AND
↪ 2000;
select * from EMPLOYEE where ID in (4, 5) and SALARY between 3000 and 4000;
```

After normalization, they are both of the following category:

```
select * from employee where id in (...) and salary between ? and ?;
```

The “plan digest” here refers to the unique identifier calculated through normalized execution plan. The normalization process ignores constants. The same SQL statements might be grouped into different categories because the same statements might have different execution plans. SQL statements of the same category have the same execution plan.

`statements_summary` stores the aggregated results of SQL monitoring metrics. In general, each of the monitoring metrics includes the maximum value and average value. For example, the execution latency metric corresponds to two fields: `AVG_LATENCY` (average latency) and `MAX_LATENCY` (maximum latency).

To make sure that the monitoring metrics are up to date, data in the `statements_summary` ↪ table is periodically cleared, and only recent aggregated results are retained and displayed. The periodical data clearing is controlled by the `tidb_stmt_summary_refresh_interval` ↪ system variable. If you happen to make a query right after the clearing, the data displayed might be very little.

The following is a sample output of querying `statements_summary`:

```
SUMMARY_BEGIN_TIME: 2020-01-02 11:00:00
SUMMARY_END_TIME: 2020-01-02 11:30:00
  STMT_TYPE: Select
  SCHEMA_NAME: test
  DIGEST: 0611
    ↪ cc2fe792f8c146cc97d39b31d9562014cf15f8d41f23a4938ca341f54182
    ↪
  DIGEST_TEXT: select * from employee where id = ?
  TABLE_NAMES: test.employee
```

```

INDEX_NAMES: NULL
SAMPLE_USER: root
EXEC_COUNT: 3
SUM_LATENCY: 1035161
MAX_LATENCY: 399594
MIN_LATENCY: 301353
AVG_LATENCY: 345053
AVG_PARSE_LATENCY: 57000
MAX_PARSE_LATENCY: 57000
AVG_COMPILE_LATENCY: 175458
MAX_COMPILE_LATENCY: 175458
.....
AVG_MEM: 103
MAX_MEM: 103
AVG_DISK: 65535
MAX_DISK: 65535
AVG_AFFECTED_ROWS: 0
FIRST_SEEN: 2020-01-02 11:12:54
LAST_SEEN: 2020-01-02 11:25:24
QUERY_SAMPLE_TEXT: select * from employee where id=3100
PREV_SAMPLE_TEXT:
PLAN_DIGEST:
  ↪ f415b8d52640b535b9b12a9c148a8630d2c6d59e419aad29397842e32e8e5de3
  ↪
PLAN: Point_Get_1  root  1      table:employee, handle:3100

```

Note:

In TiDB, the time unit of fields in statement summary tables is nanosecond (ns), whereas in MySQL the time unit is picosecond (ps).

8.7.2 statements_summary_history

The table schema of `statements_summary_history` is identical to that of `statements_summary`. `statements_summary_history` saves the historical data of a time range. By checking historical data, you can troubleshoot anomalies and compare monitoring metrics of different time ranges.

The fields `SUMMARY_BEGIN_TIME` and `SUMMARY_END_TIME` represent the start time and the end time of the historical time range.

8.7.3 `statements_summary_evicted`

The `tidb_stmt_summary_max_stmt_count` variable controls the maximum number of statements that the `statement_summary` table stores in memory. The `statement_summary` ⇨ table uses the LRU algorithm. Once the number of SQL statements exceeds the `tidb_stmt_summary_max_stmt_count` value, the longest unused record is evicted from the table. The number of evicted SQL statements during each period is recorded in the `statements_summary_evicted` table.

The `statements_summary_evicted` table is updated only when a SQL record is evicted from the `statement_summary` table. The `statements_summary_evicted` only records the period during which the eviction occurs and the number of evicted SQL statements.

8.7.4 The cluster tables for statement summary

The `statements_summary`, `statements_summary_history`, and `statements_summary_evicted` ⇨ tables only show the statement summary of a single TiDB server. To query the data of the entire cluster, you need to query the `cluster_statements_summary` ⇨ , `cluster_statements_summary_history`, or `cluster_statements_summary_evicted` tables.

`cluster_statements_summary` displays the `statements_summary` data of each TiDB server. `cluster_statements_summary_history` displays the `statements_summary_history` ⇨ data of each TiDB server. `cluster_statements_summary_evicted` displays the `statements_summary_evicted` data of each TiDB server. These tables use the `INSTANCE` field to represent the address of the TiDB server. The other fields are the same as those in `statements_summary`.

8.7.5 Parameter configuration

The following system variables are used to control the statement summary:

- `tidb_enable_stmt_summary`: Determines whether to enable the statement summary feature. 1 represents `enable`, and 0 means `disable`. The feature is enabled by default. The statistics in the system table are cleared if this feature is disabled. The statistics are re-calculated next time this feature is enabled. Tests have shown that enabling this feature has little impact on performance.
- `tidb_stmt_summary_refresh_interval`: The interval at which the `statements_summary` ⇨ table is refreshed. The time unit is second (s). The default value is 1800.
- `tidb_stmt_summary_history_size`: The size of each SQL statement category stored in the `statements_summary_history` table, which is also the maximum number of records in the `statement_summary_evicted` table. The default value is 24.
- `tidb_stmt_summary_max_stmt_count`: Limits the number of SQL statements that can be stored in statement summary tables. The default value is 3000. If the limit is exceeded, those SQL statements that recently remain unused are cleared. These cleared SQL statements are recorded in the `statement_summary_evicted` table.

- `tidb_stmt_summary_max_sql_length`: Specifies the longest display length of `DIGEST_TEXT` and `QUERY_SAMPLE_TEXT`. The default value is 4096.
- `tidb_stmt_summary_internal_query`: Determines whether to count the TiDB SQL statements. 1 means to count, and 0 means not to count. The default value is 0.

Note:

When a category of SQL statement needs to be removed because the `tidb_stmt_summary_max_stmt_count` limit is exceeded, TiDB removes the data of that SQL statement category of all time ranges from the `statement_summary_history` table. Therefore, even if the number of SQL statement categories in a certain time range does not reach the limit, the number of SQL statements stored in the `statement_summary_history` table is less than the actual number of SQL statements. If this situation occurs and affects performance, you are recommended to increase the value of `tidb_stmt_summary_max_stmt_count`.

An example of the statement summary configuration is shown as follows:

```
set global tidb_enable_stmt_summary = true;
set global tidb_stmt_summary_refresh_interval = 1800;
set global tidb_stmt_summary_history_size = 24;
```

After the configuration above takes effect, every 30 minutes the `statements_summary` table is cleared. The `statements_summary_history` table stores data generated over the recent 12 hours.

The `statements_summary_evicted` table records the recent 24 periods during which SQL statements are evicted from the statement summary. The `statements_summary_evicted` ↪ table is updated every 30 minutes.

The system variables above have two scopes: global and session. These scopes work differently from other system variables:

- After setting the global variable, your setting applies to the whole cluster immediately.
- After setting the session variable, your setting applies to the current TiDB server immediately. This is useful when you debug on a single TiDB server instance.
- The session variable has a higher read priority. The global variable is read only when no session variable is set.
- If you set the session variable to a blank string, the global variable is re-read.

Note:

The `tidb_stmt_summary_history_size`, `tidb_stmt_summary_max_stmt_count` ↪ , and `tidb_stmt_summary_max_sql_length` configuration items affect memory usage. It is recommended that you adjust these configurations based on your needs, the SQL size, SQL count, and machine configuration. It is not recommended to set them too large values. You can calculate the memory usage using `tidb_stmt_summary_history_size` ↪ * `tidb_stmt_summary_max_stmt_count` * `tidb_stmt_summary_max_sql_length` * 3.

8.7.5.1 Set a proper size for statement summary

After the system has run for a period of time (depending on the system load), you can check the `statement_summary` table to see whether SQL eviction has occurred. For example:

```
select @@global.tidb_stmt_summary_max_stmt_count;
select count(*) from information_schema.statements_summary;
```

```
+-----+
| @@global.tidb_stmt_summary_max_stmt_count |
+-----+
| 3000 |
+-----+
1 row in set (0.001 sec)

+-----+
| count(*) |
+-----+
| 3001 |
+-----+
1 row in set (0.001 sec)
```

You can see that the `statements_summary` table is full of records. Then check the evicted data from the `statements_summary_evicted` table:

```
select * from information_schema.statements_summary_evicted;
```

```
+-----+-----+-----+
| BEGIN_TIME | END_TIME | EVICTED_COUNT |
+-----+-----+-----+
| 2020-01-02 16:30:00 | 2020-01-02 17:00:00 | 59 |
+-----+-----+-----+
```

```
| 2020-01-02 16:00:00 | 2020-01-02 16:30:00 | 45 |
+-----+-----+-----+
2 row in set (0.001 sec)
```

From the preceding result, you can see that a maximum of 59 SQL categories are evicted. In this case, it is recommended that you increase the size of the `statement_summary` table by at least 59 records, which means increasing the size to at least 3059 records.

8.7.6 Limitation

The statement summary tables have the following limitation:

All data of the statement summary tables above will be lost when the TiDB server is restarted. This is because statement summary tables are all memory tables, and the data is cached in memory instead of being persisted on storage.

8.7.7 Troubleshooting examples

This section provides two examples to show how to use the statement summary feature to troubleshoot SQL performance issues.

8.7.7.1 Could high SQL latency be caused by the server end?

In this example, the client shows slow performance with point queries on the `employee` table. You can perform a fuzzy search on SQL texts:

```
SELECT avg_latency, exec_count, query_sample_text
FROM information_schema.statements_summary
WHERE digest_text LIKE 'select * from employee%';
```

1ms and 0.3ms are considered within the normal range of `avg_latency`. Therefore, it can be concluded that the server end is not the cause. You can troubleshoot with the client or the network.

```
+-----+-----+-----+
| avg_latency | exec_count | query_sample_text |
+-----+-----+-----+
| 1042040 | 2 | select * from employee where name='eric' |
| 345053 | 3 | select * from employee where id=3100 |
+-----+-----+-----+
2 rows in set (0.00 sec)
```

8.7.7.2 Which categories of SQL statements consume the longest total time?

If the QPS decrease significantly from 10:00 to 10:30, you can find out the three categories of SQL statements with the longest time consumption from the history table:

```
SELECT sum_latency, avg_latency, exec_count, query_sample_text
FROM information_schema.statements_summary_history
WHERE summary_begin_time='2020-01-02 10:00:00'
ORDER BY sum_latency DESC LIMIT 3;
```

The result shows that the following three categories of SQL statements consume the longest time in total, which need to be optimized with high priority.

```
+--
↪ -----+-----+-----+-----
↪
| sum_latency | avg_latency | exec_count | query_sample_text
↪                                     |
+--
↪ -----+-----+-----+-----
↪
|   7855660 |   1122237 |         7 | select avg(salary) from employee
↪ where company_id=2013 |
|   7241960 |   1448392 |         5 | select * from employee join company
↪ on employee.company_id=company.id |
|   2084081 |   1042040 |         2 | select * from employee where name='
↪ eric' |
+--
↪ -----+-----+-----+-----
↪
3 rows in set (0.00 sec)
```

8.7.8 Fields description

8.7.8.1 statements_summary fields description

The following are descriptions of fields in the `statements_summary` table.

Basic fields:

- `STMT_TYPE`: SQL statement type.
- `SCHEMA_NAME`: The current schema in which SQL statements of this category are executed.
- `DIGEST`: The digest of SQL statements of this category.
- `DIGEST_TEXT`: The normalized SQL statement.
- `QUERY_SAMPLE_TEXT`: The original SQL statements of the SQL category. Only one original statement is taken.
- `TABLE_NAMES`: All tables involved in SQL statements. If there is more than one table, each is separated by a comma.

- **INDEX_NAMES**: All SQL indexes used in SQL statements. If there is more than one index, each is separated by a comma.
- **SAMPLE_USER**: The users who execute SQL statements of this category. Only one user is taken.
- **PLAN_DIGEST**: The digest of the execution plan.
- **PLAN**: The original execution plan. If there are multiple statements, the plan of only one statement is taken.
- **PLAN_CACHE_HITS**: The total number of times that SQL statements of this category hit the plan cache.
- **PLAN_IN_CACHE**: Indicates whether the previous execution of SQL statements of this category hit the plan cache.

Fields related to execution time:

- **SUMMARY_BEGIN_TIME**: The beginning time of the current summary period.
- **SUMMARY_END_TIME**: The ending time of the current summary period.
- **FIRST_SEEN**: The time when SQL statements of this category are seen for the first time.
- **LAST_SEEN**: The time when SQL statements of this category are seen for the last time.

Fields related to TiDB server:

- **EXEC_COUNT**: Total execution times of SQL statements of this category.
- **SUM_ERRORS**: The sum of errors occurred during execution.
- **SUM_WARNINGS**: The sum of warnings occurred during execution.
- **SUM_LATENCY**: The total execution latency of SQL statements of this category.
- **MAX_LATENCY**: The maximum execution latency of SQL statements of this category.
- **MIN_LATENCY**: The minimum execution latency of SQL statements of this category.
- **AVG_LATENCY**: The average execution latency of SQL statements of this category.
- **AVG_PARSE_LATENCY**: The average latency of the parser.
- **MAX_PARSE_LATENCY**: The maximum latency of the parser.
- **AVG_COMPILE_LATENCY**: The average latency of the compiler.
- **MAX_COMPILE_LATENCY**: The maximum latency of the compiler.
- **AVG_MEM**: The average memory (byte) used.
- **MAX_MEM**: The maximum memory (byte) used.
- **AVG_DISK**: The average disk space (byte) used.
- **MAX_DISK**: The maximum disk space (byte) used.

Fields related to TiKV Coprocessor task:

- **SUM_COP_TASK_NUM**: The total number of Coprocessor requests sent.
- **MAX_COP_PROCESS_TIME**: The maximum execution time of Coprocessor tasks.
- **MAX_COP_PROCESS_ADDRESS**: The address of the Coprocessor task with the maximum execution time.

- `MAX_COP_WAIT_TIME`: The maximum waiting time of Coprocessor tasks.
- `MAX_COP_WAIT_ADDRESS`: The address of the Coprocessor task with the maximum waiting time.
- `AVG_PROCESS_TIME`: The average processing time of SQL statements in TiKV.
- `MAX_PROCESS_TIME`: The maximum processing time of SQL statements in TiKV.
- `AVG_WAIT_TIME`: The average waiting time of SQL statements in TiKV.
- `MAX_WAIT_TIME`: The maximum waiting time of SQL statements in TiKV.
- `AVG_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry.
- `MAX_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry.
- `AVG_TOTAL_KEYS`: The average number of keys that Coprocessor has scanned.
- `MAX_TOTAL_KEYS`: The maximum number of keys that Coprocessor has scanned.
- `AVG_PROCESSED_KEYS`: The average number of keys that Coprocessor has processed. Compared with `avg_total_keys`, `avg_processed_keys` does not include the old versions of MVCC. A great difference between `avg_total_keys` and `avg_processed_keys` indicates that many old versions exist.
- `MAX_PROCESSED_KEYS`: The maximum number of keys that Coprocessor has processed.

Transaction-related fields:

- `AVG_PREWRITE_TIME`: The average time of the prewrite phase.
- `MAX_PREWRITE_TIME`: The longest time of the prewrite phase.
- `AVG_COMMIT_TIME`: The average time of the commit phase.
- `MAX_COMMIT_TIME`: The longest time of the commit phase.
- `AVG_GET_COMMIT_TS_TIME`: The average time of getting `commit_ts`.
- `MAX_GET_COMMIT_TS_TIME`: The longest time of getting `commit_ts`.
- `AVG_COMMIT_BACKOFF_TIME`: The average waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `MAX_COMMIT_BACKOFF_TIME`: The maximum waiting time before retry when a SQL statement encounters an error that requires a retry during the commit phase.
- `AVG_RESOLVE_LOCK_TIME`: The average time for resolving lock conflicts occurred between transactions.
- `MAX_RESOLVE_LOCK_TIME`: The longest time for resolving lock conflicts occurred between transactions.
- `AVG_LOCAL_LATCH_WAIT_TIME`: The average waiting time of the local transaction.
- `MAX_LOCAL_LATCH_WAIT_TIME`: The maximum waiting time of the local transaction.
- `AVG_WRITE_KEYS`: The average count of written keys.
- `MAX_WRITE_KEYS`: The maximum count of written keys.
- `AVG_WRITE_SIZE`: The average amount of written data (in byte).
- `MAX_WRITE_SIZE`: The maximum amount of written data (in byte).
- `AVG_PREWRITE_REGIONS`: The average number of Regions involved in the prewrite phase.
- `MAX_PREWRITE_REGIONS`: The maximum number of Regions during the prewrite phase.

- **AVG_TXN_RETRY**: The average number of transaction retries.
- **MAX_TXN_RETRY**: The maximum number of transaction retries.
- **SUM_BACKOFF_TIMES**: The sum of retries when SQL statements of this category encounter errors that require a retry.
- **BACKOFF_TYPES**: All types of errors that require retries and the number of retries for each type. The format of the field is `type:number`. If there is more than one error type, each is separated by a comma, like `txnLock:2,pdRPC:1`.
- **AVG_AFFECTED_ROWS**: The average number of rows affected.
- **PREV_SAMPLE_TEXT**: When the current SQL statement is `COMMIT`, `PREV_SAMPLE_TEXT` is the previous statement to `COMMIT`. In this case, SQL statements are grouped by the digest and `prev_sample_text`. This means that `COMMIT` statements with different `prev_sample_text` are grouped to different rows. When the current SQL statement is not `COMMIT`, the `PREV_SAMPLE_TEXT` field is an empty string.

8.7.8.2 `statements_summary_evicted` fields description

- **BEGIN_TIME**: Records the starting time.
- **END_TIME**: Records the ending time.
- **EVICTED_COUNT**: The number of SQL categories that are evicted during the record period.

8.8 Troubleshoot Hotspot Issues

This document describes how to locate and resolve the problem of read and write hotspots.

As a distributed database, TiDB has a load balancing mechanism to distribute the application loads as evenly as possible to different computing or storage nodes, to make better use of server resources. However, in certain scenarios, some application loads cannot be well distributed, which can affect the performance and form a single point of high load, also known as a hotspot.

TiDB provides a complete solution to troubleshooting, resolving or avoiding hotspots. By balancing load hotspots, overall performance can be improved, including improving QPS and reducing latency.

8.8.1 Common hotspots

This section describes TiDB encoding rules, table hotspots, and index hotspots.

8.8.1.1 TiDB encoding rules

TiDB assigns a `TableID` to each table, an `IndexID` to each index, and a `RowID` to each row. By default, if the table uses an integer primary key, the value of the primary key

is treated as the RowID. Among these IDs, TableID is unique in the entire cluster, while IndexID and RowID are unique in the table. The type of all these IDs is int64.

Each row of data is encoded as a key-value pair according to the following rule:

```
Key: tablePrefix{tableID}_recordPrefixSep{rowID}
Value: [col1, col2, col3, col4]
```

The `tablePrefix` and `recordPrefixSep` of the key are specific string constants, used to distinguish from other data in the KV space.

For Index data, the key-value pair is encoded according to the following rule:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}_indexedColumnsValue
Value: rowID
```

Index data has two types: the unique index and the non-unique index.

- For unique indexes, you can follow the coding rules above.
- For non-unique indexes, a unique key cannot be constructed through this encoding, because the `tablePrefix{tableID}_indexPrefixSep{indexID}` of the same index is the same and the `ColumnsValue` of multiple rows might be the same. The encoding rule for non-unique indexes is as follows:

```
Key: tablePrefix{tableID}_indexPrefixSep{indexID}
    ↪ _indexedColumnsValue_rowID
Value: null
```

8.8.1.2 Table hotspots

According to TiDB coding rules, the data of the same table is in a range prefixed by the beginning of the TableID, and the data is arranged in the order of RowID values. When RowID values are incremented during table inserting, the inserted line can only be appended to the end. The Region will split after it reaches a certain size, and then it still can only be appended to the end of the range. The INSERT operation can only be executed on one Region, forming a hotspot.

The common auto-increment primary key is sequentially increasing. When the primary key is of the integer type, the value of the primary key is used as the RowID by default. At this time, the RowID is sequentially increasing, and a write hotspot of the table forms when a large number of INSERT operations exist.

Meanwhile, the RowID in TiDB is also sequentially auto-incremental by default. When the primary key is not an integer type, you might also encounter the problem of write hotspots.

8.8.1.3 Index hotspots

Index hotspots are similar to table hotspots. Common index hotspots appear in fields that are monotonously increasing in time order, or `INSERT` scenarios with a large number of repeated values.

8.8.2 Identify hotspot issues

Performance problems are not necessarily caused by hotspots and might be caused by multiple factors. Before troubleshooting issues, confirm whether it is related to hotspots.

- To judge write hotspots, open **Hot Write** in the **TiKV-Trouble-Shooting** monitoring panel to check whether the Raftstore CPU metric value of any TiKV node is significantly higher than that of other nodes.
- To judge read hotspots, open **Thread_CPU** in the **TiKV-Details** monitoring panel to check whether the coprocessor CPU metric value of any TiKV node is particularly high.

8.8.2.1 Use TiDB Dashboard to locate hotspot tables

The **Key Visualizer** feature in **TiDB Dashboard** helps users narrow down hotspot troubleshooting scope to the table level. The following is an example of the thermal diagram shown by **Key Visualizer**. The horizontal axis of the graph is time, and the vertical axis are various tables and indexes. The brighter the color, the greater the load. You can switch the read or write flow in the toolbar.

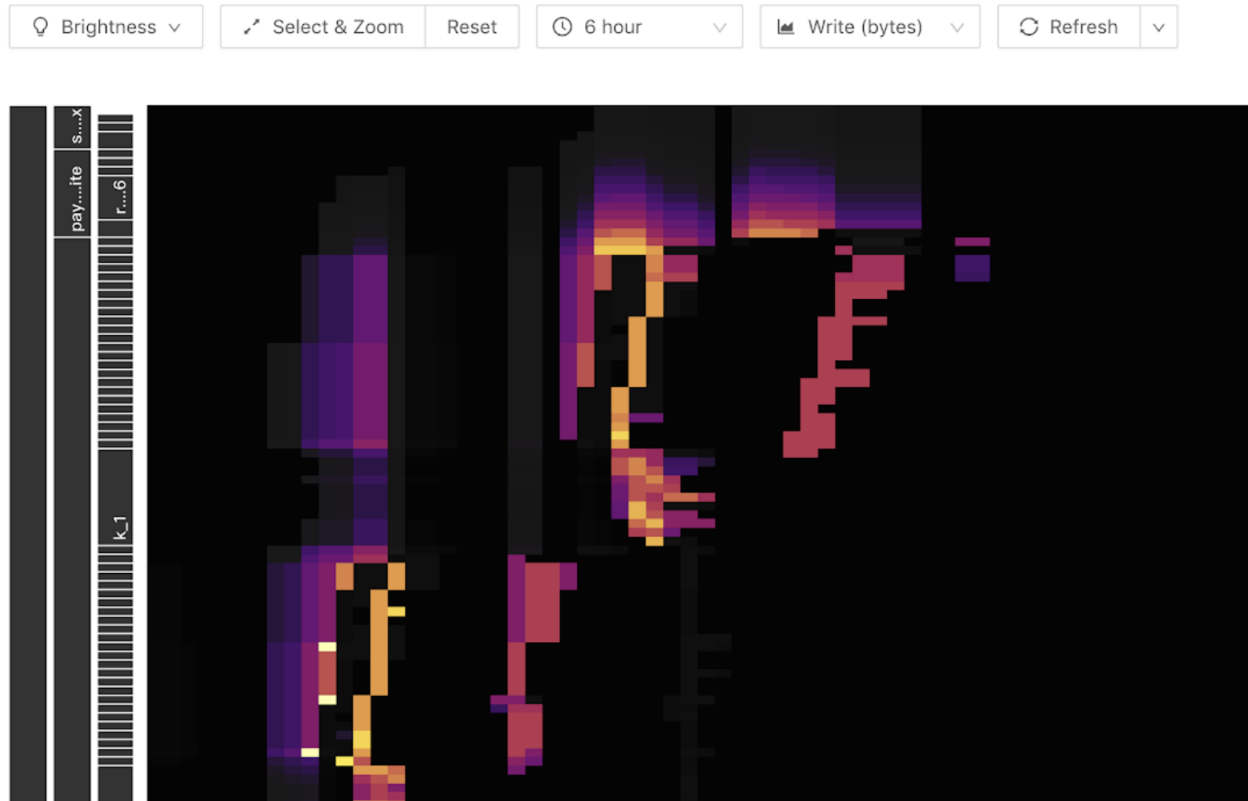

Figure 56: Dashboard Example 1

The following bright diagonal lines (oblique upward or downward) can appear in the write flow graph. Because the write only appears at the end, as the number of table Regions becomes larger, it appears as a ladder. This indicates that a write hotspot shows in this table:

Figure 57: Dashboard Example 2

For read hotspots, a bright horizontal line is generally shown in the thermal diagram. Usually these are caused by small tables with a large number of accesses, shown as follows:

Figure 58: Dashboard Example 3

Hover over the bright block, you can see what table or index has a heavy load. For example:

Figure 59: Dashboard Example 4

8.8.3 Use SHARD_ROW_ID_BITS to process hotspots

For a non-integer primary key or a table without a primary key or a joint primary key, TiDB uses an implicit auto-increment RowID. When a large number of `INSERT` operations exist, the data is written into a single Region, resulting in a write hotspot.

By setting `SHARD_ROW_ID_BITS`, row IDs are scattered and written into multiple Regions, which can alleviate the write hotspot issue.

```
SHARD_ROW_ID_BITS = 4 # Represents 16 shards.
SHARD_ROW_ID_BITS = 6 # Represents 64 shards.
SHARD_ROW_ID_BITS = 0 # Represents the default 1 shard.
```

Statement example:

```
CREATE TABLE: CREATE TABLE t (c int) SHARD_ROW_ID_BITS = 4;  
ALTER TABLE: ALTER TABLE t SHARD_ROW_ID_BITS = 4;
```

The value of `SHARD_ROW_ID_BITS` can be dynamically modified. The modified value only takes effect for newly written data.

For the table with a primary key of the `CLUSTERED` type, TiDB uses the primary key of the table as the RowID. At this time, the `SHARD_ROW_ID_BITS` option cannot be used because it changes the RowID generation rules. For the table with the primary key of the `NONCLUSTERED` type, TiDB uses an automatically allocated 64-bit integer as the RowID. In this case, you can use the `SHARD_ROW_ID_BITS` feature. For more details about the primary key of the `CLUSTERED` type, refer to [clustered index](#).

The following two load diagrams shows the case where two tables without primary keys use `SHARD_ROW_ID_BITS` to scatter hotspots. The first diagram shows the situation before scattering hotspots, while the second one shows the situation after scattering hotspots.

Figure 60: Dashboard Example 5

Figure 61: Dashboard Example 6

As shown in the load diagrams above, before setting `SHARD_ROW_ID_BITS`, load hotspots are concentrated on a single Region. After setting `SHARD_ROW_ID_BITS`, load hotspots become scattered.

8.8.4 Handle auto-increment primary key hotspot tables using `AUTO_RANDOM`

To resolve the write hotspots brought by auto-increment primary keys, use `AUTO_RANDOM` to handle hotspot tables that have auto-increment primary keys.

If this feature is enabled, TiDB generates randomly distributed and non-repeated (before the space is used up) primary keys to achieve the purpose of scattering write hotspots.

Note that the primary keys generated by TiDB are no longer auto-increment primary keys and you can use `LAST_INSERT_ID()` to obtain the primary key value assigned last time.

To use this feature, modify `AUTO_INCREMENT` to `AUTO_RANDOM` in the `CREATE TABLE` statement. This feature is suitable for non-application scenarios where the primary keys only need to guarantee uniqueness.

For example:

```
CREATE TABLE t (a BIGINT PRIMARY KEY AUTO_RANDOM, b varchar(255));
INSERT INTO t (b) VALUES ("foo");
SELECT * FROM t;
```

```
+-----+----+
| a      | b |
+-----+----+
| 1073741825 | b |
+-----+----+
```

```
SELECT LAST_INSERT_ID();
```

```
+-----+----+
| LAST_INSERT_ID() |
+-----+----+
| 1073741825      |
+-----+----+
```

The following two load diagrams shows the situations both before and after modifying `AUTO_INCREMENT` to `AUTO_RANDOM` to scatter hotspots. The first one uses `AUTO_INCREMENT`, while the second one uses `AUTO_RANDOM`.

Figure 62: Dashboard Example 7

Figure 63: Dashboard Example 8

As shown in the load diagrams above, using `AUTO_RANDOM` to replace `AUTO_INCREMENT` can well scatter hotspots.

For more details, see [AUTO_RANDOM](#).

8.8.5 Optimization of small table hotspots

The Coprocessor Cache feature of TiDB supports pushing down computing result caches. After this feature is enabled, TiDB caches the computing results that will be pushed down to TiKV. This feature works well for read hotspots of small tables.

For more details, see [Coprocessor Cache](#).

8.9 Troubleshoot Increased Read and Write Latency

This document introduces the possible causes of read and write latency and jitters, and how to troubleshoot these issues.

8.9.1 Common causes

8.9.1.1 Incorrect TiDB execution plan

The execution plan of queries is unstable and might select the incorrect index, which causes higher latency.

8.9.1.1.1 Phenomenon

- If the query execution plan is output in the slow log, you can directly view the plan. Execute the `select tidb_decode_plan('xxx...')` statement to parse the detailed execution plan.
- The number of scanned keys in the monitor abnormally increases; in the slow log, the number of `Scan Keys` are large.
- The SQL execution duration in TiDB is greatly different than that in other databases such as MySQL. You can compare the execution plan of other databases (for example, whether `Join Order` is different).

8.9.1.1.2 Possible reason

The statistics is inaccurate.

8.9.1.1.3 Troubleshooting methods

- Update the statistical information
 - Execute `analyze table` manually and execute `analyze` periodically with the `crontab` command to keep the statistics accurate.
 - Execute `auto analyze` automatically. Lower the threshold value of `analyze` \leftrightarrow `ratio`, increase the frequency of information collection, and set the start and end time of the execution. See the following examples:
 - * `set global tidb_auto_analyze_ratio=0.2;`
 - * `set global tidb_auto_analyze_start_time='00:00 +0800';`
 - * `set global tidb_auto_analyze_end_time='06:00 +0800';`
- Bind the execution plan
 - Modify the application SQL statements and execute `use index` to consistently use the index of the column.
 - In 3.0 versions, you do not need to modify the application SQL statements. Use `create global binding` to create the binding SQL statement of `force index`.
 - In 4.0 versions, [SQL Plan Management](#) is supported, which avoids the performance decrease caused by unstable execution plans.

8.9.1.2 PD anomalies

8.9.1.2.1 Phenomenon

There is an abnormal increase of the `wait duration` metric for the PD TSO. This metric represents the duration of waiting for PD to return requests.

8.9.1.2.2 Possible reasons

- Disk issue. The disk where the PD node is located has full I/O load. Investigate whether PD is deployed with other components with high I/O demand and the health of the disk. You can verify the cause by viewing the monitor metrics in **Grafana** -> **disk performance** -> **latency/load**. You can also use the FIO tool to run a check on the disk if necessary.
- Network issues between PD peers. The PD log shows `lost the TCP streaming` \leftrightarrow `connection`. You need to check whether there is a problem with the network between PD nodes and verify the cause by viewing `round trip` in the monitor **Grafana** -> **PD** -> **etcd**.
- High server load. The log shows `server is likely overloaded`.
- PD cannot elect a Leader: The PD log shows `lease is not expired`. [This issue](#) has been fixed in v3.0.x and v2.1.19.

- The leader election is slow. The Region loading duration is long. You can check this issue by running `grep "regions cost"` in the PD log. If the result is in seconds, such as `load 460927 regions cost 11.77099s`, it means the Region loading is slow. You can enable the `region storage` feature in v3.0 by setting `use-region-storage` to `true`, which significantly reduce the Region loading duration.
- The network issue between TiDB and PD. Check whether the network from TiDB to PD Leader is running normally by accessing the monitor **Grafana** -> **black-box_exporter** -> **ping latency**.
- PD reports the **FATAL** error, and the log shows `range failed to find revision` \leftrightarrow `pair`. This issue has been fixed in v3.0.8 ([#2040](#)).
- When the `/api/v1/regions` interface is used, too many Regions might cause PD OOM. This issue has been fixed in v3.0.8 ([#1986](#)).
- PD OOM during the rolling upgrade. The size of gRPC messages is not limited, and the monitor shows that `TCP InSegs` is relatively large. This issue has been fixed in v3.0.6 ([#1952](#)).
- PD panics. [Report a bug](#).
- Other causes. Get goroutine by running `curl http://127.0.0.1:2379/debug/pprof` \leftrightarrow `/goroutine?debug=2` and [report a bug](#).

8.9.1.3 TiKV anomalies

8.9.1.3.1 Phenomenon

The `KV Cmd Duration` metric in the monitor increases abnormally. This metric represents the duration between the time that TiDB sends a request to TiKV and the time that TiDB receives the response.

8.9.1.3.2 Possible reasons

- Check the `gRPC duration` metric. This metric represents the total duration of a gRPC request in TiKV. You can find out the potential network issue by comparing `gRPC` \leftrightarrow `duration` of TiKV and `KV duration` of TiDB. For example, the gRPC duration is short but the KV duration of TiDB is long, which indicates that the network latency between TiDB and TiKV might be high, or that the NIC bandwidth between TiDB and TiKV is fully occupied.
- Re-election because TiKV is restarted.
 - After TiKV panics, it is pulled up by `systemd` and runs normally. You can check whether panic has occurred by viewing the TiKV log. Because this issue is unexpected, [report a bug](#) if it happens.

- TiKV is stopped or killed by a third party and then pulled up by `systemd`. Check the cause by viewing `dmesg` and the TiKV log.
 - TiKV is OOM, which causes restart.
 - TiKV is hung because of dynamically adjusting THP (Transparent Hugepage).
- Check monitor: TiKV RocksDB encounters write stall and thus results in re-election. You can check if the monitor **Grafana -> TiKV-details -> errors** shows `server ↪ is busy`.
 - Re-election because of network isolation.
 - If the `block-cache` configuration is too large, it might cause TiKV OOM. To verify the cause of the problem, check the `block cache size` of RocksDB by selecting the corresponding instance in the monitor **Grafana -> TiKV-details**. Meanwhile, check whether the `[storage.block-cache] capacity = # "1GB"` parameter is set properly. By default, TiKV's `block-cache` is set to 45% of the total memory of the machine. You need to explicitly specify this parameter when you deploy TiKV in the container, because TiKV obtains the memory of the physical machine, which might exceed the memory limit of the container.
 - Coprocessor receives many large queries and returns a large volume of data. gRPC fails to send data as quickly as the coprocessor returns data, which results in OOM. To verify the cause, you can check whether `response size` exceeds the `network outbound traffic` by viewing the monitor **Grafana -> TiKV-details -> coprocessor overview**.

8.9.1.4 Bottleneck of a single TiKV thread

There are some single threads in TiKV that might become the bottleneck.

- Too many Regions in a TiKV instance causes a single gRPC thread to be the bottleneck (Check the **Grafana -> TiKV-details -> Thread CPU/gRPC CPU Per Thread** metric). In v3.x or later versions, you can enable `Hibernate Region` to resolve the issue.
- For versions earlier than v3.0, when the `raftstore` thread or the `apply` thread becomes the bottleneck (**Grafana -> TiKV-details -> Thread CPU/raft store CPU** and **Async apply CPU** metrics exceed 80%), you can scale out TiKV (v2.x) instances or upgrade to v3.x with multi-threading.

8.9.1.5 CPU load increases

8.9.1.5.1 Phenomenon

The usage of CPU resources becomes the bottleneck.

8.9.1.5.2 Possible reasons

- Hotspot issue
- High overall load. Check the slow queries and expensive queries of TiDB. Optimize the executing queries by adding indexes or executing queries in batches. Another solution is to scale out the cluster.

8.9.2 Other causes

8.9.2.1 Cluster maintenance

Most of each online cluster has three or five nodes. If the machine to be maintained has the PD component, you need to determine whether the node is the leader or the follower. Disabling a follower has no impact on the cluster operation. Before disabling a leader, you need to switch the leadership. During the leadership change, performance jitter of about 3 seconds will occur.

8.9.2.2 Minority of replicas are offline

By default, each TiDB cluster has three replicas, so each Region has three replicas in the cluster. These Regions elect the leader and replicate data through the Raft protocol. The Raft protocol ensures that TiDB can still provide services without data loss even when the nodes (that are fewer than half of replicas) fail or are isolated. For the cluster with three replicas, the failure of one node might cause performance jitter but the usability and correctness in theory are not affected.

8.9.2.3 New indexes

Creating indexes consumes a huge amount of resources when TiDB scans tables and backfills indexes. Index creation might even conflict with the frequently updated fields, which affects the application. Creating indexes on a large table often takes a long time, so you must try to balance the index creation time and the cluster performance (for example, creating indexes at the off-peak time).

Parameter adjustment:

Currently, you can use `tidb_ddl_reorg_worker_cnt` and `tidb_ddl_reorg_batch_size` \leftrightarrow to dynamically adjust the speed of index creation. Usually, the smaller the values, the smaller the impact on the system, with longer execution time though.

In general cases, you can first keep their default values (4 and 256), observe the resource usage and response speed of the cluster, and then increase the value of `tidb_ddl_reorg_worker_cnt` to increase the concurrency. If no obvious jitter is observed in the monitor, increase the value of `tidb_ddl_reorg_batch_size`. If the columns involved in the index creation are frequently updated, the many resulting conflicts will cause the index creation to fail and be retried.

In addition, you can also set the value of `tidb_ddl_reorg_priority` to `PRIORITY_HIGH` to prioritize the index creation and speed up the process. But in the general OLTP system, it is recommended to keep its default value.

8.9.2.4 High GC pressure

The transaction of TiDB adopts the Multi-Version Concurrency Control (MVCC) mechanism. When the newly written data overwrites the old data, the old data is not replaced, and both versions of data are stored. Timestamps are used to mark different versions. The task of GC is to clear the obsolete data.

- In the phase of Resolve Locks, a large amount of `scan_lock` requests are created in TiKV, which can be observed in the gRPC-related metrics. These `scan_lock` requests call all Regions.
- In the phase of Delete Ranges, a few (or no) `unsafe_destroy_range` requests are sent to TiKV, which can be observed in the gRPC-related metrics and the **GC tasks** panel.
- In the phase of Do GC, each TiKV by default scans the leader Regions on the machine and performs GC to each leader, which can be observed in the **GC tasks** panel.

8.10 Use `PLAN REPLAYER` to Save and Restore the On-Site Information of a Cluster

When you locate and troubleshoot the issues of a TiDB cluster, you often need to provide information on the system and the execution plan. To help you get the information and troubleshoot cluster issues in a more convenient and efficient way, the `PLAN REPLAYER` \leftrightarrow command is introduced in TiDB v5.3.0. This command enables you to easily save and restore the on-site information of a cluster, improves the efficiency of troubleshooting, and helps you more easily archive the issue for management.

The features of `PLAN REPLAYER` are as follows:

- Exports the information of a TiDB cluster at an on-site troubleshooting to a ZIP-formatted file for storage.
- Imports into a cluster the ZIP-formatted file exported from another TiDB cluster. This file contains the information of the latter TiDB cluster at an on-site troubleshooting.

8.10.1 Use `PLAN REPLAYER` to export cluster information

You can use `PLAN REPLAYER` to save the on-site information of a TiDB cluster. The export interface is as follows:

```
PLAN REPLAYER DUMP EXPLAIN [ANALYZE] sql-statement;
```

Based on `sql-statement`, TiDB sorts out and exports the following on-site information:

- TiDB version
- TiDB configuration
- TiDB session variables
- TiDB SQL bindings
- The table schema in `sql-statement`
- The statistics of the table in `sql-statement`
- The result of `EXPLAIN [ANALYZE] sql-statement`

Note:

PLAN REPLAYER DOES NOT export any table data.

8.10.1.1 Examples of exporting cluster information

```
use test;
create table t(a int, b int);
insert into t values(1,1), (2, 2), (3, 3);
analyze table t;

plan replayer dump explain select * from t;
```

PLAN REPLAYER DUMP packages the table information above into a ZIP file and returns the file identifier as the execution result. This file is a one-time file. After the file is downloaded, TiDB will delete it.

Note:

The ZIP file is stored in a TiDB cluster for at most one hour. After one hour, TiDB will delete it.

```
MySQL [test]> plan replayer dump explain select * from t;
+-----+-----+
| Dump_link |
+-----+-----+
| replayer_single_J0Gvpu4t7dssySqJfTtS4A==_1635750890568691080.zip |
+-----+-----+
1 row in set (0.015 sec)
```

Because the file cannot be downloaded on MySQL Client, you need to use the TiDB HTTP interface and the file identifier to download the file:

```
http://${tidb-server-ip}:${tidb-server-status-port}/plan_replayer/dump/${
↳ file_token}
```

`${tidb-server-ip}:${tidb-server-status-port}` is the address of any TiDB server in the cluster. For example:

```
curl http://127.0.0.1:10080/plan_replayer/dump/
↳ replayer_single_J0Gvpu4t7dssySqJfTtS4A==_1635750890568691080.zip >
↳ plan_replayer.zip
```

8.10.2 Use PLAN REPLAYER to import cluster information

Warning:

When you import the on-site information of a TiDB cluster to another cluster, the TiDB session variables, SQL bindings, table schemas and statistics of the latter cluster are modified.

With an existing ZIP file exported using PLAN REPLAYER, you can use the PLAN REPLAYER import interface to restore the on-site information of a cluster to any other TiDB cluster. The syntax is as follows:

```
PLAN REPLAYER LOAD 'file_name';
```

In the statement above, `file_name` is the name of the ZIP file to be exported.

For example:

```
PLAN REPLAYER LOAD 'plan_replayer.zip';
```

After the cluster information is imported, the TiDB cluster is loaded with the required table schema, statistics and other information that affects the construction of the execution plan. You can view the execution plan and verify statistics in the following way:

```
mysql> desc t;
+-----+-----+-----+-----+-----+-----+
| Field | Type  | Null | Key  | Default | Extra |
+-----+-----+-----+-----+-----+-----+
| a     | int(11) | YES  |      | NULL    |       |
| b     | int(11) | YES  |      | NULL    |       |
+-----+-----+-----+-----+-----+
2 rows in set (0.01 sec)
```

```
mysql> explain select * from t where a = 1 or b =1;
+---+
| id          | estRows | task      | access object | operator info |
+---+
| TableReader_7 | 0.01    | root     |               | data:Selection_6 |
| -Selection_6 | 0.01    | cop[tikv] |               | or(eq(test.t.a, 1), eq(test.t.b, 1)) |
| -TableFullScan_5 | 6.00    | cop[tikv] | table:t       | keep order:false, stats:pseudo |
+---+
3 rows in set (0.00 sec)

mysql> show stats_meta;
+---+
| Db_name | Table_name | Partition_name | Update_time | Modify_count | Row_count |
+---+
| test    | t          |                | 2022-08-26 15:52:07 | 3            | 6         |
+---+
1 row in set (0.04 sec)
```

After the scene is loaded and restored, you can diagnose and improve the execution plan for the cluster.

8.11 TiDB Cluster Troubleshooting Guide

You can use this guide to help you diagnose and solve basic problems while using TiDB. If your problem is not resolved, please collect the following information and [create an issue](#):

- The exact error message and the operations while the error occurs

- The state of all the components
- The `error/fatal/panic` information in the log of the component that reports the error
- The configuration and deployment topology
- The TiDB component related issue in `dmesg`

For other information, see [Frequently Asked Questions \(FAQ\)](#).

8.11.1 Cannot connect to the database

1. Make sure all the services are started, including `tidb-server`, `pd-server`, and `tikv-server`.
2. Use the `ps` command to check if all the processes are running.
 - If a certain process is not running, see the following corresponding sections to diagnose and solve the issue.
 - If all the processes are running, check the `tidb-server` log to see if the following messages are displayed:
 - InformationSchema is out of date: This message is displayed if the `tikv-server` cannot be connected. Check the state and log of `pd-server` and `tikv-server`.
 - panic: This message is displayed if there is an issue with the program. Please provide the detailed panic log and [create an issue](#).
3. If the data is cleared and the services are re-deployed, make sure that:
 - All the data in `tikv-server` and `pd-server` are cleared. The specific data is stored in `tikv-server` and the metadata is stored in `pd-server`. If only one of the two servers is cleared, the data will be inconsistent.
 - After the data in `pd-server` and `tikv-server` are cleared and the `pd-server` and `tikv-server` are restarted, the `tidb-server` must be restarted too. The cluster ID is randomly allocated when the `pd-server` is initialized. So when the cluster is re-deployed, the cluster ID changes and you need to restart the `tidb-server` to get the new cluster ID.

8.11.2 Cannot start tidb-server

See the following for the situations when the `tidb-server` cannot be started:

- Error in the startup parameters.
See the [TiDB configuration and options](#).

- The port is occupied.
Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tidb-server` is not occupied.
- Cannot connect to `pd-server`.
 - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
 - If there is no issue with the network, check the state and log of the `pd-server` process.

8.11.3 Cannot start `tikv-server`

See the following for the situations when the `tikv-server` cannot be started:

- Error in the startup parameters: See the [TiKV configuration and options](#).
- The port is occupied: Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `tikv-server` is not occupied.
- Cannot connect to `pd-server`.
 - Check if the network between TiDB and PD is running smoothly, including whether the network can be pinged or if there is any issue with the Firewall configuration.
 - If there is no issue with the network, check the state and log of the `pd-server` process.
- The file is occupied.
Do not open two TiKV files on one database file directory.

8.11.4 Cannot start `pd-server`

See the following for the situations when the `pd-server` cannot be started:

- Error in the startup parameters.
See the [PD configuration and options](#).
- The port is occupied.
Use the `lsof -i:port` command to show all the networking related to a given port and make sure the port to start the `pd-server` is not occupied.

8.11.5 The TiDB/TiKV/PD process aborts unexpectedly

- Is the process started on the foreground? The process might exit because the client aborts.
- Is `nohup+&` run in the command line? This might cause the process to abort because it receives the hup signal. It is recommended to write and run the startup command in a script.

8.11.6 TiDB panic

Please provide the panic log and [create an issue](#).

8.11.7 The connection is rejected

Make sure the network parameters of the operating system are correct, including but not limited to:

- The port in the connection string is consistent with the `tidb-server` starting port.
- The firewall is configured correctly.

8.11.8 Open too many files

Before starting the process, make sure the result of `ulimit -n` is large enough. It is recommended to set the value to `unlimited` or larger than 1000000.

8.11.9 Database access times out and the system load is too high

First, check the [slow query log](#) and see if it is because of some inappropriate SQL statement.

If you failed to solve the problem, provide the following information:

- The deployment topology
 - How many `tidb-server`/`pd-server`/`tikv-server` instances are deployed?
 - How are these instances distributed in the machines?
- The hardware configuration of the machines where these instances are deployed:
 - The number of CPU cores
 - The size of the memory
 - The type of the disk (SSD or Hard Drive Disk)
 - Are they physical machines or virtual machines?

- Are there other services besides the TiDB cluster?
- Are the `pd-servers` and `tikv-servers` deployed separately?
- What is the current operation?
- Check the CPU thread name using the `top -H` command.
- Are there any exceptions in the network or IO monitoring data recently?

8.12 Troubleshoot High Disk I/O Usage in TiDB

This document introduces how to locate and address the issue of high disk I/O usage in TiDB.

8.12.1 Check the current I/O metrics

If TiDB's response slows down after you have troubleshot the CPU bottleneck and the bottleneck caused by transaction conflicts, you need to check I/O metrics to help determine the current system bottleneck.

8.12.1.1 Locate I/O issues from monitor

The quickest way to locate I/O issues is to view the overall I/O status from the monitor, such as the Grafana dashboard which is deployed by default by TiUP. The dashboard panels related to I/O include **Overview**, **Node_exporter**, and **Disk-Performance**.

8.12.1.1.1 The first type of monitoring panels

In **Overview** > **System Info** > **IO Util**, you can see the I/O status of each machine in the cluster. This metric is similar to `util` in the Linux `iostat` monitor. The higher percentage represents higher disk I/O usage:

- If there is only one machine with high I/O usage in the monitor, currently there might be read and write hotspots on this machine.
- If the I/O usage of most machines in the monitor is high, the cluster now has high I/O loads.

For the first situation above (only one machine with high I/O usage), you can further observe I/O metrics from the **Disk-Performance Dashboard** such as **Disk Latency** and **Disk Load** to determine whether any anomaly exists. If necessary, use the `fiio` tool to check the disk.

8.12.1.1.2 The second type of monitoring panels

The main storage component of the TiDB cluster is TiKV. One TiKV instance contains two RocksDB instances: one for storing Raft logs, located in `data/raft`, and the other for storing real data, located in `data/db`.

In **TiKV-Details > Raft IO**, you can see the metrics related to disk writes of these two instances:

- **Append log duration:** This metric indicates the response time of writes into RockDB that stores Raft logs. The .99 response time should be within 50 ms.
- **Apply log duration:** This metric indicates the response time of writes into RockDB that stores real data. The .99 response should be within 100 ms.

These two metrics also have the **.. per server** monitoring panel to help you view the write hotspots.

8.12.1.1.3 The third type of monitoring panels

In **TiKV-Details > Storage**, there are monitoring metrics related to storage:

- **Storage command total:** Indicates the number of different commands received.
- **Storage async write duration:** Includes monitoring metrics such as `disk sync` \leftrightarrow `duration`, which might be related to Raft I/O. If you encounter an abnormal situation, check the working statuses of related components by checking logs.

8.12.1.1.4 Other panels

In addition, some other panel metrics might help you determine whether the bottleneck is I/O, and you can try to set some parameters. By checking the `prewrite/commit/raw-put` (for raw key-value clusters only) of TiKV gRPC duration, you can determine that the bottleneck is indeed the slow TiKV write. The common situations of slow TiKV writes are as follows:

- **append log is slow.** TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which is often due to slow disk writes. You can check the value of `WAL Sync Duration max` in **RocksDB-raft** to determine the cause of slow `append` \leftrightarrow `log`. Otherwise, you might need to report a bug.
- **The raftstore thread is busy.** In TiKV Grafana, `Raft Propose/propose wait` \leftrightarrow `duration` is significantly higher than `append log duration`. Check the following aspects for troubleshooting:
 - Whether the value of `store-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1,5]` and not too large.
 - Whether the CPU resource of the machine is insufficient.

- `append log` is slow. TiKV Grafana's `Raft I/O` and `append log duration` metrics are relatively high, which might usually occur along with relatively high `Raft Propose` \leftrightarrow `/apply wait duration`. The possible causes are as follows:
 - The value of `apply-pool-size` of `[raftstore]` is too small. It is recommended to set this value between `[1, 5]` and not too large. The value of `Thread CPU` \leftrightarrow `/apply cpu` is also relatively high.
 - Insufficient CPU resources on the machine.
 - Write hotspot issue of a single Region (Currently, the solution to this issue is still on the way). The CPU usage of a single `apply` thread is high (which can be viewed by modifying the Grafana expression, appended with `by (instance, name)`).
 - Slow write into RocksDB, and `RocksDB kv/max write duration` is high. A single Raft log might contain multiple key-value pairs (kv). 128 kvs are written to RocksDB in a batch, so one `apply log` might involve multiple RocksDB writes.
 - For other causes, report them as bugs.
- `raft commit log` is slow. In TiKV Grafana, `Raft I/O` and `commit log duration` (only available in Grafana 4.x) metrics are relatively high. Each Region corresponds to an independent Raft group. Raft has a flow control mechanism similar to the sliding window mechanism of TCP. To control the size of a sliding window, adjust the `[raftstore] raft-max-inflight-msgs` parameter. If there is a write hotspot and `commit log duration` is high, you can properly set this parameter to a larger value, such as 1024.

8.12.1.2 Locate I/O issues from log

- If the client reports errors such as `server is busy` or especially `raftstore is busy`, the errors might be related to I/O issues.

You can check the monitoring panel (**Grafana -> TiKV -> errors**) to confirm the specific cause of the `busy` error. `server is busy` is TiKV's flow control mechanism. In this way, TiKV informs `tidb/ti-client` that the current pressure of TiKV is too high, and the client should try later.

- `Write stall` appears in TiKV RocksDB logs.

It might be that too many level-0 SST files cause the write stall. To address the issue, you can add the `[rocksdb] max-sub-compactions = 2 (or 3)` parameter to speed up the compaction of level-0 SST files. This parameter means that the compaction tasks of level-0 to level-1 can be divided into `max-sub-compactions` subtasks for multi-threaded concurrent execution.

If the disk's I/O capability fails to keep up with the write, it is recommended to scale up the disk. If the throughput of the disk reaches the upper limit (for example, the throughput of SATA SSD is much lower than that of NVMe SSD), which results in write stall, but the CPU resource is relatively sufficient, you can try to use a compression

algorithm of higher compression ratio to relieve the pressure on the disk, that is, use CPU resources to make up for disk resources.

For example, when the pressure of default `cf compaction` is relatively high, you can change the parameter `[rocksdb.defaultcf] compression-per-level = ["no", ↵ "no", "lz4", "lz4", "lz4", "zstd", "zstd"]` to `compression-per-level ↵ = ["no", "no", "zstd", "zstd", "zstd", "zstd", "zstd"]`.

8.12.1.3 I/O issues found in alerts

The cluster deployment tool (TiUP) deploys the cluster with alert components by default that have built-in alert items and thresholds. The following alert items are related to I/O:

- `TiKV_write_stall`
- `TiKV_raft_log_lag`
- `TiKV_async_request_snapshot_duration_seconds`
- `TiKV_async_request_write_duration_seconds`
- `TiKV_raft_append_log_duration_secs`
- `TiKV_raft_apply_log_duration_secs`

8.12.2 Handle I/O issues

- When an I/O hotspot issue is confirmed to occur, you need to refer to Handle TiDB Hotspot Issues to eliminate the I/O hotspots.
- When it is confirmed that the overall I/O performance has become the bottleneck, and you can determine that the I/O performance will keep falling behind in the application side, then you can take advantage of the distributed database's capability of scaling and increase the number of TiKV nodes to have greater overall I/O throughput.
- Adjust some of the parameters as described above, and use computing/memory resources to make up for disk storage resources.

8.13 Troubleshoot Lock Conflicts

TiDB supports complete distributed transactions. Starting from v3.0, TiDB provides optimistic transaction mode and pessimistic transaction mode. This document describes how to use Lock View to troubleshoot lock issues and how to deal with common lock conflict issues in optimistic and pessimistic transactions.

8.13.1 Use Lock View to troubleshoot lock issues

Since v5.1, TiDB supports the Lock View feature. This feature has several system tables built in `information_schema` that provide more information about the lock conflicts and lock waitings.

Note:

Currently, the Lock View feature provides conflict and waiting information for pessimistic locks only.

For the detailed introduction of these tables, see the following documents:

- **TIDB_TRX** and **CLUSTER_TIDB_TRX**: Provides information of all running transactions on the current TiDB node or in the entire cluster, including whether the transaction is in the lock-waiting state, the lock-waiting time, and the digests of statements that have been executed in the transaction.
- **DATA_LOCK_WAITS**: Provides the pessimistic lock-waiting information in TiKV, including the `start_ts` of the blocking and blocked transaction, the digest of the blocked SQL statement, and the key on which the waiting occurs.
- **DEADLOCKS** and **CLUSTER_DEADLOCKS**: Provides the information of several deadlock events that have recently occurred on the current TiDB node or in the entire cluster, including the waiting relationship among transactions in the deadlock loops, the digest of the statement currently being executed in the transaction, and the key on which the waiting occurs.

Note:

The SQL statements shown in the Lock View-related system tables are normalized SQL statements (that is, SQL statements without formats and arguments), which are obtained by internal queries according to SQL digests, so the tables cannot obtain the complete statements that include the format and arguments. For the detailed description of SQL digests and normalized SQL statement, see [Statement Summary Tables](#).

The following sections show the examples of troubleshooting some issues using these tables.

8.13.1.1 Deadlock errors

To get the information of the recent deadlock errors, you can query the `DEADLOCKS` or `CLUSTER_DEADLOCKS` table.

For example, to query the `DEADLOCKS` table, you can execute the following SQL statement:

```
select * from information_schema.deadlocks;
```

The following is an example output:

```
+--
↪ -----+-----+-----+-----+
↪
| DEADLOCK_ID | OCCUR_TIME          | RETRYABLE | TRY_LOCK_TRX_ID |
↪ CURRENT_SQL_DIGEST                                |
↪ CURRENT_SQL_DIGEST_TEXT          | KEY
↪                                     | KEY_INFO
↪ | TRX_HOLDING_LOCK |
+--
↪ -----+-----+-----+-----+
↪
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406216 |
↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
↪ update `t` set `v` = ? where `id` = ? ; | 74800000000000000355
↪ F7280000000000000002 | {"db_id":1,"db_name":"test","table_id":53,"
↪ table_name":"t","handle_type":"int","handle_value":"2"} |
↪ 426812829645406217 |
|          1 | 2021-08-05 11:09:03.230341 |    0 | 426812829645406217 |
↪ 22230766411edb40f27a68dadefc63c6c6970d5827f1e5e22fc97be2c4d8350d |
↪ update `t` set `v` = ? where `id` = ? ; | 74800000000000000355
↪ F7280000000000000001 | {"db_id":1,"db_name":"test","table_id":53,"
↪ table_name":"t","handle_type":"int","handle_value":"1"} |
↪ 426812829645406216 |
+--
↪ -----+-----+-----+-----+
↪
```

The query result above shows the waiting relationship among multiple transactions in the deadlock error, the normalized form of the SQL statements currently being executed in each transaction (statements without formats and arguments), the key on which the conflict occurs, and the information of the key.

For example, in the above example, the first row means that the transaction with the ID of 426812829645406216 is executing a statement like `update `t` set `v` =? Where `id` =? ;` but is blocked by another transaction with the ID of 426812829645406217. The transaction with the ID of 426812829645406217 is also executing a statement that is in the form of `update `t` set `v` =? Where `id` =? ;` but is blocked by the transaction with the ID of 426812829645406216. The two transactions thus form a deadlock.

8.13.1.2 A few hot keys cause queueing locks

The `DATA_LOCK_WAITS` system table provides the lock-waiting status on the TiKV nodes. When you query this table, TiDB automatically obtains the real-time lock-waiting information from all TiKV nodes. If a few hot keys are frequently locked and block many transactions, you can query the `DATA_LOCK_WAITS` table and aggregate the results by key to try to find the keys on which issues frequently occur:

```
select `key`, count(*) as `count` from information_schema.data_lock_waits
↪ group by `key` order by `count` desc;
```

The following is an example output:

```
+-----+-----+
| key                | count |
+-----+-----+
| 7480000000000000415F728000000000000001 | 2 |
| 74800000000000000415F728000000000000002 | 1 |
+-----+-----+
```

To avoid contingency, you might need to make multiple queries.

If you know the key that frequently has issues occurred, you can try to get the information of the transaction that tries to lock the key from the `TIDB_TRX` or `CLUSTER_TIDB_TRX` table.

Note that the information displayed in the `TIDB_TRX` and `CLUSTER_TIDB_TRX` tables is also the information of the transactions that are running at the time the query is performed. These tables do not display the information of the completed transactions. If there is a large number of concurrent transactions, the result set of the query might also be large. You can use the `limit` clause or the `where` clause to filter transactions with a long lock-waiting time. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

For example, to filter transactions with a long lock-waiting time using the `where` clause, you can execute the following SQL statement:

```
select trx.* from information_schema.data_lock_waits as l left join
↪ information_schema.tidb_trx as trx on l.trx_id = trx.id where l.key =
↪ "7480000000000000415F728000000000000001"\G
```

The following is an example output:

```
***** 1. row *****
          ID: 426831815660273668

8.13.1.3 A transaction is blocked for a long time

If a transaction is known to be blocked by another transaction (or multiple transactions) and the `start_ts` (transaction ID) of the current transaction is known, you can use the following method to obtain the information of the blocking transaction. Note that when you join multiple tables in Lock View, the data in different tables might not be obtained at the same time, so the information in different tables might not be consistent.

```

select l.key, trx.*, tidb_decode_sql_digests(trx.all_sql_digests) as sqls
  ↪ from information_schema.data_lock_waits as l join information_schema.
  ↪ cluster_tidb_trx as trx on l.current_holding_trx_id = trx.id where l.
  ↪ trx_id = 426831965449355272\G

```

The following is an example output:

```

***** 1. row *****

```

```

        key: 7480000000000004D5F72800000000000001
    INSTANCE: 127.0.0.1:10080
        ID: 426832040186609668
    START_TIME: 2021-08-06 07:30:16.581000
    CURRENT_SQL_DIGEST: 06
        ↪ da614b93e62713bd282d4685fc5b88d688337f36e88fe55871726ce0eb80d7
    CURRENT_SQL_DIGEST_TEXT: update `t` set `v` = `v` + ? where `id` = ? ;
        STATE: LockWaiting
    WAITING_START_TIME: 2021-08-06 07:30:16.592763
    MEM_BUFFER_KEYS: 1
    MEM_BUFFER_BYTES: 19
    SESSION_ID: 113
    USER: root
    DB: test
    ALL_SQL_DIGESTS: ["0
        ↪ fdc781f19da1c6078c9de7eadef8a307889c001e05f107847bee4cfc8f3cdf3
        ↪ ", "

        ↪ ", "06
        ↪ da614b93e62713bd282d4685fc5b88d688337f36e88fe55871726ce0eb80d7
        ↪ "]
        sqls: ["begin ;", "select * from `t` where `id` = ? for
            ↪ update ;", "update `t` set `v` = `v` + ? where `id` =
            ↪ ? ;"]
1 row in set (0.01 sec)

```

In the above query, the `TIDB_DECODE_SQL_DIGESTS` function is used on the `ALL_SQL_DIGESTS` column of the `CLUSTER_TIDB_TRX` table. This function tries to convert this column (the value is a set of SQL digests) to the normalized SQL statements, which improves readability.

If the `start_ts` of the current transaction is unknown, you can try to find it out from the information in the `TIDB_TRX` / `CLUSTER_TIDB_TRX` table or in the `PROCESSLIST` / `CLUSTER_PROCESSLIST` table.

8.13.2 Troubleshoot optimistic lock conflicts

This section provides the solutions of common lock conflict issues in the optimistic transaction mode.

8.13.2.1 Read-write conflicts

As the TiDB server receives a read request from a client, it gets a globally unique and increasing timestamp at the physical time as the `start_ts` of the current transaction. The transaction needs to read the latest data before `start_ts`, that is, the target key of the latest

commit_ts that is smaller than start_ts. When the transaction finds that the target key is locked by another transaction, and it cannot know which phase the other transaction is in, a read-write conflict happens. The diagram is as follows:

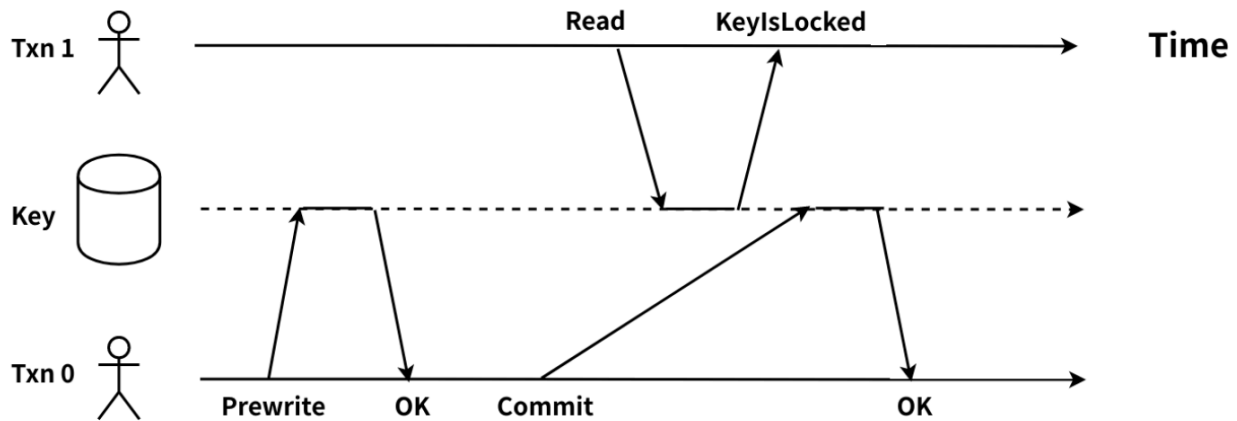

Figure 64: read-write conflict

Txn0 completes the Prewrite phase and enters the Commit phase. At this time, Txn1 requests to read the same target key. Txn1 needs to read the target key of the latest commit_ts that is smaller than its start_ts. Because Txn1's start_ts is larger than Txn0's lock_ts, Txn1 must wait for the target key's lock to be cleared, but it hasn't been done. As a result, Txn1 cannot confirm whether Txn0 has been committed or not. Thus, a read-write conflict between Txn1 and Txn0 happens.

You can detect the read-write conflict in your TiDB cluster by the following ways:

1. Monitoring metrics and logs of the TiDB server

- Monitoring data through Grafana

On the KV Errors panel in the TiDB dashboard, there are two monitoring metrics Lock Resolve OPS and KV Backoff OPS which can be used to check read-write conflicts in the transactions. If the values of both not_expired and resolve under Lock Resolve OPS increase, there might be many read-write conflicts. The not_expired item means that the transaction's lock has not timed out. The resolve item means that the other transaction tries to clean up the locks. If the value of another txnLockFast item under KV Backoff OPS increases, there might also be read-write conflicts.

- Logs of the TiDB server

If there is any read-write conflict, you can see the following message in the TiDB log:

```
[INFO] [coprocessor.go:743] ["[TIME_COP_PROCESS] resp_time
  ↳ :406.038899ms txnStartTS:416643508703592451 region_id:8297
  ↳ store_addr:10.8.1.208:20160 backoff_ms:255 backoff_types:[
  ↳ txnLockFast,txnLockFast] kv_process_ms:333 scan_total_write
  ↳ :0 scan_processed_write:0 scan_total_data:0
  ↳ scan_processed_data:0 scan_total_lock:0 scan_processed_lock
  ↳ :0"]
```

- txnStartTS: The start_ts of the transaction that is sending the read request. In the above log, 416643508703592451 is the start_ts.
- backoff_types: If a read-write conflict happens, and the read request performs backoff and retry, the type of retry is TxnLockFast.
- backoff_ms: The time that the read request spends in the backoff and retry, and the unit is milliseconds. In the above log, the read request spends 255

- milliseconds in the backoff and retry.
- `region_id`: Region ID corresponding to the target key of the read request.

2. Logs of the TiKV server

If there is any read-write conflict, you can see the following message in the TiKV log:

```
[ERROR] [endpoint.rs:454] [error-response] [err=""locked primary_lock
↳ :7480000000000004
↳ D35F6980000000000000010380000000004C788E0380000000004C0748
↳ lock_version: 411402933858205712 key: 7480000000000004
↳ D35F72800000000004C0748 lock_ttl: 3008 txn_size: 1""]
```

This message indicates that a read-write conflict occurs in TiDB. The target key of the read request has been locked by another transaction. The locks are from the uncommitted optimistic transaction and the uncommitted pessimistic transaction after the prewrite phase.

- `primary_lock`: Indicates that the target key is locked by the primary lock.
- `lock_version`: The `start_ts` of the transaction that owns the lock.
- `key`: The target key that is locked.
- `lock_ttl`: The lock’s TTL (Time To Live)
- `txn_size`: The number of keys that are in the Region of the transaction that owns the lock.

Solutions:

- A read-write conflict triggers an automatic backoff and retry. As in the above example, Txn1 has a backoff and retry. The first time of the retry is 10 ms, the longest retry is 3000 ms, and the total time is 20000 ms at maximum.
- You can use the sub-command `decoder` of TiDB Control to view the table id and rowid of the row corresponding to the specified key:

```
./tidb-ctl decoder -f table_row -k "t\x00\x00\x00\x00\x00\x00\x00\x1c_r
↳ \x00\x00\x00\x00\x00\x00\x00\xfa"

table_id: -9223372036854775780
row_id: -9223372036854775558
```

8.13.2.2 KeyIsLocked error

In the Prewrite phase of a transaction, TiDB checks whether there is any write-write conflict, and then checks whether the target key has been locked by another transaction. If the key is locked, the TiKV server outputs a “KeyIsLocked” error. At present, the error message is not printed in the logs of TiDB and TiKV. Same as read-write conflicts, when “KeyIsLocked” occurs, TiDB automatically performs backoff and retry for the transaction.

You can check whether there's any "KeyIsLocked" error in the TiDB monitoring on Grafana:

The KV Errors panel in the TiDB dashboard has two monitoring metrics Lock Resolve \leftrightarrow OPS and KV Backoff OPS which can be used to check write-write conflicts caused by a transaction. If the `resolve` item under Lock Resolve OPS and the `txnLock` item under KV Backoff OPS have a clear upward trend, a "KeyIsLocked" error occurs. `resolve` refers to the operation that attempts to clear the lock, and `txnLock` represents a write conflict.

Solutions:

- If there is a small amount of `txnLock` in the monitoring, no need to pay too much attention. The backoff and retry is automatically performed in the background. The first time of the retry is 100 ms and the maximum time is 3000 ms for a single retry.

- If there are too many “txnLock” operations in the KV Backoff OPS, it is recommended that you analyze the reasons to the write conflicts from the application side.
- If your application is a write-write conflict scenario, it is strongly recommended to use the pessimistic transaction mode.

8.13.2.3 LockNotFound error

The error log of “TxnLockNotFound” means that transaction commit time is longer than the the TTL time, and when the transaction is going to commit, its lock has been rolled back by other transactions. If the TiDB server enables transaction commit retry, this transaction is re-executed according to `tidb_retry_limit`. (Note about the difference between explicit and implicit transactions.)

You can check whether there is any “LockNotFound” error in the following ways:

1. View the logs of the TiDB server

If a “TxnLockNotFound” error occurs, the TiDB log message is like this:

```
[WARN] [session.go:446] ["commit failed"] [conn=149370] ["finished txn
↳ "="Txn{state=invalid}"] [error="[kv:6]Error: KV error safe to
↳ retry tikv restarts txn: Txn(Mvcc(TxnLockNotFound{ start_ts:
↳ 412720515987275779, commit_ts: 412720519984971777, key: [116,
↳ 128, 0, 0, 0, 0, 1, 111, 16, 95, 114, 128, 0, 0, 0, 0, 0, 2]
↳ }))] [try again later]"
```

- `start_ts`: The `start_ts` of the transaction that outputs the `TxnLockNotFound` error because its lock has been rolled back by other transactions. In the above log, `412720515987275779` is the `start_ts`.
- `commit_ts`: The `commit_ts` of the transaction that outputs the `TxnLockNotFound` error. In the above log, `412720519984971777` is the `commit_ts`.

2. View the logs of the TiKV server

If a “TxnLockNotFound” error occurs, the TiKV log message is like this:

```
Error: KV error safe to retry restarts txn: Txn(Mvcc(TxnLockNotFound))
↳ [ERROR [Kv.rs:708] ["KvService::batch_raft send response fail"] [
↳ err=RemoteStoped]
```

Solutions:

- By checking the time interval between `start_ts` and `commit_ts`, you can confirm whether the commit time exceeds the TTL time.

Checking the time interval using the PD control tool:

```
tiup ctl:<cluster-version> pd tso [start_ts]
tiup ctl:<cluster-version> pd tso [commit_ts]
```

- It is recommended to check whether the write performance is slow, which might cause that the efficiency of transaction commit is poor, and thus the lock is cleared.
- In the case of disabling the TiDB transaction retry, you need to catch the exception on the application side and try again.

8.13.3 Troubleshoot pessimistic lock conflicts

This section provides the solutions of common lock conflict issues in the pessimistic transaction mode.

Note:

Even if the pessimistic transaction mode is set, autocommit transactions still try to commit using the optimistic mode first. If a conflict occurs, the transactions will switch to the pessimistic transaction mode during automatic retry.

8.13.3.1 Read-write conflicts

The error messages and solutions are the same as [Read-write conflict](#) for optimistic lock conflict.

8.13.3.2 Pessimistic lock retry limit reached

When the transaction conflict is very serious or a write conflict occurs, the optimistic transaction will be terminated directly, and the pessimistic transaction will retry the statement with the latest data from storage until there is no write conflict.

Because TiDB's locking operation is a write operation, and the process of the operation is to read first and then write, there are two RPC requests. If a write conflict occurs in the middle of a transaction, TiDB will try again to lock the target keys, and each retry will be printed to the TiDB log. The number of retries is determined by [pessimistic-txn.max-retry-count](#).

In the pessimistic transaction mode, if a write conflict occurs and the number of retries reaches the upper limit, an error message containing the following keywords appears in the TiDB log:

```
err="pessimistic lock retry limit reached"
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust from the application side.

8.13.3.3 Lock wait timeout exceeded

In the pessimistic transaction mode, transactions wait for locks of each other. The timeout for waiting a lock is defined by the `innodb_lock_wait_timeout` parameter of TiDB. This is the maximum wait lock time at the SQL statement level, which is the expectation of a SQL statement Locking, but the lock has never been acquired. After this time, TiDB will not try to lock again and will return the corresponding error message to the client.

When a wait lock timeout occurs, the following error message will be returned to the client:

```
ERROR 1205 (HY000): Lock wait timeout exceeded; try restarting transaction
```

Solutions:

- If the above error occurs frequently, it is recommended to adjust the application logic.

8.13.3.4 TTL manager has timed out

The transaction execution time can not exceed the GC time limit. In addition, the TTL time of pessimistic transactions has an upper limit, whose default value is 1 hour. Therefore, a pessimistic transaction executed for more than 1 hour will fail to commit. This timeout threshold is controlled by the TiDB parameter `performance.max-txn-ttl`.

When the execution time of a pessimistic transaction exceeds the TTL time, the following error message occurs in the TiDB log:

```
TTL manager has timed out, pessimistic locks may expire, please commit or  
↪ rollback this transaction
```

Solutions:

- First, confirm whether the application logic can be optimized. For example, large transactions may trigger TiDB's transaction size limit, which can be split into multiple small transactions.
- Also, you can adjust the related parameters properly to meet the application transaction logic.

8.13.3.5 Deadlock found when trying to get lock

Due to resource competition between two or more transactions, a deadlock occurs. If you do not handle it manually, transactions that block each other cannot be executed successfully and will wait for each other forever. To resolve dead locks, you need to manually terminate one of the transactions to resume other transaction requests.

When a pessimistic transaction has a deadlock, one of the transactions must be terminated to unlock the deadlock. The client will return the same `Error 1213` error as in MySQL, for example:

```
[err="[executor:1213]Deadlock found when trying to get lock; try restarting
↪ transaction"]
```

Solutions:

- If it is difficult to confirm the cause of the deadlock, for v5.1 and later versions, you are recommended to try to query the `INFORMATION_SCHEMA.DEADLOCKS` or `INFORMATION_SCHEMA.CLUSTER_DEADLOCKS` system table to get the information of deadlock waiting chain. For details, see the [Deadlock errors](#) section and the [DEADLOCKS table](#) document.
- If the deadlock occurs frequently, you need to adjust the transaction query logic in your application to reduce such occurrences.

8.14 Troubleshoot a TiFlash Cluster

This section describes some commonly encountered issues when using TiFlash, the reasons, and the solutions.

8.14.1 TiFlash fails to start

The issue might occur due to different reasons. It is recommended that you troubleshoot it following the steps below:

1. Check whether your system is CentOS8.

CentOS8 does not have the `libnsl.so` system library. You can manually install it via the following command:

```
shell dnf install libnsl
```

2. Check your system's `ulimit` parameter setting.

```
shell ulimit -n 1000000
```

3. Use the PD Control tool to check whether there is any TiFlash instance that failed to go offline on the node (same IP and Port) and force the instance(s) to go offline. For detailed steps, refer to [Scale in a TiFlash cluster](#).

If the above methods cannot resolve your issue, save the TiFlash log files and email to info@pingcap.com for more information.

8.14.2 TiFlash replica is always unavailable

This is because TiFlash is in an abnormal state caused by configuration errors or environment issues. Take the following steps to identify the faulty component:

1. Check whether PD enables the Placement Rules feature:

```
echo 'config show replication' | /path/to/pd-ctl -u http://{pd-ip}:{pd-port}
```

- If `true` is returned, go to the next step.
 - If `false` is returned, [enable the Placement Rules feature](#) and go to the next step.
2. Check whether the TiFlash process is working correctly by viewing UpTime on the TiFlash-Summary monitoring panel.
 3. Check whether the TiFlash proxy status is normal through `pd-ctl`.

```
echo "store" | /path/to/pd-ctl -u http://{pd-ip}:{pd-port}
```

The TiFlash proxy's `store.labels` includes information such as `{"key": "engine" ↪ ", "value": "tiflash"}`. You can check this information to confirm a TiFlash proxy.

4. Check whether `pd buddy` can correctly print the logs (the log path is the value of `log` in the `[flash.flash_cluster]` configuration item; the default log path is under the `tmp` directory configured in the TiFlash configuration file).
5. Check whether the number of configured replicas is less than or equal to the number of TiKV nodes in the cluster. If not, PD cannot replicate data to TiFlash:

```
echo 'config placement-rules show' | /path/to/pd-ctl -u http://{pd-ip ↪ }:{pd-port}
```

Reconfirm the value of `default: count`.

Note:

After the [placement rules](#) feature is enabled, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to placement rules.

6. Check whether the remaining disk space of the machine (where `store` of the TiFlash node is) is sufficient. By default, when the remaining disk space is less than 20% of the `store` capacity (which is controlled by the `low-space-ratio` parameter), PD cannot schedule data to this TiFlash node.

```

> | Level | Code | Message
   ↪
+-----+-----+-----+
   ↪
| Warning | 1105 | Scalar function 'subtime'(signature: SubDatetimeAndString
   ↪ , return type: datetime) is not supported to push down to tiflash now
   ↪ . |
+-----+-----+-----+
   ↪

```

8.14.7 Data is not replicated to TiFlash

After deploying a TiFlash node and starting replication (by performing the ALTER operation), no data is replicated to it. In this case, you can identify and address the problem by following the steps below:

1. Check whether the replication is successful by running the ALTER table <tbl_name>
 - ↪ set tiflash replica <num> command and check the output.
 - If there is output, go to the next step.
 - If there is no output, run the SELECT * FROM information_schema.tiflash_replica
 - ↪ command to check whether TiFlash replicas have been created. If not, run the ALTER table \${tbl_name} set tiflash replica \${num} command again, check whether other statements (for example, add index) have been executed, or check whether DDL executions are successful.
2. Check whether the TiFlash process runs correctly.

Check whether there is any change in progress, the flash_region_count parameter in the tiflash_cluster_manager.log file, and the Grafana monitoring item Uptime:

- If yes, the TiFlash process runs correctly.
 - If no, the TiFlash process is abnormal. Check the tiflash log for further information.
3. Check whether the Placement Rules function has been enabled by using pd-ctl:

```

echo 'config show replication' | /path/to/pd-ctl -u http://<pd-ip>:<pd-
   ↪ port>

```

- If true is returned, go to the next step.
 - If false is returned, enable the Placement Rules feature and go to the next step.
4. Check whether the max-replicas configuration is correct:

- If the value of `max-replicas` does not exceed the number of TiKV nodes in the cluster, go to the next step.
- If the value of `max-replicas` is greater than the number of TiKV nodes in the cluster, the PD does not replicate data to the TiFlash node. To address this issue, change `max-replicas` to an integer fewer than or equal to the number of TiKV nodes in the cluster.

Note:

`max-replicas` is defaulted to 3. In production environments, the value is usually fewer than the number of TiKV nodes. In test environments, the value can be 1.

```
curl -X POST -d '{
  "group_id": "pd",
  "id": "default",
  "start_key": "",
  "end_key": "",
  "role": "voter",
  "count": 3,
  "location_labels": [
    "host"
  ]
}' <http://172.16.x.xxx:2379/pd/api/v1/config/rule>
```

5. Check whether the connection between TiDB or PD and TiFlash is normal.

Search the `flash_cluster_manager.log` file for the `ERROR` keyword.

- If no `ERROR` is found, the connection is normal. Go to the next step.
- If `ERROR` is found, the connection is abnormal. Perform the following check.
- Check whether the log records PD keywords.
If PD keywords are found, check whether `raft.pd_addr` in the TiFlash configuration file is valid. Specifically, run the `curl '{pd-addr}/pd/api/v1/config/rules'` command and check whether there is any output in 5s.
- Check whether the log records TiDB-related keywords.
If TiDB keywords are found, check whether `flash.tidb_status_addr` in the TiFlash configuration file is valid. Specifically, run the `curl '{tidb-status-addr}/tiflash/replica'` command and check whether there is any output in 5s.
- Check whether the nodes can ping through each other.

Note:

If the problem persists, collect logs of the corresponding component for troubleshooting.

6. Check whether `placement-rule` is created for tables.

Search the `flash_cluster_manager.log` file for the `Set placement rule ... table`
↪ `-<table_id>-r` keyword.

- If the keyword is found, go to the next step.
- If not, collect logs of the corresponding component for troubleshooting.

7. Check whether the PD schedules properly.

Search the `pd.log` file for the `table-<table_id>-r` keyword and scheduling behaviors like `add operator`.

- If the keyword is found, the PD schedules properly.
- If not, the PD does not schedule properly. Contact PingCAP technical support for help.

8.14.8 Data replication gets stuck

If data replication on TiFlash starts normally but then all or some data fails to be replicated after a period of time, you can confirm or resolve the issue by performing the following steps:

1. Check the disk space.

Check whether the disk space ratio is higher than the value of `low-space-ratio` (defaulted to 0.8. When the space usage of a node exceeds 80%, the PD stops migrating data to this node to avoid exhaustion of disk space).

- If the disk usage ratio is greater than or equal to the value of `low-space-ratio`, the disk space is insufficient. To relieve the disk space, remove unnecessary files, such as `space_placeholder_file` (if necessary, set `reserve-space` to 0MB after removing the file) under the `/${data}/flash/` folder.
- If the disk usage ratio is less than the value of `low-space-ratio`, the disk space is sufficient. Go to the next step.

2. Check the network connectivity between TiKV, TiFlash, and PD.

In `flash_cluster_manager.log`, check whether there are any new updates to `flash_region_count` corresponding to the table that gets stuck.

- If no, go to the next step.

- If yes, search for `down peer` (replication gets stuck if there is a peer that is down).
 - Run `pd-ctl region check-down-peer` to search for `down peer`.
 - If `down peer` is found, run `pd-ctl operator add remove-peer\<region-id> \<tiflash-store-id>` to remove it.

3. Check CPU usage.

On Grafana, choose **TiFlash-Proxy-Details > Thread CPU > Region task worker pre-handle/generate snapshot CPU**. Check the CPU usage of `<instance-id> -ip:<instance-port>-region-worker`.

If the curve is a straight line, the TiFlash node is stuck. Terminate the TiFlash process and restart it, or contact PingCAP technical support for help.

8.14.9 Data replication is slow

The causes may vary. You can address the problem by performing the following steps.

1. Adjust the value of the scheduling parameters.

- Increase `store limit` to accelerate replication.
- Decrease `config set patrol-region-interval 10ms` to make checker scan on Regions more frequent in TiKV.
- Increase `region merge` to reduce the number of Regions, which means fewer scans and higher check frequencies.

2. Adjust the load on TiFlash.

Excessively high load on TiFlash can also result in slow replication. You can check the load of TiFlash indicators on the **TiFlash-Summary** panel on Grafana:

- Applying snapshots Count: `TiFlash-summary > raft > Applying snapshots`
↔ `Count`
- Snapshot Predecode Duration: `TiFlash-summary > raft > Snapshot`
↔ `Predecode Duration`
- Snapshot Flush Duration: `TiFlash-summary > raft > Snapshot Flush`
↔ `Duration`
- Write Stall Duration: `TiFlash-summary > Storage Write Stall > Write`
↔ `Stall Duration`
- generate snapshot CPU: `TiFlash-Proxy-Details > Thread CPU > Region`
↔ `task worker pre-handle/generate snapshot CPU`

Based on your service priorities, adjust the load accordingly to achieve optimal performance.

8.15 Troubleshoot Write Conflicts in Optimistic Transactions

This document introduces the reason of and solutions to write conflicts in optimistic transactions.

Before TiDB v3.0.8, TiDB uses the optimistic transaction model by default. In this model, TiDB does not check conflicts during transaction execution. Instead, while the transaction is finally committed, the two-phase commit (2PC) is triggered and TiDB checks write conflicts. If a write conflict exists and the auto-retry mechanism is enabled, then TiDB retries the transaction within limited times. If the retry succeeds or has reached the upper limit on retry times, TiDB returns the result of transaction execution to the client. Therefore, if a lot of write conflicts exist in the TiDB cluster, the duration can be longer.

8.15.1 The reason of write conflicts

TiDB implements its transactions by using the [Percolator](#) transaction model. `percolator` is generally an implementation of 2PC. For the detailed 2PC process, see [TiDB Optimistic Transaction Model](#).

After the client sends a `COMMIT` request to TiDB, TiDB starts the 2PC process:

1. TiDB chooses one key from all keys in the transaction as the primary key of the transaction.
2. TiDB sends the `prewrite` request to all the TiKV Regions involved in this commit. TiKV judges whether all keys can preview successfully.
3. TiDB receives the result that all `prewrite` requests are successful.
4. TiDB gets the `commit_ts` from PD.
5. TiDB sends the `commit` request to the TiKV Region that contains the primary key of the transaction. After TiKV receives the `commit` request, it checks the validity of the data and clears the locks left in the `prewrite` stage.
6. After the `commit` request returns successfully, TiDB returns success to the client.

The write conflict occurs in the `prewrite` stage. When the transaction finds that another transaction is writing the current key (`data.commit_ts > txn.start_ts`), a write conflict occurs.

8.15.2 Detect write conflicts

In the TiDB Grafana panel, check the following monitoring metrics under **KV Errors**:

- **KV Backoff OPS** indicates the count of error messages per second returned by TiKV.

Figure 65: kv-backoff-ops

The `txnlock` metric indicates the write-write conflict. The `txnLockFast` metric indicates the read-write conflict.

- **Lock Resolve OPS** indicates the count of items related to transaction conflicts per second:

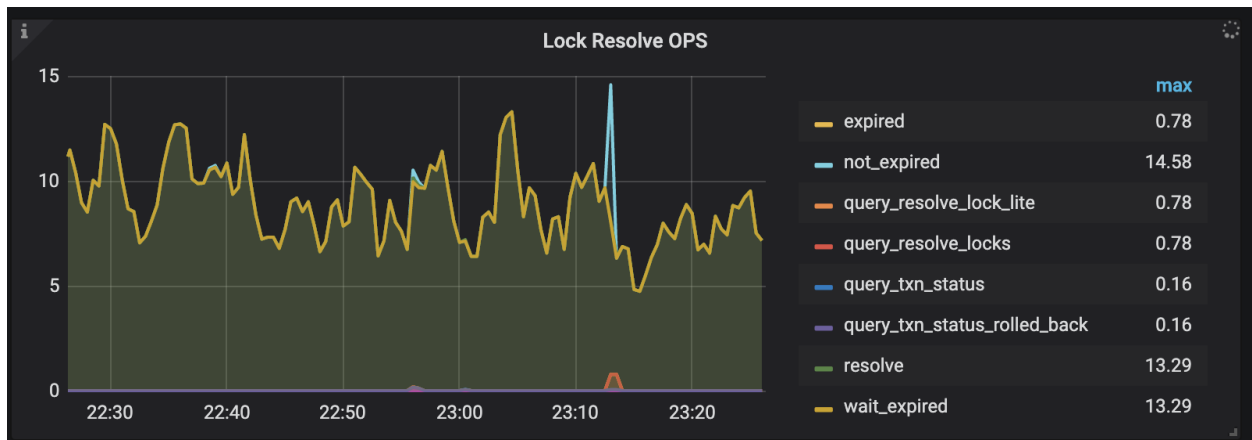

Figure 66: lock-resolve-ops

- `not_expired` indicates the TTL of the lock was not expired. The conflict transaction cannot resolve locks until the TTL is expired.
- `wait_expired` indicates that the transaction needs to wait the lock to expire.
- `expired` indicates the TTL of the lock was expired. Then the conflict transaction can resolve this lock.

- **KV Retry Duration** indicates the duration of re-sends the KV request:

Figure 67: kv-retry-duration

You can also use `[kv:9007]Write conflict` as the keywords to search in the TiDB log. The keywords also indicate the write conflict exists in the cluster.

8.15.3 Resolve write conflicts

If many write conflicts exist in the cluster, it is recommended to find out the write conflict key and the reason, and then try to change the application logic to avoid write conflicts. When the write conflict exists in the cluster, you can see the log similar to the following one in the TiDB log file:

```
[2020/05/12 15:17:01.568 +08:00] [WARN] [session.go:446] ["commit failed"] [
  ↳ conn=3] ["finished txn"="Txn{state=invalid}"] [error="[kv:9007]Write
  ↳ conflict, txnStartTS=416617006551793665, conflictStartTS
  ↳ =416617018650001409, conflictCommitTS=416617023093080065, key={
  ↳ tableID=47, indexID=1, indexValues={string, }} primary={tableID=47,
  ↳ indexID=1, indexValues={string, }} [try again later]"
```

The explanation of the log above is as follows:

- `[kv:9007]Write conflict`: indicates the write-write conflict.
- `txnStartTS=416617006551793665`: indicates the `start_ts` of the current transaction. You can use the `pd-ctl` tool to convert `start_ts` to physical time.
- `conflictStartTS=416617018650001409`: indicates the `start_ts` of the write conflict transaction.
- `conflictCommitTS=416617023093080065`: indicates the `commit_ts` of the write conflict transaction.
- `key={tableID=47, indexID=1, indexValues={string, }}`: indicates the write conflict key. `tableID` indicates the ID of the write conflict table. `indexID` indicates the ID of write conflict index. If the write conflict key is a record key, the log prints `handle=x`,

indicating which record(row) has a conflict. `indexValues` indicates the value of the index that has a conflict.

- `primary={tableID=47, indexID=1, indexValues={string, }}`: indicates the primary key information of the current transaction.

You can use the `pd-ctl` tool to convert the timestamp to readable time:

```
tiup ctl:<cluster-version> pd -u https://127.0.0.1:2379 tso {TIMESTAMP}
```

You can use `tableID` to find the name of the related table:

```
curl http://{TiDBIP}:10080/db-table/{tableID}
```

You can use `indexID` and the table name to find the name of the related index:

```
SELECT * FROM INFORMATION_SCHEMA.TIDB_INDEXES WHERE TABLE_SCHEMA='{db_name}'  
↪ ' AND TABLE_NAME='{table_name}' AND INDEX_ID={indexID};
```

In addition, in TiDB v3.0.8 and later versions, the pessimistic transaction becomes the default mode. The pessimistic transaction mode can avoid write conflicts during the transaction prewrite stage, so you do not need to modify the application any more. In the pessimistic transaction mode, each DML statement writes a pessimistic lock to the related keys during execution. This pessimistic lock can prevent other transactions from modifying the same keys, thus ensuring no write conflicts exist in the `prewrite` stage of the transaction 2PC.

9 Performance Tuning

9.1 System Tuning

9.1.1 Operating System Tuning

This document introduces how to tune each subsystem of CentOS 7.

Note:

- The default configuration of the CentOS 7 operating system is suitable for most services running under moderate workloads. Adjusting the performance of a particular subsystem might negatively affect other subsystems. Therefore, before tuning the system, back up all the user data and configuration information.
- Fully test all the changes in the test environment before applying them to the production environment.

9.1.1.1 Performance analysis methods

System tuning must be based on the results of system performance analysis. This section lists common methods for performance analysis.

9.1.1.1.1 In 60 seconds

Linux Performance Analysis in 60,000 Milliseconds is published by the author Brendan Gregg and the Netflix Performance Engineering team. All tools used can be obtained from the official release of Linux. You can analyze outputs of the following list items to troubleshoot most common performance issues.

- `uptime`
- `dmesg | tail`
- `vmstat 1`
- `mpstat -P ALL 1`
- `pidstat 1`
- `iostat -xz 1`
- `free -m`
- `sar -n DEV 1`
- `sar -n TCP,ETCP 1`
- `top`

For detailed usage, see the corresponding `man` instructions.

9.1.1.1.2 perf

`perf` is an important performance analysis tool provided by the Linux kernel, which covers hardware level (CPU/PMU, performance monitoring unit) features and software features (software counters, trace points). For detailed usage, see [perf Examples](#).

9.1.1.1.3 BCC/bpftrace

Starting from CentOS 7.6, the Linux kernel has supported Berkeley Packet Filter (BPF). Therefore, you can choose proper tools to conduct an in-depth analysis based on the results in [In 60 seconds](#). Compared with `perf`/`ftrace`, BPF provides programmability and smaller performance overhead. Compared with `kprobe`, BPF provides higher security and is more suitable for the production environments. For detailed usage of the BCC toolkit, see [BPF Compiler Collection \(BCC\)](#).

9.1.1.2 Performance tuning

This section introduces performance tuning based on the classified kernel subsystems.

9.1.1.2.1 CPU—frequency scaling

`cpufreq` is a module that dynamically adjusts the CPU frequency. It supports five modes. To ensure service performance, select the performance mode and fix the CPU frequency at the highest supported operating frequency without dynamic adjustment. The command for this operation is `cpupower frequency-set --governor performance`.

9.1.1.2.2 CPU—interrupt affinity

- Automatic balance can be implemented through the `irqbalance` service.
- Manual balance:
 - Identify the devices that need to balance interrupts. Starting from CentOS 7.5, the system automatically configures the best interrupt affinity for certain devices and their drivers, such as devices that use the `be2iscsi` driver and NVMe settings. You can no longer manually configure interrupt affinity for such devices.
 - For other devices, check the chip manual to see whether these devices support distributing interrupts.
 - * If they do not, all interrupts of these devices are routed to the same CPU and cannot be modified.
 - * If they do, calculate the `smp_affinity` mask and set the corresponding configuration file. For details, see the [kernel document](#).

9.1.1.2.3 NUMA CPU binding

To avoid accessing memory across Non-Uniform Memory Access (NUMA) nodes as much as possible, you can bind a thread/process to certain CPU cores by setting the CPU affinity of the thread. For ordinary programs, you can use the `numactl` command for the CPU binding. For detailed usage, see the Linux manual pages. For network interface card (NIC) interrupts, see [tune network](#).

9.1.1.2.4 Memory—transparent huge page (THP)

It is **NOT** recommended to use THP for database applications, because databases often have sparse rather than continuous memory access patterns. If high-level memory fragmentation is serious, a higher latency will occur when THP pages are allocated. If the direct compaction is enabled for THP, the CPU usage will surge. Therefore, it is recommended to disable THP.

```
echo never > /sys/kernel/mm/transparent_hugepage/enabled
echo never > /sys/kernel/mm/transparent_hugepage/defrag
```

9.1.1.2.5 Memory—virtual memory parameters

- `dirty_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to use the `pdflush` operation to write the dirty page caches to disk. The default value of `dirty_ratio` is 20% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, lowering this value helps improve the efficiency of memory reclamation.
- `dirty_background_ratio` percentage ratio. When the total amount of dirty page caches reach this percentage ratio of the total system memory, the system starts to write the dirty page caches to the disk in the background. The default value of `dirty_ratio` is 10% and usually does not need adjustment. For high-performance SSDs such as NVMe devices, setting a lower value helps improve the efficiency of memory reclamation.

9.1.1.2.6 Storage and file system

The core I/O stack link is long, including the file system layer, the block device layer, and the driver layer.

I/O scheduler

The I/O scheduler determines when and how long I/O operations run on the storage device. It is also called I/O elevator. For SSD devices, it is recommended to set the I/O scheduling policy to `noop`.

```
echo noop > /sys/block/${SSD_DEV_NAME}/queue/scheduler
```

Formatting parameters—block size

Blocks are the working units of the file system. The block size determines how much data can be stored in a single block, and thus determines the minimum amount of data to be written or read each time.

The default block size is suitable for most scenarios. However, if the block size (or the size of multiple blocks) is the same or slightly larger than the amount of data normally read or written each time, the file system performs better and the data storage efficiency is higher. Small files still use the entire block. Files can be distributed among multiple blocks, but this will increase runtime overhead.

When using the `mkfs` command to format a device, specify the block size as a part of the file system options. The parameters that specify the block size vary with the file system. For details, see the corresponding `mkfs` manual pages, such as using `man mkfs.ext4`.

`mount` parameters

If the `noatime` option is enabled in the `mount` command, the update of metadata is disabled when files are read. If the `nodiratime` behavior is enabled, the update of metadata is disabled when the directory is read.

9.1.1.2.7 Network tuning

The network subsystem consists of many different parts with sensitive connections. The CentOS 7 network subsystem is designed to provide the best performance for most workloads and automatically optimizes the performance of these workloads. Therefore, usually you do not need to manually adjust network performance.

Network issues are usually caused by issues of hardware or related devices. So before tuning the protocol stack, rule out hardware issues.

Although the network stack is largely self-optimizing, the following aspects in the network packet processing might become the bottleneck and affect performance:

- NIC hardware cache: To correctly observe the packet loss at the hardware level, use the `ethtool -S ${NIC_DEV_NAME}` command to observe the `drops` field. When packet loss occurs, it might be that the processing speed of the hard/soft interrupts cannot catch up with the receiving speed of NIC. If the received buffer size is less than the upper limit, you can also try to increase the RX buffer to avoid packet loss. The query command is: `ethtool -g ${NIC_DEV_NAME}`, and the modification command is `ethtool -G ${NIC_DEV_NAME}`.
- Hardware interrupts: If the NIC supports the Receive-Side Scaling (RSS, also called multi-NIC receiving) feature, observe the `/proc/interrupts` NIC interrupts. If the interrupts are uneven, see [CPU—frequency scaling](#), [CPU—interrupt affinity](#), and [NUMA CPU binding](#). If the NIC does not support RSS or the number of RSS is much smaller than the number of physical CPU cores, configure Receive Packet Steering (RPS, which can be regarded as the software implementation of RSS), and the RPS extension Receive Flow Steering (RFS). For detailed configuration, see the [kernel document](#).
- Software interrupts: Observe the monitoring of `/proc/net/softnet_stat`. If the values of the other columns except the third column are increasing, properly adjust the value of `net.core.netdev_budget` or `net.core.dev_weight` for `softirq` to get more CPU time. In addition, you also need to check the CPU usage to determine which tasks are frequently using the CPU and whether they can be optimized.
- Receive queue of application sockets: Monitor the `Resv-q` column of `ss -nmp`. If the queue is full, consider increasing the size of the application socket cache or use the automatic cache adjustment method. In addition, consider whether you can optimize the architecture of the application layer and reduce the interval between reading sockets.
- Ethernet flow control: If the NIC and switch support the flow control feature, you can use this feature to leave some time for the kernel to process the data in the NIC queue, to avoid the issue of NIC buffer overflow.
- Interrupts coalescing: Too frequent hardware interrupts reduces system performance, and too late hardware interrupts causes packet loss. Newer NICs support the interrupt coalescing feature and allow the driver to automatically adjust the number of hardware interrupts. You can execute `ethtool -c ${NIC_DEV_NAME}` to check and `ethtool -C ${NIC_DEV_NAME}` to enable this feature. The adaptive mode allows the NIC

to automatically adjust the interrupt coalescing. In this mode, the driver checks the traffic mode and kernel receiving mode, and evaluates the coalescing settings in real time to prevent packet loss. NICs of different brands have different features and default configurations. For details, see the NIC manuals.

- Adapter queue: Before processing the protocol stack, the kernel uses this queue to buffer the data received by the NIC, and each CPU has its own backlog queue. The maximum number of packets that can be cached in this queue is `netdev_max_backlog` ↪ . Observe the second column of `/proc/net/softnet_stat`. When the second column of a row continues to increase, it means that the CPU [row-1] queue is full and the data packet is lost. To resolve this problem, continue to double the `net.core` ↪ `netdev_max_backlog` value.
- Send queue: The length value of a send queue determines the number of packets that can be queued before sending. The default value is 1000, which is sufficient for 10 Gbps. But if you have observed the value of TX errors from the output of `ip -s link`, you can try to double it: `ip link set dev ${NIC_DEV_NAME} txqueuelen 2000`.
- Driver: NIC drivers usually provide tuning parameters. See the device hardware manual and its driver documentation.

9.2 Software Tuning

9.2.1 Configuration

9.2.1.1 TiDB Memory Control

Currently, TiDB can track the memory quota of a single SQL query and take actions to prevent OOM (out of memory) or troubleshoot OOM when the memory usage exceeds a specific threshold value. In the TiDB configuration file, you can configure the options as below to control TiDB behaviors when the memory quota exceeds the threshold value:

```
#### Valid options: ["log", "cancel"]
oom-action = "cancel"
```

- If the configuration item above uses “log”, when the memory quota of a single SQL query exceeds the threshold value which is controlled by the `tidb_mem_quota_query` variable, TiDB prints an entry of log. Then the SQL query continues to be executed. If OOM occurs, you can find the corresponding SQL query in the log.
- If the configuration item above uses “cancel”, when the memory quota of a single SQL query exceeds the threshold value, TiDB stops executing the SQL query immediately and returns an error to the client. The error information clearly shows the memory usage of each physical execution operator that consumes much memory in the SQL execution process.

9.2.1.1.1 Configure the memory quota of a query

In the configuration file, you can set the default Memory Quota for each Query. The following example sets it to 32GB:

```
mem-quota-query = 34359738368
```

In addition, you can control the memory quota of a query using the following session variables. Generally, you only need to configure `tidb_mem_quota_query`. Other variables are used for advanced configuration which most users do not need to care about.

Variable Name	Description	Unit	Default Value
<code>tidb_mem_quota_query</code>	Control the memory quota of a query	Byte	1 << 30 (1 GB)
<code>tidb_mem_quota_hashjoin</code>	Control the memory quota of “HashJoinExec”	Byte	32 << 30
<code>tidb_mem_quota_mergejoin</code>	Control the memory quota of “MergeJoinExec”	Byte	32 << 30
<code>tidb_mem_quota_sort</code>	Control the memory quota of “SortExec”	Byte	32 << 30
<code>tidb_mem_quota_topn</code>	Control the memory quota of “TopNExec”	Byte	32 << 30
<code>tidb_mem_quota_indexlookup</code>	Control the memory quota of “IndexLookupExecutor”	Byte	32 << 30
<code>tidb_mem_quota_indexlookupjoin</code>	Control the memory quota of “IndexLookupJoin”	Byte	32 << 30
<code>tidb_mem_quota_nestedloopapply</code>	Control the memory quota of “NestedLoopApplyExec”	Byte	32 << 30

Some usage examples:

```
-- Set the threshold value of memory quota for a single SQL query to 8GB:  
set @@tidb_mem_quota_query = 8 << 30;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8MB:  
set @@tidb_mem_quota_query = 8 << 20;
```

```
-- Set the threshold value of memory quota for a single SQL query to 8KB:  
set @@tidb_mem_quota_query = 8 << 10;
```

9.2.1.1.2 Configure the memory usage threshold of a tidb-server instance

In the TiDB configuration file, you can set the memory usage threshold of a tidb-server instance by configuring `server-memory-quota`.

The following example sets the total memory usage of a tidb-server instance to 32 GB:

```
[performance]
server-memory-quota = 34359738368
```

In this configuration, when the memory usage of a tidb-server instance reaches 32 GB, the instance starts to kill running SQL statements randomly until the memory usage drops below 32 GB. SQL operations that are forced to terminate return an `Out Of Global Memory` ↪ `Limit!` error message to the client.

Warning:

- `server-memory-quota` is still an experimental feature. It is **NOT** recommended that you use it in a production environment.
- The default value of `server-memory-quota` is 0, which means no memory limit.

9.2.1.1.3 Trigger the alarm of excessive memory usage

In the default configuration, a tidb-server instance prints an alarm log and records associated status files when the machine memory usage reaches 80% of its total memory. You can set the memory usage ratio threshold by configuring `memory-usage-alarm-ratio`. For detailed alarm rules, refer to the description of `memory-usage-alarm-ratio`.

Note that after the alarm is triggered once, it will be triggered again only if the memory usage rate has been below the threshold for more than ten seconds and reaches the threshold again. In addition, to avoid storing excessive status files generated by alarms, currently, TiDB only retains the status files generated during the recent five alarms.

The following example constructs a memory-intensive SQL statement that triggers the alarm:

1. Set `memory-usage-alarm-ratio` to 0.8:

```
mem-quota-query = 34359738368 // Increases the memory limit of each
    ↪ query to construct SQL statements that take up larger memory.
[performance]
memory-usage-alarm-ratio = 0.8
```

2. Execute `CREATE TABLE t(a int);` and insert 1000 rows of data.
3. Execute `select * from t t1 join t t2 join t t3 order by t1.a.` This SQL statement outputs one billion records, which consumes a large amount of memory and therefore triggers the alarm.

4. Check the `tidb.log` file which records the total system memory, current system memory usage, memory usage of the `tidb-server` instance, and the directory of status files.

```
[2020/11/30 15:25:17.252 +08:00] [WARN] [memory_usage_alarm.go:141] ["
  ↪ tidb-server has the risk of OOM. Running SQLs and heap profile
  ↪ will be recorded in record path"] ["is server-memory-quota set"=
  ↪ false] ["system memory total"=33682427904] ["system memory usage
  ↪ "=27142864896] ["tidb-server memory usage"=22417922896] [memory-
  ↪ usage-alarm-ratio=0.8] ["record path"="/tmp/1000_tidb/
  ↪ MC4wLjAuMDoOMDAwLzAuMC4wLjA6MTAwODA=/tmp-storage/record"]
```

The fields of the example log file above are described as follows:

- `is server-memory-quota set` indicates whether `server-memory-quota` is set.
 - `system memory total` indicates the total memory of the current system.
 - `system memory usage` indicates the current system memory usage.
 - `tidb-server memory usage` indicates the memory usage of the `tidb-server` instance.
 - `memory-usage-alarm-ratio` indicates the value of `memory-usage-alarm-ratio`.
 - `record path` indicates the directory of status files.
5. You can see a set of files in the directory of status files (In the above example, the directory is `/tmp/1000_tidb/MC4wLjAuMDoOMDAwLzAuMC4wLjA6MTAwODA=/tmp-storage ↪ /record`), including `goroutine`, `heap`, and `running_sql`. These three files are suffixed with the time when status files are logged. They respectively record goroutine stack information, the usage status of heap memory, and the running SQL information when the alarm is triggered. For the format of log content in `running_sql`, refer to [expensive-queries](#).

9.2.1.1.4 Other memory control behaviors of `tidb-server`

Flow control

- TiDB supports dynamic memory control for the operator that reads data. By default, this operator uses the maximum number of threads that `tidb_distsql_scan_concurrency` ↪ allows to read data. When the memory usage of a single SQL execution exceeds `tidb_mem_quota_query` each time, the operator that reads data stops one thread.
- This flow control behavior is controlled by the system variable `tidb_enable_rate_limit_action` ↪ . This variable is enabled by default, which might make the memory usage not under the control of `tidb_mem_quota_query` in some cases. Therefore, it is recommended to set the value of `tidb_enable_rate_limit_action` to `OFF`.
- When the flow control behavior is triggered, TiDB outputs a log containing the keywords `memory exceeds quota, destroy one token now`.

Disk spill

TiDB supports disk spill for execution operators. When the memory usage of a SQL execution exceeds the memory quota, `tidb-server` can spill the intermediate data of execution operators to the disk to relieve memory pressure. Operators supporting disk spill include Sort, MergeJoin, HashJoin, and HashAgg.

- The disk spill behavior is jointly controlled by the `mem-quota-query`, `oom-use-tmp-
↪ storage`, `tmp-storage-path`, and `tmp-storage-quota` parameters.
- When the disk spill is triggered, TiDB outputs a log containing the keywords `memory exceeds quota`, `spill to disk now` or `memory exceeds quota`, `set
↪ aggregate mode to spill-mode`.
- Disk spill for the Sort, MergeJoin, and HashJoin operator is introduced in v4.0.0; disk spill for the HashAgg operator is introduced in v5.2.0.
- When the SQL executions containing Sort, MergeJoin, or HashJoin cause OOM, TiDB triggers disk spill by default. When SQL executions containing HashAgg cause OOM, TiDB does not trigger disk spill by default. You can configure the system variable `tidb_executor_concurrency = 1` to trigger disk spill for HashAgg.

Note:

The disk spill for HashAgg does not support SQL executions containing the `DISTINCT` aggregate function. When a SQL execution containing a `DISTINCT` aggregate function uses too much memory, the disk spill does not apply.

The following example uses a memory-consuming SQL statement to demonstrate the disk spill feature for HashAgg:

1. Configure the memory quota of a SQL statement to 1GB (1 GB by default):

```
set tidb_mem_quota_query = 1 << 30;
```

2. Create a single table `CREATE TABLE t(a int)`; and insert 256 rows of different data.
3. Execute the following SQL statement:

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1  
↪ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

Because executing this SQL statement occupies too much memory, the following “Out of Memory Quota” error message is returned:

```
ERROR 1105 (HY000): Out Of Memory Quota![conn_id=3]
```

- Configure the system variable `tidb_executor_concurrency` to 1. With this configuration, when out of memory, HashAgg automatically tries to trigger disk spill.

```
set tidb_executor_concurrency = 1;
```

- Execute the same SQL statement. You can find that this time, the statement is successfully executed and no error message is returned. From the following detailed execution plan, you can see that HashAgg has used 600 MB of hard disk space.

```
[tidb]> explain analyze select /*+ HASH_AGG() */ count(*) from t t1
↳ join t t2 join t t3 group by t1.a, t2.a, t3.a;
```

```

```

- The Raftstore thread pool:
 - It processes all Raft messages and the proposal to add a new log.
 - It writes Raft logs to the disk. If the value of `store-io-pool-size` is 0, the Raftstore thread writes the logs to the disk; if the value is not 0, the Raftstore thread sends the logs to the StoreWriter thread.
 - When Raft logs in the majority of replicas are consistent, the Raftstore thread sends the logs to the Apply thread.
- The StoreWriter thread pool: it writes all Raft logs to the disk and returns the result to the Raftstore thread.
- The Apply thread pool: it receives the submitted log sent from the Raftstore thread pool, parses it as a key-value request, then writes it to RocksDB, calls the callback function to notify the gRPC thread pool that the write request is complete, and returns the result to the client.
- The RocksDB thread pool: it is a thread pool for RocksDB to compact and flush tasks. For RocksDB's architecture and Compact operation, refer to [RocksDB: A Persistent Key-Value Store for Flash and RAM Storage](#).
- The UnifyReadPool thread pool: it is a combination of the Coprocessor thread pool and Storage Read Pool. All read requests such as kv get, kv batch get, raw kv get, and coprocessor are executed in this thread pool.

9.2.1.2.2 TiKV read-only requests

TiKV's read requests are divided into the following types:

- Simple queries that specify a certain row or several rows, running in the Storage Read Pool.
- Complex aggregate calculation and range queries, running in the Coprocessor Read Pool.

Starting from TiKV v5.0, all read requests use the unified thread pool for queries by default. If your TiKV cluster is upgraded from TiKV v4.0 and the `use-unified-pool` configuration of `readpool.storage` was set to `false` before the upgrade, all read requests continue using different thread pools after the upgrade. In this scenario, to make all read requests use the unified thread pool for queries, you can set the value of `readpool.storage` \leftrightarrow `.use-unified-pool` to `true`.

9.2.1.2.3 Performance tuning for TiKV thread pools

- The gRPC thread pool.

The default size (configured by `server.grpc-concurrency`) of the gRPC thread pool is 5. This thread pool has almost no computing overhead and is mainly responsible for network I/O and deserialization requests, so generally you do not need to adjust the default configuration.

- If the machine deployed with TiKV has a small number (less than or equal to 8) of CPU cores, consider setting the `server.grpc-concurrency` configuration item to 2.
- If the machine deployed with TiKV has very high configuration, TiKV undertakes a large number of read and write requests, and the value of `gRPC poll CPU` that monitors Thread CPU on Grafana exceeds 80% of `server.grpc-concurrency` \hookrightarrow , then consider increasing the value of `server.grpc-concurrency` to keep the thread pool usage rate below 80% (that is, the metric on Grafana is lower than $80\% * \text{server.grpc-concurrency}$).

- The Scheduler thread pool.

When TiKV detects that the number of machine CPU cores is larger than or equal to 16, the default size (configured by `storage.scheduler-worker-pool-size`) of the Scheduler thread pool is 8; when TiKV detects that the number of machine CPU cores is smaller than 16, the default size is 4.

This thread pool is mainly used to convert complex transaction requests into simple key-value read and write requests. However, **the Scheduler thread pool itself does not perform any write operation.**

- If it detects a transaction conflict, then this thread pool returns the conflict result to the client in advance.
- If no conflict is detected, then this thread pool merges the key-value requests that perform write operations into a Raft log and sends it to the Raftstore thread for Raft log replication.

Generally speaking, to avoid excessive thread switching, it is best to ensure that the utilization rate of the Scheduler thread pool is between 50% and 75%. If the thread pool size is 8, then it is recommended to keep `TiKV-Details.Thread CPU.scheduler` \hookrightarrow `worker CPU` on Grafana between 400% and 600%.

- The Raftstore thread pool.

The Raftstore thread pool is the most complex thread pool in TiKV. The default size (configured by `raftstore.store-pool-size`) of this thread pool is 2. For the StoreWriter thread pool, the default size (configured by `raftstore.store-io-pool-size`) is 0.

- When the size of the StoreWriter thread pool is 0, all write requests are written into RocksDB in the way of `fsync` by the Raftstore thread. In this case, it is recommended to tune the performance as follows:

- * Keep the overall CPU usage of the Raftstore thread below 60%. When the number of Raftstore threads is 2, keep the **TiKV-Details, Thread CPU, Raft store CPU** on Grafana below 120%. Due to I/O requests, the CPU usage of Raftstore threads in theory is always lower than 100%.
 - * Do not increase the size of the Raftstore thread pool to improve write performance without careful consideration, because this might increase the disk burden and degrade performance.
- When the size of the StoreWriter thread pool is not 0, all write requests are written into RocksDB in the way of `fsync` by the StoreWriter thread. In this case, it is recommended to tune the performance as follows:
- * Enable the StoreWriter thread pool ONLY when the overall CPU resources are sufficient. When the StoreWriter thread pool is enabled, keep the CPU usage of the StoreWriter thread and the Raftstore thread below 80%.

Compared with the case that the write requests are processed by the Raftstore thread, in theory, when the write requests are processed by the StoreWriter thread, write latency and the tail latency of data read are significantly reduced. However, as the write speed grows faster, the number of Raft logs increases accordingly. This can cause the CPU overhead of the Raftstore threads, the Apply threads, and the gRPC threads to increase. In this case, insufficient CPU resources might offset the tuning effect, and as a result, the write speed might become slower than before. Therefore, if the CPU resources are not sufficient, it is not recommended to enable the StoreWriter thread. Because the Raftstore thread sends most of the I/O requests to the StoreWriter thread, you need to keep the CPU usage of the Raftstore thread below 80%.

- In most cases, set the size of the StoreWriter thread pool to 1 or 2. This is because the size of the StoreWriter thread pool affects the number of Raft logs, so the value of the thread pool size should not be too large. If the CPU usage is higher than 80%, consider increasing the thread pool size.
 - Pay attention to the impact of increasing Raft logs on the CPU overhead of other thread pools. If necessary, you need to increase the number of Raftstore threads, Apply threads, and gRPC threads accordingly.
- The UnifyReadPool thread pool.

The UnifyReadPool is responsible for handling all read requests. The default size (configured by `readpool.unified.max-thread-count`) is 80% of the number of the machine's CPU cores. For example, if the machine CPU has 16 cores, the default thread pool size is 12. It is recommended to adjust the CPU usage rate according to the application workloads and keep it between 60% and 90% of the thread pool size.

If the peak value of the `TiKV-Details.Thread CPU.Unified read pool CPU` on Grafana does not exceed 800%, then it is recommended to set `readpool.unified` \leftrightarrow `.max-thread-count` to 10. Too many threads can cause more frequent thread switching, and take up resources of other thread pools.

- The RocksDB thread pool.

The RocksDB thread pool is a thread pool for RocksDB to compact and flush tasks. Usually, you do not need to configure it.

- If the machine has a small number of CPU cores, set both `rocksdb.max-background-jobs` and `raftdb.max-background-jobs` to 4.
- If you encounter write stall, go to Write Stall Reason in **RocksDB-kv** on Grafana and check on the metrics that are not 0.
 - * If it is caused by reasons related to pending compaction bytes, set `rocksdb.max-sub-compactions` to 2 or 3. This configuration item indicates the number of sub-threads allowed for a single compaction job. Its default value is 3 in TiKV 4.0 and 1 in TiKV 3.0.
 - * If the reason is related to memtable count, it is recommended to increase the `max-write-buffer-number` of all columns (5 by default).
 - * If the reason is related to the level0 file limit, it is recommended to increase values of the following parameters to 64 or a larger number:

```
rocksdb.defaultcf.level0-slowdown-writes-trigger
rocksdb.writecf.level0-slowdown-writes-trigger
rocksdb.lockcf.level0-slowdown-writes-trigger
rocksdb.defaultcf.level0-stop-writes-trigger
rocksdb.writecf.level0-stop-writes-trigger
rocksdb.lockcf.level0-stop-writes-trigger
```

9.2.1.3 Tune TiKV Memory Parameter Performance

This document describes how to tune the TiKV parameters for optimal performance. You can find the default configuration file in [etc/config-template.toml](#). To modify the configuration, you can [use TiUP](#) or [modify TiKV online \(experimental\)](#) for a limited set of configuration items. For the complete configuration, see [TiKV configuration file](#).

TiKV uses RocksDB for persistent storage at the bottom level of the TiKV architecture. Therefore, many of the performance parameters are related to RocksDB. TiKV uses two RocksDB instances: the default RocksDB instance stores KV data, the Raft RocksDB instance (RaftDB) stores Raft logs.

TiKV implements **Column Families (CF)** from RocksDB.

- The default RocksDB instance stores KV data in the `default`, `write` and `lock` CFs.
 - The `default` CF stores the actual data. The corresponding parameters are in [`rocksdb.defaultcf`].
 - The `write` CF stores the version information in Multi-Version Concurrency Control (MVCC) and index-related data. The corresponding parameters are in [`rocksdb.writecf`].

- The `lock` CF stores the lock information. The system uses the default parameters.
- The Raft RocksDB (RaftDB) instance stores Raft logs.
 - The `default` CF stores the Raft log. The corresponding parameters are in [`↪ raftdb.defaultcf`].

After TiKV 3.0, by default, all CFs share one block cache instance. You can configure the size of the cache by setting the `capacity` parameter under [`storage.block-cache`]. The bigger the block cache, the more hot data can be cached, and the easier to read data, in the meantime, the more system memory is occupied. To use a separate block cache instance for each CF, set `shared=false` under [`storage.block-cache`], and configure individual block cache size for each CF. For example, you can configure the size of `write` CF by setting the `block-cache-size` parameter under [`rocksdb.writecf`].

Before TiKV 3.0, shared block cache is not supported, and you need to configure block cache for each CF individually.

Each CF also has a separate `write buffer`. You can configure the size by setting the `write-buffer-size` parameter.

9.2.1.3.1 Parameter specification

```
#### Log level: trace, debug, warn, error, info, off.
log-level = "info"

[server]
#### Set listening address
#### addr = "127.0.0.1:20160"

#### Size of thread pool for gRPC
#### grpc-concurrency = 4
#### The number of gRPC connections between each TiKV instance
#### grpc-raft-conn-num = 10

#### Most read requests from TiDB are sent to the coprocessor of TiKV. This
  ↪ parameter is used to set the number of threads
#### of the coprocessor. If many read requests exist, add the number of
  ↪ threads and keep the number within that of the
#### system CPU cores. For example, for a 32-core machine deployed with TiKV
  ↪ , you can even set this parameter to 30 in
#### repeatable read scenarios. If this parameter is not set, TiKV
  ↪ automatically sets it to CPU cores * 0.8.
#### end-point-concurrency = 8

#### Tag the TiKV instances to schedule replicas.
```

```
#### labels = {zone = "cn-east-1", host = "118", disk = "ssd"}

[storage]
#### The data directory
#### data-dir = "/tmp/tikv/store"

#### In most cases, you can use the default value. When importing data, it
  ↳ is recommended to set the parameter to 1024000.
#### scheduler-concurrency = 102400
#### This parameter controls the number of write threads. When write
  ↳ operations occur frequently, set this parameter value
#### higher. Run `top -H -p tikv-pid` and if the threads named `sched-worker
  ↳ -pool` are busy, set the value of parameter
#### `scheduler-worker-pool-size` higher and increase the number of write
  ↳ threads.
#### scheduler-worker-pool-size = 4

[storage.block-cache]
##### Whether to create a shared block cache for all RocksDB column families
  ↳ .
##### ## Block cache is used by RocksDB to cache uncompressed blocks. Big
  ↳ block cache can speed up read.
##### It is recommended to turn on shared block cache. Since only the total
  ↳ cache size need to be
##### set, it is easier to configure. In most cases, it should be able to
  ↳ auto-balance cache usage
##### between column families with standard LRU algorithm.
##### ## The rest of config in the storage.block-cache session is effective
  ↳ only when shared block cache
##### is on.
#### shared = true

##### Size of the shared block cache. Normally it should be tuned to 30%-50%
  ↳ of system's total memory.
##### When the config is not set, it is decided by the sum of the following
  ↳ fields or their default
##### value:
##### * rocksdb.defaultcf.block-cache-size or 25% of system's total memory
##### * rocksdb.writecf.block-cache-size or 15% of system's total memory
##### * rocksdb.lockcf.block-cache-size or 2% of system's total memory
##### * raftdb.defaultcf.block-cache-size or 2% of system's total memory
##### ## To deploy multiple TiKV nodes on a single physical machine,
  ↳ configure this parameter explicitly.
##### Otherwise, the OOM problem might occur in TiKV.
#### capacity = "1GB"
```

```
[pd]
#### PD address
#### endpoints = ["127.0.0.1:2379","127.0.0.2:2379","127.0.0.3:2379"]

[metric]
#### The interval of pushing metrics to Prometheus Pushgateway
interval = "15s"
#### Prometheus Pushgateway address
address = ""
job = "tikv"

[raftstore]
#### Raft RocksDB directory. The default value is Raft subdirectory of [
  ↪ storage.data-dir].
#### If there are multiple disks on the machine, store the data of Raft
  ↪ RocksDB on different disks to improve TiKV performance.
#### raftdb-path = "/tmp/tikv/store/raft"

#### When the data size change in a Region is larger than the threshold
  ↪ value, TiKV checks whether this Region needs split.
#### To reduce the costs of scanning data in the checking process, set the
  ↪ value to 32 MB during the data import process. In the normal
  ↪ operation status, set it to the default value.
region-split-check-diff = "32MB"

[coprocessor]
##### If the size of a Region with the range of [a,e) is larger than the
  ↪ value of `region_max_size`, TiKV trys to split the Region to several
  ↪ Regions, for example, the Regions with the ranges of [a,b), [b,c), [c
  ↪ ,d), and [d,e).
##### After the Region split, the size of the split Regions is equal to the
  ↪ value of `region_split_size` (or slightly larger than the value of `
  ↪ region_split_size`).
#### region-max-size = "144MB"
#### region-split-size = "96MB"

[rocksdb]
#### The maximum number of threads of RocksDB background tasks. The
  ↪ background tasks include compaction and flush.
#### For detailed information why RocksDB needs to implement compaction, see
  ↪ RocksDB-related materials. When write
#### traffic (like the importing data size) is big, it is recommended to
  ↪ enable more threads. But set the number of the enabled
#### threads smaller than that of CPU cores. For example, when importing
```

```
    ↪ data, for a machine with a 32-core CPU,
#### set the value to 28.
#### max-background-jobs = 8

#### The maximum number of file handles RocksDB can open
#### max-open-files = 40960

#### The file size limit of RocksDB MANIFEST. For more details, see https://
    ↪ github.com/facebook/rocksdb/wiki/MANIFEST
max-manifest-file-size = "20MB"

#### The directory of RocksDB write-ahead logs. If there are two disks on
    ↪ the machine, store the RocksDB data and WAL logs
#### on different disks to improve TiKV performance.
#### wal-dir = "/tmp/tikv/store"

#### Use the following two parameters to deal with RocksDB archiving WAL.
#### For more details, see https://github.com/facebook/rocksdb/wiki/How-to-
    ↪ persist-in-memory-RocksDB-database%3F
#### wal-ttl-seconds = 0
#### wal-size-limit = 0

#### In most cases, set the maximum total size of RocksDB WAL logs to the
    ↪ default value.
#### max-total-wal-size = "4GB"

#### Use this parameter to enable or disable the statistics of RocksDB.
#### enable-statistics = true

#### Use this parameter to enable the readahead feature during RocksDB
    ↪ compaction. If you are using mechanical disks, it is recommended to
    ↪ set the value to 2MB at least.
#### compaction-readahead-size = "2MB"

[rocksdb.defaultcf]
#### The data block size. RocksDB compresses data based on the unit of block
    ↪ .
#### Similar to page in other databases, block is the smallest unit cached
    ↪ in block-cache.
block-size = "64KB"

#### The compaction mode of each layer of RocksDB data. The optional values
    ↪ include no, snappy, zlib,
#### bzip2, lz4, lz4hc, and zstd.
#### "no:no:lz4:lz4:lz4:zstd:zstd" indicates there is no compaction of
```

```
↳ level0 and level1; lz4 compaction algorithm is used
#### from level2 to level4; zstd compaction algorithm is used from level5 to
↳ level6.
#### "no" means no compaction. "lz4" is a compaction algorithm with moderate
↳ speed and compaction ratio. The
#### compaction ratio of zlib is high. It is friendly to the storage space,
↳ but its compaction speed is slow. This
#### compaction occupies many CPU resources. Different machines deploy
↳ compaction modes according to CPU and I/O resources.
#### For example, if you use the compaction mode of "no:no:lz4:lz4:lz4:zstd:
↳ zstd" and find much I/O pressure of the
#### system (run the iostat command to find %util lasts 100%, or run the top
↳ command to find many iowaits) when writing
#### (importing) a lot of data while the CPU resources are adequate, you can
↳ compress level0 and level1 and exchange CPU
#### resources for I/O resources. If you use the compaction mode of "no:no:
↳ lz4:lz4:lz4:zstd:zstd" and you find the I/O
#### pressure of the system is not big when writing a lot of data, but CPU
↳ resources are inadequate. Then run the top
#### command and choose the -H option. If you find a lot of bg threads (
↳ namely the compaction thread of RocksDB) are
#### running, you can exchange I/O resources for CPU resources and change
↳ the compaction mode to "no:no:no:lz4:lz4:zstd:zstd".
#### In a word, it aims at making full use of the existing resources of the
↳ system and improving TiKV performance
#### in terms of the current resources.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

#### The RocksDB memtable size
write-buffer-size = "128MB"

#### The maximum number of the memtables. The data written into RocksDB is
↳ first recorded in the WAL log, and then inserted
#### into memtables. When the memtable reaches the size limit of `write-
↳ buffer-size`, it turns into read only and generates
#### a new memtable receiving new write operations. The flush threads of
↳ RocksDB will flush the read only memtable to the
#### disks to become an sst file of level0. `max-background-flushes`
↳ controls the maximum number of flush threads. When the
#### flush threads are busy, resulting in the number of the memtables
↳ waiting to be flushed to the disks reaching the limit
#### of `max-write-buffer-number`, RocksDB stalls the new operation.
#### "Stall" is a flow control mechanism of RocksDB. When importing data,
↳ you can set the `max-write-buffer-number` value
#### higher, like 10.
```

```
max-write-buffer-number = 5

#### When the number of sst files of level0 reaches the limit of `level0-
↳ slowdown-writes-trigger`, RocksDB
#### tries to slow down the write operation, because too many sst files of
↳ level0 can cause higher read pressure of
#### RocksDB. `level0-slowdown-writes-trigger` and `level0-stop-writes-
↳ trigger` are for the flow control of RocksDB.
#### When the number of sst files of level0 reaches 4 (the default value),
↳ the sst files of level0 and the sst files
#### of level1 which overlap those of level0 implement compaction to relieve
↳ the read pressure.
level0-slowdown-writes-trigger = 20

#### When the number of sst files of level0 reaches the limit of `level0-
↳ stop-writes-trigger`, RocksDB stalls the new
#### write operation.
level0-stop-writes-trigger = 36

#### When the level1 data size reaches the limit value of `max-bytes-for-
↳ level-base`, the sst files of level1
#### and their overlap sst files of level2 implement compaction. The golden
↳ rule: the first reference principle
#### of setting `max-bytes-for-level-base` is guaranteeing that the `max-
↳ bytes-for-level-base` value is roughly equal to the
#### data volume of level0. Thus unnecessary compaction is reduced. For
↳ example, if the compaction mode is
#### "no:no:lz4:lz4:lz4:lz4:lz4", the `max-bytes-for-level-base` value is
↳ write-buffer-size * 4, because there is no
#### compaction of level0 and level1 and the trigger condition of compaction
↳ for level0 is that the number of the
#### sst files reaches 4 (the default value). When both level0 and level1
↳ adopt compaction, it is necessary to analyze
#### RocksDB logs to know the size of an sst file compressed from an
↳ mentable. For example, if the file size is 32MB,
#### the proposed value of `max-bytes-for-level-base` is 32MB * 4 = 128MB.
max-bytes-for-level-base = "512MB"

#### The sst file size. The sst file size of level0 is influenced by the
↳ compaction algorithm of `write-buffer-size`
#### and level0. `target-file-size-base` is used to control the size of a
↳ single sst file of level1-level6.
target-file-size-base = "32MB"

[rocksdb.writecf]
```

```
#### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

#### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

#### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"

[raftdb]
#### The maximum number of the file handles RaftDB can open
#### max-open-files = 40960

#### Configure this parameter to enable or disable the RaftDB statistics
↳ information.
#### enable-statistics = true

#### Enable the readahead feature in RaftDB compaction. If you are using
↳ mechanical disks, it is recommended to set
#### this value to 2MB at least.
#### compaction-readahead-size = "2MB"

[raftdb.defaultcf]
#### Set it the same as `rocksdb.defaultcf.compression-per-level`.
compression-per-level = ["no", "no", "lz4", "lz4", "lz4", "zstd", "zstd"]

#### Set it the same as `rocksdb.defaultcf.write-buffer-size`.
write-buffer-size = "128MB"
max-write-buffer-number = 5
min-write-buffer-number-to-merge = 1

#### Set it the same as `rocksdb.defaultcf.max-bytes-for-level-base`.
max-bytes-for-level-base = "512MB"
target-file-size-base = "32MB"
```

9.2.1.3.2 TiKV memory usage

Besides block cache and write buffer which occupy the system memory, the system memory is occupied in the following scenarios:

- Some of the memory is reserved as the system's page cache.

- When TiKV processes large queries such as `select * from ...`, it reads data, generates the corresponding data structure in the memory, and returns this structure to TiDB. During this process, TiKV occupies some of the memory.

9.2.1.3.3 Recommended configuration of TiKV

- In production environments, it is not recommended to deploy TiKV on the machine whose CPU cores are less than 8 or the memory is less than 32GB.
- If you demand a high write throughput, it is recommended to use a disk with good throughput capacity.
- If you demand a very low read-write latency, it is recommended to use SSD with high IOPS.

9.2.1.4 Follower Read

When a read hotspot appears in a Region, the Region leader can become a read bottleneck for the entire system. In this situation, enabling the Follower Read feature can significantly reduce the load of the leader, and improve the throughput of the whole system by balancing the load among multiple followers. This document introduces the use and implementation mechanism of Follower Read.

9.2.1.4.1 Overview

The Follower Read feature refers to using any follower replica of a Region to serve a read request under the premise of strongly consistent reads. This feature improves the throughput of the TiDB cluster and reduces the load of the leader. It contains a series of load balancing mechanisms that offload TiKV read loads from the leader replica to the follower replica in a Region. TiKV's Follower Read implementation provides users with strongly consistent reads.

Note:

To achieve strongly consistent reads, the follower node currently needs to request the current execution progress from the leader node (that is `ReadIndex`), which causes an additional network request overhead. Therefore, the main benefits of Follower Read are to isolate read requests from write requests in the cluster and to increase overall read throughput.

9.2.1.4.2 Usage

To enable TiDB's Follower Read feature, modify the value of the `tidb_replica_read` variable to `follower` or `leader-and-follower`:

```
set [session | global] tidb_replica_read = '<target value>;'
```

Scope: SESSION | GLOBAL

Default: leader

This variable is used to set the expected data read mode.

- When the value of `tidb_replica_read` is set to `leader` or an empty string, TiDB maintains its original behavior and sends all read operations to the leader replica to perform.
- When the value of `tidb_replica_read` is set to `follower`, TiDB selects a follower replica of the Region to perform all read operations.
- When the value of `tidb_replica_read` is set to `leader-and-follower`, TiDB can select any replicas to perform read operations.

9.2.1.4.3 Implementation mechanism

Before the Follower Read feature was introduced, TiDB applied the strong leader principle and submitted all read and write requests to the leader node of a Region to handle. Although TiKV can distribute Regions evenly on multiple physical nodes, for each Region, only the leader can provide external services. The other followers can do nothing to handle read requests but receive the data replicated from the leader at all times and prepare for voting to elect a leader in case of a failover.

To allow data reading in the follower node without violating linearizability or affecting Snapshot Isolation in TiDB, the follower node needs to use `ReadIndex` of the Raft protocol to ensure that the read request can read the latest data that has been committed on the leader. At the TiDB level, the Follower Read feature simply needs to send the read request of a Region to a follower replica based on the load balancing policy.

Strongly consistent reads

When the follower node processes a read request, it first uses `ReadIndex` of the Raft protocol to interact with the leader of the Region, to obtain the latest commit index of the current Raft group. After the latest commit index of the leader is applied locally to the follower, the processing of a read request starts.

Follower replica selection strategy

Because the Follower Read feature does not affect TiDB's Snapshot Isolation transaction isolation level, TiDB adopts the round-robin strategy to select the follower replica. Currently, for the coprocessor requests, the granularity of the Follower Read load balancing policy is at the connection level. For a TiDB client connected to a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

However, for the non-coprocessor requests, such as a point query, the granularity of the Follower Read load balancing policy is at the transaction level. For a TiDB transaction on a specific Region, the selected follower is fixed, and is switched only when it fails or the scheduling policy is adjusted.

9.2.1.5 Tune TiFlash Performance

This document introduces how to tune the performance of TiFlash, including planning machine resources and tuning TiDB parameters.

9.2.1.5.1 Plan resources

If you want to save machine resources and have no requirement on isolation, you can use the method that combines the deployment of both TiKV and TiFlash. It is recommended that you save enough resources for TiKV and TiFlash respectively, and do not share disks.

9.2.1.5.2 Tune TiDB parameters

1. For the TiDB node dedicated to OLAP/TiFlash, it is recommended that you increase the value of the `tidb_distsql_scan_concurrency` configuration item for this node to 80:

```
set @@tidb_distsql_scan_concurrency = 80;
```

2. Enable the super batch feature:

You can use the `tidb_allow_batch_cop` variable to set whether to merge Region requests when reading from TiFlash.

When the number of Regions involved in the query is relatively large, try to set this variable to 1 (effective for coprocessor requests with `aggregation` operators that are pushed down to TiFlash), or set this variable to 2 (effective for all coprocessor requests that are pushed down to TiFlash).

```
set @@tidb_allow_batch_cop = 1;
```

3. Enable the optimization of pushing down aggregate functions before TiDB operators such as JOIN or UNION:

You can use the `tidb_opt_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations are quite slow in the query, try to set this variable to 1.

```
set @@tidb_opt_agg_push_down = 1;
```

4. Enable the optimization of pushing down aggregate functions with `Distinct` before TiDB operators such as `JOIN` or `UNION`:

You can use the `tidb_opt_distinct_agg_push_down` variable to control the optimizer to execute this optimization. When the aggregate operations with `Distinct` are quite slow in the query, try to set this variable to 1.

```
set @@tidb_opt_distinct_agg_push_down = 1;
```

9.2.2 Coprocessor Cache

Starting from v4.0, the TiDB instance supports caching the results of the calculation that is pushed down to TiKV (the Coprocessor Cache feature), which can accelerate the calculation process in some scenarios.

9.2.2.1 Configuration

You can configure Coprocessor Cache via the `tikv-client.copr-cache` configuration items in the TiDB configuration file. For details about how to enable and configure Coprocessor Cache, see [TiDB Configuration File](#).

9.2.2.2 Feature description

- When a SQL statement is executed on a single TiDB instance for the first time, the execution result is not cached.
- Calculation results are cached in the memory of TiDB. If the TiDB instance is restarted, the cache becomes invalid.
- The cache is not shared among TiDB instances.
- Only push-down calculation result is cached. Even if cache is hit, TiDB still need to perform subsequent calculation.
- The cache is in the unit of Region. Writing data to a Region causes the Region cache to be invalid. For this reason, the Coprocessor Cache feature mainly takes effect on the data that rarely changes.
- When push-down calculation requests are the same, the cache is hit. Usually in the following scenarios, the push-down calculation requests are the same or partially the same:
 - The SQL statements are the same. For example, the same SQL statement is executed repeatedly.
In this scenario, all the push-down calculation requests are consistent, and all requests can use the push-down calculation cache.
 - The SQL statements contain a changing condition, and the other parts are consistent. The changing condition is the primary key of the table or the partition.
In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.

- The SQL statements contain multiple changing conditions and the other parts are consistent. The changing conditions exactly match a compound index column.

In this scenario, some of the push-down calculation requests are the same with some previous requests, and these calculation requests can use the cached (previous) push-down calculation result.

- This feature is transparent to users. Enabling or disabling this feature does not affect the calculation result and only affects the SQL execution time.

9.2.2.3 Check the cache effect

You can check the cache effect of Coprocessor by executing `EXPLAIN ANALYZE` or viewing the Grafana monitoring panel.

9.2.2.3.1 Use `EXPLAIN ANALYZE`

You can view the cache hit rate in [Operators for accessing tables](#) by using the `EXPLAIN ANALYZE statement`. See the following example:

```
EXPLAIN ANALYZE SELECT * FROM t USE INDEX(a);
+--
↪ -----+-----+-----+-----+
↪
| id          | estRows | actRows | task  | access object
↪   | execution info
↪
↪ | operator info          | memory          | disk |
+--
↪ -----+-----+-----+-----+
↪
| IndexLookUp_6          | 262400.00 | 262400 | root  |
↪   | time:620.513742ms, loops:258, cop_task: {num:
↪   4, max: 5.530817ms, min: 1.51829ms, avg: 2.70883ms, p95: 5.530817ms,
↪   max_proc_keys: 2480, p95_proc_keys: 2480, tot_proc: 1ms, tot_wait: 1
↪   ms, rpc_num: 4, rpc_time: 10.816328ms, copr_cache_hit_rate: 0.75} | |
↪   6.685169219970703 MB | N/A |
| -IndexFullScan_4(Build) | 262400.00 | 262400 | cop[tikv] | table:t,
↪   index:a(a, c) | proc max:93ms, min:1ms, p80:93ms, p95:93ms, iters
↪   :275, tasks:4
↪
↪ | keep order:false, stats:pseudo | 1.7549400329589844 MB | N/A |
| -TableRowIDScan_5(Probe) | 262400.00 | 0      | cop[tikv] | table:t
↪   | time:0ns, loops:0
↪
↪ | keep order:false, stats:pseudo | N/A          | N/A |
```

The column `execution info` of the execution result gives the `copr_cache_hit_ratio` information, which indicates the hit rate of the Coprocessor Cache. The 0.75 in the above example means that the hit rate is about 75%.

9.2.2.3.2 View the Grafana monitoring panel

In Grafana, you can see the `copr-cache` panel in the `distsql` subsystem under the `tidb` namespace. This panel monitors the number of hits, misses, and cache discards of the Coprocessor Cache in the entire cluster.

9.3 SQL Tuning

9.3.1 SQL Tuning Overview

SQL is a declarative language. That is, an SQL statement describes *what the final result should look like* and not a set of steps to execute in sequence. TiDB will optimize the execution, and is semantically permitted to execute parts of the query in any order provided that it correctly returns the final result as described.

A useful comparison to SQL optimization, is to describe what happens when you use GPS navigation. From your provided address, *2955 Campus Drive San Mateo CA 94403*, the GPS software plans the most time-efficient way to route you. It may make use of various statistics such as previous trips, meta data such as speed limits, and in modern cases, a live feed of traffic information. Several of these analogies translate to TiDB.

This section introduces several concepts about query execution:

- [Understanding the Query Execution Plan](#) introduces how to use the `EXPLAIN` statement to understand how TiDB has decided to execute a statement.
- [SQL Optimization Process](#) introduces what optimizations TiDB is capable of using to improve query execution performance.
- [Control Execution Plans](#) introduces ways to control the generation of the execution plan. This can be useful in cases where the execution plan decided by TiDB is suboptimal.

9.3.2 Understanding the Query Execution Plan

9.3.2.1 TiDB Query Execution Plan Overview

Note:

When you use the MySQL client to connect to TiDB, to read the output result in a clearer way without line wrapping, you can use the `pager less` \hookrightarrow `-S` command. Then, after the `EXPLAIN` result is output, you can press the right arrow \rightarrow button on your keyboard to horizontally scroll through the output.

SQL is a declarative language. It describes what the results of a query should look like, **not the methodology** to actually retrieve those results. TiDB considers all the possible ways in which a query could be executed, including using what order to join tables and whether any potential indexes can be used. The process of *considering query execution plans* is known as SQL optimization.

The `EXPLAIN` statement shows the selected execution plan for a given statement. That is, after considering hundreds or thousands of ways in which the query could be executed, TiDB believes that this *plan* will consume the least resources and execute in the shortest amount of time:

```
CREATE TABLE t (id INT NOT NULL PRIMARY KEY auto_increment, a INT NOT NULL,
  ↪ pad1 VARCHAR(255), INDEX(a));
INSERT INTO t VALUES (1, 1, 'aaa'),(2,2, 'bbb');
EXPLAIN SELECT * FROM t WHERE a = 1;
```

```
Query OK, 0 rows affected (0.96 sec)
```

```
Query OK, 2 rows affected (0.02 sec)
```

```
Records: 2 Duplicates: 0 Warnings: 0
```

```
+--
```

```
↪ -----+-----+-----+-----+
↪
```

```
| id          | estRows | task  | access object |
↪ operator info          |
```

```
+--
```

```
↪ -----+-----+-----+-----+
↪
```

```
| IndexLookUp_10          | 10.00 | root  |              |
↪                          |
```

```
| -IndexRangeScan_8(Build) | 10.00 | cop[tikv] | table:t, index:a(a) |
↪ range:[1,1], keep order:false, stats:pseudo |
```

```
| -TableRowIDScan_9(Probe) | 10.00 | cop[tikv] | table:t          | keep
↪ order:false, stats:pseudo          |
```

- **IndexFullScan**: Similar to a “full table scan”, except that an index is scanned, rather than the table data.
- **IndexRangeScan**: Index scans with the specified range.

TiDB aggregates the data or calculation results scanned from TiKV/TiFlash. The data aggregation operators can be divided into the following categories:

- **TableReader**: Aggregates the data obtained by the underlying operators like `TableFullScan` or `TableRangeScan` in TiKV.
- **IndexReader**: Aggregates the data obtained by the underlying operators like `IndexFullScan` or `IndexRangeScan` in TiKV.
- **IndexLookup**: First aggregates the RowID (in TiKV) scanned by the Build side. Then at the Probe side, accurately reads the data from TiKV based on these RowIDs. At the Build side, there are operators like `IndexFullScan` or `IndexRangeScan`; at the Probe side, there is the `TableRowIDScan` operator.
- **IndexMerge**: Similar to `IndexLookup`. `IndexMerge` can be seen as an extension of `IndexLookupReader`. `IndexMerge` supports reading multiple indexes at the same time. There are many Builds and one Probe. The execution process of `IndexMerge` the same as that of `IndexLookup`.

While the structure appears as a tree, executing the query does not strictly require the child nodes to be completed before the parent nodes. TiDB supports intra-query parallelism, so a more accurate way to describe the execution is that the child nodes *flow into* their parent nodes. Parent, child and sibling operators *might* potentially be executing parts of the query in parallel.

In the previous example, the `-IndexRangeScan_8(Build)` operator finds the internal RowID for rows that match the `a(a)` index. The `-TableRowIDScan_9(Probe)` operator then retrieves these rows from the table.

Range query

In the `WHERE/HAVING/ON` conditions, the TiDB optimizer analyzes the result returned by the primary key query or the index key query. For example, these conditions might include comparison operators of the numeric and date type, such as `>`, `<`, `=`, `>=`, `<=`, and the character type such as `LIKE`.

Note:

- In order to use an index, the condition must be *sargable*. For example, the condition `YEAR(date_column) < 1992` can not use an index, but `date_column < '1992-01-01` can.

- It is recommended to compare data of the same type and **character set and collation**. Mixing types may require additional `cast` operations, or prevent indexes from being used.
- You can also use `AND` (intersection) and `OR` (union) to combine the range query conditions of one column. For a multi-dimensional composite index, you can use conditions in multiple columns. For example, regarding the composite index (a, b, c):
 - When a is an equivalent query, continue to figure out the query range of b; when b is also an equivalent query, continue to figure out the query range of c.
 - Otherwise, if a is a non-equivalent query, you can only figure out the range of a.

Task overview

Currently, calculation tasks of TiDB can be divided into two categories: cop tasks and root tasks. A `cop[tikv]` task indicates that the operator is performed inside the TiKV coprocessor. A `root` task indicates that it will be completed inside of TiDB.

One of the goals of SQL optimization is to push the calculation down to TiKV as much as possible. The Coprocessor in TiKV supports most of the built-in SQL functions (including the aggregate functions and the scalar functions), SQL `LIMIT` operations, index scans, and table scans. However, all `Join` operations can only be performed as root tasks in TiDB.

Operator info overview

The `operator info` can show useful information such as which conditions were able to be pushed down:

- `range: [1,1]` shows that the predicate from the where clause of the query (`a = 1`) was pushed right down to TiKV (the task is of `cop[tikv]`).
- `keep order:false` shows that the semantics of this query did not require TiKV to return the results in order. If the query were to be modified to require an order (such as `SELECT * FROM t WHERE a = 1 ORDER BY id`), then this condition would be `keep order:true`.
- `stats:pseudo` shows that the estimates shown in `estRows` might not be accurate. TiDB periodically updates statistics as part of a background operation. A manual update can also be performed by running `ANALYZE TABLE t`.

Different operators output different information after the `EXPLAIN` statement is executed. You can use optimizer hints to control the behavior of the optimizer, and thereby controlling the selection of the physical operators. For example, `/*+ HASH_JOIN(t1, t2)*/` means that the optimizer uses the `Hash Join` algorithm. For more details, see [Optimizer Hints](#).

9.3.2.2 EXPLAIN Walkthrough

Because SQL is a declarative language, you cannot automatically tell whether a query is executed efficiently. You must first use the **EXPLAIN** statement to learn the current execution plan.

The following statement from the **bikeshare example database** counts how many trips were taken on the July 1, 2017:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
  ↳ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
  ↳ -----+-----+-----+-----+
  ↳
  ↳ | id          | estRows | task      | access object | operator
  ↳ ↳ info
  ↳ ↳
  ↳ ↳ |
+--
  ↳ -----+-----+-----+-----+
  ↳
  ↳ | StreamAgg_20          | 1.00    | root      |               | funcs:count(
  ↳ ↳ Column#13)->Column#11
  ↳ ↳
  ↳ ↳ |
  ↳ | -TableReader_21      | 1.00    | root      |               | data:
  ↳ ↳ StreamAgg_9
  ↳ ↳
  ↳ ↳ |
  ↳ | -StreamAgg_9         | 1.00    | cop[tikv] |               | funcs:count
  ↳ ↳ (1)->Column#13
  ↳ ↳
  ↳ ↳ |
  ↳ | -Selection_19        | 250.00 | cop[tikv] |               | ge(
  ↳ ↳ bikeshare.trips.start_date, 2017-07-01 00:00:00.000000), le(bikeshare
  ↳ ↳ .trips.start_date, 2017-07-01 23:59:59.000000) |
  ↳ | -TableFullScan_18   | 10000.00 | cop[tikv] | table:trips | keep
  ↳ ↳ order:false, stats:pseudo
  ↳ ↳
  ↳ ↳ |
+--
  ↳ -----+-----+-----+-----+
  ↳
  ↳
5 rows in set (0.00 sec)
```

From the child operator `-TableFullScan_18` back, you can see its execution process as follows, which is currently suboptimal:

1. The coprocessor (TiKV) reads the entire `trips` table as a `TableFullScan` operation. It then passes the rows that it reads to the `Selection_19` operator, which is still within TiKV.
2. The `WHERE start_date BETWEEN ..` predicate is then filtered in the `Selection_19` \hookrightarrow operator. Approximately 250 rows are estimated to meet this selection. Note that this number is estimated according to the statistics and the operator's logic. The `-TableFullScan_18` operator shows `stats:pseudo`, which means that the table does not have the actual statistical information. After running `ANALYZE TABLE trips` to collect statistical information, the statistics are expected to be more accurate.
3. The rows that meet the selection criteria then have a `count` function applied to them. This is also completed inside the `StreamAgg_9` operator, which is still inside TiKV (`cop[tikv]`). The TiKV coprocessor can execute a number of MySQL built-in functions, `count` being one of them.
4. The results from `StreamAgg_9` are then sent to the `TableReader_21` operator which is now inside the TiDB server (the task of `root`). The `estRows` column value for this operator is 1, which means that the operator will receive one row from each of the TiKV Regions to be accessed. For more information about these requests, see [EXPLAIN ANALYZE](#).
5. The `StreamAgg_20` operator then applies a `count` function to each of the rows from the `-TableReader_21` operator, which you can see from `SHOW TABLE REGIONS` and will be about 56 rows. Because this is the root operator, it then returns results to the client.

Note:

For a general view of the Regions that a table contains, execute `SHOW TABLE` \hookrightarrow `REGIONS`.

9.3.2.2.1 Assess the current performance

`EXPLAIN` only returns the query execution plan but does not execute the query. To get the actual execution time, you can either execute the query or use `EXPLAIN ANALYZE`:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
  ↪ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
```

```
↪
```

```
↪
```

```

| id | estRows | actRows | task | access object |

  ↪
  ↪ | keep order:false, stats:pseudo
  ↪
  ↪ | N/A | N/A |
+---+
  ↪ -----+-----+-----+-----+-----+
  ↪
5 rows in set (1.03 sec)

```

The example query above takes 1.03 seconds to execute, which is an ideal performance.

From the result of `EXPLAIN ANALYZE` above, `actRows` indicates that some of the estimates (`estRows`) are inaccurate (expecting 10 thousand rows but finding 19 million rows), which is already indicated in the operator info (`stats:pseudo`) of `-TableFullScan_18`. If you run `ANALYZE TABLE` first and then `EXPLAIN ANALYZE` again, you can see that the estimates are much closer:

```
ANALYZE TABLE trips;
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
  ↳ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

Query OK, 0 rows affected (10.22 sec)

```

5 rows in set (0.93 sec)

```

After `ANALYZE TABLE` is executed, you can see that the estimated rows for the `-` `TableFullScan_18` operator is accurate and the estimate for `-Selection_19` is now also much closer. In the two cases above, although the execution plan (the set of operators TiDB uses to execute this query) has not changed, quite frequently sub-optimal plans are caused by outdated statistics.

In addition to `ANALYZE TABLE`, TiDB automatically regenerates statistics as a background operation after the threshold of `tidb_auto_analyze_ratio` is reached. You can see how close TiDB is to this threshold (how healthy TiDB considers the statistics to be) by executing the `SHOW STATS_HEALTHY` statement:

```
SHOW STATS_HEALTHY;
```

```

+-----+-----+-----+-----+
| Db_name | Table_name | Partition_name | Healthy |
+-----+-----+-----+-----+
| bikeshare | trips      |                | 100     |
+-----+-----+-----+-----+
1 row in set (0.00 sec)

```

9.3.2.2 Identify optimizations

The current execution plan is efficient in the following aspects:

- Most of the work is handled inside the TiKV coprocessor. Only 56 rows need to be sent across the network back to TiDB for processing. Each of these rows is short and contains only the count that matches the selection.

- Aggregating the count of rows both in TiDB (`StreamAgg_20`) and in TiKV (`-` `↔ StreamAgg_9`) uses the stream aggregation, which is very efficient in its memory usage.

The biggest issue with the current execution plan is that the predicate `start_date` `↔ BETWEEN '2017-07-01 00:00:00' AND '2017-07-01 23:59:59'` does not apply immediately. All rows are read first with a `TableFullScan` operator, and then a selection is applied afterwards. You can find out the cause from the output of `SHOW CREATE TABLE trips`:

```
SHOW CREATE TABLE trips\G
```

```
***** 1. row *****
      Table: trips
Create Table: CREATE TABLE `trips` (
  `trip_id` bigint(20) NOT NULL AUTO_INCREMENT,
  `duration` int(11) NOT NULL,
  `start_date` datetime DEFAULT NULL,
  `end_date` datetime DEFAULT NULL,
  `start_station_number` int(11) DEFAULT NULL,
  `start_station` varchar(255) DEFAULT NULL,
  `end_station_number` int(11) DEFAULT NULL,
  `end_station` varchar(255) DEFAULT NULL,
  `bike_number` varchar(255) DEFAULT NULL,
  `member_type` varchar(255) DEFAULT NULL,
  PRIMARY KEY (`trip_id`)
) ENGINE=InnoDB DEFAULT CHARSET=utf8mb4 COLLATE=utf8mb4_bin AUTO_INCREMENT
  ↳ =20477318
1 row in set (0.00 sec)
```

There is **NO** index on `start_date`. You would need an index in order to push this predicate into an index reader operator. Add an index as follows:

```
ALTER TABLE trips ADD INDEX (start_date);
```

```
Query OK, 0 rows affected (2 min 10.23 sec)
```

Note:

You can monitor the progress of DDL jobs using the `ADMIN SHOW DDL` `↔ JOBS` command. The defaults in TiDB are carefully chosen so that adding an index does not impact production workloads too much. For testing environments, consider increasing the `tidb_ddl_reorg_batch_size` and `tidb_ddl_reorg_worker_cnt` values. On a reference system, a batch size of 10240 and worker count of 32 can achieve a 10x performance improvement over the defaults.

After adding an index, you can then repeat the query in EXPLAIN. In the following output, you can see that a new execution plan is chosen, and the TableFullScan and Selection operators have been eliminated:

```
EXPLAIN SELECT count(*) FROM trips WHERE start_date BETWEEN '2017-07-01
↳ 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | task   | access object
↳          | operator info
↳
+--
↳ -----+-----+-----+-----+
↳
| StreamAgg_17 | 1.00    | root   |
↳          | funcs:count(Column#13)->Column
↳ #11
| -IndexReader_18 | 1.00    | root   |
↳          | index:StreamAgg_9
↳          |
| -StreamAgg_9   | 1.00    | cop[tikv] |
↳          | funcs:count(1)->Column#13
↳          |
| -IndexRangeScan_16 | 8471.88 | cop[tikv] | table:trips, index:
↳ start_date(start_date) | range:[2017-07-01 00:00:00,2017-07-01
↳ 23:59:59], keep order:false |
+--
↳ -----+-----+-----+-----+
↳
4 rows in set (0.00 sec)
```

To compare the actual execution time, you can again use EXPLAIN ANALYZE:

```
EXPLAIN ANALYZE SELECT count(*) FROM trips WHERE start_date BETWEEN '
↳ 2017-07-01 00:00:00' AND '2017-07-01 23:59:59';
```

```
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | actRows | task   | access object
↳          | execution info
↳
↳ | operator info | memory
↳ | disk |
```

```

+--
↪ -----+-----+-----+-----+
↪
| StreamAgg_17          | 1.00  | 1      | root      |

↪ Bytes | N/A |
| -IndexReader_18      | 1.00  | 1      | root      |
↪                                     | time:4.514278ms, loops:2,
↪ cop_task: {num: 1, max:4.462288ms, proc_keys: 11409, rpc_num: 1,
↪ rpc_time: 4.457148ms} | index:StreamAgg_9          |
↪ 238 Bytes | N/A |
| -StreamAgg_9         | 1.00  | 1      | cop[tikv] |
↪                                     | time:4ms, loops:12
↪
↪ | funcs:count(1)->Column#13          | N/A
↪ | N/A |
| -IndexRangeScan_16   | 8471.88 | 11409 | cop[tikv] | table:trips,
↪ index:start_date(start_date) | time:4ms, loops:12
↪
↪ | range:[2017-07-01 00:00:00,2017-07-01 23:59:59], keep order:false |
↪ N/A | N/A |
+--
↪ -----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

From the result above, the query time has reduced from 1.03 seconds to 0.0 seconds.

Note:

Another optimization that applies here is the coprocessor cache. If you are unable to add indexes, consider enabling the **coprocessor cache**. When it is enabled, as long as the Region has not been modified since the operator is last executed, TiKV will return the value from the cache. This will also help reduce much of the cost of the expensive **TableFullScan** and **Selection** operators.

9.3.2.3 Explain Statements That Use Indexes

TiDB supports several operators which make use of indexes to speed up query execution:

- [IndexLookup](#)
- [IndexReader](#)
- [Point_Get](#) and [Batch_Point_Get](#)
- [IndexFullScan](#)

The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (
  id INT NOT NULL PRIMARY KEY auto_increment,
  intkey INT NOT NULL,
  pad1 VARBINARY(1024),
  INDEX (intkey)
);

INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM
  ↪ dual;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
  ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
  ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, FLOOR(RAND()*1024), RANDOM_BYTES(1024) FROM t1
  ↪ a JOIN t1 b JOIN t1 c LIMIT 10000;
```

9.3.2.3.1 IndexLookup

TiDB uses the `IndexLookup` operator when retrieving data from a secondary index. In this case, the following queries will all use the `IndexLookup` operator on the `intkey` index:

```
EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT * FROM t1 WHERE intkey < 10;
EXPLAIN SELECT * FROM t1 WHERE intkey BETWEEN 300 AND 310;
EXPLAIN SELECT * FROM t1 WHERE intkey IN (123,29,98);
EXPLAIN SELECT * FROM t1 WHERE intkey >= 99 AND intkey <= 103;
```

```

↳ intkey) | range:[99,103], keep order:false |
| -TableRowIDScan_9(Probe) | 6.00  | cop[tikv] | table:t1
↳          | keep order:false          |
+--
↳ -----+-----+-----+
↳
3 rows in set (0.00 sec)

```

The IndexLookup operator has two child nodes:

- The `-IndexRangeScan_8(Build)` operator performs a range scan on the `intkey` index and retrieves the values of the internal RowID (for this table, the primary key).
- The `-TableRowIDScan_9(Probe)` operator then retrieves the full row from the table data.

Because an `IndexLookup` task requires two steps, the SQL Optimizer might choose the `TableFullScan` operator based on `statistics` in scenarios where a large number of rows match. In the following example, a large number of rows match the condition of `intkey > 100`, and a `TableFullScan` is chosen:

```
EXPLAIN SELECT * FROM t1 WHERE intkey > 100;
```

```
+--
  ↪ -----+-----+-----+-----+
  ↪
| id          | estRows | task   | access object | operator info
  ↪          |         |        |               |
+--
  ↪ -----+-----+-----+-----+
  ↪
| TableReader_7 | 898.50 | root   |               | data:Selection_6
  ↪          |         |        |               |
| -Selection_6  | 898.50 | cop[tikv] |               | gt(test.t1.intkey
  ↪          |         |        |               | , 100) |
| -TableFullScan_5 | 1010.00 | cop[tikv] | table:t1 | keep order:false
  ↪          |         |        |               |
+--
  ↪ -----+-----+-----+-----+
  ↪
3 rows in set (0.00 sec)
```

The `IndexLookup` operator can also be used to efficiently optimize `LIMIT` on an indexed column:

```
EXPLAIN SELECT * FROM t1 ORDER BY intkey DESC LIMIT 10;
```

```
+--
  ↪ -----+-----+-----+-----+
  ↪
| id          | estRows | task   | access object
  ↪          |         |        |               |
| operator info
  ↪          |
+--
  ↪ -----+-----+-----+-----+
  ↪
| IndexLookUp_21 | 10.00 | root   |
  ↪          |         |        |               |
|               | limit embedded(offset:0, count:10) |
| -Limit_20(Build) | 10.00 | cop[tikv] |
  ↪          | offset:0, count:10 |
| -IndexFullScan_18 | 10.00 | cop[tikv] | table:t1, index:intkey(
  ↪          | intkey) | keep order:true, desc |
```

```

| -TableRowIDScan_19(Probe) | 10.00 | cop[tikv] | table:t1
  ↳ | keep order:false, stats:pseudo |
+--
  ↳ -----+-----+-----+
  ↳
  ↳
4 rows in set (0.00 sec)

```

In the above example, the last 10 rows are read from the index `intkey`. These `RowID` values are then retrieved from the table data.

9.3.2.3.2 IndexReader

TiDB supports the *covering index optimization*. If all rows can be retrieved from an index, TiDB will skip the second step that is usually required in an `IndexLookup`. Consider the following two examples:

```

EXPLAIN SELECT * FROM t1 WHERE intkey = 123;
EXPLAIN SELECT id FROM t1 WHERE intkey = 123;

```

```

+--

  ↳

```

```

| Projection_4          | 1.00 | root | |
  ↳ test.t1.id         |      |      | |
| -IndexReader_6       | 1.00 | root | |
  ↳ index:IndexRangeScan_5 |      |      | |
| -IndexRangeScan_5   | 1.00 | cop[tikv] | table:t1, index:intkey(
  ↳ intkey) | range:[123,123], keep order:false |
+--
  ↳ -----+-----+-----+-----+
  ↳
3 rows in set (0.00 sec)

```

Because `id` is also the internal `RowID`, it is stored in the `intkey` index. After using the `intkey` index as part of `-IndexRangeScan_5`, the value of the `RowID` can be returned directly.

9.3.2.3.3 Point_Get and Batch_Point_Get

TiDB uses the `Point_Get` or `Batch_Point_Get` operator when retrieving data directly from a primary key or unique key. These operators are more efficient than `IndexLookup`. For example:

```

EXPLAIN SELECT * FROM t1 WHERE id = 1234;
EXPLAIN SELECT * FROM t1 WHERE id IN (1234,123);

ALTER TABLE t1 ADD unique_key INT;
UPDATE t1 SET unique_key = id;
ALTER TABLE t1 ADD UNIQUE KEY (unique_key);

EXPLAIN SELECT * FROM t1 WHERE unique_key = 1234;
EXPLAIN SELECT * FROM t1 WHERE unique_key IN (1234, 123);

```

```

9.3.2.3.4 IndexFullScan

Because indexes are ordered, the `IndexFullScan` operator can be used to optimize common queries such as the `MIN` or `MAX` values for an indexed value:

```
EXPLAIN SELECT MIN(intkey) FROM t1;
EXPLAIN SELECT MAX(intkey) FROM t1;
```

```
+--
  ↪ -----+-----+-----+
  ↪
| id          | estRows | task  | access object
  ↪ | operator info          |
+--
  ↪ -----+-----+-----+
  ↪
| StreamAgg_12          | 1.00   | root  |
  ↪ | funcs:min(test.t1.intkey)->Column#4 |
| -Limit_16            | 1.00   | root  |
  ↪ | offset:0, count:1          |
| -IndexReader_29      | 1.00   | root  |
  ↪ | index:Limit_28            |
| -Limit_28            | 1.00   | cop[tikv] |
  ↪ | offset:0, count:1          |
| -IndexFullScan_27    | 1.00   | cop[tikv] | table:t1, index:intkey(
  ↪ intkey) | keep order:true          |
+--
  ↪ -----+-----+-----+
  ↪
5 rows in set (0.00 sec)

+--
  ↪ -----+-----+-----+
  ↪
| id          | estRows | task  | access object
  ↪ | operator info          |
+--
  ↪ -----+-----+-----+
  ↪
| StreamAgg_12          | 1.00   | root  |
  ↪ | funcs:max(test.t1.intkey)->Column#4 |
| -Limit_16            | 1.00   | root  |
  ↪ | offset:0, count:1          |
| -IndexReader_29      | 1.00   | root  |
  ↪ | index:Limit_28            |
| -Limit_28            | 1.00   | cop[tikv] |
```

```
6 rows in set (0.00 sec)
```

The following statements will use the IndexFullScan operator to scan every row in the index:

```
EXPLAIN SELECT SUM(intkey) FROM t1;
EXPLAIN SELECT AVG(intkey) FROM t1;
```

```
+--
  ↪ -----+-----+-----+
  ↪
| id          | estRows | task  | access object |
  ↪ operator info          |
+--
  ↪ -----+-----+-----+
  ↪
| StreamAgg_20 | 1.00   | root  |               |
  ↪ funcs:sum(Column#6)->Column#4 |
| -IndexReader_21 | 1.00   | root  |               |
  ↪ index:StreamAgg_8          |
| -StreamAgg_8   | 1.00   | cop[tikv] |               |
  ↪ funcs:sum(test.t1.intkey)->Column#6 |
| -IndexFullScan_19 | 1010.00 | cop[tikv] | table:t1, index:intkey(
  ↪ intkey) | keep order:false          |
+--
  ↪ -----+-----+-----+
  ↪
4 rows in set (0.00 sec)

+--
  ↪ -----+-----+-----+
  ↪
| id          | estRows | task  | access object |
  ↪ operator info          |
+--
  ↪ -----+-----+-----+
  ↪
| StreamAgg_20 | 1.00   | root  |               |
  ↪ funcs:avg(Column#7, Column#8)->Column#4 |
| -IndexReader_21 | 1.00   | root  |               |
  ↪ index:StreamAgg_8          |
| -StreamAgg_8   | 1.00   | cop[tikv] |               |
  ↪ funcs:count(test.t1.intkey)->Column#7, funcs:sum(test.t1.intkey)->
  ↪ Column#8 |
| -IndexFullScan_19 | 1010.00 | cop[tikv] | table:t1, index:intkey(
```

```

    ↪ intkey) | keep order:false |
+--
    ↪ -----+-----+-----+-----+
    ↪
4 rows in set (0.00 sec)

```

In the above examples, `IndexFullScan` is more efficient than `TableFullScan` because the width of the value in the `(intkey + RowID)` index is less than the width of the full row.

The following statement does not support using an `IndexFullScan` operator because additional columns are required from the table:

```
EXPLAIN SELECT AVG(intkey), ANY_VALUE(pad1) FROM t1;
```

```

+--
    ↪ -----+-----+-----+-----+

    ↪
    ↪ |
+--
    ↪ -----+-----+-----+-----+
    ↪
5 rows in set (0.00 sec)

```

9.3.2.4 Explain Statements That Use Joins

In TiDB, the SQL Optimizer needs to decide in which order tables should be joined and what is the most efficient join algorithm for a particular SQL statement. The examples in this document are based on the following sample data:

```
CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,  
  ↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);  
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id  
  ↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM dual;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;  
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),  
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
```

```

INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↪ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
  ↪ LIMIT 1);
SELECT SLEEP(1);
ANALYZE TABLE t1, t2;

```

9.3.2.4.1 Index Join

If the number of estimated rows that need to be joined is small (typically less than 10000 rows), it is preferable to use the index join method. This method of join works similar to the primary method of join used in MySQL. In the following example, the operator `↪ TableReader_28(Build)` first reads the table `t1`. For each row that matches, TiDB will probe the table `t2`:

```

EXPLAIN SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON t1.id =
  ↪ t2.t1_id;

```

```

↳
6 rows in set (0.44 sec)

```

In the above example, the index join operation is missing an index on `t1.int_col`. Once this index is added, the performance of the operation improves from 0.61 sec to 0.14 sec, as the following result shows:

```

-- Re-add index
ALTER TABLE t2 ADD INDEX (t1_id);

EXPLAIN ANALYZE SELECT /*+ INL_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
↳ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1 INNER JOIN t2 ON
↳ t1.id = t2.t1_id WHERE t1.int_col = 1;
EXPLAIN ANALYZE SELECT * FROM t1 INNER JOIN t2 ON t1.id = t2.t1_id WHERE t1
↳ .int_col = 1;

```

```

Query OK, 0 rows affected (3.65 sec)

Note:

In the above example, the SQL Optimizer selects the hash join plan which performs worse than the index join. Query optimization is an [NP-complete problem](#), and less-than-optimal plans might be chosen. If this is a frequent query, it is recommended to use [SQL Plan Management](#) to bind a hint to a query, which can be easier to manage than inserting hints into queries that your application sends to TiDB.

Variations of Index Join

An index join operation using the hint [INL_JOIN](#) creates a hash table of the intermediate results before joining on the outer table. TiDB also supports creating a hash table on the outer table using the hint [INL_HASH_JOIN](#). Each of these variations of index join is automatically selected by the SQL Optimizer.

Configuration

Index join performance is influenced by the following system variables:

- `tidb_index_join_batch_size` (default value: 25000) - the batch size of index
↪ lookup join operations.
- `tidb_index_lookup_join_concurrency` (default value: 4) - the number of concurrent index lookup tasks.

9.3.2.4.2 Hash Join

In a hash join operation, TiDB reads and caches the data on the **Build** side of the join in a hash table, and then reads the data on the **Probe** side of the join, probing the hash table to access required rows. Hash joins require more memory to execute than index joins but execute much faster when there are a lot of rows that need to be joined. The hash join operator is multi-threaded in TiDB and executes in parallel.

An example of hash join is as follows:

```
EXPLAIN SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```

  ↪ info          |         |           |               |
+--
  ↪ -----+-----+-----+
  ↪
| HashJoin_27 | 142020.00 | root      |               | inner join,
  ↪ equal:[eq(test.t1.id, test.t2.id)] |
| -TableReader_29(Build) | 142020.00 | root      |               | data:
  ↪ TableFullScan_28           |
|   -TableFullScan_28      | 142020.00 | cop[tikv] | table:t1      | keep order:
  ↪ false                       |
| -TableReader_31(Probe)  | 180000.00 | root      |               | data:
  ↪ TableFullScan_30           |
|   -TableFullScan_30      | 180000.00 | cop[tikv] | table:t2      | keep order:
  ↪ false                       |
+--
  ↪ -----+-----+-----+
  ↪
5 rows in set (0.00 sec)
```

For the execution process of `HashJoin_27`, TiDB performs the following operations in order:

1. Cache the data of the **Build** side in memory.
2. Construct a Hash Table on the **Build** side based on the cached data.
3. Read the data at the **Probe** side.

4. Use the data of the Probe side to probe the Hash Table.
5. Return qualified data to the user.

The `operator info` column in the `EXPLAIN` result table also records other information about `HashJoin_27`, including whether the query is Inner Join or Outer Join, and what are the conditions of Join. In the above example, the query is an Inner Join, where the Join condition `equal:[eq(test.t1.id, test.t2.id)]` partly corresponds with the query condition `WHERE t1.id = t2.id`. The operator info of the other Join operators in the following examples is similar to this one.

Runtime Statistics

If `tidb_mem_quota_query` (default value: 1GB) is exceeded, TiDB will attempt to use temporary storage on condition that the `oom-use-tmp-storage` value is `true` (default). This means that the Build operator used as part of the hash join might be created on disk. Runtime statistics such as memory usage are visible in the `execution info` of the `EXPLAIN ANALYZE` result table. The following example shows the output of `EXPLAIN ANALYZE` with a 1GB (default) `tidb_mem_quota_query` quota, and a 500MB quota. At 500MB, disk is used for temporary storage:

```
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
  ↳ t2.id;
SET tidb_mem_quota_query=500 * 1024 * 1024;
EXPLAIN ANALYZE SELECT /*+ HASH_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id =
  ↳ t2.id;
```

Configuration

Hash join performance is influenced by the following system variables:

- `tidb_mem_quota_query` (default value: 1GB) - if the memory quota for a query is exceeded, TiDB will attempt to spill the Build operator of a hash join to disk to save memory.
- `tidb_hash_join_concurrency` (default value: 5) - the number of concurrent hash join tasks.

9.3.2.4.3 Merge Join

Merge join is a special sort of join that applies when both sides of the join are read in sorted order. It can be described as similar to an *efficient zipper merge*: as data is read on both the Build and the Probe sides of the join, the join operation works like a streaming operation. Merge joins require far less memory than hash join but do not execute in parallel.

The following is an example:

```
EXPLAIN SELECT /*+ MERGE_JOIN(t1, t2) */ * FROM t1, t2 WHERE t1.id = t2.id;
```

```

+--
  ↪ -----+-----+-----+-----+

  ↪ true
+--
  ↪ -----+-----+-----+-----+
  ↪
5 rows in set (0.00 sec)

```

For the execution process of the merge join operator, TiDB performs the following operations:

1. Read all the data of a Join Group from the Build side into the memory.
2. Read the data of the Probe side.
3. Compare whether each row of data on the Probe side matches a complete Join Group on the Build side. Apart from equivalent conditions, there are non-equivalent conditions. Here “match” mainly refers to checking whether non-equivalent conditions are met. Join Group refers to the data with the same value among all Join Keys.

9.3.2.5 Explain Statements in the MPP Mode

TiDB supports using the **MPP mode** to execute queries. In the MPP mode, the TiDB optimizer generates execution plans for MPP. Note that the MPP mode is only available for tables that have replicas on **TiFlash**.

The examples in this document are based on the following sample data:

```

CREATE TABLE t1 (id int, value int);
INSERT INTO t1 values(1,2),(2,3),(1,3);
ALTER TABLE t1 set tiflash replica 1;
ANALYZE TABLE t1;

```

```
SET tidb_allow_mpp = 1;
```

9.3.2.5.1 MPP query fragments and MPP tasks

In the MPP mode, a query is logically sliced into multiple query fragments. Take the following statement as an example:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

This query is divided into two fragments in the MPP mode. One for the first-stage aggregation and the other for the second-stage aggregation, also the final aggregation. When this query is executed, each query fragment is instantiated into one or more MPP tasks.

9.3.2.5.2 Exchange operators

`ExchangeReceiver` and `ExchangeSender` are two exchange operators specific for MPP execution plans. The `ExchangeReceiver` operator reads data from downstream query fragments and the `ExchangeSender` operator sends data from downstream query fragments to upstream query fragments. In the MPP mode, the root operator of each MPP query fragment is `ExchangeSender`, meaning that query fragments are delimited by the `ExchangeSender` operator.

The following is a simple MPP execution plan:

```
EXPLAIN SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--

↪ inner join, equal:[eq(test.t1.id, test.t1.id)] |
| -ExchangeReceiver_19(Build) | 6.00 | cop[tiflash] | |
↪ |
| -ExchangeSender_18 | 6.00 | cop[tiflash] | |
↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
| -Selection_17 | 6.00 | cop[tiflash] | |
↪ not(isnull(test.t1.id)) |
| -TableFullScan_16 | 6.00 | cop[tiflash] | table:a |
↪ keep order:false |
| -ExchangeReceiver_23(Probe) | 6.00 | cop[tiflash] | |
↪ |
| -ExchangeSender_22 | 6.00 | cop[tiflash] | |
↪ ExchangeType: HashPartition, Hash Cols: test.t1.id |
| -Selection_21 | 6.00 | cop[tiflash] | |
↪ not(isnull(test.t1.id)) |
| -TableFullScan_20 | 6.00 | cop[tiflash] | table:b |
↪ keep order:false |
+--
↪ -----+-----+-----+
↪
12 rows in set (0.00 sec)
```

In the above execution plan:

- The query fragment [TableFullScan_20, Selection_21, ExchangeSender_22] reads data from table b and shuffles data to upstream MPP tasks.
- The query fragment [TableFullScan_16, Selection_17, ExchangeSender_18] reads data from table a and shuffles data to upstream MPP tasks.
- The query fragment [ExchangeReceiver_19, ExchangeReceiver_23, HashJoin_44 ↪ , ExchangeSender_47] joins all data and returns it to TiDB.

A typical execution plan for Broadcast Join is as follows:

```
EXPLAIN SELECT COUNT(*) FROM t1 a JOIN t1 b ON a.id = b.id;
```

```
+--
↪ -----+-----+-----+
↪
| id          | estRows | task      | access object |
↪ operator info          |
+--
↪ -----+-----+-----+
↪
| StreamAgg_15          | 1.00    | root      |               |
↪ funcs:count(1)->Column#7          |
| -TableReader_47      | 9.00    | root      |               |
↪ data:ExchangeSender_46          |
|   -ExchangeSender_46 | 9.00    | cop[tiflash] |               |
↪ ExchangeType: PassThrough          |
|   -HashJoin_43       | 9.00    | cop[tiflash] |               |
↪ inner join, equal:[eq(test.t1.id, test.t1.id)] |
|     -ExchangeReceiver_20(Build) | 6.00    | cop[tiflash] |               |
↪                                     |
|       -ExchangeSender_19 | 6.00    | cop[tiflash] |               |
↪ ExchangeType: Broadcast          |
|         -Selection_18 | 6.00    | cop[tiflash] |               |
↪ not(isnull(test.t1.id))          |
|           -TableFullScan_17 | 6.00    | cop[tiflash] | table:a       |
↪ keep order:false          |
|             -Selection_22(Probe) | 6.00    | cop[tiflash] |               |
↪ not(isnull(test.t1.id))          |
|               -TableFullScan_21 | 6.00    | cop[tiflash] | table:b       |
↪ keep order:false          |
+--
↪ -----+-----+-----+
↪
```

In the above execution plan:

- The query fragment [TableFullScan_17, Selection_18, ExchangeSender_19] reads data from the small table (table a) and broadcasts the data to each node that contains data from the large table (table b).
- The query fragment [TableFullScan_21, Selection_22, ExchangeReceiver_20, ↪ HashJoin_43, ExchangeSender_46] joins all data and returns it to TiDB.

9.3.2.5.3 EXPLAIN ANALYZE statements in the MPP mode

The EXPLAIN ANALYZE statement is similar to EXPLAIN, but it also outputs some runtime information.

The following is the output of a simple EXPLAIN ANALYZE example:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1 GROUP BY id;
```

```
+--
↪ -----+-----+-----+-----+

↪       | group by:test.t1.id, funcs:count
↪ (1)->Column#7            | N/A  | N/A  |
|   -TableFullScan_25      | 6.00 | 0      | batchCop[tiflash] |
↪ table:t1 | tiflash_task:{time:9.49ms, loops:0, threads:0}
↪       | keep order:false
↪       | N/A   | N/A   |
+---
↪ -----+-----+-----+-----+
↪

```

Compared to the output of EXPLAIN, the operator info column of the operator ExchangeSender also shows `tasks`, which records the id of the MPP task that the query fragment instantiates into. In addition, each MPP operator has a `threads` field in the `execution info` column, which records the concurrency of operations when TiDB executes this operator. If the cluster consists of multiple nodes, this concurrency is the result of adding up the concurrency of all nodes.

9.3.2.6 Explain Statements That Use Subqueries

TiDB performs [several optimizations](#) to improve the performance of subqueries. This document describes some of these optimizations for common subqueries and how to interpret the output of EXPLAIN.

The examples in this document are based on the following sample data:

```

CREATE TABLE t1 (id BIGINT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
↪ pad2 BLOB, pad3 BLOB, int_col INT NOT NULL DEFAULT 0);
CREATE TABLE t2 (id BIGINT NOT NULL PRIMARY KEY auto_increment, t1_id
↪ BIGINT NOT NULL, pad1 BLOB, pad2 BLOB, pad3 BLOB, INDEX(t1_id));
CREATE TABLE t3 (
id INT NOT NULL PRIMARY KEY auto_increment,
t1_id INT NOT NULL,
UNIQUE (t1_id)
);

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
↪ RANDOM_BYTES(1024), 0 FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
↪ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

```

```
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024), 0 FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t2 SELECT NULL, a.id, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
UPDATE t1 SET int_col = 1 WHERE pad1 = (SELECT pad1 FROM t1 ORDER BY RAND()
  ↳ LIMIT 1);
INSERT INTO t3 SELECT NULL, id FROM t1 WHERE id < 1000;

SELECT SLEEP(1);
ANALYZE TABLE t1, t2, t3;
```

9.3.2.6.1 Inner join (non-unique subquery)

In the following example, the IN subquery searches for a list of IDs from the table t2 ↵ . For semantic correctness, TiDB needs to guarantee that the column t1_id is unique. Using EXPLAIN, you can see the execution plan used to remove duplicates and perform an INNER JOIN operation:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2);
```

```
+--

↵ order:false
|   -TableRowIDScan_12(Probe) | 1.00  | cop[tikv] | table:t1
↵          | keep order:false
```

```

↪
↪ |
+--
↪ -----+-----+-----+-----
↪
8 rows in set (0.00 sec)

```

From the query results above, you can see that TiDB uses the index join operation `| ↪ IndexJoin_14` to join and transform the subquery. In the execution plan, the execution process is as follows:

1. The index scanning operator `- IndexFullScan_31` at the TiKV side reads the values of the `t2.t1_id` column.
2. Some tasks of the `- StreamAgg_39` operator deduplicate the values of `t1_id` in TiKV.
3. Some tasks of the `- StreamAgg_49(Build)` operator deduplicate the values of `t1_id` in TiDB. The deduplication is performed by the aggregate function `firstrow(test. ↪ t2.t1_id)`.
4. The operation results are joined with the primary key of the `t1` table. The join condition is `eq(test.t1.id, test.t2.t1_id)`.

9.3.2.6.2 Inner join (unique subquery)

In the previous example, aggregation is required to ensure that the values of `t1_id` are unique before joining against the table `t1`. But in the following example, `t3.t1_id` is already guaranteed unique because of a `UNIQUE` constraint:

```
EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t3);
```

```

|  -TableRowIDScan_15(Probe) | 1.00   | cop[tikv] | table:t1
|  ↪                          | keep order:false
|  ↪
|  ↪ |
+--
|  ↪ -----+-----+-----+-----
|  ↪
6 rows in set (0.01 sec)

```

Semantically because `t3.t1_id` is guaranteed unique, it can be executed directly as an `INNER JOIN`.

9.3.2.6.3 Semi join (correlated subquery)

In the previous two examples, TiDB is able to perform an `INNER JOIN` operation after the data inside the subquery is made unique (via `StreamAgg`) or guaranteed unique. Both joins are performed using an Index Join.

In this example, TiDB chooses a different execution plan:

```

EXPLAIN SELECT * FROM t1 WHERE id IN (SELECT t1_id FROM t2 WHERE t1_id !=
|  ↪ t1.int_col);

```

```

+--
|  ↪ -----+-----+-----+-----
|  ↪
| id          | estRows | task      | access object |
|  ↪ operator info
|  ↪
|  ↪ |
+--
|  ↪ -----+-----+-----+-----
| MergeJoin_9 | 45446.40 | root      |               |
|  ↪ semi join, left key:test.t1.id, right key:test.t2.t1_id, other cond:
|  ↪ ne(test.t2.t1_id, test.t1.int_col) |

```

```

| -IndexReader_24(Build) | 180000.00 | root |
  ↳ | index:IndexFullScan_23
  ↳
| -IndexFullScan_23 | 180000.00 | cop[tikv] | table:t2, index:t1_id(
  ↳ t1_id) | keep order:true
  ↳
| -TableReader_22(Probe) | 56808.00 | root |
  ↳ | data:Selection_21
  ↳
  ↳ |
| -Selection_21 | 56808.00 | cop[tikv] |
  ↳ | ne(test.t1.id, test.t1.int_col)
  ↳
| -TableFullScan_20 | 71010.00 | cop[tikv] | table:t1
  ↳ | keep order:true
  ↳
  ↳ |
+--
  ↳ -----+-----+-----+-----
  ↳
6 rows in set (0.00 sec)

```

From the result above, you can see that TiDB uses a **Semi Join** algorithm. Semi-join differs from inner join: semi-join only permits the first value on the right key (`t2.t1_id`), which means that the duplicates are eliminated as a part of the join operator task. The join algorithm is also Merge Join, which is like an efficient zipper-merge as the operator reads data from both the left and the right side in sorted order.

The original statement is considered a *correlated subquery*, because the subquery refers to a column (`t1.int_col`) that exists outside of the subquery. However, the output of `EXPLAIN` shows the execution plan after the **subquery decorrelation optimization** has been applied. The condition `t1_id != t1.int_col` is rewritten to `t1.id != t1.int_col`. TiDB can perform this in `-Selection_21` as it is reading data from the table `t1`, so this decorrelation and rewriting make the execution a lot more efficient.

9.3.2.6.4 Anti semi join (NOT IN subquery)

In the following example, the query semantically returns all rows from the table `t3` *unless* `t3.t1_id` is in the subquery:

```

EXPLAIN SELECT * FROM t3 WHERE t1_id NOT IN (SELECT id FROM t1 WHERE
  ↳ int_col < 100);

```

```

+--
  ↳ -----+-----+-----+-----
  ↳

```

```

| id          | estRows | task  | access object | operator
  ↳ info
+---
  ↳ -----+-----+-----+-----+
  ↳
| IndexMergeJoin_20 | 1598.40 | root  |               | anti semi join
  ↳ , inner:TableReader_15, outer key:test.t3.t1_id, inner key:test.t1.id
  ↳ |
| -TableReader_28(Build) | 1998.00 | root  |               | data:
  ↳ TableFullScan_27
| -TableFullScan_27 | 1998.00 | cop[tikv] | table:t3 | keep order:
  ↳ false
| -TableReader_15(Probe) | 1.00 | root  |               | data:
  ↳ Selection_14
| -Selection_14 | 1.00 | cop[tikv] |               | lt(test.t1.
  ↳ int_col, 100)
| -TableRangeScan_13 | 1.00 | cop[tikv] | table:t1 | range:
  ↳ decided by [test.t3.t1_id], keep order:true
+---
  ↳ -----+-----+-----+-----+
  ↳
6 rows in set (0.00 sec)

```

This query starts by reading the table `t3` and then probes the table `t1` based on the PRIMARY KEY. The join type is an *anti semi join*; anti because this example is for the non-existence of the value (NOT IN) and semi-join because only the first row needs to match before the join is rejected.

9.3.2.7 Explain Statements Using Aggregation

When aggregating data, the SQL Optimizer will select either a Hash Aggregation or Stream Aggregation operator. To improve query efficiency, aggregation is performed at both the coprocessor and TiDB layers. Consider the following example:

```

CREATE TABLE t1 (id INT NOT NULL PRIMARY KEY auto_increment, pad1 BLOB,
  ↳ pad2 BLOB, pad3 BLOB);
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM dual;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

```

```

INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
SELECT SLEEP(1);
ANALYZE TABLE t1;

```

From the output of `SHOW TABLE REGIONS`, you can see that this table is split into multiple Regions:

```
SHOW TABLE t1 REGIONS;
```

```

+---
  ↳ -----+-----+-----+-----+-----+-----+
  ↳
| REGION_ID | START_KEY | END_KEY   | LEADER_ID | LEADER_STORE_ID | PEERS |
  ↳ SCATTERING | WRITTEN_BYTES | READ_BYTES | APPROXIMATE_SIZE(MB) |
  ↳ APPROXIMATE_KEYS |
+---
  ↳ -----+-----+-----+-----+-----+
  ↳
|      64 | t_64_      | t_64_r_31766 | 65 |      1 | 65 |
  ↳      0 |      1325 | 102033520 |    |     98 |
  ↳ 52797 |
|      66 | t_64_r_31766 | t_64_r_63531 | 67 |      1 | 67 |
  ↳      0 |      1325 | 72522521 |    |    104 |
  ↳ 78495 |

```

```

|      68 | t_64_r_63531 | t_64_r_95296 | 69 |      1 | 69 |
↪      0 |      1325 |      0 |      104 |
↪ 95433 |
|      2 | t_64_r_95296 |      | 3 |      1 | 3 |
↪      0 |      1501 |      0 |      81 |
↪ 63211 |
+--
↪ -----+-----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

Using EXPLAIN with the following aggregation statement, you can see that `StreamAgg_8` is first performed on each Region inside TiKV. Each TiKV Region will then send one row back to TiDB, which aggregates the data from each Region in `StreamAgg_16`:

```
EXPLAIN SELECT COUNT(*) FROM t1;
```

```

+--
↪ -----+-----+-----+-----+
↪
| id          | estRows | task      | access object | operator
↪ info          |
+--
↪ -----+-----+-----+-----+
↪
| StreamAgg_16 | 1.00    | root     |               | funcs:count(
↪ Column#7)->Column#5 |
| -TableReader_17 | 1.00    | root     |               | data:
↪ StreamAgg_8     |
| -StreamAgg_8   | 1.00    | cop[tikv] |               | funcs:count
↪ (1)->Column#7   |
| -TableFullScan_15 | 242020.00 | cop[tikv] | table:t1 | keep order:
↪ false          |
+--
↪ -----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

This is easiest to observe in EXPLAIN ANALYZE, where the `actRows` matches the number of Regions from SHOW TABLE REGIONS because a `TableFullScan` is being used and there are no secondary indexes:

```
EXPLAIN ANALYZE SELECT COUNT(*) FROM t1;
```

```

+--
↳ -----+-----+-----+-----+
↳
| id                | estRows | actRows | task    | access object |
↳ execution info

↳
↳ | funcs:count(1)->Column#7 | N/A      | N/A |
| -TableFullScan_15 | 242020.00 | 121010 | cop[tikv] | table:t1 |
↳ proc max:12ms, min:12ms, p80:12ms, p95:12ms, iters:122, tasks:4
↳
↳ | keep order:false          | N/A      | N/A |
+--
↳ -----+-----+-----+-----+
↳
4 rows in set (0.01 sec)

```

9.3.2.7.1 Hash Aggregation

The Hash Aggregation algorithm uses a hash table to store intermediate results while performing aggregation. It executes in parallel using multiple threads but consumes more memory than Stream Aggregation.

The following is an example of the HashAgg operator:

```
EXPLAIN SELECT /*+ HASH_AGG() */ count(*) FROM t1;
```

```

+--
↳ -----+-----+-----+-----+

```

```

↪
| id          | estRows | task   | access object | operator
↪ info      |         |       |               |
+---
↪ -----+-----+-----+-----+
↪
| HashAgg_9   | 1.00    | root   |               | funcs:count(
↪ Column#6)->Column#5 |
| -TableReader_10 | 1.00    | root   |               | data:
↪ HashAgg_5   |         |       |               |
| -HashAgg_5   | 1.00    | cop[tikv] |               | funcs:count
↪ (1)->Column#6 |
| -TableFullScan_8 | 242020.00 | cop[tikv] | table:t1 | keep order:
↪ false      |
+---
↪ -----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

The operator `info` shows that the hashing function used to aggregate the data is `funcs:count(1)->Column#6`.

9.3.2.7.2 Stream Aggregation

The Stream Aggregation algorithm usually consumes less memory than Hash Aggregation. However, this operator requires that data is sent ordered so that it can *stream* and apply the aggregation on values as they arrive.

Consider the following example:

```

CREATE TABLE t2 (id INT NOT NULL PRIMARY KEY, col1 INT NOT NULL);
INSERT INTO t2 VALUES (1, 9),(2, 3),(3,1),(4,8),(6,3);
EXPLAIN SELECT /*+ STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;

```

```

Query OK, 0 rows affected (0.11 sec)

```

```

Query OK, 5 rows affected (0.01 sec)

```

```

Records: 5 Duplicates: 0 Warnings: 0

```

```

+---
↪ -----+-----+-----+-----+
↪
| id          | estRows | task   | access object | operator
↪ info      |         |       |               |
↪ |

```

```

+--
↪ -----+-----+-----+-----+
↪
| Projection_4          | 8000.00 | root   |          | test.t2.col1
↪   , Column#3
| -StreamAgg_8         | 8000.00 | root   |          | group by:
↪ test.t2.col1, funcs:count(1)->Column#3, funcs:firstrow(test.t2.col1)
↪ ->test.t2.col1 |
| -Sort_13             | 10000.00 | root   |          | test.t2.
↪ col1
↪
| -TableReader_12      | 10000.00 | root   |          | data:
↪ TableFullScan_11
↪
| -TableFullScan_11    | 10000.00 | cop[tikv] | table:t2 | keep order:
↪ false, stats:pseudo
↪ |
+--
↪ -----+-----+-----+-----+
↪
5 rows in set (0.00 sec)

```

In this example, the `-Sort_13` operator can be eliminated by adding an index on `col1` `↪` . Once the index is added, the data can be read in order and the `-Sort_13` operator is eliminated:

```

ALTER TABLE t2 ADD INDEX (col1);
EXPLAIN SELECT /** STREAM_AGG() */ col1, count(*) FROM t2 GROUP BY col1;

```

Query OK, 0 rows affected (0.28 sec)

```

+--
↪ -----+-----+-----+-----+
↪
| id                    | estRows | task   | access object          |
↪ operator info
↪
↪ |
+--
↪ -----+-----+-----+-----+
↪
| Projection_4          | 4.00    | root   |          |
↪ test.t2.col1, Column#3
↪
| -StreamAgg_14        | 4.00    | root   |          |

```

```

| -IndexRangeScan_10(Build) | 6372547.67 | cop[tikv] | table:trips, index:
  ↳ duration(duration) | range:(3600,+inf], keep order:false |
| -TableRowIDScan_11(Probe) | 6372547.67 | cop[tikv] | table:trips
  ↳ | keep order:false |
+--
  ↳ -----+-----+-----+
  ↳
3 rows in set (0.00 sec)

+--
  ↳ -----+-----+-----+
  ↳
| id | estRows | task | access object
  ↳ | operator info |
+--
  ↳ -----+-----+-----+
  ↳
| IndexLookUp_10 | 833219.37 | root |
  ↳ | | |
| -IndexRangeScan_8(Build) | 833219.37 | cop[tikv] | table:trips, index:
  ↳ duration(duration) | range:(3600,+inf], keep order:false |
| -TableRowIDScan_9(Probe) | 833219.37 | cop[tikv] | table:trips
  ↳ | keep order:false |
+--
  ↳ -----+-----+-----+
  ↳
3 rows in set (0.00 sec)

```

Similarly, predicates from the view are pushed down to the base table:

```

EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';

```

```

+--
  ↳ -----+-----+-----+
  ↳
| id | estRows | task | access object
  ↳ | operator info |
+--
  ↳ -----+-----+-----+
  ↳
| IndexLookUp_14 | 3.33 | root |
  ↳ | | |
  ↳ | | |
| -IndexRangeScan_11(Build) | 3333.33 | cop[tikv] | table:trips, index:

```

```

↳ duration(duration) | range:(3600,+inf], keep order:false, stats:
↳ pseudo |
| -Selection_13(Probe)      | 3.33 | cop[tikv] |
↳                               | eq(bikeshare.trips.bike_number, "
↳ W00950") |
| -TableRowIDScan_12      | 3333.33 | cop[tikv] | table:trips
↳                               | keep order:false, stats:pseudo |
+--
↳ -----+-----+-----+
↳
4 rows in set (0.00 sec)

+--
↳ -----+-----+-----+
↳
| id                | estRows | task      | access object | operator
↳ info                |         |           |               |
+--
↳ -----+-----+-----+
↳
| TableReader_7      | 43.00   | root     |               | data:
↳ Selection_6         |         |         |               |
| -Selection_6       | 43.00   | cop[tikv] |               | eq(bikeshare.
↳ trips.bike_number, "W00950") |
| -TableFullScan_5  | 19117643.00 | cop[tikv] | table:trips | keep order
↳ :false                |
+--
↳ -----+-----+-----+
↳
3 rows in set (0.00 sec)

```

In the first statement above, you can see that the index is used to satisfy the view definition, and then the `bike_number = 'W00950'` is applied when TiDB reads the table row. In the second statement, there are no indexes to satisfy the statement, and a `TableFullScan` is used.

TiDB makes use of indexes that satisfy both the view definition and the statement itself. Consider the following composite index:

```

ALTER TABLE trips ADD INDEX (bike_number, duration);
EXPLAIN SELECT * FROM long_trips WHERE bike_number = 'W00950';
EXPLAIN SELECT * FROM trips WHERE bike_number = 'W00950';

```

```

Query OK, 0 rows affected (2 min 31.20 sec)

```

```

+--
  ↳ -----+-----+-----+
  ↳
| IndexLookUp_10          | 19117.64 | root      |
  ↳
  ↳
| -IndexRangeScan_8(Build) | 19117.64 | cop[tikv] | table:trips, index:
  ↳ bike_number(bike_number, duration) | range:["W00950","W00950"], keep
  ↳ order:false |
| -TableRowIDScan_9(Probe) | 19117.64 | cop[tikv] | table:trips
  ↳
  ↳ | keep order:false
  ↳
+--
  ↳ -----+-----+-----+
  ↳
3 rows in set (0.00 sec)

```

In the first statement, TiDB is able to use both parts of the composite index (↔ `bike_number`, `duration`). In the second statement, only the first part which is `bike_number` of the index (`bike_number`, `duration`) is used.

9.3.2.9 Explain Statements Using Partitions

The `EXPLAIN` statement displays the partitions that TiDB needs to access in order to execute a query. Because of **partition pruning**, the displayed partitions are often only a subset of the overall partitions. This document describes some of the optimizations for common partitioned tables, and how to interpret the output of `EXPLAIN`.

The sample data used in this document:

```
CREATE TABLE t1 (
  id BIGINT NOT NULL auto_increment,
  d date NOT NULL,
  pad1 BLOB,
  pad2 BLOB,
  pad3 BLOB,
  PRIMARY KEY (id,d)
) PARTITION BY RANGE (YEAR(d)) (
  PARTITION p2016 VALUES LESS THAN (2017),
  PARTITION p2017 VALUES LESS THAN (2018),
  PARTITION p2018 VALUES LESS THAN (2019),
  PARTITION p2019 VALUES LESS THAN (2020),
  PARTITION pmax VALUES LESS THAN MAXVALUE
);

INSERT INTO t1 (d, pad1, pad2, pad3) VALUES
('2016-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2016-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2016-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2017-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2018-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2018-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2018-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2019-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-01-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-06-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024)),
('2020-09-01', RANDOM_BYTES(1024), RANDOM_BYTES(1024), RANDOM_BYTES(1024));
```

```

INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;
INSERT INTO t1 SELECT NULL, a.d, RANDOM_BYTES(1024), RANDOM_BYTES(1024),
  ↳ RANDOM_BYTES(1024) FROM t1 a JOIN t1 b JOIN t1 c LIMIT 10000;

SELECT SLEEP(1);
ANALYZE TABLE t1;

```

The following example shows a statement against the newly created partitioned table:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE d = '2017-06-01';
```

```

+---
↳ -----+-----+-----+-----+
↳
| id          | estRows | task  | access object |
↳ operator info |         |      |               |

↳ data:StreamAgg_10 |
| -StreamAgg_10 | 1.00    | cop[tikv] |               |
↳ funcs:count(1)->Column#8 |
| -Selection_20 | 8.87    | cop[tikv] |               | eq
↳ (test.t1.d, 2017-06-01 00:00:00.000000) |
| -TableFullScan_19 | 8870.00 | cop[tikv] | table:t1, partition:
↳ p2017 | keep order:false |
+---
↳ -----+-----+-----+-----+
↳
5 rows in set (0.01 sec)

```

Starting from the inner-most (-TableFullScan_19) operator and working back towards the root operator (StreamAgg_21):

- TiDB successfully identified that only one partition (p2017) needed to be accessed. This is noted under access object.

- The partition itself was scanned in the operator `-TableFullScan_19` and then `-Selection_20` was applied to filter for rows that have a start date of `2017-06-01 00:00:00.000000`.
- The rows that match `-Selection_20` are then stream aggregated in the coprocessor, which natively understands the `count` function.
- Each coprocessor request then sends back one row to `-TableReader_22` inside TiDB, which is then stream aggregated under `StreamAgg_21` and one row is returned to the client.

In the following example, partition pruning does not eliminate any partitions:

```
EXPLAIN SELECT COUNT(*) FROM t1 WHERE YEAR(d) = 2017;
```

```

|   ↪
27 rows in set (0.00 sec)

```

From the output above:

- TiDB believes that it needs to access all of the partitions (p2016..pMax). This is because the predicate `YEAR(d)= 2017` is considered [non-sargable](#). This issue is not specific to TiDB.
- As each partition is scanned, a `Selection` operator filters out rows that do not match the year of 2017.
- A stream aggregation on each partition is performed to count the number of rows that match.
- The operator `-PartitionUnion_21` unions the results from accessing each partition.

9.3.2.10 Explain Statements Using Index Merge

IndexMerge is a method introduced in TiDB v4.0 to access tables. Using this method, the TiDB optimizer can use multiple indexes per table and merge the results returned by each index. In some scenarios, this method makes the query more efficient by avoiding full table scans.

```
mysql> EXPLAIN SELECT * from t where a = 1 or b = 1;
+---+
| id | estRows | task | access object | operator info |
+---+
| TableReader_7 | 8000.00 | root | | data:Selection_6 |
| -Selection_6 | 8000.00 | cop[tikv] | | or(eq(test.t.a, 1), eq(test.t.b, 1)) |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:false, stats:pseudo |
+---+

mysql> set @@tidb_enable_index_merge = 1;
mysql> explain select * from t use index(idx_a, idx_b) where a > 1 or b > 1;
+---+
| id | estRows | task | access object | operator info |
+---+
| IndexMerge_16 | 6666.67 | root | | |
| -IndexRangeScan_13(Build) | 3333.33 | cop[tikv] | table:t, index:idx_a(a > 1) | range:(1,+inf], keep order:false, stats:pseudo |
| -IndexRangeScan_14(Build) | 3333.33 | cop[tikv] | table:t, index:idx_b(b > 1) | range:(1,+inf], keep order:false, stats:pseudo |
| -TableRowIDScan_15(Probe) | 6666.67 | cop[tikv] | table:t | keep order:false, stats:pseudo |
+---+
```

In the above query, the filter condition is a `WHERE` clause that uses `OR` as the connector. Without `IndexMerge`, you can use only one index per table. `a = 1` cannot be pushed down to the index `a`; neither can `b = 1` be pushed down to the index `b`. The full table scan is inefficient when a huge volume of data exists in `t`. To handle such a scenario, `IndexMerge` is introduced in TiDB to access tables.

`IndexMerge` allows the optimizer to use multiple indexes per table, and merge the results returned by each index to generate the execution plan of the latter `IndexMerge` in the figure above. Here the `IndexMerge_16` operator has three child nodes, among which `IndexRangeScan_13` and `IndexRangeScan_14` get all the `RowIDs` that meet the conditions based on the result of range scan, and then the `TableRowIDScan_15` operator accurately reads all the data that meets the conditions according to these `RowIDs`.

For the scan operation that is performed on a specific range of data, such as `IndexRangeScan/TableRowIDScan`, the operator `info` column in the result has additional information about the scan range compared with other scan operations like `IndexFullScan/TableRowIDScan`. In the above example, the `range:(1,+inf]` in the `IndexRangeScan_13` operator indicates that the operator scans the data from 1 to positive infinity.

Note:

- The Index Merge feature is enabled by default from v5.4.0. That is, `tidb_enable_index_merge` is ON.
- You can use the SQL hint `USE_INDEX_MERGE` to force the optimizer to apply Index Merge, regardless of the setting of `tidb_enable_index_merge` \leftrightarrow . To enable Index Merge when the filtering conditions contain expressions that cannot be pushed down, you must use the SQL hint `USE_INDEX_MERGE`.
- Index Merge supports only disjunctive normal form (expressions connected by `or`) and does not support conjunctive normal form (expressions connected by `and`).
- Index Merge is not supported in `temporay tables` for now.

9.3.3 SQL Optimization Process

9.3.3.1 SQL Optimization Process

In TiDB, the process from inputting a query to getting the execution result according to the final execution plan is illustrated as follows:

Figure 68: SQL Optimization Process

After parsing the original query text by `parser` and some simple validity checks, TiDB first makes some logically equivalent changes to the query. For detailed changes, see [SQL Logical Optimization](#).

Through these equivalent changes, this query becomes easier to handle in the logical execution plan. After the equivalent change is done, TiDB obtains a query plan structure equivalent to the original query, and then obtains a final execution plan based on the data distribution and the specific execution cost of an operator. For details, see [SQL Physical Optimization](#).

At the same time, when TiDB executes the `PREPARE` statement, you can choose to enable caching to reduce the cost of generating the execution plan in TiDB. For details, see [Execution Plan Cache](#).

9.3.3.2 Logic Optimization

9.3.3.2.1 SQL Logical Optimization

This chapter explains some key logic rewrites to help you understand how TiDB generates the final query plan. For example, when you execute the `select * from t where t.a in (select t1.a from t1 where t1.b=t.b)` query in TiDB, you will find that the `IN` sub-query `t.a in (select t1.a from t1 where t1.b=t.b)` does not exist because TiDB has made some rewrites here.

This chapter introduces the following key rewrites:

- [Subquery Related Optimizations](#)
- [Column Pruning](#)
- [Decorrelation of Correlated Subquery](#)
- [Eliminate Max/Min](#)
- [Predicates Push Down](#)
- [Partition Pruning](#)
- [TopN and Limit Operator Push Down](#)
- [Join Reorder](#)

9.3.3.2.2 Subquery Related Optimizations

This article mainly introduces subquery related optimizations.

Subqueries usually appear in the following situations:

- `NOT IN (SELECT ... FROM ...)`
- `NOT EXISTS (SELECT ... FROM ...)`
- `IN (SELECT ... FROM ...)`
- `EXISTS (SELECT ... FROM ...)`
- `... >/>= / </<= / != (SELECT ... FROM ...)`

Sometimes a subquery contains non-subquery columns, such as `select * from t where ↪ t.a in (select * from t2 where t.b=t2.b)`. The `t.b` column in the subquery does not belong to the subquery, it is introduced from the outside of the subquery. This kind of subquery is usually called a “correlated subquery”, and the externally introduced column is called a “correlated column”. For optimizations about correlated subquery, see [Decorrelation of correlated subquery](#). This article focuses on subqueries that do not involve correlated columns.

By default, subqueries use `semi join` mentioned in [Understanding TiDB Execution Plan](#) as the execution method. For some special subqueries, TiDB do some logical rewrite to get better performance.

```
... < ALL (SELECT ... FROM ...) or ... > ANY (SELECT ... FROM ...)
```

In this case, `ALL` and `ANY` can be replaced by `MAX` and `MIN`. When the table is empty, the result of `MAX(EXPR)` and `MIN(EXPR)` is `NULL`. It works the same when the result of `EXPR` contains `NULL`. Whether the result of `EXPR` contains `NULL` may affect the final result of the expression, so the complete rewrite is given in the following form:

- `t.id < all (select s.id from s)` is rewritten as `t.id < min(s.id) and if(sum(↪ s.id is null)!= 0, null, true)`
- `t.id < any (select s.id from s)` is rewritten as `t.id < max(s.id) or if(sum(s↪ .id is null)!= 0, null, false)`

```
... != ANY (SELECT ... FROM ...)
```

In this case, if all the values from the subquery are distinct, it is enough to compare the query with them. If the number of different values in the subquery is more than one, then there must be inequality. Therefore, such subqueries can be rewritten as follows:

- `select * from t where t.id != any (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct ↪ from s)where (t.id != s.id or cnt_distinct > 1)`

... = ALL (SELECT ... FROM ...)

In this case, when the number of different values in the subquery is more than one, then the result of this expression must be false. Therefore, such subquery is rewritten into the following form in TiDB:

- `select * from t where t.id = all (select s.id from s)` is rewritten as `select t.* from t, (select s.id, count(distinct s.id)as cnt_distinct ↪ from s)where (t.id = s.id and cnt_distinct <= 1)`

... IN (SELECT ... FROM ...)

In this case, the subquery of IN is rewritten into `SELECT ... FROM ... GROUP ...`, and then rewritten into the normal form of JOIN.

For example, `select * from t1 where t1.a in (select t2.a from t2)` is rewritten as `select t1.* from t1, (select distinct(a)a from t2)t2 where t1.a = t2.`
 ↪ The form of a. The DISTINCT attribute here can be eliminated automatically if t2.a has the UNIQUE attribute.

```
explain select * from t1 where t1.a in (select t2.a from t2);
```

```
+--
↪ -----+-----+-----+-----+
↪
| id          | estRows | task  | access object |

| -IndexReader_28      | 9990.00 | root  |               |
↪ index:IndexFullScan_27 |
| -IndexFullScan_27    | 9990.00 | cop[tikv] | table:t2, index:idx(a)
↪ | keep order:false, stats:pseudo |
```

```

| -TableReader_11(Probe) | 1.00 | root | | data
  ↳ :TableRangeScan_10
| -TableRangeScan_10 | 1.00 | cop[tikv] | table:t1 |
  ↳ range: decided by [test.t2.a], keep order:false, stats:pseudo |
+--
  ↳ -----+-----+-----+-----+
  ↳

```

This rewrite gets better performance when the IN subquery is relatively small and the external query is relatively large, because without rewriting, using `index join` with `t2` as the driving table is impossible. However, the disadvantage is that when the aggregation cannot be automatically eliminated during the rewrite and the `t2` table is relatively large, this rewrite affects the performance of the query. Currently, the variable `tidb_opt_insubq_to_join_and_agg` is used to control this optimization. When this optimization is not suitable, you can manually disable it.

EXISTS subquery and `... >/>=/</<=/?!= (SELECT ... FROM ...)`

At present, for a subquery in such scenarios, if the subquery is not a correlated subquery, TiDB evaluates it in advance in the optimization stage, and directly replaces it with a result set. As shown in the figure below, the EXISTS subquery is evaluated to TRUE in the optimization stage in advance, so it does not show in the final execution result.

```

create table t1(a int);
create table t2(a int);
insert into t2 values(1);
explain select * from t1 where exists (select * from t2);

```

```

+--
  ↳ -----+-----+-----+-----+

| -TableFullScan_11 | 10000.00 | cop[tikv] | table:t1 | keep order:false,
  ↳ stats:pseudo |
+--
  ↳ -----+-----+-----+-----+
  ↳

```

9.3.3.2.3 Column Pruning

The basic idea of column pruning is that for columns not used in the operator, the optimizer does not need to retain them during optimization. Removing these columns reduces the use of I/O resources and facilitates the subsequent optimization. The following is an example of column repetition:

Suppose there are four columns (a, b, c, and d) in table t. You can execute the following statement:

```
select a from t where b > 5
```

In this query, only column a and column b are used, and column c and column d are redundant. Regarding the query plan of this statement, the `Selection` operator uses column b. Then the `DataSource` operator uses columns a and column b. Columns c and column d can be pruned because the `DataSource` operator does not read them.

Therefore, when TiDB performs a top-down scanning during the logic optimization phase, redundant columns are pruned to reduce waste of resources. This scanning process is called “Column Pruning”, corresponding to the `columnPruner` rule. If you want to disable this rule, refer to [The Blocklist of Optimization Rules and Expression Pushdown](#).

9.3.3.2.4 Decorrelation of Correlated Subquery

[Subquery related optimizations](#) describes how TiDB handles subqueries when there are no correlated columns. Because decorrelation of correlated subquery is complex, this article introduces some simple scenarios and the scope to which the optimization rule applies.

Introduction

Take `select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b = t1.b)` as an example. The subquery `t1.a < (select sum(t2.a) from t2 where t2.b = t1.b)` here refers to the correlated column in the query condition `t2.b=t1.b`, this condition happens to be an equivalent condition, so the query can be rewritten as `select t1.* from t1, (select b, sum(a) sum_a from t2 group by b) t2 where t1.b = t2.b and t1.a < t2.sum_a`; . In this way, a correlated subquery is rewritten into JOIN.

The reason why TiDB needs to do this rewriting is that the correlated subquery is bound to its external query result every time the subquery is executed. In the above example, if `t1.a` has 10 million values, this subquery would repeat 10 million times, because the condition `t2.b=t1.b` varies with the value of `t1.a`. When the correlation is lifted somehow, this subquery would execute only once.

Restrictions

The disadvantage of this rewriting is that when the correlation is not lifted, the optimizer can use the index on the correlated column. That is, although this subquery may repeat many times, the index can be used to filter data each time. After using the rewriting rule, the position of the correlated column usually changes. Although the subquery is only executed once, the single execution time would be longer than that without decorrelation.

Therefore, when there are few external values, do not perform decorrelation, because it may bring better execution performance. At present, this optimization can be disabled by setting subquery decorrelation optimization rules in [blocklist of optimization rules and expression pushdown](#).

Example

```
create table t1(a int, b int);
create table t2(a int, b int, index idx(b));
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
↳ = t1.b);
```

```
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | task      | access object |
↳ operator info
↳
+--
↳ -----+-----+-----+-----+
↳
| HashJoin_11          | 9990.00 | root      |              | inner
↳ join, equal:[eq(test.t1.b, test.t2.b)], other cond:lt(cast(test.t1.a)
↳ , Column#7) |
| -HashAgg_23(Build)  | 7992.00 | root      |              | group by
↳ :test.t2.b, funcs:sum(Column#8)->Column#7, funcs:firstrow(test.t2.b)
↳ ->test.t2.b |
| -TableReader_24     | 7992.00 | root      |              | data:
↳ HashAgg_16
↳
| -HashAgg_16         | 7992.00 | cop[tikv] |              | group by
↳ :test.t2.b, funcs:sum(test.t2.a)->Column#8
| -Selection_22       | 9990.00 | cop[tikv] |              | not(
↳ isnull(test.t2.b))
↳
| -TableFullScan_21   | 10000.00 | cop[tikv] | table:t2     | keep
↳ order:false, stats:pseudo
↳
| -TableReader_15(Probe) | 9990.00 | root      |              | data:
↳ Selection_14
↳
| -Selection_14       | 9990.00 | cop[tikv] |              | not(
↳ isnull(test.t1.b))
↳
| -TableFullScan_13   | 10000.00 | cop[tikv] | table:t1     | keep
↳ order:false, stats:pseudo
```

```

↪
+--
↪
↪

```

The above is an example where the optimization takes effect. HashJoin_11 is a normal inner join.

Then, turn off the subquery decorrelation rules:

```

insert into mysql.opt_rule_blacklist values("decorrelate");
admin reload opt_rule_blacklist;
explain select * from t1 where t1.a < (select sum(t2.a) from t2 where t2.b
↪ = t1.b);

```

```

+--

↪      | CARTESIAN inner join, other cond:lt(cast(test.
↪ t1.a), Column#7)
| -TableReader_14(Build) | 10000.00 | root      |
↪      | data:TableFullScan_13
↪
| -TableFullScan_13 | 10000.00 | cop[tikv] | table:t1
↪      | keep order:false, stats:pseudo
↪
| -MaxOneRow_15(Probe) | 1.00    | root      |
↪
↪
| -HashAgg_27  | 1.00    | root      |
↪      | funcs:sum(Column#10)->Column#7
↪
| -IndexLookUp_28 | 1.00    | root      |
↪
↪

```

```

|      -IndexRangeScan_25(Build) | 10.00 | cop[tikv] | table:t2, index
↳ :idx(b) | range: decided by [eq(test.t2.b, test.t1.b)], keep order:
↳ false, stats:pseudo |
|      -HashAgg_17(Probe)          | 1.00 | cop[tikv] |
↳                               | funcs:sum(test.t2.a)->Column#10
↳                               |
|      -TableRowIDScan_26          | 10.00 | cop[tikv] | table:t2
↳                               | keep order:false, stats:pseudo
↳                               |
+--
↳ -----+-----+-----+
↳

```

After disabling the subquery decorrelation rule, you can see `range: decided by [eq(test.t2.b, test.t1.b)]` in operator info of `IndexRangeScan_25(Build)`. It means that the decorrelation of correlated subquery is not performed and TiDB uses the index range query.

9.3.3.2.5 Eliminate Max/Min

When a SQL statement contains `max/min` functions, the query optimizer tries to convert the `max/min` aggregate functions to the `TopN` operator by applying the `max/min` optimization rule. In this way, TiDB can perform the query more efficiently through indexes.

This optimization rule is divided into the following two types according to the number of `max/min` functions in the `select` statement:

- The statement with only one `max/min` function
- The statement with multiple `max/min` functions

One `max/min` function

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains only one aggregate function, which is `max` or `min`.
- The aggregate function has no related `group by` clause.

For example:

```
select max(a) from t
```

The optimization rule rewrites the statement as follows:

```
select max(a) from (select a from t where a is not null order by a desc
↳ limit 1) t
```

When column `a` has an index, or when column `a` is the prefix of some composite index, with the help of index, the new SQL statement can find the maximum or minimum value by scanning only one row of data. This optimization avoids full table scan.

The example statement has the following execution plan:

```
mysql> explain select max(a) from t;
+---+
| id          | estRows | task  | access object |
+---+
| StreamAgg_13 | 1.00    | root  |               |
|  -Limit_17  | 1.00    | root  |               |
|    -IndexReader_27 | 1.00    | root  |               |
|      index:Limit_26 |         |       |               |
|        -Limit_26 | 1.00    | cop[tikv] |               |
|          offset:0, count:1 |         |       |               |
|            -IndexFullScan_25 | 1.00    | cop[tikv] | table:t, index:idx_a(a) |
|              keep order:true, desc, stats:pseudo |         |       |               |
+---+
5 rows in set (0.00 sec)
```

Multiple max/min functions

When a SQL statement meets the following conditions, this rule is applied:

- The statement contains multiple aggregate functions, which are all `max` or `min` functions.
- None of the aggregate functions has a related `group by` clause.
- The columns in each `max/min` function has indexes to preserve the order.

For example:

```
select max(a) - min(a) from t
```

The optimization rule first checks whether column `a` has an index to preserve its order. If yes, the SQL statement is rewritten as the Cartesian product of two subqueries:

```
select max_a - min_a
from
  (select max(a) as max_a from t) t1,
  (select min(a) as min_a from t) t2
```

Through the rewrite, the optimizer can apply the rule for statements with only one `max` \leftrightarrow /`min` function to the two subqueries respectively. The statement is then rewritten as follows:

```
select max_a - min_a
from
  (select max(a) as max_a from (select a from t where a is not null order
     $\leftrightarrow$  by a desc limit 1) t) t1,
  (select min(a) as min_a from (select a from t where a is not null order
     $\leftrightarrow$  by a asc limit 1) t) t2
```

Similarly, if column `a` has an index to preserve its order, the optimized execution only scans two rows of data instead of the whole table. However, if column `a` does not have an index to preserve its order, this rule results in two full table scans, but the execution only needs one full table scan if it is not rewritten. Therefore, in such cases, this rule is not applied.

The final execution plan is as follows:

```
mysql> explain select max(a)-min(a) from t;
+---+
 $\leftrightarrow$  -----+-----+-----+
 $\leftrightarrow$ 
| id | estRows | task | access object |
 $\leftrightarrow$  operator info |
+---+
 $\leftrightarrow$  -----+-----+-----+
 $\leftrightarrow$ 
| Projection_17 | 1.00 | root | |
 $\leftrightarrow$  minus(Column#4, Column#5)->Column#6 |
| -HashJoin_18 | 1.00 | root | |
 $\leftrightarrow$  | CARTESIAN inner join |
| -StreamAgg_45(Build) | 1.00 | root | |
 $\leftrightarrow$  | funcs:min(test.t.a)->Column#5 |
| -Limit_49 | 1.00 | root | |
 $\leftrightarrow$  | offset:0, count:1 |
| -IndexReader_59 | 1.00 | root | |
 $\leftrightarrow$  | index:Limit_58 |
| -Limit_58 | 1.00 | cop[tikv] | |
 $\leftrightarrow$  | offset:0, count:1 |
```

```

|      -IndexFullScan_57      | 1.00  | cop[tikv] | table:t, index:
↳ idx_a(a) | keep order:true, stats:pseudo |
|      -StreamAgg_24(Probe)   | 1.00  | root      |
↳ | funcs:max(test.t.a)->Column#4 |
|      -Limit_28              | 1.00  | root      |
↳ | offset:0, count:1          |
|      -IndexReader_38       | 1.00  | root      |
↳ | index:Limit_37             |
|      -Limit_37             | 1.00  | cop[tikv] |
↳ | offset:0, count:1          |
|      -IndexFullScan_36     | 1.00  | cop[tikv] | table:t, index:
↳ idx_a(a) | keep order:true, desc, stats:pseudo |
+--
↳ -----+-----+-----+-----+
↳
12 rows in set (0.01 sec)

```

9.3.3.2.6 Predicates Push Down (PPD)

This document introduces one of the TiDB's logic optimization rules—Predicate Push Down (PPD). It aims to help you understand the predicate push down and know its applicable and inapplicable scenarios.

PPD pushes down selection operators to data source as close as possible to complete data filtering as early as possible, which significantly reduces the cost of data transmission or computation.

Examples

The following cases describe the optimization of PPD. Case 1, 2, and 3 are scenarios where PPD is applicable, and Case 4, 5, and 6 are scenarios where PPD is not applicable.

Case 1: push predicates to storage layer

```

create table t(id int primary key, a int);
explain select * from t where a < 1;
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | task      | access object | operator info
↳          |
+--
↳ -----+-----+-----+-----+
↳
| TableReader_7      | 3323.33 | root      |               | data:Selection_6
↳          |
| -Selection_6      | 3323.33 | cop[tikv] |               | lt(test.t.a, 1)
↳          |

```

```

|  -TableFullScan_5  | 10000.00 | cop[tikv] | table:t | keep order:false
↳ , stats:pseudo |
+--
↳ -----+-----+-----+-----+
↳
3 rows in set (0.00 sec)

```

In this query, pushing down the predicate $a < 1$ to the TiKV layer to filter the data can reduce the overhead of network transmission.

Case 2: push predicates to storage layer

```

create table t(id int primary key, a int not null);
explain select * from t where a < substring('123', 1, 1);
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | task      | access object | operator info
↳          |
+--
↳ -----+-----+-----+-----+
↳
| TableReader_7      | 3323.33 | root      |               | data:Selection_6
↳          |
| -Selection_6      | 3323.33 | cop[tikv] |               | lt(test.t.a, 1)
↳          |
|  -TableFullScan_5  | 10000.00 | cop[tikv] | table:t | keep order:false
↳ , stats:pseudo |
+--
↳ -----+-----+-----+-----+
↳

```

This query has the same execution plan as the query in case 1, because the input parameters of the `substring` of the predicate $a < \text{substring}('123', 1, 1)$ are constants, so they can be calculated in advance. Then the predicate is simplified to the equivalent predicate $a < 1$. After that, TiDB can push $a < 1$ down to TiKV.

Case 3: push predicates below join operator

```

create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a where t.a < 1;
+--
↳ -----+-----+-----+-----+
↳
| id          | estRows | task      | access object | operator
↳ info          |

```

```

+--
↪ -----+-----+-----+-----+
↪
| HashJoin_8          | 4154.17 | root    |          | inner join,
↪ equal:[eq(test.t.a, test.s.a)] |
| -TableReader_15(Build) | 3323.33 | root    |          | data:
↪ Selection_14          |          |          |          |
| -Selection_14       | 3323.33 | cop[tikv] |          | lt(test.s.a
↪ , 1)                  |          |          |          |
| -TableFullScan_13   | 10000.00 | cop[tikv] | table:s | keep order:
↪ false, stats:pseudo  |          |          |          |
| -TableReader_12(Probe) | 3323.33 | root    |          | data:
↪ Selection_11          |          |          |          |
| -Selection_11       | 3323.33 | cop[tikv] |          | lt(test.t.a
↪ , 1)                  |          |          |          |
| -TableFullScan_10   | 10000.00 | cop[tikv] | table:t | keep order:
↪ false, stats:pseudo  |          |          |          |
+--
↪ -----+-----+-----+-----+
↪
7 rows in set (0.00 sec)

```

In this query, the predicate `t.a < 1` is pushed below join to filter in advance, which can reduce the calculation overhead of join.

In addition, This SQL statement has an inner join executed, and the ON condition is `t.a = s.a`. The predicate `s.a < 1` can be derived from `t.a < 1` and pushed down to `s` table below the join operator. Filtering the `s` table can further reduce the calculation overhead of join.

Case 4: predicates that are not supported by storage layers cannot be pushed down

```

create table t(id int primary key, a int not null);
desc select * from t where substring('123', a, 1) = '1';
+--
↪ -----+-----+-----+-----+
↪
| id          | estRows | task    | access object | operator info
↪          |         |         |               |
+--
↪ -----+-----+-----+-----+
↪
| Selection_7   | 2.00    | root    |               | eq(substring("123
↪ ", test.t.a, 1), "1") |
| -TableReader_6   | 2.00    | root    |               | data:
↪ TableFullScan_5   |         |         |               |

```

```

| -TableFullScan_5 | 2.00 | cop[tikv] | table:t | keep order:false,
↳ stats:pseudo |
+--
↳ -----+-----+-----+-----+
↳

```

In this query, there is a predicate `substring('123', a, 1)= '1'`.

From the `explain` results, we can see that the predicate is not pushed down to TiKV for calculation. This is because the TiKV coprocessor does not support the built-in function `substring`.

Case 5: predicates of inner tables on the outer join can't be pushed down

```

create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a where s.a is null;
+--
↳ -----+-----+-----+-----+
↳
| id | estRows | task | access object | operator
↳ info |
+--
↳ -----+-----+-----+-----+
↳
| Selection_7 | 10000.00 | root | | isnull(test
↳ .s.a) |
| -HashJoin_8 | 12500.00 | root | | left outer
↳ join, equal:[eq(test.t.a, test.s.a)] |
| -TableReader_13(Build) | 10000.00 | root | | data:
↳ TableFullScan_12 |
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:s | keep order:
↳ false, stats:pseudo |
| -TableReader_11(Probe) | 10000.00 | root | | data:
↳ TableFullScan_10 |
| -TableFullScan_10 | 10000.00 | cop[tikv] | table:t | keep order:
↳ false, stats:pseudo |
+--
↳ -----+-----+-----+-----+
↳
6 rows in set (0.00 sec)

```

In this query, there is a predicate `s.a is null` on the inner table `s`.

From the `explain` results, we can see that the predicate is not pushed below join operator. This is because the outer join fills the inner table with NULL values when the `on` condition isn't satisfied, and the predicate `s.a is null` is used to filter the results after the join. If

it is pushed down to the inner table below join, the execution plan is not equivalent to the original one.

Case 6: the predicates which contain user variables cannot be pushed down

```

create table t(id int primary key, a char);
set @a = 1;
explain select * from t where a < @a;
+---+
  ↪ -----+-----+-----+-----+
  ↪
| id          | estRows | task   | access object | operator info
  ↪          |         |       |              |
+---+
  ↪ -----+-----+-----+-----+
  ↪
| Selection_5 | 8000.00 | root   |              | lt(test.t.a,
  ↪   getvar("a")) |
| -TableReader_7 | 10000.00 | root   |              | data:
  ↪   TableFullScan_6 |
|   -TableFullScan_6 | 10000.00 | cop[tikv] | table:t | keep order:false
  ↪   , stats:pseudo |
+---+
  ↪ -----+-----+-----+-----+
  ↪
3 rows in set (0.00 sec)

```

In this query, there is a predicate `a < @a` on table `t`. The `@a` of the predicate is a user variable.

As can be seen from `explain` results, the predicate is not like case 2, which is simplified to `a < 1` and pushed down to TiKV. This is because the value of the user variable `@a` may change during the computation, and TiKV is not aware of the changes. So TiDB does not replace `@a` with 1, and does not push down it to TiKV.

An example to help you understand is as follows:

```

create table t(id int primary key, a int);
insert into t values(1, 1), (2,2);
set @a = 1;
select id, a, @a:=@a+1 from t where a = @a;
+---+-----+-----+
| id | a  | @a:=@a+1 |
+---+-----+-----+
| 1  | 1  | 2        |
| 2  | 2  | 3        |
+---+-----+-----+
2 rows in set (0.00 sec)

```

As you can see from this query, the value of @a will change during the query. So if you replace `a = @a` with `a = 1` and push it down to TiKV, it's not an equivalent execution plan.

9.3.3.2.7 Partition Pruning

Partition pruning is a performance optimization that applies to partitioned tables. It analyzes the filter conditions in query statements, and eliminates (*prunes*) partitions from consideration when they do not contain any data that will be required. By eliminating the non-required partitions, TiDB is able to reduce the amount of data that needs to be accessed and potentially significantly improving query execution times.

The following is an example:

```
CREATE TABLE t1 (
  id INT NOT NULL PRIMARY KEY,
  pad VARCHAR(100)
)
PARTITION BY RANGE COLUMNS(id) (
  PARTITION p0 VALUES LESS THAN (100),
  PARTITION p1 VALUES LESS THAN (200),
  PARTITION p2 VALUES LESS THAN (MAXVALUE)
);

INSERT INTO t1 VALUES (1, 'test1'),(101, 'test2'), (201, 'test3');
EXPLAIN SELECT * FROM t1 WHERE id BETWEEN 80 AND 120;
```

```
+--
  ↪ -----+-----+-----+-----+
  ↪
| id          | estRows | task  | access object  |
  ↪ operator info          |
+--
  ↪ -----+-----+-----+-----+
  ↪
| PartitionUnion_8 | 80.00 | root  |                |
  ↪                               |
| -TableReader_10 | 40.00 | root  |                | data:
  ↪ TableRangeScan_9          |
|   -TableRangeScan_9 | 40.00 | cop[tikv] | table:t1, partition:p0 |
  ↪ range:[80,120], keep order:false, stats:pseudo |
| -TableReader_12 | 40.00 | root  |                | data:
  ↪ TableRangeScan_11          |
|   -TableRangeScan_11 | 40.00 | cop[tikv] | table:t1, partition:p1 |
  ↪ range:[80,120], keep order:false, stats:pseudo |
+--
  ↪ -----+-----+-----+-----+
  ↪
```

```
↪

Usage scenarios of partition pruning

The usage scenarios of partition pruning are different for the two types of partitioned tables: Range partitioned tables and Hash partitioned tables.

Use partition pruning in Hash partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Applicable scenario in Hash partitioned tables

Partition pruning applies only to the query condition of equality comparison in Hash partitioned tables.

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x = 1;
```

```
+--
↪ -----+-----+-----+-----+
↪
| id                | estRows | task      | access object      | operator
↪ info              |         |           |                    |
+--
↪ -----+-----+-----+-----+
↪
| TableReader_8     | 10.00   | root     |                    | data:
↪ Selection_7       |         |           |                    |
| -Selection_7     | 10.00   | cop[tikv] |                    | eq(test.t
↪ .x, 1)           |         |           |                    |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t, partition:p1 |
↪ keep order:false, stats:pseudo |
+--
↪ -----+-----+-----+-----+
↪
```

In the SQL statement above, it can be known from the condition $x = 1$ that all results fall in one partition. The value 1 can be confirmed to be in the p1 partition after passing through the Hash partition. Therefore, only the p1 partition needs to be scanned, and there is no need to access the p2, p3, and p4 partitions that will not have matching results. From the execution plan, only one TableFullScan operator appears and the p1 partition is specified in access object, so it can be confirmed that partition pruning takes effect.

Inapplicable scenarios in Hash partitioned tables

This section describes two inapplicable usage scenarios of partition pruning in Hash partitioned tables.

Scenario one

If you cannot confirm the condition that the query result falls in only one partition (such as `in`, `between`, `>`, `<`, `>=`, `<=`), you cannot use the partition pruning optimization. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t where x > 2;
```

```
+--
  ↪ -----+-----+-----+-----+

| -Selection_15     | 3333.33  | cop[tikv] |                    | gt(
  ↪ test.t.x, 2)       |          |           |                    |
| -TableFullScan_14 | 10000.00 | cop[tikv] | table:t, partition:p1
  ↪ | keep order:false, stats:pseudo |
| -TableReader_19   | 3333.33  | root      |                    | data
  ↪ :Selection_18      |          |           |                    |
| -Selection_18     | 3333.33  | cop[tikv] |                    | gt(
  ↪ test.t.x, 2)       |          |           |                    |
| -TableFullScan_17 | 10000.00 | cop[tikv] | table:t, partition:p2
  ↪ | keep order:false, stats:pseudo |
| -TableReader_22   | 3333.33  | root      |                    | data
  ↪ :Selection_21      |          |           |                    |
| -Selection_21     | 3333.33  | cop[tikv] |                    | gt(
  ↪ test.t.x, 2)       |          |           |                    |
| -TableFullScan_20 | 10000.00 | cop[tikv] | table:t, partition:p3
  ↪ | keep order:false, stats:pseudo |
+--
  ↪ -----+-----+-----+-----+
  ↪
```

In this case, partition pruning is inapplicable because the corresponding Hash partition cannot be confirmed by the $x > 2$ condition.

Scenario two

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t (x int) partition by hash(x) partitions 4;
explain select * from t2 where x = (select * from t1 where t2.x = t1.x and
  ↪ t2.x < 2);
```

```

| -Selection_26    | 2.00    | cop[tikv] |
↪   | eq(test.t2.x, test.t1.x), lt(test.t2.x, 2) |
```

```

|           -TableFullScan_25      | 2500.00 | cop[tikv] | table:t1,
↳ partition:p1 | keep order:false, stats:pseudo |
+---
↳ -----+-----+-----+-----
↳

```

Each time this query reads a row from `t2`, it will query on the `t1` partitioned table. Theoretically, the filter condition of `t1.x = val` is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

Use partition pruning in Range partitioned tables

This section describes the applicable and inapplicable usage scenarios of partition pruning in Range partitioned tables.

Applicable scenarios in Range partitioned tables

This section describes three applicable usage scenarios of partition pruning in Range partitioned tables.

Scenario one

Partition pruning applies to the query condition of equality comparison in Range partitioned tables. For example:

```

create table t (x int) partition by range (x) (
  partition p0 values less than (5),
  partition p1 values less than (10),
  partition p2 values less than (15)
);
explain select * from t where x = 3;

```

```

+---
↳ -----+-----+-----+-----
↳
| id                | estRows | task    | access object      | operator
↳ info                |         |         |                    |
+---
↳ -----+-----+-----+-----
↳
| TableReader_8     | 10.00   | root    |                    | data:
↳ Selection_7        |         |         |                    |
| -Selection_7      | 10.00   | cop[tikv] |                    | eq(test.t
↳ .x, 3)             |         |         |                    |
| -TableFullScan_6 | 10000.00 | cop[tikv] | table:t, partition:p0 |
↳ keep order:false, stats:pseudo |
+---
↳ -----+-----+-----+-----
↳

```

Partition pruning also applies to the equality comparison that uses the `in` query condition. For example:

```
create table t (x int) partition by range (x) (
  partition p0 values less than (5),
  partition p1 values less than (10),
  partition p2 values less than (15)
);
explain select * from t where x in(1,13);
```

```
+--
  ↪ -----+-----+-----+-----+
  ↪
| id          | estRows | task   | access object |
  ↪ operator info          |
+--
  ↪ -----+-----+-----+-----+
  ↪
| Union_8     | 40.00   | root   |               |
  ↪               |         |        |               |
| -TableReader_11 | 20.00   | root   |               | data:
  ↪ Selection_10   |         |        |               |
| -Selection_10  | 20.00   | cop[tikv] |               | in(
  ↪ test.t.x, 1, 13) |         |        |               |
| -TableFullScan_9 | 10000.00 | cop[tikv] | table:t, partition:p0 |
  ↪ keep order:false, stats:pseudo |         |        |               |
| -TableReader_14 | 20.00   | root   |               | data:
  ↪ Selection_13   |         |        |               |
| -Selection_13  | 20.00   | cop[tikv] |               | in(
  ↪ test.t.x, 1, 13) |         |        |               |
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:t, partition:p2 |
  ↪ keep order:false, stats:pseudo |         |        |               |
+--
  ↪ -----+-----+-----+-----+
  ↪
```

In the SQL statement above, it can be known from the `x in(1,13)` condition that all results fall in a few partitions. After analysis, it is found that all records of `x = 1` are in the `p0` partition, and all records of `x = 13` are in the `p2` partition, so only `p0` and `p2` partitions need to be accessed.

Scenario two

Partition pruning applies to the query condition of interval comparison, such as `between`, `>`, `<`, `=`, `>=`, `<=`. For example:

```
create table t (x int) partition by range (x) (
```

```

partition p0 values less than (5),
partition p1 values less than (10),
partition p2 values less than (15)
);
explain select * from t where x between 7 and 14;

```

```

| -Selection_10  | 250.00 | cop[tikv] |               | ge(
↪ test.t.x, 7), le(test.t.x, 14) |
| -TableFullScan_9 | 10000.00 | cop[tikv] | table:t, partition:p1 |
↪ keep order:false, stats:pseudo |
| -TableReader_14 | 250.00 | root   |               | data:
↪ Selection_13   |         |         |               |
| -Selection_13  | 250.00 | cop[tikv] |               | ge(
↪ test.t.x, 7), le(test.t.x, 14) |
| -TableFullScan_12 | 10000.00 | cop[tikv] | table:t, partition:p2 |
↪ keep order:false, stats:pseudo |
+--
↪ -----+-----+-----+-----+
↪

```

Scenario three

Partition pruning applies to the scenario where the partition expression is in the simple form of $fn(col)$, the query condition is one of $>$, $<$, $=$, $>=$, and $<=$, and the fn function is monotonous.

If the fn function is monotonous, for any x and y , if $x > y$, then $fn(x) > fn(y)$. Then this fn function can be called strictly monotonous. For any x and y , if $x > y$, then $fn(x) >= fn(y)$. In this case, fn could also be called “monotonous”. Theoretically, all monotonous functions, strictly or not, are supported by partition pruning. Currently, TiDB only supports the following monotonous functions:

```

unix_timestamp
to_days

```

For example, partition pruning takes effect when the partition expression is in the form of `fn(col)`, where the `fn` is monotonous function `to_days`:

```
create table t (id datetime) partition by range (to_days(id)) (
  partition p0 values less than (to_days('2020-04-01')),
  partition p1 values less than (to_days('2020-05-01')));
explain select * from t where id > '2020-04-18';
```

```

Inapplicable scenario in Range partitioned tables

Because the rule optimization of partition pruning is performed during the generation phase of the query plan, partition pruning is not suitable for scenarios where the filter conditions can be obtained only during the execution phase. For example:

```
create table t1 (x int) partition by range (x) (
  partition p0 values less than (5),
  partition p1 values less than (10));
create table t2 (x int);
explain select * from t2 where x < (select * from t1 where t2.x < t1.x and
  ↪ t2.x < 2);
```

```

| ↪                    |
| -TableFullScan_25     | 2.50    | cop[tikv] | table:t1,
| ↪ partition:p1 | keep order:false, stats:pseudo
+--
| ↪ -----+-----+-----+
| ↪
14 rows in set (0.00 sec)

```

Each time this query reads a row from t2, it will query on the t1 partitioned table.

Theoretically, the `t1.x > val` filter condition is met at this time, but in fact, partition pruning takes effect only in the generation phase of the query plan, not the execution phase.

9.3.3.2.8 TopN and Limit Operator Push Down

This document describes the implementation of TopN and Limit operator pushdown.

In the TiDB execution plan tree, the `LIMIT` clause in SQL corresponds to the Limit operator node, and the `ORDER BY` clause corresponds to the Sort operator node. The adjacent Limit operator and Sort operator are combined as the TopN operator node, which means that the top N records are returned according to a certain sorting rule. That is to say, a Limit operator is equivalent to a TopN operator node with a null sorting rule.

Similar to predicate pushdown, TopN and Limit are pushed down in the execution plan tree to a position as close to the data source as possible so that the required data is filtered at an early stage. In this way, the pushdown significantly reduces the overhead of data transmission and calculation.

To disable this rule, refer to [Optimization Rules and Blocklist for Expression Pushdown](#).

Examples

This section illustrates TopN pushdown through some examples.

Example 1: Push down to the Coprocessors in the storage layer

```
create table t(id int primary key, a int not null);
explain select * from t order by a limit 10;
```

```

| false, stats:pseudo | | | | |
+-----+-----+-----+-----+
| | | | |
4 rows in set (0.00 sec)
```

In this query, the TopN operator node is pushed down to TiKV for data filtering, and each Coprocessor returns only 10 records to TiDB. After TiDB aggregates the data, the final filtering is performed.

Example 2: TopN can be pushed down into Join (the sorting rule only depends on the columns in the outer table)

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.a limit 10;
```

```
+-----+-----+-----+-----+
      ↪
| id                | estRows | task  | access object |
      ↪ operator info          |
+-----+-----+-----+-----+
      ↪
| TopN_12           | 10.00   | root  |               | test.t.a,
      ↪ offset:0, count:10      |
| -HashJoin_17     | 12.50   | root  |               | left
      ↪ outer join, equal:[eq(test.t.a, test.s.a)] |
| -TopN_18(Build)  | 10.00   | root  |               | test.t.a
      ↪ , offset:0, count:10      |
| -TableReader_26  | 10.00   | root  |               | data:
      ↪ TopN_25                    |
|   -TopN_25       | 10.00   | cop[tikv] |               | test.t.a
      ↪ , offset:0, count:10      |
|   -TableFullScan_24 | 10000.00 | cop[tikv] | table:t | keep
      ↪ order:false, stats:pseudo  |
| -TableReader_30(Probe) | 10000.00 | root  |               | data:
      ↪ TableFullScan_29            |
|   -TableFullScan_29 | 10000.00 | cop[tikv] | table:s | keep
      ↪ order:false, stats:pseudo  |
+-----+-----+-----+-----+
      ↪
8 rows in set (0.01 sec)
```

In this query, the sorting rule of the TopN operator only depends on the columns in the outer table `t`, so a calculation can be performed before pushing down TopN to Join, to reduce the calculation cost of the Join operation. Besides, TiDB also pushes TopN down to the storage layer.

Example 3: TopN cannot be pushed down before Join

```
create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t join s on t.a = s.a order by t.id limit 10;
```

```
+-----+-----+-----+-----+
      ↪
```

```

| id          | estRows | task  | access object | operator
↳ info
+-----+-----+-----+-----+

| -TableFullScan_18 | 10000.00 | cop[tikv] | table:t | keep order:
↳ false, stats:pseudo
+-----+-----+-----+-----+
↳
6 rows in set (0.00 sec)

```

TopN cannot be pushed down before Inner Join. Taking the query above as an example, if you get 100 records after Join, then you can have 10 records left after TopN. However, if TopN is performed first to get 10 records, only 5 records are left after Join. In such cases, the pushdown results in different results.

Similarly, TopN can neither be pushed down to the inner table of Outer Join, nor can it be pushed down when its sorting rule is related to columns on multiple tables, such as `t.a+s.a`. Only when the sorting rule of TopN exclusively depends on columns on the outer table, can TopN be pushed down.

Example 4: Convert TopN to Limit

```

create table t(id int primary key, a int not null);
create table s(id int primary key, a int not null);
explain select * from t left join s on t.a = s.a order by t.id limit 10;

```

```

+-----+-----+-----+-----+
↳

↳ , offset:0, count:10
| -HashJoin_17 | 12.50  | root  |               | left
↳ outer join, equal:[eq(test.t.a, test.s.a)] |

```

	-Limit_21(Build)	10.00	root		offset
	↪ :0, count:10				
	-TableReader_31	10.00	root		data:
	↪ Limit_30				
	-Limit_30	10.00	cop[tikv]		offset
	↪ :0, count:10				
	-TableFullScan_29	10.00	cop[tikv]	table:t	keep
	↪ order:true, stats:pseudo				
	-TableReader_35(Probe)	10000.00	root		data:
	↪ TableFullScan_34				
	-TableFullScan_34	10000.00	cop[tikv]	table:s	keep
	↪ order:false, stats:pseudo				
+-----+-----+-----+-----+					
	↪				
	8 rows in set (0.00 sec)				

In the query above, TopN is first pushed to the outer table `t`. TopN needs to sort by `t` ↪ `.id`, which is the primary key and can be directly read in order (`keep order: true`) without extra sorting in TopN. Therefore, TopN is simplified as Limit.

9.3.3.2.9 Introduction to Join Reorder

In real application scenarios, it is common to join multiple tables. The execution efficiency of join is associated with the order in which each table joins.

For example:

```
SELECT * FROM t1, t2, t3 WHERE t1.a=t2.a AND t3.a=t2.a;
```

In this query, tables can be joined in the following two orders:

- t1 joins t2, and then joins t3
- t2 joins t3, and then joins t1

As t1 and t3 have different data volumes and distribution, these two execution orders might show different performances.

Therefore, the optimizer needs an algorithm to determine the join order. Currently, TiDB uses the Join Reorder algorithm, also known as the greedy algorithm.

Instance of Join Reorder algorithm

Take the three tables above (t1, t2, and t3) as an example.

First, TiDB obtains all the nodes that participates in the join operation, and sorts the nodes in the ascending order of row numbers.

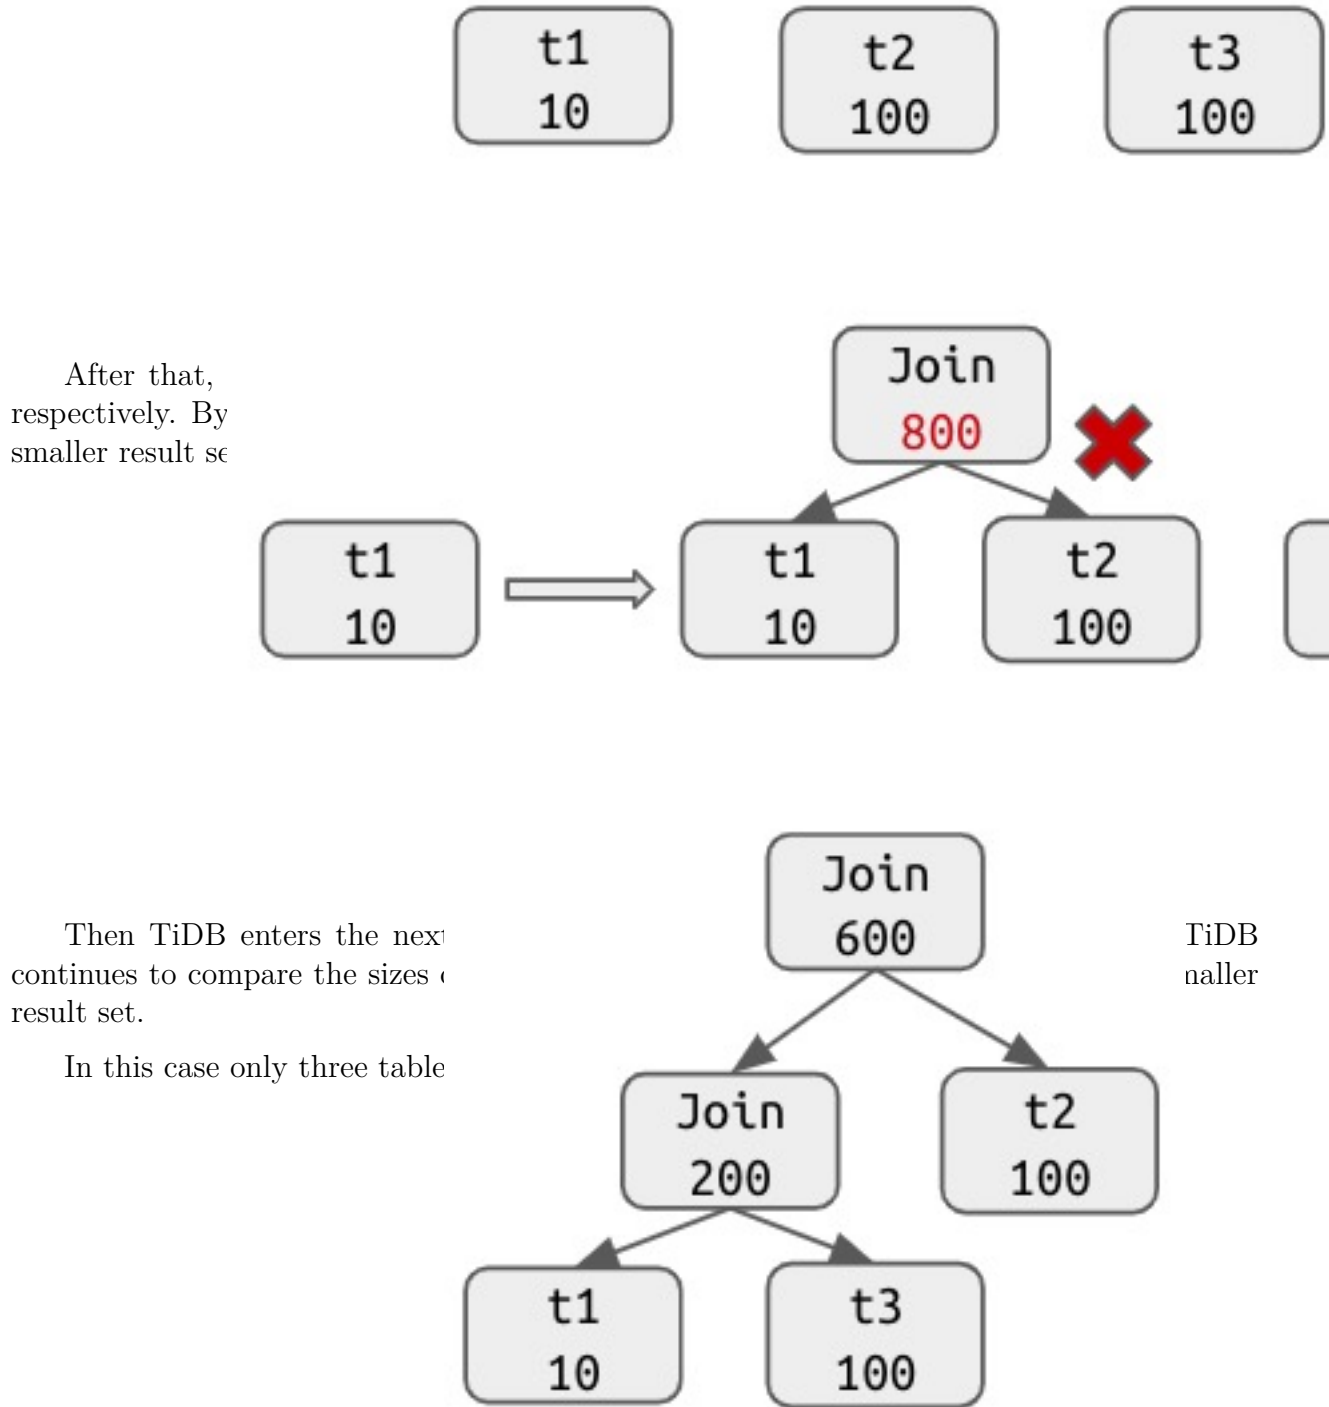

Figure 71: join-reorder-3

The above process is the Join Reorder algorithm currently used in TiDB.

Limitations of Join Reorder algorithm

The current Join Reorder algorithm has the following limitations:

- The Join Reorder for Outer Join is not supported

- Limited by the calculation methods of the result sets, the algorithm cannot ensure it selects the optimum join order.

Currently, the `STRAIGHT_JOIN` syntax is supported in TiDB to force a join order. For more information, refer to [Description of the syntax elements](#).

9.3.3.3 Physical Optimization

9.3.3.3.1 SQL Physical Optimization

Physical optimization is cost-based optimization, which makes a physical execution plan for the logical execution plan generated in the previous stage. In this stage, the optimizer selects a specific physical implementation for each operator in the logical execution plan. Different physical implementations of logical operators have different time complexity, resource consumption and physical properties. In this process, the optimizer determines the cost of different physical implementations based on the statistics of the data, and selects the physical execution plan with the smallest overall cost.

[Understand the Query Execution Plan](#) has introduced some physical operators. This chapter focuses on the following aspects:

- In [Index Selection](#), you will learn how to select the optimal index to access tables when TiDB has multiple indexes on a table.
- In [Introduction to Statistics](#), you will learn what statistics TiDB collects to obtain the data distribution of a table.
- [Wrong Index Solution](#) introduces how to use the right index when you find the index is selected wrongly.
- [Distinct Optimization](#) introduces an optimization related to the `DISTINCT` keyword during physical optimization. In this section, you will learn its advantages and disadvantages and how to use it.

9.3.3.3.2 Index Selection

Reading data from storage engines is one of the most time-consuming steps during the SQL execution. Currently, TiDB supports reading data from different storage engines and different indexes. Query execution performance depends largely on whether you select a suitable index or not.

This document introduces how to select an index to access a table, and some related ways to control index selection.

Access tables

Before introducing index selection, it is important to understand the ways TiDB accesses tables, what triggers each way, what differences each way makes, and what the pros and cons are.

Operators for accessing tables

Operator	Trigger Conditions	Applicable Scenarios	Explanations
PointGet / Batch-PointGet	When accessing tables in one or more single point ranges.	Any scenario	If triggered, it is usually considered as the fastest operator, since it calls the kvget interface directly to perform the calculations rather than calls the coprocessor interface.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	None	Any scenario	It is generally considered as the least efficient operator that scans table data directly from the TiKV layer. It can be selected only if there is a range query on the <code>_tidb_rowid</code> column, or if there are no other operators for accessing tables to

Operator	Trigger Conditions	Applicable Scenarios	Explanations
TableReader	A table has a replica on the TiFlash node.	There are fewer columns to read, but many rows to evaluate.	Tiflash is column-based storage. If you need to calculate a small number of columns and a large number of rows, it is recommended to choose this operator.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexReader	A table has one or more indexes, and the columns needed for the calculation are included in the indexes.	When there is a smaller range query on the indexes, or when there is an order requirement for indexed columns.	When multiple indexes exist, a reasonable index is selected based on the cost estimation.

Operator	Trigger Conditions	Applicable Scenarios	Explanations
IndexLookupReader	A Table has one or more indexes, and the columns needed for calculation are not completely included in the indexes.	Same as IndexReader.	Since the <code>index</code> does not completely cover calculated columns, TiDB needs to retrieve rows from a table after reading indexes. There is an extra cost compared to the IndexReader operator.

Note:

The TableReader operator is based on the `_tidb_rowid` column index, and TiFlash uses a column storage index, so the selection of index is the selection

of an operator for accessing tables.

Index selection rules

TiDB selects indexes based on rules or cost. The based rules include pre-rules and skyline-pruning. When selecting an index, TiDB tries the pre-rule first. If an index satisfies a pre-rule, TiDB directly selects this index. Otherwise, TiDB uses skyline-pruning to exclude unsuitable indexes, and then selects the index with the lowest cost based on the cost estimation of each operator that accesses tables.

Rule-based selection

Pre-rules

TiDB uses the following heuristic pre-rules to select indexes:

- Rule 1: If an index satisfies “unique index with full match + no need to retrieve rows from a table (which means that the plan generated by the index is the IndexReader operator)”, TiDB directly selects this index.
- Rule 2: If an index satisfies “unique index with full match + the need to retrieve rows from a table (which means that the plan generated by the index is the IndexLookupReader operator)”, TiDB selects the index with the smallest number of rows to be retrieved from a table as a candidate index.
- Rule 3: If an index satisfies “ordinary index + no need to retrieve rows from a table + the number of rows to be read is less than the value of a certain threshold”, TiDB selects the index with the smallest number of rows to be read as a candidate index.
- Rule 4: If only one candidate index is selected based on rule 2 and 3, select this candidate index. If two candidate indexes are respectively selected based on rule 2 and 3, select the index with the smaller number of rows to be read (the number of rows with index + the number of rows to be retrieved from a table).

The “index with full match” in the above rules means each indexed column has the equal condition. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if the pre-rules match an index, TiDB outputs a NOTE-level warning indicating that the index matches the pre-rule.

In the following example, because the index `idx_b` meets the condition “unique index with full match + the need to retrieve rows from a table” in rule 2, TiDB selects the index `idx_b` as the access path, and `SHOW WARNING` returns a note indicating that the index `idx_b` matches the pre-rule.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, UNIQUE INDEX idx_b(b  
↪ ));
```

```

Query OK, 0 rows affected (0.01 sec)

mysql> EXPLAIN FORMAT = 'verbose' SELECT b, c FROM t WHERE b = 3 OR b = 6;

  ↪ -----+-----+-----+-----+-----+
  ↪
1 row in set (0.00 sec)

```

Skyline-pruning

Skyline-pruning is a heuristic filtering rule for indexes, which can reduce the probability of wrong index selection caused by wrong estimation. To judge an index, the following three dimensions are needed:

- How many access conditions are covered by the indexed columns. An “access condition” is a where condition that can be converted to a column range. And the more access conditions an indexed column set covers, the better it is in this dimension.
- Whether it needs to retrieve rows from a table when you select the index to access the table (that is, the plan generated by the index is IndexReader operator or In-

dexLookupReader operator). Indexes that do not retrieve rows from a table are better on this dimension than indexes that do. If both indexes need TiDB to retrieve rows from the table, compare how many filtering conditions are covered by the indexed columns. Filtering conditions mean the `where` condition that can be judged based on the index. If the column set of an index covers more access conditions, the smaller the number of retrieved rows from a table, and the better the index is in this dimension.

- Select whether the index satisfies a certain order. Because index reading can guarantee the order of certain column sets, indexes that satisfy the query order are superior to indexes that do not satisfy on this dimension.

For these three dimensions above, if the index `idx_a` performs no worse than the index `idx_b` in all three dimensions and performs better than `idx_b` in one dimension, then `idx_a` is preferred. When executing the `EXPLAIN FORMAT = 'verbose' ...` statement, if skyline-pruning excludes some indexes, TiDB outputs a NOTE-level warning listing the remaining indexes after the skyline-pruning exclusion.

In the following example, the indexes `idx_b` and `idx_e` are both inferior to `idx_b_c`, so they are excluded by skyline-pruning. The returned result of `SHOW WARNING` displays the remaining indexes after skyline-pruning.

```
mysql> CREATE TABLE t(a INT PRIMARY KEY, b INT, c INT, d INT, e INT, INDEX
  ↪ idx_b(b), INDEX idx_b_c(b, c), INDEX idx_e(e));
Query OK, 0 rows affected (0.01 sec)

Cost estimation-based selection

After using the skyline-pruning rule to rule out inappropriate indexes, the selection of indexes is based entirely on the cost estimation. The cost estimation of accessing tables requires the following considerations:

- The average length of each row of the indexed data in the storage engine.
- The number of rows in the query range generated by the index.
- The cost for retrieving rows from a table.
- The number of ranges generated by index during the query execution.

According to these factors and the cost model, the optimizer selects an index with the lowest cost to access the table.

Common tuning problems with cost estimation based selection

1. The estimated number of rows is not accurate?

This is usually due to stale or inaccurate statistics. You can re-execute the `analyze ↪ table` statement or modify the parameters of the `analyze table` statement.

2. Statistics are accurate, and reading from TiFlash is faster, but why does the optimizer choose to read from TiKV?

At present, the cost model of distinguishing TiFlash from TiKV is still rough. You can decrease the value of `tidb_opt_seek_factor` parameter, then the optimizer prefers to choose TiFlash.

3. The statistics are accurate. Index A needs to retrieve rows from tables, but it actually executes faster than Index B that does not retrieve rows from tables. Why does the optimizer choose Index B?

In this case, the cost estimation may be too large for retrieving rows from tables. You can decrease the value of `tidb_opt_network_factor` parameter to reduce the cost of retrieving rows from tables.

Control index selection

The index selection can be controlled by a single query through [Optimizer Hints](#).

- `USE_INDEX / IGNORE_INDEX` can force the optimizer to use / not use certain indexes.
- `READ_FROM_STORAGE` can force the optimizer to choose the TiKV / TiFlash storage engine for certain tables to execute queries.

9.3.3.3 Introduction to Statistics

TiDB uses statistics to decide [which index to choose](#). The `tidb_analyze_version` variable controls the statistics collected by TiDB. Currently, two versions of statistics are supported: `tidb_analyze_version = 1` and `tidb_analyze_version = 2`. In versions before v5.1.0, the default value of this variable is 1. In v5.3.0 and later versions, the default value of this variable is 2. If your cluster is upgraded from a version earlier than v5.3.0 to v5.3.0 or later, the default value of `tidb_analyze_version` does not change.

Note:

When `tidb_analyze_version = 2`, if memory overflow occurs after `ANALYZE` is executed, you need to set `tidb_analyze_version = 1` and perform one of the following operations:

- If the `ANALYZE` statement is executed manually, manually analyze every table to be analyzed.

```
sql  SELECT DISTINCT(CONCAT('ANALYZE TABLE ', table_schema
↪ , '.', table_name, ';'))FROM information_schema.tables,
↪ mysql.stats_histograms WHERE stats_ver = 2 AND table_id =
↪ tidb_table_id;
```

- If TiDB automatically executes the `ANALYZE` statement because the auto-analysis has been enabled, execute the following statement that generates the `DROP STATS` statement:

```
sql  SELECT DISTINCT(CONCAT('DROP STATS ', table_schema,
↪ '.', table_name, ';'))FROM information_schema.tables,
↪ mysql.stats_histograms WHERE stats_ver = 2 AND table_id =
↪ tidb_table_id;
```

- If the result of the preceding statement is too long to copy and paste, you can export the result to a temporary text file and then perform execution from the file like this:

```
sql SELECT DISTINCT ... INTO OUTFILE '/tmp/sql.txt'; mysql -h
↪ XXX -u user -P 4000 ... < '/tmp/sql.txt';
```

These two versions include different information in TiDB:

	Version 1	Version 2
The total number of rows in the table	✓	✓
Column Count-Min Sketch	✓	×
Index Count-Min Sketch	✓	×
Column Top-N	✓	✓ (Maintenance methods and precision are improved)

	Version 1	Version 2
Index	✓	✓
Top-N	(Insufficient maintenance and precision might cause inaccuracy)	(Main methods and precision are improved)
Column histogram	✓	(The histogram does not include Top-N values.)

Information	Version 1	Version 2
Index	√	√
his-togram		(The his-togram buckets record the number of different values in each bucket, and the his-togram does not include Top-N values.)
The number of NULL ↔ s in the column	√	√

	Version 1	Version 2
The number of NULL \leftrightarrow s in the index	✓	✓
The average length of columns	✓	✓
The average length of indexes	✓	✓

Compared to Version 1, Version 2 statistics avoids the potential inaccuracy caused by hash collision when the data volume is huge. It also maintains the estimate precision in most scenarios.

This document briefly introduces the histogram, Count-Min Sketch, and Top-N, and details the collection and maintenance of statistics.

Histogram

A histogram is an approximate representation of the distribution of data. It divides the entire range of values into a series of buckets, and uses simple data to describe each bucket, such as the number of values falling in the bucket. In TiDB, an equal-depth histogram is created for the specific columns of each table. The equal-depth histogram can be used to estimate the interval query.

Here “equal-depth” means that the number of values falling into each bucket is as equal as possible. For example, for a given set $\{1.6, 1.9, 1.9, 2.0, 2.4, 2.6, 2.7, 2.7, 2.8, 2.9, 3.4, 3.5\}$, you want to generate 4 buckets. The equal-depth histogram is as follows. It contains

four buckets [1.6, 1.9], [2.0, 2.6], [2.7, 2.8], [2.9, 3.5]. The bucket depth is 3.

Figure 72: Equal-depth Histogram Example

For details about the parameter that determines the upper limit to the number of histogram buckets, refer to [Manual Collection](#). When the number of buckets is larger, the accuracy of the histogram is higher; however, higher accuracy is at the cost of the usage of memory resources. You can adjust this number appropriately according to the actual scenario.

Count-Min Sketch

Count-Min Sketch is a hash structure. When an equivalence query contains `a = 1` or `IN` query (for example, `a in (1, 2, 3)`), TiDB uses this data structure for estimation.

A hash collision might occur since Count-Min Sketch is a hash structure. In the `EXPLAIN` statement, if the estimate of the equivalent query deviates greatly from the actual value, it can be considered that a larger value and a smaller value have been hashed together. In this case, you can take one of the following ways to avoid the hash collision:

- Modify the `WITH NUM TOPN` parameter. TiDB stores the high-frequency (top x) data separately, with the other data stored in Count-Min Sketch. Therefore, to prevent a larger value and a smaller value from being hashed together, you can increase the value of `WITH NUM TOPN`. In TiDB, its default value is 20. The maximum value is 1024. For more information about this parameter, see [Full Collection](#).
- Modify two parameters `WITH NUM CMSKETCH DEPTH` and `WITH NUM CMSKETCH WIDTH`. Both affect the number of hash buckets and the collision probability. You can increase the values of the two parameters appropriately according to the actual scenario to reduce the probability of hash collision, but at the cost of higher memory usage of statistics. In TiDB, the default value of `WITH NUM CMSKETCH DEPTH` is 5, and the

default value of `WITH NUM CMSKETCH WIDTH` is 2048. For more information about the two parameters, see [Full Collection](#).

Top-N values

Top-N values are values with the top N occurrences in a column or index. TiDB records the values and occurrences of Top-N values.

Collect statistics

Manual collection

You can run the `ANALYZE` statement to collect statistics.

Note:

The execution time of `ANALYZE TABLE` in TiDB is longer than that in MySQL or InnoDB. In InnoDB, only a small number of pages are sampled, while in TiDB a comprehensive set of statistics is completely rebuilt. Scripts that were written for MySQL may naively expect `ANALYZE TABLE` will be a short-lived operation.

For quicker analysis, you can set `tidb_enable_fast_analyze` to 1 to enable the Quick Analysis feature. The default value for this parameter is 0.

After Quick Analysis is enabled, TiDB randomly samples approximately 10,000 rows of data to build statistics. Therefore, in the case of uneven data distribution or a relatively small amount of data, the accuracy of statistical information is relatively poor. It might lead to poor execution plans, such as choosing the wrong index. If the execution time of the normal `ANALYZE` \leftrightarrow statement is acceptable, it is recommended to disable the Quick Analysis feature.

`tidb_enable_fast_analyze` is an experimental feature, which currently **does not match exactly** with the statistical information of `tidb_analyze_version=2`. Therefore, you need to set the value of `tidb_analyze_version` to 1 when `tidb_enable_fast_analyze` is enabled.

Full collection

You can perform full collection using the following syntax.

- To collect statistics of all the tables in `TableNameList`:

```
ANALYZE TABLE TableNameList [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|  
   $\leftrightarrow$  CMSKETCH WIDTH] |[WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- `WITH NUM BUCKETS` specifies the maximum number of buckets in the generated histogram.
- `WITH NUM TOPN` specifies the maximum number of the generated TOPNs.
- `WITH NUM CMSKETCH DEPTH` specifies the depth of the CM Sketch.
- `WITH NUM CMSKETCH WIDTH` specifies the width of the CM Sketch.
- `WITH NUM SAMPLES` specifies the number of samples.
- `WITH FLOAT_NUM SAMPLERATE` specifies the sampling rate.

`WITH NUM SAMPLES` and `WITH FLOAT_NUM SAMPLERATE` correspond to two different algorithms of collecting samples.

- `WITH NUM SAMPLES` specifies the size of the sampling set, which is implemented in the reservoir sampling method in TiDB. When a table is large, it is not recommended to use this method to collect statistics. Because the intermediate result set of the reservoir sampling contains redundant results, it causes additional pressure on resources such as memory.
- `WITH FLOAT_NUM SAMPLERATE` is a sampling method introduced in v5.3.0. With the value range (0, 1], this parameter specifies the sampling rate. It is implemented in the way of Bernoulli sampling in TiDB, which is more suitable for sampling larger tables and performs better in collection efficiency and resource usage.

Before v5.3.0, TiDB uses the reservoir sampling method to collect statistics. Since v5.3.0, the TiDB Version 2 statistics uses the Bernoulli sampling method to collect statistics by default. To re-use the reservoir sampling method, you can use the `WITH NUM SAMPLES` statement.

Note:

The current sampling rate is calculated based on an adaptive algorithm. When you can observe the number of rows in a table using `SHOW STATS_META`, you can use this number of rows to calculate the sampling rate corresponding to 100,000 rows. If you cannot observe this number, you can use the `TABLE_KEYS` column in the `TABLE_STORAGE_STATS` table as another reference to calculate the sampling rate.

Normally, `STATS_META` is more credible than `TABLE_KEYS`. However, after importing data through the methods like `TiDB Lightning local-backend`, the result of `STATS_META` is 0. To handle this situation, you can use `TABLE_KEYS` to calculate the sampling rate when the result of `STATS_META` is much smaller than the result of `TABLE_KEYS`.

Collect statistics on some columns

In most cases, when executing SQL statements, the optimizer only uses statistics on some columns (such as columns in the `WHERE`, `JOIN`, `ORDER BY`, and `GROUP BY` statements). These columns are called `PREDICATE COLUMNS`.

If a table has many columns, collecting statistics on all the columns can cause a large overhead. To reduce the overhead, you can collect statistics on only specific columns or `PREDICATE COLUMNS` to be used by the optimizer.

Note:

Collecting statistics on some columns is only applicable for `tidb_analyze_version = 2`.

- To collect statistics on specific columns, use the following syntax:

```
ANALYZE TABLE TableName COLUMNS ColumnNameList [WITH NUM BUCKETS|TOPN|  
↪ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM  
↪ SAMPLERATE] ;
```

In the syntax, `ColumnNameList` specifies the name list of the target columns. If you need to specify more than one column, use comma `,` to separate the column names. For example, `ANALYZE table t columns a, b`. Besides collecting statistics on the specific columns in a specific table, this syntax collects statistics on the indexed columns and all indexes in that table at the same time.

Note:

The syntax above is a full collection. For example, after collecting statistics on columns `a` and `b` using this syntax, if you also want to collect statistics on column `c`, you need to specify all three columns using `ANALYZE ↪ table t columns a, b, c`, rather than only specifying the additional column `c` using `ANALYZE TABLE t COLUMNS c`.

- To collect statistics on `PREDICATE COLUMNS`, do the following:

Warning:

Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

1. Set the value of the `tidb_enable_column_tracking` system variable to ON to enable TiDB to collect PREDICATE COLUMNS.

After the setting, TiDB writes the PREDICATE COLUMNS information to the `mysql.column_stats_usage` system table every $100 * \text{stats-lease}$.

2. After the query pattern of your business is relatively stable, collect statistics on PREDICATE COLUMNS by using the following syntax:

```
ANALYZE TABLE TableName PREDICATE COLUMNS [WITH NUM BUCKETS|TOPN|
↳ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
↳ FLOATNUM SAMPLERATE];
```

Besides collecting statistics on PREDICATE COLUMNS in a specific table, this syntax collects statistics on indexed columns and all indexes in that table at the same time.

Note:

- If the `mysql.column_stats_usage` system table does not contain any PREDICATE COLUMNS record for that table, the preceding syntax collects statistics on all columns and all indexes in that table.
- After using this syntax to collect statistics, when executing a new type of SQL query, the optimizer might temporarily use the old or pseudo column statistics for this time, and TiDB will collect the statistics on the used columns from the next time.

- To collect statistics on all columns and indexes, use the following syntax:

```
ANALYZE TABLE TableName ALL COLUMNS [WITH NUM BUCKETS|TOPN|CMSKETCH
↳ DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE
↳ ];
```

If you want to persist the column configuration in the ANALYZE statement (including COLUMNS ColumnNameList, PREDICATE COLUMNS, and ALL COLUMNS), set the value of the `tidb_persist_analyze_options` system variable to ON to enable the **ANALYZE configuration persistence** feature. After enabling the ANALYZE configuration persistence feature:

- When TiDB collects statistics automatically or when you manually collect statistics by executing the ANALYZE statement without specifying the column configuration, TiDB continues using the previously persisted configuration for statistics collection.
- When you manually execute the ANALYZE statement multiple times with column configuration specified, TiDB overwrites the previously recorded persistent configuration using the new configuration specified by the latest ANALYZE statement.

To locate PREDICATE COLUMNS and columns on which statistics have been collected, use the following syntax:

```
SHOW COLUMN_STATS_USAGE [ShowLikeOrWhere];
```

The `SHOW COLUMN_STATS_USAGE` statement returns the following 6 columns:

Column name	Description
<code>Db_name</code>	The database name
<code>Table_name</code>	The table name
<code>Partition_name</code>	The partition name
<code>Column_name</code>	The column name
<code>Last_used_at</code>	The last time when the column statistics were used in the query optimization
<code>Last_analyzed_at</code>	The last time when the column statistics were collected

In the following example, after executing `ANALYZE TABLE t PREDICATE COLUMNS;`, TiDB collects statistics on columns `b`, `c`, and `d`, where column `b` is a `PREDICATE COLUMN` and columns `c` and `d` are index columns.

```
SET GLOBAL tidb_enable_column_tracking = ON;
Query OK, 0 rows affected (0.00 sec)

CREATE TABLE t (a INT, b INT, c INT, d INT, INDEX idx_c_d(c, d));
Query OK, 0 rows affected (0.00 sec)

-- The optimizer uses the statistics on column b in this query.
SELECT * FROM t WHERE b > 1;
Empty set (0.00 sec)

-- After waiting for a period of time (100 * stats-lease), TiDB writes the
↳ collected `PREDICATE COLUMNS` to mysql.column_stats_usage.
```

```

-- Specify `last_used_at IS NOT NULL` to show the `PREDICATE COLUMNS`
↳ collected by TiDB.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
↳ last_used_at IS NOT NULL;
+--
↳ -----+-----+-----+-----+-----+
↳
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
↳ Last_analyzed_at |
+--
↳ -----+-----+-----+-----+-----+
↳
| test   | t         |                | b           | 2022-01-05 17:21:33 | NULL
↳
+--
↳ -----+-----+-----+-----+-----+
↳
1 row in set (0.00 sec)

ANALYZE TABLE t PREDICATE COLUMNS;
Query OK, 0 rows affected, 1 warning (0.03 sec)

-- Specify `last_analyzed_at IS NOT NULL` to show the columns for which
↳ statistics have been collected.
SHOW COLUMN_STATS_USAGE WHERE db_name = 'test' AND table_name = 't' AND
↳ last_analyzed_at IS NOT NULL;
+--
↳ -----+-----+-----+-----+-----+
↳
| Db_name | Table_name | Partition_name | Column_name | Last_used_at |
↳ Last_analyzed_at |
+--
↳ -----+-----+-----+-----+-----+
↳
| test   | t         |                | b           | 2022-01-05 17:21:33 |
↳ 2022-01-05 17:23:06 |
| test   | t         |                | c           | NULL                |
↳ 2022-01-05 17:23:06 |
| test   | t         |                | d           | NULL                |
↳ 2022-01-05 17:23:06 |
+--
↳ -----+-----+-----+-----+-----+
↳
3 rows in set (0.00 sec)

```

Collect statistics on indexes

To collect statistics on all indexes in `IndexNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName INDEX [IndexNameList] [WITH NUM BUCKETS|TOPN|
↪ CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM
↪ SAMPLERATE];
```

When `IndexNameList` is empty, this syntax collects statistics on all indexes in `TableName`
↪ .

Note:

To ensure that the statistical information before and after the collection is consistent, when `tidb_analyze_version` is 2, this syntax collects statistics on the entire table (including all columns and indexes), instead of only on indexes.

Collect statistics on partitions

- To collect statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList [WITH NUM BUCKETS|
↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
↪ FLOATNUM SAMPLERATE];
```

- To collect index statistics on all partitions in `PartitionNameList` in `TableName`, use the following syntax:

```
ANALYZE TABLE TableName PARTITION PartitionNameList INDEX [
↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
↪ WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];
```

- If you only need to **collect statistics on some columns** of some partitions in a table, use the following syntax:

Warning:

Currently, collecting statistics on `PREDICATE COLUMNS` is an experimental feature. It is not recommended that you use it in production environments.

```

ANALYZE TABLE TableName PARTITION PartitionNameList [COLUMNS
  ↪ ColumnNameList|PREDICATE COLUMNS|ALL COLUMNS] [WITH NUM BUCKETS|
  ↪ TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|WITH
  ↪ FLOATNUM SAMPLERATE];

```

Incremental collection

To improve the speed of analysis after full collection, incremental collection could be used to analyze the newly added sections in monotonically non-decreasing columns such as time columns.

Note:

- Currently, the incremental collection is only provided for index.
- When using the incremental collection, you must ensure that only INSERT operations exist on the table, and that the newly inserted value on the index column is monotonically non-decreasing. Otherwise, the statistical information might be inaccurate, affecting the TiDB optimizer to select an appropriate execution plan.

You can perform incremental collection using the following syntax.

- To incrementally collect statistics on index columns in all IndexNameLists in TableName:

```

ANALYZE INCREMENTAL TABLE TableName INDEX [IndexNameList] [WITH NUM
  ↪ BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH WIDTH] | [WITH NUM SAMPLES|
  ↪ WITH FLOATNUM SAMPLERATE];

```

- To incrementally collect statistics on index columns for partitions in all PartitionNameLists ↪ in TableName:

```

ANALYZE INCREMENTAL TABLE TableName PARTITION PartitionNameList INDEX [
  ↪ IndexNameList] [WITH NUM BUCKETS|TOPN|CMSKETCH DEPTH|CMSKETCH
  ↪ WIDTH] | [WITH NUM SAMPLES|WITH FLOATNUM SAMPLERATE];

```

Automatic update

For the INSERT, DELETE, or UPDATE statements, TiDB automatically updates the number of rows and updated rows. TiDB persists this information regularly and the update cycle is $20 * \text{stats-lease}$. The default value of `stats-lease` is 3s. If you specify the value as 0, it does not update automatically.

Three system variables related to automatic update of statistics are as follows:

System Variable	Default Value	Description
<code>tidb_auto_analyze_ratio</code>	0.5	Threshold value of automatic update
<code>tidb_auto_analyze_start_time</code>	00:00:00	Start time in a day when TiDB can perform automatic update
<code>tidb_auto_analyze_end_time</code>	23:59:59	End time in a day when TiDB can perform automatic update

When the ratio of the number of modified rows to the total number of rows of `tbl` ↪ in a table is greater than `tidb_auto_analyze_ratio`, and the current time is between `tidb_auto_analyze_start_time` and `tidb_auto_analyze_end_time`, TiDB executes the `ANALYZE TABLE tbl` statement in the background to automatically update the statistics on this table.

To avoid the situation that modifying a small amount of data on a small table frequently triggers the automatic update, when a table has less than 1000 rows, such data modifying does not trigger the automatic update in TiDB. You can use the `SHOW STATS_META` statement to view the number of rows in a table.

Note:

Currently, the automatic update does not record the configuration items input at manual `ANALYZE`. Therefore, when you use the `WITH` syntax to control the collecting behavior of `ANALYZE`, you need to manually set scheduled tasks to collect statistics.

Before TiDB v5.0, when you execute a query, TiDB collects feedback with `feedback- ↪ probability` and updates the histogram and Count-Min Sketch based on the feedback. **Since v5.0, this feature is disabled by default. Since v5.4, this feature has been deprecated, and it is not recommended to enable this feature.**

Control `ANALYZE` concurrency

When you run the `ANALYZE` statement, you can adjust the concurrency using the following parameters, to control its effect on the system.

`tidb_build_stats_concurrency`

Currently, when you run the `ANALYZE` statement, the task is divided into multiple small tasks. Each task only works on one column or index. You can use the `tidb_build_stats_concurrency` parameter to control the number of simultaneous tasks. The default value is 4.

`tidb_distsql_scan_concurrency`

When you analyze regular columns, you can use the `tidb_distsql_scan_concurrency` parameter to control the number of Region to be read at one time. The default value is 15.

`tidb_index_serial_scan_concurrency`

When you analyze index columns, you can use the `tidb_index_serial_scan_concurrency ↪` parameter to control the number of Region to be read at one time. The default value is 1.

Persist `ANALYZE` configurations

Since v5.4.0, TiDB supports persisting some **ANALYZE** configurations. With this feature, the existing configurations can be easily reused for future statistics collection.

The following are the **ANALYZE** configurations that support persistence:

Configurations	Corresponding
The number of histograms buckets	AN- A- LYZE syn-
The number of top-N buckets	WITH NUM BUCK- ETS
The number of top-N	WITH NUM TOPN
The number of samples	WITH NUM SAM- PLES
The sampling rate	WITH FLOAT- NUM SAM- PLER- ATE

ti-
fier
)*

Enable ANALYZE configuration persistence

The ANALYZE configuration persistence feature is enabled by default (the system variable `tidb_analyze_version` is 2 and `tidb_persist_analyze_options` is ON by default). You can use this feature to record the persistence configurations specified in the ANALYZE statement when executing the statement manually. Once recorded, the next time TiDB automatically updates statistics or you manually collect statistics without specifying these configuration, TiDB will collect statistics according to the recorded configurations.

To query the configuration persisted on a specific table used for auto analyze operations, you can use the following SQL statement:

```
SELECT sample_num, sample_rate, buckets, topn, column_choice, column_ids
↪ FROM mysql.analyze_options opt JOIN information_schema.tables tbl ON
```

```

↪ opt.table_id = tbl.tidb_table_id WHERE tbl.table_schema = '{db_name}'
↪ AND tbl.table_name = '{table_name}';

```

TiDB will overwrite the previously recorded persistent configuration using the new configurations specified by the latest `ANALYZE` statement. For example, if you run `ANALYZE ↪ TABLE t WITH 200 TOPN;`, it will set the top 200 values in the `ANALYZE` statement. Subsequently, executing `ANALYZE TABLE t WITH 0.1 SAMPLERATE;` will set both the top 200 values and a sampling rate of 0.1 for auto `ANALYZE` statements, similar to `ANALYZE ↪ TABLE t WITH 200 TOPN, 0.1 SAMPLERATE;`.

Disable `ANALYZE` configuration persistence

To disable the `ANALYZE` configuration persistence feature, set the `tidb_persist_analyze_options` ↪ system variable to `OFF`. Because the `ANALYZE` configuration persistence feature is not applicable to `tidb_analyze_version = 1`, setting `tidb_analyze_version = 1` can also disable the feature.

After disabling the `ANALYZE` configuration persistence feature, TiDB does not clear the persisted configuration records. Therefore, if you enable this feature again, TiDB continues to collect statistics using the previously recorded persistent configurations.

Note:

When you enable the `ANALYZE` configuration persistence feature again, if the previously recorded persistence configurations are no longer applicable to the latest data, you need to execute the `ANALYZE` statement manually and specify the new persistence configurations.

View `ANALYZE` state

When executing the `ANALYZE` statement, you can view the current state of `ANALYZE` using the following SQL statement:

```
SHOW ANALYZE STATUS [ShowLikeOrWhere]
```

This statement returns the state of `ANALYZE`. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW ANALYZE STATUS` statement returns the following 7 columns:

Column	Description
name	
table_schema	The database name
table_name	The table name

Column name	Description
partition_name	The partition name
job_info	The task information. The element includes index names when index analysis is performed.
row_count	The number of rows that have been analyzed
start_time	The time at which the task starts
state	The state of a task, including pending, running, finished, and failed

View statistics

You can view the statistics status using the following statements.

Metadata of tables

You can use the `SHOW STATS_META` statement to view the total number of rows and the number of updated rows.

```
SHOW STATS_META [ShowLikeOrWhere];
```

The syntax of `ShowLikeOrWhereOpt` is as follows:

Figure 73: `ShowLikeOrWhereOpt`

Currently, the `SHOW STATS_META` statement returns the following 6 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>update_time</code>	The time of the update
<code>modify_count</code>	The number of modified rows
<code>row_count</code>	The total number of rows

Note:

When TiDB automatically updates the total number of rows and the number of modified rows according to DML statements, `update_time` is also updated. Therefore, `update_time` does not necessarily indicate the last time when the `ANALYZE` statement is executed.

Health state of tables

You can use the `SHOW STATS_HEALTHY` statement to check the health state of tables and roughly estimate the accuracy of the statistics. When `modify_count` \geq `row_count`, the health state is 0; when `modify_count` $<$ `row_count`, the health state is $(1 - \text{modify_count} \div \text{row_count}) * 100$.

The syntax is as follows:

```
SHOW STATS_HEALTHY [ShowLikeOrWhere];
```

The synopsis of `SHOW STATS_HEALTHY` is:

Figure 74: ShowStatsHealthy

Currently, the `SHOW STATS_HEALTHY` statement returns the following 4 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>healthy</code>	The health state of tables

Metadata of columns

You can use the `SHOW STATS_HISTOGRAMS` statement to view the number of different values and the number of `NULL` in all the columns.

Syntax as follows:

```
SHOW STATS_HISTOGRAMS [ShowLikeOrWhere]
```

This statement returns the number of different values and the number of `NULL` in all the columns. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_HISTOGRAMS` statement returns the following 10 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>column_name</code>	The column name (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>update_time</code>	The time of the update
<code>distinct_count</code>	The number of different values
<code>null_count</code>	The number of <code>NULL</code>
<code>avg_col_size</code>	The average length of columns

Column name	Description
correlation	The Pearson correlation coefficient of the column and the integer primary key, which indicates the degree of association between the two columns

Buckets of histogram

You can use the `SHOW STATS_BUCKETS` statement to view each bucket of the histogram.

The syntax is as follows:

```
SHOW STATS_BUCKETS [ShowLikeOrWhere]
```

The diagram is as follows:

Figure 75: SHOW STATS_BUCKETS

This statement returns information about all the buckets. You can use `ShowLikeOrWhere` to filter the information you need.

Currently, the `SHOW STATS_BUCKETS` statement returns the following 11 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name

Column name	Description
<code>column_name</code> ↔	The column name (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>bucket_id</code>	The ID of a bucket
<code>count</code>	The number of all the values that falls on the bucket and the previous buckets
<code>repeats</code>	The occurrence number of the maximum value
<code>lower_bound</code> ↔	The minimum value
<code>upper_bound</code> ↔	The maximum value
<code>ndv</code>	The number of different values in the bucket. When <code>tidb_analyze_version</code> ↔ = 1, <code>ndv</code> is always 0, which has no actual meaning.

Top-N information

You can use the `SHOW STATS_TOPN` statement to view the Top-N information currently collected by TiDB.

The syntax is as follows:

```
SHOW STATS_TOPN [ShowLikeOrWhere];
```

Currently, the `SHOW STATS_TOPN` statement returns the following 7 columns:

Column name	Description
<code>db_name</code>	The database name
<code>table_name</code>	The table name
<code>partition_name</code>	The partition name
<code>column_name</code>	The column name (when <code>is_index</code> is 0) or the index name (when <code>is_index</code> is 1)
<code>is_index</code>	Whether it is an index column or not
<code>value</code>	The value of this column

Column name	Description
count	How many times the value appears

Delete statistics

You can run the `DROP STATS` statement to delete statistics.

Syntax as follows:

```
DROP STATS TableName
```

The statement deletes statistics of all the tables in `TableName`.

Load statistics

By default, depending on the size of column statistics, TiDB loads statistics differently as follows:

- For statistics that consume small amounts of memory (such as `count`, `distinctCount`, and `nullCount`), as long as the column data is updated, TiDB automatically loads the corresponding statistics into memory for use in the SQL optimization stage.
- For statistics that consume large amounts of memory (such as histograms, `TopN`, and `Count-Min Sketch`), to ensure the performance of SQL execution, TiDB loads the statistics asynchronously on demand. Take histograms as an example. TiDB loads histogram statistics on a column into memory only when the optimizer uses the histogram statistics on that column. On-demand asynchronous statistics loading does not affect the performance of SQL execution but might provide incomplete statistics for SQL optimization.

Since v5.4.0, TiDB introduces the synchronously loading statistics feature. This feature allows TiDB to synchronously load large-sized statistics (such as histograms, `TopN`, and `Count-Min Sketch` statistics) into memory when you execute SQL statements, which improves the completeness of statistics for SQL optimization.

Warning:

Currently, synchronously loading statistics is an experimental feature. It is not recommended that you use it in production environments.

The synchronously loading statistics feature is disabled by default. To enable this feature, set the value of the `tidb_stats_load_sync_wait` system variable to a timeout (in milliseconds) that SQL optimization can wait for at most to synchronously load complete column statistics. The default value of this variable is 0, indicating that the feature is disabled.

After enabling the synchronously loading statistics feature, you can further configure the feature as follows:

- To control how TiDB behaves when the waiting time of SQL optimization reaches the timeout, modify the value of the `tidb_stats_load_pseudo_timeout` system variable. The default value of this variable is `OFF`, indicating that the SQL execution fails after the timeout. If you set this variable to `ON`, after the timeout, the SQL optimization process does not use any histogram, TopN, or CMSketch statistics on any columns, but gets back to using pseudo statistics.
- To specify the maximum number of columns that the synchronously loading statistics feature can process concurrently, modify the value of the `stats-load-concurrency` option in the TiDB configuration file. The default value is 5.
- To specify the maximum number of column requests that the synchronously loading statistics feature can cache, modify the value of the `stats-load-queue-size` option in the TiDB configuration file. The default value is 1000.

Import and export statistics

Export statistics

The interface to export statistics is as follows:

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_name}/${table_name}
```

For example:

```
curl -s http://127.0.0.1:10080/stats/dump/test/t1 -o /tmp/t1.json
```

- To obtain the JSON format statistics of the `${table_name}` table in the `${db_name}` database at specific time:

```
http://${tidb-server-ip}:${tidb-server-status-port}/stats/dump/${db_name}/${table_name}/${yyyyMMddHHmmss}
```

Import statistics

Note:

When you start the MySQL client, use the `--local-infile=1` option.

Generally, the imported statistics refer to the JSON file obtained using the export interface.

Syntax:

```
LOAD STATS 'file_name'
```

`file_name` is the file name of the statistics to be imported.

- [DROP STATS](#)

9.3.3.3.4 Wrong Index Solution

If you find that the execution speed of some query does not reach the expectation, the optimizer might choose the wrong index to run the query.

You can first view the [health state of tables](#) in the statistics, and then solve this issue according to the different health states.

Low health state

The low health state means TiDB has not performed the `ANALYZE` statement for a long time. You can update the statistics by running the `ANALYZE` command. After the update, if the optimizer still uses the wrong index, refer to the next section.

Near 100% health state

The near 100% health state suggests that the `ANALYZE` statement is just completed or was completed a short time ago. In this case, the wrong index issue might be related to TiDB's estimation logic for the number of rows.

For equivalence queries, the cause might be [Count-Min Sketch](#). You can check whether Count-Min Sketch is the cause and take corresponding solutions.

If the cause above does not apply to your problem, you can force-select indexes by using the `USE_INDEX` or `use index` optimizer hint (see [USE_INDEX](#) for details). Also, you can change the query behavior by using [SQL Plan Management](#) in a non-intrusive way.

Other situations

Apart from the aforementioned situations, the wrong index issue might also be caused by data updates which renders all the indexes no longer applicable. In such cases, you need to perform analysis on the conditions and data distribution to see whether new indexes can speed up the query. If so, you can add new indexes by running the `ADD INDEX` command.

9.3.3.3.5 Distinct Optimization

This document introduces the `distinct` optimization in the TiDB query optimizer, including `SELECT DISTINCT` and `DISTINCT` in the aggregate functions.

`DISTINCT` modifier in `SELECT` statements

The `DISTINCT` modifier specifies removal of duplicate rows from the result set. `SELECT` \leftrightarrow `DISTINCT` is transformed to `GROUP BY`, for example:

```
mysql> explain SELECT DISTINCT a from t;
+---+
| id | estRows | task | access object | operator info |
+---+
| HashAgg_6 | 2.40 | root | | group by:test.t.a |
| -TableReader_11 | 3.00 | root | | data: |
| -TableFullScan_10 | 3.00 | cop[tikv] | table:t | keep order:false |
+---+
3 rows in set (0.00 sec)
```

`DISTINCT` option in aggregate functions

Usually, aggregate functions with the `DISTINCT` option is executed in the TiDB layer in a single-threaded execution model.

The `tidb_opt_distinct_agg_push_down` system variable or the `distinct-agg-push` \leftrightarrow `-down` configuration item in TiDB controls whether to rewrite the distinct aggregate queries and push them to the TiKV/TiFlash Coprocessor.

Take the following queries as an example of this optimization. `tidb_opt_distinct_agg_push_down` \leftrightarrow is disabled by default, which means the aggregate functions are executed in the TiDB layer. After enabling this optimization by setting its value to 1, the `distinct a` part of `count(distinct a)` is pushed to TiKV/TiFlash Coprocessor: there is a `HashAgg_5` to remove the duplicated values on column `a` in the TiKV Coprocessor. It might reduce the computation overhead of `HashAgg_8` in the TiDB layer.

```
mysql> desc select count(distinct a) from test.t;
+---+
| id | estRows | task | access object | operator info |
+---+
3 rows in set (0.00 sec)
```

```

| id          | estRows | task   | access object | operator info

+---+
4 rows in set (0.00 sec)

```

9.3.3.4 SQL Prepare Execution Plan Cache

TiDB supports execution plan caching for Prepare and Execute queries. This includes

both forms of prepared statements:

- Using the `COM_STMT_PREPARE` and `COM_STMT_EXECUTE` protocol features.
- Using the SQL statements `PREPARE` and `EXECUTE`.

The TiDB optimizer handles these two types of queries in the same way: when preparing, the parameterized query is parsed into an AST (Abstract Syntax Tree) and cached; in later execution, the execution plan is generated based on the stored AST and specific parameter values.

When the execution plan cache is enabled, in the first execution every `Prepare` statement checks whether the current query can use the execution plan cache, and if the query can use it, then put the generated execution plan into a cache implemented by LRU (Least Recently Used) linked list. In the subsequent `Execute` queries, the execution plan is obtained from the cache and checked for availability. If the check succeeds, the step of generating an execution plan is skipped. Otherwise, the execution plan is regenerated and saved in the cache.

In the current version of TiDB, if a `Prepare` statement meets any of the following conditions, the query or the plan is not cached:

- The query contains SQL statements other than `SELECT`, `UPDATE`, `INSERT`, `DELETE`, `Union`, `Intersect`, and `Except`.
- The query accesses partitioned tables or temporary tables, or a table that contains generated columns.
- The query contains sub-queries, such as `select * from t where a > (select ...)`.
- The query contains the `ignore_plan_cache` hint, such as `select /*+ ignore_plan_cache ↪ ()*/ * from t`.
- The query contains variables other than `?` (including system variables or user-defined variables), such as `select * from t where a>? and b>@x`.
- The query contains the functions that cannot be cached: `database()`, `current_user ↪`, `current_role`, `user`, `connection_id`, `last_insert_id`, `row_count`, `version`, and `like`.
- The query contains `?` after `Limit`, such as `Limit ?` and `Limit 10, ?`. Such queries are not cached because the specific value of `?` has a great impact on query performance.
- The query contains `?` after `Order By`, such as `Order By ?`. Such queries sort data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Order By a+?`, it is cached.
- The query contains `?` after `Group By`, such as `Group By?`. Such queries group data based on the column specified by `?`. If the queries targeting different columns use the same execution plan, the results will be wrong. Therefore, such queries are not cached. However, if the query is a common one, such as `Group By a+?`, it is cached.
- The query contains `?` in the definition of the `Window Frame` window function, such as `(partition by year order by sale rows ? preceding)`. If `?` appears elsewhere in the window function, the query is cached.

- The query contains parameters for comparing `int` and `string`, such as `c_int >= ?` \leftrightarrow or `c_int in (?, ?)`, in which `?` indicates the string type, such as `set @x='123'`. To ensure that the query result is compatible with MySQL, parameters need to be adjusted in each query, so such queries are not cached.
- The plan attempts to access `TiFlash`.
- In most cases, the plan that contains `TableDual` is not cached, unless the current `Prepare` statement does not have parameters.

The LRU linked list is designed as a session-level cache because `Prepare / Execute` cannot be executed across sessions. Each element of the LRU list is a key-value pair. The value is the execution plan, and the key is composed of the following parts:

- The name of the database where `Execute` is executed
- The identifier of the `Prepare` statement, that is, the name after the `PREPARE` keyword
- The current schema version, which is updated after every successfully executed DDL statement
- The SQL mode when executing `Execute`
- The current time zone, which is the value of the `time_zone` system variable
- The value of the `sql_select_limit` system variable

Any change in the above information (for example, switching databases, renaming `Prepare` statement, executing DDL statements, or modifying the value of SQL mode / `time_zone`), or the LRU cache elimination mechanism causes the execution plan cache miss when executing.

After the execution plan cache is obtained from the cache, TiDB first checks whether the execution plan is still valid. If the current `Execute` statement is executed in an explicit transaction, and the referenced table is modified in the transaction pre-order statement, the cached execution plan accessing this table does not contain the `UnionScan` operator, then it cannot be executed.

After the validation test is passed, the scan range of the execution plan is adjusted according to the current parameter values, and then used to perform data querying.

There are several points worth noting about execution plan caching and query performance:

- No matter an execution plan is cached or not, it is affected by SQL bindings. For execution plans that have not been cached (the first `Execute`), these plans are affected by existing SQL bindings. For execution plans that have been cached, if new SQL Bindings are created, these plans become invalid.
- Cached plans are not affected by changes in statistics, optimization rules, and blocklist pushdown by expressions.
- Considering that the parameters of `Execute` are different, the execution plan cache prohibits some aggressive query optimization methods that are closely related to specific parameter values to ensure adaptability. This causes that the query plan may not

be optimal for certain parameter values. For example, the filter condition of the query is `where a > ? And a < ?`, the parameters of the first `Execute` statement are 2 and 1 respectively. Considering that these two parameters maybe be 1 and 2 in the next execution time, the optimizer does not generate the optimal `TableDual` execution plan that is specific to current parameter values;

- If cache invalidation and elimination are not considered, an execution plan cache is applied to various parameter values, which in theory also results in non-optimal execution plans for certain values. For example, if the filter condition is `where a < ?` and the parameter value used for the first execution is 1, then the optimizer generates the optimal `IndexScan` execution plan and puts it into the cache. In the subsequent executions, if the value becomes 10000, the `TableScan` plan might be the better one. But due to the execution plan cache, the previously generated `IndexScan` is used for execution. Therefore, the execution plan cache is more suitable for application scenarios where the query is simple (the ratio of compilation is high) and the execution plan is relatively fixed.

Currently, the execution plan cache is disabled by default. You can enable this feature by enabling the `prepared-plan-cache` in the TiDB configuration file.

Note:

The execution plan cache feature applies only to `Prepare / Execute` queries and does not take effect for normal queries.

After the execution plan cache feature is enabled, you can use the session-level system variable `last_plan_from_cache` to see whether the previous `Execute` statement used the cached execution plan, for example:

```
MySQL [test]> create table t(a int);
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> prepare stmt from 'select * from t where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)

-- The first execution generates an execution plan and saves it in the
   ↪ cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
```

```

+-----+
| 0          |
+-----+
1 row in set (0.00 sec)

-- The second execution hits the cache.
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 1          |
+-----+
1 row in set (0.00 sec)

```

If you find that a certain set of Prepare / Execute has unexpected behavior due to the execution plan cache, you can use the `ignore_plan_cache()` SQL hint to skip using the execution plan cache for the current statement. Still, use the above statement as an example:

```

MySQL [test]> prepare stmt from 'select /*+ ignore_plan_cache() */ * from t
    ↪ where a = ?';
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> set @a = 1;
Query OK, 0 rows affected (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 0          |
+-----+
1 row in set (0.00 sec)
MySQL [test]> execute stmt using @a;
Empty set (0.00 sec)
MySQL [test]> select @@last_plan_from_cache;
+-----+
| @@last_plan_from_cache |
+-----+
| 0          |
+-----+
1 row in set (0.00 sec)

```

9.3.4 Control Execution Plans

9.3.4.1 Control Execution Plan

The first two chapters of SQL Tuning introduce how to understand TiDB's execution plan and how TiDB generates an execution plan. This chapter introduces what methods can be used to control the generation of the execution plan when you determine the problems with the execution plan. This chapter mainly includes the following three aspects:

- In [Optimizer Hints](#), you will learn how to use hints to guide TiDB to generate an execution plan.
- But hints change the SQL statement intrusively. In some scenarios, hints cannot be simply inserted. In [SQL Plan Management](#), you will know how TiDB uses another syntax to non-intrusively control the generation of execution plans, and the methods of automatic execution plan evolution in the background to alleviate the execution plan instability caused by reasons such as version upgrades, which degrades cluster performance.
- Finally, you will learn how to use the blocklist in [Blocklist of Optimization Rules and Expression Pushdown](#).

9.3.4.2 Optimizer Hints

TiDB supports optimizer hints, which are based on the comment-like syntax introduced in MySQL 5.7. For example, one of the common syntaxes is `/*+ HINT_NAME([t1_name [, ↵ t2_name] ...])*/`. Use of optimizer hints is recommended in cases where the TiDB optimizer selects a less optimal query plan.

Note:

MySQL command-line clients earlier than 5.7.7 strip optimizer hints by default. If you want to use the `Hint` syntax in these earlier versions, add the `--comments` option when starting the client. For example: `mysql -h ↵ 127.0.0.1 -P 4000 -uroot --comments`.

9.3.4.2.1 Syntax

Optimizer hints are case insensitive and specified within `/*+ ... */` comments following the `SELECT`, `UPDATE` or `DELETE` keyword in a SQL statement. Optimizer hints are not currently supported for `INSERT` statements.

Multiple hints can be specified by separating with commas. For example, the following query uses three different hints:

```
SELECT /*+ USE_INDEX(t1, idx1), HASH_AGG(), HASH_JOIN(t1) */ count(*) FROM
↪ t t1, t t2 WHERE t1.a = t2.b;
```

How optimizer hints affect query execution plans can be observed in the output of `EXPLAIN` and `EXPLAIN ANALYZE`.

An incorrect or incomplete hint will not result in a statement error. This is because hints are intended to have only a *hint* (suggestion) semantic to query execution. Similarly, TiDB will at most return a warning if a hint is not applicable.

Note:

If the comments do not follow behind the specified keywords, they will be treated as common MySQL comments. The comments do not take effect, and no warning is reported.

Currently, TiDB supports two categories of hints, which are different in scope. The first category of hints takes effect in the scope of query blocks, such as `/*+ HASH_AGG()*/`; the second category of hints takes effect in the whole query, such as `/*+ MEMORY_QUOTA(1024 MB)*/`.

Each query or sub-query in a statement corresponds to a different query block, and each query block has its own name. For example:

```
SELECT * FROM (SELECT * FROM t) t1, (SELECT * FROM t) t2;
```

The above query statement has three query blocks: the outermost `SELECT` corresponds to the first query block, whose name is `sel_1`; the two `SELECT` sub-queries correspond to the second and the third query block, whose names are `sel_2` and `sel_3`, respectively. The sequence of the numbers is based on the appearance of `SELECT` from left to right. If you replace the first `SELECT` with `DELETE` or `UPDATE`, then the corresponding query block names are `del_1` or `upd_1`.

9.3.4.2.2 Hints that take effect in query blocks

This category of hints can follow behind **any** `SELECT`, `UPDATE` or `DELETE` keywords. To control the effective scope of the hint, use the name of the query block in the hint. You can make the hint parameters clear by accurately identifying each table in the query (in case of duplicated table names or aliases). If no query block is specified in the hint, the hint takes effect in the current block by default.

For example:

```
SELECT /*+ HASH_JOIN(@sel_1 t1@sel_1, t3) */ * FROM (SELECT t1.a, t1.b
↪ FROM t t1, t t2 WHERE t1.a = t2.a) t1, t t3 WHERE t1.b = t3.b;
```

This hint takes effect in the `sel_1` query block, and its parameters are the `t1` and `t3` tables in `sel_1` (`sel_2` also contains a `t1` table).

As described above, you can specify the name of the query block in the hint in the following ways:

- Set the query block name as the first parameter of the hint, and separate it from other parameters with a space. In addition to `QB_NAME`, all the hints listed in this section also have another optional hidden parameter `@QB_NAME`. By using this parameter, you can specify the effective scope of this hint.
- Append `@QB_NAME` to a table name in the parameter to explicitly specify which query block this table belongs to.

Note:

You must put the hint in or before the query block where the hint takes effect. If the hint is put after the query block, it cannot take effect.

QB_NAME

If the query statement is a complicated statement that includes multiple nested queries, the ID and name of a certain query block might be mistakenly identified. The hint `QB_NAME` can help us in this regard.

`QB_NAME` means Query Block Name. You can specify a new name to a query block. The specified `QB_NAME` and the previous default name are both valid. For example:

```
SELECT /*+ QB_NAME(QB1) */ * FROM (SELECT * FROM t) t1, (SELECT * FROM t)
↪ t2;
```

This hint specifies the outer `SELECT` query block's name to `QB1`, which makes `QB1` and the default name `sel_1` both valid for the query block.

Note:

In the above example, if the hint specifies the `QB_NAME` to `sel_2` and does not specify a new `QB_NAME` for the original second `SELECT` query block, then `sel_2` becomes an invalid name for the second `SELECT` query block.

`MERGE_JOIN(t1_name [, t1_name ...])`

The `MERGE_JOIN(t1_name [, t1_name ...])` hint tells the optimizer to use the sort-merge join algorithm for the given table(s). Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ MERGE_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

Note:

`TIDB_SMJ` is the alias for `MERGE_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_SMJ(t1_name ↪ [, t1_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_SMJ` and `MERGE_JOIN` are both valid names for the hint, but `MERGE_JOIN` is recommended.

`INL_JOIN(t1_name [, t1_name ...])`

The `INL_JOIN(t1_name [, t1_name ...])` hint tells the optimizer to use the index nested loop join algorithm for the given table(s). This algorithm might consume less system resources and take shorter processing time in some scenarios and might produce an opposite result in other scenarios. If the result set is less than 10,000 rows after the outer table is filtered by the `WHERE` condition, it is recommended to use this hint. For example:

```
select /*+ INL_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

The parameter(s) given in `INL_JOIN()` is the candidate table for the inner table when you create the query plan. For example, `INL_JOIN(t1)` means that TiDB only considers using `t1` as the inner table to create a query plan. If the candidate table has an alias, you must use the alias as the parameter in `INL_JOIN()`; if it does not have an alias, use the table's original name as the parameter. For example, in the `select /*+ INL_JOIN(t1)*/ ↪ * from t t1, t t2 where t1.a = t2.b;` query, you must use the `t` table's alias `t1` or `t2` rather than `t` as `INL_JOIN()`'s parameter.

Note:

`TIDB_INLJ` is the alias for `INL_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_INLJ(t1_name ↪ [, t1_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_INLJ` and `INL_JOIN` are both valid names for the hint, but `INL_JOIN` is recommended.

INL_HASH_JOIN

The `INL_HASH_JOIN(t1_name [, t1_name])` hint tells the optimizer to use the index nested loop hash join algorithm. The conditions for using this algorithm are the same with the conditions for using the index nested loop join algorithm. The difference between the two algorithms is that `INL_JOIN` creates a hash table on the joined inner table, but `INL_HASH_JOIN` creates a hash table on the joined outer table. `INL_HASH_JOIN` has a fixed limit on memory usage, while the memory used by `INL_JOIN` depends on the number of rows matched in the inner table.

`HASH_JOIN(t1_name [, t1_name ...])`

The `HASH_JOIN(t1_name [, t1_name ...])` hint tells the optimizer to use the hash join algorithm for the given table(s). This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_JOIN(t1, t2) */ * from t1, t2 where t1.id = t2.id;
```

Note:

`TIDB_HJ` is the alias for `HASH_JOIN` in TiDB 3.0.x and earlier versions. If you are using any of these versions, you must apply the `TIDB_HJ(t1_name ↪ [, t1_name ...])` syntax for the hint. For the later versions of TiDB, `TIDB_HJ` and `HASH_JOIN` are both valid names for the hint, but `HASH_JOIN` is recommended.

HASH_AGG()

The `HASH_AGG()` hint tells the optimizer to use the hash aggregation algorithm in all the aggregate functions in the specified query block. This algorithm allows the query to be executed concurrently with multiple threads, which achieves a higher processing speed but consumes more memory. For example:

```
select /*+ HASH_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.  
↪ id;
```

STREAM_AGG()

The `STREAM_AGG()` hint tells the optimizer to use the stream aggregation algorithm in all the aggregate functions in the specified query block. Generally, this algorithm consumes less memory but takes longer processing time. If there is a very large data volume or insufficient system memory, it is recommended to use this hint. For example:

```
select /*+ STREAM_AGG() */ count(*) from t1, t2 where t1.a > 10 group by t1.  
↪ .id;
```

USE_INDEX(t1_name, idx1_name [, idx2_name ...])

The USE_INDEX(t1_name, idx1_name [, idx2_name ...]) hint tells the optimizer to use only the given index(es) for a specified t1_name table. For example, applying the following hint has the same effect as executing the `select * from t t1 use index(idx1, ↵ idx2);` statement.

```
SELECT /*+ USE_INDEX(t1, idx1, idx2) */ * FROM t1;
```

Note:

If you specify only the table name but not index name in this hint, the execution does not consider any index but scan the entire table.

IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...])

The IGNORE_INDEX(t1_name, idx1_name [, idx2_name ...]) hint tells the optimizer to ignore the given index(es) for a specified t1_name table. For example, applying the following hint has the same effect as executing the `select * from t t1 ignore index(↵ idx1, idx2);` statement.

```
select /*+ IGNORE_INDEX(t1, idx1, idx2) */ * from t t1;
```

AGG_TO_COP()

The AGG_TO_COP() hint tells the optimizer to push down the aggregate operation in the specified query block to the coprocessor. If the optimizer does not push down some aggregate function that is suitable for pushdown, then it is recommended to use this hint. For example:

```
select /*+ AGG_TO_COP() */ sum(t1.a) from t t1;
```

LIMIT_TO_COP()

The LIMIT_TO_COP() hint tells the optimizer to push down the Limit and TopN operators in the specified query block to the coprocessor. If the optimizer does not perform such an operation, it is recommended to use this hint. For example:

```
SELECT /*+ LIMIT_TO_COP() */ * FROM t WHERE a = 1 AND b > 10 ORDER BY c  
↵ LIMIT 1;
```

READ_FROM_STORAGE(TIFLASH[t1_name [, t1_name ...]], TIKV[t2_name [, t1_name ...]])

The READ_FROM_STORAGE(TIFLASH[t1_name [, t1_name ...]], TIKV[t2_name [, ↵ t1_name ...]]) hint tells the optimizer to read specific table(s) from specific storage engine(s). Currently, this hint supports two storage engine parameters - TIKV and TIFLASH. If a table has an alias, use the alias as the parameter of READ_FROM_STORAGE(); if the table does not has an alias, use the table's original name as the parameter. For example:

```
select /*+ READ_FROM_STORAGE(TIFLASH[t1], TIKV[t2]) */ t1.a from t t1, t
  ↪ t2 where t1.a = t2.a;
```

Note:

If you want the optimizer to use a table from another schema, you need to explicitly specify the schema name. For example:

```
SELECT /*+ READ_FROM_STORAGE(TIFLASH[test1.t1,test2.t2]) */ t1
  ↪ .a FROM test1.t t1, test2.t t2 WHERE t1.a = t2.a;
```

`USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])`

The `USE_INDEX_MERGE(t1_name, idx1_name [, idx2_name ...])` hint tells the optimizer to access a specific table with the index merge method. The given list of indexes are optional parameters. If you explicitly specify the list, TiDB selects indexes from the list to build index merge; if you do not give the list of indexes, TiDB selects indexes from all available indexes to build index merge. For example:

```
SELECT /*+ USE_INDEX_MERGE(t1, idx_a, idx_b, idx_c) */ * FROM t1 WHERE t1.
  ↪ a > 10 OR t1.b > 10;
```

When multiple `USE_INDEX_MERGE` hints are made to the same table, the optimizer tries to select the index from the union of the index sets specified by these hints.

Note:

The parameters of `USE_INDEX_MERGE` refer to index names, rather than column names. The index name of the primary key is `primary`.

This hint takes effect on strict conditions, including:

- If the query can select a single index scan in addition to full table scan, the optimizer does not select index merge.

9.3.4.2.3 Hints that take effect in the whole query

This category of hints can only follow behind the **first** `SELECT`, `UPDATE` or `DELETE` keyword, which is equivalent to modifying the value of the specified system variable when this query is executed. The priority of the hint is higher than that of existing system variables.

Note:

This category of hints also has an optional hidden variable `@QB_NAME`, but the hint takes effect in the whole query even if you specify the variable.

NO_INDEX_MERGE()

The `NO_INDEX_MERGE()` hint disables the index merge feature of the optimizer.

For example, the following query will not use index merge:

```
select /*+ NO_INDEX_MERGE() */ * from t where t.a > 0 or t.b > 0;
```

In addition to this hint, setting the `tidb_enable_index_merge` system variable also controls whether to enable this feature.

Note:

- `NO_INDEX_MERGE` has a higher priority over `USE_INDEX_MERGE`. When both hints are used, `USE_INDEX_MERGE` does not take effect.
- For a subquery, `NO_INDEX_MERGE` only takes effect when it is placed at the outermost level of the subquery.

USE_TOJA(boolean_value)

The `boolean_value` parameter can be `TRUE` or `FALSE`. The `USE_TOJA(TRUE)` hint enables the optimizer to convert an `in` condition (containing a sub-query) to join and aggregation operations. Comparatively, the `USE_TOJA(FALSE)` hint disables this feature.

For example, the following query will convert `in (select t2.a from t2)subq` to corresponding join and aggregation operations:

```
select /*+ USE_TOJA(TRUE) */ t1.a, t1.b from t1 where t1.a in (select t2.a  
↪ from t2) subq;
```

In addition to this hint, setting the `tidb_opt_insubq_to_join_and_agg` system variable also controls whether to enable this feature.

MAX_EXECUTION_TIME(N)

The `MAX_EXECUTION_TIME(N)` hint places a limit `N` (a timeout value in milliseconds) on how long a statement is permitted to execute before the server terminates it. In the following hint, `MAX_EXECUTION_TIME(1000)` means that the timeout is 1000 milliseconds (that is, 1 second):

```
select /*+ MAX_EXECUTION_TIME(1000) */ * from t1 inner join t2 where t1.id  
↪ = t2.id;
```

In addition to this hint, the `global.max_execution_time` system variable can also limit the execution time of a statement.

MEMORY_QUOTA(N)

The `MEMORY_QUOTA(N)` hint places a limit `N` (a threshold value in MB or GB) on how much memory a statement is permitted to use. When a statement's memory usage exceeds this limit, TiDB produces a log message based on the statement's over-limit behavior or just terminates it.

In the following hint, `MEMORY_QUOTA(1024 MB)` means that the memory usage is limited to 1024 MB:

```
select /*+ MEMORY_QUOTA(1024 MB) */ * from t;
```

In addition to this hint, the `tidb_mem_quota_query` system variable can also limit the memory usage of a statement.

READ_CONSISTENT_REPLICA()

The `READ_CONSISTENT_REPLICA()` hint enables the feature of reading consistent data from the TiKV follower node. For example:

```
select /*+ READ_CONSISTENT_REPLICA() */ * from t;
```

In addition to this hint, setting the `tidb_replica_read` environment variable to '`↪ follower`' or '`leader`' also controls whether to enable this feature.

IGNORE_PLAN_CACHE()

The `IGNORE_PLAN_CACHE()` hint reminds the optimizer not to use the Plan Cache when handling the current `prepare` statement.

This hint is used to temporarily disable the Plan Cache for a certain type of queries when the `execution plan cache` feature is enabled.

In the following example, the Plan Cache is forcibly disabled when executing the `prepare` statement.

```
prepare stmt from 'select /*+ IGNORE_PLAN_CACHE() */ * from t where t.id =  
↪ ?';
```

NTH_PLAN(N)

The `NTH_PLAN(N)` hint reminds the optimizer to select the `N`th physical plan found during the physical optimization. `N` must be a positive integer.

If the specified `N` is beyond the search range of the physical optimization, TiDB will return a warning and select the optimal physical plan based on the strategy that ignores this hint.

This hint does not take effect when the cascades planner is enabled.

In the following example, the optimizer is forced to select the third physical plan found during the physical optimization:

```
SELECT /*+ NTH_PLAN(3) */ count(*) from t where a > 5;
```

Note:

`NTH_PLAN(N)` is mainly used for testing, and its compatibility is not guaranteed in later versions. Use this hint **with caution**.

9.3.4.3 SQL Plan Management (SPM)

SQL Plan Management is a set of functions that execute SQL bindings to manually interfere with SQL execution plans. These functions include SQL binding, baseline capturing, and baseline evolution.

9.3.4.3.1 SQL binding

An SQL binding is the basis of SPM. The [Optimizer Hints](#) document introduces how to select a specific execution plan using hints. However, sometimes you need to interfere with execution selection without modifying SQL statements. With SQL bindings, you can select a specified execution plan without modifying SQL statements.

Create a binding

```
CREATE [GLOBAL | SESSION] BINDING FOR BindableStmt USING BindableStmt
```

This statement binds SQL execution plans at the GLOBAL or SESSION level. Currently, supported bindable SQL statements (BindableStmt) in TiDB include SELECT, DELETE, UPDATE, and INSERT / REPLACE with SELECT subqueries.

Specifically, two types of these statements cannot be bound to execution plans due to syntax conflicts. See the following examples:

```
-- Type one: Statements that get the Cartesian product by using the `join`  
↳ keyword and not specifying the associated columns with the `using`  
↳ keyword.  
create global binding for  
  select * from t t1 join t t2  
using  
  select * from t t1 join t t2;  
  
-- Type two: `DELETE` statements that contain the `using` keyword.
```

```
create global binding for
  delete from t1 using t1 join t2 on t1.a = t2.a
using
  delete from t1 using t1 join t2 on t1.a = t2.a;
```

You can bypass syntax conflicts by using equivalent statements. For example, you can rewrite the above statements in the following ways:

```
-- First rewrite of type one statements: Add a `using` clause for the `
  ↪ join` keyword.
create global binding for
  select * from t t1 join t t2 using (a)
using
  select * from t t1 join t t2 using (a);

-- Second rewrite of type one statements: Delete the `join` keyword.
create global binding for
  select * from t t1, t t2
using
  select * from t t1, t t2;

-- Rewrite of type two statements: Remove the `using` keyword from the `
  ↪ delete` statement.
create global binding for
  delete t1 from t1 join t2 on t1.a = t2.a
using
  delete t1 from t1 join t2 on t1.a = t2.a;
```

Note:

When creating execution plan bindings for INSERT / REPLACE statements with SELECT subqueries, you need to specify the optimizer hints you want to bind in the SELECT subquery, not after the INSERT / REPLACE keyword. Otherwise, the optimizer hints do not take effect as intended.

Here are two examples:

```
-- The hint takes effect in the following statement.
create global binding for
  insert into t1 select * from t2 where a > 1 and b = 1
using
  insert into t1 select /*+ use_index(@sel_1 t2, a) */ * from t2 where a
  ↪ > 1 and b = 1;
```

```

-- The hint cannot take effect in the following statement.
create global binding for
  insert into t1 select * from t2 where a > 1 and b = 1
using
  insert /*+ use_index(@sel_1 t2, a) */ into t1 select * from t2 where a
  ↪ > 1 and b = 1;

```

If you do not specify the scope when creating an execution plan binding, the default scope is SESSION. The TiDB optimizer normalizes bound SQL statements and stores them in the system table. When processing SQL queries, if a normalized statement matches one of the bound SQL statements in the system table and the system variable `tidb_use_plan_baselines` is set to `on` (the default value is `on`), TiDB then uses the corresponding optimizer hint for this statement. If there are multiple matchable execution plans, the optimizer chooses the least costly one to bind.

Normalization is a process that converts a constant in an SQL statement to a variable parameter and explicitly specifies the database for tables referenced in the query, with standardized processing on the spaces and line breaks in the SQL statement. See the following example:

```

select * from t where a > 1
-- After normalization, the above statement is as follows:
select * from test . t where a > ?

```

Note:

Multiple constants joined by commas `,` are normalized as `...` instead of `?`.

For example:

```

select * from t limit 10
select * from t limit 10, 20
select * from t where a in (1)
select * from t where a in (1,2,3)
-- After normalization, the above statements are as follows:
select * from test . t limit ?
select * from test . t limit ...
select * from test . t where a in ( ? )
select * from test . t where a in ( ... )

```

When bindings are created, TiDB treats SQL statements that contain a single constant and SQL statements that contain multiple constants joined by commas differently. Therefore, you need to create bindings for the two SQL types separately.

For example:

```

CREATE TABLE t(a INT, b INT, KEY idx(a));
CREATE SESSION BINDING for SELECT * FROM t WHERE a IN (?)
  ↪ USING SELECT /*+ use_index(t, idx) */ * FROM t WHERE a
  ↪ in (?);

```

When a SQL statement has bound execution plans in both GLOBAL and SESSION scopes, because the optimizer ignores the bound execution plan in the GLOBAL scope when it encounters the SESSION binding, the bound execution plan of this statement in the SESSION scope shields the execution plan in the GLOBAL scope.

For example:

```

-- Creates a GLOBAL binding and specifies using `sort merge join` in this
  ↪ binding.

```

```

create global binding for
  select * from t1, t2 where t1.id = t2.id
using
  select /*+ merge_join(t1, t2) */ * from t1, t2 where t1.id = t2.id;

-- The execution plan of this SQL statement uses the `sort merge join`
  ↪ specified in the GLOBAL binding.
explain select * from t1, t2 where t1.id = t2.id;

-- Creates another SESSION binding and specifies using `hash join` in this
  ↪ binding.
create binding for
  select * from t1, t2 where t1.id = t2.id
using
  select /*+ hash_join(t1, t2) */ * from t1, t2 where t1.id = t2.id;

-- In the execution plan of this statement, `hash join` specified in the
  ↪ SESSION binding is used, instead of `sort merge join` specified in
  ↪ the GLOBAL binding.
explain select * from t1, t2 where t1.id = t2.id;

```

When the first `select` statement is being executed, the optimizer adds the `sm_join(↪ t1, t2)` hint to the statement through the binding in the GLOBAL scope. The top node of the execution plan in the `explain` result is `MergeJoin`. When the second `select` statement is being executed, the optimizer uses the binding in the SESSION scope instead of the binding in the GLOBAL scope and adds the `hash_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is `HashJoin`.

Each standardized SQL statement can have only one binding created using `CREATE ↪ BINDING` at a time. When multiple bindings are created for the same standardized SQL statement, the last created binding is retained, and all previous bindings (created and evolved) are marked as deleted. But session bindings and global bindings can coexist and are not affected by this logic.

In addition, when you create a binding, TiDB requires that the session is in a database context, which means that a database is specified when the client is connected or `use ${↪ database}` is executed.

The original SQL statement and the bound statement must have the same text after normalization and hint removal, or the binding will fail. Take the following examples:

- This binding can be created successfully because the texts before and after parameterization and hint removal are the same: `select * from test . t where a > ?`
`sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM ↪ t use index (idx)WHERE a > 2`

- This binding will fail because the original SQL statement is processed as `select * ↵ from test . t where a > ?`, while the bound SQL statement is processed differently as `select * from test . t where b > ?`.

```
sql CREATE BINDING FOR SELECT * FROM t WHERE a > 1 USING SELECT * FROM  
↵ t use index(idx)WHERE b > 2
```

Note:

For PREPARE / EXECUTE statements and for queries executed with binary protocols, you need to create execution plan bindings for the real query statements, not for the PREPARE / EXECUTE statements.

Remove binding

```
DROP [GLOBAL | SESSION] BINDING FOR BindableStmt;
```

This statement removes a specified execution plan binding at the GLOBAL or SESSION level. The default scope is SESSION.

Generally, the binding in the SESSION scope is mainly used for test or in special situations. For a binding to take effect in all TiDB processes, you need to use the GLOBAL binding. A created SESSION binding shields the corresponding GLOBAL binding until the end of the SESSION, even if the SESSION binding is dropped before the session closes. In this case, no binding takes effect and the plan is selected by the optimizer.

The following example is based on the example in [create binding](#) in which the SESSION binding shields the GLOBAL binding:

```
-- Drops the binding created in the SESSION scope.  
drop session binding for select * from t1, t2 where t1.id = t2.id;  
  
-- Views the SQL execution plan again.  
explain select * from t1,t2 where t1.id = t2.id;
```

In the example above, the dropped binding in the SESSION scope shields the corresponding binding in the GLOBAL scope. The optimizer does not add the `sm_join(t1, t2)` hint to the statement. The top node of the execution plan in the `explain` result is not fixed to MergeJoin by this hint. Instead, the top node is independently selected by the optimizer according to the cost estimation.

Note:

Executing `DROP GLOBAL BINDING` drops the binding in the current tidb-server instance cache and changes the status of the corresponding row in the system table to 'deleted'. This statement does not directly delete the records in the system table, because other tidb-server instances need to read the 'deleted' status to drop the corresponding binding in their cache. For the records in these system tables with the status of 'deleted', at every `100 bind-info-lease` (the default value is `3s`, and `300s` in total) interval, the background thread triggers an operation of reclaiming and clearing on the bindings of `update_time` before `10 bind-info-lease` (to ensure that all tidb-server instances have read the 'deleted' status and updated the cache).

View binding

```
SHOW [GLOBAL | SESSION] BINDINGS [ShowLikeOrWhere]
```

This statement outputs the execution plan bindings at the GLOBAL or SESSION level according to the order of binding update time from the latest to earliest. The default scope is SESSION. Currently `SHOW BINDINGS` outputs eight columns, as shown below:

Column Name	Note
<code>original_sql</code>	Original SQL statement after parameterization
<code>bind_sql</code>	Bound SQL statement with hints
<code>default_db</code>	Default database
<code>status</code>	Status including <code>using</code> , <code>deleted</code> , <code>invalid</code> , <code>rejected</code> , and <code>pending</code> ↔ <code>verify</code>
<code>create_time</code>	Creating time
<code>update_time</code>	Updating time
<code>charset</code>	Character set
<code>collation</code>	Ordering rule

Column Name	Note
source	The way in which a binding is created, including <code>manual</code> (created by the <code>create</code> <code>↪ [global]</code> <code>↪ binding</code> SQL statement), <code>capture</code> (captured automatically by TiDB), and <code>evolve</code> (evolved automatically by TiDB)

Troubleshoot binding

```
SELECT @@[SESSION.]last_plan_from_binding;
```

This statement uses the system variable `last_plan_from_binding` to show whether the execution plan used by the last executed statement is from the binding.

In addition, when you use the `explain format = 'verbose'` statement to view the query plan of a SQL statement, if the SQL statement uses binding, the `explain` statement will return a warning. In this situation, you can check the warning message to learn which binding is used in the SQL statement.

```
-- Create a global binding.

create global binding for
  select * from t
using
  select * from t;

-- Use the `explain format = 'verbose'` statement to check the SQL
  ↪ execution plan. Check the warning message to view the binding used
  ↪ in the query.

explain format = 'verbose' select * from t;
show warnings;
```

9.3.4.3.2 Baseline capturing

To enable baseline capturing, set `tidb_capture_plan_baselines` to `on`. The default value is `off`.

Note:

Because the automatic binding creation function relies on [Statement Summary](#), make sure to enable Statement Summary before using automatic binding.

After automatic binding creation is enabled, the historical SQL statements in the Statement Summary are traversed every `bind-info-lease` (the default value is `3s`), and a binding is automatically created for SQL statements that appear at least twice. For these SQL statements, TiDB automatically binds the execution plan recorded in Statement Summary.

However, TiDB does not automatically capture bindings for the following types of SQL statements:

- `EXPLAIN` and `EXPLAIN ANALYZE` statements.
- SQL statements executed internally in TiDB, such as `SELECT` queries used for automatically loading statistical information.
- SQL statements that are bound to a manually created execution plan.

For `PREPARE` / `EXECUTE` statements and for queries executed with binary protocols, TiDB automatically captures bindings for the real query statements, not for the `PREPARE` / `EXECUTE` statements.

Note:

Because TiDB has some embedded SQL statements to ensure the correctness of some features, baseline capturing by default automatically shields these SQL statements.

9.3.4.3.3 Baseline evolution

Baseline evolution is an important feature of SPM introduced in TiDB v4.0.

As data updates, the previously bound execution plan might no longer be optimal. The baseline evolution feature can automatically optimize the bound execution plan.

In addition, baseline evolution, to a certain extent, can also avoid the jitter brought to the execution plan caused by the change of statistical information.

Usage

Use the following statement to enable automatic binding evolution:

```
set global tidb_evolve_plan_baselines = on;
```

The default value of `tidb_evolve_plan_baselines` is `off`.

Warning:

- Baseline evolution is an experimental feature. Unknown risks might exist. It is **NOT** recommended that you use it in the production environment.
- This variable is forcibly set to `off` until the baseline evolution feature becomes generally available (GA). If you try to enable this feature, an error is returned. If you have already used this feature in a production environment, disable it as soon as possible. If you find that the binding status is not as expected, contact PingCAP's technical support for help.

After the automatic binding evolution feature is enabled, if the optimal execution plan selected by the optimizer is not among the binding execution plans, the optimizer marks the plan as an execution plan that waits for verification. At every `bind-info-lease` (the default value is `3s`) interval, an execution plan to be verified is selected and compared with the binding execution plan that has the least cost in terms of the actual execution time. If the plan to be verified has shorter execution time (the current criterion for the comparison is that the execution time of the plan to be verified is no longer than $2/3$ that of the binding execution plan), this plan is marked as a usable binding. The following example describes the process above.

Assume that table `t` is defined as follows:

```
create table t(a int, b int, key(a), key(b));
```

Perform the following query on table `t`:

```
select * from t where a < 100 and b < 100;
```

In the table defined above, few rows meet the `a < 100` condition. But for some reason, the optimizer mistakenly selects the full table scan instead of the optimal execution plan that uses index `a`. You can first use the following statement to create a binding:

```
create global binding for select * from t where a < 100 and b < 100 using  
↪ select * from t use index(a) where a < 100 and b < 100;
```

When the query above is executed again, the optimizer selects index **a** (influenced by the binding created above) to reduce the query time.

Assuming that as insertions and deletions are performed on table **t**, an increasing number of rows meet the $a < 100$ condition and a decreasing number of rows meet the $b < 100$ condition. At this time, using index **a** under the binding might no longer be the optimal plan.

The binding evolution can address this kind of issues. When the optimizer recognizes data change in a table, it generates an execution plan for the query that uses index **b**. However, because the binding of the current plan exists, this query plan is not adopted and executed. Instead, this plan is stored in the backend evolution list. During the evolution process, if this plan is verified to have an obviously shorter execution time than that of the current execution plan that uses index **a**, index **b** is added into the available binding list. After this, when the query is executed again, the optimizer first generates the execution plan that uses index **b** and makes sure that this plan is in the binding list. Then the optimizer adopts and executes this plan to reduce the query time after data changes.

To reduce the impact that the automatic evolution has on clusters, use the following configurations:

- Set `tidb_evolve_plan_task_max_time` to limit the maximum execution time of each execution plan. The default value is `600s`. In the actual verification process, the maximum execution time is also limited to no more than twice the time of the verified execution plan.
- Set `tidb_evolve_plan_task_start_time` (`00:00 +0000` by default) and `tidb_evolve_plan_task_end_time` (`23:59 +0000` by default) to limit the time window.

Notes

Because the baseline evolution automatically creates a new binding, when the query environment changes, the automatically created binding might have multiple behavior choices. Pay attention to the following notes:

- Baseline evolution only evolves standardized SQL statements that have at least one global binding.
- Because creating a new binding deletes all previous bindings (for a standardized SQL statement), the automatically evolved binding will be deleted after manually creating a new binding.
- All hints related to the calculation process are retained during the evolution. These hints are as follows:

Hint	Description
<code>memory_quota</code> ↪	The maximum memory that can be used for a query.
<code>use_toja</code>	Whether the optimizer transforms sub-queries to Join.
<code>use_cascades</code> ↪	Whether to use the cascades optimizer.
<code>no_index_merge</code> ↪	Whether the optimizer uses Index Merge as an option for reading tables.
<code>read_consistent_replica</code> ↪	Whether to forcibly enable Follower Read when reading tables.
<code>max_execution_time</code> ↪	The longest duration for a query.

- `read_from_storage` is a special hint in that it specifies whether to read data from TiKV or from TiFlash when reading tables. Because TiDB provides isolation reads, when the isolation condition changes, this hint has a great influence on the evolved execution plan. Therefore, when this hint exists in the initially created binding, TiDB ignores all its evolved bindings.

9.3.4.3.4 Upgrade checklist

During cluster upgrade, SQL Plan Management (SPM) might cause compatibility issues and make the upgrade fail. To ensure a successful upgrade, you need to include the following list for upgrade precheck:

- When you upgrade from a version earlier than v5.2.0 (that is, v4.0, v5.0, and v5.1) to the current version, make sure that `tidb_evolve_plan_baselines` is disabled before the upgrade. To disable this variable, perform the following steps.

```
-- Check whether `tidb_evolve_plan_baselines` is disabled in the  
↪ earlier version.
```

```
select @@global.tidb_evolve_plan_baselines;

-- If `tidb_evolve_plan_baselines` is still enabled, disable it.

set global tidb_evolve_plan_baselines = off;
```

- Before you upgrade from v4.0 to the current version, you need to check whether the syntax of all queries corresponding to the available SQL bindings is correct in the new version. If any syntax errors exist, delete the corresponding SQL binding. To do that, perform the following steps.

```
-- Check the query corresponding to the available SQL binding in the
  ↪ version to be upgraded.

select bind_sql from mysql.bind_info where status = 'using';

-- Verify the result from the above SQL query in the test environment
  ↪ of the new version.

bind_sql_0;
bind_sql_1;
...

-- In the case of a syntax error (ERROR 1064 (42000): You have an
  ↪ error in your SQL syntax), delete the corresponding binding.
-- For any other errors (for example, tables are not found), it means
  ↪ that the syntax is compatible. No other operation is needed.
```

9.3.4.4 The Blocklist of Optimization Rules and Expression Pushdown

This document introduces how to use the blocklist of optimization rules and the blocklist of expression pushdown to control the behavior of TiDB.

9.3.4.4.1 The blocklist of optimization rules

The blocklist of optimization rules is one way to tune optimization rules, mainly used to manually disable some optimization rules.

Important optimization rules

Optimization Rule	Rule Name	Description
Column pruning	column_pruning	operator will prune the column if it is not needed by the upper executor.
Decorrelated subquery	decorrelated_subquery	The correlated subquery to rewrite the correlated subquery to non-correlated join or aggregation.

Optimization Rule	Name	Description
Aggregation elimination	agg_eliminate	Eliminate unnecessary aggregation operators from the execution plan.
Projection elimination	proj_eliminate	Eliminate unnecessary projection operators from the execution plan.

Optimization Rule	Rule Name	Description
Max/Min elimination	max_min_rewrite	Eliminate some max/min functions in aggregation to the order \hookrightarrow by \hookrightarrow + limit \hookrightarrow 1 form.
Predicate push-down	predicate_push_down	Push predicates down to the operator that is closer to the data source.

Optimization Rule	Rule Name	Description
Outer join elimination	outer_join_elimination	Tries to eliminate the unnecessary left join or right join from the execution plan.

Optimization Rule	Rule Name	Description
Partition pruning	partition_pruning	Processor partitions which are rejected by the predicates and rewrite partitioned table query to the UnionAll form. \hookrightarrow $\hookrightarrow +$ \hookrightarrow \hookrightarrow Partition \hookrightarrow \hookrightarrow Datasource \hookrightarrow
Aggregation push-down	agg_push_down	Aggregations are pushed down to their children.

Optimization Rule	Name	Description
TopN push-down	topn_pushdown	Pushes the TopN operator to the place closer to the data source.
Join re-order	join_reorder	Decides the order of multi-table joins.

Disable optimization rules

You can use the blacklist of optimization rules to disable some of them if some rules lead to a sub-optimal execution plan for special queries.

Usage

Note:

All the following operations need the `super privilege` privilege of the database. Each optimization rule has a name. For example, the name of column pruning is `column_prune`. The names of all optimization rules can be found in the second column of the table [Important Optimization Rules](#).

- If you want to disable some rules, write its name to the `mysql.opt_rule_blacklist` table. For example:

```
INSERT INTO mysql.opt_rule_blacklist VALUES("join_reorder"), ("
↳ topn_push_down");
```

Executing the following SQL statement can make the above operation take effect immediately. The effective range includes all old connections of the corresponding TiDB server:

```
admin reload opt_rule_blacklist;
```

Note:

`admin reload opt_rule_blacklist` only takes effect on the TiDB server where the above statement has been run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

- If you want to re-enable a rule, delete the corresponding data in the table, and then run the `admin reload` statement:

```
DELETE FROM mysql.opt_rule_blacklist WHERE name IN ("join_reorder", "
↳ topn_push_down");
```

```
admin reload opt_rule_blacklist;
```

9.3.4.4.2 The blacklist of expression pushdown

The blacklist of expression pushdown is one way to tune the expression pushdown, mainly used to manually disable some expressions of some specific data types.

Expressions which are supported to be pushed down

Expression Classification	Concrete Operations
Logical operations	AND (&&), OR (), NOT (!)
Comparison functions and operators	<, <=, =, != (<>), >, >=, <=>, IN(), IS NULL, LIKE, IS TRUE, IS FALSE, COALESCE()
Numeric functions and operators	+, -, *, /, ABS(), CEIL(), CEILING(), FLOOR()
Control flow functions	CASE, IF(), IFNULL()

Expression Classification	Concrete Operations
JSON functions	JSON_TYPE(json_val), JSON_EXTRACT(json_doc, path[, path] ...), JSON_UNQUOTE(json_val), JSON_OBJECT(key, val[, key, val] ...), JSON_ARRAY([val[, val] ...]), JSON_MERGE(json_doc, json_doc[, json_doc] ...), JSON_SET(json_doc, path, val[, path, val] ...), JSON_INSERT(json_doc, path, val[, path, val] ...), JSON_REPLACE(json_doc, path, val[, path, val] ...), JSON_REMOVE(json_doc, path[, path] ...)
Date and time functions	DATE_FORMAT()

Disable the pushdown of specific expressions

When you get wrong results due to the expression pushdown, you can use the blacklist to make a quick recovery for the application. More specifically, you can add some of the supported functions or operators to the `mysql.expr_pushdown_blacklist` table to disable the pushdown of specific expressions.

The schema of `mysql.expr_pushdown_blacklist` is shown as follows:

```
DESC mysql.expr_pushdown_blacklist;
```

```
+-----+-----+-----+-----+-----+-----+
| Field      | Type          | Null | Key | Default          | Extra |
+-----+-----+-----+-----+-----+-----+
| name       | char(100)     | NO   |     | NULL             |       |
| store_type | char(100)     | NO   |     | tikv,tiflash,tidb |       |
| reason     | varchar(200)  | YES  |     | NULL             |       |
+-----+-----+-----+-----+-----+-----+
3 rows in set (0.00 sec)
```

Here is the description of each field above:

- **name**: The name of the function that is disabled to be pushed down.
- **store_type**: To specify the component that you want to prevent the function from being pushed down to for computing. Available components are `tidb`, `tikv`, and `tiflash`. The `store_type` is case-insensitive. If you need to specify multiple components, use a comma to separate each component.

- When `store_type` is `tiddb`, it indicates whether the function can be executed in other TiDB servers while the TiDB memory table is being read.
 - When `store_type` is `tikv`, it indicates whether the function can be executed in TiKV server's Coprocessor component.
 - When `store_type` is `tiflash`, it indicates whether the function can be executed in TiFlash Server's Coprocessor component.
- **reason:** To record the reason why this function is added to the blacklist.

Usage

This section describes how to use the blacklist of expression pushdown.

Add to the blacklist

To add one or more expressions (functions or operators) to the blacklist, perform the following steps:

1. Insert the corresponding function name or operator name, and the set of components you want to disable the pushdown, to the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

Remove from the blacklist

To remove one or more expressions from the blacklist, perform the following steps:

1. Delete the corresponding function name or operator name, and the set of components you want to disable the pushdown, from the `mysql.expr_pushdown_blacklist` table.
2. Execute `admin reload expr_pushdown_blacklist`.

Note:

`admin reload expr_pushdown_blacklist` only takes effect on the TiDB server where this statement is run. If you want all TiDB servers of the cluster to take effect, run this command on each TiDB server.

9.3.4.4.3 Expression blacklist usage example

In the following example, the `<` and `>` operators are added to the blacklist, and then the `>` operator is removed from the blacklist.

To judge whether the blacklist takes effect, observe the results of `EXPLAIN` (See [TiDB Query Execution Plan Overview](#)).

1. The predicates `a < 2` and `a > 2` in the `WHERE` clause of the following SQL statement can be pushed down to TiKV.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```
+--
↪ -----+-----+-----+-----+
↪
| id                | estRows | task   | access object | operator
↪ info                |         |        |                |
+--
↪ -----+-----+-----+-----+
↪
| TableReader_7     | 0.00    | root   |                | data:
↪ Selection_6       |         |        |                |
| -Selection_6      | 0.00    | cop[tikv] |                | gt(ssb_1.t.
↪ a, 2), lt(ssb_1.t.a, 2) |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t       | keep order:
↪ false, stats:pseudo |
+--
↪ -----+-----+-----+-----+
↪
3 rows in set (0.00 sec)
```

2. Insert the expression to the `mysql.expr_pushdown_blacklist` table and execute `admin reload expr_pushdown_blacklist`.

```
INSERT INTO mysql.expr_pushdown_blacklist VALUES('<','tikv',''), ('>',
↪ 'tikv','');
```

```
Query OK, 2 rows affected (0.01 sec)
Records: 2 Duplicates: 0 Warnings: 0
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

3. Observe the execution plan again and you will find that both the `<` and `>` operators are not pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 and a > 2;
```

```
+--
↪ -----+-----+-----+-----+
↪
```

```

| id          | estRows | task  | access object | operator
↳ info      |         |      |              |
+---
↳ -----+-----+-----+-----+
↳
| Selection_7 | 10000.00 | root  |              | gt(ssb_1.t.a
↳ , 2), lt(ssb_1.t.a, 2) |
| -TableReader_6 | 10000.00 | root  |              | data:
↳ TableFullScan_5 |         |
| -TableFullScan_5 | 10000.00 | cop[tikv] | table:t | keep order:
↳ false, stats:pseudo |
+---
↳ -----+-----+-----+-----+
↳
3 rows in set (0.00 sec)

```

4. Remove one expression (here is >) from the blacklist and execute `admin reload`
↳ `expr_pushdown_blacklist`.

```
DELETE FROM mysql.expr_pushdown_blacklist WHERE name = '>';
```

```
Query OK, 1 row affected (0.01 sec)
```

```
admin reload expr_pushdown_blacklist;
```

```
Query OK, 0 rows affected (0.00 sec)
```

5. Observe the execution plan again and you will find that < is not pushed down while > is pushed down to TiKV Coprocessor.

```
EXPLAIN SELECT * FROM t WHERE a < 2 AND a > 2;
```

```

+---
↳ -----+-----+-----+-----+
↳
| id          | estRows | task  | access object | operator
↳ info      |         |      |              |
+---
↳ -----+-----+-----+-----+
↳
| Selection_8 | 0.00    | root  |              | lt(ssb_1.t
↳ .a, 2) |
| -TableReader_7 | 0.00    | root  |              | data:
↳ Selection_6 |         |

```

```

| -Selection_6          | 0.00    | cop[tikv] |          | gt(ssb_1.
↪ t.a, 2)              |
| -TableFullScan_5    | 10000.00 | cop[tikv] | table:t  | keep
↪ order:false, stats:pseudo |
+---
↪ -----+-----+-----+-----+
↪
4 rows in set (0.00 sec)

```

10 Tutorials

10.1 Multiple Data Centers in One City Deployment

As a NewSQL database, TiDB combines the best features of the traditional relational database and the scalability of the NoSQL database, and is highly available across data centers (DC). This document introduces the deployment of multiple DCs in one city.

10.1.1 Raft protocol

Raft is a distributed consensus algorithm. Using this algorithm, both PD and TiKV, among components of the TiDB cluster, achieve disaster recovery of data, which is implemented through the following mechanisms:

- The essential role of Raft members is to perform log replication and act as a state machine. Among Raft members, data replication is implemented by replicating logs. Raft members change their own states in different conditions to elect a leader to provide services.
- Raft is a voting system that follows the majority protocol. In a Raft group, if a member gets the majority of votes, its membership changes to leader. In other words, when the majority of nodes remain in the Raft group, a leader can be elected to provide services.

To take advantage of Raft's reliability, the following conditions must be met in a real deployment scenario:

- Use at least three servers in case one server fails.
- Use at least three racks in case one rack fails.
- Use at least three DCs in case one DC fails.
- Deploy TiDB in at least three cities in case data safety issue occurs in one city.

The native Raft protocol does not have a good support for an even number of replicas. Considering the impact of cross-city network latency, three DCs in the same city might be the most suitable solution to a highly available and disaster tolerant Raft deployment.

10.1.2 Three DCs in one city deployment

TiDB clusters can be deployed in three DCs in the same city. In this solution, data replication across the three DCs is implemented using the Raft protocol within the cluster. These three DCs can provide read and write services at the same time. Data consistency is not affected even if one DC fails.

10.1.2.1 Simple architecture

TiDB, TiKV and PD are distributed among three DCs, which is the most common deployment with the highest availability.

Figure 76: 3-DC Deployment Architecture

Advantages:

- All replicas are distributed among three DCs, with high availability and disaster recovery capability.
- No data will be lost if one DC is down (RPO = 0).
- Even if one DC is down, the other two DCs will automatically start leader election and automatically resume services within a reasonable amount of time (within 20 seconds in most cases). See the following diagram for more information:

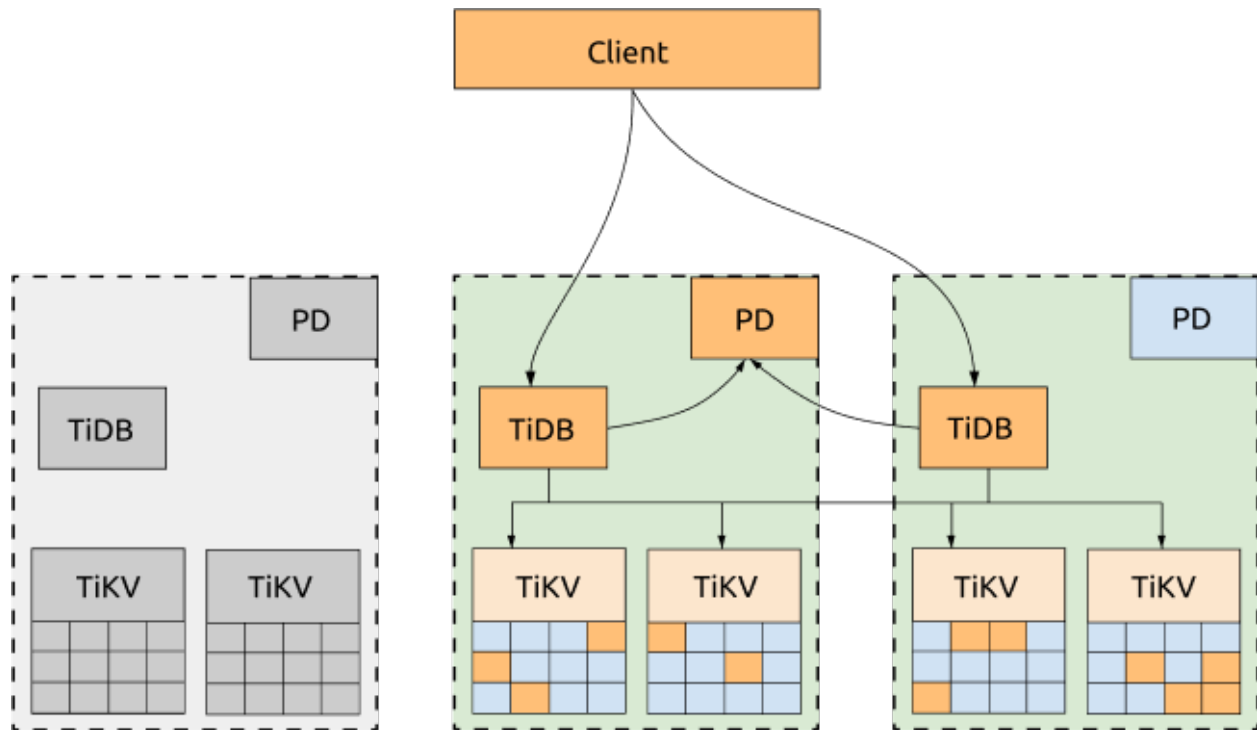

Figure 77: Disaster Recovery for 3-DC Deployment

Disadvantages:

The performance can be affected by the network latency.

- For writes, all the data has to be replicated to at least 2 DCs. Because TiDB uses 2-phase commit for writes, the write latency is at least twice the latency of the network between two DCs.
- The read performance will also be affected by the network latency if the leader is not in the same DC with the TiDB node that sends the read request.
- Each TiDB transaction needs to obtain TimeStamp Oracle (TSO) from the PD leader. So if the TiDB and PD leaders are not in the same DC, the performance of the transactions will also be affected by the network latency because each transaction with the write request has to obtain TSO twice.

10.1.2.2 Optimized architecture

If not all of the three DCs need to provide services to the applications, you can dispatch all the requests to one DC and configure the scheduling policy to migrate all the TiKV Region leader and PD leader to the same DC. In this way, neither obtaining TSO nor reading TiKV Regions will be impacted by the network latency across DCs. If this DC is down, the PD leader and TiKV Region leader will be automatically elected in other surviving DCs, and you just need to switch the requests to the DCs that are still alive.

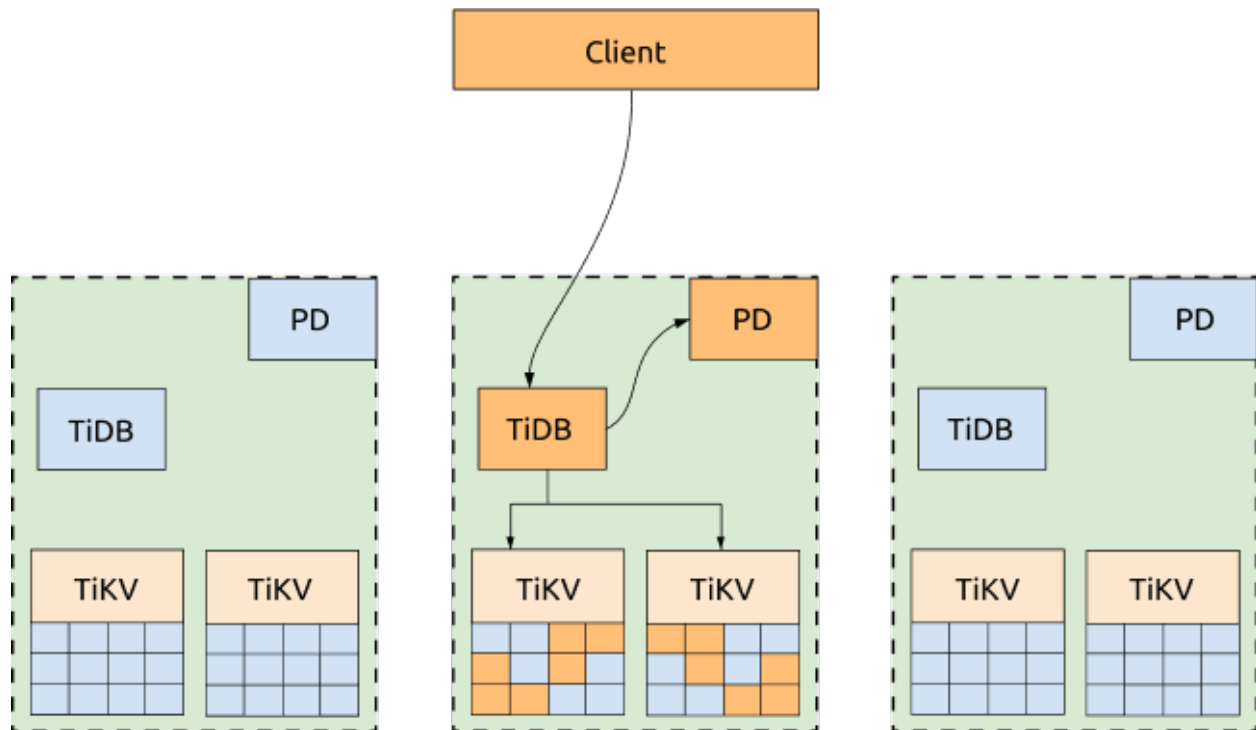

Figure 78: Read Performance Optimized 3-DC Deployment

Advantages:

The cluster's read performance and the capability to get TSO are improved. A configuration template of scheduling policy is as follows:

```
-- Evicts all leaders of other DCs to the DC that provides services to the
↪ application.
config set label-property reject-leader LabelName labelValue

-- Migrates PD leaders and sets priority.
member leader transfer pdName1
member leader_priority pdName1 5
member leader_priority pdName2 4
member leader_priority pdName3 3
```

Note:

Since TiDB 5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the [placement rules](#).

Disadvantages:

- Write scenarios are still affected by network latency across DCs. This is because Raft follows the majority protocol and all written data must be replicated to at least two DCs.
- The TiDB server that provides services is only in one DC.
- All application traffic is processed by one DC and the performance is limited by the network bandwidth pressure of that DC.
- The capability to get TSO and the read performance are affected by whether the PD server and TiKV server are up in the DC that processes application traffic. If these servers are down, the application is still affected by the cross-center network latency.

10.1.2.3 Deployment example

This section provides a topology example, and introduces TiKV labels and TiKV labels planning.

10.1.2.3.1 Topology example

The following example assumes that three DCs (IDC1, IDC2, and IDC3) are located in one city; each IDC has two sets of racks and each rack has three servers. The example ignores the hybrid deployment or the scenario where multiple instances are deployed on one machine. The deployment of a TiDB cluster (three replicas) on three DCs in one city is as follows:

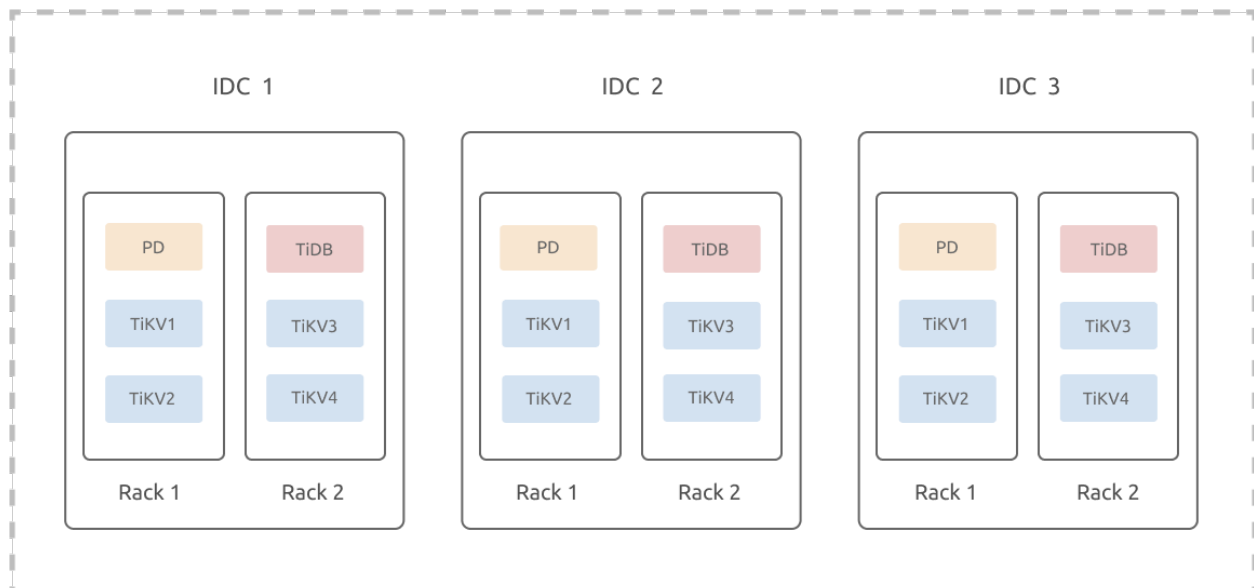

Figure 79: 3-DC in One City

10.1.2.3.2 TiKV labels

TiKV is a Multi-Raft system where data is divided into Regions and the size of each Region is 96 MB by default. Three replicas of each Region form a Raft group. For a TiDB cluster of three replicas, because the number of Region replicas is independent of the TiKV instance numbers, three replicas of a Region are only scheduled to three TiKV instances. This means that even if the cluster is scaled out to have N TiKV instances, it is still a cluster of three replicas.

Because a Raft group of three replicas tolerates only one replica failure, even if the cluster is scaled out to have N TiKV instances, this cluster still tolerates only one replica failure. Two failed TiKV instances might cause some Regions to lose replicas and the data in this cluster is no longer complete. SQL requests that access data from these Regions will fail. The probability of two simultaneous failures among N TiKV instances is much higher than the probability of two simultaneous failures among three TiKV instances. This means that the more TiKV instances the Multi-Raft system is scaled out to have, the less the availability of the system.

Because of the limitation described above, `label` is used to describe the location information of TiKV. The label information is refreshed to the TiKV startup configuration file with deployment or rolling upgrade operations. The started TiKV reports its latest label information to PD. Based on the user-registered label name (the label metadata) and the TiKV topology, PD optimally schedules Region replicas and improves the system availability.

10.1.2.3.3 TiKV labels planning example

To improve the availability and disaster recovery of the system, you need to design and plan TiKV labels according to your existing physical resources and the disaster recovery capability. You also need to configure in the cluster initialization configuration file according to the planned topology:

```
server_configs:
  pd:
    replication.location-labels: ["zone","dc","rack","host"]

tikv_servers:
- host: 10.63.10.30
  config:
    server.labels: { zone: "z1", dc: "d1", rack: "r1", host: "30" }
- host: 10.63.10.31
  config:
    server.labels: { zone: "z1", dc: "d1", rack: "r1", host: "31" }
- host: 10.63.10.32
  config:
    server.labels: { zone: "z1", dc: "d1", rack: "r2", host: "32" }
- host: 10.63.10.33
  config:
```

```
    server.labels: { zone: "z1", dc: "d1", rack: "r2", host: "33" }
- host: 10.63.10.34
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r1", host: "34" }
- host: 10.63.10.35
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r1", host: "35" }
- host: 10.63.10.36
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r2", host: "36" }
- host: 10.63.10.37
  config:
    server.labels: { zone: "z2", dc: "d1", rack: "r2", host: "37" }
- host: 10.63.10.38
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r1", host: "38" }
- host: 10.63.10.39
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r1", host: "39" }
- host: 10.63.10.40
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r2", host: "40" }
- host: 10.63.10.41
  config:
    server.labels: { zone: "z3", dc: "d1", rack: "r2", host: "41" }
```

In the example above, `zone` is the logical availability zone layer that controls the isolation of replicas (three replicas in the example cluster).

Considering that the DC might be scaled out in the future, the three-layer label structure (`dc`, `rack`, `host`) is not directly adopted. Assuming that `d2`, `d3`, and `d4` are to be scaled out, you only need to scale out the DCs in the corresponding availability zone and scale out the racks in the corresponding DC.

If this three-layer label structure is directly adopted, after scaling out a DC, you might need to apply new labels and the data in TiKV needs to be rebalanced.

10.1.2.4 High availability and disaster recovery analysis

The multiple DCs in one city deployment can guarantee that if one DC fails, the cluster can automatically recover services without manual intervention. Data consistency is also guaranteed. Note that scheduling policies are used to optimize performance, but when failure occurs, these policies prioritize availability over performance.

10.2 Three Data Centers in Two Cities Deployment

This document introduces the architecture and configuration of the three data centers (DC) in two cities deployment.

10.2.1 Overview

The architecture of three DCs in two cities is a highly available and disaster tolerant deployment solution that provides a production data center, a disaster recovery center in the same city, and a disaster recovery center in another city. In this mode, the three DCs in two cities are interconnected. If one DC fails or suffers from a disaster, other DCs can still operate well and take over the the key applications or all applications. Compared with the the multi-DC in one city deployment, this solution has the advantage of cross-city high availability and can survive city-level natural disasters.

The distributed database TiDB natively supports the three-DC-in-two-city architecture by using the Raft algorithm, and guarantees the consistency and high availability of data within a database cluster. Because the network latency across DCs in the same city is relatively low, the application traffic can be dispatched to two DCs in the same city, and the traffic load can be shared by these two DCs by controlling the distribution of TiKV Region leaders and PD leaders.

10.2.2 Deployment architecture

This section takes the example of Seattle and San Francisco to explain the deployment mode of three DCs in two cities for the distributed database of TiDB.

In this example, two DCs (IDC1 and IDC2) are located in Seattle and another DC (IDC3) is located in San Francisco. The network latency between IDC1 and IDC2 is lower than 3 milliseconds. The network latency between IDC3 and IDC1/IDC2 in Seattle is about 20 milliseconds (ISP dedicated network is used).

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to three DCs in two cities: IDC1 in Seattle, IDC2 in Seattle, and IDC3 in San Francisco.
- The cluster has five replicas, two in IDC1, two in IDC2, and one in IDC3. For the TiKV component, each rack has a label, which means that each rack has a replica.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

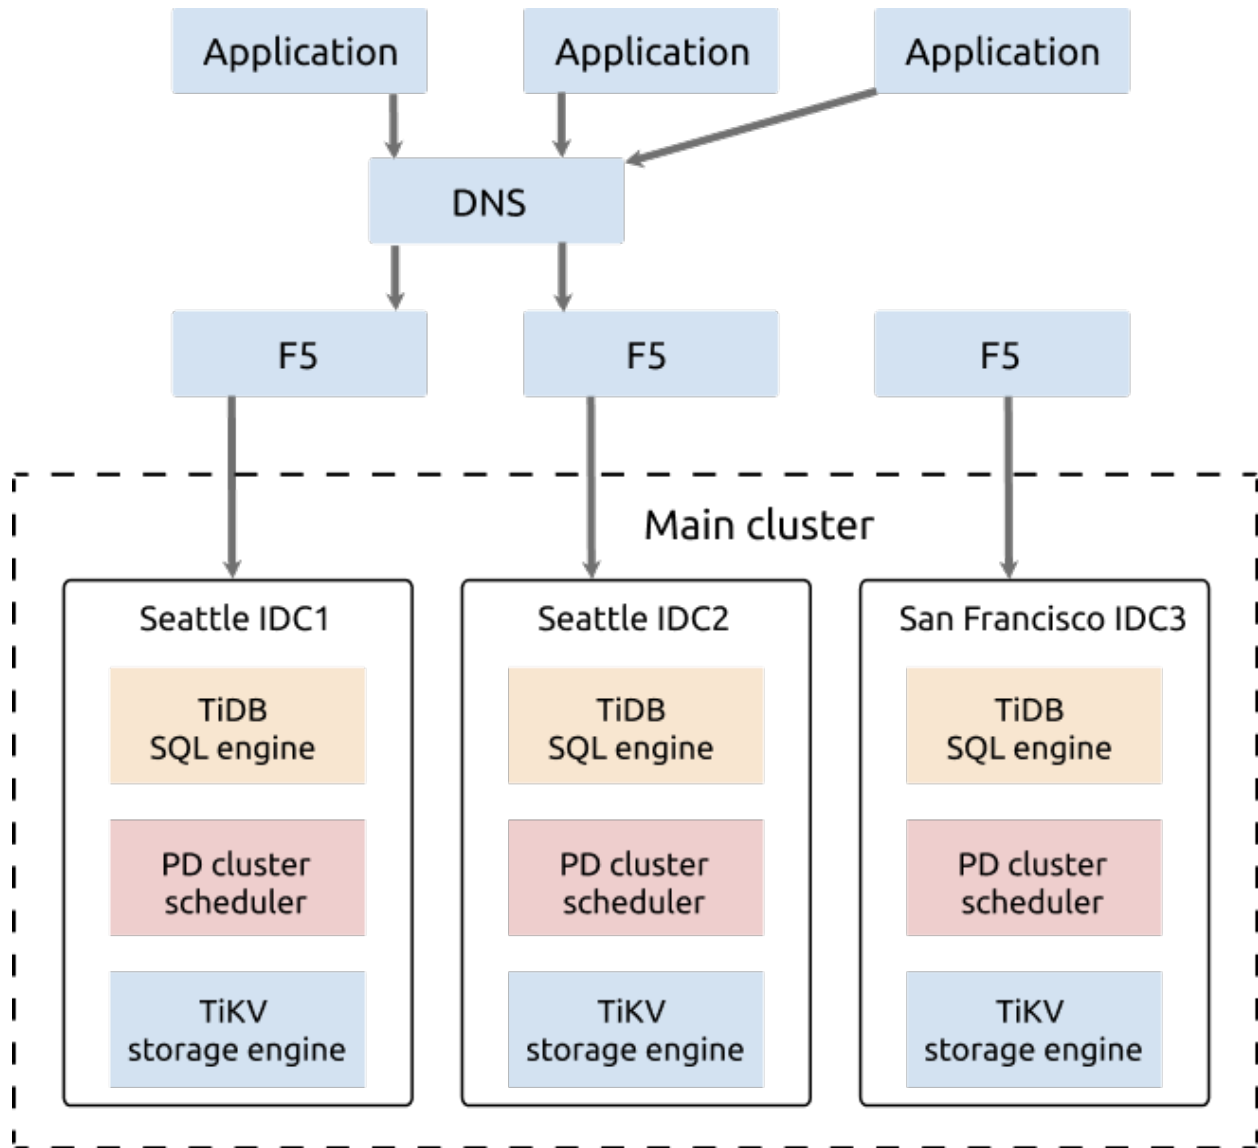

Figure 80: 3-DC-in-2-city architecture

This architecture is highly available. The distribution of Region leaders is restricted to the two DCs (IDC1 and IDC2) that are in the same city (Seattle). Compared with the three-DC solution in which the distribution of Region leaders is not restricted, this architecture has the following advantages and disadvantages:

- **Advantages**

- Region leaders are in DCs of the same city with low latency, so the write is faster.
- The two DCs can provide services at the same time, so the resources usage rate is higher.
- If one DC fails, services are still available and data safety is ensured.

- **Disadvantages**

- Because the data consistency is achieved by the Raft algorithm, when two DCs in the same city fail at the same time, only one surviving replica remains in the disaster recovery DC in another city (San Francisco). This cannot meet the requirement of the Raft algorithm that most replicas survive. As a result, the cluster can be temporarily unavailable. Maintenance staff needs to recover the cluster from the one surviving replica and a small amount of hot data that has not been replicated will be lost. But this case is a rare occurrence.
- Because the ISP dedicated network is used, the network infrastructure of this architecture has a high cost.
- Five replicas are configured in three DCs in two cities, data redundancy increases, which brings a higher storage cost.

10.2.2.1 Deployment details

The configuration of the three DCs in two cities (Seattle and San Francisco) deployment plan is illustrated as follows:

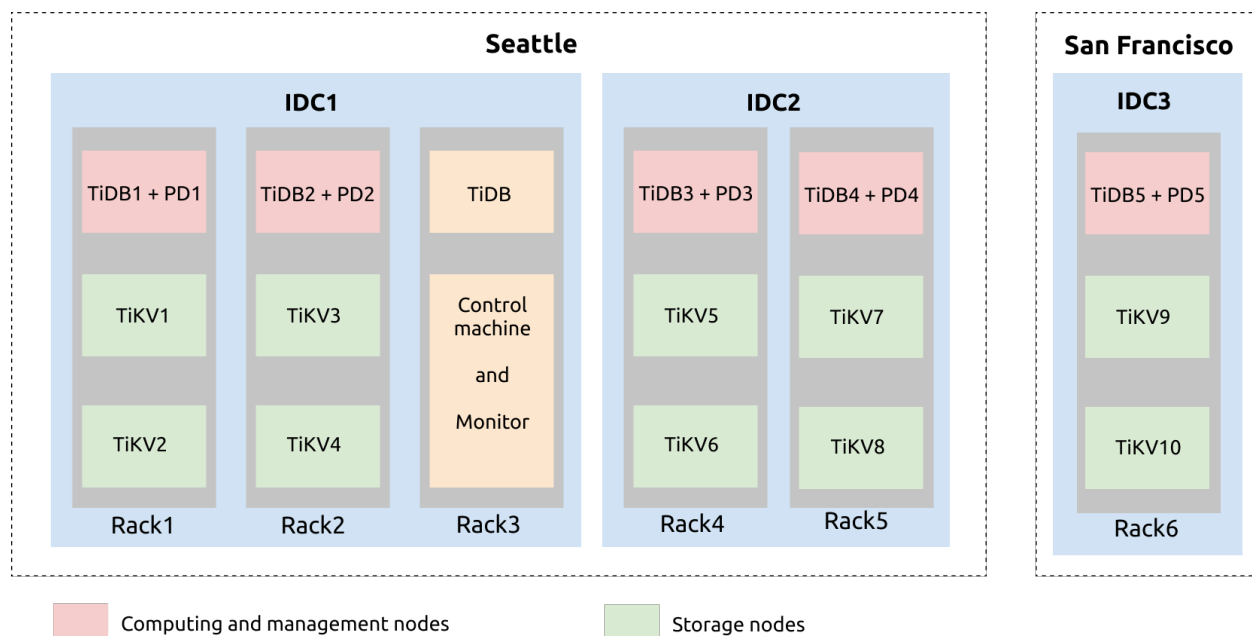

Figure 81: 3-DC-2-city

- From the illustration above, you can see that Seattle has two DCs: IDC1 and IDC2. IDC1 has three sets of racks: RAC1, RAC2, and RAC3. IDC2 has two racks: RAC4 and RAC5. The IDC3 DC in San Francisco has the RAC6 rack.
- From the RAC1 rack illustrated above, TiDB and PD services are deployed on the same server. Each of the two TiKV servers are deployed with two TiKV instances (tikv-server). This is similar to RAC2, RAC4, RAC5, and RAC6.

- The TiDB server, the control machine, and the monitoring server are on RAC3. The TiDB server is deployed for regular maintenance and backup. Prometheus, Grafana, and the restore tools are deployed on the control machine and monitoring machine.
- Another backup server can be added to deploy Drainer. Drainer saves binlog data to a specified location by outputting files, to achieve incremental backup.

10.2.3 Configuration

10.2.3.1 Example

See the following `tiup topology.yaml` file for example:

```
## # Global variables are applied to all deployments and used as the default
  ↳ value of
## # the deployments if a specific deployment value is missing.
global
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"

server_configs:
  tikv:
    server.grpc-compression-type: gzip
  pd:
    replication.location-labels: ["dc","zone","rack","host"]

pd_servers:
- host: 10.63.10.10
  name: "pd-10"
- host: 10.63.10.11
  name: "pd-11"
- host: 10.63.10.12
  name: "pd-12"
- host: 10.63.10.13
  name: "pd-13"
- host: 10.63.10.14
  name: "pd-14"

tidb_servers:
- host: 10.63.10.10
- host: 10.63.10.11
- host: 10.63.10.12
- host: 10.63.10.13
- host: 10.63.10.14
```

```
tikv_servers:
- host: 10.63.10.30
  config:
    server.labels: { dc: "1", zone: "1", rack: "1", host: "30" }
- host: 10.63.10.31
  config:
    server.labels: { dc: "1", zone: "2", rack: "2", host: "31" }
- host: 10.63.10.32
  config:
    server.labels: { dc: "2", zone: "3", rack: "3", host: "32" }
- host: 10.63.10.33
  config:
    server.labels: { dc: "2", zone: "4", rack: "4", host: "33" }
- host: 10.63.10.34
  config:
    server.labels: { dc: "3", zone: "5", rack: "5", host: "34" }
    raftstore.raft-min-election-timeout-ticks: 1000
    raftstore.raft-max-election-timeout-ticks: 1200

monitoring_servers:
- host: 10.63.10.60

grafana_servers:
- host: 10.63.10.60

alertmanager_servers:
- host: 10.63.10.60
```

10.2.3.2 Labels design

In the deployment of three DCs in two cities, the label design requires taking availability and disaster recovery into account. It is recommended that you define the four levels (`dc`, `zone`, `rack`, `host`) based on the physical structure of the deployment.

Figure 82: Label logical definition

In the PD configuration, add level information of TiKV labels:

```
server_configs:
  pd:
    replication.location-labels: ["dc","zone","rack","host"]
```

The configuration of `tikv_servers` is based on the label information of the real physical deployment location of TiKV, which makes it easier for PD to perform global management and scheduling.

```
tikv_servers:
- host: 10.63.10.30
  config:
    server.labels: { dc: "1", zone: "1", rack: "1", host: "30" }
- host: 10.63.10.31
  config:
    server.labels: { dc: "1", zone: "2", rack: "2", host: "31" }
- host: 10.63.10.32
  config:
```

```
server.labels: { dc: "2", zone: "3", rack: "3", host: "32" }  
- host: 10.63.10.33  
config:  
  server.labels: { dc: "2", zone: "4", rack: "4", host: "33" }  
- host: 10.63.10.34  
config:  
  server.labels: { dc: "3", zone: "5", rack: "5", host: "34" }
```

10.2.3.3 Optimize parameter configuration

In the deployment of three DCs in two cities, to optimize performance, you need to not only configure regular parameters, but also adjust component parameters.

- Enable gRPC message compression in TiKV. Because data of the cluster is transmitted in the network, you can enable the gRPC message compression to lower the network traffic.

```
server.grpc-compression-type: gzip
```

- Optimize the network configuration of the TiKV node in another city (San Francisco). Modify the following TiKV parameters for IDC3 (alone) in San Francisco and try to prevent the replica in this TiKV node from participating in the Raft election.

```
raftstore.raft-min-election-timeout-ticks: 1000  
raftstore.raft-max-election-timeout-ticks: 1200
```

- Configure scheduling. After the cluster is enabled, use the `tiup ctl:<cluster-version> pd` tool to modify the scheduling policy. Modify the number of TiKV Raft replicas. Configure this number as planned. In this example, the number of replicas is five.

```
config set max-replicas 5
```

- Forbid scheduling the Raft leader to IDC3. Scheduling the Raft leader to in another city (IDC3) causes unnecessary network overhead between IDC1/IDC2 in Seattle and IDC3 in San Francisco. The network bandwidth and latency also affect performance of the TiDB cluster.

```
config set label-property reject-leader dc 3
```

Note:

Since TiDB 5.2, the `label-property` configuration is not supported by default. To set the replica policy, use the [placement rules](#).

- Configure the priority of PD. To avoid the situation where the PD leader is in another city (IDC3), you can increase the priority of local PD (in Seattle) and decrease the priority of PD in another city (San Francisco). The larger the number, the higher the priority.

```
member leader_priority PD-10 5
member leader_priority PD-11 5
member leader_priority PD-12 5
member leader_priority PD-13 5
member leader_priority PD-14 1
```

10.3 Two Data Centers in One City Deployment

This document introduces the deployment mode of two data centers (DCs) in one city, including the architecture, configuration, how to enable this deployment mode, and how to use replicas in this mode.

In a self-hosted environment, TiDB usually adopts the multi-data-center deployment solution to ensure high availability and disaster recovery capability. The multi-data-center deployment solution includes multiple deployment modes, such as three data centers in two cities and three data centers in one city. This document introduces the deployment mode of two data centers in one city. Deployed in this mode, TiDB can also meet the requirements of high availability and disaster recovery, with a lower cost. This deployment solution adopts Data Replication Auto Synchronous mode, or the DR Auto-Sync mode.

Under the mode of two data centers in one city, the two data centers are less than 50 kilometers apart. They are usually located in the same city or in two adjacent cities. The network latency between the two data centers is lower than 1.5 milliseconds and the bandwidth is higher than 10 Gbps.

10.3.1 Deployment architecture

This section takes the example of a city where two data centers IDC1 and IDC2 are located respectively in the east and west.

The architecture of the cluster deployment is as follows:

- The TiDB cluster is deployed to two DCs in one city: the primary IDC1 in the east, and the disaster recovery (DR) IDC2 in the west.
- The cluster has 4 replicas: 2 Voter replicas in IDC1, 1 Voter replica and 1 Learner replica in IDC2. For the TiKV component, each rack has a proper label.
- The Raft protocol is adopted to ensure consistency and high availability of data, which is transparent to users.

Figure 83: 2-DC-in-1-city architecture

This deployment solution defines three statuses to control and identify the replication status of the cluster, which restricts the replication mode of TiKV. The replication mode of the cluster can automatically and adaptively switch between the three statuses. For details, see the [Status switch](#) section.

- **sync**: Synchronous replication mode. In this mode, at least one replica in the disaster recovery (DR) data center synchronizes with the primary data center. The Raft algorithm ensures that each log is replicated to the DR based on the label.
- **async**: Asynchronous replication mode. In this mode, the DR data center is not fully synchronized with the primary data center. The Raft algorithm follows the majority protocol to replicate logs.
- **sync-recover**: Synchronous recovery mode. In this mode, the DR data center is not fully synchronized with the primary data center. Raft gradually switches to the label replication mode and then reports the label information to PD.

10.3.2 Configuration

10.3.2.1 Example

The following `tiup topology.yaml` example file is a typical topology configuration for the two data centers in one city deployment mode:

```
## # Global variables are applied to all deployments and used as the default
    ↪ value of
## # the deployments if a specific deployment value is missing.
global:
  user: "tidb"
  ssh_port: 22
  deploy_dir: "/data/tidb_cluster/tidb-deploy"
  data_dir: "/data/tidb_cluster/tidb-data"
server_configs:
  pd:
    replication.location-labels: ["zone","rack","host"]
pd_servers:
- host: 10.63.10.10
  name: "pd-10"
- host: 10.63.10.11
  name: "pd-11"
- host: 10.63.10.12
  name: "pd-12"
tidb_servers:
- host: 10.63.10.10
- host: 10.63.10.11
- host: 10.63.10.12
tikv_servers:
- host: 10.63.10.30
  config:
    server.labels: { zone: "east", rack: "east-1", host: "30" }
- host: 10.63.10.31
  config:
    server.labels: { zone: "east", rack: "east-2", host: "31" }
- host: 10.63.10.32
  config:
    server.labels: { zone: "west", rack: "west-1", host: "32" }
- host: 10.63.10.33
  config:
    server.labels: { zone: "west", rack: "west-2", host: "33" }
monitoring_servers:
- host: 10.63.10.60
grafana_servers:
- host: 10.63.10.60
alertmanager_servers:
- host: 10.63.10.60
```

10.3.2.2 Placement Rules

To deploy a cluster based on the planned topology, you need to use **Placement Rules** to determine the locations of the cluster replicas. Taking the deployment of 4 replicas (2 Voter replicas are at the primary center, 1 Voter replica and 1 Learner replica are at the DR center) as an example, you can use the Placement Rules to configure the replicas as follows:

```
cat rule.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "zone-east",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 2,
        "label_constraints": [
          {
            "key": "zone",
            "op": "in",
            "values": [
              "east"
            ]
          }
        ],
        "location_labels": [
          "zone",
          "rack",
          "host"
        ]
      },
      {
        "group_id": "pd",
        "id": "zone-west",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 1,
        "label_constraints": [
          {
            "key": "zone",
            "op": "in",
```

```
        "values": [
            "west"
        ]
    },
    ],
    "location_labels": [
        "zone",
        "rack",
        "host"
    ]
},
{
    "group_id": "pd",
    "id": "zone-west",
    "start_key": "",
    "end_key": "",
    "role": "learner",
    "count": 1,
    "label_constraints": [
        {
            "key": "zone",
            "op": "in",
            "values": [
                "west"
            ]
        }
    ],
    "location_labels": [
        "zone",
        "rack",
        "host"
    ]
}
]
}
```

To use the configurations in `rule.json`, run the following command to back up the existing configuration to the `default.json` file and overwrite the existing configuration with `rule.json`:

```
pd-ctl config placement-rules rule-bundle load --out="default.json"
pd-ctl config placement-rules rule-bundle save --in="rule.json"
```

If you need to roll back to the previous configuration, you can restore the backup file

default.json or write the following JSON file manually and overwrite the current configuration with this JSON file:

```
cat default.json
[
  {
    "group_id": "pd",
    "group_index": 0,
    "group_override": false,
    "rules": [
      {
        "group_id": "pd",
        "id": "default",
        "start_key": "",
        "end_key": "",
        "role": "voter",
        "count": 3
      }
    ]
  }
]
```

10.3.2.3 Enable the DR Auto-Sync mode

The replication mode is controlled by PD. You can configure the replication mode in the PD configuration file using one of the following methods:

- Method 1: Configure the PD configuration file, and then deploy a cluster.

```
[replication-mode]
replication-mode = "dr-auto-sync"
[replication-mode.dr-auto-sync]
label-key = "zone"
primary = "east"
dr = "west"
primary-replicas = 2
dr-replicas = 1
wait-store-timeout = "1m"
wait-sync-timeout = "1m"
```

- Method 2: If you have deployed a cluster, use pd-ctl commands to modify the configurations of PD.

```
config set replication-mode dr-auto-sync
config set replication-mode dr-auto-sync label-key zone
config set replication-mode dr-auto-sync primary east
```

```
config set replication-mode dr-auto-sync dr west
config set replication-mode dr-auto-sync primary-replicas 2
config set replication-mode dr-auto-sync dr-replicas 1
```

Descriptions of configuration items:

- `replication-mode` is the replication mode to be enabled. In the above example, it is set to `dr-auto-sync`. By default, the majority protocol is used.
- `label-key` is used to distinguish different data centers and needs to match Placement Rules. In this example, the primary data center is “east” and the DR data center is “west”.
- `primary-replicas` is the number of Voter replicas in the primary data center.
- `dr-replicas` is the number of Voter replicas in the DR data center.
- `wait-store-timeout` is the waiting time for switching to asynchronous replication mode when network isolation or failure occurs. If the time of network failure exceeds the waiting time, asynchronous replication mode is enabled. The default waiting time is 60 seconds.

To check the current replication status of the cluster, use the following API:

```
curl http://pd_ip:pd_port/pd/api/v1/replication_mode/status
```

```
{
  "mode": "dr-auto-sync",
  "dr-auto-sync": {
    "label-key": "zone",
    "state": "sync"
  }
}
```

10.3.2.3.1 Status switch

The replication mode of a cluster can automatically and adaptively switch between three statuses:

- When the cluster is normal, the synchronous replication mode is enabled to maximize the data integrity of the disaster recovery data center.
- When the network connection between the two data centers fails or the DR data center breaks down, after a pre-set protective interval, the cluster enables the asynchronous replication mode to ensure the availability of the application.
- When the network reconnects or the DR data center recovers, the TiKV node joins the cluster again and gradually replicates the data. Finally, the cluster switches to the synchronous replication mode.

The details for the status switch are as follows:

1. **Initialization:** At the initialization stage, the cluster is in the synchronous replication mode. PD sends the status information to TiKV, and all TiKV nodes strictly follow the synchronous replication mode to work.
2. **Switch from sync to async:** PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node fails or is disconnected. If the number of failed nodes exceeds the number of replicas of the primary data center (`primary-replicas`) and the DR data center (`dr-replicas`), the synchronous replication mode can no longer serve the data replication and it is necessary to switch the status. When the failure or disconnect time exceeds the time set by `wait-store-timeout`, PD switches the status of the cluster to the async mode. Then PD sends the status of async to all TiKV nodes, and the replication mode for TiKV switches from two-center replication to the native Raft majority.
3. **Switch from async to sync:** PD regularly checks the heartbeat information of TiKV to judge whether the TiKV node is reconnected. If the number of failed nodes is less than the number of replicas of the primary data center (`primary-replicas`) and the DR data center (`dr-replicas`), the synchronous replication mode can be enabled again. PD first switches the status of the cluster to `sync-recover` and sends the status information to all TiKV nodes. All Regions of TiKV gradually switch to the two-data-center synchronous replication mode and then report the heartbeat information to PD. PD records the status of TiKV Regions and calculates the recovery progress. When all TiKV Regions finish the switching, PD switches the replication mode to `sync`.

10.3.2.4 Disaster recovery

This section introduces the disaster recovery solution of the two data centers in one city deployment.

When a disaster occurs to a cluster in the synchronous replication mode, you can perform data recovery with `RPO = 0`:

- If the primary data center fails and most of the Voter replicas are lost, but complete data exists in the DR data center, the lost data can be recovered from the DR data center. At this time, manual intervention is required with professional tools. You can contact the TiDB team for a recovery solution.
- If the DR center fails and a few Voter replicas are lost, the cluster automatically switches to the asynchronous replication mode.

When a disaster occurs to a cluster that is not in the synchronous replication mode and you cannot perform data recovery with `RPO = 0`:

- If most of the Voter replicas are lost, manual intervention is required with professional tools. You can contact the TiDB team for a recovery solution.

10.4 Read Historical Data

10.4.1 Use Stale Read (Recommended)

10.4.1.1 Usage Scenarios of Stale Read

This document describes the usage scenarios of Stale Read. Stale Read is a mechanism that TiDB applies to read historical versions of data stored in TiDB. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes.

When you are using Stale Read, TiDB will randomly select a replica for data reading, which means that all replicas are available for data reading. If your application cannot tolerate reading non-real-time data, do not use Stale Read; otherwise, the data read from the replica might not be the latest data written into TiDB.

10.4.1.1.1 Scenario examples

- Scenario one: If a transaction only involves read operations and is tolerant of data staleness to some extent, you can use Stale Read to get historical data. Using Stale Read, TiDB makes the query requests sent to any replica at the expense of some real-time performance, and thus increases the throughput of query executions. Especially in some scenarios where small tables are queried, if strongly consistent reads are used, leader might be concentrated on a certain storage node, causing the query pressure to be concentrated on that node as well. Therefore, that node might become a bottleneck for the whole query. Stale Read, however, can improve the overall query throughput and significantly improve the query performance.
- Scenario two: In some scenarios of geo-distributed deployment, if strongly consistent follower reads are used, to make sure that the data read from the Followers is consistent with that stored in the Leader, TiDB requests `Readindex` from different data centers for verification, which increases the access latency for the whole query process. With Stale Read, TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query. For more information, see [Local Read under Three Data Centers Deployment](#).

10.4.1.1.2 Usages

TiDB provides the methods of performing Stale Read at the statement level and the session level as follows:

- Statement level
 - Specifying an exact point in time (**recommended**): If you need TiDB to read data that is globally consistent from a specific point in time without violating the isolation level, you can specify the corresponding timestamp of that point in time in the query statement. For detailed usage, see [AS OF TIMESTAMP clause](#).

- Specifying a time range: If you need TiDB to read the data as new as possible within a time range without violating the isolation level, you can specify the time range in the query statement. Within the specified time range, TiDB selects a suitable timestamp to read the corresponding data. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. For detailed usage, refer to the introduction of the [AS OF TIMESTAMP Clause](#) and the [TIDB_BOUNDED_STALENESS function](#).
- Session level
 - Specifying a time range: In a session, if you need TiDB to read the data as new as possible within a time range in subsequent queries without violating the isolation level, you can specify the time range by setting the `tidb_read_staleness` system variable. For detailed usage, refer to [tidb_read_staleness](#).

10.4.1.2 Read Historical Data Using the AS OF TIMESTAMP Clause

This document describes how to perform the [Stale Read](#) feature using the [AS OF](#) \leftrightarrow [TIMESTAMP](#) clause to read historical data in TiDB, including specific usage examples and strategies for saving historical data.

Warning:

Currently, you cannot use Stale Read together with TiFlash. If your SQL query contains the [AS OF TIMESTAMP](#) clause and TiDB might read data from TiFlash replicas, you might encounter an error with a message like `ERROR \leftrightarrow 1105 (HY000): stale requests require tikv backend`.

To fix the problem, disable TiFlash replicas for your Stale Read query. To do that, perform one of the following operations:

- Use the `set session tidb_isolation_read_engines='tidb,tikv'` variable.
- Use the [hint](#) to enforce TiDB to read data from TiKV.

TiDB supports reading historical data through a standard SQL interface, which is the [AS OF TIMESTAMP SQL](#) clause, without the need for special clients or drivers. After data is updated or deleted, you can read the historical data before the update or deletion using this SQL interface.

Note:

When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

10.4.1.2.1 Syntax

You can use the `AS OF TIMESTAMP` clause in the following three ways:

- `SELECT ... FROM ... AS OF TIMESTAMP`
- `START TRANSACTION READ ONLY AS OF TIMESTAMP`
- `SET TRANSACTION READ ONLY AS OF TIMESTAMP`

If you want to specify an exact point of time, you can set a datetime value or use a time function in the `AS OF TIMESTAMP` clause. The format of datetime is like “2016-10-08 16:45:26.999”, with millisecond as the minimum time unit, but for most of the time, the time unit of second is enough for specifying a datetime, such as “2016-10-08 16:45:26”. You can also get the current time to the millisecond using the `NOW(3)` function. If you want to read the data of several seconds ago, it is **recommended** to use an expression such as `NOW() - INTERVAL 10 SECOND`.

If you want to specify a time range, you can use the `TIDB_BOUNDED_STALENESS()` function in the clause. When this function is used, TiDB selects a suitable timestamp within the specified time range. “Suitable” means there are no transactions that start before this timestamp and have not been committed on the accessed replica, that is, TiDB can perform read operations on the accessed replica and the read operations are not blocked. You need to use `TIDB_BOUNDED_STALENESS(t1, t2)` to call this function. `t1` and `t2` are the two ends of the time range, which can be specified using either datetime values or time functions.

Here are some examples of the `AS OF TIMESTAMP` clause:

- `AS OF TIMESTAMP '2016-10-08 16:45:26'`: Tells TiDB to read the latest data stored at 16:45:26 on October 8, 2016.
- `AS OF TIMESTAMP NOW() - INTERVAL 10 SECOND`: Tells TiDB to read the latest data stored 10 seconds ago.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS('2016-10-08 16:45:26', '2016-10-08 ↪ 16:45:29')`: Tells TiDB to read the data as new as possible within the time range of 16:45:26 to 16:45:29 on October 8, 2016.
- `AS OF TIMESTAMP TIDB_BOUNDED_STALENESS(NOW() - INTERVAL 20 SECOND, NOW() ↪)`: Tells TiDB to read the data as new as possible within the time range of 20 seconds ago to the present.

Note:

In addition to specifying a timestamp, the most common use of the `AS OF` \leftrightarrow `TIMESTAMP` clause is to read data that is several seconds old. If this approach is used, it is recommended to read historical data older than 5 seconds.

You need to deploy the NTP service for your TiDB and PD nodes when you use Stale Read. This avoids the situation where the specified timestamp used by TiDB goes ahead of the latest TSO allocating progress (such as a timestamp several seconds ahead), or is later than the GC safe point timestamp. When the specified timestamp goes beyond the service scope, TiDB returns an error.

10.4.1.2.2 Usage examples

This section describes different ways to use the `AS OF` `TIMESTAMP` clause with several examples. It first introduces how to prepare the data for recovery, and then shows how to use `AS OF` `TIMESTAMP` in `SELECT`, `START TRANSACTION READ ONLY AS OF` `TIMESTAMP`, and `SET TRANSACTION READ ONLY AS OF` `TIMESTAMP` respectively.

Prepare data sample

To prepare data for recovery, create a table first and insert several rows of data:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

View the data in the table:

```
select * from t;
```

```
+-----+
| c   |
+-----+
|  1  |
|  2  |
|  3  |
+-----+
3 rows in set (0.00 sec)
```

View the current time:

```
select now();
```

```
+-----+
| now()          |
+-----+
| 2021-05-26 16:45:26 |
+-----+
1 row in set (0.00 sec)
```

Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

Confirm that the data of the row is updated:

```
select * from t;
```

```
+-----+
| c    |
+-----+
| 1    |
| 22   |
| 3    |
+-----+
3 rows in set (0.00 sec)
```

Read historical data using the **SELECT** statement

You can use the **SELECT ... FROM ... AS OF TIMESTAMP** statement to read data from a time point in the past.

```
select * from t as of timestamp '2021-05-26 16:45:26';
```

```
+-----+
| c    |
+-----+
| 1    |
| 2    |
| 3    |
+-----+
3 rows in set (0.00 sec)
```

Note:

When reading multiple tables using one `SELECT` statement, you need to make sure that the format of `TIMESTAMP EXPRESSIONS` is consistent. For example, `select * from t as of timestamp NOW()- INTERVAL 2 SECOND, ↵ c as of timestamp NOW()- INTERVAL 2 SECOND;`. In addition, you must specify the `AS OF` information for the relevant table in the `SELECT` statement; otherwise, the `SELECT` statement reads the latest data by default.

Read historical data using the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `START TRANSACTION READ ONLY AS OF TIMESTAMP` statement to start a read-only transaction based on a time point in the past. The transaction reads historical data of the given time.

```
start transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+
| c   |
+-----+
|  1  |
|  2  |
|  3  |
+-----+
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+-----+
| c   |
+-----+
|  1  |
```

```
| 22 |  
| 3 |  
+-----+  
3 rows in set (0.00 sec)
```

Note:

If you start a transaction with the statement `START TRANSACTION READ ONLY AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

Read historical data using the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement

You can use the `SET TRANSACTION READ ONLY AS OF TIMESTAMP` statement to set the next transaction as a read-only transaction based on a specified time point in the past. The transaction reads historical data of the given time.

```
set transaction read only as of timestamp '2021-05-26 16:45:26';
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
begin;
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+  
| c |  
+-----+  
| 1 |  
| 2 |  
| 3 |  
+-----+  
3 rows in set (0.00 sec)
```

```
commit;
```

```
Query OK, 0 rows affected (0.00 sec)
```

After the transaction is committed, you can read the latest data.

```
select * from t;
```

```
+-----+
| c     |
+-----+
|  1   |
| 22   |
|  3   |
+-----+
3 rows in set (0.00 sec)
```

Note:

If you start a transaction with the statement `SET TRANSACTION READ ONLY ↪ AS OF TIMESTAMP`, it is a read-only transaction. Write operations are rejected in this transaction.

10.4.1.3 Read Historical Data Using the `tidb_read_staleness` System Variable

To support reading the historical data, in v5.4, TiDB introduces a new system variable `tidb_read_staleness`. This document describes how to read historical data through this system variable, including detailed operating procedures.

10.4.1.3.1 Feature description

The `tidb_read_staleness` system variable is used to set the time range of historical data that TiDB can read in the current session. The data type of this variable is `int` type, and the scope of it is `SESSION`. After setting the value, TiDB selects a timestamp as new as possible from the range allowed by this variable, and all subsequent read operations are performed against this timestamp. For example, if the value of this variable is set to `-5`, on the condition that TiKV has the corresponding historical version's data, TiDB selects a timestamp as new as possible within a 5-second time range.

After enabling `tidb_read_staleness`, you still can perform the following operations:

- Insert, modify, delete data or perform DML operations in the current session. These statements are not affected by `tidb_read_staleness`.
- Start an interactive transaction in the current session. Queries within this transaction still read the latest data.

After reading the historical data, you can read the latest data in the following two ways:

- Start a new session.
- Set the value of the `tidb_read_staleness` variable to "" using the `SET` statement.

10.4.1.3.2 Usage examples

This section describes how to use `tidb_read_staleness` with examples.

1. Create a table, and insert a few rows of data into the table:

```
create table t (c int);
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
insert into t values (1), (2), (3);
```

```
Query OK, 3 rows affected (0.00 sec)
```

2. Check out the data in the table:

```
select * from t;
```

```
+-----+  
| c   |  
+-----+  
|  1  |  
|  2  |  
|  3  |  
+-----+  
3 rows in set (0.00 sec)
```

3. Update the data in a row:

```
update t set c=22 where c=2;
```

```
Query OK, 1 row affected (0.00 sec)
```

4. Confirm that the data has been updated:

```
select * from t;
```

```
+-----+  
| c   |  
+-----+  
|  1  |  
| 22  |  
|  3  |  
+-----+  
3 rows in set (0.00 sec)
```

5. Set the `tidb_read_staleness` system variable.

The scope of this variable is `SESSION`. After setting its value, TiDB reads the latest version data before the time set by the value.

The following setting indicates that TiDB selects a timestamp as new as possible within the time range from 5 seconds ago to now and uses it as the timestamp for reading historical data:

```
set @@tidb_read_staleness="-5";
```

```
Query OK, 0 rows affected (0.00 sec)
```

Note:

- Use `@@` instead of `@` before `tidb_read_staleness`. `@@` means system variables, and `@` means user variables.
- You need to set the historical time range (the value of `tidb_read_staleness`) according to the total time that you spent in step 3 and step 4. Otherwise, the latest data will be displayed in the query results, not the historical data. Therefore, you need to adjust this time range according to the time you spent on operations. For example, in this example, since the set time range is 5 seconds, you need to complete step 3 and step 4 within 5 seconds.

The data read here is the data before the update, that is, the historical data:

```
select * from t;
```

```
+-----+
| c   |
+-----+
|  1  |
|  2  |
|  3  |
+-----+
3 rows in set (0.00 sec)
```

6. After un-setting this variable as follows, TiDB can read the latest data:

```
set @@tidb_read_staleness="";
```

```
Query OK, 0 rows affected (0.00 sec)
```

```
select * from t;
```

```
+-----+
| c     |
+-----+
|  1   |
| 22   |
|  3   |
+-----+
3 rows in set (0.00 sec)
```

10.4.2 Read Historical Data Using the System Variable `tidb_snapshot`

This document describes how to read data from the history versions using the system variable `tidb_snapshot`, including specific usage examples and strategies for saving historical data.

Note:

You can also use the [Stale Read](#) feature to read historical data, which is more recommended.

10.4.2.1 Feature description

TiDB implements a feature to read history data using the standard SQL interface directly without special clients or drivers.

Note:

- Even when data is updated or removed, its history versions can be read using the SQL interface.
- When reading historical data, TiDB returns the data with the old table structure even if the current table structure is different.

10.4.2.2 How TiDB reads data from history versions

The `tidb_snapshot` system variable is introduced to support reading history data. About the `tidb_snapshot` variable:

- The variable is valid in the `SESSION` scope.

- Its value can be modified using the `SET` statement.
- The data type for the variable is text.
- The variable accepts TSO (Timestamp Oracle) and datetime. TSO is a globally unique time service, which is obtained from PD. The acceptable datetime format is “2016-10-08 16:45:26.999”. Generally, the datetime can be set using second precision, for example “2016-10-08 16:45:26”.
- When the variable is set, TiDB creates a Snapshot using its value as the timestamp, just for the data structure and there is no any overhead. After that, all the `SELECT` operations will read data from this Snapshot.

Note:

Because the timestamp in TiDB transactions is allocated by Placement Driver (PD), the version of the stored data is also marked based on the timestamp allocated by PD. When a Snapshot is created, the version number is based on the value of the `tidb_snapshot` variable. If there is a large difference between the local time of the TiDB server and the PD server, use the time of the PD server.

After reading data from history versions, you can read data from the latest version by ending the current Session or using the `SET` statement to set the value of the `tidb_snapshot` variable to “” (empty string).

10.4.2.3 How TiDB manages the data versions

TiDB implements Multi-Version Concurrency Control (MVCC) to manage data versions. The history versions of data are kept because each update/removal creates a new version of the data object instead of updating/removing the data object in-place. But not all the versions are kept. If the versions are older than a specific time, they will be removed completely to reduce the storage occupancy and the performance overhead caused by too many history versions.

In TiDB, Garbage Collection (GC) runs periodically to remove the obsolete data versions. For GC details, see [TiDB Garbage Collection \(GC\)](#)

Pay special attention to the following:

- `tidb_gc_life_time`: This system variable is used to configure the retention time of earlier modifications (default: 10m0s).
- The output of `SELECT * FROM mysql.tidb WHERE variable_name = 'tikv_gc_safe_point' ↪ '`. This is the current `safePoint` where you can read historical data up to. It is updated every time the garbage collection process is run.

10.4.2.4 Example

1. At the initial stage, create a table and insert several rows of data:

```
mysql> create table t (c int);
Query OK, 0 rows affected (0.01 sec)

mysql> insert into t values (1), (2), (3);
Query OK, 3 rows affected (0.00 sec)
```

2. View the data in the table:

```
mysql> select * from t;
+-----+
| c  |
+-----+
|  1 |
|  2 |
|  3 |
+-----+
3 rows in set (0.00 sec)
```

3. View the timestamp of the table:

```
mysql> select now();
+-----+
| now()          |
+-----+
| 2016-10-08 16:45:26 |
+-----+
1 row in set (0.00 sec)
```

4. Update the data in one row:

```
mysql> update t set c=22 where c=2;
Query OK, 1 row affected (0.00 sec)
```

5. Make sure the data is updated:

```
mysql> select * from t;
+-----+
| c  |
+-----+
|  1 |
| 22 |
|  3 |
```

```
+-----+
3 rows in set (0.00 sec)
```

- Set the `tidb_snapshot` variable whose scope is Session. The variable is set so that the latest version before the value can be read.

Note:

In this example, the value is set to be the time before the update operation.

```
mysql> set @@tidb_snapshot="2016-10-08 16:45:26";
Query OK, 0 rows affected (0.00 sec)
```

Note:

You should use `@@` instead of `@` before `tidb_snapshot` because `@@` is used to denote the system variable while `@` is used to denote the user variable.

Result: The read from the following statement is the data before the update operation, which is the history data.

```
mysql> select * from t;
+-----+
| c    |
+-----+
|  1  |
|  2  |
|  3  |
+-----+
3 rows in set (0.00 sec)
```

- Set the `tidb_snapshot` variable to be "" (empty string) and you can read the data from the latest version:

```
mysql> set @@tidb_snapshot="";
Query OK, 0 rows affected (0.00 sec)
```

```
mysql> select * from t;
+-----+
| c    |
+-----+
|  1  |
```

```
| 22 |  
| 3 |  
+-----+  
3 rows in set (0.00 sec)
```

Note:

You should use @@ instead of @ before `tidb_snapshot` because @@ is used to denote the system variable while @ is used to denote the user variable.

10.4.2.5 How to restore historical data

Before you restore data from an older version, make sure that Garbage Collection (GC) does not clear the history data while you are working on it. This can be done by setting the `tidb_gc_life_time` variable as the following example shows. Do not forget to set the variable back to the previous value after the restore.

```
SET GLOBAL tidb_gc_life_time="60m";
```

Note:

Increasing the GC life time from the default 10 minutes to half an hour or more will result in additional versions of rows being retained, which might require more disk space. This might also affect the performance of certain operations such as scans when TiDB needs to skip these additional versions of the same rows during data reads.

To restore data from an older version, you can use one of the following methods:

- For simple cases, use `SELECT` after setting the `tidb_snapshot` variable and copy-paste the output, or use `SELECT ... INTO LOCAL OUTFLE` and use `LOAD DATA` to import the data later on.
- Use [Dumpling](#) to export a historical snapshot. Dumpling performs well in exporting larger sets of data.
- Use [Dumpling](#) to export a historical snapshot. Dumpling performs well in exporting larger sets of data.

10.5 Best Practices

10.5.1 TiDB Best Practices

This document summarizes the best practices of using TiDB, including the use of SQL and optimization tips for Online Analytical Processing (OLAP) and Online Transactional Processing (OLTP) scenarios, especially the optimization options specific for TiDB.

Before you read this document, it is recommended that you read three blog posts that introduce the technical principles of TiDB:

- [TiDB Internal \(I\) - Data Storage](#)
- [TiDB Internal \(II\) - Computing](#)
- [TiDB Internal \(III\) - Scheduling](#)

10.5.1.1 Preface

Database is a generic infrastructure system. It is important to consider various user scenarios during the development process and to modify the data parameters or the way to use according to actual situations in specific business scenarios.

TiDB is a distributed database compatible with the MySQL protocol and syntax. But with the internal implementation and supporting of distributed storage and transactions, the way of using TiDB is different from MySQL.

10.5.1.2 Basic concepts

The best practices are closely related to its implementation principles. It is recommended that you learn some of the basic mechanisms, including the Raft consensus algorithm, distributed transactions, data sharding, load balancing, the mapping solution from SQL to Key-Value (KV), the implementation method of secondary indexing, and distributed execution engines.

This section is an introduction to these concepts. For detailed information, refer to [PingCAP blog posts](#).

10.5.1.2.1 Raft

Raft is a consensus algorithm that ensures data replication with strong consistency. At the bottom layer, TiDB uses Raft to replicate data. TiDB writes data to the majority of the replicas before returning the result of success. In this way, even though a few replicas might get lost, the system still has the latest data. For example, if there are three replicas, the system does not return the result of success until data has been written to two replicas. Whenever a replica is lost, at least one of the remaining two replicas have the latest data.

To store three replicas, compared with the replication of Source-Replica, Raft is more efficient. The write latency of Raft depends on the two fastest replicas, instead of the slowest one. Therefore, the implementation of geo-distributed and multiple active data centers

becomes possible by using the Raft replication. In the typical scenario of three data centers distributing in two sites, to guarantee the data consistency, TiDB just needs to successfully write data into the local data center and the closer one, instead of writing to all three data centers. However, this does not mean that cross-data center deployment can be implemented in any scenario. When the amount of data to be written is large, the bandwidth and latency between data centers become the key factors. If the write speed exceeds the bandwidth or the latency is too high, the Raft replication mechanism still cannot work well.

10.5.1.2.2 Distributed transactions

TiDB provides complete distributed transactions and the model has some optimizations on the basis of [Google Percolator](#). This document introduces the following features:

- Optimistic transaction model

TiDB's optimistic transaction model does not detect conflicts until the commit phase. If there are conflicts, the transaction needs retry. But this model is inefficient if the conflict is severe, because operations before retry are invalid and need to repeat.

Assume that the database is used as a counter. High access concurrency might lead to severe conflicts, resulting in multiple retries or even timeouts. Therefore, in the scenario of severe conflicts, it is recommended to use the pessimistic transaction mode or to solve problems at the system architecture level, such as placing counter in Redis. Nonetheless, the optimistic transaction model is efficient if the access conflict is not very severe.

- Pessimistic transaction mode

In TiDB, the pessimistic transaction mode has almost the same behavior as in MySQL. The transaction applies a lock during the execution phase, which avoids retries in conflict situations and ensures a higher success rate. By applying the pessimistic locking, you can also lock data in advance using `SELECT FOR UPDATE`.

However, if the application scenario has fewer conflicts, the optimistic transaction model has better performance.

- Transaction size limit

As distributed transactions need to conduct two-phase commit and the bottom layer performs Raft replication, if a transaction is very large, the commit process would be quite slow, and the following Raft replication process is thus stuck. To avoid this problem, the transaction size is limited:

- A transaction is limited to 5,000 SQL statements (by default)
- Each Key-Value entry is no more than 6 MB (by default)
- The total size of Key-Value entries is no more than 10 GB.

You can find similar limits in [Google Cloud Spanner](#).

10.5.1.2.3 Data sharding

TiKV automatically shards bottom-layered data according to the range of keys. Each Region is a range of keys, which is a left-closed and right-open interval, [`StartKey`, `EndKey` \hookrightarrow). When the amount of Key-Value pairs in a Region exceeds a certain value, the Region automatically splits into two.

10.5.1.2.4 Load balancing

Placement Driver (PD) balances the load of the cluster according to the status of the entire TiKV cluster. The unit of scheduling is Region and the logic is the strategy configured by PD.

10.5.1.2.5 SQL on KV

TiDB automatically maps the SQL structure into Key-Value structure. For details, see [TiDB Internal \(II\) - Computing](#).

Simply put, TiDB performs the following operations:

- A row of data is mapped to a Key-Value pair. The key is prefixed with `TableID` and suffixed with the row ID.
- An index is mapped as a Key-Value pair. The key is prefixed with `TableID+IndexID` and suffixed with the index value.

The data or indexes in the same table have the same prefix. These Key-Values are at adjacent positions in the key space of TiKV. Therefore, when the amount of data to be written is large and all is written to one table, the write hotspot is created. The situation gets worse when some index values of the continuous written data is also continuous (for example, fields that increase with time, like `update time`), which creates a few write hotspots and becomes the bottleneck of the entire system.

Similarly, if all data is read from a focused small range (for example, the continuous tens or hundreds of thousands of rows of data), an access hotspot of data is likely to occur.

10.5.1.2.6 Secondary index

TiDB supports the complete secondary indexes, which are also global indexes. Many queries can be optimized by index. Thus, it is important for applications to make good use of secondary indexes.

Lots of MySQL experience is also applicable to TiDB. It is noted that TiDB has its unique features. The following are a few notes when using secondary indexes in TiDB.

- The more secondary indexes, the better?

Secondary indexes can speed up queries, but adding an index has side effects. The previous section introduces the storage model of indexes. For each additional index,

there will be one more Key-Value when inserting a row. Therefore, the more indexes, the slower the writing speed and the more space it takes up.

In addition, too many indexes affects the runtime of the optimizer, and inappropriate indexes mislead the optimizer. Thus, more secondary indexes does not mean better performance.

- Which columns should create indexes?

As is mentioned above, index is important but the number of indexes should be proper. You must create appropriate indexes according to the application characteristics. In principle, you need to create an index on the columns involved in the query to improve the performance. The following are situations that need to create indexes:

- For columns with a high degree of differentiation, filtered rows are remarkably reduced through indexes.
- If there are multiple query criteria, you can choose composite indexes. Note to put the columns with the equivalent condition before composite indexes.

For example, if a commonly used query is `select * from t where c1 = 10 and c2 \rightarrow = 100 and c3 > 10`, you can create a composite index `Index cidx (c1, c2, \rightarrow c3)`. In this way, you can use the query condition to create an index prefix and then scan.

- The difference between querying through indexes and directly scanning the table

TiDB has implemented global indexes, so indexes and data of the table are not necessarily on the same data sharding. When querying through indexes, it should firstly scan indexes to get the corresponding row ID and then use the row ID to get the data. Thus, this method involves two network requests and has a certain performance overhead.

If the query involves lots of rows, scanning index proceeds concurrently. When the first batch of results is returned, getting the data of the table can then proceed. Therefore, this is a parallel + pipeline model. Though the two accesses create overhead, the latency is not high.

The following two conditions do not have the problem of two accesses:

- Columns of the index have already met the query requirement. Assume that the `c` column on the `t` table has an index and the query is `select c from t where \rightarrow c > 10`; . At this time, all needed data can be obtained if you access the index. This situation is called **Covering Index**. But if you focus more on the query performance, you can put into index a portion of columns that do not need to be filtered but need to be returned in the query result, creating composite index. Take `select c1, c2 from t where c1 > 10`; as an example. You can optimize this query by creating composite index `Index c12 (c1, c2)`.

- The primary key of the table is integer. In this case, TiDB uses the value of the primary key as row ID. Thus, if the query condition is on the primary key, you can directly construct the range of the row ID, scan the table data, and get the result.

- Query concurrency

As data is distributed across many Regions, queries run in TiDB concurrently. But the concurrency by default is not high in case it consumes lots of system resources. Besides, the OLTP query usually does not involve a large amount of data and the low concurrency is enough. But for the OLAP query, the concurrency is high and TiDB modifies the query concurrency through the following system variables:

- `tidb_distsql_scan_concurrency`:

The concurrency of scanning data, including scanning the table and index data.

- `tidb_index_lookup_size`:

If it needs to access the index to get row IDs before accessing the table data, it uses a batch of row IDs as a single request to access the table data. This parameter sets the size of a batch. The larger batch increases latency, while the smaller one might lead to more queries. The proper size of this parameter is related to the amount of data that the query involves. Generally, no modification is required.

- `tidb_index_lookup_concurrency`:

If it needs to access the index to get row IDs before accessing the table data, the concurrency of getting data through row IDs every time is modified through this parameter.

- Ensure the order of results through indexes

You can use indexes to filter or sort data. Firstly, get row IDs according to the index order. Then, return the row content according to the return order of row IDs. In this way, the returned results are ordered according to the index column. It has been mentioned earlier that the model of scanning index and getting row is parallel + pipeline. If the row is returned according to the index order, a high concurrency between two queries does not reduce latency. Thus, the concurrency is low by default, but it can be modified through the `tidb_index_serial_scan_concurrency` variable.

- Reverse index scan

TiDB supports scanning an ascending index in reverse order, at a speed slower than normal scan by 20%. If the data is changed frequently and thus too many versions exist, the performance overhead might be higher. It is recommended to avoid reverse index scans as much as possible.

10.5.1.3 Scenarios and practices

In the last section, we discussed some basic implementation mechanisms of TiDB and their influence on usage. This section introduces specific usage scenarios and operation practices, from deployment to application usage.

10.5.1.3.1 Deployment

Before deployment, read [Software and Hardware Requirements](#).

It is recommended to deploy the TiDB cluster using [TiUP](#). This tool can deploy, stop, destroy, and upgrade the whole cluster, which is quite convenient. It is not recommended to manually deploy the TiDB cluster, which might be troublesome to maintain and upgrade later.

10.5.1.3.2 Data import

To improve the write performance during the import process, you can tune TiKV's parameters as stated in [Tune TiKV Memory Parameter Performance](#).

10.5.1.3.3 Write

As mentioned before, TiDB limits the size of a single transaction in the Key-Value layer. As for the SQL layer, a row of data is mapped to a Key-Value entry. For each additional index, one more Key-Value entry is added.

Note:

When you set the size limit for transactions, you need to consider the overhead of TiDB encoding and the extra transaction key. It is recommended that **the number of rows of each transaction is less than 200 and the data size of a single row is less than 100 KB**; otherwise, the performance is bad.

It is recommended to split statements into batches or add a limit to the statements, whether they are INSERT, UPDATE or DELETE statements.

When deleting a large amount of data, it is recommended to use `Delete from t where ↪ xx limit 5000;`. It deletes through the loop and use `Affected Rows == 0` as a condition to end the loop.

If the amount of data that needs to be deleted at a time is large, this loop method gets slower and slower because each deletion traverses backward. After deleting the previous data, lots of deleted flags remain for a short period (then all is cleared by Garbage Collection) and affect the following DELETE statement. If possible, it is recommended to refine the WHERE condition. Assume that you need to delete all data on 2017-05-26, you can use the following statements:

```
for i from 0 to 23:
  while affected_rows > 0:
    delete from t where insert_time >= i:00:00 and insert_time < (i+1)
      ↪ :00:00 limit 5000;
```

```
affected_rows = select affected_rows()
```

This pseudocode means to split huge chunks of data into small ones and then delete, so that the earlier `Delete` statements do not affect the later ones.

10.5.1.3.4 Query

For query requirements and specific statements, refer to [System Variables](#).

You can control the concurrency of SQL execution through the `SET` statement and the selection of the `Join` operator through hints.

In addition, you can also use MySQL's standard index selection, the hint syntax, or control the optimizer to select indexes through `Use Index/Ignore Index` hint.

If the application scenario has both OLTP and OLAP workloads, you can send the OLTP request and OLAP request to different TiDB servers, diminishing the impact of OLAP on OLTP. It is recommended to use machines with high-performance hardware (for example, more processor cores and larger memory) for the TiDB server that processes OLAP workloads.

To completely isolate OLTP and OLAP workloads, it is recommended to run OLAP applications on TiFlash. TiFlash is a columnar storage engine with great performance on OLAP workloads. TiFlash can achieve physical isolation on the storage layer and guarantees consistent reads.

10.5.1.3.5 Monitoring and log

The monitoring metrics is the best method to learn the status of the system. It is recommended that you deploy the monitoring system along with your TiDB cluster.

TiDB uses [Grafana + Prometheus](#) to monitor the system status. The monitoring system is automatically deployed and configured if you deploy TiDB using TiUP.

There are lots of items in the monitoring system, the majority of which are for TiDB developers. You do not have to understand these items without an in-depth knowledge of the source code. Some items that are related to applications or to the state of system key components are selected and put in a separate `overview` panel for users.

In addition to monitoring, you can also view the system logs. The three components of TiDB, `tidb-server`, `tikv-server`, and `pd-server`, each has a `--log-file` parameter. If this parameter has been configured when the cluster is started, logs are stored in the file configured by the parameter and log files are automatically archived on a daily basis. If the `--log-file` parameter has not been configured, the log is output to `stderr`.

Starting from TiDB 4.0, TiDB provides [TiDB Dashboard](#) UI to improve usability. You can access TiDB Dashboard by visiting [http://\\$%7BPD_IP%7D:\\$%7BPD_PORT%7D/dashboard](http://$%7BPD_IP%7D:$%7BPD_PORT%7D/dashboard) in your browser. TiDB Dashboard provides features such as viewing cluster status, performance analysis, traffic visualization, cluster diagnostics, and log searching.

10.5.1.3.6 Documentation

The best way to learn about a system or solve the problem is to read its documentation and understand its implementation principles.

TiDB has a large number of official documents both in Chinese and English. If you have met an issue, you can start from [FAQ](#) and [TiDB Cluster Troubleshooting Guide](#). You can also search the issue list or create an issue in [TiDB repository on GitHub](#).

TiDB also has many useful migration tools. See [Migration Tool Overview](#) for details.

For more articles on the technical details of TiDB, see the [PingCAP official blog site](#).

10.5.1.4 Best scenarios for TiDB

TiDB is suitable for the following scenarios:

- The data volume is too large for a standalone database
- You do not want to do sharding
- The access mode has no obvious hotspot
- Transactions, strong consistency, and disaster recovery are required
- You hope to have real-time Hybrid Transaction/Analytical Processing (HTAP) analytics and reduce storage links

10.5.2 Best Practices for Developing Java Applications with TiDB

This document introduces the best practice for developing Java applications to better use TiDB. Based on some common Java application components that interact with the backend TiDB database, this document also provides the solutions to commonly encountered issues during development.

10.5.2.1 Database-related components in Java applications

Common components that interact with the TiDB database in Java applications include:

- Network protocol: A client interacts with a TiDB server via the standard [MySQL protocol](#).
- JDBC API and JDBC drivers: Java applications usually use the standard [JDBC \(Java Database Connectivity\)](#) API to access a database. To connect to TiDB, you can use a JDBC driver that implements the MySQL protocol via the JDBC API. Such common JDBC drivers for MySQL include [MySQL Connector/J](#) and [MariaDB Connector/J](#).
- Database connection pool: To reduce the overhead of creating a connection each time it is requested, applications usually use a connection pool to cache and reuse connections. JDBC [DataSource](#) defines a connection pool API. You can choose from different open-source connection pool implementations as needed.
- Data access framework: Applications usually use a data access framework such as [MyBatis](#) and [Hibernate](#) to further simplify and manage the database access operations.

- Application implementation: The application logic controls when to send what commands to the database. Some applications use [Spring Transaction](#) aspects to manage transactions' start and commit logics.

Figure 84: Java application components

From the above diagram, you can see that a Java application might do the following things:

- Implement the MySQL protocol via the JDBC API to interact with TiDB.
- Get a persistent connection from the connection pool.
- Use a data access framework such as MyBatis to generate and execute SQL statements.
- Use Spring Transaction to automatically start or stop a transaction.

The rest of this document describes the issues and their solutions when you develop a Java application using the above components.

10.5.2.2 JDBC

Java applications can be encapsulated with various frameworks. In most of the frameworks, JDBC API is called on the bottommost level to interact with the database server. For JDBC, it is recommended that you focus on the following things:

- JDBC API usage choice
- API Implementer's parameter configuration

10.5.2.2.1 JDBC API

For JDBC API usage, see [JDBC official tutorial](#). This section covers the usage of several important APIs.

Use Prepare API

For OLTP (Online Transactional Processing) scenarios, the SQL statements sent by the program to the database are several types that can be exhausted after removing parameter changes. Therefore, it is recommended to use [Prepared Statements](#) instead of regular [execution from a text file](#) and reuse Prepared Statements to execute directly. This avoids the overhead of repeatedly parsing and generating SQL execution plans in TiDB.

At present, most upper-level frameworks call the Prepare API for SQL execution. If you use the JDBC API directly for development, pay attention to choosing the Prepare API.

In addition, with the default implementation of MySQL Connector/J, only client-side statements are preprocessed, and the statements are sent to the server in a text file after `?` \rightarrow is replaced on the client. Therefore, in addition to using the Prepare API, you also need to configure `useServerPrepStmts = true` in JDBC connection parameters before you perform statement preprocessing on the TiDB server. For detailed parameter configuration, see [MySQL JDBC parameters](#).

Use Batch API

For batch inserts, you can use the [addBatch/executeBatch API](#). The `addBatch()` \rightarrow method is used to cache multiple SQL statements first on the client, and then send them to the database server together when calling the `executeBatch` method.

Note:

In the default MySQL Connector/J implementation, the sending time of the SQL statements that are added to batch with `addBatch()` is delayed to the time when `executeBatch()` is called, but the statements will still be sent one by one during the actual network transfer. Therefore, this method usually does not reduce the amount of communication overhead.

If you want to batch network transfer, you need to configure `rewriteBatchedStatements = true` in the JDBC connection parameters. For the detailed parameter configuration, see [Batch-related parameters](#).

Use `StreamingResult` to get the execution result

In most scenarios, to improve execution efficiency, JDBC obtains query results in advance and save them in client memory by default. But when the query returns a super large result set, the client often wants the database server to reduce the number of records returned at a time, and waits until the client's memory is ready and it requests for the next batch.

Usually, there are two kinds of processing methods in JDBC:

- Set `FetchSize` to `Integer.MIN_VALUE` to ensure that the client does not cache. The client will read the execution result from the network connection through `StreamingResult`.

When the client uses the streaming read method, it needs to finish reading or close `resultset` before continuing to use the statement to make a query. Otherwise, the error `No statements may be issued when any streaming result sets are open and in use on a given connection`. Ensure that you have called `.close()` on any active streaming result sets before attempting more queries. is returned.

To avoid such an error in queries before the client finishes reading or closes `resultset`, you can add the `clobberStreamingResults=true` parameter in the URL. Then, `resultset` is automatically closed but the result set to be read in the previous streaming query is lost.

- To use Cursor Fetch, first set `FetchSize` as a positive integer and configure `useCursorFetch=true` in the JDBC URL.

TiDB supports both methods, but it is preferred that you use the first method, because it is a simpler implementation and has a better execution efficiency.

10.5.2.2.2 MySQL JDBC parameters

JDBC usually provides implementation-related configurations in the form of JDBC URL parameters. This section introduces [MySQL Connector/J's parameter configurations](#) (If

you use MariaDB, see [MariaDB's parameter configurations](#)). Because this document cannot cover all configuration items, it mainly focuses on several parameters that might affect performance.

Prepare-related parameters

This section introduces parameters related to **Prepare**.

`useServerPrepStmts`

`useServerPrepStmts` is set to `false` by default, that is, even if you use the Prepare API, the “prepare” operation will be done only on the client. To avoid the parsing overhead of the server, if the same SQL statement uses the Prepare API multiple times, it is recommended to set this configuration to `true`.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If `COM_QUERY` is replaced by `COM_STMT_EXECUTE` or `COM_STMT_PREPARE` in the request, it means this setting already takes effect.

`cachePrepStmts`

Although `useServerPrepStmts=true` allows the server to execute Prepared Statements, by default, the client closes the Prepared Statements after each execution and does not reuse them. This means that the “prepare” operation is not even as efficient as text file execution. To solve this, it is recommended that after setting `useServerPrepStmts=true`, you should also configure `cachePrepStmts=true`. This allows the client to cache Prepared Statements.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

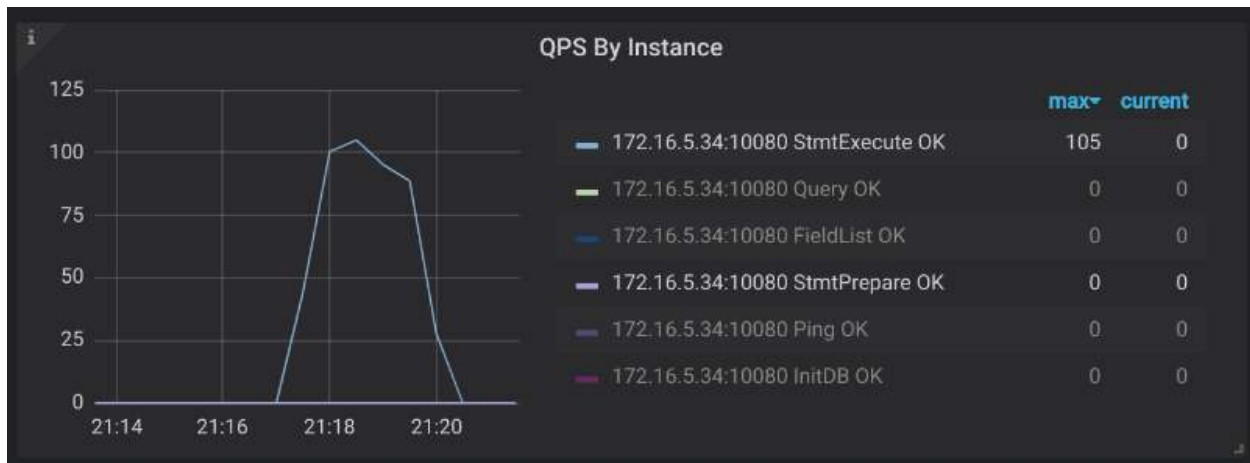

Figure 85: QPS By Instance

In addition, configuring `useConfigs=maxPerformance` will configure multiple parameters at the same time, including `cachePrepStmts=true`.

`prepStmtCacheSqlLimit`

After configuring `cachePrepStmts`, also pay attention to the `prepStmtCacheSqlLimit` configuration (the default value is 256). This configuration controls the maximum length of the Prepared Statements cached on the client.

The Prepared Statements that exceed this maximum length will not be cached, so they cannot be reused. In this case, you may consider increasing the value of this configuration depending on the actual SQL length of the application.

You need to check whether this setting is too small if you:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- And find that `cachePrepStmts=true` has been configured, but `COM_STMT_PREPARE` is still mostly equal to `COM_STMT_EXECUTE` and `COM_STMT_CLOSE` exists.

`prepStmtCacheSize`

`prepStmtCacheSize` controls the number of cached Prepared Statements (the default value is 25). If your application requires “preparing” many types of SQL statements and wants to reuse Prepared Statements, you can increase this value.

To verify that this setting already takes effect, you can do:

- Go to TiDB monitoring dashboard and view the request command type through **Query Summary > QPS By Instance**.
- If the number of `COM_STMT_EXECUTE` in the request is far more than the number of `COM_STMT_PREPARE`, it means this setting already takes effect.

Batch-related parameters

While processing batch writes, it is recommended to configure `rewriteBatchedStatements` \hookrightarrow `=true`. After using `addBatch()` or `executeBatch()`, JDBC still sends SQL one by one by default, for example:

```
pstmt = prepare( "insert into t (a) values(?" );
pstmt.setInt(1, 10);
pstmt.addBatch();
pstmt.setInt(1, 11);
pstmt.addBatch();
pstmt.setInt(1, 12);
pstmt.executeBatch();
```

Although `Batch` methods are used, the SQL statements sent to TiDB are still individual `INSERT` statements:

```
insert into t(a) values(10);
insert into t(a) values(11);
insert into t(a) values(12);
```

But if you set `rewriteBatchedStatements=true`, the SQL statements sent to TiDB will be a single `INSERT` statement:

```
insert into t(a) values(10),(11),(12);
```

Note that the rewrite of the `INSERT` statements is to concatenate the values after multiple “values” keywords into a whole SQL statement. If the `INSERT` statements have other differences, they cannot be rewritten, for example:

```
insert into t (a) values (10) on duplicate key update a = 10;
insert into t (a) values (11) on duplicate key update a = 11;
insert into t (a) values (12) on duplicate key update a = 12;
```

The above `INSERT` statements cannot be rewritten into one statement. But if you change the three statements into the following ones:

```
insert into t (a) values (10) on duplicate key update a = values(a);
insert into t (a) values (11) on duplicate key update a = values(a);
insert into t (a) values (12) on duplicate key update a = values(a);
```

Then they meet the rewrite requirement. The above `INSERT` statements will be rewritten into the following one statement:

```
insert into t (a) values (10), (11), (12) on duplicate key update a =
 $\hookrightarrow$  values(a);
```

If there are three or more updates during the batch update, the SQL statements will be rewritten and sent as multiple queries. This effectively reduces the client-to-server request overhead, but the side effect is that a larger SQL statement is generated. For example:

```
update t set a = 10 where id = 1; update t set a = 11 where id = 2; update
↪ t set a = 12 where id = 3;
```

In addition, because of a [client bug](#), if you want to configure `rewriteBatchedStatements` `↪ =true` and `useServerPrepStmts=true` during batch update, it is recommended that you also configure the `allowMultiQueries=true` parameter to avoid this bug.

Integrate parameters

Through monitoring, you might notice that although the application only performs INSERT operations to the TiDB cluster, there are a lot of redundant SELECT statements. Usually this happens because JDBC sends some SQL statements to query the settings, for example, `select @@session.transaction_read_only`. These SQL statements are useless for TiDB, so it is recommended that you configure `useConfigs=maxPerformance` to avoid extra overhead.

`useConfigs=maxPerformance` configuration includes a group of configurations:

```
cacheServerConfiguration=true
useLocalSessionState=true
elideSetAutoCommits=true
alwaysSendSetIsolation=false
enableQueryTimeouts=false
```

After it is configured, you can check the monitoring to see a decreased number of SELECT statements.

Timeout-related parameters

TiDB provides two MySQL-compatible parameters that controls the timeout: `wait_timeout` and `max_execution_time`. These two parameters respectively control the connection idle timeout with the Java application and the timeout of the SQL execution in the connection; that is to say, these parameters control the longest idle time and the longest busy time for the connection between TiDB and the Java application. The default value of both parameters is 0, which by default allows the connection to be infinitely idle and infinitely busy (an infinite duration for one SQL statement to execute).

However, in an actual production environment, idle connections and SQL statements with excessively long execution time negatively affect databases and applications. To avoid idle connections and SQL statements that are executed for too long, you can configure these two parameters in your application's connection string. For example, set `sessionVariables` `↪ =wait_timeout=3600` (1 hour) and `sessionVariables=max_execution_time=300000` (5 minutes).

10.5.2.3 Connection pool

Building TiDB (MySQL) connections is relatively expensive (for OLTP scenarios at least), because in addition to building a TCP connection, connection authentication is also

required. Therefore, the client usually saves the TiDB (MySQL) connections to the connection pool for reuse.

Java has many connection pool implementations such as [HikariCP](#), [tomcat-jdbc](#), [druid](#), [c3p0](#), and [dbcp](#). TiDB does not limit which connection pool you use, so you can choose whichever you like for your application.

10.5.2.3.1 Configure the number of connections

It is a common practice that the connection pool size is well adjusted according to the application's own needs. Take HikariCP as an example:

- **maximumPoolSize**: The maximum number of connections in the connection pool. If this value is too large, TiDB consumes resources to maintain useless connections. If this value is too small, the application gets slow connections. So configure this value for your own good. For details, see [About Pool Sizing](#).
- **minimumIdle**: The minimum number of idle connections in the connection pool. It is mainly used to reserve some connections to respond to sudden requests when the application is idle. You can also configure it according to your application needs.

The application needs to return the connection after finishing using it. It is also recommended that the application use the corresponding connection pool monitoring (such as `metricRegistry`) to locate the connection pool issue in time.

10.5.2.3.2 Probe configuration

The connection pool maintains persistent connections to TiDB. TiDB does not proactively close client connections by default (unless an error is reported), but generally there will be network proxies such as LVS or HAProxy between the client and TiDB. Usually, these proxies will proactively clean up connections that are idle for a certain period of time (controlled by the proxy's idle configuration). In addition to paying attention to the idle configuration of the proxies, the connection pool also needs to keep alive or probe connections.

If you often see the following error in your Java application:

```
The last packet sent successfully to the server was 3600000 milliseconds ago
↳ . The driver has not received any packets from the server. com.mysql.
↳ jdbc.exceptions.jdbc4.CommunicationsException: Communications link
↳ failure
```

If `n in n milliseconds ago` is 0 or a very small value, it is usually because the executed SQL operation causes TiDB to exit abnormally. To find the cause, it is recommended to check the TiDB stderr log.

If `n` is a very large value (such as 3600000 in the above example), it is likely that this connection was idle for a long time and then closed by the intermediate proxy. The usual solution is to increase the value of the proxy's idle configuration and allow the connection pool to:

- Check whether the connection is available before using the connection every time
- Regularly check whether the connection is available using a separate thread.
- Send a test query regularly to keep alive connections

Different connection pool implementations might support one or more of the above methods. You can check your connection pool documentation to find the corresponding configuration.

10.5.2.4 Data access framework

Applications often use some kind of data access framework to simplify database access.

10.5.2.4.1 MyBatis

[MyBatis](#) is a popular Java data access framework. It is mainly used to manage SQL queries and complete the mapping between result sets and Java objects. MyBatis is highly compatible with TiDB. MyBatis rarely has problems based on its historical issues.

Here this document mainly focuses on the following configurations.

Mapper parameters

MyBatis Mapper supports two parameters:

- `select 1 from t where id = #{param1}` will be converted to `select 1 from t`
↔ `where id =?` as a Prepared Statement and be “prepared”, and the actual parameter will be used for reuse. You can get the best performance when using this parameter with the previously mentioned Prepare connection parameters.
- `select 1 from t where id = ${param2}` will be replaced with `select 1 from t`
↔ `where id = 1` as a text file and be executed. If this statement is replaced with different parameters and is executed, MyBatis will send different requests for “preparing” the statements to TiDB. This might cause TiDB to cache a large number of Prepared Statements, and executing SQL operations this way has injection security risks.

Dynamic SQL Batch

[Dynamic SQL - foreach](#)

To support the automatic rewriting of multiple INSERT statements into the form of `insert ... values(...), (...), ...`, in addition to configuring `rewriteBatchedStatements` ↔ `=true` in JDBC as mentioned before, MyBatis can also use dynamic SQL to semi-automatically generate batch inserts. Take the following mapper as an example:

```
<insert id="insertTestBatch" parameterType="java.util.List" fetchSize="1">
  insert into test
    (id, v1, v2)
  values
```

```
<foreach item="item" index="index" collection="list" separator=",">
(
  #{item.id}, #{item.v1}, #{item.v2}
)
</foreach>
on duplicate key update v2 = v1 + values(v1)
</insert>
```

This mapper generates an `insert on duplicate key update` statement. The number of (?, ?, ?) following “values” is determined by the number of passed lists. Its final effect is similar to using `rewriteBatchStatements=true`, which also effectively reduces communication overhead between the client and TiDB.

As mentioned before, you also need to note that the Prepared Statements will not be cached after their maximum length exceeds the value of `prepStmtCacheSqlLimit`.

Streaming result

A [previous section](#) introduces how to stream read execution results in JDBC. In addition to the corresponding configurations of JDBC, if you want to read a super large result set in MyBatis, you also need to note that:

- You can set `fetchSize` for a single SQL statement in the mapper configuration (see the previous code block). Its effect is equivalent to calling `setFetchSize` in JDBC.
- You can use the query interface with `ResultHandler` to avoid getting the entire result set at once.
- You can use the `Cursor` class for stream reading.

If you configure mappings using XML, you can stream read results by configuring `fetchSize="-2147483648"(Integer.MIN_VALUE)` in the mapping’s `<select>` section.

```
<select id="getAll" resultMap="postResultMap" fetchSize="-2147483648">
  select * from post;
</select>
```

If you configure mappings using code, you can add the `@Options(fetchSize = Integer ↪ .MIN_VALUE)` annotation and keep the type of results as `Cursor` so that the SQL results can be read in streaming.

```
@Select("select * from post")
@Options(fetchSize = Integer.MIN_VALUE)
Cursor<Post> queryAllPost();
```

10.5.2.4.2 ExecutorType

You can choose `ExecutorType` during `openSession`. MyBatis supports three types of executors:

- Simple: The Prepared Statements are called to JDBC for each execution (if the JDBC configuration item `cachePrepStmts` is enabled, repeated Prepared Statements will be reused)
- Reuse: The Prepared Statements are cached in `executor`, so that you can reduce duplicate calls for Prepared Statements without using the JDBC `cachePrepStmts`
- Batch: Each update operation (`INSERT/DELETE/UPDATE`) will first be added to the batch, and will be executed until the transaction commits or a `SELECT` query is performed. If `rewriteBatchStatements` is enabled in the JDBC layer, it will try to rewrite the statements. If not, the statements will be sent one by one.

Usually, the default value of `ExecutorType` is `Simple`. You need to change `ExecutorType` when calling `openSession`. If it is the batch execution, you might find that in a transaction the `UPDATE` or `INSERT` statements are executed pretty fast, but it is slower when reading data or committing the transaction. This is actually normal, so you need to note this when troubleshooting slow SQL queries.

10.5.2.5 Spring Transaction

In the real world, applications might use [Spring Transaction](#) and AOP aspects to start and stop transactions.

By adding the `@Transactional` annotation to the method definition, AOP starts the transaction before the method is called, and commits the transaction before the method returns the result. If your application has a similar need, you can find `@Transactional` in code to determine when the transaction is started and closed.

Pay attention to a special case of embedding. If it occurs, Spring will behave differently based on the [Propagation](#) configuration. Because TiDB does not support savepoint, nested transactions are not supported yet.

10.5.2.6 Misc

This section introduces some useful tools for Java to help you troubleshoot issues.

10.5.2.6.1 Troubleshooting tools

Using the powerful troubleshooting tools of JVM is recommended when an issue occurs in your Java application and you do not know the application logic. Here are a few common tools:

`jstack`

[jstack](#) is similar to `pprof/goroutine` in Go, which can easily troubleshoot the process stuck issue.

By executing `jstack pid`, you can output the IDs and stack information of all threads in the target process. By default, only the Java stack is output. If you want to output the C++ stack in the JVM at the same time, add the `-m` option.

By using `jstack` multiple times, you can easily locate the stuck issue (for example, a slow query from application's view due to using `Batch ExecutorType` in Mybatis) or the application deadlock issue (for example, the application does not send any SQL statement because it is preempting a lock before sending it).

In addition, `top -p $ PID -H` or Java swiss knife are common methods to view the thread ID. Also, to locate the issue of “a thread occupies a lot of CPU resources and I don't know what it is executing”, do the following steps:

- Use `printf "%x\n" pid` to convert the thread ID to hexadecimal.
- Go to the `jstack` output to find the stack information of the corresponding thread.

`jmap & mat`

Unlike `pprof/heap` in Go, `jmap` dumps the memory snapshot of the entire process (in Go, it is the sampling of the distributor), and then the snapshot can be analyzed by another tool `mat`.

Through `mat`, you can see the associated information and attributes of all objects in the process, and you can also observe the running status of the thread. For example, you can use `mat` to find out how many MySQL connection objects exist in the current application, and what is the address and status information of each connection object.

Note that `mat` only handles reachable objects by default. If you want to troubleshoot young GC issues, you can adjust `mat` configuration to view unreachable objects. In addition, for investigating the memory allocation of young GC issues (or a large number of short-lived objects), using Java Flight Recorder is more convenient.

`trace`

Online applications usually do not support modifying the code, but it is often desired that dynamic instrumentation is performed in Java to locate issues. Therefore, using `btrace` or `arthas trace` is a good option. They can dynamically insert trace code without restarting the application process.

Flame graph

Obtaining flame graphs in Java applications is tedious. For details, see [Java Flame Graphs Introduction: Fire For Everyone!](#).

10.5.2.7 Conclusion

Based on commonly used Java components that interact with databases, this document describes the common problems and solutions for developing Java applications with TiDB. TiDB is highly compatible with the MySQL protocol, so most of the best practices for MySQL-based Java applications also apply to TiDB.

Join us at [TiDB Community slack channel](#), and share with broad TiDB user group about your experience or problems when you develop Java applications with TiDB.

10.5.3 Best Practices for Using HAProxy in TiDB

This document describes best practices for configuration and usage of [HAProxy](#) in TiDB. HAProxy provides load balancing for TCP-based applications. From TiDB clients, you can manipulate data just by connecting to the floating virtual IP address provided by HAProxy, which helps to achieve load balance in the TiDB server layer.

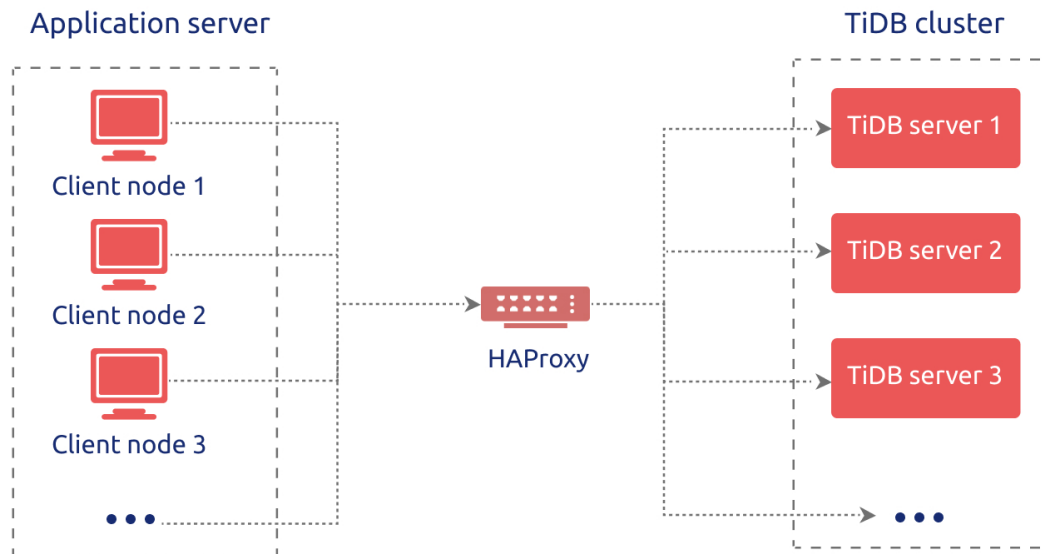

Figure 86: HAProxy Best Practices in TiDB

10.5.3.1 HAProxy overview

HAProxy is free, open-source software written in C language that provides a high availability load balancer and proxy server for TCP and HTTP-based applications. Because of its fast and efficient use of CPU and memory, HAProxy is now widely used by many well-known websites such as GitHub, Bitbucket, Stack Overflow, Reddit, Tumblr, Twitter, Tuenti, and AWS (Amazon Web Services).

HAProxy is written in the year 2000 by Willy Tarreau, the core contributor to the Linux kernel, who is still responsible for the maintenance of the project and provides free software updates in the open-source community. In this guide, HAProxy 2.5.0 is used. It is recommended to use the latest stable version. See [the released version of HAProxy](#) for details.

10.5.3.2 Basic features

- **High Availability:** HAProxy provides high availability with support for a graceful shut-down and a seamless switchover;

- **Load Balancing:** Two major proxy modes are supported: TCP, also known as layer 4, and HTTP, also known as layer 7. No less than 9 load balancing algorithms are supported, such as roundrobin, leastconn and random;
- **Health Check:** HAProxy periodically checks the status of HTTP or TCP mode of the server;
- **Sticky Session:** HAProxy can stick a client to a specific server for the duration when the application does not support sticky sessions;
- **SSL:** HTTPS communication and resolution are supported;
- **Monitoring and Statistics:** Through the web page, you can monitor the service state and traffic flow in real time.

10.5.3.3 Before you begin

Before you deploy HAProxy, make sure that you meet the hardware and software requirements.

10.5.3.3.1 Hardware requirements

For your server, it is recommended to meet the following hardware requirements. You can also improve server specifications according to the load balancing environment.

Hardware resource	Minimum specification
CPU	2 cores, 3.5 GHz
Memory	16 GB
Storage	50 GB (SATA)
Network Interface Card	10G Network Card

10.5.3.3.2 Software requirements

You can use the following operating systems and make sure the required dependencies are installed. If you use yum to install HAProxy, the dependencies are installed along with it and you do not need to separately install them again.

Operating systems

Linux distribution	Version
Red Hat Enterprise Linux	7 or 8
CentOS	7 or 8
Oracle Enterprise Linux	7 or 8
Ubuntu LTS	18.04 or later versions

Note:

- For more information about other supported operating systems, see [HAProxy documentation](#).

Dependencies

- epel-release
- gcc
- systemd-devel

To install the dependencies above, run the following command:

```
yum -y install epel-release gcc systemd-devel
```

10.5.3.4 Deploy HAProxy

You can easily use HAProxy to configure and set up a load-balanced database environment. This section shows general deployment operations. You can customize the [configuration file](#) based on your actual scenario.

10.5.3.4.1 Install HAProxy

1. Download the package of the HAProxy 2.5.0 source code:

```
wget https://github.com/haproxy/haproxy/archive/refs/tags/v2.5.0.zip
```

2. Unzip the package:

```
unzip v2.5.0.zip
```

3. Compile the application from the source code:

```
cd haproxy-2.5.0
make clean
make -j 8 TARGET=linux-glibc USE_THREAD=1
make PREFIX=${/app/haproxy} SBINDIR=${/app/haproxy/bin} install #
  ↳ Replace `${/app/haproxy}` and `${/app/haproxy/bin}` with your
  ↳ custom directories.
```

4. Reconfigure the profile:

```
echo 'export PATH=/app/haproxy/bin:$PATH' >> /etc/profile
```

5. Check whether the installation is successful:

```
which haproxy
```

HAProxy commands

Execute the following command to print a list of keywords and their basic usage:

```
haproxy --help
```

Option	Description
-v	Reports the version and build date.
-vv	Displays the version, build options, libraries versions and usable pollers.
-d	Enables debug mode.
-db	Disables background mode and multi-process mode.

Option	Description
<code>-dM [< ↪ byte ↪ >]</code>	Forces memory poisoning, which means that each and every memory region allocated with <code>malloc()</code> or <code>pool_alloc2()</code> will be filled with <code><byte></code> before being passed to the caller.
<code>-V</code>	Enables verbose mode (disables quiet mode).
<code>-D</code>	Starts as a daemon.
<code>-C <dir></code>	Changes to directory <code><dir></code> before loading configuration files.
<code>-W</code>	Master-worker mode.

Option	Description
<code>-q</code>	Sets “quiet” mode: This disables some messages during the configuration parsing and during startup.
<code>-c</code>	Only performs a check of the configuration files and exits before trying to bind.
<code>-n <limit></code>	Limits the per-process connection limit to <code><limit></code> .
<code>-m <limit></code>	Limits the total allocatable memory to <code><limit></code> megabytes across all processes.

Option	Description
<code>-N <limit></code>	Sets the default per-proxy maxconn to <code><limit></code> instead of the builtin default value (usually 2000).
<code>-L <name></code>	Changes the local peer name to <code><name></code> , which defaults to the local hostname.
<code>-p <file></code>	Writes all processes' PIDs into <code><file></code> during startup.
<code>-de</code>	Disables the use of <code>epoll(7)</code> . <code>epoll(7)</code> is available only on Linux 2.6 and some custom Linux 2.4 systems.
<code>-dp</code>	Disables the use of <code>poll(2)</code> . <code>select(2)</code> might be used instead.

Option	Description
-dS	Disables the use of splice(2), which is broken on older kernels.
-dR	Disables SO_REUSEPORT usage.
-dr	Ignores server address resolution failures.
-dV	Disables SSL verify on the server side.

Option	Description
<code>-sf <</code> <code>↪ pidlist</code> <code>↪ ></code>	Sends the “finish” signal to the PIDs in pidlist after startup. The processes which receive this signal wait for all sessions to finish before exiting. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGUSR1 are sent.

Option	Description
<code>-st <</code> <code>↪ pidlist</code> <code>↪ ></code>	Sends the “terminate” signal to the PIDs in pidlist after startup. The processes which receive this signal terminate immediately, closing all active sessions. This option must be specified last, followed by any number of PIDs. Technically speaking, SIGTTOU and SIGTERM are sent.

Option	Description
<code>-x <</code>	Connects
<code>↪ unix_socket</code>	to the
<code>↪ ></code>	specified socket and retrieves all the listening sockets from the old process. Then, these sockets are used instead of binding new ones.
<code>-S <bind</code>	In master-
<code>↪ >[,<</code>	worker
<code>↪ bind_options,</code>	mode,
<code>↪ >...]</code>	creates a master CLI. This CLI enables access to the CLI of every worker. Useful for debugging, it's a convenient way of accessing a leaving process.

For more details on HAProxy command line options, refer to [Management Guide of HAProxy](#) and [General Commands Manual of HAProxy](#).

10.5.3.4.2 Configure HAProxy

A configuration template is generated when you use yum to install HAProxy. You can also customize the following configuration items according to your scenario.

```
global                                # Global configuration.
log      127.0.0.1 local2              # Global syslog servers (up to two).
chroot   /var/lib/haproxy            # Changes the current directory and
  ↪ sets superuser privileges for the startup process to improve
  ↪ security.
pidfile  /var/run/haproxy.pid        # Writes the PIDs of HAProxy processes
  ↪ into this file.
maxconn  4096                         # The maximum number of concurrent
  ↪ connections for a single HAProxy process. It is equivalent to the
  ↪ command-line argument "-n".
nbthread 48                           # The maximum number of threads. (The
  ↪ upper limit is equal to the number of CPUs)
user     haproxy                      # Same with the UID parameter.
group    haproxy                      # Same with the GID parameter. A
  ↪ dedicated user group is recommended.
daemon                                 # Makes the process fork into
  ↪ background. It is equivalent to the command line "-D" argument. It
  ↪ can be disabled by the command line "-db" argument.
stats socket /var/lib/haproxy/stats # The directory where statistics
  ↪ output is saved.

defaults                                # Default configuration.
log global                              # Inherits the settings of the global
  ↪ configuration.
retries  2                             # The maximum number of retries to
  ↪ connect to an upstream server. If the number of connection attempts
  ↪ exceeds the value, the backend server is considered unavailable.
timeout connect 2s                      # The maximum time to wait for a
  ↪ connection attempt to a backend server to succeed. It should be set
  ↪ to a shorter time if the server is located on the same LAN as
  ↪ HAProxy.

    ↪ backend server (supported in HAProxy 1.4.9 or later versions).

listen tidb-cluster             # Database load balancing.
bind 0.0.0.0:3390               # The Floating IP address and
    ↪ listening port.
mode tcp                        # HAProxy uses layer 4, the transport
    ↪ layer.
balance leastconn               # The server with the smallest number
    ↪ of connections receives the connection. "leastconn" is recommended
    ↪ where long sessions are expected, such as LDAP, SQL and TSE, rather
    ↪ than protocols using short sessions, such as HTTP. The algorithm
    ↪ is dynamic, which means that server weights might be adjusted on
    ↪ the fly for slow starts for instance.
server tidb-1 10.9.18.229:4000 check inter 2000 rise 2 fall 3 # Detects
    ↪ port 4000 at a frequency of once every 2000 milliseconds. If it is
    ↪ detected as successful twice, the server is considered available;
    ↪ if it is detected as failed three times, the server is considered
    ↪ unavailable.
server tidb-2 10.9.39.208:4000 check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 check inter 2000 rise 2 fall 3
```

To check the source IP address using `SHOW PROCESSLIST`, you need to configure the [PROXY protocol](#) to connect to TiDB.

```
server tidb-1 10.9.18.229:4000 send-proxy check inter 2000 rise 2 fall 3
server tidb-2 10.9.39.208:4000 send-proxy check inter 2000 rise 2 fall 3
server tidb-3 10.9.64.166:4000 send-proxy check inter 2000 rise 2 fall 3
```

Note:

Before using the PROXY protocol, you need to configure [proxy-protocol](#).
↪ [networks](#) in the configuration file of the TiDB server.

10.5.3.4.3 Start HAProxy

To start HAProxy, run `haproxy`. `/etc/haproxy/haproxy.cfg` is read by default (recommended).

```
haproxy -f /etc/haproxy/haproxy.cfg
```

10.5.3.4.4 Stop HAProxy

To stop HAProxy, use the `kill -9` command.

1. Run the following command:

```
ps -ef | grep haproxy
```

2. Terminate the process of HAProxy:

```
kill -9 ${haproxy.pid}
```

10.5.4 Highly Concurrent Write Best Practices

This document describes best practices for handling highly-concurrent write-heavy workloads in TiDB, which can help to facilitate your application development.

10.5.4.1 Target audience

This document assumes that you have a basic understanding of TiDB. It is recommended that you first read the following three blog articles that explain TiDB fundamentals, and [TiDB Best Practices](#):

- [Data Storage](#)
- [Computing](#)
- [Scheduling](#)

10.5.4.2 Highly-concurrent write-intensive scenario

The highly concurrent write scenario often occurs when you perform batch tasks in applications, such as clearing, settlement and so on. This scenario has the following features:

- A huge volume of data
- The need to import historical data into database in a short time
- The need to read a huge volume of data from database in a short time

These features pose these challenges to TiDB:

- The write or read capacity must be linearly scalable.
- Database performance is stable and does not decrease as a huge volume of data is written concurrently.

For a distributed database, it is important to make full use of the capacity of all nodes and to prevent a single node from becoming the bottleneck.

10.5.4.3 Data distribution principles in TiDB

To address the above challenges, it is necessary to start with the data segmentation and scheduling principle of TiDB. Refer to [Scheduling](#) for more details.

TiDB splits data into Regions, each representing a range of data with a size limit of 96M by default. Each Region has multiple replicas, and each group of replicas is called a Raft Group. In a Raft Group, the Region Leader executes the read and write tasks (TiDB supports [Follower-Read](#)) within the data range. The Region Leader is automatically scheduled by the Placement Driver (PD) component to different physical nodes evenly to distribute the read and write pressure.

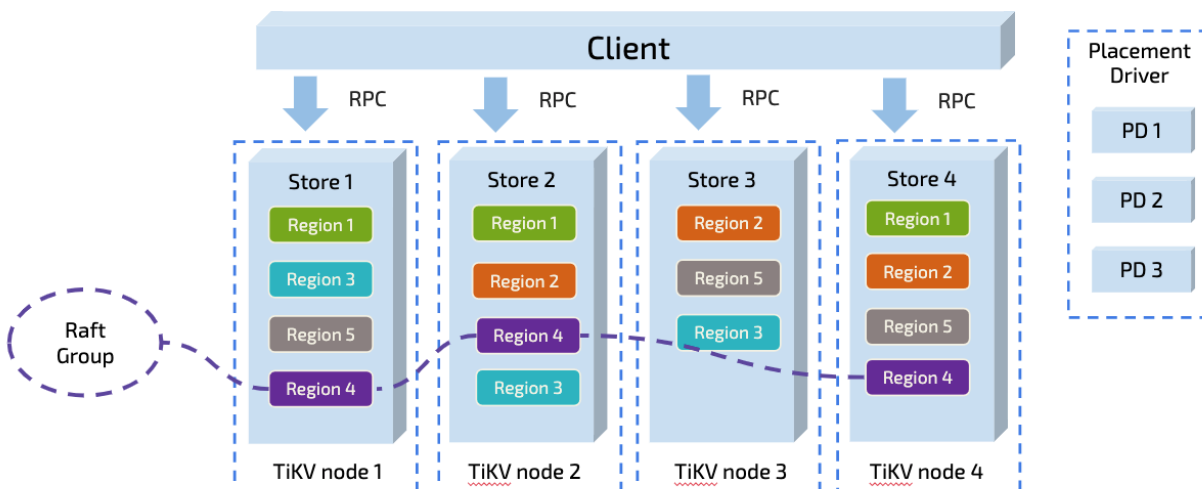

Figure 87: TiDB Data Overview

In theory, if an application has no write hotspot, TiDB, by the virtue of its architecture, can not only linearly scale its read and write capacities, but also make full use of the distributed resources. From this point of view, TiDB is especially suitable for the high-concurrent and write-intensive scenario.

However, the actual situation often differs from the theoretical assumption.

Note:

No write hotspot in an application means the write scenario does not have any AUTO_INCREMENT primary key or monotonically increasing index.

10.5.4.4 Hotspot case

The following case explains how a hotspot is generated. Take the table below as an example:

```
CREATE TABLE IF NOT EXISTS TEST_HOTSPOT(  
  id      BIGINT PRIMARY KEY,  
  age     INT,  
  user_name VARCHAR(32),  
  email   VARCHAR(128)  
)
```

This table is simple in structure. In addition to `id` as the primary key, no secondary index exists. Execute the following statement to write data into this table. `id` is discretely generated as a random number.

```
INSERT INTO TEST_HOTSPOT(id, age, user_name, email) values(%v, %v, '%v', '%  
↪ v');
```

The load comes from executing the above statement intensively in a short time.

In theory, the above operation seems to comply with the TiDB best practices, and no hotspot is caused in the application. The distributed capacity of TiDB can be fully used with adequate machines. To verify whether it is truly in line with the best practices, a test is conducted in the experimental environment, which is described as follows:

For the cluster topology, 2 TiDB nodes, 3 PD nodes and 6 TiKV nodes are deployed. Ignore the QPS performance, because this test is to clarify the principle rather than for benchmark.

Figure 88: QPS1

The client starts “intensive” write requests in a short time, which is 3K QPS received by TiDB. In theory, the load pressure should be evenly distributed to 6 TiKV nodes. However, from the CPU usage of each TiKV node, the load distribution is uneven. The `tikv-3` node is the write hotspot.

Figure 89: QPS2

Figure 90: QPS3

Raft store CPU is the CPU usage rate for the `raftstore` thread, usually representing the write load. In this scenario, `tikv-3` is the Leader of this Raft Group; `tikv-0` and `tikv-1` are the followers. The loads of other nodes are almost empty.

The monitoring metrics of PD also confirms that hotspot has been caused.

Figure 91: QPS4

10.5.4.5 Hotspot causes

In the above test, the operation does not reach the ideal performance expected in the best practices. This is because only one Region is split by default to store the data of each newly created table in TiDB, with the following data range:

```
[CommonPrefix + TableID, CommonPrefix + TableID + 1)
```

In a short period of time, a huge volume of data is continuously written to the same Region.

Figure 92: TiKV Region Split

The above diagram illustrates the Region splitting process. As data is continuously written into TiKV, TiKV splits a Region into multiple Regions. Because the leader election is started on the original store where the Region Leader to be split is located, the leaders of the two newly split Regions might be still on the same store. This splitting process might also happen on the newly split Region 2 and Region 3. In this way, write pressure is concentrated on TiKV-Node 1.

During the continuous write process, after finding that hotspot is caused on Node 1, PD evenly distributes the concentrated Leaders to other nodes. If the number of TiKV nodes is more than the number of Region replicas, TiKV will try to migrate these Regions to idle nodes. These two operations during the write process are also reflected in the PD's monitoring metrics:

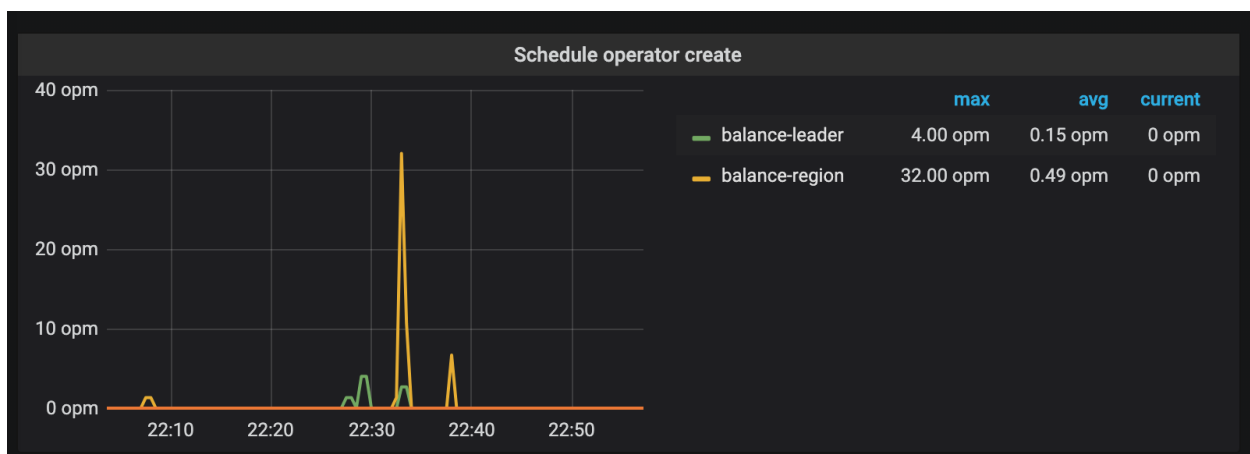

Figure 93: QPS5

After a period of continuous writes, PD automatically schedules the entire TiKV cluster to a state where pressure is evenly distributed. By that time, the capacity of the whole cluster can be fully used.

In most cases, the above process of causing a hotspot is normal, which is the Region warm-up phase of database. However, you need to avoid this phase in highly-concurrent write-intensive scenarios.

10.5.4.6 Hotspot solution

To achieve the ideal performance expected in theory, you can skip the warm-up phase by directly splitting a Region into the desired number of Regions and scheduling these Regions in advance to other nodes in the cluster.

In v3.0.x, v2.1.13 and later versions, TiDB supports a new feature called **Split Region**. This new feature provides the following new syntaxes:

```
SPLIT TABLE table_name [INDEX index_name] BETWEEN (lower_value) AND (
  ↪ upper_value) REGIONS region_num
```

```
SPLIT TABLE table_name [INDEX index_name] BY (value_list) [, (value_list)]
```

However, TiDB does not automatically perform this pre-split operation. The reason is related to the data distribution in TiDB.

Figure 94: Table Region Range

From the diagram above, according to the encoding rule of a row's key, the `rowID` is the only variable part. In TiDB, `rowID` is an `Int64` integer. However, you might not need to evenly split the `Int64` integer range to the desired number of ranges and then to distribute these ranges to different nodes, because Region split must also be based on the actual situation.

If the write of `rowID` is completely discrete, the above method will not cause hotspots. If the row ID or index has a fixed range or prefix (for example, discretely insert data into the range of `[2000w, 5000w)`), no hotspot will be caused either. However, if you split a Region using the above method, data might still be written to the same Region at the beginning.

TiDB is a database for general usage and does not make assumptions about the data distribution. So it uses only one Region at the beginning to store the data of a table and automatically splits the Region according to the data distribution after real data is inserted.

Given this situation and the need to avoid the hotspot problem, TiDB offers the `Split` \leftrightarrow `Region` syntax to optimize performance for the highly-concurrent write-heavy scenario. Based on the above case, now scatter Regions using the `Split Region` syntax and observe the load distribution.

Because the data to be written in the test is entirely discrete within the positive range, you can use the following statement to pre-split the table into 128 Regions within the range of `minInt64` and `maxInt64`:

```
SPLIT TABLE TEST_HOTSPOT BETWEEN (0) AND (9223372036854775807) REGIONS 128;
```

After the pre-split operation, execute the `SHOW TABLE test_hotspot REGIONS;` statement to check the status of Region scattering. If the values of the `SCATTERING` column are all 0, the scheduling is successful.

You can also check the Region leader distribution using the following SQL statement. You need to replace `table_name` with the actual table name.

```
SELECT
  p.STORE_ID,
  COUNT(s.REGION_ID) PEER_COUNT
FROM
  INFORMATION_SCHEMA.TIKV_REGION_STATUS s
  JOIN INFORMATION_SCHEMA.TIKV_REGION_PEERS p ON s.REGION_ID = p.REGION_ID
WHERE
  TABLE_NAME = 'table_name'
  AND p.is_leader = 1
GROUP BY
  p.STORE_ID
ORDER BY
  PEER_COUNT DESC;
```

Then operate the write load again:

Figure 95: QPS6

Figure 96: QPS7

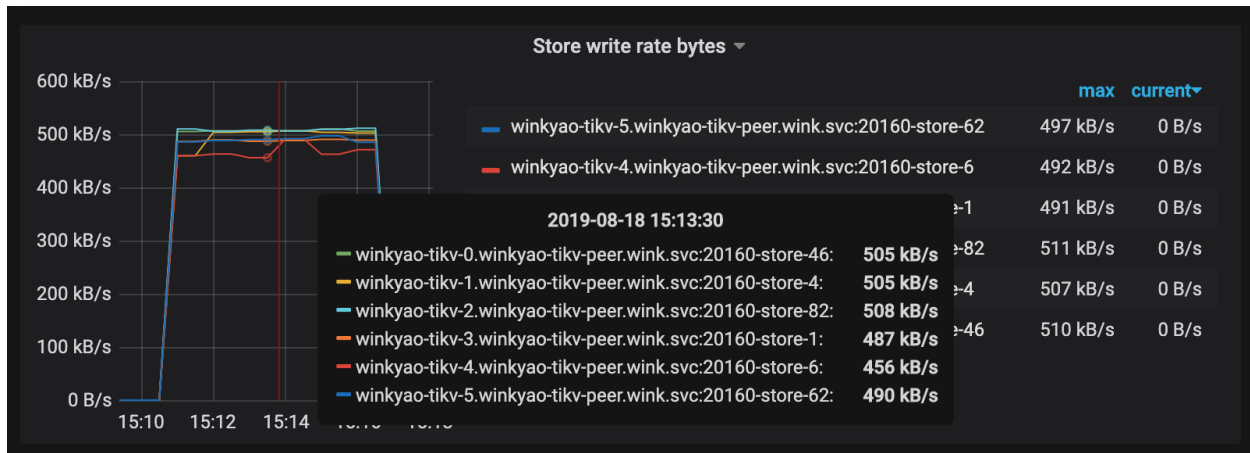

Figure 97: QPS8

You can see that the apparent hotspot problem has been resolved now.

In this case, the table is simple. In other cases, you might also need to consider the hotspot problem of index. For more details on how to pre-split the index Region, refer to [Split Region](#).

10.5.4.7 Complex hotspot problems

Problem one:

If a table does not have a primary key, or the primary key is not the `Int` type and you do not want to generate a randomly distributed primary key ID, TiDB provides an implicit `_tidb_rowid` column as the row ID. Generally, when you do not use the `SHARD_ROW_ID_BITS` parameter, the values of the `_tidb_rowid` column are also monotonically increasing, which might causes hotspots too. Refer to [SHARD_ROW_ID_BITS](#) for more details.

To avoid the hotspot problem in this situation, you can use `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` when creating a table. For more details about `PRE_SPLIT_REGIONS`, refer to [Pre-split Regions](#).

`SHARD_ROW_ID_BITS` is used to randomly scatter the row ID generated in the `_tidb_rowid` column. `PRE_SPLIT_REGIONS` is used to pre-split the Region after a table is created.

Note:

The value of `PRE_SPLIT_REGIONS` must be smaller than or equal to that of `SHARD_ROW_ID_BITS`.

Example:

```
create table t (a int, b int) SHARD_ROW_ID_BITS = 4 PRE_SPLIT_REGIONS=3;
```

- `SHARD_ROW_ID_BITS = 4` means that the values of `tidb_rowid` will be randomly distributed into 16 ($16=2^4$) ranges.
- `PRE_SPLIT_REGIONS=3` means that the table will be pre-split into 8 (2^3) Regions after it is created.

When data starts to be written into table `t`, the data is written into the pre-split 8 Regions, which avoids the hotspot problem that might be caused if only one Region exists after table creation.

Note:

The `tidb_scatter_region` global variable affects the behavior of `PRE_SPLIT_REGIONS`.

This variable controls whether to wait for Regions to be pre-split and scattered before returning results after the table creation. If there are intensive writes after creating the table, you need to set the value of this variable to 1, then TiDB will not return the results to the client until all the Regions are split and scattered. Otherwise, TiDB writes data before the scattering is completed, which will have a significant impact on write performance.

Problem two:

If a table's primary key is an integer type, and if the table uses `AUTO_INCREMENT` to ensure the uniqueness of the primary key (not necessarily continuous or incremental), you cannot use `SHARD_ROW_ID_BITS` to scatter the hotspot on this table because TiDB directly uses the row values of the primary key as `_tidb_rowid`.

To address the problem in this scenario, you can replace `AUTO_INCREMENT` with `AUTO_RANDOM` (a column attribute) when inserting data. Then TiDB automatically assigns values to the integer primary key column, which eliminates the continuity of the row ID and scatters the hotspot.

10.5.4.8 Parameter configuration

In v2.1, the `latch mechanism` is introduced in TiDB to identify transaction conflicts in advance in scenarios where write conflicts frequently appear. The aim is to reduce the retry of transaction commits in TiDB and TiKV caused by write conflicts. Generally, batch tasks use the data already stored in TiDB, so the write conflicts of transaction do not exist. In this situation, you can disable the latch in TiDB to reduce memory allocation for small objects:

```
[txn-local-latches]
enabled = false
```

10.5.5 Best Practices for Monitoring TiDB Using Grafana

When you [deploy a TiDB cluster using TiUP](#) and have added Grafana and Prometheus in the topology configuration, a set of [Grafana + Prometheus monitoring platform](#) is deployed simultaneously to collect and display metrics for various components and machines in the TiDB cluster. This document describes best practices for monitoring TiDB using Grafana. It aims to help you use metrics to analyze the status of the TiDB cluster and diagnose problems.

10.5.5.1 Monitoring architecture

[Prometheus](#) is a time series database with a multi-dimensional data model and a flexible query language. [Grafana](#) is an open source monitoring system for analyzing and visualizing metrics.

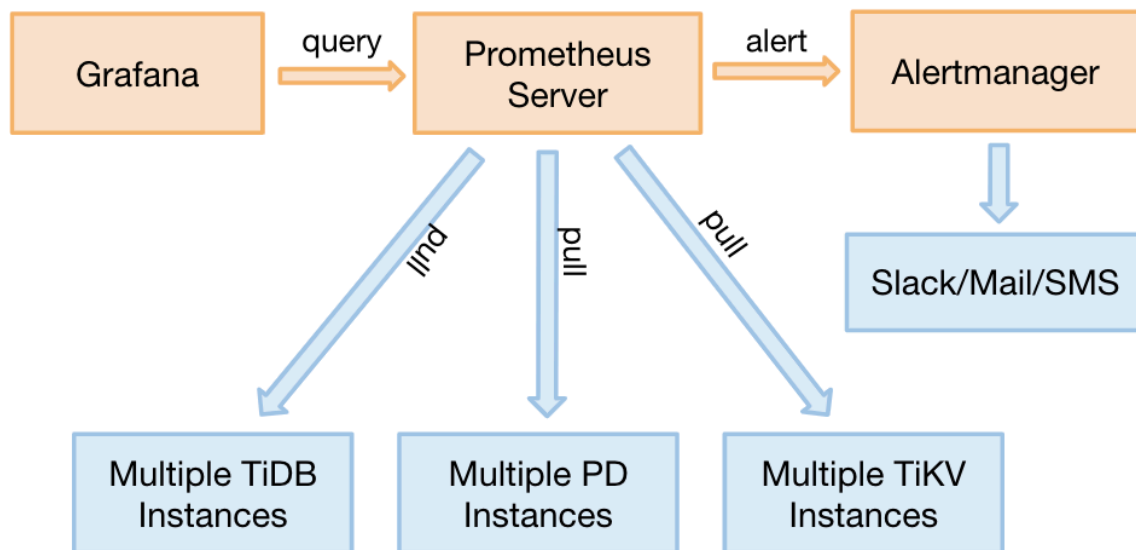

Figure 98: The monitoring architecture in the TiDB cluster

For TiDB 2.1.3 or later versions, TiDB monitoring supports the pull method. It is a good adjustment with the following benefits:

- There is no need to restart the entire TiDB cluster if you need to migrate Prometheus. Before adjustment, migrating Prometheus requires restarting the entire cluster because the target address needs to be updated.

- You can deploy 2 separate sets of Grafana + Prometheus monitoring platforms (not highly available) to prevent a single point of monitoring.
- The Pushgateway which might become a single point of failure is removed.

10.5.5.2 Source and display of monitoring data

The three core components of TiDB (TiDB server, TiKV server and PD server) obtain metrics through the HTTP interface. These metrics are collected from the program code, and the ports are as follows:

Component	Port
TiDB server	10080
TiKV server	20181
PD server	2379

Execute the following command to check the QPS of a SQL statement through the HTTP interface. Take the TiDB server as an example:

```
curl http://__tidb_ip__:10080/metrics |grep tidb_executor_statement_total
```

```
### Check the real-time QPS of different types of SQL statements. The
  ↳ numbers below are the cumulative values of counter type (scientific
  ↳ notation).
tidb_executor_statement_total{type="Delete"} 520197
tidb_executor_statement_total{type="Explain"} 1
tidb_executor_statement_total{type="Insert"} 7.20799402e+08
tidb_executor_statement_total{type="Select"} 2.64983586e+08
tidb_executor_statement_total{type="Set"} 2.399075e+06
tidb_executor_statement_total{type="Show"} 500531
tidb_executor_statement_total{type="Use"} 466016
```

The data above is stored in Prometheus and displayed on Grafana. Right-click the panel and then click the **Edit** button (or directly press the E key) shown in the following figure:

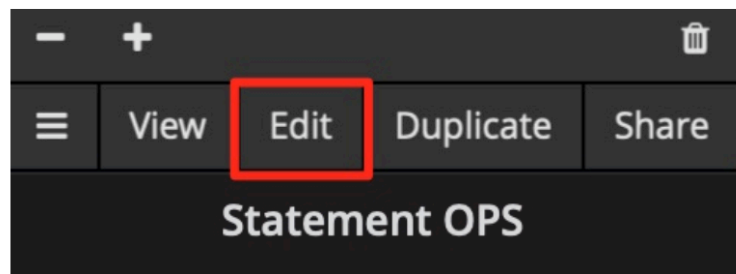

Figure 99: The Edit entry for the Metrics tab

After clicking the **Edit** button, you can see the query expression with the `tidb_executor_statement_total` metric name on the Metrics tab. The meanings of some items on the panel are as follows:

- **rate[1m]**: The growth rate in one minute. It can only be used for the data of counter type.
- **sum**: The sum of values.
- **by type**: The summed data is grouped by type in the original metric value.
- **Legend format**: The format of the metric name.
- **Resolution**: The step width defaults to 15 seconds. Resolution means whether to generate one data point for multiple pixels.

The query expression on the **Metrics** tab is as follows:

Figure 100: The query expression on the Metrics tab

Prometheus supports many query expressions and functions. For more details, refer to [Prometheus official website](#).

10.5.5.3 Grafana tips

This section introduces seven tips for efficiently using Grafana to monitor and analyze the metrics of TiDB.

10.5.5.3.1 Tip 1: Check all dimensions and edit the query expression

In the example shown in the [source and display of monitoring data](#) section, the data is grouped by type. If you want to know whether you can group by other dimensions and quickly check which dimensions are available, you can use the following method: **Only keep**

the metric name on the query expression, no calculation, and leave the Legend \leftrightarrow format field blank. In this way, the original metrics are displayed. For example, the following figure shows that there are three dimensions (instance, job and type):

Figure 101: Edit query expression and check all dimensions

Then you can modify the query expression by adding the instance dimension after type, and adding `{{instance}}` to the Legend format field. In this way, you can check the QPS of different types of SQL statements that are executed on each TiDB server:

Figure 102: Add an instance dimension to the query expression

10.5.5.3.2 Tip 2: Switch the scale of the Y-axis

Take Query Duration as an example, the Y-axis defaults to be on a binary logarithmic scale ($\log_2 n$), which narrows the gap in display. To amplify changes, you can switch it to a linear scale. Comparing the following two figures, you can easily notice the difference in display, and locate the time when an SQL statement runs slowly.

Of course, a linear scale is not suitable for all situations. For example, if you observe the performance trend for the duration of a month, there might be noises with a linear scale, making it hard to observe.

The Y-axis uses a binary logarithmic scale by default:

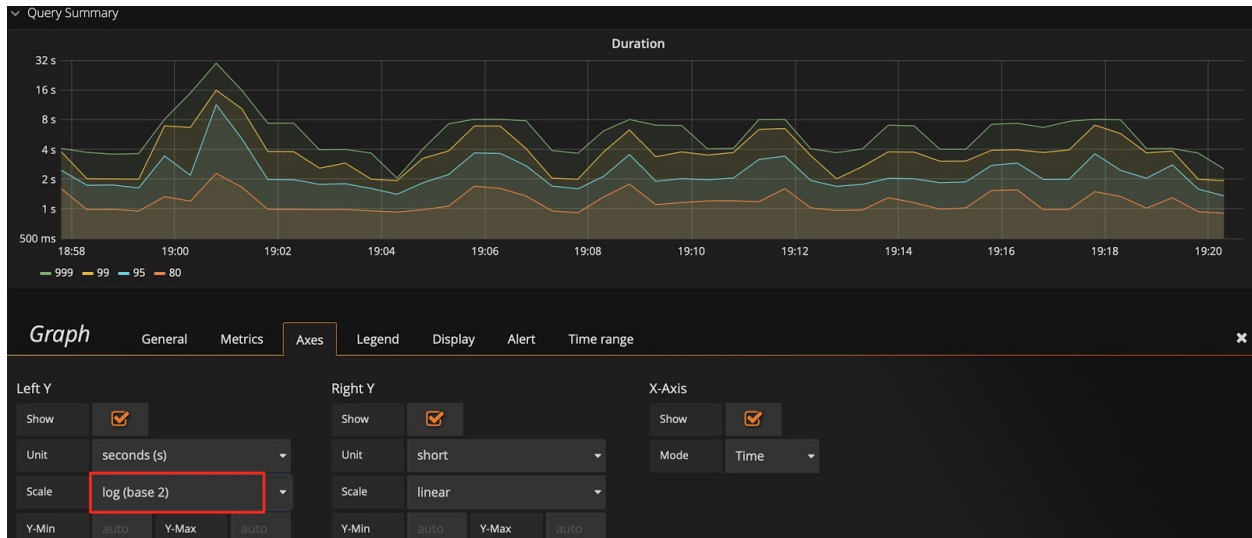

Figure 103: The Y-axis uses a binary logarithmic scale

Switch the Y-axis to a linear scale:

Figure 104: Switch to a linear scale

Tip:

Combining tip 2 with tip 1, you can find a `sql_type` dimension to help you immediately analyze whether the `SELECT` statement or the `UPDATE` statement is slow; you can even locate the instance with slow SQL statements.

10.5.5.3.3 Tip 3: Modify the baseline of the Y-axis to amplify changes

You might still cannot see the trend after switching to the linear scale. For example, in the following figure, you want to observe the real-time change of `Store size` after scaling the cluster, but due to the large baseline, small changes are not visible. In this situation, you can modify the baseline of the Y-axis from 0 to `auto` to zoom in the upper part. Check the two figures below, you can see data migration begins.

The baseline defaults to 0:

Figure 105: Baseline defaults to 0

Change the baseline to auto:

Figure 106: Change the baseline to auto

10.5.5.3.4 Tip 4: Use Shared crosshair or Tooltip

In the **Settings** panel, there is a **Graph Tooltip** panel option which defaults to **Default**.

Figure 107: Graphic presentation tools

You can use **Shared crosshair** and **Shared Tooltip** respectively to test the effect as shown in the following figures. Then, the scales are displayed in linkage, which is convenient to confirm the correlation of two metrics when diagnosing problems.

Set the graphic presentation tool to **Shared crosshair**:

Figure 108: Set the graphical presentation tool to Shared crosshair

Set the graphical presentation tool to **Shared Tooltip**:

Figure 109: Set the graphic presentation tool to Shared Tooltip

10.5.5.3.5 Tip 5: Enter IP address:port number to check the metrics in history

PD's dashboard only shows the metrics of the current leader. If you want to check the status of a PD leader in history and it no longer exists in the drop-down list of the instance field, you can manually enter IP address:2379 to check the data of the leader.

Figure 110: Check the metrics in history

10.5.5.3.6 Tip 6: Use the Avg function

Generally, only **Max** and **Current** functions are available in the legend by default. When the metrics fluctuate greatly, you can add other summary functions such as the **Avg** function to the legend to check the overall trend for the duration of time.

Add summary functions such as the **Avg** function:

Figure 111: Add summary functions such as Avg

Then check the overall trend:

Figure 112: Add Avg function to check the overall trend

10.5.5.3.7 Tip 7: Use the API of Prometheus to obtain the result of query expressions

Grafana obtains data through the API of Prometheus and you can use this API to obtain information as well. In addition, it also has the following usages:

- Automatically obtains information such as the cluster size and status.
- Makes minor changes to the expression to provide information for the report, such as counting the total amount of QPS per day, the peak value of QPS per day, and the response time per day.
- Performs regular health inspection on the important metrics.

The API of Prometheus is shown as follows:

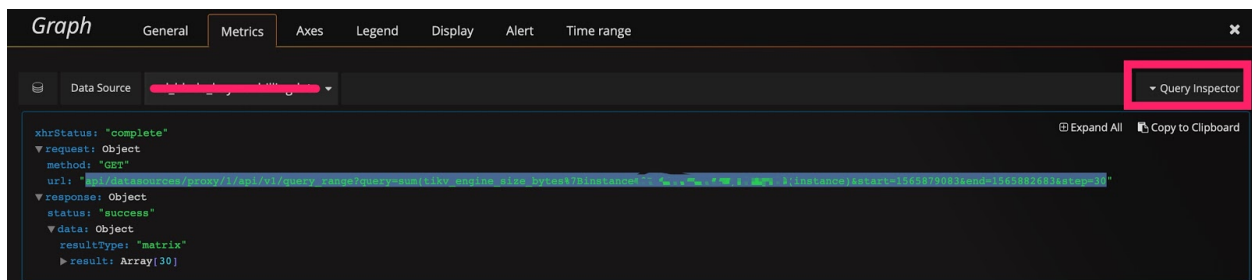

Figure 113: The API of Prometheus

```

curl -u user:pass 'http://__grafana_ip__:3000/api/datasources/proxy/1/api/v1
  ↪ /query_range?query=sum(tikv_engine_size_bytes%7
  ↪ Binstancexxxxxxxxxx20181%22%7D)%20by%20(instance)&start=1565879269&end
  ↪ =1565882869&step=30' |python -m json.tool

```

```

{
  "data": {

```

```
"result": [
  {
    "metric": {
      "instance": "xxxxxxxxxx:20181"
    },
    "values": [
      [
        1565879269,

      [
        1565879299,
        "1006057877794"
      ],
      [
        1565879329,
        "1006021550039"
      ],
      [
        1565879359,
        "1006021550039"
      ],
      [
        1565882869,
        "1006132630123"
      ]
    ]
  }
],
"resultType": "matrix"
},
"status": "success"
}
```

10.5.5.4 Summary

The Grafana + Prometheus monitoring platform is a very powerful tool. Making good use of it can improve efficiency, saving you a lot of time on analyzing the status of the TiDB cluster. More importantly, it can help you diagnose problems. This tool is very useful in the operation and maintenance of TiDB clusters, especially when there is a large amount of data.

10.5.6 PD Scheduling Best Practices

This document details the principles and strategies of PD scheduling through common scenarios to facilitate your application. This document assumes that you have a basic understanding of TiDB, TiKV and PD with the following core concepts:

- leader/follower/learner
- operator
- operator step
- pending/down
- region/peer/Raft group
- region split
- scheduler
- store

Note:

This document initially targets TiDB 3.0. Although some features are not supported in earlier versions (2.x), the underlying mechanisms are similar and this document can still be used as a reference.

10.5.6.1 PD scheduling policies

This section introduces the principles and processes involved in the scheduling system.

10.5.6.1.1 Scheduling process

The scheduling process generally has three steps:

1. Collect information

Each TiKV node periodically reports two types of heartbeats to PD:

- **StoreHeartbeat:** Contains the overall information of stores, including disk capacity, available storage, and read/write traffic
- **RegionHeartbeat:** Contains the overall information of regions, including the range of each region, peer distribution, peer status, data volume, and read/write traffic

PD collects and restores this information for scheduling decisions.

2. Generate operators

Different schedulers generate the operators based on their own logic and requirements, with the following considerations:

- Do not add peers to a store in abnormal states (disconnected, down, busy, low space)
- Do not balance regions in abnormal states
- Do not transfer a leader to a pending peer
- Do not remove a leader directly
- Do not break the physical isolation of various region peers
- Do not violate constraints such as label property

3. Execute operators

To execute the operators, the general procedure is:

1. The generated operator first joins a queue managed by `OperatorController`.
2. `OperatorController` takes the operator out of the queue and executes it with a certain amount of concurrency based on the configuration. This step is to assign each operator step to the corresponding region leader.
3. The operator is marked as “finish” or “timeout” and removed from the queue.

10.5.6.1.2 Load balancing

Region primarily relies on `balance-leader` and `balance-region` schedulers to achieve load balance. Both schedulers target distributing regions evenly across all stores in the cluster but with separate focuses: `balance-leader` deals with region leader to balance incoming client requests, whereas `balance-region` concerns itself with each region peer to redistribute the pressure of storage and avoid exceptions like out of storage space.

`balance-leader` and `balance-region` share a similar scheduling process:

1. Rate stores according to their resource availability.
2. `balance-leader` or `balance-region` constantly transfer leaders or peers from stores with high scores to those with low scores.

However, their rating methods are different. `balance-leader` uses the sum of all region sizes corresponding to leaders in a store, whereas the way of `balance-region` is relatively complicated. Depending on the specific storage capacity of each node, the rating method of `balance-region` might:

- based on the amount of data when there is sufficient storage (to balance data distribution among nodes).
- based on the available storage when there is insufficient storage (to balance the storage availability on different nodes).
- based on the weighted sum of the two factors above when neither of the situations applies.

Because different nodes might differ in performance, you can also set the weight of load balancing for different stores. `leader-weight` and `region-weight` are used to control the leader weight and region weight respectively (“1” by default for both). For example, when the `leader-weight` of a store is set to “2”, the number of leaders on the node is about twice as many as that of other nodes after the scheduling stabilizes. Similarly, when the `leader-weight` of a store is set to “0.5”, the number of leaders on the node is about half as many as that of other nodes.

10.5.6.1.3 Hot regions scheduling

For hot regions scheduling, use `hot-region-scheduler`. Since TiDB v3.0, the process is performed as follows:

1. Count hot regions by determining read/write traffic that exceeds a certain threshold for a certain period based on the information reported by stores.
2. Redistribute these regions in a similar way to load balancing.

For hot write regions, `hot-region-scheduler` attempts to redistribute both region peers and leaders; for hot read regions, `hot-region-scheduler` only redistributes region leaders.

10.5.6.1.4 Cluster topology awareness

Cluster topology awareness enables PD to distribute replicas of a region as much as possible. This is how TiKV ensures high availability and disaster recovery capability. PD continuously scans all regions in the background. When PD finds that the distribution of regions is not optimal, it generates an operator to replace peers and redistribute regions.

The component to check region distribution is `replicaChecker`, which is similar to a scheduler except that it cannot be disabled. `replicaChecker` schedules based on the configuration of `location-labels`. For example, `[zone,rack,host]` defines a three-tier topology for a cluster. PD attempts to schedule region peers to different zones first, or to different racks when zones are insufficient (for example, 2 zones for 3 replicas), or to different hosts when racks are insufficient, and so on.

10.5.6.1.5 Scale-down and failure recovery

Scale-down refers to the process when you take a store offline and mark it as “offline” using a command. PD replicates the regions on the offline node to other nodes by scheduling. Failure recovery applies when stores failed and cannot be recovered. In this case, regions with peers distributed on the corresponding store might lose replicas, which requires PD to replenish on other nodes.

The processes of scale-down and failure recovery are basically the same. `replicaChecker` \leftrightarrow finds a region peer in abnormal states, and then generates an operator to replace the abnormal peer with a new one on a healthy store.

10.5.6.1.6 Region merge

Region merge refers to the process of merging adjacent small regions. It serves to avoid unnecessary resource consumption by a large number of small or even empty regions after data deletion. Region merge is performed by `mergeChecker`, which processes in a similar way to `replicaChecker`: PD continuously scans all regions in the background, and generates an operator when contiguous small regions are found.

Specifically, when a newly split Region exists for more than the value of `split-merge-interval` (1h by default), if the following conditions occur at the same time, this Region triggers the Region merge scheduling:

- The size of this Region is smaller than the value of the `max-merge-region-size` (20 MiB by default)
- The number of keys in this Region is smaller than the value of `max-merge-region-keys` (200,000 by default).

10.5.6.2 Query scheduling status

You can check the status of scheduling system through metrics, `pd-ctl` and logs. This section briefly introduces the methods of metrics and `pd-ctl`. Refer to [PD Monitoring Metrics](#) and [PD Control](#) for details.

10.5.6.2.1 Operator status

The **Grafana PD/Operator** page shows the metrics about operators, among which:

- Schedule operator create: Operator creating information
- Operator finish duration: Execution time consumed by each operator
- Operator step duration: Execution time consumed by the operator step

You can query operators using `pd-ctl` with the following commands:

- `operator show`: Queries all operators generated in the current scheduling task
- `operator show [admin | leader | region]`: Queries operators by type

10.5.6.2.2 Balance status

The **Grafana PD/Statistics - Balance** page shows the metrics about load balancing, among which:

- Store leader/region score: Score of each store
- Store leader/region count: The number of leaders/regions in each store
- Store available: Available storage on each store

You can use store commands of `pd-ctl` to query balance status of each store.

10.5.6.2.3 Hot Region status

The **Grafana PD/Statistics - hotspot** page shows the metrics about hot regions, among which:

- Hot write region's leader/peer distribution: the leader/peer distribution in hot write regions
- Hot read region's leader distribution: the leader distribution in hot read regions

You can also query the status of hot regions using `pd-ctl` with the following commands:

- `hot read`: Queries hot read regions
- `hot write`: Queries hot write regions
- `hot store`: Queries the distribution of hot regions by store
- `region topread [limit]`: Queries the region with top read traffic
- `region topwrite [limit]`: Queries the region with top write traffic

10.5.6.2.4 Region health

The **Grafana PD/Cluster/Region health** panel shows the metrics about regions in abnormal states.

You can query the list of regions in abnormal states using `pd-ctl` with region check commands:

- `region check miss-peer`: Queries regions without enough peers
- `region check extra-peer`: Queries regions with extra peers
- `region check down-peer`: Queries regions with down peers
- `region check pending-peer`: Queries regions with pending peers

10.5.6.3 Control scheduling strategy

You can use `pd-ctl` to adjust the scheduling strategy from the following three aspects. Refer to [PD Control](#) for more details.

10.5.6.3.1 Add/delete scheduler manually

PD supports dynamically adding and removing schedulers directly through `pd-ctl`. For example:

- `scheduler show`: Shows currently running schedulers in the system
- `scheduler remove balance-leader-scheduler`: Removes (disable) balance-leader-scheduler
- `scheduler add evict-leader-scheduler 1`: Adds a scheduler to remove all leaders in Store 1

10.5.6.3.2 Add/delete Operators manually

PD also supports adding or removing operators directly through `pd-ctl`. For example:

- `operator add add-peer 2 5`: Adds peers to Region 2 in Store 5
- `operator add transfer-leader 2 5`: Migrates the leader of Region 2 to Store 5
- `operator add split-region 2`: Splits Region 2 into two regions evenly in size
- `operator remove 2`: Removes currently pending operator in Region 2

10.5.6.3.3 Adjust scheduling parameter

You can check the scheduling configuration using the `config show` command in `pd-ctl`, and adjust the values using `config set {key} {value}`. Common adjustments include:

- `leader-schedule-limit`: Controls the concurrency of transferring leader scheduling
- `region-schedule-limit`: Controls the concurrency of adding/deleting peer scheduling
- `enable-replace-offline-replica`: Determines whether to enable the scheduling to take nodes offline
- `enable-location-replacement`: Determines whether to enable the scheduling that handles the isolation level of regions
- `max-snapshot-count`: Controls the maximum concurrency of sending/receiving snapshots for each store

10.5.6.4 PD scheduling in common scenarios

This section illustrates the best practices of PD scheduling strategies through several typical scenarios.

10.5.6.4.1 Leaders/regions are not evenly distributed

The rating mechanism of PD determines that leader count and region count of different stores cannot fully reflect the load balancing status. Therefore, it is necessary to confirm whether there is load imbalancing from the actual load of TiKV or storage usage.

Once you have confirmed that leaders/region are not evenly distributed, you need to check the rating of different stores.

If the scores of different stores are close, it means PD mistakenly believes that leaders/regions are evenly distributed. Possible reasons are:

- There are hot regions that cause load imbalancing. In this case, you need to analyze further based on [hot regions scheduling](#).
- There are a large number of empty regions or small regions, which leads to a great difference in the number of leaders in different stores and high pressure on Raft store. This is the time for a [region merge](#) scheduling.

- Hardware and software environment varies among stores. You can adjust the values of `leader-weight` and `region-weight` accordingly to control the distribution of leader/region.
- Other unknown reasons. Still you can adjust the values of `leader-weight` and `region-weight` to control the distribution of leader/region.

If there is a big difference in the rating of different stores, you need to examine the operator-related metrics, with special focus on the generation and execution of operators. There are two main situations:

- When operators are generated normally but the scheduling process is slow, it is possible that:
 - The scheduling speed is limited by default for load balancing purpose. You can adjust `leader-schedule-limit` or `region-schedule-limit` to larger values without significantly impacting regular services. In addition, you can also properly ease the restrictions specified by `max-pending-peer-count` and `max-snapshot-count`.
 - Other scheduling tasks are running concurrently, which slows down the balancing. In this case, if the balancing takes precedence over other scheduling tasks, you can stop other tasks or limit their speeds. For example, if you take some nodes offline when balancing is in progress, both operations consume the quota of `region-schedule-limit`. In this case, you can limit the speed of scheduler to remove nodes, or simply set `enable-replace-offline-replica = false` to temporarily disable it.
 - The scheduling process is too slow. You can check the **Operator step duration** metric to confirm the cause. Generally, steps that do not involve sending and receiving snapshots (such as `TransferLeader`, `RemovePeer`, `PromoteLearner`) should be completed in milliseconds, while steps that involve snapshots (such as `AddLearner` and `AddPeer`) are expected to be completed in tens of seconds. If the duration is obviously too long, it could be caused by high pressure on TiKV or bottleneck in network, etc., which needs specific analysis.
- PD fails to generate the corresponding balancing scheduler. Possible reasons include:
 - The scheduler is not activated. For example, the corresponding scheduler is deleted, or its limit is set to “0”.
 - Other constraints. For example, `evict-leader-scheduler` in the system prevents leaders from being migrating to the corresponding store. Or label property is set, which makes some stores reject leaders.
 - Restrictions from the cluster topology. For example, in a cluster of 3 replicas across 3 data centers, 3 replicas of each region are distributed in different data centers due to replica isolation. If the number of stores is different among these data centers, the scheduling can only reach a balanced state within each data center, but not balanced globally.

10.5.6.4.2 Taking nodes offline is slow

This scenario requires examining the generation and execution of operators through related metrics.

If operators are successfully generated but the scheduling process is slow, possible reasons are:

- The scheduling speed is limited by default. You can adjust `leader-schedule-limit` or `replica-schedule-limit` to larger values. Similarly, you can consider loosening the limits on `max-pending-peer-count` and `max-snapshot-count`.
- Other scheduling tasks are running concurrently and racing for resources in the system. You can refer to the solution in [Leaders/regions are not evenly distributed](#).
- When you take a single node offline, a number of region leaders to be processed (around 1/3 under the configuration of 3 replicas) are distributed on the node to remove. Therefore, the speed is limited by the speed at which snapshots are generated by this single node. You can speed it up by manually adding an `evict-leader-scheduler` to migrate leaders.

If the corresponding operator fails to generate, possible reasons are:

- The operator is stopped, or `replica-schedule-limit` is set to “0”.
- There is no proper node for region migration. For example, if the available capacity size of the replacing node (of the same label) is less than 20%, PD will stop scheduling to avoid running out of storage on that node. In such case, you need to add more nodes or delete some data to free the space.

10.5.6.4.3 Bringing nodes online is slow

Currently, bringing nodes online is scheduled through the balance region mechanism. You can refer to [Leaders/regions are not evenly distributed](#) for troubleshooting.

10.5.6.4.4 Hot regions are not evenly distributed

Hot regions scheduling issues generally fall into the following categories:

- Hot regions can be observed via PD metrics, but the scheduling speed cannot keep up to redistribute hot regions in time.

Solution: adjust `hot-region-schedule-limit` to a larger value, and reduce the limit quota of other schedulers to speed up hot regions scheduling. Or you can adjust `hot-region-cache-hits-threshold` to a smaller value to make PD more sensitive to traffic changes.

- Hotspot formed on a single region. For example, a small table is intensively scanned by a massive amount of requests. This can also be detected from PD metrics. Because you cannot actually distribute a single hotspot, you need to manually add a `split-region` operator to split such a region.

- The load of some nodes is significantly higher than that of other nodes from TiKV-related metrics, which becomes the bottleneck of the whole system. Currently, PD counts hotspots through traffic analysis only, so it is possible that PD fails to identify hotspots in certain scenarios. For example, when there are intensive point lookup requests for some regions, it might not be obvious to detect in traffic, but still the high QPS might lead to bottlenecks in key modules.

Solutions: Firstly, locate the table where hot regions are formed based on the specific business. Then add a `scatter-range-scheduler` scheduler to make all regions of this table evenly distributed. TiDB also provides an interface in its HTTP API to simplify this operation. Refer to [TiDB HTTP API](#) for more details.

10.5.6.4.5 Region merge is slow

Similar to slow scheduling, the speed of region merge is most likely limited by the configurations of `merge-schedule-limit` and `region-schedule-limit`, or the region merge scheduler is competing with other schedulers. Specifically, the solutions are:

- If it is known from metrics that there are a large number of empty regions in the system, you can adjust `max-merge-region-size` and `max-merge-region-keys` to smaller values to speed up the merge. This is because the merge process involves replica migration, so the smaller the region to be merged, the faster the merge is. If the merge operators are already generated rapidly, to further speed up the process, you can set `patrol-region-interval` to 10ms (the default value of this configuration item is 10ms in v5.3.0 and later versions of TiDB). This makes region scanning faster at the cost of more CPU consumption.
- A lot of tables have been created and then emptied (including truncated tables). These empty Regions cannot be merged if the split table attribute is enabled. You can disable this attribute by adjusting the following parameters:
 - TiKV: Set `split-region-on-table` to `false`. You cannot modify the parameter dynamically.
 - PD: Use PD Control to set the parameters required by your cluster situation.
 - * Suppose that your cluster has no TiDB instance, and the value of `key-type` is set to `raw` or `txn`. In this case, PD can merge Regions across tables, regardless of the value of `enable-cross-table-merge` setting. You can modify the `key-type` parameter dynamically.

```
config set key-type txn
```

- * Suppose that your cluster has a TiDB instance, and the value of `key-type` is set to `table`. In this case, PD can merge Regions across tables only if the value of `enable-cross-table-merge` is set to `true`. You can modify the `key-type` parameter dynamically.

```
config set enable-cross-table-merge true
```

If the modification does not take effect, refer to [FAQ - Why the modified toml configuration for TiKV/PD does not take effect?](#).

Note:

After enabling Placement Rules, properly switch the value of `key-type` to avoid the failure of decoding.

For v3.0.4 and v2.1.16 or earlier, the `approximate_keys` of regions are inaccurate in specific circumstances (most of which occur after dropping tables), which makes the number of keys break the constraints of `max-merge-region-keys`. To avoid this problem, you can adjust `max-merge-region-keys` to a larger value.

10.5.6.4.6 Troubleshoot TiKV node

If a TiKV node fails, PD defaults to setting the corresponding node to the **down** state after 30 minutes (customizable by configuration item `max-store-down-time`), and rebalancing replicas for regions involved.

Practically, if a node failure is considered unrecoverable, you can immediately take it offline. This makes PD replenish replicas soon in another node and reduces the risk of data loss. In contrast, if a node is considered recoverable, but the recovery cannot be done in 30 minutes, you can temporarily adjust `max-store-down-time` to a larger value to avoid unnecessary replenishment of the replicas and resources waste after the timeout.

In TiDB v5.2.0, TiKV introduces the mechanism of slow TiKV node detection. By sampling the requests in TiKV, this mechanism works out a score ranging from 1 to 100. A TiKV node with a score higher than or equal to 80 is marked as slow. You can add `evict-slow-store-scheduler` to detect and schedule slow nodes. If only one TiKV is detected as slow, and the slow score reaches the upper limit (100 by default), the leader in this node will be evicted (similar to the effect of `evict-leader-scheduler`).

10.5.7 Best Practices for TiKV Performance Tuning with Massive Regions

In TiDB, data is split into Regions, each storing data for a specific key range. These Regions are distributed among multiple TiKV instances. As data is written into a cluster, millions of or even tens of millions of Regions are created. Too many Regions on a single TiKV instance can bring a heavy burden to the cluster and affect its performance.

This document introduces the workflow of Raftstore (a core module of TiKV), explains why a massive amount of Regions affect the performance, and offers methods for tuning TiKV performance.

10.5.7.1 Raftstore workflow

A TiKV instance has multiple Regions on it. The Raftstore module drives the Raft state machine to process Region messages. These messages include processing read or write requests on Regions, persisting or replicating Raft logs, and processing Raft heartbeats. However, an increasing number of Regions can affect performance of the whole cluster. To understand this, it is necessary to learn the workflow of Raftstore shown as follows:

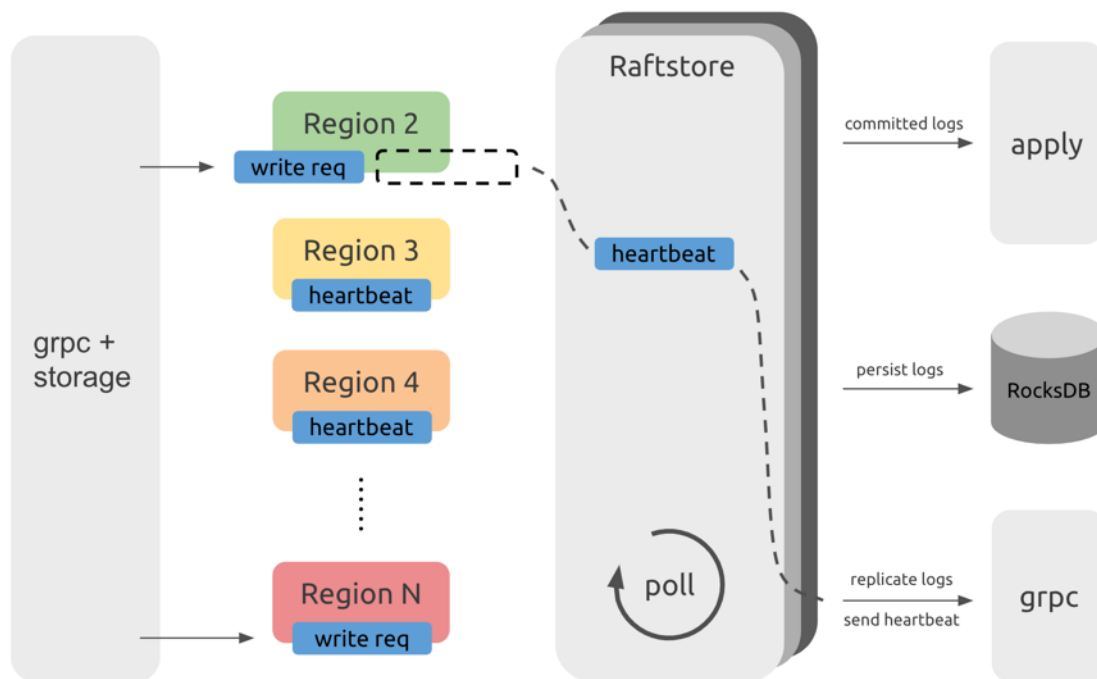

Figure 114: Raftstore Workflow

Note:

This diagram only illustrates the workflow of Raftstore and does not represent the actual code structure.

From the above diagram, you can see that requests from the TiDB servers, after passing through the gRPC and storage modules, become read and write messages of KV (key-value), and are sent to the corresponding Regions. These messages are not immediately processed but are temporarily stored. Raftstore polls to check whether each Region has messages to process. If a Region has messages to process, Raftstore drives the Raft state machine of this Region to process these messages and perform subsequent operations according to the state changes of these messages. For example, when write requests come in, the Raft state machine stores logs into disk and sends logs to other Region replicas; when the heartbeat interval is reached, the Raft state machine sends heartbeat information to other Region replicas.

10.5.7.2 Performance problem

From the Raftstore workflow diagram, messages in each Region are processed one by one. When a large number of Regions exist, it takes Raftstore some time to process the heartbeats of these Regions, which can cause some delay. As a result, some read and write requests are not processed in time. If read and write pressure is high, the CPU usage of the Raftstore thread might easily become the bottleneck, which further increases the delay and affects the performance.

Generally, if the CPU usage of the loaded Raftstore reaches 85% or higher, Raftstore goes into a busy state and becomes the bottleneck. At the same time, propose wait duration can be as high as hundreds of milliseconds.

Note:

- For the CPU usage of Raftstore as mentioned above, Raftstore is single-threaded. If Raftstore is multi-threaded, you can increase the CPU usage threshold (85%) proportionally.
- Because I/O operations exist in the Raftstore thread, CPU usage cannot reach 100%.

10.5.7.2.1 Performance monitoring

You can check the following monitoring metrics in Grafana's **TiKV Dashboard**:

- Raft store CPU in the **Thread-CPU** panel

Reference value: lower than `raftstore.store-pool-size * 85%`.

Figure 115: Check Raftstore CPU

- Propose wait duration in the **Raft Propose** panel

Propose wait duration is the delay between the time a request is sent to Raftstore and the time Raftstore actually starts processing the request. Long delay means that Raftstore is busy, or that processing the append log is time-consuming, making Raftstore unable to process the request in time.

Reference value: lower than 50~100 ms according to the cluster size

Figure 116: Check Propose wait duration

- **Commit log duration** in the **Raft IO** panel

Commit log duration is the time Raftstore takes to commit Raft logs to the majority of members in the respective Region. The possible reasons for a high value of this metric with significant fluctuations include the following:

- The workload on Raftstore is heavy.
- The append log operation is slow.
- Raft logs cannot be committed timely due to network congestion.

Reference value: lower than 200-500 ms.

![Check Commit log duration](./media/best-practices/commit-log-duration.png)

10.5.7.3 Performance tuning methods

After finding out the cause of a performance problem, try to solve it from the following two aspects:

- Reduce the number of Regions on a single TiKV instance
- Reduce the number of messages for a single Region

10.5.7.3.1 Method 1: Increase Raftstore concurrency

Raftstore has been upgraded to a multi-threaded module since TiDB v3.0, which greatly reduces the possibility that a Raftstore thread becomes the bottleneck.

By default, `raftstore.store-pool-size` is configured to 2 in TiKV. If a bottleneck occurs in Raftstore, you can properly increase the value of this configuration item according to the actual situation. But to avoid introducing unnecessary thread switching overhead, it is recommended that you do not set this value too high.

10.5.7.3.2 Method 2: Enable Hibernate Region

In the actual situation, read and write requests are not evenly distributed on every Region. Instead, they are concentrated on a few Regions. Then you can minimize the number of messages between the Raft leader and the followers for the temporarily idle Regions, which is the feature of Hibernate Region. In this feature, Raftstore doesn't send tick messages to the Raft state machines of idle Regions if not necessary. Then these Raft state machines will not be triggered to generate heartbeat messages, which can greatly reduce the workload of Raftstore.

Hibernate Region is enabled by default in [TiKV master](#). You can configure this feature according to your needs. For details, refer to [Configure Hibernate Region](#).

10.5.7.3.3 Method 3: Enable Region Merge

Note:

Region Merge is enabled by default since TiDB v3.0.

You can also reduce the number of Regions by enabling [Region Merge](#). Contrary to [Region Split](#), [Region Merge](#) is the process of merging adjacent small Regions through scheduling. After dropping data or executing the `Drop Table` or `Truncate Table` statement, you can merge small Regions or even empty Regions to reduce resource consumption.

Enable [Region Merge](#) by configuring the following parameters:

```
config set max-merge-region-size 20
config set max-merge-region-keys 200000
config set merge-schedule-limit 8
```

Refer to [Region Merge](#) and the following three configuration parameters in the [PD configuration file](#) for more details:

- [max-merge-region-size](#)
- [max-merge-region-keys](#)
- [merge-schedule-limit](#)

The default configuration of the [Region Merge](#) parameters is rather conservative. You can speed up the [Region Merge](#) process by referring to the method provided in [PD Scheduling Best Practices](#).

10.5.7.3.4 Method 4: Increase the number of TiKV instances

If I/O resources and CPU resources are sufficient, you can deploy multiple TiKV instances on a single machine to reduce the number of Regions on a single TiKV instance; or you can increase the number of machines in the TiKV cluster.

10.5.7.3.5 Method 5: Adjust `raft-base-tick-interval`

In addition to reducing the number of Regions, you can also reduce pressure on Raftstore by reducing the number of messages for each Region within a unit of time. For example, you can properly increase the value of the `raft-base-tick-interval` configuration item:

```
[raftstore]
raft-base-tick-interval = "2s"
```

In the above configuration, `raft-base-tick-interval` is the time interval at which Raftstore drives the Raft state machine of each Region, which means at this time interval, Raftstore sends a tick message to the Raft state machine. Increasing this interval can effectively reduce the number of messages from Raftstore.

Note that this interval between tick messages also determines the intervals between election timeout and heartbeat. See the following example:

```
raft-election-timeout = raft-base-tick-interval * raft-election-timeout-
    ↪ ticks
raft-heartbeat-interval = raft-base-tick-interval * raft-heartbeat-ticks
```

If Region followers have not received the heartbeat from the leader within the `raft ↪ -election-timeout` interval, these followers determine that the leader has failed and start a new election. `raft-heartbeat-interval` is the interval at which a leader sends a heartbeat to followers. Therefore, increasing the value of `raft-base-tick-interval` can reduce the number of network messages sent from Raft state machines but also makes it longer for Raft state machines to detect the leader failure.

10.5.7.3.6 Method 6: Increase the maximum number of connections for Raft communication

By default, the maximum number of connections used for Raft communication between TiKV nodes is 1. Increasing this number can help alleviate blockage issues caused by heavy communication workloads of a large number of Regions. For detailed instructions, see `grpc ↪ -raft-conn-num`.

Note:

To reduce unnecessary thread switching overhead and mitigate potential negative impacts from batch processing, it is recommended to set the number within the range of [1, 4].

10.5.7.4 Other problems and solutions

This section describes some other problems and solutions.

10.5.7.4.1 Switching PD Leader is slow

PD needs to persist Region Meta information on etcd to ensure that PD can quickly resume to provide Region routing services after switching the PD Leader node. As the number of Regions increases, the performance problem of etcd appears, making it slower for PD to get Region Meta information from etcd when PD is switching the Leader. With millions of Regions, it might take more than ten seconds or even tens of seconds to get the meta information from etcd.

To address this problem, `use-region-storage` is enabled by default in PD since TiDB v3.0. With this feature enabled, PD stores Region Meta information on local LevelDB and synchronizes the information among PD nodes through other mechanisms.

10.5.7.4.2 PD routing information is not updated in time

In TiKV, `pd-worker` regularly reports Region Meta information to PD. When TiKV is restarted or switches the Region leader, PD needs to recalculate Region's approximate \hookrightarrow `size / keys` through statistics. Therefore, with a large number of Regions, the single-threaded `pd-worker` might become the bottleneck, causing tasks to be piled up and not processed in time. In this situation, PD cannot obtain certain Region Meta information in time so that the routing information is not updated in time. This problem does not affect the actual reads and writes, but might cause inaccurate PD scheduling and require several round trips when TiDB updates Region cache.

You can check **Worker pending tasks** under **Task** in the **TiKV Grafana** panel to determine whether `pd-worker` has tasks piled up. Generally, **pending tasks** should be kept at a relatively low value.

Figure 117: Check `pd-worker`

pd-worker has been optimized for better performance since **v3.0.5**. If you encounter a similar problem, it is recommended to upgrade to the latest version.

10.5.7.4.3 Prometheus is slow to query metrics

In a large-scale cluster, as the number of TiKV instances increases, Prometheus has greater pressure to query metrics, making it slower for Grafana to display these metrics. To ease this problem, metrics pre-calculation is configured since v3.0.

10.5.8 Best Practices for Three-Node Hybrid Deployment

For a TiDB cluster, if you have no requirements on high performance but need to control the cost, you can deploy the TiDB, TiKV, and PD components on three machines in a hybrid way.

This document offers an example of three-node hybrid deployment and a TPC-C test against the deployed cluster. Based on this example, this document offers best practices for the deployment scenario and its parameter adjustment.

10.5.8.1 Prerequisites for deployment and the test method

In this example, three physical machines are used for deployment, each with 16 CPU cores and 32 GB of memory. On each machine (node), one TiDB instance, one TiKV instance, and one PD instance are deployed in a hybrid way.

Because PD and TiKV both store information on the disk, the read and write latency of disk directly affects the latency of the PD and TiKV services. To avoid the situation that PD and TiKV compete for disk resources and affect each other, it is recommended to use different disks for PD and TiKV.

In this example, the TPC-C 5000 Warehouse data is used in TiUP bench and the test lasts 12 hours with the `terminals` parameter set to 128 (concurrency). Close attention is paid to metrics related to performance stability of the cluster.

The image below shows the QPS monitor of the cluster within 12 hours with the default parameter configuration. From the image, you can see an obvious performance jitter.

Figure 118: QPS with default config

After the parameter adjustment, the performance is improved.

Figure 119: QPS with modified config

10.5.8.2 Parameter adjustment

Performance jitter occurs in the image above, because the default thread pool configuration and the resource allocation to background tasks are for machines with sufficient resources. In the hybrid deployment scenario, the resources are shared among multiple components, so you need to limit the resource consumption via configuration parameters.

The final cluster configuration for this test is as follows:

```

tikv:
  readpool.unified.max-thread-count: 6
  server.grpc-concurrency: 2
  storage.scheduler-worker-pool-size: 2
  gc.max-write-bytes-per-sec: 300K
  rocksdb.max-background-jobs: 3
  rocksdb.max-sub-compactions: 1
  rocksdb.rate-bytes-per-sec: "200M"

tidb:
  performance.committer-concurrency: 4
  performance.max-procs: 8

```

The following sections introduce the meanings and the adjustment methods of these parameters.

10.5.8.2.1 Configuration of TiKV thread pool size

This section offers best practices for adjusting parameters that relate to the resource allocation of thread pools for foreground applications. Reducing these thread pool sizes will compromise performance, but in the hybrid deployment scenario with limited resources, the cluster itself is hard to achieve high performance. In this scenario, the overall stability of the cluster is preferred over performance.

If you conduct an actual load test, you can first use the default configuration and observe the actual resource usage of each thread pool. Then you can adjust the corresponding configuration items and reduce the sizes of the thread pools that have lower usage.

```
readpool.unified.max-thread-count
```

The default value of this parameter is 80% of the number of machine threads. In a hybrid deployment scenario, you need to manually calculate and specify this value. You can first set it to 80% of the expected number of CPU threads used by TiKV.

```
server.grpc-concurrency
```

This parameter defaults to 4. Because in the existing deployment plan, the CPU resources are limited and the actual requests are few. You can observe the monitoring panel, lower the value of this parameter, and keep the usage rate below 80%.

In this test, the value of this parameter is set to 2. Observe the **gRPC poll CPU** panel and you can see that the usage rate is just around 80%.

Figure 120: gRPC Pool CPU

```
storage.scheduler-worker-pool-size
```

When TiKV detects that the CPU core number of the machine is greater than or equal to 16, this parameter value defaults to 8. When the CPU core number is smaller than 16, the parameter value defaults to 4. This parameter is used when TiKV converts complex transaction requests to simple key-value reads or writes, but the scheduler thread pool does not perform any writes.

Ideally, the usage rate of the scheduler thread pool is kept between 50% and 75%. Similar to the gRPC thread pool, the `storage.scheduler-worker-pool-size` parameter defaults to a larger value during the hybrid deployment, which makes resource usage insufficient. In this test, the value of this parameter is set to 2, which is in line with the best practices, a conclusion drawn by observing the corresponding metrics in the **Scheduler worker CPU** panel.

Figure 121: Scheduler Worker CPU

10.5.8.2.2 Resource configuration for TiKV background tasks

In addition to foreground tasks, TiKV regularly sorts data and cleans outdated data in background tasks. The default configuration allocates sufficient resources to these tasks for the scenario of high-traffic writes.

However, in the hybrid deployment scenario, this default configuration is not in line with the best practices. You need to limit the resource usage of background tasks by adjusting the following parameters.

`rocksdb.max-background-jobs` and `rocksdb.max-sub-compactions`

The RocksDB thread pool is used to perform compaction and flush jobs. The default value of `rocksdb.max-background-jobs` is 8, which obviously exceeds the resource that is in need. Therefore, the value should be adjusted to limit the resource usage.

`rocksdb.max-sub-compactions` indicates the number of concurrent sub-tasks allowed for a single compaction job, which defaults to 3. You can lower this value when the write traffic is not high.

In the test, the `rocksdb.max-background-jobs` value is set to 3 and the `rocksdb.max-sub-compactions` value is set to 1. No write stall occurs during the 12-hour test with the TPC-C load. When optimizing the two parameter values according to the actual load, you can lower the values gradually based on monitoring metrics:

- If write stall occurs, increase the value of `rocksdb.max-background-jobs`.
- If the write stall persists, set the value of `rocksdb.max-sub-compactions` to 2 or 3.

`rocksdb.rate-bytes-per-sec`

This parameter is used to limit the disk traffic for the background compaction jobs. The default configuration has no limit for this parameter. To avoid the situation that compaction jobs occupy the resources of foreground services, you can adjust this parameter value according to the sequential read and write speed of the disk, which reserves enough disk bandwidth for foreground services.

The method of optimizing the RocksDB thread pool is similar to that of optimizing the compaction thread pool. You can determine whether the value you have adjusted is suitable according to whether write stall occurs.

`gc.max_write_bytes_per_sec`

Because TiDB uses the multi-version concurrency control (MVCC) model, TiKV periodically cleans old version data in the background. When the available resources are limited, this operation causes periodical performance jitter. You can use the `gc.max_write_bytes_per_sec` parameter to limit the resource usage of such an operation.

Figure 122: GC Impact

In addition to setting this parameter value in the configuration file, you can also dynamically adjust this value in `tikv-ctl`.

```
tiup ctl:<cluster-version> tikv --host=${ip:port} modify-tikv-config -n gc.  
↳ max_write_bytes_per_sec -v ${limit}
```

Note:

In application scenarios with frequent updates, limiting GC traffic might cause the MVCC versions to pile up and affect read performance. Currently, to achieve a balance between performance jitter and performance decrease, you might need to try multiple times to adjust the value of this parameter.

10.5.8.2.3 TiDB parameter adjustment

Generally, you can adjust the TiDB parameters of execution operators using system variables such as `tidb_hash_join_concurrency` and `tidb_index_lookup_join_concurrency`.

In this test, these parameters are not adjusted. In the load test of your actual application, if the execution operators consume an excessive amount of CPU resources, you can limit the resource usage of specific operators according to your application scenario. For more details, see [TiDB system variables](#).

`performance.max-procs`

This parameter is used to control how many CPU cores an entire Go process can use. By default, the value is equal to the number of CPU cores of the current machine or cgroups.

When Go is running, a proportion of threads is used for background tasks such as GC. If you do not limit the value of the `performance.max-procs` parameter, these background tasks will consume too much CPU.

10.5.9 Local Read under Three Data Centers Deployment

In the model of three data centers, a Region has three replicas which are isolated in each data center. However, due to the requirement of strongly consistent read, TiDB must access the Leader replica of the corresponding data for every query. If the query is generated in a data center different from that of the Leader replica, TiDB needs to read data from another data center, thus causing the access latency to increase.

This document describes how to use the [Stale Read](#) feature to avoid cross-center access and reduce the access latency at the expense of real-time data availability.

10.5.9.1 Deploy a TiDB cluster of three data centers

For the three-data-center deployment method, refer to [Multiple Data Centers in One City Deployment](#).

Note that if both the TiKV and TiDB nodes have the configuration item `labels` configured, the TiKV and TiDB nodes in the same data center must have the same value for the `zone` label. For example, if a TiKV node and a TiDB node are both in the data center `dc-1`, then the two nodes need to be configured with the following label:

```
[labels]
zone=dc-1
```

10.5.9.2 Perform local read using Stale Read

[Stale Read](#) is a mechanism that TiDB provides for the users to read historical data. Using this mechanism, you can read the corresponding historical data of a specific point in time or within a specified time range, and thus save the latency brought by data replication between storage nodes. When using Stale Read in some scenarios of geo-distributed deployment,

TiDB accesses the replica in the current data center to read the corresponding data at the expense of some real-time performance, which avoids network latency brought by cross-center connection and reduces the access latency for the entire query process.

When TiDB receives a Stale Read query, if the `zone` label of that TiDB node is configured, then TiDB sends the request to the TiKV node with the same `zone` label where the corresponding data replica resides.

For how to perform Stale Read, see [Perform Stale Read using the AS OF TIMESTAMP clause](#).

10.6 Placement Rules

Note:

TiDB v5.3.0 introduces an experimental support for [Placement Rules in SQL](#). This offers a more convenient way to configure the placement of tables and partitions. Placement Rules in SQL might replace placement configuration with PD in future releases.

Placement Rules, introduced in v5.0, is a replica rule system that guides PD to generate corresponding schedules for different types of data. By combining different scheduling rules, you can finely control the attributes of any continuous data range, such as the number of replicas, the storage location, the host type, whether to participate in Raft election, and whether to act as the Raft leader.

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to [Disable Placement Rules](#).

10.6.1 Rule system

The configuration of the whole rule system consists of multiple rules. Each rule can specify attributes such as the number of replicas, the Raft role, the placement location, and the key range in which this rule takes effect. When PD is performing schedule, it first finds the rule corresponding to the Region in the rule system according to the key range of the Region, and then generates the corresponding schedule to make the distribution of the Region replica comply with the rule.

The key ranges of multiple rules can have overlapping parts, which means that a Region can match multiple rules. In this case, PD decides whether the rules overwrite each other or take effect at the same time according to the attributes of rules. If multiple rules take effect at the same time, PD will generate schedules in sequence according to the stacking order of the rules for rule matching.

In addition, to meet the requirement that rules from different sources are isolated from each other, these rules can be organized in a more flexible way. Therefore, the concept of “Group” is introduced. Generally, users can place rules in different groups according to different sources.

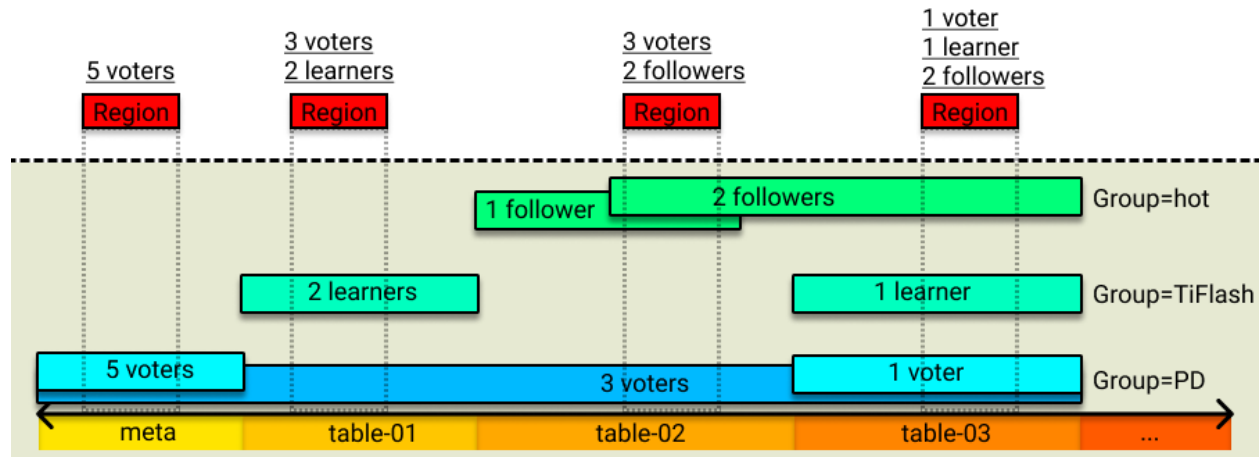

Figure 123: Placement rules overview

10.6.1.1 Rule fields

The following table shows the meaning of each field in a rule:

Field name	Type and restriction	Description
GroupID	string	The group ID that marks the source of the rule.
ID	string	The unique ID of a rule in a group.
Index	int	The stacking sequence of rules in a group.
Override	true/false	Whether to overwrite rules with smaller index (in a group).
StartKey	string, in hexadecimal form	Applies to the starting key of a range.
EndKey	string, in hexadecimal form	Applies to the ending key of a range.
Role	string	Replica roles, including voter/leader/follower/learner.
Count	int, positive integer	The number of replicas.
LabelConstraint	[]Constraint	Filters nodes based on the label.
LocationLabels	[]string	Used for physical isolation.
IsolationLevel	string	Used to set the minimum physical isolation level.

LabelConstraint is similar to the function in Kubernetes that filters labels based on these four primitives: `in`, `notIn`, `exists`, and `notExists`. The meanings of these four primitives are as follows:

- `in`: the label value of the given key is included in the given list.

- **notIn**: the label value of the given key is not included in the given list.
- **exists**: includes the given label key.
- **notExists**: does not include the given label key.

The meaning and function of `LocationLabels` are the same with those earlier than v4.0. For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology: the cluster has multiple zones (Availability Zones), each zone has multiple racks, and each rack has multiple hosts. When performing schedule, PD first tries to place the Region's peers in different zones. If this try fails (such as there are three replicas but only two zones in total), PD guarantees to place these replicas in different racks. If the number of racks is not enough to guarantee isolation, then PD tries the host-level isolation.

The meaning and function of `IsolationLevel` is elaborated in [Cluster topology configuration](#). For example, if you have deployed `[zone,rack,host]` that defines a three-layer topology with `LocationLabels` and set `IsolationLevel` to `zone`, then PD ensures that all peers of each Region are placed in different zones during the scheduling. If the minimum isolation level restriction on `IsolationLevel` cannot be met (for example, 3 replicas are configured but there are only 2 data zones in total), PD will not try to make up to meet this restriction. The default value of `IsolationLevel` is an empty string, which means that it is disabled.

10.6.1.2 Fields of the rule group

The following table shows the description of each field in a rule group:

Field name	Type and restriction	Description
ID	string	The group ID that marks the source of the rule.
Index	int	The stacking sequence of different groups.
Override	true/false	Whether to override groups with smaller indexes.

10.6.2 Configure rules

The operations in this section are based on [pd-ctl](#), and the commands involved in the operations also support calls via HTTP API.

10.6.2.1 Enable Placement Rules

The Placement Rules feature is enabled by default in v5.0 and later versions of TiDB. To disable it, refer to [Disable Placement Rules](#). To enable this feature after it has been disabled, you can modify the PD configuration file as follows before initializing the cluster:

```
[replication]
enable-placement-rules = true
```

In this way, PD enables this feature after the cluster is successfully bootstrapped and generates corresponding rules according to the `max-replicas` and `location-labels` configurations:

```
{
  "group_id": "pd",
  "id": "default",
  "start_key": "",
  "end_key": "",
  "role": "voter",
  "count": 3,
  "location_labels": ["zone", "rack", "host"],
  "isolation_level": ""
}
```

For a bootstrapped cluster, you can also enable Placement Rules online through `pd-ctl`:

```
pd-ctl config placement-rules enable
```

PD also generates default rules based on the `max-replicas` and `location-labels` configurations.

Note:

After enabling Placement Rules, the previously configured `max-replicas` and `location-labels` no longer take effect. To adjust the replica policy, use the interface related to Placement Rules.

10.6.2.2 Disable Placement Rules

You can use `pd-ctl` to disable the Placement Rules feature and switch to the previous scheduling strategy.

```
pd-ctl config placement-rules disable
```

Note:

After disabling Placement Rules, PD uses the original `max-replicas` and `location-labels` configurations. The modification of rules (when Placement Rules is enabled) will not update these two configurations in real time. In addition, all the rules that have been configured remain in PD and will be used the next time you enable Placement Rules.

10.6.2.3 Set rules using pd-ctl

Note:

The change of rules affects the PD scheduling in real time. Improper rule setting might result in fewer replicas and affect the high availability of the system.

pd-ctl supports using the following methods to view rules in the system, and the output is a JSON-format rule or a rule list.

- To view the list of all rules:

```
pd-ctl config placement-rules show
```

- To view the list of all rules in a PD Group:

```
pd-ctl config placement-rules show --group=pd
```

- To view the rule of a specific ID in a Group:

```
pd-ctl config placement-rules show --group=pd --id=default
```

- To view the rule list that matches a Region:

```
pd-ctl config placement-rules show --region=2
```

In the above example, 2 is the Region ID.

Adding rules and editing rules are similar. You need to write the corresponding rules into a file and then use the `save` command to save the rules to PD:

```
cat > rules.json <<EOF
[
  {
    "group_id": "pd",
    "id": "rule1",
    "role": "voter",
    "count": 3,
    "location_labels": ["zone", "rack", "host"]
  },
  {
    "group_id": "pd",
```

```
    "id": "rule2",
    "role": "voter",
    "count": 2,
    "location_labels": ["zone", "rack", "host"]
  }
]
EOF
pd-ctl config placement save --in=rules.json
```

The above operation writes `rule1` and `rule2` to PD. If a rule with the same `GroupID` + `ID` already exists in the system, this rule is overwritten.

To delete a rule, you only need to set the `count` of the rule to 0, and the rule with the same `GroupID` + `ID` will be deleted. The following command deletes the `pd / rule2` rule:

```
cat > rules.json <<EOF
[
  {
    "group_id": "pd",
    "id": "rule2"
  }
]
EOF
pd-ctl config placement save --in=rules.json
```

10.6.2.4 Use `pd-ctl` to configure rule groups

- To view the list of all rule groups:

```
pd-ctl config placement-rules rule-group show
```

- To view the rule group of a specific ID:

```
pd-ctl config placement-rules rule-group show pd
```

- To set the `index` and `override` attributes of the rule group:

```
pd-ctl config placement-rules rule-group set pd 100 true
```

- To delete the configuration of a rule group (use the default group configuration if there is any rule in the group):

```
pd-ctl config placement-rules rule-group delete pd
```

10.6.2.5 Use pd-ctl to batch update groups and rules in groups

To view and modify the rule groups and all rules in the groups at the same time, execute the `rule-bundle` subcommand.

In this subcommand, `get {group_id}` is used to query a group, and the output result shows the rule group and rules of the group in a nested form:

```
pd-ctl config placement-rules rule-bundle get pd
```

The output of the above command:

```
{
  "group_id": "pd",
  "group_index": 0,
  "group_override": false,
  "rules": [
    {
      "group_id": "pd",
      "id": "default",
      "start_key": "",
      "end_key": "",
      "role": "voter",
      "count": 3
    }
  ]
}
```

To write the output to a file, add the `--out` argument to the `rule-bundle get` subcommand, which is convenient for subsequent modification and saving.

```
pd-ctl config placement-rules rule-bundle get pd --out="group.json"
```

After the modification is finished, you can use the `rule-bundle set` subcommand to save the configuration in the file to the PD server. Unlike the `save` command described in [Set rules using pd-ctl](#), this command replaces all the rules of this group on the server side.

```
pd-ctl config placement-rules rule-bundle set pd --in="group.json"
```

10.6.2.6 Use pd-ctl to view and modify all configurations

You can also view and modify all configuration using `pd-ctl`. To do that, save all configuration to a file, edit the configuration file, and then save the file to the PD server to overwrite the previous configuration. This operation also uses the `rule-bundle` subcommand.

For example, to save all configuration to the `rules.json` file, execute the following command:

```
pd-ctl config placement-rules rule-bundle load --out="rules.json"
```

After editing the file, execute the following command to save the configuration to the PD server:

```
pd-ctl config placement-rules rule-bundle save --in="rules.json"
```

10.6.2.7 Use tidb-ctl to query the table-related key range

If you need special configuration for metadata or a specific table, you can execute the [keyrange command](#) in [tidb-ctl](#) to query related keys. Remember to add `--encode` at the end of the command.

```
tidb-ctl keyrange --database test --table ttt --encode
```

```
global ranges:
meta: (6d00000000000000f8, 6e00000000000000f8)
table: (7400000000000000f8, 7500000000000000f8)
table ttt ranges: (NOTE: key range might be changed after DDL)
table: (7480000000000000ff2d000000000000f8, 7480000000000000
↪ ff2e00000000000000f8)
table indexes: (7480000000000000ff2d5f698000000000fa, 7480000000000000
↪ ff2d5f720000000000fa)
index c2: (7480000000000000ff2d5f69800000000ff0000010000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000020000000000fa)
index c3: (7480000000000000ff2d5f69800000000ff0000020000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000030000000000fa)
index c4: (7480000000000000ff2d5f69800000000ff0000030000000000fa,
↪ 7480000000000000ff2d5f69800000000ff0000040000000000fa)
table rows: (7480000000000000ff2d5f720000000000fa, 7480000000000000
↪ ff2e00000000000000f8)
```

Note:

DDL and other operations can cause table ID changes, so you need to update the corresponding rules at the same time.

10.6.3 Typical usage scenarios

This section introduces the typical usage scenarios of Placement Rules.

10.6.3.1 Scenario 1: Use three replicas for normal tables and five replicas for the metadata to improve cluster disaster tolerance

You only need to add a rule that limits the key range to the range of metadata, and set the value of count to 5. Here is an example of this rule:

```
{
  "group_id": "pd",
  "id": "meta",
  "index": 1,
  "override": true,
  "start_key": "6d00000000000000f8",
  "end_key": "6e00000000000000f8",
  "role": "voter",
  "count": 5,
  "location_labels": ["zone", "rack", "host"]
}
```

10.6.3.2 Scenario 2: Place five replicas in three data centers in the proportion of 2:2:1, and the Leader should not be in the third data center

Create three rules. Set the number of replicas to 2, 2, and 1 respectively. Limit the replicas to the corresponding data centers through `label_constraints` in each rule. In addition, change role to `follower` for the data center that does not need a Leader.

```
[
  {
    "group_id": "pd",
    "id": "zone1",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 2,
    "label_constraints": [
      {"key": "zone", "op": "in", "values": ["zone1"]}
    ],
    "location_labels": ["rack", "host"]
  },
  {
    "group_id": "pd",
    "id": "zone2",
    "start_key": "",
    "end_key": "",
    "role": "voter",
    "count": 2,
    "label_constraints": [
      {"key": "zone", "op": "in", "values": ["zone2"]}
    ],
    "location_labels": ["rack", "host"]
  }
]
```

```
    },
    {
      "group_id": "pd",
      "id": "zone3",
      "start_key": "",
      "end_key": "",
      "role": "follower",
      "count": 1,
      "label_constraints": [
        {"key": "zone", "op": "in", "values": ["zone3"]}
      ],
      "location_labels": ["rack", "host"]
    }
  ]
}
```

10.6.3.3 Scenario 3: Add two TiFlash replicas for a table

Add a separate rule for the row key of the table and limit count to 2. Use `label_constraints` to ensure that the replicas are generated on the node of `engine` \leftrightarrow = `tiflash`. Note that a separate `group_id` is used here to ensure that this rule does not overlap or conflict with rules from other sources in the system.

```
{
  "group_id": "tiflash",
  "id": "learner-replica-table-ttt",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e000000000000f8",
  "role": "learner",
  "count": 2,
  "label_constraints": [
    {"key": "engine", "op": "in", "values": ["tiflash"]}
  ],
  "location_labels": ["host"]
}
```

10.6.3.4 Scenario 4: Add two follower replicas for a table in the Beijing node with high-performance disks

The following example shows a more complicated `label_constraints` configuration. In this rule, the replicas must be placed in the `bj1` or `bj2` machine room, and the disk type must not be `ssd`.

```
{
  "group_id": "follower-read",
  "id": "follower-read-table-ttt",
```

```

"start_key": "7480000000000000ff2d000000000000f8",
"end_key": "7480000000000000ff2e000000000000f8",
"role": "follower",
"count": 2,
"label_constraints": [
  {"key": "zone", "op": "in", "values": ["bj1", "bj2"]},
  {"key": "disk", "op": "notIn", "values": ["ssd"]}
],
"location_labels": ["host"]
}

```

10.6.3.5 Scenario 5: Migrate a table to the nodes with SSD disks

Different from scenario 3, this scenario is not to add new replica(s) on the basis of the existing configuration, but to forcibly override the other configuration of a data range. So you need to specify an `index` value large enough and set `override` to `true` in the rule group configuration to override the existing rule.

The rule:

```

{
  "group_id": "ssd-override",
  "id": "ssd-table-45",
  "start_key": "7480000000000000ff2d5f720000000000fa",
  "end_key": "7480000000000000ff2e000000000000f8",
  "role": "voter",
  "count": 3,
  "label_constraints": [
    {"key": "disk", "op": "in", "values": ["ssd"]}
  ],
  "location_labels": ["rack", "host"]
}

```

The rule group:

```

{
  "id": "ssd-override",
  "index": 1024,
  "override": true,
}

```

10.7 Load Base Split

Load Base Split is a new feature introduced in TiDB 4.0. It aims to solve the hotspot issue caused by unbalanced access between Regions, such as full table scans for small tables.

10.7.1 Scenarios

In TiDB, it is easy to generate hotspots when the load is concentrated on certain nodes. PD tries to schedule the hot Regions so that they are distributed as evenly as possible across all nodes for better performance.

However, the minimum unit for PD scheduling is Region. If the number of hotspots in a cluster is smaller than the number of nodes, or if a few hotspots have far more load than other Regions, PD can only move the hotspot from one node to another, but not make the entire cluster share the load.

This scenario is especially common with workloads that are mostly read requests, such as full table scans and index lookups for small tables, or frequent access to some fields.

Previously, the solution to this problem was to manually execute a command to split one or more hotspot Regions, but this approach has two problems:

- Evenly splitting a Region is not always the best choice, because requests might be concentrated on a few keys. In such cases, hotspots might still be on one of the Regions after evenly splitting, and it might take multiple even splits to realize the goal.
- Human intervention is not timely or simple.

10.7.2 Implementation principles

Load Base Split automatically splits the Region based on statistics. It identifies the Regions whose read load consistently exceeds the threshold for 10 seconds, and splits these Regions at a proper position. When choosing the split position, Load Base Split tries to balance the access load of both Regions after the split and avoid access across Regions.

The Region split by Load Base Split will not be merged quickly. On the one hand, PD's `MergeChecker` skips the hot Regions; on the other hand, PD also determines whether to merge two Regions according to QPS in the heartbeat information, to avoid the merging of two Regions with high QPS.

10.7.3 Usage

The Load Base Split feature is currently controlled by the `split.qps-threshold` parameter (QPS threshold) and `split.byte-threshold` parameter (traffic threshold). If the sum of all types of read requests per second for a Region exceeds the QPS threshold or traffic threshold for 10 consecutive seconds, PD splits the Region.

Load Base Split is enabled by default, but the parameter is set to a rather high value. `split.qps-threshold` defaults to 3000 and `split.byte-threshold` defaults to 30MB/s. If you want to disable this feature, set the two thresholds high enough at the same time.

To modify the parameter, take either of the following two methods:

- Use a SQL statement:

```
# Set the QPS threshold to 1500
SET config tikv split.qps-threshold=1500;
# Set the byte threshold to 15 MiB (15 * 1024 * 1024)
SET config tikv split.byte-threshold=15728640;
```

- Use TiKV:

```
curl -X POST "http://ip:status_port/config" -H "accept: application/
  ↪ json" -d '{"split.qps-threshold":"1500"}'
curl -X POST "http://ip:status_port/config" -H "accept: application/
  ↪ json" -d '{"split.byte-threshold":"15728640"}'
```

Accordingly, you can view the configuration by either of the following two methods:

- Use a SQL statement:

```
show config where type='tikv' and name like '%split.qps-threshold%';
```

- Use TiKV:

```
curl "http://ip:status_port/config"
```

Note:

Starting from v4.0.0-rc.2, you can modify and view the configuration using SQL statements.

10.8 Store Limit

Store Limit is a feature of PD, introduced in TiDB 3.0. It is designed to control the scheduling speed in a finer manner for better performance in different scenarios.

10.8.1 Implementation principles

PD performs scheduling at the unit of operator. An operator might contain several scheduling operations. For example:

```
"replace-down-replica {mv peer: store [2] to [3]} (kind:region,replica,
  ↪ region:10(4,5), createAt:2020-05-18 06:40:25.775636418 +0000 UTC m
  ↪ +=2168762.679540369, startAt:2020-05-18 06:40:25.775684648 +0000 UTC
  ↪ m+=2168762.679588599, currentStep:0, steps:[add learner peer 20 on
  ↪ store 3, promote learner peer 20 on store 3 to voter, remove peer on
  ↪ store 2])"
```

In this above example, the `replace-down-replica` operator contains the following specific operations:

1. Add a learner peer with the ID 20 to `store 3`.
2. Promote the learner peer with the ID 20 on `store 3` to a voter.
3. Delete the peer on `store 2`.

Store Limit achieves the store-level speed limit by maintaining a mapping from store IDs to token buckets in memory. The different operations here correspond to different token buckets. Currently, Store Limit only supports limiting the speed of two operations: adding learners/peers and deleting peers. That is, each store has two types of token buckets.

Every time an operator is generated, it checks whether enough tokens exist in the token buckets for its operations. If yes, the operator is added to the scheduling queue, and the corresponding token is taken from the token bucket. Otherwise, the operator is abandoned. Because the token bucket replenishes tokens at a fixed rate, the speed limit is thus achieved.

Store Limit is different from other limit-related parameters in PD (such as `region-schedule-limit` and `leader-schedule-limit`) in that it mainly limits the consuming speed of operators, while other parameters limits the generating speed of operators. Before introducing the Store Limit feature, the speed limit of scheduling is mostly at the global scope. Therefore, even if the global speed is limited, it is still possible that the scheduling operations are concentrated on some stores, affecting the performance of the cluster. By limiting the speed at a finer level, Store Limit can better control the scheduling behavior.

10.8.2 Usage

The parameters of Store Limit can be configured using `pd-ctl`.

10.8.2.1 View setting of the current store

To view the limit setting of the current store, run the following commands:

```
store limit // Shows the speed limit of adding and
  ↪ deleting peers in all stores.
store limit add-peer // Shows the speed limit of adding peers in
  ↪ all stores.
store limit remove-peer // Shows the speed limit of deleting peers
  ↪ in all stores.
```

10.8.2.2 Set limit for all stores

To set the speed limit for all stores, run the following commands:

```
store limit all 5          // All stores can at most add and delete 5
  ↳ peers per minute.
store limit all 5 add-peer // All stores can at most add 5 peers per
  ↳ minute.
store limit all 5 remove-peer // All stores can at most delete 5 peers per
  ↳ minute.
```

10.8.2.3 Set limit for a single store

To set the speed limit for a single store, run the following commands:

```
store limit 1 5          // store 1 can at most add and delete 5
  ↳ peers per minute.
store limit 1 5 add-peer // store 1 can at most add 5 peers per
  ↳ minute.
store limit 1 5 remove-peer // store 1 can at most delete 5 peers per
  ↳ minute.
```

11 TiDB Tools

11.1 TiDB Tools Overview

TiDB provides a rich set of tools to help you with deployment operations, data management (such as import and export, data migration, backup & recovery), and complex OLAP queries. You can select the applicable tools according to your needs.

11.1.1 Deployment and operation Tools

To meet your deployment and operation needs in different system environments, TiDB provides two deployment and Operation tools, TiUP and TiDB Operator.

11.1.1.1 Deploy and operate TiDB on physical or virtual machines

TiUP is a TiDB package manager on physical or virtual machines. TiUP can manage multiple TiDB components such as TiDB, PD, TiKV. To start any component in the TiDB ecosystem, you just need to execute a single TiUP command.

TiUP provides [TiUP cluster](#), a cluster management component written in Golang. By using TiUP cluster, you can easily perform daily database operations, including deploying, starting, stopping, destroying, scaling, and upgrading a TiDB cluster, and manage TiDB cluster parameters.

The following are the basics of TiUP:

- [Terminology and Concepts](#)
- [Deploy a TiDB Cluster Using TiUP](#)
- [Manage TiUP Components with TiUP Commands](#)
- Applicable TiDB versions: v4.0 and above

11.1.1.2 Deploy and operate TiDB in Kubernetes

[TiDB Operator](#) is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

The following are the basics of TiDB Operator:

- [TiDB Operator Architecture](#)
- [Get Started with TiDB Operator in Kubernetes](#)
- Applicable TiDB versions: v2.1 and above

11.1.2 Data management tools

TiDB provides multiple data management tools, such as import and export, backup and restore, data replication, data migration, incremental synchronization, and data validation.

11.1.2.1 Full data export

[Dumpling](#) is a tool for the logical full data export from MySQL or TiDB.

The following are the basics of Dumpling:

- Input: MySQL/TiDB cluster
- Output: SQL/CSV file
- Supported TiDB versions: all versions
- Kubernetes support: No

Note:

PingCAP previously maintained a fork of the [mydumper project](#) with enhancements specific to TiDB. Starting from v7.5.0, [Mydumper](#) is deprecated and most of its features have been replaced by [Dumpling](#). It is strongly recommended that you use Dumpling instead of Mydumper.

11.1.2.2 Full data import

TiDB Lightning (Lightning) is a tool used for the full import of large amounts of data into a TiDB cluster. Currently, TiDB Lightning supports reading SQL dump exported via Dumping or CSV data source.

TiDB Lightning supports three modes:

- **local**: TiDB Lightning parses data into ordered key-value pairs and directly imports them into TiKV. This mode is usually for importing a large amount of data (at the TB level) to a new cluster. During the import, the cluster cannot provide services.
- **importer**: This mode is similar to the **local** mode. To use this mode, you need to deploy an additional component **tikv-importer** to help import key-value pairs. If the target cluster is in v4.0 or later versions, it is recommended to use the **local** mode.
- **tidb**: This mode uses TiDB/MySQL as the backend, which is slower than the **local** mode and **importer** mode but can be performed online. It also supports importing data to MySQL.

The following are the basics of TiDB Lightning:

- Input data source:
 - The output file of Dumping
 - Other compatible CSV file
- Supported TiDB versions: v2.1 or later
- Kubernetes support: Yes. See [Quickly restore data into a TiDB cluster in Kubernetes using TiDB Lightning](#) for details.

Note:

The Loader tool is no longer maintained. For scenarios related to Loader, it is recommended that you use the **tidb** mode of TiDB Lightning instead. For details, see [TiDB Lightning TiDB backends](#).

11.1.2.3 Backup and restore

Backup & Restore (BR) is a command-line tool for distributed backup and restore of the TiDB cluster data. BR can effectively back up and restore TiDB clusters of huge data volume.

The following are the basics of BR:

- **Input and output data source**: SST + **backupmeta** file
- Supported TiDB versions: v3.1 and v4.0
- Kubernetes support: Yes. See [Back up Data to S3-Compatible Storage Using BR and Restore Data from S3-Compatible Storage Using BR](#) for details.

11.1.2.4 Incremental data replication

TiDB Binlog is a tool that collects binlog for TiDB clusters and provides near real-time sync and backup. It can be used for incremental data replication between TiDB clusters, such as making a TiDB cluster the secondary cluster of the primary TiDB cluster.

The following are the basics of TiDB Binlog:

- Input/Output:
 - Input: TiDB cluster
 - Output: TiDB cluster, MySQL, Kafka or incremental backup files
- Supported TiDB versions: v2.1 or later
- Kubernetes support: Yes. See [TiDB Binlog Cluster Operations](#) and [TiDB Binlog Drainer Configurations in Kubernetes](#) for details.

11.1.2.5 Data migration

TiDB Data Migration (DM) is an integrated data replication task management platform that supports the full data migration and the incremental data replication from MySQL/MariaDB to TiDB.

The following are the basics of DM:

- Input: MySQL/MariaDB
- Output: TiDB cluster
- Supported TiDB versions: all versions
- Kubernetes support: No, under development

If the data volume is below the TB level, it is recommended to migrate data from MySQL/MariaDB to TiDB directly using DM. The migration process includes the full data import and export and the incremental data replication.

If the data volume is at the TB level, take the following steps:

1. Use **Dumpling** to export the full data from MySQL/MariaDB.
2. Use **TiDB Lightning** to import the data exported in Step 1 to the TiDB cluster.
3. Use DM to replicate the incremental data from MySQL/MariaDB to TiDB.

Note:

The Syncer tool is no longer maintained. For scenarios related to Syncer, it is recommended that you use DM's incremental task mode instead.

11.1.3 OLAP Query tool

TiDB provides the OLAP query tool TiSpark, which allows you to query TiDB tables as if you were using native Spark.

11.1.3.1 Query TiKV data source using Spark

TiSpark is a thin layer built for running Apache Spark on top of TiKV to answer the complex OLAP queries. It takes advantages of both the Spark platform and the distributed TiKV cluster and seamlessly glues to TiDB, and provides a one-stop Hybrid Transactional and Analytical Processing (HTAP) solution.

11.2 TiDB Tools Use Cases

This document introduces the common use cases of TiDB tools and how to choose the right tool for your scenario.

11.2.1 Deploy and operate TiDB on physical or virtual machines

If you need to deploy and operate TiDB on physical or virtual machines, you can install **TiUP**, and then use TiUP to manage TiDB components such as TiDB, PD, and TiKV.

11.2.2 Deploy and operate TiDB in Kubernetes

If you need to deploy and operate TiDB in Kubernetes, you can deploy a Kubernetes cluster, and then deploy **TiDB Operator**. After that, you can use TiDB Operator to deploy and operate a TiDB cluster.

11.2.3 Import data from CSV to TiDB

If you need to import the compatible CSV files exported by other tools to TiDB, use **TiDB Lightning**.

11.2.4 Import full data from MySQL/Aurora

If you need to import full data from MySQL/Aurora, use **Dumpling** first to export data as SQL dump files, and then use **TiDB Lightning** to import data into the TiDB cluster.

11.2.5 Migrate data from MySQL/Aurora

If you need to migrate both full data and incremental data from MySQL/Aurora, use **TiDB Data Migration (DM)** to perform the **Migrate Data from Amazon Aurora to TiDB**.

If the full data volume is large (at the TB level), you can first use [Dumpling](#) and [TiDB Lightning](#) to perform the full data migration, and then use DM to perform the incremental data migration.

11.2.6 Back up and restore TiDB cluster

If you need to back up a TiDB cluster or restore backed up data to the cluster, use [BR](#) (Backup & Restore).

In addition, BR can also be used to perform [incremental backup](#) and [incremental restore](#) of TiDB cluster data.

11.2.7 Migrate data to TiDB

If you need to migrate data from a TiDB cluster to another TiDB cluster, use [Dumpling](#) to export full data from TiDB as SQL dump files, and then use [TiDB Lightning](#) to import data to another TiDB cluster.

If you also need to migrate incremental data, use [TiDB Binlog](#).

11.2.8 TiDB incremental data subscription

If you need to subscribe to TiDB's incremental changes, use [TiDB Binlog](#).

11.3 Download TiDB Tools

This document collects the available downloads for most officially maintained versions of TiDB tools.

11.3.1 TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems. For more information, see [Install TiUP](#).

11.3.2 TiDB Operator

TiDB Operator runs in Kubernetes. After deploying the Kubernetes cluster, you can choose to deploy TiDB Operator either online or offline. For more information, see [Deploying TiDB Operator in Kubernetes](#).

11.3.3 TiDB Binlog

If you want to download the latest version of [TiDB Binlog](#), directly download the TiDB package, because TiDB Binlog is included in the TiDB package.

Package name	OS	Architecture	SHA256 checksum
<a href="https://download.pingcap.org/tidb-
{version}-linux-
amd64.tar.gz">https:// download. . pingcap. .org/ tidb- -{ version- }- linux- - amd64. .tar. gz	Linux	amd64	<a href="https://download.pingcap.org/tidb-

↪ .			↪ .
↪ tar			↪ sha256
↪ .			↪
↪ gz			
↪			

Note:

{version} in the above download link indicates the version number of TiDB Lightning. For example, the download link for v5.4.3 is <https://download.pingcap.org/tidb-toolkit-v5.4.3-linux-amd64.tar.gz>.

11.3.5 BR (backup and restore)

Download **BR** by using the download link in the following table:

Package name	OS	Architecture	SHA256 checksum
http://download.pingcap.org/tidb-toolkit- {version}-linux-amd64.tar.gz	Linux	amd64	http://download.pingcap.org/tidb-toolkit- {version}-linux-amd64.tar.gz.sha256

Note:

{version} in the above download link indicates the version number of BR. For example, the download link for v5.4.3 is <https://download.pingcap.org/tidb-toolkit-v5.4.3-linux-amd64.tar.gz>.

11.3.6 TiDB DM (Data Migration)

Download **DM** by using the download link in the following table:

Package name	OS	Architecture	SHA256 checksum
https://download.pingcap.org/dm-v{version}-linux-amd64.tar.gz	Linux	amd64	https://download.pingcap.org/dm-v{version}-linux-amd64.tar.gz.sha256

Note:

{version} in the above download link indicates the version number of DM. For example, the download link for v5.4.3 is <https://download.pingcap.org/dm-v5.4.3-linux-amd64.tar.gz>. You can check the published DM versions in the [DM Release](#) page.

11.3.7 Dumpling

Download [Dumpling](#) from the links below:

Installation package age	Operating system Architecture	SHA256 checksum
https	Linux amd64	https
↪ ://		↪ ://
↪ download		↪ download
↪ .		↪ .
↪ pingcap		↪ pingcap
↪ .		↪ .
↪ org		↪ org
↪ /		↪ /
↪ tidb		↪ tidb
↪ -		↪ -
↪ toolkit		↪ toolkit
↪ --{		↪ --{
↪ version		↪ version
↪ }-		↪ }-
↪ linux		↪ linux
↪ -		↪ -
↪ amd64		↪ amd64
↪ .		↪ .
↪ tar		↪ sha256
↪ .		↪
↪ gz		
↪		

Note:

The {version} in the download link is the version number of Dumpling. For example, the link for downloading the v5.4.3 version of Dumpling is <https://download.pingcap.org/tidb-toolkit-v5.4.3-linux-amd64.tar.gz>. You can view the currently released versions in [TiDB Releases](#).

Dumpling supports arm64 linux. You can replace amd64 in the download link with arm64, which means the arm64 version of Dumpling.

11.3.8 sync-diff-inspector

Download [sync-diff-inspector](#) from the links below:

Package name	OS	Architecture	SHA256 checksum
https	Linux	amd64	https
↪ ://			↪ ://
↪ download			↪ download
↪ .			↪ .
↪ pingcap			↪ pingcap
↪ .			↪ .

↪			

Note:

{version} in the download link is the version number of TiDB. For example, the download link for v5.4.3 is <https://download.pingcap.org/tidb-5.4.3-linux-amd64.tar.gz>. You can view the currently released versions in [TiDB Releases](#).

11.3.9 TiCDC

To download [TiCDC](#), refer to [Deploy TiCDC](#).

11.4 TiUP

11.4.1 TiUP Documentation Map

11.4.1.1 User guide

- **TiUP Overview**: Gives an overall introduction to TiUP, for example, how to install and use TiUP, and the related terminologies.
- **TiUP Terminology and Concepts**: Explains the terms that you might bump into when using TiUP, and help you understand the key concepts of TiUP
- **TiUP Component Management**: Introduces all TiUP commands in detail, and how to use TiUP to download, update and delete components
- **TiUP FAQ**: Introduces common issues when you use TiUP, including FAQs of the third-party components of TiUP
- **TiUP Troubleshooting Guide**: Introduces the troubleshooting methods and solutions if you encounter issues when using TiUP
- **TiUP Reference Guide**: Introduces detailed references, including commands, components, and mirrors.

11.4.1.2 TiUP resources

- **TiUP Issues**: Lists TiUP GitHub issues

11.4.2 TiUP Overview

Starting with TiDB 4.0, TiUP, as the package manager, makes it far easier to manage different cluster components in the TiDB ecosystem. Now you can run any component with only a single line of TiUP commands.

11.4.2.1 Install TiUP

You can install TiUP with a single command in both Darwin and Linux operating systems:

```
curl --proto '=https' --tlsv1.2 -sSf https://tiup-mirrors.pingcap.com/  
↳ install.sh | sh
```

This command installs TiUP in the `$HOME/.tiup` folder. The installed components and the data generated by their operation are also placed in this folder. This command also automatically adds `$HOME/.tiup/bin` to the `PATH` environment variable in the Shell `.profile` file, so you can use TiUP directly.

After installation, you can check the version of TiUP:

```
tiup --version
```

Note:

By default, TiUP shares usage details with PingCAP to help understand how to improve the product. For details about what is shared and how to disable the sharing, see [Telemetry](#).

11.4.2.2 TiUP ecosystem introduction

TiUP is not only a package manager in the TiDB ecosystem. Its ultimate mission is to enable everyone to use TiDB ecosystem tools **easier than ever before** by building its own ecosystem. This requires introducing additional packages to enrich the TiUP ecosystem.

This series of TiUP documents introduce what these packages do and how you can use them.

In the TiUP ecosystem, you can get help information by adding `--help` to any command, such as the following command to get help information for TiUP itself:

```
tiup --help
```

```
TiUP is a command-line component management tool that can help to download
↳ and install
TiDB platform components to the local system. You can run a specific version
↳ of a component via
"tiup <component>[:version]". If no version number is specified, the latest
↳ version installed
locally will be used. If the specified component does not have any version
↳ installed locally,
the latest stable version will be downloaded from the repository.
```

Usage:

```
tiup [flags] <command> [args...]
tiup [flags] <component> [args...]
```

Available Commands:

```
install    Install a specific version of a component
list       List the available TiDB components or versions
uninstall  Uninstall components or versions of a component
update     Update tiup components to the latest version
status     List the status of instantiated components
clean      Clean the data of instantiated components
mirror     Manage a repository mirror for TiUP components
help       Help about any command or component
```

Components Manifest:

```
use "tiup list" to fetch the latest components manifest
```

Flags:

```
--binary <component>[:version] Print binary path of a specific version
    ↪ of a component <component>[:version]
                                and the latest version installed will be
                                ↪ selected if no version specified
--binpath string                Specify the binary path of component
    ↪ instance
-h, --help                      help for tiup
--skip-version-check           Skip the strict version check, by default
    ↪ a version must be a valid SemVer string
-T, --tag string              Specify a tag for component instance
-v, --version                 version for tiup
```

Component instances with the same "tag" will share a data directory (

```
    ↪ $TIUP_HOME/data/$tag):
```

```
$ tiup --tag mycluster playground
```

Examples:

```
$ tiup playground                # Quick start
$ tiup playground nightly        # Start a playground with the latest
    ↪ nightly version
$ tiup install <component>[:version] # Install a component of specific
    ↪ version
$ tiup update --all              # Update all installed components to the
    ↪ latest version
$ tiup update --nightly         # Update all installed components to the
    ↪ nightly version
$ tiup update --self            # Update the "tiup" to the latest version
$ tiup list                     # Fetch the latest supported components
    ↪ list
$ tiup status                   # Display all running/terminated
    ↪ instances
$ tiup clean <name>             # Clean the data of running/terminated
    ↪ instance (Kill process if it's running)
$ tiup clean --all              # Clean the data of all running/
    ↪ terminated instances
```

Use "tiup [command] --help" for more information about a command.

The output is long but you can focus on only two parts:

- Available commands

- install: used to install components
 - list: used to view the list of available components
 - uninstall: used to uninstall components
 - update: used to update the component version
 - status: used to view the running history of components
 - clean: used to clear the running log of components
 - mirror: used to clone a private mirror from the official mirror
 - help: used to print out help information
- Available components
 - playground: used to start a TiDB cluster locally
 - client: used to connect to a TiDB cluster in a local machine
 - cluster: used to deploy a TiDB cluster for production environments
 - bench: used to stress test the database

Note:

- The number of available components will continue to grow. To check the latest supported components, execute the `tiup list` command.
- The list of available versions of components will also continue to grow. To check the latest supported component versions, execute the `tiup ↪ list <component>` command.

TiUP commands are implemented in TiUP’s internal code and used for package management operations, while TiUP components are independent component packages installed by TiUP commands.

For example, if you run the `tiup list` command, TiUP directly runs its own internal code; if you run the `tiup playground` command, TiUP first checks whether there is a local package named “playground”, and if not, TiUP downloads the package from the mirror, and then run it.

11.4.3 TiUP Terminology and Concepts

This document explains important terms and concepts of TiUP.

11.4.3.1 TiUP components

The TiUP program contains only a few commands for downloading, updating, and uninstalling components. TiUP expands its functions with various components. A **component** is

a program or script that can be run. When running a component through `tiup <component> ↔ >`, TiUP adds a set of environment variables, creates the data directory for the program, and then runs the program.

By running the `tiup <component>` command, you can run a component supported by TiUP. The running logic is:

- If you specify a version of a component through `tiup <component>[:version]:`
 - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
 - If the component has one or more versions installed locally, but there is no version specified by you, TiUP downloads the specified version from the mirror server.
 - If the specified version of the component is installed locally, TiUP sets the environment variable to run the installed version.
- If you run a component through `tiup <component>` and specify no version:
 - If the component does not have any version installed locally, TiUP downloads the latest stable version from the mirror server.
 - If one or more versions have been installed locally, TiUP sets the environment variable to run the latest installed version.

11.4.3.2 TiUP mirrors

All components of TiUP are downloaded from the TiUP mirrors. TiUP mirrors contain the TAR package of each component and the corresponding meta information (version, entry startup file, checksum). TiUP uses PingCAP's official mirrors by default. You can customize the mirror source through the `TIUP_MIRRORS` environment variable.

TiUP mirrors can be a local file directory or an online HTTP server:

- `TIUP_MIRRORS=/path/to/local tiup list`
- `TIUP_MIRRORS=https://private-mirrors.example.com tiup list`

11.4.4 Manage TiUP Components with TiUP Commands

You can use the following TiUP commands to manage components in the TiUP ecosystem:

- `list`: Queries the component list. By using this TiUP command, you can see all the optional components to install and all the optional versions of each component.
- `install`: Installs the specific version of a component.
- `update`: Updates a component to the latest version.
- `uninstall`: Uninstalls a component.
- `status`: Checks the status of a running component.

- `clean`: Cleans up the instance on which a component is deployed.
- `help`: Prints the help information. If you append another TiUP command to this command, the usage of the appended command is printed.

This document introduces the common component management operations and the corresponding TiUP commands.

11.4.4.1 Query the component list

You can use the `tiup list` command to query the component list. This usage of this command is as follows:

- `tiup list`: checks which components can be installed.
- `tiup list ${component}`: checks which versions of a specific component can be installed.

You can also use the following flags in the above commands:

- `--installed`: checks which components or which version of a specific component has been installed locally. `---all`: views all components, including the hidden ones `---↔ verbose`: views all columns (including installed versions and supported platforms)

Example 1: View all currently installed components.

```
tiup list --installed
```

Example 2: Get a list of the TiKV component of all installable versions from the server.

```
tiup list tikv
```

11.4.4.2 Install components

You can use the `tiup install` command to query the component list. This usage of this command is as follows:

- `tiup install <component>`: installs the latest stable version of a specified component.
- `tiup install <component>:[version]`: installs the specified version of a specified component.

Example 1: Use TiUP to install the latest stable version of TiDB.

```
tiup install tidb
```

Example 2: Use TiUP to install the nightly version of TiDB.

```
tiup install tidb:nightly
```

Example 3: Use TiUP to install TiKV v5.4.3.

```
tiup install tikv:v5.4.3
```

11.4.4.3 Upgrade components

After a new version of a component is published, you can use the `tiup update` command to upgrade this component. The usage of this command is basically the same as that of `tiup install`, except for the following flags:

- `--all`: Upgrades all components.
- `--nightly`: Upgrades to the nightly version.
- `--self`: Upgrades TiUP itself to the latest version.
- `--force`: Forcibly upgrades to the latest version.

Example 1: Upgrade all components to the latest versions.

```
tiup update --all
```

Example 2: Upgrade all components to the nightly version.

```
tiup update --all --nightly
```

Example 3: Upgrade TiUP to the latest version.

```
tiup update --self
```

11.4.4.4 Operate components

After the installation is complete, you can use the `tiup <component>` command to start the corresponding component:

```
tiup [flags] <component>[:version] [args...]
```

Flags:

<code>-T, --tag string</code>	Specifies the tag for the component
<code>↪ instance.</code>	

To use this command, you need to specify the component name and the optional version. If no version is specified, the latest stable version (installed) of this component is used.

Before the component is started, TiUP creates a directory for it, and then puts this component into the directory for operation. The component generates all the data in this directory, and the name of this directory is the tag name specified when the component

operates. If no tag is specified, a tag name is randomly generated. This working directory will be *automatically deleted* when the instance is terminated.

If you want to start the same component multiple times and reuse the previous working directory, you can use `--tag` to specify the same name when the component is started. After the tag is specified, the working directory will *not be automatically deleted* when the instance is terminated, which makes it convenient to reuse the working directory.

Example 1: Operate TiDB v5.4.3.

```
tiup tidb:v5.4.3
```

Example 2: Specify the tag with which TiKV operates.

```
tiup --tag=experiment tikv
```

11.4.4.4.1 Query the operating status of a component

You can use the `tiup status` command to check the operating status of a component:

```
tiup status
```

By executing this command, you will get a list of instances, one instance per line. The list contains the following columns:

- **Name:** The tag name of the instance.
- **Component:** The component name of the instance.
- **PID:** The process ID of the operating instance.
- **Status:** The instance status. `RUNNING` means that the instance is operating. `TERM` means that the instance is terminated.
- **Created Time:** The starting time of the instance.
- **Directory:** The working directory of the instance, which can be specified using `--tag`.
- **Binary:** The executable program of the instance, which can be specified using `--binpath`.
- **Args:** The arguments of the operating instance.

11.4.4.4.2 Clean component instance

You can use the `tiup clean` command to clean up component instances and delete the working directory. If the instance is still operating before the cleaning, the related process is killed first. The command usage is as follows:

```
tiup clean [tag] [flags]
```

The following flag is supported:

- `--all`: Cleans up all instance information.

In the above command, `tag` is the instance tag to be cleaned. If `--all` is used, no tag is passed.

Example 1: Clean up the component instance with the `experiment` tag name.

```
tiup clean experiment
```

Example 2: Clean up all component instances.

```
tiup clean --all
```

11.4.4.4.3 Uninstall components

The components installed using TiUP take up local disk space. If you do not want to keep too many components of old versions, you can check which versions of a component are currently installed, and then uninstall this component.

You can use the `tiup uninstall` command to uninstall all versions or specific versions of a component. This command also supports uninstalling all components. The command usage is as follows:

```
tiup uninstall [component][:version] [flags]
```

The following flags are supported in this command:

- `--all`: Uninstalls all components or versions.
- `--self`: Uninstalls TiUP itself.

`component` is the component to be uninstalled. `version` is the version to be uninstalled. Both `component` and `version` can be ignored in the `tiup uninstall` command. If you ignore either one of these two, you need to add the `--all` flag.

- If the version is ignored, adding `--all` means to uninstall all versions of this component.
- If the version and the component are both ignored, adding `--all` means to uninstall all components of all versions.

Example 1: Uninstall TiDB v5.4.3.

```
tiup uninstall tidb:v5.4.3
```

Example 2: Uninstall TiKV of all versions.

```
tiup uninstall tikv --all
```

Example 3: Uninstall all installed components.

```
tiup uninstall --all
```

11.4.5 TiUP FAQ

11.4.5.1 Can TiUP not use the official mirror source?

TiUP supports specifying the mirror source through the `TIUP_MIRRORS` environment variable. The address of the mirror source can be a local directory or an HTTP server address. If your environment cannot access the network, you can create your own offline mirror source to use TiUP.

After using an unofficial mirror, if you want the official mirror back and use it, take one of the following measures:

- Set the `TIUP_MIRRORS` variable to the official mirror address: `https://tiup-mirrors`
↪ `.pingcap.com`.
- Make sure that the `TIUP_MIRRORS` variable is not set, and then execute the `tiup`
↪ `mirror set https://tiup-mirrors.pingcap.com` command.

11.4.5.2 How do I put my own component into the TiUP mirrors?

TiUP does not support third-party components for the time being, but the TiUP Team has developed the TiUP component development specifications and is developing the `tiup-publish` component. After everything is ready, a contributor can publish their own components to TiUP's official mirrors by using the `tiup publish <comp> <version>` command.

11.4.5.3 What is the difference between the TiUP playground and TiUP cluster components?

The TiUP playground component is mainly used to build a stand-alone development environment on Linux or macOS operating systems. It helps you get started quickly and run a specified version of the TiUP cluster easily. The TiUP cluster component is mainly used to deploy and maintain a production environment cluster, which is usually a large-scale cluster.

11.4.5.4 How do I write the topology file for the TiUP cluster component?

Refer to [these templates](#) to write the topology file. The templates include:

- Multi-DC deployment topology
- Minimal deployment topology
- Complete topology file

You can edit your topology file based on the templates and your needs.

11.4.5.5 Can multiple instances be deployed on the same host?

You can use the TiUP cluster component to deploy multiple instances on the same host, but with different ports and directories configured; otherwise, directory and port conflicts might occur.

11.4.5.6 Are port and directory conflicts detected within the same cluster?

Port and directory conflicts in the same cluster are detected during deployment and scaling. If there is any directory or port conflict, the deployment or scaling process is interrupted.

11.4.5.7 Are port and directory conflicts detected among different clusters?

If multiple different clusters are deployed by the same TiUP control machine, the port and directory conflicts among these clusters are detected during deployment and scaling. If the clusters are deployed by different TiUP control machines, conflict detection is not supported currently.

11.4.5.8 During cluster deployment, TiUP received an `ssh: handshake failed: read tcp 10.10.10.34:38980 -> 10.10.10.34:3600: read: connection reset by peer error`

The error might occur because the default number of concurrent threads of TiUP exceeds the default maximum number of SSH connections. To solve the issue, you can increase the default number of SSH connections, and then restart the `sshd` service:

```
vi /etc/ssh/sshd_config
```

```
MaxSessions 1000  
MaxStartups 1000
```

11.4.6 TiUP Troubleshooting Guide

This document introduces some common issues when you use TiUP and the troubleshooting methods. If this document does not include the issues you bump into, [file a new issue](#) in the Github TiUP repository.

11.4.6.1 Troubleshoot TiUP commands

11.4.6.1.1 Can't see the latest component list using `tiup list`

TiUP does not update the latest component list from the mirror server every time. You can forcibly refresh the component list by running `tiup list`.

11.4.6.1.2 Can't see the latest version information of a component using `tiup list <component>`

Same as the previous issue, the component version information is only obtained from the mirror server when there is no local cache. You can refresh the component list by running `tiup list <component>`.

11.4.6.1.3 Component downloading process is interrupted

Unstable network might result in an interrupted component downloading process. You can try to download the component again. If you cannot download it after trying multiple times, it might be caused by the CDN server and you can report the issue [here](#).

11.4.6.1.4 A checksum error occurs during component downloading process

Because the CDN server has a short cache time, the new checksum file might not match the component package. Try to download again after 5 minutes. If the new checksum file still does not match the component package, report the issue [here](#).

11.4.6.2 Troubleshoot TiUP cluster component

11.4.6.2.1 unable to authenticate, attempted methods [none publickey] is prompted during deployment

During deployment, component packages are uploaded to the remote host and the initialization is performed. This process requires connecting to the remote host. This error is caused by the failure to find the SSH private key to connect to the remote host.

To solve this issue, confirm whether you have specified the private key by running `tiup`
↪ `cluster deploy -i identity_file`:

- If the `-i` flag is not specified, it might be that TiUP does not automatically find the private key path. It is recommended to explicitly specify the private key path using `-i`.
- If the `-i` flag is specified, it might be that TiUP cannot log in to the remote host using the specified private key. You can verify it by manually executing the `ssh -i`
↪ `identity_file user@remote` command.
- If a password is used to log in to the remote host, make sure that you have specified the `-p` flag and entered the correct login password.

11.4.6.2.2 The process of upgrading the cluster using the TiUP cluster component is interrupted

To avoid misuse cases, the TiUP cluster component does not support the upgrade of specified nodes, so after the upgrade fails, you need to perform the upgrade operations again, including idempotent operations during the upgrade process.

The upgrade process can be divided into the following steps:

1. Back up the old version of components on all nodes
2. Distribute new components to remote
3. Perform a rolling restart to all components

If the upgrade is interrupted during a rolling restart, instead of repeating the `tiup cluster upgrade` operation, you can use `tiup cluster restart -N <node1> -N <node2>` to restart the nodes that have not completed the restart.

If the number of un-restarted nodes of the same component is relatively large, you can also restart a certain type of component by running `tiup cluster restart -R <component>`.

11.4.6.2.3 During the upgrade, you find that `node_exporter-9100.service/blackbox_exporter` does not exist

If you previously migrated your cluster from TiDB Ansible and the exporter was not deployed in TiDB Ansible, this situation might happen. To solve it, you can manually copy the missing files from other nodes to the new node for the time being. The TiUP team will complete the missing components during the migration process.

11.4.7 Command Reference

11.4.7.1 TiUP Reference

TiUP serves as the package manager of the TiDB ecosystem. It manages components in the TiDB ecosystem, such as TiDB, PD, and TiKV.

11.4.7.1.1 Syntax

```
tiup [flags] <command> [args...] # Executes a command
#### or
tiup [flags] <component> [args...] # Runs a component
```

You can use the `--help` command to get the information of a specific command. The summary of each command shows its parameters and their usage. Mandatory parameters are shown in angle brackets, and optional parameters are shown in square brackets.

`<command>` represents the command name. For the list of supported commands, see the [Command list](#) below. `<component>` represents the component name. For the list of supported components, see the [Component list](#) below.

11.4.7.1.2 Options

`-binary`

- If you enable this option, the specified binary file path is printed.
 - Executing `tiup --binary <component>` will have the path of the latest stable installed `<component>` component printed. If `<component>` is not installed, an error is returned.

- Executing `tiup --binary <component>:<version>` will have the path of the installed `<component>` component's `<version>` printed. If this `<version>` is not printed, an error is returned.

- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Note:

This option can only be used in commands of the `tiup [flags] <component ↵>` `> [args...]` format.

`-binpath`

Note:

This option can only be used in commands of the `tiup [flags] <component ↵>` `> [args...]` format.

- Specifies the path of the component to be executed. When a component is executed, if you do not want to use the binary file in the TiUP mirror, you can add this option to specify using the binary file in a custom path.
- Data type: `STRING`

`-skip-version-check`

Note:

This option is deprecated since v1.3.0.

- Skips the validity check for version numbers. By default, the specified version number can only be the semantic version.
- Data type: `BOOLEAN`

- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-T, --tag`

- Specifies a tag for the component to be started. Some components need to use disk storage during the execution, and TiUP allocates a temporary storage directory for this execution. If you want TiUP to allocate a fixed directory, you can use `-T/--tag` to specify the name of the directory, so that the same batch of files can be read and written in multiple executions with the same tag.
- Data type: `STRING`

`-v, --version`

Prints the TiUP version.

`-help`

Prints the help information.

11.4.7.1.3 Command list

TiUP has multiple commands, and these commands have multiple sub-commands. For the specific commands and their detailed descriptions, click the corresponding links in the list below:

- [install](#): Installs a component.
- [list](#): Shows the component list.
- [uninstall](#): Uninstalls a component.
- [update](#): Updates the installed component.
- [status](#): Shows the running status of a component.
- [clean](#): Cleans the data directory of a component.
- [mirror](#): Manages the mirror.
- [telemetry](#): Enables or disables the telemetry.
- [completion](#): Completes the TiUP command.
- [env](#): Shows the TiUP-related environment variables.
- [help](#): Shows the help information of a command or component.

11.4.7.1.4 Component list

- [cluster](#): Manages the TiDB cluster in a production environment.
- [dm](#): Manages the TiDB Data Migration (DM) cluster in a production environment.

11.4.7.2 TiUP Commands

11.4.7.2.1 tiup clean

The `tiup clean` command is used to clear the data generated during component operation.

Syntax

```
tiup clean [name] [flags]
```

The value of `[name]` is the `Name` field output by the `status` command. If `[name]` is omitted, you must add the `--all` option in the `tiup clean` command.

Option

`-all`

- Clears all operation records
- Data type: Boolean
- Default: false

Output

```
Clean instance of `%s`, directory: %s
```

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.2 tiup completion

To reduce user costs, TiUP provides the `tiup completion` command to generate a configuration file for automatic command-line completion. Currently, TiUP supports completing `bash` and `zsh` commands.

If you want to complete `bash` commands, you need to install `bash-completion` first. See the following instructions:

- On macOS: If your `bash` version is earlier than 4.1, run `brew install bash-completion`; otherwise, run `brew install bash-completion@2`.
- On Linux: Use a package manager to install `bash-completion`. For example, run `yum install bash-completion` or `apt install bash-completion`.

Syntax

```
tiup completion <shell>
```

`<shell>` is used to set the type of shell you use. Currently, `bash` and `zsh` are supported.

Usage

`bash`

Write the `tiup completion bash` command into a file and source the file in `.bash_profile`. See the following example:

```
tiup completion bash > ~/.tiup.completion.bash

printf "
##### tiup shell completion
source '$HOME/.tiup.completion.bash'
" >> $HOME/.bash_profile

source $HOME/.bash_profile
```

zsh

```
tiup completion zsh > "${fpath[1]}/_tiup"
```

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.3 tiup env

TiUP provides users with flexible and customized interfaces, some of which are implemented using environment variables. The `tiup env` command is used to query the user-defined environment variables that TiUP supports and their values.

Syntax

```
tiup env [name1...N]
```

[name1...N] is used to view the specified environment variables. If it is not specified, all supported environment variables are viewed by default.

Option

None

Output

- If [name1...N] is not specified, a list of “{key}”=“{value}” is output.
- If [name1...N] is specified, the “{value}” list is output in order.

In the above output, if value is empty, it means that the value of the environment variable is not set. In this case, TiUP uses the default value.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.4 tiup help

The TiUP command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option.

Syntax

```
tiup help [command]
```

[command] is used to specify the help information of which command that users need to view. If it is not specified, the help information of TiUP is viewed.

Option

None

Output

The help information of [command] or TiUP.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.5 tiup install

The `tiup install` command is used for component installation. It downloads the component package of a specified version from the mirror repository and decompresses it in the local TiUP data directory for later use. In addition, when TiUP needs to run a component that does not exist in the mirror repository, it tries to download the component first and then runs it automatically. If the component does not exist in the repository, an error is reported.

Syntax

```
tiup install <component1>[:version] [component2...N] [flags]
```

<component1> and <component2> represent component names, and [version] represents an optional version number. If `version` is not added, the latest stable version of the specified component is installed. [component2...N] means that you can specify multiple components or multiple versions of the same component at the same time.

Option

None

Output

- Normally outputs the download information of the component.
- If the component does not exist, the `The component "%s" not found` error is reported.
- If the version does not exist, the `version %s not supported by component %s` error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.6 tiup list

The command `tiup list` is used to get the list of available components of a mirror.

Syntax

```
tiup list [component] [flags]
```

[component] is an optional parameter used to specify a certain component. If [component] is set, TiUP lists all versions of the specified component; if not, TiUP lists all components.

Options

`-all`

- Displays all components. By default, TiUP does not show hidden components.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-installed`

- Only displays components and versions that have been installed.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-verbose`

- Displays installed component versions in the components list.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Outputs

- If [component] is not set:
 - If `--verbose` is specified: TiUP outputs a component information list consisting of **Name** (component name), **Installed** (installed versions), **Owner** (component owner), and **Description** (component description).

- If `--verbose` is not specified: TiUP outputs a component information list consisting of **Name** (component name), **Owner** (component owner), and **Description** (component description).
- If `[component]` is set:
 - If the specified component exists: TiUP outputs a version information list of the specified component, consisting of **Version** (version number), **Installed** (installation status), **Release** (release date), and **Platforms** (supported platforms).
 - If the specified component does not exist: TiUP reports the error `failed to ↪ fetch component: unknown component`.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.7 tiup mirror

tiup mirror

In TiUP, **mirror** is an important concept. TiUP currently supports two forms of mirroring:

- **Local mirror**: the TiUP client and the mirror are on the same machine, and the client accesses the mirror through the file system.
- **Remote mirror**: the TiUP client and the mirror are not on the same machine, and the client accesses the mirror through network.

The `tiup mirror` command is used to manage mirrors and provides ways to create mirrors, distribute components, and manage keys.

Syntax

```
tiup mirror <command> [flags]
```

`<command>` stands for sub-commands. For the list of supported sub-commands, refer to the [command list](#) below.

Option

None

Command list

- **genkey**: generates the private key file
- **sign**: signs a specific file using a private key file
- **init**: initiates an empty mirror
- **set**: sets the current mirror
- **grant**: grants a new component owner for the current mirror
- **publish**: publishes new components to the current mirror

- **modify**: modifies the attributes of the components in the current mirror
- **rotate**: updates the root certificate in the current mirror
- **clone**: clones a new mirror from an existing one
- **merge**: merges mirrors

[<< Back to the previous page - TiUP Reference command list](#)

tiup mirror clone

The command `tiup mirror clone` is used to clone an existing mirror or clone some of its components to create a new mirror. The new mirror has the same components as the old one, but uses a different signature key.

Syntax

```
tiup mirror clone <target-dir> [global version] [flags]
```

- `<target-dir>` is used to set the local path to the cloned mirror. If the path does not exist, TiUP automatically creates one.
- If `[global version]` is specified, TiUP tries to clone all components of the specified version. If some components do not have the specified version, then TiUP clones its latest version.

Options

`-f, -full`

- Whether to clone the whole mirror. If this option is set, other options becomes ignored and TiUP completely clones all components of all versions from the targeted mirror.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-a, -arch`

- Only clones components that can run on the specified platform.
- Data type: **STRING**
- Default: `"amd64,arm64"`

`-o, -os`

- Only clones components that can run on the specified operating system.
- Data type: **STRING**
- Default: `"linux,darwin"`

-prefix

- Whether to only match the prefix of versions. By default, TiUP downloads a component version when it is strictly matched. If this option is set, TiUP also downloads component versions of which prefixes are matched.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

-{component}

- Specifies the version list of the component to be cloned. Fill component names in `{component}`. You can run `tiup list --all` to view available component names.
- Data type: Strings
- Default: Null

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror genkey`

TiUP `mirror`, according its definition, has three roles of users:

- Mirror administrators: They have the permission to modify `root.json`, `index.json`, `snapshot.json`, and `timestamp.json`.
- Component owners: They have the permission to modify the corresponding component.
- Normal users: They can download and use the components.

Because TiUP requires the signature of the corresponding owner/administrator to modify a file, owners/administrators must have his or her own private key. The command `tiup ↪ mirror genkey` is used to generate a private key.

Warning:

DO NOT transmit private keys over the Internet.

Syntax

```
tiup mirror genkey [flags]
```

Options

-n, -name

- Specifies the name of the key, which also determines the name of the final generated file. The path of the generated private key file is `${TIUP_HOME}/keys/{name}.json`. `TIUP_HOME` refers to the home directory of TiUP, which is `$HOME/.tiup` by default. `name` refers to the private key name that `-n/--name` specifies.
- Data type: `STRING`
- Default: “private”

`-p, --public`

- Shows the corresponding public key of the private key specified in the option `-n/--name`.
↪ `name`.
- TiUP does not create a new private key when `-p/--public` is specified. If the private key specified in `-n/--name` does not exist, TiUP returns an error.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`--save`

- Saves the information of the public key as a file in the current directory. The file name is `{hash-prefix}-public.json`. `hash-prefix` is the first 16 bits of the key ID.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `-p/--public` is not specified:
 - If the private key specified in `-n/--name` exists: TiUP outputs `Key already exists, skipped`.
↪ `exists, skipped`.
 - If the private key specified in `-n/--name` does not exist: TiUP outputs `private key have been write to ${TIUP_HOME}/keys/{name}.json`.
↪ `key have been write to ${TIUP_HOME}/keys/{name}.json`.
- If `-p/--public` is specified:
 - If the private key specified in `-n/--name` does not exist: TiUP reports the error `Error: open ${TIUP_HOME}/keys/{name}.json: no such file or directory`.
↪ `directory`.
 - If the private key specified in `-n/--name` exists: TiUP outputs the content of the corresponding public key.

[<< Back to the previous page - TiUP Mirror command list](#)

tiup mirror grant

The `tiup mirror grant` command is used to introduce a component owner to the current mirror.

Component owners can use their keys to publish new components or to modify components they previously published. Before adding a new component owner, the component owner to be added needs to send his or her own public key to the mirror administrator.

Note:

This command is only supported when the current mirror is a local mirror.

Syntax

```
tiup mirror grant <id> [flags]
```

`<id>` stands for the component owner's ID, which must be unique in the whole mirror. It is recommended to use an ID that matches the regular expression `^[a-z\d](?:[a-z\d]|\s|-|_|(?=[a-z\d])){0,38}$`.

Options

`-k, -key`

- Specifies the key of the introduced component owner. This key can either be public or private. If it is a private key, TiUP converts it to the corresponding public key before storing it in the mirror.
- A key can be used by only one component owner.
- Data type: `STRING`
- Default: “`${TIUP_HOME}/keys/private.json`”

`-n, -name`

- Specifies the name of the component owner. The name is displayed on the `Owner` field of the component list. If `-n/--name` is not specified, `<id>` is used as the component owner's name.
- Data type: `STRING`
- Default: `<id>`

Outputs

- If the command is executed successfully, there is no output.

- If the component owner's ID is duplicated, TiUP reports the error `Error: owner %s ↪ exists.`
- If the key is used by another component owner, TiUP reports the error `Error: key ↪ %s exists.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror init`

The command `tiup mirror init` is used to initialize an empty mirror. The initialized mirror does not contain any components or component owners. The command only generates the following files for the initialized mirror:

```
+ <mirror-dir>                # Mirror's root directory
|-- root.json                 # Mirror's root certificate
|-- 1.index.json              # Component/user index
|-- snapshot.json             # Mirror's latest snapshot
|-- timestamp.json            # Mirror's latest timestamp
|--+ keys                      # Mirror's private key (can be
    ↪ moved to other locations)
  |-- {hash1..hashN}-root.json # Private key of the root
    ↪ certificate
  |-- {hash}-index.json        # Private key of the indexes
  |-- {hash}-snapshot.json     # Private key of the snapshots
  |-- {hash}-timestamp.json    # Private key of the timestamps
```

For the specific usage and content format of the above files, refer to [TiUP Mirror Reference Guide](#).

Syntax

```
tiup mirror init <path> [flags]
```

`<path>` is used to specify a local directory where TiUP generates and stores mirror files. The local directory can be a relative path. If the specified directory already exists, it must be empty; if it does not exist, TiUP creates it automatically.

Options

`-k, --key-dir`

- Specifies the directory where TiUP generates private key files. If the specified directory does not exist, TiUP automatically creates it.
- Data type: `STRING`
- If this option is not specified in the command, TiUP generates private key files in `{path}/keys` by default.

Outputs

- If the command is executed successfully, there is no output.
- If the specified <path> is not empty, TiUP reports the error `Error: the target path ↪ '%s' is not an empty directory.`
- If the specified <path> is not a directory, TiUP reports the error `Error: fdopendir: ↪ not a directory.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror merge`

The `tiup mirror merge` command is used to merge one or more mirrors to the current mirror.

To execute this command, the following conditions must be met:

- The owner IDs of all components of the target mirror exist in the current mirror.
- The `/${TIUP_HOME}/keys` directory of the user who executes this command contains all the private keys corresponding to the above owner IDs in the current mirror (you can use the command `tiup mirror set` to switch the current mirror to the mirror that is currently authorized to modify).

Syntax

```
tiup mirror merge <mirror-dir-1> [mirror-dir-N] [flags]
```

- `<mirror-dir-1>`: the first mirror to be merged into the current mirror
- `[mirror-dir-N]`: the Nth mirror to be merged into the current mirror

Option

None

Outputs

- If the command is executed successfully, there is no output.
- If the current mirror does not have a component owner of the target mirror, or if `/${TIUP_HOME}/keys` does not have the owner's private key, TiUP reports the `Error: ↪ missing owner keys for owner %s on component %s error.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror modify`

The `tiup mirror modify` command is used to modify published components. Only valid component owners can modify the components that they have published on their own. For the method to publish a component, refer to the [publish command](#).

Syntax

```
tiup mirror modify <component>[:version] [flags]
```

Each parameter is explained as follows:

- **<component>**: the component name
- **[version]**: the component version to modify. If it is not specified, the entire component is modified.

Options

-k, -key

- Specifies the component owner's private key used for signing the component information (`{component}.json`).
- Data type: **STRING**
- If this option is not specified in the command, "`#{TIUP_HOME}/keys/private.json`" is used by default to sign the component information.

-yank

Marks a specified component or version as unavailable.

- After the component is marked as unavailable, you can neither see it in the result list of `tiup list` nor install the new version of the component.
- After a component version is marked as unavailable, you can neither see it in the result list of `tiup list <component>` nor install this version.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

-hide

- Specifies whether to hide the component. If a component is hidden, you cannot see it in the result list of `tiup list`. To see the hidden component, you can use `tiup list ↪ --all`.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

Note:

This option can only be applied to the component, not to the component version.

–standalone

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Note:

This option can only be applied to the component, not to the component version.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
 - If the mirror is a remote mirror, TiUP reports the error `Error: The server ↪ refused, make sure you have access to this component.`
 - If the mirror is a local mirror, TiUP reports the error `Error: the signature ↪ is not correct.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror publish`

The command `tiup mirror publish` is used to publish a new component or a new version of an existing component. Only component owner that has the access to the target component can publish it. To add a new component owner, see the usage of the [grant command](#).

Syntax

```
tiup mirror publish <comp-name> <version> <tarball> <entry> [flags]
```

The meaning of each parameter is as follows:

- **<comp-name>**: The name of the components, such as `tidb`. It is recommended to use a string that matches the regular expression `^[a-z\d](?:[a-z\d]|-(?=[a-z\d])|↔){0,38}$`.
- **<version>**: The version of the component to be published. The version number needs to follow the requirements of [Semantic Versioning](#).
- **<tarball>**: The local directory of the `.tar.gz` package. You need to put dependencies and the executable file of the component in this package. TiUP uploads this package to the mirror.
- **<entry>**: The location of the component's executable file in `<tarball>`.

Options

`-k, --key`

- Specifies the component owner's private key. The client uses the private key to sign `{component}.json` files.
- Data type: `STRING`
- Default: `"${TIUP_HOME}/keys/private.json"`

`--arch`

- Specifies the platform on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the platform from the following options:
 - `amd64`: Indicates that the files run on AMD64 machines.
 - `arm64`: Indicates that the files run on ARM64 machines.
 - `any`: Indicates that the files, such as scripts, run on both AMD64 and ARM64 machines.
- Data type: `STRING`
- Default: `"${GOARCH}"`

Note:

If `--arch` is set to `any`, then `--os` must be set to `any` as well.

`--os`

- Specifies the operating system on which the binary files in `<tarball>` can run. For a single `<tarball>` package, you can only choose the operating system from the following options:
 - `linux`: Indicates that the files run on the Linux operating system.
 - `darwin`: Indicates that the files run on the Darwin operating system.
 - `any`: Indicates that the files, such as scripts, run on both the Linux and Darwin operating systems.
- Data type: `STRING`
- Default: “`${GOOS}`”

Note:

If `--os` is set to `any`, then `--arch` must be set to `any` as well.

`-desc`

- Specifies the description of the component.
- Data type: `String`
- Default: `NULL`

`-hide`

- Specifies whether the component is hidden. If it is a hidden component, it can be seen in the result list of `tiup list -all`, but not in that of `tiup list`.
- Data type: `STRING`
- Default: `NULL`

`-standalone`

- Controls whether the component can run standalone. This option is currently **NOT available**.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command is executed successfully, there is no output.
- If the component owner is not authorized to modify the target component:
 - If the mirror is a remote mirror, TiUP reports the error `Error: The server ↪ refused, make sure you have access to this component.`
 - If the mirror is a local mirror, TiUP reports the error `Error: the signature ↪ is not correct.`

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror rotate`

`root.json` is an important file in a TiUP mirror. It stores the public keys needed for the entire system and is the basis of the chain of trust in TiUP. It mainly contains the following parts:

- Signatures of mirror administrators. For the official mirror, there are five signatures. For an initialized mirror, there are three signatures by default.
- The public keys used to verify the following files:
 - `root.json`
 - `index.json`
 - `snapshot.json`
 - `timestamp.json`
- Expiration date of `root.json`. For the official mirror, the expiration date is one year later than the creation date of `root.json`.

For detailed description of TiUP mirror, see [TiUP Mirror Reference](#).

You need to update `root.json` in the following cases:

- Replace the key of the mirror.
- Update the expiration date of certificate files.

After the content of `root.json` is updated, the file must be re-signed by all administrators; otherwise, the client rejects the file. The update process is as follows:

1. The user (client) updates the content of `root.json`.
2. All administrators sign the new `root.json` file.
3. `tiup-server` updates `snapshot.json` to record the version of the new `root.json` file.
4. `tiup-server` signs the new `snapshot.json` file.
5. `tiup-server` updates `timestamp.json` to record the hash value of the new `snapshot.json` file.
6. `tiup-server` signs the new `timestamp.json` file.

TiUP uses the command `tiup mirror rotate` to automate the above process.

Note:

- For TiUP versions earlier than v1.5.0, running this command does not return a correct new `root.json` file. See [#983](#).
- Before using this command, make sure that all TiUP clients are upgraded to v1.5.0 or a later version.

Syntax

```
tiup mirror rotate [flags]
```

After executing this command, TiUP starts an editor for the user to modify the file content to the target value, such as changing the value of the `expires` field to a later date. Then, TiUP changes the `version` field from `N` to `N+1` and saves the file. After the file is saved, TiUP starts a temporary HTTP server and waits for all mirror administrators to sign the file.

For how mirror administrators sign files, refer to the [sign command](#).

Options

`-addr`

- Specifies the listening address of the temporary server. You need to make sure that the address is accessible to other mirror administrators so that they can use the [sign command](#) to sign the file.
- Data type: `STRING`
- If this option is not specified in the command, TiUP listens on `0.0.0.0:8080` by default.

Outputs

The current signature status of each mirror administrator.

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror set`

The `tiup mirror set` command is used to switch the current mirror and supports two forms of mirrors: local file system and remote network address.

The address of the official mirror is <https://tiup-mirrors.pingcap.com>.

Syntax

```
tiup mirror set <mirror-addr> [flags]
```

<mirror-addr> is the mirror address, which has two forms:

- Network address: starts with `http` or `https`. For example, `http://172.16.5.5:8080`, `https://tiup-mirrors.pingcap.com`.
- Local file path: the absolute path of the mirror directory. For example, `/path/to/`
↪ `local-tiup-mirror`.

Option

`-r, -root`

This option specifies the root certificate.

As the most critical part of mirror security, the root certificate of each mirror is different from one another. When you use the network mirror, it might suffer from man-in-the-middle attacks. To avoid such attacks, it is recommended to manually download the root certificate of the root network mirror to the local:

```
wget <mirror-addr>/root.json -O /path/to/local/root.json
```

Perform a manual check to ensure that the root certificate is correct, and then switch the mirror by manually specifying the root certificate:

```
tiup mirror set <mirror-addr> -r /path/to/local/root.json
```

In the steps above, if the mirror is attacked before the `wget` command, you can find that the root certificate is incorrect. If the mirror is attacked after the `wget` command, TiUP will find that the mirror does not match the root certificate.

- Data type: `String`
- Default: `{mirror-dir}/root.json`

Output

None

[<< Back to the previous page - TiUP Mirror command list](#)

`tiup mirror sign`

The `tiup mirror sign` command is used to sign the metadata files (*.json) defined in TiUP `mirror`. These metadata files might be stored on the local file system or remotely stored using the HTTP protocol to provide a signature entry.

Syntax

```
tiup mirror sign <manifest-file> [flags]
```

<manifest-file> is the address of the file to be signed, which has two forms:

- Network address, which starts with HTTP or HTTPS, such as `http://172.16.5.5:8080/rotate/root.json`
- Local file path, which is a relative path or an absolute path

If it is a network address, this address must provide the following features:

- Supports the access via `http get` that returns the complete content of the signed file (including the `signatures` field).
- Supports the access via `http post`. The client adds the signature to the `signatures` field of the content that is returned by `http get` and posts to this network address.

Options

`-k, -key`

- Specifies the location of the private key used for signing the `{component}.json` file.
- Data type: `STRING`
- - If this option is not specified in the command, `"${TIUP_HOME}/keys/private.json"` is used by default.

`-timeout`

- Specifies the access timeout time for signing through the network. The unit is in seconds.
- Data type: `INT`
- Default: 10

Note:

This option is valid only when `<manifest-file>` is a network address.

Output

- If the command is executed successfully, there is no output.
- If the file has been signed by the specified key, TiUP reports the error `Error: this manifest file has already been signed by specified key.`
- If the file is not a valid manifest, TiUP reports the error `Error: unmarshal manifest : %s.`

[<< Back to the previous page - TiUP Mirror command list](#)

11.4.7.2.8 tiup status

The `tiup status` command is used to view the operation information of the components after you run the components using the `tiup [flags] <component> [args...]` command.

Note:

You can only check the information of the following components:

- Components that are still in operation
- Components that run through the tag specified by `tiup -T/--tag`

Syntax

```
tiup status [flags]
```

Option

None

Output

A table consisting of the following fields:

- **Name:** The tag name specified by `-T/--tag`. If not specified, it is a random string.
- **Component:** The operating components.
- **PID:** The corresponding process ID of the operating components.
- **Status:** The status of the operating components.
- **Created Time:** The starting time of the components.
- **Directory:** The data directory of the components.
- **Binary:** The binary file path of the components.
- **Args:** The starting arguments of the operating components.

Component status

A component can run in one of the following statuses:

- **Up:** The component is running normally.
- **Down or Unreachable:** The component is not running or a network problem exists on the corresponding host.
- **Tombstone:** The data on the component has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- **Pending Offline:** The data on the component is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- **Unknown:** The running status of the component is unknown.

Note:

Pending Offline in TiUP, Offline returned by PD API, and Leaving in TiDB Dashboard indicate the same status.

Component status derives from the PD scheduling information. For more details, see [Information collection](#).

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.9 tiup telemetry

TiDB, TiUP, and TiDB Dashboard collect usage information by default and share the information with PingCAP to improve the product. For example, through this usage information, PingCAP learns about common TiDB cluster operations and thereby determines the priority of new features.

When TiUP telemetry is enabled, usage information is shared with PingCAP when TiUP commands are executed, including (but not limited to):

- Randomly generated telemetry identifiers.
- The execution status of the TiUP command, such as whether the command execution is successful and the duration of command execution.
- Situations using TiUP for deployment, such as target machine hardware information, component version number, and modified deployment configuration name.

The information below is not shared:

- The accurate name of the cluster
- The cluster topology
- The cluster configuration file

TiUP uses the `tiup telemetry` command to control telemetry.

Note:

This feature is enabled by default.

Syntax

```
tiup telemetry <command>
```

<command> stands for sub-commands. For the list of supported sub-commands, refer to the commands section below.

Commands

status

The `tiup telemetry status` command is used to view the current telemetry settings and output the following information:

- **status:** specifies enabling or disabling the telemetry (`enable|disable`).
- **uuid:** specifies the randomly generated telemetry identifiers.

reset

The `tiup telemetry reset` command is used to reset the current telemetry identifier and replaces it with a new random identifier.

enable

The `tiup telemetry enable` command is used to enable the telemetry.

disable

The `tiup telemetry disable` command is used to disable the telemetry.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.10 tiup uninstall

The `tiup uninstall` command is used to uninstall the installed components.

Syntax

```
tiup uninstall <component1>:<version> [component2...N] [flags]
```

- **<component1>:** the name of the component to uninstall.
- **<version>:** the version to uninstall. If this field is omitted, all installed versions of the component are uninstalled. For security reasons, the `--all` option must be added when `<version>` is omitted, indicating that all versions of a component need to be uninstalled.
- **[component2...N]:** multiple components or versions to uninstall.

Options

`-all`

- Uninstalls all installed versions of the specified component(s). You must use this option when `<version>` is omitted.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`--self`

- Uninstalls TiUP itself. When this option is used, all data downloaded from the mirror is deleted, but the data generated by TiUP and its components is retained. The data is stored in the directory specified by the `TIUP_HOME` environment variable. If `TIUP_HOME` is not set, the default value is `~/.tiup/`.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the command exits without any error, `Uninstalled component "%s" successfully`
↪ `!` is output.
- If neither `<version>` nor `--all` is specified, the Use `"tiup uninstall tidbx --all`
↪ `"` if you want to remove all versions. error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.2.11 `tiup update`

The `tiup update` command is used to update the installed components or TiUP itself.

Syntax

```
tiup update [component1][:version] [component2..N] [flags]
```

- `[component1]`: the name of the component to update.
- `[version]`: the version to update. If this field is omitted, it means updating to the latest stable version of the component.
- `[component2..N]`: specifies updating multiple components or versions. If no component is specified, which means `[component1][:version] [component2..N]` is empty, you need to use the `--all` or the `--self` option together.

The update operation does not delete the old version. You can still specify using the old version during execution.

Options

`--all`

- If no component is specified, this option must be specified.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-force`

- If the specified version of the component is already installed, the update operation is skipped by default. Specifying this option will have the installed version forcibly updated.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-nightly`

- Updates the specified components to the nightly version. The `tiup update` command with this option is equivalent to the `tiup update <component>:nightly` command.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-self`

- Updates TiUP itself.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If the update is successful, `Updated successfully!` is output.
- If target version does not exist, the `Error: version %s not supported by`
→ `component %s` error is reported.

[<< Back to the previous page - TiUP Reference command list](#)

11.4.7.3 TiUP Cluster Commands

11.4.7.3.1 TiUP Cluster

TiUP Cluster is a cluster management component of TiUP written in Golang. You can use the TiUP Cluster component to perform daily operations and maintenance, including deploying, starting, shutting down, destroying, elastic scaling, upgrading TiDB clusters, and managing TiDB cluster parameters.

Syntax

```
tiup cluster [command] [flags]
```

[command] is the name of the command. For the supported commands, refer to the [command list](#) below.

Options

–ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: **STRING**
- Supported values:
 - **builtin**: uses the easyssh client built in tiup-cluster as the SSH client.
 - **system**: uses the default SSH client of the current operating system.
 - **none**: The SSH client is not used. The deployment is only for the current machine.
- If this option is not specified in the command, **builtin** is used as the default value.

–ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: **UINT**
- If this option is not specified in the command, the default timeout is 5 seconds.

–wait-timeout

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying systemctl to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: **UINT**
- If this option is not specified in the command, the maximum waiting time for each step is 120 seconds.

-y, -yes

- Skips the secondary confirmation of all risky operations. Using this option is not recommended, unless you are using a script to call TiUP.
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-v, -version

- Prints the current version of TiUP Cluster.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, -help

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- `import`: imports a cluster deployed by Ansible
- `template`: outputs the topology template
- `check`: checks a cluster before and after the deployment
- `deploy`: deploys a cluster based on a specified topology
- `list`: queries the list of deployed clusters
- `display`: displays the status of a specified cluster
- `start`: starts a specified cluster
- `stop`: stops a specified cluster
- `restart`: restarts a specified cluster
- `scale-in`: scales in a specified cluster
- `scale-out`: scales out a specified cluster
- `upgrade`: upgrades a specified cluster
- `prune`: cleans up the instances in the Tombstone status for a specified cluster
- `edit-config`: modifies the configuration of a specified cluster
- `reload`: reloads the configuration of a specified cluster
- `patch`: replaces a service in a deployed cluster
- `rename`: renames a cluster
- `clean`: deletes data from the specified cluster
- `destroy`: destroys a specified cluster
- `audit`: queries the operation audit log of a specified cluster

- **replay**: retries the specified command
- **enable**: enables the auto-enabling of the cluster service after a machine is restarted.
- **disable**: disables the auto-enabling of the cluster service after a machine is restarted.
- **help**: prints the help information

[<< Back to the previous page - TiUP Reference component list](#)

11.4.7.3.2 tiup cluster audit

The `tiup cluster audit` command is used to view commands executed on all clusters in the history and the execution log of each command.

Syntax

```
tiup cluster audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, it means checking the execution log of the specified `audit-id`.

Option

`-h, -help`

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- If `[audit-id]` is specified, the corresponding execution log is output.
- If `[audit-id]` is not specified, a table with the following fields is output:
 - `ID`: the `audit-id` corresponding to the record
 - `Time`: the execution time of the command corresponding to the record
 - `Command`: the command corresponding to the record

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.3 tiup cluster audit cleanup

The `tiup cluster audit cleanup` command is used to clean up the logs generated in executing the `tiup cluster` command.

Syntax

```
tiup cluster audit cleanup [flags]
```

Options

`-retain-days`

- Specifies the days for which logs are retained.
- Data type: `INT`
- Default value: `60`, in the unit of day.
- By default, logs generated within the last 60 days are retained, which means logs generated before 60 days are removed.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

```
clean audit log successfully
```

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.4 tiup cluster check

For a formal production environment, before the environment goes live, you need to perform a series of checks to ensure the clusters are in their best performance. To simplify the manual check steps, TiUP Cluster provides the `check` command to check whether the hardware and software environments of the target machines of a specified cluster meet the requirements to work normally.

List of check items

Operating system version

Check the operating system distribution and version of the deployed machines. Currently, only CentOS 7 is supported for deployment. More system versions may be supported in later releases for compatibility improvement.

CPU EPOLLEXCLUSIVE

Check whether the CPU of the target machine supports EPOLLEXCLUSIVE.

numactl

Check whether numactl is installed on the target machine. If tied cores are configured on the target machine, you must install numactl.

System time

Check whether the system time of the target machine is synchronized. Compare the system time of the target machine with that of the central control machine, and report an error if the deviation exceeds a certain threshold (500ms).

Time synchronization service

Check whether the time synchronization service is configured on the target machine. Namely, check whether ntpd is running.

Swap partitioning

Check whether swap partitioning is enabled on the target machine. It is recommended to disable swap partitioning.

Kernel parameters

Check the values of the following kernel parameters:

- net.ipv4.tcp_tw_recycle: 0
- net.ipv4.tcp_syncookies: 0
- net.core.somaxconn: 32768
- vm.swappiness: 0
- vm.overcommit_memory: 0 or 1
- fs.file-max: 1000000

Transparent Huge Pages (THP)

Check whether THP is enabled on the target machine. It is recommended to disable THP.

System limits

Check the limit values in the `/etc/security/limits.conf` file:

```
<deploy-user> soft nofile 1000000
<deploy-user> hard nofile 1000000
<deploy-user> soft stack 10240
```

`<deploy-user>` is the user who deploys and runs the TiDB cluster, and the last column is the minimum value required for the system.

SELinux

Check whether SELinux is enabled. It is recommended to disable SELinux.

Firewall

Check whether the FirewallD service is enabled. It is recommended to either disable the FirewallD service or add permission rules for each service in the TiDB cluster.

irqbalance

Check whether the irqbalance service is enabled. It is recommended to enable the irqbalance service.

Disk mount options

Check the mount options for ext4 partitions. Make sure the mount options include the `nodelalloc` option and the `noatime` option.

Port usage

Check if the ports defined in the topology (including the auto-completion default ports) are already used by the processes on the target machine.

Note:

The port usage check assumes that a cluster is not started yet. If a cluster is already deployed and started, the port usage check on the cluster fails because the ports must be in use in this case.

CPU core number

Check the CPU information of the target machine. For a production cluster, it is recommended that the number of the CPU logical core is greater than or equal to 16.

Note:

CPU core number is not checked by default. To enable the check, you need to add the `-enable-cpu` option to the command.

Memory size

Check the memory size of the target machine. For a production cluster, it is recommended that the total memory capacity is greater than or equal to 32GB.

Note:

Memory size is not checked by default. To enable the check, you need to add the `-enable-mem` option to the command.

Fio disk performance test

Use flexible I/O tester (fio) to test the performance of the disk where `data_dir` is located, including the following three test items:

- `fio_randread_write_latency`
- `fio_randread_write`
- `fio_randread`

Note:

The fio disk performance test is not performed by default. To perform the test, you need to add the `-enable-disk` option to the command.

Syntax

```
tiup cluster check <topology.yml | cluster-name> [flags]
```

- If a cluster is not deployed yet, you need to pass the `topology.yml` file that is used to deploy the cluster. According to the content in this file, `tiup-cluster` connects to the corresponding machine to perform the check.
- If a cluster is already deployed, you can use the `<cluster-name>` as the check object.

Note:

If `<cluster-name>` is used for the check, you need to add the `--cluster` option in the command.

Options

`-apply`

- Attempts to automatically repair the failed check items. Currently, tiup-cluster only attempts to repair the following check items:
 - SELinux
 - firewall
 - irqbalance
 - kernel parameters
 - System limits
 - THP (Transparent Huge Pages)
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

`--cluster`

- Indicates that the check is for the deployed clusters.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

Note:

tiup-cluster supports checking both un-deployed clusters and deployed clusters with the following command format:

```
tiup cluster check <topology.yml | cluster-name> [flags]
```

If the `tiup cluster check <cluster-name>` command is used, you must add the `--cluster` option: `tiup cluster check <cluster-name> --cluster`.

`-N, --node`

- Specifies the nodes to be checked. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all nodes are checked by default.

Note:

If the `-R`, `--role` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are checked.

`-R, --role`

- Specifies the roles to be checked. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are checked by default.

Note:

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are checked.

`--enable-cpu`

- Enables the check of CPU core number.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`--enable-disk`

- Enables the fio disk performance test.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`--enable-mem`

- Enables the memory size check.
- Data type: `BOOLEAN`

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-u, --user`

- Specifies the user name to connect to the target machine. The specified user needs to have the password-free sudo root privileges on the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the user who executes the command is used as the default value.

Note:

This option is valid only if the `-cluster` option is false. Otherwise, the value of this option is fixed to the username specified in the topology file for the cluster deployment.

`-i, --identity_file`

- Specifies the key file to connect to the target machine.
- Data type: `STRING`
- The option is enabled by default with `~/.ssh/id_rsa` (the default value) passed in.

Note:

This option is valid only if the `--cluster` option is false. Otherwise, the value of this option is fixed to `${TIUP_HOME}/storage/cluster/clusters ↪ /<cluster-name>/ssh/id_rsa`.

`-p, --password`

- Logs in with a password when connecting to the target machine.
 - If the `--cluster` option is added for a cluster, the password is the password of the user specified in the topology file when the cluster was deployed.
 - If the `--cluster` option is not added for a cluster, the password is the password of the user specified in the `-u/--user` option.
- Data type: `BOOLEAN`

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, -help`

- Prints the help information of the related commands.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table containing the following fields:

- **Node:** the target node
- **Check:** the check item
- **Result:** the check result (Pass, Warn, or Fail)
- **Message:** the result description

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.5 `tiup cluster clean`

In the test environment, sometimes you might need to reset the cluster back to the state as it has been just deployed, which means deleting all data. You can do that easily using the `tiup cluster clean` command. After running it, the cluster is stopped and then cluster data is deleted. After restarting the cluster manually, you will get a clean cluster.

Warning:

This command will first stop the cluster even if you choose only to clean up logs. Therefore, do not use it in a production environment.

Syntax

```
tiup cluster clean <cluster-name> [flags]
```

`<cluster-name>` is the cluster to clean.

Options

`-all`

- Cleans data and the log at the same time. It is equivalent to specifying `--data` and `--log` at the same time.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.
- If it is not specified, you must specify at least one of the following options:
 - `-data`: Cleans data
 - `-log`: Cleans the log

`-data`

- Cleans data. If neither of it nor `--all` is specified, data will not be cleaned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-log`

- Cleans the log. If neither of it nor `--all` is specified, the log will not be cleaned.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`--ignore-node`

- Specifies the node that does not need cleaning. To specify multiple nodes, you can use this option multiple times. For example, `--ignore-node <node-A> --ignore-node <node-B>`.
- Data type: `StringArray`
- Default: empty

`--ignore-role`

- Specifies the role that does not need cleaning. To specify multiple roles, you can use this option multiple times. For example, `--ignore-role <role-A> --ignore-role <role-B>`.
- Data type: `StringArray`
- Default: empty

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution logs of `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.6 `tiup cluster deploy`

The `tiup cluster deploy` command is used to deploy a new cluster.

Syntax

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.
- `<version>`: the version number of the TiDB cluster to deploy, such as `v5.4.3`.
- `<topology.yaml>`: the prepared [topology file](#).

Options

`-u, -user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

`-i, -identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

`-p, -password`

- Specifies the password used to connect to the target machine. Do not use this option with `-i/--identity_file` at the same time.

- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-ignore-config-check`

- This option is used to skip the configuration check. After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration.
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.
- Default: **false**

`-no-labels`

- This option is used to skip the label check.
- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD cannot learn the cluster topology, so PD might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See [Schedule Replicas by Topology Labels](#) for label configuration.
- For the test environment, this risk might matter and you can use `--no-labels` to skip the check.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-skip-create-user`

- During the cluster deployment, `tiup-cluster` checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: **BOOLEAN**
- This option is disabled by default and its default value is **false**. To enable this option, you can add this option to the command, and pass the **true** value or do not pass any value.

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The deployment log.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.7 tiup cluster destroy

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup cluster destroy` command performs the following operations:

- Stops the cluster.
- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by `tiup-cluster`, also delete the parent directory.

Syntax

```
tiup cluster destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to destroy.

Options

`-force`

- In some cases, some nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to ignore these errors.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-retain-node-data`

- Specifies the nodes that need to retain data. If you need to specify more than one node, use this option multiple times: `--retain-node-data <node-A> --retain-node-data ↵ <node-B>`.

- Data type: `StringArray`
- Default: empty

`-retain-role-data`

- Specifies the role that needs to retain data. If you need to specify more than one role, use this option multiple times: `--retain-role-data <role-A> --retain-role-data <role-B>`.
- Data type: `StringArray`
- Default: empty

`-h, -help`

- Prints the help information.
- Data type: `Boolean`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.8 `tiup cluster disable`

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup cluster disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup cluster disable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be disabled.

Options

`-N, -node`

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`

- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

Note:

If the `-R`, `--role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is disabled.

`-R, --role`

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

Note:

If the `-N`, `--node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is disabled.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.9 tiup cluster display

If you want to see the operation status of each component in the cluster, it is obviously inefficient to log in to each machine one by one. Therefore, `tiup-cluster` provides the `tiup cluster display` command to efficiently complete this task.

Syntax

```
tiup cluster display <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

Options

`-dashboard`

- By default, all node information of the entire cluster is displayed. With the `--dashboard` option, only dashboard information is displayed.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-N, --node`

- Specifies the node to display. If this option is not specified, all nodes are displayed. The value of this option is a comma-separated list of node IDs. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are checked by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are checked.

`-R, --role`

- Specifies the role to display. If it is not specified, all roles are displayed. The value of this option is a comma-separated list of node roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.

- Data type: `STRINGS`
- If this option is not specified in the command, all roles are displayed by default.

Note:

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are displayed.

`-process`

- Displays the CPU and memory usage information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-uptime`

- Displays the `uptime` information of the node when this option is enabled. This option is disabled by default.
- Data type: `BOOLEAN`
- Default value: `false`
- To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

`-status-timeout`

- Specifies the timeout period for obtaining the node status information.
- Data type: `INT`
- Default value: `10`, in the unit of second.

`-h`, `-help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

- The cluster name
- The cluster version
- SSH Client Type
- Dashboard address
- The table with the following fields:
 - ID: the node ID, composed of IP:PORT
 - Role: the service role deployed on this node (such as TiDB, TiKV)
 - Host: the IP of the machine corresponding to the node
 - Ports: the port number occupied by the service
 - OS/Arch: the operating system and the machine architecture of this node
 - Status: the current status of the node service
 - Data Dir: the data directory of the service. - means no data directory.
 - Deploy Dir: the deployment directory of the service

Node service status

A node service can run in one of the following statuses:

- Up: The node service is running normally.
- Down or Unreachable: The node service is not running or a network problem exists on the corresponding host.
- Tombstone: The data on the node service has been completely migrated out and the scaling-in is complete. This status exists only on TiKV or TiFlash.
- Pending Offline: The data on the node service is being migrated out and the scaling-in is in process. This status exists only on TiKV or TiFlash.
- Unknown: The running status of the node service is unknown.

Note:

Pending Offline in TiUP, Offline returned by PD API, and Leaving in TiDB Dashboard indicate the same status.

Node service status derives from the PD scheduling information. For more details, see [Information collection](#).

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.10 tiup cluster edit-config

If you need to modify the cluster configuration after the cluster is deployed, you can use the `tiup cluster edit-config` command that starts an editor for you to modify the [topology file](#) of a cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

Note:

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see [Scale out a cluster](#). For how to delete machines, see [Scale in a cluster](#).
- After you execute the `tiup cluster edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup cluster reload` command to reload the configuration.

Syntax

```
tiup cluster edit-config <cluster-name> [flags]
```

`<cluster-name>` is the cluster to operate on.

Option

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Output

- If the command is successfully executed, there is no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error will be reported, reminding you to edit the file again. For the fields that cannot be modified, see the [topology file](#).

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.11 tiup cluster enable

The `tiup cluster enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

Note:

When all clusters are shut down and restarted, the order of service startup is determined by the node's operating system startup order. When the restart order is incorrect, in some cases, the restarted cluster still cannot provide services. For example, if TiKV is started first but PD is not started, systemd gives up if TiKV is restarted multiple times while PD is not found).

Syntax

```
tiup cluster enable <cluster-name> [flags]
```

`<cluster-name>`: the cluster whose service auto-enabling is to be enabled.

Options

`-N, --node`

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

Note:

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is enabled.

`-R, --role`

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup cluster display` command.

- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

Note:

If the `-N`, `--node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is enabled.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.12 `tiup cluster help`

`tiup-cluster` provides a wealth of help information for users in the command line interface. You can obtain it via the `help` command or the `--help` option. `tiup cluster help <command>` \leftrightarrow `command` is basically equivalent to `tiup cluster <command> --help`.

Syntax

```
tiup cluster help [command] [flags]
```

`[command]` is used to specify the help information of which command that users need to view. If it is not specified, the help information of `tiup-cluster` is viewed.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The help information of the `[command]` or `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.13 tiup cluster import

Before TiDB v4.0, TiDB clusters were mainly deployed using TiDB Ansible. For TiDB v4.0 and later releases, TiUP Cluster provides the `import` command to transfer the clusters to the `tiup-cluster` component for management.

Note:

- After importing the TiDB Ansible configuration to TiUP for management, **DO NOT** use TiDB Ansible for cluster operations anymore. Otherwise, conflicts might be caused due to inconsistent meta information.
- If the clusters deployed using TiDB Ansible are in any of the following situations, do not use the `import` command.
 - Clusters with TLS encryption enabled
 - Pure KV clusters (clusters without TiDB instances)
 - Clusters with Kafka enabled
 - Clusters with Spark enabled
 - Clusters with TiDB Lightning/TiKV Importer enabled
 - Clusters still using the old `push` mode to collect monitoring metrics (if you keep the default mode `pull` unchanged, using the `import` command is supported)
 - Clusters in which the non-default ports (the ports configured in the `group_vars` directory are compatible) are separately configured in the `inventory.ini` configuration file using `node_exporter_port` / `blackbox_exporter_port`
- If some nodes in the cluster deployed using TiDB Ansible are deployed without monitoring components, you should first use TiDB Ansible to add the corresponding node information in the `monitored_servers` section of the `inventory.ini` file, and then use the `deploy.yaml` playbook to fully deploy monitoring components. Otherwise, when you perform maintenance operations after the cluster is imported into TiUP, errors might occur due to the lack of monitoring components.

Syntax

```
tiup cluster import [flags]
```

Options

`-d, -dir`

- Specifies the directory where TiDB Ansible is located.

- Data type: `STRING`
- The option is enabled by default with the current directory (the default value) passed in.

`-ansible-config`

- Specifies the path of the Ansible configuration file.
- Data type: `STRING`
- The option is enabled by default with `./ansible.cfg` (the default value) passed in.

`-inventory`

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- The option is enabled by default with `inventory.ini` (the default value) passed in.

`-no-backup`

- Controls whether to disable the backup of files in the directory where TiDB Ansible is located.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. After a successful import, everything in the directory specified by the `-dir` option is backed up to the `/${TIUP_HOME}/.tiup/storage/cluster/clusters/{cluster-name}/ansible-backup` directory. If there are multiple inventory files (when multiple clusters are deployed) in this directory, it is recommended to enable this option. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-rename`

- Renames the imported cluster.
- Data type: `STRING`
- Default: `NULL`. If this option is not specified in the command, the `cluster_name` specified in inventory is used as the cluster name.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the import process.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.14 tiup cluster list

tiup-cluster supports deploying multiple clusters using the same control machine. The `tiup cluster list` command outputs all clusters deployed by the currently logged-in user using this control machine.

Note:

The deployed cluster data is stored in the `~/.tiup/storage/cluster/` → `clusters/` directory by default, so on the same control machine, the currently logged-in user cannot view the clusters deployed by other users.

Syntax

```
tiup cluster list [flags]
```

Options

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default and its default value is `false`. To enable this option, you can add this option to the command, and pass the `true` value or do not pass any value.

Outputs

Outputs the table with the following fields:

- Name: the cluster name
- User: the deployment user
- Version: the cluster version
- Path: the path of the cluster deployment data on the control machine
- PrivateKey: the path of the private key that is used to connect the cluster

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.15 tiup cluster patch

If you need to dynamically replace the binaries of a service while the cluster is running (namely, keep the cluster available during the replacement process), you can use the `tiup` → `cluster patch` command. After the command is executed, TiUP does the following things:

- Uploads the binary package for replacement to the target machine.
- If the target service is a storage service such as TiKV, TiFlash, or TiDB Binlog, TiUP first takes the related nodes offline via the API.
- Stops the target service.
- Unpacks the binary package and replace the service.
- Starts the target service.

Syntax

```
tiup cluster patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated.
- `<package-path>`: The path to the binary package used for replacement.

Preparation

You need to pack the binary package required for this command in advance according to the following steps:

- Determine the name `#{component}` of the component to be replaced (tidb, tikv, pd...), the `#{version}` of the component (v4.0.0, v4.0.1 ...), and the operating system `#{os}` (linux) and platform `#{arch}` on which the component runs.
- Download the current component package using the command `wget https://tiup-mirrors.pingcap.com/#{component}-#{version}-#{os}-#{arch}.tar.gz -O /tmp/#{component}-#{version}-#{os}-#{arch}.tar.gz`.
- Run `mkdir -p /tmp/package && cd /tmp/package` to create a temporary directory to pack files.
- Run `tar xf /tmp/#{component}-#{version}-#{os}-#{arch}.tar.gz` to unpack the original binary package.
- Run `find .` to view the file structure in the temporary package directory.
- Copy the binary files or configuration files to the corresponding locations in the temporary directory.
- Run `tar czf /tmp/#{component}-hotfix-#{os}-#{arch}.tar.gz *` to pack the files in the temporary directory.
- Finally, you can use `/tmp/#{component}-hotfix-#{os}-#{arch}.tar.gz` as the `<package-path>` in the `tiup cluster patch` command.

Options

`-overwrite`

- After you patch a certain component (such as TiDB or TiKV), when the tiup cluster scales out the component, TiUP uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.

- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-transfer-timeout`

- When restarting the PD or TiKV service, TiKV/PD first transfers the leader of the node to be restarted to another node. Because the transfer process takes some time, you can use the option `--transfer-timeout` to set the maximum waiting time (in seconds). After the timeout, TiUP directly restarts the service.
- Data type: `UINT`
- If this option is not specified, TiUP directly restarts the service after waiting for 300 seconds.

Note:

If TiUP directly restarts the service after the timeout, the service performance might jitter.

`-N, --node`

- Specifies nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node ID from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any nodes to replace by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

`-R, --role`

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the role deployed on a node from the second column of the `cluster status table` returned by the `tiup cluster display` command.

- Data type: `STRINGS`
- If this option is not specified, TiUP does not select any roles to replace by default.

Note:

If the option `-N`, `--node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N`, `--node` and `-R`, `--`
↪ `role`.

`-offline`

- Declares that the current cluster is not running. When the option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.16 tiup cluster prune

When [scaling in the cluster](#), for some components, TiUP does not immediately stop their services or delete their data. You need to wait for the data scheduling to complete and then manually execute the `tiup cluster prune` command to clean up.

Syntax

```
tiup cluster prune <cluster-name> [flags]
```

Option

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of the cleanup process.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.17 `tiup cluster reload`

After [modifying the cluster configuration](#), the cluster needs to be reloaded using the `tiup cluster reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running, and follows the upgrade process to restart the services in order according to the upgrade process. The cluster is still available during the restart process.

Syntax

```
tiup cluster reload <cluster-name> [flags]
```

`<cluster-name>`: the cluster name to operate on.

Options

`-force`

- Ignores errors in the reloading process and forces reload.
- Data type: `BOOLEAN`
- Default: `false`

`-transfer-timeout`

- When restarting PD or TiKV, the leader of the restarted node is migrated to other nodes first, and the migration process takes some time. You can set the maximum wait time (in seconds) by setting `-transfer-timeout`. After the timeout, the service can be restarted directly without waiting.
- Data type: `UINT`
- Default: `300`

Note:

In the case of skipping the waiting and restarting directly, the service performance might jitter.

`-ignore-config-check`

- After the binary files of components are deployed, the configurations of TiDB, TiKV, and PD components are checked using `<binary> --config-check <config-file>`. `<binary>` is the path of the deployed binary file. `<config-file>` is the configuration file generated based on the user configuration. If you want to skip this check, you can use this option.
- Data type: **BOOLEAN**
- Default: `false`

`-N, --node`

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all nodes are selected by default.

Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

`-R, --role`

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. The role is the second column of the `cluster status` table.
- Data type: **STRINGS**
- If this option is not specified in the command, all roles are selected by default.

Note:

1. If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are restarted.
2. If the `--skip-restart` option is specified, the `-R`, `--role` option is invalid.

`--skip-restart`

The `tiup cluster reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: `false`

`-h`, `--help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.18 `tiup cluster rename`

The cluster name is specified when [the cluster is deployed](#). If you want to change the cluster name after the cluster is deployed, you can use the command `tiup cluster rename`.

Note:

If the `dashboard_dir` field of `grafana_servers` is configured for the TiUP cluster, after you execute the command `tiup cluster rename` to rename the cluster, the following additional steps are required:

- For the *.json files in the local dashboards directory, update the `datasource` field of each file to the new cluster name, because the value of `datasource` must be the name of the cluster.
- Execute the command `tiup cluster reload -R grafana`.

Syntax

```
tiup cluster rename <old-cluster-name> <new-cluster-name> [flags]
```

- `<old-cluster-name>`: The old cluster name.
- `<new-cluster-name>`: The new cluster name.

Options

`-h, -help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The execution log of the `tiup-cluster`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.19 tiup cluster replay

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup cluster replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup cluster replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-ids` using the `tiup cluster audit` command.

Option

-h, -help

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.20 tiup cluster restart

The command `tiup cluster restart` is used to restart all or some of the services of the specified cluster.

Note:

During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup cluster restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

Options

-N, -node

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

-R, -role

- Specified the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

Note:

If the option `-N`, `--node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-h`, `-help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the service restart process.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.21 tiup cluster scale-in

The `tiup cluster scale-in` command is used to scale in the cluster, which takes the services of the specified nodes offline, removes the specified nodes from the cluster, and deletes the remaining files from those nodes.

Particular handling of components' offline process

Because the TiKV, TiFlash, and TiDB Binlog components are taken offline asynchronously (which requires TiUP to remove the node through API first) and the stopping process takes a long time (which requires TiUP to continuously check whether the node is successfully taken offline), the TiKV, TiFlash, and TiDB Binlog components are handled particularly as follows:

- For TiKV, TiFlash and, TiDB Binlog components:
 1. TiUP Cluster takes the node offline through API and directly exits without waiting for the process to be completed.

2. To check the status of the nodes being scaled in, you need to execute the `tiup` \leftrightarrow `cluster display` command and wait for the status to become `Tombstone`.
3. To clean up the nodes in the `Tombstone` status, you need to execute the `tiup` \leftrightarrow `cluster prune` command. The `tiup cluster prune` command performs the following operations:
 - Stops the services of the nodes that have been taken offline.
 - Cleans up the data files of the nodes that have been taken offline.
 - Updates the cluster topology and removes the nodes that have been taken offline.

For other components:

- When taking the PD components offline, TiUP Cluster quickly deletes the specified nodes from the cluster through API, stops the service of the specified PD nodes, and then deletes the related data files from the nodes.
- When taking other components down, TiUP Cluster directly stops the node services and deletes the related data files from the specified nodes.

Syntax

```
tiup cluster scale-in <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to scale in. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

`-N, -node`

- Specifies the nodes to take down. Multiple nodes are separated by commas.
- Data type: `STRING`
- There is no default value. This option is mandatory and the value must be not null.

`-force`

- Controls whether to forcibly remove the specified nodes from the cluster. Sometimes, the host of the node to take offline might be down, which makes it impossible to connect to the node via SSH for operations, so you can forcibly remove the node from the cluster using the `-force` option.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Warning:

When you use this option to forcibly remove TiKV or TiFlash nodes that are in service or are pending offline, these nodes will be deleted immediately without waiting for data to be migrated. This imposes a high risk of data loss. Therefore, it is recommended to use this option only on down nodes.

`-transfer-timeout`

- When a PD or TiKV node is to be removed, the Region leader on the node will be transferred to another node first. Because the transferring process takes some time, you can set the maximum waiting time (in seconds) by configuring `--transfer-timeout`. After the timeout, the `tiup cluster scale-in` command skips waiting and starts the scaling-in directly.
- Data type: `UINT`
- The option is enabled by default with 300 seconds (the default value) passed in.

Note:

If a PD or TiKV node is taken offline directly without waiting for the leader transfer to be completed, the service performance might jitter.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Shows the logs of the scaling-in process.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.22 `tiup cluster scale-out`

The `tiup cluster scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-cluster` component first establishes an SSH connection to the new node, creates the necessary directories on the target node, then performs the deployment and starts the service.

When PD is scaled out, new PD nodes are added to the cluster by the join operation, and the configuration of the services associated with PD is updated; other services are directly started and added to the cluster.

Syntax

```
tiup cluster scale-out <cluster-name> <topology.yaml> [flags]
```

<cluster-name>: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

<topology.yaml>: the prepared [topology file](#). This topology file should only contain the new nodes that are to be added to the current cluster.

Options

-u, --user

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: **STRING**
- Default: the current user who executes the command.

-i, --identity_file

- Specifies the key file used to connect to the target machine.
- Data type: **STRING**
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, --password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: **BOOLEAN**
- Default: `false`

--no-labels

- This option is used to skip the label check.
- When two or more TiKV nodes are deployed on the same physical machine, a risk exists: PD does not know the cluster topology, so it might schedule multiple replicas of a Region to different TiKV nodes on one physical machine, which makes this physical machine a single point of failure. To avoid this risk, you can use labels to tell PD not to schedule the same Region to the same machine. See [Schedule Replicas by Topology Labels](#) for label configuration.

- For the test environment, this risk might not matter, and you can use `--no-labels` to skip the check.
- Data type: `BOOLEAN`
- Default: `false`

`-skip-create-user`

- During the cluster deployment, `tiup-cluster` checks whether the specified user name in the topology file exists or not. If not, it creates one. To skip this check, you can use the `--skip-create-user` option.
- Data type: `BOOLEAN`
- Default: `false`

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of scaling out.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.23 `tiup cluster start`

The `tiup cluster start` command is used to start all services or some services of the specified cluster.

Syntax

```
tiup cluster start <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

`-N, -node`

- Specifies the nodes to be started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started by default.

Note:

If the `-R`, `--role` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are started.

`-R`, `--role`

- Specifies the roles of nodes to be started. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the [cluster status table](#) returned by the `tiup cluster display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started by default.

Note:

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are started.

`-h`, `--help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of starting the service.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.24 `tiup cluster stop`

The `tiup cluster stop` command is used to stop all services or some services of the specified cluster.

Note:

If the core services of a cluster are stopped, the cluster cannot provide services anymore.

Syntax

```
tiup cluster stop <cluster-name> [flags]
```

<cluster-name> is the name of the cluster to operate on. If you forget the cluster name, you can check it using the `tiup cluster list` command.

Options

-N, --node

- Specifies the nodes to be stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the command stops all the nodes by default.

Note:

If the `-R`, `--role` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are stopped.

-R, --role

- Specifies the roles of nodes to be stopped. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the `cluster status table` returned by the `tiup cluster display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the command stops all the roles by default.

Note:

If the `-N`, `--node` option is specified at the same time, only the service nodes that match both the specifications of `-N`, `--node` and `-R`, `--role` are stopped.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

The log of stopping the service.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.25 tiup cluster template

Before deploying the cluster, you need to prepare a [topology file](#) of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup cluster ↵ template` command.

Syntax

```
tiup cluster template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 PD instances
- 3 TiKV instances
- 1 TiDB instance
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

`-full`

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

`-multi-dc`

- Outputs the topology template of multiple data centers. To enable this option, add it to the command.
- If this option is not specified, the topology template of a single data center is output by default.

`-h, -help`

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.3.26 `tiup cluster upgrade`

The `tiup cluster upgrade` command is used to upgrade the specified cluster to a specific version.

Syntax

```
tiup cluster upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>`: the cluster name to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.
- `<version>`: the target version to upgrade to. Currently, it is only allowed to upgrade to a version higher than the current cluster, that is, no downgrade is allowed. It is also not allowed to upgrade to the nightly version.

Options

`-force`

- To upgrade the cluster, you need to ensure that the cluster is currently started. In some cases, you might want to upgrade when the cluster is not started. At this time, you can use `--force` to ignore the error during the upgrade, forcibly replace the binary file and start the cluster.
- Data type: `BOOLEAN`
- Default: `false`

Note:

Forcing an upgrade of the cluster that is providing services might result in service unavailability. Unstarted clusters are started automatically after a successful upgrade.

`-transfer-timeout`

- When upgrading PD or TiKV, the leader of the upgraded node is migrated to other nodes first. The migration process takes some time, and you can set the maximum wait time (in seconds) by the `-transfer-timeout` option. After the timeout, the wait is skipped and the service is upgraded directly.
- Data type: `uint`
- Default: 300

Note:

If the wait is skipped and the service is upgraded directly, the service performance might jitter.

`-ignore-config-check`

- After the binary is updated, a configuration check is performed on the TiDB, TiKV and PD components using `<binary> --config-check <config-file>`. `<binary>` is the path to the newly deployed binary and `<config-file>` is the configuration file generated based on the user configuration. To skip this check, you can use the `--↔ ignore-config-check` option.
- Data type: `BOOLEAN`
- Default: `false`

`-offline`

- Declares that the current cluster is not running. When this option is specified, TiUP does not evict the service leader to another node or restart the service, but only replaces the binary files of the cluster components.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

-h, -help

- Prints the help information.
- Data type: **BOOLEAN**
- Default: false

Output

The log of the upgrading progress.

[<< Back to the previous page - TiUP Cluster command list](#)

11.4.7.4 TiUP DM Commands

11.4.7.4.1 TiUP DM

Similar to [TiUP Cluster](#) which is used to manage TiDB clusters, TiUP DM is used to manage DM clusters. You can use the TiUP DM component to perform daily operations and maintenance tasks of DM clusters, including deploying, starting, stopping, destroying, elastic scaling, upgrading DM clusters, and managing the configuration parameters of DM clusters.

Syntax

```
tiup dm [command] [flags]
```

[command] is used to pass the name of the command. See the [Command list](#) for supported commands.

Options

-ssh

- Specifies the SSH client to connect to the remote end (the machine where the TiDB service is deployed) for the command execution.
- Data type: **STRING**
- Support values:
 - **builtin**: Uses the built-in easyssh client of tiup-cluster as the SSH client.
 - **system**: Uses the default SSH client of the current operating system.
 - **none**: No SSH client is used. The deployment is only for the current machine.
- If this option is not specified in the command, **builtin** is used as the default value.

-ssh-timeout

- Specifies the SSH connection timeout in seconds.
- Data type: `UINT`
- If this option is not specified in the command, the default timeout is 5 seconds.

`-wait-timeout`

- Specifies the maximum waiting time (in seconds) for each step in the operation process. The operation process consists of many steps, such as specifying `systemctl` to start or stop services, and waiting for ports to be online or offline. Each step may take several seconds. If the execution time of a step exceeds the specified timeout, the step exits with an error.
- Data type: `UINT`
- If this option is not specified in the command, the maximum waiting time for each steps is 120 seconds.

`-y`, `-yes`

- Skips the secondary confirmation of all risky operations. It is not recommended to use this option unless you use a script to call TiUP.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-v`, `-version`

- Prints the current version of TiUP DM.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-h`, `-help`

- Prints help information about the specified command.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Command list

- `import`: Imports a DM v1.0 cluster deployed by DM-Ansible.
- `template`: Outputs the topology template.
- `deploy`: Deploys a cluster based on a specified topology.

- **list**: Queries the list of deployed clusters.
- **display**: Displays the status of a specified cluster.
- **start**: Starts a specified cluster.
- **stop**: Stops a specified cluster.
- **restart**: Restarts a specified cluster.
- **scale-in**: Scales in a specified cluster.
- **scale-out**: Scales out a specified cluster.
- **upgrade**: Upgrades a specified cluster.
- **prune**: Cleans up instances in the Tombstone status for a specified cluster.
- **edit-config**: Modifies the configuration of a specified cluster.
- **reload**: Reloads the configuration of a specified cluster.
- **patch**: Replaces a specified service in a deployed cluster.
- **destroy**: Destroys a specified cluster.
- **audit**: Queries the operation audit log of a specified cluster.
- **replay**: Replays the specified commands
- **enable**: Enables the auto-enabling of the cluster service after a machine is restarted.
- **disable**: Disables the auto-enabling of the cluster service after a machine is restarted.
- **help**: Prints help information.

[<< Back to the previous page - TiUP Reference component list](#)

11.4.7.4.2 tiup dm audit

The `tiup dm audit` command is used to view historical commands executed on all clusters and the execution log of each command.

Syntax

```
tiup dm audit [audit-id] [flags]
```

- If you do not fill in the `[audit-id]`, the table of operation records is output in reverse chronological order. The first column is the `audit-id`.
- If you fill in the `[audit-id]`, the execution log of the specified `audit-id` is checked.

Option

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

- If `[audit-id]` is specified, the corresponding execution log is output.

- If [audit-id] is not specified, a table with the following fields is output:
 - ID: the audit-id corresponding to this record
 - Time: the execution time of the command corresponding to the record
 - Command: the command corresponding to the record

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.3 tiup dm deploy

The `tiup dm deploy` command is used to deploy a new cluster.

Syntax

```
tiup dm deploy <cluster-name> <version> <topology.yaml> [flags]
```

- `<cluster-name>`: the name of the new cluster, which cannot be the same as the existing cluster names.
- `<version>`: the version number of the DM cluster to be deployed, such as `v2.0.0`.
- `<topology.yaml>`: the prepared [topology file](#).

Options

`-u, -user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: `STRING`
- Default: the current user who executes the command.

`-i, -identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: `STRING`
- Default: `~/.ssh/id_rsa`

`-p, -password`

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: `false`

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The deployment log.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.4 `tiup dm destroy`

After an application goes offline, if you want to release the machines occupied by the cluster for use by other applications, you need to clean up the data on the cluster and the deployed binary files. To destroy the cluster, the `tiup dm destroy` command performs the following operations:

- Stops the cluster.
- For each service, delete its log directory, deployment directory, and data directory.
- If the parent directory of the data directory or deployment directory of each service is created by `tiup-dm`, also delete the parent directory.

Syntax

```
tiup dm destroy <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to be destroyed.

Option

`-h, -help`

- Prints the help information.
- Data type: `Boolean`
- Default: `false`

Output

The execution log of the `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.5 `tiup dm disable`

After restarting the machine on which the cluster service is located, the cluster service will be automatically enabled. To disable the auto-enabling of cluster service, you can use the `tiup dm disable` command. This command executes `systemctl disable <service>` on the specified node to disable the auto-enabling of the service.

Syntax

```
tiup dm disable <cluster-name> [flags]
```

<cluster-name> is the cluster whose service auto-enabling is to be disabled.

Options

-N, --node

- Specifies the nodes whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is disabled by default.

Note:

If the `-R, --role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-R, --role

- Specifies the roles whose service auto-enabling is to be disabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all roles is disabled by default.

Note:

If the `-N, --node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N, --node` and `-R, --role` is disabled.

-h, --help

Prints the help information.

Output

The execution log of the `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.6 tiup dm display

If you want to check the operational status of each component in a DM cluster, it is inefficient to log in to each machine one by one. Therefore, `tiup-dm` provides the `tiup dm ↪ display` command to do this job efficiently.

Syntax

```
tiup dm display <cluster-name> [flags]
```

`<cluster-name>` is the name of the cluster to be operated. If you forget the cluster name, you can check it using the `tiup dm list` command.

Options

`-N, --node`

- Specifies the IDs of the nodes to query, splitting by commas for multiple nodes. If you are not sure about the ID of a node, you can skip this option in the command to show the IDs and status of all nodes in the output.
- Data type: **STRING**
- This option is enabled by default with `[]` (which means all nodes) passed in.

Note:

If `-R, --role` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

`-R, --role`

- Specifies the roles to query, splitting by commas for multiple roles. If you are not sure about the role deployed on a node, you can skip this option in the command to show the roles and status of all nodes in the output.
- Data type: **STRING**
- This option is enabled by default with `[]` (which means all roles) passed in.

Note:

If `-N, --node` is also specified, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are queried.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

- Cluster name
- Cluster version
- SSH client type
- A table containing the following fields:
 - `ID`: the node ID, consisting of `IP:PORT`.
 - `Role`: the service role deployed on the node (for example, TiDB or TiKV).
 - `Host`: the IP address of the machine corresponding to the node.
 - `Ports`: the port number used by the service.
 - `OS/Arch`: the operating system and machine architecture of the node.
 - `Status`: the current status of the services on the node.
 - `Data Dir`: the data directory of the service. `-` means that there is no data directory.
 - `Deploy Dir`: the deployment directory of the service.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.7 `tiup dm edit-config`

If you need to modify the cluster service configuration after the cluster is deployed, you can use the `tiup dm edit-config` command that starts an editor for you to modify the [topology file](#). of the specified cluster. This editor is specified in the `$EDITOR` environment variable by default. If the `$EDITOR` environment variable does not exist, the `vi` editor is used.

Note:

- When you modify the configuration, you cannot add or delete machines. For how to add machines, see [Scale out a cluster](#). For how to delete machines, see [Scale in a cluster](#).
- After you execute the `tiup dm edit-config` command, the configuration is modified only on the control machine. Then you need to execute the `tiup dm reload` command to reload the configuration.

Syntax

```
tiup dm edit-config <cluster-name> [flags]
```

<cluster-name>: the cluster to operate on.

Option

-h, -help

- Prints the help information.
- Data type: **BOOLEAN**
- Default: false

Output

- Normally, no output.
- If you have mistakenly modified the fields that cannot be modified, when you save the file, an error is reported, reminding you to edit the file again. For the fields that cannot be modified, see [the topology file](#).

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.8 tiup dm enable

The `tiup dm enable` command is used to set the auto-enabling of the cluster service after a machine is restarted. This command enables the auto-enabling of the service by executing `systemctl enable <service>` at the specified node.

Syntax

```
tiup dm enable <cluster-name> [flags]
```

<cluster-name> is the cluster whose service auto-enabling is to be enabled.

Options

-N, -node

- Specifies the nodes whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, the auto-enabling of all nodes is enabled by default.

Note:

If the `-R`, `--role` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is enabled.

`-R`, `--role`

- Specifies the roles whose service auto-enabling is to be enabled. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, the auto-enabling of all roles is enabled by default.

Note:

If the `-N`, `--node` option is specified at the same time, the auto-enabling of services that match both the specifications of `-N`, `--node` and `-R`, `--role` is enabled.

`-h`, `--help`

Prints the help information.

Output

the execution log of `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.9 tiup dm help

`tiup-dm` command-line interface provides users with a wealth of help information. You can view it via the `help` command or the `--help` option. Basically, `tiup dm help <command>` \leftrightarrow `>` is equivalent to `tiup dm <command> --help`.

Syntax

```
tiup dm help [command] [flags]
```

[command] is used to specify the help information of which command that users need to view. If it is not specified, the help information of `tiup-dm` is viewed.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The help information of [command] or `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.10 `tiup dm import` Only for upgrading DM v1.0

This command is used only for upgrading DM clusters from v1.0 to v2.0 or later versions.

In DM v1.0, the cluster is basically deployed using TiDB Ansible. TiUP DM provides the `import` command to import v1.0 clusters and redeploy the clusters in DM v2.0.

Note:

- The command does not support importing DM Portal components from DM v1.0 clusters.
- Before importing the cluster, stop running the original cluster first.
- For data migration tasks that need to be upgraded to v2.0, do not execute `stop-task` on these tasks.
- The command only supports importing to DM v2.0.0-rc.2 and later versions.
- The `import` command is used to import a DM v1.0 cluster to a new DM v2.0 cluster. If you need to import data migration tasks to an existing v2.0 cluster, refer to [Manually Upgrade TiDB Data Migration from v1.0.x to v2.0+](#)
- The deployment directories of some components might be different from those in the original cluster. You can check it with the `display` command.
- Before importing the cluster, run `tiup update --self && tiup ↪ update dm` to upgrade TiUP DM components to the latest version.
- After the cluster is imported, there is only one DM-master node in the cluster. You can refer to [the scale out command](#) to scale out the DM-master node.

Syntax

```
tiup dm import [flags]
```

Options

`-v, --cluster-version`

- Specifies the version number for redeploying. You must use a version later than v2.0.0-rc.2 (including v2.0.0-rc.2).
- Data type: `STRING`
- This option is **required** to execute the command.

`-d, --dir`

- Specifies the directory of TiDB Ansible.
- Data type: `STRING`
- If this option is not specified in the command, the current directory is the default directory.

`--inventory`

- Specifies the name of the Ansible inventory file.
- Data type: `STRING`
- If this option is not specified in the command, the default file name is "inventory.
↔ `ini`".

`--rename`

- Renames the imported cluster.
- Data type: `STRING`
- If this option is not specified in the command, the default cluster name is the `cluster_name` specified in the inventory file.

`-h, --help`

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Outputs

The log of the importing process.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.11 tiup dm list

`tiup-dm` supports deploying multiple clusters using the same control machine. You can use the `tiup dm list` command to check which clusters are deployed using the control machine by the currently logged-in user.

Note:

By default, the data of the deployed clusters is stored in the `~/.tiup/storage` ↪ `/dm/clusters/` directory. The currently logged-in user cannot view the clusters deployed by other users on the same control machine.

Syntax

```
tiup dm list [flags]
```

Options

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

A table consisting of the following fields:

- **Name:** the cluster name.
- **User:** the user who deployed the cluster.
- **Version:** the cluster version.
- **Path:** the path of the cluster deployment data on the control machine.
- **PrivateKey:** the path of the private key to the cluster.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.12 Apply Hotfix to DM Clusters Online

If you need to dynamically replace the binaries of a service while the cluster is running (that is, to keep the cluster available during the replacement), you can use the `tiup dm` ↪ `patch` command. The command does the following:

- Uploads the binary package for replacement to the target machine.

- Takes the related nodes offline using the API.
- Stops the target service.
- Unpacks the binary package and replaces the service.
- Starts the target service.

Syntax

```
tiup dm patch <cluster-name> <package-path> [flags]
```

- `<cluster-name>`: The name of the cluster to be operated
- `<package-path>`: The path to the binary package used for replacement

Preparation

You need to pack the binary package required for this command in advance according to the following steps:

- Determine the name `${component}` of the component to be replaced (dm-master, dm-worker ...), the `${version}` of the component (v2.0.0, v2.0.1 ...), and the operating system `${os}` and platform `${arch}` on which the component runs.
- Download the current component package using the command `wget https://tiup-mirrors.pingcap.com/${component}-${version}-${os}-${arch}.tar.gz -O /tmp/${component}-${version}-${os}-${arch}.tar.gz`.
- Run `mkdir -p /tmp/package && cd /tmp/package` to create a temporary directory to pack files.
- Run `tar xf /tmp/${component}-${version}-${os}-${arch}.tar.gz` to unpack the original binary package.
- Run `find .` to view the file structure in the temporary package directory.
- Copy the binary files or configuration files to the corresponding locations in the temporary directory.
- Run `tar czf /tmp/${component}-hotfix-${os}-${arch}.tar.gz *` to pack the files in the temporary directory.
- Finally, you can use `/tmp/${component}-hotfix-${os}-${arch}.tar.gz` as the value of `<package-path>` in the `tiup dm patch` command.

Options

`-overwrite`

- After you patch a certain component (such as dm-worker), when the tiup-dm scales out the component, tiup-dm uses the original component version by default. To use the version that you patch when the cluster scales out in the future, you need to specify the option `--overwrite` in the command.
- Data type: BOOLEAN

- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

`-N, --node`

- Specifies the nodes to be replaced. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all nodes to replace by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

`-R, --role`

- Specifies the roles to be replaced. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP selects all roles to replace by default.

Note:

If the option `-N, --node` is specified at the same time, TiUP then replaces service nodes that match both the requirements of `-N, --node` and `-R, --role`.

`-offline`

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

-h, -help

- Prints help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Example

The following example shows how to apply `v5.3.0-hotfix` to the `v5.3.0` cluster deployed using TiUP. The operations might vary if you deploy the cluster using other methods.

Note:

Hotfix is used only for emergency fixes. Its daily maintenance is complicated. It is recommend that you upgrade the DM cluster to an official version as soon as it is released.

Preparations

Before applying a hotfix, prepare the hotfix package `dm-linux-amd64.tar.gz` and confirm the current DM software version:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0

Git Commit Hash: 20626babf21fc381d4364646c40dd84598533d66
Git Branch: heads/refs/tags/v5.3.0
UTC Build Time: 2021-11-29 08:29:49
Go Version: go version go1.16.4 linux/amd64
```

Prepare the patch package and apply it to the DM cluster

1. Prepare the DM software package that matches the current version:

```
mkdir -p /tmp/package
tar -zxvf /root/.tiup/storage/dm/packages/dm-master-v5.3.0-linux-amd64.
  ↪ tar.gz -C /tmp/package/
tar -zxvf /root/.tiup/storage/dm/packages/dm-worker-v5.3.0-linux-amd64.
  ↪ tar.gz -C /tmp/package/
```

2. Replace the binary file with the hotfix package:

```
# Decompress the hotfix package and use it to replace the binary file.
cd /root; tar -zxvf dm-linux-amd64.tar.gz
cp /root/dm-linux-amd64/bin/dm-master /tmp/package/dm-master/dm-master
cp /root/dm-linux-amd64/bin/dm-worker /tmp/package/dm-worker/dm-worker
# Re-package the modified files.
# Note that the packaging method might be different for other
  ↪ deployment methods.
cd /tmp/package/ && tar -czvf dm-master-hotfix-linux-amd64.tar.gz dm-
  ↪ master/
cd /tmp/package/ && tar -czvf dm-worker-hotfix-linux-amd64.tar.gz dm-
  ↪ worker/
```

3. Apply the hotfix:

Query the cluster status. The following uses the cluster named `dm-test` as an example:

```
tiup dm display dm-test
```

Output:

```
Cluster type:      dm
Cluster name:      dm-test
Cluster version:   v5.3.0
Deploy user:       tidb
SSH type:          builtin
ID                Role                Host                Ports                OS/Arch
  ↪ Status        Data Dir
--              ----
  ↪ -----
172.16.100.21:9093 alertmanager        172.16.100.21 9093/9094 linux/
  ↪ x86_64 Up      /home/tidb/dm/data/alertmanager-9093 /home/tidb/dm
  ↪ /deploy/alertmanager-9093
172.16.100.21:8261 dm-master           172.16.100.21 8261/8291 linux/
  ↪ x86_64 Healthy|L /home/tidb/dm/data/dm-master-8261 /home/tidb/dm/
  ↪ deploy/dm-master-8261
172.16.100.21:8262 dm-worker           172.16.100.21 8262      linux/x86_64
  ↪ Free      /home/tidb/dm/data/dm-worker-8262 /home/tidb/dm/deploy/

  ↪ Up        -                               /home/tidb/dm/deploy/
  ↪ grafana-3000
172.16.100.21:9090 prometheus           172.16.100.21 9090      linux/x86_64
  ↪ Up        /home/tidb/dm/data/prometheus-9090 /home/tidb/dm/deploy
  ↪ /prometheus-9090
Total nodes: 5
```

Apply the hotfix to the specified node or specified role. If both `-R` and `-N` are specified, the intersection will be taken.

```
# Apply hotfix to a specified node.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -N
  ↪ 172.16.100.21:8261
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -N
  ↪ 172.16.100.21:8262
# Apply hotfix to a specified role.
tiup dm patch dm-test dm-master-hotfix-linux-amd64.tar.gz -R dm-master
tiup dm patch dm-test dm-worker-hotfix-linux-amd64.tar.gz -R dm-worker
```

4. Query the hotfix application result:

```
/home/tidb/dm/deploy/dm-master-8261/bin/dm-master/dm-master -V
```

Output:

```
Release Version: v5.3.0-20211230
Git Commit Hash: ca7070c45013c24d34bd9c1e936071253451d707

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.13 tiup dm prune

When you scale in the cluster([/tiup/tiup-component-dm-scale-in.md](#)), a small amount of metadata in etcd is not cleaned up, which usually causes no problem. If you need to clean up the metadata, you can manually execute the `tiup dm prune` command.

Syntax

```
tiup dm prune <cluster-name> [flags]
```

Option

`-h, -help`

- Prints the help information.
- Data type: BOOLEAN
- Default: false

Output

The log of the cleanup process.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.14 tiup dm reload

After [modifying the cluster configuration](#), the cluster needs to be reloaded using the `tiup dm reload` command for the configuration to take effect. This command publishes the configuration of the control machine to the remote machine where the service is running and restarts the service in order according to the upgrade process. The cluster remains available during the restart process.

Syntax

```
tiup dm reload <cluster-name> [flags]
```

<cluster-name>: the name of the cluster to operate on.

Options

-N, --node

- Specifies the nodes to be restarted. If not specified, all nodes are restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all nodes are selected by default.

Note:

- If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-N, --node` option is invalid.

-R, --role

- Specifies the roles to be restarted. If not specified, all roles are restarted. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: **STRINGS**
- If this option is not specified in the command, all roles are selected by default.

Note:

- If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are restarted.
- If the `--skip-restart` option is specified, the `-R, --role` option is invalid.

--skip-restart

The `tiup dm reload` command performs two operations:

- Refreshes all node configurations
- Restarts the specified node

After you specify the `--skip-restart` option, it only refreshes the configuration without restarting any nodes, so that the refreshed configuration is not applied and does not take effect until the next restart of the corresponding service.

- Data type: `BOOLEAN`
- Default: `false`

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The execution log of the `tiup-dm`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.15 `tiup dm replay`

When you perform a cluster operation such as upgrade or restart, the operation might fail due to cluster environment issues. If you re-perform the operation, you need to perform all the steps from the very beginning. If the cluster is large, re-performing these steps will take a long time. In this case, you can use the `tiup dm replay` command to retry the failed commands and skip the successfully performed steps.

Syntax

```
tiup dm replay <audit-id> [flags]
```

- `<audit-id>`: the `audit-id` of the command to be retried. You can view the historical commands and their `audit-ids` using the `tiup dm audit` command.

Option

`-h, -help`

Prints the help information.

Output

The output of the command corresponding to `<audit-id>`.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.16 tiup dm restart

The command `tiup dm restart` is used to restart all or some of the services of the specified cluster.

Note:

During the restart process, the related services are unavailable for a period of time.

Syntax

```
tiup dm restart <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

Options

`-N, --node`

- Specifies the nodes to be restarted. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts all nodes by default.

Note:

If the option `-R, --role` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N, --node` and `-R, --role`.

`-R, --role`

- Specifies the roles of nodes to be restarted. The value of this option is a comma-separated list of the roles of the nodes. You can get the roles of the nodes from the second column of the cluster status table returned by the `[tiup dm display](#tiup-dm-display)` command.
- Data type: `STRING`
- If this option is not specified, TiUP restarts nodes of all roles by default.

Note:

If the option `-N`, `--node` is specified at the same time, TiUP restarts service nodes that match both the requirements of `-N`, `--node` and `-R`, `--role`.

`-h`, `-help`

- Prints help information.
- Data type: **BOOLEAN**
- This option is disabled by default with the **false** value. To enable this option, add this option to the command, and either pass the **true** value or do not pass any value.

Outputs

The log of the service restart process.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.17 tiup dm scale-in

The `tiup dm scale-in` command is used to scale in the cluster. Scaling in the cluster means taking the service offline, which eventually removes the specified node from the cluster and deletes the remaining related files.

Syntax

```
tiup dm scale-in <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

Options

`-N`, `-node`

- Specifies the nodes to be scaled in. If you need to scale in multiple nodes, split them by commas.
- Data type: **STRINGS**
- Default: **no**. This option is mandatory and the value must be not null.

`-force`

- In some cases, some scale-in nodes in the cluster have been down, making it impossible to connect to the node through SSH for operation. At this time, you can use the `--force` option to remove these nodes from the cluster.

- Data type: **BOOLEAN**
- Default: `false`. If this option is not specified in the command, the specified nodes are not forcibly removed.

`-h, -help`

- Prints the help information.
- Data type: **BOOLEAN**
- Default: `false`

Output

The log of scaling in.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.18 `tiup dm scale-out`

The `tiup dm scale-out` command is used for scaling out the cluster. The internal logic of scaling out the cluster is similar to the cluster deployment. The `tiup-dm` components first establish an SSH connection to the new node, create the necessary directories on the target node, then perform the deployment and start the service.

Syntax

```
tiup dm scale-out <cluster-name> <topology.yaml> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

`<topology.yaml>`: the prepared [topology file](#). This topology file should only contain the new nodes that are to be added to the current cluster.

Options

`-u, -user`

- Specifies the user name used to connect to the target machine. This user must have the secret-free sudo root permission on the target machine.
- Data type: **STRING**
- Default: the current user who executes the command.

`-i, -identity_file`

- Specifies the key file used to connect to the target machine.
- Data type: **STRING**
- If this option is not specified in the command, the `~/.ssh/id_rsa` file is used to connect to the target machine by default.

-p, -password

- Specifies the password used to connect to the target machine. Do not use this option and `-i/--identity_file` at the same time.
- Data type: `BOOLEAN`
- Default: `false`

-h, -help

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of scaling out.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.19 tiup dm start

The `tiup dm start` command is used to start all or part of the services of the specified cluster.

Syntax

```
tiup dm start <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the [cluster list](#) command.

Options

-N, -node

- Specifies the nodes to be started. If not specified, all nodes are started. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are started.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

`-R, --role`

- Specifies the roles to be started. If not specified, all roles are started. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are started.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are started.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of starting the service.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.20 `tiup dm stop`

The `tiup dm stop` command is used to stop all or part of the services of the specified cluster.

Note:

The cluster cannot provide services after the core service is stopped.

Syntax

```
tiup dm stop <cluster-name> [flags]
```

`<cluster-name>`: the name of the cluster to operate on. If you forget the cluster name, you can check it with the `cluster list` command.

Options

`-N, --node`

- Specifies the nodes to be stopped. If not specified, all nodes are stopped. The value of this option is a comma-separated list of node IDs. You can get the node IDs from the first column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all nodes are selected by default.

Note:

If the `-R, --role` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

`-R, --role`

- Specifies the roles to be stopped. If not specified, all roles are stopped. The value of this option is a comma-separated list of node roles. You can get the roles of nodes from the second column of the cluster status table returned by the `tiup dm display` command.
- Data type: `STRINGS`
- If this option is not specified in the command, all roles are selected by default.

Note:

If the `-N, --node` option is specified at the same time, only the service nodes that match both the specifications of `-N, --node` and `-R, --role` are stopped.

`-h, --help`

- Prints the help information.
- Data type: `BOOLEAN`
- Default: `false`

Output

The log of stopping the service.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.21 tiup dm template

Before deploying the cluster, you need to prepare a **topology file** of the cluster. TiUP has a built-in topology file template, and you can modify this template to create the final topology file. To output the built-in template content, you can use the `tiup dm template` command.

Syntax

```
tiup dm template [flags]
```

If this option is not specified, the output default template contains the following instances:

- 3 DM-master instances
- 3 DM-worker instances
- 1 Prometheus instance
- 1 Grafana instance
- 1 Alertmanager instance

Options

`-full`

- Outputs a detailed topology template that is commented with configurable parameters. To enable this option, add it to the command.
- If this option is not specified, the simple topology template is output by default.

`-h, -help`

Prints the help information.

Output

Outputs the topology template according to the specified options, which can be redirected to the topology file for deployment.

[<< Back to the previous page - TiUP DM command list](#)

11.4.7.4.22 tiup dm upgrade

The `tiup dm upgrade` command is used to upgrade a specified cluster to a specific version.

Syntax

```
tiup dm upgrade <cluster-name> <version> [flags]
```

- `<cluster-name>` is the name of the cluster to be operated on. If you forget the cluster name, you can check it using the `tiup dm list` command.
- `<version>` is the target version to be upgraded to. Currently, only upgrading to a later version is allowed, and upgrading to an earlier version is not allowed, which means the downgrade is not allowed. Upgrading to a nightly version is not allowed either.

Options

`-offline`

- Declares that the current cluster is offline. When this option is specified, TiUP DM only replaces the binary files of the cluster components in place without restarting the service.

`-h, -help`

- Prints the help information.
- Data type: `BOOLEAN`
- This option is disabled by default with the `false` value. To enable this option, add this option to the command, and either pass the `true` value or do not pass any value.

Output

Log of the service upgrade process.

[<< Back to the previous page - TiUP DM command list](#)

11.4.8 Topology Configuration File for TiDB Deployment Using TiUP

To deploy or scale TiDB using TiUP, you need to provide a topology file ([sample](#)) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

11.4.8.1 File structure

A topology configuration file for TiDB deployment using TiUP might contain the following sections:

- **global**: The cluster's global configuration. Some of the configuration items use the default values and you can configure them separately in each instance.
- **monitored**: Configuration for monitoring services, namely, the `blackbox_exporter` and the `node_exporter`. On each machine, a `node_exporter` and a `blackbox_exporter` are deployed.
- **server_configs**: Components' global configuration. You can configure each component separately. If an instance has a configuration item with the same name, the instance's configuration item will take effect.
- **pd_servers**: The configuration of the PD instance. This configuration specifies the machines to which the PD component is deployed.
- **tidb_servers**: The configuration of the TiDB instance. This configuration specifies the machines to which the TiDB component is deployed.
- **tikv_servers**: The configuration of the TiKV instance. This configuration specifies the machines to which the TiKV component is deployed.
- **tiflash_servers**: The configuration of the TiFlash instance. This configuration specifies the machines to which the TiFlash component is deployed.
- **pump_servers**: The configuration of the Pump instance. This configuration specifies the machines to which the Pump component is deployed.
- **drainer_servers**: The configuration of the Drainer instance. This configuration specifies the machines to which the Drainer component is deployed.
- **cdc_servers**: The configuration of the TiCDC instance. This configuration specifies the machines to which the TiCDC component is deployed.
- **tispark_masters**: The configuration of the TiSpark master instance. This configuration specifies the machines to which the TiSpark master component is deployed. Only one node of TiSpark master can be deployed.
- **tispark_workers**: The configuration of the TiSpark worker instance. This configuration specifies the machines to which the TiSpark worker component is deployed.
- **monitoring_servers**: Specifies the machines to which Prometheus and NGMonitoring are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- **grafana_servers**: The configuration of the Grafana instance. This configuration specifies the machines to which Grafana is deployed.
- **alertmanager_servers**: The configuration of the Alertmanager instance. This configuration specifies the machines to which Alertmanager is deployed.

11.4.8.1.1 global

The `global` section corresponds to the cluster's global configuration and has the following fields:

- **user**: The user used to start the deployed cluster. The default value is "tidb". If the user specified in the <user> field does not exist on the target machine, this user is automatically created.
- **group**: The user group to which a user belongs. It is specified when the user is created. The value defaults to that of the <user> field. If the specified group does not exist, it is automatically created.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. The default value is 22.
- **enable_tls**: Specifies whether to enable TLS for the cluster. After TLS is enabled, the generated TLS certificate must be used for connections between components or between the client and the component. The default value is **false**.
- **deploy_dir**: The deployment directory of each component. The default value is "↔ deployed". Its application rules are as follows:
 - If the absolute path of **deploy_dir** is configured at the instance level, the actual deployment directory is **deploy_dir** configured for the instance.
 - For each instance, if you do not configure **deploy_dir**, its default value is the relative path <component-name>-<component-port>.
 - If **global.deploy_dir** is an absolute path, the component is deployed to the <global.deploy_dir>/<instance.deploy_dir> directory.
 - If **global.deploy_dir** is a relative path, the component is deployed to the /↔ home/<global.user>/<global.deploy_dir>/<instance.deploy_dir> directory.
- **data_dir**: The data directory. Default value: "data". Its application rules are as follows:
 - If the absolute path of **data_dir** is configured at the instance level, the actual deployment directory is **data_dir** configured for the instance.
 - For each instance, if you do not configure **data_dir**, its default value is <global ↔ .data_dir>.
 - If **data_dir** is a relative path, the component data is placed in <deploy_dir>/< ↔ data_dir>. For the calculation rules of <deploy_dir>, see the application rules of the **deploy_dir** field.
- **log_dir**: The log directory. Default value: "log". Its application rules are as follows:
 - If the absolute path **log_dir** is configured at the instance level, the actual log directory is the **log_dir** configured for the instance.
 - For each instance, if you not configure **log_dir**, its default value is <global. ↔ log_dir>.

- If `log_dir` is a relative path, the component log is placed in `<deploy_dir>/<log_dir>`. For the calculation rules of `<deploy_dir>`, see the application rules of the `deploy_dir` field.
- **os**: The operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is “linux”.
- **arch**: The CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are “amd64” and “arm64”. The default value is “amd64”.
- **resource_control**: Runtime resource control. All configurations in this field are written into the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
 - **memory_limit**: Limits the maximum runtime memory. For example, “2G” means that the maximum memory of 2 GB can be used.
 - **cpu_quota**: Limits the maximum CPU usage at runtime. For example, “200%”.
 - **io_read_bandwidth_max**: Limits the maximum I/O bandwidth for disk reads. For example, `"/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M"`.
 - **io_write_bandwidth_max**: Limits maximum I/O bandwidth for disk writes. For example, `/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0 100M`.
 - **limit_core**: Controls the size of core dump.

A global configuration example is as follows:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the above configuration, the `tidb` user is used to start the cluster. At the same time, each component is restricted to a maximum of 2 GB of memory when it is running.

11.4.8.1.2 monitored

`monitored` is used to configure the monitoring service on the target machine: `node_exporter` and `blackbox_exporter`. The following fields are included:

- **node_exporter_port**: The service port of `node_exporter`. The default value is 9100.
- **blackbox_exporter_port**: The service port of `blackbox_exporter`. The default value is 9115.

- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

A monitored configuration example is as follows:

```
monitored:  
node_exporter_port: 9100  
blackbox_exporter_port: 9115
```

The above configuration specifies that `node_exporter` uses the 9100 port and `blackbox_exporter` uses the 9115 port.

11.4.8.1.3 `server_configs`

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configuration of this section can be overwritten by the configurations with the same names in an instance. `server_configs` mainly includes the following fields:

- `tidb`: TiDB service-related configuration. For the complete configuration, see [TiDB configuration file](#).
- `tikv`: TiKV service-related configuration. For the complete configuration, see [TiKV configuration file](#).
- `pd`: PD service-related configuration. For the complete configuration, see [PD configuration file](#).
- `tiflash`: TiFlash service-related configuration. For the complete configuration, see [TiFlash configuration file](#).
- `tiflash_learner`: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- `pump`: Pump service-related configuration. For the complete configuration, see [TiDB Binlog configuration file](#).
- `drainer`: Drainer service-related configuration. For the complete configuration, see [TiDB Binlog configuration file](#).

- **cdc**: TiCDC service-related configuration. For the complete configuration, see [Deploy TiCDC](#).

A `server_configs` configuration example is as follows:

```
server_configs:
  tidb:
    run-ddl: true
    lease: "45s"
    split-table: true
    token-limit: 1000
  tikv:
    log-level: "info"
    readpool.unified.min-thread-count: 1
```

The above configuration specifies the global configuration of TiDB and TiKV.

11.4.8.1.4 `pd_servers`

`pd_servers` specifies the machines to which PD services are deployed. It also specifies the service configuration on each machine. `pd_servers` is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the PD services are deployed. The field value is an IP address and is mandatory.
- **listen_host**: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **name**: Specifies the name of the PD instance. Different instances must have unique names; otherwise, instances cannot be deployed.
- **client_port**: Specifies the port that PD uses to connect to the client. The default value is `2379`.
- **peer_port**: Specifies the port for communication between PDs. The default value is `2380`.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.

- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: The configuration rule of this field is the same as the `pd` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pd` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `name`
- `client_port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `pd_servers` configuration example is as follows:

```
pd_servers:
- host: 10.0.1.11
  config:
    schedule.max-merge-region-size: 20
    schedule.max-merge-region-keys: 200000
- host: 10.0.1.12
```

The above configuration specifies that PD will be deployed on 10.0.1.11 and 10.0.1.12, and makes specific configurations for the PD of 10.0.1.11.

11.4.8.1.5 `tidb_servers`

`tidb_servers` specifies the machines to which TiDB services are deployed. It also specifies the service configuration on each machine. `tidb_servers` is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the TiDB services are deployed. The field value is an IP address and is mandatory.
- **listen_host**: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is 0.0.0.0.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of TiDB services, which is used to provide connection to the MySQL client. The default value is 4000.
- **status_port**: The listening port of the TiDB status service, which is used to view the status of the TiDB services from the external via HTTP requests. The default value is 10080.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **log_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **numa_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The configuration rule of this field is the same as the `tidb` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tidb` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- **resource_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource_control** are the same as the **resource_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **listen_host**
- **port**
- **status_port**
- **deploy_dir**
- **log_dir**
- **arch**
- **os**

A **tidb_servers** configuration example is as follows:

```
tidb_servers:
- host: 10.0.1.14
  config:
    log.level: warn
    log.slow-query-file: tidb-slow-overwrited.log
- host: 10.0.1.15
```

11.4.8.1.6 **tikv_servers**

tikv_servers specifies the machines to which TiKV services are deployed. It also specifies the service configuration on each machine. **tikv_servers** is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the TiKV services are deployed. The field value is an IP address and is mandatory.
- **listen_host**: When the machine has multiple IP addresses, **listen_host** specifies the listening IP address of the service. The default value is **0.0.0.0**.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh_port** of the **global** section is used.
- **port**: The listening port of the TiKV services. The default value is **20160**.
- **status_port**: The listening port of the TiKV status service. The default value is **20180**.

- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: The configuration rule of this field is the same as the `tikv` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tikv` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `status_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `tikv_servers` configuration example is as follows:

```
tikv_servers:
- host: 10.0.1.14
  config:
    server.labels: { zone: "zone1", host: "host1" }
- host: 10.0.1.15
  config:
    server.labels: { zone: "zone1", host: "host2" }
```

11.4.8.1.7 tiflash_servers

`tiflash_servers` specifies the machines to which TiFlash services are deployed. It also specifies the service configuration on each machine. This section is an array, and each element of the array contains the following fields:

- `host`: Specifies the machine to which the TiFlash services are deployed. The field value is an IP address and is mandatory.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `tcp_port`: The port of the TiFlash TCP service. The default value is 9000.
- `http_port`: The port of the TiFlash HTTP service. The default value is 8123.
- `flash_service_port`: The port via which TiFlash provides services. TiDB reads data from TiFlash via this port. The default value is 3930.
- `metrics_port`: TiFlash's status port, which is used to output metric data. The default value is 8234.
- `flash_proxy_port`: The port of the built-in TiKV. The default value is 20170.
- `flash_proxy_status_port`: The status port of the built-in TiKV. The default value is 20292.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`. TiFlash supports multiple `data_dir` directories separated by commas.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.

- **tmp_path**: The storage path of TiFlash temporary files. The default value is [path or the first directory of `storage.latest.dir`] + “/tmp”.
- **numa_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The configuration rule of this field is the same as the `tiflash` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `tiflash` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **learner_config**: Each TiFlash node has a special built-in TiKV. This configuration item is used to configure this special TiKV. It is generally not recommended to modify the content under this configuration item.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- **resource_control**: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

After the deployment, for the fields above, you can only add directories to `data_dir`; for the fields below, you cannot modified these fields:

- `host`
- `tcp_port`
- `http_port`
- `flash_service_port`
- `flash_proxy_port`
- `flash_proxy_status_port`
- `metrics_port`
- `deploy_dir`
- `log_dir`
- `tmp_path`
- `arch`
- `os`

A `tiflash_servers` configuration example is as follows:

```
tiflash_servers:  
- host: 10.0.1.21  
- host: 10.0.1.22
```

11.4.8.1.8 `pump_servers`

`pump_servers` specifies the machines to which the Pump services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. `pump_servers` is an array, and each element of the array contains the following fields:

- **host**: Specifies the machine to which the Pump services are deployed. The field value is an IP address and is mandatory.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of the Pump services. The default value is 8250.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- **log_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **numa_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: The configuration rule of this field is the same as the `pump` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `pump` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

- **resource_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource_control** are the same as the **resource_control** content in **global**.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **port**
- **deploy_dir**
- **data_dir**
- **log_dir**
- **arch**
- **os**

A **pump_servers** configuration example is as follows:

```
pump_servers:
- host: 10.0.1.21
  config:
    gc: 7
- host: 10.0.1.22
```

11.4.8.1.9 drainer_servers

drainer_servers specifies the machines to which the Drainer services of TiDB Binlog are deployed. It also specifies the service configuration on each machine. **drainer_servers** is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the Drainer services are deployed. The field value is an IP address and is mandatory.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh_port** of the **global** section is used.
- **port**: The listening port of Drainer services. The default value is 8249.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the **deploy_dir** directory configured in **global**.
- **data_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the **data_dir** directory configured in **global**.

- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `commit_ts`: When Drainer starts, it reads the checkpoint. If Drainer cannot read the checkpoint, it uses this field as the replication time point for the initial startup. This field defaults to `-1` (Drainer always gets the latest timestamp from the PD as the `commit_ts`).
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as `"0,1"`.
- `config`: The configuration rule of this field is the same as the `drainer` configuration rule in `server_configs`. If this field is configured, the field content is merged with the `drainer` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `commit_ts`
- `arch`
- `os`

A `drainer_servers` configuration example is as follows:

```
drainer_servers:  
- host: 10.0.1.21  
  config:
```

```
syncer.db-type: "mysql"
syncer.to.host: "127.0.0.1"
syncer.to.user: "root"
syncer.to.password: ""
syncer.to.port: 3306
syncer.ignore-table:
  - db-name: test
    tbl-name: log
  - db-name: test
    tbl-name: audit
```

11.4.8.1.10 `cdc_servers`

`cdc_servers` specifies the machines to which the TiCDC services are deployed. It also specifies the service configuration on each machine. `cdc_servers` is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the TiCDC services are deployed. The field value is an IP address and is mandatory.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of the TiCDC services. The default value is 8300.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- **log_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **gc-ttl**: The Time To Live (TTL) duration of the service level GC safepoint set by TiCDC in PD, in seconds. The default value is 86400, which is 24 hours.
- **tz**: The time zone that the TiCDC services use. TiCDC uses this time zone when internally converting time data types such as timestamp and when replicating data to the downstream. The default value is the local time zone where the process runs.
- **numa_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.

- **config**: The field content is merged with the `cdc` content in `server_configs` (if the two fields overlap, the content of this field takes effect). Then, a configuration file is generated and sent to the machine specified in `host`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- **resource_control**: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `cdc_servers` configuration example is as follows:

```
cdc_servers:
- host: 10.0.1.20
  gc-ttl: 86400
  data_dir: "/cdc-data"
- host: 10.0.1.21
  gc-ttl: 86400
  data_dir: "/cdc-data"
```

11.4.8.1.11 `tispark_masters`

`tispark_masters` specifies the machines to which the master node of TiSpark is deployed. It also specifies the service configuration on each machine. `tispark_masters` is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the TiSpark master is deployed. The field value is an IP address and is mandatory.

- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path of the JRE environment to be used. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `spark_config`: Configures to configure the TiSpark services. Then, a configuration file is generated and sent to the machine specified in `host`.
- `spark_env`: Configures the environment variables when Spark starts.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `listen_host`
- `port`
- `web_port`
- `deploy_dir`
- `arch`
- `os`

A `tispark_masters` configuration example is as follows:

```
tispark_masters:  
- host: 10.0.1.21  
  spark_config:  
    spark.driver.memory: "2g"  
    spark.eventLog.enabled: "False"  
    spark.tispark.grpc.framesize: 2147483647
```

```
spark.tispark.grpc.timeout_in_sec: 100
spark.tispark.meta.reload_period_in_sec: 60
spark.tispark.request.command.priority: "Low"
spark.tispark.table.scan_concurrency: 256
spark_env:
  SPARK_EXECUTOR_CORES: 5
  SPARK_EXECUTOR_MEMORY: "10g"
  SPARK_WORKER_CORES: 5
  SPARK_WORKER_MEMORY: "10g"
- host: 10.0.1.22
```

11.4.8.1.12 tispark_workers

`tispark_workers` specifies the machines to which the worker nodes of TiSpark are deployed. It also specifies the service configuration on each machine. `tispark_workers` is an array. Each array element contains the following fields:

- `host`: Specifies the machine to which the TiSpark workers are deployed. The field value is an IP address and is mandatory.
- `listen_host`: When the machine has multiple IP addresses, `listen_host` specifies the listening IP address of the service. The default value is `0.0.0.0`.
- `ssh_port`: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- `port`: Spark's listening port, used for communication before the node. The default value is `7077`.
- `web_port`: Spark's web port, which provides web services and the task status. The default value is `8080`.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `java_home`: Specifies the path in which the JRE environment to be used is located. This parameter corresponds to the `JAVA_HOME` system environment variable.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- host
- listen_host
- port
- web_port
- deploy_dir
- arch
- os

A `tispark_workers` configuration example is as follows:

```
tispark_workers:  
- host: 10.0.1.22  
- host: 10.0.1.23
```

11.4.8.1.13 monitoring_servers

`monitoring_servers` specifies the machines to which the Prometheus services are deployed. It also specifies the service configuration on each machine. `monitoring_servers` is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the monitoring services are deployed. The field value is an IP address and is mandatory.
- **ng_port**: Specifies the SSH port connecting to NGMonitoring. Introduced in TiUP v1.7.0, this field supports **Continuous Profiling** and Top SQL in TiDB 5.3.0 and above.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of the Prometheus services. The default value is 9090.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **data_dir**: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- **log_dir**: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- **numa_node**: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.

- `storage_retention`: The retention time of the Prometheus monitoring data. The default value is "30d".
- `rule_dir`: Specifies a local directory that should contain complete `*.rules.yml` files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the rules for Prometheus.
- `remote_config`: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
 - `remote_write`: See the Prometheus document [<remote_write>](#).
 - `remote_read`: See the Prometheus document [<remote_read>](#).
- `external_alertmanagers`: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:  
- host: 10.0.1.11  
  rule_dir: /local/rule/dir  
  remote_config:
```

```
remote_write:
- queue_config:
  batch_send_deadline: 5m
  capacity: 100000
  max_samples_per_send: 10000
  max_shards: 300
  url: http://127.0.0.1:8003/write
remote_read:
- url: http://127.0.0.1:8003/read
external_alertmanagers:
- host: 10.1.1.1
  web_port: 9093
- host: 10.1.1.2
  web_port: 9094
```

11.4.8.1.14 grafana_servers

`grafana_servers` specifies the machines to which the Grafana services are deployed. It also specifies the service configuration on each machine. `grafana_servers` is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the Grafana services are deployed. The field value is an IP address and is mandatory.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the `ssh_port` of the `global` section is used.
- **port**: The listening port of the Grafana services. The default value is 3000.
- **deploy_dir**: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- **os**: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- **arch**: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- **username**: The user name on the Grafana login interface.
- **password**: The password corresponding to Grafana.
- **dashboard_dir**: Specifies a local directory that should contain complete `dashboard` \hookrightarrow (`*.json`) files. These files are transferred to the target machine during the initialization phase of the cluster configuration as the dashboards for Grafana.

- **resource_control**: Resource control for the service. If this field is configured, the field content is merged with the **resource_control** content in **global** (if the two fields overlap, the content of this field takes effect). Then, a systemd configuration file is generated and sent to the machine specified in **host**. The configuration rules of **resource_control** are the same as the **resource_control** content in **global**.

Note:

If the **dashboard_dir** field of **grafana_servers** is configured, after executing the **tiup cluster rename** command to rename the cluster, you need to perform the following operations:

1. For the ***.json** files in the local dashboards directory, update the value of the **datasource** field to the new cluster name (because **datasource** is named after the cluster name).
2. Execute the **tiup cluster reload -R grafana** command.

For the above fields, you cannot modify these configured fields after the deployment:

- **host**
- **port**
- **deploy_dir**
- **arch**
- **os**

A **grafana_servers** configuration example is as follows:

```
grafana_servers:  
- host: 10.0.1.11  
  dashboard_dir: /local/dashboard/dir
```

11.4.8.1.15 alertmanager_servers

alertmanager_servers specifies the machines to which the Alertmanager services are deployed. It also specifies the service configuration on each machine. **alertmanager_servers** is an array. Each array element contains the following fields:

- **host**: Specifies the machine to which the Alertmanager services are deployed. The field value is an IP address and is mandatory.
- **ssh_port**: Specifies the SSH port to connect to the target machine for operations. If it is not specified, the **ssh_port** of the **global** section is used.

- `web_port`: Specifies the port used that Alertmanager uses to provide web services. The default value is 9093.
- `cluster_port`: Specifies the communication port between one Alertmanager and other Alertmanager. The default value is 9094.
- `deploy_dir`: Specifies the deployment directory. If it is not specified or specified as a relative directory, the directory is generated according to the `deploy_dir` directory configured in `global`.
- `data_dir`: Specifies the data directory. If it is not specified or specified as a relative directory, the directory is generated according to the `data_dir` directory configured in `global`.
- `log_dir`: Specifies the log directory. If it is not specified or specified as a relative directory, the log is generated according to the `log_dir` directory configured in `global`.
- `numa_node`: Allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is the string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config_file`: Specifies a local file that is transferred to the target machine during the initialization phase of the cluster configuration as the configuration of Alertmanager.
- `os`: The operating system of the machine specified in `host`. If this field is not specified, the default value is the `os` value in `global`.
- `arch`: The architecture of the machine specified in `host`. If this field is not specified, the default value is the `arch` value in `global`.
- `resource_control`: Resource control for the service. If this field is configured, the field content is merged with the `resource_control` content in `global` (if the two fields overlap, the content of this field takes effect). Then, a `systemd` configuration file is generated and sent to the machine specified in `host`. The configuration rules of `resource_control` are the same as the `resource_control` content in `global`.

For the above fields, you cannot modify these configured fields after the deployment:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:
- host: 10.0.1.11
  config_file: /local/config/file
- host: 10.0.1.12
  config_file: /local/config/file
```

11.4.9 Topology Configuration File for DM Cluster Deployment Using TiUP

To deploy or scale a TiDB Data Migration (DM) cluster, you need to provide a topology file ([sample](#)) to describe the cluster topology.

Similarly, to modify the cluster topology, you need to modify the topology file. The difference is that, after the cluster is deployed, you can only modify a part of the fields in the topology file. This document introduces each section of the topology file and each field in each section.

11.4.9.1 File structure

A topology configuration file for DM cluster deployment using TiUP might contain the following sections:

- **global**: the cluster's global configuration. Some of the configuration items use the default values of the cluster, and you can configure them separately in each instance.
- **server_configs**: the components' global configuration. You can configure each component separately. If an instance has a configuration item with the same key, the instance's configuration item will take effect.
- **master_servers**: the configuration of the DM-master instance. The configuration specifies the machines to which the master service of the DM component is deployed.
- **worker_servers**: the configuration of the DM-worker instance. The configuration specifies the machines to which the worker service of the DM component is deployed.
- **monitoring_servers**: specifies the machines to which the Prometheus instances are deployed. TiUP supports deploying multiple Prometheus instances but only the first instance is used.
- **grafana_servers**: the configuration of the Grafana instances. The configuration specifies the machines to which the Grafana instances are deployed.
- **alertmanager_servers**: the configuration of the Alertmanager instances. The configuration specifies the machines to which the Alertmanager instances are deployed.

11.4.9.1.1 global

The `global` section corresponds to the cluster's global configuration and has the following fields:

- **user**: the user to start the deployed cluster. The default value is “tidb”. If the user specified in the `<user>` field does not exist on the target machine, TiUP will automatically try to create the user.
- **group**: the user group to which a user belongs when the user is automatically created. The default value is the same as the `<user>` field. If the specified group does not exist, it will be created automatically.
- **ssh_port**: the SSH port to connect to the target machine for operations. The default value is “22”.
- **deploy_dir**: the deployment directory for each component. The default value is “deploy”. The construction rules are as follows:
 - If the absolute path `deploy_dir` is configured at the instance level, the actual deployment directory is the `deploy_dir` configured for the instance.
 - For each instance, if you do not configure `deploy_dir`, the default value is the relative path `<component-name>-<component-port>`.
 - If `global.deploy_dir` is set to an absolute path, the component is deployed to the `<global.deploy_dir>/<instance.deploy_dir>` directory.
 - If `global.deploy_dir` is set to a relative path, the component is deployed to the `/home/<global.user>/<global.deploy_dir>/<instance.deploy_dir>` directory.
- **data_dir**: the data directory. The default value is “data”. The construction rules are as follows.
 - If the absolute path `data_dir` is configured at the instance level, the actual data directory is the `data_dir` configured for the instance.
 - For each instance, if `data_dir` is not configured, the default value is `<global.data_dir>`.
 - If `data_dir` is set to a relative path, the component data is stored in `<deploy_dir>/<data_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- **log_dir**: the data directory. The default value is “log”. The construction rules are as follows.
 - If the absolute path of `log_dir` is configured at the instance level, the actual log directory is the `log_dir` configured for the instance.
 - For each instance, if `log_dir` is not configured by the user, the default value is `<global.log_dir>`.
 - If `log_dir` is a relative path, the component logs will be stored in `<deploy_dir>/<log_dir>`. For the construction rules of `<deploy_dir>`, see the construction rules of the `deploy_dir` field.
- **os**: the operating system of the target machine. The field controls which operating system to adapt to for the components pushed to the target machine. The default value is “linux”.

- **arch**: the CPU architecture of the target machine. The field controls which platform to adapt to for the binary packages pushed to the target machine. The supported values are “amd64” and “arm64”. The default value is “amd64”.
- **resource_control**: runtime resource control. All configurations in this field are written to the service file of systemd. There is no limit by default. The resources that can be controlled are as follows:
 - **memory_limit**: limits the maximum memory at runtime. For example, “2G” means that the maximum memory of 2 GB can be used.
 - **cpu_quota**: limits the maximum CPU usage at runtime. For example, “200%”.
 - **io_read_bandwidth_max**: limits the maximum I/O bandwidth for disk reads. For example, “/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M”.
 - **io_write_bandwidth_max**: limits the maximum I/O bandwidth for disk writes. For example, “/dev/disk/by-path/pci-0000:00:1f.2-scsi-0:0:0:0:0 100M”
↪ .
 - **limit_core**: controls the size of core dump.

A global configuration example:

```
global:
  user: "tidb"
  resource_control:
    memory_limit: "2G"
```

In the example, the configuration specifies that the `tidb` user is used to start the cluster, and that each component is limited to a maximum of 2 GB of memory when it is running.

11.4.9.1.2 server_configs

`server_configs` is used to configure services and to generate configuration files for each component. Similar to the `global` section, the configurations in the `server_configs` section can be overwritten by the configurations with the same keys in an instance. `server_configs` mainly contains the following fields:

- **master**: the configuration related to the DM-master service. For all the supported configuration items, see [DM-master Configuration File](#).
- **worker**: the configuration related to the DM-worker service, For all the supported configuration items, see [DM-worker Configuration File](#).

A `server_configs` configuration example is as follows:

```
server_configs:
  master:
    log-level: info
    rpc-timeout: "30s"
    rpc-rate-limit: 10.0
```

```
rpc-rate-burst: 40
worker:
  log-level: info
```

11.4.9.2 master_servers

`master_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `master_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `name`: specifies the name of the DM-master instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- `port`: specifies the port on which DM-master provides services. The default value is “8261”.
- `peer_port`: specifies the port for communication between DM-masters. The default value is “8291”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”.
- `config`: the configuration rules of this field are the same as that of `master` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `master` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control`

in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

- `v1_source_path`: when upgrading from `v1.0.x`, you can specify the directory where the configuration file of the V1 source is located in this field.

In the `master_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `name`
- `port`
- `peer_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`
- `v1_source_path`

A `master_servers` configuration example is as follows:

```
master_servers:
- host: 10.0.1.11
  name: master1
  ssh_port: 22
  port: 8261
  peer_port: 8291
  deploy_dir: "/dm-deploy/dm-master-8261"
  data_dir: "/dm-data/dm-master-8261"
  log_dir: "/dm-deploy/dm-master-8261/log"
  numa_node: "0,1"
  # The following configs are used to overwrite the `server_configs.master
  ↪ ` values.
  config:
    log-level: info
    rpc-timeout: "30s"
    rpc-rate-limit: 10.0
    rpc-rate-burst: 40
- host: 10.0.1.18
  name: master2
- host: 10.0.1.19
  name: master3
```

11.4.9.3 worker_servers

`worker_servers` specifies the machines to which the master node of the DM component is deployed. You can also specify the service configuration on each machine. `worker_servers` is an array. Each array element contains the following fields:

- **host**: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- **ssh_port**: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- **name**: specifies the name of the DM-worker instance. The name must be unique for different instances. Otherwise, the cluster cannot be deployed.
- **port**: specifies the port on which DM-worker provides services. The default value is “8262”.
- **deploy_dir**: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- **data_dir**: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- **log_dir**: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- **numa_node**: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”.
- **config**: the configuration rules of this field are the same as that of `worker` in the `server_configs` section. If `config` is specified, the configuration of `config` will be merged with the configuration of `worker` in `server_configs` (if the two fields overlap, the configuration of this field takes effect), and then the configuration file is generated and distributed to the machine specified in the `host` field.
- **os**: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- **arch**: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- **resource_control**: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `worker_servers` section, the following fields cannot be modified after the deployment is completed:

- host
- name
- port
- deploy_dir
- data_dir
- log_dir
- arch
- os

A `worker_servers` configuration example is as follows:

```
worker_servers:
- host: 10.0.1.12
  ssh_port: 22
  port: 8262
  deploy_dir: "/dm-deploy/dm-worker-8262"
  log_dir: "/dm-deploy/dm-worker-8262/log"
  numa_node: "0,1"
  # config is used to overwrite the `server_configs.worker` values
  config:
    log-level: info
- host: 10.0.1.19
```

11.4.9.3.1 monitoring_servers

`monitoring_servers` specifies the machines to which the Prometheus service is deployed. You can also specify the service configuration on the machine. `monitoring_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Prometheus provides services. The default value is “9090”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.

- **numa_node**: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”
- **storage_retention**: specifies the retention time of the Prometheus monitoring data. The default value is “15d”.
- **rule_dir**: specifies a local directory where the complete `*.rules.yml` files are located. The files in the specified directory will be sent to the target machine as the Prometheus rules during the initialization phase of the cluster configuration.
- **remote_config**: Supports writing Prometheus data to the remote, or reading data from the remote. This field has two configurations:
 - **remote_write**: See the Prometheus document [<remote_write>](#).
 - **remote_read**: See the Prometheus document [<remote_read>](#).
- **external_alertmanagers**: If the `external_alertmanagers` field is configured, Prometheus alerts the configuration behavior to the Alertmanager that is outside the cluster. This field is an array, each element of which is an external Alertmanager and consists of the `host` and `web_port` fields.
- **os**: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- **arch**: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- **resource_control**: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In the `monitoring_servers` section, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

A `monitoring_servers` configuration example is as follows:

```
monitoring_servers:  
- host: 10.0.1.11  
  rule_dir: /local/rule/dir
```

```
remote_config:
  remote_write:
  - queue_config:
    batch_send_deadline: 5m
    capacity: 100000
    max_samples_per_send: 10000
    max_shards: 300
    url: http://127.0.0.1:8003/write
  remote_read:
  - url: http://127.0.0.1:8003/read\
external_alertmanagers:
- host: 10.1.1.1
web_port: 9093
- host: 10.1.1.2
web_port: 9094
```

11.4.9.3.2 grafana_servers

`grafana_servers` specifies the machines to which the Grafana service is deployed. You can also specify the service configuration on the machine. `grafana_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `port`: specifies the port on which Grafana provides services. The default value is “3000”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `username`: specifies the username of the Grafana login screen.
- `password`: specifies the corresponding password of Grafana.
- `dashboard_dir`: specifies a local directory where the complete `dashboard(*.json)` files are located. The files in the specified directory will be sent to the target machine as Grafana dashboards during the initialization phase of the cluster configuration.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the

machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

Note:

If the `dashboard_dir` field of `grafana_servers` is configured, after executing the `tiup cluster rename` command to rename the cluster, you need to perform the following operations:

1. In the local `dashboards` directory, update the value of the `datasource` field to the new cluster name (the `datasource` is named after the cluster name).
2. Execute the `tiup cluster reload -R grafana` command.

In `grafana_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `port`
- `deploy_dir`
- `arch`
- `os`

A `grafana_servers` configuration example is as follows:

```
grafana_servers:  
- host: 10.0.1.11  
  dashboard_dir: /local/dashboard/dir
```

11.4.9.3.3 `alertmanager_servers`

`alertmanager_servers` specifies the machines to which the Alertmanager service is deployed. You can also specify the service configuration on each machine. `alertmanager_servers` is an array. Each array element contains the following fields:

- `host`: specifies the machine to deploy to. The field value is an IP address and is mandatory.
- `ssh_port`: specifies the SSH port to connect to the target machine for operations. If the field is not specified, the `ssh_port` in the `global` section is used.
- `web_port`: specify the port on which Alertmanager provides web services. The default value is “9093”.

- `cluster_port`: Specify the communication port between one Alertmanager and other Alertmanager. The default value is “9094”.
- `deploy_dir`: specifies the deployment directory. If the field is not specified, or specified as a relative directory, the deployment directory is generated according to the `deploy_dir` configuration in the `global` section.
- `data_dir`: specifies the data directory. If the field is not specified, or specified as a relative directory, the data directory is generated according to the `data_dir` configuration in the `global` section.
- `log_dir`: specifies the log directory. If the field is not specified, or specified as a relative directory, the log directory is generated according to the `log_dir` configuration in the `global` section.
- `numa_node`: allocates the NUMA policy to the instance. Before specifying this field, you need to make sure that the target machine has `numactl` installed. If this field is specified, `cpubind` and `membind` policies are allocated using `numactl`. This field is a string type. The field value is the ID of the NUMA node, such as “0,1”
- `config_file`: specifies a local file. The specified file will be sent to the target machine as the configuration for Alertmanager during the initialization phase of the cluster configuration.
- `os`: the operating system of the machine specified in the `host` field. If the field is not specified, the default value is the `os` value configured in the `global` section.
- `arch`: the architecture of the machine specified in the `host` field. If the field is not specified, the default value is the `arch` value configured in the `global` section.
- `resource_control`: resource control on this service. If this field is specified, the configuration of this field will be merged with the configuration of `resource_control` in the `global` section (if the two fields overlap, the configuration of this field takes effect), and then the configuration file of `systemd` is generated and distributed to the machine specified in the `host` field. The configuration rules of this field are the same as that of `resource_control` in the `global` section.

In `alertmanager_servers`, the following fields cannot be modified after the deployment is completed:

- `host`
- `web_port`
- `cluster_port`
- `deploy_dir`
- `data_dir`
- `log_dir`
- `arch`
- `os`

An `alertmanager_servers` configuration example is as follows:

```
alertmanager_servers:  
- host: 10.0.1.11
```

```
config_file: /local/config/file
- host: 10.0.1.12
config_file: /local/config/file
```

11.4.10 TiUP Mirror Reference Guide

TiUP mirrors are TiUP's component warehouse, which stores components and their metadata. TiUP mirrors take the following two forms:

- Directory on the local disk: serves the local TiUP client, which is called a local mirror in this document.
- HTTP mirror started based on the remote disk directory: serves the remote TiUP client, which is called a remote mirror in this document.

11.4.10.1 Create and update mirror

You can create a TiUP mirror using one of the following two methods:

- Execute `tiup mirror init` to create a mirror from scratch.
- Execute `tiup mirror clone` to clone from an existing mirror.

After the mirror is created, you can add components to or delete components from the mirror using the `tiup mirror` commands. TiUP updates a mirror by adding files and assigning a new version number to it, rather than deleting any files from the mirror.

11.4.10.2 Mirror structure

A typical mirror structure is as follows:

```
+ <mirror-dir>                # Mirror's root directory
|-- root.json                 # Mirror's root certificate
|-- {2..N}.root.json         # Mirror's root certificate
|-- {1..N}.index.json        # Component/user index
|-- {1..N}.{component}.json  # Component metadata
|-- {component}-{version}-{os}-{arch}.tar.gz # Component binary package
|-- snapshot.json            # Mirror's latest snapshot
|-- timestamp.json           # Mirror's latest timestamp
|--+ commits                  # Mirror's update log (deletable)

    |-- snapshot.json
```

```

|-- timestamp.json
|---+ keys                                # Mirror's private key (can be
    ↳ moved to other locations)
|-- {hash1..hashN}-root.json             # Private key of the root
    ↳ certificate
|-- {hash}-index.json                    # Private key of the indexes
|-- {hash}-snapshot.json                 # Private key of the snapshots
|-- {hash}-timestamp.json                # Private key of the timestamps

```

Note:

- The `commits` directory stores the logs generated in the process of mirror update and is used to roll back the mirror. You can delete the old log directories regularly when the disk space is insufficient.
- The private key stored in the `keys` directory is sensitive. It is recommended to keep it separately.

11.4.10.2.1 Root directory

In a TiUP mirror, the root certificate is used to store the public key of other metadata files. Each time any metadata file (*.json) is obtained, TiUP client needs to find the corresponding public key in the installed `root.json` based on the metadata file type (root, index, snapshot, timestamp). Then TiUP client uses the public key to verify whether the signature is valid.

The root certificate's format is as follows:

```

{
  "signatures": [                                # Each metadata file
    ↳ has some signatures which are signed by several private keys
    ↳ corresponding to the file.
    {
      "keyid": "{id-of-root-key-1}",             # The ID of the
        ↳ first private key that participates in the signature. This
        ↳ ID is obtained by hashing the content of the public key
        ↳ that corresponds to the private key.
      "sig": "{signature-by-root-key-1}"         # The signed part of
        ↳ this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}",             # The ID of the Nth
        ↳ private key that participates in the signature.
    }
  ]
}

```

```

    "sig": "{signature-by-root-key-N}"           # The signed part of
        ↪ this file by this private key.
    }
],
"signed": {                                     # The signed part.
    "_type": "root",                           # The type of this
        ↪ file. root.json's type is root.
    "expires": "{expiration-date-of-this-file}", # The expiration
        ↪ time of the file. If the file expires, the client rejects the
        ↪ file.
    "roles": {                                  # Records the keys
        ↪ used to sign each metadata file.
        "{role:index,root,snapshot,timestamp}": { # Each involved
            ↪ metadata file includes index, root, snapshot, and timestamp
            ↪ .
            "keys": {                            # Only the key's
                ↪ signature recorded in `keys` is valid.
                "{id-of-the-key-1}": {           # The ID of the
                    ↪ first key used to sign {role}.
                    "keytype": "rsa",           # The key's type.
                        ↪ Currently, the key type is fixed as rsa.
                    "keyval": {                 # The key's payload.
                        "public": "{public-key-content}" # The public key's
                            ↪ content.
                    },
                    "scheme": "rsassa-pss-sha256" # Currently, the
                        ↪ scheme is fixed as rsassa-pss-sha256.
                },
                "{id-of-the-key-N}": {         # The ID of the Nth
                    ↪ key used to sign {role}.
                    "keytype": "rsa",
                    "keyval": {
                        "public": "{public-key-content}"
                    },
                    "scheme": "rsassa-pss-sha256"
                }
            },
            "threshold": {N},                 # Indicates that the
                ↪ metadata file needs at least N key signatures.
            "url": "{role}.json"              # The address from
                ↪ which the file can be obtained. For index files, prefix
                ↪ it with the version number (for example, /{N}.index.
                ↪ json).
        }
    },
},

```

```

"spec_version": "0.1.0",          # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
"version": {N}                    # The version number
    ↪ of this file. You need to create a new {N+1}.root.json every
    ↪ time you update the file, and set its version to N + 1.
}
}

```

11.4.10.2.2 Index

The index file records all the components in the mirror and the owner information of the components.

The index file's format is as follows:

```

{
  "signatures": [                 # The file's
    ↪ signature.
    {
      "keyid": "{id-of-index-key-1}", # The ID of the
        ↪ first private key that participates in the signature.
      "sig": "{signature-by-index-key-1}", # The signed part of
        ↪ this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}", # The ID of the Nth
        ↪ private key that participates in the signature.
      "sig": "{signature-by-root-key-N}" # The signed part of
        ↪ this file by this private key.
    }
  ],
  "signed": {
    "_type": "index",             # The file type.
    "components": {              # The component list
      ↪ .
      "{component1}": {          # The name of the
        ↪ first component.
        "hidden": {bool},        # Whether it is a
          ↪ hidden component.
        "owner": "{owner-id}",   # The component
          ↪ owner's ID.
        "standalone": {bool},    # Whether it is a
          ↪ standalone component.
      }
    }
  }
}

```

```
"url": "{component}.json",          # The address from
    ↪ which the component can be obtained. You need to prefix
    ↪ it with the version number (for example, /{N}.{
    ↪ component}.json).
"yanked": {bool}                   # Indicates whether
    ↪ the component is marked as deleted.
},
...
"{componentN}": {                  # The name of the
    ↪ Nth component.
    ...
},
},
"default_components": [{"component1"}.."{componentN}"], # The default
    ↪ component that a mirror must contain. Currently, this field
    ↪ defaults to empty (disabled).
"expires": "{expiration-date-of-this-file}", # The expiration
    ↪ time of the file. If the file expires, the client rejects the
    ↪ file.
"owners": {
  "{owner1}": {                   # The ID of the
    ↪ first owner.
    "keys": {                     # Only the key's
      ↪ signature recorded in `keys` is valid.
      "{id-of-the-key-1}": {      # The first key of
        ↪ the owner.
        "keytype": "rsa",        # The key's type.
          ↪ Currently, the key type is fixed as rsa.
        "keyval": {              # The key's payload.
          "public": "{public-key-content}" # The public key's
            ↪ content.
        },
        "scheme": "rsassa-pss-sha256" # Currently, the
          ↪ scheme is fixed as rsassa-pss-sha256.
      },
      ...
      "{id-of-the-key-N}": {      # The Nth key of the
        ↪ owner.
        ...
      }
    },
    "name": "{owner-name}",       # The name of the
      ↪ owner.
    "threshod": {N}              # Indicates that the
      ↪ components owned by the owner must have at least N
```

```

        ↪ valid signatures.
    },
    ...
    "{ownerN}": {                                # The ID of the Nth
        ↪ owner.
        ...
    }
}
"spec_version": "0.1.0",                        # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
"version": {N}                                  # The version number
    ↪ of this file. You need to create a new {N+1}.index.json every
    ↪ time you update the file, and set its version to N + 1.
}
}

```

11.4.10.2.3 Component

The component's metadata file records information of the component-specific platform and the version.

The component metadata file's format is as follows:

```

{
  "signatures": [                                # The file's
    ↪ signature.
    {
      "keyid": "{id-of-index-key-1}",           # The ID of the
        ↪ first private key that participates in the signature.
      "sig": "{signature-by-index-key-1}",      # The signed part of
        ↪ this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}",           # The ID of the Nth
        ↪ private key that participates in the signature.
      "sig": "{signature-by-root-key-N}"       # The signed part of
        ↪ this file by this private key.
    }
  ],
  "signed": {
    "_type": "component",                       # The file type.
    "description": "{description-of-the-component}", # The description of
      ↪ the component.
  }
}

```

```

"expires": "{expiration-date-of-this-file}",      # The expiration
  ↪ time of the file. If the file expires, the client rejects the
  ↪ file.
"id": "{component-id}",                          # The globally
  ↪ unique ID of the component.
"nightly": "{nightly-cursor}",                   # The nightly cursor
  ↪ , and the value is the latest nightly version number (for
  ↪ example, v5.0.0-nightly-20201209).
"platforms": {                                    # The component's
  ↪ supported platforms (such as darwin/amd64, linux/arm64).
  "{platform-pair-1}": {
    "{version-1}": {                              # The semantic
      ↪ version number (for example, v1.0.0).
      "dependencies": null,                       # Specifies the
        ↪ dependency relationship between components. The
        ↪ field is not used yet and is fixed as null.
      "entry": "{entry}",                        # The relative path
        ↪ of the entry binary file in the tar package.
      "hashs": {                                  # The checksum of
        ↪ the tar package. sha256 and sha512 are used.
        "sha256": "{sum-of-sha256}",
        "sha512": "{sum-of-sha512}",
      },
      "length": {length-of-tar},                  # The length of the
        ↪ tar package.
      "released": "{release-time}",              # The release date
        ↪ of the version.
      "url": "{url-of-tar}",                     # The download
        ↪ address of the tar package.
      "yanked": {bool}                           # Indicates whether
        ↪ this version is disabled.
    }
  },
  ...
  "{platform-pair-N}": {
    ...
  }
},
"spec_version": "0.1.0",                         # The specified
  ↪ version followed by this file. If the file structure is
  ↪ changed in the future, the version number needs to be upgraded
  ↪ . The current version number is 0.1.0.
"version": {N}                                    # The version number
  ↪ of this file. You need to create a new {N+1}.{component}.json
  ↪ every time you update the file, and set its version to N + 1.

```

```
}

```

11.4.10.2.4 Snapshot

The snapshot file records the version number of each metadata file:

The snapshot file's structure is as follows:

```
{
  "signatures": [                                # The file's
    ↪ signature.
    {
      "keyid": "{id-of-index-key-1}",            # The ID of the
        ↪ first private key that participates in the signature.
      "sig": "{signature-by-index-key-1}",        # The signed part of
        ↪ this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}",            # The ID of the Nth
        ↪ private key that participates in the signature.
      "sig": "{signature-by-root-key-N}"         # The signed part of
        ↪ this file by this private key.
    }
  ],
  "signed": {
    "_type": "snapshot",                        # The file type.
    "expires": "{expiration-date-of-this-file}", # The expiration
      ↪ time of the file. If the file expires, the client rejects the
      ↪ file.
    "meta": {                                    # Other metadata
      ↪ files' information.
      "/root.json": {
        "length": {length-of-json-file},        # The length of root
          ↪ .json
        "version": {version-of-json-file}       # The version of
          ↪ root.json
      },
      "/index.json": {
        "length": {length-of-json-file},
        "version": {version-of-json-file}
      },
      "/{component-1}.json": {
        "length": {length-of-json-file},
        "version": {version-of-json-file}
      },
    },
  },
}
```

```

    ...
    "/{component-N}.json": {
        ...
    }
},
"spec_version": "0.1.0",           # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
"version": 0                       # The version number
    ↪ of this file, which is fixed as 0.
}

```

11.4.10.2.5 Timestamp

The timestamp file records the checksum of the current snapshot.

The timestamp file's format is as follows:

```

{
  "signatures": [                  # The file's
    ↪ signature.
    {
      "keyid": "{id-of-index-key-1}", # The ID of the
        ↪ first private key that participates in the signature.
      "sig": "{signature-by-index-key-1}", # The signed part of
        ↪ this file by this private key.
    },
    ...
    {
      "keyid": "{id-of-root-key-N}", # The ID of the Nth
        ↪ private key that participates in the signature.
      "sig": "{signature-by-root-key-N}" # The signed part of
        ↪ this file by this private key.
    }
  ],
  "signed": {
    "_type": "timestamp",          # The file type.
    "expires": "{expiration-date-of-this-file}", # The expiration
      ↪ time of the file. If the file expires, the client rejects the
      ↪ file.
    "meta": {                     # The information of
      ↪ snapshot.json.
      "/snapshot.json": {
        "hashes": {

```

```
        "sha256": "{sum-of-sha256}"                # snapshot.json's
            ↪ sha256.
    },
    "length": {length-of-json-file}              # The length of
            ↪ snapshot.json.
}
},
"spec_version": "0.1.0",                        # The specified
    ↪ version followed by this file. If the file structure is
    ↪ changed in the future, the version number needs to be upgraded
    ↪ . The current version number is 0.1.0.
"version": {N}                                  # The version number
    ↪ of this file. You need to overwrite timestamp.json every time
    ↪ you update the file, and set its version to N + 1.
```

11.4.10.3 Client workflow

The client uses the following logic to ensure that the files downloaded from the mirror are safe:

- A `root.json` file is included with the binary when the client is installed.
- The running client performs the following tasks based on the existing `root.json`:
 1. Obtain the version from `root.json` and mark it as `N`.
 2. Request `{N+1}.root.json` from the mirror. If the request is successful, use the public key recorded in `root.json` to verify whether the file is valid.
 3. Request `timestamp.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
 4. Check whether the checksum of `snapshot.json` recorded in `timestamp.json` matches the checksum of the local `snapshot.json`. If the two do not match, request the latest `snapshot.json` from the mirror and use the public key recorded in `root.json` to verify whether the file is valid.
 5. Obtain the version number `N` of the `index.json` file from `snapshot.json` and request `{N}.index.json` from the mirror. Then use the public key recorded in `root.json` to verify whether the file is valid.
 6. For components such as `tidb.json` and `tikv.json`, the client obtains the version numbers `N` of the components from `snapshot.json` and requests `{N}.component ↪ .json` from the mirror. Then the client uses the public key recorded in `index.json` to verify whether the file is valid.
 7. For component's tar files, the client obtains the URLs and checksums of the files from `{component}.json` and request the URLs for the tar packages. Then the client verifies whether the checksum is correct.

11.4.11 TiUP Components

11.4.11.1 Quickly Deploy a Local TiDB Cluster

The TiDB cluster is a distributed system that consists of multiple components. A typical TiDB cluster consists of at least three PD nodes, three TiKV nodes, and two TiDB nodes. If you want to have a quick experience on TiDB, you might find it time-consuming and complicated to manually deploy so many components. This document introduces the playground component of TiUP and how to use it to quickly build a local TiDB test environment.

11.4.11.1.1 TiUP playground overview

The basic usage of the playground component is shown as follows:

```
tiup playground ${version} [flags]
```

If you directly execute the `tiup playground` command, TiUP uses the locally installed TiDB, TiKV, and PD components or installs the stable version of these components to start a TiDB cluster that consists of one TiKV instance, one TiDB instance, one PD instance, and one TiFlash instance.

This command actually performs the following operations:

- Because this command does not specify the version of the playground component, TiUP first checks the latest version of the installed playground component. Assume that the latest version is v1.9.0, then this command works the same as `tiup playground:v1.9.0`.
- If you have not used TiUP playground to install the TiDB, TiKV, and PD components, the playground component installs the latest stable version of these components, and then start these instances.
- Because this command does not specify the version of the TiDB, PD, and TiKV component, TiUP playground uses the latest version of each component by default. Assume that the latest version is v5.4.3, then this command works the same as `tiup playground:v1.9.0 v5.4.3`.
- Because this command does not specify the number of each component, TiUP playground, by default, starts a smallest cluster that consists of one TiDB instance, one TiKV instance, one PD instance, and one TiFlash instance.
- After starting each TiDB component, TiUP playground reminds you that the cluster is successfully started and provides you some useful information, such as how to connect to the TiDB cluster through the MySQL client and how to access the [TiDB Dashboard](#).

The command-line flags of the playground component are described as follows:

```
Flags:
  --db int          Specify the number of TiDB instances (default:
    ↪ 1)
  --db.host host    Specify the listening address of TiDB
```

```
--db.port int          Specify the port of TiDB
--db.binpath string    Specify the TiDB instance binary path (optional
  ↪ , for debugging)
--db.config string     Specify the TiDB instance configuration file (
  ↪ optional, for debugging)
--db.timeout int       Specify TiDB maximum wait time in seconds for
  ↪ starting. 0 means no limit
--drainer int          Specify Drainer data of the cluster
--drainer.binpath string Specify the location of the Drainer binary
  ↪ files (optional, for debugging)
--drainer.config string Specify the Drainer configuration file
-h, --help             help for tiup
--host string          Specify the listening address of each component
  ↪ (default: `127.0.0.1`). Set it to `0.0.0.0` if provided for
  ↪ access of other machines
--kv int               Specify the number of TiKV instances (default:
  ↪ 1)
--kv.binpath string    Specify the TiKV instance binary path (optional
  ↪ , for debugging)
--kv.config string     Specify the TiKV instance configuration file (
  ↪ optional, for debugging)
--mode string          Specify the playground mode: 'tidb' (default)
  ↪ and 'tikv-slim'
--pd int               Specify the number of PD instances (default: 1)
--pd.host host         Specify the listening address of PD
--pd.binpath string    Specify the PD instance binary path (optional,
  ↪ for debugging)
--pd.config string     Specify the PD instance configuration file (
  ↪ optional, for debugging)
--pump int             Specify the number of Pump instances. If the
  ↪ value is not `0`, TiDB Binlog is enabled.
--pump.binpath string  Specify the location of the Pump binary files (
  ↪ optional, for debugging)
--pump.config string   Specify the Pump configuration file (optional,
  ↪ for debugging)
-T, --tag string       Specify a tag for playground
--ticdc int            Specify the number of TiCDC instances (default:
  ↪ 0)
--ticdc.binpath string Specify the TiCDC instance binary path (
  ↪ optional, for debugging)
--ticdc.config string  Specify the TiCDC instance configuration file (
  ↪ optional, for debugging)
--tiflash int         Specify the number of TiFlash instances (
  ↪ default: 1)
--tiflash.binpath string Specify the TiFlash instance binary path (
```

```
    ↪ optional, for debugging)
--tiflash.config string Specify the TiFlash instance configuration
    ↪ file (optional, for debugging)
--tiflash.timeout int   Specify TiFlash maximum wait time in seconds
    ↪ for starting. 0 means no limit
-v, --version           Specify the version of playground
--without-monitor       Disable the monitoring function of Prometheus
    ↪ and Grafana. If you do not add this flag, the monitoring
    ↪ function is enabled by default.
```

11.4.11.1.2 Examples

Check available TiDB versions

```
tiup list tidb
```

Start a TiDB cluster of a specific version

```
tiup playground ${version}
```

Replace `${version}` with the target version number.

Start a TiDB cluster of the nightly version

```
tiup playground nightly
```

In the command above, `nightly` indicates the latest development version of TiDB.

Override PD's default configuration

First, you need to copy the [PD configuration template](#). Assume you place the copied file to `~/config/pd.toml` and make some changes according to your need, then you can execute the following command to override PD's default configuration:

```
tiup playground --pd.config ~/config/pd.toml
```

Replace the default binary files

By default, when playground is started, each component is started using the binary files from the official mirror. If you want to put a temporarily compiled local binary file into the cluster for testing, you can use the `--{comp}.binpath` flag for replacement. For example, execute the following command to replace the binary file of TiDB:

```
tiup playground --db.binpath /xx/tidb-server
```

Start multiple component instances

By default, only one instance is started for each TiDB, TiKV, and PD component. To start multiple instances for each component, add the following flag:

```
tiup playground --db 3 --pd 3 --kv 3
```

11.4.11.1.3 Quickly connect to the TiDB cluster started by playground

TiUP provides the `client` component, which is used to automatically find and connect to a local TiDB cluster started by playground. The usage is as follows:

```
tiup client
```

This command provides a list of TiDB clusters that are started by playground on the current machine on the console. Select the TiDB cluster to be connected. After clicking Enter, a built-in MySQL client is opened to connect to TiDB.

11.4.11.1.4 View information of the started cluster

```
tiup playground display
```

The command above returns the following results:

Pid	Role	Uptime
---	----	-----
84518	pd	35m22.929404512s
84519	tikv	35m22.927757153s
84520	pump	35m22.92618275s
86189	tidb	exited
86526	tidb	34m28.293148663s
86190	drainer	35m19.91349249s

11.4.11.1.5 Scale out a cluster

The command-line parameter for scaling out a cluster is similar to that for starting a cluster. You can scale out two TiDB instances by executing the following command:

```
tiup playground scale-out --db 2
```

11.4.11.1.6 Scale in a cluster

You can specify a `pid` in the `tiup playground scale-in` command to scale in the corresponding instance. To view the `pid`, execute `tiup playground display`.

```
tiup playground scale-in --pid 86526
```

11.4.11.2 Deploy and Maintain an Online TiDB Cluster Using TiUP

This document focuses on how to use the TiUP cluster component. For the complete steps of online deployment, refer to [Deploy a TiDB Cluster Using TiUP](#).

Similar to [the TiUP playground component](#) used for a local test deployment, the TiUP cluster component quickly deploys TiDB for production environment. Compared with playground, the cluster component provides more powerful production cluster management features, including upgrading, scaling, and even operation and auditing.

For the help information of the cluster component, run the following command:

```
tiup cluster
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.9.0/
```

```
↳ cluster
```

```
Deploy a TiDB cluster for production
```

```
Usage:
```

```
cluster [flags]
```

```
cluster [command]
```

```
Available Commands:
```

```
check      Perform preflight checks for the cluster
```

```
deploy     Deploy a cluster for production
```

```
start      Start a TiDB cluster
```

```
stop       Stop a TiDB cluster
```

```
restart    Restart a TiDB cluster
```

```
scale-in   Scale in a TiDB cluster
```

```
scale-out  Scale out a TiDB cluster
```

```
clean      Clean up cluster data
```

```
destroy    Destroy a specified cluster
```

```
upgrade    Upgrade a specified TiDB cluster
```

```
exec       Run shell command on host in the tidb cluster
```

```
display    Display information of a TiDB cluster
```

```
list       List all clusters
```

```
audit      Show audit log of cluster operation
```

```
import     Import an exist TiDB cluster from TiDB Ansible
```

```
edit-config Edit TiDB cluster config
```

```
reload     Reload a TiDB cluster's config and restart if needed
```

```
patch      Replace the remote package with a specified package and restart
```

```
↳ the service
```

```
help       Help about any command
```

```
Flags:
```

```
-h, --help      help for cluster
```

```
--native-ssh    Use the system's native SSH client
```

```
--wait-timeout int Timeout of waiting the operation
```

```
--ssh-timeout int Timeout in seconds to connect host via SSH, ignored
```

```
↳ for operations that don't need an SSH connection. (default 5)
```

```
-y, --yes       Skip all confirmations and assumes 'yes'
```

11.4.11.2.1 Deploy the cluster

To deploy the cluster, run the `tiup cluster deploy` command. The usage of the command is as follows:

```
tiup cluster deploy <cluster-name> <version> <topology.yaml> [flags]
```

This command requires you to provide the cluster name, the TiDB cluster version, and a topology file of the cluster.

To write a topology file, refer to [the example](#). The following file is an example of the simplest topology:

Note:

The topology file used by the TiUP cluster component for deployment and scaling is written using [yaml](#) syntax, so make sure that the indentation is correct.

```
---

pd_servers:
  - host: 172.16.5.134
    name: pd-134
  - host: 172.16.5.139
    name: pd-139
  - host: 172.16.5.140
    name: pd-140

tidb_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

tikv_servers:
  - host: 172.16.5.134
  - host: 172.16.5.139
  - host: 172.16.5.140

grafana_servers:
  - host: 172.16.5.134

monitoring_servers:
  - host: 172.16.5.134
```

By default, TiUP is deployed as the binary files running on the amd64 architecture. If the target machine is the arm64 architecture, you can configure it in the topology file:

```
global:
  arch: "arm64"          # Configures all machines to use the binary files of
                        ↪ the arm64 architecture by default

tidb_servers:
  - host: 172.16.5.134
    arch: "amd64"       # Configures this machine to use the binary files of
                        ↪ the amd64 architecture
  - host: 172.16.5.139
    arch: "arm64"       # Configures this machine to use the binary files of
                        ↪ the arm64 architecture
  - host: 172.16.5.140 # Machines that are not configured with the arch
                        ↪ field use the default value in the global field, which is arm64 in
                        ↪ this case.

...
```

Save the file as `/tmp/topology.yaml`. If you want to use TiDB v5.4.3 and your cluster name is `prod-cluster`, run the following command:

```
tiup cluster deploy -p prod-cluster v5.4.3 /tmp/topology.yaml
```

During the execution, TiUP asks you to confirm your topology again and requires the root password of the target machine (the `-p` flag means inputting password):

```
Please confirm your topology:
TiDB Cluster: prod-cluster
TiDB Version: v5.4.3
Type      Host      Ports      Directories
-----
pd        172.16.5.134 2379/2380  deploy/pd-2379,data/pd-2379
pd        172.16.5.139 2379/2380  deploy/pd-2379,data/pd-2379
pd        172.16.5.140 2379/2380  deploy/pd-2379,data/pd-2379
tikv     172.16.5.134 20160/20180 deploy/tikv-20160,data/tikv-20160
tikv     172.16.5.139 20160/20180 deploy/tikv-20160,data/tikv-20160
tikv     172.16.5.140 20160/20180 deploy/tikv-20160,data/tikv-20160
tidb     172.16.5.134 4000/10080 deploy/tidb-4000
tidb     172.16.5.139 4000/10080 deploy/tidb-4000
tidb     172.16.5.140 4000/10080 deploy/tidb-4000
prometheus 172.16.5.134 9090      deploy/prometheus-9090,data/prometheus
        ↪ -9090
grafana  172.16.5.134 3000      deploy/grafana-3000
Attention:
```

```
1. If the topology is not what you expected, check your yaml file.
2. Please confirm there is no port/directory conflicts in same host.
Do you want to continue? [y/N]:
```

After you enter the password, TiUP cluster downloads the required components and deploy them on the corresponding machines. When you see the following message, the deployment is successful:

```
Deployed cluster `prod-cluster` successfully
```

11.4.11.2.2 View the cluster list

After the cluster is successfully deployed, view the cluster list by running the following command:

```
tiup cluster list
```

```
Starting /root/.tiup/components/cluster/v1.9.0/cluster list
Name      User Version  Path
  ↪ PrivateKey
-----
  ↪ -----
prod-cluster tidb v5.4.3  /root/.tiup/storage/cluster/clusters/prod-cluster
  ↪ /root/.tiup/storage/cluster/clusters/prod-cluster/ssh/id_rsa
```

11.4.11.2.3 Start the cluster

After the cluster is successfully deployed, start the cluster by running the following command:

```
tiup cluster start prod-cluster
```

If you forget the name of your cluster, view the cluster list by running `tiup cluster ↪ list`.

11.4.11.2.4 Check the cluster status

TiUP provides the `tiup cluster display` command to view the status of each component in the cluster. With this command, you don't have to log in to each machine to see the component status. The usage of the command is as follows:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.9.0/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v5.4.3
```

ID	Role	Host	Ports	Status	Data Dir
↪	Deploy Dir				
---	----	----	-----	-----	-----
↪	-----				
172.16.5.134:3000	grafana	172.16.5.134	3000	Up	-
↪	deploy/grafana-3000				
172.16.5.134:2379	pd	172.16.5.134	2379/2380	Up L	data/pd-2379
↪	deploy/pd-2379				
172.16.5.139:2379	pd	172.16.5.139	2379/2380	Up UI	data/pd-2379
↪	deploy/pd-2379				
172.16.5.140:2379	pd	172.16.5.140	2379/2380	Up	data/pd-2379
↪	deploy/pd-2379				
172.16.5.134:9090	prometheus	172.16.5.134	9090	Up	data/
↪	prometheus-9090	deploy/prometheus-9090			
172.16.5.134:4000	tidb	172.16.5.134	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.139:4000	tidb	172.16.5.139	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.140:4000	tidb	172.16.5.140	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.134:20160	tikv	172.16.5.134	20160/20180	Up	data/tikv
↪	-20160	deploy/tikv-20160			
172.16.5.139:20160	tikv	172.16.5.139	20160/20180	Up	data/tikv
↪	-20160	deploy/tikv-20160			
172.16.5.140:20160	tikv	172.16.5.140	20160/20180	Up	data/tikv
↪	-20160	deploy/tikv-20160			

The **Status** column uses **Up** or **Down** to indicate whether the service is running normally.

For the PD component, **|L** or **|UI** might be appended to **Up** or **Down**. **|L** indicates that the PD node is a Leader, and **|UI** indicates that **TiDB Dashboard** is running on the PD node.

11.4.11.2.5 Scale in a cluster

Note:

This section describes only the syntax of the scale-in command. For detailed steps of online scaling, refer to [Scale a TiDB Cluster Using TiUP](#).

Scaling in a cluster means making some node(s) offline. This operation removes the specific node(s) from the cluster and deletes the remaining files.

Because the offline process of the TiKV and TiDB Binlog components is asynchronous (which requires removing the node through API), and the process takes a long time (which requires continuous observation on whether the node is successfully taken offline), special treatment is given to the TiKV and TiDB Binlog components.

- For TiKV and Binlog:
 - TiUP cluster takes the node offline through API and directly exits without waiting for the process to be completed.
 - Afterwards, when a command related to the cluster operation is executed, TiUP cluster examines whether there is a TiKV/Binlog node that has been taken offline. If not, TiUP cluster continues with the specified operation; If there is, TiUP cluster takes the following steps:
 1. Stop the service of the node that has been taken offline.
 2. Clean up the data files related to the node.
 3. Remove the node from the cluster topology.
- For other components:
 - When taking the PD component down, TiUP cluster quickly deletes the specified node from the cluster through API, stops the service of the specified PD node, and deletes the related data files.
 - When taking other components down, TiUP cluster directly stops the node service and deletes the related data files.

The basic usage of the scale-in command:

```
tiup cluster scale-in <cluster-name> -N <node-id>
```

To use this command, you need to specify at least two flags: the cluster name and the node ID. The node ID can be obtained by using the `tiup cluster display` command in the previous section.

For example, to make the TiKV node on 172.16.5.140 offline, run the following command:

```
tiup cluster scale-in prod-cluster -N 172.16.5.140:20160
```

By running `tiup cluster display`, you can see that the TiKV node is marked **Offline**:

```
tiup cluster display prod-cluster
```

```
Starting /root/.tiup/components/cluster/v1.9.0/cluster display prod-cluster
TiDB Cluster: prod-cluster
TiDB Version: v5.4.3
```

ID	Role	Host	Ports	Status	Data Dir
↪	Deploy Dir				
---	----	----	-----	-----	-----
↪	-----				
172.16.5.134:3000	grafana	172.16.5.134	3000	Up	-
↪	deploy/grafana-3000				
172.16.5.134:2379	pd	172.16.5.134	2379/2380	Up L	data/pd-2379
↪	deploy/pd-2379				
172.16.5.139:2379	pd	172.16.5.139	2379/2380	Up UI	data/pd-2379
↪	deploy/pd-2379				
172.16.5.140:2379	pd	172.16.5.140	2379/2380	Up	data/pd-2379
↪	deploy/pd-2379				
172.16.5.134:9090	prometheus	172.16.5.134	9090	Up	data/
↪	prometheus-9090	deploy/prometheus-9090			
172.16.5.134:4000	tidb	172.16.5.134	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.139:4000	tidb	172.16.5.139	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.140:4000	tidb	172.16.5.140	4000/10080	Up	-
↪	deploy/tidb-4000				
172.16.5.134:20160	tikv	172.16.5.134	20160/20180	Up	data/tikv
↪	-20160	deploy/tikv-20160			
172.16.5.139:20160	tikv	172.16.5.139	20160/20180	Up	data/tikv
↪	-20160	deploy/tikv-20160			
172.16.5.140:20160	tikv	172.16.5.140	20160/20180	Offline	data/tikv
↪	-20160	deploy/tikv-20160			

After PD schedules the data on the node to other TiKV nodes, this node will be deleted automatically.

11.4.11.2.6 Scale out a cluster

Note:

This section describes only the syntax of the scale-out command. For detailed steps of online scaling, refer to [Scale a TiDB Cluster Using TiUP](#).

The scale-out operation has an inner logic similar to that of deployment: the TiUP cluster component firstly ensures the SSH connection of the node, creates the required directories on the target node, then executes the deployment operation, and starts the node service.

When you scale out PD, the node is added to the cluster by `join`, and the configurations of services associated with PD are updated. When you scale out other services, the service

is started directly and added to the cluster.

All services conduct correctness validation when they are scaled out. The validation results show whether the scaling-out is successful.

To add a TiKV node and a PD node in the `tidb-test` cluster, take the following steps:

1. Create a `scale.yaml` file, and add IPs of the new TiKV and PD nodes:

Note:

You need to create a topology file, which includes only the description of the new nodes, not the existing nodes.

```
---  
  
pd_servers:  
  - ip: 172.16.5.140  
  
tikv_servers:  
  - ip: 172.16.5.140
```

2. Perform the scale-out operation. TiUP cluster adds the corresponding nodes to the cluster according to the port, directory, and other information described in `scale.yaml`.

```
tiup cluster scale-out tidb-test scale.yaml
```

After the command is executed, you can check the status of the scaled-out cluster by running `tiup cluster display tidb-test`.

11.4.11.2.7 Rolling upgrade

Note:

This section describes only the syntax of the upgrade command. For detailed steps of online upgrade, refer to [Upgrade TiDB Using TiUP](#).

The rolling upgrade feature leverages the distributed capabilities of TiDB. The upgrade process is made as transparent as possible to the application, and does not affect the business.

Before the upgrade, TiUP cluster checks whether the configuration file of each component is rational. If so, the components are upgraded node by node; if not, TiUP reports an error and exits. The operations vary with different nodes.

Operations for different nodes

- Upgrade the PD node
 - First, upgrade non-Leader nodes.
 - After all the non-Leader nodes are upgraded, upgrade the Leader node.
 - * The upgrade tool sends a command to PD that migrates Leader to an already upgraded node.
 - * After the Leader role is switched to another node, upgrade the previous Leader node.
 - During the upgrade, if any unhealthy node is detected, the tool stops this upgrade operation and exits. You need to manually analyze the cause, fix the issue and run the upgrade again.
- Upgrade the TiKV node
 - First, add a scheduling operation in PD that migrates the Region Leader of this TiKV node. This ensures that the upgrade process does not affect the business.
 - After the Leader is migrated, upgrade this TiKV node.
 - After the upgraded TiKV is started normally, remove the scheduling of the Leader.
- Upgrade other services
 - Stop the service normally and update the node.

Upgrade command

The flags for the upgrade command is as follows:

```
Usage:
cluster upgrade <cluster-name> <version> [flags]

Flags:
  --force           Force upgrade won't transfer leader
  -h, --help       help for upgrade
  --transfer-timeout int Timeout in seconds when transferring PD and
                  ↪ TiKV store leaders (default 300)

Global Flags:
  --native-ssh      Use the system's native SSH client
  --wait-timeout int Timeout of waiting the operation
  --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
                  ↪ for operations that don't need an SSH connection. (default 5)
  -y, --yes        Skip all confirmations and assumes 'yes'
```

For example, the following command upgrades the cluster to v5.4.3:

```
tiup cluster upgrade tidb-test v5.4.3
```

11.4.11.2.8 Update configuration

If you want to dynamically update the component configurations, the TiUP cluster component saves a current configuration for each cluster. To edit this configuration, execute the `tiup cluster edit-config <cluster-name>` command. For example:

```
tiup cluster edit-config prod-cluster
```

TiUP cluster opens the configuration file in the vi editor. If you want to use other editors, use the `EDITOR` environment variable to customize the editor, such as `export EDITOR=nano`.

After editing the file, save the changes. To apply the new configuration to the cluster, execute the following command:

```
tiup cluster reload prod-cluster
```

The command sends the configuration to the target machine and restarts the cluster to make the configuration take effect.

Note:

For monitoring components, customize the configuration by executing the `tiup cluster edit-config` command to add a custom configuration path on the corresponding instance. For example:

```
---  
  
grafana_servers:  
  - host: 172.16.5.134  
    dashboard_dir: /path/to/local/dashboards/dir  
  
monitoring_servers:  
  - host: 172.16.5.134  
    rule_dir: /path/to/local/rules/dir  
  
alertmanager_servers:  
  - host: 172.16.5.134  
    config_file: /path/to/local/alertmanager.yml
```

The content and format requirements for files under the specified path are as follows:

- The folder specified in the `dashboard_dir` field of `grafana_servers` must contain full `*.json` files.
- The folder specified in the `rule_dir` field of `monitoring_servers` must contain full `*.rules.yml` files.
- For the format of files specified in the `config_file` field of `alertmanager_servers`, refer to [the Alertmanager configuration template](#).

When you execute `tiup reload`, TiUP first deletes all old configuration files in the target machine and then uploads the corresponding configuration from the control machine to the corresponding configuration directory of the target machine. Therefore, if you want to modify a particular configuration file, make sure that all configuration files (including the unmodified ones) are in the same directory. For example, to modify Grafana's `tidb.json` file, you need to first copy all the `*.json` files from Grafana's `dashboards` directory to your local directory. Otherwise, other JSON files will be missing from the target machine.

Note:

If you have configured the `dashboard_dir` field of `grafana_servers`, after executing the `tiup cluster rename` command to rename the cluster, you need to complete the following operations:

1. In the local `dashboards` directory, change the cluster name to the new cluster name.
2. In the local `dashboards` directory, change `datasource` to the new cluster name, because `datasource` is named after the cluster name.
3. Execute the `tiup cluster reload -R grafana` command.

11.4.11.2.9 Update component

For normal upgrade, you can use the `upgrade` command. But in some scenarios, such as debugging, you might need to replace the currently running component with a temporary package. To achieve this, use the `patch` command:

```
tiup cluster patch --help
```

```
Replace the remote package with a specified package and restart the service
```

```
Usage:
```

```
cluster patch <cluster-name> <package-path> [flags]
```

```
Flags:
```

```
-h, --help           help for patch
-N, --node strings   Specify the nodes
```

```
--overwrite          Use this package in the future scale-out
  ↳ operations
-R, --role strings    Specify the role
--transfer-timeout int Timeout in seconds when transferring PD and
  ↳ TiKV store leaders (default 300)
```

Global Flags:

```
--native-ssh         Use the system's native SSH client
--wait-timeout int   Timeout of waiting the operation
--ssh-timeout int    Timeout in seconds to connect host via SSH, ignored
  ↳ for operations that don't need an SSH connection. (default 5)
-y, --yes            Skip all confirmations and assumes 'yes'
```

If a TiDB hotfix package is in `/tmp/tidb-hotfix.tar.gz` and you want to replace all the TiDB packages in the cluster, run the following command:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -R tidb
```

You can also replace only one TiDB package in the cluster:

```
tiup cluster patch test-cluster /tmp/tidb-hotfix.tar.gz -N 172.16.4.5:4000
```

11.4.11.2.10 Import TiDB Ansible cluster

Note:

Currently, TiUP cluster's support for TiSpark is still **experimental**. It is not supported to import a TiDB cluster with TiSpark enabled.

Before TiUP is released, TiDB Ansible is often used to deploy TiDB clusters. To enable TiUP to take over the cluster deployed by TiDB Ansible, use the `import` command.

The usage of the `import` command is as follows:

```
tiup cluster import --help
```

```
Import an exist TiDB cluster from TiDB-Ansible
```

Usage:

```
cluster import [flags]
```

Flags:

```
-d, --dir string      The path to TiDB-Ansible directory
```

```
-h, --help          help for import
--inventory string The name of inventory file (default "inventory.ini
    ↪ ")
--no-backup         Don't backup ansible dir, useful when there're
    ↪ multiple inventory files
-r, --rename NAME   Rename the imported cluster to NAME
```

Global Flags:

```
--native-ssh       Use the system's native SSH client
--wait-timeout int Timeout of waiting the operation
--ssh-timeout int  Timeout in seconds to connect host via SSH, ignored
    ↪ for operations that don't need an SSH connection. (default 5)
-y, --yes          Skip all confirmations and assumes 'yes'
```

You can use either of the following commands to import a TiDB Ansible cluster:

```
cd tidb-ansible
tiup cluster import
```

```
tiup cluster import --dir=/path/to/tidb-ansible
```

11.4.11.2.11 View the operation log

To view the operation log, use the `audit` command. The usage of the `audit` command is as follows:

```
Usage:
tiup cluster audit [audit-id] [flags]
```

```
Flags:
-h, --help help for audit
```

If the `[audit-id]` flag is not specified, the command shows a list of commands that have been executed. For example:

```
tiup cluster audit
```

```
Starting component `cluster`: /home/tidb/.tiup/components/cluster/v1.9.0/
    ↪ cluster audit
ID      Time                Command
--      ----                -
4BLhr0  2022-07-08T13:25:09+08:00 /home/tidb/.tiup/components/cluster/v1.9.0/
    ↪ cluster deploy test v5.4.3 /tmp/topology.yaml
4BKWjF  2022-07-08T23:36:57+08:00 /home/tidb/.tiup/components/cluster/v1.9.0/
    ↪ cluster deploy test v5.4.3 /tmp/topology.yaml
```

```
4BKVwH 2022-07-08T23:02:08+08:00 /home/tidb/.tiup/components/cluster/v1.9.0/
↳ cluster deploy test v5.4.3 /tmp/topology.yaml
4BKKH1 2022-07-08T16:39:04+08:00 /home/tidb/.tiup/components/cluster/v1.9.0/
↳ cluster destroy test
4BKKDx 2022-07-08T16:36:57+08:00 /home/tidb/.tiup/components/cluster/v1.9.0/
↳ cluster deploy test v5.4.3 /tmp/topology.yaml
```

The first column is `audit-id`. To view the execution log of a certain command, pass the `audit-id` of a command as the flag as follows:

```
tiup cluster audit 4BLhr0
```

11.4.11.2.12 Run commands on a host in the TiDB cluster

To run command on a host in the TiDB cluster, use the `exec` command. The usage of the `exec` command is as follows:

```
Usage:
cluster exec <cluster-name> [flags]

Flags:
  --command string the command run on cluster host (default "ls")
  -h, --help          help for exec
  -N, --node strings Only exec on host with specified nodes
  -R, --role strings Only exec on host with specified roles
  --sudo              use root permissions (default false)

Global Flags:
  --ssh-timeout int Timeout in seconds to connect host via SSH, ignored
  ↳ for operations that don't need an SSH connection. (default 5)
  -y, --yes          Skip all confirmations and assumes 'yes'
```

For example, to execute `ls /tmp` on all TiDB nodes, run the following command:

```
tiup cluster exec test-cluster --command='ls /tmp'
```

11.4.11.2.13 Cluster controllers

Before TiUP is released, you can control the cluster using `tidb-ctl`, `tikv-ctl`, `pd-ctl`, and other tools. To make the tools easier to download and use, TiUP integrates them into an all-in-one component, `ctl`.

```
Usage:
tiup ctl:<cluster-version> {tidb/pd/tikv/binlog/etcd} [flags]

Flags:
  -h, --help help for tiup
```

This command has a corresponding relationship with those of the previous tools:

```
tidb-ctl [args] = tiup ctl tidb [args]
pd-ctl [args] = tiup ctl pd [args]
tikv-ctl [args] = tiup ctl tikv [args]
binlogctl [args] = tiup ctl binlog [args]
etcdctl [args] = tiup ctl etcd [args]
```

For example, if you previously view the store by running `pd-ctl -u http://127.0.0.1:2379 ↪ store`, now you can run the following command in TiUP:

```
tiup ctl:<cluster-version> pd -u http://127.0.0.1:2379 store
```

11.4.11.2.14 Environment checks for target machines

You can use the `check` command to perform a series of checks on the environment of the target machine and output the check results. By executing the `check` command, you can find common unreasonable configurations or unsupported situations. The command flag list is as follows:

```
Usage:
  tiup cluster check <topology.yml | cluster-name> [flags]
Flags:
  --apply                Try to fix failed checks
  --cluster              Check existing cluster, the input is a cluster
                       ↪ name.
  --enable-cpu           Enable CPU thread count check
  --enable-disk         Enable disk IO (fio) check
  --enable-mem          Enable memory size check
  -h, --help            help for check
  -i, --identity_file string The path of the SSH identity file. If specified
                       ↪ , public key authentication will be used.
  -p, --password        Use password of target hosts. If specified,
                       ↪ password authentication will be used.
  --user string         The user name to login via SSH. The user must
                       ↪ has root (or sudo) privilege.
```

By default, this command is used to check the environment before deployment. By specifying the `--cluster` flag to switch the mode, you can also check the target machines of an existing cluster, for example:

```
#### check deployed servers before deployment
tiup cluster check topology.yml --user tidb -p
#### check deployed servers of an existing cluster
tiup cluster check <cluster-name> --cluster
```

The CPU thread count check, memory size check, and disk performance check are disabled by default. For the production environment, it is recommended that you enable the three checks and make sure they pass to obtain the best performance.

- CPU: If the number of threads is greater than or equal to 16, the check is passed.
- Memory: If the total size of physical memory is greater than or equal to 32 GB, the check is passed.
- Disk: Execute `fiio` test on the partitions of `data_dir` and record the results.

When running the checks, if the `--apply` flag is specified, the program automatically repairs the failed items. Automatic repair is limited to some items that can be adjusted by modifying the configuration or system parameters. Other unrepaired items need to be handled manually according to the actual situation.

Environment checks are not necessary for deploying a cluster. For the production environment, it is recommended to perform environment checks and pass all check items before deployment. If not all the check items are passed, the cluster might be deployed and run normally, but the best performance might not be obtained.

11.4.11.2.15 Use the system's native SSH client to connect to cluster

All operations above performed on the cluster machine use the SSH client embedded in TiUP to connect to the cluster and execute commands. However, in some scenarios, you might also need to use the SSH client native to the control machine system to perform such cluster operations. For example:

- To use a SSH plug-in for authentication
- To use a customized SSH client

Then you can use the `--native-ssh` command-line flag to enable the system-native command-line tool:

- Deploy a cluster: `tiup cluster deploy <cluster-name> <version> <topo> --native-ssh`
- Start a cluster: `tiup cluster start <cluster-name> --native-ssh`
- Upgrade a cluster: `tiup cluster upgrade ... --native-ssh`

You can add `--native-ssh` in all cluster operation commands above to use the system's native SSH client.

To avoid adding such a flag in every command, you can use the `TIUP_NATIVE_SSH` system variable to specify whether to use the local SSH client:

```
export TIUP_NATIVE_SSH=true
#### or
export TIUP_NATIVE_SSH=1
#### or
export TIUP_NATIVE_SSH=enable
```

If you specify this environment variable and `--native-ssh` at the same time, `--native` \leftrightarrow `-ssh` has higher priority.

Note:

During the process of cluster deployment, if you need to use a password for connection (`-p`) or `passphrase` is configured in the key file, you must ensure that `sshpass` is installed on the control machine; otherwise, a timeout error is reported.

11.4.11.2.16 Migrate control machine and back up TiUP data

The TiUP data is stored in the `.tiup` directory in the user's home directory. To migrate the control machine, you can take the following steps to copy the `.tiup` directory to the corresponding target machine:

1. Execute `tar czvf tiup.tar.gz .tiup` in the home directory of the original machine.
2. Copy `tiup.tar.gz` to the home directory of the target machine.
3. Execute `tar xzvf tiup.tar.gz` in the home directory of the target machine.
4. Add the `.tiup` directory to the `PATH` environment variable.

If you use `bash` and you are a `tidb` user, you can add `export PATH=/home/tidb` \leftrightarrow `./tiup/bin:$PATH` in `~/.bashrc` and execute `source ~/.bashrc`. Then make corresponding adjustments according to the shell and the user you use.

Note:

It is recommended that you back up the `.tiup` directory regularly to avoid the loss of TiUP data caused by abnormal conditions, such as disk damage of the control machine.

11.4.11.3 Create a Private Mirror

When creating a private cloud, usually, you need to use an isolated network environment, where the official mirror of TiUP is not accessible. Therefore, you can create a private mirror, which is mainly implemented by the `mirror` command. You can also use the `mirror` command for offline deployment. A private mirror also allows you to use components that you build and package by yourself.

11.4.11.3.1 TiUP mirror overview

Execute the following command to get the help information of the `mirror` command:

```
tiup mirror --help
```

The `mirror` command is used to manage a component repository for TiUP, you
↪ can use

it to create a private repository, or to add new component to an existing
↪ repository.

The repository can be used either online or offline.

It also provides some useful utilities to `help` manage keys, users, and
↪ versions

of components or the repository itself.

Usage:

```
tiup mirror <command> [flags]
```

Available Commands:

<code>init</code>	Initialize an empty repository
<code>sign</code>	Add signatures to a manifest file
<code>genkey</code>	Generate a new key pair
<code>clone</code>	Clone a <code>local</code> mirror from a remote mirror and download all ↪ selected components
<code>merge</code>	Merge two or more offline mirrors
<code>publish</code>	Publish a component
<code>show</code>	Show the mirror address
<code>set</code>	Set mirror address
<code>modify</code>	Modify published component
<code>renew</code>	Renew the manifest of a published component.
<code>grant</code>	grant a new owner
<code>rotate</code>	Rotate root.json

Global Flags:

<code>--help</code>	Help for this command
<code>--skip-version-check</code>	Skip the strict version check, by default a ↪ version must be a valid SemVer string

Use `"tiup mirror [command] --help"` for more information about a `command`.

11.4.11.3.2 Clone a mirror

You can run the `tiup mirror clone` command to build a local mirror:

```
tiup mirror clone <target-dir> [global-version] [flags]
```

- `target-dir`: used to specify the directory in which cloned data is stored.
- `global-version`: used to quickly set a global version for all components.

The `tiup mirror clone` command provides many optional flags (might provide more in the future). These flags can be divided into the following categories according to their intended usages:

- Determines whether to use prefix matching to match the version when cloning
If the `--prefix` flag is specified, the version number is matched by prefix for the clone. For example, if you specify `--prefix` as “v5.0.0”, then “v5.0.0-rc”, and “v5.0.0” are matched.
- Determines whether to use the full clone
If you specify the `--full` flag, you can clone the official mirror fully.

Note:

If `--full`, `global-version` flags, and the component versions are not specified, only some meta information is cloned.

- Determines whether to clone packages from the specific platform
If you want to clone packages only for a specific platform, use `-os` and `-arch` to specify the platform. For example:
 - Execute the `tiup mirror clone <target-dir> [global-version] --os= ↪ linux` command to clone for linux.
 - Execute the `tiup mirror clone <target-dir> [global-version] --arch= ↪ amd64` command to clone for amd64.
 - Execute the `tiup mirror clone <target-dir> [global-version] --os= ↪ linux --arch=amd64` command to clone for linux/amd64.
- Determines whether to clone a specific version of a package
If you want to clone only one version (not all versions) of a component, use `--< ↪ component>=<version>` to specify this version. For example:

- Execute the `tiup mirror clone <target-dir> --tidb v5.4.3` command to clone the v5.4.3 version of the TiDB component.
- Run the `tiup mirror clone <target-dir> --tidb v5.4.3 --tikv all` command to clone the v5.4.3 version of the TiDB component and all versions of the TiKV component.
- Run the `tiup mirror clone <target-dir> v5.4.3` command to clone the v5.4.3 version of all components in a cluster.

After cloning, signing keys are set up automatically.

Manage the private repository

You can share the repository cloned using `tiup mirror clone` among hosts either by sharing files via SCP, NFS, or by making the repository available over the HTTP or HTTPS protocol. Use `tiup mirror set <location>` to specify the location of the repository.

```
tiup mirror set /shared_data/tiup
```

```
tiup mirror set https://tiup-mirror.example.com/
```

Note:

If you run `tiup mirror set...` on the machine where you run `tiup mirror` \leftrightarrow `clone`, the next time you run `tiup mirror clone...`, the machine clones from the local mirror, not the remote one. Therefore, you need to reset the mirror by running `tiup mirror set --reset` before updating the private mirror.

Another way of using a mirror is to use the `TIUP_MIRRORS` environment variable. Here is an example for running `tiup list` with a private repository.

```
export TIUP_MIRRORS=/shared_data/tiup  
tiup list
```

`TIUP_MIRRORS` setting can permanently change the mirror configuration, for example, `tiup mirror set`. For details, see [tiup issue #651](#).

Update the private repository

If you run the `tiup mirror clone` command again with the same `target-dir`, the machine will create new manifests and download the latest versions of components available.

Note:

Before recreating the manifest, ensure that all components and versions (including earlier ones downloaded previously) are included.

11.4.11.3.3 Custom repository

You can create a custom repository to work with TiDB components like TiDB, TiKV, or PD that you build by yourself. It is also possible to create your own tiup components.

To create your own components, run the `tiup package` command and perform as instructed in [Component packaging](#).

Create a custom repository

To create an empty repository in `/data/mirror`:

```
tiup mirror init /data/mirror
```

As part of creating the repository, keys will be written to `/data/mirror/keys`.

To create a new private key in `~/.tiup/keys/private.json`:

```
tiup mirror genkey
```

Grant `jdoue` with private key `~/.tiup/keys/private.json` ownership of `/data/mirror`:

```
tiup mirror set /data/mirror
tiup mirror grant jdoue
```

Work with custom components

1. Create a custom component called `hello`.

```
$ cat > hello.c << END
> #include <stdio.h>
int main() {
    printf("hello\n");
    return (0);
}
END
$ gcc hello.c -o hello
$ tiup package hello --entry hello --name hello --release v0.0.1
```

`package/hello-v0.0.1-linux-amd64.tar.gz` is created.

2. Create a repository and a private key, and grant ownership to the repository.

```
$ tiup mirror init /tmp/m
$ tiup mirror genkey
$ tiup mirror set /tmp/m
$ tiup mirror grant $USER
```

```
tiup mirror publish hello v0.0.1 package/hello-v0.0.1-linux-amd64.tar.
↪ gz hello
```

3. Run the component. If it is not installed yet, it will be downloaded first.

```
$ tiup hello
```

```
The component `hello` version is not installed; downloading from
↪ repository.
Starting component `hello`: /home/dvaneeden/.tiup/components/hello/v0
↪ .0.1/hello
hello
```

With `tiup mirror merge`, you can merge a repository with custom components into another one. This assumes that all components in `/data/my_custom_components` are signed by the current `$USER`.

```
$ tiup mirror set /data/my_mirror
$ tiup mirror grant $USER
$ tiup mirror merge /data/my_custom_components
```

11.4.11.4 Stress Test TiDB Using TiUP Bench Component

When you test the performance of a database, it is often required to stress test the database. To facilitate this, TiUP has integrated the bench component, which provides two workloads for stress testing: [TPC-C](#) and [TPC-H](#). The commands and flags are as follows. For more information, see the [TPC official website](#).

```
tiup bench
```

```
Starting component `bench`: /home/tidb/.tiup/components/bench/v1.5.0/bench
Benchmark database with different workloads
```

Usage:

```
tiup bench [command]
```

Available Commands:

```
help      Help about any command
tpcc
tpch
```

```

Flags:
  --count int           Total execution count, 0 means infinite
  -D, --db string       Database name (default "test")
  -d, --driver string   Database driver: mysql
  --dropdata            Cleanup data before prepare
  -h, --help            help for /Users/joshua/.tiup/components/bench/v0
                       ↪ .0.1/bench
  -H, --host string     Database host (default "127.0.0.1")
  --ignore-error        Ignore error when running workload
  --interval duration  Output interval time (default 10s)
  --isolation int       Isolation Level 0: Default, 1: ReadUncommitted,
                       2: ReadCommitted, 3: WriteCommitted, 4:
                       ↪ RepeatableRead,
                       5: Snapshot, 6: Serializable, 7: Linerizable
  --max-procs int      runtime.GOMAXPROCS
  -p, --password string Database password
  -P, --port int        Database port (default 4000)
  --pprof string        Address of pprof endpoint
  --silence             Don't print error when running workload
  --summary             Print summary TPM only, or also print current TPM
                       ↪ when running workload
  -T, --threads int     Thread concurrency (default 16)
  --time duration       Total execution time (default 2562047h47m16
                       ↪ .854775807s)
  -U, --user string     Database user (default "root")

```

The following sections describe how to run TPC-C and TPC-H tests using TiUP.

11.4.11.4.1 Run TPC-C test using TiUP

The TiUP bench component supports the following commands and flags to run the TPC-C test:

```

Available Commands:
  check      Check data consistency for the workload
  cleanup    Cleanup data for the workload
  prepare    Prepare data for the workload
  run        Run workload

Flags:
  --check-all  Run all consistency checks
  -h, --help    help for tpcc
  --parts int   Number to partition warehouses (default 1)
  --warehouses int Number of warehouses (default 10)

```

Test procedures

1. Create 4 warehouses using 4 partitions via hash:

```
tiup bench tpcc --warehouses 4 --parts 4 prepare
```

2. Run the TPC-C test:

```
tiup bench tpcc --warehouses 4 run
```

3. Clean up data:

```
tiup bench tpcc --warehouses 4 cleanup
```

4. Check the consistency:

```
tiup bench tpcc --warehouses 4 check
```

5. Generate the CSV file:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=  
↪ csv
```

6. Generate the CSV file for the specified table:

```
tiup bench tpcc --warehouses 4 prepare --output-dir data --output-type=  
↪ csv --tables history,orders
```

11.4.11.4.2 Run TPC-H test using TiUP

The TiUP bench component supports the following commands and parameters to run the TPC-H test:

Available Commands:

```
cleanup    Cleanup data for the workload  
prepare    Prepare data for the workload  
run        Run workload
```

Flags:

```
--check      Check output data, only when the scale factor equals 1  
-h, --help   help for tpch  
--queries string All queries (default "q1,q2,q3,q4,q5,q6,q7,q8,q9,q10,  
↪ q11,q12,q13,q14,q15,q16,q17,q18,q19,q20,q21,q22")  
--sf int      scale factor
```

Test procedures

1. Prepare data:

```
tiup bench tpch --sf=1 prepare
```

2. Run the TPC-H test by executing one of the following commands:

- If you check the result, run this command:

```
tiup bench tpch --sf=1 --check=true run
```

- If you do not check the result, run this command:

```
tiup bench tpch --sf=1 run
```

3. Clean up data:

```
tiup bench tpch cleanup
```

11.5 TiDB Operator

[TiDB Operator](#) is an automatic operation system for TiDB clusters in Kubernetes. It provides full life-cycle management for TiDB including deployment, upgrades, scaling, backup, fail-over, and configuration changes. With TiDB Operator, TiDB can run seamlessly in the Kubernetes clusters deployed on a public or private cloud.

Currently, the TiDB Operator documentation (also named as TiDB in Kubernetes documentation) is independent of the TiDB documentation. To access the documentation, click the following link:

- [TiDB in Kubernetes documentation](#)

11.6 Backup & Restore (BR)

11.6.1 BR Tool Overview

[BR](#) (Backup & Restore) is a command-line tool for distributed backup and restoration of the TiDB cluster data.

Compared with [Dumpling](#), BR is more suitable for scenarios involved huge data volumes.

In addition to regular backup and restoration, you can also use BR for large-scale data migration as long as compatibility is ensured.

This document describes BR's implementation principles, recommended deployment configuration, usage restrictions and several methods to use BR.

11.6.1.1 Implementation principles

BR sends the backup or restoration commands to each TiKV node. After receiving these commands, TiKV performs the corresponding backup or restoration operations.

Each TiKV node has a path in which the backup files generated in the backup operation are stored and from which the stored backup files are read during the restoration.

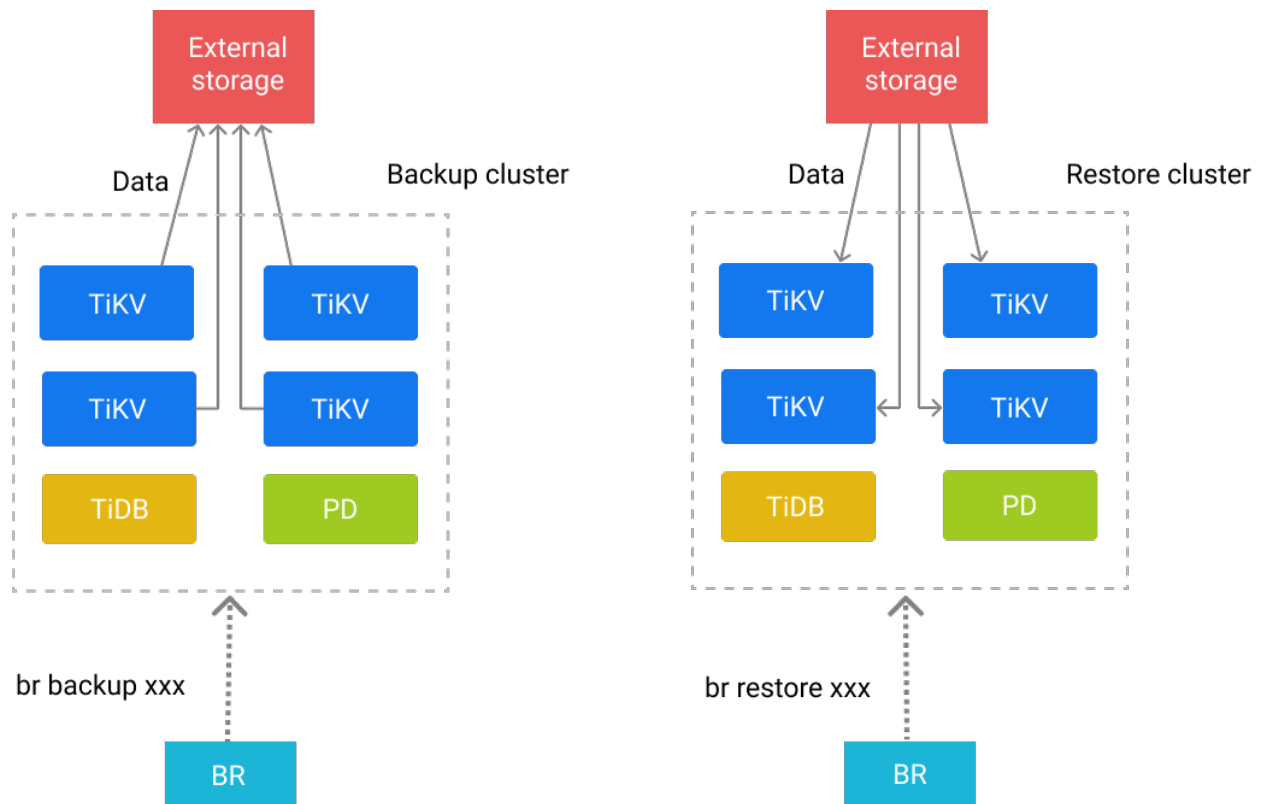

Figure 124: br-arch

Backup principle

When BR performs a backup operation, it first obtains the following information from PD:

- The current TS (timestamp) as the time of the backup snapshot
- The TiKV node information of the current cluster

According to these information, BR starts a TiDB instance internally to obtain the database or table information corresponding to the TS, and filters out the system databases (`information_schema`, `performance_schema`, `mysql`) at the same time.

According to the backup sub-command, BR adopts the following two types of backup logic:

- Full backup: BR traverses all the tables and constructs the KV range to be backed up according to each table.
- Single table backup: BR constructs the KV range to be backed up according a single table.

Finally, BR collects the KV range to be backed up and sends the complete backup request to the TiKV node of the cluster.

The structure of the request:

```
BackupRequest{
  ClusterId,    // The cluster ID.
  StartKey,    // The starting key of the backup (backed up).
  EndKey,      // The ending key of the backup (not backed up).
  StartVersion, // The version of the last backup snapshot, used for the
               ↪ incremental backup.
  EndVersion,  // The backup snapshot time.
  StorageBackend, // The path where backup files are stored.
  RateLimit,   // Backup speed (MB/s).
}
```

After receiving the backup request, the TiKV node traverses all Region leaders on the node to find the Regions that overlap with the KV ranges in this request. The TiKV node backs up some or all of the data within the range, and generates the corresponding SST file.

After finishing backing up the data of the corresponding Region, the TiKV node returns the metadata to BR. BR collects the metadata and stores it in the `backupmeta` file which is used for restoration.

If `StartVersion` is not 0, the backup is seen as an incremental backup. In addition to KVs, BR also collects DDLs between `[StartVersion, EndVersion)`. During data restoration, these DDLs are restored first.

If checksum is enabled when you execute the backup command, BR calculates the checksum of each backed up table for data check.

11.6.1.1.1 Types of backup files

Two types of backup files are generated in the path where backup files are stored:

- **The SST file:** stores the data that the TiKV node backed up.
- **The backupmeta file:** stores the metadata of this backup operation, including the number, the key range, the size, and the Hash (sha256) value of the backup files.
- **The backup.lock file:** prevents multiple backup operations from storing data to the same directory.

11.6.1.1.2 The format of the SST file name

The SST file is named in the format of `storeID_regionID_regionEpoch_keyHash_cf`, where

- `storeID` is the TiKV node ID;
- `regionID` is the Region ID;
- `regionEpoch` is the version number of the Region;
- `keyHash` is the Hash (sha256) value of the startKey of a range, which ensures the uniqueness of a key;
- `cf` indicates the **Column Family** of RocksDB (`default` or `write by default`).

Restoration principle

During the data restoration process, BR performs the following tasks in order:

1. It parses the `backupmeta` file in the backup path, and then starts a TiDB instance internally to create the corresponding databases and tables based on the parsed information.
2. It aggregates the parsed SST files according to the tables.
3. It pre-splits Regions according to the key range of the SST file so that every Region corresponds to at least one SST file.
4. It traverses each table to be restored and the SST file corresponding to each tables.
5. It finds the Region corresponding to the SST file and sends a request to the corresponding TiKV node for downloading the file. Then it sends a request for loading the file after the file is successfully downloaded.

After TiKV receives the request to load the SST file, TiKV uses the Raft mechanism to ensure the strong consistency of the SST data. After the downloaded SST file is loaded successfully, the file is deleted asynchronously.

After the restoration operation is completed, BR performs a checksum calculation on the restored data to compare the stored data with the backed up data.

11.6.1.2 Deploy and use BR

11.6.1.2.1 Recommended deployment configuration

- It is recommended that you deploy BR on the PD node.
- It is recommended that you mount a high-performance SSD to BR nodes and all TiKV nodes. A 10-gigabit network card is recommended. Otherwise, bandwidth is likely to be the performance bottleneck during the backup and restore process.

Note:

- If you do not mount a network disk or use other shared storage, the data backed up by BR will be generated on each TiKV node. Because BR only backs up leader replicas, you should estimate the space reserved for each node based on the leader size.
- Because TiDB uses leader count for load balancing by default, leaders can greatly differ in size. This might result in uneven distribution of backup data on each node.

11.6.1.2.2 Usage restrictions

The following are the limitations of using BR for backup and restoration:

- When BR restores data to the upstream cluster of TiCDC/Drainer, TiCDC/Drainer cannot replicate the restored data to the downstream.
- BR supports operations only between clusters with the same `new_collations_enabled_on_first_bootstrap` value because BR only backs up KV data. If the cluster to be backed up and the cluster to be restored use different collations, the data validation fails. Therefore, before restoring a cluster, make sure that the switch value from the query result of the `select VARIABLE_VALUE from mysql.tidb where VARIABLE_NAME='new_collation_enabled'`; statement is consistent with that during the backup process.

11.6.1.2.3 Compatibility

The compatibility issues of BR and the TiDB cluster are divided into the following categories:

- Some versions of BR are not compatible with the interface of the TiDB cluster.
 - BR versions earlier than v5.4.0 do not support recovering `charset=GBK` tables. No version of BR supports recovering `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- The KV format might change when some features are enabled or disabled. If these features are not consistently enabled or disabled during backup and restore, compatibility issues might occur.

These features are as follows:

Features	Issues	Solutions
New collation	#352	Make sure that the value of the <code>new_collations_enabled_on_first_bootstrap</code> ↪ variable is consistent with that during backup. Otherwise, inconsistent data index might occur and checksum might fail to pass.

Features	Related issues	Solutions
enabled on the restore cluster	TiCDC #364	Currently, TiKV cannot push down the BR-ingested SST files to TiCDC. Therefore, you need to disable TiCDC when using BR to restore data.

Related is-	
Features	Solutions
Global temporary tables	Make sure that you are using BR v5.3.0 or a later version to back up and restore data. Otherwise, an error occurs in the definition of the backed global temporary tables.

However, even after you have ensured that the above features are consistently enabled or disabled during backup and restore, compatibility issues might still occur due to the inconsistent internal versions or inconsistent interfaces between BR and TiKV/TiDB/PD. To avoid such cases, BR has the built-in version check.

Version check

Before performing backup and restore, BR compares and checks the TiDB cluster version and the BR version. If there is a major-version mismatch (for example, BR v4.x and TiDB v5.x), BR prompts a reminder to exit. To forcibly skip the version check, you can set `--check-requirements=false`.

Note that skipping the version check might introduce incompatibility. The version compatibility information between BR and TiDB versions are as follows:

Backup ver- sion (ver- tical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Use BR nightly to back up TiDB nightly	(If a table with the pri- mary key of the non- integer clus- tered index type is re- stored to a TiDB v4.0 clus- ter, BR will cause data error with- out warn- ing.)		

Backup ver- sion (ver- tical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Use BR v5.0 to back up TiDB v5.0	(If a table with the pri- mary key of the non- integer clus- tered index type is re- stored to a TiDB v4.0 clus- ter, BR will cause data error with- out warn- ing.)		

Backup ver- sion (ver- tical)	Use BR nightly	Use BR v5.0 to re- store TiDB nightly	Use BR v4.0 to re- store TiDB v4.0
Use BR v4.0 to back up TiDB v4.0	(If TiKV >= v4.0.0- rc.1, and if BR con- tains the #233 bug fix and TiKV does not con- tain the #7241 bug fix, BR will cause the TiKV node to restart.)		

Backup ver- sion (ver- tical)	Re- store ver- sion (hori- zon- tal)	Use BR nightly to re- store TiDB nightly	Use BR v5.0 to re- store TiDB v5.0	Use BR v4.0 to re- store TiDB v4.0
Use BR nightly or v5.0 to back up TiDB v4.0	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	(If the TiDB ver- sion is ear- lier than v4.0.9, the #609 issue might oc- cur.)	

11.6.1.2.4 Back up and restore table data in the `mysql` system schema (experimental feature)

Warning:

This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`. But the technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default.

If you want the data of a system table (for example, `mysql.usertable1`) to be restored to the system schema `mysql`, you can set the **filter parameter** to filter the table name (`-f "mysql.usertable1"`). After the setting, the system table is first restored to the temporary schema, and then to the system schema through renaming.

It should be noted that the following system tables cannot be restored correctly due to technical reasons. Even if `-f "mysql.*"` is specified, these tables will not be restored:

- Tables related to statistics: “stats_buckets”, “stats_extended”, “stats_feedback”, “stats_fm_sketch”, “stats_histograms”, “stats_meta”, “stats_top_n”
- Tables related to privileges or the system: “tidb”, “global_variables”, “columns_priv”, “db”, “default_roles”, “global_grants”, “global_priv”, “role_edges”, “tables_priv”, “user”, “gc_delete_range”, “Gc_delete_range_done”, “schema_index_usage”

11.6.1.2.5 Minimum machine configuration required for running BR

The minimum machine configuration required for running BR is as follows:

CPU	Memory	Hard Disk Type	Network
1 core	4 GB	HDD	Gigabit network card

In general scenarios (less than 1000 tables for backup and restore), the CPU consumption of BR at runtime does not exceed 200%, and the memory consumption does not exceed 4 GB. However, when backing up and restoring a large number of tables, BR might consume more than 4 GB of memory. In a test of backing up 24000 tables, BR consumes about 2.7 GB of memory, and the CPU consumption remains below 100%.

11.6.1.2.6 Best practices

The following are some recommended operations for using BR:

- It is recommended that you perform the backup operation during off-peak hours to minimize the impact on applications.
- When restoring data, BR consumes resources of the target cluster as much as possible. Therefore, it is recommended that you restore data to new clusters or offline clusters. Do not restore data to a production cluster in service. Otherwise, services might be affected.
- It is recommended that you execute multiple backup or restoration operations one by one. Running backup or restoration operations in parallel reduces performance and also affects online applications. Worse still, lack of collaboration between multiple tasks might result in task failures and affect cluster performance.
- Amazon S3, Google Cloud Storage, and Azure Blob Storage are recommended to store backup data.

- Make sure that the BR and TiKV nodes, and the backup storage backend have sufficient network bandwidth to ensure read and write performance. Insufficient storage capacity might be the bottleneck for a backup or restoration operation.

11.6.1.2.7 How to use BR

Currently, the following methods are supported to run the BR tool:

- Use SQL statements
- Use the command-line tool
- Use BR In the Kubernetes environment

Use SQL statements

TiDB supports both [BACKUP](#) and [RESTORE](#) SQL statements. The progress of these operations can be monitored with the statement [SHOW BACKUPS|RESTORES](#).

Use the command-line tool

The `br` command-line utility is available as a [separate download](#). For details, see [Use BR Command-line for Backup and Restoration](#).

In the Kubernetes environment

In the Kubernetes environment, you can use the BR tool to back up TiDB cluster data to S3-compatible storage, Google Cloud Storage (GCS) and persistent volumes (PV), and restore them:

Note:

For Amazon S3 and Google Cloud Storage parameter descriptions, see the [External Storages](#) document.

- [Back up Data to S3-Compatible Storage Using BR](#)
- [Restore Data from S3-Compatible Storage Using BR](#)
- [Back up Data to GCS Using BR](#)
- [Restore Data from GCS Using BR](#)
- [Back up Data to PV Using BR](#)
- [Restore Data from PV Using BR](#)

11.6.2 Use BR Command-line for Backup and Restoration

This document describes how to back up and restore TiDB cluster data using the BR command line.

Make sure you have read [BR Tool Overview](#), especially [Usage Restrictions](#) and [Best Practices](#).

11.6.2.1 BR command-line description

A `br` command consists of sub-commands, options, and parameters.

- Sub-command: the characters without `-` or `--`.
- Option: the characters that start with `-` or `--`.
- Parameter: the characters that immediately follow behind and are passed to the sub-command or the option.

This is a complete `br` command:

```
br backup full --pd "${PDIP}:2379" -s "local:///tmp/backup"
```

Explanations for the above command are as follows:

- `backup`: the sub-command of `br`.
- `full`: the sub-command of `backup`.
- `-s` (or `--storage`): the option that specifies the path where the backup files are stored.
- `"local:///tmp/backup"`: the parameter of `-s`. `/tmp/backup` is the path in the local disk where the backed up files of each TiKV node are stored.
- `--pd`: the option that specifies the Placement Driver (PD) service address.
- `"${PDIP}:2379"`: the parameter of `--pd`.

Note:

- When the `local` storage is used, the backup data are scattered in the local file system of each node.
- It is **not recommended** to back up to a local disk in the production environment because you **have to** manually aggregate these data to complete the data restoration. For more information, see [Restore Cluster Data](#).
- Aggregating these backup data might cause redundancy and bring troubles to operation and maintenance. Even worse, if restoring data without aggregating these data, you can receive a rather confusing error message `SST file not found`.
- It is recommended to mount the NFS disk on each node, or back up to the S3 object storage.

11.6.2.1.1 Sub-commands

A `br` command consists of multiple layers of sub-commands. Currently, BR has the following three sub-commands:

- `br backup`: used to back up the data of the TiDB cluster.
- `br restore`: used to restore the data of the TiDB cluster.

Each of the above three sub-commands might still include the following three sub-commands to specify the scope of an operation:

- `full`: used to back up or restore all the cluster data.
- `db`: used to back up or restore the specified database of the cluster.
- `table`: used to back up or restore a single table in the specified database of the cluster.

11.6.2.1.2 Common options

- `--pd`: used for connection, specifying the PD server address. For example, "``${PDIP}`:2379`".
- `-h` (or `--help`): used to get help on all sub-commands. For example, `br backup --help`.
- `-V` (or `--version`): used to check the version of BR.
- `--ca`: specifies the path to the trusted CA certificate in the PEM format.
- `--cert`: specifies the path to the SSL certificate in the PEM format.
- `--key`: specifies the path to the SSL certificate key in the PEM format.
- `--status-addr`: specifies the listening address through which BR provides statistics to Prometheus.

11.6.2.2 Use BR command-line to back up cluster data

To back up the cluster data, use the `br backup` command. You can add the `full` or `table` sub-command to specify the scope of your backup operation: the whole cluster or a single table.

11.6.2.2.1 Back up all the cluster data

To back up all the cluster data, execute the `br backup full` command. To get help on this command, execute `br backup full -h` or `br backup full --help`.

Usage example:

Back up all the cluster data to the `/tmp/backup` path of each TiKV node and write the `backupmeta` file to this path.

Note:

- If the backup disk and the service disk are different, it has been tested that online backup reduces QPS of the read-only online service by about 15%-25% in case of full-speed backup. If you want to reduce the impact on QPS, use `--ratelimit` to limit the rate.
- If the backup disk and the service disk are the same, the backup competes with the service for I/O resources. This might decrease the QPS of the read-only online service by more than half. Therefore, it is **highly not recommended** to back up the online service data to the TiKV data disk.

```
br backup full \
  --pd "${PDIP}:2379" \
  --storage "local:///tmp/backup" \
  --ratelimit 128 \
  --log-file backupfull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a backup operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `backupfull.log` file.

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety. The progress bar is displayed as follows:

```
br backup full \
  --pd "${PDIP}:2379" \
  --storage "local:///tmp/backup" \
  --ratelimit 128 \
  --log-file backupfull.log
Full Backup <-----/.....>
↪ 17.12%.
```

11.6.2.2.2 Back up a database

To back up a database in the cluster, execute the `br backup db` command. To get help on this command, execute `br backup db -h` or `br backup db --help`.

Usage example:

Back up the data of the `test` database to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup db \  
  --pd "${PDIP}:2379" \  
  --db test \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backupdb.log
```

In the above command, `--db` specifies the name of the database to be backed up. For descriptions of other options, see [Back up all the cluster data](#).

A progress bar is displayed in the terminal during the backup. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

11.6.2.2.3 Back up a table

To back up the data of a single table in the cluster, execute the `br backup table` command. To get help on this command, execute `br backup table -h` or `br backup ↵ table --help`.

Usage example:

Back up the data of the `test.usertable` table to the `/tmp/backup` path on each TiKV node and write the `backupmeta` file to this path.

```
br backup table \  
  --pd "${PDIP}:2379" \  
  --db test \  
  --table usertable \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backuptable.log
```

The `table` sub-command has two options:

- `--db`: specifies the database name
- `--table`: specifies the table name.

For descriptions of other options, see [Back up all cluster data](#).

A progress bar is displayed in the terminal during the backup operation. When the progress bar advances to 100%, the backup is complete. Then the BR also checks the backup data to ensure data safety.

11.6.2.2.4 Back up with table filter

To back up multiple tables with more complex criteria, execute the `br backup full` command and specify the **table filters** with `--filter` or `-f`.

Usage example:

The following command backs up the data of all tables in the form `db*.tbl*` to the `/tmp/backup` path on each TiKV node and writes the `backupmeta` file to this path.

```
br backup full \  
  --pd "${PDIP}:2379" \  
  --filter 'db*.tbl*' \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file backupfull.log
```

11.6.2.2.5 Back up data to Amazon S3 backend

If you back up the data to the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

You can refer to the [AWS Official Document](#) to create an S3 Bucket in the specified Region. You can also refer to another [AWS Official Document](#) to create a Folder in the Bucket.

Note:

To complete one backup, TiKV and BR usually require the minimum privileges of `s3:ListBucket`, `s3:PutObject`, and `s3:AbortMultipartUpload`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}  
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When backing up using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

```
br backup full \  
  --pd "${PDIP}:2379" \  
  --storage "s3://${Bucket}/${Folder}" \  
  --s3.region us-east-1 \  
  --send-credentials-to-tikv
```

```
--s3.region "${region}" \  
--send-credentials-to-tikv=true \  
--ratelimit 128 \  
--log-file backupfull.log
```

11.6.2.2.6 Back up incremental data

This feature is currently experimental and is not recommended for use in the production environment.

If you want to back up incrementally, you only need to specify the **last backup timestamp** `--lastbackupts`.

The incremental backup has two limitations:

- The incremental backup needs to be under a different path from the previous full backup.
- GC (Garbage Collection) safepoint must be before the `lastbackupts`.

To back up the incremental data between (LAST_BACKUP_TS, current PD timestamp], execute the following command:

```
br backup full\  
  --pd ${PDIP}:2379 \  
  --ratelimit 128 \  
  -s local:///home/tidb/backupdata/incr \  
  --lastbackupts ${LAST_BACKUP_TS}
```

To get the timestamp of the last backup, execute the `validate` command. For example:

```
LAST_BACKUP_TS=`br validate decode --field="end-version" -s local:///home/  
↪ tidb/backupdata | tail -n1`
```

In the above example, for the incremental backup data, BR records the data changes and the DDL operations during (LAST_BACKUP_TS, current PD timestamp]. When restoring data, BR first restores DDL operations and then the data.

11.6.2.2.7 Encrypt data during backup (experimental feature)

Since TiDB v5.3.0, TiDB supports backup encryption. You can configure the following parameters to encrypt data during backup:

- `--crypter.method`: Encryption algorithm. Supports three algorithms `aes128-ctr`/
↪ `aes192-ctr/aes256-ctr`. The default value is `plaintext` and indicates no encryption.

- `--crypter.key`: Encryption key in hexadecimal string format. `aes128-ctr` means 128 bit (16 bytes) key length, `aes192-ctr` means 24 bytes and `aes256-ctr` means 32 bytes.
- `--crypter.key-file`: The key file. You can directly pass in the file path where the key is stored as a parameter without passing in “`crypter.key`”

Warning:

- This is still an experimental feature. It is **NOT** recommended that you use it in the production environment.
- If the key is lost, the backup data cannot be restored to the cluster.
- The encryption feature needs to be used on BR tools and TiDB clusters v5.3.0 or later versions, and the encrypted backup data cannot be restored on clusters earlier than v5.3.0.

The configuration example for backup encryption is as follows:

```
br backup full \  
  --pd ${PDIP}:2379 \  
  -s local:///home/tidb/backupdata/incr \  
  --crypter.method aes128-ctr \  
  --crypter.key 0123456789abcdef0123456789abcdef
```

11.6.2.2.8 Back up Raw KV (experimental feature)

Warning:

This feature is experimental and not thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

In some scenarios, TiKV might run independently of TiDB. Given that, BR also supports bypassing the TiDB layer and backing up data in TiKV.

For example, you can execute the following command to back up all keys between [0x31 ↪ , 0x3130303030303030) in the default CF to `$BACKUP_DIR`:

```
br backup raw --pd $PD_ADDR \  
  -s "$BACKUP_DIR" \  
  --start 31 \  
  --end 3130303030303030
```

```
--ratelimit 128 \  
--end 3130303030303030 \  
--format hex \  
--cf default
```

Here, the parameters of `--start` and `--end` are decoded using the method specified by `--format` before being sent to TiKV. Currently, the following methods are available:

- “raw”: The input string is directly encoded as a key in binary format.
- “hex”: The default encoding method. The input string is treated as a hexadecimal number.
- “escape”: First escape the input string, and then encode it into binary format.

11.6.2.3 Use BR command-line to restore cluster data

To restore the cluster data, use the `br restore` command. You can add the `full`, `db` or `table` sub-command to specify the scope of your restoration: the whole cluster, a database or a single table.

Note:

If you use the local storage, you **must** copy all backup SST files to every TiKV node in the path specified by `--storage`.

Even if each TiKV node eventually only need to read a part of the all SST files, they all need full access to the complete archive because:

- Data are replicated into multiple peers. When ingesting SSTs, these files have to be present on *all* peers. This is unlike backup where reading from a single node is enough.
- Where each peer is scattered to during restore is random. We don't know in advance which node will read which file.

These can be avoided using shared storage, for example mounting an NFS on the local path, or using S3. With network storage, every node can automatically read every SST file, so these caveats no longer apply.

Also, note that you can only run one restore operation for a single cluster at the same time. Otherwise, unexpected behaviors might occur. For details, see [FAQ](#).

11.6.2.3.1 Restore all the backup data

To restore all the backup data to the cluster, execute the `br restore full` command. To get help on this command, execute `br restore full -h` or `br restore full --help`.

Usage example:

Restore all the backup data in the `/tmp/backup` path to the cluster.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file restorefull.log
```

Explanations for some options in the above command are as follows:

- `--ratelimit`: specifies the maximum speed at which a restoration operation is performed (MiB/s) on each TiKV node.
- `--log-file`: specifies writing the BR log to the `restorefull.log` file.

A progress bar is displayed in the terminal during the restoration. When the progress bar advances to 100%, the restoration is complete. Then the BR also checks the backup data to ensure data safety.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --storage "local:///tmp/backup" \  
  --ratelimit 128 \  
  --log-file restorefull.log  
Full Restore <-----/.....>  
↔ 17.12%.
```

11.6.2.3.2 Restore a database

To restore a database to the cluster, execute the `br restore db` command. To get help on this command, execute `br restore db -h` or `br restore db --help`.

Usage example:

Restore a database backed up in the `/tmp/backup` path to the cluster.

```
br restore db \  
  --pd "${PDIP}:2379" \  
  --db "test" \  
  --ratelimit 128 \  
  --storage "local:///tmp/backup" \  
  --log-file restoredb.log
```

In the above command, `--db` specifies the name of the database to be restored. For descriptions of other options, see [Restore all backup data](#)).

Note:

When you restore the backup data, the name of the database specified by `--db` \leftrightarrow must be the same as the one specified by `--db` in the backup command. Otherwise, the restore fails. This is because the metafile of the backup data (`backupmeta` file) records the database name, you can only restore data to the database with the same name. The recommended method is to restore the backup data to the database with the same name in another cluster.

11.6.2.3.3 Restore a table

To restore a single table to the cluster, execute the `br restore table` command. To get help on this command, execute `br restore table -h` or `br restore table --help`.

Usage example:

Restore a table backed up in the `/tmp/backup` path to the cluster.

```
br restore table \  
  --pd "${PDIP}:2379" \  
  --db "test" \  
  --table "usertable" \  
  --ratelimit 128 \  
  --storage "local:///tmp/backup" \  
  --log-file restoretable.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see [Restore all backup data](#) and [Restore a database](#).

11.6.2.3.4 Restore with table filter

To restore multiple tables with more complex criteria, execute the `br restore full` command and specify the [table filters](#) with `--filter` or `-f`.

Usage example:

The following command restores a subset of tables backed up in the `/tmp/backup` path to the cluster.

```
br restore full \  
  --pd "${PDIP}:2379" \  
  --filter 'db*.tbl*' \  
  --storage "local:///tmp/backup" \  
  --log-file restorefull.log
```

```
--log-file restorefull.log
```

11.6.2.3.5 Restore data from Amazon S3 backend

If you restore data from the Amazon S3 backend, instead of `local` storage, you need to specify the S3 storage path in the `storage` sub-command, and allow the BR node and the TiKV node to access Amazon S3.

Note:

To complete one restore, TiKV and BR usually require the minimum privileges of `s3:ListBucket` and `s3:GetObject`.

Pass `SecretKey` and `AccessKey` of the account that has privilege to access the S3 backend to the BR node. Here `SecretKey` and `AccessKey` are passed as environment variables. Then pass the privilege to the TiKV node through BR.

```
export AWS_ACCESS_KEY_ID=${AccessKey}
export AWS_SECRET_ACCESS_KEY=${SecretKey}
```

When restoring data using BR, explicitly specify the parameters `--s3.region` and `--send-credentials-to-tikv`. `--s3.region` indicates the region where S3 is located, and `--send-credentials-to-tikv` means passing the privilege to access S3 to the TiKV node.

`Bucket` and `Folder` in the `--storage` parameter represent the S3 bucket and the folder where the data to be restored is located.

```
br restore full \
  --pd "${PDIP}:2379" \
  --storage "s3://${Bucket}/${Folder}" \
  --s3.region "${region}" \
  --ratelimit 128 \
  --send-credentials-to-tikv=true \
  --log-file restorefull.log
```

In the above command, `--table` specifies the name of the table to be restored. For descriptions of other options, see [Restore a database](#).

11.6.2.3.6 Restore incremental data

This feature is currently experimental and is not recommended for use in the production environment.

Restoring incremental data is similar to [restoring full data using BR](#). Note that when restoring incremental data, make sure that all the data backed up before `last backup ts` has been restored to the target cluster.

11.6.2.3.7 Restore tables created in the mysql schema (experimental feature)

BR backs up tables created in the `mysql` schema by default.

When you restore data using BR, the tables created in the `mysql` schema are not restored by default. If you need to restore these tables, you can explicitly include them using the [table filter](#). The following example restores `mysql.usertable` created in `mysql` schema. The command restores `mysql.usertable` along with other data.

```
br restore full -f ' *.* ' -f '!mysql.*' -f 'mysql.usertable' -s  
↪ $external_storage_url --ratelimit 128
```

In the above command, `-f ' *.* '` is used to override the default rules and `-f '!mysql ↪ *.*'` instructs BR not to restore tables in `mysql` unless otherwise stated. `-f 'mysql. ↪ usertable'` indicates that `mysql.usertable` is required for restore. For detailed implementation, refer to the [table filter document](#).

If you only need to restore `mysql.usertable`, use the following command:

```
br restore full -f 'mysql.usertable' -s $external_storage_url --ratelimit  
↪ 128
```

Warning:

Although you can back up system tables (such as `mysql.tidb`) using the BR tool, BR ignores the following system tables even if you use the `--filter` setting to perform the restoration:

- Statistical information tables (`mysql.stat_*`)
- System variable tables (`mysql.tidb`, `mysql.global_variables`)
- User information tables (such as `mysql.user` and `mysql.columns_priv`)
- [Other system tables](#)

11.6.2.3.8 Decrypt data during restore (experimental feature)

Warning:

This is still an experimental feature. It is **NOT** recommended that you use it in the production environment.

After encrypting the backup data, you need to pass in the corresponding decryption parameters to restore the data. You need to ensure that the decryption parameters and encryption parameters are consistent. If the decryption algorithm or key is incorrect, the data cannot be restored.

The following is an example of decrypting the backup data:

```
br restore full\  
  --pd ${PDIP}:2379 \  
  -s local:///home/tidb/backupdata/incr \  
  --crypter.method aes128-ctr \  
  --crypter.key 0123456789abcdef0123456789abcdef
```

11.6.2.3.9 Restore Raw KV (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It is highly **not recommended** to use this feature in the production environment.

Similar to [backing up Raw KV](#), you can execute the following command to restore Raw KV:

```
br restore raw --pd $PD_ADDR \  
  -s "$BACKUP_DIR" \  
  --start 31 \  
  --end 3130303030303030 \  
  --ratelimit 128 \  
  --format hex \  
  --cf default
```

In the above example, all the backed up keys in the range [0x31, 0x3130303030303030 ↪) are restored to the TiKV cluster. The coding methods of these keys are identical to that of [keys during the backup process](#)

11.6.2.3.10 Online restore (experimental feature)

Warning:

This feature is in the experiment, without being thoroughly tested. It also relies on the unstable Placement Rules feature of PD. It is highly **not recommended** to use this feature in the production environment.

During data restoration, writing too much data affects the performance of the online cluster. To avoid this effect as much as possible, BR supports [Placement rules](#) to isolate resources. In this case, downloading and importing SST are only performed on a few specified nodes (or “restore nodes” for short). To complete the online restore, take the following steps.

1. Configure PD, and start Placement rules:

```
echo "config set enable-placement-rules true" | pd-ctl
```

2. Edit the configuration file of the “restore node” in TiKV, and specify “restore” to the `server` configuration item:

```
[server]
labels = { exclusive = "restore" }
```

3. Start TiKV of the “restore node” and restore the backed up files using BR. Compared with the offline restore, you only need to add the `--online` flag:

```
br restore full \
  -s "local://$BACKUP_DIR" \
  --ratelimit 128 \
  --pd $PD_ADDR \
  --online
```

11.6.3 BR Use Cases

[BR](#) is a tool for distributed backup and restoration of the TiDB cluster data.

This document describes how to run BR in the following use cases:

- Back up a single table to a network disk (recommended in production environment)
- Restore data from a network disk (recommended in production environment)
- Back up a single table to a local disk (recommended in testing environment)
- Restore data from a local disk (recommended in testing environment)

This document aims to help you achieve the following goals:

- Back up and restore data using a network disk or local disk correctly.
- Get the status of a backup or restoration operation through monitoring metrics.
- Learn how to tune performance during the operation.
- Troubleshoot the possible anomalies during the backup operation.

11.6.3.1 Audience

You are expected to have a basic understanding of TiDB and [TiKV](#).

Before reading on, make sure you have read [BR Tool Overview](#), especially [Usage Restrictions](#) and [Best Practices](#).

11.6.3.2 Prerequisites

This section introduces the recommended method of deploying TiDB, cluster versions, the hardware information of the TiKV cluster, and the cluster configuration for the use case demonstrations.

You can estimate the performance of your backup or restoration operation based on your own hardware and configuration.

11.6.3.2.1 Deployment method

It is recommended that you deploy the TiDB cluster using [TiUP](#) and get BR by downloading [TiDB Toolkit](#).

11.6.3.2.2 Cluster versions

- TiDB: v5.0.0
- TiKV: v5.0.0
- PD: v5.0.0
- BR: v5.0.0

Note:

v5.0.0 was the latest version at the time this document was written. It is recommended that you use the latest version of [TiDB/TiKV/PD/BR](#) and make sure that the BR version is **consistent with** the TiDB version.

11.6.3.2.3 TiKV hardware information

- Operating system: CentOS Linux release 7.6.1810 (Core)
- CPU: 16-Core Common KVM processor
- RAM: 32GB
- Disk: 500G SSD * 2
- NIC: 10 Gigabit network card

11.6.3.2.4 Cluster configuration

BR directly sends commands to the TiKV cluster and are not dependent on the TiDB server, so you do not need to configure the TiDB server when using BR.

- TiKV: default configuration
- PD: default configuration

11.6.3.3 Use cases

This document describes the following use cases:

- [Back up a single table to a network disk \(recommended in production environment\)](#)
- [Restore data from a network disk \(recommended in production environment\)](#)
- [Back up a single table to a local disk \(recommended in testing environment\)](#)
- [Restore data from a local disk \(recommended in testing environment\)](#)

It is recommended that you use a network disk to back up and restore data. This spares you from collecting backup files and greatly improves the backup efficiency especially when the TiKV cluster is in a large scale.

Before the backup or restoration operations, you need to do some preparations:

- [Preparation for backup](#)
- [Preparation for restoration](#)

11.6.3.3.1 Preparation for backup

The BR tool already supports self-adapting to GC. It automatically registers `backupTS` \leftrightarrow (the latest PD timestamp by default) to PD's `safePoint` to ensure that TiDB's GC Safe Point does not move forward during the backup, thus avoiding manually setting GC configurations.

For the detailed usage of the `br backup` command, refer to [Use BR Command-line for Backup and Restoration](#).

1. Before executing the `br backup` command, ensure that no DDL is running on the TiDB cluster.
2. Ensure that the storage device where the backup will be created has sufficient space (no less than 1/3 of the disk space of the backup cluster).

11.6.3.3.2 Preparation for restoration

Before executing the `br restore` command, check the new cluster to make sure that the table in the cluster does not have a duplicate name.

11.6.3.3.3 Back up a single table to a network disk (recommended in production environment)

Use the `br backup` command to back up the single table data `--db batchmark --table order_line` to the specified path `local:///br_data` in the network disk.

Backup prerequisites

- [Preparation for backup](#)

- Configure a high-performance SSD hard disk host as the NFS server to store data, and all BR nodes, TiKV nodes, and TiFlash nodes as NFS clients. Mount the same path (for example, `/br_data`) to the NFS server for NFS clients to access the server.
- The total transfer rate between the NFS server and all NFS clients must reach at least the number of TiKV instances * 150MB/s. Otherwise the network I/O might become the performance bottleneck.

Note:

- During data backup, because only the data of leader replicas are backed up, even if there is a TiFlash replica in the cluster, BR can complete the backup without mounting TiFlash nodes.
- When restoring data, BR will restore the data of all replicas. Also, TiFlash nodes need access to the backup data for BR to complete the restore. Therefore, before the restore, you must mount TiFlash nodes to the NFS server.

Topology

The following diagram shows the typology of BR:

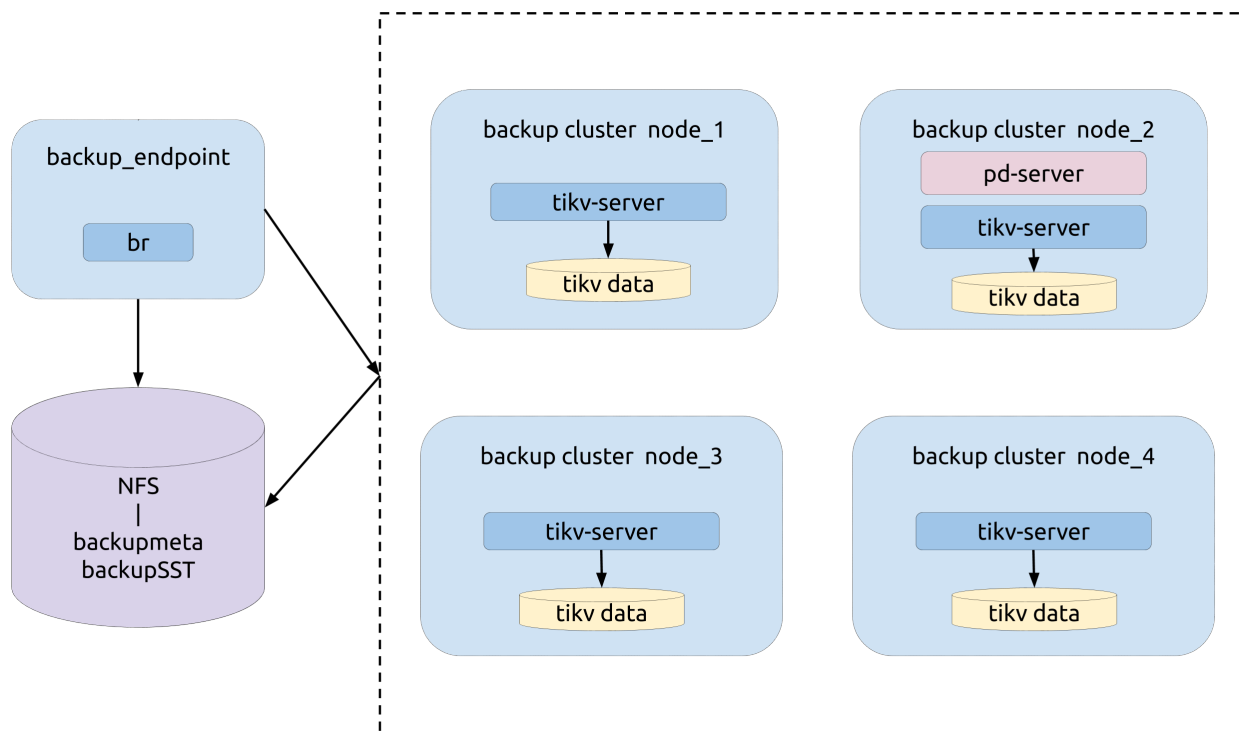

Figure 125: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark` \leftrightarrow `--table order_line`). The following image shows an example of this information:

```

+-----+-----+-----+-----+-----+
| Db_name   | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+-----+-----+-----+-----+-----+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----+-----+-----+-----+-----+
1 row in set (5 min 47.59 sec)

```

Figure 126: img

Execute the `br backup table` command:

```

bin/br backup table \
  --db batchmark \
  --table order_line \
  -s local:///br_data \
  --pd ${PD_ADDR}:2379 \
  --log-file backup-nfs.log

```

Monitoring metrics for the backup

During the backup process, pay attention to the following metrics on the monitoring panels to get the status of the backup process.

Backup CPU Utilization: the CPU usage rate of each working TiKV node in the backup operation (for example, backup-worker and backup-endpoint).

Figure 127: img

IO Utilization: the I/O usage rate of each working TiKV node in the backup operation.

Figure 128: img

BackupSST Generation Throughput: the backupSST generation throughput of each working TiKV node in the backup operation, which is normally around 150MB/s.

Figure 129: img

One Backup Range Duration: the duration of backing up a range, which is the total time cost of scanning KVs and storing the range as the backupSST file.

Figure 130: img

One Backup Subtask Duration: the duration of each sub-task into which a backup task is divided.

Note:

- In this task, the single table to be backed up has three indexes and the task is normally divided into four sub-tasks.
- The panel in the following image has thirteen points on it, which means nine (namely, 13-4) retries. Region scheduling might occur during the backup process, so a few retries is normal.

Figure 131: img

Backup Errors: the errors occurred during the backup process. No error occurs in normal situations. Even if a few errors occur, the backup operation has the retry mechanism which might increase the backup time but does not affect the operation correctness.

Figure 132: img

Checksum Request Duration: the duration of the admin checksum request in the backup cluster.

Figure 133: img

Backup results explanation

When finishing the backup, BR outputs the backup summary to the console.

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search “summary” in this log, you can see the following information:

```
[Full backup Success summary:
total backup ranges: 2,
total success: 2,
total failed: 0,
total take(Full backup time): 31.802912166s,
total take(real time): 49.799662427s,
total size(MB): 5997.49,
avg speed(MB/s): 188.58,
total kv: 120000000"]
```

```
["backup checksum"]=17.907153678s]
["backup fast checksum"]=349.333µs]
["backup total regions"]=43]
[BackupTS=422618409346269185]
[Size=826765915]
```

The above log includes the following information:

- Backup duration: total take(Full backup time): 31.802912166s
- Total runtime of the application: total take(real time): 49.799662427s
- Backup data size: total size(MB): 5997.49
- Backup throughput: avg speed(MB/s): 188.58
- Number of backed-up KV pairs: total kv: 120000000
- Backup checksum duration: ["backup checksum"]=17.907153678s]
- Total duration of calculating the checksum, KV pairs, and bytes of each table: ["↔ backup fast checksum"]=349.333µs]
- Total number of backup Regions: ["backup total regions"]=43]
- The actual size of the backup data in the disk after compression: [Size=826765915]
- Snapshot timestamp of the backup data: [BackupTS=422618409346269185]

From the above information, the throughput of a single TiKV instance can be calculated:
 $\text{avg speed(MB/s)}/\text{tikv_count} = 62.86$.

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the backup process (for example, in the [Monitoring metrics for the backup](#), the highest CPU usage rate of backup-worker is around 1500% and the overall I/O usage rate is below 30%), you can try to increase the value of `--concurrency` (4 by default) to tune the performance. But this performance tuning method is not suitable for the use cases of many small tables. See the following example:

```
bin/br backup table \  
  --db batchmark \  
  --table order_line \  
  -s local:///br_data/ \  
  --pd ${PD_ADDR}:2379 \  
  --log-file backup-nfs.log \  
  --concurrency 16
```

Figure 134: img

Figure 135: img

The tuned performance results are as follows (with the same data size):

- Backup duration: `total take(s)` reduced from 986.43 to 535.53
- Backup throughput: `avg speed(MB/s)` increased from 358.09 to 659.59
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from 89 to 164.89

11.6.3.3.4 Restore data from a network disk (recommended in production environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- [Preparation for restoration](#)

Topology

The following diagram shows the typology of BR:

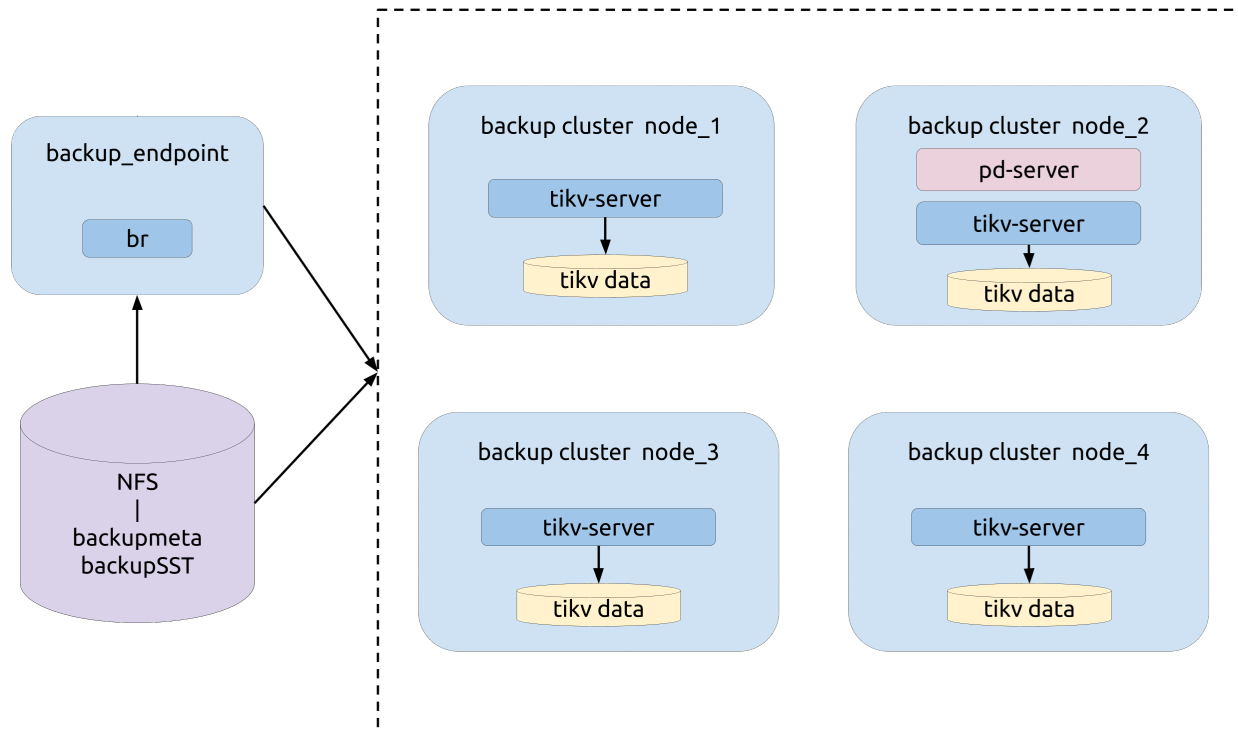

Figure 136: img

Restoration operation

Before the restoration, refer to [Preparation for restoration](#) for the preparation.

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data
↪ --pd 172.16.5.198:2379 --log-file restore-nfs.log
```

Monitoring metrics for the restoration

During the restoration process, pay attention to the following metrics on the monitoring panels to get the status of the restoration process.

CPU Utilization: the CPU usage rate of each working TiKV node in the restoration operation.

Figure 137: img

IO Utilization: the I/O usage rate of each working TiKV node in the restoration operation.

Figure 138: img

Region: the Region distribution. The more even Regions are distributed, the better the restoration resources are used.

Figure 139: img

Process SST Duration: the delay of processing the SST files. When restoring a table, if `tableID` is changed, you need to rewrite `tableID`. Otherwise, `tableID` is renamed. Generally, the delay of rewriting is longer than that of renaming.

Figure 140: img

DownLoad SST Throughput: the throughput of downloading SST files from External Storage.

Figure 141: img

Restore Errors: the errors occurred during the restoration process.

Figure 142: img

Checksum Request duration: the duration of the admin checksum request. This duration for the restoration is longer than that for the backup.

Figure 143: img

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search “summary” in this log, you can see the following information:

```
[Table Restore summary:
  total restore tables: 1,
  total success: 1,
  total failed: 0,
  total take(Full restore time): 17m1.001611365s,
  total take(real time): 16m1.371611365s,
  total kv: 5659888624,
  total size(MB): 353227.18,
  avg speed(MB/s): 367.42]
["restore files"]=9263]
["restore ranges"]=6888]
["split region"]=49.049182743s]
["restore checksum"]=6m34.879439498s]
[Size=48693068713]
```

The above log includes the following information:

- Restore duration: total take(Full restore time): 17m1.001611365s
- Total runtime of the application: total take(real time): 16m1.371611365s
- Restore data size: total size(MB): 353227.18
- Restore KV pair number: total kv: 5659888624
- Restore throughput: avg speed(MB/s): 367.42
- Region Split duration: take=49.049182743s
- Restore checksum duration: restore checksum=6m34.879439498s

- The actual size of the restored data in the disk: [Size=48693068713]

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: $\text{avg speed(MB/s)}/\text{tikv_count} = 91.8$
- The average restore speed of a single TiKV instance: $\text{total size(MB)}/(\text{split time} + \text{restore time})/\text{tikv_count} = 87.4$

Performance tuning

If the resource usage of TiKV does not become an obvious bottleneck during the restore process, you can try to increase the value of `--concurrency` which is 128 by default. See the following example:

```
bin/br restore table --db batchmark --table order_line -s local:///br_data/  
  ↪ --pd 172.16.5.198:2379 --log-file restore-concurrency.log --  
  ↪ concurrency 1024
```

The tuned performance results are as follows (with the same data size):

- Restore duration: `total take(s)` reduced from 961.37 to 443.49
- Restore throughput: `avg speed(MB/s)` increased from 367.42 to 796.47
- Throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count` increased from 91.8 to 199.1
- Average restore speed of a single TiKV instance: `total size(MB)/(split time + restore time)/tikv_count` increased from 87.4 to 162.3

11.6.3.3.5 Back up a single table to a local disk (recommended in testing environment)

Use the `br backup` command to back up the single table `--db batchmark --table order_line` to the specified path `local:///home/tidb/backup_local` in the local disk.

Backup prerequisites

- **Preparation for backup**
- Each TiKV node has a separate disk to store the backupSST file.
- The `backup_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `backup_endpoint` node must have the same directory for the backup (for example, `/home/tidb/backup_local`).

Topology

The following diagram shows the typology of BR:

Figure 144: img

Backup operation

Before the backup operation, execute the `admin checksum table order_line` command to get the statistical information of the table to be backed up (`--db batchmark` \leftrightarrow `--table order_line`). The following image shows an example of this information:

```

+-----+-----+-----+-----+
| Db_name  | Table_name | Checksum_crc64_xor | Total_kvs | Total_bytes |
+-----+-----+-----+-----+
| batchmark | order_line | 10912722838344822475 | 5659888624 | 370385538778 |
+-----+-----+-----+-----+
1 row in set (5 min 47.59 sec)

```

Figure 145: img

Execute the `br backup` command:

```

bin/br backup table \
  --db batchmark \
  --table order_line \
  -s local:///home/tidb/backup_local/ \

```

```
--pd ${PD_ADDR}:2379 \  
--log-file backup_local.log
```

During the backup process, pay attention to the metrics on the monitoring panels to get the status of the backup process. See [Monitoring metrics for the backup](#) for details.

Backup results explanation

Before executing the backup command, a path in which the log is stored has been specified. You can get the statistical information of the backup operation from this log. Search “summary” in this log, you can see the following information:

```
["Table backup summary: total backup ranges: 4, total success: 4, total  
↪ failed: 0, total take(s): 551.31, total kv: 5659888624, total size(MB  
↪ ): 353227.18, avg speed(MB/s): 640.71"] ["backup total regions"=6795]  
↪ ["backup checksum"=6m33.962719217s] ["backup fast checksum  
↪ "=22.995552ms]
```

The information from the above log includes:

- Backup duration: total take(s): 551.31
- Data size: total size(MB): 353227.18
- Backup throughput: avg speed(MB/s): 640.71
- Backup checksum duration: take=6m33.962719217s

From the above information, the throughput of a single TiKV instance can be calculated: $\text{avg speed(MB/s)} / \text{tikv_count} = 160$.

11.6.3.3.6 Restore data from a local disk (recommended in testing environment)

Use the `br restore` command to restore the complete backup data to an offline cluster. Currently, BR does not support restoring data to an online cluster.

Restoration prerequisites

- [Preparation for restoration](#)
- The TiKV cluster and the backup data do not have a duplicate database or table. Currently, BR does not support table route.
- Each TiKV node has a separate disk to store the backupSST file.
- The `restore_endpoint` node has a separate disk to store the `backupmeta` file.
- TiKV and the `restore_endpoint` node must have the same directory for the restoration (for example, `/home/tidb/backup_local/`).

Before the restoration, follow these steps:

1. Collect all backupSST files into the same directory.
2. Copy the collected backupSST files to all TiKV nodes of the cluster.
3. Copy the backupmeta file to the restore endpoint node.

Topology

The following diagram shows the typology of BR:

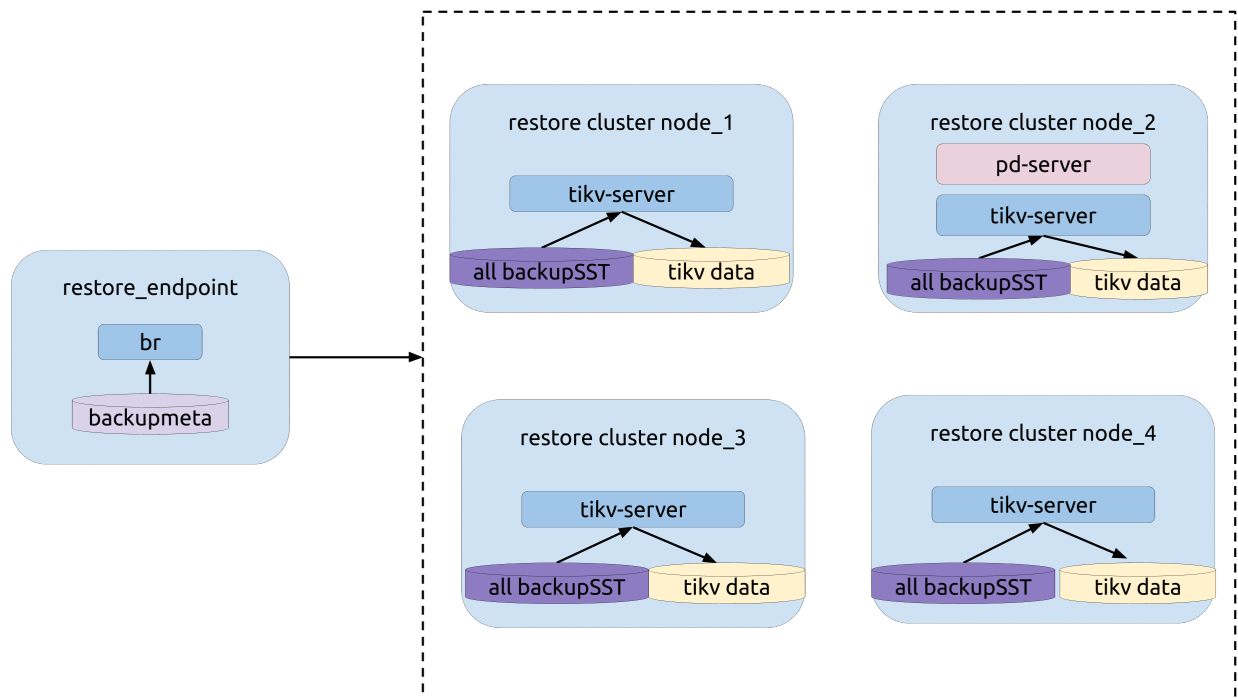

Figure 146: img

Restoration operation

Execute the `br restore` command:

```
bin/br restore table --db batchmark --table order_line -s local:///home/tidb
↪ /backup_local/ --pd 172.16.5.198:2379 --log-file restore_local.log
```

During the restoration process, pay attention to the metrics on the monitoring panels to get the status of the restoration process. See [Monitoring metrics for the restoration](#) for details.

Restoration results explanation

Before executing the restoration command, a path in which the log is stored has been specified. You can get the statistical information of the restoration operation from this log. Search “summary” in this log, you can see the following information:

```
["Table Restore summary: total restore tables: 1, total success: 1, total
↪ failed: 0, total take(s): 908.42, total kv: 5659888624, total size(MB
↪ ): 353227.18, avg speed(MB/s): 388.84"] ["restore files"=9263] ["
↪ restore ranges"=6888] ["split region"=58.7885518s] ["restore checksum
↪ "=6m19.349067937s]
```

The above log includes the following information:

- Restoration duration: `total take(s): 908.42`
- Data size: `total size(MB): 353227.18`
- Restoration throughput: `avg speed(MB/s): 388.84`
- Region Split duration: `take=58.7885518s`
- Restoration checksum duration: `take=6m19.349067937s`

From the above information, the following items can be calculated:

- The throughput of a single TiKV instance: `avg speed(MB/s)/tikv_count = 97.2`
- The average restoration speed of a single TiKV instance: `total size(MB)/(split ↪ time + restore time)/tikv_count = 92.4`

11.6.3.4 Error handling during backup

This section introduces the common errors occurred during the backup process.

11.6.3.4.1 key locked Error in the backup log

Error message in the log: `log - ["backup occur kv error"][error="{\"KvError ↪ \":{\\"locked\"}:`

If a key is locked during the backup process, BR tries to resolve the lock. A small number of these errors do not affect the correctness of the backup.

11.6.3.4.2 Backup failure

Error message in the log: `log - Error: msg:"Io(Custom { kind: AlreadyExists, ↪ error: \"[5_5359_42_123_default.sst] is already exists in /dir/backup_local ↪ /\\" })"`

If the backup operation fails and the above message occurs, perform one of the following operations and then start the backup operation again:

- Change the directory for the backup. For example, change `/dir/backup-2020-01-01/` to `/dir/backup_local/`.
- Delete the backup directory of all TiKV nodes and BR nodes.

11.6.4 External Storages

Backup & Restore (BR), TiDB Lightning, and Dumpling support reading and writing data on the local filesystem and on Amazon S3. BR also supports reading and writing data on the Google Cloud Storage (GCS) and [Azure Blob Storage \(Azblob\)](#). These are distinguished by the URL scheme in the `--storage` parameter passed into BR, in the `-d` parameter passed into TiDB Lightning, and in the `--output (-o)` parameter passed into Dumpling.

11.6.4.1 Schemes

The following services are supported:

Service	Schemes	Example URL
Local filesystem, distributed on every node	local	local:///path/to/dest/
Amazon S3 and compatible services	s3	s3://bucket-name/prefix/of/dest/
Google Cloud Storage (GCS)	gcs, gs	gcs://bucket-name/prefix/of/dest/
Azure Blob Storage	azure, azblob	azure://container-name/prefix/of/dest/
Write to nowhere (for benchmarking only)	noop	noop://

11.6.4.2 URL parameters

Cloud storages such as S3, GCS and Azblob sometimes require additional configuration for connection. You can specify parameters for such configuration. For example:

- Use Dumpling to export data to S3:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
-o 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3:

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/sql-backup?region=us-west-2'
```

- Use TiDB Lightning to import data from S3 (using the path style in the request mode):

```
./tidb-lightning --tidb-port=4000 --pd-urls=127.0.0.1:2379 --backend=
↪ local --sorted-kv-dir=/tmp/sorted-kvs \
-d 's3://my-bucket/sql-backup?force-path-style=true&endpoint=http
↪ ://10.154.10.132:8088'
```

- Use BR to back up data to GCS:

```
./br backup full -u 127.0.0.1:2379 \
-s 'gcs://bucket-name/prefix'
```

- Use BR to back up data to Azblob:

```
./br backup full -u 127.0.0.1:2379 \
  -s 'azure://container-name/prefix'
```

11.6.4.2.1 S3 URL parameters

URL parameter	Description
<code>access-key</code>	The access key
<code>secret-access-key</code>	The secret access key
<code>region</code>	Service Region for Amazon S3 (default to <code>us-east-1</code>)
<code>use-accelerate-endpoint</code>	Whether to use the accelerate endpoint on Amazon S3 (default to <code>false</code>)
<code>endpoint</code>	URL of custom endpoint for S3-compatible services (for example, <code>https://s3.example.com/</code>)

URL parameter	Description
<code>force-path</code> ↪ <code>-style</code>	Use path style access rather than virtual hosted style access (default to <code>false</code>)
<code>storage-</code> ↪ <code>class</code>	Storage class of the uploaded objects (for example, <code>STANDARD</code> , <code>STANDARD_IA</code> ↪)
<code>sse</code>	Server-side encryption algorithm used to encrypt the upload (empty, <code>AES256</code> or <code>aws:kms</code>)
<code>sse-kms-</code> ↪ <code>key-id</code>	If <code>sse</code> is set to <code>aws:kms</code> , specifies the KMS ID
<code>acl</code>	Canned ACL of the uploaded objects (for example, <code>private</code> , <code>authenticated</code> ↪ <code>-read</code>)

Note:

It is not recommended to pass in the access key and secret access key directly in the storage URL, because these keys are logged in plain text. The migration tools try to infer these keys from the environment in the following order:

1. `$AWS_ACCESS_KEY_ID` and `$AWS_SECRET_ACCESS_KEY` environment variables
2. `$AWS_ACCESS_KEY` and `$AWS_SECRET_KEY` environment variables
3. Shared credentials file on the tool node at the path specified by the `$AWS_SHARED_CREDENTIALS_FILE`
 ↪ environment variable
4. Shared credentials file on the tool node at `~/.aws/credentials`
5. Current IAM role of the Amazon EC2 container
6. Current IAM role of the Amazon ECS task

11.6.4.2.2 GCS URL parameters

URL parameter	Description
<code>credentials</code> ↪ <code>-file</code>	The path to the credentials JSON file on the tool node
<code>storage-</code> ↪ <code>class</code>	Storage class of the uploaded objects (for example, <code>STANDARD</code> , <code>COLDLINE</code>)
<code>predefined</code> ↪ <code>-acl</code>	Predefined ACL of the uploaded objects (for example, <code>private</code> , <code>project-private</code> ↪ <code>private</code> ↪ <code>)</code>

When `credentials-file` is not specified, the migration tool will try to infer the credentials from the environment, in the following order:

1. Content of the file on the tool node at the path specified by the `$GOOGLE_APPLICATION_CREDENTIALS`
 ↪ environment variable
2. Content of the file on the tool node at `~/.config/gcloud/application_default_credentials`
 ↪ `.json`
3. When running in GCE or GAE, the credentials fetched from the metadata server.

11.6.4.2.3 Azblob URL parameters

URL parameter	Description
↪ <code>account-name</code>	The account name of the storage
↪ <code>account-key</code>	The access key
↪ <code>access-tier</code>	Access tier of the uploaded objects (for example, Hot, Cool, Archive ↪). If <code>access</code> ↪ - ↪ <code>tier</code> ↪ is not set (the value is empty), the value is Hot by default.

To ensure that TiKV and BR use the same storage account, BR determines the value of `account-name`. That is, `send-credentials-to-tikv = true` is set by default. BR infers these keys from the environment in the following order:

1. If both `account-name` and `account-key` are specified, the key specified by this parameter is used.
2. If `account-key` is not specified, then BR tries to read the related credentials from environment variables on the node of BR.
 - BR reads `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` first. At the same time, BR allows TiKV to read the above three environment variables from the respective nodes and access using Azure AD (Azure Active Directory).
 - `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET` respectively refer to the application ID `client_id`, the tenant ID `tenant_id`, and the client password `client_secret` of Azure application.
 - To learn how to check whether the operating system has configured `$AZURE_CLIENT_ID`, `$AZURE_TENANT_ID`, and `$AZURE_CLIENT_SECRET`, or if you need to configure these variables as parameters, refer to [Configure environment variables as parameters](#).
3. If the above three environment variables are not configured in the BR node, BR tries to read `$AZURE_STORAGE_KEY` using an access key.

Note:

When using Azure Blob Storage as the external storage, you must set `send-credentials-to-tikv = true` (which is set by default). Otherwise, the backup task will fail.

11.6.4.3 Command-line parameters

In addition to the URL parameters, BR and Dumpling also support specifying these configurations using command-line parameters. For example:

```
./dumpling -u root -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \  
-o 's3://my-bucket/sql-backup' \  
--s3.region 'us-west-2'
```

If you have specified URL parameters and command-line parameters at the same time, the URL parameters are overwritten by the command-line parameters.

11.6.4.3.1 S3 command-line parameters

Command-line parameter	Description
<code>--s3. ↪ region</code>	Amazon S3's service region, which defaults to <code>us-east-1</code> .
<code>--s3. ↪ endpoint ↪</code>	The URL of custom endpoint for S3-compatible services. For example, <code>https://s3.example.com/</code> .
<code>--s3. ↪ storage ↪ -class</code>	The storage class of the upload object. For example, <code>STANDARD</code> and <code>STANDARD_IA</code> .

Command-line parameter	Description
<code>--s3.sse</code>	The server-side encryption algorithm used to encrypt the upload. The value options are empty, <code>AES256</code> and <code>aws:</code> <code>↪ kms.</code>
<code>--s3.sse- ↪ kms-key ↪ -id</code>	If <code>--s3.sse</code> is configured as <code>aws:</code> <code>↪ kms,</code> this parameter is used to specify the KMS ID.

Command-line parameter	Description
<code>--s3.acl</code>	The canned ACL of the upload object. For example, <code>private</code> ↪ and <code>authenticated</code> ↪ - ↪ <code>read</code> ↪ .
<code>--s3.</code> ↪ <code>provider</code> ↪	The type of the S3-compatible service. The supported types are <code>aws</code> , <code>alibaba</code> ↪ , <code>ceph</code> , <code>netease</code> ↪ and <code>other</code> .

To export data to non-AWS S3 cloud storage, specify the cloud provider and whether to use `virtual-hosted` style. In the following examples, data is exported to the Alibaba Cloud OSS storage:

- Export data to Alibaba Cloud OSS using Dumpling:

```
./dumpling -h 127.0.0.1 -P 3306 -B mydb -F 256MiB \
-o "s3://my-bucket/dumpling/" \
--s3.endpoint="http://oss-cn-hangzhou-internal.aliyuncs.com" \
--s3.provider="alibaba" \
```

```
-r 200000 -F 256MiB
```

- Back up data to Alibaba Cloud OSS using BR:

```
./br backup full --pd "127.0.0.1:2379" \
  --storage "s3://my-bucket/full/" \
  --s3.endpoint="http://oss-cn-hangzhou-internal.aliyuncs.com" \
  --s3.provider="alibaba" \
  --send-credentials-to-tikv=true \
  --ratelimit 128 \
  --log-file backuptable.log
```

- Export data to Alibaba Cloud OSS using TiDB Lightning. You need to specify the following content in the YAML-formatted configuration file:

```
[mydumper]
data-source-dir = "s3://my-bucket/dumpling/?endpoint=http://oss-cn-
  ↪ hangzhou-internal.aliyuncs.com&provider=alibaba"
```

11.6.4.3.2 GCS command-line parameters

Command-line parameter	Description
<code>--gcs.↪ credentials↪ -file</code>	The path of the JSON-formatted credential on the tool node.
<code>--gcs.↪ storage↪ -class</code>	The storage type of the upload object, such as STANDARD ↪ and COLDLINE ↪ .

Command-line parameter	Description
<code>--gcs.</code>	The pre-
<code>↪ predefined</code>	defined
<code>↪ -acl</code>	ACL of the upload object, such as private
	<code>↪ and project</code>
	<code>↪ -</code>
	<code>↪ private</code>
	<code>↪ .</code>

11.6.4.3 Azblob command-line parameters

Command-line parameter	Description
<code>--azblob.account-name</code>	The account name of the storage
<code>--azblob.account-key</code>	The access key
<code>--azblob.access-tier</code>	Access tier of the uploaded objects (for example, Hot, Cool, Archive). If <code>access-tier</code> is not set (the value is empty), the value is Hot by default.

11.6.4.4 BR sending credentials to TiKV

By default, when using S3, GCS, or Azblob destinations, BR will send the credentials to every TiKV node to reduce setup complexity.

However, this is unsuitable on cloud environment, where every node has their own role and permission. In such cases, you need to disable credentials sending with `--send-credentials-to-tikv=false` (or the short form `-c=0`):

```
./br backup full -c=0 -u pd-service:2379 -s 's3://bucket-name/prefix'
```

When using SQL statements to **back up** and **restore** data, you can add the `SEND_CREDENTIALS_TO_TIKV = FALSE` option:

```
BACKUP DATABASE * TO 's3://bucket-name/prefix' SEND_CREDENTIALS_TO_TIKV =
↪ FALSE;
```

This option is not supported in TiDB Lightning and Dumping, because the two applications are currently standalone.

11.6.5 BR Features

11.6.5.1 BR Auto-Tune New in v5.4.0

Before TiDB v5.4.0, when you back up data using BR, the number of threads used for backup makes up 75% of the logical CPU cores. Without a speed limit, the backup process can consume a lot of cluster resources, which has a considerable impact on the performance of the online cluster. Although you can reduce the impact of backup by adjusting the size of the thread pool, it is a tedious task to observe the CPU load and manually adjust the thread pool size.

To reduce the impact of backup tasks on the cluster, starting from TiDB v5.4.0, BR introduces the auto-tune feature. When the cluster resource utilization is high, BR automatically limits the resources used by backup tasks and thereby reduces their impact on the cluster. The auto-tune feature is enabled by default.

11.6.5.1.1 User scenario

If you want to reduce the impact of backup tasks on the cluster, you can enable the auto-tune feature. With this feature enabled, BR performs backup tasks as fast as possible without excessively affecting the cluster.

Alternatively, you can limit the backup speed by using the TiKV configuration item `backup.num-threads` or using the parameter `--ratelimit`.

11.6.5.1.2 Use auto-tune

The auto-tune feature is enabled by default, without additional configuration.

Note:

For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To manually enable the auto-tune feature, you need to set the TiKV configuration item `backup.enable-auto-tune` to `true`.

TiKV supports dynamically configuring the auto-tune feature. You can enable or disable the feature without restarting your cluster. To dynamically enable or disable the auto-tune feature, run the following command:

```
tikv-ctl modify-tikv-config -n backup.enable-auto-tune -v <true|false>
```

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

11.6.5.1.3 Limitations

Auto-tune is a coarse-grained solution for limiting backup speed. It reduces the need for manual tuning. However, because of the lack of fine-grained control, auto-tune might not be able to completely remove the impact of backup on the cluster.

The auto-tune feature has the following issues and corresponding solutions:

- Issue 1: For **write-heavy clusters**, auto-tune might put the workload and backup tasks into a “positive feedback loop”: the backup tasks take up too many resources, which causes the cluster to use fewer resources; at this point, auto-tune might mistakenly assume that the cluster is not under heavy workload and thus allow BR to run faster. In such cases, auto-tune is ineffective.
 - Solution: Manually adjust `backup.num-threads` to a smaller number to limit the number of threads used by backup tasks. The working principle is as follows:
The backup process includes lots of SST decoding, encoding, compression, and decompression, which consume CPU resources. In addition, previous test cases have shown that during the backup process, the CPU utilization of the thread pool used for backup is close to 100%. This means that the backup tasks take up a lot of CPU resources. By adjusting the number of threads used by the backup tasks, TiKV can limit the CPU cores used by backup tasks, thus reducing the impact of backup tasks on the cluster performance.
- Issue 2: For **clusters with hotspots**, backup tasks on the TiKV node that has hotspots might be excessively limited, which slows down the overall backup process.
 - Solution: Eliminate the hotspot node, or disable auto-tune on the hotspot node (this might reduce the cluster performance).
- Issue 3: For scenarios with **high traffic jitter**, because auto-tune adjusts the speed limit on a fixed interval (1 minute by default), it might not be able to handle high traffic jitter. For details, see [auto-tune-refresh-interval](#).
 - Solution: Disable auto-tune.

11.6.5.1.4 Implementation

Auto-tune adjusts the size of the thread pool used by backup tasks using BR to ensure that the overall CPU utilization of the cluster does not exceed a specific threshold.

This feature has two related configuration items not listed in the TiKV configuration file. These two configuration items are only for internal tuning. You do **not** need to configure these two configuration items when you perform backup tasks.

- `backup.auto-tune-remain-threads`:

- Auto-tune controls the resources used by the backup tasks and ensures that at least `backup.auto-tune-remain-threads` cores are available for other tasks on the same node.
- Default value: `round(0.2 * vCPU)`

- `backup.auto-tune-refresh-interval`:

- Every `backup.auto-tune-refresh-interval` minute(s), auto-tune refreshes the statistics and recalculates the maximum number of CPU cores that backup tasks can use.
- Default value: `1m`

The following is an example of how auto-tune works. * denotes a CPU core used by backup tasks. ^ denotes a CPU core used by other tasks. - denotes an idle CPU core.

```
|-----| The server has 8 logical CPU cores.
|****---| By default, `backup.num-threads` is `4`. Note that auto-tune
  ↳ makes sure that the thread pool size is never larger than `backup.num
  ↳ -threads`.
|^~****--| By default, `auto-tune-remain-threads` = round(8 * 0.2) = 2. Auto
  ↳ -tune adjusts the size of the thread pool to `4`.
|^~~^*---| Because the cluster workload gets higher, auto-tune adjusts the
  ↳ size of the thread pool to `2`. After that, the cluster still has 2
  ↳ idle CPU cores.
```

In the **Backup CPU Utilization** panel, you can see the size of the thread pool adjusted by auto-tune:

Figure 147: Grafana dashboard example of backup auto-tune metrics

In the image above, the yellow semi-transparent area represents the threads available for backup tasks. You can see the CPU utilization of backup tasks does not go beyond the yellow area.

11.6.6 Backup & Restore FAQ

This document lists the frequently asked questions (FAQs) and the solutions about Backup & Restore (BR).

11.6.6.1 In TiDB v5.4.0 and later versions, when backup tasks are performed on the cluster under high workload, why does the speed of backup tasks become slow?

Starting from TiDB v5.4.0, BR introduces the auto-tune feature for backup tasks. For clusters in v5.4.0 or later versions, this feature is enabled by default. When the cluster workload is heavy, the feature limits the resources used by backup tasks to reduce the impact on the online cluster. For more information, refer to [BR Auto-Tune](#).

TiKV supports [dynamically configuring](#) the auto-tune feature. You can enable or disable the feature by the following methods without restarting your cluster:

- Disable auto-tune: Set the TiKV configuration item `backup.enable-auto-tune` to `false`.
- Enable auto-tune: Set `backup.enable-auto-tune` to `true`. For clusters that upgrade from v5.3.x to v5.4.0 or later versions, the auto-tune feature is disabled by default. You need to manually enable it.

To use `tikv-ctl` to enable or disable auto-tune, refer to [Use auto-tune](#).

In addition, this feature also reduces the default number of threads used by backup tasks. For details, see `backup.num-threads`[\[\(/tikv-configuration-file.md#num-threads-1\)\]](#). Therefore, on the Grafana Dashboard, the speed, CPU usage, and I/O resource utilization used by backup tasks are lower than those of versions earlier than v5.4. Before v5.4, the default value of `backup.num-threads` was $\text{CPU} * 0.75$, that is, the number of threads used by backup tasks makes up 75% of the logical CPU cores. The maximum value of it was 32. Starting from v5.4, the default value of this configuration item is $\text{CPU} * 0.5$, and its maximum value is 8.

When you perform backup tasks on an offline cluster, to speed up the backup, you can modify the value of `backup.num-threads` to a larger number using `tikv-ctl`.

11.6.6.2 What should I do if the error message `could not read local://...:download sst failed` is returned during data restoration?

When you restore data, each node must have access to **all** backup files (SST files). By default, if `local` storage is used, you cannot restore data because the backup files are scattered among different nodes. Therefore, you have to copy the backup file of each TiKV node to the other TiKV nodes.

It is recommended to mount an NFS disk as a backup disk during backup. For details, see [Back up a single table to a network disk](#).

11.6.6.3 How much does it affect the cluster during backup using BR?

For TiDB v5.4.0 or later versions, BR not only reduces the default CPU utilization used by backup tasks but also limits the resources used by backup tasks in the cluster with heavy workloads. Therefore, when you use the default configuration for backup tasks in the v5.4.0 cluster with heavy workloads, the impact of the tasks on the cluster performance is significantly less than the impact for the clusters earlier than v5.4.0. For details, see [BR Auto-tune](#).

The following is an internal test on a single node. The test results show that when you use the default configuration of v5.4.0 and v5.3.0 in the **full-speed backup** scenario, the impact of backup using BR on cluster performance is quite different. The detailed test results are as follows:

- When BR uses the default configuration of v5.3.0, the QPS of write-only workload is reduced by 75%.
- When BR uses the default configuration of v5.4.0, the QPS for the same workload is reduced by 25%. However, when this configuration is used, the speed of backup tasks using BR becomes correspondingly slower. The time required is 1.7 times that of the v5.3.0 configuration.

If you need to manually control the impact of backup tasks on cluster performance, you can use the following solutions. These two methods can reduce the impact of backup tasks on the cluster, but they also reduce the speed of backup tasks.

- Use the `--ratelimit` parameter to limit the speed of backup tasks. Note that this parameter limits the speed of **saving backup files to external storage**. When calculating the total size of backup files, use the `backup data size(after compressed)` in the backup log as a benchmark.
- Adjust the TiKV configuration item `backup.num-threads` to limit the resources used by backup tasks. This configuration item determines the number of threads used by backup tasks. When BR uses no more than 8 threads for backup tasks, and the total CPU utilization of the cluster does not exceed 60%, the backup tasks have little impact on the cluster, regardless of the read and write workload.

11.6.6.4 Does BR back up system tables? During data restoration, do they raise conflicts?

Before v5.1.0, BR filtered out data from the system schema `mysql` during the backup. Since v5.1.0, BR **backs up** all data by default, including the system schemas `mysql.*`.

During data restoration, system tables do not raise conflicts. The technical implementation of restoring the system tables in `mysql.*` is not complete yet, so the tables in the system schema `mysql` are **not** restored by default, which means no conflicts will be raised. For more details, refer to the [Back up and restore table data in the mysql system schema \(experimental feature\)](#).

11.6.6.5 What should I do to handle the Permission denied or No such file or directory error, even if I have tried to run BR using root in vain?

You need to confirm whether TiKV has access to the backup directory. To back up data, confirm whether TiKV has the write permission. To restore data, confirm whether it has the read permission.

During the backup operation, if the storage medium is the local disk or a network file system (NFS), make sure that the user to start BR and the user to start TiKV are consistent (if BR and TiKV are on different machines, the users' UIDs must be consistent). Otherwise, the **Permission denied** issue might occur.

Running BR with the root access might fail due to the disk permission, because the backup files (SST files) are saved by TiKV.

Note:

You might encounter the same problem during data restoration. When the SST files are read for the first time, the read permission is verified. The execution duration of DDL suggests that there might be a long interval between checking the permission and running BR. You might receive the error message **Permission denied** after waiting for a long time.

Therefore, it is recommended to check the permission before data restore according to the following steps:

1. Run the Linux-native command for process query:

```
ps aux | grep tikv-server
```

The output of the above command:

```
tidb_ouo 9235 10.9 3.8 2019248 622776 ? Ssl 08:28 1:12 bin/tikv-
↳ server --addr 0.0.0.0:20162 --advertise-addr 172.16.6.118:20162
↳ --status-addr 0.0.0.0:20188 --advertise-status-addr
↳ 172.16.6.118:20188 --pd 172.16.6.118:2379 --data-dir /home/user1/
↳ tidb-data/tikv-20162 --config conf/tikv.toml --log-file /home/
↳ user1/tidb-deploy/tikv-20162/log/tikv.log
tidb_ouo 9236 9.8 3.8 2048940 631136 ? Ssl 08:28 1:05 bin/tikv-
↳ server --addr 0.0.0.0:20161 --advertise-addr 172.16.6.118:20161
↳ --status-addr 0.0.0.0:20189 --advertise-status-addr
↳ 172.16.6.118:20189 --pd 172.16.6.118:2379 --data-dir /home/user1/
↳ tidb-data/tikv-20161 --config conf/tikv.toml --log-file /home/
↳ user1/tidb-deploy/tikv-20161/log/tikv.log
```

Or you can run the following command:

```
ps aux | grep tikv-server | awk '{print $1}'
```

The output of the above command:

```
tidb_ouo
tidb_ouo
```

2. Query the startup information of the cluster using the TiUP command:

```
tiup cluster list
```

The output of the above command:

```
[root@Copy-of-VM-EE-CentOS76-v1 br]# tiup cluster list
Starting component `cluster`: /root/.tiup/components/cluster/v1.5.2/
  ↳ tiup-cluster list
Name          User      Version Path
  ↳
-----      -
  ↳
tidb_cluster tidb_ouo v5.0.2 /root/.tiup/storage/cluster/clusters/
  ↳ tidb_cluster /root/.tiup/storage/cluster/clusters/tidb_cluster/
  ↳ ssh/id_rsa
PrivateKey
```

3. Check the permission for the backup directory. For example, backup is for backup data storage:

```
ls -al backup
```

The output of the above command:

```
[root@Copy-of-VM-EE-CentOS76-v1 user1]# ls -al backup
total 0
drwxr-xr-x 2 root root 6 Jun 28 17:48 .
drwxr-xr-x 11 root root 310 Jul 4 10:35 ..
```

From the above output, you can find that the `tikv-server` instance is started by the user `tidb_ouo`. But the user `tidb_ouo` does not have the write permission for `backup`, the backup fails.

11.6.6.6 What should I do to handle the `Io(0s...)` error?

Almost all of these problems are system call errors that occur when TiKV writes data to the disk. For example, if you encounter error messages such as `Io(0s {code: 13, kind: PermissionDenied...})` or `Io(0s {code: 2, kind: NotFound...})`, you can first check the mounting method and the file system of the backup directory, and try to back up data to another folder or another hard disk.

For example, you might encounter the `Code: 22(invalid argument)` error when backing up data to the network disk built by `samba`.

11.6.6.7 What should I do to handle the `rpc error: code = Unavailable desc = ... error occurred in BR?`

This error might occur when the capacity of the cluster to restore (using BR) is insufficient. You can further confirm the cause by checking the monitoring metrics of this cluster or the TiKV log.

To handle this issue, you can try to scale out the cluster resources, reduce the concurrency during restore, and enable the `RATE_LIMIT` option.

11.6.6.8 Where are the backed up files stored when I use local storage?

When you use `local` storage, `backupmeta` is generated on the node where BR is running, and backup files are generated on the Leader nodes of each Region.

11.6.6.9 How about the size of the backup data? Are there replicas of the backup?

During data backup, backup files are generated on the Leader nodes of each Region. The size of the backup is equal to the data size, with no redundant replicas. Therefore, the total data size is approximately the total number of TiKV data divided by the number of replicas.

However, if you want to restore data from local storage, the number of replicas is equal to that of the TiKV nodes, because each TiKV must have access to all backup files.

11.6.6.10 What should I do when BR restores data to the upstream cluster of TiCDC/Drainer?

- **The data restored using BR cannot be replicated to the downstream.** This is because BR directly imports SST files but the downstream cluster currently cannot obtain these files from the upstream.
- Before v4.0.3, DDL jobs generated during the BR restore might cause unexpected DDL executions in TiCDC/Drainer. Therefore, if you need to perform restore on the upstream cluster of TiCDC/Drainer, add all tables restored using BR to the TiCDC/Drainer block list.

You can use `filter.rules` to configure the block list for TiCDC and use `syncer.ignore` ↪ `-table` to configure the block list for Drainer.

11.6.6.11 Does BR back up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table? Does the restored table have multiple Regions?

Yes. BR backs up the `SHARD_ROW_ID_BITS` and `PRE_SPLIT_REGIONS` information of a table. The data of the restored table is also split into multiple Regions.

11.6.6.12 Why is the region is unavailable error reported for a SQL query after I use BR to restore the backup data?

If the cluster backed up using BR has TiFlash, `TableInfo` stores the TiFlash information when BR restores the backup data. If the cluster to be restored does not have TiFlash, the `region is unavailable` error is reported.

11.6.6.13 Does BR support in-place full recovery of some historical backup?

No. BR does not support in-place full recovery of some historical backup.

11.6.6.14 How can I use BR for incremental backup in the Kubernetes environment?

To get the `commitTs` field of the last BR backup, run the `kubectl -n ${namespace} ↵ } get bk ${name}` command using `kubectl`. You can use the content of this field as `--lastbackupts`.

11.6.6.15 How can I convert BR backupTS to Unix time?

BR `backupTS` defaults to the latest timestamp obtained from PD before the backup starts. You can use `pd-ctl tso timestamp` to parse the timestamp to obtain an accurate value, or use `backupTS >> 18` to quickly obtain an estimated value.

11.6.6.16 After BR restores the backup data, do I need to execute the ANALYZE statement on the table to update the statistics of TiDB on the tables and indexes?

BR does not back up statistics (except in v4.0.9). Therefore, after restoring the backup data, you need to manually execute `ANALYZE TABLE` or wait for TiDB to automatically execute `ANALYZE`.

In v4.0.9, BR backs up statistics by default, which consumes too much memory. To ensure that the backup process goes well, the backup for statistics is disabled by default starting from v4.0.10.

If you do not execute `ANALYZE` on the table, TiDB will fail to select the optimized execution plan due to inaccurate statistics. If query performance is not a key concern, you can ignore `ANALYZE`.

11.6.6.17 Can I use multiple BR processes at the same time to restore the data of a single cluster?

It is strongly not recommended to use multiple BR processes at the same time to restore the data of a single cluster for the following reasons:

- When BR restores data, it modifies some global configurations of PD. Therefore, if you use multiple BR processes for data restore at the same time, these configurations might be mistakenly overwritten and cause abnormal cluster status.

- BR consumes a lot of cluster resources to restore data, so in fact, running BR processes in parallel improves the restore speed only to a limited extent.
- There has been no test for running multiple BR processes in parallel for data restore, so it is not guaranteed to succeed.

11.7 TiDB Binlog

11.7.1 TiDB Binlog Cluster Overview

This document introduces the architecture and the deployment of the cluster version of TiDB Binlog.

TiDB Binlog is a tool used to collect binlog data from TiDB and provide near real-time backup and replication to downstream platforms.

TiDB Binlog has the following features:

- **Data replication:** replicate the data in the TiDB cluster to other databases
- **Real-time backup and restoration:** back up the data in the TiDB cluster and restore the TiDB cluster when the cluster fails

Note:

TiDB Binlog is not compatible with some features introduced in TiDB v5.0 and they cannot be used together. For details, see [Notes](#). It is recommended to use [TiCDC](#) instead of TiDB Binlog.

11.7.1.1 TiDB Binlog architecture

The TiDB Binlog architecture is as follows:

Figure 148: TiDB Binlog architecture

The TiDB Binlog cluster is composed of Pump and Drainer.

11.7.1.1.1 Pump

Pump is used to record the binlogs generated in TiDB, sort the binlogs based on the commit time of the transaction, and send binlogs to Drainer for consumption.

11.7.1.1.2 Drainer

Drainer collects and merges binlogs from each Pump, converts the binlog to SQL or data of a specific format, and replicates the data to a specific downstream platform.

11.7.1.1.3 binlogctl guide

binlogctl is an operations tool for TiDB Binlog with the following features:

- Obtaining the current `tso` of TiDB cluster
- Checking the Pump/Drainer state
- Modifying the Pump/Drainer state
- Pausing or closing Pump/Drainer

11.7.1.2 Main features

- Multiple Pumps form a cluster which can scale out horizontally
- TiDB uses the built-in Pump Client to send the binlog to each Pump
- Pump stores binlogs and sends the binlogs to Drainer in order

- Drainer reads binlogs of each Pump, merges and sorts the binlogs, and sends the binlogs downstream
- Drainer supports **relay log**. By the relay log, Drainer ensures that the downstream clusters are in a consistent state.

11.7.1.3 Notes

- In v5.1, the incompatibility between the clustered index feature introduced in v5.0 and TiDB Binlog has been resolved. After you upgrade TiDB Binlog and TiDB Server to v5.1 and enable TiDB Binlog, TiDB will support creating tables with clustered indexes; data insertion, deletion, and update on the created tables with clustered indexes will be replicated to the downstream via TiDB Binlog. When you use TiDB Binlog to replicate the tables with clustered indexes, pay attention to the following:
 - If you have upgraded the cluster to v5.1 from v5.0 by manually controlling the upgrade sequence, make sure that TiDB binlog is upgraded to v5.1 before upgrading the TiDB server to v5.1.
 - It is recommended to configure the system variable **tidb_enable_clustered_index** \leftrightarrow to a same value to ensure that the structure of TiDB clustered index tables between the upstream and downstream is consistent.
- TiDB Binlog is incompatible with the following features introduced in TiDB v5.0 and they cannot be used together.
 - **TiDB Clustered Index**: After TiDB Binlog is enabled, TiDB does not allow creating clustered indexes with non-single integer columns as primary keys; data insertion, deletion, and update of the created clustered index tables will not be replicated downstream via TiDB Binlog. If you need to replicate tables with clustered indexes, upgrade your cluster to v5.1 or use **TiCDC** instead.
 - TiDB system variable **tidb_enable_async_commit**: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use **TiCDC** instead of TiDB Binlog.
 - TiDB system variable **tidb_enable_1pc**: After TiDB Binlog is enabled, performance cannot be improved by enabling this option. It is recommended to use **TiCDC** instead of TiDB Binlog.
- TiDB Binlog is incompatible with the following feature introduced in TiDB v4.0.7 and they cannot be used together:
 - TiDB system variable **tidb_enable_amend_pessimistic_txn**: The two features have compatibility issues. Using them together might cause the issue that TiDB Binlog replicates data inconsistently.
- Drainer supports replicating binlogs to MySQL, TiDB, Kafka or local files. If you need to replicate binlogs to other Drainer unsupported destinations, you can set Drainer to

replicate the binlog to Kafka and read the data in Kafka for customized processing according to binlog consumer protocol. See [Binlog Consumer Client User Guide](#).

- To use TiDB Binlog for recovering incremental data, set the config `db-type` to `file` \leftrightarrow (local files in the proto buffer format). Drainer converts the binlog to data in the specified [proto buffer format](#) and writes the data to local files. In this way, you can use [Reparo](#) to recover data incrementally.

Pay attention to the value of `db-type`:

- If your TiDB version is earlier than 2.1.9, set `db-type="pb"`.
 - If your TiDB version is 2.1.9 or later, set `db-type="file"` or `db-type="pb"`.
- If the downstream is MySQL, MariaDB, or another TiDB cluster, you can use [sync-diff-inspector](#) to verify the data after data replication.

11.7.2 TiDB Binlog Tutorial

This tutorial starts with a simple TiDB Binlog deployment with a single node of each component (Placement Driver, TiKV Server, TiDB Server, Pump, and Drainer), set up to push data into a MariaDB Server instance.

This tutorial is targeted toward users who have some familiarity with the [TiDB Architecture](#), who may have already set up a TiDB cluster (not mandatory), and who wants to gain hands-on experience with TiDB Binlog. This tutorial is a good way to “kick the tires” of TiDB Binlog and to familiarize yourself with the concepts of its architecture.

Warning:

The instructions to deploy TiDB in this tutorial should **not** be used to deploy TiDB in a production or development setting.

This tutorial assumes you’re using a modern Linux distribution on x86-64. A minimal CentOS 7 installation running in VMware is used in this tutorial for the examples. It’s recommended that you start from a clean install, so that you aren’t impacted by quirks of your existing environment. If you don’t want to use local virtualization, you can easily start a CentOS 7 VM using your cloud service.

11.7.2.1 TiDB Binlog Overview

TiDB Binlog is a solution to collect binary log data from TiDB and provide real-time data backup and replication. It pushes incremental data updates from a TiDB Server cluster into downstream platforms.

You can use TiDB Binlog for incremental backups, to replicate data from one TiDB cluster to another, or to send TiDB updates through Kafka to a downstream platform of your choice.

TiDB Binlog is particularly useful when you migrate data from MySQL or MariaDB to TiDB, in which case you may use the TiDB DM (Data Migration) platform to get data from a MySQL/MariaDB cluster into TiDB, and then use TiDB Binlog to keep a separate, downstream MySQL/MariaDB instance/cluster in sync with your TiDB cluster. TiDB Binlog enables application traffic to TiDB to be pushed to a downstream MySQL or MariaDB instance/cluster, which reduces the risk of a migration to TiDB because you can easily revert the application to MySQL or MariaDB without downtime or data loss.

See [TiDB Binlog Cluster User Guide](#) for more information.

11.7.2.2 Architecture

TiDB Binlog comprises two components: the **Pump** and the **Drainer**. Several Pump nodes make up a pump cluster. Each Pump node connects to TiDB Server instances and receives updates made to each of the TiDB Server instances in a cluster. A Drainer connects to the Pump cluster and transforms the received updates into the correct format for a particular downstream destination, for example, Kafka, another TiDB Cluster or a MySQL/MariaDB server.

Figure 149: TiDB-Binlog architecture

The clustered architecture of Pump ensures that updates won't be lost as new TiDB Server instances join or leave the TiDB Cluster or Pump nodes join or leave the Pump cluster.

11.7.2.3 Installation

We're using MariaDB Server in this case instead of MySQL Server because RHEL/CentOS 7 includes MariaDB Server in their default package repositories. We'll need the client as well as the server for later use. Let's install them now:

```
sudo yum install -y mariadb-server
```

```
curl -L https://download.pingcap.org/tidb-latest-linux-amd64.tar.gz | tar
  ↪ xzf -
cd tidb-latest-linux-amd64
```

Expected output:

```
[kolbe@localhost ~]$ curl -LO https://download.pingcap.org/tidb-latest-linux
  ↪ -amd64.tar.gz | tar xzf -
% Total    % Received % Xferd Average Speed Time Time     Time Current
           Dload Upload  Total  Spent  Left  Speed
100 368M 100 368M    0    0 8394k    0 0:00:44 0:00:44 --:--:-- 11.1M
[kolbe@localhost ~]$ cd tidb-latest-linux-amd64
[kolbe@localhost tidb-latest-linux-amd64]$
```

11.7.2.4 Configuration

Now we'll start a simple TiDB cluster, with a single instance for each of `pd-server`, `tikv-server`, and `tidb-server`.

Populate the config files using:

```
printf > pd.toml %s\n 'log-file="pd.log"' 'data-dir="pd.data"'
printf > tikv.toml %s\n 'log-file="tikv.log"' '[storage]' 'data-dir="tikv.
  ↪ data"' '[pd]' 'endpoints=["127.0.0.1:2379"]' '[rocksdb]' max-open-
  ↪ files=1024 '[raftdb]' max-open-files=1024
printf > pump.toml %s\n 'log-file="pump.log"' 'data-dir="pump.data"' 'addr
  ↪ ="127.0.0.1:8250"' 'advertise-addr="127.0.0.1:8250"' 'pd-urls="http
  ↪ ://127.0.0.1:2379"'
printf > tidb.toml %s\n 'store="tikv"' 'path="127.0.0.1:2379"' '[log.file
  ↪ ]' 'filename="tidb.log"' '[binlog]' 'enable=true'
printf > drainer.toml %s\n 'log-file="drainer.log"' '[syncer]' 'db-type="
  ↪ mysql"' '[syncer.to]' 'host="127.0.0.1"' 'user="root"' 'password=""'
  ↪ 'port=3306'
```

Use the following commands to see the configuration details:

```
for f in *.toml; do echo "$f:"; cat "$f"; echo; done
```

Expected output:

```
drainer.toml:
log-file="drainer.log"
[syncer]
db-type="mysql"
[syncer.to]
host="127.0.0.1"
user="root"
password=""
port=3306

pd.toml:
log-file="pd.log"
data-dir="pd.data"

pump.toml:
log-file="pump.log"
data-dir="pump.data"
addr="127.0.0.1:8250"
advertise-addr="127.0.0.1:8250"
pd-urls="http://127.0.0.1:2379"

tidb.toml:
store="tikv"
path="127.0.0.1:2379"
[log.file]
filename="tidb.log"
[binlog]
enable=true

tikv.toml:
log-file="tikv.log"
[storage]
data-dir="tikv.data"
[pd]
endpoints=["127.0.0.1:2379"]
[rocksdb]
max-open-files=1024
[raftdb]
max-open-files=1024
```

11.7.2.5 Bootstrapping

Now we can start each component. This is best done in a specific order - firstly the Placement Driver (PD), then TiKV Server, then Pump (because TiDB must connect to the

Pump service to send the binary log), and finally the TiDB Server.

Start all the services using:

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./bin/pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/pd-server --config=pd.toml
↪ &>pd.out &
[1] 20935
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/tikv-server --config=tikv.
↪ toml &>tikv.out &
[2] 20944
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/pump --config=pump.toml &>
↪ pump.out &
[3] 21050
[kolbe@localhost tidb-latest-linux-amd64]$ sleep 3
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/tidb-server --config=tidb.
↪ toml &>tidb.out &
[4] 21058
```

If you execute jobs, you should see a list of running daemons:

```
[kolbe@localhost tidb-latest-linux-amd64]$ jobs
[1]  Running          ./bin/pd-server --config=pd.toml &>pd.out &
[2]  Running          ./bin/tikv-server --config=tikv.toml &>tikv.out &
[3]- Running         ./bin/pump --config=pump.toml &>pump.out &
[4]+ Running         ./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If one of the services has failed to start (if you see “Exit 1” instead of “Running”, for example), try to restart that individual service.

11.7.2.6 Connecting

You should have all 4 components of our TiDB Cluster running now, and you can now connect to the TiDB Server on port 4000 using the MariaDB/MySQL command-line client:

```
mysql -h 127.0.0.1 -P 4000 -u root -e 'select tidb_version()\G'
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ mysql -h 127.0.0.1 -P 4000 -u
↪ root -e 'select tidb_version()\G'
```

```
***** 1. row *****
tidb_version(): Release Version: v3.0.0-beta.1-154-gd5afff70c
Git Commit Hash: d5afff70cdd825d5fab125c8e52e686cc5fb9a6e
Git Branch: master
UTC Build Time: 2019-04-24 03:10:00
GoVersion: go version go1.12 linux/amd64
Race Enabled: false
TiKV Min Version: 2.1.0-alpha.1-ff3dd160846b7d1aed9079c389fc188f7f5ea13e
Check Table Before Drop: false
```

At this point we have a TiDB Cluster running, and we have pump reading binary logs from the cluster and storing them as relay logs in its data directory. The next step is to start a MariaDB server that drainer can write to.

Start drainer using:

```
sudo systemctl start mariadb
./bin/drainer --config=drainer.toml &>drainer.out &
```

If you are using an operating system that makes it easier to install MySQL server, that's also OK. Just make sure it's listening on port 3306 and that you can either connect to it as user "root" with an empty password, or adjust drainer.toml as necessary.

```
mysql -h 127.0.0.1 -P 3306 -u root
```

```
show databases;
```

Expected output:

```
[kolbe@localhost ~]$ mysql -h 127.0.0.1 -P 3306 -u root
Welcome to the MariaDB monitor. Commands end with ; or \g.
Your MariaDB connection id is 20
Server version: 5.5.60-MariaDB MariaDB Server

Copyright (c) 2000, 2018, Oracle, MariaDB Corporation Ab and others.

Type 'help;' or '\h' for help. Type '\c' to clear the current input
    ↪ statement.

MariaDB [(none)]> show databases;
+-----+

+-----+
| information_schema|
| mysql             |
| performance_schema|
| test              |
+-----+
```

```
| tidb_binlog      |
+-----+
5 rows in set (0.01 sec)
```

Here we can already see the `tidb_binlog` database, which contains the `checkpoint` table used by `drainer` to record up to what point binary logs from the TiDB cluster have been applied.

```
MariaDB [tidb_binlog]> use tidb_binlog;
Database changed
MariaDB [tidb_binlog]> select * from checkpoint;
+-----+-----+
| clusterID      | checkPoint      |
+-----+-----+
| 6678715361817107733 | {"commitTS":407637466476445697,"ts-map":{}} |
+-----+-----+
1 row in set (0.00 sec)
```

Now, let's open another client connection to the TiDB server, so that we can create a table and insert some rows into it. (It's recommended that you do this under a GNU screen so you can keep multiple clients open at the same time.)

```
mysql -h 127.0.0.1 -P 4000 --prompt='TiDB [\d]> ' -u root
```

```
create database tidbtest;
use tidbtest;
create table t1 (id int unsigned not null AUTO_INCREMENT primary key);
insert into t1 () values (),(),(),(),();
select * from t1;
```

Expected output:

```
TiDB [(none)]> create database tidbtest;
Query OK, 0 rows affected (0.12 sec)

TiDB [(none)]> use tidbtest;
Database changed
TiDB [tidbtest]> create table t1 (id int unsigned not null AUTO_INCREMENT
↪ primary key);
Query OK, 0 rows affected (0.11 sec)

TiDB [tidbtest]> insert into t1 () values (),(),(),(),();
Query OK, 5 rows affected (0.01 sec)
Records: 5 Duplicates: 0 Warnings: 0

TiDB [tidbtest]> select * from t1;
```

```
+-----+
| id |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
5 rows in set (0.00 sec)
```

Switching back to the MariaDB client, we should find the new database, new table, and the newly inserted rows:

```
use tidbtest;
show tables;
select * from t1;
```

Expected output:

```
MariaDB [(none)]> use tidbtest;
Reading table information for completion of table and column names
You can turn off this feature to get a quicker startup with -A

Database changed
MariaDB [tidbtest]> show tables;
+-----+
| Tables_in_tidbtest |
+-----+
| t1                  |
+-----+
1 row in set (0.00 sec)

MariaDB [tidbtest]> select * from t1;
+-----+
| id |
+-----+
| 1 |
| 2 |
| 3 |
| 4 |
| 5 |
+-----+
5 rows in set (0.00 sec)
```

You should see the same rows that you inserted into TiDB when querying the MariaDB server. Congratulations! You've just set up TiDB Binlog!

11.7.2.7 binlogctl

Information about Pumps and Drainers that have joined the cluster is stored in PD. You can use the `binlogctl` tool query and manipulate information about their states. See [binlogctl guide](#) for more information.

Use `binlogctl` to get a view of the current status of Pumps and Drainers in the cluster:

```
./bin/binlogctl -cmd drainers
./bin/binlogctl -cmd pumps
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd drainers
[2019/04/11 17:44:10.861 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
↳ 192.168.236.128:8249, State: online, MaxCommitTS: 407638907719778305,
↳ UpdateTime: 2019-04-11 17:44:10 -0400 EDT}"]

[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd pumps
[2019/04/11 17:44:13.904 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ pump] [node="{NodeID: localhost.localdomain:8250, Addr:
↳ 192.168.236.128:8250, State: online, MaxCommitTS: 407638914024079361,
↳ UpdateTime: 2019-04-11 17:44:13 -0400 EDT}"]
```

If you kill a Drainer, the cluster puts it in the “paused” state, which means that the cluster expects it to rejoin:

```
pkill drainer
./bin/binlogctl -cmd drainers
```

Expected output:

```
[kolbe@localhost tidb-latest-linux-amd64]$ pkill drainer
[kolbe@localhost tidb-latest-linux-amd64]$ ./bin/binlogctl -cmd drainers
[2019/04/11 17:44:22.640 -04:00] [INFO] [nodes.go:47] ["query node"] [type=
↳ drainer] [node="{NodeID: localhost.localdomain:8249, Addr:
↳ 192.168.236.128:8249, State: paused, MaxCommitTS: 407638915597467649,
↳ UpdateTime: 2019-04-11 17:44:18 -0400 EDT}"]
```

You can use “NodeIDs” with `binlogctl` to control individual nodes. In this case, the NodeID of the drainer is “localhost.localdomain:8249” and the NodeID of the Pump is “localhost.localdomain:8250”.

The main use of `binlogctl` in this tutorial is likely to be in the event of a cluster restart. If you end all processes in the TiDB cluster and try to restart them (not including

the downstream MySQL/MariaDB server or Drainer), Pump will refuse to start because it cannot contact Drainer and believe that Drainer is still “online”.

There are 3 solutions to this issue:

- Stop Drainer using `binlogctl` instead of killing the process:

```
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=drainers
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=offline-drainer
  ↪ --node-id=localhost.localdomain:8249
```

- Start Drainer *before* starting Pump.
- Use `binlogctl` after starting PD (but before starting Drainer and Pump) to update the state of the paused Drainer:

```
./bin/binlogctl --pd-urls=http://127.0.0.1:2379 --cmd=update-drainer --
  ↪ node-id=localhost.localdomain:8249 --state=offline
```

11.7.2.8 Cleanup

To stop the TiDB cluster and TiDB Binlog processes, you can execute `kill -P $$` in the shell where you started all the processes that form the cluster (pd-server, tikv-server, pump, tidb-server, drainer). To give each component enough time to shut down cleanly, it's helpful to stop them in a particular order:

```
for p in tidb-server drainer pump tikv-server pd-server; do kill -P "$p";
  ↪ sleep 1; done
```

Expected output:

```
kolbe@localhost tidb-latest-linux-amd64]$ for p in tidb-server drainer pump
  ↪ tikv-server pd-server; do kill -P "$p"; sleep 1; done
[4]- Done          ./bin/tidb-server --config=tidb.toml &>tidb.out
[5]+ Done          ./bin/drainer --config=drainer.toml &>drainer.out
[3]+ Done          ./bin/pump --config=pump.toml &>pump.out
[2]+ Done          ./bin/tikv-server --config=tikv.toml &>tikv.out
[1]+ Done          ./bin/pd-server --config=pd.toml &>pd.out
```

If you wish to restart the cluster after all services exit, use the same commands you ran originally to start the services. As discussed in the `binlogctl` section above, you'll need to start `drainer` before `pump`, and `pump` before `tidb-server`.

```
./bin/pd-server --config=pd.toml &>pd.out &
./bin/tikv-server --config=tikv.toml &>tikv.out &
./bin/drainer --config=drainer.toml &>drainer.out &
sleep 3
```

```
./bin/pump --config=pump.toml &>pump.out &
sleep 3
./bin/tidb-server --config=tidb.toml &>tidb.out &
```

If any of the components fail to start, try to restart the failed individual component(s).

11.7.2.9 Conclusion

In this tutorial, we've set up TiDB Binlog to replicate from a TiDB cluster to a downstream MariaDB server, using a cluster with a single Pump and a single Drainer. As we've seen, TiDB Binlog is a comprehensive platform for capturing and processing changes to a TiDB cluster.

In a more robust development, testing, or production deployment, you'd have multiple TiDB servers for high availability and scaling purposes, and you'd use multiple Pump instances to ensure that application traffic to TiDB server instances is unaffected by problems in the Pump cluster. You may also use additional Drainer instances to push updates to different downstream platforms or to implement incremental backups.

11.7.3 TiDB Binlog Cluster Deployment

This document describes how to [deploy TiDB Binlog using a Binary package](#).

11.7.3.1 Hardware requirements

Pump and Drainer are deployed and operate on 64-bit universal hardware server platforms with Intel x86-64 architecture.

In environments of development, testing and production, the requirements on server hardware are as follows:

Service	The Number of Servers	CPU	Disk	Memory
Pump	3	8 core+	SSD, 200 GB+	16G
Drainer	1	8 core+	SAS, 100 GB+	16G

(If binlogs are output as local files, the disk size depends on how long these files are retained.)

11.7.3.2 Deploy TiDB Binlog using TiUP

It is recommended to deploy TiDB Binlog using TiUP. To do that, when deploying TiDB using TiUP, you need to add the node information of drainer and pump of TiDB Binlog in [TiDB Binlog Deployment Topology](#). For detailed deployment information, refer to [Deploy a TiDB Cluster Using TiUP](#).

11.7.3.3 Deploy TiDB Binlog using a Binary package

11.7.3.3.1 Download the official Binary package

Run the following commands to download the packages:

```
version="latest" for nightly builds &&  
wget https://download.pingcap.org/tidb-latest-linux-amd64.{tar.gz,sha256}
```

Check the file integrity. If the result is OK, the file is correct.

```
sha256sum -c tidb-latest-linux-amd64.sha256
```

For TiDB v2.1.0 GA or later versions, Pump and Drainer are already included in the TiDB download package. For other TiDB versions, you need to download Pump and Drainer separately using the following command:

```
wget https://download.pingcap.org/tidb-binlog-$version-linux-amd64.{tar.gz,  
↪ sha256}
```

Check the file integrity. If the result is OK, the file is correct.

```
sha256sum -c tidb-binlog-$version-linux-amd64.sha256
```

11.7.3.3.2 The usage example

Assuming that you have three PD nodes, one TiDB node, two Pump nodes, and one Drainer node, the information of each node is as follows:

Node	IP
TiDB	192.168.0.10
PD1	192.168.0.16
PD2	192.168.0.15
PD3	192.168.0.14
Pump	192.168.0.11
Pump	192.168.0.12
Drainer	192.168.0.13

The following part shows how to use Pump and Drainer based on the nodes above.

1. Deploy Pump using the binary.

- To view the command line parameters of Pump, execute `./bin/pump -help`:

```
Usage of Pump:
-L string
    the output information level of logs: debug, info, warn, error,
    ↪ fatal ("info" by default)
-V
    the print version information
-addr string
    the RPC address through which Pump provides the service (-addr=
    ↪ "192.168.0.11:8250")
-advertise-addr string
    the RPC address through which Pump provides the external
    ↪ service (-advertise-addr="192.168.0.11:8250")
-config string
    the path of the configuration file. If you specify the
    ↪ configuration file, Pump reads the configuration in the
    ↪ configuration file first. If the corresponding
    ↪ configuration also exists in the command line parameters,
    ↪ Pump uses the configuration of the command line
    ↪ parameters to cover that of the configuration file.
-data-dir string
    the path where the Pump data is stored
-gc int
    the number of days to retain the data in Pump ("7" by default)
-heartbeat-interval int
    the interval of the heartbeats Pump sends to PD (in seconds)
-log-file string
    the file path of logs
-log-rotate string
    the switch frequency of logs (hour/day)
-metrics-addr string
    the Prometheus Pushgateway address. If not set, it is forbidden
    ↪ to report the monitoring metrics.
-metrics-interval int
    the report frequency of the monitoring metrics ("15" by default
    ↪ , in seconds)
-node-id string
    the unique ID of a Pump node. If you do not specify this ID,
    ↪ the system automatically generates an ID based on the
    ↪ host name and listening port.
-pd-urls string
    the address of the PD cluster nodes (-pd-urls="http
    ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
```

```
↪ ://192.168.0.14:2379")
-fake-binlog-interval int
    the frequency at which a Pump node generates fake binlog ("3"
    ↪ by default, in seconds)
```

- Taking deploying Pump on “192.168.0.11” as an example, the Pump configuration file is as follows:

```
# Pump Configuration

# the bound address of Pump
addr = "192.168.0.11:8250"

# the address through which Pump provides the service
advertise-addr = "192.168.0.11:8250"

# the number of days to retain the data in Pump ("7" by default)
gc = 7

# the directory where the Pump data is stored
data-dir = "data.pump"

# the interval of the heartbeats Pump sends to PD (in seconds)
heartbeat-interval = 2

# the address of the PD cluster nodes (each separated by a comma
↪ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
↪ ://192.168.0.14:2379"

# [security]
# This section is generally commented out if no special security
↪ settings are required.
# The file path containing a list of trusted SSL CAs connected to
↪ the cluster.
# ssl-ca = "/path/to/ca.pem"
# The path to the X509 certificate in PEM format that is connected
↪ to the cluster.
# ssl-cert = "/path/to/drainer.pem"
# The path to the X509 key in PEM format that is connected to the
↪ cluster.
# ssl-key = "/path/to/drainer-key.pem"

# [storage]
# Set to true (by default) to guarantee reliability by ensuring
```

```
    ↪ binlog data is flushed to the disk
# sync-log = true

# When the available disk capacity is less than the set value, Pump
    ↪ stops writing data.
# 42 MB -> 42000000, 42 mib -> 44040192
# default: 10 gib
# stop-write-at-available-space = "10 gib"
# The LSM DB settings embedded in Pump. Unless you know this part
    ↪ well, it is usually commented out.
# [storage.kv]
# block-cache-capacity = 8388608
# block-restart-interval = 16
# block-size = 4096
# compaction-L0-trigger = 8
# compaction-table-size = 67108864
# compaction-total-size = 536870912
# compaction-total-size-multiplier = 8.0
# write-buffer = 67108864
# write-L0-pause-trigger = 24
# write-L0-slowdown-trigger = 17
```

- The example of starting Pump:

```
./bin/pump -config pump.toml
```

If the command line parameters is the same with the configuration file parameters, the values of command line parameters are used.

2. Deploy Drainer using binary.

- To view the command line parameters of Drainer, execute `./bin/drainer -help`:

```
Usage of Drainer:
-L string
    the output information level of logs: debug, info, warn, error,
    ↪ fatal ("info" by default)
-V
    the print version information
-addr string
    the address through which Drainer provides the service (-addr="
    ↪ 192.168.0.13:8249")
-c int
    the number of the concurrency of the downstream for replication
    ↪ . The bigger the value, the better throughput performance
    ↪ of the concurrency ("1" by default).
```

```
-cache-binlog-count int
    the limit on the number of binlog items in the cache ("8" by
    ↪ default)
    If a large single binlog item in the upstream causes OOM in
    ↪ Drainer, try to lower the value of this parameter to
    ↪ reduce memory usage.
-config string
    the directory of the configuration file. Drainer reads the
    ↪ configuration file first.
    If the corresponding configuration exists in the command line
    ↪ parameters, Drainer uses the configuration of the command
    ↪ line parameters to cover that of the configuration file.
-data-dir string
    the directory where the Drainer data is stored ("data.drainer"
    ↪ by default)
-dest-db-type string
    the downstream service type of Drainer
    The value can be "mysql", "tidb", "kafka", and "file". ("mysql"
    ↪ by default)
-detect-interval int
    the interval of checking the online Pump in PD ("10" by default
    ↪ , in seconds)
-disable-detect
    whether to disable the conflict monitoring
-disable-dispatch
    whether to disable the SQL feature of splitting a single binlog
    ↪ file. If it is set to "true", each binlog file is
    ↪ restored to a single transaction for replication based on
    ↪ the order of binlogs.
    It is set to "False", when the downstream is MySQL.
-ignore-schemas string
    the db filter list ("INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,
    ↪ mysql,test" by default)
    It does not support the Rename DDL operation on tables of `
    ↪ ignore schemas`.
-initial-commit-ts
    If Drainer does not have the related breakpoint information,
    ↪ you can configure the related breakpoint information
    ↪ using this parameter. ("-1" by default)
    If the value of this parameter is `-1`, Drainer automatically
    ↪ obtains the latest timestamp from PD.
-log-file string
    the path of the log file
-log-rotate string
    the switch frequency of log files, hour/day
```

```
-metrics-addr string
    the Prometheus Pushgateway address
    It it is not set, the monitoring metrics are not reported.
-metrics-interval int
    the report frequency of the monitoring metrics ("15" by default
    ↪ , in seconds)
-node-id string
    the unique ID of a Drainer node. If you do not specify this ID,
    ↪ the system automatically generates an ID based on the
    ↪ host name and listening port.
-pd-urls string
    the address of the PD cluster nodes (-pd-urls="http
    ↪ ://192.168.0.16:2379,http://192.168.0.15:2379,http
    ↪ ://192.168.0.14:2379")
-safe-mode
    Whether to enable safe mode so that data can be written into
    ↪ the downstream MySQL/TiDB repeatedly.
    This mode replaces the `INSERT` statement with the `REPLACE`
    ↪ statement and splits the `UPDATE` statement into `DELETE`
    ↪ plus `REPLACE`.
-txn-batch int
    the number of SQL statements of a transaction which are output
    ↪ to the downstream database ("1" by default)
```

- Taking deploying Drainer on “192.168.0.13” as an example, the Drainer configuration file is as follows:

```
# Drainer Configuration.

# the address through which Drainer provides the service
  ↪ ("192.168.0.13:8249")
addr = "192.168.0.13:8249"

# the address through which Drainer provides the external service
advertise-addr = "192.168.0.13:8249"

# the interval of checking the online Pump in PD ("10" by default,
  ↪ in seconds)
detect-interval = 10

# the directory where the Drainer data is stored "data.drainer" by
  ↪ default)
data-dir = "data.drainer"

# the address of the PD cluster nodes (each separated by a comma
```

```
    ↪ with no whitespace)
pd-urls = "http://192.168.0.16:2379,http://192.168.0.15:2379,http
    ↪ ://192.168.0.14:2379"

# the directory of the log file
log-file = "drainer.log"

# Drainer compresses the data when it gets the binlog from Pump.
    ↪ The value can be "gzip". If it is not configured, it will
    ↪ not be compressed
# compressor = "gzip"

# [security]
# This section is generally commented out if no special security
    ↪ settings are required.
# The file path containing a list of trusted SSL CAs connected to
    ↪ the cluster.
# ssl-ca = "/path/to/ca.pem"
# The path to the X509 certificate in PEM format that is connected
    ↪ to the cluster.
# ssl-cert = "/path/to/pump.pem"
# The path to the X509 key in PEM format that is connected to the
    ↪ cluster.
# ssl-key = "/path/to/pump-key.pem"

# Syncer Configuration
[syncer]
# If the item is set, the sql-mode will be used to parse the DDL
    ↪ statement.
# If the downstream database is MySQL or TiDB, then the downstream
    ↪ sql-mode
# is also set to this value.
# sql-mode = "STRICT_TRANS_TABLES,NO_ENGINE_SUBSTITUTION"

# the number of SQL statements of a transaction that are output to
    ↪ the downstream database ("20" by default)
txn-batch = 20

# the number of the concurrency of the downstream for replication.
    ↪ The bigger the value,
# the better throughput performance of the concurrency ("16" by
    ↪ default)
worker-count = 16

# whether to disable the SQL feature of splitting a single binlog
```

```
    ↪ file. If it is set to "true",

  ↪ The default value is <cluster-id>_obinlog.
# To run multiple Drainers to replicate data to the same Kafka
  ↪ cluster, you need to set different `topic-name`s for each
  ↪ Drainer.
# topic-name = ""
```

- Starting Drainer:

Note:

If the downstream is MySQL/TiDB, to guarantee the data integrity, you need to obtain the `initial-commit-ts` value and make a full backup of the data and restore the data before the initial start of Drainer.

When Drainer is started for the first time, use the `initial-commit-ts` parameter.

```
./bin/drainer -config drainer.toml -initial-commit-ts {initial-
  ↪ commit-ts}
```

If the command line parameter and the configuration file parameter are the same, the parameter value in the command line is used.

3. Starting TiDB server:

- After starting Pump and Drainer, start TiDB server with binlog enabled by adding this section to your config file for TiDB server:

```
[binlog]
enable=true
```

- TiDB server will obtain the addresses of registered Pumps from PD and will stream data to all of them. If there are no registered Pump instances, TiDB server will refuse to start or will block starting until a Pump instance comes online.

Note:

- When TiDB is running, you need to guarantee that at least one Pump is running normally.
- To enable the TiDB Binlog service in TiDB server, use the `-enable-binlog` startup parameter in TiDB, or add `enable=true` to the `binlog` section of the TiDB server configuration file.
- Make sure that the TiDB Binlog service is enabled in all TiDB instances in a same cluster, otherwise upstream and downstream data inconsistency might occur during data replication. If you want to temporarily run a TiDB instance where the TiDB Binlog service is not enabled, set `run_ddl=false` in the TiDB configuration file.
- Drainer does not support the `rename` DDL operation on the table of `ignore_schemas` (the schemas in the filter list).
- If you want to start Drainer in an existing TiDB cluster, generally you need to make a full backup of the cluster data, obtain **snapshot timestamp**, import the data to the target database, and then start Drainer to replicate the incremental data from the corresponding **snapshot timestamp**.
- When the downstream database is TiDB or MySQL, ensure that the `sql_mode` in the upstream and downstream databases are consistent. In other words, the `sql_mode` should be the same when each SQL statement is executed in the upstream and replicated to the downstream. You can execute the `select @@sql_mode;` statement in the upstream and downstream respectively to compare `sql_mode`.
- When a DDL statement is supported in the upstream but incompatible with the downstream, Drainer fails to replicate data. An example is to

replicate the `CREATE TABLE t1(a INT)ROW_FORMAT=FIXED;` statement when the downstream database MySQL uses the InnoDB engine. In this case, you can configure **skipping transactions** in Drainer, and manually execute compatible statements in the downstream database.

11.7.4 TiDB Binlog Cluster Operations

This document introduces the following TiDB Binlog cluster operations:

- The state of a Pump and Drainer nodes
- Starting or exiting a Pump or Drainer process
- Managing the TiDB Binlog cluster by using the `binlogctl` tool or by directly performing SQL operations in TiDB

11.7.4.1 Pump or Drainer state

Pump or Drainer state description:

- **online**: running normally
- **pausing**: in the pausing process
- **paused**: has been stopped
- **closing**: in the offline process
- **offline**: has been offline

Note:

The state information of a Pump or Drainer node is maintained by the service itself and is regularly updated to the Placement Driver (PD).

11.7.4.2 Starting and exiting a Pump or Drainer process

11.7.4.2.1 Pump

- **Starting**: When started, the Pump node notifies all Drainer nodes in the **online** state. If the notification is successful, the Pump node sets its state to **online**. Otherwise, the Pump node reports an error, sets its state to **paused** and exits the process.
- **Exiting**: The Pump node enters the **paused** or **offline** state before the process is exited normally; if the process is exited abnormally (caused by the `kill -9` command, process panic, crash), the node is still in the **online** state.

- **Pause:** You can pause a Pump process by using the `kill` command (not `kill -9 ↩`), pressing `Ctrl+C` or using the `pause-pump` command in the `binlogctl` tool. After receiving the pause instruction, the Pump node sets its state to `pausing`, stops receiving binlog write requests and stops providing binlog data to Drainer nodes. After all threads are safely exited, the Pump node updates its state to `paused` and exits the process.
- **Offline:** You can close a Pump process only by using the `offline-pump` command in the `binlogctl` tool. After receiving the offline instruction, the Pump node sets its state to `closing` and stops receiving the binlog write requests. The Pump node continues providing binlog to Drainer nodes until all binlog data is consumed by Drainer nodes. Then, the Pump node sets its state to `offline` and exits the process.

11.7.4.2.2 Drainer

- **Starting:** When started, the Drainer node sets its state to `online` and tries to pull binlogs from all Pump nodes which are not in the `offline` state. If it fails to get the binlogs, it keeps trying.
- **Exiting:** The Drainer node enters the `paused` or `offline` state before the process is exited normally; if the process is exited abnormally (caused by `kill -9`, process panic, crash), the Drainer node is still in the `online` state.
 - **Pause:** You can pause a Drainer process by using the `kill` command (not `kill ↩ -9`), pressing `Ctrl+C` or using the `pause-drainer` command in the `binlogctl` tool. After receiving the pause instruction, the Drainer node sets its state to `pausing` and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node sets its state to `paused` and exits the process.
 - **Offline:** You can close a Drainer process only by using the `offline-drainer` command in the `binlogctl` tool. After receiving the offline instruction, the Drainer node sets its state to `closing` and stops pulling binlogs from Pump nodes. After all threads are safely exited, the Drainer node updates its state to `offline` and exits the process.

For how to pause, close, check, and modify the state of Drainer, see the [binlogctl guide](#).

11.7.4.3 Use `binlogctl` to manage Pump/Drainer

`binlogctl` is an operations tool for TiDB Binlog with the following features:

- Checking the state of Pump or Drainer
- Pausing or closing Pump or Drainer
- Handling the abnormal state of Pump or Drainer

For detailed usage of `binlogctl`, refer to [binlogctl overview](#).

11.7.4.4 Use SQL statements to manage Pump or Drainer

To view or modify binlog related states, execute corresponding SQL statements in TiDB.

- Check whether binlog is enabled:

```
show variables like "log_bin";
```

```
+-----+-----+
| Variable_name | Value |
+-----+-----+
| log_bin      | 0    |
+-----+-----+
```

When the Value is 0, binlog is enabled. When the Value is 1, binlog is disabled.

- Check the status of all the Pump or Drainer nodes:

```
show pump status;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| NodeID | Address | State | Max_Commit_Ts | Update_Time |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| pump1 | 127.0.0.1:8250 | Online | 408553768673342237 | 2019-05-01
↪ 00:00:01 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| pump2 | 127.0.0.2:8250 | Online | 408553768673342335 | 2019-05-01
↪ 00:00:02 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
```

```
show drainer status;
```

```
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| NodeID | Address | State | Max_Commit_Ts | Update_Time |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| drainer1 | 127.0.0.3:8249 | Online | 408553768673342532 | 2019-05-01
↪ 00:00:03 |
+-----+-----+-----+-----+-----+-----+-----+-----+-----+
↪
| drainer2 | 127.0.0.4:8249 | Online | 408553768673345531 | 2019-05-01
↪ 00:00:04 |
```

- Modify the state of a Pump or Drainer node in abnormal situations

```
change pump to node_state = 'paused' for node_id 'pump1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

```
change drainer to node_state = 'paused' for node_id 'drainer1';
```

```
Query OK, 0 rows affected (0.01 sec)
```

Executing the above SQL statements works the same as the `update-pump` or `update ↔ -drainer` commands in `binlogctl`. Use the above SQL statements **only** when the Pump or Drainer node is in abnormal situations.

Note:

- Checking whether binlog is enabled and the running status of Pump or Drainer is supported in TiDB v2.1.7 and later versions.
- Modifying the status of Pump or Drainer is supported in TiDB v3.0.0-rc.1 and later versions. This feature only supports modifying the status of Pump or Drainer nodes stored in PD. To pause or close the node, use the `binlogctl` tool.

11.7.5 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

11.7.5.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see [Pump Configuration](#).

11.7.5.1.1 addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

11.7.5.1.2 advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

11.7.5.1.3 socket

- The Unix socket address that HTTP API listens to.
- Default value: `“”`

11.7.5.1.4 pd-urls

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

11.7.5.1.5 data-dir

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

11.7.5.1.6 heartbeat-interval

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: `2`

11.7.5.1.7 gen-binlog-interval

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: `3`

11.7.5.1.8 gc

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: `7`

11.7.5.1.9 log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

11.7.5.1.10 log-level

- Specifies the log level.
- Default value: `info`

11.7.5.1.11 node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

11.7.5.1.12 security

This section introduces configuration items related to security.

`ssl-ca`

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

`ssl-cert`

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: “”

`ssl-key`

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

11.7.5.1.13 storage

This section introduces configuration items related to storage.

sync-log

- Specifies whether to use `fsync` after each **batch** write to binlog to ensure data safety.
- Default value: `true`

kv_chan_cap

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: 1048576 (that is, 2 to the power of 20)

slow_write_threshold

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and "take a long time to `write binlog`" is output in the log.
↔ `write binlog`
- Default value: 1

stop-write-at-available-space

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as 900 MB, 5 GB, and 12 GiB to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: 10 GiB

kv

Currently the storage of Pump is implemented based on [GoLevelDB](#). Under `storage` there is also a `kv` subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- `block-cache-capacity`
- `block-restart-interval`
- `block-size`
- `compaction-L0-trigger`
- `compaction-table-size`
- `compaction-total-size`
- `compaction-total-size-multiplier`
- `write-buffer`
- `write-L0-pause-trigger`
- `write-L0-slowdown-trigger`

For the detailed description of the above items, see [GoLevelDB Document](#).

11.7.5.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see [Drainer Configuration](#)

11.7.5.2.1 `addr`

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8249`

11.7.5.2.2 `advertise-addr`

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

11.7.5.2.3 `log-file`

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

11.7.5.2.4 `log-level`

- Specifies the log level.
- Default value: `info`

11.7.5.2.5 `node-id`

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

11.7.5.2.6 `data-dir`

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

11.7.5.2.7 `detect-interval`

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: `5`

11.7.5.2.8 pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

11.7.5.2.9 initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- `commit ts` (commit timestamp) is a specific point in time for **transaction** commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
 - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (backupmeta).
 - If Dumpling is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumpling (metadata),
 - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

11.7.5.2.10 synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: `5`

11.7.5.2.11 compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: `“”`, which means no compression.

11.7.5.2.12 security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

ssl-cert

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainert.pem`.
- Default value: “”

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: “”

11.7.5.2.13 syncer

The `syncer` section includes configuration items related to the downstream.

db-type

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

sql-mode

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: “”

ignore-txn-commit-ts

- Specifies the commit timestamp at which the binlog is ignored, such as [416815754209656834, ↔ 421349811963822081].
- Default value: []

ignore-schemas

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql

ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the `toml` file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: []

replicate-do-db

- Specifies the database to be replicated. For example, [db1, db2].
- Default value: []

replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"
```

Default value: []

txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: 20

`worker-count`

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: 16

`disable-dispatch`

- Disables the concurrency and forcibly set `worker-count` to 1.
- Default value: `false`

`safe-mode`

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete plus Replace Into`

Default value: `false`

11.7.5.2.14 `syncer.to`

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

`mysql/tidb`

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is 3306 by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.
- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is "" by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is 1m. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

file

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

kafka

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addr`s
- `kafka-addr`s
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

11.7.5.2.15 `syncer.to.checkpoint`

- `type`: Specifies in what way the replication progress is saved. Currently, the available options are `mysql`, `tidb`, and `file`.

This configuration item is the same as the downstream type by default. For example, when the downstream is `file`, the checkpoint progress is saved in the local file `<data-dir>/savepoint`; when the downstream is `mysql`, the progress is saved in the downstream database. If you need to explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:

- `schema`: "`tidb_binlog`" by default.

Note:

When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

- `host`
- `user`
- `password`
- `port`

11.7.5.3 TiDB Binlog Configuration File

This document introduces the configuration items of TiDB Binlog.

11.7.5.3.1 Pump

This section introduces the configuration items of Pump. For the example of a complete Pump configuration file, see [Pump Configuration](#).

addr

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8250`

advertise-addr

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8250`

socket

- The Unix socket address that HTTP API listens to.
- Default value: `“”`

pd-urls

- Specifies the comma-separated list of PD URLs. If multiple addresses are specified, when the PD client fails to connect to one address, it automatically tries to connect to another address.
- Default value: `http://127.0.0.1:2379`

data-dir

- Specifies the directory where binlogs and their indexes are stored locally.
- Default value: `data.pump`

heartbeat-interval

- Specifies the heartbeat interval (in seconds) at which the latest status is reported to PD.
- Default value: `2`

gen-binlog-interval

- Specifies the interval (in seconds) at which data is written into fake binlog.
- Default value: `3`

gc

- Specifies the number of days (integer) that binlogs can be stored locally. Binlogs stored longer than the specified number of days are automatically deleted.
- Default value: 7

log-file

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: “”

log-level

- Specifies the log level.
- Default value: `info`

node-id

- Specifies the Pump node ID. With this ID, this Pump process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8250`.

security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: “”

ssl-cert

- Specifies the path of the X509 certificate file encoded in the Privacy Enhanced Mail (PEM) format. For example, `/path/to/pump.pem`.
- Default value: “”

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.

- Default value: “”

storage

This section introduces configuration items related to storage.

sync-log

- Specifies whether to use **fsync** after each **batch** write to binlog to ensure data safety.
- Default value: **true**

kv_chan_cap

- Specifies the number of write requests that the buffer can store before Pump receives these requests.
- Default value: 1048576 (that is, 2 to the power of 20)

slow_write_threshold

- The threshold (in seconds). If it takes longer to write a single binlog file than this specified threshold, the write is considered slow write and "take a long time to ↪ write binlog" is output in the log.
- Default value: 1

stop-write-at-available-space

- Binlog write requests is no longer accepted when the available storage space is below this specified value. You can use the format such as 900 MB, 5 GB, and 12 GiB to specify the storage space. If there is more than one Pump node in the cluster, when a Pump node refuses a write request because of the insufficient space, TiDB will automatically write binlogs to other Pump nodes.
- Default value: 10 GiB

kv

Currently the storage of Pump is implemented based on [GoLevelDB](#). Under **storage** there is also a **kv** subgroup that is used to adjust the GoLevel configuration. The supported configuration items are shown as below:

- block-cache-capacity
- block-restart-interval
- block-size
- compaction-L0-trigger
- compaction-table-size

- `compaction-total-size`
- `compaction-total-size-multiplier`
- `write-buffer`
- `write-L0-pause-trigger`
- `write-L0-slowdown-trigger`

For the detailed description of the above items, see [GoLevelDB Document](#).

11.7.5.3.2 Drainer

This section introduces the configuration items of Drainer. For the example of a complete Drainer configuration file, see [Drainer Configuration](#)

`addr`

- Specifies the listening address of HTTP API in the format of `host:port`.
- Default value: `127.0.0.1:8249`

`advertise-addr`

- Specifies the externally accessible HTTP API address. This address is registered in PD in the format of `host:port`.
- Default value: `127.0.0.1:8249`

`log-file`

- Specifies the path where log files are stored. If the parameter is set to an empty value, log files are not stored.
- Default value: `“”`

`log-level`

- Specifies the log level.
- Default value: `info`

`node-id`

- Specifies the Drainer node ID. With this ID, this Drainer process can be identified in the cluster.
- Default value: `hostname:port number`. For example, `node-1:8249`.

`data-dir`

- Specifies the directory used to store files that need to be saved during Drainer operation.
- Default value: `data.drainer`

detect-interval

- Specifies the interval (in seconds) at which PD updates the Pump information.
- Default value: 5

pd-urls

- The comma-separated list of PD URLs. If multiple addresses are specified, the PD client will automatically attempt to connect to another address if an error occurs when connecting to one address.
- Default value: `http://127.0.0.1:2379`

initial-commit-ts

- Specifies from which commit timestamp of the transaction the replication process starts. This configuration is applicable only to the Drainer node that is in the replication process for the first time. If a checkpoint already exists in the downstream, the replication will be performed according to the time recorded in the checkpoint.
- `commit ts` (commit timestamp) is a specific point in time for **transaction** commits in TiDB. It is a globally unique and increasing timestamp from PD as the unique ID of the current transaction. You can get the `initial-commit-ts` configuration in the following typical ways:
 - If BR is used, you can get `initial-commit-ts` from the backup TS recorded in the metadata backed up by BR (`backupmeta`).
 - If Dumpling is used, you can get `initial-commit-ts` from the Pos recorded in the metadata backed up by Dumpling (`metadata`),
 - If PD Control is used, `initial-commit-ts` is in the output of the `tso` command.
- Default value: `-1`. Drainer will get a new timestamp from PD as the starting time, which means that the replication process starts from the current time.

synced-check-time

- You can access the `/status` path through the HTTP API to query the status of Drainer replication. `synced-check-time` specifies how many minutes from the last successful replication is considered as `synced`, that is, the replication is complete.
- Default value: 5

compressor

- Specifies the compression algorithm used for data transfer between Pump and Drainer. Currently only the `gzip` algorithm is supported.
- Default value: `""`, which means no compression.

security

This section introduces configuration items related to security.

ssl-ca

- Specifies the file path of the trusted SSL certificate list or CA list. For example, `/path/to/ca.pem`.
- Default value: `""`

ssl-cert

- Specifies the path of the X509 certificate file encoded in the PEM format. For example, `/path/to/drainert.pem`.
- Default value: `""`

ssl-key

- Specifies the path of the X509 key file encoded in the PEM format. For example, `/path/to/pump-key.pem`.
- Default value: `""`

syncer

The `syncer` section includes configuration items related to the downstream.

db-type

Currently, the following downstream types are supported:

- `mysql`
- `tidb`
- `kafka`
- `file`

Default value: `mysql`

sql-mode

- Specifies the SQL mode when the downstream is the `mysql` or `tidb` type. If there is more than one mode, use commas to separate them.
- Default value: `""`

ignore-txn-commit-ts

- Specifies the commit timestamp at which the binlog is ignored, such as [416815754209656834, ↪ 421349811963822081].
- Default value: []

ignore-schemas

- Specifies the database to be ignored during replication. If there is more than one database to be ignored, use commas to separate them. If all changes in a binlog file are filtered, the whole binlog file is ignored.
- Default value: INFORMATION_SCHEMA,PERFORMANCE_SCHEMA,mysql

ignore-table

Ignores the specified table changes during replication. You can specify multiple tables to be ignored in the toml file. For example:

```
[[syncer.ignore-table]]
db-name = "test"
tbl-name = "log"

[[syncer.ignore-table]]
db-name = "test"
tbl-name = "audit"
```

If all changes in a binlog file are filtered, the whole binlog file is ignored.

Default value: []

replicate-do-db

- Specifies the database to be replicated. For example, [db1, db2].
- Default value: []

replicate-do-table

Specifies the table to be replicated. For example:

```
[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "log"

[[syncer.replicate-do-table]]
db-name = "test"
tbl-name = "~^a.*"
```

Default value: []

txn-batch

- When the downstream is the `mysql` or `tidb` type, DML operations are executed in different batches. This parameter specifies how many DML operations can be included in each transaction.
- Default value: 20

worker-count

- When the downstream is the `mysql` or `tidb` type, DML operations are executed concurrently. This parameter specifies the concurrency numbers of DML operations.
- Default value: 16

disable-dispatch

- Disables the concurrency and forcibly set `worker-count` to 1.
- Default value: `false`

safe-mode

If the safe mode is enabled, Drainer modifies the replication updates in the following way:

- `Insert` is modified to `Replace Into`
- `Update` is modified to `Delete plus Replace Into`

Default value: `false`

syncer.to

The `syncer.to` section introduces different types of downstream configuration items according to configuration types.

mysql/tidb

The following configuration items are related to connection to downstream databases:

- `host`: If this item is not set, TiDB Binlog tries to check the `MYSQL_HOST` environment variable which is `localhost` by default.
- `port`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PORT` environment variable which is 3306 by default.
- `user`: If this item is not set, TiDB Binlog tries to check the `MYSQL_USER` environment variable which is `root` by default.

- `password`: If this item is not set, TiDB Binlog tries to check the `MYSQL_PSWD` environment variable which is "" by default.
- `read-timeout`: Specifies the I/O read timeout of the downstream database connection. The default value is 1m. If Drainer keeps failing on some DDLs that take a long time, you can set this configuration to a larger value.

file

- `dir`: Specifies the directory where binlog files are stored. If this item is not set, `data-dir` is used.

kafka

When the downstream is Kafka, the valid configuration items are as follows:

- `zookeeper-addr`s
- `kafka-addr`s
- `kafka-version`
- `kafka-max-messages`
- `kafka-max-message-size`
- `topic-name`

syncer.to.checkpoint

- `type`: Specifies in what way the replication progress is saved. Currently, the available options are `mysql`, `tidb`, and `file`.

This configuration item is the same as the downstream type by default. For example, when the downstream is `file`, the checkpoint progress is saved in the local file `<data-dir>/savepoint`; when the downstream is `mysql`, the progress is saved in the downstream database. If you need to explicitly specify using `mysql` or `tidb` to store the progress, make the following configuration:

- `schema`: "tidb_binlog" by default.

Note:

When deploying multiple Drainer nodes in the same TiDB cluster, you need to specify a different checkpoint schema for each node. Otherwise, the replication progress of two instances will overwrite each other.

- `host`
- `user`
- `password`
- `port`

11.7.6 Upgrade TiDB Binlog

This document introduces how to upgrade TiDB Binlog that is deployed manually to the latest `cluster` version. There is also a section on how to upgrade TiDB Binlog from an earlier incompatible version (Kafka/Local version) to the latest version.

11.7.6.1 Upgrade TiDB Binlog deployed manually

Follow the steps in this section if you deploy TiDB Binlog manually.

11.7.6.1.1 Upgrade Pump

First, upgrade each Pump instance in the cluster one by one. This ensures that there are always Pump instances in the cluster that can receive binlogs from TiDB. The steps are as below:

1. Replace the original file with the new version of `pump`.
2. Restart the Pump process.

11.7.6.1.2 Upgrade Drainer

Second, upgrade the Drainer component:

1. Replace the original file with the new version of `drainer`.
2. Restart the Drainer process.

11.7.6.2 Upgrade TiDB Binlog from Kafka/Local version to the cluster version

The new TiDB versions (v2.0.8-binlog, v2.1.0-rc.5 or later) are not compatible with the Kafka version or Local version of TiDB Binlog. If TiDB is upgraded to one of the new versions, it is required to use the cluster version of TiDB Binlog. If the Kafka or local version of TiDB Binlog is used before upgrading, you need to upgrade your TiDB Binlog to the cluster version.

The corresponding relationship between TiDB Binlog versions and TiDB versions is shown in the following table:

TiDB Binlog version	TiDB version	Note
Local	TiDB 1.0 or earlier	
Kafka	TiDB 1.0 ~ TiDB 2.1 RC5	TiDB 1.0 supports both the local and Kafka versions of TiDB Binlog.
Cluster	TiDB v2.0.8-binlog, TiDB 2.1 RC5 or later	TiDB v2.0.8-binlog is a special 2.0 version supporting the cluster version of TiDB Binlog.

11.7.6.2.1 Upgrade process

Note:

If importing the full data is acceptable, you can abandon the old version and deploy TiDB Binlog following [TiDB Binlog Cluster Deployment](#).

If you want to resume replication from the original checkpoint, perform the following steps to upgrade TiDB Binlog:

1. Deploy the new version of Pump.
2. Stop the TiDB cluster service.
3. Upgrade TiDB and the configuration, and write the binlog data to the new Pump cluster.
4. Reconnect the TiDB cluster to the service.
5. Make sure that the old version of Drainer has replicated the data in the old version of Pump to the downstream completely;

Query the `status` interface of Drainer, command as below:

```
curl 'http://172.16.10.49:8249/status'
```

```
{"PumpPos":{"172.16.10.49:8250":{"offset":32686}},"Synced": true ,"  
  ↳ DepositWindow":{"Upper":398907800202772481,"Lower  
  ↳ ":398907799455662081}}
```

If the return value of `Synced` is `True`, it means Drainer has replicated the data in the old version of Pump to the downstream completely.

6. Start the new version of Drainer.
7. Close the Pump and Drainer of the old versions and the dependent Kafka and ZooKeeper.

11.7.7 TiDB Binlog Monitoring

After you have deployed TiDB Binlog successfully, you can go to the Grafana Web (default address: http://grafana_ip:3000, default account: admin, password: admin) to check the state of Pump and Drainer.

11.7.7.1 Monitoring metrics

TiDB Binlog consists of two components: Pump and Drainer. This section shows the monitoring metrics of Pump and Drainer.

11.7.7.1.1 Pump monitoring metrics

To understand the Pump monitoring metrics, check the following table:

Pump monitoring metrics	Description
StorageSize	Records the total disk space (capacity) and the available disk space (available)

Pump
mon-
itor-
ing
met-
rics

	Description
--	-------------

Metadata	Records the biggest TSO (<code>gc_tso</code> <code>↔</code>) of the bin- log that each Pump node can delete, and the biggest com- mit TSO (<code>max_commit_tso</code> <code>↔</code>) of the saved bin- log
----------	--

	Description
Pump mon- itor- ing met- rics	
Write Bin- log QPS by In- stance	Shows QPS of writ- ing bin- log re- quests re- ceived by each Pump node
Write Bin- log La- tency	Records the la- tency time of each Pump node writ- ing bin- log

Pump
mon-
itor-
ing
met-
rics Description

Storage Shows
Write the
Bin- size
log of
Size the
bin-
log
data
writ-
ten
by
Pump

Storage Records
Write the
Bin- la-
log tency

tency of
the
Pump
stor-
age
mod-
ule
writ-
ing
bin-
log

	Description
Pump monitoring metrics	
Pump Records	
Storage Error By Type	the number of errors encountered by Pump, counted based on the type of error
Query TiKV	The number of times that Pump queries the transaction status through TiKV

11.7.7.1.2 Drainer monitoring metrics

To understand the Drainer monitoring metrics, check the following table:

Drainer
mon-
itor-
ing
met-
rics

Description

Drainer
mon-
itor-
ing
met-
rics

Description

Shows
Checkpoints

TSO the
biggest
TSO
time
of
the
bin-
log
that
Drainer
has
al-
ready
repli-
cated
into
the
down-
stream.
You

get
the
lag
by
us-
ing
the
cur-
rent
time
to

1287
sub-
tract
the
bin-

	Description
Drainer mon- itor- ing met- rics	
Pump Records	
Handle TSO	the biggest TSO time among the bin-log files that Drainer obtains from each Pump node
Pull Bin-log QPS by Pump NodeID	Shows the QPS when Drainer obtains bin-log from each Pump node

Drainer mon- itor- ing met- rics	Description
95%	Records
Bin- log Reach Du- ra- tion By Pump	the de- lay from the time when bin- log is writ- ten into Pump to the time when the bin- log is ob- tained by Drainer

Drainer mon- itor- ing met- rics	Description
Error By Type	Shows the num- ber of er- rors en- coun- tered by Drainer, counted based on the type of er- ror
SQL Query Time	Records the time it takes Drainer to exe- cute the SQL state- ment in the down- stream

Drainer
mon-
itor-
ing
met-
rics Description

DrainEvents

Event the
num-
ber
of
vari-
ous
types
of
events,
in-
clud-
ing
“ddl”,
“in-
sert”,
“delete”,
“up-
date”,
“flush”,
and
“save-
point”

	Description
Drainer mon- itor- ing met- rics	
Execute Time	Records the time it takes to write bin- log into the down- stream sync- ing mod- ule
95% Bin- log Size	Shows the size of the bin- log data that Drainer ob- tains from each Pump node

	Description
Drainer mon- itor- ing met- rics	
DDL Job Count	Records the num- ber of DDL state- ments han- dled by Drainer
Queue Size	Records the work queue size in Drainer

11.7.7.2 Alert rules

This section gives the alert rules for TiDB Binlog. According to the severity level, TiDB Binlog alert rules are divided into three categories (from high to low): emergency-level, critical-level and warning-level.

11.7.7.2.1 Emergency-level alerts

Emergency-level alerts are often caused by a service or node failure. Manual intervention is required immediately.

`binlog_pump_storage_error_count`

- Alert rule:
`changes(binlog_pump_storage_error_count[1m])> 0`
- Description:
Pump fails to write the binlog data to the local storage.

- Solution:
Check whether an error exists in the `pump_storage_error` monitoring and check the Pump log to find the causes.

11.7.7.2.2 Critical-level alerts

For the critical-level alerts, a close watch on the abnormal metrics is required.

`binlog_drainer_checkpoint_high_delay`

- Alert rule:

```
(time()- binlog_drainer_checkpoint_tso / 1000)> 3600
```
- Description:
The delay of Drainer replication exceeds one hour.
- Solution:
 - Check whether it is too slow to obtain the data from Pump:
You can check `handle tso` of Pump to get the time for the latest message of each Pump. Check whether a high latency exists for Pump and make sure the corresponding Pump is running normally.
 - Check whether it is too slow to replicate data in the downstream based on Drainer `event` and Drainer `execute latency`:
 - * If Drainer `execute time` is too large, check the network bandwidth and latency between the machine with Drainer deployed and the machine with the target database deployed, and the state of the target database.
 - * If Drainer `execute time` is not too large and Drainer `event` is too small, add `work count` and `batch` and `retry`.
 - If the two solutions above cannot work, contact support@pingcap.com.

11.7.7.2.3 Warning-level alerts

Warning-level alerts are a reminder for an issue or error.

`binlog_pump_write_binlog_rpc_duration_seconds_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(binlog_pump_rpc_duration_seconds_bucket{  
↔ method="WriteBinlog"}[5m]))> 1
```
- Description:
It takes too much time for Pump to handle the TiDB request of writing binlog.
- Solution:

- Verify the disk performance pressure and check the disk performance monitoring via `node_exported`.
- If both disk latency and util are low, contact support@pingcap.com.

`binlog_pump_storage_write_binlog_duration_time_bucket`

- Alert rule:

```
histogram_quantile(0.9, rate(binlog_pump_storage_write_binlog_duration_time_bucket  
↪ {type="batch"}[5m])) > 1
```

- Description:

The time it takes for Pump to write the local binlog to the local disk.

- Solution:

Check the state of the local disk of Pump and fix the problem.

`binlog_pump_storage_available_size_less_than_20G`

- Alert rule:

```
binlog_pump_storage_size_bytes{type="available"} < 20 * 1024 *  
↪ 1024 * 1024
```

- Description:

The available disk space of Pump is less than 20 GB.

- Solution:

Check whether Pump `gc_tso` is normal. If not, adjust the GC time configuration of Pump or get the corresponding Pump offline.

`binlog_drainer_checkpoint_tso_no_change_for_1m`

- Alert rule:

```
changes(binlog_drainer_checkpoint_tso[1m]) < 1
```

- Description:

Drainer `checkpoint` has not been updated for one minute.

- Solution:

Check whether all the Pumps that are not offline are running normally.

`binlog_drainer_execute_duration_time_more_than_10s`

- Alert rule:
`histogram_quantile(0.9, rate(binlog_drainer_execute_duration_time_bucket ↪ [1m])) > 10`
- Description:
 The transaction time it takes Drainer to replicate data to TiDB. If it is too large, the Drainer replication of data is affected.
- Solution:
 - Check the TiDB cluster state.
 - Check the Drainer log or monitor. If a DDL operation causes this problem, you can ignore it.

11.7.8 Reparo User Guide

Reparo is a TiDB Binlog tool, used to recover the incremental data. To back up the incremental data, you can use Drainer of TiDB Binlog to output the binlog data in the protobuf format to files. To restore the incremental data, you can use Reparo to parse the binlog data in the files and apply the binlog in TiDB/MySQL.

Download Reparo via [tidb-binlog-cluster-latest-linux-amd64.tar.gz](https://github.com/pingcap/tidb-binlog-cluster-latest-linux-amd64.tar.gz)

11.7.8.1 Reparo usage

11.7.8.1.1 Description of command line parameters

Usage of Reparo:

`-L string`
 The level of the output information of logs
 Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)

`-V` Prints the version.

`-c int`
 The number of concurrencies in the downstream for the replication
 ↪ process (`16` by default). A higher value indicates a better
 ↪ throughput for the replication.

`-config string`
 The path of the configuration file
 If the configuration file is specified, Reparo reads the configuration
 ↪ data in this file.
 If the configuration data also exists in the command line parameters,
 ↪ Reparo uses the configuration data in the command line parameters
 ↪ to cover that in the configuration file.

`-data-dir string`

```
The storage directory for the binlog file in the protobuf format that
  ↳ Drainer outputs ("data.drainer" by default)
-dest-type string
  The downstream service type
  Value: "print"/"mysql" ("print" by default)
  If it is set to "print", the data is parsed and printed to standard
  ↳ output while the SQL statement is not executed.
  If it is set to "mysql", you need to configure the "host", "port", "user
  ↳ " and "password" information in the configuration file.
-log-file string
  The path of the log file
-log-rotate string
  The switch frequency of log files
  Value: "hour"/"day"
-start-datetime string
  Specifies the time point for starting recovery.
  Format: "2006-01-02 15:04:05"
  If it is not set, the recovery process starts from the earliest binlog
  ↳ file.
-stop-datetime string
  Specifies the time point of finishing the recovery process.
  Format: "2006-01-02 15:04:05"
  If it is not set, the recovery process ends up with the last binlog file
  ↳ .
-safe-mode bool
  Specifies whether to enable safe mode. When enabled, it supports
  ↳ repeated replication.
-txn-batch int
  The number of SQL statements in a transaction that is output to the
  ↳ downstream database (`20` by default).
```

11.7.8.1.2 Description of the configuration file

```
### The storage directory for the binlog file in the protobuf format that
  ↳ Drainer outputs
data-dir = "./data.drainer"

### The level of the output information of logs
### Value: "debug"/"info"/"warn"/"error"/"fatal" ("info" by default)
log-level = "info"

### Uses `start-datetime` and `stop-datetime` to specify the time range in
  ↳ which
### the binlog files are to be recovered.
```

```
### Format: "2006-01-02 15:04:05"
### start-datetime = ""
### stop-datetime = ""

### Correspond to `start-datetime` and `stop-datetime` respectively.
### They are used to specify the time range in which the binlog files are to
    ↪ be recovered.
### If `start-datetime` and `stop-datetime` are set, there is no need to set
    ↪ `start-tso` and `stop-tso`.
### When you perform a full recovery or resume an incremental recovery, set
    ↪ start-tso to tso + 1 or stop-tso + 1, respectively.
### start-tso = 0
### stop-tso = 0

### The downstream service type
### Value: "print"/"mysql" ("print" by default)
### If it is set to "print", the data is parsed and printed to standard
    ↪ output
### while the SQL statement is not executed.
### If it is set to "mysql", you need to configure `host`, `port`, `user`
    ↪ and `password` in [dest-db].
dest-type = "mysql"

### The number of SQL statements in a transaction that is output to the
    ↪ downstream database (`20` by default).
txn-batch = 20

### The number of concurrencies in the downstream for the replication
    ↪ process (`16` by default). A higher value indicates a better
    ↪ throughput for the replication.
worker-count = 16

### Safe-mode configuration
### Value: "true"/"false" ("false" by default)
### If it is set to "true", Reparo splits the `UPDATE` statement into a `
    ↪ DELETE` statement plus a `REPLACE` statement.
safe-mode = false

### `replicate-do-db` and `replicate-do-table` specify the database and
    ↪ table to be recovered.
### `replicate-do-db` has priority over `replicate-do-table`.
### You can use a regular expression for configuration. The regular
    ↪ expression should start with "~".
### The configuration method for `replicate-do-db` and `replicate-do-table`
    ↪ is
```

```
### the same with that for `replicate-do-db` and `replicate-do-table` of
↳ Drainer.
### replicate-do-db = ["~^b.*","s1"]
### [[replicate-do-table]]
### db-name = "test"
### tbl-name = "log"
### [[replicate-do-table]]
### db-name = "test"
### tbl-name = "~^a.*"

### If `dest-type` is set to `mysql`, `dest-db` needs to be configured.
[dest-db]
host = "127.0.0.1"
port = 3309
user = "root"
password = ""
```

11.7.8.1.3 Start example

```
./bin/reparo -config reparo.toml
```

Note:

- `data-dir` specifies the directory for the binlog file that Drainer outputs.
- Both `start-datetime` and `start-tso` are used to specify the time point for starting recovery, but they are different in the time format. If they are not set, the recovery process starts from the earliest binlog file by default.
- Both `stop-datetime` and `stop-tso` are used to specify the time point for finishing recovery, but they are different in the time format. If they are not set, the recovery process ends up with the last binlog file by default.
- `dest-type` specifies the destination type. Its value can be “mysql” and “print.”
 - When it is set to `mysql`, the data can be recovered to MySQL or TiDB that uses or is compatible with the MySQL protocol. In this case, you need to specify the database information in `[dest-db]` of the configuration information.
 - When it is set to `print`, only the binlog information is printed. It is generally used for debugging and checking the binlog information. In this case, there is no need to specify `[dest-db]`.

- `replicate-do-db` specifies the database for recovery. If it is not set, all the databases are to be recovered.
- `replicate-do-table` specifies the table for recovery. If it is not set, all the tables are to be recovered.

11.7.9 binlogctl

Binlog Control (`binlogctl` for short) is a command line tool for TiDB Binlog. You can use `binlogctl` to manage TiDB Binlog clusters.

You can use `binlogctl` to:

- Check the state of Pump or Drainer
- Pause or close Pump or Drainer
- Handle the abnormal state of Pump or Drainer

The following are its usage scenarios:

- An error occurs during data replication or you need to check the running state of Pump or Drainer.
- You need to pause or close Pump or Drainer when maintaining the cluster.
- A Pump or Drainer process exits abnormally, while the node state is not updated or is unexpected. This affects the data replication task.

11.7.9.1 Download binlogctl

Note:

It is recommended that the version of the Control tool you use is consistent with the version of the cluster.

```
wget https://download.pingcap.org/tidb-{version}-linux-amd64.tar.gz &&  
wget https://download.pingcap.org/tidb-{version}-linux-amd64.sha256
```

To check the file integrity, execute the following command. If the result is OK, the file is correct.

```
sha256sum -c tidb-{version}-linux-amd64.sha256
```

To check the file integrity, execute the following command. If the result is OK, the file is correct.

```
sha256sum -c tidb-enterprise-tools-latest-linux-amd64.sha256
```

11.7.9.2 Descriptions

Command line parameters:

Usage of binlogctl:

```
-V prints version and exit
-cmd string
  operator: "generate_meta", "pumps", "drainers", "update-pump", "
  ↪ update-drainer", "pause-pump", "pause-drainer", "offline-pump
  ↪ ", "offline-drainer", "encrypt" (default "pumps")
-data-dir string
  meta directory path (default "binlog_position")
-node-id string
  id of node, used to update some nodes with operations update-pump,
  ↪ update-drainer, pause-pump, pause-drainer, offline-pump and
  ↪ offline-drainer
-pd-urls string
  a comma separated list of PD endpoints (default "http
  ↪ ://127.0.0.1:2379")
-show-offline-nodes
  include offline nodes when querying pumps/drainers
-ssl-ca string
  Path of file that contains list of trusted SSL CAs for connection
  ↪ with cluster components.
-ssl-cert string
  Path of file that contains X509 certificate in PEM format for
  ↪ connection with cluster components.
-ssl-key string
  Path of file that contains X509 key in PEM format for connection with
  ↪ cluster components.
-state string
  set node's state, can be set to online, pausing, paused, closing or
  ↪ offline.
-text string
  text to be encrypted when using encrypt command
-time-zone Asia/Shanghai
  set time zone if you want to save time info in savepoint file; for
  ↪ example, Asia/Shanghai for CST time, `Local` for local time
```

Command examples:

- Check the state of all the Pump or Drainer nodes.

Set `cmd` to `pumps` or `drainers`. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd pumps
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node" [
  ↪ type=pump] [node="{NodeID: 1.1.1.1:8250, Addr: pump:8250, State:
  ↪ online, MaxCommitTS: 408012403141509121, UpdateTime: 2019-04-28
  ↪ 09:29:57 +0000 UTC}"]]
```

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd drainers
```

```
[2019/04/28 09:29:59.016 +00:00] [INFO] [nodes.go:48] ["query node" [
  ↪ type=drainer] [node="{NodeID: 1.1.1.1:8249, Addr: 1.1.1.1:8249,
  ↪ State: online, MaxCommitTS: 408012403141509121, UpdateTime:
  ↪ 2019-04-28 09:29:57 +0000 UTC}"]]
```

- Pause or close Pump or Drainer.

You can use the following commands to pause or close services:

Command	Description	Example
<code>pause-pump</code>	Pause Pump	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-pump -node-id ip-127-0-0-1:8250</code>
<code>pause-drainer</code>	Pause Drainer	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ pause-drainer -node-id ip-127-0-0-1:8249</code>
<code>offline-pump</code>	Close Pump	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-pump -node-id ip-127-0-0-1:8250</code>
<code>offline-drainer</code>	Close Drainer	<code>bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd ↪ offline-drainer -node-id ip-127-0-0-1:8249</code>

`binlogctl` sends the HTTP request to the Pump or Drainer node. After receiving the request, the node executes the exiting procedures accordingly.

- Modify the state of a Pump or Drainer node in abnormal states.

When a Pump or Drainer node runs normally or when it is paused or closed in the normal process, it is in the normal state. In abnormal states, the Pump or Drainer node cannot correctly maintain its state. This affects data replication tasks. In this case, use `binlogctl` to repair the state information.

To update the state of a Pump or Drainer node, set `cmd` to `update-pump` or `update-drainer`. The state can be `paused` or `offline`. For example:

```
bin/binlogctl -pd-urls=http://127.0.0.1:2379 -cmd update-pump -node-id
  ↪ ip-127-0-0-1:8250 -state paused
```

Note:

When a Pump or Drainer node runs normally, it regularly updates its state to PD. The above command directly modifies the Pump or Drainer state saved in PD; therefore, do not use the command when the Pump or Drainer node runs normally. For more information, refer to [TiDB Binlog FAQ](#).

11.7.10 Binlog Consumer Client User Guide

Binlog Consumer Client is used to consume TiDB secondary binlog data from Kafka and output the data in a specific format. Currently, Drainer supports multiple kinds of down streaming, including MySQL, TiDB, file and Kafka. But sometimes users have customized requirements for outputting data to other formats, for example, Elasticsearch and Hive, so this feature is introduced.

11.7.10.1 Configure Drainer

Modify the configuration file of Drainer and set it to output the data to Kafka:

```
[syncer]
db-type = "kafka"

[syncer.to]
### the Kafka address
kafka-addr = "127.0.0.1:9092"
### the Kafka version
kafka-version = "2.4.0"
```

11.7.10.2 Customized development

11.7.10.2.1 Data format

Firstly, you need to obtain the format information of the data which is output to Kafka by Drainer:

```
// `Column` stores the column data in the corresponding variable based on
↳ the data type.
message Column {
  // Indicates whether the data is null
  optional bool is_null = 1 [ default = false ];
  // Stores `int` data
  optional int64 int64_value = 2;
  // Stores `uint`, `enum`, and `set` data
```

```
optional uint64 uint64_value = 3;
// Stores `float` and `double` data

}
```

For the definition of the data format, see [secondary_binlog.proto](#)

11.7.10.2.2 Driver

The [TiDB-Tools](#) project provides [Driver](#), which is used to read the binlog data in Kafka. It has the following features:

- Read the Kafka data.
- Locate the binlog stored in Kafka based on `commit ts`.

You need to configure the following information when using Driver:

- `KafkaAddr`: the address of the Kafka cluster
- `CommitTS`: from which `commit ts` to start reading the binlog
- `Offset`: from which Kafka `offset` to start reading data. If `CommitTS` is set, you needn't configure this parameter.
- `ClusterID`: the cluster ID of the TiDB cluster
- `Topic`: the topic name of Kafka. If `Topic` is empty, use the default name in Drainer `<ClusterID>_obinlog`.

You can use Driver by quoting the Driver code in package and refer to the example code provided by Driver to learn how to use Driver and parse the binlog data.

Currently, two examples are provided:

- Using Driver to replicate data to MySQL. This example shows how to convert a binlog to SQL
- Using Driver to print data

Note:

- The example code only shows how to use Driver. If you want to use Driver in the production environment, you need to optimize the code.
- Currently, only the Golang version of Driver and example code are available. If you want to use other languages, you need to generate the code file in the corresponding language based on the binlog proto file and develop an application to read the binlog data in Kafka, parse the data, and output the data to the downstream. You are also welcome to optimize the example code and submit the example code of other languages to [TiDB-Tools](#).

11.7.11 TiDB Binlog Relay Log

When replicating binlogs, Drainer splits transactions from the upstream and replicates the split transactions concurrently to the downstream.

In extreme cases where the upstream clusters are not available and Drainer exits abnormally, the downstream clusters (MySQL or TiDB) might be in the intermediate states with inconsistent data. In such cases, Drainer can use the relay log to ensure that the downstream clusters are in a consistent state.

11.7.11.1 Consistent state during Drainer replication

The downstream clusters reaching a consistent state means the data of the downstream clusters are the same as the snapshot of the upstream which sets `tidb_snapshot = ts`.

The checkpoint consistency means Drainer checkpoint saves the consistent state of replication in `consistent`. When Drainer runs, `consistent` is `false`. After Drainer exits normally, `consistent` is set to `true`.

You can query the downstream checkpoint table as follows:

```
select * from tidb_binlog.checkpoint;
```

clusterID	checkPoint
6791641053252586769	{"consistent":false,"commitTS":414529105591271429,"ts-map":{}}

11.7.11.2 Implementation principles

After Drainer enables the relay log, it first writes the binlog events to the disks and then replicates the events to the downstream clusters.

If the upstream clusters are not available, Drainer can restore the downstream clusters to a consistent state by reading the relay log.

Note:

If the relay log data is lost at the same time, this method does not work, but its incidence is very low. In addition, you can use the Network File System to ensure data safety of the relay log.

11.7.11.2.1 Trigger scenarios where Drainer consumes binlogs from the relay log

When Drainer is started, if it fails to connect to the Placement Driver (PD) of the upstream clusters, and it detects that `consistent = false` in the checkpoint, Drainer will try to read the relay log, and restore the downstream clusters to a consistent state. After that, the Drainer process sets the checkpoint `consistent` to `true` and then exits.

11.7.11.2.2 GC mechanism of relay log

Before data is replicated to the downstream, Drainer writes data to the relay log file. If the size of a relay log file reaches 10 MB (by default) and the binlog data of the current transaction is completely written, Drainer starts to write data to the next relay log file. After Drainer successfully replicates data to the downstream, it automatically cleans up the relay log files whose data has been replicated. The relay log into which data is currently being written will not be cleaned up.

11.7.11.3 Configuration

To enable the relay log, add the following configuration in Drainer:

```
[syncer.relay]
### It saves the directory of the relay log. The relay log is not enabled if
  ↳ the value is empty.
### The configuration only comes to effect if the downstream is TiDB or
  ↳ MySQL.
log-dir = "/dir/to/save/log"
### The size limit of a single relay log file (unit: byte).
### When the size of a relay log file reaches this limit, data is written to
  ↳ the next relay log file.
max-file-size = 10485760
```

11.7.12 Bidirectional Replication between TiDB Clusters

Warning:

Currently, bidirectional replication is still an experimental feature. It is **NOT** recommended to use it in the production environment.

This document describes the bidirectional replication between two TiDB clusters, how the replication works, how to enable it, and how to replicate DDL operations.

11.7.12.1 User scenario

If you want two TiDB clusters to exchange data changes with each other, TiDB Binlog allows you to do that. For example, you want cluster A and cluster B to replicate data with each other.

Note:

The data written to these two clusters must be conflict-free, that is, in the two clusters, the same primary key or the rows with the unique index of the tables must not be modified.

The user scenario is shown as below:

Figure 150: Architect

11.7.12.2 Implementation details

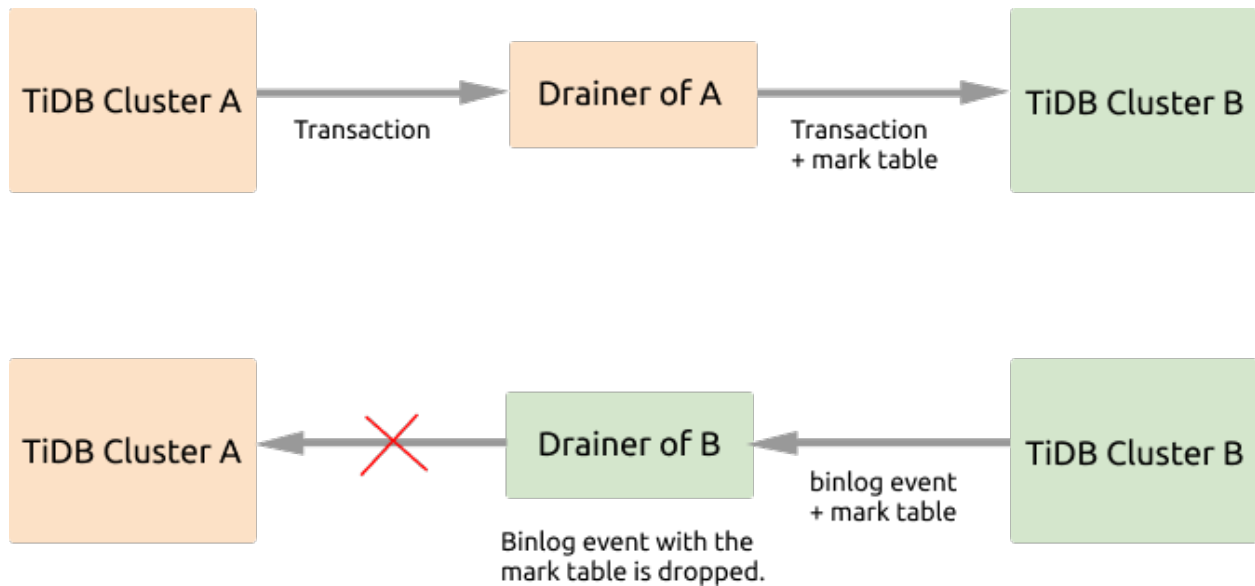

Figure 151: Mark Table

If the bidirectional replication is enabled between cluster A and cluster B, the data written to cluster A will be replicated to cluster B, and then these data changes will be replicated back to cluster A, which causes an infinite loop of replication. From the figure above, you can see that during the data replication, Drainer marks the binlog events, and filters out the marked events to avoid such a replication loop.

The detailed implementation is described as follows:

1. Start the TiDB Binlog replication program for each of the two clusters.
2. When the transaction to be replicated passes through the Drainer of cluster A, this Drainer adds the `_drainer_repl_mark` table to the transaction, writes this DML event update to the mark table, and replicate this transaction to cluster B.
3. Cluster B returns binlog events with the `_drainer_repl_mark` mark table to cluster A. The Drainer of cluster B identifies the mark table with the DML event when parsing the binlog event, and gives up replicating this binlog event to cluster A.

The replication process from cluster B to cluster A is the same as above. The two clusters can be upstream and downstream of each other.

Note:

- When updating the `_drainer_repl_mark` mark table, data changes are required to generate binlogs.

- DDL operations are not transactional, so you need to use the one-way replication method to replicate DDL operations. See [Replicate DDL operations](#) for details.

Drainer can use a unique ID for each connection to downstream to avoid conflicts. `channel_id` is used to indicate a channel for bidirectional replication. The two clusters should have the same `channel_id` configuration (with the same value).

If you add or delete columns in the upstream, there might be extra or missing columns of the data to be replicated to the downstream. Drainer allows this situation by ignoring the extra columns or by inserting default values to the missing columns.

11.7.12.3 Mark table

The `_drainer_repl_mark` mark table has the following structure:

```
CREATE TABLE `_drainer_repl_mark` (  
  `id` bigint(20) NOT NULL,  
  `channel_id` bigint(20) NOT NULL DEFAULT '0',  
  `val` bigint(20) DEFAULT '0',  
  `channel_info` varchar(64) DEFAULT NULL,  
  PRIMARY KEY (`id`,`channel_id`)  
);
```

Drainer uses the following SQL statement to update `_drainer_repl_mark`, which ensures data change and the generation of binlog:

```
update drainer_repl_mark set val = val + 1 where id = ? && channel_id = ?;
```

11.7.12.4 Replicate DDL operations

Because Drainer cannot add the mark table to DDL operations, you can only use the one-way replication method to replicate DDL operations.

For example, if DDL replication is enabled from cluster A to cluster B, then the replication is disabled from cluster B to cluster A. This means that all DDL operations are performed on cluster A.

Note:

DDL operations cannot be executed on two clusters at the same time. When a DDL operation is executed, if any DML operation is being executed at the same time or any DML binlog is being replicated, the upstream and downstream table structures of the DML replication might be inconsistent.

11.7.12.5 Configure and enable bidirectional replication

For bidirectional replication between cluster A and cluster B, assume that all DDL operations are executed on cluster A. On the replication path from cluster A to cluster B, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = true # Enables it if you need to perform DDL replication.

[syncer.to]
### 1 means SyncFullColumn and 2 means SyncPartialColumn.
### If set to SyncPartialColumn, Drainer allows the downstream table
### structure to have more or fewer columns than the data to be replicated
### And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
    ↪ columns, and insert zero values to the downstream.
sync-mode = 2

### Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

On the replication path from cluster B to cluster A, add the following configuration to Drainer:

```
[syncer]
loopback-control = true
channel-id = 1 # Configures the same ID for both clusters to be replicated.
sync-ddl = false # Disables it if you do not need to perform DDL replication
    ↪ .

[syncer.to]
### 1 means SyncFullColumn and 2 means SyncPartialColumn.
### If set to SyncPartialColumn, Drainer allows the downstream table
### structure to have more or fewer columns than the data to be replicated
### And remove the STRICT_TRANS_TABLES of the SQL mode to allow fewer
    ↪ columns, and insert zero values to the downstream.
sync-mode = 2

### Ignores the checkpoint table.
[[syncer.ignore-table]]
db-name = "tidb_binlog"
tbl-name = "checkpoint"
```

11.7.13 TiDB Binlog Glossary

This document lists the terms used in the logs, monitoring, configurations, and documentation of TiDB Binlog.

11.7.13.1 Binlog

In TiDB Binlog, binlogs refer to the binary log data from TiDB. They also refer to the binary log data that Drainer writes to Kafka or files. The former and the latter are in different formats. In addition, binlogs in TiDB and binlogs in MySQL are also in different formats.

11.7.13.2 Binlog event

The DML binlogs from TiDB have three types of event: `INSERT`, `UPDATE`, and `DELETE`. In the monitoring dashboard of Drainer, you can see the number of different events that correspond to the replication data.

11.7.13.3 Checkpoint

A checkpoint indicates the position from which a replication task is paused and resumed, or is stopped and restarted. It records the commit-ts that Drainer replicates to the downstream. When restarted, Drainer reads the checkpoint and starts replicating data from the corresponding commit-ts.

11.7.13.4 Safe mode

Safe mode refers to the mode that supports the idempotent import of DML when a primary key or unique index exists in the table schema in the incremental replication task.

In this mode, the `INSERT` statement is re-written as `REPLACE`, and the `UPDATE` statement is re-written as `DELETE` and `REPLACE`. Then the re-written statement is executed to the downstream. Safe mode is automatically enabled within 5 minutes after Drainer is started. You can manually enable the mode by modifying the `safe-mode` parameter in the configuration file, but this configuration is valid only when the downstream is MySQL or TiDB.

11.7.14 Troubleshoot

11.7.14.1 TiDB Binlog Troubleshooting

This document describes how to troubleshoot TiDB Binlog to find the problem.

If you encounter errors while running TiDB Binlog, take the following steps to troubleshoot:

1. Check whether each monitoring metric is normal or not. Refer to [TiDB Binlog Monitoring](#) for details.

2. Use the `binlogctl` tool to check whether the state of each Pump or Drainer node is normal or not.
3. Check whether `ERROR` or `WARN` exists in the Pump log or Drainer log.

After finding out the problem by the above steps, refer to [FAQ](#) and [TiDB Binlog Error Handling](#) for the solution. If you fail to find the solution or the solution provided does not help, submit an [issue](#) for help.

11.7.14.2 TiDB Binlog Error Handling

This document introduces common errors that you might encounter and solutions to these errors when you use TiDB Binlog.

11.7.14.2.1 `kafka server: Message was too large, server rejected it to avoid allocation error is returned when Drainer replicates data to Kafka`

Cause: Executing a large transaction in TiDB generates binlog data of a large size, which might exceed Kafka's limit on the message size.

Solution: Adjust the configuration parameters of Kafka as shown below:

```
message.max.bytes=1073741824
replica.fetch.max.bytes=1073741824
fetch.message.max.bytes=1073741824
```

11.7.14.2.2 `Pump returns no space left on device error`

Cause: The local disk space is insufficient for Pump to write binlog data normally.

Solution: Clean up the disk space and then restart Pump.

11.7.14.2.3 `fail to notify all living drainer is returned when Pump is started`

Cause: When Pump is started, it notifies all Drainer nodes that are in the `online` state. If it fails to notify Drainer, this error log is printed.

Solution: Use the `binlogctl` tool to check whether each Drainer node is normal or not. This is to ensure that all Drainer nodes that are in the `online` state are working normally. If the state of a Drainer node is not consistent with its actual working status, use the `binlogctl` tool to change its state and then restart Pump.

11.7.14.2.4 `Data loss occurs during the TiDB Binlog replication`

You need to confirm that TiDB Binlog is enabled on all TiDB instances and runs normally. If the cluster version is later than v3.0, use the `curl {TiDB_IP}:{STATUS_PORT}/↵ info/all` command to confirm the TiDB Binlog status on all TiDB instances.

11.7.14.2.5 When the upstream transaction is large, Pump reports an error `rpc error: code = ResourceExhausted desc = trying to send message larger than max (2191430008 vs. 2147483647)`

This error occurs because the gRPC message sent by TiDB to Pump exceeds the size limit. You can adjust the maximum size of a gRPC message that Pump allows by specifying `max-message-size` when starting Pump.

11.7.14.2.6 Is there any cleaning mechanism for the incremental data of the file format output by Drainer? Will the data be deleted?

- In Drainer v3.0.x, there is no cleaning mechanism for incremental data of the file format.
- In the v4.0.x version, there is a time-based data cleaning mechanism. For details, refer to [Drainer's retention-time configuration item](#).

11.7.15 TiDB Binlog FAQ

This document collects the frequently asked questions (FAQs) about TiDB Binlog.

11.7.15.1 What is the impact of enabling TiDB Binlog on the performance of TiDB?

- There is no impact on the query.
- There is a slight performance impact on `INSERT`, `DELETE` and `UPDATE` transactions. In latency, a p-binlog is written concurrently in the TiKV prewrite stage before the transactions are committed. Generally, writing binlog is faster than TiKV prewrite, so it does not increase latency. You can check the response time of writing binlog in Pump's monitoring panel.

11.7.15.2 How high is the replication latency of TiDB Binlog?

The latency of TiDB Binlog replication is measured in seconds, which is generally about 3 seconds during off-peak hours.

11.7.15.3 What privileges does Drainer need to replicate data to the downstream MySQL or TiDB cluster?

To replicate data to the downstream MySQL or TiDB cluster, Drainer must have the following privileges:

- Insert
- Update

- Delete
- Create
- Drop
- Alter
- Execute
- Index
- Select
- Create View

11.7.15.4 What can I do if the Pump disk is almost full?

1. Check whether Pump's GC works well:
 - Check whether the `gc_tso` time in Pump's monitoring panel is identical with that of the configuration file.
2. If GC works well, perform the following steps to reduce the amount of space required for a single Pump:
 - Modify the `GC` parameter of Pump to reduce the number of days to retain data.
 - Add pump instances.

11.7.15.5 What can I do if Drainer replication is interrupted?

Execute the following command to check whether the status of Pump is normal and whether all the Pump instances that are not in the `offline` state are running.

```
binlogctl -cmd pumps
```

Then, check whether the Drainer monitor or log outputs corresponding errors. If so, resolve them accordingly.

11.7.15.6 What can I do if Drainer is slow to replicate data to the downstream MySQL or TiDB cluster?

Check the following monitoring items:

- For the **Drainer Event** monitoring metric, check the speed of Drainer replicating INSERT, UPDATE and DELETE transactions to the downstream per second.
- For the **SQL Query Time** monitoring metric, check the time Drainer takes to execute SQL statements in the downstream.

Possible causes and solutions for slow replication:

- If the replicated database contains a table without a primary key or unique index, add a primary key to the table.
- If the latency between Drainer and the downstream is high, increase the value of the `worker-count` parameter of Drainer. For cross-datacenter replication, it is recommended to deploy Drainer in the downstream.
- If the load in the downstream is not high, increase the value of the `worker-count` parameter of Drainer.

11.7.15.7 What can I do if a Pump instance crashes?

If a Pump instance crashes, Drainer cannot replicate data to the downstream because it cannot obtain the data of this instance. If this Pump instance can recover to the normal state, Drainer resumes replication; if not, perform the following steps:

1. Use `binlogctl` to change the state of this Pump instance to `offline` to discard the data of this Pump instance.
2. Because Drainer cannot obtain the data of this pump instance, the data in the downstream and upstream is inconsistent. In this situation, perform full and incremental backups again. The steps are as follows:
 1. Stop the Drainer.
 2. Perform a full backup in the upstream.
 3. Clear the data in the downstream including the `tidb_binlog.checkpoint` table.
 4. Restore the full backup to the downstream.
 5. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

11.7.15.8 What is checkpoint?

Checkpoint records the `commit-ts` that Drainer replicates to the downstream. When Drainer restarts, it reads the checkpoint and then replicates data to the downstream starting from the corresponding `commit-ts`. The `["write save point"] [ts ↪ =411222863322546177]` Drainer log means saving the checkpoint with the corresponding timestamp.

Checkpoint is saved in different ways for different types of downstream platforms:

- For MySQL/TiDB, it is saved in the `tidb_binlog.checkpoint` table.
- For Kafka/file, it is saved in the file of the corresponding configuration directory.

The data of kafka/file contains `commit-ts`, so if the checkpoint is lost, you can check the latest `commit-ts` of the downstream data by consuming the latest data in the downstream .

Drainer reads the checkpoint when it starts. If Drainer cannot read the checkpoint, it uses the configured `initialCommitTs` as the start point of the initial replication.

11.7.15.9 How to redeploy Drainer on the new machine when Drainer fails and the data in the downstream remains?

If the data in the downstream is not affected, you can redeploy Drainer on the new machine as long as the data can be replicated from the corresponding checkpoint.

- If the checkpoint is not lost, perform the following steps:
 1. Deploy and start a new Drainer (Drainer can read checkpoint and resumes replication).
 2. Use `binlogctl` to change the state of the old Drainer to offline.
- If the checkpoint is lost, perform the following steps:
 1. To deploy a new Drainer, obtain the `commit-ts` of the old Drainer as the `initialCommitTs` of the new Drainer.
 2. Use `binlogctl` to change the state of the old Drainer to offline.

11.7.15.10 How to restore the data of a cluster using a full backup and a binlog backup file?

1. Clean up the cluster and restore a full backup.
2. To restore the latest data of the backup file, use Reparo to set `start-tso = {snapshot timestamp of the full backup + 1}` and `end-ts = 0` (or you can specify a point in time).

11.7.15.11 How to redeploy Drainer when enabling `ignore-error` in Primary-Secondary replication triggers a critical error?

If a critical error is triggered when TiDB fails to write binlog after enabling `ignore-error`, TiDB stops writing binlog and binlog data loss occurs. To resume replication, perform the following steps:

1. Stop the Drainer instance.
2. Restart the `tidb-server` instance that triggers critical error and resume writing binlog (TiDB does not write binlog to Pump after critical error is triggered).
3. Perform a full backup in the upstream.
4. Clear the data in the downstream including the `tidb_binlog.checkpoint` table.
5. Restore the full backup to the downstream.
6. Deploy Drainer and use `initialCommitTs` (set `initialCommitTs` as the snapshot timestamp of the full backup) as the start point of initial replication.

11.7.15.12 When can I pause or close a Pump or Drainer node?

Refer to [TiDB Binlog Cluster Operations](#) to learn the description of the Pump or Drainer state and how to start and exit the process.

Pause a Pump or Drainer node when you need to temporarily stop the service. For example:

- Version upgrade

Use the new binary to restart the service after the process is stopped.

- Server maintenance

When the server needs a downtime maintenance, exit the process and restart the service after the maintenance is finished.

Close a Pump or Drainer node when you no longer need the service. For example:

- Pump scale-in

If you do not need too many Pump services, close some of them.

- Cancelling replication tasks

If you no longer need to replicate data to a downstream database, close the corresponding Drainer node.

- Service migration

If you need to migrate the service to another server, close the service and re-deploy it on the new server.

11.7.15.13 How can I pause a Pump or Drainer process?

- Directly kill the process.

Note:

Do not use the `kill -9` command. Otherwise, the Pump or Drainer node cannot process signals.

- If the Pump or Drainer node runs in the foreground, pause it by pressing `Ctrl+C`.
- Use the `pause-pump` or `pause-drainer` command in `binlogctl`.

11.7.15.14 Can I use the `update-pump` or `update-drainer` command in `binlogctl` to pause the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands can interrupt data replication and might even cause data loss.

11.7.15.15 Can I use the `update-pump` or `update-drainer` command in `binlogctl` to close the Pump or Drainer service?

No. The `update-pump` or `update-drainer` command directly modifies the state information saved in PD without notifying Pump or Drainer to perform the corresponding operation. Misusing the two commands interrupts data replication and might even cause data inconsistency. For example:

- When a Pump node runs normally or is in the `paused` state, if you use the `update-pump` command to set the Pump state to `offline`, the Drainer node stops pulling the binlog data from the `offline` Pump. In this situation, the newest binlog cannot be replicated to the Drainer node, causing data inconsistency between upstream and downstream.
- When a Drainer node runs normally, if you use the `update-drainer` command to set the Drainer state to `offline`, the newly started Pump node only notifies Drainer nodes in the `online` state. In this situation, the `offline` Drainer fails to pull the binlog data from the Pump node in time, causing data inconsistency between upstream and downstream.

11.7.15.16 When can I use the `update-pump` command in `binlogctl` to set the Pump state to `paused`?

In some abnormal situations, Pump fails to correctly maintain its state. Then, use the `update-pump` command to modify the state.

For example, when a Pump process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Pump state information saved in PD is still `online`. In this situation, if you do not need to restart Pump to recover the service at the moment, use the `update-pump` command to update the Pump state to `paused`. Then, interruptions can be avoided when TiDB writes binlogs and Drainer pulls binlogs.

11.7.15.17 When can I use the `update-drainer` command in `binlogctl` to set the Drainer state to `paused`?

In some abnormal situations, the Drainer node fails to correctly maintain its state, which has influenced the replication task. Then, use the `update-drainer` command to modify the state.

For example, when a Drainer process is exited abnormally (caused by directly exiting the process when a panic occurs or mistakenly using the `kill -9` command to kill the process), the Drainer state information saved in PD is still `online`. When a Pump node is started, it fails to notify the exited Drainer node (the `notify drainer ... error`), which cause the Pump node failure. In this situation, use the `update-drainer` command to update the Drainer state to `paused` and restart the Pump node.

11.7.15.18 How can I close a Pump or Drainer node?

Currently, you can only use the `offline-pump` or `offline-drainer` command in `binlogctl` to close a Pump or Drainer node.

11.7.15.19 When can I use the `update-pump` command in `binlogctl` to set the Pump state to `offline`?

You can use the `update-pump` command to set the Pump state to `offline` in the following situations:

- When a Pump process is exited abnormally and the service cannot be recovered, the replication task is interrupted. If you want to recover the replication and accept some losses of binlog data, use the `update-pump` command to set the Pump state to `offline` \leftrightarrow . Then, the Drainer node stops pulling binlog from the Pump node and continues replicating data.
- Some stale Pump nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-pump` command to set their state to `offline`.

For other situations, use the `offline-pump` command to close the Pump service, which is the regular process.

Warning:

Do not use the `update-pump` command unless you can tolerate binlog data loss and data inconsistency between upstream and downstream, or you no longer need the binlog data stored in the Pump node.

11.7.15.20 Can I use the `update-pump` command in `binlogctl` to set the Pump state to `offline` if I want to close a Pump node that is exited and set to `paused`?

When a Pump process is exited and the node is in the `paused` state, not all the binlog data in the node is consumed in its downstream Drainer node. Therefore, doing so might risk data inconsistency between upstream and downstream. In this situation, restart the Pump and use the `offline-pump` command to close the Pump node.

11.7.15.21 When can I use the `update-drainer` command in `binlogctl` to set the Drainer state to `offline`?

Some stale Drainer nodes are left over from historical tasks. Their processes have been exited and their services are no longer needed. Then, use the `update-drainer` command to set their state to `offline`.

11.7.15.22 Can I use SQL operations such as `change pump` and `change drainer` to pause or close the Pump or Drainer service?

No. For more details on these SQL operations, refer to [Use SQL statements to manage Pump or Drainer](#).

These SQL operations directly modifies the state information saved in PD and are functionally equivalent to the `update-pump` and `update-drainer` commands in `binlogctl`. To pause or close the Pump or Drainer service, use the `binlogctl` tool.

11.7.15.23 What can I do when some DDL statements supported by the upstream database cause error when executed in the downstream database?

To solve the problem, follow these steps:

1. Check `drainer.log`. Search `exec failed` for the last failed DDL operation before the Drainer process is exited.
2. Change the DDL version to the one compatible to the downstream. Perform this step manually in the downstream database.
3. Check `drainer.log`. Search for the failed DDL operation and find the `commit-ts` of this operation. For example:

```
[2020/05/21 09:51:58.019 +08:00] [INFO] [syncer.go:398] ["add ddl item
  ↪ to syncer, you can add this commit ts to `ignore-txn-commit-ts`
  ↪ to skip this ddl if needed"] [sql="ALTER TABLE `test` ADD INDEX
  ↪ (`index1`)" ] ["commit ts"]=416815754209656834].
```

4. Modify the `drainer.toml` configuration file. Add the `commit-ts` in the `ignore-txn-`
↪ `commit-ts` item and restart the Drainer node.

11.7.15.24 TiDB fails to write to binlog and gets stuck, and listener stopped, waiting for manual stop appears in the log

In TiDB v3.0.12 and earlier versions, the binlog write failure causes TiDB to report the fatal error. TiDB does not automatically exit but only stops the service, which seems like getting stuck. You can see the `listener stopped, waiting for manual stop` error in the log.

You need to determine the specific causes of the binlog write failure. If the failure occurs because binlog is slowly written into the downstream, you can consider scaling out Pump or increasing the timeout time for writing binlog.

Since v3.0.13, the error-reporting logic is optimized. The binlog write failure causes transaction execution to fail and TiDB Binlog will return an error but will not get TiDB stuck.

11.7.15.25 TiDB writes duplicate binlogs to Pump

This issue does not affect the downstream and replication logic.

When the binlog write fails or becomes timeout, TiDB retries writing binlog to the next available Pump node until the write succeeds. Therefore, if the binlog write to a Pump node is slow and causes TiDB timeout (default 15s), then TiDB determines that the write fails and tries to write to the next Pump node. If binlog is actually successfully written to the timeout-causing Pump node, the same binlog is written to multiple Pump nodes. When Drainer processes the binlog, it automatically de-duplicates binlogs with the same TSO, so this duplicate write does not affect the downstream and replication logic.

11.7.15.26 Reparo is interrupted during the full and incremental restore process. Can I use the last TSO in the log to resume replication?

Yes. Reparo does not automatically enable the safe-mode when you start it. You need to perform the following steps manually:

1. After Reparo is interrupted, record the last TSO in the log as `checkpoint-tso`.
2. Modify the Reparo configuration file, set the configuration item `start-tso` to `checkpoint-tso + 1`, set `stop-tso` to `checkpoint-tso + 80,000,000,000` (approximately five minutes after the `checkpoint-tso`), and set `safe-mode` to `true`. Start Reparo, and Reparo replicates data to `stop-tso` and then stops automatically.
3. After Reparo stops automatically, set `start-tso` to `checkpoint tso + 80,000,000,001` ↪ , set `stop-tso` to `0`, and set `safe-mode` to `false`. Start Reparo to resume replication.

11.8 TiDB Lightning

11.8.1 TiDB Lightning Overview

[TiDB Lightning](#) is a tool used for fast full import of large amounts of data into a TiDB

cluster. You can download TiDB Lightning from [here](#).

Currently, TiDB Lightning can mainly be used in the following two scenarios:

- Importing **large amounts** of **new data quickly**
- Restore all backup data

Currently, TiDB Lightning supports:

- Importing files exported by [Dumpling](#), CSV files, and [Apache Parquet files generated by Amazon Aurora](#).
- Reading data from a local disk or from the Amazon S3 storage. For details, see [External Storages](#).

11.8.1.1 TiDB Lightning architecture

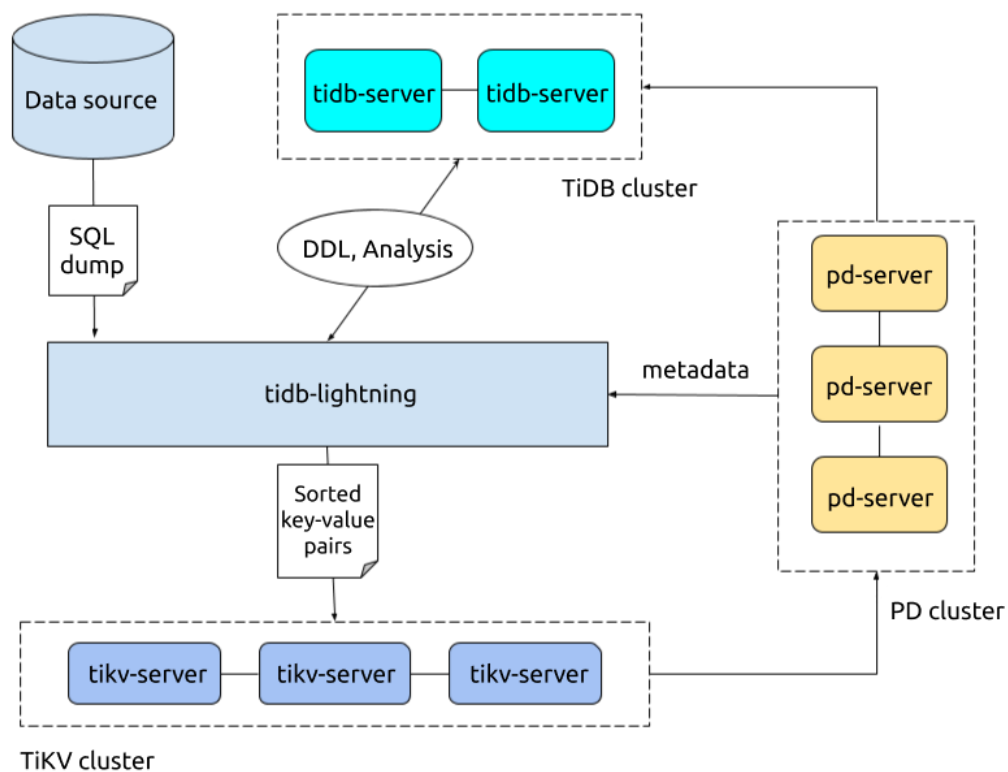

Figure 152: Architecture of TiDB Lightning tool set

The complete import process is as follows:

1. Before importing, `tidb-lightning` switches the TiKV cluster to “import mode”, which optimizes the cluster for writing and disables automatic compaction.
2. `tidb-lightning` creates the skeleton of all tables from the data source.
3. Each table is split into multiple continuous *batches*, so that data from a huge table (200 GB+) can be imported incrementally and concurrently.
4. For each batch, `tidb-lightning` creates an *engine file* to store KV pairs. `tidb-lightning` then reads the data source in parallel, transforms each row into KV pairs according to the TiDB rules, and writes these KV pairs into the local files for temporary storage.
5. Once a complete engine file is written, `tidb-lightning` divides and schedules these data and imports them into the target TiKV cluster.

There are two kinds of engine files: *data engines* and *index engines*, each corresponding to two kinds of KV pairs: the row data and secondary indices. Normally, the row data are entirely sorted in the data source, while the secondary indices are out of order. Because of this, the data engines are uploaded as soon as a batch is completed, while the index engines are imported only after all batches of the entire table are encoded.

6. After all engines associated to a table are imported, `tidb-lightning` performs a checksum comparison between the local data source and those calculated from the cluster, to ensure there is no data corruption in the process; tells TiDB to `ANALYZE` all imported tables, to prepare for optimal query planning; and adjusts the `AUTO_INCREMENT` value so future insertions will not cause conflict.

The auto-increment ID of a table is computed by the estimated *upper bound* of the number of rows, which is proportional to the total file size of the data files of the table. Therefore, the final auto-increment ID is often much larger than the actual number of rows. This is expected since in TiDB auto-increment is **not necessarily allocated sequentially**.

7. Finally, `tidb-lightning` switches the TiKV cluster back to “normal mode”, so the cluster resumes normal services.

If the target cluster of data import is v3.x or earlier versions, you need to use the `Importer-backend` to import data. In this mode, `tidb-lightning` sends the parsed KV pairs to `tikv-importer` via gRPC and `tikv-importer` imports the data.

TiDB Lightning also supports using TiDB-backend for data import. In this mode, `tidb-lightning` transforms data into `INSERT SQL` statements and directly executes them on the target cluster. See **TiDB Lightning Backends** for details.

11.8.1.2 Restrictions

- If you use TiDB Lightning together with TiFlash:
No matter a table has TiFlash replica(s) or not, you can import data to that table using TiDB Lightning. Note that this might slow the TiDB Lightning procedure, which depends on the NIC bandwidth on the lightning host, the CPU and disk load of the TiFlash node, and the number of TiFlash replicas.
- If you use TiDB Lightning together with TiDB:
TiDB Lightning does not support importing `charset=GBK` tables to TiDB clusters earlier than v5.4.0.
- For Apache Parquet files, TiDB Lightning currently only accepts Amazon Aurora Parquet files.

11.8.2 TiDB Lightning Tutorial

[TiDB Lightning](#) is a tool used for fast full import of large amounts of data into a TiDB cluster. Currently, TiDB Lightning supports reading SQL dump exported via SQL or CSV data source. You can use it in the following two scenarios:

- Import **large amounts** of **new** data **quickly**
- Back up and restore all the data

Figure 153: Architecture of TiDB Lightning tool set

11.8.2.1 Prerequisites

This tutorial assumes you use several new and clean CentOS 7 instances. You can use VMware, VirtualBox or other tools to deploy a virtual machine locally or a small cloud virtual machine on a vendor-supplied platform. Because TiDB Lightning consumes a large amount of computer resources, it is recommended that you allocate at least 16 GB memory and CPU of 32 cores for running it with the best performance.

Warning:

The deployment method in this tutorial is only recommended for test and trial. **Do not apply it in the production or development environment.**

11.8.2.2 Prepare full backup data

First, use **dumpling** to export data from MySQL:

```
./bin/dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f 'test
↳ .t[12]' -o /data/my_database/
```

In the above command:

- **-B test**: means the data is exported from the **test** database.
- **-f test.t[12]**: means only the **test.t1** and **test.t2** tables are exported.
- **-t 16**: means 16 threads are used to export the data.
- **-F 256MB**: means a table is partitioned into chunks and one chunk is 256 MB.

After executing this command, the full backup data is exported to the **/data/**
↳ **my_database** directory.

11.8.2.3 Deploy TiDB Lightning

11.8.2.3.1 Step 1: Deploy TiDB cluster

Before the data import, you need to deploy a TiDB cluster. In this tutorial, TiDB v5.4.0 is used as an example. For the deployment method, refer to [Deploy a TiDB Cluster Using TiUP](#).

11.8.2.3.2 Step 2: Download TiDB Lightning installation package

Download the TiDB Lightning installation package from the following link:

- **v5.4.0**: [tidb-toolkit-v5.4.0-linux-amd64.tar.gz](#)

Note:

TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

11.8.2.3.3 Step 3: Start tidb-lightning

1. Upload **bin/tidb-lightning** and **bin/tidb-lightning-ctl** in the package to the server where TiDB Lightning is deployed.

2. Upload the [prepared data source](#) to the server.
3. Configure `tidb-lightning.toml` as follows:

```
[lightning]
# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# Uses the Local-backend
backend = "local"
# Sets the directory for temporarily storing the sorted key-value pairs
↳ .
# The target directory must be empty.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
# Local source data directory
data-source-dir = "/data/my_datasource/"

# Configures the wildcard rule. By default, all tables in the mysql,
↳ sys, INFORMATION_SCHEMA, PERFORMANCE_SCHEMA, METRICS_SCHEMA, and
↳ INSPECTION_SCHEMA system databases are filtered.
# If this item is not configured, the "cannot find schema" error occurs
↳ when system tables are imported.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
↳ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA
↳ .*']

[tidb]
# Information of the target cluster
host = "172.16.31.2"
port = 4000
user = "root"
password = "rootroot"
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
# The PD address of the cluster
pd-addr = "172.16.31.3:2379"
```

4. After configuring the parameters properly, use a `nohup` command to start the `tidb` `↳ -lightning` process. If you directly run the command in the command-line, the process might exit because of the `SIGHUP` signal received. Instead, it's preferable to run a bash script that contains the `nohup` command:

```
#!/bin/bash
```

```
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

11.8.2.3.4 Step 4: Check data integrity

After the import is completed, TiDB Lightning exits automatically. If the import is successful, you can find `tidb lightning exit` in the last line of the log file.

If any error occurs, refer to [TiDB Lightning FAQs](#).

11.8.2.4 Summary

This tutorial briefly introduces what TiDB Lightning is and how to quickly deploy a TiDB Lightning cluster to import full backup data to the TiDB cluster.

For detailed features and usage about TiDB Lightning, refer to [TiDB Lightning Overview](#).

11.8.3 TiDB Lightning Deployment

This document describes the hardware requirements of TiDB Lightning using the Local-backend, and how to deploy it manually.

If Local-backend is used for data import, during the import process, **the cluster cannot provide services**. If you do not want the TiDB services to be impacted, perform the data import according to [TiDB Lightning TiDB-backend](#).

11.8.3.1 Notes

Before starting TiDB Lightning, note that:

- If `tidb-lightning` crashes, the cluster is left in “import mode”. Forgetting to switch back to “normal mode” can lead to a high amount of uncompact data on the TiKV cluster, and cause abnormally high CPU usage and stall. You can manually switch the cluster back to “normal mode” via the `tidb-lightning-ctl` tool:

```
bin/tidb-lightning-ctl --switch-mode=normal
```

- TiDB Lightning is required to have the following privileges in the downstream TiDB:

Privilege	Scope
SELECT	Tables
INSERT	Tables
UPDATE	Tables
DELETE	Tables
CREATE	Databases, tables
DROP	Databases, tables
ALTER	Tables

If the `checksum` configuration item of TiDB Lightning is set to `true`, then the admin user privileges in the downstream TiDB need to be granted to TiDB Lightning.

11.8.3.2 Hardware requirements

`tidb-lightning` is a resource-intensive program. It is recommended to deploy it as follows.

- 32+ logical cores CPU
- 20GB+ memory
- An SSD large enough to store the entire data source, preferring higher read speed
- 10 Gigabit network card (capable of transferring at 1 GB/s)
- `tidb-lightning` fully consumes all CPU cores when running, and deploying on a dedicated machine is highly recommended. If not possible, `tidb-lightning` could be deployed together with other components like `tidb-server`, and the CPU usage could be limited via the `region-concurrency` setting.

Note:

- `tidb-lightning` is a CPU intensive program. In an environment with mixed components, the resources allocated to `tidb-lightning` must be limited. Otherwise, other components might not be able to run. It is recommended to set the `region-concurrency` to 75% of CPU logical cores. For instance, if the CPU has 32 logical cores, you can set the `region-concurrency` to 24.

Additionally, the target TiKV cluster should have enough space to absorb the new data. Besides [the standard requirements](#), the total free space of the target TiKV cluster should be larger than **Size of data source** × **Number of replicas** × **2**.

With the default replica count of 3, this means the total free space should be at least 6 times the size of data source.

11.8.3.3 Export data

Use the [dumping tool](#) to export data from MySQL by using the following command:

```
./bin/dumpling -h 127.0.0.1 -P 3306 -u root -t 16 -F 256MB -B test -f 'test  
↪ .t[12]' -o /data/my_database/
```

In this command,

- `-B test`: means the data is exported from the `test` database.

- `-f test.t[12]`: means only the `test.t1` and `test.t2` tables are exported.
- `-t 16`: means 16 threads are used to export the data.
- `-F 256MB`: means a table is partitioned into chunks and one chunk is 256 MB.

If the data source consists of CSV files, see [CSV support](#) for configuration.

11.8.3.4 Deploy TiDB Lightning

This section describes how to [deploy TiDB Lightning manually](#).

11.8.3.4.1 Deploy TiDB Lightning manually

Step 1: Deploy a TiDB cluster

Before importing data, you need to have a deployed TiDB cluster. It is highly recommended to use the latest stable version.

You can find deployment instructions in [TiDB Quick Start Guide](#).

Step 2: Download the TiDB Lightning installation package

Refer to the [TiDB enterprise tools download page](#) to download the TiDB Lightning package.

Note:

TiDB Lightning is compatible with TiDB clusters of earlier versions. It is recommended that you download the latest stable version of the TiDB Lightning installation package.

Step 3: Start `tidb-lightning`

1. Upload `bin/tidb-lightning` and `bin/tidb-lightning-ctl` from the tool set.
2. Mount the data source onto the same machine.
3. Configure `tidb-lightning.toml`. For configurations that do not appear in the template below, TiDB Lightning writes a configuration error to the log file and exits.

`sorted-kv-dir` sets the temporary storage directory for the sorted Key-Value files. The directory must be empty, and the storage space **must be greater than the size of the dataset to be imported**.

```
[lightning]
# The concurrency number of data. It is set to the number of logical
  ↪ CPU
```

```
# cores by default. When deploying together with other components, you
  ↪ can
# set it to 75% of the size of logical CPU cores to limit the CPU usage
  ↪ .
# region-concurrency =

# Logging
level = "info"
file = "tidb-lightning.log"

[tikv-importer]
# Sets the backend to the "local" mode.
backend = "local"
# Sets the directory of temporary local storage.
sorted-kv-dir = "/mnt/ssd/sorted-kv-dir"

[mydumper]
# Local source data directory
data-source-dir = "/data/my_database"

[tidb]
# Configuration of any TiDB server from the cluster
host = "172.16.31.1"
port = 4000
user = "root"
password = ""
# Table schema information is fetched from TiDB via this status-port.
status-port = 10080
# An address of pd-server.
pd-addr = "172.16.31.4:2379"
```

The above only shows the essential settings. See the [Configuration](#) section for the full list of settings.

4. Run tidb-lightning.

```
nohup ./tidb-lightning -config tidb-lightning.toml > nohup.out &
```

11.8.3.5 Upgrading TiDB Lightning

You can upgrade TiDB Lightning by replacing the binaries alone. No further configuration is needed. See [FAQ](#) for the detailed instructions of restarting TiDB Lightning.

If an import task is running, we recommend you to wait until it finishes before upgrading TiDB Lightning. Otherwise, there might be chances that you need to reimport from scratch, because there is no guarantee that checkpoints work across versions.

11.8.4 TiDB Lightning Prechecks

Starting from TiDB 5.3.0, TiDB Lightning provides the ability to check the configuration before running a migration task. It is enabled by default. This feature automatically performs some routine checks for disk space and execution configuration. The main purpose is to ensure that the whole subsequent import process goes smoothly.

The following table describes each check item and detailed explanation.

Check Items	Supported Ver- sion	Description
Cluster version and status	\geq 5.3.0	Check whether the cluster can be connected in the configuration, and whether the TiKV/PD/TiFlash version supports the Local import mode when the backend mode is Local.

Check Items	Supported Ver- sion	Description
Read permission	>= 5.3.0	Check whether TiDB Lightning can access data stored on cloud (Amazon S3). This ensures that the import is not interrupted by the lack of the read permission.

Check Items	Supported Ver- sion	Description
Disk space	>= 5.3.0	Check whether there is enough space on the local disk and on the TiKV cluster for importing data. TiDB Lightning samples the data sources and estimates the percentage of the index size from the sample result.

Check Items	Supported Version	Description
Region distribution status	>= 5.3.0	Check whether the Regions in the TiKV cluster are distributed evenly and whether there are too many empty Regions. If the number of empty Regions exceeds $\max(1000, \text{number of tables} * 3)$, i.e. greater than the bigger one of "1000"

Check Items	Version	Description
Exceedingly Large CSV files in the data file	5.3.0	When there are CSV files larger than 10 GiB in the backup file and auto-slicing is not enabled (Strict-Format=false), it will impact the import performance. The purpose of this check is to remind you to ensure the

Check Items	Supported Version	Description
Recovery from break-points	≥ 5.3.0	This check ensures that no changes are made to the source file or schema in the database during the break-point recovery process that would result in importing the wrong data.

Check Items	Supported Ver- sion	Description
Import into an existing table	\geq 5.3.0	When importing into an already created table, it checks, as much as possible, whether the source file matches the existing table. Check if the number of columns matches. If the source file has column names, check if the column

Check Items	Supported Version	Description
Whether the target table is empty	≥ 5.3.1	<p>TiDB Lightning automatically exits with an error if the target table is not empty. If parallel import mode is enabled (incremental <code>↪ -</code> <code>↪ import</code> <code>↪</code> <code>↪ =</code> <code>↪</code> <code>↪ true</code> <code>↪</code> <code>↪</code>), this check item will be skipped.</p>

11.8.5 TiDB Lightning Configuration

This document provides samples for global configuration, task configuration, and TiKV Importer configuration in TiDB Lightning, and describes the usage of command-line parameters.

11.8.5.1 Configuration files

TiDB Lightning has two configuration classes: “global” and “task”, and they have compatible structures. Their distinction arises only when the **server mode** is enabled. When server mode is disabled (the default), TiDB Lightning will only execute one task, and the same configuration file is used for both global and task configurations.

11.8.5.1.1 TiDB Lightning (Global)

```
##### tidb-lightning global configuration

[lightning]
### The HTTP port for displaying the web interface, pulling Prometheus
  ↳ metrics, exposing debug data, and submitting import tasks (in server
  ↳ mode). Setting it to 0 disables the port.
status-addr = ':8289'

### Server mode. Defaults to false, which means an import task starts
  ↳ immediately after you execute the command.
### If this value is set to true, after you execute the command, TiDB
  ↳ Lightning waits until you submit an import task in the web interface.
### See the "TiDB Lightning Web Interface" section for details.
server-mode = false

### Logging
level = "info"
file = "tidb-lightning.log"
max-size = 128 # MB
max-days = 28
max-backups = 14
```

11.8.5.1.2 TiDB Lightning (Task)

```
##### tidb-lightning task configuration

[lightning]
### Checks whether the cluster satisfies the minimum requirement before
  ↳ starting the task, and check whether TiKV has more than 10% free
  ↳ space left during running time.
```

```
#check-requirements = true

### The maximum number of engines to be opened concurrently.
### Each table is split into one "index engine" to store indices, and
    ↪ multiple
### "data engines" to store row data. These settings control the maximum
### concurrent number for each type of engines.
### These values affect the memory and disk usage of tikv-importer.
### The sum of these two values must not exceed the max-open-engines setting
### for tikv-importer.
index-concurrency = 2
table-concurrency = 6

### The concurrency number of data. It is set to the number of logical CPU
### cores by default. When deploying together with other components, you can
### set it to 75% of the size of logical CPU cores to limit the CPU usage.
#region-concurrency =

### The maximum I/O concurrency. Excessive I/O concurrency causes an
    ↪ increase in
### I/O latency because the disk's internal buffer is frequently refreshed,
### which causes the cache miss and slows down the read speed. Depending on
    ↪ the storage
### medium, this value might need to be adjusted for optimal performance.
io-concurrency = 5

### The maximum number of non-fatal errors to tolerate before stopping TiDB
    ↪ Lightning.
### Non-fatal errors are localized to a few rows, and ignoring those rows
    ↪ allows the import process to continue.
### Setting this to N means that TiDB Lightning will stop as soon as
    ↪ possible when the (N+1)-th error is encountered.
### The skipped rows will be inserted into tables inside the "task info"
    ↪ schema on the target TiDB, which can be configured below.
max-error = 0
### task-info-schema-name is the name of the schema or database that stores
    ↪ TiDB Lightning execution results.
### To disable error recording, set this to an empty string.
### task-info-schema-name = 'lightning_task_info'

### In parallel import mode, the schema name that stores the meta
    ↪ information for each TiDB Lightning instance in the target cluster.
    ↪ By default, the value is "lightning_metadata".
### Configure this parameter only if parallel import is enabled.
### **Note:**
```

```
### - The value set for this parameter must be the same for each TiDB
↳ Lightning instance that participates in the same parallel import;
↳ otherwise, the correctness of the imported data cannot be ensured.
### - If parallel import mode is enabled, make sure that the user used for
↳ import (for the tidb.user configuration) has permissions to create
↳ and access the databases corresponding to this configuration.
### - TiDB Lightning removes this schema after the import is completed. So
↳ do not use any existing schema name to configure this parameter.
meta-schema-name = "lightning_metadata"

[security]
### Specifies certificates and keys for TLS connections within the cluster.
### Public certificate of the CA. Leave empty to disable TLS.
### ca-path = "/path/to/ca.pem"
### Public certificate of this service.
### cert-path = "/path/to/lightning.pem"
### Private key of this service.
### key-path = "/path/to/lightning.key"

[checkpoint]
### Whether to enable checkpoints.
### While importing data, TiDB Lightning records which tables have been
↳ imported, so
### even if TiDB Lightning or another component crashes, you can start from
↳ a known
### good state instead of restarting from scratch.
enable = true
### The schema name (database name) to store the checkpoints.
schema = "tidb_lightning_checkpoint"
### Where to store the checkpoints.
### - file: store as a local file.
### - mysql: store into a remote MySQL-compatible database
driver = "file"
### The data source name (DSN) indicating the location of the checkpoint
↳ storage.
### For the "file" driver, the DSN is a path. If the path is not specified,
↳ TiDB Lightning would
### default to "/tmp/CHECKPOINT_SCHEMA.pb".
### For the "mysql" driver, the DSN is a URL in the form of "USER:PASS@tcp(
↳ HOST:PORT)/".
### If the URL is not specified, the TiDB server from the [tidb] section is
↳ used to
### store the checkpoints. You should specify a different MySQL-compatible
### database server to reduce the load of the target TiDB cluster.
### dsn = "/tmp/tidb_lightning_checkpoint.pb"
```

```
### Whether to keep the checkpoints after all data are imported. If false,
↳ the
### checkpoints will be deleted. Keeping the checkpoints can aid debugging
↳ but
### will leak metadata about the data source.
### keep-after-success = false

[tikv-importer]
### "local": The default mode. It applies to large dataset import, for
↳ example, greater than 1 TiB. However, during the import, downstream
↳ TiDB is not available to provide services.
### "tidb": You can use this mode for small dataset import, for example,
↳ smaller than 1 TiB. During the import, downstream TiDB is available
↳ to provide services.
### backend = "local"
### Whether to allow importing data to tables with data. The default value
↳ is `false`.
### When you use parallel import mode, you must set it to `true`, because
↳ multiple TiDB Lightning instances are importing the same table at the
↳ same time.
### incremental-import = false

### The listening address of tikv-importer when backend is "importer".
↳ Change it to the actual address.
addr = "172.16.31.10:8287"
### Action to do when trying to insert a duplicated entry in the "tidb"
↳ backend.
### - replace: use new entry to replace the existing entry
### - ignore: keep the existing entry, and ignore the new entry
### - error: report error and quit the program
### on-duplicate = "replace"
### Whether to detect and resolve duplicate records (unique key conflict)
↳ when the backend is 'local'.
### The following resolution algorithms are supported:
### - record: only records duplicate records to the `lightning_task_info`.
↳ conflict_error_v1` table on the target TiDB. Note that the
### required version of the target TiKV is no earlier than v5.2.0;
↳ otherwise it falls back to 'none'.
### - none: does not detect duplicate records, which has the best
↳ performance of the three algorithms, but might lead to
### inconsistent data in the target TiDB.
### - remove: records all duplicate records to the lightning_task_info
↳ database, like the 'record' algorithm. But it removes all duplicate
↳ records from the target table to ensure a consistent
### state in the target TiDB.
```

```
### duplicate-resolution = 'none'
### The number of KV pairs sent in one request in the "local" backend.
### send-kv-pairs = 32768
### The directory of local KV sorting in the "local" backend. If the disk
### performance is low (such as in HDD), it is recommended to set the
    ↪ directory
### on a different disk from `data-source-dir` to improve import speed.
### sorted-kv-dir = ""
### The concurrency that TiKV writes KV data in the "local" backend.
### When the network transmission speed between TiDB Lightning and TiKV
### exceeds 10 Gigabit, you can increase this value accordingly.
### range-concurrency = 16

[mydumper]
### Block size for file reading. Keep it longer than the longest string of
    ↪ the data source.
read-block-size = "64KiB" # default value

### The engine file needs to be imported sequentially. Due to parallel
    ↪ processing,
### multiple data engines will be imported at nearly the same time, and this
### creates a queue and wastes resources. Therefore, TiDB Lightning slightly
### increases the size of the first few batches to properly distribute
### resources. The scale up factor is controlled by this parameter, which
### expresses the ratio of duration between the "import" and "write" steps
### with full concurrency. This can be calculated by using the ratio
### (import duration/write duration) of a single table of size around 1 GiB.
### The exact timing can be found in the log. If "import" is faster, the
    ↪ batch
### size variance is smaller, and a ratio of zero means a uniform batch size
    ↪ .
### This value should be in the range (0 <= batch-import-ratio < 1).
batch-import-ratio = 0.75

### Local source data directory or the URL of the external storage.
data-source-dir = "/data/my_database"
### If no-schema is set to true, tidb-lightning assumes that the table
    ↪ skeletons
### already exist on the target TiDB cluster, and will not execute the `
    ↪ CREATE
### TABLE` statements.
no-schema = false
### The character set of the schema files, containing CREATE TABLE
    ↪ statements;
### only supports one of:
```

```
### - utf8mb4: the schema files must be encoded as UTF-8; otherwise, an
↳ error is reported.
### - gb18030: the schema files must be encoded as GB-18030; otherwise,
###       an error is reported
### - auto:   (default) automatically detects whether the schema is UTF-8 or
###       GB-18030. An error is reported if the encoding is neither.
### - binary: do not try to decode the schema files
character-set = "auto"

### Specifies the character set of the source data file. Lightning converts
↳ the source file from the specified character set to UTF-8 encoding
↳ when importing.
### Currently, this configuration only specifies the character set of the
↳ CSV files with the following options supported:
### - utf8mb4: Indicates that the source data file uses UTF-8 encoding.
### - GB18030: Indicates that the source data file uses the GB-18030
↳ encoding.
### - GBK: The source data file uses GBK encoding (GBK encoding is an
↳ extension of the GB-2312 character set, also known as Code Page 936).
### - binary: Indicates that Lightning does not convert the encoding (by
↳ default).
### If left blank, the default value "binary" is used, that is to say,
↳ Lightning does not convert the encoding.
### Note that Lightning does not predict about the character set of the
↳ source data file and only converts the source file and import the
↳ data based on this configuration.
### If the value of this configuration is not the same as the actual
↳ encoding of the source data file, a failed import, data loss or data
↳ disorder might appear.
data-character-set = "binary"
### Specifies the replacement character in case of incompatible characters
↳ during the character set conversion of the source data file.
### This configuration must not be duplicated with field separators, quote
↳ definers, and line breaks.
### The default value is "\uFFFD", which is the "error" Rune or Unicode
↳ replacement character in UTF-8 encoding.
### Changing the default value might result in potential degradation of
↳ parsing performance for the source data file.
data-invalid-char-replace = "\uFFFD"

### the input data in a "strict" format speeds up processing.
### "strict-format = true" requires that:
### in CSV, every value cannot contain literal new lines (U+000A and U+000D,
↳ or \r and \n) even
### when quoted, which means new lines are strictly used to separate rows.
```

```
### "Strict" format allows TiDB Lightning to quickly locate split positions
↳ of a large file for parallel processing.
### However, if the input data is not "strict", it may split a valid data in
↳ half and
### corrupt the result.
### The default value is false for safety instead of speed.
strict-format = false

### If strict-format is true, TiDB Lightning splits large CSV files into
↳ multiple chunks to process in
### parallel. max-region-size is the maximum size of each chunk after
↳ splitting.
### max-region-size = "256MiB" # default value

### Only import tables if these wildcard rules are matched. See the
↳ corresponding section for details.
filter = ['*.*', '!mysql.*', '!sys.*', '!INFORMATION_SCHEMA.*', '!
↳ PERFORMANCE_SCHEMA.*', '!METRICS_SCHEMA.*', '!INSPECTION_SCHEMA.*']

### Configures how CSV files are parsed.
[mydumper.csv]
### Separator between fields. Must not be empty.
separator = ','
### Quoting delimiter. Empty value means no quoting.
delimiter = ''
### Line terminator. Empty value means both "\n" (LF) and "\r\n" (CRLF) are
↳ line terminators.
terminator = ''
### Whether the CSV files contain a header.
### If `header` is true, the first line will be skipped.
header = true
### Whether the CSV contains any NULL value.
### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
### When `not-null` is false (that is, CSV can contain NULL),
### fields equal to this value will be treated as NULL.
null = '\N'
### Whether to interpret backslash escapes inside fields.
backslash-escape = true
### If a line ends with a separator, remove it.
trim-last-separator = false

### [[mydumper.files]]
### Expression used for parsing AWS Aurora parquet files
### pattern = '(?i)^(?:[~/]*/*)*([a-z0-9_]+)\.([a-z0-9_]+)/(?:[~/]*/*)*(?:[a-

sql-mode = "ONLY_FULL_GROUP_BY,NO_ENGINE_SUBSTITUTION"
### Sets maximum packet size allowed for SQL connections.
### Set this to 0 to automatically fetch the `max_allowed_packet` variable
    ↪ from server on every connection.
max-allowed-packet = 67_108_864

### Whether to use TLS for SQL connections. Valid values are:
### - "": if configuration items in the [tidb.security] section are
    ↪ configured, TiDB Lightning requires TLS for SQL connections (same
    ↪ behavior as "cluster"). Otherwise, it uses an unencrypted connection.
### - "false": same behavior as "".
### - "cluster": requires TLS and verifies the server's certificate with
    ↪ the CA specified in the [tidb.security] section.
### - "skip-verify": requires TLS but does not verify the server's
    ↪ certificate (insecure). If the server does not support TLS, the
```

```
    ↪ connection falls back to an unencrypted state.
### - "preferred": same behavior as "skip-verify".
### tls = ""

### Specifies certificates and keys for TLS-enabled MySQL connections.
### Defaults to a copy of the [security] section.
### [tidb.security]
### Public certificate of the CA. Set to empty string to disable TLS for SQL
    ↪ .
### ca-path = "/path/to/ca.pem"
### Public certificate of this service. Default to copy of `security.cert-
    ↪ path`
### cert-path = "/path/to/lightning.pem"
### Private key of this service. Default to copy of `security.key-path`
### key-path = "/path/to/lightning.key"

### In the local backend mode, when data import is completed, TiDB Lightning
### can automatically perform the Checksum and Analyze operations. It is
### recommended to leave these as true in the production environment.
### The execution order: Checksum -> Analyze
### Note that these two operations are not needed for the tidb backend mode,
### so they are skipped in operation.
[post-restore]
### Specifies whether to perform `ADMIN CHECKSUM TABLE <table>` for each
    ↪ table to verify data integrity after importing.
### The following options are available:
### - "required" (default value): Perform admin checksum. If checksum fails,
    ↪ TiDB Lightning will exit with failure.
### - "optional": Perform admin checksum. If checksum fails, TiDB Lightning
    ↪ will report a WARN log but ignore any error.
### - "off": Do not perform checksum.
### Note that since v4.0.8, the default value has changed from "true" to "
    ↪ required".
### Note:
### 1. Checksum failure usually means import exception (data loss or
    ↪ inconsistency). It is recommended to always enable checksum.
### 2. For backward compatibility, bool values "true" and "false" are also
    ↪ allowed for this field.
### "true" is equivalent to "required" and "false" is equivalent to "off".
checksum = "required"
### Specifies whether to perform `ANALYZE TABLE <table>` for each table
    ↪ after checksum is done.
### Options available for this field are the same as `checksum`. However,

If a command line parameter and the corresponding setting in the configuration file are both provided, the command line parameter will be used. For example, running `./tidb` ↔ `-lightning -L debug --config cfg.toml` would always set the log level to “debug” regardless of the content of `cfg.toml`.

11.8.5.3 Usage of `tidb-lightning-ctl`

This tool can execute various actions given one of the following parameters:

Parameter	Explanation
<code>-compact</code>	Performs a full compaction
<code>-switch-mode</code>	Switches every TiKV store to the given mode: normal, import
<code>-fetch-mode</code>	Prints the current mode of every TiKV store
<code>-import-engine</code>	Imports the closed engine file from TiKV Importer into the TiKV cluster
<code><i>uuid</i></code>	

Parameter	Explanation
<code>cleanup-engine</code>	Deletes the engine file from TiKV Importer
<code>checkpoint-dump-folder</code>	Dumps the content of checkpoint as CSVs into the folder
<code>checkpoint-error-destroy-table-name</code>	Removes the checkpoint and drops the table if it caused error
<code>checkpoint-error-ignore-table-name</code>	Ignores the error recorded in the checkpoint involving the given table

Parameter	Explanation
-	Unconditionally
<i>checkpoint-</i>	remove
<i>table-</i>	moves
<i>name</i>	the check- point of the table

The *tablename* must either be a qualified table name in the form ``db`.`tbl`` (including the backquotes), or the keyword “all”.

Additionally, all parameters of `tidb-lightning` described in the section above are valid in `tidb-lightning-ctl`.

11.8.5.4 Usage of `tikv-importer`

Parameter	Explanation	Corresponding set-
-C, - config <i>file</i>	Reads config- ura- tion from <i>file</i> . If not speci- fied, the de- fault config- ura- tion would be used.	<code>importer.config</code>
-V, - version	Prints pro- gram ver- sion	<code>importer.version</code>

<i>file</i>	path	↔

11.8.6 Key Features

11.8.6.1 TiDB Lightning Checkpoints

Importing a large database usually takes hours or days, and if such long running processes spuriously crashes, it can be very time-wasting to redo the previously completed tasks. To solve this, TiDB Lightning uses *checkpoints* to store the import progress, so that `tidb-↔ lightning` continues importing from where it lefts off after restarting.

This document describes how to enable, configure, store, and control *checkpoints*.

11.8.6.1.1 Enable and configure checkpoints

```
[checkpoint]
#### Whether to enable checkpoints.
#### While importing data, TiDB Lightning records which tables have been
    ↪ imported, so
#### even if TiDB Lightning or some other component crashes, you can start
    ↪ from a known
#### good state instead of restarting from scratch.
enable = true

#### Where to store the checkpoints.
#### - file: store as a local file (requires v2.1.1 or later)
#### - mysql: store into a remote MySQL-compatible database
driver = "file"

#### The schema name (database name) to store the checkpoints
#### Enabled only when `driver = "mysql"`.
#### schema = "tidb_lightning_checkpoint"

#### The data source name (DSN) indicating the location of the checkpoint
    ↪ storage.
#### # For the "file" driver, the DSN is a path. If the path is not
    ↪ specified, Lightning would
#### default to "/tmp/CHECKPOINT_SCHEMA.pb".
#### # For the "mysql" driver, the DSN is a URL in the form of "USER:
    ↪ PASS@tcp(HOST:PORT)/".
#### If the URL is not specified, the TiDB server from the [tidb] section is
    ↪ used to
#### store the checkpoints. You should specify a different MySQL-compatible
#### database server to reduce the load of the target TiDB cluster.
#dsn = "/tmp/tidb_lightning_checkpoint.pb"

#### Whether to keep the checkpoints after all data are imported. If false,
    ↪ the
#### checkpoints are deleted. Keeping the checkpoints can aid debugging but
#### might leak metadata about the data source.
#### keep-after-success = false
```

11.8.6.1.2 Checkpoints storage

TiDB Lightning supports two kinds of checkpoint storage: a local file or a remote MySQL-compatible database.

- With `driver = "file"`, checkpoints are stored in a local file at the path given by the `dsn` setting. Checkpoints are updated rapidly, so we highly recommend placing the checkpoint file on a drive with very high write endurance, such as a RAM disk.
- With `driver = "mysql"`, checkpoints can be saved in any databases compatible with MySQL 5.7 or later, including MariaDB and TiDB. By default, the checkpoints are saved in the target database.

While using the target database as the checkpoints storage, Lightning is importing large amounts of data at the same time. This puts extra stress on the target database and sometimes leads to communication timeout. Therefore, **it is strongly recommended to install a temporary MySQL server to store these checkpoints**. This server can be installed on the same host as `tidb-lightning` and can be uninstalled after the importer progress is completed.

11.8.6.1.3 Checkpoints control

If `tidb-lightning` exits abnormally due to unrecoverable errors (for example, data corruption), it refuses to reuse the checkpoints until the errors are resolved. This is to prevent worsening the situation. The checkpoint errors can be resolved using the `tidb-↔ lightning-ctl` program.

```
--checkpoint-error-destroy
```

```
tidb-lightning-ctl --checkpoint-error-destroy='`schema`.`table`'
```

This option allows you to restart importing the table from scratch. The schema and table names must be quoted with backquotes and are case-sensitive.

- If importing the table ``schema`.`table`` failed previously, this option executes the following operations:
 1. DROPs the table ``schema`.`table`` from the target database, which means removing all imported data.
 2. Resets the checkpoints record of this table to be “not yet started”.
- If there is no errors involving the table ``schema`.`table``, this operation does nothing.

It is the same as applying the above on every table. This is the most convenient, safe and conservative solution to fix the checkpoint error problem:

```
tidb-lightning-ctl --checkpoint-error-destroy=all
```

```
--checkpoint-error-ignore
```

```
tidb-lightning-ctl --checkpoint-error-ignore='`schema`.`table`'  
tidb-lightning-ctl --checkpoint-error-ignore=all
```

If importing the table ``schema`.`table`` failed previously, this clears the error status as if nothing ever happened. The `all` variant applies this operation to all tables.

Note:

Use this option only when you are sure that the error can indeed be ignored. If not, some imported data can be lost. The only safety net is the final “checksum” check, and thus you need to keep the “checksum” option always enabled when using `--checkpoint-error-ignore`.

`--checkpoint-remove`

```
tidb-lightning-ctl --checkpoint-remove='`schema`.`table`'  
tidb-lightning-ctl --checkpoint-remove=all
```

This option simply removes all checkpoint information about one table or all tables, regardless of their status.

`--checkpoint-dump`

```
tidb-lightning-ctl --checkpoint-dump=output/directory
```

This option dumps the content of the checkpoint into the given directory, which is mainly used for debugging by the technical staff. This option is only enabled when `driver = "mysql"` \leftrightarrow `"`.

11.8.6.2 Table Filter

The TiDB migration tools operate on all the databases by default, but oftentimes only a subset is needed. For example, you only want to work with the schemas in the form of `foo*` and `bar*` and nothing else.

Since TiDB 4.0, all TiDB migration tools share a common filter syntax to define subsets. This document describes how to use the table filter feature.

11.8.6.2.1 Usage

CLI

Table filters can be applied to the tools using multiple `-f` or `--filter` command line parameters. Each filter is in the form of `db.table`, where each part can be a wildcard (further explained in the [next section](#)). The following lists the example usage in each tool.

- **BR:**

```
./br backup full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

```
./br restore full -f 'foo*.*' -f 'bar*.*' -s 'local:///tmp/backup'
```

- **Dumpling:**

```
./dumpling -f 'foo*.*' -f 'bar*.*' -P 3306 -o /tmp/data/
```

- **TiDB Lightning:**

```
./tidb-lightning -f 'foo*.*' -f 'bar*.*' -d /tmp/data/ --backend tidb
```

TOML configuration files

Table filters in TOML files are specified as [array of strings](#). The following lists the example usage in each tool.

- **TiDB Lightning:**

```
[mydumper]
filter = ['foo*.*', 'bar*.*']
```

- **TiCDC:**

```
[filter]
rules = ['foo*.*', 'bar*.*']

[[sink.dispatchers]]
matcher = ['db1.*', 'db2.*', 'db3.*']
dispatcher = 'ts'
```

11.8.6.2.2 Syntax

Plain table names

Each table filter rule consists of a “schema pattern” and a “table pattern”, separated by a dot (.). Tables whose fully-qualified name matches the rules are accepted.

```
db1.tb11
db2.tb12
db3.tb13
```

A plain name must only consist of valid [identifier characters](#), such as:

- digits (0 to 9)

- letters (a to z, A to Z)
- \$
- _
- non ASCII characters (U+0080 to U+10FFFF)

All other ASCII characters are reserved. Some punctuations have special meanings, as described in the next section.

Wildcards

Each part of the name can be a wildcard symbol described in [fnmatch\(3\)](#):

- * — matches zero or more characters
- ? — matches one character
- [a-z] — matches one character between “a” and “z” inclusively
- [!a-z] — matches one character except “a” to “z”.

```
db[0-9].tbl[0-9a-f][0-9a-f]
data.*
*.backup_*
```

“Character” here means a Unicode code point, such as:

- U+00E9 (é) is 1 character.
- U+0065 U+0301 (é) are 2 characters.
- U+1F926 U+1F3FF U+200D U+2640 U+FE0F () are 5 characters.

File import

To import a file as the filter rule, include an @ at the beginning of the rule to specify the file name. The table filter parser treats each line of the imported file as additional filter rules.

For example, if a file `config/filter.txt` has the following content:

```
employees.*
*.WorkOrder
```

the following two invocations are equivalent:

```
./dumpling -f '@config/filter.txt'
./dumpling -f 'employees.*' -f '*.WorkOrder'
```

A filter file cannot further import another file.

Comments and blank lines

Inside a filter file, leading and trailing white-spaces of every line are trimmed. Furthermore, blank lines (empty strings) are ignored.

A leading # marks a comment and is ignored. # not at start of line is considered syntax error.

```
#### this line is a comment
db.table # but this part is not comment and may cause error
```

Exclusion

An ! at the beginning of the rule means the pattern after it is used to exclude tables from being processed. This effectively turns the filter into a block list.

```
*.*
#^ note: must add the *.* to include all tables first
!*.Password
!employees.salaries
```

Escape character

To turn a special character into an identifier character, precede it with a backslash \.

```
db\.with\.dots.*
```

For simplicity and future compatibility, the following sequences are prohibited:

- \ at the end of the line after trimming whitespaces (use [] to match a literal whitespace at the end).
- \ followed by any ASCII alphanumeric character ([0-9a-zA-Z]). In particular, C-like escape sequences like \0, \r, \n and \t currently are meaningless.

Quoted identifier

Besides \, special characters can also be suppressed by quoting using " or `.

```
"db.with.dots"."tbl\1"
`db.with.dots`.`tbl\2`
```

The quotation mark can be included within an identifier by doubling itself.

```
"foo""bar"`.`foo``bar`
#### equivalent to:
foo\"bar.foo\"bar
```

Quoted identifiers cannot span multiple lines.

It is invalid to partially quote an identifier:

```
"this is "invalid*.*
```

Regular expression

In case very complex rules are needed, each pattern can be written as a regular expression delimited with /:

```
/^db\d{2,}$/. / ^tbl\d{2,}$/
```

These regular expressions use the [Go dialect](#). The pattern is matched if the identifier contains a substring matching the regular expression. For instance, `/b/` matches `db01`.

Note:

Every `/` in the regular expression must be escaped as `\/`, including inside `[...]`. You cannot place an unescaped `/` between `\Q...E`.

11.8.6.2.3 Multiple rules

When a table name matches none of the rules in the filter list, the default behavior is to ignore such unmatched tables.

To build a block list, an explicit `*.*` must be used as the first rule, otherwise all tables will be excluded.

```
#### every table will be filtered out
./dumping -f '!*.Password'

#### only the "Password" table is filtered out, the rest are included.
./dumping -f '*.*' -f '!*.Password'
```

In a filter list, if a table name matches multiple patterns, the last match decides the outcome. For instance:

```
#### rule 1
employees.*
#### rule 2
!*.dep*
#### rule 3
*.departments
```

The filtered outcome is as follows:

Table name	Rule 1	Rule 2	Rule 3	Outcome
irrelevant.table				Default (reject)
employees.employees				Rule 1 (accept)
employees.dept_emp				Rule 2 (reject)
employees.departments				Rule 3 (accept)
else.departments				Rule 3 (accept)

Note:

In TiDB tools, the system schemas are always excluded in the default configuration. The system schemas are:

- INFORMATION_SCHEMA
- PERFORMANCE_SCHEMA
- METRICS_SCHEMA
- INSPECTION_SCHEMA
- mysql
- sys

11.8.6.3 TiDB Lightning CSV Support and Restrictions

This document describes how to migrate data from CSV files to TiDB using TiDB Lightning. For information about how to generate CSV files from MySQL, see [Export to CSV files using Dumping](#).

TiDB Lightning supports reading CSV (comma-separated values) data source, as well as other delimited format such as TSV (tab-separated values).

11.8.6.3.1 File name

A CSV file representing a whole table must be named as `db_name.table_name.csv`. This will be restored as a table `table_name` inside the database `db_name`.

If a table spans multiple CSV files, they should be named like `db_name.table_name` ↪ `.003.csv`. The number part do not need to be continuous, but must be increasing and zero-padded.

The file extension must be `*.csv`, even if the content is not separated by commas.

11.8.6.3.2 Schema

CSV files are schema-less. To import them into TiDB, a table schema must be provided. This could be done either by:

- Providing a file named `db_name.table_name-schema.sql` containing the `CREATE` ↪ `TABLE` DDL statement, and also a file named `db_name-schema-create.sql` containing the `CREATE DATABASE` DDL statement.
- Creating the empty tables directly in TiDB in the first place, and then setting [↪ `mydumper`] `no-schema = true` in `tidb-lightning.toml`.

11.8.6.3.3 Configuration

The CSV format can be configured in `tidb-lightning.toml` under the `[mydumper.csv]` section. Most settings have a corresponding option in the MySQL [LOAD DATA](#) statement.

```
[mydumper.csv]
#### Separator between fields. Must be ASCII characters. It is not
    ↪ recommended to use the default ','. It is recommended to use '\\|+\\|'
    ↪ or other uncommon character combinations.
separator = ','
#### Quoting delimiter. Empty value means no quoting.
delimiter = ''
#### Line terminator. Empty value means both "\n" (LF) and "\r\n" (CRLF) are
    ↪ line terminators.
terminator = ''
#### Whether the CSV files contain a header.
#### If `header` is true, the first line will be skipped.
header = true
#### Whether the CSV contains any NULL value.
#### If `not-null` is true, all columns from CSV cannot be NULL.
not-null = false
#### When `not-null` is false (that is, CSV can contain NULL),
#### fields equal to this value will be treated as NULL.
null = '\\N'
#### Whether to interpret backslash escapes inside fields.
backslash-escape = true
#### If a line ends with a separator, remove it.
trim-last-separator = false
```

In all string fields such as `separator`, `delimiter` and `terminator`, if the input involves special characters, you can use backslash escape sequence to represent them in a *double-quoted* string ("..."). For example, `separator = "\\u001f"` means using the ASCII character 0x1F as separator.

Additionally, you can use *single-quoted* strings ('...') to suppress backslash escaping. For example, `terminator = '\\n'` means using the two-character string: a backslash followed by the letter “n”, as the terminator.

See the [TOML v1.0.0 specification](#) for details.

`separator`

- Defines the field separator.
- Can be multiple characters, but must not be empty.
- Common values:
 - ',', for CSV (comma-separated values)

- "\t" for TSV (tab-separated values)
 - "\u0001" to use the ASCII character 0x01 as separator
- Corresponds to the `FIELDS TERMINATED BY` option in the `LOAD DATA` statement.

`delimiter`

- Defines the delimiter used for quoting.
- If `delimiter` is empty, all fields are unquoted.
- Common values:
 - ''' quote fields with double-quote, same as [RFC 4180](#)
 - '' disable quoting
- Corresponds to the `FIELDS ENCLOSED BY` option in the `LOAD DATA` statement.

`terminator`

- Defines the line terminator.
- If `terminator` is empty, both "\r" (U+000D Carriage Return) and "\n" (U+000A Line Feed) are used as terminator.
- Corresponds to the `LINES TERMINATED BY` option in the `LOAD DATA` statement.

`header`

- Whether *all* CSV files contain a header row.
- If `header` is true, the first row will be used as the *column names*. If `header` is false, the first row is not special and treated as an ordinary data row.

`not-null` and `null`

- The `not-null` setting controls whether all fields are non-nullable.
- If `not-null` is false, the string specified by `null` will be transformed to the SQL NULL instead of a concrete value.
- Quoting will not affect whether a field is null.

For example, with the CSV file:

```
A,B,C
\n, "\N",
```

In the default settings (`not-null = false`; `null = '\N'`), the columns **A** and **B** are both converted to `NULL` after importing to TiDB. The column **C** is simply the empty string `' '` but not `NULL`.

`backslash-escape`

- Whether to interpret backslash escapes inside fields.
- If `backslash-escape` is true, the following sequences are recognized and transformed:

Sequence	Converted to
<code>\0</code>	Null character (U+0000)
<code>\b</code>	Backspace (U+0008)
<code>\n</code>	Line feed (U+000A)
<code>\r</code>	Carriage return (U+000D)
<code>\t</code>	Tab (U+0009)
<code>\Z</code>	Windows EOF (U+001A)

In all other cases (for example, `\"`) the backslash is simply stripped, leaving the next character (`"`) in the field. The character left has no special roles (for example, delimiters) and is just an ordinary character.

- Quoting will not affect whether backslash escapes are interpreted.
- Corresponds to the `FIELDS ESCAPED BY '\'` option in the `LOAD DATA` statement.

`trim-last-separator`

- Treats the field `separator` as a terminator, and removes all trailing separators.

For example, with the CSV file:

```
A,,B,,
```

- When `trim-last-separator = false`, this is interpreted as a row of 5 fields (`'A'`, `↪ ''`, `'B'`, `''`, `''`).
- When `trim-last-separator = true`, this is interpreted as a row of 3 fields (`'A'`, `↪ ''`, `'B'`).
- This option is deprecated, because the behavior with multiple trailing separators is not intuitive. Use the `terminator` option instead. If your old configuration was

```
separator = ','
trim-last-separator = true
```

we recommend changing this to

```
separator = ','  
terminator = ",\n"
```

Non-configurable options

TiDB Lightning does not support every option supported by the `LOAD DATA` statement. Some examples:

- There cannot be line prefixes (`LINES STARTING BY`).
- The header cannot be simply skipped (`IGNORE n LINES`). It must be valid column names if present.

11.8.6.3.4 Strict format

Lightning works the best when the input files have uniform size around 256 MB. When the input is a single huge CSV file, Lightning can only use one thread to process it, which slows down import speed a lot.

This can be fixed by splitting the CSV into multiple files first. For the generic CSV format, there is no way to quickly identify when a row starts and ends without reading the whole file. Therefore, Lightning by default does *not* automatically split a CSV file. However, if you are certain that the CSV input adheres to certain restrictions, you can enable the `strict-format` setting to allow Lightning to split the file into multiple 256 MB-sized chunks for parallel processing.

```
[mydumper]  
strict-format = true
```

Currently, a strict CSV file means every field occupies only a single line. In other words, one of the following must be true:

- Delimiter is empty, or
- Every field does not contain the terminator itself. In the default configuration, this means every field does not contain CR (`\r`) or LF (`\n`).

If a CSV file is not strict, but `strict-format` was wrongly set to `true`, a field spanning multiple lines may be cut in half into two chunks, causing parse failure, or even worse, quietly importing corrupted data.

11.8.6.3.5 Common configurations

CSV

The default setting is already tuned for CSV following RFC 4180.

```
[mydumper.csv]
separator = ',' # It is not recommended to use the default ','. It is
    ↪ recommended to use '\\|+\\| ' or other uncommon character combinations
    ↪ .
delimiter = ''
header = true
not-null = false
null = '\\N'
backslash-escape = true
```

Example content:

```
ID,Region,Count
1,"East",32
2,"South",\\N
3,"West",10
4,"North",39
```

TSV

```
[mydumper.csv]
separator = "\\t"
delimiter = ''
header = true
not-null = false
null = 'NULL'
backslash-escape = false
```

Example content:

```
ID  Region  Count
1   East    32
2   South   NULL
3   West    10
4   North   39
```

TPC-H DBGEN

```
[mydumper.csv]
separator = '|'
delimiter = ''
terminator = "\\n"
header = false
not-null = true
backslash-escape = false
```

Example content:

```
1|East|32|
2|South|0|
3|West|10|
4|North|39|
```

11.8.6.4 TiDB Lightning Backends

The backend determines how TiDB Lightning imports data into the target cluster.

TiDB Lightning supports the following **backends**:

- **Local-backend**
- **Importer-backend**
- **TiDB-backend**

The **Local-backend**: `tidb-lightning` first encodes data into key-value pairs, sorts and stores them in a local temporary directory, and *upload* these key-value pairs to each TiKV node *as SST files*. Then, TiKV ingests these *SST files* into the cluster. The implementation of Local-backend is the same with that of Importer-backend but does not rely on the external `tikv-importer` component.

The **Importer-backend**: `tidb-lightning` first encodes the SQL or CSV data into KV pairs, and relies on the external `tikv-importer` program to sort these KV pairs and ingest directly into the TiKV nodes.

The **TiDB-backend**: `tidb-lightning` first encodes these data into SQL INSERT statements, and has these statements executed directly on the TiDB node.

Backend	Local-backend	Importer-backend	TiDB-backend
Speed	Fast (~500 GB/hr)	Fast (~300 GB/hr)	Slow (~50 GB/hr)
Resource usage	High	High	Low
Network bandwidth usage	High	Medium	Low
ACID respected while importing	No	No	Yes
Target tables	Must be empty	Must be empty	Can be populated
Additional component required	No	<code>tikv-importer</code>	No
TiDB versions supported	\geq v4.0.0	All	All
TiDB services impacted	Yes	Yes	No

Note:

- Apply only one backend at a time when using multiple TiDB Lightning instances to import data to the same target. For example, you cannot

import data to the same TiDB cluster in both Local-backend and TiDB-backend modes at the same time.

- By default, you cannot start multiple TiDB Lightning instances to import data into the same TiDB cluster. Instead, you can use the [Parallel Import](#) feature.

11.8.6.4.1 How to choose the backend modes

- If the target cluster of data import is v4.0 or later versions, consider using the Local-backend mode first, which is easier to use and has higher performance than that of the other two modes.
- If the target cluster of data import is v3.x or earlier versions, it is recommended to use the Importer-backend mode.
- If the target cluster of data import is in the online production environment, or if the target table of data import already has data on it, it is recommended to use the TiDB-backend mode.

11.8.6.4.2 TiDB Lightning Local-backend

The Local-backend feature is introduced to TiDB Lightning since TiDB v4.0.3. You can use this feature to import data to TiDB clusters of v4.0.0 or above.

Deployment for Local-backend

To deploy TiDB Lightning in the Local-backend mode, see [TiDB Lightning Deployment](#).

11.8.6.4.3 TiDB Lightning TiDB-backend

Note:

Since TiDB v4.0, PingCAP no longer maintains the [Loader](#) tool. Since v5.0, the Loader documentation is no longer available. Loader's functionality has been completely replaced by the TiDB-backend of TiDB Lightning, so it is highly recommended to switch to TiDB Lightning.

Deployment for TiDB-backend

When using the TiDB-backend, deploying `tikv-importer` is not necessary. Compared with the [standard deployment procedure](#), the TiDB-backend deployment has the following two differences:

- All steps involving `tikv-importer` can be skipped.
- The configuration must be changed to declare that the TiDB-backend is used.

Hardware requirements

The speed of TiDB Lightning using TiDB-backend is limited by the SQL processing speed of TiDB. Therefore, even a lower-end machine may max out the possible performance. The recommended hardware configuration is:

- 16 logical cores CPU
- An SSD large enough to store the entire data source, preferring higher read speed
- 1 Gigabit network card

Manual deployment

You do not need to download and configure `tikv-importer`. You can download TiDB Lightning from [here](#).

Before running `tidb-lightning`, add the following lines into the configuration file:

```
[tikv-importer]
backend = "tidb"
```

or supplying the `--backend tidb` arguments when executing `tidb-lightning`.

Configuration description and samples

This section provides the samples for task configuration in TiDB Lightning.

```
#### tidb-lightning task configuration

[lightning]
#### Checks whether the cluster satisfies the minimum requirement before
↳ starting.
check-requirements = true

#### Each table is split into one "index engine" to store indices, and
↳ multiple
#### "data engines" to store row data. These settings control the maximum
#### concurrent number for each type of engines.
#### Controls the maximum number of tables that can be imported in parallel.
↳ For TiDB-backend, the default value is the number of CPU cores.
index-concurrency = 40

#### Controls the maximum number of "data engines" allowed to be imported in
↳ parallel. The default value is the number of CPU cores. The value
↳ should be no less than the value of index-concurrency.
table-concurrency = 40
```

```
#### The number of concurrent SQL statements executed. It is set to the
↳ number of logical CPU cores by default. The bottleneck of TiDB-
↳ backend is usually not the CPU. You can increase this value based on
↳ the actual load of the downstream cluster to optimize the write speed
↳ . At the same time, when adjusting this configuration, it is
↳ recommended to adjust the index-concurrency and table-concurrency to
↳ the same value.
region-concurrency = 40

#### Logging
level = "info"
#### The directory to which the log is output. If it is empty (default), the
↳ file is saved to /tmp/lightning.log.{timestamp}. If you want the
↳ logs to be written to the system standard output, set it to "-".
file = "tidb-lightning.log"

[checkpoint]
#### Whether to enable checkpoints.
#### While importing data, TiDB Lightning records which tables have been
↳ imported, so
#### even if TiDB Lightning or some other component crashes, you can start
↳ from a known
#### good state instead of restarting from scratch.
enable = true

#### Where to store the checkpoints.
#### - file (default): store as a local file (requires v2.1.1 or later)
#### - mysql: store into a remote MySQL-compatible database
driver = "file"

#### The schema name (database name) to store the checkpoints
#### Enabled only when `driver = "mysql"`.
#### schema = "tidb_lightning_checkpoint"

#### The data source name (DSN) indicating the location of the checkpoint
↳ storage.
#### # For the "file" driver, the DSN is a path. If the path is not
↳ specified, Lightning would
#### default to "/tmp/CHECKPOINT_SCHEMA.pb".
